BEING

A COLLECTION OF TREATISES,

AND

A DICTIONARY OF TERMS,

ILLUSTRATIVE OF THE

ARTS AND SCIENCES.

COMPILED FROM MODERN AUTHORS OF THE FIRST EMINENCE IN THE DIFFERENT
BRANCHES OF SCIENCE.

IN TEN VOLUMES.

THE WHOLE ILLUSTRATED WITH UPWARDS OF FOUR HUNDRED COPPER-PLATES.

VOL. IV.

LONDON:

PRINTED FOR G. KEARSLEY, FLEET-STREET.

SOLD BY BELL AND BRADFUTE, EDINBURGH; BRASH AND REID, GLASGOW; BROWN AND BY BURNETT, ABERDEEN;
COLBERT, DUBLIN; AND ALL OTHER BOOKSELLERS IN THE UNITED KINGDOM.

1802.

ENGLISH ENCYCLOPÆDIA.

G L A

GLASTONBURY, a town of Somersetshire, with a market on Tuesday. It is seated near a high hill called the Tor, and is noted for a famous abbey, some magnificent ruins of which are still remaining; but they have been much diminished for the sake of the stones: however, the curious structure called the abbot's kitchen is entire, and is of a very unusual contrivance. The only manufacture here is stockings; but the chief support of the place is the resort of people to see the ruins of the abbey. The George Inn was formerly called the Abbot's Inn, because it was a receptacle for the pilgrims that came to the abbey. It was pretended that the bodies of Joseph of Arimathea, of king Arthur, and of king Edward the Confessor, were buried here. The last abbot of this place was hanged on the top of the Tor, by order of king Henry VIII. for not acknowledging his supremacy. This place is at present pretty large and well built, containing two parish churches. Nearly adjoining, on a high steep hill, is placed a tower, which commands an extensive prospect, and serves as a landmark to seamen. It is six miles S. W. of Wells, and 129 W. by S. of London. Lon. 2. 40. W. Lat. 51. 8. N.

GLATZ, a handsome well fortified town of Bohemia, capital of a county of the same name. It is seated on the river Neisse, and has a strong castle built upon a mountain. This county was ceded to the king of Prussia by the queen of Hungary in 1742, and is about 45 miles in length, and 25 in breadth. It has mines of coal, silver, and iron, good quarries, plenty of cattle, and fine springs of mineral waters. The town is 45 miles from Breslaw, and 82 E. by N. of Prague. Lon. 16. 50. E. Lat. 50. 25. N.

GLAUBER (John Rodolphus), a celebrated German chemist, who flourished about the year 1646. He wrote a great number of different treatises on chemistry, some of which have been translated into Latin and French. All his works have been collected into one volume, entitled, *Glauberus concentratus*, which has been translated into English, and was printed at London in folio in 1689.

GLAUBER'S Salts, a kind of purging salts, now called by the London College *natron vitriolatum*. Every one is acquainted with their properties. See CHEMISTRY, page 414.

GLAUCOMA, in surgery, a species of cataract wherein the crystalline humour of the eye is of a blueish or greenish colour, and its transparency diminished. The word comes from *γλαυκος, cerfus*, "sea green, sky-coloured, or greyish." See SURGERY.

GLAUCUS, a marine god, or deity of the sea. There are a great many fabulous accounts of this divinity: but the poetical history of him is, that, before his deification, he was a fisherman of the town of Anthedon, who having one day taken a considerable number of fishes, which he laid upon the bank, on a sudden perceived that these fishes, having touched a kind of

herb that grew on the shore, received new strength, and leaped again into the sea; upon the sight of which extraordinary accident, he was tempted to taste of the herb himself, and presently leaped into the sea after them, where he was metamorphosed into a Triton, and became one of the sea-gods.

GLAUX, in botany; a genus of the monogynia order, belonging to the pentandria class of plants, and in the natural method ranking under the 17th order, *Calycantbema*. The calyx is monophyllous; there is no corolla: the capsule is unilocular, quinquevalved, and pentaspermous.

GLAZIER, an artificer who works in glass. The principal part of a glazier's business consists in fitting panes of glass to the sashes and window-frames of houses, pictures, &c. and in cleaning the same when required.

GLAZING, the crusting over earthen ware by a vitreous substance, the basis of which is lead. See GLASS of Lead. The workers of common earthen ware, however, are not at the trouble of thus previously making a pure glass of lead. Their usual composition for glazing their ware is formed of white sand 40 pounds, of red lead 20 pounds, of pearl-ashes 20 pounds, and of common salt 12 pounds. Powder the sand by grinding it, and then add it to the other ingredients and grind them together: after which calcine them for some time with a moderate heat, and when the mixture is cold, reduce it to powder; and when wanted for use temper it with water. The proportion of these ingredients may be occasionally varied. The ware, after being turned on the wheel and dried in the open air, is covered over with the above composition by means of a brush; and when set in the furnace, the violent heat soon reduces it to a perfect glass, covering the whole internal and external surface of the vessel. We may observe, however, that lead, being poisonous, ought to be excluded from the composition of glazings, and other fluxes substituted in its stead. A transparent glazing may be prepared without lead by calcining 40 pounds of white sand, 25 pounds of pearl ashes, and 15 pounds of common salt, and proceeding as before: and a more perfect transparent glazing may be made of sand 40 pounds, of wood-ashes perfectly burned 50 pounds, of pearl-ashes 10 pounds, and of common salt 12 pounds. The following receipts are taken for the most part from Kunckel, who says that they are the true glazings used at Delft and other Dutch manufactories.

Black is made of eight parts of red-lead, iron-filings three, copper-ashes three, and zaffer two measures. This when melted will make a brown-black; and if wanted blacker, add more zaffer to it.

Blue is thus prepared: Take lead-ashes or red-lead, one pound; clear sand or powdered flints, two pounds; common salt, two pounds; white calcined tartar, one pound; Venice or other glass, half a pound; zaffer, half a pound; mix them well together and melt them for several times, quenching them always in cold

water. If you would have it fine and good, it will be proper to put the mixture into a glass furnace for a day or two. Another blue glazing may be formed of one pound of tartar, a quarter of a pound of red-lead, half an ounce of zaffer, and a quarter of a pound of powdered flints, which are to be fused and managed as in the last receipt. Or, take two pounds of calcined lead and tin, add five pounds of common salt, five pounds of powdered flints, and of zaffer, tartar, and Venetian glass, each one pound. Calcine and fuse the mixture as before. Or again, take of red-lead one part, of sand three parts, and of zaffer one part. For a violet blue glazing, take four ounces of tartar, two ounces of red-lead, five ounces of powdered flints, and half a dram of manganese.

Brown is made of red-lead and flints, of each 14 parts, and of manganese two parts fused; or of red-lead 12 parts, and manganese one part fused. A brown glazing, to be laid on a white ground, may be made of manganese two parts, and of red-lead and white-glass, of each one part, twice fused.

Flsb-coloured is made of 12 parts of lead-ashes, and one of white-glass.

Gold-coloured. Take of litharge three parts, of sand or calcined flint one part; pound and mix these very well together, then run them into a yellow glass with a strong fire. Pound this glass, and grind it into a subtile powder, which moisten with a well-saturated solution of silver; make it into a paste, which put into a crucible, and cover it with a cover. Give at first a gentle degree of fire; then increase it, and continue it till you have a glass, which will be green. Pound this glass again, and grind it to a fine powder; moisten this powder with some beer, so that by means of an hair pencil you may apply it upon the vessels or any piece of earthen ware. The vessels that are painted or covered over with this glazing must be first well heated, then put under a muffle; and as soon as the glass runs, you must smoke them by holding them over burning vegetables, and take out the vessels. Mr. Hiesinus of Petersburg, who sent this receipt to the Royal Society, uses the words *afflare debet fumum*, which is rendered *smoke them* in the Transactions. See Phil. Trans. N^o 465. sect. 6.

Kunckel gives several preparations for a gold-coloured yellow glazing. This may be produced by fusing a mixture of three parts of red-lead, two parts of antimony, and one part of saffron of Mars; by again melting the powdered mass, and repeating the operation four times, or by fusing four or five times a composition of red-lead and antimony, of each an ounce, and of scales of iron, half an ounce; or by calcining and fusing together eight parts of red-lead, six parts of flint, one part of yellow ochre, one part of antimony, and one part of white glass. A transparent gold-coloured glazing may be obtained by twice fusing red-lead and white flints, of each 12 parts, and of filings of iron, one part.

Green may be prepared of eight parts of litharge or red-lead, eight parts of Venice glass, four parts of brass-dust or filings of copper, or of ten parts of litharge, twelve of flint or pebble, and one of *es usum* or copper-ashes. A fine green glazing may be produced by fusing one part of the Bohemian granate, one part of filings of copper, one part of red-lead, and one part of Venetian glass; or by fusing one part of white glass, the same quantity of red-lead, and also of filings of copper; powdering the mass, and adding one part of Bohemian granate to two parts of this powder. A fine green may be obtained by mixing and grinding together any of the yellow glazings with equal quantities of the blue glazings; and all the shades and tints of green will be had by varying the proportion of the one to the other, and by the choice of the kind of yellow and blue.

Sea-green is made of five pounds of lead-ashes, one pound of tin ashes, three pounds of flint, three quarters of a pound

of salt, half a pound of tartar, and half a pound of copper-dust.

Iron-colour is prepared of 15 parts of lead-ashes or red-lead, 14 of white-sand or flints, and five of calcined copper. This mixture is to be calcined and fused.

Liver-colour is prepared of 12 parts of litharge, eight of salt, six of pebble or flint and one of manganese.

Purple brown consists of lead-ashes, 15 parts; clean sand or powdered flints, 18 parts; manganese, one part; and white glass, 15 measures; to which some add one measure of zaffer.

Red is made of antimony, three pounds; litharge or red-lead, three; and rust of iron, one; grind them to a fine powder. Or, take two pounds of antimony, three of red-lead, and one of calcined saffron of Mars, and proceed as before.

White. The white glazing for common ware is made of 40 pounds of clear sand, 75 pounds of litharge or lead-ashes, 26 of pot-ashes, and 10 pounds of salt; these are three times melted into a cake, quenching it each time in clear cold water. Or it may be made of 50 pounds of clean sand, 70 of lead-ashes, 30 of wood-ashes, and 12 of salt. For a fine white: Take two pounds of lead and one of tin; calcine them to ashes: of this take two parts; calcined flint, white sand, or broken white glass, one part; and salt, one part; mix them well together, and melt them into a cake for use. The trouble of calcining the tin and lead may be prevented by procuring them in a proper state. A very fine white glazing may be obtained by calcining two parts of lead and one part of tin; and taking one part of this mass, and of flints and common salt, of each one part, and fusing the mixture. A white glazing may be also prepared by mixing 100 pounds of masticot, 60 pounds of red-lead, 20 pounds of calcined tin or putty, and 10 pounds of common salt, and calcining and powdering the mixture several times.

Yellow is prepared of red-lead, three pounds; calcined antimony and tin, of each two pounds; or, according to some, of equal quantities of the three ingredients. These must be melted into a cake, then ground fine; and this operation repeated several times: or it may be made of 15 parts of lead-ore, three parts of litharge of silver, and 15 parts of sand. A fine yellow glazing may be procured by mixing five parts of red-lead, two parts of powdered brick, one part of sand, one part of the white glazings, and two parts of antimony, calcining the mixture and then fusing it. Or, take four parts of white-glass, one part of antimony, three parts of red-lead, and one part of iron-scales, and fuse the mixture; or fuse 16 parts of flints, one part of iron-filings, and 24 parts of litharge. A light yellow glazing may be produced with ten parts of red-lead, three parts of antimony, and three of glass, and two parts of calcined tin. See *Gold-colour* above. A *citron yellow* is made of six parts of red-lead, seven parts of fine red brick-dust, and two parts of antimony. This mixture must be calcined day and night for the space of four days, in the ash-hole of a glass-house furnace, and at last urged to fusion. For the glazing of Delft-ware, Porcelain, Stone-ware, &c. see the articles *DELFT-WARE*, *PORCELAIN*, and *POTTERY*.

The Romans had a method of glazing their earthen vessels, which in many respects appears to have been superior to ours. The common brown-glazing easily scales off, cracks, and in a short time becomes disagreeable to the eye. Besides, it is very easily destroyed by acids; nor can vessels glazed in this manner be even employed to hold water, without part of it oozing through their pores. Lead is also very destructive to the human body; and if acids are unwarily put into vessels glazed with lead, the liquors will receive a very dangerous impregnation from the metal. The Roman glazing, which is yet to be seen upon urns dug up in several places, appears to have been made of some kind of varnish; and Pliny gives us a hint that it was made of bitumen. He tells us that it never lost its

beauty, and that at length it became customary to glaze their statues in this manner. As this varnish sunk deep into the substance of the ware, it was not subject to those cracks and flaws which disfigure our vessels; and as it was not liable to be corroded by acids, it could not be subject to any of the accidents which may ensue from the use of vessels glazed with lead.

GLEAD, or GLADE, a name used in the northern parts of the kingdom for the kite. See FALCO.

GLEAM is popularly used for a ray or beam of light. Among falconers a hawk is said to gleam when she casts or throws up filth from the gorge.

GLEANING, the act of gathering or picking up the ears of corn left behind after the field has been reaped and the crop carried home. By the customs of some countries, particularly those of Melun and Estampes, all farmers and others are forbid, either by themselves or servants, to put any cattle into the fields, or prevent the gleanings in any manner whatever for the space of 24 hours after the carrying off the corn, under penalty of confiscation.

GLEBE, among miners, signifies a piece of earth in which is contained some mineral ore.

GLEBE, in law, the land belonging to a parish-church besides the tithes.

GLECHOMA, GROUND-IVY; a genus of the gymnospermia order, belonging to the didynamia class of plants, and in the natural method ranking under the 42d order, *Verticillatae*. Each pair of the antheræ come together in the form of a cross; the calyx is quinquefid. There are three species, the most remarkable of which is the hederacea, or common ground-ivy, which is so well known that it requires no description. Many virtues were formerly attributed to this plant, which it is now found not to be possessed of. Some however it has. The leaves are thrown into the vat with ale, to clarify it and give it a flavour. Ale thus prepared is often drunk as an antiscorbutic. The expressed juice, mixed with a little wine, and applied morning and evening, is said to destroy specks upon horses' eyes. The plants that grow near it do not flourish. It is said to be hurtful to horses if they eat much of it. Sheep eat it; horses are not fond of it; cows, goats, and swine refuse it.

GLEDISTIA, TRIPLE-THORNED ACACIA, or *Honey-locust*; a genus of the diccia order, belonging to the polygamia class of plants, and in the natural method ranking under the 33d order, *Lomentaceæ*. The hermaphrodite calyx is quadrifid, the corolla tetrapetalous, the stamina six, one pistil and legumen. The male calyx is triphyllous; the corolla tripetalous, with six stamina. The female calyx is pentaphyllous, the corolla pentapetalous, one pistil and legumen.

There are two species. 1. The *triacanthos*, a native of Virginia and Pennsylvania, is of an upright growth, and its trunk is guarded by thorns of three or four inches in length in a remarkable manner. These thorns have also others coming out of their sides at nearly right angles: their colour is red. The branches are smooth, and of a white colour. These are likewise armed with red thorns, that are proportionably smaller: they are of several directions, and at the ends of the branches often stand single. The young shoots of the preceding summer are perfectly smooth, of a reddish green, and retain their leaves often until the middle of November. Although there is a peculiar oddity in the nature and position of the spines, yet the leaves constitute the greatest beauty of these trees: they are doubly pinnated, and of a delightful shining green. The pinnated leaves that form the duplication do not always stand opposite by pairs on the middle rib; the pinnae of which they are composed are small and numerous; no less than 10 or 11 pair belong to each of them; and as no less than 4 or 5 pair of small leaves are arranged along the middle rib, the whole compound leaf consists often of more than 200 pinnae

of this fine green colour: they sit close, and spread open in fine weather; though during bad weather they will droop, and their upper surfaces nearly join, as if in a sleeping state. The flowers are produced from the sides of the young branches in July: they are a greenish catkin, and make little show; though many are succeeded by pods that have a wonderful effect; for these are exceedingly large, more than a foot, sometimes a foot and a half in length, and two inches in breadth, and of a nut-brown colour when ripe, so that the effect they occasion, when hanging on the sides of the branches, may easily be guessed.—

There is a variety of this species with fewer thorns, smaller leaves, and oval pods. It has nearly the resemblance of the other; though the thorns being not so frequent, and the pods being smaller, each containing only one seed, this sort loses that singular effect which the other produces by them. These trees are easily propagated. We receive the seeds from America in the spring, which keep well in the pods, and are for the most part good. They generally arrive in February; and, as soon as possible after, they should be sown in a well-sheltered warm border of light sandy earth. If no border is to be found that is naturally so, it may be improved by applying drift sand, and making it fine. The seeds should be sown about half an inch deep, and they will for the most part come up the first spring. If the summer should prove dry, they must be constantly watered; and if shade could be afforded them in the heat of the day, they would make stronger plants by the autumn. A careful attention to this article is peculiarly requisite; for, as the ends of the branches are often killed, if the young plant has not made some progress, it will be liable to be wholly destroyed by the winter's frost, without protection: and this renders the sowing the seeds in a warm border under an hedge in a well-sheltered place necessary; for there these shrubs will endure our winters, even when seedlings, and so will require no farther trouble; nay, though the tops should be nipped, they will shoot out again lower, and will soon overcome it. It will be proper to let them remain two years in the seed-bed before they are planted out in the nursery. The spring is the best time for the work. Their distances should be one foot by two; the rows should be dug between every winter; and, being weeded in summer, here they may be left, with no other particular care, until they are set out to remain. These trees are late in the spring before they exhibit their leaves, but keep shooting long in the autumn. 2. The other species is the *inermis*, the stem of which is unarmed or without thorns. It is a native of South America, and in this country requires to be kept in a stove.

GLEET, in surgery, a thin purulent or limpid discharge from the urethra. See SURGERY.

GLENOIDES, the name of two cavities, or small depressions in the inferior part of the first vertebra of the neck. See ANATOMY, page 165.

GLICAS, or GLYCAS, (Michael), a Greek historian about the middle of the 15th century, lived in Sicily, and wrote Annals of what passed from the creation of the world to the death of Alexis Comnenus in 1118. Leunclavius added to it a fifth part, which carries it down to the taking of Constantinople. Glicas was also the author of several useful and curious letters.

GLIMMER, or GLIST. See MICA.

GLINUS, in botany; a genus of the pentagynia order, belonging to the decandria class of plants, and in the natural method ranking under the 22d class, *Cary. phyllæi*. The calyx is pentaphyllous, there is no corolla, the nectarium is composed of bifid bristles, the capsule is quinqueangular, quinquelocular, quinquevalved, and polyspermous.

GLIRES, the name of Linnæus's fourth order of mammalia. See ZOOLOGY.

GLISSON (Francis), a learned English physician in the 17th century, was educated at Cambridge, and was made regius professor of that university. In 1634 he was admitted a fellow of the college of physicians in London. During the civil wars he practised physic at Colchester, and afterwards settled in London. He greatly improved physic by his anatomical dissections and observations, and made several new discoveries of singular use towards establishing a rational practice. He wrote, 1. *De rationibus*, &c. 2. *De lymphæductis nuper reperi- tis*; with the *Anatomica prolegomena, & Anatomia hepatis*. 3. *De natura substantiæ energeticæ; seu de via vite naturæ, ejusque tribus primis facultatibus*, &c. quarto. 4. *Tractatus de nerviculo & intellectus*, &c. The world is obliged to him for the *capitula communis*, or *va. ina portæ*.

GLISTER, in surgery. See CLYSTER.

GLOBBA, in botany; a genus of the monogynia order, belonging to the monandria class of plants. The corolla is equal and trifold, the calyx trifold above, the capsule trilocular, with many seeds.

GLOBE, in geometry, a round or spherical body more usually called a *sphere*. See SPHERE.

GLOBE is more particularly used for an artificial sphere of metal, plaster, paper, or other matter, on whose convex surface is drawn a map or representation either of the earth or heavens, with the several circles conceived thereon. See GEOGRAPHY, p. 740. Globes are of two kinds, *terrestrial* and *celestial*, each of very considerable use, the one in astronomy and the other in geography, for performing many of the operations thereof in an easy obvious manner, so as to be conceived without any knowledge of the mathematical grounds of those arts. The fundamental parts, common to both globes, are an axis, representing that of the world, and a spherical shell or cover, which makes the body of the globe, on the external surface of which the representation is drawn. See AXIS, POLE, &c.

The globes commonly used are composed of plaster and paper in the following manner: A wooden axis is provided, somewhat less than the intended diameter of the globe, and into the extremes thereof two iron wires are driven for poles: this axis is to be the beam or basis of the whole structure. On the axis are applied two spherical or rather hemispherical caps, formed on a kind of wooden mould or block. These caps consist of pasteboard or paper, laid one lay after another on the mould to the thickness of a crown-piece; after which, having stood to dry and embody, making an incision along the middle, the two caps thus parted are slipped off the mould. They remain now to be applied on the poles of the axis, as before they were on those of the mould: and to fix them in their new place, the two edges are sewed together with pack-thread, &c.

The rudiments of the globe thus laid, they proceed to strengthen and make it smooth and regular. In order to this, the two poles are halped in a metalline semicircle of the size intended; and a kind of plaster made of whiting, water, and glue, heated, melted, and incorporated together, is daubed all over the paper-surface. In proportion as the plaster is applied, the ball is turned round in the semicircle, the edge whereof pares off whatever is superfluous and beyond the due dimension, leaving the rest adhering in places that are short of it. After such application of plaster the ball stands to dry; which done, it is put again in the semicircle, and fresh matter applied: thus they continue alternately to apply the composition and dry it, till such time as the ball every where accurately touches the semicircle; in which state it is perfectly smooth, regular, and complete.

The ball thus finished, it remains to paste the map or description thereon: in order to this, the map is projected in several

gores or gussets; all which join accurately on the spherical surface, and cover the whole ball. To direct the application of these gores, lines are drawn by a semicircle on the surface of the ball, dividing it into a number of equal parts corresponding to those of the gores, and subdividing those again answerably to the lines and divisions of the gores.

The papers thus pasted on, there remains nothing but to colour and illuminate the globe, and to varnish it, the letter to resist dust, moisture, &c. The globe itself thus finished, they hang it in a brass meridian, with an hour-circle and a quadrant of altitude, and thus fit it into a wooden horizon.

To describe the gores or gussets for the globes. In Chambers's Dictionary the following method is directed: "1. From the given diameter of the globe find a right line AB, fig. 1. pl. 44. equal to the circumference of a great circle, and divide it into 12 equal parts. 2. Through the several points of division, 1, 2, 3, 4, &c. with the interval of ten of them, describe arches mutually intersecting each other in D and E; these figures or pieces, duly pasted or joined together, will make the whole surface of the globe. 3. Divide each part of the right line AB into 30 equal parts, so that the whole line AB, representing the periphery of the equator, may be divided into 360 degrees. 4. From the poles D and E, fig. 2. with the interval of $23\frac{1}{2}$ deg. describe arches *ab*; these will be twelfth-parts of the polar circles. 5. After the like manner, from the same poles D and E, with the interval of $66\frac{1}{2}$ deg. reckoned from the equator, describe arches *cd*; these will be twelfth parts of the tropics. 6. Through the degree of the equator *e*, corresponding to the right ascension of any given star and the poles D and E, draw an arch of a circle, and, taking in the compasses the complement of the declination from the pole D, describe an arch intersecting it in *i*; this point *i* will be the place of that star. 7. All the stars of a constellation being thus laid down, the figure of the constellation is to be drawn according to Bayer, Hevelius, or Flamsteed. 8. Lastly, after the same manner are the declinations and right ascensions of each degree of the ecliptic *d g* to be determined. 9. The surface of the globe thus projected on a plane is to be engraven on copper, to save the trouble of doing this over again for each globe. 10. A ball in the mean time is to be prepared of paper, plaster, &c. as before directed, and of the intended diameter of the globe; on this, by means of a semicircle and style, is the equator to be drawn, and through every 30th degree a meridian. The ball thus divided into twelve parts, corresponding to the segments before projected, the latter are to be cut from the printed paper and pasted on the ball. 11. Nothing now remains but to hang the globe as before in a brazen meridian and wooden horizon, to which may be added a quadrant of altitude made of brass, and divided in the same manner as the ecliptic and equator."

If the declinations and right ascensions of the stars be not given, but the longitudes and latitudes in lieu thereof, the surface of the globe is to be projected after the same manner as before, except that in this case D and E, fig. 2. are the poles of the ecliptic, and *fb* the ecliptic itself; and that the polar circles and tropics, with the equator *gd*, and the parallels thereof, are to be determined from their declinations.

M. De La Lande, in his *Astronomie*, 1771, tom. 3. p. 736, describes the following methods. "To construct celestial and terrestrial globes gores must be engraved, which are a kind of projection or inclosure of the globe (fig. 3.) similar to what is now to be explained. The length PC of the axis of this curve is equal to a quarter of the circumference of the globe; the intervals of the parallels on the axis PC are all equal, the radii of the circles KDI, which represent the parallels, are equal to the cotangents of the latitudes; and the arches of each, as DI, are nearly equal to the number of the degrees of the breadth of the gore, (which is usually 30) multiplied by the sine of the latitude:

thus there will be found no intricacy in tracing them; but the difficulty proceeds from the variation found in the trial of the gores when pasting them on the globe, and of the quantity that must be taken from the paper, less on the sides than in the middle (because the sides are longer), to apply it exactly to the space that it should cover.

“The method used among workmen to delineate the gores, and which is described by Mr. Bion (*L'usage des Globes, Tome 3.*) and by Mr. Robert de Vaugendy in the 7th volume of the *Encyclopédie*, is little geometrical, but yet is sufficient in practice. Draw on the paper a line AC, equal to the chord of 15° , to make the half breadth of the gore; and a perpendicular PC, equal to three times the chord of 30° , to make the half length: for these papers, the dimensions of which will be equal to the chords, become equal to the arcs themselves when they are pasted on the globe. Divide the height CP into 9 parts, if the parallels are to be drawn in every 10° ; divide also the quadrant BE into 9 equal parts through each division point of the quadrant, as G; and through the corresponding point D of the right line CP draw the perpendiculars HGF and DF, the meeting of which in F gives one of the points of the curve BEP, which will terminate the circumference of the gore. When a sufficient number of points are thus found, trace the outline PIB with a curved rule. By this construction are given the gore breadths which are on the globe, in the ratio of the cosines of the latitudes; supposing these breadths, taken perpendicular to CD, which is not very exact (but it is impossible to prescribe a rigid operation), sufficient to make a plane which shall cover a curved surface, and that on a right line AB shall make lines PA, PC, PB, equal among themselves, as they ought to be on the globe. To describe the circle KDI which is at 30° from the equator: there must be taken above D a point, which shall be distant from it the value of the tangent of 60° , taken out either from the tables, or on a circle equal to the circumference of the globe to be traced; this point will serve as a centre for the parallel DI, which should pass through the point D, for it is supposed equal to that of a cone circumscribing the globe, and which would touch at the point D.

“The meridians may be traced to every 10 degrees by dividing each parallel, as KI, into three parts at the points L and M, and drawing from the pole P, through all these division points, curves, which represent the intermediate meridians between PA and PB (as BR and ST, fig. 4.). The ecliptic may be described by means of the known declination from different points of the equator that may be found in a table; for 10° , it is $3^\circ 58'$; for 20° , $7^\circ 50' = BQ$; for 30° , $11^\circ 29'$, &c.”

It is observed in general, that the paper on which charts are printed, such as the *colombier*, shortens itself $\frac{1}{2}$ part or a line in six inches upon an average, when it is dried after printing; this inconvenience must therefore be corrected in the engraving of the gores: if, notwithstanding that, the gores are found too short, it must be remedied by taking from the surface of the ball a little of the white with which it is covered, thereby making the dimensions suitable to the gore as it was printed. But what is singular is, that in drawing the gore, moistened with the paste to apply on the globe, the axis GH lengthens, and the side AK shortens, in such a manner, that neither the length of the side ACK nor that of the axis GHI of the gore are exactly equal to the quarter of the circumference of the globe, when compared to the figure on the copper, or to the numbered sides shown in fig. 4. Mr. Bonne having made several experiments on the dimensions that gores take after they had been parted ready to apply to the globe, and particularly with the paper named *je fus* that he made use of for a globe of one foot in diameter, found that it was necessary to give to the gores on the copper the dimensions shewn in fig. 4. Supposing that the

radius of the globe contained 720 parts, the half breadth of the gore is $AG = 188\frac{5}{8}$, the distance AC for the parallel of 10 degrees taken on the right line LM is 128.1, the small deviation from the parallel of 10 degrees in the middle of the gore ED is 4, the line ABN is right, the radius of the parallel of 10° , or of the circle CEF, is 4083; and so of the others as marked in the figure. The small circular cap, which is placed under H, has its radius 253, instead of 274, which it would have if the sine of 20° had been the radius of it.—For the uses, &c. of the globes, see GEOGRAPHY and ASTRONOMY, with the plates there referred to.

GLOBE-Animal. See the article ANIMALCULE.

GLOBE-Fish. See OSTRACION.

GLOBULARIA, GLOBULAR BLUE DAISY; a genus of the monogynia order, belonging to the tetrandria class of plants, and in the natural method ranking under the 48th order, *Aggregatæ*. The common calyx is imbricated, the proper one tubulated inferior, the upper lip of the florets bipartite, the under one tripartite, the receptacle paleaceous. There are several species, but one only is commonly to be met with in our gardens, viz. the vulgaris, or common blue daisy. It hath broad thick radical leaves three-parted at the ends, upright stalks from about six to 10 or 12 inches high, garnished with spear-shaped leaves, and the top crowned by a globular head of fine blue flowers, composed of many florets in one cup. It flowers in June, and makes a good appearance, but thrives best in a moist shady situation. It is propagated by parting the roots in September.

GLOBULE, a diminutive of globe, frequently used by physiologists in speaking of the red particles of the blood. See BLOOD.

GLOUCESTER, a city of Gloucestershire, with two markets on Wednesday and Saturday. It is seated on the E. side of the Severn, where, by two streams, it makes the isle of Alney. It is a large and well-inhabited place, has been lately much improved, and its four principal streets are admired for the regularity of their junction in the centre of the town. It contains 12 churches, of which six only are in use, beside the cathedral of St. Peter, which is a handsome structure, remarkable for its large cloister and whispering gallery. Gloucester is a city and county of itself, and governed by a mayor, 12 aldermen, and 26 common-council, a town-clerk, and sword-bearer: the mayor is recorder of the city. It contains five hospitals, two free-schools, and a new county gaol, and was fortified with a wall, which king Charles II. after the restoration ordered to be demolished. It sends two members to parliament. The eminent persons buried here were Robert duke of Normandy, eldest son of William the Conqueror, and the unfortunate Edward II. Great quantities of pins are made here. It is 24 miles N. E. by N. of Bristol, and 106 W. by N. of London. W. lon. 2. 16. N. lat. 51. 50.

GLOUCESTERSHIRE, a county of England, is bounded on the west by Monmouthshire and Herefordshire, on the north by Worcestershire, on the east by Oxfordshire and Warwickshire, and on the south by Wiltshire and part of Somersetshire. It is sixty miles in length, twenty-six in breadth, and one hundred and sixty in circumference; containing 1,100,000 acres, 26,760 houses, 162,560 inhabitants, 290 parishes, 140 are impropriations, 129 villages, 2 cities, and 28 market-towns. It sends only 8 members to parliament: 6 for three towns, viz. Gloucester, Tewkesbury, and Cirencester, and two for the county. Its manufactures are woollen cloths of various kinds, mens' hats, leather, pens, paper, bar-iron, edge-tools, nails, wire, tinned-plates, brass, &c.: and of the principal articles of commerce of the county, it exports cheese, 8000 tons; bacon, grain, cyder, 5000l. worth; perry, fish, 4000l. worth, &c. It lies in the diocese that takes its name from the capital, and in the Oxford

circuit. The air of the county is very wholesome, but the face of it is very different in different parts: for the eastern part is hilly, and is called *Cotteswold*; the western woody, and called the *Forest of Dean*; and the rest is a fruitful valley, through which runs the river Severn. This river is in some places between two and three miles broad; and its course through the country, including its windings, is not less than seventy miles. The tide of flood called the *Boar* rises very high, and is very impetuous. It is remarkable that the greatest tides are one year at the full-moon and the other at the new; one year the night-tides, and the next the day. This river affords a noble conveyance for goods and merchandize of all sorts to and from the county, but it is watered by several others, as the Wye, the Avon, the Isis, the Leden, the Frome, the Stroud, and Windrush, besides the lesser streams, all abounding with fish, the Severn in particular with salmon, conger-eels, and lampreys. The soil is in general very fertile though pretty much diversified, yielding plenty of corn, pasture, fruit and wood. In the hilly part of the county or Cotteswold the air is sharper than in the lowlands; and the soil, though not so fit for grain, produces excellent pasture for sheep; so that of the four hundred thousand that are computed to be kept in the county the greater part are fed here. Of these sheep the wool is exceeding fine, and hence it is that this shire is so eminent for its manufacture of cloth, of which fifty thousand pieces are said to have been made yearly, before the practice of clandestinely exporting English wool became so common. In the vale or lower part of the county, through which the Severn passes, the air and soil are very different from those of the Cotteswold: for the former is much warmer, and the latter richer, yielding the most luxuriant pastures; in consequence of which, numerous herds of black cattle are kept, and great quantities of that excellent cheese for which it is so much celebrated made in it. The remaining part of the county, called the *Forest of Dean*, was formerly almost entirely over-run with wood, and extended 20 miles in length and 10 in breadth. It was then a nest of robbers, especially towards the Severn; but now it contains many towns and villages, consisting chiefly of miners, employed in the coal-pits, or in digging for or forging iron-ore, with both which the forest abounds. These miners have their particular laws, customs, courts, and judges; and the king, as in all royal forests, has a swain-mote for the preservation of the vert and venison. This forest was anciently and is still noted for its oaks, which thrive here surprisingly; but as there is a prodigious consumption of wood in the forges, it is continually dwindling away. A navigable canal is made from the Stroud to Framilode, forming a junction between the Severn and Thames. Another has been begun from Gloucester to Berkeley, on a very extensive scale, and, when completed, will give the former all the advantages of a sea-port. The iron springs in Gloucestershire are: St. Anthony's well, in Abbenhall parish; at Barrow and Mareton, in Bodington parish; at Ash-Church, near Tewkesbury; at Dumbleton, near Winchcomb; at Easington, near Dursley; and at Cheltenham. Its ancient fortifications attributed to the Romans, Saxons, or Danes, are at Abston and Wick, and at Dointon, Dixton, Addleshorp, Knole, Over Upton, Hanham, Bodington, and Bourton on the Water.

GLOCHIDION, in botany; a genus of the syngenesia order, belonging to the monœcia class of plants. There is no calyx; the corolla consists of six egg-shaped concave petals; the stamina are three very small inconspicuous filaments, the antheræ cylindrical and erect, the female flowers have no calyx, the corolla is parted into six, the pericarpium is a depressed roundish capsule with six cells, the seeds are roundish and solitary.

GLOGAW, a town of Silesia, capital of a duchy of the same name. It is not very large, but is well fortified on the side of Poland. It has a castle with a tower, in which several counsel-

lors were condemned by duke John in 1498 to perish with hunger. Beside the Papists, there is a great number of Protestants and Jews. It was taken by assault by the king of Prussia in 1741. After the peace in 1742, that king settled the supreme court of justice here, it being, next to Breslaw, the most populous place in Silesia. It is seated on the river Oder, 50 miles N. W. of Breslaw, and 115 N. by E. of Prague. E. lon. 16. 31. N. lat. 51. 40.

Little GLOGAW, a town of Silesia, in the duchy of Opelen, subject to the king of Prussia. It is two miles S. E. of Great Glogaw, and 45 N. W. of Breslaw. E. lon. 16. 13. N. lat. 51. 38.

GLORIA PATRI, among ecclesiastical writers. See the article **DOXOLOGY**.

GLORIOSA, SUPERB LILY; a genus of the monogynia order, belonging to the hexandria class of plants, and in the natural method ranking under the 11th order, *Sarmentaceæ*. The corolla is hexapetalous, undulated, and reflexed; the style oblique. There is but one species, a native of Malabar. It hath a thick, fleshy, tuberous root, sending forth from its centre declinated round stalks, growing eight or ten feet long, and garnished with very long narrow leaves running out into a point, terminated by a long tendril. From the upper part of the stalks proceed large flame-coloured drooping flowers, consisting of six widely-spreading reflexed petals. It flowers in June and July, and is of admirable beauty, whence its name of *Gloriosa*, or *Superb Lily*. This plant, being a native of a very warm climate, requires the protection of a hot-house in this country. The flower-stalks shoot forth in March or April; which, being long and trailing, must have tall sticks placed for their support. The plants are propagated by offsets, which are produced in tolerable plenty, and may be separated any time after the stalks decay, or in spring before new ones arise.

GLOSS, a comment on the text of any author, to explain his sense more fully and at large, whether in the same language or any other. See the article **COMMENTARY**. The word, according to some, comes from the Greek *γλωσσα*, "tongue;" the office of a *gloss* being to explain the text, as that of the tongue is to discover the mind.

Gloss is likewise used for a literal translation, or an interpretation of an author in another language word for word.

Gloss is also used in matters of commerce, &c. for the lustre of a silk, stuff, or the like.

GLOSSARY, a sort of dictionary, explaining the obscure and antiquated terms in some old author; such are Du Cange's Latin and Greek Glossaries, Spelman's Glossary, and Kennet's Glossary at the end of his *Parochial Antiquities*.

GLOSSOPETRA, or **GLOTTOPETRA**, in natural history, a kind of extraneous fossil, somewhat in form of a serpent's tongue; frequently found in the island of Malta and other parts. See Plate 31. The vulgar notion is, that they are the tongues of serpents petrified; and hence their name, which is a compound of *γλωσσα*, "tongue," and *πετρα*, "stone." Hence also their traditionary virtue in curing the bites of serpents. The general opinion of naturalists is, that they are the teeth of fishes, left at land by the waters of the deluge, and since petrified.

The several sizes of the teeth of the same species, and those of the several different species of sharks, afford a vast variety of these fossil substances. Their usual colours are black, blueish, whitish, yellowish, or brown, and in shape they usually approach to a triangular figure. Some of them are simple, others are tricuspidate, having a small point on each side of the large one: many of them are quite straight, but they are frequently found crooked and bent in all directions; many of them are serrated on their edges, and others plain; some are undulated on

their edges, and slightly serrated on these undulations. They differ also in size as much as in figure; the larger being four or five inches long, and the smaller less than a quarter of an inch.

They are most usually found with us in the strata of blue clay, though sometimes also in other substances, and are frequent in the clay pits of Richmond and other places. They are very frequent also in Germany, but no where so plentiful as in the island of Malta.

The Germans attribute many virtues to these fossil teeth, which they rank amongst their cordial, sudorific, and alexipharmic medicines. The people of Malta, where they are extremely plentiful, hang them about their childrens' necks to promote dentition, and no doubt with the same degree of success as attends that ridiculous imposture known by the name of the *anodyne necklace*.

GLOTTIS, in anatomy, the narrow slit at the upper part of the *aspera arteria*, which is covered by the *epiglottis* when we hold our breath and when we swallow. The glottis, by its dilatation and contraction, modulates the voice. See ANATOMY, page 192.

GLOVE, a covering for the hand and wrist. Gloves, with respect to commerce, are distinguished into leathern, silk, thread, cotton, worsted, &c. Leathern gloves are made of chamois, kid, lamb, doe, elk, buff, &c. To *throw the glove* was a practice or ceremony very usual among our forefathers, being the challenge whereby another was defied to single combat. It is still retained at the coronation of our kings, when the king's champion casts his glove in Westminster-hall. See CHAMPION. Favyn supposes the custom to have arisen from the eastern nations, who, in all their sales and deliveries of lands, goods, &c. used to give the purchaser their glove by way of livery or investiture. To this effect he quotes Ruth iv. 7. where the Chaldee paraphrase calls *glove* what the common version renders by *shoe*. He adds that the Rabbins interpret by *glove* that passage in the ciiiith Psalm, *In Idumeam extendam calcamentum meum*, "Over Edom will I cast out my shoe." Accordingly, among us, he who took up the *glove* declared thereby his acceptance of the challenge; and as a part of the ceremony, continues Favyn, took the *glove* off his own right hand and cast it upon the ground, to be taken up by the challenger. This had the force of a mutual engagement on each side, to meet at the time and place which should be appointed by the king, parliament, or judges. The same author asserts, that the custom which once obtained of blessing *gloves* in the coronation of the kings of France was a remain of the eastern practice of giving possession with the *glove*, l. xvi. p. 1017, &c. Anciently it was prohibited the judges to wear gloves on the bench; and at present, in the stables of some princes, it is said to be unsafe going in without pulling off the gloves.

GLOVER (Richard), the author of *Leonidas* and several other esteemed works, was the son of Richard Glover, a Hamburgh merchant in London, and was born in St. Martin's-lane in the year 1712. He very early showed a strong propensity and genius for poetry: and while at school he wrote, amongst other pieces, a poem to the memory of Sir Isaac Newton, prefixed to the view of that incomparable author's philosophy published in 4to in 1728 by his intimate friend Dr. Pemberton. But, though possessed of talents which were calculated to excel in the literary world, he was content to devote his attention to commerce, and at a proper period commenced a Hamburgh merchant. He still however cultivated literature, and associated with those who were eminent in science. One of his earliest friends was Matthew Green, the ingenious but obscure author of some admirable poems, which in 1737, after his death, were collected and published by Mr. Glover. In 1737 Mr. Glover married Miss Nunn, with whom he received a handsome for-

tune; and in the same month published *Leonidas*, a poem in 4to, which in this and the next year passed through three editions. This poem was inscribed to Lord Cobham, and on its first appearance was received by the world with great approbation, though it has since been unaccountably neglected. Lord Lyttleton, in a popular publication called *Common Sense*, and in a poem addressed to the author, praised it in the warmest terms; and Dr. Pemberton published *Observations on Poetry*, especially epic, occasioned by the late poem upon *Leonidas*, 1738, 12mo, merely with a view to point out its beauties. In 1739 Mr. Glover published "London, or the Progress of Commerce", 4to; and a ballad, intitled *Hosier's Ghost*. Both these pieces seem to have been written with a view to incite the public to resent the misbehaviour of the Spaniards; and the latter had a very considerable effect. The political dissensions at this period raged with great violence, and more especially in the metropolis; and at different meetings of the livery on those occasions, Mr. Glover was always called to the chair and acquitted himself in a very able manner, his conduct being patriotic and his speeches masterly. His talents for public speaking, his knowledge of political affairs, and his information concerning trade and commerce, soon after pointed him out to the merchants of London as a proper person to conduct their application to parliament on the subject of the neglect of their trade. He accepted the office, and in summing up the evidence gave very striking proofs of his oratorical powers. This speech was pronounced Jan. 27, 1742.

In the year 1744 died the Dukes of Marlborough, and by her will left to Mr. Glover and Mr. Mallet 500l. each, to write the *History of the Duke of Marlborough's Life*. This bequest, however, never took place. It is supposed that Mr. Glover very early renounced his share of it; and Mallet, though he continued to talk of performing the task almost as long as he lived, is now known never to have made the least progress in it. About this period Mr. Glover withdrew a good deal from public notice, and lived a life of retirement. He had been unsuccessful in his business; and, with a very laudable delicacy, had preferred an obscure retreat to popular observation, until his affairs should be put on a more prosperous appearance. He had been honoured with the attention of Frederic Prince of Wales, who once presented him with a complete set of the Classics, elegantly bound; and, on his absentsing himself for some time on account of the embarrassment in his circumstances, he sent him, it is said, 500l. The prince died in March 1751; and in May following Mr. Glover was once more drawn from his retreat by the importunity of his friends, and stood candidate for the place of chamberlain of London. It unfortunately happened that he did not declare himself until most of the livery had engaged their votes, by which means he lost his election.

In 1753 Mr. Glover produced at Drury-lane his tragedy of *Boadicea*, which was acted nine nights in the month of December. It had the advantage of the performance of Mr. Garrick, Mr. Maffop, Mrs. Cibber, and Mrs. Pritchard. From the prologue it seems to have been patronized by the author's friends in the city; and Dr. Pemberton wrote a pamphlet to recommend it. In 1761 Mr. Glover published *Medea*, a tragedy written on the Greek model; but it was not acted until 1767, when it appeared, for the first time, on the stage at Drury-lane for Mrs. Yates's benefit. At the accession of his present Majesty, he appears to have surmounted the difficulties of his situation. In the parliament which was then called, he was chosen member for Weymouth, and continued to sit as such until the dissolution of it. He about this time interested himself about India affairs at one of Mr. Sullivan's elections; and in a speech introduced the fable of the man, horse, and bear; and drew this conclusion, that, whenever merchants made use

of armed forces to maintain their trade, it would end in their destruction.

In 1770, the poem of Leonidas requiring a new edition, it was republished in two volumes 12mo, corrected throughout, and extended from nine books to twelve. It had also several new characters added, besides placing the old ones in new situations. The improvements made in it were very considerable; but we believe the public curiosity at this period was not sufficiently alive to recompence the pains bestowed on this once popular performance. The calamities arising from the wounds given to public credit in June 1772 by the failure of the bank of Douglas, Heron, and Co. in Scotland, occasioned Mr. Glover's taking a very active part in the settling those complicated concerns, and in stopping the distress then so universally felt. In February 1774, he called the annuitants of that banking-house together at the King's Arms tavern, and laid proposals before them for the security of their demands, with which they were fully satisfied. He also undertook to manage the interests of the merchants and traders of London, concerned in the trade to Germany and Holland, and of the dealers in foreign linens, in their application to parliament in May 1774. Both the speeches made on these occasions were published in a pamphlet in that year. In the succeeding year he engaged on behalf of the West-India merchants in their application to parliament, and examined the witnesses and summed up the evidence in the same masterly manner he had done on former occasions. For the assistance he afforded the merchants in this business, he was complimented by them with a service of plate, of the value of 300l. The speech which he delivered in the house was in the same year printed. This, we believe, was the last opportunity he had of displaying his oratorical talents in public. Having now arrived at a period of life which demanded a recess from business, Mr. Glover retired to ease and independence, and wore out the remainder of his days with dignity and with honour. It is probable that he still continued his attention to his muse, as we are informed that, besides an epic poem of considerable length, he has left some tragedies and comedies behind him in manuscript. After experiencing for some time the infirmities of age, he departed this life 25th November 1785; leaving behind him a most estimable character as a man, a citizen, and a writer.

GLOW-WORM, in zoology. See LAMPYRIS.

GLUCKSTADT, a considerable town of Germany, in the circle of Lower Saxony, and duchy of Holstein, with a strong castle, subject to Denmark. It is seated on the Elbe, near its mouth, 30 miles N. W. of Hamburg, and 55 N. of Bremen. E. lon. 9. 15. N. lat. 53. 53.

GLUE, among artificers, a tenacious viscid matter, which serves as a cement to bind or connect things together. Glues are of different kinds, according to the various uses they are designed for: as the common-gluce, glove-gluce, and parchment-gluce; whereof the two last are more properly called *size*. The common or strong glue is chiefly used by carpenters, joiners, cabinet-makers, &c. It is made of skins of animals, as oxen, cows, calves, sheep, &c.; and the older the creature is, the better is the glue made of its hide. Whole skins, however, are but rarely used for this purpose, but only the shavings, parings, or scraps of them; or the feet, sinews, &c. That made of whole skins is undoubtedly reckoned the best; as that made of sinews is the very worst.

In making glue of parings, they first steep them two or three days in water: then, washing them well out, they boil them to the consistence of a thick jelly; which they pass while hot through ozier-baskets, to separate the impurities from it; and then let it stand some time to purify it further: when all the filth and ordures are settled to the bottom of the vessel, they melt and boil it a second time. They next pour it into flat

frames or moulds, whence it is taken out pretty hard and solid, and cut into square pieces or cakes. They afterwards dry it in the wind in a sort of coarse net, and at last string it to finish its drying. The glue made of sinews, feet, &c. is managed after the same manner, only with this difference, that they bone and scour the feet, and do not lay them to steep.

Of this commodity there is a very great exportation from England; the English glue being universally allowed to be the best in Europe, partly from the excellency of the materials, and partly from the skill of the manufacturers. Next to this is the Flanders glue. In both countries it is made by the tanners from fragments of good skins dried with much care. In France it is a separate trade: and the glue-makers pick up their materials as they can from the several dealers in skins, and boiling these with cow-heels, make their glue; which, as they purchase every thing, must render it dear, as well as of an inferior quality. The duty on exportation is tenpence, and on importation three shillings and tenpence, on every hundred weight. The best glue is that which is made from the skin of the oldest beast, especially if a bull's hide is used. Experience likewise shows that glue is considerably improved in quality by keeping.

A glue that will hold against fire or water, it is said, may be made thus: Mix a handful of quicklime with four ounces of linseed oil; boil them to a good thickness; then spread it on tin-plates in the shade, and it will become extremely hard, but may be easily dissolved over a fire, as glue, and will effect the business for which it is intended.

Neumann observes, that glue dissolved in a solution of lapis calaminaris in spirit of nitre, and afterwards inspissated, forms an extremely slippery tenacious mass, which might be of use for entangling flies, caterpillars, and other insects, if it was not too expensive.

To prepare glue for use, it is merely required to set a quart of water on the fire, and put in about half a pound of glue, keeping them close to the fire, nearly in a boiling state, till the glue is dissolved. When glue is to be used, it must be made hot; after which, with a brush dipped in it, besinear the faces of the joints as quick as possible: then clapping them together, slide or rub them lengthwise one upon another, two or three times, to settle them close; and so let them stand till they are dry and firm.

GLUME, *gluma*, among botanists, a species of calyx, consisting of two or three membranous valves, which are often pellucid at the edges. This kind of calyx belongs to the grasses.

GLUT, among falconers, the slimy substance that lies in a hawk's paunch.

GLUTA, in botany; a genus of the pentandria order, belonging to the gynandria class of plants. The calyx is campanulated and deciduous; there are five petals glued below to the column of the germ; and the filaments inserted on the top of the column, on which also the germen sits.

GLUTÆUS, a name common to three muscles whose office it is to extend the thigh. See ANATOMY, *Table of the Muscles*.

GLUTTON, in zoology. See MUSTELA.

GLUTTONY, a voracity of appetite, or a propensity to gormandizing. A morbid sort of gluttony has been supposed to exist, called *fames canina*, "dog-like appetite," which sometimes occurs, and renders the person seized with it an object of cure as in other diseases. See BULIMY. But professed habitual gluttons may be reckoned amongst the monsters of nature, and for this reason king James I. was not greatly in the wrong when he asked a man who was presented to him that could eat a whole sheep at one meal, "What he could do more than another man?" and being answered "He could not do so much," said, "Hang him then; for it is unfit a man should

five that eats as much as twenty men, and cannot do so much as one."

The emperor Clodius Albinus would devour more apples at once than a bushel would hold. He would eat 500 figs to his breakfast, 100 peaches, 10 melons, 20 pound weight of grapes, 100 gnat snappers, and 400 oysters. "Eye upon him (saith Lipsius); God keep such a curse from the earth."

One of our Danish kings named *Hardiknute* was so great a glutton, that a historian calls him *Bacca de Porco*, "Swine's-mouth." His tables were covered four times a-day with the most costly viands that either the air, sea, or land, could furnish: and as he lived he died; for, revelling and carousing at a wedding banquet at Lambeth, he fell down dead. His death was so welcome to his subjects, that they celebrated the day with sports and pastimes, calling it *Hock-tide*, which signifies scorn and contempt. With this king ended the reign of the Danes in England. One Phagon, under the reign of the emperor Aurelianus, at one meal ate a whole boar, 100 loaves of bread, a sheep, a pig, and drank above three gallons of wine.

We are told by Fuller, that one Nicholas Wood, of Harrison in Kent, ate a whole sheep of 16s. price at one meal, raw; at another time, 30 dozen of pigeons. At Sir William Sidley's in the same county, he ate as much victuals as would have sufficed 30 men. At Lord Wotton's mansion-house in Kent, he devoured at one dinner 84 rabbits; which, by computation at half a rabbit a man, would have served 168 men. He ate to his breakfast 18 yards of black pudding. He devoured a whole hog at one sitting down; and after it, being accommodated with fruit, he ate three pecks of damosins.

A counsellor at law, whose name was Mallet, well known in the reign of Charles I. ate at one time an ordinary provided in Westminster for 30 men at twelve-pence a piece. His practice not being sufficient to supply him with better sort of meat, he fed generally on offals, ox-livers, hearts, &c. He lived to almost 60 years of age, and for the seven last years of his life ate as moderately as other men. A narrative of his life was published.

GLYCINE, KNOBBED-ROOTED LIQUORICE-VETCH; a genus of the decandria order, belonging to the diadelphia class of plants, and in the natural method ranking under the 32d order, *Papilionaceæ*. The calyx is bilabiate; the carina of the corolla turning back the vexillum with its point. There is but one species commonly cultivated in our gardens, viz. the frutescens, or Carolina kidney-bean tree. This hath shrubby climbing stalks, twining round any support, 15 or 20 feet high, adorned with pinnated leaves of three pair of foliicles terminated by an odd one, and from the axillas clusters of large blueish-purple flowers, succeeded by long pods like those of the climbing kidney-bean. It flowers in June and July, but the seeds do not ripen in this country. It is easily propagated, either by seeds imported from America, where it is native, or by layers. The stalks and roots of the *abrus*, another species of glycine, which grows in Egypt and the Indies, are very sweet to the taste. Herman affirms, that the juice obtained from them by decoction is little inferior to liquorice; whence its name of *wild liquorice* in those parts of America where it is native.

GLYCIRRHIZA, LIQUORICE; a genus of the decandria order, belonging to the diadelphia class of plants, and in the natural method ranking under the 32d order, *Papilionaceæ*. The calyx is bilabiate; the upper lip tripartite, and the under one entire; the legumen ovate and compressed. There are two species. 1. The *glabra*, or common liquorice, hath a long, thick, creeping root, striking several feet deep into the ground; upright, firm, herbaceous stalks annually, three or four feet high, garnished with winged leaves of four or five pair of oval lobes, terminated by an odd one; and from the axillas erect spikes of pale blue flowers in July, succeeded by short smooth

Pods. The root of this is the useful part, which is replete with a sweet, balsamic, pectoral juice, much used in all compositions for coughs and disorders of the stomach. 2. The *erbinata*, or prickly-podded liquorice, is nearly like the common sort, only the seed pods are prickly. Both these species are very hardy perennials; but the first is the sort commonly cultivated for use, its roots being fuller of juice and sweeter than the other. The roots are perennial; but the stalks rise in spring and decay in autumn.

Their *propagation* is effected by cuttings of the small roots issuing from the sides of the main ones near the surface of the earth, dividing them into lengths of six or eight inches, each having one or more good buds or eyes; and the proper season for procuring the sets for planting is any time in open weather from October till March, though from the middle of February till the middle of March is rather the most successful season for planting. An open situation is the most suitable for a plantation of these plants. Particular regard should also be had to the soil: it ought to be of a light loose composition, and three or four feet deep if possible; for the roots of the liquorice will arrive at that depth and more, and the longer the roots the more valuable they are for sale by weight.

Having fixed on the ground, let it be trenched three spades deep, if the depth of proper soil will admit; then having your sets ready, proceed to plant them by line and dibble, planting the sets a foot distance in each row; putting them perpendicular into the ground, with the tops about an inch under the surface; and let the rows be a foot and a half asunder; though the London gardeners seldom allow more than twelve inches between row and row. These gardeners also sow a crop of onions on the same ground the first year; which, as the onions' root but slender, and spread but little at top, may be done without any detriment to the liquorice, or to the onions, as it does not rise above ten or twelve inches high the first summer; observing to keep the ground clean from weeds during that season by hoeing. If there is a crop of onions, use the small hoe, cutting out the onions to four or five inches distance, clearing away such as grow immediately close to the liquorice plants; and when the onions are gathered, give the ground a thorough hoeing with a large hoe, to loosen the surface and destroy all weeds effectually; and in autumn cut down the decayed stalks of the liquorice, and nothing more is necessary to be done till spring; when, in February or March, give a slight digging between the rows; during spring and summer, keep down all weeds by broad-hoeing; and in autumn, when the stalks are in a decaying state, cut them down to the surface of the earth.

In three years after planting, the roots of the liquorice will be fit to take up: and the proper season for this is, any time from the beginning of November till February; for it should neither be taken up before the stalks are fully decayed, nor deferred till late in spring, otherwise the roots will be apt to shrivel and diminish in weight. In taking them up, the small side-roots are trimmed off, and the best divided into lengths for fresh sets, and the main roots are tied in bundles ready for sale. It is of advantage to sell them as soon as possible after they are taken up, before they lose much of their weight. They are sold to the druggists from about twenty to thirty or forty shillings per hundred weight; and an acre of ground has produced three thousand and upwards, which has been sold for more than sixty pounds: but the price is commonly in proportion to the goodness of the roots.

Although the common liquorice is cultivated in most countries of Europe for the sake of its root, yet that which is produced in Britain is preferable to such as comes from abroad; this last being generally mouldy, which this root is very apt to become, unless kept in a dry place. The powder of liquorice usually sold is often mingled with flour, and probably too often with

Substances not quite so wholesome : the best sort is of a brownish yellow colour (the fine pale yellow being generally sophisticated), and of a very rich sweet taste, much more agreeable than that of the fresh root. Liquorice is almost the only sweet that quenches thirst ; whence it was called by the Greeks *adipson*. Galen takes notice, that it was employed in this intention in hydropic cases, to prevent the necessity of drinking. Mr. Fuller, in his *Medicina Gymnastica*, recommends this root as a very useful pectoral ; an assertion warranted by experience. An extract is directed to be made from it in the shops ; yet this preparation is chiefly brought from abroad, though the foreign extract is not the best.

GLYPH, in sculpture and architecture, denotes any canal or cavity used as an ornament.

GMELIN (Dr. Samuel), professor at Tubingen, and afterwards member of the Imperial Academy of Sciences at St. Petersburg, commenced his travels in June 1768 ; and having traversed the provinces of Moscow, Voronetz, New Russia, Azof, Casan, and Astracan, he visited in 1770 and 1771 the different harbours of the Caspian, and examined with peculiar attention those parts of the Persian provinces which border upon that sea, of which he has given a circumstantial account in the three volumes of his travels already published. Actuated by a zeal for extending his observations, he attempted to pass through the western provinces of Persia, which are in a perpetual state of warfare, and infested by numerous banditti. Upon this expedition he quitted in April 1772 Einzillee, a small trading place in Ghilan, upon the southern shore of the Caspian ; and, on account of many difficulties and dangers, did not until December 2, 1773, reach Sallian, a town situated upon the mouth of the river Koor. Thence he proceeded to Baku and Kuba in the province of Shirvan, where he met with a friendly reception from Ali Feth Khan, the sovereign of that district. After he had been joined by 20 Uralian Cossacks, and when he was only four days journey from the Russian fortress Kislar, he and his companions were, on the 5th of February 1774, arrested by order of Ufmei Khan, a petty Tartar prince, through whose territories he was obliged to pass. Ufmei urged, as a pretence for this arrest, that 30 years ago several families had escaped from his dominions, and had found an asylum in the Russian territories ; adding, that Gmelin should not be released until these families were restored. The professor was removed from prison to prison ; and at length, wearied out with continual persecutions, he expired July 27th, at Achmet-Kent, a village of Mount Caucassus. His death was occasioned partly by vexation for the loss of several papers and collections, and partly by disorders contracted from the fatigues of his long journey. Some of his papers had been sent to Kislar during his imprisonment, and the others were not without great difficulty rescued from the hands of the barbarian who had detained him in captivity. The arrangement of these papers, which form a fourth volume of his travels, was at first consigned to the care of Guldenstaedt, but upon his death the task was transferred to the learned Pallas.

GMELINA, in botany ; a genus of the angiospermia order, belonging to the didynamia class of plants, and in the natural method ranking under the 40th order, *Personateæ*. The calyx is nearly quadridentated ; the corolla campanulated or bell-shaped ; there are two bipartite and two simple antheræ ; the fruit is a plum with a bilocular kernel.

GNAPHALIUM, CUDWEED, GOLDY LOCKS, ETERNAL FLOWER, &c. ; a genus of the polygamia superflua order, belonging to the syngenesia class of plants, and in the natural method ranking under the 49th order, *Compositæ*. The receptacle is naked ; the pappus feathered ; the calyx imbricated, with the marginal scales roundish, parched, and coloured. There are 41 species ; the most remarkable of which are,

1. The *margaritaceum*, or pearly-white eternal flower, hath creeping, very spreading roots, crowned with broad, spear-shaped, white, hoary leaves ; herbaceous, thick, woolly stalks, a foot and a half high, branching outward, garnished with long, acute-pointed, white, woolly leaves, and terminated by a corymbose cluster of yellowish flowers, which appear in June and July, and are very ornamental. 2. The *plantaginifolium*, hath large woolly radical leaves, decumbent running roots, and herbaceous simple stalks, rising six or eight inches high, terminated by a corymbus of white flowers in June, July, &c. 3. The *steebas*, hath a shrubby stalk, dividing into slender branches three feet long, terminated by corymbose clusters of yellow flowers, appearing in May and June. 4. The *orientale*, or oriental goldy locks, hath three varieties, with yellow, gold-coloured, and white silvery flowers. They have shrubby stalks, rising two or three feet high. 5. The *odoratissimum*, or sweet-scented eternal flower, hath shrubby winged stalks, branching irregularly a yard high, with corymbose clusters of bright yellow flowers, changing to a dark yellow. 6. The *arborcum*, or tree gnaphalium, hath a woody stem, branching four or five feet high, narrow sessile leaves, with revolute borders, smooth on their upper side, and roundish bunches of pale yellow flowers. The first three sorts are hardy, and will thrive in any soil or situation. The two first increase exceedingly by their roots ; and the third is easily propagated by slips. The fourth, fifth, and sixth sorts are somewhat tender, and therefore should be kept in pots, to be sheltered in a green-house or garden frame in winter. Others may be planted in the full ground, in a dry and warm situation, especially the oriental kind and varieties, and likewise the sweet-scented kind ; for these two species will struggle tolerably through an ordinary winter, and make a pretty appearance during the summer months. All these are propagated by slips or cuttings of their shoots. The flowers of all these species are remarkable for retaining their beauty for years, if carefully gathered in a dry day, soon after they are blown.

GNAT, in zoology. See CULEX.

GNESNA, a large and strong town of Great Poland, of which it is capital, and in the palatinate of Calish, with an archbishop's see, whose prelate is primate of Poland, and viceroys during the vacancy of the throne. It was the first town built in the kingdom, and formerly more considerable than at present. E. lon. 18. 20. N. lat. 52. 28.

GNETUM, in botany ; a genus of the monadelphia order, belonging to the monœcia class of plants. The amentum of the male is a single scale ; there is no corolla, and but one filament with a pair of antheræ. The calyx of the female is of the same form ; there is no corolla ; the style with the stigma is trifid ; the fruit a monospermous plum.

GNIDIA, in botany ; a genus of the monogynia order, belonging to the octandria class of plants. The calyx is funnel-shaped and quadrifid, with four petals inserted into it : there is one seed somewhat resembling a berry.

GNOMES, GNOMI, certain imaginary beings who, according to the cabbalists, inhabit the inner parts of the earth. They are supposed small in stature, and the guardians of quarries, mines, &c. See FAIRY.

GNOMON, in dialling, the style, pin, or cock of a dial, which by its shadow shows the hour of the day. The gnomon of every dial represents the axis of the world (See DIAL and DIALLING). The word is Greek, γνομων, which literally implies something that makes a thing known ; by reason that the style or pin indicates or makes the hour known.

GNOMON, in astronomy, a style erected perpendicular to the horizon, in order to find the altitude of the sun. Thus in the right-angled triangle ABC (pl. 91. Vol. II.), are given, AB the length of the style, BC the length of its shadow, and the right angle ABC. Hence, making CB the radius, we have this ana-

logy for finding the angle ACB, the sun's altitude, viz. BC : AB : : radius : tangent of the angle C. By means of a gnomon, the sun's meridian altitude, and consequently the latitude of the place, may be found more exactly than with the smaller quadrants. See QUADRANT. By the same instrument the height of any object GH may be found; for as DF, the distance of the observer's eye from the gnomon, is to DE, the height of the style; so is FH, the distance of the observer's eye from the object, to GH, its height. See further on the uses and application of Gnomons, the article GEOGRAPHY, page 734.

GNOMON of a *Globe*; the index of the hour circle.

GNOMONICS, the art of dialling. See DIALLING.

GNOSTICS, ancient heretics, famous from the first rise of Christianity, principally in the east. It appears from several passages of the sacred writings, particularly 1 John ii. 18. 1 Tim. vi. 20. and Col. ii. 8. that many persons were infected with the gnostic heresy in the first century; though the sect did not render itself conspicuous, either for number or reputation, before the time of Adrian, when some writers erroneously date its rise. The name is formed of the Latin *gnosticus*, and that of the Greek γνωστῆς "knowing," of γνωσκω "I know;" and was adopted by those of this sect, as if they were the only persons who had the true knowledge of Christianity. Accordingly, they looked on all other Christians as simple, ignorant, and barbarous persons, who explained and interpreted the sacred writings in a too low, literal, and unedifying signification. At first the Gnostics were only the philosophers and wits of those times, who formed for themselves a peculiar system of theology, agreeable to the philosophy of Pythagoras and Plato; to which they accommodated all their interpretations of scripture. But

GNOSTICS afterwards became a generical name, comprehending many sects and parties of heretics, who rose in the first centuries, and who, though they differed among themselves as to circumstances, yet all agreed in some common principles. They were such as corrupted the doctrine of the gospel by a profane mixture of the tenets of the oriental philosophy, concerning the origin of evil and the creation of the world, with its divine truths. Such were the Valentinians, Simonians, Carpocratians, Nicolaitans, &c.

GNOSTICS was sometimes also more particularly attributed to the successors of the first Nicolaitans and Carpocratians, in the second century, upon their laying aside the names of the first authors. Such as would be thoroughly acquainted with all their doctrines, reveries, and visions, may consult St. Irenæus, Tertullian, Clemens Alexandrinus, Origen, and St. Epiphanius; particularly the first of these writers, who relates their sentiments at large, and confutes them at the same time: indeed he dwells more expressly on the Valentinians than any other sort of Gnostics; but he shows the general principles whereon all their mistaken opinions were founded, and the method they followed in explaining scripture. He accuses them with introducing into religion certain vain and ridiculous genealogies, i. e. a kind of divine processions or emanations, which had no other foundation but in their own wild imaginations.

In effect, the Gnostics confessed that these æons or emanations were no where expressly delivered in the sacred writings, but insisted, at the same time, that Jesus Christ had intimated them in parables to such as could understand him. They built their theology not only on the gospels and the epistles of St. Paul; but also on the law of Moses and the prophets. These last laws were peculiarly serviceable to them, on account of the allegories and allusions with which they abound which are capable of different interpretations: Though their doctrine, concerning the creation of the world by one or more inferior beings of an evil or imperfect nature, led them to deny the divine authority of the books of the Old Testament, which contradicted

this idle fiction, and filled them with an abhorrence of Moses and the religion he taught: alleging, that he was actuated by the malignant author of this world, who consulted his own glory and authority, and not the real advantage of men. Their persuasion that evil resided in matter as its centre and source made them treat the body with contempt, discourage marriage, and reject the doctrine of the resurrection of the body and its reunion with the immortal spirit. Their notion, that malevolent genii presided in nature, and occasioned diseases and calamities, wars, and desolations, induced them to apply themselves to the study of magic, in order to weaken the powers or suspend the influence of their malignant agents.

The Gnostics considered Jesus Christ as the Son of God, and consequently inferior to the Father, who came into the world for the rescue and happiness of miserable mortals, oppressed by matter and evil beings: but they rejected our Lord's humanity, on the principle that every thing corporeal is essentially and intrinsically evil; and therefore the greatest part of them denied the reality of his sufferings. They set a great value on the beginning of the gospel of St. John, where they fancied they saw a great deal of their æons or emanations under the *Word*, the *Life*, the *Light*, &c. They divided all nature into three kinds of beings, viz. *hylic*, or material; *psychic*, or animal; and *pneumatic*, or spiritual. On the like principle they also distinguished three sorts of men; *material*, *animal*, and *spiritual*. The first, who were material and incapable of knowledge, inevitably perished, both soul and body: the third, such as the Gnostics themselves pretended to be, were all certainly saved: the psychic, or animal, who were the middle between the other two, were capable either of being saved or damned, according to their good or evil actions.

With regard to their moral doctrines and conduct, they were much divided. The greatest part of this sect adopted very austere rules of life, recommended rigorous abstinence, and prescribed severe bodily mortifications, with a view of purifying and exalting the mind. However, some maintained that there was no moral difference in human actions; and thus, confounding right with wrong, they gave a loose rein to all the passions, and asserted the innocence of following blindly all their notions, and of living by their tumultuous dictates. They supported their opinions and practice by various authorities: some referred to fictitious and apocryphal writings of Adam, Abraham, Zoroaster, Christ, and his apostles; others boasted that they had deduced their sentiments from secret doctrines of Christ, concealed from the vulgar; others affirmed that they arrived at superior degrees of wisdom by an innate vigour of mind; and others asserted that they were instructed in these mysterious parts of theological science by Theudas, a disciple of St. Paul, and by Matthias, one of the friends of our Lord. The tenets of the ancient Gnostics were revived in Spain, in the fourth century, by a sect called the *Priscillianists*.

The appellation *Gnostic* sometimes also occurs in a good sense in the ancient ecclesiastical writers, and particularly Clemens Alexandrinus, who, in the person of his Gnostic, describes the characters and qualities of a perfect Christian. This point he labours in the seventh book of his *Stromata*, where he shows that none but the Gnostic, or learned person, has any true religion. He affirms, that were it possible for the knowledge of God to be separated from eternal salvation, the Gnostic would make no scruple to choose the knowledge; and that if God would promise him impunity in doing of any thing he has once spoken against, or offer him heaven on those terms, he would never alter a whit of his measures. In this sense the father uses Gnostics in opposition to the heretics of the same name, affirming, that the true Gnostic is grown old in the study of the holy scripture, and that he preserves the orthodox doctrine of the apostles and of the church; whereas the false Gnostic

abandons all the apostolical traditions, as imagining himself wiser than the apostles. At length the name *Gnostic*, which originally was the most glorious, became infamous, by the idle opinions and dissolute lives of the persons who bore it.

GNU, or ΓΝΟΥ, in zoology. See CAPRA.

GOA, a considerable city of the peninsula of Hindoostan, on the coast of Malabar; the capital of the Portuguese settlements in India, and the seat of a viceroy. It was first taken by Albuquerque in 1510 from a prince of Saracen extraction. It stands in an island about 22 miles in length, and six in breadth, and is built on the N. side of it, having the conveniency of a fine river, capable of receiving ships of the greatest burden, where they lie within a mile of the town. The banks of the river are beautified with a great number of handsome structures, such as churches, castles, and gentlemen's houses. The air within the town is unwholesome, for which reason it is not so well inhabited now as it was formerly. The viceroy's palace is a noble building, and stands at a small distance from the river, over one of the gates of the city, which leads to a spacious street, terminated by a beautiful church. This city contains a great number of handsome churches and convents, with a stately hospital. The market-place takes up an acre of ground; and in the shops about it may be had the produce of Europe, China, Bengal, and other countries. Their religion is the Roman Catholic, and they have a severe inquisition. The clergy are numerous and illiterate: the churches are finely embellished, and have a great number of images. Their houses are large, and make a fine appearance, but are poorly furnished. The inhabitants are contented with greens, fruits, and roots, which, with a little bread, rice, and fish, is their principal diet, though they have hogs and fowls in plenty. It is remarkable, that only one of the churches has glass windows; for they make use of clear oyster-shells instead of glass, and all their fine houses have the same. Goa has few manufactures or productions, their best trade being in arrack, which they distil from the sap of the cocoa nut-tree. The harbour is defended by several forts and batteries. Goa is 292 miles S. by E. of Bombay. Lon. 72. 45. E. Lat. 15. 28. N.

GOAL. See GAOL.

GOAT, in zoology. See CAPRA.

GOAT'S-Beard, in botany. See TRAGOPOGON.

GOAT-Sucker, in ornithology. See CAPRIMULGUS.

GOBBO (Pietro Paolo Cortonese, so called), a celebrated painter of fruit and landscapes, was born at Cortona in 1580, and learned the principles of design from his father; but was afterwards the disciple of one Crescentio at Rome, and perfected himself in the most essential parts of his profession, by studying after nature, with judgment and accuracy. His merit soon recommended him to the notice and esteem of the most able judges at Rome; and as he excelled equally in painting fruit and landscape, he found a generous patron in cardinal Borghese, who employed him to adorn his palace. The fruit which he painted had so true and expressive an imitation of nature, that nothing could possibly be more exact; and by his thorough knowledge of the chiaro-scuro, he gave an extraordinary roundness and relief to every object. But his greatest excellence consisted in his colouring; for in design he was not remarkably superior to others. He died in 1640.

GOBELIN (Giles), a famous French dyer, in the reign of Francis I. discovered a method of dyeing a beautiful scarlet, and his name has been given ever since to the finest French scarlets. His house, in the suburb of St. Marcel at Paris, and the river he made use of, are still called *the Gobelins*. An academy for drawing, and a manufactory of fine tapestries, were erected in this quarter in 1666; for which reason the tapestries are called *the Gobelins*.

GOBIUS, in ichthyology, a genus of fishes belonging to the

order of thoracici. They have two holes between the eyes, four rays in the membrane of the gills, and the belly fins are united in an oval form. There are eight species, principally distinguished by the number of rays in their fins.

GOBLET, or GOBELET, a kind of drinking cup or bowl, ordinarily of a round figure, and without either foot or handle. The word is French, *goblet*; which Salmasius and others derive from the barbarous Latin *cupa*. Budeus deduces it from the Greek *κυπελλον*, a sort of cup.

GOD, one of the many names of the Supreme Being. See CHRISTIANITY, METAPHYSICS, MORAL PHILOSOPHY, and THEOLOGY.

GOD is also used in speaking of the false deities of the heathens, many of which were only creatures to which divine honours and worship were superstitiously paid. The Greeks and Latins, it is observable, did not mean by the name of *God* an all-perfect being, whereof eternity, infinity, omnipresence, &c. were essential attributes: with them, the word only implied an excellent and superior nature, and accordingly they give the appellation *gods* to all beings of a rank or class higher or more perfect than that of men, and especially to those who were inferior agents in the divine administration, all subject to the one Supreme. Thus men themselves, according to their system, might become gods after death; inasmuch as their souls might attain to a degree of excellence superior to what they were capable of in life.

The first divines, father Bossu observes, were the poets: the two functions, though now separated, were originally combined; or, rather, were one and the same thing. Now the great variety of attributes in God, that is, the number of relations, capacities, and circumstances, wherein they had occasion to consider him, put these poets, &c. under a necessity of making a partition, and of separating the divine attributes into several persons; because the weakness of the human mind could not conceive so much power and action in the simplicity of one single divine nature. Thus the omnipotence of God came to be represented under the person and appellation of Jupiter; the wisdom of God, under that of Minerva; the justice of God, under that of Juno. The first idols or false gods that are said to have been adored were the stars, sun, moon, &c. on account of the light, heat, and other benefits, which we derive from them. Afterwards the earth came to be deified, for furnishing fruits necessary for the subsistence of men and animals; then fire and water became objects of divine worship, for their usefulness to human life. In process of time, and by degrees, gods became multiplied to infinity; and there was scarce any thing but the weakness or caprice of some devotee or other elevated into the rank of deity; things useless or even destructive not excepted. See MYTHOLOGY.

GODALMING, a town of Surry, with a market on Saturday. It is seated on the river Wey, where it divides into several streams. It is four miles S. W. of Guildford, and 34 S. W. of London. Lon. 0. 34. W. Lat. 51. 13. N.

GODAVERY, or GONDA GODOWRY, a river of the Decan of Hindoostan, which has its source about 90 miles to the N. E. of Bombay; and, in the upper part of its course at least, is esteemed a sacred river by the Hindoos; that is, ablutions performed in its stream have a religious efficacy superior to those performed in ordinary streams. After crossing Dowlatabad and Golconda, from W. to E. it turns to the S. E. and receiving the Bain Gongga about 90 miles above the sea, divides into two principal channels at Rajamundry; and these subdividing again, form all together several tide harbours for vessels of moderate burden. Ingeram, Coringa, Yalam, Bandarmalanka, and Narfapour, are among the places situated at the mouth of this river, which appears to be the most considerable one between the Ganges and Cape Comorin. Extensive forests of teak

timber border on its banks, within the mountains, and supply ship timber for the use of the above mentioned ports. The word *Gonga* is the Indian name of a river.

GODDARD (Jonathan), an eminent physician and chemist, and one of the first promoters of the Royal Society, was born about the year 1617. He was elected a fellow of the college of physicians in 1646, and appointed reader of the anatomical lecture in that college in 1647. As he took part against Charles I. accepted the wardenship of Merton-college, Oxford, from Oliver Cromwell when chancellor, and sat sole representative of that university in Cromwell's parliament, he was removed from his wardenship in a manner disgraceful to him by Charles II. He was however then professor of physic at Gresham college, to which he retired, and continued to attend those meetings that gave birth to the Royal Society; upon the first establishment of which, he was nominated one of the council. Being fully persuaded that the preparation of medicines was no less the physician's duty than the prescribing them, he constantly prepared his own; and in 1668 published a treatise recommending his example to general practice. He died of an apoplectic fit in 1674; and his memory was preserved by the drops that bore his name, otherwise called *Gutta Anglicana*, the secret of which he sold to Charles II. for 5000*l.* and which Dr. Lister assures us was only the volatile spirit of raw silk rectified with oil of cinnamon or some other essential oil. But he claims more particular regard, if what bishop Seth Ward says be true, that he was the first Englishman who made that noble astronomical instrument, the telescope.

GODDESS, a heathen deity of the female sex. The ancients had almost as many goddesses as gods: such were, Juno the goddess of air, Diana the goddess of woods, &c. and under this character were represented the virtues, graces, and principal advantages of life; truth, justice, piety, liberty, fortune, victory, &c. It was the peculiar privilege of the goddesses to be represented naked on medals; for it was supposed that the imagination must be awed and restrained by the consideration of the divine character.

GODEAU (Anthony), bishop of Grasse and Vence in France, was born at Dreux in 1605. He was a very voluminous writer, both in prose and verse; but his principal works are, 1. *An ecclesiastical history*, 3 vols. folio, containing the first eight centuries only, as he never finished more. 2. *Translation of the Psalms into French verse*; which was so well approved, that even those of the reformed religion preferred it to that of Marat. He died in 1671.

GODFATHERS and **GODMOTHERS**, persons who, at the baptism of infants, answer for their future conduct, and solemnly promise that they will renounce the devil and all his works, and follow a life of piety and virtue; and by this means lay themselves under an indispensable obligation to instruct them, and watch over their conduct. This custom is of great antiquity in the Christian church, and was probably instituted to prevent children being brought up in idolatry, in case their parents died before they arrived at years of discretion. The number of godfathers and godmothers is reduced to two in the church of Rome; and three in the church of England; but formerly they had as many as they pleased.

GODFREY (of Bouillon), prince of Lorraine, a most celebrated crusader and victorious general. He was chosen general of the expedition which the Christians undertook for the recovery of the Holy Land, and sold his dukedom to prepare for the war. He took Jerusalem from the Turks in 1099; but his piety, as historians relate, would not permit him to wear a diadem of gold in the city where his Saviour had been crowned with thorns. The sultan of Egypt afterwards sent a terrible army against him; which he defeated, with the slaughter of about 100,000 of the enemy. He died in 1160.

VOL. IV.

GODMANCHESTER, a town of Huntingdonshire, parted from Huntingdon by the river Ouse. It was incorporated by James I. and is seated in a rich and fertile soil, which yields great plenty of corn. It is inhabited by a great number of yeomen and farmers, who are said to have very extraordinary teams of horses.

GODOLPHIN (John), an eminent English civilian, was born in the island of Scilly in 1617, and educated at Oxford. In 1642-3 he was created doctor of civil law; in 1653 he was appointed one of the judges of the admiralty; and at the Restoration, he was made one of his majesty's advocates. He was esteemed as great a master of divinity as of his own faculty, and published, 1. *The holy limbeck*. 2. *The holy harbour*. 3. *A view of the admiral's jurisdiction*. 4. *The orphan's legacy*. 5. *Reperitorium canonicum*, &c. He died in 1678.

GODSTOW, a place northwest of Oxford, in a sort of island formed by the divided streams of the Isis after being joined by the Evenlode. It is noted for fish and their excellent manner of dressing them; but more so for the ruins of that nunnery which fair Rosamond quitted for the embraces of Henry II. The people show a great hole in the earth here, where they say is a subterraneous passage, which goes under the river to Woodstock, by which she used to pass and repass. Little more remains at present than ragged walls, scattered over a considerable extent of ground. An arched gateway, and another venerable ruin, part of the tower of the conventual church, are still standing. Near the altar in this church fair Rosamond was buried; but the body was afterwards removed by order of a bishop of Lincoln, the visitor. The only entire part is small, formerly a private chapel. Not many years since a stone coffin, said to have been Rosamond's, who perhaps was removed from the church to this place, was to be seen here. The building has been put to various uses, and at present serves occasionally for a stable.

GODWIN (Francis), successively bishop of Landaff and Hereford, was born in 1567. He was eminent for his learning and abilities, being a good mathematician, an excellent philosopher, a pure Latinist, and an accurate historian. He understood the true theory of the moon's motion, a century before it was generally known. He first started those hints, afterwards pursued by bishop Wilkins, in his "Secret and swift messenger;" and published "A catalogue of the lives of English bishops." He has nevertheless been represented as a great simoniac, for omitting no opportunity of disposing of preferments in order to provide for his children. He died in 1648.

GODWIN (Thomas), a learned English writer born in 1517, was master of the free-school at Abington in Berkshire; where he educated a great many youths who became eminent both in church and state. His works show him to have been a man of great learning: such as, *Historia Romanæ antologia*, *Synopsis antiquitatum Hebraicarum*, *Moses & Aaron*, *Florilegium Phrasicon*, &c. He died in 1642.

GODWIN, or *Goodwin Sands*. See **GOODWIN-SANDS**.

GODWIT, in ornithology. See **SCOLOPAX**.

GOES, or **TER GOES**, a strong and considerable town of the United Provinces in Zealand, and capital of the island of South Beveland. It communicates with the sea by a canal, and is 10 miles east of Middleburg, and 30 north of Ghent. E. lon. 3. 50. N. lat. 51. 33.

GOG and **MAGOG**, two names generally joined together in scripture (Ezek. xxxviii. 2, 3, &c. xxxix. 1, 2, &c. Rev. xx. 8.). Moses speaks of Magog the son of Japhet, but says nothing of Gog, (Gen. x. 2. 1. Chr. i. 5.). Gog was prince of Magog, according to Ezekiel. Magog signifies the country or people, and Gog the king of that country. The generality of the ancients made Magog the father of the Scythians and Tartars; and several interpreters discovered many footsteps of their

E

name in the provinces of Great Tartary. Others have been of opinion that the Persians were the descendants of Magog; and some have imagined that the Goths were descended from Gog and Magog; and that the wars described by Ezekiel, and undertaken by Gog against the saints, are no other than those which the Goths carried on in the fifth age against the Roman empire.

Bochart has placed Gog in the neighbourhood of Caucasus. He derives the name of this celebrated mountain from the Hebrew *Gog-chaziv*, "the fortress of Gog." He maintains that Prometheus, said to be chained to Caucasus by Jupiter, is Gog, and no other. There is a province in Iberia called the Gogarene. Lastly, the generality believe that Gog and Magog, mentioned in Ezekiel and the Revelations, are to be taken in an allegorical sense, for such princes as were enemies to the church and saints. Thus many by Gog in Ezekiel understand Antiochus Epiphanes, the persecutor of those Jews who were firm to their religion; and by the person of the same name in the Revelations, they suppose Antichrist to be meant; the great enemy of the church and faithful. Some have endeavoured to prove that Gog, spoken of in Ezekiel, and Cambyfes king of Persia, were one and the same person; and that Gog and Magog, in the Revelations, denote all the enemies of the church, who should be persecutors of it to the consummation of ages.

GOGGLES, in surgery, are instruments used for curing squinting, or that distortion of the eyes which occasions this disorder. They are short conical tubes, composed of ivory stained black, with a thin plate of the same ivory fixed in the tubes near their anterior extremities. Through the centre of each of these plates is a small circular hole, about the size of the pupil of the eye, for the transmission of the rays of light. These goggles must be continually worn in the day-time, till the muscles of the eye are brought to act regularly and uniformly, so as to direct the pupil straight forward; and by these means the cure will be sooner or later effected.

GOGMAGOG-HILLS, are hills so called, three miles from Cambridge, remarkable for the intrenchments and other works cast up here: whence some suppose it was a Roman camp; and others, that it was the work of the Danes.

GOGUET (Antony-Yves), a French writer, and author of a celebrated work, intitled, *L'Origine des Loix, des Arts, des Sciences, & de leur Progres chez les anciens Peuples*, 1758, 3 vols. 4to. His father was an advocate, and he was born at Paris in 1716. He was very unpromising as to abilities, and reckoned even dull in his early years; but his understanding developing itself, he applied to letters, and at length produced the above work. The reputation he gained by it was great: but he enjoyed it a very short time; dying the same year of the small-pox, which disorder it seems he always dreaded. It is remarkable that Conrad Fugere, to whom he left his library and his MSS. was so deeply affected with the death of his friend, as to die himself three days after him. The above work has been translated into English, and published in 3 vols. 8vo.

GOITO, a town of Italy, in the duchy of Mantua, taken by the Germans in 1701, and by the prince of Hesse in 1706. It is seated on the river Mincio, between the lake of Mantua and that of Garda, 10 miles north-west of Mantua. E. lon. 11. 0. N. lat. 45. 16.

GOLCONDA, a country of the Decan of Hindoostan, situated between the lower parts of the rivers Kistna and Godavery, and the principal part of Dowlatabad. It was formerly called Tellingana, or Tilling, and is now subject to the Nizam of the Decan. It abounds in corn, rice, and cattle; but it is most remarkable for its diamond mines, the most considerable in the world. The black merchants buy parcels of ground to search for these precious stones in. They sometimes fail in

meeting with any, and in others they find immense riches. They have also mines of salt, fine iron for sword-blades, and curious calicoes and chintzes. Hyderabad is the capital.

GOLCONDA, a celebrated fortress in the country of the same name, situated about six miles W. N. W. of Hyderabad, and joined to that city by a wall of communication. It occupies the summit of a hill of a conical form, and is deemed impregnable. When Aurangzebe conquered the kingdom of Golconda in 1737, this fortress was taken possession of by treachery.

GOLD, the most valuable of all the metals, is of a bright yellow colour when pure, but becomes more or less changed in proportion as it is alloyed with other metals. It is the heaviest of all known bodies, platina only excepted; its specific gravity being to that of distilled water as 19.640 to 1000. It melts in a low white heat, requiring, according to Mr. Wedgwood's calculation, 5237 degrees of Fahrenheit's, or 32 of his own thermometer for its fusion; a heat greatly superior to that which melts silver or copper, the former requiring only 4717, and the latter 4587 of Fahrenheit. Other metallurgists, however, have differed, and assert that copper requires for its fusion a greater degree of heat than either gold or silver.

Gold is by far the most tough and ductile, as well as the most malleable, of all metals. According to Cronstedt, one grain of it may be stretched out so as to cover 98 Swedish ells, equal to 63.66 English yards of silver wire; but Wallerius asserts, that a grain of gold may be stretched in such a manner as to cover 500 ells of wire. At any rate the extension is prodigious; for, according to the least of these calculations, the millionth part of a grain of gold may be made visible to the naked eye. Nor is its malleability inferior to its ductility. Boyle, quoted by Apligny in his Treatise of Colours, says that one grain and an half of gold may be beaten into 50 leaves of one inch square, which, if intersected by parallel lines, drawn at right angles to each other, and distant only the 100th part of an inch from each other, will produce 25 millions of little squares, each very easily discernible by the naked eye. Mr. Magellan tells us, that its surface may be extended by the hammer 159,092 times. "I am informed (says he) by an intelligent gold-beater in England, that the finest gold leaf is that made in new skins, and must have an alloy of three grains of copper to the ounce troy of pure gold, or else it would be too soft to pass over the irregularities of the skins. He affirms that 80 books, or 2000 leaves of gold, each measuring 3.3 square inches, viz. each leaf containing 10.89 square inches, weigh less than 384 grains. Each book, therefore, or 25 leaves, = 272.23 inches, weighs less than 4.8 grains; so that each grain of the metal will produce 56.718 square inches." From further calculations it may be made to appear, that the thickness of these leaves is less than $\frac{1}{21,2026}$ th of an inch; and that 16 ounces of gold would be sufficient to gild a silver wire equal to the whole circumference of the globe.

Gold is more elastic than lead or tin, but less so than iron or even copper. It grows hard and brittle by hammering, but resumes its ductility on being slowly heated. Gold leaf exhibits a fine green colour on being interposed between the eye and the beams of the sun or any other luminous body. When exposed for some time to a strong heat it becomes ignited, and at last melts, assuming at the same time a fine bluish-green colour; and, when cold, crystallizes into quadrilateral pyramids. This bluish-green colour, according to Mr. Magellan, as well as the former, when a thin film of the metal is interposed betwixt the eye and the luminous body, is owing to transmitted light. "The green light (says he) is transmitted in both cases, since all reflected colours are produced by the transmission of light; as the ingenious philosopher Mr. Delaval has lately discovered and

demonstrated, in his very elaborate treatise on this subject inserted in the second volume of the memoirs published in 1785 by the Philosophical Society of Manchester." Sir Isaac Newton, in his Optics (page 162, edition of 1730), accounts for that phenomenon, saying, that "gold foliated, and held between the eyes and the light, looks of a greenish blue; and therefore (says he) mostly gold lets into its body the blue rays, to be reflected to and fro within it, till they be stopped and stifled; while it reflects the yellow outwards, and therefore looks yellow." It is therefore in the two above cases that some of the blue rays are transmitted along with the yellow ones, and both together appear of a bluish green. If gold be exposed to the joined rays of light, excepting only the yellow ones, which we suppose stopped after they were separated by a prism, it only looks white like silver; "which shows (says Sir Isaac Newton) that its yellowness arises from the excess of intercepted rays, tinging that whiteness with their colour when they are let to pass. It is a pleasing observation to look with a deep magnifier on various pieces of gold, silver, and Dutch (copper) leaves between the eye and the sunshine. The particles of silver are seen in the form of oblong dark lumps, with some interstices, like net-work, between them: those of the copper leaf are more numerous and more regularly distributed; but the particles of the gold-leaf appear like little green semitransparent and similar particles, uniting between themselves by nearly diaphanous joints, as if they were forced to flatten in their edges, rather than they would break their mutual cohesion with one another."

Gold is more generally found native than any other metal; though Bergman informs us, that he does not know an instance of its ever being found perfectly free of alloy. Kirwan says it is seldom found so, being generally alloyed with silver, copper, or iron, and sometimes with all the three. According to Wallerius, native gold is found, 1. In solid masses in Hungary, Transylvania, and Peru. 2. In grains in the Spanish West Indies. 3. In a vegetable form like the branches or twigs of plants. 4. In a *druse* figure, as if composed of groupes or clusters of small particles united together, found in Hungary. 5. Composed of thin plates, or thin pellicles, covering other bodies, found in Siberia. 6. In a crystalline form in Hungary.

The same author informs us that gold, in its reguline state, is formed either into angular crystals, composed of yellow octaedrons, or into yellow irregular masses, which show a grain-like texture. Brunnich says that the native gold found in leaves is always crystallized on the surface, and with a magnifier they may be seen of a triangular pyramidal form. He informs us also, that in Transylvania he procured a specimen of cubic native gold, but never saw it any where else.

Gold is also found in the form of thick solid pieces. It is in general more frequently imbedded in quartz, and mixed with it, than with any other stone; and the quartz in which the gold is found in the Hungarian mines, Mr. Magellan tells us, is of a peculiar mild appearance. Sometimes, however, it is found in limestone or in hornblende, &c.

Europe is principally supplied with gold from Chili and Peru in South America. A small quantity is likewise imported from China and the coast of Africa. The principal gold mines of Europe are those of Hungary, and next to them the mines of Saltzberg. The mines of Adelfors in Smoland are likewise worked to advantage, and the veins of metal appear to be diffused over a great tract of land. Some gold, from four to seven grains in the mark, is also said to be extracted from the silver of the mines of Osterfilvarberget in the province of Dalarna. Native gold has also been found in Lapland above Tornea, and in Westmanland. In Peru it is found mixed with a stony matter, not well known, from which it is extracted by amalgamation. Mr. Pallas mentions three gold mines that are worked there

near the river Pyschma, in which 500 men are employed. The metal is found in a powdery form, and also in thin plates or leaves. Sometimes kernels or lumps of a spongy texture, and very light, are met with which contain a good quantity of gold-dust. This gold-dust or wash gold is usually washed out of sands, wherein it lies in the form of loose grains or lumps. It is distinguished by the variously coloured substances wherewith it is mixed. The metal is also found, separate from any matrix, in lumps or visible grains mixed with sands. Thus it is met with in many rivers of Europe as well as the other quarters of the world. It is also visibly dispersed through masses of sand, particularly such as is of a yellowish-red or violet colour; and in this state it is so universally diffused through every kind of earth, that Mr. Bergman thinks it the most common of all the metals, iron alone excepted. If 100 pounds of sand contain 24 grains of gold, the separation is said to be worth attending to. In Africa 5 pounds of sand often yield 63 grains of gold, or even more; and the heaviest sand, which is often black or red, contains the most. In Hungary, however, only 10 or 12 grains of gold are contained in 10,000 pounds of sand; and even this trifling quantity has been extracted, though with loss.

Gold is brought down with most of the large rivers; even those which do not take their rise in mountains where gold is found. In Transylvania the river of Avanyos affords subsistence to upwards of 700 gipsy families, who collect the gold from it. In Brasil it is found in such abundance, that their torrents are often turned with great labour and expence into new beds, in order to gather the gold there deposited by the running waters. Gold has also been found lately near the Wicklow mountains in Ireland. Of this discovery a very circumstantial account is given in the Philosophical Transactions for the year 1796.

Gold is said to be mineralized, when it is mixed with some other substance in such a manner as not to be acted upon by aqua regia. In this manner gold is mineralized.

1. *By Sulphur.* Many have insisted, that, as gold and sulphur are not found to have any chemical attraction for one another, it is impossible that marcasite can contain any of the metal, or indeed that it can be found in any ore containing sulphur: but since we know by experience that gold can be melted out of these ores, even after they have been digested in aqua-regia, and that gold likewise enters into their sulphurated regulus, there is the greatest reason to believe that some third substance, probably a metal, has by its admixture enabled the sulphur to unite with a certain quantity of gold. Marcasites however contain, at any rate, only a small quantity of the precious metal; and none is to be expected from them in places where no gold is in the neighbourhood. "I am not perfectly clear (says Cronstedt) whether the gold is really dissolved and indurated, or, if I may so express myself, *vitriified* in the *sebirks*; provided by this mineral body we mean a garnet substance. But I have seen a piece of what is called *sbir*, whose texture was exactly like the Schemnitz blende, and in this case it might perhaps hold the same contents."

2. *With Sulphur by means of Iron:* Golden pyrites, or marcasitical gold-ore. This is a close and compact substance of a bright yellow colour. Here the gold is said to be mineralized by sulphur by means of iron, because it cannot be extracted by aqua-regia or by amalgamation. A kind of gold pyrites is found at Adelfors in the province of Smoland, which contains an ounce or less of gold in an hundred weight of the ore. The Transylvania gold pyrites, according to Brunnich, in which no gold can be perceived by the naked eye, contain from 50 to 100 and 110 ounces and upwards in an hundred weight. Those where the gold appears in the pyrites like fireweed Spanish snuff hold 250 ounces; but they are very scarce. The mountain of Facebayaya, near Zalathna, is remarkable for its

gold pyrites; and here they seem also to contain semimetallic parts.

The following is M. Magellan's method of accounting for the union of gold with this kind of pyrites. "It is well known that gold may be dissolved by liver of sulphur. The process given for this purpose by M. Apligny, p. 156 of his Treatise on Colours, is as follows: Reduce to powder four pounds of vegetable alkali (salt of tartar), and as many of sulphur, with one of leaves of gold. Melt the mixture in a crucible with its cover, pour the fused matter out on a marble stone, pound it again when cold, and put the whole in a matress with hot water; which, being filtrated, is of a greenish-yellow colour, containing the gold dissolved. Now, as we know that *hepar sulphuris* has been found in several pyrites, and Mascagni says that he found it in those lagoons near Sienna in Italy, is it not very natural to conclude, that this noble metal may be really mineralized in the auriferous pyrites?"

3. *Auriferous Cinnabar*, in which the metal is mineralized by means of quicksilver, said to be found in Hungary. Mr. Sage speaks of a specimen of gold from Hungary, late in the French king's cabinet at Paris, which is crystallized into quadrangular prisms of a grey-yellowish colour and a brittle consistency, which he supposes to be the result of a mercurial amalgam of native gold.

4. *The Schemnitz Blende*, in which the gold is mineralized by means of zinc and iron. Cronstedt informs us that the ores of zinc at Schemnitz in Hungary contain a great deal of silver, and that this silver is very rich in gold. Professor Brunnich enumerates the following varieties of this ore. 1. Where the metal is mineralized by means of a cubic lead-ore, containing silver found in the mines of Michaeli and some places in Transylvania. 2. By a copper pyrites with silver. This kind of ore is called *gifs* in Hungary: it has a compact surface of a pale yellow colour, but must not for that reason be confounded with the auriferous pyrites. 3. The Cremnitz-ores in which the metal is mineralized by means of red gilder ore. 4. By means of antimony, in which it sometimes appears. This kind is found at the foot of the Carpathian mountains. 5. By cubic lead-ore, iron, and some unknown volatile parts. This ore, as described by Scopoli, is of a black colour; the richest pieces are lamellated almost like an iron-glimmer, with a degree of flexibility. The vein is quartz, which is sometimes loose, and the metal scattered very minutely in it. It is found in Transylvania. 6. Native gold, with black-lead (or molybdæna), has been found near Rimezemat in Upper Hungary; but our author (Professor Brunnich) has not had any opportunity of examining whether it is mineralized by it or not. In all the above species the gold is either entirely native, but so minutely divided, and so loosely scattered, that it can only be seen through microscopes, and often cannot be seen at all before it is separated by various processes: or it may not be in the form of native gold, but the metal as it were in embryo; in which case fire is necessary to bring the constituent parts together, and to add those that are wanting; in that case likewise it is never without silver.

"To these (says Mr. Magellan) may be added the following ores. 1. Gold, with arsenical pyrites, is found also at Saltzberg in Tyrol, in mountains of quartz and schistus. It contains only 25 grains in the quintal; nevertheless it affords a profit of 500l. *per annum*. 2. With a white, red, or vitreous silver-ore, near Cremnitz and Schemnitz in Hungary. 3. With a sulphurated ore of silver, iron, lead, and manganese, at Nagaya in Transylvania. Its specific gravity is 4.043, and it is said to afford 10 ounces per quintal. 4. With sulphurated iron, copper, and manganese, at Nagaya."

The strongest heat of any furnace does not change the metallic properties of gold. Kunckel and Boyle made the experiment

by exposing gold for several months to the fire of a glass-house. It appears, however, that, by the violent heat of the sun-beams collected in the focus of a burning-glass, some alteration may be produced in it. Homberg observed that gold, when exposed to the lens of Tschirnhausen, formed, was volatilized, and even vitrified; and Macquer found, that the metal, when exposed to the lens of Mr. Trudaine, exhaled a fume which gilded silver, and was therefore gold in a volatile state: the globule of melted gold was agitated with a rapid circular motion, and became covered with a dull and as it were calciform pellicle; and lastly, that a violet vitrification was formed on the middle of the globule. This vitrification gradually extended, and produced a kind of button, flatter, or of a larger curvature, than that of the globule, and which stuck upon it as the transparent cornea appears on the sclerotica of the eye. This glass increased in size, while the gold itself continually diminished: the support always appeared tinged with a purple colour, seemingly produced by the absorption of part of the glass. Time did not permit him to vitrify a quantity of gold entirely. He observes, that it is a necessary condition that the violet glass should be reduced with combustible matters, in order to justify the assertion that it is the calx of that perfect metal, which would evidently appear to be the case if it became revived into gold. But however this may be, Mr. Fourcroy is of opinion that this ought to be considered as a true vitrified calx of gold; and this with the greater probability, as in many operations with this metal the purple colour is constantly produced, and many preparations of gold are employed to give that colour to enamel and porcelain. "Gold (says he) is therefore calcinable like the other metals; and only requires, as likewise does silver, a stronger heat, and a longer time to unite with the base of air than other metallic substances." Mr. Kirwan on the other hand tells us, that "gold exposed to the utmost heat of Mr. Parker's lens for some hours lost no sensible part of its weight; yet, when in contact with earthy matters, it communicated a blue or purplish tinge to them; so that he believes an exceeding small portion of it might be dephlogisticated."

This experiment with the lens of Mr. Parker does not invalidate that of Macquer: for either Trudaine's lens may be more powerful than Mr. Parker's, or, the air in France being more clear than in England, the action of the sun might be stronger. We are assured, however, that by means of the electric shock gold may be instantaneously calcined and even vitrified; whence we must conclude, not only that gold is really calcinable, but that the electric fire is almost infinitely more powerful than any other; as by its means we may in a moment accomplish what either cannot be done otherwise at all, or very imperfectly, even by the fiercest fire we can raise. The flame of a lamp blown by dephlogisticated air is also found sufficient to volatilize gold.

Gold, being thus indestructible by the common operations of fire, equally resists its slow action in the atmosphere. It is altogether exempted from rusting; and though its surface becomes tarnished by exposure to the air, it is merely in consequence of the deposition of foreign bodies upon it. Water produces no change, says Mr. Fourcroy; though, according to the experiments of Lagaraye, it seems capable of dividing it nearly in the same manner as it does iron.

Gold combines with various metals, and is commonly alloyed in a certain proportion with copper, which gives it a red colour and greater firmness than it possesses when very pure, at the same time that it is thus rendered more fusible. In this state it is used for money, plate, and toys of different kind. It is sometimes also alloyed with silver, which deprives it of its colour, and renders it very pale: this alloy, however, is not made without some difficulty, on account of the very different specific gravities of the two metals, as Homberg observed, who saw

them separate during their fusion. It is the alloy of gold with silver that forms the green gold of the jewellers and gold-beaters.

As gold has been rendered, by the universal consent of mankind, the most valuable substance in the world, it is of great consequence to be able to discover its degree of purity, in order to prevent the adulterations which would naturally be practised, and to produce an equality of value in the different pieces dispersed in commerce. The chemical methods by which this is accomplished are related under the articles CHEMISTRY and ESSAYING of Metals. To ascertain with precision the quantity of imperfect metal it may contain, a given mass of gold is supposed to contain 24 parts called *carats*; each carat being supposed divided into 32 parts called *thirty seconds of a carat*. If the gold after the operation has lost one grain in 24, it is gold of 23 carats; if it has lost a grain and a half, it is gold of 22 carats, 16 thirty-seconds, and so on. The weight used in the assay of gold is called the *assay weight*, and usually consists of 24 grains; it is divided into 24 carats, which are likewise subdivided into 32 parts. An assay weight is likewise used which weighs 12 grains; and is likewise divided into 24 carats, subdivided again into thirty-seconds.

The scarcity and great price of gold prevent its being made into vessels or utensils; but as its brilliancy and colour are agreeable, methods have been found of applying it to the surface of a great number of bodies, which it thus not only beautifies, but by its indestructibility preserves from the injuries of the atmosphere. The art of applying it in this manner is called *gilding*; and the immense ductility of gold, already mentioned, renders it capable of being applied in this manner at much less expence than could be imagined. It is also commonly employed either in a state of solution by acids, or amalgamated with mercury, in what is called *water gilding*. It was formerly used in medicine, and great virtues were ascribed to it; whence the great number of golden tinctures, elixirs, &c. of quacks; but all these are now deservedly exploded, and the best practitioners allow that gold, in whatsoever manner it be prepared, is either inactive or dangerous.

Gold, in its metallic state, cannot be combined with the vitrifiable earths, but its calces may; for which reason they are often used in enamel-painting and in porcelain, where they produce a beautiful violet-colour. Glass is tinged by them of a beautiful red; of which we have an account in Neri's art of glass-making; though Dr. Lewis says he never could succeed in making the colour diffuse itself equally throughout the substance of the glass. See *Colouring of GLASS*.

The preparation of gold called *aurum fulminans* is taken notice of under the article CHEMISTRY, p. 447. M. Magellan takes notice of its extraordinary fulminating property, and says that its *fragor* is 64 times greater than that of an equal quantity of gunpowder. According to Bergman, the strength of the explosion is 176 times greater than that of gunpowder (20 grains of aurum fulminans being equivalent to half a pound of gunpowder). Bergman accounts for the amazing strength of this explosion, by supposing it owing to the quantity of air extricated at the time; but this, according to his own account, cannot be at all sufficient for such a purpose; and Magellan is of opinion that "this wonderful phenomenon seems not yet completely accounted for by any hypothesis yet known." See the article EXPLOSION.

"It is on account of the singular and excellent natural qualities of this metal (says our author), which are considerably heightened by its scarcity, that gold is so much valued among all the civilized nations of the world." Mr. Panton, in his *Metrologie*, p. 94. says, that one cubic foot (French measure) of gold is worth 2,153,000 *livres tournoises*, or 89,708 guineas and seven shillings, supposing the *Louis d'Or* to be equal to the

guinea; and that the respective value of the same cubic foot of gold is equal to 25.6 cubic feet of silver; each of this last metal being reckoned worth about 84,000 French livres, or 3503 guineas and eight shillings: so that if we suppose the monied specie in France to be but two *milliards* of French livres, according to the estimation of Mr. Neckar in his *Treatise upon the Commerce of Corn*, the whole amount should make but a solid cube of gold less than 10 feet on each side. So trifling is the physical object that excites the activity of 25 millions of the human species, the number that is said to be that of the inhabitants of France.

We shall close this article with some observations by M. Magellan on the state in which gold is found in the bowels of the earth, and consequently of the origin of gold ores. "As to the natural existence of gold in the bowels of the earth (says he), there have been two opinions among mineralogists; some pretending that it is only found in its *metallic* or *native* form; and others, that it is sometimes found *mineralized* in an intimate union with other substances. Mr. Kirwan holds the former, and the celebrated Bergman the latter. But, says Mr. Kirwan, 'though Mr. Bergman inclines to the opinion of the mineralization, yet he is candid enough to own, that the gold, when extracted from this ore, is of a granular or angular form. It is therefore very doubtful, whether it was not rather *mixed*, than truly combined with the sulphur and iron: and its proportion being exceedingly small, so that 100 pounds of the pyrites scarcely contain an ounce of gold, it is not a wonder that it should escape the action of aqua-regia; more especially as the nitrous acid becomes so phlogisticated by acting on the pyrites, as not to be able to dephlogisticate the mine. Likewise mercury, by reason of the gold particles being enveloped in the sulphureous iron, can have no access to it.'

"These arguments (says M. Magellan) against the true mineralization of gold are fully answered by the facts already mentioned. Besides, it is well known, that gold can be combined and calcined, *via ficta*, by the liver of sulphur and semimetals. This being acknowledged on both sides of the question, why should we insist on denying this mineralization, when it is out of doubt, among mineralogists of rank, that volcanic fires have had a great share in the convulsions and revolutions of this globe, of which every one has the most convincing proofs almost every where. The account given by Mr. Hiequet of the gold mines at Nagyag in Transylvania, the ancient Dacia, which lies about 45° latitude, offers the most convincing proofs of this assertion. The country all round these mines bears an incontestable appearance of being a volcanic one; and among various other metals, there are at least 13 kinds of gold ores, most of them mineralized. These are, 1. Gold mineralized by sulphur, zinc, and arsenic, in a grey-yellowish volcanic ore, which is called *cottoners*, or cotton-ore, on account of its lightness and texture. 2. By iron and arsenic, formed by strata; one containing black silver ore, then spatum, galena, quartz, and grey gold ore: it yields about half an ounce in the 100 pounds. 3. By sulphur, antimony, zinc, some arsenic, and sometimes iron: this is a grey-gold ore mixed with quartz and gypseous spath; a poor mine. 4. In the form of crooked threads mixed with quartz and gypseous spath; a poor mine. 5. Dendritiform, like the mocho stone, or the agate from Aberstein in the Palatinate; but these black dendrites are in a reddish stone. 6. Amorphous, very compact, in small grains, with spath and quartz. A quintal of it yields two ounces of gold, and more of silver. 7. By sulphur, great part of zinc, and a little antimony and arsenic; not rich. 8. Of a black or dark-reddish colour, containing an auriferous pyrites; not rich. 9. Of a bluish colour, mineralized by sulphur, antimony, iron, and a little arsenic mixed with silver; very rich in gold. 10. Partly laminated with needles of a blackish yellow colour: this gives 66 ounces of gold per 2 of gold, according to Scopoli

11. Foliated with gypseous spath and yellow pyrites. 12. In irregular lamina, on a greyish argille. The gold looks like silver, and is surrounded by spars of a pale rosy colour. 13. In crystallized laminae from two to four lines diameter, of an hexangular form, and very much resembling *molybdæna*. The vein was lost for some time, but lately found again on mining for letting out water from the main. This ore is very rare, and has given 372 ounces per $\frac{1}{2}$ of a mixed metal; five of which were gold, and one of silver.

Method of Recovering Gold from Gilt Works. The solubility of gold, and the indissolubility of silver, in aqua regia, affords a principle on which gold may be separated from the surface of silver; and on this foundation different processes have been contrived, of which the two following appear to be the best. Some powdered sal ammoniac, moistened with aquafortis into the consistence of a paste, is spread upon the gilt silver, and the piece heated till the matter smokes and becomes nearly dry; being then thrown into water, it is rubbed with a scratch brush composed of fine brass-wire bound together, by which the gold easily comes off. The other way is, by putting the gilt silver into common aqua regia, kept so hot as nearly to boil, and turning the metal frequently till it becomes all over black: it is then to be washed with a little water, and rubbed with the scratch brush, to get off what gold the aqua regia may have left. This last method appears preferable to the other; as the same aqua regia may be made to serve repeatedly till it becomes saturated with the gold, after which the gold may be recovered pure by precipitation with solution of vitriol, as directed under the article METALLURGY.

For separating gold from gilt copper, some direct a solution of borax to be applied on the gilt parts, but no where else, with a pencil, and a little powdered sulphur to be sprinkled on the places thus moistened; the principal use of the solution of borax seems to be to make the sulphur adhere; the piece being then made red hot, and quenched in water, the gold is said to be so far loosened as to be wiped off with a brush. Others mix the sulphur with nitre and tartar, and form the mixture with vinegar into a paste, which is spread upon the gilt parts.

Schlutter recommends mechanical means, as being generally the least expensive, for separating gold from the surface both of silver and copper. If the gilt vessel is round, the gold is conveniently got off by turning it in a lathe, and applying a proper tool, a skin being placed underneath for receiving the shavings: he says it is easy to collect into two ounces of shavings all the gold of a gilt vessel weighing thrice as many pounds. Where the figure of the piece does not admit of this method, it is to be properly fixed, and scrapers applied of different kinds according to its size and figure; some large, and furnished with two handles, one at each end; others small and narrow, for penetrating into depressed parts. If the gold cannot be got off by either of these ways, the file must be had recourse to, which takes off more of the metal underneath than the turning tool or the scraper, particularly than the former. The gold scrapings or filings may be purified from the silver or copper they contain, by the methods described under the article METALLURGY.

The editors of the *Encyclopédie* give a method of recovering the gold from wood that has been gilt on a water-size: this account is extracted from a memoir on the same subject, presented to the Academy of Sciences by M. de Montamy. The gilt wood is steeped for a quarter of an hour in a quantity of water sufficient to cover it, made very hot: the size being thus softened, the wood is taken out and scrubbed, piece by piece, in a little warm water, with short stiff bristle brushes of different sizes, some small for penetrating into the carvings, and others large for the greater dispatch in flat pieces. The whole mixture of water, size, gold, &c. is to be boiled to dryness, the dry matter

made red hot in a crucible to burn off the size, and the remainder ground with mercury, either in a mortar, or, where the quantity is large, in a mill.

GOLD-Coast. See GUINEA.

GOLD-Wire, a cylindrical ingot of silver, superficially gilt or covered with gold at the fire, and afterwards drawn successively through a great number of little round holes, of a wire-drawing iron, each less than the other, till it be sometimes no bigger than a hair of the head. See *WIRE-Drawing*. It may be observed that, before the wire be reduced to this excessive fineness, it is drawn through above 140 different holes; and that each time they draw it, it is rubbed afresh over with new wax, both to facilitate its passage, and to prevent the silver's appearing through it.

GOLD-Wire flattened, is the former wire flatted between two rollers of polished steel, to fit it to be spun on a stick, or to be used flat, as it is, without spinning, in certain stuffs, laces, embroideries, &c.

GOLD-Thread, or *Spun-gold*, is flatted gold, wrapped or laid over a thread of silk, by twisting it with wheel and iron-bobbins. To dispose the wire to be spun on silk, they pass it between two rollers of a little mill: these rollers are of nicely polished steel, and about three inches in diameter. They are set very close to each other, and turned by means of a handle fastened to one of them, which gives motion to the other. The gold wire in passing between the two is rendered quite flat, but without losing any thing of its gilding; and is rendered so exceedingly thin and flexible, that it is easily spun on silk-thread by means of a hand-wheel, and so wound on a spool or bobbin. See *WIRE-Drawing*.

GOLD-Leaf, or *Beaten Gold*, is gold beaten with a hammer into exceeding thin leaves, so that it is computed that an ounce may be beaten into 1600 leaves, each three inches square, in which state it takes up more than 159,052 times its former surface. See *GOLD-LEAF*. It must be observed, however, that gold is beaten more or less, according to the kind or quality of the work it is intended for; that for the gold-wire drawers to gild their ingots with is left much thicker than that for gilding the frames of pictures, &c. See *GILDING*.

Fulminating GOLD. See CHEMISTRY, p. 447.

Mosaic GOLD, is gold applied in pannels on a proper ground, distributed into squares, lozenges, and other compartments; part of which is shadowed to raise or heighten the rest. See *MOSAIC*.

GOLD Plates for Enamelling are generally made of ducat gold, whose fineness is from $23\frac{1}{2}$ to $23\frac{3}{4}$ carats; and the finest gold is the best for this purpose, unless where some parts of the gold are left bare and unpolished, as in watch-cases, snuff-boxes, &c. for which purpose a mixture of alloy is necessary, and silver is preferred to copper, because the latter disposes the plates to tarnish and turn green. See *ENAMELLING*.

Shell-GOLD, is that used by the gilders and illuminers, and with which gold letters are written. It is made by grinding gold leaves or gold-beaters' fragments with a little honey, and afterwards separating the honey from the powdered gold by means of water. When the honey is washed away, the gold may be put on paper or kept in shells; whence its name. When it is used, it is diluted with gum-water or soap-suds. The German gold-powder, prepared from the Dutch gold-leaf in the same manner, is frequently used; and when it is well coated with varnish, answers the end in japanners' gilding as well as the genuine.

GOLD-Size for burnished gilding is prepared of one pound and an half of tobacco-pipe clay, half an ounce of red chalk, a quarter of an ounce of black lead, forty drops of sweet oil, and three drams of pure tallow: grind the clay, chalk, and black lead, separately, very fine in water; then mix them

together, add the oil and tallow, and grind the mixture to a due consistence. Gold size of *Japanners* may be made by pulverizing gum animi and asphaltum, of each one ounce; red-lead, litharge of gold, and umbre, of each one ounce and a half, mixing them with a pound of linseed oil, and boiling them, observing to stir them till the whole be incorporated, and appears on growing cold of the consistence of tar: strain the mixture through a flannel, and keep it stopped up in a bottle for use. When it is used, it must be ground with as much vermilion as will give it an opaque body, and diluted with oil of turpentine, so that it may be worked freely with the pencil. A more simple preparation consists of one pound of linseed oil and four ounces of gum animi; powder the gum, and mix it gradually with the boiling oil; let it continue to boil till it becomes of the consistence of tar; strain it through a coarse cloth; keep and use it as the other.

GOLD-Finch, in ornithology. See FRINGILLA. These are seed-birds of very curious colours, and which, were they not so common in this country, would probably be very much esteemed.

They are usually taken about Michaelmas, and soon become tame; but they differ very much in their song. They frequently breed in the upper part of plum-trees, making their nests of the moss that grows upon apple-trees, and of wool; quilting the inside with all sorts of hairs they find upon the ground. They breed three times a-year; and the young are to be taken with the nest at about ten days old, and fed as follows: Pound some hemp-seed very fine in a mortar; then sift it through a sieve, and add to it as much wheat-bread as hemp-seed; and likewise a little flour of canary-seeds: then with a small stick or quill take up as much as the bigness of a white pea, and give them several times a-day. This ought to be made fresh every day: for if it is suffered to sour, it will hurt their stomachs, causing them to cast up their meat; which if they do, it is very probable that they will die. These young birds must be carefully kept warm till they can feed themselves, for they are very tender. In feeding, be sure to make your bird clean his bill and mouth. If any of the meat falls upon his feathers, take it off, or else he will not thrive. Such as eat hemp-seed, to purge them, should have the seeds of melons, succory, and mercury; or else let them have lettuce and plantane for that purpose. When there is no need of purging, give them two or three times a-week a little sugar or loam in their meat, or at the bottom of the cage; for all seeds have an oiliness, so that if they have not something to absorb it, in length of time it fouls their stomachs, and brings on them a flux which is very dangerous.

GOLD Fish. See the article BARBEL.

GOLDEN, something that has a relation to gold, or consists of gold.

GOLDEN-Calf, was a figure of a calf which the Israelites cast in that metal, and set up in the wilderness to worship during Moses's absence into the mount; and which that legislator at his return burnt, grinded to powder, and mixed with the water the people were to drink of; as related in Exod. xxxii. The commentators have been divided on this article: the pulverizing of gold, and rendering it potable, is a very difficult operation in chemistry. Many, therefore, suppose it done by a miracle; and the rest, who allow of nothing supernatural in it, advance nothing but conjectures as to the manner of the process. Moses could not have done it by simple calcination, nor amalgamation, nor antimony, nor calcination; nor is there one of those operations that quadrates with the text.

M. Stahl has endeavoured to remove this difficulty. The method Moses made use of, according to this author, was by dissolving the metal with hepar sulphuris; only, instead of the

vegetable alkali, he made use of the Egyptian natron, which is common enough throughout the east.

GOLDEN Fleece, in the ancient mythology, was the skin or fleece of the ram upon which Phryxus and Hella are supposed to have swam over the sea to Colchis; and which, being sacrificed to Jupiter, was hung upon a tree in the grove of Mars, guarded by two brazen-hoofed bulls, and a monstrous dragon that never slept; but was taken and carried off by Jason and the Argonauts.

Many authors have endeavoured to show that this fable is an allegorical representation of some real history, particularly of the philosopher's stone. Others have explained it by the profit of the wool-trade to Colchis, or the gold which they commonly gathered there with fleeces in the rivers. See ARGONAUTS.

Order of the GOLDEN Fleece, is a military order instituted by Philip the Good, duke of Burgundy, in 1429. It took its denomination from a representation of the golden fleece, borne by the knights on their collars, which consisted of flints and steels. The king of Spain is now grand master of the order, in quality of duke of Burgundy: the number of knights is fixed to thirty-one. It is usually said to have been instituted on occasion of an immense profit which that prince made by wool; though others will have a chemical mystery couched under it, as under that famous one of the ancients, which the adepts contend to be no other than the secret of the elixir wrote on the fleece of a sheep.

Oliver de la Marche writes, that he had suggested to Philip I. archduke of Austria, that the order was instituted by his grandfather Philip the Good, duke of Burgundy, with a view to that of Jason; and that John Germain bishop of Chalons, chancellor of the order, upon this occasion made him change his opinion, and assured the young prince that the order had been instituted with a view to the fleece of Gideon. William bishop of Tournay, chancellor likewise of the order, pretends that the duke of Burgundy had in view both the golden fleece of Jason and Jacob's fleece, i. e. the speckled sheep belonging to this patriarch, according to agreement made with his father-in-law Laban. Which sentiment gave birth to a great work of this prelate, in two parts: in the first, under the symbol of the fleece of Jason, is represented the virtue of magnanimity, which a knight ought to possess; and under the symbol of the fleece of Jacob he represents the virtue of justice. Paradin is of the same mind, and tells us that the duke designed to insinuate that the fabulous conquest which Jason is said to have made of the golden fleece in Colchis was nothing else but the conquest of virtue, which gains a victory over those horrible monsters, vice and our evil inclinations.

GOLDEN Number, in chronology, a number showing what year of the moon's cycle any given year is. See CHRONOLOGY, p. 525.

GOLDEN Rod, in botany. See SOLIDAGO.

GOLDEN Rose. The pope annually consecrates a golden rose on the fourth Sunday in Lent, which is sent to princesses, or to some church, as a mark of his peculiar affection.

GOLDEN Rule, in arithmetic, a rule or praxis, of great use and extent in the art of numbers; whereby we find a fourth proportional to three quantities given. The golden rule is also called the *Rule of Three* and *Rule of Proportion*. See its nature and use under the article ARITHMETIC, p. 317.

GOLDENGEN, a town of Poland in the duchy of Courland, with a handsome castle, seated on the river Weia, in E. lon. 22. 31. N. lat. 56. 48.

GOLDSMITH, or, as some choose to express it, *silversmith*, an artist who makes vessels, utensils, and ornaments, in gold and silver. The goldsmith's work is either performed in the mould, or beaten out with a hammer or other instrument. All

works that have raised figures are cast in a mould, and afterwards polished and finished: plates or dishes, of silver or gold, are beat out from thin flat plates; and tankards, and other vessels of that kind, are formed of plates folded together, and their mouldings are beaten, not cast. The business of the goldsmiths formerly required much more labour than it does at present; for they were obliged to hammer the metal from the ingot to the thinness they wanted; but there are now invented stamping-mills, which reduce metals to the thinness that is required at a very small expence. The goldsmith is to make his own moulds, and for that reason ought to be a good designer, and have a taste in sculpture: he also ought to know enough of metallurgy to be able to assay mixed metals, and to mix the alloy.

The goldsmiths in London employ several hands under them for the various articles of their trade: such are the jeweller, the snuff-box and toy maker, the silver-turner, the gilder, the burnisher, the chaser, the refiner, and the gold beater. Goldsmiths are superior tradesmen: their wares must be assayed by the wardens of the company of this name in London, and marked; and gold is to be of a certain touch. No goldsmith may take above one shilling the ounce of gold, besides what he has for the fashioning, more than the buyer may be allowed for it at the king's exchange; and here any false metal shall be seized and forfeited to the king. The cities of York, Exeter, Bristol, &c. are places appointed for the assaying wrought-plate of goldsmiths; also a duty is granted on silver-plate of one and sixpence an ounce. Plate made by goldsmiths shall be of a particular fineness, on pain of forfeiting 10l.; and if any parcel of plate sent to the assayers is discovered to be of a coarser alloy than the respective standards, it may be broken and defaced. The fees for assaying are particularly limited.

GOLDSMITH (Oliver), a celebrated English writer, was born at Roscommon in Ireland in the year 1731. His father, who possessed a small estate in that county, had nine sons, of whom Oliver was the third. He was originally intended for the church; and with that view, after being well instructed in the classics, was, with his brother the Rev. Henry Goldsmith, placed in Trinity-college, Dublin, about the latter end of the year 1749. In this seminary of learning he continued a few years, when he took a bachelor's degree; but his brother not being able to obtain any preferment after he left the college, Oliver, by the advice of Dean Goldsmith of Cork, turned his thoughts to the study of physic; and, after attending some courses of anatomy in Dublin, proceeded to Edinburgh in the year 1751, where he studied the several branches of medicine under the different professors in that university. His beneficent disposition soon involved him in unexpected difficulties; and he was obliged precipitately to leave Scotland, in consequence of engaging himself to pay a considerable sum of money for a fellow-student.

A few days after, about the beginning of the year 1754, he arrived at Sunderland near Newcastle, where he was arrested at the suit of a taylor in Edinburgh, to whom he had given security for his friend. By the good offices of Laughlin Maclane, Esq. and Dr. Sleight, who were then in the college, he was soon delivered out of the hands of the bailiff; and took his passage on board a Dutch ship to Rotterdam, where, after a short stay, he proceeded to Brussels: he then visited great part of Flanders; and after passing some time at Strasbourg and Lonvain, where he obtained a degree of bachelor of physic, he accompanied an English gentleman to Berne and Geneva.

It is undoubtedly fact, that this ingenious unfortunate man travelled on foot most part of this tour. He had left England with very little money; and being of a philosophical turn, and at that time possessing a body capable of sustaining every fatigue, and a heart not easily terrified with danger, he became an en-

thusiast to the design he had formed of seeing the manners of different countries. He had some knowledge of the French language and of music, and he played tolerably well on the German flute; which, from an amusement, became at some times the means of his subsistence. His learning produced him a hospitable reception at most of the religious houses; and his music made him welcome to the peasants of Flanders and other parts of Germany. "Whenever I approached," he used to say, "a peasant's house towards night-fall, I played one of the most merry tunes; and that procured me not only a lodging, but subsistence for the next day: but in truth (his constant expression) I must own, whenever I attempted to entertain persons of a higher rank, they always thought my performance odious, and never made me any return for my endeavours to please them."

On Mr. Goldsmith's arrival at Geneva, he was recommended as a proper person for a travelling tutor to a young man, who had been unexpectedly left a considerable sum of money by his uncle Mr. S——, formerly an eminent pawnbroker near Holborn. This youth, who had been articled to an attorney, on receipt of his fortune determined to see the world; and, on his engaging with his preceptor, made a proviso that he should be permitted to govern himself; and Goldsmith soon found his pupil understood the art of directing in money-concerns extremely well, as avarice was his prevailing passion. His questions were usually how money might be saved, and which was the least expensive course of travel; whether any thing could be bought that would turn to account when disposed of again in London? Such curiosities on the way as could be seen for nothing he was ready enough to look at; but if the sight of them was to be paid for, he usually asserted that he had been told they were not worth seeing. He never paid a bill that he would not observe how amazingly expensive travelling was; and all this, though he was not yet twenty-one. During Goldsmith's continuance in Switzerland, he assiduously cultivated his poetical talent, of which he had given some striking proofs while at the college of Edinburgh. It was here he sent the first sketch of his delightful poem called the *Traveller* to his brother the clergyman in Ireland, who, giving up fame and fortune, had retired with an amiable wife to happiness and obscurity, on an income of only 40l. a-year.

From Geneva Mr. Goldsmith and his pupil visited the south of France; where the young man, upon some disagreement with his preceptor, paid him the small part of his salary which was due, and embarked at Marseilles for England. Our wanderer was left once more upon the world at large, and passed through a variety of difficulties in traversing the greatest part of France. At length his curiosity being satiated, he bent his course towards England, and arrived at Dover the beginning of the winter 1758. When he came to London, his stock of cash did not amount to two livres. An entire stranger in this metropolis, his mind was filled with the most gloomy reflections on his embarrassed situation. With some difficulty he discovered that part of the town in which his old acquaintance Dr. Sleight resided. This gentleman received him with the warmest affection, and liberally invited him to share his purse till some establishment could be procured for him. Goldsmith, unwilling to be a burden to his friend, a short time after eagerly embraced an offer which was made him to assist the late Rev. Dr. Milner in instructing the young gentlemen at the academy at Peckham; and acquitted himself greatly to the Doctor's satisfaction for a short time: but having obtained some reputation by the criticisms he had written in the Monthly Review, Mr. Griffith the proprietor engaged him in the compilation of it; and, resolving to pursue the profession of writing, he returned to London, as the mart where abilities of every kind were sure of meeting distinction and reward. As his finances were by no means in a good state, he

determined to adopt a plan of the strictest economy, and took lodgings in an obscure court in the Old Bailey, where he wrote several ingenious little pieces. The late Mr. Newberry, who at that time gave great encouragement to men of literary abilities, became a kind of patron to our young author; and introduced him as one of the writers in the Public Ledger, in which his *Citizen of the World* originally appeared, under the title of *Chinese Letters*.

Fortune now seemed to take some notice of a man she had long neglected. The simplicity of his character, the integrity of his heart, and the merit of his productions, made his company very acceptable to a number of respectable families; and he emerged from his shabby apartments in the Old Bailey to the politer air of the Temple, where he took handsome chambers, and lived in a genteel style. The publication of his *Traveller* and his *Vicar of Wakefield* was followed by the performance of his comedy of the *Good-natured Man* at Covent-Garden theatre, and placed him in the first rank of the poets of the present age.

Among many other persons of distinction who were desirous to know him, was the duke of Northumberland, and the circumstance that attended his introduction to that nobleman is worthy of being related, in order to show a striking trait of his character. "I was invited," said the Doctor (as he was then universally called), "by my friend Mr. Piercy, to wait upon the duke, in consequence of the satisfaction he had received from the perusal of one of my productions. I dressed myself in the best manner I could; and, after studying some compliments I thought necessary on such an occasion, proceeded to Northumberland-house, and acquainted the servants that I had particular business with his Grace. They showed me into an anti-chamber; where, after waiting some time, a gentleman very genteely dressed made his appearance. Taking him for the duke, I delivered all the fine things I had composed in order to compliment him on the honour he had done me: when, to my great astonishment, he told me I had mistaken him for his master, who would see me immediately. At that instant the duke came into the apartment; and I was so confused on the occasion, that I wanted words barely sufficient to express the sense I entertained of the duke's politeness, and went away extremely chagrined at the blunder I had committed."

Another feature of his character we cannot help laying before the reader. Previous to the publication of his *Deserted Village*, the bookseller had given him a note for one hundred guineas for the copy, which the Doctor mentioned a few hours after to one of his friends: who observed, it was a very great sum for so short a performance. "In truth," replied Goldsmith, "I think so too; I have not been easy since I received it; therefore I will go back and return him his note:" which he absolutely did; and left it entirely to the bookseller to pay him according to the profits produced by the sale of the piece, which turned out very considerable.

During the last rehearsal of his comedy intitled *She stoops to Conquer*, which Mr. Coleman had no opinion would succeed, on the Doctor's objecting to the repetition of one of Tony Lumpkin's speeches, being apprehensive it might injure the play, the manager with great keenness replied, "Piha, my dear Doctor, do not be fearful of squibs, when we have been sitting almost these two hours upon a barrel of gunpowder." The piece, however, contrary to Mr. Coleman's expectation, was received with uncommon applause by the audience; and Goldsmith's pride was so hurt by the severity of the above observation, that it entirely put an end to his friendship for the gentleman that made it.

Notwithstanding the great success of his pieces, by some of which, it is asserted upon good authority, he cleared 1800*l.* in one year, his circumstances were by no means in a prosperous

situation; which was partly owing to the liberality of his disposition, and partly to an unfortunate habit he had contracted of gaming; the arts of which he knew very little of, and consequently became the prey of those who were unprincipled enough to take advantage of his simplicity.

Just before his death he had formed a design for executing an Universal Dictionary of Arts and Sciences, the prospectus of which he actually published. In this work several of his literary friends (particularly Sir Joshua Reynolds, Dr. Johnson, Mr. Beauclerc, and Mr. Garrick) had undertaken to furnish him with articles upon different subjects. He had entertained the most sanguine expectations from the success of it. The undertaking, however, did not meet with that encouragement from the booksellers which he had imagined it would undoubtedly receive; and he used to lament this circumstance almost to the last hour of his existence.

He had been for some years afflicted, at different times, with a violent strangury, which contributed not a little to embitter the latter part of his life; and which, united with the vexations which he suffered upon other occasions, brought on a kind of habitual despondency. In this unhappy condition he was attacked by a nervous fever, which, being improperly treated, terminated in his dissolution on the 4th of April 1774.

As to his character, it is strongly illustrated by Mr. Pope's line, "*In wit a man, simplicity a child.*" The learned leisure he loved to enjoy was too often interrupted by distresses which arose from the liberality of his temper, and which sometimes threw him into loud fits of passion: but this impetuosity was corrected upon a moment's reflection; and his servants have been known, upon these occasions, purposely to throw themselves in his way, that they might profit by it immediately after; for he who had the good fortune to be reproved was certain of being rewarded for it. The universal esteem in which his poems were held, and the repeated pleasure they give in the perusal, is a striking test of their merit. He was a studious and correct observer of nature; happy in the selection of his images, in the choice of his subjects, and in the harmony of his versification; and though his embarrassed situation prevented him from putting the last hand to many of his productions, his *Hermit*, his *Traveller*, and his *Deserted Village*, decidedly claim a place among the most finished pieces in the English language.

Besides the works already mentioned, he wrote, 1. *History of the earth and animated nature*, 6 vols. 8vo. 2. *History of England*, 4 vols. 8vo. 3. *History of Rome*, 2 vols. 4. *Abridgments of the two last*, for the use of schools. 5. *A view of experimental philosophy*, 3 vols. 8vo.; a posthumous work, not esteemed. 6. *Miscellanies*, &c.

GOLF, the name of a certain game among the Scots, and said to be peculiar to their country. Among them it has been very ancient; for there are statutes prohibiting it as early as the year 1457, lest it should interfere with the sport of archery. It is commonly played on rugged broken ground, covered with short grass, in the neighbourhood of the sea-shore. A field of this sort is in Scotland called *links*. The game is generally played in parties of one or two on each side. Each party has an exceeding hard ball, somewhat larger than a hen's egg. This they strike with a slender and elastic club, of about four feet long, crooked in the head, and having lead run into it, to make it heavy. The ball being struck with this club will fly to the distance of 200 yards, and the game is gained by the party who puts his ball into the hole with the fewest strokes. But the game does not depend solely upon the striking of the longest ball, but also upon measuring the strength of the stroke, and applying it in such direction as to lay the ball in smooth ground, whence it may be easily moved at the next stroke. To encourage this amusement, the city of Edinburgh, A. D. 1744, gave to

the company of golfers a silver club, to be played for annually by the company, the victor to append a gold or silver piece to the prize. It has been played for every year since, except the years 1746, 1747. For their better accommodation, 22 members of the company subscribed 30*l.* each in the year 1768, for building a house, where their meetings might be held. The spot chosen for this purpose was the southwest corner of Leith links, where an area was taken in feu from the magistrates of Edinburgh, and a commodious house and tavern built upon it.

GOLIUS (James), a celebrated professor of Arabic and the mathematics at Leyden, was descended from a very honourable family, and born at the Hague in the year 1596. He was put to the university of Leyden, where he studied under Erpinus; and having made himself master of all the learned languages, applied himself to the mathematics, physics, and divinity. He afterwards travelled into Africa and Asia, and became greatly esteemed by the king of Morocco, and the sultan of the Turks. He at length returned to Leyden, loaded with manuscripts, and in 1624 succeeded Erpinus in the Arabic chair. As he had been an eye-witness of the wretched state of Christianity in the Mahometan countries, he was filled with the compassion of a fellow-christian; and none ever solicited for a place of honour and profit with greater eagerness, than he for procuring a new edition of the New Testament, in the original language, with a translation into the vulgar Greek, by an Archimandrite; and as there are some of these Christians who use the Arabic tongue in divine service, he also took care to have dispersed among them an Arabic translation of the Confession of the Protestants, together with the Catechism and Liturgy. In 1626 he was also chosen professor of mathematics, and discharged the functions of both professorships with the greatest applause during 40 years. He was likewise appointed interpreter in ordinary to the states for the Arabic, Turkish, Persian, and other eastern languages, for which he had an annual pension, and a present of a gold chain, with a very beautiful medal which he wore as a badge of his office. He published, 1. The life of Tamerlane, written in Arabic. 2. The history of the Saracens, written by Elmacen. 3. Alferganus's elements of Astronomy, with a new version and learned commentaries. 4. An excellent Arabic Lexicon. 5. A Persian Dictionary. He died in 1667.

GOLTZIUS (Henry), a famous engraver and painter, born in 1558 at Mulbreck in the duchy of Juliers. He was taught the art of engraving by Theodore Cuerehert; and succeeded very wonderfully in it, notwithstanding the disadvantage of a lame hand, which was occasioned by his falling into the fire whilst young. He was first employed by his master, and afterwards he worked for Philip Galle. Domestic troubles and ill health occasioned him to travel. He went through Germany into Italy, and passed under a feigned name, that his studies might not be interrupted. He visited Bologna, Florence, Naples, and Venice, constantly applying himself to drawing from the antique statues, and the works of the great masters. At Rome he resided the longest; and there he produced several excellent engravings from Polidoro Raphael, and other eminent painters. On his return to his native country he established himself at Haerlem, where he engraved many of the drawings which he had made during his abode in Italy. He died at Haerlem in 1617, aged 59. He is said to have been forty years old before he began to paint; yet his pictures are spoken of with the greatest commendation; but as he did not produce any great number of them, they are of course but rarely to be met with. As an engraver, he deserves the highest commendation. No man ever surpassed, and few have equalled him in the command of the graver and freedom of execution. He copied the style of Albert Durer, Lucas of Leyden, and other old masters, with

astonishing exactness. Sometimes his engravings are neat in the extreme; at other times they are performed in a bold open manner, without the least restraint. He also engraved several of his own designs on wood, in that manner which is distinguished by the appellation of *chiaro-scuro*. Of his prints, which are very numerous, it may here suffice to specify two or three of the most celebrated: 1. Six large upright plates, known by the name of his *master-pieces*. These, it is said, he engraved to convince the public that he was perfectly capable of imitating the styles of Albert Durer, Lucas Van Leyden, and other masters, whose works were then held in higher estimation than his own: for he had adopted a new manner, which he pursued because he thought it superior, and not because he was incapable of following the others. It is reported that with one of them, the Circumcision, which he smoked to give it the more plausible air of antiquity, he actually deceived some of the most capital connoisseurs of the day; by one of whom it was bought for an original engraving of Albert Durer. The subjects of these plates are, The Annunciation of the Virgin; the Meeting of the Virgin with Elizabeth, called the Visitation; the Nativity of Christ; the Circumcision of Christ; the Adoration of the wise Men; the Holy Family. 2. The Judgment of Midas, a large plate lengthwise. 3. The Venetian Gall, a large plate lengthwise, from Theodore Bernard. 4. The Boy and Dog, a middling sized upright plate, from a design of his own; an admirable print. 5. The Necromancer, a middling sized upright oval print, in *chiaro scuro*. 6. Night in her Chariot, the same.

GOLTZIUS (Hubert), a learned German, born at Venlo in the duchy of Gueldres in 1526. His father was a painter, and himself was bred to the art under Lambert Lombard: but he did little at painting, or at least his pictures are very scarce; for having a peculiar turn to antiquities, he devoted himself to the study of medals. He travelled through Germany, France, and Italy, to make collections, as well as to draw from thence all the lights he could towards clearing up ancient history: he was the author of several excellent works, in which he was so accurate and nice, that he had them printed at his own house, under his own correction, and even engraved the plates and medals with his own hand. His veneration for Roman antiquities was so great, that he gave all his children Roman names: and married for his second wife, the widow of the antiquarian Martinus Smetius; probably more for the sake of Smetius's medals and inscriptions than for his own sake; and was punished accordingly by her plaguing him all his life, if she did not shorten it. He died in 1583.

GOMBAULD (John Ogier de), one of the best French poets in the 17th century, and one of the first members of the French academy, was born at St. Just de Lussac. He acquired the esteem of Mary de Medicis, and of the wits of his time. He was a Protestant, and died in a very advanced age. He wrote many works in verse and prose. His epigrams, and some of his sonnets, are particularly esteemed.

GOMBROON, a considerable seaport of Persia, in the province of Farsistan. It is called by the natives Bandar Abassi, and is seated on a bay, 12 miles N. of the E. end of the island of Kismish, and nine miles from the famous island of Ormus. The best houses are built of brick dried in the sun, and stand close to each other, being flat at the top, with a square turret, having holes on each side for the free passage of the air. Upon these roofs, those that stay in the town sleep every night in the summer season. The common people have wretched huts, made with the boughs of palm-trees, and covered with leaves. The streets are narrow and irregular. The English and Dutch have factories here, which is a great advantage to the trade of the place. The soil is barren, but provisions brought from other countries are very plentiful. The weather is so hot in June,

July, and August, that this place is extremely unhealthy; and therefore the English factory retire to Assen during those months. It is frequented by people of several nations, as well Europeans as others; and the Banyans are so numerous, that they bribe the governor not to permit any cows to be killed in the town. Lon. 36. 35. E. Lat. 27. 30. N.

GOMERA, one of the Canary islands lying between Ferro and Teneriffe. It has one good town of the same name, with an excellent harbour, where the Spanish fleet often take in refreshments. They have corn sufficient to supply the inhabitants, with one sugar-work, and great plenty of wine and fruits. It is subject to the Spaniards, who conquered it in 1445. W. lon. 17. 10. N. lat. 28. 0.

GOMOZIA, in botany; a genus of the digynia order, belonging to the tetrandria class of plants. The corolla is campanulated, quadrifid above; there is no calyx; the berry is bilocular.

GOMPHOSIS, in anatomy, that kind of articulation by which the teeth are fixed in the jaw-bone. See ANATOMY, page 164.

GOMPHRÆNA, GLOBE AMARANTH, in botany; a genus of the digynia order, belonging to the pentandria class of plants, and in the natural method ranking under the 54th order, *Miscellanææ*. The calyx is coloured; the exterior one triphyllous, or diphyllous, with two carinated connivent leaflets; the nectarium cylindrical, with ten teeth; the capsule monospermous. There are seven species; but only one of them is commonly cultivated in our gardens, viz. the globosa. It hath an upright stalk branching all round, two or three feet high, garnished with oval, lanceolate, and opposite leaves; and every branch and side-shoot terminated by a close globular head of flowers, composed of numerous, very small starry florets, closely covered with dry scaly calices placed *imbricatim*, persistent, and beautifully coloured purple, white, red, or striped and variegated. The flowers themselves are so small, and closely covered with the scaly calices, that they scarcely appear. The numerous closely placed scaly coverings being of a dry firm consistence, coloured and glittering, collected into a compact round head, about the size of an ordinary cherry, make a fine appearance. They are annual plants, natives of India; and require artificial heat to raise and forward them to a proper growth, so that they may flower in perfection, and produce ripe seed. They flower from June to November; and if the flowers are gathered when at full growth, and placed out of the sun, they will retain their beauty several months.

GONAQUA, the name of a nation inhabiting about the Cape, and supposed by Dr. Sparman to be a mixture of Hotentots and Caffres.

GONDAR, the metropolis of Abyssinia, situated on a hill of considerable height, and containing about 10,000 families in time of peace. The houses are chiefly of clay; the roofs thatched in the form of cones, which is always the construction within the tropical rains. They have no shops; but carry on their trade in a large square, where they expose their merchandise to sale, laid upon mats; and gold and rock-salt are the only money made use of. Each bar of salt is a foot in length, and they break off as much as they agree for in the purchase of small wares. There are about 100 churches, and their patriarch depends on that of Alexandria. The priests have a great power with the people, and sometimes abuse it grossly. The rainy season begins in April, and does not cease till the end of September, whence the Nile, and other rivers that have their source in Abyssinia, overflow their banks every year. The inhabitants are tall and comely, and their complexion a dun, or olive colour. The habit of the better sort is made of silks and cottons; but the common people have only drawers to hide their nakedness. It is 180 miles S. E. of

Sennar, and near 1000 S. of Grand Cairo. Lon. 37. 33. E. Lat. 12. 34. N.

GONDI (John Francis Paul), Cardinal de Retz, was the son of Philip Emanuel de Gondi, Count de Joigny, lieutenant-general, &c. and was born in 1613. From a doctor of the Sorbonne, he first became coadjutor to his uncle John Francis de Gondi, whom he succeeded in 1654 as archbishop of Paris; and was finally made a cardinal. This extraordinary person has drawn his own character in his memoirs with impartiality. He was a man who, from the greatest degree of debauchery, and long languishing under its consequences, made himself adored by the people as a preacher. At the age of 23, he was at the head of a conspiracy against the life of Cardinal Richelieu; he precipitated the parliament into cabals, and the people into sedition: he was (says M. Voltaire) the first bishop who carried on a civil war without the mask of religion. However, his intrigues and schemes turned out so ill, that he was obliged to quit France; and he lived the life of a vagrant exile for five or six years, till the death of his great enemy Cardinal Mazarin, when he returned on certain stipulated conditions. After assisting in the conclave at Rome which chose Clement IX. he retired from the world, and ended his life like a philosopher in 1679; which made Voltaire say, that in his youth he lived like Catiline, and like Atticus in his old age. He wrote his Memoirs in his retirement; the best edition of which is that of Amsterdam, 4 vols. 12mo. 1719.

GONDOLA, a flat boat, very long and narrow, chiefly used at Venice to row on the canals. The word is Italian, *gondola*. Du Cange derives it from the vulgar Greek *κοννελος*, "a bark," or "little ship;" Lancelot deduces it from *γονδου*, a term in Athenæus for a sort of vase. The middle-sized gondolas are upwards of thirty feet long and four broad: they always terminate at each end in a very sharp point, which is raised perpendicularly to the full height of a man. The address of the Venetian gondoliers, in passing along their narrow canals, is very remarkable: there are usually two to each gondola, and they row by pushing before them. The fore-man rests his oar on the left side of the gondola: the hind-man is placed on the stern, that he may see the head over the tilt or covering of the gondola, and rests his oar, which is very long, on the right side of the gondola. *Gondola* is also the name of a passage boat of six or eight oars, used in other parts of the coast of Italy.

GONORRHEEA, an efflux of white, yellow, or greenish matter from the urethra; most commonly owing to venereal infection. See SURGERY.

GONZAGA (Lucretia), was one of the most illustrious ladies of the 16th century, and much celebrated for her wit, her learning, and her delicate style. Hortensio Lando wrote a beautiful panegyric upon her, and dedicated to her his dialogue of moderating the passions. Her beautiful letters have been collected with the greatest care. We learn from these, that her marriage with John Paul Manfrone was unhappy. She was married to him when she was not 14 years of age, and his conduct afterwards gave her infinite uneasiness. He engaged in a conspiracy against the duke of Ferrara; was detected and imprisoned by him; but, though condemned by the judges, not put to death. She did all in her power to obtain his enlargement, but in vain; for he died in prison, having shown such impatience under his misfortunes, as made it imagined he had lost his senses. She never would listen afterwards to any proposals of marriage, though several were made to her. All that came from her pen was so much esteemed, that a collection was made even of the notes she wrote to her servants; several of which are to be met with in the edition of her letters.

GOOD, in general, whatever is apt to increase pleasure, or to diminish pain in us; or, which amounts to the same, whatever is able to procure or preserve to us the possession of agreeable

sensations, and remove those of an opposite nature. *Moral* GOOD denotes the right conduct of the several senses and passions, or their just proportion and accommodation to their respective objects and relations. See *MORALS*.

GOOD Abearing, (*onus gestus*), signifies an exact carriage or behaviour of a subject towards the king and the people, whereunto some persons upon their misbehaviour are bound: and he that is bound to this is said to be more strictly bound than to the peace; because where the peace is not broken, the surety *de bono gestu* may be forfeited by the number of a man's company, or by their weapons.

GOOD Behaviour, in law, an exact carriage and behaviour to the king and his people. A justice of the peace may, at the request of another, or where he himself sees cause, demand surety for the good behaviour; and to that end the justice may issue out his warrant against any person whatsoever, under the degree of nobility; but when it is a nobleman, complaint is to be made in the court of chancery, or king's bench, where such nobleman may be bound to keep the peace. Infants and femecoverts, who ought to find surety by their friends, may be bound over to their good behaviour; as also lunatics that have sometimes lucid intervals, and all others who break the peace, or being suspected to do it by affrays, assaults, battery, wounding, fighting, quarrelling, threatening, &c. A person may be likewise bound to his good behaviour for a scandalous way of living, keeping bawdy-houses, gaming-houses, &c. and so may common drunkards, whoremongers, common whores, cheats, libellers, &c. He who demands surety for the peace, on any violence offered, must take an oath before the justice, that he goes in fear of his life, or some bodily harm, &c. and that it is not out of malice, but from a regard to his own safety.

GOOD-Friday, a fast of the Christian church, in memory of the sufferings and death of Jesus Christ. It is observed on the Friday in *holy* or *passion week*; and it is called, by way of eminence, *good*, because of the blessed effects of our Saviour's sufferings, which were a propitiatory or expiating sacrifice for the sins of the world. The commemoration of our Saviour's sufferings has been kept from the very first ages of Christianity, and was always observed as a day of the strictest fasting and humiliation. Among the Saxons it was called *Long-Friday*; but for what reason, except on account of the long fastings and offices then used, is uncertain. On Good-Friday the pope sits on a plain form; and after service is ended, when the cardinals wait on him back to his chamber, they are obliged to keep a deep silence, as a testimony of their sorrow. In the night of Good-Friday, the Greeks perform the obsequies of our Saviour round a great crucifix, laid on a bed of state, adorned with flowers; these the bishops distribute among the assistants when the office is ended. The Armenians, on this day, set open a holy sepulchre, in imitation of that of mount Calvary.

Good-Hope, or *Cape of Good-Hope*, the southern extremity of Africa, in 81. 23. E. lon. and 34. 29. S. lat. discovered by the Portuguese in 1493. Here is a neat well-built town, rising in the midst of a desert, surrounded by black and dreary mountains; or, in other words, the picture of successful industry. The storehouses of the Dutch East India company are situated next the water, and the private buildings lie beyond them, on a gentle ascent. The principal fort which commands the road is on the E. side; and another strong fort, called Amsterdam Fort, has been built on the W. side since the last war with England. The streets are broad and regular, intersecting each other at right angles. The houses in general are built of stone, and white-washed. There are two churches, one for the Calvinists, the established religion; the other for the Lutherans. The religion of the slaves is as little regarded here as in the colonies of other European states. In other respects, however, they are treated with humanity, and are lodged and boarded in a spacious house,

where they are likewise kept at work. These slaves, a few Hottentots excepted, were all originally brought from the E. Indies, and principally from Malacca. Another great building serves as an hospital for the sailors belonging to the Dutch East India ships which touch here. It is situated close to the Company's gardens. It is an honour to that commercial body, and an ornament to the town. The convalescents have free access to these gardens, where they enjoy the benefit of a pure wholesome air, perfumed by the fragrance of a great number of rich fruit-trees, aromatic shrubs, and odoriferous plants and flowers: they have likewise the use of every production in them. The inhabitants are fond of gardens, which they keep in excellent order. Though stout and athletic, they have not all that phlegm about them which is the characteristic of the Dutch in general. The ladies are lively, good-natured, familiar and gay. The heavy draught-work about the Cape is chiefly performed by oxen, which are here brought to an uncommon degree of docility and usefulness. The inhabitants in general travel in a kind of covered waggons, drawn by oxen, which better suit the roughness of the country than more elegant vehicles; but the governor and some of the principal people keep coaches, which are much in the English style, and are drawn by six horses. The ground behind the town gradually rises on all sides toward the mountains, called the Table Mountain, which is the highest; the Sugar loaf, so named from its form; the Lion's Head, Charles Mount and James Mount, or the Lion's Rump. From these mountains descend several rivulets, which fall into the different bays, as Table Bay, False Bay, &c. The view from the Table Mountain is very extensive and picturesque; and all along the vallies and rivulets among these mountains are a great number of delightful plantations. This place is at present in the hands of the English.

GOOGINGS, in sea-language, are clamps of iron bolted on the stern-post of a ship, whereon to hang the rudder and keep it steady: for which purpose there is a hole in each of them, to receive a correspondent spindle bolted on the back of the rudder, which turns thereby as upon hinges.

GOOMPTY, a river of Hindoostan Proper, which rises in the Rohilla Country, and flowing S. E. by Lucknow and Jionpour, falls into the Ganges, a little below Benaies.

GOOSE, in ornithology. See *ANAS*. The goose was held in great esteem among the Romans, for having saved the Capitol from the invasion of the Gauls by cackling and clapping its wings. Geese were kept in the temple of Juno; and the censors, when they entered upon their office, provided meat for them. There was also an annual feast at Rome, at which they carried a silver image of a goose in state; and hanged a dog, to punish that animal because he did not bark at the arrival of the Gauls.

GOOSE-Ander, in ornithology. See *MERGUS*.

GOOSE-Berry, in botany. See *RIBES*.

GOOSE-Neck, in a ship, a piece of iron fixed on the one end of the tiller, to which the laniard of the whip-staff or the wheel-rope comes, for steering the ship.

GOOSE-Wing, in the sea-language. When a ship sails before, or with a quarter-wind on a fresh gale, to make the more haste, they launch out a boom and sail on the lee-side; and a sail so fitted is called a *goose-wing*.

GOOTY, or *GURTI*, a strong fortress in the peninsula of Hindoostan, formerly the seat of government of Morari Row, a Mahratta prince. It is now subject to Tippoo Sultan, regent of Mysore, and lies beyond the river Pennar, 25 miles S. by E. of Adoni. E. lon. 77. 35. N. lat. 15. 15.

GORCUM, a town of the United Provinces, in S. Holland, which carries on a considerable trade in cheese and butter. It is seated on the rivers Linghe and Maese, 12 miles E. of Dordrecht, and 32 S. of Amsterdam. E. lon. 4. 51. N. lat. 51. 51.

GORDIANUS I. (a Roman general), was for his valour and virtues chosen emperor by the army in the reign of Maximinus, A. D. 237; but his son, whom he had associated with himself in the throne, being slain by Capellian, the governor of Mauritania for Maximinus, Gordianus killed himself the same year. See **ROME**.

GORDIANUS III. (grandson of the former), a renowned warrior, and styled *The guardian of the Roman commonwealth*. He was treacherously assassinated by Philippus, an Arabian, one of his generals; who, to the eternal disgrace of the Romans of that era, succeeded him in the empire, Anno Domini 244.

GORDIAN-KNOT, in antiquity, a knot made in the leathers or harness of the chariot of Gordius king of Phrygia, so very intricate, that there was no finding where it began or ended. The inhabitants had a tradition, that the oracle had declared, that he who untied this knot should be master of Asia. Alexander, having undertaken it, was unable to accomplish it; when, fearing lest his not untying it should be deemed an ill augury, and prove a check in the way of his conquests, he cut it asunder with his sword, and thus either accomplished or eluded the oracle.

GORDIUS, the **HAIR-WORM**, a genus of insects belonging to the class of *vermes intestina*. There are several species, 1. The *aquaticus*, or water hair-worm, is 10 or 12 inches in length, and of about the thickness of a horse hair: its skin is smooth and somewhat glossy, without furrows: its colour pale yellowish white all over, except the head and tail, which are black and glossy. The body is rounded, and very slender in proportion to its length: the mouth is small, and placed horizontally; the jaws are both of the same length, and obtuse at their extremities. This species is common in our fresh waters, more especially in clay, through which it passes as a fish does through the water, and is the author of many springs. This is the worm that in Guinea and in some other of the hot countries gets into the flesh of the natives, and occasions great mischief; with us, though frequent enough in water where people bathe, it never attempts this.—2. The *argillaceous*, or clay hair-worm, is only a variation of the preceding one in colour, being yellowish at the extremities. It chiefly inhabits the clay; and Linnæus calls that its proper element, from its being generally dug out of it.—3. The *medicinis*, or muscular hair-worm, is all over of a pale yellowish colour. It is a native of both Indies; frequent in the morning dew, from whence it enters the naked feet of the slaves, and occasions a disease much known in those countries, and to which children are very liable: it creates the most troublesome itchings, and too often excites a fever and inflammation. It particularly attacks the muscles of the arms and legs, from whence it may be drawn out by means of a piece of silk or thread tied round the head: but the greatest caution is necessary in this simple operation, lest the animal, by being strained too much, should break; for if any part remains under the skin, it quickly grows with redoubled vigour, and becomes a cruel, and sometimes fatal enemy to the poor slaves in particular. Baths with infusions of bitter plants, and all vermifuges, destroy it. 4. The *marinus* or sea hair-worm is filiform, twisted spirally and lying flat, about half an inch in length; of a whitish colour, smooth, and scarcely diminishing at the head. It is as great a tormentor of herrings, bleaks, and various other fish, as the *gordius medicinis* is of man. The fish when infested with these animals rise to the surface, and tumble about as if in great agony. See plate 15. Vol. iii.

GORDIUS, king of Phrygia, and father of Midas, was a poor husbandman, with two yokes of oxen, wherewith he ploughed his land and drew his wain. An eagle sitting a long while upon one of his oxen, he consulted the soothsayers. A virgin bid him sacrifice to Jupiter in the capacity of a king. He married

the virgin, who brought forth Midas. The Persians, instructed by the oracle to set the first person they met in a wain upon the throne, met Gordius, and made him king. Midas, for this good fortune, dedicated to Jupiter his father's cart. The knot of the yoke, they say, was so well twisted, that he who could unloose it was promised the empire of Asia; hence the proverb of *the Gordian knot* had its original. See **GARDIAN Knot**.

GORDON (Alexander), an excellent draughtsman and a good Grecian, who resided many years in Italy, visited most parts of that country, and had also travelled into France, Germany, &c. was secretary to the Society for Encouragement of Learning; and afterwards to the Egyptian Club, composed of gentlemen who had visited Egypt (viz. Lord Sandwich, Dr. Shaw, Dr. Pococke, &c.). He succeeded Dr. Stukely as secretary to the Antiquarian Society, which office he resigned in 1741 to Mr. Joseph Ames. He went to Carolina with governor Glen, where, besides a grant of land, he had several offices, such as register of the province, &c.; and died a justice of the peace, leaving a handsome estate to his family. He published, 1. *Itinerarium Septentrionale*, or a Journey through most parts of the Counties of Scotland, in two parts, with 66 copper-plates, 1726, folio. 2. Supplement to the *Itinerarium*, 1732, folio. 3. The Lives of Pope Alexander VI. and his son Cæsar Borgia. 4. A complete History of the ancient Amphitheatres, 1730, 8vo. afterwards enlarged in a second edition. 5. An Essay towards explaining the hieroglyphical figures on the Coffin of the ancient Mummy belonging to Capt. William Lethieuller, 1737, folio, with cuts. 6. Twenty-five Plates of all the Egyptian Mummies and other Egyptian Antiquities in England, 1739, folio.

GORDON (Thomas), noted for his translations and political writings, was born at Kirkcudbright in North Britain. He came young to London, where he supported himself by teaching languages, until he procured employment under the earl of Oxford in queen Anne's time, but in what capacity is not known. He first distinguished himself in the defence of Dr. Hoadley in the Bangorian controversy; which recommended him to Mr. Trenchard, in conjunction with whom he wrote the well-known Cato's Letters, upon a variety of important public subjects. These were followed by another periodical paper, under the title of the Independent Whig; which was continued, some years after Mr. Trenchard's death, by Gordon alone, against the hierarchy of the church, but with more acrimony than was shown in Cato's Letters. At length Sir Robert Walpole retained him to defend his administration, to which end he wrote several pamphlets. At the time of his death, July 28th, 1750, he was first commissioner of the wine-licences, an office which he had enjoyed many years. He was twice married. His second wife was the widow of his great friend Trenchard, by whom he had children. He published English translations of Sallust and Tacitus, with additional discourses to each author, which contain much good matter. Also two collections of his tracts have been preserved: the first intitled, A Cordial for Low-Spirits, in three volumes; and the second, The Pillars of Priestcraft and Orthodoxy shaken, in two volumes. But these, like many other posthumous things, had better have been suppressed. In his translation as well as his other works, he places the verbs at the ends of sentences, according to the Latin idiom, in a very stiff and affected manner.

GORDONIA, in botany; a genus of the polyandria order, belonging to the monadelphia class of plants. The calyx is simple; the style five-cornered, with the stigma quinquefid; the capsule quincloocular; the seeds two-fold with a leafy wing. This is a tall and very straight tree, with a regular pyramidal head. Its leaves are shaped like those of the common bay, but serrated. It begins to blossom in May, and continues bringing forth its flowers the greatest part of the summer. The

flowers are fixed to foot-stalks, four or five inches long; are monopetalous, divided into five segments, encompassing a tuft of stamina headed with yellow apices; these flowers, in November, are succeeded by a conic capsule, having a divided calyx. The capsule, when ripe, opens and divides into five sections, disclosing many small half-winged seeds. This tree retains its leaves all the year, and grows only in wet places and usually in water. The wood is somewhat soft; yet Mr. Catesby mentions his having seen some beautiful tables made of it. It grows in Carolina, but not in any of the more northern colonies.

GORÉ, in heraldry, one of the abatements, which, according to Guillim, denotes a coward. It is a figure consisting of two arch lines, drawn one from the sinister chief, and the other from the sinister base, both meeting in an acute angle in the middle of the fess point. See HERALDRY.

GORÉE, a small island of Africa, near Cape de Verd, subject to the French. It is barren, but of great importance on account of its good trade. W. lon. 17. 25. N. lat. 14. 40.

GORÉE, a capital town of the island of the same name, in Holland, 8 miles S. S. W. of Briel. E. lon. 4. 20. N. lat. 51. 44.

GORE Island, an island in the N. Pacific Ocean, so named by Captain Cook, who discovered it in his last voyage. It appears to be barren and uninhabited. It lies in about lon. 169. W. lat. 64. N.

GORGE, in architecture, the narrowest part of the Tuscan and Doric capitals, lying between the astragal, above the shaft of the pillar, and the annulets.

GORGE, in fortification, the entrance of the platform of any work. See FORTIFICATION.

GORGED, in heraldry, the bearing of a crown, coronet, or the like, about the neck of a lion, a swan, &c. and in that case it is said, the lion or cygnet is gorged with a ducal coronet, &c. This term is also used when the gorge or neck of a peacock, swan, or the like bird, is of a different colour or metal from the rest.

GORGET, a kind of breast-plate like a half-moon, with the arms of the prince thereon, worn by the officers of the army. They are either gilt or silver, according to the colour of the buttons on the uniform.

GORGET, or GORGERET, in surgery, is the name which the French give to the concave or canulated conductor, used in lithotomy. See SURGERY.

GORGONA, a small island of Italy, in the sea of Tuscany, about eight miles in circumference, remarkable for the large quantity of anchovies taken near it. E. lon. 10. 0. N. lat. 43. 22.

GORGONA, an island of the South Sea, 12 miles W. of the coast of Peru. It is high land, very woody, and some of the trees are tall, large, and proper for masts. It is 10 miles in circumference, and has several rivulets of excellent water. There are a great number of monkeys, Guinea-pigs, lions, lizards, and sloths remarkable for their ugliness and the slowness of their motions, though by the shape they seem to be of the monkey kind. W. lon. 77. 50. S. lat. 3. 20.

GORGONIA, in natural history, a genus of zoophytes, which formerly were called *ceratophytens*, and are known in English by the names of *sea-fans*, *sea-feathers*, and *sea-whips*. Linnæus and Dr. Pallas consider them as of a mixed nature in their growth, between animals and vegetables; but Mr. Ellis shows them to be true animals of the polype kind, growing up in a branched form resembling a shrub, and in no part vegetable. They differ from the fresh-water polype in many of their qualities, and particularly in producing from their own substance a hard and solid support, serving many of the purposes of the bone in other animals. This is formed by a concreting juice,

thrown out from a peculiar set of longitudinal parallel tubes running along the internal surface of the fleshy part: in the coats of these tubes are a number of small orifices, through which the ossæous liquor exudes, and, concreting, forms the layers of that hard part of the annular circles, which some, judging from the consistence rather than the texture, have erroneously denominated *wood*. The surface of the gorgonia is composed of a kind of scales, so well adapted to each other, as to serve for defence from external injuries: and the flesh, or, as some have called it, the *bark* or *cortex*, consists of proper muscles and tendons for extending the opening of their cells; for sending forth from thence their polype suckers in search of food; and for drawing them in suddenly, and contracting the sphincter muscles of these starry cells, in order to secure these tender parts from danger; and also of proper secretory ducts, to furnish and deposit the ossæous matter that forms the stem and branches as well as the base of the bone. Mr. Ellis affirms, that there are ovaries in these animals, and thinks it very probable that many of them are viviparous. See CORALLINES.

GORGONS, in antiquity and mythology. Authors are not agreed in the account they give of the Gorgons. The poets represent them as three sisters, whose names were *Sibeno*, *Euryale*, and *Medusa*; the latter of whom was mortal, and, having been deslowered by Neptune, was killed by Perseus; the two former were subject neither to age nor death. They are described with wings on their shoulders, with serpents round their heads, their hands were of brass, and their teeth of a prodigious size, so that they were objects of terror to mankind. After the death of Medusa, her sisters, according to Virgil, were appointed to keep the gate of the palace of Pluto.

Multaque præterea variarum monstra ferarum—
GORGONES, *Harpeicæque—*

Diodorus Siculus will have the Gorgons and Amazons to have been two warlike nations of women, who inhabited that part of Libya which lay on the lake Tritonidis. The extermination of these female nations was not effected till Hercules undertook and performed it.

Pausanias says the Gorgons were the daughters of Phorbus; after whose death Medusa his daughter reigned over the people, dwelling near the lake Tritonidis. The queen was passionately fond of hunting and war, so that she laid the neighbouring countries quite waste. At last, Perseus having made war on them and killed the queen herself, when he came to take a view of the field of battle he found the queen's corpse so extremely beautiful, that he ordered her head to be cut off, which he carried with him to show his countrymen the Greeks, who could not behold it without being struck with astonishment. Others represent them as a kind of monstrous women, covered with hair, who lived in woods and forests. Others again make them animals, resembling wild sheep, whose eyes had a poisonous and fatal influence.

GORITIA, or GORITE, a strong town of Germany, in the circle of Austria, and duchy of Carniola, with a castle; seated on the river Lizonzo, 16 miles north-east of Aquileia, and 66 north-east of Venice. E. lon. 13. 43. N. lat. 46. 12.

GORLÆUS (Abraham), an eminent antiquary, was born at Antwerp, and gained a reputation by collecting medals and other antiques. He was chiefly fond of the rings and seals of the ancients, of which he published a prodigious number in 1601, under this title, *Dactylothebea; sive Annulorum Sigillarium, quorum apud præcos tam Græcos quam Romanos usus ex ferro, ære, argento, et auro, Promptuarium*. This was the first part of the work: the second was intitled, *Variarum Gemmarum, quibus antiquitas in signando uti solita sculpturæ*. This work has undergone several editions, the best of which is that of Leyden, 1695; for it not only contains a vast number of cuts,

but also a short explication of them by Gronovius. In 1608 he published a collection of medals: which however, if we may believe the *Scaligerana*, it is not safe always to trust. Gorlaeus pitched upon Delft for the place of his residence, and died there in 1609. His collections of antiques were sold by his heirs to the prince of Wales.

GORLITZ, a town of Germany in Upper Lusatia, subject to the elector of Saxony. It is a handsome strong place, and seated on the river Neitze, in E. lon. 15. 15. N. lat. 51. 10.

GORTERIA, in botany; a genus of the polygamia frustranea order, belonging to the syngenesia class of plants, and in the natural method ranking under the 49th order, *Compositæ*. The receptacle is naked; the pappus woolly; the florets of the radius ligulated or plane; the calyx imbricated with spinous scales.

GOSHAWK. See **FALCO**.

GOSLAR, a large and ancient town of Lower Saxony, and in the territory of Brunswick; it is a free imperial city, and it was here that gunpowder was first invented, by a monk as is generally supposed. It is a large place, but the buildings are in the ancient taste. In 1728, 280 houses and St. Stephen's fine church were reduced to ashes. It is seated on a mountain near the river Gose, and near it are rich mines of iron. The inhabitants are famous for brewing excellent beer. E. lon. 3. 37. N. lat. 51. 55.

GOSPEL, the history of the life, actions, death, resurrection, ascension, and doctrine of Jesus Christ. The word is Saxon, and of the same import with the Latin term, *evangelium*, which signifies glad tidings, or good news. The history is contained in the writings of St. Matthew, St. Mark, St. Luke, and St. John, who from thence are called *evangelists*. The Christian church never acknowledged any more than these four gospels as canonical; notwithstanding which, several apocryphal gospels are handed down to us, and others are entirely lost.

GOSPORT, a town of Hampshire, 79 miles from London, in the parish of Alverstock. It has a ferry over the mouth of the harbour to Portsmouth, and is a large town and of great trade, especially in time of war. Travellers choose to lodge here, where every thing is cheaper and more commodious for them than at Portsmouth. The mouth of the harbour, which is not so broad here as the Thames at Westminster, is secured on this side by four forts, and a platform of above 20 cannon level with the water. Here is a noble hospital built for the cure of the sick and wounded sailors in the service of the navy; besides a free school.

GOSSAMER is the name of a fine filmy substance, like cobweb, which is seen to float in the air in clear days in autumn, and is more observable in stubble-fields, and upon furze and other low bushes. This is probably formed by the flying-spider, which, in traversing the air for food, shoots out these threads from its anus, which are borne down by the dew, &c.

GOSSYPIUM, or **COTTON**; a genus of the polyandria order, belonging to the monadelphia class of plants, and in the natural method ranking under the 37th order, *Columifera*. The calyx is double, the exterior one tritid; the capsule quadrilocular; the seeds wrapt in cotton-wool. There are four species, all of them natives of warm climates. 1. The *herbaceum*, or common herbaceous cotton, hath an herbaceous smooth stalk two feet high, branching upwards; five-lobed smooth leaves; and yellow flowers from the ends of the branches, succeeded by roundish capsules full of seed and cotton. 2. The *hirsutum*, or hairy American cotton, hath hairy stalks branching laterally two or three feet high; palmated, three and five-lobed hairy leaves; and yellow flowers, succeeded by large oval pods furnished with seeds and cotton. 3. The *barbadense*, or Barbadoes shrubby

cotton, hath a shrubby stalk branching four or five feet high, three-lobed smooth-leaves, glandulous underneath; and yellow flowers succeeded by oval pods, containing seeds and cotton. 4. The *arboresum*, or tree cotton, has an upright woody perennial stalk, branching six or eight feet high; palmated, four or five-lobed smooth leaves, and yellow flowers, succeeded by large pods filled with seeds and cotton. The first three species are annual, but the fourth is perennial both in root and stalk. In warm countries these plants are cultivated in great quantities in the fields for the sake of the cotton they produce; but the first species is most generally cultivated. The pods are sometimes as large as middling-sized apples, closely filled with the cotton surrounding the seed. When these plants are raised in this country, they must be continually kept in a warm stove, where they will produce seeds and cotton. They are propagated by seeds. See **COTTON**.

The American Islands produce cotton shrubs of various sizes, which rise and grow up without any culture, especially in low and marshy grounds. Their produce is of a pale red; some paler than others; but so short that it cannot be spun. None of this is brought to Europe, though it might be usefully employed in making of hats. The little that is picked up serves to make mattresses and pillows.

The cotton-shrub that supplies our manufactures requires a dry and stony soil, and thrives best in grounds that have already been tilled. Not but that the plant appears more flourishing in fresh lands than in those which are exhausted; but while it produces more wood, it bears less fruit. A western exposure is fittest for it. The culture of it begins in March and April, and continues during the first spring-rains. Holes are made at seven or eight feet distance from each other, and a few seeds thrown in. When they are grown to the height of five or six inches, all the stems are pulled up, except two or three of the strongest. These are cropped twice before the end of August. This precaution is the more necessary, as the wood bears no fruit till after the second pruning; and, if the shrub was suffered to grow more than four feet high, the crop would not be the greater, nor the fruit so easily gathered. The same method is pursued for three years; for so long the shrub may continue, if it cannot conveniently be renewed oftener with the prospect of an advantage that will compensate the trouble. This useful plant will not thrive if great attention is not paid to pluck up the weeds that grow about it. Frequent rains will promote its growth: but they must not be incessant. Dry weather is particularly necessary in the months of March and April, which is the time of gathering the cotton, to prevent it from being discoloured and spotted. When it is all gathered in, the seeds must be picked out from the wool with which they are naturally mixed. This is done by means of a cotton-mill; which is an engine composed of two rods of hard wood, about 18 feet long, 18 lines in circumference, and fluted two lines deep. They are confined at both ends, so as to leave no more distance between them than is necessary for the seed to slip through. At one end is a kind of little millstone, which, being put in motion with the foot, turns the rods in contrary directions. They separate the cotton, and throw out the seed contained in it.

GOTHA, a town of Germany, in the circle of Upper Saxony, and capital of a duchy of the same name. It is 18 miles W. of Erfurt. Lon. 10. 52. E. Lat. 51. 0. N.

GOTHA, a river of W. Gothland in Sweden, which issues out of lake Wenner, and falls into the North Sea at Gotheborg.

GOTHARD, one of the highest mountains of Switzerland; and from the top, where there is an hospital for monks, is one of the finest prospects in the world. It is eight miles from Aldorf.

GOTHEBORG, or **GOTTENBURG**, a rich and flourishing

town of W. Gothland in Sweden, seated at the mouth of the river Gotha, which forms an excellent harbour; and it is the best situated for foreign trade of any in the kingdom, as it lies without the Sound. The inhabitants are computed to be 20,000. Here is a considerable herring fishery; and from this port the Swedish E. India ships take their departure. The fortifications of this town are so weak, that the Danes, who attacked the Swedes in 1788, under the pretence of an alliance with Russia, must have taken it, with the king of Sweden in person, but for the interference of Mr. Elliot, the British minister, under whose mediation an armistice, and afterward a convention, were concluded between the two contending powers. Gotheborg is 188 miles S. W. of Stockholm. Lon. 11. 44. E. Lat. 57. 42. N.

GOTHIC, in general, whatever has any relation to the Goths: thus we say, Gothic customs, Gothic architecture, &c. See ARCHITECTURE.

GOTHLAND, one of the five general divisions of the kingdom of Sweden, containing the provinces of Ostrogothia or E. Gothland, Smoland, Westrogothia or W. Gothland, the isles of Gothland and Oeland, Wermland, Dalia, Halland, Blekingen, and Scania or Schonen.

GOTHS, a warlike nation, and above all others famous in the Roman history, came originally out of Scandinavia (the name by which the ancients distinguished the present countries of Sweden, Norway, Lapland, and Finmark). According to the most probable accounts, they were the first inhabitants of those countries; and from thence sent colonies into the islands of the Baltic, the Cimbric Cheronesus, and the adjacent places yet destitute of inhabitants. The time of their first settling in Scandinavia, and the time when they first peopled with their colonies the abovementioned islands and Cheronesus, are equally uncertain; though the Gothic annals suppose the latter to have happened in the time of Serug the great grandfather of Abraham. This first migration of the Goths is said to have been conducted by their king Eric; in which all the ancient Gothic chronicles, as well as the Danish and Swedish ones, agree. Their second migration is supposed to have happened many ages after; when, the abovementioned countries being overstocked with people, Berig, at that time king of the Goths, went out with a fleet in quest of new settlements. He landed in the country of the Ulmerugians, now Pomerania, drove out the ancient inhabitants, and divided their lands among his followers. He fell next upon the Vandals, whose country bordered on that of the Ulmerugians, and overcame them; but instead of forcing them to abandon their country, he only made them share their possessions with the Goths.

The Goths who had settled in Pomerania and the adjacent parts of Germany being greatly increased, inasmuch that the country could no longer contain them, they undertook a third migration in great numbers, under Filimer surnamed the *Great*, their fifth prince after leaving Scandinavia; and taking their route eastward, entered Scythia, advanced to the Cimberian Bosphorus, and, driving out the Cimberians, settled in the neighbourhood of the Palus Mæotis. Thence in process of time, being greatly increased in Scythia, they resolved to seek new settlements; and, accordingly taking their route eastward, they traversed several countries, and at length returned into Germany.

Their leader in this expedition was the celebrated Woden, called also *Voden*, *Othen*, *Oden*, *Godan*, and *Guadan*. Of this Woden many wonderful things are related in the Sueo-gothic chronicles. He was king of the Asgardians, whom the northern writers will have to be the same with a people called *Aspurgians* mentioned by Strabo and Ptolemy. By Strabo they are placed near the Cimberian Bosphorus. Aspurgia was the metropolis of a province which Strabo calls *Asia*; and Woden and his followers

are styled by the ancient Gothic writers *Asæ*, *Asiana*, and *Asioæ*. The kings of Aspurgia were masters of all that part of Scythia which lay to the westward of Imaus, and was by the Latins called *Scythia intra Imaum*, or "Scythia within Imaus."

At what time Woden reigned in this country, is quite uncertain; but all historians agree, that he went out in quest of new settlements with incredible numbers of people following him. He first entered Roxolania, comprehending the countries of Prussia, Livonia, and great part of Muscovy. From thence he went by sea into the north parts of Germany; and having reduced Saxony and Jutland, he at last settled in Sweden, where he reigned till his death, and became so famous that his name reached all countries, and he was by the northern nations worshipped as a god. He is supposed to have brought with him the Runic characters out of Asia, and to have taught the northern nations the art of poetry; whence he is styled the father of the Scaldi or Scaldri, their poets, who described in verse the exploits of the great men of their nation, as the bards did among the Gauls and Britons.

The Romans distinguished the Goths into two classes; the Ostrogoths and Visigoths. These names they received before they left Scandinavia, the *Visigoths* being softened by the Latins from *Westrogoths*, or those who inhabited the western parts of Scandinavia, as the Ostrogoths were those who inhabited the eastern part of that country. Their history affords nothing of moment till the time of their quarrelling with the Romans; which happened under the reign of the emperor Caracalla, son to Severus. After that time their history becomes so closely interwoven with that of the Romans, that for the most remarkable particulars of it we must refer to the histories of ROME. After the destruction of the Roman empire by the Heruli, the Ostrogoths, under their king Theodoric, became masters of the greatest part of Italy, having overcome and put to death Odoacer, king of the Heruli, in 494. They retained their dominion in this country till the year 553; when they were finally conquered by Narfes, the emperor Justinian's general. The Visigoths settled in Spain in the time of the emperor Honorius, where they founded a kingdom which continued till the country was subdued by the Saracens.

The Goths were famous for their hospitality and kindness to strangers, even before they embraced the Christian religion. Nay, it is said, that, from their being eminently good, they were called *Goths* by the neighbouring nations; that name, according to Grotius and most other writers, being derived from the German word *guten*, which signifies "good." They encouraged, says Dio, the study of philosophy above all other barbarous or foreign nations, and often chose kings from among their philosophers. Polygamy was not only allowed but countenanced among them; every one being valued or respected according to the number of his wives. By so many wives they had an incredible number of children, of whom they kept but one at home, sending out the rest in quest of new settlements; and hence those swarms of people which overran so many countries. With them adultery was a capital crime, and irremissibly punished with death. This severity, and likewise polygamy, prevailed among them when they were known to the Romans only by the name of *Getes* (their most ancient name); as appears from the poet Menander, who was himself one of that nation; and from Horace, who greatly commends the chastity of their women. Their laws fell little short of those of the ancient Romans. Their government was monarchical; their religion was much the same with that of the ancient Germans or Celtes; and their dress is described by Apollinaris Sidonius in the following words: "They are shod (says he) with high shoes made of hair, and reaching up to their ankles; their knees, thighs, and legs, are without any covering; their garments

of various colours scarce reaching to the knee; their sleeves only cover the top of their arms; they wear green calsocks with a red border; their belts hang on their shoulder; their cars are covered with twisted locks; they use hooked lances and missile weapons."

GOTHOFRED, or **GODFREY**, (Denis or Dionysius), an eminent civil lawyer, born of an illustrious house at Paris, in 1549. Finding his country involved in the confusion of the leaguers, he accepted of a professor's chair at Geneva, until he was patronized and employed by Henry IV.; but being afterwards stripped of his employments as a huguenot, he at length retired to Heidelberg, from whence no offers were able to detach him. He was, however, disappointed of his intention to end his days there: for the disturbances that broke out in the Palatinate obliged him in 1621 to take refuge in Strasburg, where he died the following year. He wrote a great number of books; but his principal work is the *Corpus Juris Civilis, cum notis*.

GOTHOFRED (Theodore), son of the former, was born at Geneva in 1580. As soon as he had finished his studies, he went to Paris; where he conformed to the Romish religion, and applied with indefatigable industry to the study of history, that of France particularly, wherein he became very eminent, as appears by his works. In 1632 the king made him one of his historiographers, with a stipend of 3000 livres; and in 1636 he was sent to Cologne, to assist at the treaty of peace negotiating there, on the part of France, by the cardinal of Lyons. This treaty being removed to Munster, Gothofred was sent thither, where he drew up Memoirs on the subject; and continued in that city, in the king's service, to his death in 1649. His principal work is his "Account of the Ceremonial of the Kings of France."

GOTHOFRED (James), brother of the preceding, was born at Geneva in 1587. Applying himself to the study of the law, he obtained the professor's chair there, was made counsellor of the city, and was several times employed in France, Germany, Piedmont, and Switzerland, to negotiate their affairs in the name of the republic. He died in 1562; and his chief work is his *Codex Theodosianus, cum perpetuis commentariis, &c.*

GOTHOFRED (Denis), son of Theodore above mentioned, was born at Paris in 1615. He studied history after his father's example, became as eminent in that department of knowledge, and obtained the reversion of his father's place of historiographer royal, from Louis XIII. when he was but 25 years of age. He published his father's *Ceremonial of France*; finished his *Memoirs of Philip de Commines*; and was preparing a *History of Charles VIII.* when he died in 1681. It was published by his eldest son Denis in 1684.

GOTTENBURG. See **GOTTEBORG**.

GOTTINGEN, a considerable town of Lower Saxony in Germany, and in the duchy of Brunswick; formerly free and imperial, but now subject to the elector of Hanover. Here his late Majesty George II. founded an university. It is seated on the river Leine, in E. lon. 10. 5. N. lat. 51. 32.

GOTTORP, a town of Denmark, in the duchy of Sleswick, capital of the duchy of Holstein Gottorp, where the ducal palace is very fine. Lon. 9. 56. E. Lat. 54. 36. N.

GOUANIA, in botany; a genus of the monœcia or ler, belonging to the polygamia class of plants. The calyx of the hermaphrodite is quinquefid; there is no corolla; there are five antheræ covered with an elastic calyptra or hood; the style trifid; the fruit, inferior to the receptacle of the flower, divisible into three seeds. The male is like the hermaphrodite, but wanting stigma and germen.

GOUDA, or **TURGOW**, a considerable town of South Holland,

in the United Provinces, remarkable for its stately church. It is seated on the river Issel, 8 miles N. E. of Rotterdam, in E. lon. 4. 41. N. lat. 51. 8.

GOUDT (Henry), usually called *Count Goudt*, was born of a noble family at Utrecht in 1570, and was a knight of the Palatinate. Being passionately fond of the arts, particularly painting and engraving, and desirous of engaging in them, he applied himself diligently to drawing, and made a great proficiency therein. He went to Rome to examine the works of the great masters in that city. Here he contracted an intimacy with that excellent artist Adam Elsheimer; studied his manner of penciling, designing, and colouring; and made his works models for his own imitation. He pre-engaged all the pictures that his friend and favourite could finish, and even paid liberally for them before-hand; by which means he found himself in possession of a most desirable treasure. Those pictures which Goudt himself painted were neatly and delicately touched, in colour and pencil resembling Elsheimer, though they were in no degree equal to the paintings of that admirable master. On his return to his native country, a young woman who was in love with him, and desirous of marrying him, it is said, gave him in his drink a love philtre; which, however, terminated in a very melancholy manner, by depriving him totally of his senses; and in the dreadful state of idiotism he dragged on a miserable life to the age of 69, his death happening in 1639. It is remarkable, that though lost to every other subject, when painting was spoken of he would discourse upon it in a very rational manner.

Goudt practised engraving as well as painting, and made seven beautiful prints after the pictures of Elsheimer, which are well known to the curious, and are to be met with in most choice collections. He worked with the graver only, in a very neat style; and produced a most powerful effect, not by strengthening the strokes, according to the usual method, but by crossing them with additional strokes, equally neat, and that five or six times, one over another, in the deep shadows. Considering the precision with which he executed his engravings, the freedom of handling the graver which may be discovered in them is very astonishing. The weeds and other parts of the fore-ground in that admirable print of the Ceres are very finely expressed. The heads of the figures are correctly drawn, and the other extremities are managed in a judicious manner. The seven prints done by him from Elsheimer, mentioned above, are, 1. Ceres drinking from a pitcher. An old woman appears holding a candle at the door of the cottage, and a boy naked standing by her is laughing and pointing at the goddess; for which contempt he was metamorphosed by her into a frog. The powerful and striking effect of this engraving cannot be properly described. This print is distinguished also by the name of the *serenity*. 2. The flight into Egypt: A night-scene, in which the moon and stars are introduced with great success. 3. The angel with Tobit, who is drawing a fish by his side. The back-ground is a landscape; the weeds in the foreground, and the branches of the trees in front, as well as the foliage and weeds hanging from them, are beautifully expressed. 4. The angel with Tobit, crossing a stream of water: The back ground, a landscape. 5. Baucis and Philemon entertaining Jupiter and Mercury. 6. A landscape, called the *Aurora*, representing the dawn of day. The effect is very beautiful. 7. The beheading of St. John in prison, a very small upright oval print, which is by far the scarcest.

GOVERNMENT, in general, is the polity of a state, or an orderly power constituted for the public good. Civil government was instituted for the preservation and advancement of men's civil interests, and for the better security of their lives, li

erties, and property. The use and necessity of government is such, that there never was an age or country without some sort of civil authority: but as men are seldom unanimous in the means of attaining their ends, so their difference in opinion in relation to government has produced a variety of forms of it. To enumerate them would be to recapitulate the history of the whole earth. But, according to Montesquieu and most other writers, they may in general be reduced to one of these three kinds. 1. The republican. 2. The monarchical. 3. The despotic. The first is that, where the people in a body, or only a part of the people, have the sovereign power; the second, where one alone governs, but by fixed and established laws; but in the despotic government, one person alone, without law and without rule, directs every thing by his own will and caprice. See the article LAW. The subject of government was, perhaps, never so much the subject of discussion as at present; the French Revolution and the writings of Mr. Burke and Thomas Paine, having rendered the enquiry into the comparative merits of monarchical and republican forms of government universal. The possible evils of the former are the result of experiment, and admit of a remedy by a judicious limitation. The latter is a form fraught with great apparent benefits to the people, but it has, nevertheless, the great disadvantage of never having undergone the test of experiment; a circumstance that should make men careful how they adopt it in preference even to a form of government confessedly not free from objections. On the subject of government at large, see Montesquieu's *L'Esprit des Loix*, l. 2. c. 1.; Locke, ii. 129, &c. quarto edition, 1768; Sidney on Government; Sir Thomas Smith *de Repub. Angl.*; and Archerly's *Britannic Constitution*. As to the Gothic government, its original, and faults, &c. see Montesquieu's *L'Esprit des Loix*, l. 11. c. 8. With respect to the feudal policy, how it limited government, see *FEUDAL System*.

GOVERNMENT is also a post or office, which gives a person the power or right to rule over a place, a city, or a province, either supremely or by deputation.

GOVERNMENT is likewise used for the city, country, or place in which the power of governing is exercised.

GOUGE, an instrument used by various artificers, being a sort of round hollow chissel; serving to cut holes, channels, grooves, &c. in wood, stone, &c.

GOULART (Simon), a famous minister of Geneva, was born at Senlis in 1543, and was one of the most indefatigable writers of his time. He made considerable additions to the Catalogue of Witnesses of the Truth, composed by Illyricus; and acquired a great reputation by his works; the principal of which are, 1. A translation of Seneca. 2. A collection of memorable histories. 3. A translation of St. Cyprian *De lapsis*. 4. Several devotional and moral treatises. He died at Geneva in 1628.

GOURD, in botany. See CUCURBITA.

GOURGUES (Dominique de), an illustrious French patriot, a private gentleman of Gascony. The Spaniards having inhumanly massacred a colony of Frenchmen who had settled in Florida, Gourgues took a severe revenge on them, an account of which is given in the history of that place. On his return, he was received with acclamations by his countrymen, but was forbid to appear at court. Queen Elizabeth invited him to command an English fleet against the Spaniards in 1593; but he died at Tours in his way to England.

GOURNAY, a town of France, in the department of Lower Seine and late province of Normandy, remarkable for its market of fine butter. It is seated on the river Epte, 52 miles N. W. of Paris. Lon. o. 36. W. Lat. 49. 32. N.

GOURNAY (Mary de Jars de), a lady celebrated for her learn-

ing, was the daughter of William de Jars, lord of Neufvi and Gournay. After the death of her father, she was protected by Montaigne and Cardinal Richelieu. To the daughter of the former she dedicated her *Nofegay of Pindus*; and composed several other works, the most considerable of which is *Les Avis*. She died at Paris in 1685, aged 80. The critics are divided concerning the reputation of this lady: by some she is styled the *Syren of France*; others say her works should have been buried with her.

GOUT. See MEDICINE.

GOWER (John), one of our most ancient English poets, was cotemporary with Chaucer, and his intimate friend. Of what family or in what country he was born is uncertain. He studied the law, and was some time a member of the society of Lincoln's-inn, where his acquaintance with Chaucer began. Some have asserted that he was a judge; but this is by no means certain. In the first year of Henry IV. he became blind; a misfortune which he laments in one of his Latin poems. He died in the year 1402, and was buried in St. Mary Overie, which church he had rebuilt chiefly at his own expence, so that he must have lived in affluent circumstances. His tomb was magnificent, and curiously ornamented. It still remains, but hath been repaired in later times. From the collar of SS. round the neck of his effigies, which lies upon the tomb, it is conjectured that he had been knighted. As to his character as a man, it is impossible, at this distance of time, to say any thing with certainty. With regard to his poetical talents, he was undoubtedly admired at the time when he wrote, though a modern reader may find it difficult to discover much harmony or genius in any of his compositions. He wrote, 1. *Speculum meditantis*, in French, in ten books. There are two copies of this in the Bodleian library. 2. *Vox clamantis*, in Latin verse, in seven books. Preserved also in the Bodleian library, and in that of All-Souls. It is a chronicle of the infurrection of the commons in the reign of Richard II. 3. *Confessio amantis*; printed at Westminster by Caxton in 1493. Lond. 1532, 1554. It is a sort of poetical system of morality, interspersed with a variety of moral tales. 4. *De rege Henrico IV.* Printed in Chaucer's works. There are likewise several historical tracts in manuscript, written by our author, which are to be found in different libraries; also some short poems printed in Chaucer's works.

GOWN, ROBE, a long upper garment, worn by lawyers, divines, and other graduates; who are hence called *men of the gown*, or *gownmen*. The gown is an ample sort of garment, worn over the ordinary clothes, hanging down to the feet. It is fashioned differently for ecclesiastics and for laymen. At Rome they gave the name "virile gown," *toga virilis*, to a plain kind of gown which their youth assumed when arrived at puberty. This they particularly denominated *prætexta*. See TOGA, PRÆTEXTA, &c.

"The remarkable drefs of our British ancestors (Mr. Whitaker observes in his *History of Manchester*, vol. 1. p. 302.), which continued very nearly the same to the commencement of the last century among the natives of Ireland, and has actually descended to the present among the mountaineers of Scotland, and is therefore rendered very familiar to our ideas, carried in it an astonishing appearance to the Romans. And it seems to have been equally the drefs of the men and women among the nobles of Britain. Put in a few years after the erection of the Roman-British towns in the north, and in the progress of refinement among them, this ancient habit began to be disesteemed by the chiefs of the cities, and looked upon as the badge of ancient barbarism. And the growing prejudices were soon so greatly improved, that within 20 years only after the construction of

the towns, the British sagum was actually resigned, and the Roman *toga* or gown assumed by many of them.

"The gown, however, never became universal in Britain: and it seems to have been adopted only by the barons of the cities and the officers of the crown; and has therefore been transmitted to us as the robe of reverence, the ensign of literature, and the mantle of magistracy. The woollen and plaided garments of the chiefs having naturally superseded the leathern vestures of their clients, the former were still worn by the generality of the Britons; and they were retained by the gentlemen of the country, and by the commonalty both in country and city. That this was the case appears evident from the correspondent conduct of the Gauls and Britons, who kept their *Virgata Sagula* to the last, and communicated them to the Franks and Saxons. The plaided drapery of the Britons still appeared general in the streets of Manchester; and must have formed a striking contrast to the gown of the chief, the dark mantle of Italy: and it and the ornamented buttons on the shoulder are preserved among us even to the present moment, in the parti-coloured clothing and the tasseled shoulder-knots of our footmen."

GOWN is also taken in the general for civil magistrature, or the profession opposite to that of arms. In this sense it was that Cicero said *cedant arma togæ*.

GOYEN (John Van), painter of landscapes, cattle, and sea-pieces, was born at Leyden in 1596; and was for some time instructed by Isaac Nicolaï, who was reputed a good painter; but afterwards he became the disciple of Esaias Vandervelde, the most celebrated landscape painter of his time. Van Goyen very soon rose into general esteem; and his works are more universally spread through all Europe than the works of any other master, for he possessed an uncommon readiness and practice to sketch the views of villages and towns situated on the banks of rivers or canals; of the sea-ports in the Low Countries; and sometimes of inland villages, where the scenes around them appeared to him pleasing or picturesque. Those he afterwards used as subjects for his future landscapes; enriching them with cattle, boats, and figures in character, just as the liveliness of his imagination directed. He understood perspective extremely well, and also the principles of the chiaro-scuro; which branches of knowledge enabled him to give his pictures a strong and agreeable effect. He died in 1656, aged 60. His usual subjects were sea-pieces, or landscapes with views of rivers, enlivened with figures of peasants either ferrying over cattle, drawing their nets in still water, or going to or returning from market. Sometimes he represented huts of boors on the banks of rivers, with overhanging trees, and a beautiful reflexion of their branches from the transparent surface of the water. These were the subjects of his best time, which he generally marked with his name and the year; and the high-finished pictures of Van Goyen will be for ever estimable. But as he painted abundance of pictures, some are slight, some too yellow, and some negligently finished: though all of them have merit, being marked with a free, expeditious, and easy pencil, and a light touch. His pictures frequently have a greyish cast; which did not arise from any mismanagement of the tints, or any want of skill in laying on the colours; but was occasioned by his using a colour called *Haerlem blue*, much approved of at that time, though now entirely disused, because the artists found it apt to fade into that greyish tint; and it hath also rendered the pictures of this master exceedingly difficult to be cleaned without injuring the finer touches of the finishing. His best works are valued so highly in most parts of Europe, and especially in the Low Countries, that they deservedly afford large prices, being ranked in Holland with the pictures of Teniers; and at this time are not

easily procured, particularly if they are undamaged, though his slighter performances are sufficiently common.

GRAAF (Regnier de), a celebrated physician, born at Schoonhaven in Holland in 1641. Although he studied physic in Prussia, he was educated at Leyden, where he acquired great honour by publishing a treatise *De Succo Pancreatico*. He also published three pieces upon the organs of generation, both male and female; upon which subject he had a controversy with Swammerdam. He died young, in 1673; and his works, with his life prefixed, were published at Leyden in 1677, in 8vo.

GRABE (John Ernest), a very learned writer in the beginning of the 18th century, a native of Königsberg in Prussia. He was educated in the Lutheran religion; but the reading of the fathers led him into doubts. He presented to the electoral consistory at Sambia in Prussia a memorial containing his doubts. The elector gave orders to three eminent divines to answer them. Their answers shook him a little in his resolution of embracing the Roman Catholic religion; and one of them, Spenser, advised him to go to England. He went; and king William gave him a pension, which was continued by queen Anne. He was ordained a priest of the church of England, and honoured with the degree of doctor of divinity by the university of Oxford; upon which occasion Dr. George Smalridge pronounced two Latin orations, which were afterwards printed. He wrote, 1. *Spicilegium S. S. Patrum, ut et Hereticorum sæculi post Christum nati*, 8vo. 2. An edition of the Septuagint, from the Alexandrian manuscript in St. James's library. 3. Notes on Jullin, &c.; and other works, which are esteemed by the learned.

GRACCHUS (Tiberius), elected tribune of the Roman people, demanded in the senate, in their name, the execution of the Agrarian law; by which all persons possessing above 200 acres of land were to be deprived of the surplus, for the benefit of the poor citizens, amongst whom an equal distribution of them was to be made. Having carried his plan into execution by violent measures, he fell a victim to his zeal, being assassinated by his own party, 133 B. C. Caius his brother, pursuing the same steps, was killed by the consul Opimius, 121 B. C.

GRACE, among divines, is taken, 1. For the free love and favour of God, which is the spring and source of all the benefits we receive from him. 2. For the work of the Spirit renewing the soul after the image of God; and continually guiding and strengthening the believer to obey his will, to resist and mortify sin, and overcome it.

GRACE is also used, in a peculiar sense, for a short prayer said before and after meat. The proofs of the moral obligation of this ceremony, drawn from different passages of the New Testament, are well known. Some others, drawn from the practice of different nations, and of very remote antiquity, we shall introduce in this place.

1. Athenæus tells us, in his *Deipnosoph.* lib. ii. that in the famous regulation made by Amphictyon king of Athens with respect to the use of wine, both in sacrifices and at home, he required that the name of *Jupiter the Sustainer* should be decently and reverently pronounced. The same writer, in lib. iv. p. 149. quotes Hærmias, an author extant in his time, who informs us of a people in Egypt, inhabitants of the city of Naucratis, whose custom it was on certain occasions, after they had placed themselves in the usual posture of eating at the table, to rise again and kneel; when the priest or precentor of the solemnity began to chant a grace, according to a stated form amongst them; and when that was over, they joined in the meal in a solemn sacrificial manner. Heliodorus has a passage in his *Æthiopics* to the same purpose, that it was the custom of the

Egyptian philosophers to pour out libations and put up ejaculations before they sat down to meals. Porphyry, in his treatise *De abstin.* lib. iv. p. 408. gives a great character of the Samaritan gymnosophists in Egypt for the strictness of their life: as one article in their favour, he observes, that at the founding of a bell before their meals, which consisted only of rice, bread, fruits, and herbs, they went to prayers; which being ended, and not before, the bell sounded again, and they sat down to eating. In general this was a religious usage or rite amongst the ancient Greeks, and derived from yet older ages, if Clement of Alexandria rightly informs us. He mentions, that these people, when they met together to refresh themselves with the juice of the grape, sung a piece of music in imitation of the Hebrew psalms, which they called a *schelion*. Livy, lib. xxxix. speaks of it as a settled custom among the old Romans, that they offered sacrifice and prayer to the gods at their meals and computations. But one of the fullest testimonies to our purpose is given by Quintilian, *Declam.* 301. *Adisti mensam*, says he, *ad quam cum venire capimus, Deos invocamus*; "We approached the table (at supper together), and then invoked the gods."

The Jesuit Trigautius, in his very elegant and instructive narrative of the Christian expedition of their missionaries into China, book i. p. 69. gives this account of the people there in the particular now under consideration. "Before they place themselves for partaking of an entertainment, the person who makes it sets a vessel, either of gold, or silver, or marble, or some such valuable material, in a charger full of wine, which he holds with both his hands, and then makes a low bow to the person of chief quality or character at the table. Then, from the hall or dining-room, he goes into the porch or entry, where he again makes a very low bow, and, turning his face to the south, pours out this wine upon the ground as a thankful oblation to the Lord of heaven. After this, repeating his reverential obeisance, he returns into the hall," &c.

The Turks pray for a blessing on their meat; and many more instances might be produced of infidels who have constantly observed the like custom in some way or other.

2. The fact therefore, with respect to the heathen world, being thus evident, we proceed to the sentiments and behaviour of the Jews in this particular. Their celebrated historian Josephus, giving a detail of the rites and customs of the Essenes, who were confessedly the strictest and most pious professors of the Jewish religion, has this remarkable passage to the present purpose: "The priest," says he, "begs a blessing before they presume to take any nourishment; and it is looked upon as a great sin to take or taste before." Then follows the thanksgiving before meat: and "when the meal," proceeds he, "is over, the priest prays again; and the company with him bless and praise God as their preserver, and the donor of their life and nourishment."

Philo, in his book *De vita contemplativa*, gives an account of a body of men and women stricter than even the Essenes themselves. He distinguishes them by no particular name, though his relation is very accurate and circumstantial; namely, that on certain special occasions, before "they took their meals, they placed themselves in a proper decent order; when, lifting up their hands and eyes to heaven, they prayed to God that he would be pleased to be propitious to them in the use of those his good creatures."

From the Hebrew ritual it appears, that the Jews had their *hymns* and psalms of thanksgiving, not only after eating their *passover*, but on a variety of other occasions, at and after meals, and even between their several courses and dishes; as when the bet of their wine was brought upon the table, or their aromatic confectiions, or the fruit of the garden, &c. On the day of

the passover was sung Psalm cxiv. "When Israel came out of Egypt," &c.

Aristæus has a passage full on the present subject. "Moses," says he, "commands, that when the Jews are going to eat or drink, the company should immediately join in sacrifice or prayer." Where Rabbi Eleazar (upon that author) met with this sentence, has been controverted. But supposing it not to be found *in scriptis*, it is sufficient for us to know that the Jews did constantly practise this custom, upon the foundation of an ancient and general tradition and usage. That the prophet Daniel gave thanks before meat is evident from the Apocryphal book concerning Bel and the Dragon, where, ver. 38, 39. we find, that "Daniel said, Thou hast remembered me, O God! neither hast thou forsaken them who seek thee and love thee. So Daniel arose, and did eat." Of this text Prudentius takes notice in *Cathem.* hymn iv.

GRACE, or *Gracefulness*, in the human character; an agreeable attribute, inseparable from motion as opposed to rest, and as comprehending speech, looks, gesture, and loco-motion. In a word, grace may be defined, "that agreeable appearance which arises from elegance of motion and from a countenance expressive of dignity." Expressions of other mental qualities are not essential to that appearance, but they heighten it greatly. Of all external objects, a graceful person is the most agreeable. Dancing affords great opportunity for displaying grace, and haranguing still more. See DANCING, DECLAMATION, and ORATORY.

Act of GRACE, the appellation given to any act of parliament which allows prisoners for civil debts to be set at liberty, upon making oath that they have surrendered to their creditors their whole property, and have not wherewithal to support themselves in prison. Other conditions have also been imposed in the acts for the relief of insolvent debtors which have of late years been passed by parliament.

Days of GRACE, three days immediately following the term of payment of a bill, within which the creditor must note and protest it if payment is not obtained, in order to intitle him to recover against the drawer.

GRACE is also a title of dignity given to dukes, archbishops, and in Germany to barons and other inferior princes.

GRACES, *GRATIÆ*, *Charites*, in the heathen theology, were fabulous deities, three in number, who attended on Venus. Their names are, *Aglia*, *Thalia*, and *Euphrosyne*; i. e. shining, flourishing, and gay; or, according to some authors, *Pasithea*, *Euphrosyne*, and *Ægiale*. They were supposed by some to be the daughters of Jupiter and Eurynome the daughter of Oceanus; and by others, to be the daughters of Bacchus and Venus.

Some will have the Graces to have been four; and make them the same with the *Horæ* "hours," or rather with the four seasons of the year. A marble in the king of Prussia's cabinet represents the three Graces in the usual manner, with a fourth seated and covered with a large veil, with the words underneath, *Ad Sorores IIII*. But this group we may understand to be the three Graces, and Venus, who was their sister, as being daughter of Jupiter and Dione.

The Graces are always supposed to have hold of each other's hands, and never parted. They were painted naked, to show that the Graces borrow nothing from art, and that they have no other beauties than what are natural. Yet in the first ages they were not represented naked, as appears from Pausanias, lib. vi. and lib. ix. who describes their temple and statues. They were of wood, all but their heads, feet, and hands, which were white marble. Their robe or gown was gilt; one of them held in her hand a rose, another a dye, and the third a sprig of myrtle.

GRACILIS, a muscle of the leg, thus called from its slender shape. See ANATOMY, *Table of the Muscles*.

GRACULA, the GRAKLE, in ornithology, a genus belonging to the order of picæ. See plate 15. Vol. iii. The bill is convex, cultrated, and bare at the point; the tongue is not cloven, but is fleshy and sharp; it has three toes before and one behind.

1. The *religiosa*, lesser grakle, or Indian stare, is about the size of a blackbird, the bill an inch and a half long, and of an orange colour. The general colour of the plumage is black, glossed with violet, purple, and green, in different reflections of light: on the quills is a bar of white; the feathers and legs are orange yellow, and the claws of a pale brown. This species, which is found in several parts of the East Indies, in the Isle of Hainan, and almost every isle beyond the Ganges, is remarkable for whistling, singing, and talking well, much better than any of the parrot genus, and in particular very distinct. Its food is of the vegetable kind. Those kept in this climate are observed to be very fond of cherries and grapes: if cherries are offered to one, and it does not immediately get them, it cries and whines like a young child, till it has obtained its desire. It is a very tame and familiar bird.

2. The *larita*, or boat-tailed grakle, is about the size of a cuckow. The bill is sharp, black, and an inch and a half in length; the general colour of the plumage is black, with a gloss of purple, especially on the upper parts; the legs and claws are black, the latter hooked. There is a singularity in the folding up of the tail-feathers, which, instead of forming a plain surface at top, sink into a hollow like a deep gutter. It always carries its tail expanded when on the ground, folding it up in the above singular manner only when perched or flying. It inhabits Jamaica: and it feeds on maize, beetles, and other insects, as well as on the fruit of the banana. It is likewise common in North America, keeping company with the flocks of the maize-thieves, and red-winged oriole. These breed in the swamps, and migrate in September, after which none are seen.

3. The *quiscula*, purple-jackdaw, or Barbadoes blackbird, is about the size of a blackbird: the whole bird is black, but most beautifully and richly glossed with purple, especially on the head and neck. The female is wholly of a brown colour, deepest on the wings and tail. This species inhabits Carolina, Mexico, and other parts of North America, also Jamaica. These birds for the most part feed on maize, whence the name of *maize-thieves* has been given them; but this is not their only food, for they are known also to feed on many other things. In spring, soon after the maize seed is put into the ground, they scratch it up again; and as soon as the leaf comes out, they take it up with their bills, root and all; but when it is ripe they do still more damage, for at that time they come in troops of thousands, and are so bold, that if disturbed in one part of a field they only go to another. In New Jersey and Pennsylvania three pence per dozen was once given for the dead birds, and by means of the premium they were nearly extirpated in 1750; when the persecution of them was abated on account of the great increase of worms which had taken place in the meadows, and which in the preceding year had left so little hay in New England as to occasion an importation from other parts. The grakles were therefore again tolerated, as it was observed that they fed on these worms till the maize was ripe. These birds build in trees. They are said to pass the winter in swamps which are quite overgrown with wood, from thence only appearing in mild weather; and after the maize is got in, are content to feed on other things, as the aquatic tare-grafs, and if pressed by hunger, buck-wheat and oats, &c.; they are said also to destroy that pernicious insect the bruchus pisi. Their note is pretty and agreeable; but their flesh is not good to eat.

4. The *crispatella*, or Chinese starling, is a little bigger than a blackbird. The bill is yellow or orange; and the general colour of the plumage blackish, with a tinge of blue: the legs are of a

dull yellow. These birds, which are said to talk and whistle very well, are common in China, where they are very much esteemed, and the figures of them are seen frequently in Chinese paintings. Their food is rice, insects, worms, and such-like. They are seldom brought to England alive, requiring the greatest care in the passage. There are eight other species of Gracula.

GRACULUS, in ornithology. See CORVUS.

GRADATION, in general, the ascending step by step, or in a regular and uniform manner. Thus it denotes in *logic* a form of reasoning, otherwise called *SORITES*; in painting, a gradual and insensible change of colour, by the diminution of the tints and shades. In rhetoric, it denotes the same with *CLIMAX*.

GRADISKA, a strong town of Slavonia, on the frontiers of Croatia, taken by the Turks in 1691. It is seated on the river Save, 20 miles S. W. of Posega. Lon. 18. 39. E. Lat. 45. 21. N.

GRADISKA, a strong town of Italy, in the county of Geritz, seated on the river Lisonzo, on the frontiers of Friuli. It belongs to the house of Austria, and is 15 miles S. E. of Udino. Lon. 13. 14. E. Lat. 46. 6. N.

GRADO, a strong town of Italy, in a small island of the same name, on the coast of Friuli, and in the territory of Venice, 50 miles E. by N. of Venice. Lon. 13. 10. E. Lat. 45. 46. N.

GRADUATE, a person who has taken a degree in the university. See DEGREE.

GRÆVIUS (John George), one of the most learned writers in the 17th century. In the 24th year of his age the elector of Brandenburg made him professor at Doisbourg. In 1658 he was invited to Deventer to succeed his former master Gronovius. In 1661 he was appointed professor of eloquence at Utrecht; and 12 years after he had the professorship of politics and history conferred on him. He fixed his thoughts here, and refused several advantageous offers. He had, however, the satisfaction to be sought after by many princes, and to see several of them come from Germany to study under him. He died in 1703, aged 71. His *Thesaurus antiquitatum et historiarum Italiae*, &c. and other works, are well known.

GRAFTING, or ENGRAFTING, in gardening, is the taking a shoot from one tree, and inserting it into another, in such a manner that both may unite closely and become one tree. By the ancient writers on husbandry and gardening, this operation is called *incision*, to distinguish it from inoculation or budding, which they call *inserere oculos*. Grafting has been practised from the most remote antiquity; but its origin and invention is differently related by naturalists. Theophrastus tells us, that a bird, having swallowed a fruit whole, cast it forth into a cleft or cavity of a rotten tree; where mixing with some of the putrefied parts of the wood, and being washed with the rains, it budded, and produced within this tree another tree of a different kind. This led the husbandman to certain reflections, from which, soon afterwards arose the art of engrafting.

Pliny sets the same thing in a different light: A countryman having a mind to make a pallisade in his grounds, that it might endure the longer, he bethought himself to fill up and strengthen the bottom of the pallisade, by running or wattling it with the trunks of ivy. The effect of this was, that the stakes of the pallisades taking root became engrafted into the trunks, and produced large trees; which suggested to the husbandman the art of engrafting.

The use of grafting is to propagate any curious sorts of fruit so as to be certain of the kinds; which cannot be done by any other method: for as all the good fruits have been accidentally obtained from seeds, so the seeds of these, when sown, will many of them degenerate, and produce such fruit as is not worth the cultivating: but when shoots are taken from such trees as pro-

duce good fruit, these will never alter from their kind, whatever be their stock or tree on which they are grafted.

The reason or philosophy of engrafting is somewhat obscure; and had not accident given the first hint, all our knowledge of nature would never have led us to it. The effect is ordinarily attributed to the diversity of the pores or ducts of the graft from those of the stock, which change the figure of the particles of the juices in passing through them to the rest of the tree.

Mr. Bradley, on occasion of some observations of Agricola, suggests something new on this head. The stock grafted on, he thinks, is only to be considered as a fund of vegetable matter, which is to be filtered through the cyon, and digested, and brought to maturity, as the time of growth in the vessels of the cyon directs. A cyon, therefore, of one kind, grafted on a tree of another, may be rather said to take root in the tree it is grafted in, than to unite itself with it: for it is visible that the cyon preserves its natural purity and intent, though it be fed and nourished with a mere crab; which is, without doubt, occasioned by the difference of the vessels in the cyon from those of the stock: so that grafting may be justly compared to planting.

In prosecution of this view of that ingenious author, we add, that the natural juices of the earth, by their secretion and comminution in passing through the roots, &c. before they arrive at the cyon, must doubtless arrive there half elaborated and concocted; and so disposed for a more easy, plentiful, and perfect assimilation and nutrition; whence the cyon must necessarily grow and thrive better and faster than if it were put immediately in the ground, there to live on coarse diet and harder of digestion: and the fruit produced by this further preparation in the cyon must be finer and further exalted than if fed immediately from the more imperfectly prepared and altered juices of the stock.

Many have talked of changing of species, or producing mixed fruits, by engrafting one tree on another of the same class; but as the graft carries the juices from the stock to the pulp of the fruit, there is little hope of succeeding in such an expectation by ever so many repeated grafts: but if, after changing the graft and stock several successive times, you set the seed of the fruit produced on the graft in a good mould, it is possible that a change may happen, and a new mixed plant may be produced. Thus the almond and peach may, by many changes in the graftings, and by interrations of the stones of the peaches, and of the shells of the almonds, and by teribrations of the stem of the root here and there, alter their nature so much, that the coat or pulp of the almond may approach to the nature of the peach, and the peach may have its kernel enlarged into a kind of almond; and on the same principle, the curious gardener may produce many such mixed kinds of things.

Mr. Du Hamel has observed, that, in grafting of trees, there is always found at the insertion of the graft, a change in the directions of fibres, and a sort of twisting or turning about of the vessels, which greatly imitates that in the formation of certain glands in animal bodies: and from thence he infers, that a new sort of viscus being formed by this means, the fruit may very naturally be so far influenced by it, as to be meliorated on the new branch; but that no such sudden and essential changes can be effected by those means, as too many of the writers on agriculture pretend. He observes, however, that this anatomical observation would not have been sufficient to convince him of the falsity of too many of these relations, had not experiment joined to confirm him in this opinion. He tried many grafts on different trees; and, for fear of error, repeated every experiment of consequence several times; but all served only to convince him of the truth of what he at first suspected. He grafted in the common way the peach upon the almond, the

plum upon the apricot, the pear upon the apple, the quince, and the white thorn; one species of plum on other very different species, and upon the peach the apricot and the almond. All these succeeded alike: the species of the fruit was never altered; and in those which would not come to fruit, the leaves, the wood, and the flowers, were all the same with those of the tree from whence the graft was taken.

Authors on agriculture have also mentioned a very different sort of grafting; namely, the setting grafts of one tree upon stocks of a different genus; such as the grafting the pear upon the oak, the elm, the maple, or the plum, &c. Mr. Du Hamel tried a great number of those experiments carefully, and found every one of them unsuccessful; and the natural conclusion from this was, that there must be some natural alliance between the stocks and their grafts, otherwise the latter will either never grow at all or very soon perish.

Notwithstanding the facility with which grafts generally take on good stocks, there are many accidents and uncertainties attending them in their different periods. Some perish immediately; some, after appearing healthy for many months; and some even for years. Of these last some die without the stock suffering any thing; others perish together with the stocks. It is very certain, that the greater part of grafted trees do not live so long as they would have done in their natural state; yet this is no unexceptionable rule: for there are some which evidently live the longer for this practice; nay, there are instances of grafts which, being placed on stocks naturally of short duration, live longer than when placed on those which are more robust and lasting. These irregularities have been but little considered hitherto, though they might be made productive of considerable advantages. One great requisite for the succeeding of any graft is, that it be in its own nature capable of so close and intimate an union with the substance of the stock, that it becomes as it were a natural branch of it. If all trees resembled one another in their structure and juices, the size and elasticity of their vessels, &c. probably the grafts of all trees would succeed upon one another; but this is by no means the case.

Trees are well known to be composed of numerous arrangements of hollow fibres, and these are different and unequal in every species of tree. In order to the succeeding of a graft, it is plain that there must be a conformity in its vessels and juices with those of the stock; and the more nearly they agree in this, probably the better they succeed; and the farther they differ, the worse. If there be, however, some difference in the solid parts of trees, there are evidently many more in the juices. The sap in some trees is white as milk, in others it is reddish, and in some as clear and limpid as water. In some, it is thin and very fluid; in others, thick and viscous. In the taste and smell of these juices there are also not less differences: some are sweet, some insipid, some bitter, some acrid, and some fetid: the quality of the sap thus makes a very great difference in the nature of trees; but its quantity, and derivation to the parts, is scarce less observable. Of this we have familiar instances in the willow and the box; one of which will produce longer shoots in one year than the other in twenty.

Another difference yet more striking, and indeed more essential in regard to the growth of grafts than all these, is the different season of the year at which trees shoot out their leaves, or ripen their flowers. The almond-tree is in flower before other trees in general have opened their earliest buds; and when other trees are in flower, this is full of leaves, and has its fruit set before the mulberry begins to push out its earliest buttons. When we consider all these differences in trees, we cannot but wonder how it is possible for a branch of one to live upon another; and it becomes a much more perplexing question how any graft can succeed, than how such numbers come to miscarry. A graft of one pear upon another shall be seen

to succeed presently as if upon its own tree; and in a fortnight will gain six inches in length, and so of some others.—This must be owing to the great similarity between the stock and the graft in all respects; and a great contrariety or difference in structure of parts will make as remarkable a difference on the other hand. An instance of this may be observed in the plum and the elm; which no art can ever make to succeed upon one another, whether the plum be grafted on the elm, or the elm upon the plum stock. These are examples of the extremes of easy growth, and of absolute decay; but there are many conjunctions of trees which seem of a middle nature between the two, and neither immediately perish nor totally succeed. Of these, such as were grafted in autumn usually remain green the whole winter without pushing; and those which are grafted in spring remain green a month or longer, but still without shooting. Some particular ones have also been known to make a few shoots the first, or even the second sap season after the operation; but all perish at the end of these times. Of this kind are the grafts of the pear-tree upon the elm, the maple, and the hornbeam, and the mulberry upon the elm and fig, with many others.

When we come to inquire into the cause of this, we find that these grafts, though unnatural, have yet had a communication with the stock by means of a few small vessels, which has been sufficient to keep them green, or even to make them shoot a little, during the great ascent of the sap: But the far greater number of the fibres have had all the while no communication, and are found putrefied, dried up, or covered with a putrid juice. This has evidently happened by means of the disproportion in size between the vessels of the stock and of the graft, and the great difference between their natural juices, which are obstacles abundantly sufficient to prevent either an union of the fibres or the introduction of new sap.

The grafts of the almond on the plum, and of the plum on the almond, always grow very vigorously for the first year, and give all the appearances imaginable of succeeding entirely; yet they always perish in the second or third year. The almond graft upon the plum stock always pushes out very vigorously at first; but the part of the stock immediately under the graft grows smaller and perishes, the graft absorbing too much of the juices, and the graft necessarily perishes with it. The decay of the whole generally happens early in the spring; and that plainly from the different season of the natural shooting of the two trees, the almond pushing very vigorously, and consequently draining the stock of its juices, at a time when, according to its nature, the juices are but in small quantity in it, and the sap does not begin to ascend. The grafts of the plum on the almond are, from the same cause, furnished with an abundance of sap which they have at that time no occasion for; and consequently they as certainly perish of repletion, as the other of inanition.

The peach grafted on the plum succeeds excellently, and lives longer than it would have done in a natural state; the reason seems to be, that the peach is a tender tree, shoots with great vivacity, and produces more branches than the root is able to maintain. Thus the peach trees are usually full of dead wood; and often their large branches perish, and sometimes their whole trunk. On this occasion the plum, being a slow shooting tree, communicates its virtue to the graft; and the peach consequently sends out shoots which are more robust and strong, and are no more in number than the root is able to supply with nourishment, and consequently the tree is the more lasting.

The grafts, or cyons, with which the grafting is effected, are young shoots of last summer's growth, for they must not be more than one year, and such as grow on the outside branches, and robust but moderate shooters: such also as are firm and well ripened should always be chosen from healthful trees: observ-

ing, that the middle part of each shoot is always the best graft, cut at the time of grafting to five or six inches in length, or so as to have four or five good eyes or buds; but should be preserved at full length till grafting time, and then prepared as hereafter directed.

They should be collected or cut from the trees in February, in mild weather, before their buds begin to swell, or advance much for shooting: in collecting them, choose such as have not made lateral or side shoots; cut them off at full length; and if they are not to be used as soon as they are collected, lay their lower ends in some dry earth in a warm border till grafting time, and, if severe weather should happen, cover them with dry litter.

The proper tools and other materials used in grafting are, 1. A strong knife for cutting off the heads of the stocks, previous to the insertion of the graft; also a small hand-saw for occasional use in cutting off the heads of large stocks. 2. A common grafting knife, or strong sharp pen-knife, for cutting and shaping the grafts ready for insertion; also to slope and form the stocks for the reception of the grafts. 3. A flat grafting-chisel and small mallet for clefting large stocks, in cleft-grafting, for the reception of the graft. 4. A quantity of new bals strings for bandages, for tying the grafted parts close, to secure the grafts, and promote their speedy union with the stock. And, 5. A quantity of grafting clay, for claying closely round the grafts after their insertion and binding, to defend the parts from being dried by the sun and winds, or too much liquefied by wet, or pinched by cold; for these parts ought to be closely surrounded with a coat of clay in such a manner as effectually to guard them from all weathers, which would prove injurious to young grafts, and destroy their cementing property, so as to prevent the junction. For this, a kind of stiff loamy mortar must be prepared of strong fat loam, or, in default thereof, any sort of tough binding clay, either of which should be laid in an heap, adding thereto about a fourth of fresh horse-dung free from litter, and a portion of cut hay, mixing the whole well together, and adding a little water: then let the whole be well beaten with a stick upon a floor, or other hard substance; and as it becomes too dry, apply more water, at every beating turning it over, always continuing to beat it well at top till it becomes flat; which must be repeated more or less according to the nature of the clay, but should be several times done the first day: next morning repeat the beating, still moistening it with water; and by thus repeating the beating six or eight times every day for two or three days, or every other day at least, for a week, it will be in proper order for use; observing, it should be prepared a week at least before it is used, but if a month the better.

The season for performing the operation of grafting is February and March: though, when the work is performed in February, it for the general part proves the most successful, more especially for cherries, plums, and pears; and March grafting is well adapted for apples.

There are different methods of grafting in practice, termed Whip-grafting—Cleft-grafting—Crown-grafting—Check-grafting—Side-grafting—Root-grafting—and Grafting by approach or Inarching: but Whip-grafting and Cleft-grafting, are most commonly used; and Whip-grafting most of all, as being the most expeditious and successful of any.

Whip-grafting.—This being the most successful method of grafting is the most commonly practised in all the nurseries; it is always performed upon small stocks, from about the size of a goose-quill to half an inch or a little more or less in diameter, but the nearer the stock and graft approach in size the better. It is called *whip-grafting*; because the grafts and stocks being nearly of a size are sloped on one side so as to fit each other, and tied together in the manner of whips, or joints of angling-

rods, &c. and the method is as follows. Having got the cyons or grafts, knife, bandages, and clay ready, then begin the work by cutting off the head of the stock at some clear smooth part thereof; this done, cut one side sloping upward, about an inch and a half or near two inches in length, and make a notch or small slit near the upper part of the slope downward about half an inch long, to receive the tongue of the cyon; then prepare the cyon, cutting it to five or six inches in length, forming the lower end also in a sloping manner, so as exactly to fit the sloped part of the stock, as if cut from the same place, that the rinds of both may join evenly in every part; and fashion it so as to form a sort of tongue to fit the slit made in the slope of the stock; then place the graft, inserting the tongue of it into the slit of the stock, applying the parts as evenly and close as possible; and immediately tie the parts close together with a string of bas, bringing it in a neat manner several times round the stock and graft; then clay the whole over near an inch thick on every side, from about half an inch or more below the bottom of the graft, to an inch over the top of the stock, finishing the whole coat of clay in a kind of oval globular form, rather longwise, up and down, closing it effectually about the cyon and every part, so as no sun, wind, nor wet may penetrate, to prevent which is the whole intention of claying. You should examine it now and then, to see if it any where cracks or falls off, and if it does it must be instantly repaired with fresh clay. This sort of grafting may also be performed, if necessary, upon the young shoots of any bearing tree, if intended to alter the sorts of fruit, or have more than one sort on the same tree. By the middle or latter end of May, the grafts will be well united with the stock, as will be evident by the shooting of the graft; then the clay should be wholly taken away; but suffer the bas bandage to remain some time longer until the united parts seem to swell and be too much confined by the ligature; then take the tying wholly off. Their farther culture is directed under the respective articles, whether designed for dwarfs or standards, &c.

Cleft-grafting.—This is so called, because the stock being too large for whip-grafting is cleft or slit down the middle for the reception of the graft: and is performed upon stocks from about one to two inches diameter. First, with a strong knife cut off the head of the stock; or if the stock is very large, it may be headed with a saw; and cut one side sloping upwards about an inch and half to the top; then proceed with a strong knife or chisel, to cleave the stock at top, cross-way the slope, fixing the knife or chisel towards the back of the slope, and with your mallet strike it, so as to cleave the stock about two inches, or long enough to admit the graft, keeping it open with the chisel; this done, prepare the cyon, cutting it to such length as to leave four or five eyes, the lower part of which being sloped on each side, wedge-fashion, an inch and half or two inches long, making one side to a thin edge, the other much thicker, leaving the rind thereon, which side must be placed outward in the stock. The cyon being thus formed, and the cleft in the stock being made and kept open with the chisel, place the graft therein at the back of the stock the thickest side outward, placing the whole cut part down into the cleft of the stock, making the rind of the stock and graft join exactly; then removing the grafting chisel, each side of the cleft will closely squeeze the graft, so as to hold it fast; it is then to be bound with a ligature of bas, and clayed over, as observed in whip-grafting, leaving three or four eyes of the cyons uncovered. If intended to graft any pretty large stocks or branches by this method, two or more grafts may be inserted in each; in this case the head must be cut off horizontally, making no slope on the side, but smooth the top, then cleave it quite across, and place a graft on each side, as the stock may be cleft in two places, and insert two grafts in each cleft; they are thus to be

tied and clayed as in the other methods. This method of grafting may be performed upon the branches of bearing trees, when intended either to renew the wood or change the sort of fruit. Towards the latter end of May, or the beginning of June, the junction of the graft and stock in either method will be effectually formed, and the graft begin to shoot, when the clay may be taken off, and in a fortnight or three weeks after take off also the bandages.

Crown-grafting.—This kind of grafting is commonly practised upon such stocks as are too large to cleave, and is often performed upon the large branches of apple and pear trees, &c. that already bear fruit, when it is intended to change the sorts, or renew the tree with fresh-bearing wood. It is termed *crown-grafting*, because the stock or branch being headed down, several grafts are inserted at top all around betwixt the wood and bark, so as to give it a crown-like appearance: observing, that this kind of grafting should not be performed until March or early in April; for then the sap being in motion renders the bark and wood of the stock much easier to be separated for the admission of the graft.—The manner of performing this sort of grafting is as follows: First, cut off the head of the stock or branch with a saw horizontally, and pare the top smooth; then having the grafts, cut one side of each flat, and somewhat sloping, an inch and a half, forming a sort of shoulder at top of the slope to rest upon the crown of the stock; and then raising the rind of the stock with a wedge, so as to admit the cyon between that and the wood two inches down, place the grafts with the flat side next the wood, thrusting it down far enough for the shoulder to rest upon the top of the stock; and in this manner may be put three, four, five, or more grafts in one large stock or branch. When the grafts are all thus inserted, let the whole be tied tight and well clayed: observing to leave two or three eyes of each graft uncovered, but raising the clay an inch above the top of the stock, so as to throw the wet quickly off, without lodging about the grafted parts, which would ruin the whole work. Crown-grafting may also be performed, by making several clefts in the crown of the stock, and inserting the grafts round the top of the clefts. The grafts will be pretty well united with the stock, and exhibit a state of growth, by the end of May or beginning of June, and the clay may then be taken away. The trees grafted by this method will succeed extremely well; but, for the first two or three years, have this inconvenience attending them, of being liable to be blown out of the stock by violent winds; which must be remedied by tying long sticks to the body of the stock or branch, and each graft tied up to one of the sticks.

Check-grafting.—Cut the head of the stock off horizontally, and pare the top smooth; then cut one side sloping an inch and half or two inches deep, and cut the lower part of the graft sloping the same length, making a sort of shoulder at top of the sloped part: it is then to be placed upon the sloped part of the stock, resting the shoulder upon the crown of it: bind it with bas, and finish with a covering of clay as in the other methods.

Side-grafting.—This is done by inserting grafts into the sides of the branches without heading them down; and may be practised upon trees to fill up any vacancy, or for the purpose of variety, to have several sorts of apples, pears, plums, &c. upon the same tree. It is performed thus. Fix upon such parts of the branches where wood is wanted to furnish the head or any part of the tree; there slope off the bark and a little of the wood, and cut the lower end of the grafts to fit the part as near as possible; then join them to the branch, and tie them with bas, and clay them over.

Root-grafting.—This is done by Whip-grafting cyons upon pieces of the root of any tree of the same genus, and planting the root where it is to remain; it will take root, draw nourishment, and feed the graft.

Grafting by Approach, or Inarching.—This sort of grafting is, when the stocks designed to be grafted, and the tree from which you intend to take the graft, either grow so near, or can be placed so near together, that the branch or graft may be made to approach the stock, without separating it from the tree, till after its union or junction with the stock; so that the branch or graft being bent to the stock, they together form a sort of arch; whence it is called Grafting by Approach, or Inarching. Being a sure method, it is commonly practised upon such trees as are with difficulty made to succeed by any of the former ways of grafting. When intended to propagate any kind of tree or shrub by this method of grafting, if the tree, &c. is of the hardy kind, and growing in the full ground, a proper quantity of young plants for stocks must be set round it; and when grown of a proper height, the work of inarching must be performed; or, if the branches of the tree you design to graft from be too high for the stocks, in that case stocks must be planted in pots, and a slight stage must be erected round the tree, of due height to reach the branches, and the pots containing the stocks must be placed upon the stage. As to the method of performing the work: Observe, that in this method of grafting it is sometimes performed with the head of the stock cut off, and sometimes with the head left on till the graft is united with the stock; though, by previously heading the stock, the work is much easier performed; and having no top, its whole effort will be directed to the nourishment of the graft; having, however, the stocks properly placed, either planted in the ground, or in pots around the tree to be propagated: then make the most convenient branches approach the stock, and mark on the body of the branches the parts where they will most easily join to the stock, and in those parts of each branch pare away the bark and part of the wood two or three inches in length, and in the same manner pare the stock in the proper place for the junction of the graft; then make a cut upwards in the branch, so as to form a sort of tongue, and make a slit downwards in the stock to admit it; let the parts be then joined, slipping the tongue of the graft into the slit of the stock, making the whole join in an exact manner, and tie them closely together with bals, and afterwards cover the whole with a due quantity of clay, as before directed in the other methods. After this, let a stout stake be fixed, if possible, for the support of each graft; to which let that part of the stock and graft be fastened, which is necessary to prevent their being disjoined by the wind. The operation being performed in spring, let them remain in that position about four months, when they will be united, and the graft may then be separated from the mother-tree. In doing this, be careful to perform it with a steady hand, so as not to loosen or break out the graft, sloping it off downwards close to the stock: and if the head of the stock was not cut down at the time of grafting, it must now be done close to the graft, and all the old clay and bandage must also be cleared away, and replaced with new, to remain a few weeks longer. Observe, however, that if you shall think the grafts are not firmly united with the stock in the period of time above mentioned, let them remain another year till autumn, before you separate the grafts from the parent-tree. By this kind of grafting, you may raise almost any kind of tree or shrub, which is often done by way of curiosity, to ingraft a fruit-bearing branch of a fruit-tree upon any common stock of the same fraternity or genus, whereby a new tree bearing fruit is raised in a few months. This is sometimes practised upon orange and lemon trees, &c. by grafting bearing-branches upon stocks raised from the kernels of any of the same kind of fruit, or into branches of each other, so as to have oranges, lemons, and citrons, all on the same tree.

The foregoing we have chiefly extracted from Mr. Mawe's *Treatise on Gardening*; but an anonymous author has given us, in a treatise published at Hamburgh under the title *Amanitates*

Hortenses Novae, a new method of grafting trees, so as to have very beautiful pyramids of fruit upon them, which will exceed in beauty, flavour, and quantity, all that can be otherwise produced. This, he says, he had long experienced, and gives the following method of doing it. The trees are to be transplanted in autumn, and all their branches cut off. Early in the following summer the young shoots are to be pulled off, and the buds are then to be ingrafted into them in an inverted direction. This, he says, adds not only to the beauty of the pyramids, but also makes the branches more fruitful. These are to be closely connected to the trunk, and to be fastened in with the common ligature: they are to be placed circularly round the tree, three buds in each circle, and these circles at six inches distance from one another. The old trees may be grafted in this manner, the success having been found very good in those of twenty years standing; but the most eligible trees are those which are young, vigorous, and full of juice, and are not above a finger or two thick. When these young trees are transplanted, they must be fenced round with pales to defend them from the violence of the wind; and there must be no dung put to them till they are thoroughly rooted, for fear of rotting them before the fibres strike. The buds ingrafted must be small, that the wounds made in the bark to receive them, not being very large, may heal the sooner; and if the buds do not succeed, which will be perceived in a fortnight, there must be others put in their place. The wound made to receive these buds must be a straight cut, parallel to the horizon; and the piece of bark taken out must be downward, that the rain may not get in at the wound. In the autumn of the same year, this will be a green and flourishing pyramid; and the next summer it will flower, and ripen its fruit in autumn.

We shall conclude this article with an extract from a paper by Mr. Knight of Elton, in Herefordshire, published in the *Phil. Trans.* for 1795. "Previous, says he, to making any experiments, I had conversed with several planters, who entertained an opinion, that it was impossible to obtain healthy trees of those varieties which flourished in the beginning and middle of the present century, and which now form the largest orchards in this country. The appearance of the young trees which I had seen justified the conclusion they had drawn; but the silence of every writer on the subject of planting, which had come in my way, convinced me that it was a vulgar error, and the following experiments were undertaken to prove it so.

"I suspected that the appearance of decay in the trees I had seen lately grafted arose from the diseased state of the grafts, and concluded that, if I took scions or buds from trees grafted in the year preceding, I should succeed in propagating any kind I chose. With this view I inserted some cuttings of the best wood I could find in the old trees, on young stocks raised from seed. I again inserted grafts and buds taken from these on other young stocks, and wishing to be rid of all connection with the old trees, I repeated this six years; each year taking the young shoots from the trees last grafted. Stocks of different kinds were tried, some were double grafted, others obtained from apple-trees which grew from cuttings, and others from the seed of each kind of fruit afterwards inserted on them; I was surprised to find that many of these stocks inherited all the diseases of the parent trees.

"The wood appearing perfect and healthy in many of my last grafted trees, I flattered myself that I had succeeded; but my old enemies, the moss and canker, in three years convinced me of my mistake. Some of them, however, trained to a south wall, escaped all their diseases, and seemed (like invalids) to enjoy the benefit of a better climate. I had before frequently observed, that all the old fruits suffered least in warm situations, where the soil was not unfavourable. I tried the effects of laying one kind, but the canker destroyed it at the ground. In-

deed I had no hopes of success from this method, as I had observed that several sorts which had always been propagated from cuttings were as much diseased as any others. The wood of all the old fruits has long appeared to me to possess less elasticity and hardness, and to feel more soft and spongy under the knife, than that of the new varieties which I have obtained from seed. This defect may, I think, be the immediate cause of the canker and moss, though it is probably itself the effect of old age, and therefore incurable.

“ Being at length convinced that all efforts to make grafts from old and worn-out trees grow were ineffectual, I thought it probable that those taken from very young trees, raised from seed, could not be made to bear fruit. The event here answered my expectation. Cuttings from seedling apple-trees of two years old were inserted on stocks of twenty, and in a bearing state. These have now been grafted nine years, and though they have been frequently transplanted to check their growth, they have not yet produced a single blossom. I have since grafted some very old trees with cuttings from seedling apple-trees of five years old: their growth has been extremely rapid, and there appears no probability that their time of producing fruit will be accelerated, or that their health will be injured, by the great age of the stocks. A seedling apple-tree usually bears fruit in thirteen or fourteen years; and I therefore conclude, that I have to wait for a blossom till the trees from which the grafts were taken attain that age, though I have reason to believe, from the form of their buds, that they will be extremely prolific. Every cutting, therefore, taken from the apple (and probably from every other) tree, will be affected by the state of the parent stock. If that be too young to produce fruit, it will grow with vigour, but will not blossom; and if it be too old, it will immediately produce fruit, but will never produce a healthy tree, and consequently never answer the intention of the planter. The root, however, and the part of the stock adjoining it, are greatly more durable than the bearing branches; and I have no doubt but that scions obtained from either would grow with vigour, when those taken from the bearing branches would not. The following experiment will at least evince the probability of this in the pear-tree. I took cuttings from the extremities of the bearing branches of some old ungrafted pear-trees, and others from scions which sprang out of the trunks near the ground, and inserted some of each on the same stocks. The former grew without thorns, as in the cultivated varieties, and produced blossoms the second year; whilst the latter assumed the appearance of stocks just raised from seeds, were covered with thorns, and have not yet produced any blossoms.

“ The extremities of those branches which produce seeds in every tree probably shew the first indication of decay; and we frequently see (particularly in the oak) young branches produced from the trunk, when the ends of the old ones have long been dead. The same tree when cropped will produce an almost eternal succession of branches. The durability of the apple and pear I have long suspected to be different in different varieties, but that none of either would vegetate with vigour much, if at all, beyond the life of the parent stock, provided that died from mere old age. I am confirmed in this opinion by the books you did me the honour to send me: of the apples mentioned and described by Parkinson, the names only remain, and those since applied to other kinds now also worn out; but many of Evelyn's are still well known, particularly the red-streak. This apple, he informs us, was raised from seed by lord Scudamore in the beginning of the last century. We have many trees of it, but they appear to have been in a state of decay during the last forty years. Some others mentioned by him are in a much better state of vegetation; but they have all ceased to deserve the attention of the planter. The durability of the pear is probably something more than double that of the apple.

“ It has been remarked by Evelyn, and by almost every writer since on the subject of planting, that the growth of plants raised from seeds was more rapid, and that they produced better trees than those obtained from layers or cuttings. This seems to point out some kind of decay attending the latter modes of propagation, though the custom in the public nurseries of taking layers from stools (trees cropped annually close to the ground) probably retards its effects, as each plant rises immediately from the root of the parent stock.

“ Were a tree capable of affording an eternal succession of healthy plants from its roots, I think our woods must have been wholly overrun with those species of trees which propagate in this manner, as those scions from the roots always grow in the first three or four years with much greater rapidity than seedling plants. An aspen is seldom seen without a thousand suckers rising from its roots; yet this tree is thin, though universally, scattered over the woodlands of this country. I can speak from experience, that the luxuriance and excessive disposition to extend itself in another plant, which propagates itself from the root (the raspberry), decline in twenty years from the seed. The common elm being always propagated from scions or layers, and growing with luxuriance, seems to form an exception; but as some varieties grow much better than others, it appears not improbable that the most healthy are those which have last been obtained from seed. The different degrees of health in our peach and nectarine trees may, I think, arise from the same source. The oak is much more long-lived in the north of Europe than here; though its timber is less durable, from the numerous pores attending its slow growth. The climate of this country being colder than its native may in the same way add to the durability of the elm; which may possibly be further increased by its not producing seeds in this climate, as the life of many annuals may be increased to twice its natural period, if not more, by preventing their seeding.

“ I have been induced to say a great deal more on this subject than, I fear, you will think it deserves, from a conviction that immense advantages would arise from the cultivation of the pear and apple in other countries, and that the ill success which has attended any efforts to propagate them has arisen from the use of worn out and diseased kinds. Their cultivation is ill understood in this country, and worse practised; yet an acre of ground, fully planted, frequently affords an average produce of more than five hundred gallons of liquor, with a tolerably good crop of grass; and I have not the least doubt but that there are large quantities of ground in almost every county in England capable of affording an equal produce.”

GRAHAM (George), clock and watch maker, the most ingenious and accurate artist of his time, was born in 1675. After his apprenticeship, Mr. Tompion received him into his family, purely on account of his merit; and treated him with a kind of parental affection as long as he lived. Beside his universally acknowledged skill in his profession, he was a complete mechanic and astronomer; the great mural arch in the observatory at Greenwich was made for Dr. Halley, under his immediate inspection, and divided by his own hand: and from this incomparable original, the best foreign instruments of the kind are copies made by English artists. The sector by which Dr. Bradley first discovered two new motions in the fixed stars was of his invention and fabric: and when the French academicians were sent to the north to ascertain the figure of the earth, Mr. Graham was thought the fittest person in Europe to supply them with instruments; those who went to the south were not so well furnished. He was for many years a member of the Royal Society, to which he communicated several ingenious and important discoveries, and regarded the advancement of science more than the accumulation of wealth. He died in 1751.

GRAMMAM's Dyke. See ANTONINUS's Wall.

GRAIN, corn of all sorts, as barley, oats, rye, &c. See CORN, WHEAT, &c.

GRAIN is also the name of a small weight, the twentieth part of a scruple in apothecaries weight, and the twenty-fourth of a penny-weight troy. A grain-weight of gold-bullion is worth two-pence, and that of silver but half a farthing.

GRAIN also denotes the component particles of stones and metals, the veins of wood, &c. Hence cross-grained, or against the grain, means contrary to the fibres, of wood, &c.

GRAIN (Baptist le), master of the requests in ordinary to Mary de Medicis queen of France's household, wrote *The History of Henry the Great*, and of *Louis XIII.* from the beginning of his reign to the death of the marshal d'Ancre in 1617. This history is reckoned to be written with impartiality, and the spirit of a true patriot, and contains many things not to be found any where else. He vigorously asserts the edict that had been granted to the reformed.

GRALLÆ, in ornithology, is an order of birds analogous to the *bruta* in the class of *mammalia*, in the Linnæan system. See ZOOLOGY and ORNITHOLOGY.

GRAMINA, GRASSES; one of the seven tribes or natural families, into which all vegetables are distributed by Linnæus in his *Philosophia Botanica*. They are defined to be plants which have very simple leaves, a jointed stem, a husky calyx termed *gluma*, and a single seed. This description includes the several sorts of corn as well as grasses. In Tournefort they constitute a part of the fifteenth class, termed *apetalæ*; and in Linnæus's sexual method, they are mostly contained in the second order of the third class, called *triandria digynia*. This numerous and natural family of the grasses has engaged the attention and researches of several eminent botanists. The principal of these are, Ray, Monti, Micheli, and Linnæus.

M. Monti, in his *Catalogus stirpium agri Bononiensis gramina ac hujus modi affinia complectens*, printed at Bononia in 1719, divides the grasses from the disposition of their flowers, as Theophrastus and Ray have divided them before him, into three sections or orders—These are, 1. Grasses having flowers col-

lected in a spike. 2. Grasses having their flowers collected in a panicle or loose spike. 3. Plants that in their habit and external appearance are allied to the grasses. This class would have been natural if the author had not improperly introduced sweet rush, juncus, and arrow-headed grass, into the third section. Monti enumerates about 306 species of the grasses, which he reduces under Tournefort's genera; to these he has added three new genera.

Scheuchzer, in his *Aristographia*, published likewise in 1719, divides the grasses, as Monti, from the disposition of their flowers, into the five following sections: 1. Grasses with flowers in a spike, as phalaris, anthoxanthum, and frumentum. 2. Irregular grasses, as scœnanthus and cornucopiæ. 3. Grasses with flowers growing in a simple panicle or loose spike, as reed and millet. 4. Grasses with flowers growing in a compound panicle, or diffused spike, as oats and poa. 5. Plants by their habit nearly allied to the grasses, as cypress grass, scirpus, linagrostis, rush, and scœuchzeria. Scheuchzer has enumerated about four hundred species, which he describes with amazing exactness. Micheli has divided the grasses into six sections, which contain in all 44 genera, and are arranged from the situation and number of the flowers.

GRAMINA, the name of the fourth order in Linnæus's *Fragmenta of a Natural Method*, consisting of the numerous and natural family of the grasses, *viz.* agrostis, aira, alopecurus or fox-tail grass, anthoxanthum or vernal grass, aristida, arundo or reed, avena or oats, bobartia, briza, bromus, cinna, cornucopiæ or horn of plenty grass, cynosurus, dactylis, elymus, festuca or fescue-grass, hordeum or barley, lagurus or hare's-tail grass, lolium or darnel, lygeum or hooded matweed, melica, mileum or millet, nardus, oryza or rice, panicum or panic-grass, paspalum, phalaris or canary-grass, phleum, poa, saccharum or sugar-cane, secale or rye, stipa or winged spike-grass, triticum or wheat, uiola or sea-side oats of Carolina, coix or Job's tears; olyra, pharus, tripfacum, zea, Indian Turkey wheat or Indian corn, zizania, ægilops or wild fescue-grass, andropogon, apluda; cenchrus, holcus or Indian millet, ischæmum. See farther the article GRASSES.

G R A M M A R.

GRAMMAR is the art of rightly expressing our thoughts by words.

Grammar in general, or universal grammar, explains the principles which are common to all languages.

The grammar of any particular language, as the English grammar, applies those common principles to that particular language, according to the established usage and custom of it.

Grammar treats of sentences; and of the several parts, of which they are compounded.

Sentences consist of words; words, of one or more syllables; syllables, of one or more letters.

So that letters, syllables, words, and sentences, make up the whole subject of grammar.

INTRODUCTION.

A *letter* is the first principle, or least part, of a word.

An articulate sound is the sound of the human voice, formed by the organs of speech.

A *vowel* is a simple articulate sound, formed by the impulse of the voice, and by the opening only of the mouth in a particular manner.

A *consonant* cannot be perfectly sounded by itself; but joined with a vowel forms a compound articulate sound, by a particular motion or contact of the parts of the mouth.

A *diphthong*, or compound vowel, is the union of two or more vowels pronounced by a single impulse of the voice.

By means of inarticulate sounds beasts can express certain feelings, but man is distinguished from the brute creation by the power of modifying a much greater variety of sounds, and of fixing to each modification a particular meaning. The sounds thus modified are called words; and as words have no *natural* relation to the ideas and perceptions of which they are significant, the use of them must either have been the result of human sagacity, or have been suggested to the first man by the Author of nature.

Upon either supposition, the first language, compared with those which succeeded it, or even with itself as afterwards enlarged, must have been extremely rude and narrow. If it was of *human* contrivance, this will be readily granted; for what art was ever invented and brought to a state of perfection by illiterate savages? If it was taught by God, which is at least the more probable supposition, we cannot imagine that it would be more comprehensive than the ideas of those for whose immediate use it was intended; that the first men should have been taught

to express pains or pleasures which they never felt, or to utter sounds that should be afterwards significant of ideas, which at the time of utterance had not occurred to the mind of the speaker: man, having learned the elements of language, would be able himself to improve and enlarge it as his future occasions should require.

Since all our ideas are derived from sensation, it is probable that the first language possessed very few words of those denoting only the names of the external objects, with which the first inhabitants of the earth were chiefly conversant. By degrees a variety of actions and qualities would be noticed, and when men began to reflect, they would endeavour to express the inward thoughts of their mind by some metaphors taken from sensitive objects. After a considerable interval, the derivation of the last class of words is in many languages lost, and hence it is difficult to ascertain their precise meaning.

From the difference of organization in individuals, it is probable that no two persons derive exactly the same sensation from the impression made upon them by a variety of objects in nature, and the sounds used to express these objects will convey imperfectly their notions, and this imperfection will be increased when the sound denotes some thoughts of the mind transferred from these objects. Language, therefore, in general labours under a defect, which, in the present state of things, it is impossible to correct: artful men will naturally avail themselves of it to serve a bad purpose, and men of the best intentions must expect that their thoughts, when expressed by sounds, will be liable to misinterpretation. That language is the best which is capable of distinguishing every external object by its proper sound, and in which the thoughts of our mind may be expressed with the greatest facility and perspicuity.

Since it does not appear that any language has been formed by determinate rules, and each has been subject to different degrees of cultivation, they will all have their respective excellencies and defects. In determining these excellencies and defects, we may expect to meet with much altercation; and, according to the notions derived from the country which gave us birth, or the language which it was our chance to study, we shall form probably a standard for all countries. In Europe we are much attached to the structure of the Greek language. In the East the grammars are formed chiefly on the plan of the Arabic.

In expressing our thoughts, some object must be denoted by a sound, of which we affirm something. Thus, gold is heavy. *Gold* is the object: *is* denotes existence, and *heavy* is the mode of that existence. The thought may be dilated thus: Gold is heavier than lead. Where the thing affirmed is, that it is heavier than lead: and a new object is introduced with sounds to denote comparison; *or*, or more than. From the various modes used by different nations to express the property affirmed of any object, great disputes have arisen, not only on the different sorts of words necessary to constitute a language, but on the sorts of words actually existing in a given language. Thus, some writers affirm that language requires only two sorts of words; and others have written grammars for the use of children, which lay down ten sorts of words in the English language, each class being distinguished by some name derived from the Latin. Though it appears to us that words might be more commodiously distributed into the general divisions of name, and attribute or property, yet, as the Latin language has obtained universal authority, we shall bow to the established practice, and treat of words under the accustomed division, into *Noun, Article, Pronoun, Verb, Participle, Adverb, Preposition, Conjunction, and Interjection.*

CHAPTER I.

Of the NOUN or SUBSTANTIVE.

Nouns are all those words by which objects or sub-

*stances are denominated, and which distinguish them from one another, without marking either quantity, quality, action, or relation. The substantive or noun is the name of the thing spoken of, and in Greek and Latin is called name; for it is *ονομα* in the one, and *nomen* in the other; and if in English we had called it the name rather than the noun, the appellation would have been more proper. That nouns or the names of things must make a part of every language, and that they must have been the words first suggested to the human mind, will not be disputed. Men could not speak of themselves or of any thing else, without having names for themselves and the various objects with which they are surrounded. Now, as all the objects which exist must be either in the same state in which they were produced by nature, or changed from their original state by art, or abstracted from substances by the powers of imagination, and conceived by the mind as having at least the capacity of being characterized by qualities; this naturally suggests a division of nouns into NATURAL, as *man, vegetable, tree, &c.* ARTIFICIAL, as *house, ship, watch, &c.* and ABSTRACT, as *whiteness, motion, temperance, &c.**

But the diversity of objects is so great, that had each individual a distinct and proper name, it would be impossible for the most tenacious memory, during the course of the longest life, to retain even the nouns of the narrowest language. It has therefore been found expedient, when a number of things resemble each other in some important particulars, to arrange them all under one species; to which is given a name that belongs equally to the whole species, and to each individual comprehended under it. Thus the word *man* denotes a species of animals, and is equally applicable to every human being: The word *horse* denotes another species of animals, and is equally applicable to every individual of that species of quadrupeds; but it cannot be applied to the species of men, or to any individual comprehended under that species. We find, however, that there are some qualities in which several species resemble each other; and therefore we refer them to a higher order called a genus, to which we give a name that is equally applicable to every species and every individual comprehended under it. Thus, *men* and *horses* and all living things on earth resemble each other in this respect, that they have life. We refer them therefore to the genus called animal; and this word belongs to every species of animals, and to each individual animal. The same classification is made both of artificial and abstract substances; of each of which there are genera, species, and individuals. Thus, in natural substances, animal, vegetable, and fossil, denote GENERA; *man, horse, tree, metal,* are SPECIES; and *Alexander, Bucephalus, oak, gold,* are INDIVIDUALS. In artificial substances, *edifice* is a GENUS; *house, church, tower,* are SPECIES; and the *Vatican, St. Paul's, and the Tower of London,* are INDIVIDUALS. In abstract substances, *motion* and *virtue* are GENERA; *flight* and *temperance* are SPECIES; the *flight of Mahomet, and temperance in wine,* are INDIVIDUALS. By arranging substances in this manner, and giving a name to each genus and species, the nouns necessary to any language are comparatively few, and easily acquired: and when we meet with an object unknown to us, we have only to examine it with attention; and, comparing it with other objects, to refer it to the genus or species which it most nearly resembles. By this contrivance we supply the want of a proper name for the individual; and so far as the resemblance is complete between it and the species to which it is referred, and of which we have given it the name, we may converse and reason about it without danger of error: Whereas, had each individual in nature a distinct and proper name, words would be innumerable and incomprehensible; and to employ our labours in language would be as idle as that study of numberless written symbols which distinguishes the Chinese.

Although nouns are thus adapted to express not the indi-

individuals, but the *genera* or *species* into which substances are classed; yet, in speaking of these substances, whether *natural*, *artificial*, or *abstract*, all men must have occasion to mention sometimes *one* of a kind, and sometimes *more* than one. In every language, therefore, nouns must admit of some variation in their form, to denote *unity* and *plurality*; and this variation is called *number*. Thus in the English language, when we speak of a single place of habitation, we call it a *house*; but if of more, we call them *houses*. In the first of these cases the noun is said to be in the *singular*, in the last case it is in the *plural* number. Greek nouns have also a *dual* number to express *two* individuals, as have likewise some Hebrew nouns: but this variation is evidently not essential to language; and it is perhaps doubtful whether it ought to be considered as an elegance or a deformity.

But although number be a natural accident of nouns, it can only be considered as *essential* to those which denote genera or species. Thus we may have occasion to speak of *one animal* or of *many animals*, of *one man* or of *many men*; and therefore the nouns *animal* and *man* must be capable of expressing *plurality* as well as *unity*. But this is not the case with respect to the *proper names* of *individuals*: for we can only say *Xenophon*, *Aristotle*, *Plato*, &c. in the *singular*; as, were any one of these names to assume a *plural* form, it would cease to be the *proper name* of an *individual*, and become the *common name* of a *species*. Thus, we say the *Cæsars*, the *Howards*, the *Pelbams*, the *Montagues*, &c.: but *Socrates* can never become *plural*, so long as we know of *no more* than *one man* of that name.

Besides *number*, another characteristic visible in substance is that of *SEX*. Every substance is either *male* or *female*; or *both male and female*; or *neither one nor the other*. With regard to this great natural characteristic, grammarians have made only a threefold distinction of nouns: those which denote *males* are said to be of the *masculine gender*; those which denote *females*, of the *feminine*: and those which denote substances, that admit not of *sex*, are said to be *neuter* or of *neither gender*. All *animals* have *sex*: and therefore the *names* of all animals should have *gender*. But the *sex* of all is not equally obvious, nor equally worthy of attention. In those species that are most common, or of which the *male* and the *female* are, by their *size*, *form*, *colour*, or other outward circumstances, *eminently distinguished*, the *male* is sometimes called by *one name*, which is *masculine*; and the *female* by a *different name*, which is *feminine*. Thus in English we say *husband*, *wife*; *king*, *queen*; *father*, *mother*; *son*, *daughter*, &c. In others of similar distinction, the name of the *male* is applied to the *female*, only by prefixing a syllable or by altering the termination; as *man*, *woman*; *lion*, *lioness*; *emperor*, *empress*, anciently *emperess*; *master*, *mistress*, anciently *mastress*, &c. When the *sex* of any animal is not obvious, or not material to be known, the same name, in some languages, is applied without variation to *all* the *species*, and that name is said to be of the *common gender*. Thus in Latin *bos albus* is a white ox, and *bos alba* a white cow. Diminutive insects, though they are doubtless male and female, seem to be considered in the English language as if they were really creeping *things*. No man, speaking of a *worm*, would say *he* creeps, but *it* creeps, upon the ground. But, although the origin of *genders* is thus clear and obvious, yet the English is the only language, with which we are acquainted, that deviates not, except in this single instance of insects, from the order of nature. *Greek* and *Latin*, and many of the modern tongues, have nouns, some masculine, some feminine, which denote substances where *sex* never had existence. Nay, some languages are so particularly defective in this respect, as to class every object, inanimate as well as animate, under either the *masculine* or the *feminine gender*, as they have no *neuter gender* for those which are of neither sex. This is the case with the

Hebrew, *French*, *Italian*, and *Spanish*. But the *English*, strictly following the order of nature, puts every noun which denotes a *male* animal, and no other, in the *masculine gender*; every name of a *female* animal, in the *feminine*; and every animal, whose *sex* is not *obvious* or *known*, as well as every *inanimate* object whatever, in the *neuter gender*. And this gives our language an advantage above most others in the poetical and rhetorical style: for, when nouns naturally neuter are converted into masculine and feminine, the *personification* is more distinctly and more forcibly marked.

In some languages there is a variation in the noun, called by grammarians *case*. The Latin has five cases, the Greek four, the German three, the English one, the Hebrew none. From this difference in the use of cases, it is evident that they are not to be considered as essential in language. In English the variation in the ending of the noun expresses possession: and hence it is called the possessive case. Thus, from *God* we have, for the possessive case, *God's*; by thus adding *s* or *is* to the name, we express a connection between him and some other object then spoken of. Thus, *God's house* implies the house belonging to *God*: and old writers frequently used the word *his*, which may have given rise to the case: thus *God his house*. In the Hebrew this connection is expressed by the mere position of the two words. For other relations of one thing to another, we use prepositions; thus, *to*, *from*, *by*, which relations in other languages are expressed by a change in the end of the noun, and this change derives its origin probably from some suffix which had the force of our preposition.

CHAPTER II.

On ARTICLES or DEFINITIVES.

MANY and severe have been the disputes among grammarians upon the use and meaning of these little words. Reasoning oftentimes from a metaphor, they persuade themselves at last that they have made some notable discovery: and because in a building there must be joints and nails, we must have in language little words or pegs to keep all things together. Thus Mr. Harris, whose knowledge was derived from the Greek language and Greek grammarians, and whose principles, as is natural from knowledge founded on so narrow a basis, are contradicted by the slightest acquaintance with the Teutonic and Arabic, leads us through many a maze; and we might have wandered till this moment, if Mr. Tooke, in his excellent work on the word *that*, enlarged in his *Upea Pterocenta*, had not pointed out to us the open and straight road of etymology, when we can travel upon it, and, when that fails us, of analogy. In the English language we call the words *a* and *the* articles: the Germans have *ein* and *der*: the French *un* and *le*: the Greeks ϵ : the Hebrews, \aleph : but the unfortunate Latins are said to be without these joints and pegs in speech. But if one language is without them, they are, it is evident, not essential to language: and it will be found difficult to make such a definition as shall exclude a variety of words, such as, *hic*, *this*, *that*, &c. from making a part of this division.

In the languages above mentioned the precise meaning of the words, *the*, *der*, *le*, ϵ , and \aleph , cannot at first sight be ascertained. The English word *a* points obscurely to its meaning. The German *ein* and the French *un* clear the road for investigation. They are to be found continually applied to substantives, and mean one: for it is obvious that in common conversation we must frequently find it necessary to limit the object of it to one of a species. As the object must sometimes be limited, at others this limitation may not be necessary; and it is curious to observe how different nations express the same idea. Thus if a thing is generally reported, we say in English "they say," meaning a great number say so: and so in French it is, *on dit*, or

unus dicit, "one person says," so meaning more than one person by an ellipsis very common in that language: in German it is *man sagt*, by *man* meaning man in general. We have thus found, that in two languages one of the articles is merely a word of number. Probably it may be so in English; *a* may mean *one*, or it is an abbreviation of *any*. By trying the two senses it is evident, that *any* cannot be applied in the room of *a*, but that *one* always can: and hence we might conclude that *a* and *an* are only other words for *one*, and answer to the German *ein*.

The article *the*, as it is called, may not discover itself so easily. Yet let us try the same analogy, for the etymology of it is not ascertained. *The* answers to *der* of the Germans, and *le* of the French: but what is *le*? the *ille* of the Latins, and hence we may reasonably presume that our word *the* is no more an article than *ille*, and in fact that it comes from some adjective of the same signification. Let us try by etymology. In German we have *der*, *die*, *das*: which was antiently *ther*, *thia* (*thio* *thiu*) *thiz*, and in the plural *thie* (*thier*). This looks very much like our *the*. In the Anglo-Saxon we find *sa* *seo*, *that*: in Islandic, *sa*, *su*, *that*: in Gothick *sa*, *so*, *thata*: in Hebrew *הוא*, *היא*: Etymologists perhaps will not be displeas'd at our making the words *הוא* and *the* proceed from the same original, and we shall not be afraid of exposing ourselves to the laughter of critics, if we refer the Doric *τῆνος* to the same stock. - If we are right in our conjectures, the word *the* is as much a pronoun as the *ille* of the Latins: but, if persons choose to have a distinct class of words under the name of articles, we may say, that the English has two, *a* and *the*, which "serve to define and ascertain any particular object, so as to distinguish it from the other objects of the general class to which it belongs, and of course to denote its individuality."

CHAPTER III.

ON PRONOUNS, or SUBSTANTIVES of the SECOND ORDER.

IN communicating thoughts, a person must either speak of himself, of the person to whom he is speaking, or of some other persons or things. The word referring to the speaker is called the pronoun of the first person; the word referring to the person spoken to is the pronoun of the second person; the word referring to other persons is the pronoun of the third person. The use of such words is to avoid repetition. "The man speaking says so and so" must be used continually, if the word *I* did not answer the same purpose: in the same manner *THOU*, *HE*, *SHE*, *THEY*, &c. answer similar purposes.

Hence we see why it is improper to say *the I* or *the THOU*; for each of these pronouns has of *itself* the force of a *noun* with *the* definite article prefixed, and denotes a person of whom something is predicated, which distinguishes him from all other persons. *I* is the person who now speaks, *THOU* is the person who is now addressed by the speaker. Hence too we see the reason why the pronoun *I* is said to be of the first, and the pronoun *THOU* of the second person. These pronouns can have place only in conversation, or when a man, in the character of a public speaker, addresses himself to an audience; but it is obvious, that there *must* be a speaker before there *can* be a bearer; and therefore, that the pronouns may follow the order of nature, *I*, which denotes the person of the speaker, must take place of *THOU*, which denotes the person of the bearer. Now the speaker and the bearer being the only persons engaged in conversation or declamation, *I* is with great propriety called the pronoun of the first, and *THOU* the pronoun of the second person. With respect to pronouns, the third person, as it is called, is merely a negation of the other two. This is evident from the slightest attention to the import of those words which are called pronouns of the third person. *HE*, *SHE*, or *IT*, denotes

not the person either of the speaker or of the bearer; and, as we have just observed, no other person can have a share in conversation or declamation. An absent person or an absent thing may be the subject of conversation, but cannot be the speaker or the person addressed. *HE*, *SHE*, and *IT*, however, as they stand by themselves, and assume the power of nouns, are very properly denominated pronouns; but they are not personal pronouns in any other sense than as the negation of sex is the neuter gender.

We have already seen that nouns admit of number; pronouns, which are their substitutes, likewise admit of number. There may be many speakers at once of the same sentiment, as well as one, who, including himself, speaks the sentiment of many: speech may likewise be addressed to many at a time, as well as to one; and the subject of the discourse may likewise be many. The pronoun, therefore, of every one of the persons must admit of number to express this singularity or plurality. Hence the pronoun of the first person *I* has the plural *WE*; that of the second person *THOU* has the plural *YE* or *YOU*; and that of the third person *HE*, *SHE*, or *IT*, has the plural *THEY*, which is equally applied to all the three genders.

There is a great deal of caprice in the use of these pronouns in different nations. Thus the English in addressing a person use the second pronoun plural instead of the second singular: the Italians speak in the third person singular of the person spoken to; and the Germans, from the ridiculous notions which they entertain of birth, and the servile state into which in consequence their minds have been reduced, use the third and the second persons plural, the third and the second persons singular according to the respect which they have for the person addressed. When the second person is used, it is either to God, an object of the greatest familiarity and affection, or as a mark of the utmost contempt or superiority. The pronoun *WE* is in general used by a king when speaking of himself: but as he then speaks as an officer of and in the name of the people, this may plead in favour of an abuse of speech.

In most languages the first and second persons are without gender: in Hebrew, however, the second is modified to signify the male or female. This distinction has been considered as superfluous, since the sexes of the two persons in conversation are known by their appearance. But sometimes it may be elegant. Thus if we were to say to a woman, Wouldest *thou* do such a thing? then a woman implying that the action was derogatory to the female character, we cannot do it by the pronoun alone. The change of *at* for *attab* may convey this reproof very pointedly in the Hebrew, *thou!* *at!*

The pronoun of the third person denoting neither the speaker nor the bearer, but the subject of the discourse, and being merely the substitute of a noun which may be either masculine, feminine, or neuter, must of necessity agree with the noun which it represents, and admit of a triple distinction significant of gender. In English, which allows its adjectives no genders, this pronoun is *HE* in the masculine, *SHE* in the feminine, and *IT* in the neuter; the utility of which distinction may be better found in supposing it away. Suppose, for example, that we should in history read these words: *He* caused him to destroy him—and were informed that the pronoun, which is here thrice repeated, stood each time for something different; that is to say, for a man, for a woman, and for a city, whose names were *Alexander*, *Tbais*, and *Persepolis*. Taking the pronoun in this manner—divested of its gender—how would it appear which was destroyed, which the destroyer, and which the cause that moved to the destruction? But there is no ambiguity when we hear the genders distinguished: when we are told, with the proper distinctions, that *she* caused him to destroy *it*, we know with certainty that the promoter was the woman; that her instrument was the hero; and that the subject of their cruelty was the unfortunate city. From this example we should be surpris'd how the Italians,

French, and *Spaniards*, could express themselves with precision or elegance with no more than two variations of this pronoun.

Although, in every language with which we are now acquainted, there is but one pronoun for each of the first and second persons; and although it is obvious from the nature and import of those words, that no more can be necessary; yet the mere *English* reader may perhaps be puzzled with finding three distinct words applied to each; I, MINE, and ME, for the first person, THOU, THINE, and THEE, for the second. The learned reader will see at once that the words MINE and ME, THINE and THEE, are equivalent to the *genitive* and *accusative cases* of the Latin pronouns of the first and second persons. That MINE is a pronoun in the possessive case is obvious; for if I were asked "whose book is that before me?" I should reply—"It is MINE;" meaning that it belongs to me. That the word ME is the same pronoun in the case which the Latin grammarians call the *accusative*, is evident from the import of that word in the sentence HE ADMIRES ME, where the admiration is supposed to proceed from the person spoken of to the person who speaks. It appears therefore, that though *English nouns* have only two cases, the *nominative* and *possessive*, the pronouns of that language have three, as I, MINE, ME; THOU, THINE, THEE; HE, HIS, HIM, &c. Both pronouns, the *Latin* and the *English*, are irregularly inflected: and those words which are called the oblique cases of each were originally derived from nominatives different from EGO and I; but these nominatives are now lost, and *mei* and *mine* have, beyond all dispute, the effect of the genitives of the *Latin* and *English* pronouns of the first person.

From the account here given of the personal pronouns, it appears that the first or second will, either of them, coalesce with the third, but not with each other. For example, it is good sense, as well as good grammar, to say in any language, I AM HE—THOU ART HE—WE WERE THEY—YOU WERE THEY; but we cannot say—I AM THOU—nor THOU ART I—nor WE ARE YOU, &c. The reason is, there is no absurdity for the speaker to be the subject also of the discourse, as when it is said—I am he; or for the person addressed, as when we say, thou art he. But for the same person, in the same circumstances, to be at once the speaker and the party addressed, is impossible; for which reason the coalescence of the pronouns of the first and second persons is likewise impossible.

I, THOU, HE, SHE, and IT, are all that are usually called personal pronouns. There is another class of words, which are called sometimes *pronominal adjectives*, sometimes *adjective pronouns*, sometimes *possessive pronouns*; and by one writer of grammar they have been most absurdly termed *pronominal articles*. It is not worth while to dispute about a name; but the words in question are MY, THY, HER, OUR, YOUR, THEIR. These words are evidently in the form of *adjectives*: for, like other *English* adjectives, they have no variation to indicate either gender, number, or case; and yet they are put in concord with nouns of every gender and both numbers, as MY WIFE, MY SON, MY BOOK—HER HUSBAND, HER SONS, HER DAUGHTERS, &c. But, though in the form of *adjectives*, they have the power of the personal pronouns in the *possessive case*: MY BOOK is the book of ME, or the book of HIM WHO NOW SPEAKS; OUR HOUSE is the house of US, or the house occupied by the PERSONS WHO NOW SPEAK; HER HUSBAND is the husband of a woman who can be known only from something preceding in the discourse; and THEIR PROPERTY is the property of them—of any persons, whether men or women, or both, who have been previously mentioned. Words which have the form of *adjectives*, with the power of pronouns, may, without impropriety, be called *pronominal adjectives*; and such is the name by which we shall henceforth distinguish them. To these pronominal adjectives, as well as to the personal pronouns, are subjoined the words *own* and *self*—in the plural *selves*; in which case they are emphatical, and imply a

silent contrariety or opposition. Thus, I live in my own house; that is, not in a hired house. This I did with my own hand; that is, not by proxy. This was done by myself; that is, not by another. The word *self* subjoined to a personal pronoun forms also the reciprocal pronoun; as, We hurt ourselves by vain rage; he blamed himself for his misfortune. Himself, itself, themselves, are supposed by Wallis to be put, by corruption, for his self, its self, their selves; so that *self* is always a *substantive* or noun, and not a pronoun. This seems to be a just observation: for we say, the man came himself; they went themselves; where the words *himself* and *themselves* cannot be accusatives but nominatives, and were anciently written *his self*, *their selves*.

There are other words which are usually ranked under the class of pronouns; as *who*, *which*, *what*. These, when employed in asking questions, are called *interrogative pronouns*; though a name more characteristic might surely be found for them. Their import, however, will be more easily ascertained after we have considered another species of pronouns, which have been denominated *relatives*, and with which they are intimately connected.

The pronouns already mentioned may be called *prepositive*, as may indeed all substantives, because they are capable of introducing or leading a sentence: but there is another pronoun which has a character peculiar to itself; and which, as it is never employed but to connect sentences, and must therefore have always a reference to something preceding, is called the *subjunctive* or *relative* pronoun. This pronoun is in Greek, *ὃς, ἃ, ὅ*; in Latin, QUI, QUÆ, QUOD; and in English, WHO, WHICH, THAT.

In order to determine with precision the nature and import of the *relative pronoun*, it will be necessary to ascertain the powers which it contains, or the parts of speech into which it is capable of being resolved. Now it is obvious, that there is not a single noun, or *prepositive pronoun*, which the *relative* is not capable of representing: for we say, I, who saw him yesterday, cannot be mistaken; YOU, who did not see him, may have been misinformed; THEY, who neither saw nor heard, can know nothing of the matter; THE THINGS, WHICH he exhibited, were wonderful. From these examples it is apparent, in the first place, that the *relative* contains in itself the force of any other pronoun: but it contains something more.

If from any sentence in which there is a *relative*, that relative be taken away, and the *prepositive* pronoun, which it represents, be substituted in its stead, the sentence will lose its bond of union, and stand quite loose and unconnected. Thus, if instead of saying the man is wise who speaks little, we should say the man is wise, he speaks little, the sentence would be resolved into two; and what is affirmed of the man's wisdom would have no connection with the circumstance of his speaking little. Hence it is evident, in the second place, that the *relative* contains the force of a *connective* as well as of the *prepositive* pronoun. What kind of connection it denotes, is next to be ascertained.

It may be laid down as a general principle, "that, by means of the *relative pronoun*, a clause of a sentence, in which there is a verb, is converted into the nature of an *adjective*, and made to denote some attribute of a substance, or some property or circumstance belonging to the antecedent noun." Thus, when it is said, homo qui prudentia præditus est, the relative clause—qui prudentia præditus est, expresses nothing more than the quality of prudence in concrete with the subject homo, which might have been equally well expressed by the adjective prudens.

Now if a relative clause expresses that which might be expressed by an adjective, the presumption is, that it may be resolved into the same constituent parts. But every adjective contains the powers of an abstract substantive, together with an expression of connection; and may be resolved into the *genitive*

case of that substantive, or into the *nominative* with the particle *of* prefixed, which in English corresponds to the termination of the genitive in the ancient languages. That the member of a sentence, in which there is a relative, may, in every instance, be analysed in the same manner, will be apparent from the following examples. *Vir qui sapit, vir sapiens, and vir sapientia;* "a man who is wise, a wise man, and a man of wisdom;" are certainly phrases of the same import. Again, *homo, cui ingratus est animus, malus fit amicus,* may be translated into Greek, ἀνθρώπος ἀχαριστίας κακός γίνεται φίλος; and into English, "the man of ingratitude is a bad friend."

Thus then it appears, that the *relative pronoun* contains in itself the force of the *prepositive pronoun*, together with that *connection* implied in English by the preposition *of*, and in the ancient languages by the *genitive case*. When one says, *vir sapit qui pauca loquitur*, the relative clause *qui pauca loquitur* expresses that attribute of the man from which his wisdom is inferred: it is conceived by the mind as stripped of its propositional form, and standing in the place of a substantive noun governed in the genitive case by *vir*. The whole sentence might be thus translated, "the man of little speaking is wise;" or, did the use of the English language admit of it, "the man of he speaks little is wise."

We are sensible, that these expressions will appear extremely uncouth and offensive; but we mean not to recommend them as common modes of phraseology. Against their being employed as such, present use loudly remonstrates. They are introduced only with a view to show the true import of the *relative pronoun*; and for that purpose they are well adapted. That pronoun seems to be of use only when there is a deficiency of *adjectives* or *substantives* to denote some *complex attribute* by which we want to *limit a general term or expression*. Where such adjectives or substantives exist in language, we may indeed use the *relative* or not at pleasure. Thus we say, *homo qui grandia loquitur, or homo grandiloquus*; because the *adjective* and the *relative clause* are perfectly of the same meaning. But if the Latins were called upon to translate ἄνθρωπος αἰδοδιδακτός, we believe they must have made use of the *relative pronoun*, as we know not any correspondent adjective in their language.

Some persons have supposed that the *relative* is equivalent to another pronoun, together with an expression of connection of that kind which is denoted by the particle *and*.

But the absurdity of this opinion will appear from the following sentence: "Charles XII. was the only monarch who conquered kingdoms to bestow them on his friends." Here it is evident there is but one proposition, of which the predicate is expressed by the words—"only monarch who conquered kingdoms to bestow them on his friends;" so that the *relative clause* is a *necessary part* of the predicate, and has, like an *abstract noun* in the genitive case, the effect of modifying the general term *monarch*. Resolve this sentence, and you have two propositions, of which the first is a notorious falsehood:—"Charles XII. was the only monarch; and he conquered kingdoms to bestow them on his friends." But instead of *and* substitute of—saying, "Charles XII. was the only monarch of he conquered kingdoms to bestow them on his friends," and you preserve the true import of the expression.

Are there no cases, then, in which the relative may be resolved into the connective *and* with a prepositive pronoun? Undoubtedly there are, and we shall now endeavour to ascertain them.

Adjectives in language have two different effects upon the substantives to which they belong, according to the nature of the attribute which they express. If the attribute expressed by the adjective be competent to all the species of which the substantive is the specific name, it is plain that the adjective does not *modify or limit* the substantive, for this obvious reason, that no-

thing can modify which is not discriminative. Thus, when Horace says, "Prata canis albicant pruinis," the adjective *canis* denotes a quality common to all *boar-frost*; and therefore cannot modify the *substantive*, because it adds nothing to the conception of which that substantive is the name. But when the attribute expressed by the adjective is competent to some *individuals* only of the species of which the substantive is the name, the adjective has then the effect of *modifying or limiting* the substantive. Thus, when one says *vir bonus*, he makes use of an adjective which modifies the substantive *vir*, because it expresses a quality or attribute which does not belong to *all men*.

The clause of a sentence in which there is a *relative*, as it is in every other respect, so is it in this, equivalent to an *adjective*; it either *modifies*, or does not *modify*, the *antecedent*, according as the *attribute* which it expresses is or is not characteristic of the *species* to which the antecedent belongs. Thus, when it is said, "Man, who is born of a woman, is of few days and full of trouble," the relative clause—*who is born of a woman*, expresses an attribute common to *all men*, and therefore cannot modify. In like manner, when we say—"SOCRATES, who taught moral philosophy, was virtuous,"—the clause, *who taught moral philosophy*, does not modify. In both these instances the relative clause might be omitted; and it might be said with equal truth, "Man is of few days and full of trouble,"—and "SOCRATES was virtuous."

But if it be said, *vir sapit qui pauca loquitur*, the relative clause—*qui pauca loquitur*, modifies the antecedent *vir*; for it is not affirmed of *every man*, that he is wise, but only of *such men as speak little*. So—"Charles XII. was the only monarch who conquered kingdoms to bestow them on his friends;" and, "the man that endureth to the end shall be saved;" with many more examples that will occur to every reader.

Now it will be found, that it is only when the relative clause expresses such a property or circumstance of the antecedent as does not limit its signification, that the *relative pronoun* can be resolved into a *prepositive pronoun* with the conjunction *and*, and that in these cases the relative clause itself is of very little importance. Thus in the assertion—"Charles XII. was the only monarch who conquered kingdoms to bestow them on his friends,"—where the relative clause is *restrictive*, the *who* cannot be resolved into *and he* consistently with truth or common sense. But in the expression, "Man, who is born of a woman, is of few days and full of trouble," the relative *who* may be so resolved, at least without violating truth;—"Man is of few days and full of trouble, and he is born of a woman." The only difference between the sentence with the relative *who*, and the same sentence thus resolved,—is—that, in the former case, it contains but *one predication*; in the latter two, and these but loosely connected.

Thus then it appears that the general analysis of the *relative pronoun* is into the particle *of*, and a prepositive pronoun; but that there are also occasions on which it may be resolved into a prepositive pronoun and the particle *and*, without materially altering the sense. Now what is the reason of this distinction?

If the relative clause be equivalent to an *adjective* or to an *abstract substantive* in the genitive case, it is easy to see that the relative itself may, in every instance, be resolved into another pronoun and the particle *of*; but it will not perhaps be quite so evident how it should in any instance be resolved by *and*. This last analysis has its foundation in the nature of the particles *of* and *and*; or, to speak more properly, in the nature of the attribute which the relative clause expresses. Both the particles *of* and *and* are used to link or join conceptions together; but with this difference, that *of* has the effect of making the conceptions it connects figure in the mind as *one object*; whereas the conceptions connected by *and* are still conceived separately

as before. To explain ourselves by an example: Suppose we take two words, *man* and *virtue*, which denote two distinct ideas or conceptions, and join them together by the particle *of*, saying *man of virtue*; the mind no longer views them separately as significant of *two* conceptions, but of *one*. Take the same words, and join them together by the particle *and*, saying *man and virtue*: the conceptions denoted by *man* and *virtue* are still viewed separately as *two*; notice is only given that they are *col- laterally connected*.

This being the case, it follows, that when the relative modifies the antecedent, or, in other words, when the *relative clause* and the *antecedent* denote but *one conception*, the relative must then be resolved by *of*, in order to preserve this *unity of conception*. But when the relative does *not* modify the antecedent; that is, when its clause does not express any *necessary* part of a complex conception; then the conceptions or ideas denoted by the *relative clause* and the *antecedent* may be viewed separately as *two*; and therefore the relative *may* be resolved into the corresponding prepositive pronoun and the particle *and*.

If the clause of the relative be equivalent to an adjective, as in every instance it seems to be, it will naturally occur, that in the ancient languages, the relative should agree with its antecedent, in *gender, number, and case*. They do agree for the most part in *gender* and *number*; in *case* they cannot often, because the very intention of introducing a *relative* into language is to represent the antecedent in a *different case*. Whenever we have occasion to use a *substantive* or *noun* in a clause of a sentence, and afterwards to express by *another clause*, in which there is a verb, an *attribute* of the *object* denoted by that *substantive*, we then employ the *relative pronoun*. Now it seldom happens that the two clauses *admit* of the same *regimen*; and hence the *case* of the *relative* is often *necessarily different* from that of the antecedent, as the case of each must be accommodated to the clause in which it is found. Thus we cannot say, "Deus qui colimus bonus est;" but "Deus quem colimus bonus est;" because the *regimen* of the verb *colo* is always the *accusative*.

This shows the necessity of introducing a relative into those languages which give inflexions to their nouns. Were all the nouns of a language indeclinable, there would be little occasion for a relative; and accordingly in English it is often omitted. Examples are frequent in our best authors. Suffice it to quote the following:

"For I have *business* would employ an age." Jane Shore.

"I had several *men* died in my ship of calentures." Swift.

"They who affect to guess at the *object* they cannot see." Bolingbroke.

We are not ignorant that our most eminent grammarians consider such expressions as chargeable with impropriety; and we are far from recommending them in any dignified or solemn composition. But in the instances adduced there is not the smallest degree of *obscurity*; at least there is none occasioned by the *omission of the relative*. The reason seems to be, that the mind can easily, by an effort of its own, make the *antecedent* unite, first with the one clause, and then with the other. Thus when it is said—"I have *business* would employ an age;" the mind can, without any difficulty, as the word *business* has no inflexions, consider it first as the *objective case* after *have*, and then as the *nominative* to *would employ*: but this cannot be so easily done in the ancient languages, where the termination of the noun is changed by the variation of its cases.

Both in the learned and in the living languages the relative has different *forms*, corresponding to the different *genders of nouns*; and by these it gives notice whether it is applied to *persons*, or to *things without life*. Thus in the English language we say, *The man or the woman who went to Rome*; *The tree which stands on yonder plain*. It admits likewise, when applied to males or females, a variation of cases similar to that of the *personal pronouns*. Thus we say, *The man whose book is now before me*; *The man or woman whom I saw yesterday*: but the neuter admits of no such distinction*; as we say *the tree which I saw*, as well as *the tree which stands on yonder plain*. In modern languages the relative admits not of any distinction to denote *number*: for we say, *The man or the men who came yesterday*; *The man or the men of whom I speak*.

In English, the word *that* is often used instead of the *relative*, as in the following examples: "He is the same man *that* I saw yesterday:—He was the ablest prince *that* ever filled a throne." With regard to the principle upon which this acceptance of the word *that* depends, we offer the following conjecture:

In English, from the cool and phlegmatic arrangement of the language, occasioned by the want of inflexions and conjugations, the place of every part of a sentence is almost uniformly determined, and very little variety is allowed in the collocation of the words. The *adjective* is almost always placed in apposition with its *substantive*, and the *nominative* with its *verb*. In consequence of this uniformity in the collocation of the words, the mind acquires a habit of connecting in idea any kind of *word* with the *place* in which it is used to stand; and is naturally led to consider *every word* that stands in *such a place* as belonging to *such a class*. Hence it is, we imagine, that the definitive *that* passes into the nature of the *relative pronoun*; as in those instances in which it occupies the *place* of the relative, it was natural to consider it as having the same *import*. Yet the word *that* has undoubtedly in itself no more the force of the relative pronoun than *the* or *this*, or any other definitive whatever. In such expressions as the foregoing, it is not improbable that originally the clause of the definitive *that*, which we now call the *relative clause*, was thrown in as a kind of modifying circumstance in the following manner: "The book (I read *that*) is elegant;" where the speaker, finding the word *book* too general for his purpose, throws in a clause to qualify and restrict it, or to confine his affirmation to that particular book which he is then reading. We can easily suppose, that through time the definitive *that* in such an expression might be transposed or removed from its own place to that of the *relative*: so that the expression would run thus, "The book *that* I read is elegant;" which would be considered as precisely equivalent to "The book *which* I read is elegant." This opinion is not a little confirmed by a similar use of the article in Greek, which, though undoubtedly a definitive like the English *the*, is often used instead of the relative pronoun. Numberless examples may be found in *Homer* and *Herodotus*, especially in the latter, who seldom uses what is properly called the relative. We shall produce one instance from each:

Γύσειαι Ατρείδην Αγαμέμνονα, ΤΟΝ περι παύλιον
Ζεύς ενέηκε πειροισι διαίπερις. *Iliad* x. 88.

Οριστοι γαρ υπεγαλονται καλιχρόνο (Αθηναίοι scil.) δεκκ
ελευ κρησεσθαι νομοισι Τ.ΥΣ αν σφισι Σοτων ησικαι.
Herod. Clie.

We have said that the *interrogative* pronouns, as they are called, *who, which, what*, are intimately connected with re-

* "Whose is by some authors made the possessive case of *which*, and applied to things as well as persons; I think improperly." *Lowth*.

Latin; we now affirm, that the *two first* of these words are *nothing* but relatives, and that the *last* contains in itself the united powers of a *relative* and *definitive*. With respect to *cases, number, and gender*, the words *who* and *which*, when employed as *interrogatives*, differ not from the same words when employed as *relatives*; and we hold it as a maxim, without which science could not be applied to the subject of language, that the *same word* has always the *same radical import* in whatever different situations it may be placed. To understand this, it is necessary to observe, that all men have a natural propensity to communicate their thoughts in the fewest words possible: hence it follows, that words are often omitted which are necessary to complete the construction of the sentence; and this no where happens more frequently than in the use of *who* and *which*. In sentences where these words are confessedly *relatives*, we often find them without an antecedent; as,

“*Who* steals my purse, steals trash.” *Shakespeare.*

“Which *who* would learn, as soon may tell the sands.”
Dryden.

“*Qui Bavianum non odit, amet tua carmina, Mævi.* Virg.

That is, “*He* who steals my purse, &c. ;” “Which *he* would learn as soon, &c. ;” and “*Ille qui Bavianum non odit,*” &c. Such abbreviations occasion no obscurity, because from previous circumstances the hearer knows the mind of the speaker and the persons to whom he refers. But it is not with respect to the *relative* and *antecedent* only that such abbreviations have place: in sentences of a different form, whole clauses are sometimes omitted, while the meaning of the speaker is made sufficiently plain. Thus when king Richard III. having lost his horse in battle, exclaims—“*A horse! a horse! my kingdom for a horse!*” there is no complete thought *expressed*; but the circumstances in which the king then was, enabled those about him to understand that he *wanted a horse*. Accordingly Catesby answers him—“*Withdraw, my lord, I’ll help you to a horse.*”

In like manner when a person asks a question, his expression is frequently incomplete; but the tone of his voice, or some other circumstance, enables us to ascertain his meaning, and to supply, if we please, the words that are omitted. Thus when it is said, *An fecisti?* nothing more is *expressed* than, *If you did it* (the Latin *an* being nothing else but the Greek *an si*); but some circumstance enables the person who hears it to know that the meaning is, “*Say if you did it.*” Let us apply these observations to the words *who* and *which*. If these words be *relatives*, and if our analysis of the relative be just, it is obvious, that no *complete* meaning can be contained in the clause, “*Who* is your principal friend?” for that clause contains nothing more than the circumstance of *being your principal friend* predicated of some *unknown* person; “*of he* is your principal friend.” That this is indeed the case, every man may be convinced, by asking himself what he means by the interrogative *who* in such a sentence; for he will find it impossible to affix to it *any* meaning without supplying an *antecedent clause*, by which that which is *called* an *interrogative* will be immediately converted into the *relative pronoun*. The custom, however, of language, and the tone of voice with which the *relative clause* is uttered, intimates, without the help of the *antecedent*, the wish of the speaker to be informed by the person addressed of the name and designation of his principal friend; and we know that the sentence when completed is, “*Tell me the name and designation of the person who is your principal friend.*” Again, when the prophet says, “*Who* is this that cometh from Edom, with dyed garments from Bozrah?” he utters but *part* of a sentence, which when completed will run thus: “*Describe the person who cometh from Edom (this is that person), with dyed garments from Bozrah.*”

He *sees* a person coming from Edom, of whose name and designation he is ignorant; he calls upon some one for information concerning these particulars; and that there may be no mistake, he describes the unknown person as having *dyed garments from Bozrah*; but lest even that description should not be sufficiently accurate, he throws in the definitive clause, *this is that person*, pointing at him, we may suppose, with his finger.—*Which*, used as an interrogative, indicates a wish of knowing a particular person or thing out of more than one mentioned; as, “*Which* of the two did it?” that is, “*Tell me the one of the two which did it?*” for in old English *which* as a *relative* is often used, where in modern English we should say *who*; and that mode of speech is still retained when the antecedent is omitted, and the relative clause employed to indicate such a wish as that before us. *What* includes in itself the signification of a *definitive* and a *relative pronoun*; as, “*from what* has gone before, *what* follows may easily be guessed;” where the word *what* is equivalent to *that which*. When therefore we say, “*What* rude fellow is that?” our meaning is, “*Describe that person who is that rude fellow.*” Upon the whole, then, it is evident, that the words called *interrogatives* are merely *relative pronouns*; and that interrogative sentences are *relative clauses* uttered in such circumstances as to enable the hearer to supply the antecedents necessary to complete the meaning.

To conclude: We have seen that *SUBSTANTIVES* are either *primary* or *secondary*; or, in other words, *NOUNS* or *PRONOUNS*. *NOUNS* denote *substances*, and those either *natural, artificial, or abstract*. They moreover denote things either *general, or special, or particular*; and a *general* or *specific* name is made to denote an *individual* by means of words called *articles* or *definitives*. *PRONOUNS* are the substitutes of *NOUNS*, and are either *prepositive* or *subjunctive*. The *PREPOSITIVE* is distinguished into *three* orders, called the *first*, the *second*, and the *third* person. The *SUBJUNCTIVE*, otherwise called the *RELATIVE*, includes the powers of all those three, having *superadded* as of its own the peculiar force of a *connective*.

CHAPTER IV.

ON VERBS.

OF all the constituent parts of speech none has given the grammarians greater trouble than the *VERB*. Every schoolboy is told that the words, *IS, LOVETH, WALKETH, STANDETH*, in *English*; and *EST, AMAT, AMATUR, AMBULAT, STAT*, in *Latin*, are *VERBS*: he knows likewise that they are of different *kinds*; that some of them are said to be *active*, some *passive*, and some *neuter*. But it should seem, that the first object of our investigation ought to be the *characteristic* of the verb, or that which all these words have in *common*, and which constitutes them *VERBS*, distinguishing them from *every other species of words*. Now what does distinguish these verbs from nouns? It is affirmation or assertion, according to a generally received notion: then as all languages have verbs, we are to expect that this property of affirming, the essential of the verb, will not universally exist without the verb. But our first enquiry after verbs strikes us in an extraordinary manner. The Hebrew language wants that essential *is* or affirmative quality, when it joins the predicate to the subject with affirmation. Thus in English we say, “*Happy is* the man; the fear of God *is* the beginning of wisdom;” but this supposed essential verb is not to be found in Hebrew. *Happy the man. The fear of the Lord the beginning of wisdom.* To prove the position that affirmation is the essential attribute of the verb, the following reasoning has been used:

Should we be required to exemplify our theory by language, and to produce instances of this simplified verb in practice, we might answer, that the not being able to produce such instances would be no good argument against the truth of our principles.

It is the nature of language to express many circumstances by the same word, all of which however are not *essential* to distinguish the *species* to which that word belongs from the *other species* of words; and it is the nature of man to *infer* from discourse many things which are not *actually expressed*. Perhaps, however, something nearly approaching to an exemplification of our idea of a *simple verb* will be found in the following proposition: "The three angles of every plane triangle *are* equal to two right angles." What other office the verb *are* here performs than simply to join the *subject* and *predicate*, it is difficult to perceive. It does not give notice of *time*; or such notice, if given, is an imperfection; for the truth of the proposition is independent on time. Neither ought it to imply *existence*; for the proposition would be true, were there neither a triangle nor a right angle in nature.

Now the fact is, that the word *are* does mean existence, and existence only; and it is the word *equal*, which modifies the peculiar mode of the existence of the three angles.

Again in the English and the Hebrew languages, many words are at the same time acknowledged to be both nouns and verbs. The word *love* is a noun and a verb: but how by placing the pronoun *I* before *love*, does the latter acquire this affirmative quality? *Love is sweet*: *sweetness* is evidently affirmed of *love*: but when we say, "We love," how do we alter the nature of the noun but by joining the quality to ourselves? The word *love* is evidently the same in both cases, and the affirmation is not in the word itself, but understood. For this is equally good sense, "We affirm we love," which would make sad tautology if affirmation was also in love.

It has been said, and the assertion may very easily be maintained, that in all languages the radix of the verb is always a noun. It is so frequently apparent in English, that there is sufficient ground for enquiry. In Hebrew also the same analogy holds us out. In English the pronoun is separated from the verb. In Hebrew we see clearly that it is joined to it in general by abbreviation, either before or behind the verb. Hence the *o* and the *s* terminating *amo amas*, are probably the abbreviations of *ego* and *su*; and though we cannot ascertain precisely the meaning of every termination in the verbs of various languages, with increased knowledge it may perhaps be acquired.

Supposing then that the noun and the verb are in the radix exactly the same, let us examine the changes to which they are subject in consequence of their different appellation. The noun has cases, the verb has tenses. These tenses denote the different times in which a person or thing may be said to exist; also to every verb it is found that the pronoun is or may be applied; and hence perhaps we may be led to conclude, that the verb is a noun only which is capable of personal application at different times. *Desire* may be made a verb, because it can be applied to ourselves at this moment, or at a time past—*we desired*. *Globe* cannot become a verb, because though we may make a globe, be in a globe, &c. as yet it does not express a quality which can belong to persons, and it retains unchangeably its own qualities. Hence we shall not be at a loss to determine in our own language what are verbs and what are not: and the same may be applied to the infinitives of other languages, on which the learned have not determined, whether they are characteristics of the verbs, or no verbs at all.

The verb then requires *time* and *person*, the substantive does not. If the whole human race had never existed, and consequently *time* had not been the substantive, *earth* as well as the substance itself might have been the object of contemplation. Now *time*, if we speak of any event, is either *past* or *future*: and to express these tenses something must be done in the connection of the pronoun and the noun. To express *past time*, the Hebrew language places the pronoun after the noun: to express the *future*, it places the pronoun before the noun. The

English language expresses but imperfectly the *times*, and is consequently obliged to call in auxiliary verbs; it adds a syllable to the noun to express the *past time*. The Latin and Greek languages go beyond the necessity of the case, and modify the periods of *past* and *future time*.

From not attending to the nature of time in itself, philosophical grammarians, as they are called, have endeavoured to ascertain the number of *times* or *tenses*, which must be expressed by some means or other in every language. As a matter of speculation it may amuse them: they find no language agreeing with their theory, nor upon their principles can any number of tenses beyond the *past* and the *future* be allowed, which may not be doubled or trebled at pleasure. The modifications of the *past* and *future* are infinite; and different methods are used in different languages to express some of these modifications. In these modifications consists much of what is called the idiom of the language; and which, in learning a language, ought particularly to be attended to. From want of this attention, an Englishman makes continual mistakes between the *etois* and the *fus* of the French: and the translators of the Bible, from a similar want of care, or ignorance of the structure of the English and Hebrew verbs, show in a thousand instances, that they were manifestly incompetent, in this respect, for the task which they had undertaken.

Our grammars having been constructed on those of the Greek and Latin languages, a certain variation in verbs is said to take place in our language, called *moods*; but though from *amo* we have *ama, amem, amarem*, &c. yet no such change is to be found in the corresponding verb *love*. We can express the same ideas in English as in Latin: but we do not do it by *moods*, nor is a number of moods essential to any language. In English and Hebrew we see nothing like the variety of the Greek and Latin. One *mood*, if it may be so called, is necessary: the *indicative mood*; if we allow more, we can see no reason for stopping. The Latins may express by *amem*, what the English express by *I may or can love*; and consequently the English has the advantage in precision: but *I may love or can love* is indicative of possibility applied to the quality in the person, and the *I may or I can* is to be found in the *em* of the Latins. *Mood* of verb has been defined to be a concise mode of expressing some of those combinations of thoughts "which occur most frequently and are most important and striking." The definition will certainly apply to the languages which have *moods*; but of them it may perhaps be justly said, that by an addition to the radix of the verb, which is an abbreviation of some definite verbs formerly in use, several languages express certain combinations of ideas, which in other languages, from this abbreviation not having taken place, are expressed by the use of other verbs applied to the principal verb.

The Greek and Latin languages have a certain variation in their verb, which goes by the name of *voices*; and hence it has been inferred that these *voices* are essential to language: but when we come to the true philosophy of language, that is, the comparison of various languages now in or which formerly had been in existence, we shall scarcely find that any two languages agree together in the number of voices. Thus the Hebrew, in the opinion of some, has three; of others, has five voices: the Greek has three, the Latin two, the English certainly only one. These *voices* are in general distinguished from the nature, as it is called, of action or suffering; and all verbs are to be reduced to one of three classes—*acting, suffering*, or neither the one nor the other. Such a division may very well suit this or any other subject: the verb must be or not be any given thing, that may be proposed. There cannot be a doubt, that many verbs imply action, and the *agent* may become the *patient*, and he may suffer either from himself or another. Thus for the verb *beat*: *A beats B*; *A is beaten by B*; or *A beats himself*;

instead of using the verb *is*, and the noun *himself*, these parts may be comprehended in the inflection of the verb, but this modification of the verb can apply only to a small class of words relating to actions. What are we to do with such verbs as *sleep* and similar ones? They must be called *neuters*; but then this class of neuters may be made very large, and verbs may be introduced which, if known to the Greeks and Latins, have not been formed in a separate class. Thus *to act* and *to cause to act*, may be distinguished in the verb as in the Hebrew language: and instead therefore of classing the verbs under three voices, *active, passive, and neuter*, we should perhaps look rather to the idiom of each language, and from that discover the changes made on the radix of the verb, to which if we please the name of *voice* may be applied. Thus in parts of action, where the agent may become the patient, there are evidently two states of the person. *I beat*, or *I am beaten*; which may be distinguished by the names of the *active* and the *passive voice*. *I beat myself*, the reflex voice in use among the Hebrews. *I cause to beat*, the causative voice in use in Hebrew: and there may be modifications without end in other languages, to which in a similar manner the name of *voice* may be applied. Since the English requires the use of another verb to express those states of the person which in other languages are implied by the form of the verb, this distinction of voices is superfluous, and should not be admitted into the grammar of the language.

Though the English language exceeds much in simplicity, with respect to voices, either the Latin, Greek, or Hebrew languages; yet there is an addition to the radix, which is analogous to a change in the verb of other languages, going by the name of *participles*. Of these participles we have two; in general called *participles of the present*, and *participles of the past*; *loving, loved*; *learning, learned*. They are called *participles* because they partake of the nature of the verb. *Loving, learning*, may be applied to persons, as may *loved, learned*, the former implying the actual existence of the quality in the person at the time spoken of; the latter that the quality had existed in the person. *He is learning English*, or *he has been learning English for some time past*. The present tense of the English language being rather an indefinite tense, this participle is also indefinite: learning in both of the above instances showing that the quality was existing in the man for an indefinite time. In the sentences, "he is loved," or, "he has been loved," the participle *loved* shows that the quality had existed in the man at a former period; "he has been loved," namely, at a distant time; "he is loved," implies that the person at the present time is one who had love, and no intimation being given that the love of him ceased to exist, it naturally follows that we presume he will continue to be beloved. In all languages the participle has thus the circumstance of time attending the quality expressed, which may belong to a person; and hence it differs from another class of words generally called *adjectives*.

CHAPTER V.

On ADJECTIVES.

Nouns we have said are words, by which objects are denominated, and which distinguish them from one another without marking their quality; and hence as these objects have a vast variety of qualities by which they may be compared together, there must be words to express these qualities only, and these words are called *adjectives*. Thus of apples we may say, "This is a sweet apple, that a sour apple." The words *sweet* and *sour* are adjectives. Since the adjective is the word expressing the quality of some object, it can have no meaning by itself, and requires the presence or the implied presence of the substantive; and hence in some languages a change takes place in the adjective according to the nature of the substantive, which is very perplexing oftentimes to a learner. In English, agreeably to the

simplicity of its noun, there is no such change: in most other languages the adjective varies its termination according to the gender or the number of the substantive to which it is applied.

Qualities admit of intensity or remission. One apple may be four, but another may have more of that quality; and hence in some languages a distinction is made of comparison, and that by degrees, which sometimes are called the *comparative* and the *superlative* degrees. These degrees are expressed by an addition to the adjective, in English as *four, fourest, fourst*, or by applying the words *more* and *most*, as *more delightful, most delightful*; and from those different ways of expressing the same thing in the same language, it is evident that the confining of adjectives to two degrees is superfluous in the philosophy of language, and that we may expect to find some language, in which this classification does not take place. This is the case in the Hebrew language, to which of all others the English approaches nearest in simplicity. If we allowed of these degrees in general, there would be no end to the classes: if one is allowed for adjectives which denote a quality greater, there should be another for a quality less; *more delightful, less delightful*, would be two classes of the comparative, and the superlative is evidently a comparative of greater intensity.

Since adjectives express qualities, and therefore cannot be used without the substantives expressed or implied, we may now see why participles should frequently be taken for, or seem to pass into the class of adjectives. "A learned man is never esteemed by a man whose claim to distinction is founded on his wealth or his rank." In this sentence, *learned* may be considered as an adjective, because from long use the quality only is expressed without reference to time. From having learned, the man is supposed to possess a quality which distinguishes him from others, and this quality is seen when placed in opposition to others who have not had the same advantages. They are called *rude, barbarous*. Thus we say, "A rude man and a learned man are opposites;" where *rude* is acknowledged at once to be an adjective, and *learned* is considered of the same class, because it is significant only of quality without reference to time.

The name of *adverbs* is given to a class of words in most languages, such as to the words *exceedingly, awhile, olim, éti*, and the like; and as adjectives are called the *attributes of substances*, these adverbs are called *attributives of the second order*, because they modify the attributes. Unfortunately in all languages a number of words is placed in this class, which strike the observer at first sight to be compound words. Thus, notwithstanding in the English, *pendant* in the French, are evidently compounds. *While* is a substantive, meaning time, as is *éti* of the Greeks. *Wisely* is a compound of two adjectives, and we may say, "He speaks wisely," or "He speaks like a wise man," indifferently; the use of the adverb, as it is called, giving conciseness only to the expression. This class of words was formed from the ignorance of the parts in every compound; thus if, instead of *like a wise man*, we translate the phrase into Latin, and use the word *sapienter*, this *sapienter* is immediately classed as an adverb or something distinct from the adjective or verb; yet the *er* probably has the same force with the *ly* in our own tongue.

We may modify the quality expressed by a verb or a noun various ways. A high mountain may be called, "An exceedingly high mountain;" where *exceedingly* is applied to *high*, *high like exceeding*, namely, most mountains we know. "He suffers patiently;" namely, "Like a patient man." "While the country was alarmed by spies and pretended plots, the alarmists were really attacking the lives and property of their fellow-countrymen." *While* is called an adverb, but it is a substantive; and we frequently say, "All the while, i. e. all the time;" *while* therefore means *during the time*; *really* is *like real men*, and is in opposition to *pretended*. In all languages therefore where this class is admitted, the student should en-

deavour to learn the force of the word not by fanciful modifications of verbs and adjectives in a variety of senses, but by learning the real meaning of the word. For our language we may shortly expect to see great improvement made in this branch of our science, as it will afford great scope for the researches of our best, and we might almost say, our only grammarian.

CHAPTER VI.

On CONJUNCTIONS, PREPOSITIONS, and INTERJECTIONS.

Conjunctions and prepositions come next in the general division of words. Conjunctions are words which are to "connect words, either two or more words in a sentence, or to make of two simple sentences one compound sentence." This is the general account: but unfortunately, we stumble at the next step without having enquired after any of these words, for these conjunctions are immediately after divided into two classes,

the one called *connective*, and the other *disjunctive*; that is, on^e class of these connecting words, instead of connecting, disjoinⁿ and so many other equally fanciful distinctions take place, that instead of following such absurdities, let us hearken to plain sober sense, whose dictates are confirmed by matter of fact and experiment. There are certain words in all languages, which by frequent repetition have lost their original form, and their meaning is not obvious. Such are the words *if*, *and*, *because*, *or*. From their meaning not being known, fanciful writers have supposed them to have no meaning at all, and that they were mere sounds to connect or disjoin, were continuative, subcontinuative, collective, &c. &c. But Mr. H. Tooke has shown us, that many of these words are the imperatives of old Saxon verbs; and the Hebrew language is a confirmation of his theory. We shall subjoin his table, which will save the trouble of many tedious metaphysical enquiries.

IF	} Are the Imperatives	GIF	} Of their Respective Verbs	GIFAN	To give.
AN		AN		ANAN	To grant.
UNLESS		ONLES		ONLESAN	To dismiss.
EKE		EAC		EACAN	To add.
YET		GET		GETAN	To get.
STILL		STELL		STELLAN	To put.
ELSE		ALES		ALESAN	To diminish.
THOUGH		THAFIG		THAFIGAN	} To allow.
OR		OR		OR	
THO'		THAF		THAFIAN	} To boot, to superadd.
BUT		BOT		BOTAN	
BUT		BE-UTAN		BEON-UTAN	To be out.
WITHOUT		WYRTH-UTAN		WYRTHAN-UTAN	To be out.
AND		AN-AD		ANAN-AD	Dare congeriem.

LEST is the participle LESED of LESAN, to dismiss.

SINCE	} is the participle of SEON, to see.	SITHTHAN
		SYNE
		SEAND-ES
		SITHTHE
		OR
		SIN-ES

THAT is the article or pronoun THAT.

AS is ES, a German article, meaning *it*, *that*, or *wobich*. And

SO is SA or so, a Gothic article of the same import with AS.

From considering the above table, and referring to a similar derivation in other languages, we have reason to believe, that there is no such separate class as conjunctions or words without meaning, to connect and disjoin, but that the connection or disjunction is to be found in the meaning of the word.

If we are right in our opinion with respect to conjunctions, we shall naturally be little inclined to admit prepositions as another class of words without meaning, to unite two "words of meaning together, which without this assistance could not coalesce." We shall look to derivation for the meaning of these words; and if we have any grounds for giving them a meaning, we shall class them accordingly. Let us try then with the supposed prepositions, *with*, *without*, *chez*, *χωρις*, *sonder*.

Witb means, in all cases where it is employed, addition; *without*, the contrary. "The king of England, with the lords and commons, can make a law: without the lords and commons, cannot make a law." Join the lords and commons to the king, and his act is good: take them away, and in law-making he becomes a cypher. There is an Anglo-Saxon verb, *witban*, whose imperative is *witb*; this imperative we say remains in use in what is called the preposition *witb*; the other parts of the verb are obsolete. *Without* comes from the Saxon *wyrthban-utan*, *be out*. Thus in French *avec*, corresponding to our *witb*, is from the imperative of *avoir* and the adjective *ce*, *have that*. *Chez* is called a preposition in French; but it is in reality a corruption

of *casa*, "a house;" *chez moi*, "at my house." *χωρις* may very reasonably be referred to *χωριζω*, when *sonder* of the Germans, of similar import, seems to have the same relationship to *sondern*, the verb.

THOROUGH, THOUROUGH, THOROW, THROUGH, or THRO', is no other, says *Horne Tooke*, than the Gothic substantive DAURO, or the Teutonic substantive THURUH, and, like them, means *door*, *gate*, *passage*. So that the sentence cited by him, resolved upon his principles, stands thus: "The splendid sun—JOIN his beams—genially warmeth—PASSAGE the air, (or, the air being the *passage* or *medium*)—the fertile earth." And in the same manner may we translate the preposition *through* in every instance where *through* is used in English, or its equivalent preposition in any language; as from the Latin and Italian word *porta* (in Spanish *puerta* and in French *porte*), have come the Latin and Italian preposition *per*, the French *par*, and the Spanish *por*.

UP, UPON, OVER, BOVE, ABOVE, have all, says *Horne Tooke*, one common origin and signification. In the Anglo-Saxon, UFA, UFERA, UFEMÆST, are the *adjectives* ALTUS, ALTIOR, ALTISSIMUS. UFA or UFAN, *up*; comparative UFERA, OFERE or OFER, *over*, or *upper*; superlative UFEMÆST, *upmost* or *uppermost*. BEUFAN, BUFAN, ON-BUFAN, *bove*, *above*. If this be a just account of the origin of these words, the sentences in the text, where *upon*, *over*, and *above*, occur, will run thus: "The

statue stood ON HIGH a pedestal;" "the river ran HIGHER a sand;" "the sun is risen ON HIGH the hills." And here we may observe, that the mere relation between *standing*, *running*, &c. and *place*, is rather *inferred* from the *verb itself*, than expressed by a *separated word*; and the reason is obvious. For if a statue *stand*, every one knows that it must stand on *some* thing as well as *at* some time. There is therefore no *necessity*, whatever *elegance* there may be in it, for employing any word to denote that *relation*, which is commonly believed to be signified by *on*; but it is *necessary* to insert, between the *verb* and *pedestal*, a word significant of *place*, that *pedestal* may not be mistaken, by an ignorant person, for a *portion of time*, or any thing else connected with the *standing of the statue*.

Hence we may see the absurdity of a sentence given sometimes by our judges. The man shall stand in and upon the pillory: by which they do not mean two distinct placings of the convict, though the words themselves do; but this is one only out of the thousand instances of the absurdity in the courts of law, of giving sanction to an absurd precedent, instead of correcting every absurdity the moment it is detected.

Having thus restored meaning to our prepositions and conjunctions, we come to the last part of the general division of words in modern grammars, to the class of *interjections*, on which we shall make use of good authority. "The neighing of a horse, the lowing of a cow, the barking of a dog, the purring of a cat, sneezing, coughing, groaning, shrieking, and every other involuntary convulsion and oral sound, have almost as good a title to be called parts of speech as *interjections*. In the intercourse of language, *interjections* are employed only when the suddenness or vehemence of some affection or passion returns men to their natural state, and makes them for a moment forget the use of speech: or when, for some circumstance, the shortness of time will not permit them to exercise it." It is pleasant to observe, what curious words, nay sentences, are placed by writers in the class of *interjections*. Thus Dr. Beattie ranks *strange*, *prodigious*, *amazing*, *dear me*, in this class; and we may go on with this author in making a pretty list. Thus *God damn you* is an infamous *interjection* common to the English, but it still is a sentence. *Od's blood and ounds* is used by many with little meaning, though the phrase has a very strong meaning, and was introduced into common use by the ignorance and folly of our forefathers, who supposed that *God* could have *blood and wounds*. In general the *interjections* are inarticulate sounds, which have nothing to do with speech, and may be significant of *pleasure* or *pain*, *surprise*, &c. A *laugh*, or a *shriek*, or a *sneeze*, will intervene in conversation: but they cannot, either of them, come into any division of words.

Upon the whole then we may observe of *grammar*, that as a science it is at present very defective: instead of making an intimate acquaintance with a variety of languages the basis of a general theory, most writers have employed themselves in

what are called metaphysical disquisitions, and the result of their speculations has been frequently contradicted by a plain reference to matter of fact in the languages with which they were unacquainted. It seems natural to suppose, that language in its origin must have been very imperfect: that signs were frequently used to give signification to men's words, just as difference of the tone of the voice makes now a difference in the meaning of the same sentence. Objects in nature were first expressed by certain sounds; qualities were observed in them which were imitated by sounds, as the hissing of the snake: words were connected together into sentences, and after a considerable length of time, words which occurred very frequently suffered abbreviation. Hence imperfect ideas were annexed to many words; the art of speech was abused: it frequently did not convey the ideas of the speaker, and was intended to deceive the hearer.

As most knowledge is communicated by language, it is evidently incumbent that the principles of it should be well understood: and hence the first requisite is to instruct the learner in the meaning of every word, and to shew how, by various processes, it came to lose some part of its original meaning, to have more or fewer ideas annexed to it. This is not a trifling knowledge in itself; when we consider that the perfect knowledge of any science will imply a knowledge of all the objects with which that language is conversant; and an accuracy and precision in the thoughts of every educated man will be the consequence of the first principles of his education. But there are many obstacles to the promotion of this science, among which we do not know a greater than the practice of the law at present in England. In this profession there is an affectation of accuracy in the use of words; but, from the want of studying the principles of language, by a multiplicity of words, oftentimes of a contradictory nature, the judges and barristers envelop a plain matter in the utmost obscurity. This obscurity is increased by the retaining of antient laws, which ought to be modernized: by paying the profession according to the number of words employed, instead of the judgment and mode of sagacity exercised. We might add, that the drawing up acts of parliament must necessarily injure our language: they should not be intrusted to a technical lawyer, but to a master of language. Moliere's housekeeper would be a better judge of the propriety of a sentence than a lord chief justice.

To understand the theory of language, then, we must do as in other sciences, make experiment the basis of our proceedings. We must not make distinctions in our language, because such are necessary in another. We must attend to the structure of each particular language, and from combining together the various facts in which they all agree, we may at last form our notions into principles, and lay the foundation of UNIVERSAL GRAMMAR.

G R A

GRAMMARIAN, one that is skilled in or teaches grammar. Anciently the name *grammarian* was a title of honour, literature, and erudition, being given to persons accounted learned in any art or faculty whatever. But it is otherwise now, being frequently used as a term of reproach, to signify a dry plodding person, employed about words and phrases, but inattentive to the true beauties of expression and delicacy of sentiment. The ancient grammarians, called also *philologers*, must not be confounded with the grammatists, whose sole business was to teach children the first elements of language. Varro, Cicero, Messala, and even Julius Cæsar, thought it no dishonour

G R A

to be ranked grammarians, who had many privileges granted to them by the Roman emperors.

GRAMMONT, a town of France, in the department of Upper Vienne and late province of Limosin, remarkable for its late abbey, which was the chief of the order. It is 15 miles N. E. of Limoges. Lon. 1. 30. E. Lat. 46. 1. N.

GRAMMONT, a town of Austrian Flanders, seated on the river Dender, 18 miles N. E. of Tournay, and 17 S. E. of Ghent. Lon. 3. 59. E. Lat. 50. 47. N.

GRAMPIAN-HILLS; a chain of high mountains in Scotland, which run from east to west almost the whole breadth of

the kingdom. They take their name from only a single hill, the *Mons Grampius* of Tacitus, where Galgacus waited the approach of Agricola, and where the battle was fought so fatal to the brave Caledonians.

GRAMPOUND, a small borough in Cornwall, with a market on Saturday. It is seated on the river Valles, and the inhabitants have a considerable manufacture of gloves. It is 46 miles S. W. of Launceston, and 244 W. by S. of London. Lon. 4. 49. W. Lat. 50. 22. N.

GRAMPUS, in ichthyology; a species of delphinus. See **DELPHINUS**.

GRANADA, a province of Spain, bounded on the N. and W. by Andalusia, on the E. by Murcia, and on the S. by the Mediterranean Sea. It is about 175 miles in length, and 75 in breadth; is a mountainous country, and yet the soil is good; but it has not been well cultivated since the Moors were expelled from it in 1492. However, it produces corn, wine, oil, sugar, flax, hemp, excellent fruits, honey, wax, grapes, and mulberry-trees, which feed a great number of silk-worms. The forests produce gall-nuts, palm-trees, and oaks. Granada is the capital.

GRANADA, a large, handsome, and delightful city of Spain, capital of the kingdom of Granada, with an archbishop's see, and a university. It is built on four hills, and divided into four parts, in one of which is the large church, containing the tombs of Ferdinand and Isabella, who took this place from the Moors in 1492. In another is a palace of the kings of Spain, and an ancient palace of the Moorish kings, with so many rooms, that it is like a labyrinth; in the third the university stands; the fourth has nothing considerable: but all the public buildings are very magnificent. It is seated not far from the river Oro, near its confluence with the Xenil, 125 miles S. W. of Murcia, and 225 S. of Madrid. Lon. 3. 30. W. Lat. 37. 8. N.

GRANADA, an island in the W. Indies, the principal of the Granadillas, or Granadines, situated in 61. 40. W. lon. and between 11. 55. and 12. 23. N. lat. It is the last of the Windward Caribbees, and is 30 leagues to the N. W. of Tobago. The chief port, called Lewis, is on the W. side, and is very spacious. This island is finely wooded; and the soil is suited to produce sugar, tobacco, and indigo. It was taken from the French in 1762, confirmed to the English in 1763, taken by the French in 1779, and restored to the English in 1783.

GRANADA, a town of N. America, in the province of Nicaragua, seated on lake Nicaragua, 70 miles from the South Sea. It was taken twice by the French buccaneers, and pillaged. The inhabitants carry on a great trade by means of the lake, which communicates with the Atlantic Ocean. Lon. 87. 0. W. Lat. 11. 28. N.

New GRANADA, a province of S. America, in Terra Firma, about 75 miles in length, and as much in breadth. It is bounded on the N. by Carthagena and St. Martha, on the E. by Venezuela, on the S. by Popayan, and on the W. by Darien. It contains mines of gold, copper, and iron; horses, mules, good pastures, corn, and fruits. Santa-Fe-de-Bagota is the capital.

GRANADILLOES, the name of some islands of the Caribbees, in America, having St. Vincent to the north and Granada to the south. They are so inconsiderable that they are quite neglected; but were ceded to England by the treaty of peace in 1763.

GRANADIER, a soldier armed with a firelock, a bayonet, and, occasionally, a pouch full of hand-granadoes. They wear high caps, are generally the tallest and briskest fellows, and are always the first upon all attacks. Every battalion of foot has generally a company of granadiers belonging to it; or else four or five granadiers belong to each company of the battalion, which, on occasion, are drawn out, and form a company of themselves. These always take the right of the battalion.

GRANADO or **GRENADÉ**, in the art of war, a hollow ball or shell of iron or other metal, of about 2½ inches diameter, which being filled with fine powder, is set on fire by means of a small fuse made of well-seasoned beech-wood, driven into the fuse-hole, and thrown by the grenadiers into those places where the men stand thick, particularly into the trenches and other lodgements made by the enemy. As soon as the composition within the fuse gets to the powder in the granado, it bursts into many pieces, greatly to the damage of all who happen to be in its way. Granadoes were invented about the year 1594. The author of the Military Dictionary has the following remark on the use of granadoes. "Grenades have unaccountably sunk into disuse; but I am persuaded there is nothing more proper than to have grenades to throw among the enemy who have jumped into the ditch. During the siege of Cassel under the Count de La Lippe, in the campaign of 1762, a young engineer undertook to carry one of the outworks with a much smaller detachment than one which had been repulsed, and succeeded with ease from the use of grenades; which is a proof that they should not be neglected, either in the attack or defence of posts."—The word Granado takes its rise from hence, that the shell is filled with grains of powder, as a pomegranate is with kernels.

GRANARD, a borough, market, fair, and post town in the county of Longford, province of Leinster; it gives title of earl to the family of Forbes; situated 52 miles from Dublin, and about 16 north east of Longford. N. lat. 53. 44. W. long. 7. 30.

GRANARY, a building to lay or store corn in, especially that designed to be kept a considerable time. Sir Henry Wotton advises to make it look to the north, because that aspect is the coolest and most temperate. Mr. Worlidge observes, that the best granaries are built of brick, with quarters of timber wrought in the inside, to which the boards may be nailed, with which the inside of the granary must be lined so close to the bricks, that there may not be any room left for vermin to shelter themselves. There may be many stories one above another, which should be near the one to the other; because the shallower the corn lies, the better it is, and more easily turned.

The two great cautions to be observed in the erecting of granaries are, to make them sufficiently strong, and to expose them to the most drying winds. The ordering of the corn in many parts of England, particularly in Kent, is thus: To separate it from dust and other impurities after it is thrashed, they toss it with shovels from one end to the other of a long and large room; the lighter substances fall down in the middle of the room, and the corn only is carried from side to side, or end to end of it. After this they screen the corn, and then bringing it into the granaries, it is spread about half a foot thick, and turned from time to time about twice in a week; once a week they also repeat the screening it. This sort of management they continue about two months, and after that they lay it a foot thick for two months more; and in this time they turn it once a week, or twice if the season be damp, and now and then screen it again. After about five or six months they raise it to two feet thickness in the heaps, and then they turn it once or twice in a month, and screen it now and then. After a year, they lay it two and a half or three feet deep, and turn it once in three weeks or a month, and screen it proportionably. When it has lain two years or more, they turn it once in two months, and screen it once a quarter; and how long soever it is kept, the oftener the turning and screening is repeated, the better the grain will be found to keep.—It is proper to leave an area of a yard wide on every side of the heap of corn, and other empty spaces, into which they turn and toss the corn as often as they find occasion. In Kent they make two square holes at each end of the floor, and one round in the middle, by

means of which they throw the corn out of the upper into the lower rooms, and so up again, to turn and air it the better. Their screens are made with two partitions, to separate the dust from the corn, which falls into a bag, and when sufficiently full this is thrown away, the pure and good corn remaining behind. Corn has by these means been kept in our granaries 30 years; and it is observed, that the longer it is kept the more flour it yields in proportion to the corn, and the purer and whiter the bread is, the superfluous humidity only evaporating in the keeping. At Zurich in Swisserland, they keep corn 80 years, or longer, by the same sort of methods.

The public granaries at Dantzick are seven, eight, or nine stories high, having a funnel in the midst of every floor to let down the corn from one to another. They are built so securely, that though every way surrounded with water, the corn contracts no damp, and the vessels have the convenience of coming up to the walls for their lading. The Russians preserve their corn in subterranean granaries of the figure of a sugar-loaf, wide below and narrow at top: the sides are well plastered, and the top covered with stones. They are very careful to have the corn well dried before it is laid into these storehouses, and often dry it by means of ovens; the summer dry weather being too short to effect it sufficiently.—Dantzick is the grand storehouse or repository of all the fruitful kingdom of Poland. The wheat, barley, and rye, of a great part of the country, are there laid up in parcels of 20, 30, or 60 lasts in a chamber, according to the size of the room; and this they keep turning every day or two, to keep it sweet and fit for shipping. A thunder storm has sometimes caused very terrible consequences to these stores. All the corn of the growth of former years having been found so much altered by one night's thunder, that though over night it was dry, fit for shipping or keeping, and proper for uses of any sort, yet in the morning it was found clammy and sticking. In this case there is no remedy but the turning of all such corn three or four times a day for two months or longer; in which time it will sometimes come to itself, though sometimes not. This effect of thunder and lightning is only observed to take place in such corn as is not a year old, or has not sweated thoroughly in the straw before it was threshed out. The latter inconvenience is easily prevented by a timely care: but as to the former, all that can be done is carefully to examine all stores of the last year's corn after every thunder storm, that if any of this have been so affected, it may be cured in time; for a neglect of turning will certainly utterly destroy it.

According to Vitruvius's rules, a granary should always be at the top of a house, and have its openings only to the north or east, that the corn may not be exposed to the damp winds from the south and west, which are very destructive to it; whereas the contrary ones are very necessary and wholesome to it, serving to cool and dry it from all external humidity, from whatever cause. There must also be openings in the roof to be set open in dry weather, partly to let in fresh air, and partly to let out the warm effluvia which are often emitted by the corn. The covering of the roofs should always be of tiles, because in the worst seasons, when the other openings cannot be safe, there will always be a considerable inlet for fresh air, and a way out for the vapours by their joinings, which are never close. If there happen to be any windows to the south, great care must be taken to shut them up in moist weather, and in the time of the hot southern winds. There must never be a cellar, or any other damp place under a granary, nor should it ever be built over stables; for in either of these cases the corn will certainly suffer by the vapours, and be made damp in one, and ill-tasted in the other.

M. Du Hamel and Dr. Hales recommend various contrivances for ventilating or blowing fresh air through corn laid up in granaries or ships, in order to preserve it sweet and dry, and to

prevent its being devoured by weevils or other insects. This may be done by nailing wooden bars or laths on the floor of the granary about an inch distant from each other, when they are covered with hair-cloth only; or at the distance of two or three inches, when coarse wire-work, or basket-work of osier is laid under the hair-cloth, or when an iron plate full of holes is laid upon them. These laths may be laid across other laths, nailed at the distance of 15 inches, and two or more deep, that there may be a free passage for the air under them. The under laths must come about six inches short of the wall of the granary at one end of them; on which end a board is to be set edgeways, and sloping against the wall: by this disposition a large air-pipe is formed, which, having an open communication with all the interstices between and under the bars, will admit the passage of air below forcibly through a hole at the extremity of it, into all the corn of the granary, that will consequently carry off the moist exhalations of the corn. The ventilators for supplying fresh air may be fixed against the wall, on the inside or outside of the granary, or under the floor, or in the ceiling; but wherever they are fixed, the handle of the lever that works them must be out of the granary, otherwise the person who works them would be in danger of suffocation, when the corn is fumed with burning brimstone, as is sometimes done for destroying weevils. Small moveable ventilators will answer the purpose for ventilating corn in large bins in granaries, and may be easily moved from one bin to another. If the granary or corn ship be very long, the main air-pipe may pass lengthwise along the middle of it, and convey air, on both sides, under the corn. In large granaries, large double ventilators, laid on each other, may be fixed at the middle and near the top of the granary, that they may be worked by a wind-mill fixed on the roof of the building, or by a water-mill. The air is to be conveyed from the ventilators through a large trunk or trunks, reaching down through the several floors to the bottom of the granary, with branching trunks on each floor, by means of which the air may be made to pass into a large trunk along the adjoining cross walls: from these trunks several lesser trunks, about four inches wide, are to branch off, at the distance of three or four feet from each other, which are to reach through the whole length of the granary, and their farther ends are to be closed: seams of $\frac{1}{16}$ or $\frac{1}{8}$ of an inch are to be left open at the four joinings of the boards, where they are nailed together, that the air may pass through them into the corn. In some of these lesser trunks there may be sliding shutters, in order to stop the passage of the air through those trunks which are not covered with corn; or to ventilate one part of the granary more briskly than others, as there may be occasion. There must also be wooden shutters, hung on hinges at their upper part; so as to shut close of themselves; these must be fixed to the openings in the walls of the granary on their outside: by these means they will readily open to give a free passage for the ventilating air, which ascends through the corn, to pass off, but will instantly shut when the ventilation ceases, and thereby prevent any dampness of the external air from entering: to prevent this, the ventilation should be made only in the middle of dry days, unless the corn, when first put in, is cold and damp.

In lesser granaries, where the ventilators must be worked by hand, if these granaries stand on staddles, so as to have their lowest floor at some distance from the ground, the ventilators may be fixed under the lowest floor, between the staddles, so as to be worked by men standing on the ground, without or within the granary. A very commodious and cheap ventilator may be had for small granaries, by making a ventilator of the door of the granary; which may be easily done by making a circular screen, of the size of a quarter of a circle, behind the door: but in order to this, the door must open, not inwards but outwards of the granary, so that, as it falls back, it may be

worked to and fro in the screen; which must be exactly adapted to it in all parts of the circular side of the screen, as well as at the top and bottom. But there must be a stop at about eight or ten inches distance from the wall, to prevent the door's falling back farther; that there may be room for a valve in the screen to supply it with air: which air will be driven in by the door, through a hole made in the wall near the floor, into the main air-trunk, in which there must be another valve over the hole in the wall, to prevent the return of the air.

The preservation of grain from the ravages of insects may be best effected by timely and frequent screening, and ventilation: as little or no inconvenience will follow corn or malt lodged dry, but what evidently results from a neglect of these precautions. For, whether the obvious damage arise from the weevil, the moth, or the beetle, that damage has ceased at the time the vermin make their appearance under either of these species, they being, when in this last state of existence, only propagators of their respective kinds of vermiculi; which, while they continue in that form, do the mischief.

In this last or insect state, they eat little, their principal business being to deposit their ova (eggs), which unerring instinct prompts them to do where large collections of grain furnish food for their successors while in a vermicular state. It is therefore the farmer's business to prevent future generations of these ravagers, by destroying the eggs previous to their hatching; and this is best accomplished by frequent screening, and exposure to draughts of wind or fresh air. By frequently stirring the grain, the cohesion of their ova is broken, and the nidus of those minute worms is destroyed, which on hatching collect together, and spin or weave numerous nests of a cobweb-like substance for their security. To these nests they attach, by an infinity of small threads, many grains of corn together, first for their protection, and then for their food. When their habitations are broken and separated by the screen, they fall through its small interstices, and may be easily removed from the granary with the dust. Those that escape an early screening will be destroyed by subsequent ones, while the grain is but little injured; and the corn will acquire thereby a superior purity. But by inattention to this, and sometimes by receiving grain already infested into the granary, these vermin, particularly the weevils, will in a short time spread themselves in that state every where upon its surface, and darken even the walls by their number. Under such circumstances a hen or hens, with new hatched chickens, if turned on the heap, will traverse, without feeding (or very sparingly so) on the corn, wherever they spread; and are seemingly insatiable in the pursuit of these insects. When the numbers are reduced within their reach, a hen will fly up against the walls, and brush them down with her wings, while her chickens seize them with the greatest avidity. This being repeated as often as they want food, the whole species will in a day or two be destroyed. Of the phalæna (moth), and the small beetle, they seem equally voracious: on which account they may be deemed the most useful instruments in nature for eradicating these noxious and destructive vermin.

GRANATE, or GARNET; a genus of fossils ranked among the siliceous earths; but, according to M. Magellan, analogous to gems, all of them being composed of the siliceous, argillaceous, and calcareous earths, with a greater or less proportion of iron. The opaque and black garnets contain about a fifth part of iron; but the diaphanous ones only $\frac{1}{56}$ th, according to Bergman. The garnets, properly so called, contain a greater quantity of siliceous earth than the shirls, and both are now justly ranked with the siliceous earths. The general properties of the garnet, according to Cronstedt, are as follow: 1. It is more fusible, as it contains less metallic matter, and is more transparent or glassy in its texture. 2. Mixed with salt of kelp, it may on a piece of charcoal be converted into glass by the blow-

pipe, which cannot be done with flint. 3. The most transparent garnet may, without any addition, be brought to a black opaque slag by the same means. 4. It is never, as far as is hitherto known, found pure, or without some mixture of metal, especially iron, which may be extracted by the common methods. 5. The garnet matter, during the crystallization, has either been formed in small detached quantities, or else has had the power of shooting into crystals, though closely confined in different substances: since garnets are generally found dispersed in other solid stones, and oftentimes in the harder ones, such as quartz and chert. Fabroni informs us, that the garnet is easily melted by means of borax or the vegetable alkali. Its specific gravity is greater than that of the precious stones; viz. from 3600, and even from 4400 to 5000. According to Brunich, most of the garnets strike fire with steel.

Cronstedt observes, that the metallic calces, when mixed with other earthy substances, make great alteration in their fusibility; iron, for instance, in the argillaceous and micaceous earths, renders them fusible, though otherwise they are not so. Hence there may be some reasons for considering the garnet as a quartz impregnated with iron; yet on the whole he thinks it will be better to call the garnet a stone of a different order, until we have experiments sufficient to warrant us to reduce the number of earths. The garnet earth is never found but in an indurated state, and is divided into the garnet properly so called, and shirl or cockle; though this perhaps is owing more to the figure of their crystals than any thing else. The species are,

1. The *granatus*, or coarse-grained garnet; a heavy hard stone, crystallizing in form of polygonal balls, mostly of a red or reddish brown colour. It is found of a reddish brown and whitish or pale yellow, in different parts of Sweden.

2. The *granatus crystallizatus*, or crystallized garnet, is reckoned among the precious stones, but varying in its colour and form of its crystal more than any of them. Sometimes it is of a deep and dark red colour; sometimes yellowish or purplish; sometimes brown, black, or opaque. It is inferior both in lustre and hardness to the other gems, yielding to the file, although it will strike fire with steel. The crystals are sometimes irregular, but frequently assume rhomboidal, tetradecahedral, and almost all other regular forms.

Wallerius makes the specific gravity of the garnet from 3600 to 3900, and even 4400; Brissen makes it 4100; and Cotes says that the garnets of Bohemia are 4360, those of Sweden being 3978. The most esteemed is the Syrian garnet; which is of a fine red, inclining to purple, very transparent, but less beautiful than the oriental amethyst. This, according to Magellan, is the amethystizant of Pliny; and is found in Syria, Calcutta, Cananor, Camboya, and Ethiopia. The soranus of the ancients was another kind of garnet of a red colour inclining to yellow, called *vermeille* by the French, and *giacinto guarnacino* by the Italians; the former having the name of *rubine di rocca* among the last-mentioned people. The name *Soranus* comes from Sorian or *Surian*, a town of Pegu, from whence these gems are brought.

Sometimes the garnets have a yellow colour, in which case they obtain the name of *hyacinths*. Like other gems, they are divided into oriental and occidental; but this means in fact no more than *more or less* valuable; the finest stones being always called *oriental*, wherever they come from. Some very fine ones are found in Bohemia; they are also met with in Hungary, at Pyna in Silesia, S. Sapho in the canton of Berne in Switzerland, in Spain, and in Norway. Their colour is supposed to proceed from iron; and, according to M. Saussure, even the finest oriental garnets attract the magnetic needle at a small distance. In the focus of a good burning-glass the garnet melts into a brown mass, which is attracted by the magnet; which shows that iron enters into its composition in a considerable pro-

portion. Some garnets, however, contain a little gold; and some, called by the Germans *zingraupen*, contain tin. M. Magellan is of opinion, that the *lapis alabandicus* of Pliny, and another gem which he mentions of a deep purple, were both true garnets.

3. The *cockle* or *shirl*. See COCKLE. The garnets abound so much with iron that they are sometimes worked with profit as ores of that metal; in which case no notice is taken of the natural character of the stone, in the same manner as is done with clays and jaspers that contain iron; for in these the quantity of metal is gradually augmented, until at last they acquire the appearance of iron itself. The greatest part of this genus, however, contain only from six to twelve *per cent.* of iron, which is too poor to be worked any where with advantage as an ore of that metal. When any of the garnet kind are to be tried for the metal they contain, the iron ought to be melted out of them by the common process; and if the garnet at the same time contains tin or lead, these will likewise be included in the iron. They may be extracted out of it, however, by a heat gradually augmented; the lead and tin sweating out in form of drops, though always somewhat mixed with iron. None of the garnet kind have yet been found in the form of an earth properly so called; though at Swappawari in Lapland, there is found a bole which has the same figure with the garnet; and the hornblende of the Swedes, which is somewhat harder than this bole, has often the appearance of a cockle.

GRANATE-Paste. See GARNET.

GRAND, a term rather French than English, though used on many occasions in our language. It has the same import with *great*, being formed of the Latin *grandis*. In this sense we say, the grand-master of an order, the grand-master of Malta, of the free masons, &c. So also the grand-signor, the grand-vizir, &c. grand-father, grand-mother, &c. In the former French polity and customs there were several officers thus denominated, and from their example, we retain the English titles; grand almoner, grand ecuyer, grand jury, &c.

GRAND-Affize. See ASSISE.

GRAND *Distress*, *districcio magna*, in English law, a writ of distress, so called on account of its extent, which reaches to all the goods and chattels of the party within the county. This writ lies in two cases: either when the tenant or defendant is attached and appears not, but makes default; or where the tenant or defendant hath once appeared, and after makes default. On such occasions, this writ lies by common law, in lieu of a petit cape.

GRAND *Gusto*, among painters, a term used to express that there is something in the picture very great and extraordinary, calculated to surprise, please, and instruct. Where this is found, they say, the painter was a man of *grand gusto*; and they use the words *sublime* and *marvellous*, when they speak of a picture, in much the same sense.

GRAND Jury, *larceny*, *serjeantry*, &c. See JURY, &c.

GRANDEE, is understood of a lord of the first rank or prime quality. In Spain, the term *grandees* is used absolutely to denote the prime lords of the court, to whom the king has once given leave to be covered in his presence: there are some grandees for life only; made by the king's saying simply, Be covered. Others are grandees by descent; made by the king's saying, Be covered for thyself and heirs. These last are reputed far above the former. Some have three or four grandeeships in their family.

GRANDGOR, a term once used in Scotland to signify the pox. In the Philosophical Transactions, n^o 469. sect. 5. is a proclamation of king James IV. of Scotland, ordering all who had this disease, or who had attended others under it, forthwith to repair to an island in the Frith of Forth. If the grandgor was the pox, and this distemper came into Europe at the siege of Naples in 1495, it must have made a very quick progress to cause such an alarm at Edinburgh in 1497.

GRANGE, an ancient term for a barn or place wherein to lay up and thrash corn. The word is formed of the Latin *grana*: or of *grammum*, "grain, corn," &c. Hence also *granger* or *grangier*, "a grange-keeper or farmer." This term has been also used, in a more extensive sense, for a whole farm, with all the appendages of stables for horses, stalls for cattle, &c. and for an inn.

GRANI, in our ancient writers, mustachoes or whiskers of a beard. The word seems formed from the ancient British or Irish *greann*, a beard. It is given for a reason why the cup is refused to the laity, *Quia barbati, & prolixos habent granos, dum poculum inter epulas sumunt, prius liquore pilos inficiunt, quam ori infundunt.*

GRANICUS, a small river near the Hellespont in Lesser Asia, remarkable for the first victory gained by Alexander the Great over the armies of Darius.

GRANITE, in natural history, a distinct genus of stones, composed of separate and very large concretions rudely compacted together; of great hardness, giving fire with steel, not fermenting with acids, and slowly and imperfectly calcinable in a great fire. Of this genus there are three *species*: 1. The hard *white* granite, with black spots, commonly called moor-stone. This is a very valuable kind, consisting of a beautiful congeries of very variously constructed and differently coloured particles, not diffused among or running into one another, but each pure and distinct, though firmly adhering to whichever of the others it comes in contact with, and forming a very firm mass. It is much used in London for the steps of public buildings, and on other occasions where great strength and hardness are required. 2. The hard *red* granite variegated with black and white, and common in Egypt and Arabia. 3. The *pale* or *whitish* granite, variegated with black and yellow. This is sometimes found in strata, but more frequently in loose nodules, and is used for paving the streets.

Some of these kinds of stones are found in almost every country, and in many places they are found of immense bigness. The largest mass of this kind in the known world, lying as an unconnected stone, is found near the Cape of Good Hope in Africa, and of which we have the following description in the Philosoph. Transact. vol. 68. p. 102, given by Mr. Anderson in a letter to Sir John Pringle. "The stone is so remarkable, that it is called by the people here the *Tower of Babel*, and by some the *Pearl Diamond*. It either takes the last name from a place near which it is situated, or it gives name to the tract of cultivated land called the Pearl. It lies upon the top of a ridge of low hills, beyond a large plain, at the distance of about thirty miles from the Cape Town; beyond which, at a little distance, is a range of hills of a much greater height. It is of an oblong shape, and lies north and south. The south end is highest: the east and west sides are steep and high; but the top is rounded, and slopes away gradually to the north end, so that you can ascend it by that way, and enjoy a most extensive prospect of the whole country. I could not precisely determine its circumference, but it took us above half an hour to walk round it; and by making every allowance for the rugged way, and stopping a little, I think the most moderate computation must make it exceed half a mile. The same difficulty occurred with respect to knowing its height: but I think, that, at the south end, it is nearly equal to half its length: or, were I to compare it to an object you are acquainted with, I should say it equalled the dome of St. Paul's church.

"I am uncertain whether it ought to be considered as the top of the hill, or a detached stone, because there is no positive proof of either, unless we were to dig about its base; but it would certainly impress every beholder, at first sight, with the idea of its being one stone, not only from its figure, but because it is really one solid uniform mass from top to bottom, without

any interruption; which is contrary to the general character of the high hills of this country, they being commonly divided, or composed of different strata, at least if we may judge from the rows of plants or shrubs which grow on the sides of the steepest, and, as I suppose, are produced from the small quantity of earth interposed between them. It has indeed a few fissures, or rather impressions, which do not reach deeper than four or five feet; and near its north end a stratum of a more compact stone runs across, which is not above twelve or fourteen inches thick, with its surface divided into little squares, or oblongs, disposed obliquely. This stratum is perpendicular; but whether it cuts the other to its base, or is superficial, I cannot determine. Its surface is also so smooth, that it does not appear to have formerly been joined to, or separated from, any other part by violence, as is the case with many other large fragments; but enjoys the exact situation where it was originally placed, and has undergone little change from being exposed for so many successive ages to the calcining power of a very hot climate."—A part of this stone being examined by Sir William Hamilton, he determined it to be a granite, and of the same nature with the tops of some of the Alps; and supposes both of them to have been elevated by volcanic explosions.

GRANITE, a genus of stones of the order of petræ, belonging to the class of saxa. The principal constituent parts of this stone are felt-spar or rhombic quartz, mica, and quartz. These ingredients constitute the hardest sort of granite, and that most anciently known. That into which schoerl enters is more subject to decomposition. They never have any particular texture or regular form, but consist of enormous shapeless masses extremely hard. In the finer granites the quartz is transparent; in others generally white or grey, violet or brown. The felt-spar is generally the most copious ingredient, and of a white, yellow, red, black, or brown colour. The mica is also grey, brown, yellow, green, red, violet, or black; and commonly the least copious. The schoerl is generally black, and abounds in the granites that contain it. Hence the colour of the granites depends principally on that of the spar or schoerl. The red granites consist commonly of white quartz, red felt-spar, and grey mica; the grey ones of white quartz, grey or violet felt-spar, and black mica. The black granites commonly contain schoerl instead of felt-spar; and the green usually contain green quartz.

On exposing granite to the flame of a blow-pipe, the component ingredients separate from one another. Mr. Gerhard having melted some in a crucible, found the felt-spar run into a transparent glass; below it the mica lay in form of a black slag, the quartz remaining unaltered. It melted somewhat better when all the three were powdered and mixed together; though even then the quartz was still discernible by a magnifying glass. Hence we may explain the reason why grains of a white colour are sometimes found in volcanic lavas. The mixture of mica prevents the flux or quartz from splitting or cracking; and hence its infusibility and use in furnace-building.

Granites are seldom slaty or laminated. In those which are of a close texture, the quartz and schoerl predominate. They take a good polish; for which reason the Egyptians formerly, and the Italians still work them into large pieces of ornamental architecture, for which they are extremely fit, as not being liable to decay in the air. Farber, in his letters from Italy, mentions a kind of stone named *granitone*, composed of felt-spar and mica: "a substance of this kind, which moulders in the air, is found in Finland; which is said to contain nitre, and sometimes common salt. In that country it is called *rapakiri*. Wallerius describes 18 species of granites, besides many others akin to this genus. Those described by Cronstedt are, 1. Loose or friable, which comes from France, and is used at the

brass-works for casting that metal in. 2. Hard or compact, of which there are two varieties, red and grey. The former is met with of two kinds; viz. fine-grained from Swappari in Lapland, or coarse-grained from the province of Dalarna in Sweden. The grey, with other colours, is met with on the coast round Stockholm and Norland in Sweden.

GRANITELLO, a genus of stones of the order of petræ, belonging to the class of saxa. There are two species, 1. That composed of distinct particles, found in several of the mountainous parts of Sweden. In some of these there is a predominance of quartzose particles, in others of micaceous; in which last case the stone is slaty, and easily split. 2. Granitello, composed of convoluted particles. This is met with of different colours, as whitish grey, greenish, and reddish. Both these kinds of stone are used in building furnaces, on account of the powerful resistance they make to the fire; but the latter is preferable to the other, on account of its containing a little of a refractory clayish substance. It is likewise of great use in mills, where the fellow is a coarse sand-stone.

GRANIVOROUS, an appellation given to animals which feed on corn or seeds. These are principally of the bird kind.

GRANT, in law, a conveyance in writing of such things as cannot pass or be conveyed by word only; such are rents, reversions, services, &c.

GRANTHAM, a borough of Lincolnshire, with a market on Saturday. It is seated on the river Witham, and has a free-school, and a handsome church famous for its high spire, which seems to lean on one side. It is 21 miles N. by W. of Stamford, and 110 N. by W. from London. Lon. o. 36. W. Lat. 52. 59. N.

GRANVILLE (George), lord Lansdowne, was descended from a very ancient family, derived from Rollo the first duke of Normandy. At eleven years of age he was sent to Trinity College in Cambridge, where he remained five years: but at the age of 13 was admitted to the degree of master of arts; having, before he was 12, spoken a copy of verses of his own composition to the duchess of York at his college, when she paid a visit to the University of Cambridge. In 1696 his comedy called the *Sbe-gallants* was acted at the theatre-royal in Lincoln's-inn-fields, as his tragedy called *Heroic Love* was in the year 1698. In 1702 he translated into English the *second Olymbian of Demosthenes*. He was member for the county of Cornwall in the parliament which met in 1740; was afterwards secretary at war, comptroller of the household, then treasurer, and sworn one of the privy-council. The year following, he was created baron Lansdowne. On the accession of king George I. in 1714, he was removed from his treasurer's place; and the next year entered his protest against the bills for attainting lord Bolingbroke and the duke of Ormond. He entered deeply into the scheme for raising an insurrection in the west of England; and being seized as a suspected person, was committed to the Tower, where he continued two years. In 1719 he made a speech in the house of Lords, against the bill to prevent occasional conformity. In 1722 he withdrew to France, and continued abroad almost ten years. At his return in 1732, he published a fine edition of his works in 2 vols. quarto. He died in 1735, leaving no male issue.

GRANVILLE, a seaport of France, in the department of the Channel and late province of Normandy, partly seated on a rock, and partly on a plain. It is 15 miles S. by E. of Coutances, and 185 W. of Paris. Lon. 1. 32. W. Lat. 48. 50. N.

GRANULATION, in chemistry, an operation by which metallic substances are reduced into small grains, or roundish particles; the use of which is, to facilitate their combination with other substances.—This operation is very simple; it consists only in pouring a melted metal slowly into a vessel filled

with water, which is in the mean time to be agitated with a broom. With melted copper, however, which is apt to explode with great violence on the contact of water, some precautions are to be observed. Lead or tin may be granulated by pouring them when melted into a box; the internal surface of which is to be rubbed with powdered chalk, and the box strongly shaken till the lead has become solid. Metals are granulated, because their ductility renders them incapable of being pounded, and because filing is long and tedious, and might render the metal impure by an admixture of iron from the file.

GRAPE, the fruit of the vine. See VINE and WINE. See also CURRANT and RAISIN.

GRAPE-Shot, in artillery, is a combination of small shot, put into a thick canvas bag, and corded strongly together, so as to form a kind of cylinder, whose diameter is equal to that of the ball adapted to the cannon. The number of shot in a grape varies according to the service or size of the guns: in sea-service nine is always the number; but by land it is increased to any number or size, from an ounce and a quarter in weight to three or four pounds. In sea-service the bottoms and pins are made of iron, whereas those used by land are of wood.

GRAPES, in the manege, a term used to signify the arrests or mangy tumours that appear on the horse's legs.

GRAPHOMETER, a mathematical instrument, otherwise called a *Semicircle*; the use of which is to observe any angle whose vertex is at the centre of the instrument in any plane (though it is most commonly horizontal, or nearly so), and to find how many degrees it contains. See GEOMETRY.

GRAPNEL, or GRAPPLING, a sort of small anchor, fitted with four or five flukes or claws, and commonly used to ride a boat or other small vessel.

Fire-GRAPPLING, an instrument nearly resembling the former, but differing in the construction of its flukes, which are furnished with strong barbs on their points. These machines are usually fixed on the yard-arms of a ship, in order to grapple any adversary whom she intends to board. They are, however, more particularly used in *Fire Ships* for the purposes described in the article *Fire-BARREL*.

GRASS, in botany, is defined to be a plant having simple leaves, a stem generally jointed and tubular, a husky calyx (called *gluma*), and the seed single. Hence wheat, oats, barley, &c. are properly grasses, according to the definition given; while clover and some other similar plants are not grasses, though so frequently called by that name. Of grass, the leaves are food for cattle, the small seeds for birds, and the larger grain chiefly for man. And it is observable, that nature has so provided, that cattle, in grazing, seldom eat the flower intended to produce seed, unless compelled by hunger. For the culture of the different sorts of grain, see HUSBANDRY; and also for that of the grasses commonly so called.

Culmiferous grasses might be divided into two general classes for the purposes of the farmer, which it might be of use for him to attend to: viz. 1st, Those which, like the common annual kinds of corn, run chiefly to seed-stalks; the leaves gradually decaying as these advance towards perfection, and becoming totally withered or falling off entirely when the seeds are ripe. Rye-grass belongs to this class in the strictest sense. To it likewise may be assigned the vernal-grass, dogs'-tail-grass, and fine bent-grass. 2dly, Those whose leaves continue to advance even after the seed-stalks are formed, and retain their verdure and succulence during the whole season, as is the case with the fescue and poa tribes of grasses, whose leaves are as green and succulent when the seeds are ripe and the flower-stalks fading, as at any other time.

"It is wonderful, (says Mr. Stillingfleet) to see how long mankind has neglected to make a proper advantage of plants of

such importance, and which, in almost every country, are the chief food of cattle. The farmer, for want of distinguishing and selecting grasses for seed, fills his pastures either with weeds or bad or improper grasses; when, by making a right choice, after some trials, he might be sure of the best grass, and in the greatest abundance that his land admits of. At present, if a farmer wants to lay down his land to grass, what does he do? He either takes his seeds indiscriminately from his own foul hay-rick, or sends to his next neighbour for a supply. By this means, besides a certain mixture of all sorts of rubbish, which must necessarily happen, if he chances to have a large proportion of good seeds, it is not unlikely but that what he intends for dry land may come from moist, where it grew naturally, and the contrary. This is such a slovenly method of proceeding, as one would think could not possibly prevail universally: yet this is the case as to all grasses except the darnel-grass, and what is known in some few counties by the name of the *Suffolk grass*; and this latter instance is owing, I believe, more to the soil than any care of the husbandman. Now, would the farmer be at the pains of separating once in his life half a pint or a pint of the different kinds of grass-seeds, and take care to sow them separately, in a very little time he would have wherewithal to stock his farm properly, according to the nature of each soil, and might at the same time spread these seeds separately over the nation, by supplying the seed-shops. The number of grasses fit for the farmer is, I believe, small; perhaps half a dozen or half a score are all he need to cultivate: and how small the trouble would be of such a task, and how great the benefit, must be obvious to every one at first sight. Would not any one be looked on as wild who should sow wheat, barley, oats, rye, pease, beans, vetches, buck-wheat, turnips, and weeds of all sorts together? Yet how is it much less absurd to do what is equivalent in relation to grasses? Does it not import the farmer to have good hay and grass in plenty? and will cattle thrive equally on all sorts of food? We know the contrary. Horses will scarcely eat hay that will do well enough for oxen and cows. Sheep are particularly fond of one sort of grass, and fatten upon it faster than any other, in Sweden, if we may give credit to Linnæus. And may they not do the same in Britain? How shall we know till we have tried?"

As the generality of farmers know scarce any of the grasses by name, and as without such knowledge little improvement can be made in this branch of husbandry, we have in Plate 1. given figures of those sorts which have been recommended as the most profitable, viz.

1. *Hordeum murinum*, RYE GRASS *vulgo*. [*Rye-grass proprie is the SECALE villosum*. Perennial darnel, *lolium perenne*, is also, in some counties of England, improperly called *rye-grass*.] See the section on *Grasses* in the Treatise on HUSBANDRY.

2. *Festuca rubra*, PURPLE FESCUE-GRASS. See HUSBANDRY.

3. *Festuca ovina*, SHEEPS ditto. See HUSBANDRY. This is perhaps the most valuable grass of all. It is observed to grow and thrive on lands of all qualities and in all situations, from the driest upland pastures to the very moist parts of meadows. It does not part with its seeds till some time after they are ripe, and even quite dry. It makes the thickest and closest pile of any of them, and sends up but few flower-stalks in proportion to its leaves. It flowers in June, and is ripe in July.

4. *Holcus lanatus*, CREEPING SOFT-GRASS. See HUSBANDRY.

5. *Alopecurus bulbosus*, BULBOUS FOXTAIL-GRASS, is recommended by Dr. Anderson, as promising on some occasions to afford a valuable pasture-grass. It seems chiefly, he observes, to delight in a moist soil, and therefore promises to be only fit for a meadow pasture grass. The quality that first recommended it

to his notice, was the unusual firmness that its matted roots gave to the surface of the ground, naturally soft and moist, in which it grew; which seemed to promise that it might be of use upon such soils, chiefly in preventing them from being much poached by the feet of cattle which might pasture upon them. Moist soils especially are so much hurt by poaching, that any thing that promises to be of use in preventing it deserves to be attended to.

6. *Poa pratensis*, GREAT MEADOW-GRASS, seems to approach in many respects to the nature of the purple-fescue; only that its leaves are broader, and not near so long; being only about a foot or 16 inches at their greatest length. Like it, it produces few seed-stalks and many leaves, and is an abiding plant. It affects chiefly the dry parts of meadows, though it is to be found on most good pastures. It is very retentive of its seeds, and may therefore be suffered to remain till the stalks are quite dry. It blossoms the beginning of June, and its seeds are ripe in July.

7. *Poa compressa*, CREEPING MEADOW-GRASS, some writers describe to be the most valuable grass of any of this genus. Its leaves are firm and succulent, of a dark Saxon-green colour, and grow so close upon one another as to form the richest pile of pasture-grass. The flower-stalks, if suffered to grow, appear in sufficient quantities; but the growth of these does not prevent the growth of the leaves, both advancing together during the whole summer; and when the stalks fade, the leaves continue as green as before. Its leaves are much larger and more abundant than the common meadow-grass, *poa trivialis*; and therefore it better deserves to be cultivated.

8. *Anthoxanthum odoratum*, VERNAL GRASS, grows very commonly on dry hills, and likewise on sound rich meadow-land. It is one of the earliest grasses we have; and from its being found on such kinds of pasture as sheep are fond of, and from whence excellent mutton comes, it is most likely to be a good grass for sheep-pasture. It gives a grateful odour to hay. In one respect, it is very easy to gather, as it sheds its seeds upon the least rubbing. A correspondent of the Bath Society, however, mentions a difficulty that occurs in collecting them, owing to its being surrounded with taller grasses at the time of its ripening, and being almost hid among them. If it be not carefully watched when nearly ripe, he observes, and gathered within a few days after it comes to maturity, great part of the seed will be lost. The twisted elastic awns, which adhere to the seed, lift them out of their receptacles with the least motion from the wind, even while the straw and ear remain quite erect. It is found mostly in the moist parts of meadows; very little of it on dry pastures. It flowers about the beginning of May, and is ripe about the middle of June.

9. *Cynosurus cristatus*, CRESTED DOG'S-TAIL GRASS. Mr. Stillingfleet imagines this grass to be proper for parks, from his having known one, where it abounds, that is famous for excellent venison. He recommends it also, from experience, as good for sheep; the best mutton he ever tasted, next to that which comes from hills where the purple and sheeps-fescue, the fine bent, and the silver hair grasses abound, having been from sheep fed with it. He adds, that it makes a very fine turf upon dry sandy or chalky soils: but unless swept over with the scythe, its flowering-stems will look brown: which is the case of all grasses which are not fed on by variety of animals. For that some animals will eat the flowering-stems is evident by commons, where scarcely any parts of grasses appear but the radical leaves. This grass is said to be the easiest of the whole groupe to collect a quantity of seed from. It flowers in June, and is ripe in July.

10. *Stipa pennata*, COCK'S-TAIL OR FEATHER-GRASS.

11. *Agrostis capillaris*, FINE BENT, is recommended by Mr. Stillingfleet, from his having always found it in great plenty on

the best sheep pastures in the different counties of England that are remarkable for good mutton. This grass flowers and ripens its seed the latest of them all. It seems to be lost the former part of the year, but vegetates luxuriantly towards the autumn. It appears to be fond of moist ground. It retains its seed till full ripe; flowers the latter end of July, and is ripe the latter end of August.

12. *Arrida flexuosa*, MOUNTAIN HAIR.

13. *Arrida caryophyllæa*, SILVER HAIR.

The same may be said of these two grasses as of the preceding species.

14. *Festuca fluitans*, FLOTE FESCUE. In a paper published in the *Amœnitates Academicæ*, vol. 3. intitled *Plantæ Esculentæ*, we are informed, that "the seeds of this grass are gathered yearly in Poland, and from thence carried into Germany, and sometimes into Sweden, and sold under the name of *manna-seeds*. These are much used at the tables of the great, on account of their nourishing quality and agreeable taste. It is wonderful (adds the author), that amongst us these seeds have hitherto been neglected, since they are so easily collected and cleaned." There is a clamminess on the ear of the flote-fescue, when the seeds are ripe, that tastes like honey; and for this reason perhaps they are called *manna-seeds*. Linnæus (*Flor. Suec.* art. 95.) says that the bran of this grass will cure horses troubled with bots, if kept from drinking for some hours.

Concerning this grass we have the following information by Mr. Stillingfleet. "Mr. Dean, a very sensible farmer at Ruscomb, Berkshire, assured me that a field, always lying under water, of about four acres, that was occupied by his father when he was a boy, was covered with a kind of grass, that maintained five farm-horses, in good heart, from April to the end of harvest, without giving them any other kind of food, and that it yielded more than they could eat. He, at my desire, brought me some of the grass, which proved to be the flote-fescue with a mixture of the marsh-bent; whether this last contributes much towards furnishing so good pasture for horses, I cannot say. They both throw out roots at the joints of the stalks, and therefore are likely to grow to a great length. In the index of dubious plants, at the end of Ray's Synopsis, there is mention made of a grass under the name of *gramen carinatum supinum longissimum*, growing not far from Salisbury, 24 feet long. This must, by its length, be a grass with a creeping stalk; and that there is a grass in Wiltshire, growing in watery meadows, so valuable, that an acre of it lets from 10 to 12 pounds, I have been informed by several persons. These circumstances incline me to think it must be the flote-fescue; but whatever grass it be, it certainly must deserve to be inquired after."

15. *Alopecurus pratensis*, MEADOW FOXTAIL. Linnæus says that this is a proper grass to sow on grounds that have been drained. Mr. Stillingfleet was informed, that the best hay which comes to London is from the meadows where this grass abounds. It is scarce in many parts of England, particularly Herefordshire, Berkshire, and Norfolk. It might be gathered at almost any time of the year from hay-ricks, as it does not shed its seeds without rubbing, which is the case of but few grasses. It is amongst the most grateful of all grasses to cattle. It is ripe about the latter end of June.

16. *Poa annua*, ANNUAL MEADOW GRASS. "This grass (says Mr. Stillingfleet) makes the finest of turfs. It grows every where by way sides, and on rich sound commons. It is called in some parts the *Suffolk grass*. I have seen whole fields of it in High Suffolk without any mixture of other grasses; and as some of the best salt-butter we have in London comes from that country, it is most likely to be the best grass for the dairy. I have seen a whole park in Suffolk covered with this grass; but whether it affords good venison, I cannot tell, having never

tasted of any from it. I should rather think not, and that the best pasture for sheep is also the best for deer. However, this wants trial. I remarked on Malvern-hill something particular in relation to this grass. A walk that was made there for the convenience of the water-drinkers, in less than a year was covered in many places with it, though I could not find one single plant of it besides in any part of the hill. This was, no doubt, owing to the frequent treading, which above all things makes this grass flourish; and therefore it is evident, that rolling must be very serviceable to it. It has been objected, that this grass is not free from *bents*, by which word is meant the flowering-stems. I answer, that this is most certainly true, and that there is no grass without them. But the flowers and stems do not grow so soon brown as those of other grasses; and, being much shorter, they do not cover the radical leaves so much; and therefore this grass affords a more agreeable turf without mowing, than any other whatever that I know of." The seeds of this species drop off before they are dry, and, to appearance, before they are ripe. The utmost care is therefore necessary in gathering the blades, without which very few of the seeds will be saved. It ripens from the middle of April to so late, it is believed, as the end of October, but mostly disappears in the middle of the summer. It grows in any soil and situation, but rather affects the shade.

17. A new grass from America, named *Agrostis cornucopiæ*, was some time ago much advertised and extolled, as possessing the most wonderful qualities, and the seeds of it were sold at the enormous rate of 68l. the bushel. But we have not heard that it has at all answered expectation. On the contrary, we are informed by Dr. Anderson, in his new publication entitled "The Bee," that "it has upon trial been found to be good for nothing. Of the seeds sown, few of them ever germinated: but even of plants made their appearance, to ascertain, that the grass, in respect of quality, is among the poorest of the tribe; and that it is an *annual* plant, and altogether unprofitable to the farmer."

Grass-Walks are made, for the most part, not by sowing grass-seeds, but by laying turfs: and indeed the turfs, from a fine common or down, are much preferable to sown grass: but if walks or plats are to be made by sowing, the best way is to procure the seed from those pastures where the grass is naturally fine and clear; or else the trouble of keeping it from spiry or bent grass will be very great, and it will scarce ever look handsome.

In order to sow grass-walks, the ground must be first dug; and when it has been dressed and laid even, it must be very carefully raked over, and all the clods and stones taken off, and then covered over an inch thick with good mould. This being done, the seed is to be sown pretty thick, that it may come up close and short; it must then be raked over again, to cover the seed, that, if the weather should happen to be windy, it may not be blown away. It ought also to be observed, that where grass is sown in gardens, either for lawns or walks, there should always be a good quantity of the white trefoil or Dutch clover sown with it; for this will make a fine turf much sooner than any other sown grass, and will continue a better verdure than any other of the grass-tribe.

In order to keep grass-plats or walks handsome, and in good order, you may sow in autumn fresh seed over any places that are not well filled, or where the grass is dead: but nothing improves grass so much as mowing and constant rolling. When turf is laid in gardens, it is a general practice to cover the surface of the ground under the turf, either with sand or very poor earth: the design of this is to keep the grass fine, by preventing its growing too rank. This is proper enough for very rich ground: but it is not so for such land as is middling, or but poor; for, when this is practised in such places, the grass will

soon wear out and decay in patches. When turf is taken from a common or down, such ought to be chosen as is free from weeds: and when it is designed to remain for years without renewing, a dressing should be laid upon it every other year, either of very rotten dung, ashes, or, when it can be easily procured, very rotten tan; but these dressings should be laid on early in the winter, that the rain may wash them into the ground, otherwise they will occasion the grass to burn, when the warmth of the summer begins. When grass is so dressed, and well rolled and mowed, it may be kept very beautiful for many years; but, where it is not dressed, or fed with sheep, it will rarely continue handsome more than eight or ten years.

GRASSHOPPER, in zoology, a species of gryllus. See GRYLLUS.

GRATAROLUS (William), a learned physician in the 16th century, was born at Bergamo in Italy; and taught physic with reputation at Padua: but, having embraced the Protestant religion, he retired to Switzerland, where he was made professor of physic. He died at Basil in 1568, aged 52. He wrote several curious works in Latin; amongst which are, 1. The manner of preserving and improving the memory. 2. Of preserving in health of travellers, men of letters, magistrates, and studious persons, &c.

GRATES for FIRES, are composed of ribs of iron placed at small distances from one another, so that the air may have sufficient access to the fuel, and the accumulation of the ashes, which would choke the fire, may be prevented. Grates seem peculiarly adapted to the use of pit-coal, which requires a greater quantity of air to make it burn freely than other kinds of fuel. The hearths of the Britons seem to have been fixed in the centre of their halls, as is yet practised in some parts of Scotland, where the fire is nearly in the middle of the house, and the family sit all around it. Their fire-place was perhaps nothing more than a large stone, depressed a little below the level of the ground, and thereby adapted to receive the ashes. About a century ago, it was only the floor of the room, with the addition of a bank or hob of clay. But it was now changed among the gentlemen for a portable fire-pan, raised upon low supporters, and fitted with a circular grating of bars. Such were in use among the Gauls in the first century, and among the Welch in the tenth. See the article FIRE-PLACE.

GRATIAN, the son of Valentinian I. by his first wife, was declared Augustus by his father at the city of Amiens in 365, and succeeded him in 367; a prince equally extolled for his wit, eloquence, modesty, chastity, and zeal against heretics. He associated Theodosius with him in the empire, and advanced the poet Ausonius to the consulate. He made a great slaughter of the Germans at Strasburg, and hence was surnamed *Alemannicus*. He was the first emperor who refused the title of *Pontifex Maximus*, upon the score of its being a Pagan dignity. He was assassinated by Andragathius in 375, in the 24th year of his age.

GRATIAN, a famous Benedictine monk, in the 12th century, was born at Chiufi, and employed near twenty-four years in composing a work, entitled, *Decretum*, or *Concordantia Discordantium Canonum*, because he there endeavoured to reconcile the canons which seemed contradictory to each other. This work he published in 1151. As he is frequently mistaken in taking one canon of one council, or one passage of one father for another, and has often cited false decretals, several authors have endeavoured to correct his faults; and chiefly Anthony Augustine, in his excellent work, entitled, *De emendatione Gratiani*. To the decretals of Gratian the popes principally owed the great authority they exercised in the thirteenth and following centuries.

GRATINGS, in a ship, are small edges of sawed plank, framed one into another like a lattice or prison grate, lying on

the upper deck, between the main-mast and fore-mast, serving for a defence in a close fight, and also for the coolness, light, and convenience of the ship's company.

GRATIOLA, HEDGE HYSSOP; a genus of the monogynia order, belonging to the diandria class of plants. The corolla is irregular; there are two barren stamens; the capsule is bilocular; the calyx has seven leaves, with the two exterior ones spatulous. There are four species; the most remarkable of which is the *officinalis*, or common hedge-hyssop. This grows naturally on the Alps and other mountainous parts of Europe. It has a thick, fleshy, fibrous, creeping root, which propagates very much, when planted in a proper soil and situation. From this arise several upright square stalks, garnished with narrow spear-shaped leaves, placed opposite. The flowers are produced on the side of the stalks at each joint; they are shaped like those of the fox glove, but are small, and of a pale yellowish colour. This herb has an emetic and purgative virtue; to answer which intentions, it was formerly used by the common people in England, but was never much prescribed by the physicians, and at last fell totally into disuse. Of late, however, it has been the subject of a dissertation by Dr. James Kofszewski of Warsaw, in Poland, who gives some remarkable accounts of its effects in mania and obstinate venereal cases. It was given in powder, or in extract, to the quantity of half a drachm of the first, and a whole drachm of the second, at each dose. From the cases related in his dissertation, the author draws the following conclusions: 1. The gratiola may be given with safety both to male and female patients. 2. In all disorders proceeding from a superabundance of serum in the fluids, it appears to be a most effectual remedy. 3. In consequence of this, it is had recourse to, with very great advantage, in melancholy and mania arising from that state of the system. 4. It powerfully promotes purging, vomiting, sweat, and urine; and is therefore much superior to any of the usual evacuating medicines, most of which prove only active in promoting one of these discharges at once. 5. The most obstinate cases of gonorrhœa, fluor albus, and venereal ulcers, are cured by the powder. In some instances it has induced salivation; but whether or not it can always be made to produce that effect, is not as yet altogether certain. 6. The powder of gratiola, prepared from the extract, and exhibited with sugar, does not induce vomiting; and, on the contrary, the powder of the root always promotes that evacuation.

GRATITUDE, in ethics, a virtue disposing the mind to an inward sense and outward acknowledgment of benefits received. Examples of ingratitude, Mr. Paley observes, check and discourage voluntary beneficence; hence the cultivation of a grateful temper is a consideration of public importance. A second reason for cultivating in ourselves that temper is: That the same principle, which is touched with the kindness of a human benefactor, is capable of being affected by the divine goodness, and of becoming, under the influence of that affection, a source of the purest and most exalted virtue. The love of God is the sublimest gratitude. It is a mistake, therefore, to imagine, that this virtue is omitted in the Scriptures; for every precept, which commands us "to love God, because he first loved us," presupposes the principle of gratitude, and directs it to its proper object. It is impossible to particularize the several expressions of gratitude, which vary with the character and situation of the benefactor, and with the opportunities of the person obliged; for this variety admits of no bounds. It may be observed, however, that on one part gratitude can never oblige a man to do what is wrong, and what by consequence he is obliged previously not to do: On the other part, it argues a total want of every generous principle, as well as of moral probity, to take advantage of that ascendancy, which the conferring of benefits justly creates, to draw or drive those whom we have obliged into mean or dishonest compliances.

There is a species of grateful remorse, which sometimes has been known to operate forcibly on the minds of the most hardened in impudence. Of this Mr. Andrews, who makes the remark, gives an instance in the following anecdote, said to have been a favourite one with the late Dr. Campbell: "Towards the beginning of this century, an actor, celebrated for mimicry, was to have been employed by a comic author, to take off the person, the manner, and the singularly awkward delivery of the celebrated Dr. Woodward, who was intended to be introduced on the stage in a laughable character (*viz.* in that of *Dr. Fossile*, in *Three Hours after Marriage*). The mimic dressed himself as a countryman, and waited on the doctor with a long catalogue of ailments, which he said attended on his wife. The physician heard with amazement diseases and pains of the most opposite nature, repeated and redoubled on the wretched patient. For, since the actor's greatest wish was to keep Dr. Woodward in his company as long as possible, that he might make the more observations on his gestures, he loaded his poor imaginary spouse with every infirmity which had any probable chance of prolonging the interview. At length, having become completely master of his errand, he drew from his purse a guinea, and, with a scrape, made an uncouth offer of it. 'Put up thy money, poor fellow,' cried the Doctor; 'thou hast need of all thy cash and all thy patience too, with such a bundle of diseases tied to thy back.' The actor returned to his employer, and recounted the whole conversation, with such true feeling of the physician's character, that the author screamed with approbation. His raptures were soon checked; for the mimic told him, with the emphasis of sensibility, that he would sooner die than prostitute his talents to the rendering such genuine humanity a public laughing-stock. The player's name was *Griffin*."

GRATZ, a handsome strong town of Germany, capital of Stiria, with a castle seated on a rock, and a university. Here are many handsome palaces, and a fine arsenal. The castle stands on a lofty hill, and communicates with the river by means of a very deep well. It is seated on the river Muehr, 85 miles S. W. of Vienna. E. lon. 15. 30. N. lat. 47. 4.

GRATIUS, a Latin poet, cotemporary with Ovid, and author of a poem entitled *Cynegeticon*, or the *Manner of hunting with dogs*; the best edition of which is that of Leyden, 12mo, with the learned notes of Janus Ulitius.

GRAVE, in grammar, a species of accent opposite to acute. The grave accent is expressed thus (`), and shows that the voice is to be depressed, and the syllable over which it is placed pronounced in a low deep tone.

GRAVE, in music, is applied to a sound which is in a low or deep tone. The thicker the chord or string, the more grave the tone or note, and the smaller the acuter. Notes are supposed to be the more grave, in proportion as the vibrations of the chord are less quick.

GRAVE, in the Italian music, is used to denote the slowest movement.

GRAVE is also used for a tomb, wherein a person deceased is interred. Graves, among the Jews, were generally out of the city, though we meet with instances of their interring the dead in towns. Frequent mention is made of graves upon mountains, in highways, in gardens, and private houses. So that nothing on this head seems to have been determined. The same may be observed with respect to the Greeks. The Thebans had a law that every person who built an house should provide a burial-ground. Men who had distinguished themselves were frequently buried in the public forum. The most general custom was, however, to bury out of the city, chiefly by the highway side. The Romans were forbidden by the law of the 12 tables to bury or burn the dead in the city; but some we find had their sepulchres in Rome, though they paid a fine for the indulgence.

GRAVE, a strong town of Dutch Brabant, seated on the river Maete, beyond which there is a fort, eight miles S. of Nimeguen. E. lon. 5. 45. N. lat. 51. 47.

GRAVEL, in natural history and gardening, a congeries of pebbles, which, mixed with a stiff loam, makes lasting and elegant gravel-walks; an ornament peculiar to our gardens, and which gives them an advantage over those of other nations.

GRAVEL, in medicine. See MEDICINE.

GRAVEL-Walks. To make these properly, the bottom should be laid with lime-rubbish, large flint-stones, or any other hard matter, for eight or ten inches thick, to keep weeds from growing through, and over this the gravel is to be laid six or eight inches thick. This should be laid rounding up in the middle, by which means the larger stones will run off to the sides, and may be raked away; for the gravel should never be screened before it is laid on. It is a common mistake to lay these walks too round, which not only makes them uneasy to walk upon, but takes off from their apparent breadth. One inch in five feet is a sufficient proportion for the rise in the middle; so that a walk of 20 feet wide should be four inches higher at the middle than at the edges, and so in proportion. As soon as the gravel is laid, it should be raked, and the large stones thrown back again: then the whole should be rolled both lengthwise and crosswise; and the person who draws the roller should wear shoes with flat heels, that he may make no holes, because holes made in a new walk are not easily remedied. The walks should always be rolled three or four times after very hard showers, from which they will bind more firmly than otherwise they could ever be made to do.

Gravel, with some loam among it, binds more firmly than the rawer kinds; and when gravel is naturally very harsh and sharp, it is proper to add a mixture of loam to it. The best gravel for walks is such as abounds with smooth round pebbles, which, being mixed with a little loam, are bound so firmly together, that they are never afterwards injured either by wet or dry weather. These are not so liable to be turned up by the feet in walking, as the more irregularly shaped pebbles, and remain much more firmly in their places after rolling.

GRAVELINES, a strong seaport of France, in the department of the North, and late French Flanders. It was ceded to France, by the treaty of the Pyrenees, and is seated on the river Aa, 12 miles East of Calais. E. lon. 2. 13. N. lat. 50. 59.

GRAVENAC, a town of Germany, in the circle of Suabia, and capital of a county of the same name, 30 miles W. of Ulm. E. lon. 9. 28. N. lat. 48. 22.

GRAVER, in the art of engraving, a tool by which all the lines, scratches, and shades, are cut in copper, &c. See ENGRAVING.

GRAVESANDE (William James), was born of an ancient and honourable family at Delft in Holland in 1688. He studied the civil law at Leyden: but mathematical learning was his favourite amusement. When he had taken his doctor's degree in 1707, he settled at the Hague and practised at the bar, in which situation he cultivated an acquaintance among learned men; with a society of whom he published a periodical review, entitled *Le Journal Littéraire*, which was continued without interruption from the year 1713 to the year 1722, when he died. The most considerable of his works are, "A Treatise on Perspective; an Introduction to the Newtonian Philosophy, or a Treatise on the Elements of Physics confirmed by experiments; a Treatise on the Elements of Algebra, for the use of young students;" and "A Course of Logic and Metaphysics." He had intended to have presented the public with a system of morality, but his death prevented its execution. The ministers of the republic consulted him on all occasions wherein his talents were requisite; and his skill in calculation was often of service

to them; as was his address in decyphering, for detecting the secret correspondence of their enemies. As professor of mathematics and astronomy at Leyden, none ever applied the powers of nature with more success, or to more useful purposes.

GRAVESEND, a town in Kent, with a market on Wednesday and Saturday. It is seated on the Thames, and is a place of great resort, being the common landing place for seamen and strangers in their passage to London. It has a block-house over against Tilbury fort. A great part of it was burnt down, with the church, in 1727: the latter was afterwards rebuilt as one of the 50 new churches. It is commonly called the corporation of Gravesend and Milton, those two places being united under the government of a mayor, 12 aldermen, 24 common-council, a townclerk, &c. They were incorporated by queen Elizabeth; but, long before, Richard II. had granted them the exclusive privilege of conveying passengers to London in boats, at twopence a head, or a whole boat's fare at four shillings. They still enjoy this privilege; but the fare is now ninepence a head. The boats depart from Billingsgate, near London Bridge, at high water, and from Gravesend at low-water; the ringing of a bell at each place, for a quarter of an hour, giving notice of the time. Coaches attend the arrival of the boats from London, to convey the passengers to Rochester, at one shilling and sixpence each. The townhouse was erected in 1764. The chief employment of the labouring people is spinning of hemp, to make nets for fishing, and ropes. It is also famous for asparagus. It is 22 miles S. E. of London. E. lon. 0. 27. N. lat. 51. 25.

GRAVINA, a town of Italy, in the kingdom of Naples, and Terra di Bori, with a bishop's see, and the title of a duchy. E. lon. 17. N. lat. 41.

GRAVINA (John Vincent), an eminent scholar, and illustrious lawyer of Italy, born at Roggiana in 1664. He was professor of the canon law in the college of Sapienzi at Rome; and though many foreign universities made proposals to draw him to them, he never quitted that city, but died there in 1718. His works are both curious and useful; the greatest of them is *De ortu et progressu Juris Civilis*. A collection of his works was printed in 4to at Leipzig in 1737, with the notes of Mascovius.

GRAVINA (Peter), an Italian poet, much esteemed by the great general Gonsalvo, and Prosper Colonna. He wrote, in a pure Roman style, Discourses on Matters relating to the Law and to the Belles Lettres; as well as Poems. He died in 1527.

GRAVITY, or GRAVITATION (for the words are most commonly used synonymously), signifies either the force by which bodies are pressed towards the surface of the earth, or the manifest effect of that force; in which last sense the word has the same signification with *weight* or *heaviness*. Concerning gravity, in the first sense of the word, or that active power by which all bodies are impelled towards the earth, there have been great disputes. Many eminent philosophers, and among the rest Sir Isaac Newton himself, have considered it as the first of all second causes; an incorporeal or spiritual substance, which never can be perceived any other way than by its effects; an universal property of matter, &c. Others have attempted to explain the phenomena of gravitation by the action of a very subtle ethereal fluid; and to this explanation Sir Isaac, in the latter part of his life, seems not to have been averse. He hath even given a conjecture concerning a matter in which this fluid might occasion these phenomena. But for a full account of the discoveries of this great philosopher concerning the laws of gravitation, the conjectures made by him and others concerning its cause, the various objections that have been made to his doctrine, and the state of the dispute at present, see the articles *NEWTONIAN Philosophy*, *ASTRONOMY*, *ATMOSPHERE*, *EARTH*,

ELECTRICITY, FIRE, LIGHT, ATTRACTION, REPULSION, PLENUM, VACUUM, &c.

Specific GRAVITY, denotes the weight belonging to an equal bulk of every different substance. Thus, the exact weight of a cubic inch of gold, compared with a cubic inch of water, tin, lead, &c. is called its *specific gravity*. See HYDROSTATICS.

GRAUNT (John), author of a curious and celebrated book, entitled, *Natural and Political Observations made upon the Bills of Mortality*. He was a haberdasher of small wares; but laid down his trade and all public employments on account of his religion. He was educated a Puritan; afterwards professed himself a Socinian; yet, in the latter part of his life, declared himself of the Roman Catholic religion. He was a member of the Royal Society, and died in 1674.

GRAY, or GREY, a mixed colour partaking of the two extremes, black and white. In the manege they describe several sorts of grays; as the branded or blackened gray, which has spots quite black dispersed here and there. The dappled gray, which has spots of a darker colour than the rest of the body. The light or silver gray, wherein there is but a small mixture of black hairs. The sad or iron gray, which has but a small mixture of white. And the brownish or sandy-coloured gray, where there are bay-coloured hairs mixed with the black.

GRAY, a town of France, in the department of Upper Saone and late province of Franche Comté. It is a trading place, and seated on the river Saone, 25 miles N. E. of Dijon. E. lon. 5. 41. N. lat. 47. 28.

GRAY (Thomas), an admired English poet, was the youngest and only surviving son of a reputable citizen of London, and was born in Cornhill in 1716. He was educated at Eton, where he contracted a friendship with Mr. Horace Walpole, and with Mr. Richard West, son of the lord chancellor of Ireland. Mr. West and Mr. Gray were both intended for the bar; but the former died early in life, and the latter was diverted from that pursuit by an invitation to accompany Mr. Walpole in his travels; which he accepted, without any determined plan for his future life. During Mr. Gray's travels, he wrote a variety of letters to Mr. West and to his parents, which are printed with his poems; and when he returned, finding himself in narrow circumstances, yet with a mind indisposed for active employment, he retired to Cambridge, and devoted himself to study. Soon after his return, his friend West died: and the melancholy impressed on him by this event may be traced in his admired "Elegy written in a country church-yard;" which is thought to have been begun, if not finished, at this time: though the conclusion, as it stands at present, is certainly different from what it was in the first manuscript copy. The first impulse of his sorrow for the death of his friend gave birth to a very tender sonnet in English, on the Petrarchian model; and also to a sublime apostrophe in hexameters, written in the genuine strain of classical majesty, with which he intended to begin one of his books *De Principiis cogitandi*.

From the winter of the year 1742 to the day of his death, his principal residence was at Cambridge: from which he was seldom absent any considerable time, except between the years 1759 and 1762; when, on the opening of the British Museum, he took lodgings in Southampton-row, in order to have recourse to the Harleian and other manuscripts there deposited, from which he made several curious extracts, amounting in all to a tolerable sized folio, at present in the hands of Mr. Walpole.

About the year 1747, Mr. Mason, the editor of Mr. Gray's poems, was introduced to him. The former had written, a year or two before, some imitations of Milton's juvenile poems, viz. A Monody on the death of Mr. Pope, and two pieces, entitled *Il Bellisoso* and *Il Pacifico* on the peace of Aix-la-Chapelle.

and the latter revised them at the request of a friend. This laid the foundation of an intimacy, which continued without interruption to the death of Mr. Gray.

About the year 1750, Mr. Gray had put his last hand to his celebrated Elegy written in a country church-yard, and had communicated it to his friend Mr. Walpole, whose good taste was too much charmed with it to suffer him to withhold the sight of it from his acquaintance. Accordingly it was shown about for some time in manuscript, and received with all the applause it so justly merited. At last, the publisher of one of the magazines, having obtained a surreptitious copy of it, Mr. Gray wrote to Mr. Walpole, desiring that he would put his own manuscript into the hands of Mr. Doddsley, and order him to print it immediately. This was the most popular of all our author's publications. It ran through eleven editions in a very short space of time; was finely translated into Latin by Messrs. Anstey and Roberts; and in the same year by Mr. Lloyd.

From July 1759 to the year 1762, he generally resided in London, with a view, as we have already observed, of having recourse to the British Museum. In July 1768, his grace the duke of Grafton wrote him a polite letter, informing him, that his majesty had been pleased to offer to him the professorship of Modern History in the university of Cambridge, then vacant by the death of Mr. Laurence-Brocket. This place was valuable in itself, the salary being 400l. a year; but what rendered it particularly acceptable to Mr. Gray, was its being given him without any solicitation. He was indeed remarkably disinterested in all his pursuits. Though his income, before this addition, was very small, he never read or wrote with a view of making his labours useful to himself. He may be said to have been of those few personages in the annals of literature, especially in the poetical class, who are devoid of self-interest, and at the same time attentive to economy; and also was, among mankind in general, one of those very few economists, who possess that talent, untinged with the slightest stain of avarice. When his circumstances were at the lowest, he gave away such sums in private charity, as would have done credit to an ample purse. But what chiefly deterred him from seeking any advantage by his literary pursuits, was a certain degree of pride, which led him to despise the idea of being thought an author by profession.

However, it is probable, that early in life he had an intention of publishing an edition of Strabo; for his papers contain a great number of notes and geographical disquisitions on that author, particularly with respect to that part of Asia which comprehends Persia and India. The indefatigable pains which he took with the writings of Plato, and the quantity of critical as well as explanatory observations which he has left upon almost every part of his works, plainly indicate, that no man in Europe was better prepared to republish and illustrate that philosopher than Mr. Gray. Another work, on which he bestowed uncommon labour, was the Anthologia. In an interleaved copy of that collection of Greek epigrams, he has transcribed several additional ones, which he selected in his extensive reading; has inserted a great number of critical notes and emendations, and subjoined a copious index. But whether he intended this performance for the press or not, is uncertain. The only work which he meditated upon with this direct view, from the beginning, was a history of English poetry, upon a plan sketched out by Mr. Pope. He has mentioned this himself in an advertisement to those three fine imitations of Norse and Welch poetry, which he gave the world in the last edition of his poems. But, after he made some considerable preparations for the execution of this design, and Mr. Mason had offered him his assistance, he was informed that Mr. Warton, of Trinity College, Oxford, was engaged in a work of the same kind. The undertaking was there-

fore relinquished by mutual consent; and soon after, on that gentleman's desiring a sight of the plan, our author readily lent him a copy of it.

Among other sciences, Mr. Gray had acquired a great knowledge of Gothic architecture. He had seen and accurately studied in his youth, while abroad, the Roman proportions on the spot, both in ancient times and in the works of Palladio. In his later years he applied himself to consider those stupendous structures of more modern date that adorn our own country; which, if they have not the same grace, have undoubtedly equal dignity. He endeavoured to trace this ancient mode of building from the time it commenced, through its various changes, till it arrived at its perfection in the reign of Henry VIII. and ended in that of Elizabeth. For this purpose, he did not so much depend upon written accounts, as that internal evidence which the buildings themselves give of their respective antiquity; since they constantly furnish to the well-informed eye, arms, ornaments, and other marks, by which their several ages may be ascertained. On this account he applied himself to the study of heraldry as a preparatory science; and has left behind him a number of genealogical papers, more than sufficient to prove him a complete master of it. By these means he arrived at so very extraordinary a pitch of sagacity, as to be enabled to pronounce, at first sight, on the precise time when every particular part of any of our cathedrals was erected. But the favourite study of Mr. Gray, for the last ten years of his life, was natural history, which he then rather resumed than began; as, by the instructions of his uncle Antrobus, he was a considerable botanist at 15. The marginal notes which he has left on Linnæus and other writers on the vegetable, animal, and fossil kingdoms, are very numerous: but the most considerable are on Hudson's *Flora Anglica*, and the tenth edition of the *Systema Naturæ*; which latter he interleaved and filled almost entirely. While employed on zoology, he read Aristotle's treatise on that subject with great care, and explained many difficult passages of that obscure ancient by the lights he had received from modern naturalists. In a word, excepting pure mathematics, and the studies dependent on that science, there was hardly any part of human learning in which he had not acquired a competent skill, and in most of them a consummate mastery. To this account of his literary character we may add, that he had a fine taste in painting, prints, gardening, and music; and was moreover a man of good-breeding, virtue, and humanity.

He died in 1771; and an edition of his poems, with memoirs of his life and writings, was published in 4to, in 1775, by Mr. Mason. This gentleman, however, instead of employing his own pen in drawing Mr. Gray's character, has adopted one drawn by the Rev. Mr. Temple, rector of Mamhead in Devonshire, in a letter to Mr. Boswell; to whom the public are indebted for communicating it. "Perhaps (says Mr. Temple) he was the most learned man in Europe. He was equally acquainted with the elegant and profound parts of science, and that not superficially but thoroughly. He knew every branch of history, both natural and civil; had read all the original historians of England, France, and Italy: and was a great antiquarian. Criticism, metaphysics, morals, politics, made a principal part of his plan of study; voyages and travels of all sorts were his favourite amusement; and he had a fine taste in painting, prints, architecture, and gardening. With such a fund of knowledge, his conversation must have been equally instructing and entertaining; but he was also a good man, a well-bred man, a man of virtue and humanity. There is no character without some speck, some imperfection; and I think the greatest defect in his was an affectation of delicacy, or rather effeminacy, and a visible fastidiousness, or contempt and disdain of his inferiors in science. He also had, in some degree, that

weakness which disgusted Voltaire so much in Mr. Congreve: though he seemed to value others chiefly according to the progress they had made in knowledge, yet he could not bear to be considered himself merely as a man of letters; and though without birth, or fortune, or station, his desire was to be looked upon as a private independent gentleman, who read for his amusement. Perhaps it may be said, What signifies so much knowledge, when it produces so little? Is it worth taking so much pains to leave no memorial but a few poems? But let it be considered, that Mr. Gray was, to others, at least innocently employed; to himself, certainly beneficially. His time passed agreeably; he was every day making some new acquisition in science; his mind was enlarged, his heart softened, and his virtue strengthened; the world and mankind were shown to him without a mask; and he was taught to consider every thing as trifling, and unworthy the attention of a wise man, except the pursuit of knowledge, and the practice of virtue in that state wherein God hath placed us."

GRAYLING, in ornithology, a species of SALMO. In angling for this fish, the hook must be armed upon the shanks with a very narrow plate of lead, which should be slenderest at the bend of the hook, that the bait (which is to be a large grasshopper, the uppermost wing of which must be pulled off) may come over to it the more easily. At the point let there be a cad-bait in a continual motion. The jag-tail, which is a worm of a pale flesh-colour, with a yellow tag on its tail, is an excellent bait for the grayling in March and April.

GREASE, a swelling and disease in the skin of the legs of a horse. See FARRIERY, page 438.

GREATER TONE, in music. See TONE.

GREAVES (John), an eminent physician and antiquary, was the eldest son of John Greaves, rector of Colemore, near Alresford in Hampshire, and born in 1602. He was educated at Baliol College in Oxford, from which he removed to Merton. He was afterwards, on account of his great merit, chosen geometry professor of Gresham college. His ardent thirst of knowledge soon carried him into several parts of Europe, where he eagerly seized every opportunity of improving it. His next voyage was into the eastern countries; where nothing remarkable in the heavens, earth, or even subterraneous places, seems to have escaped his nice observation. He, with indefatigable industry, and even at the peril of his life, collected a considerable number of Arabic, Persian, and Greek manuscripts, for archbishop Laud. Of these he well knew the value, as he was a master of the languages in which they were written. He also collected for that prelate many oriental gems and coins. He took a more accurate survey of the pyramids than any traveller who went before him. On his return from the East, he visited several parts of Italy a second time. During his stay at Rome, he made a particular inquiry into the true state of the ancient weights and measures. Soon after he had finished his second voyage, he was chosen Savilian professor of astronomy at Oxford. He was eminently qualified for this professorship, as the works of ancient and modern astronomers were familiar to him. His books relating to oriental learning, his *Pyramidographia*, or a description of the pyramids in Egypt, his *Epocha Celebriores*, and other curious and useful pieces, of which Mr. Ward has given us a catalogue, show him to have been a great man. Those which he intended to publish would have shown him to be a greater; but he was stopped in his great career by death in 1652.

GREBE, in ornithology. See COLYMBUS.

GREECE, the present Rumelia, and in many respects one of the most deservedly celebrated countries in the world, was anciently bounded on the north by Macedonia and the river Strymon; on the west by the Ionian sea; on the south by the

Mediterranean; on the East by the Egean sea and Archipelago. It extended from the Strymon, by which it was parted from Thrace, to the promontory of Tenarus, the southmost point of the Peloponnesus, now the Morea, about $6^{\circ} 20'$ of latitude, or nearly 440 English miles, and in breadth from east to west about 359 miles.

The general names by which the inhabitants of this country were known to the ancients were those of *Graioi*, or *Graivoi*, from whence the name of *Greece* is plainly derived. These names are thought to come from Græcus, the father, or (according to some) the son, of Theſſalus, who gave name to Theſſaly; but some modern critics choose to derive it from *Ragau*, the same with *Reu*, the son of Peleg, by the transposition of a letter to soften the sound. These names were afterwards changed for *Achæi* and *Hellenes*; the first, as is supposed, from *Achæus*, the son of Xuthus, the son of Hellen, and father of Ion; or, according to the fable, the son of Jupiter: the other from Hellen above-mentioned, the son of Deucalion, and father of Dorus, from whom came the *Dores*, afterwards a famous nation among the Greeks. Another name by which the Greeks were known in some parts of the country was that of *Pelaſgi*, which the Arcadians, the most ancient people in Greece, deduced from their pretended founder *Pelaſgus*; who is said to have got such footing in Peloponnesus, that the whole peninsula from him was called *Pelaſgia*. But the most ancient name of all is universally allowed to have been that of *Ionæ*, which the Greeks themselves derived from Ion the son of Xuthus; or, as the fable hath it, of Apollo, by Creusa the daughter of Erichtheus the grandson of Deucalion. Josephus, however, affirms, that their original is of much older date; and that Javan, the son of Japhet, and grandson of Noah, was the first who peopled these countries; which Bochart hath also shown is very probable. It is true, indeed, that among the Greeks themselves, only the Athenians, and such colonies as sprung from them, were called *Ionæ*: but it is also plain beyond exception, that other nations gave this name to all the inhabitants of Greece.

The inhabitants of Greece in the first ages, even by the confession of their own historians, appear to have been savages scarce a degree removed from brutes. They lived indifferently on every fruit, herb, or root that came in their way; and lay either in the open fields, or at best sheltered themselves in dens, caves, and hollow trees; the country itself in the mean time remaining one continued uncultivated desert. The first improvement they made in their way of living, was the exchanging of their old food for the more wholesome acorns, building huts for themselves to sleep in, and covering their bodies with the skins of beasts. For all this, it seems they were beholden to *Pelaſgus* above mentioned (supposed by some to be Peleg spoken of in Scripture), and who was highly revered by them on that account. This reformation in their way of life, however, it seems, wrought none in their manners. On the contrary, they who had nothing to fight for but a hole to sleep in, began now to envy and rob one another of these slender acquisitions. This, in process of time, put them under a necessity of joining themselves into companies, under some head, that they might either more safely plunder their neighbours, or preserve what they had got. Laws they had none, except that of the sword: so that those only lived in safety who inhabited the most barren and craggy places; and hence Greece for a long time had no settled inhabitants, the weakest being always turned out by the strongest. Their gigantic size and strength, if we may believe Plutarch, added so much to their insolence and cruelty, that they seemed to glory in committing the greatest acts of violence and barbarity on those that unhappily fell into their hands.

The next advance towards civilization was their forming themselves into regular societies, to cultivate the lands, and build themselves towns and cities for their safety. Their origi-

nal barbarity and mutual violences against each other naturally prevented them from uniting as one nation, or even into any considerable community: and hence the great number of states into which Greece was originally divided. The most remarkable of these small principalities mentioned in history are the following: In Peloponnesus were those of Sicyon, Argos, and Messenia, Achaia Propria, Arcadia, and Laconia. In Grecia Propria (that part of Greece which lay without Peloponnesus), were those of Attica, Megara, Bœotia, Locris, Epichnemidia, Doris, Phœis, Locris, Ozolæa, and Ætolia. In Epirus were the Molossi, Amphiloichi, Cassiopæi, Dræopes, Chaoces, Threſſopotii, Almeni, and Acarnani. In Theſſaly were those of Theſſaliotis, Estiotis, Pelasgiotis, Magnesia, and Phthia. All these have at one time or other been severally governed by kings of their own, though we only find the names of many of them mentioned in the histories of the more considerable kingdoms of Sparta, Attica, Thebes, &c. The erection of these kingdoms; however, for some time, did not much alter the case; the inhabitants of the new kingdoms plundered and destroyed one another without mercy. Attica was the only place in any degree free from these incursions, because it was naturally destitute of every thing that could invite a plundering enemy; but those cities fared much worse which were situated on the sea-coasts; because they were in continual danger of being plundered either by the sea or land: for pirates at that time did not less infest all those seas than robbers did the land. And this was one main cause why most of the ancient cities of Greece were situated at some considerable distance from the shore; but even in these, as all their safety consisted in the resistance they could make against an invader, their inhabitants were under a necessity of going constantly armed, and being ever on their guard.

Another mischief arising from these continual piracies and robberies was, that they occasioned the far greater parts of the lands to lie uncultivated, so that the people only planted and sowed as much as was barely necessary for their present support; and where there was such an universal neglect of agriculture, there could be as little room for any discoveries in other useful arts and trades. Hence, when other nations, as the Jews, Egyptians, Midianites, Phœnicians, &c. had improved themselves to a very high degree, the Greeks seem to have been utter strangers to every useful art.

During this period of savage barbarity, the most renowned Grecian heroes, as Hercules, Theseus, &c. performed their exploits; which, however exaggerated by poetic fiction, no doubt had a foundation in truth. Some indeed are of opinion that the Grecian heroes are entirely fictitious, and their exploits derived from those of the Hebrew worthies, such as Samson, Gideon, &c. Yet, considering the extreme degree of barbarity which at that time prevailed throughout Greece, it seems not at all improbable that some persons of extraordinary strength and courage might undertake the cause of the oppressed, and travel about like the more modern knights-errant in quest of adventures.

The first expedition in which we find the Greeks united was that against Troy, some particulars of which are noticed under the article TROY. Their success here (which happened about 1184 B. C.) cost them very dear; vast numbers of their bravest warriors being slain; great numbers of the survivors being cast away in their return; and many of those who had the good luck to get back again being soon after murdered, or driven out of their country. It is probable, however, that their having staid for such a long time in Asia might contribute to civilize the Greeks somewhat sooner than what they otherwise would have been; and accordingly from this time, we find their history somewhat less obscure, and, as it were, beginning to emerge out of darkness. The continual wars, indeed, in which they were engaged among themselves, no doubt, for a long time, prevented them

from making any considerable advances in those arts in which they afterwards made so great a progress. These wars, which indeed never ceased as long as the Greeks preserved their liberty, rendered them brave, and skilled in the military art, above all other nations; but at the same time they effectually prevented them from making permanent conquests, and confined them within the bounds of their own country; while the different states were one way or other so equally balanced, that scarce one of them was able perfectly to subdue any other. The Spartans, however, having with great difficulty reduced the kingdom of Melene, and added its territories to their own, became the leading people in Greece. Their superiority was long disputed by Athens; but the Peloponnesian war at last determined that point in favour of the Spartans, when the city of Athens was taken, and its walls demolished as history informs us, by Lysander the Spartan general. By the battle of Leuctra, the Spartans lost that superiority which they had maintained for 500 years, and which now devolved on the Thebans. After the death of Epaminondas, the celebrated Theban general, however, as no person was found possessed of his abilities, the Thebans were again obliged to yield the superiority to the Spartans. But by this time the Greeks had become acquainted with the luxuries and elegancies of life; and all the rigour of their original laws could not prevent them from valuing these as highly as other people. This did not indeed abate their valour, but it heightened their mutual animosities; at the same time that, for the sake of a more easy and comfortable life, they became more disposed to submit to a master. The Persians, whose power they had long dreaded, and who were unable to resist them by force of arms, at last found out (by the advice of Alcibiades) the proper method of reducing the Grecian power; namely, by assisting them by turns, and supplying one state with money to fight against another, till they should all be so much reduced, that they might become an easy prey. Thus the Greeks were weakened, though the Persians did not reap any benefit from their weakness. Philip of Macedon entered into the same political views; and partly by intrigue, partly by force, got himself declared Generalissimo of Greece. His successor Alexander the Great completed their subjection; and by destroying the city of Thebes, and exterminating its inhabitants, struck such a terror throughout Greece, that he was as fully obeyed by all the states as by any of the rest of his subjects. During his absence in Persia, however, they attempted to shake off the Macedonian yoke, but were quelled by his general Antipater. The news of Alexander's death was to them a matter of the utmost joy; but their mutual animosities prevented them from joining in any solid plan for the recovery of their liberties, and hence they continued to be oppressed by Alexander's successors, or other tyrants, till Aratus, an Achæan, about 268 B. C. formed a design of setting his country free from these oppressors. He persuaded a number of the small republics to enter into a league for their own defence, which was called the *Achæan league*; and notwithstanding that the republics, taken singly, had very little strength, they not only maintained their independency, but soon became formidable when united. This association continued to become daily more and more powerful; but received a severe check from Cleomenes, king of Sparta, which obliged them to call in Antigonus to their assistance. This prince overcame Cleomenes at the battle of Sellasia, and afterwards made himself master of Sparta. Thus he became a more formidable enemy than the one he had conquered, and the recovery of the Grecian liberties was incomplete.

Soon after this, the Greeks began to feel the weight of a power more formidable than any which they had yet experienced, namely, that of the Romans. That insidious and haughty republic first intermeddled with the Grecian affairs, under pretence of setting them at liberty from the oppression of

Philip of Macedon. This, by a proper union among themselves, they might have accomplished; but in this they acted as though they had been insatuated; receiving with the utmost joy the decree of the Roman consul, who declared them free; without considering, that he who had thus given them liberty might take it away at his pleasure. This lesson, however, they were soon taught, by the total reduction of their country to a Roman province; yet this can scarce be called a misfortune, when we look back to their history, and consider their outrages upon one another: nor can we sympathise with them for the loss of that liberty which they only made use of to fill their country with slaughter and bloodshed. After their conquest by the Romans, they made no united effort to recover their liberty. They continued in quiet subjection till the beginning of the 15th century. About that time, they began to suffer under the tyranny of the Turks, and their sufferings were completed by the taking of Constantinople in 1453. Since that time, they have groaned under the yoke of a most despotic government; so that all traces of their former valour, ingenuity, and learning, are now in a manner totally extinct.

Modern Greece comprehends Macedonia; Albania, now called *Arnaut*; Epirus; Thessaly, now *Jana*; Achaia, now *Livadia*; the Peloponnesus, now *Morea*; together with the islands on its coast, and in the Archipelago. The continent of Greece is seated betwixt the 36th and 43d degrees of north latitude; and between the 19th and 27th degrees of longitude, east of London. To the north it is bounded by Bulgaria and Servia, from which it is divided by a ridge of mountains; to the south by the Mediterranean sea; to the east by Romania and the Archipelago, and to the west by the Adriatic, or gulph of Venice. Its length is said to be about 400 miles, and its utmost breadth about 350 miles. The air is extremely temperate and healthy; and the soil fruitful, though badly cultivated, yielding corn, wine, delicious fruits, and abounding with cattle, fowls, and venison. As to religion, Christianity was planted in Greece soon after the death of our Saviour, and flourished there for many ages in great purity; but since the Greeks became subject to the Turkish yoke, they have sunk into the most deplorable ignorance, in consequence of the slavery and thralldom under which they groan, and their religion is now greatly corrupted. It is indeed little better than a heap of ridiculous ceremonies and absurdities. The head of the Greek church is the patriarch of Constantinople; who is chosen by the neighbouring archbishops and metropolitans, and confirmed by the emperor or grand visir. He is a person of great dignity, being the head and director of the eastern church. The other patriarchs are those of Jerusalem, Antioch, and Alexandria. Mr. Tournefort tells us, that the patriarchates are now generally set to sale, and bestowed upon those who are the highest bidders. The patriarchs, metropolitans, archbishops, bishops, are always chosen from among the Caloyers or Greek monks. Before the patriarchs receive their patents and the castan, which is a vest of linsy-woolsey, or some other stuff, presented by the grand signior to ambassadors and other persons newly invested with some considerable dignity, they are obliged to make large presents to the visir, &c. The income of the patriarch of Constantinople is said to amount to no less than one hundred and twenty thousand guilders, of which he pays the one-half, by way of annual tribute, to the Ottoman Porte, adding six thousand guilders besides as a present at the feast of Bairam. The next person to a bishop among the clergy is an archimandrite, who is the director of one or more convents, which are called *mandren*; then come the abbot, the arch-priest, the priest, the deacon, the under-deacon, the chanter, and the lecturer. The secular clergy are subjected to no rules, and never rise higher than high-priest. They are allowed to marry once; but it must be with a virgin, and before they are ordained.

They have neither glebe nor tythes, but depend on the perquisites that arise from their office; and they seldom preach but in Lent. The Greeks have few nunneries; but a great many convents of monks, who are all priests, and, students excepted, obliged to follow some handicraft employment, and lead a very austere life. The Greeks deny the supremacy of the pope, and abhor the worship of images; but have a multitude of pictures of saints in their churches, whom they pray to as mediators. Their fasts are very severe. They believe also in the doctrine of transubstantiation, and that the Holy Ghost does not proceed from the Son. They admit not of purgatory, says Mr. Thevenot: but yet they allow a third place, where they say the blessed remain, in expectation of the day of judgment. At mass they consecrate with leavened bread; and communicate under both kinds, as well laics as priests, and as well women and children as men. When they carry the sacrament to the sick, they do not prostrate themselves before it, nor expose it to be adored: neither do they carry it in procession, or have any particular feast in honour of it. Baptism is performed among them by plunging the whole body of the child thrice into water. Immediately after baptism, they give it confirmation and the communion; and seven days after that, it undergoes the ceremony of ablution. When a priest is married, among other ceremonies, the bridegroom and bride drink each two glasses of wine; then the glass is given to the priest, who merrily drinks off the rest of the wine, and, breaking the glass, says, So may the bridegroom break the virginity of the bride. As to the character of the modern Greeks, they are said to be very covetous, hypocritical, treacherous, great pederasts, and at the same time revengeful to the highest degree, but very superstitious. They are so much despised by the Turks, that these do not value even a Greek who turns Mahometan. The Turks are remarkable for their taciturnity; they never use any unnecessary words; but the Greeks, on the contrary, are very talkative and lively. The Turks generally practise what their religion enjoins, but the Greeks do not; and their misery puts them upon a thousand mean shifts and scandalous practices, authorized by bad example, and perpetuated from father to son. The Greek women have fine features and beautiful complexions: their countenances still very much resemble those of the ancient Greek statues.

GREEK, or GRECIAN, any thing belonging to ancient Greece. The Greek language, as preserved in the writings of the celebrated authors of antiquity, as Homer, Hesiod, Demosthenes, Aristotle, Plato, Xenophon, &c. has a great variety of terms and expressions, suitable to the genius and occasions of a polite and learned people, who had a taste for arts and sciences. In it, proper names are significant; which is the reason that the modern languages borrow so many terms from it. When any new invention, instrument, machine, or the like, is discovered, recourse is generally had to the Greek for a name to it; the facility wherewith words are there compounded, affording such as will be expressive of its use: such are, barometer, hygrometer, microscope, telescope, thermometer, &c. But of all sciences, medicine most abounds with such terms; as diaphoretic, diagnosis, diarrhoea, hæmorrhage, hydrophobia, phthisis, atrophy, &c. Besides the copiousness and significance of the Greek, wherein it excels most, if not all, the other languages, it has also three numbers, viz. a singular, dual, and plural: also abundance of tenses in its verbs, which makes a variety in discourse, prevents a certain dryness that always accompanies too great a uniformity, and renders that language peculiarly proper for all kinds of verse. The use of the participles, of the aorist and preterite, together with the compound words already mentioned, give it a peculiar force and brevity, without taking any thing from its perspicuity.

It is no easy matter to assign the precise difference between

the modern and ancient Greek; which consists in the terminations of the nouns, pronouns, verbs, &c. not unlike what obtains between some of the dialects of the Italian or Spanish. There are also in the modern Greek many new words, not to be met with in the ancient. We may therefore distinguish three ages of the Greek tongue: the first of these ends at the time when Constantinople became the capital of the Roman empire; the second lasted from that period to the taking of Constantinople by the Turks; and the third from that time to the present.

GREEK Bible. See BIBLE.

GREEK Church, is that part of the Christian church which is established in Greece; extending likewise to some other parts of Turkey. See GREECE. It is thus called in Europe, Asia, and Africa, in contradistinction from the Latin or Romish church; as also the Eastern church, in distinction from the Western. The Romanists call the Greek church, the *Greek schism*; because the Greeks do not allow the authority of the pope, but depend wholly, as to matters of religion, on their own patriarchs. They have treated them as schismatics ever since the revolt, as they call it, of the patriarch Photius.

GREEK Monks and Nuns, of whatever order, consider St. Basil as their founder and common father, and esteem it the highest crime to deviate in the least from his constitutions. There are several beautiful convents with churches, in which the monks perform divine service day and night. Some of the monks are cœnobites, or live together, wear the same habit, eat at the same table, and perform the same exercises and employments.

GREEK Orders, in architecture, are the Doric, Ionic, and Corinthian; in contradistinction to the two Latin orders, the Tuscan and Composite. See ORDER.

GREEN, one of the original prismatic colours, exhibited by the refraction of the rays of light. See CHROMATICS and COLOUR.

GREEN, among painters and dyers. See COLOUR-Making, and the article DYEING, page 136.

GREEN-Finch, in ornithology, the English name of the greenish fringilla, with the wings and tail variegated with yellow. See FRINGILLA.

GREEN-House, or Conservatory, a house in a garden, contrived for sheltering and preserving the most curious and tender exotic plants, which in our climate will not bear to be exposed to the open air, especially during the winter season. These are generally large and beautiful structures, equally ornamental and useful.

The length of greenhouses must be proportioned to the number of plants intended to be preserved in them, and cannot therefore be reduced to rule: but their depth should never be greater than their height in the clear; which, in small or middling houses, may be 16 or 18 feet, but in large ones from 20 to 24 feet; and the length of the windows should reach from about one foot and a half above the pavement, and within the same distance of the ceiling, which will admit of a cornice round the building over the heads of the windows. Their breadth cannot be in proportion to their length; for, if in the largest buildings they are more than seven or seven feet and a half broad, they will be extremely heavy and inconvenient. The piers between the windows must be as narrow as may be to support the buildings; for which reason they should either be of stone or of hard burnt bricks. If the piers are made of stone, they should be 30 inches wide in front, and sloped off behind to about 18 inches, by which means there will be no corners to take off the rays of the sun. If they are of brick, they will require to be at least three feet in front, but they should be in the same manner sloped off behind. Over the greenhouse may be rooms for dry-

ing and preserving seeds, roots, &c. and behind it a place for tools and other purposes; and both these behind, and the rooms above, will be of great use in keeping off the frosts, so that the wall between these need not be of more than two bricks and a half in thickness.

The floor of the greenhouse, which should be laid either with Bremen squares, Purbeck stone, or flat tiles, must be raised two feet above the surface of the adjoining ground, or, if the situation be damp, at least three feet; and if the whole is arched with low brick arches under the floor, they will be of great service in preventing damps; and under the floor, about two feet from the front, it will be very advisable to make a flue of ten inches wide and two feet deep; this should be carried the whole length of the house, and then returned back along the hinder part, and there be carried up into funnels adjoining to the tool-house, by which the smoke may be carried off. The fire-place may be contrived at one end of the house, and the door at which the fuel is put in, as also the ash-grate, may be contrived to open into the tool-house, and the fuel being laid in the same place, the whole will be out of sight. Bradley advises, that the front of greenhouses in the colder parts of England be built in a sweep or semicircle, so that one part or other of it may receive the sun's rays all day. The use of fires must, however, be very sparing in this place; and it is not one winter in three or four that will require them in any part, only when the weather is very severe, and the frost cannot well be kept out any other way; this is an expedient that is good to have in readiness, as it may save a whole house of plants. Within side of the windows, in front of the greenhouse, there should be good strong shutters, made with hinges, to fold back close to the piers, that they may not obstruct the rays of the sun. The back part of the house should be either laid over with stucco, or plastered with mortar, and whitewashed, in order to prevent the frosty air from penetrating through the walls. When the greenhouse is wainscoted, the walls should be plastered with lime and hair behind the wainscot, to keep out the cold; and the wainscot, as well as the ceiling, and every part within the house, should be painted white, for the reflection of the sun's rays. There must be a number of trellises, with forms of wood upon them, to support the pots of plants; the tallest to be placed hindmost, the lowest within four feet of the windows: and the rows of plants should rise gradually, so that the heads of the second row should be entirely above the first; and behind them there should be a space of at least five feet, for the convenience of watering the plants, and for a free circulation of air. It has been observed, that the placing of the euphorbiums, cereuses, and other succulent plants among orange-trees, and other common greenhouse-plants, is always destructive of them, by making them receive an improper sort of effluvia, which plants of that kind imbibe very freely. They should therefore be placed in two wings built at each end of the greenhouse; which, if well contrived, will be a great beauty as well as use to the building. These wings may be made capable of a greater warmth also by more flues, and may be made to contain a hot-bed of tanners' bark for the raising many of the tender plants that are natives of warm climates.

Whilst the front of the greenhouse is exactly south, one of the wings may be made to face the south-east and the other the south-west. By this disposition the heat of the sun is reflected from one part of the building to the other all day, and the front of the main greenhouse is guarded from the cold winds. These two wings may be so contrived as to maintain plants of different degrees of hardness, which may be easily effected by the situation and extent of the fire-place, and the manner of conducting the flues: the wing facing the south-east is evidently the most proper for the warmest stove; this may be divided in the middle by a partition of glass, with glass-doors opening from one

division to the other. In each of these there should be a fire-place, with flues carried up against the back-wall, through which the smoke should be made to pass as many times the length of the house as the height will admit of the number of flues; for the longer the smoke is in passing, the more heat will be given to the house with a less quantity of fuel. The other wing, facing the south-west, should be divided and furnished with flues in the same manner; and thus different degrees of heat may be obtained, according to the seasons and the particular sorts of plants that are to be preserved. If there are no sheds behind these wings, the walls should not be less than three bricks thick; and the back part, having sloping roofs, which are covered with tiles or slates, should be lined with reeds, &c. under the covering. The sloping glasses of these houses should be made to slide and take off, so that they may be drawn down more or less in warm weather to admit air to the plants; and the upright glasses in the front may be so contrived, as that every other may open as doors upon hinges, and the alternate glasses may be divided into two: the upper part of each should be so contrived as to be drawn down like shades, so that either of them may be used to admit air in a greater or less quantity as there may be occasion.

As to the management of plants in a greenhouse, Mortimer recommends the opening of the mould about them from time to time, and sprinkling a little fresh mould in them, and a little warm dung on that: as also to water them when the leaves begin to wither and curl, and not oftener, which would make them fade and be sickly; and to take off such leaves as wither and grow dry.

GREEN-Sickness, Chlorosis. See MEDICINE.

GREEN-Silver, the name of an ancient custom within the manor of Writtel in the county of Essex in England; which is, that every tenant, whose fore-door opens to Greenbury, shall pay an halfpenny yearly to the lord, by the name of *green-silver*.

GREEN-Wax, is used where estates are delivered to the sheriffs out of the exchequer, under the seal of that court, made in green-wax, to be levied in the several counties. This word is mentioned in 43d stat. Ed. III. c. 9. and 7 Hen. IV. c. 4.

GREENLAND, a general name by which are denoted the most easterly parts of America, stretching towards the N. Pole, and likewise some islands to the N. of the continent of Europe, lying in very high latitudes. This country is divided into W. and E. Greenland. West Greenland is now determined by our latest maps to be a part of the continent of America, though on what authority is not very clear. That part of it of which the Europeans have any knowledge, is bounded on the W. by Baffin's Bay, on the S. by Davis' Straits, and on the E. by the northern part of the Atlantic Ocean. East Greenland was for a long time considered as a part of the continent of W. Greenland, but is now discovered to be an assemblage of islands lying between 9° and 20° E. lon. and 76. 46. and 80. 30. N. lat. It was discovered in 1533 by sir Hugh Willoughby, who called it Greenland, supposing it to be part of the western continent. In 1595 it was visited by William Barentz and John Cornelius, two Dutchmen, who pretended to be the original discoverers, and called the country Spitzbergen, or sharp mountains, from the many sharp-pointed and rocky mountains with which the country abounds. The few inhabitants of Greenland are savages, and much like the Esquimaux. It is a cold miserable country, and has very few animals, except deer, white bears, foxes, and a few wild fowls. Here the English, Dutch, and other nations, go every year to catch whales, for the sake of their fins and oil. It was so called, because those that discovered it at first found the shore covered with green moss. Attempts have been made to settle in it; but the men generally perished with the severity of the cold.

GREENLAND Company. A joint stock of 40,000l. was by statute to be raised by subscribers, who were incorporated for 14 years from the first of October 1693, and the company to use the trade of catching whales, &c. into and from Greenland, and the Greenland seas. They may make bye-laws for the government of the persons employed in their ships, &c. Stat. 4 and 5 W. III. cap. 17. This company was farther encouraged by parliament in 1696; but partly by unskilful management, and partly by real losses, it was under the necessity of entirely breaking up, before the expiration of the term assigned to it, ending in 1707. But any person who will adventure to Greenland for whale-fishing shall have all the privileges granted to the Greenland company by 1 Anne, cap. 16. and thus the trade was again laid open. Any subjects may import whale-fins, oil, &c. of fish caught in the Greenland seas, without paying any customs, &c. Stat. 10 Geo. I. cap. 16. And ships employed in the Greenland fishery are to be of a given burden, provided with boats, so many men, fishing-lines, harping-irons, &c. and be licensed to proceed; and on their return shall be paid 20s. per ton bounty for whale-fins, &c. imported. 6 Geo. II. cap. 33. The bounty was afterwards increased, but has been lately diminished, and since this diminution the trade has increased. See *BALÆNA* and *Whale-FISHERY*.

GREENOCK, a considerable seaport of Scotland, in the county of Renfrew, at the mouth of the Clyde. It is a place of great resort for shipping; but its trade chiefly depends on Glasgow. It has a great share in the herring-fishery; and the town has much increased within the last 30 years. Here is a sugar-house, and a rope and sail manufactory. At the W. end of the town is a small fort for the defence of the harbour. It is 22 miles W. of Glasgow. W. lon. 4. 29. N. lat. 55. 54.

GREENWICH, a town in Kent, five miles E. of London, noted for its magnificent hospital for decayed seamen, its delightful park, and its astronomical observatory, on the summit of a hill, called Flamstead Hill, from the great astronomer of that name, who was here the first astronomer-royal. The English compute the longitude from the meridian of this place. The hospital is thought to be the finest structure of the kind in the world; and its noble hall is finely painted by Sir James Thornhill. The chapel was destroyed, Jan. 2, 1779, by a dreadful fire, which likewise consumed the dining-hall and eight wards. But the whole is rebuilt; and the chapel was opened for divine service on the 20th of September 1789. The rebuilding of this beautiful structure, which is decorated in a style of the most elegant simplicity, cost 84,000l. Here was once a royal palace, in which queen Mary and queen Elizabeth were born, and in which Edward VI. died. It has been long pulled down, and on part of the site of it now stands the house belonging to the ranger of the park; and which, from the Thames, appears in the centre, beyond the two extremities of the hospital. The church, one of the 50 new churches, is dedicated to St. Alphage. In this town is a college, called the Duke of Norfolk's College, although founded by Henry earl of Northampton, father of the celebrated earl of Surry. It is for the maintenance of 20 decayed housekeepers; 12 from Greenwich, and eight chosen alternately from Snettisham and Castle Rising in Norfolk. Here is also an hospital, called Queen Elizabeth's College, founded by Mr. Lambard, author of the *Peregrination of Kent*, the first erected by any English Protestant subject.

GREGARIOUS, among zoologists, a term applied to such animals as do not live solitary, but associate in herds or flocks.

GREGORIAN CALENDAR, that which shews the new and full moon, with the time of Easter, and the moveable feasts de-

pending thereon, by means of epacts disposed through the several months of the Gregorian year. See *CHRONOLOGY*, page 523.

GREGORIAN Telescope. See *OPTICS*.

GREGORIAN Year. See *CHRONOLOGY*, page 523.

GREGORY the Great, was born at Rome, of a patrician family. He discovered such abilities in the exercise of the senatorial employments, that the emperor Justin the younger appointed him prefect of Rome. Pope Pelasgius II. sent him nuncio to Constantinople, to demand succours against the Lombards. When he thought of enjoying a solitary life, he was elected pope by the clergy, the senate, and the people of Rome. Besides his learning and diligence in instructing the church, both by writing and preaching, he had a very happy talent in winning over princes in favour of the temporal as well as spiritual interests of religion. He undertook the conversion of the English, and sent over some monks of his order, under the direction of Augustin their abbot. His morality with respect to the chastity of churchmen was very rigid, asserting, that a man who had ever known a woman ought not to be admitted to the priesthood; and he always caused the candidates for it to be examined upon that point. He likewise vigorously exerted himself against such as were found guilty of calumny. However, he flattered the emperor Phocas, while his hands were yet reeking with the blood of Mauritius, and of his three children, who had been butchered in his sight. He likewise flattered Brunehaut, a very wicked queen of France. He is accused of destroying the noble monuments of ancient Roman magnificence, that those who visited the city might not attend more to the triumphal arches than to holy things; and burnt a multitude of heathen books, those of Livy in particular. He died in 604.

GREGORY of Nazianzen, surnamed the *Divine*, was one of the most illustrious ornaments of the Greek church in the fourth age. He was made bishop of Constantinople in 379; but finding his election contested by Timotheus archbishop of Alexandria, he voluntarily resigned his dignity about 382, in the general council of Constantinople. His works are extant, in two volumes, printed at Paris in 1609. His style is said to be equal to that of the most celebrated orators of ancient Greece.

GREGORY (Theodorus), surnamed *Theomaturgus*, on account of his miracles, was the scholar of Origen; and was elected bishop of Neocæsarea, the place of his birth, about the year 240, during his absence. He assisted at the council of Antioch in 255, against Paulus Samosetanus, and died in 270. He had the satisfaction of leaving only seventeen idolaters in his diocese, where there were but seventeen Christians when he was ordained. There is still extant of his, A gratulatory oration to Origen, A canonical epistle, and some other works.

GREGORY, bishop of Nyssa, one of the fathers of the church, and author of the Nicene creed, was born in Cappadocia about the year 331. He was chosen bishop of Nyssa in 372; and banished by the emperor Valens for adhering to the council of Nice. He was nevertheless afterwards employed by the bishops in several important affairs, and died in 396. He wrote Commentaries on the Scriptures; Sermons on the mysteries; Moral discourses; Dogmatical treatises; Panegyrics on the saints; some letters on church discipline; and other works. His style is very allegorical and affected.

GREGORY of Tours, or *Georgius Florentinus Gregorius*, one of the most illustrious bishops and celebrated writers of the sixth century, was descended from a noble family in Auvergne. He was educated by his uncle Gallus, bishop of Clermont, and distinguished himself so much by his learning and virtue, that in

573 he was chosen bishop of Tours. He afterwards went to Rome to visit the tomb of the apostles, where he contracted a friendship with Gregory the Great, and died in 595. This author was extremely credulous with regard to miracles. He wrote, 1. The history of France. 2. The lives of the saints; and other works. The best edition is that published by Father Rumart, in 1699.

GREGORY (James), one of the most eminent mathematicians of the last century, was a son of the Rev. Mr. John Gregory, minister of Drumoak in the county of Aberdeen, and was born at Aberdeen in 1638. His mother was a daughter of Mr. David Anderson of Finzaugh, a gentleman who possessed a singular turn for mathematical and mechanical knowledge. This mathematical genius was hereditary in the family of the Andersons, and from them seems to have been transmitted to their descendants of the name of Gregory. Alexander Anderson, cousin-german of the above-mentioned David, was professor of mathematics at Paris in the beginning of the 17th century, and published there, in 1612, *Supplementum Apollonii redivivi, &c.* The mother of James Gregory inherited the genius of her family; and observing in her son, while yet a child, a strong propensity to mathematics, she instructed him herself in the elements of that science. He received his education in the languages at the grammar school of Aberdeen, and went through the usual course of academical studies in the Marischal college.

At the age of 24 he published his treatise, intitled *Optica Promota, seu abilita radiorum reflexorum et refractorum mysteria, geometricæ enucleata; cui subnectitur appendix subtilissimorum astronomiæ problematon resolutionem exhibens*, London 1663: a work of great genius, in which he gave the world an invention of his own, and one of the most valuable of the modern discoveries, the construction of the reflecting telescope. This discovery immediately attracted the attention of the mathematicians, both of our own and foreign countries, who were soon convinced of its great importance to the sciences of optics and astronomy. The manner of placing the two specula upon the same axis appearing to Sir Isaac Newton to be attended with the disadvantage of losing the central rays of the larger speculum, he proposed an improvement on the instrument, by giving an oblique position to the smaller speculum, and placing the eye-glass in the side of the tube. But it is worth remarking, that the Newtonian construction of that instrument was long abandoned for the original or Gregorian, which is at this day universally employed where the instrument is of a moderate size; though Mr. Herschel has preferred the Newtonian form for the construction of those immense telescopes, which of late years he has so successfully employed in examining the heavens.

The university of Padua being at that time in high reputation for mathematical studies, James Gregory went thither soon after the publication of his first work; and fixing his residence there for some years, he published in 1667, *Vera Circuli et Hyperboles quadratura*; in which he propounded another discovery of his own, the invention of an infinitely converging series for the areas of the circle and hyperbole. To this treatise, when published in 1668, he added a new work, intitled, *Geometriæ pars universalis, inserviens quantitatum curvarum transmutationi et mensuræ*; in which he is allowed to have shown, for the first time, a method for the transmutation of curves. These works engaged the notice, and procured Mr. Gregory the correspondence, of the greatest mathematicians of the age, Newton, Huygens, Halley, and Wallis; and their author being soon after chosen a fellow of the royal society of London, contributed to enrich the Philosophical Transactions at that time by many excellent papers. Through this channel, in particular, he carried on a dispute with Mr. Huygens, upon the occasion of his

treatise on the quadrature of the circle and hyperbole, to which that able mathematician had started some objections. Of this controversy, it is unnecessary to enter into particulars. It is sufficient to say, that, in the opinion of Leibnitz, who allows Mr. Gregory the highest merit for his genius and discoveries, Mr. Huygens has pointed out, though not errors, some considerable deficiencies in the treatise above mentioned, and shown a much simpler method of attaining the end in view.

In 1668 Mr. James Gregory published at London another work, intitled *Exercitationes Geometricæ*, which contributed still to extend his reputation. About this time he was elected professor of mathematics in the university of St. Andrew's; an office which he held for six years. During his residence there, he married in 1669 Mary, the daughter of George Jameſon the celebrated painter, whom Mr. Walpole has termed the Vandyke of Scotland, and who was fellow-disciple with that great artist in the school of Rubens at Antwerp.

In 1674 he was called to Edinburgh, to fill the chair of mathematics in that university. This place he had held for little more than a year, when, in October 1675, being employed in showing the satellites of Jupiter through a telescope to some of his pupils, he was suddenly struck with total blindness, and died a few days after, at the early age of 37.

He was a man of an acute and penetrating genius. His temper seems to have been warm, as appears from the conduct of his dispute with Mr. Huygens; and, conscious perhaps of his own merits as a discoverer, he seems to have been jealous of losing any portion of his reputation by the improvements of others upon his inventions.

GREGORY (David), Savilian professor of astronomy at Oxford, whom Dr. Smith has termed *subtilissimi ingenii mathematicus*, was the eldest son of Mr. Gregory of Kinnairdy, brother of the abovementioned Mr. James Gregory. He was born at Aberdeen in 1661, and received the earlier parts of his education in that city. He completed his studies at Edinburgh; and, being possessed of the mathematical papers of his uncle, soon distinguished himself likewise as the heir of his genius. In the 23d year of his age, he was elected professor of mathematics in the university of Edinburgh; and published, in the same year, *Exercitatio Geometrica de dimensione figurarum, sive specimen methodi generalis dimetiendi quasvis figuras*, Edinburgh, 1684, 4to. He saw very early the excellence of the Newtonian philosophy; and had the merit of being the first who introduced it into the schools by his public lectures at Edinburgh. "He had (says Mr. Whiston) already caused several of his scholars to keep acts, as we call them, upon several branches of the Newtonian philosophy; while we at Cambridge, poor wretches, were ignominiously studying the fictitious hypotheses of the Cartesian."

In 1691, on the report of Dr. Bernard's intention of resigning the Savilian professorship of astronomy at Oxford, David Gregory went to London; and being patronised by Sir Isaac Newton, and warmly befriended by Mr. Flamsteed the astronomer royal, he obtained the vacant professorship, for which Dr. Halley was a competitor. This rivalry, however, instead of animosity, laid the foundation of friendship between these eminent men; and Halley soon after became the colleague of Gregory, by obtaining the professorship of geometry in the same university. Soon after his arrival in London, Mr. Gregory had been elected a fellow of the royal society; and, previously to his election into the Savilian professorship, had the degree of doctor of physic conferred on him by the university of Oxford.

In 1693 he published in the Philosophical Transactions a re-

solution of the Florentine problem *de Testuline veliformi quadribili*; and he continued to communicate to the public, from time to time, many ingenious mathematical papers by the same channel. In 1695 he printed at Oxford *Catoptrica et Dioptrica Sphæricæ Elementa*; a work which, as he informs us in his preface, contains the substance of some of his public lectures read, eleven years before, at Edinburgh. This valuable treatise was republished first with additions by Dr. William Brown, with the recommendation of Mr. Jones and Dr. Desaguliers; and afterwards by the latter of these gentlemen, with an appendix containing an account of the Gregorian and Newtonian telescopes, together with Mr. Hadley's tables for the construction of both those instruments. It is not unworthy of remark, that, in the end of this treatise, there is an observation which shows, that what is generally believed to be a discovery of a much later date, the construction of achromatic telescopes, which has been carried to great perfection by Mr. Dollond and Mr. Ramsden, had suggested itself to the mind of David Gregory, from the reflection on the admirable contrivance of nature in combining the different humours of the eye. The passage is as follows: "Quod si ob difficultates physicas in speculis idoneis torno elaborandis et poliendis, etiamnum lentibus uti oporteat, fortassis media diversæ densitatis ad lentem objectivam componendam adhibere utile foret, ut a natura factum observamus in oculi fabrica, ubi crystallinus humor (fere ejusdem cum vitro virtutis ad radios lucis refringendos) aqueo et vitreo (aquæ quoad refractionem haud ab similibus) conjungitur, ad imaginem quam distincte fieri poterit, a natura nihil frustra moliente, in oculi fundo depingendam." *Catopt. et Dioptr. Sphær. Elem. Oxon. 1695, p. 98.*

In 1702 our author published at Oxford, *Astronomicæ Physicæ et Geometricæ Elementa*; a work which is accounted his masterpiece. It is founded on the Newtonian doctrines, and was esteemed by Sir Isaac Newton himself as a most excellent explanation and defence of his philosophy. In the following year he gave to the world an edition in folio of the works of Euclid in Greek and Latin; in prosecution of a design of his predecessor Dr. Bernard, of printing the works of all the ancient mathematicians. In this work, although it contains all the treatises attributed to Euclid, Dr. Gregory has been careful to point out such as he found reason, from internal evidence, to believe to be the productions of some inferior geometrician. In prosecution of Dr. Bernard's plan, Dr. Gregory engaged soon after, with his colleague Halley, in the publication of the Conics of Apollonius; but he had proceeded but a little way in this undertaking when he died, in the 49th year of his age, at Maidenhead in Berkshire, A. D. 1710. To the genius and abilities of David Gregory, the most celebrated mathematicians of the age, Sir Isaac Newton, Dr. Halley, and Dr. Keill, have given ample testimonies. Besides those works published in his lifetime, he left in manuscript, *A Short Treatise of the Nature and Arithmetical of Logarithms*, which is printed at the end of Dr. Keill's translation of Commandine's Euclid; and a *Treatise of Practical Geometry*, which was afterwards translated, and published in 1745, by Mr. Maclaurin.

Dr. David Gregory married in 1695 Elizabeth, the daughter of Mr. Oliphant of Langtown in Scotland. By this lady he had four sons, of whom, the eldest, David, was appointed regius professor of modern history at Oxford by king George I. and died in 1767, in an advanced age, after enjoying for many years the dignity of dean of Christ church in that university.

GREGORY (Dr. John), professor of medicine in the university of Edinburgh, was the son of Dr. James Gregory, professor of medicine in King's college, Aberdeen, and grandson of James the inventor of the Gregorian telescope. He owed much in his

infant years, and during the whole course of his studies, to his cousin, the celebrated Dr. Reid of Glasgow. The rudiments of a classical education he received at the grammar-school of Aberdeen; and completed in King's college his studies in the Latin and Greek languages, and in the sciences of ethics, mathematics, and natural philosophy.

In 1742 Mr. Gregory went to attend the lectures at Edinburgh; and in the year 1745 for the same purpose went to Leyden. While at the latter place he received from the King's college of Aberdeen, his *alma mater*, an unsolicited degree in medicine; and soon after, on his return thither from Holland, he was elected professor of philosophy in the same university. In this capacity he read lectures during the years 1747, 1748, and 1749, on mathematics, on experimental philosophy, and on moral philosophy. In the end of 1749, however, he chose to resign his professorship of philosophy, his views being turned chiefly to the practice of physic, with which he apprehended the duties of this professorship, occupying a great portion of his time, too much interfered. Previously, however, to his settling as a physician at Aberdeen, he went for a few months to the Continent; a tour of which the chief motive was probably amusement, though, to a mind like his, certainly not without its profit in the enlargement of ideas, and an increased knowledge of mankind.

Some time after his return to Scotland, Dr. Gregory married, in 1752, Elizabeth daughter of William Lord Forbes; a lady of great beauty and wit. The field of medical practice at Aberdeen being at that time pre-occupied, our author determined to attempt the practice of his profession in London; whither accordingly he went in 1754; and being already known by reputation as a man of genius, he found an easy introduction to many persons of distinction both in the literary and polite world. The late George Lord Lyttelton was his friend and patron; and to that nobleman's advice the world is indebted for the publication of the *Comparative View of the State and Faculties of Man*, which made him first known as an author. Dr. Gregory likewise enjoyed the friendship of many of the most distinguished literary characters of his time.

In 1754 Dr. Gregory was chosen fellow of the royal society of London; and, daily advancing in the public esteem, it is not to be doubted, that, had he continued his residence in that metropolis, his professional talents would have found their reward in a very extensive practice. But the death of his brother, Dr. James Gregory, in November 1755, occasioning a vacancy in the professorship of physic in King's college, Aberdeen, which he was solicited to fill, he returned to his native country in the beginning of the following year, and took upon him the duties of that office, to which he had been elected in his absence.

Here our author remained till the end of the year 1764, when, urged by a very laudable ambition, and presuming on the reputation he had acquired as affording a reasonable prospect of success in a more extended field of practice, he changed his place of residence for Edinburgh. His friends in that metropolis had represented to him the situation of the college of medicine as favourable to his views of filling a professorial chair in that university; which accordingly he obtained in 1766, on the resignation of Dr. Rutherford, professor of the practice of physic. In the same year he had the honour of being appointed first physician to his majesty for Scotland on the death of Dr. Whytt.

On his first establishment in the university of Edinburgh, Dr. Gregory gave lectures on the practice of physic during the years 1767, 1768, and 1769. Afterwards, by agreement with Dr. Cullen, professor of the theory of physic, these two eminent

men gave alternate courses of the theory and of the practice. As a public speaker, Dr. Gregory's manner was simple, natural, and animated. Without the graces of oratory, which the subject he had to treat in a great degree precluded, he expressed his ideas with uncommon perspicuity, and in a style happily attempered between the formality of studied composition and the ease of conversation. It was his custom to premeditate, for a short time before entering the college, the subject of his lecture, consulting those authors to whom he had occasion to refer, and marking in short notes the arrangement of his intended discourse: then fully master of his subject, and confident of his own powers, he trusted to his natural facility of expression to convey those opinions which he had maturely deliberated. The only lectures which he committed fully to writing, were those introductory discourses which he read at the beginning of his annual course, and which in 1770 were published under the title of *Lectures on the Duties and Qualifications of a Physician*. In the year 1772 Dr. Gregory published *Elements of the Practice of Physic, for the use of Students*; a work intended solely for his own pupils, and to be used by himself as a text-book to be commented upon in his course of lectures. In an advertisement prefixed to this work, he signified his intention of comprehending in it the whole series of diseases of which he treated in his lectures on the Practice of Physic; but this intention he did not live to accomplish, having brought down the work no further than to the end of the class of Febrile Diseases.

Soon after the death of his wife, and, as he himself says, "for the amusement of his solitary hours," our author employed himself in the composition of that admirable tract, intitled, *A Father's Legacy to his Daughters*; a work which, though certainly never intended by its author for the public eye, it would have been an unwarrantable diminution of his fame, and a capricious refusal of a general benefit to mankind, to have limited to the sole purpose for which it was originally designed. These letters to his daughters were evidently written under the impression of an early death, which Dr. Gregory had reason to apprehend from a constitution subject to the gout, which had begun to show itself at irregular intervals even from the 18th year of his age. His mother, from whom he inherited that disease, died suddenly in 1770, while sitting at table; and Dr. Gregory had prognosticated for himself a similar death. The prediction, indeed, was too true; for having gone to bed on the 9th of February 1773, with no apparent disorder, he was found dead in the morning. His death had been instantaneous, and probably in his sleep; for there was not the smallest discomposure of limb or of feature, a perfect *Euthanasia*. Some time after his death, the professorship of the Theory of Medicine was bestowed upon his eldest son the present Dr. James Gregory; who has since succeeded to the Practical Chair of the late Dr. Cullen.

GRE-HOUND, often written GREY-HOUND. See CANIS. Among a litter of gre-hound puppies, the best are always those which are lightest. These will make the nimblest dogs as they grow up. The gre-hound is best for open countries where there is little covert. In these places there will sometimes be a course after a hare of two or three miles or more, and both the dogs and the game in sight all the while. It is generally supposed that the gre-hound bitch will beat the dog in running: but this seems to be an error; for the dog is both longer made, and considerably stronger than the bitch of the same kind. In the breeding these dogs the bitch is principally to be regarded; for it is found by experience, that the best dog and a bad bitch will not get so good puppies as an indifferent dog with a good bitch. The dog and bitch should be as nearly as may be of the same age; and for the breeding of fine and perfect dogs, they should

not be more than four years old. An old bitch may be used with a young dog, but the puppies of a young bitch and an old dog will never be good for any thing.

The proper exercise for a gre-hound is coursing him three times a-week, and rewarding him with blood; which will animate him in the highest degree, and encourage him to prosecute his game. But the hare also should ever have fair play. She should have the law, as it is called; that is, have leave to run about twelve score yards before the dog is slipped at her, that he may have some difficulty in the course, and not pick up the game too easily. If he kills the hare, he must never be suffered to tear her; but she must be taken from him, his mouth cleaned of the wool, and the liver and lights given him by way of encouragement. Then he is to be led home, and his feet washed with butter and beer, and about an hour after, he is to be fed. When the dog is to be taken out to course, he should have nothing in the morning but a toast and butter, and then he is to be kennelled till taken out to the field. The kennelling these dogs is of great use, always giving them spirit and nimbleness when they are let loose: and the best way of managing a fine gre-hound is, never to let him stir out of the kennel, except at the times of feeding, walking, or coursing.

GRENAILLE, a name given by the French writers to a preparation of copper, which the Chinese use as a red colour in some of their finest china, particularly for that colour which is called *oil-red*, or *red in oil*. The china-ware coloured with this is very dear. The manner in which they procure the preparation is thus: They have in China no such thing as silver-coined money, but they use in commerce bars or masses of silver; these they pay and receive in large bargains; and among a nation so full of fraud as the Chinese, it is no wonder that these are too often adulterated with too great an alloy of copper. They pass, however, in this state in the common payments. There are some occasions, however, such as the paying the taxes and contributions, on which they must have their silver pure and fine: on this occasion they have recourse to certain people, whose sole business it is to refine the silver, and separate it from the copper and the lead it contains. This they do in furnaces made for the purpose, and with very convenient vessels. While the copper is in fusion, they take a small brush, and dip the end of it into water; then striking the handle of the brush, they sprinkle the water by degrees upon the melted copper; a sort of pellicle forms itself by this means on the surface of the matter, which they take off while hot with pincers of iron, and immediately throwing it into a large vessel of cold water, it forms that red powder which is called the *grenaille*; they repeat the operation every time they in this manner separate the copper; and this furnishes them with as much of the *grenaille* as they have occasion for in their china works.

GRENOBLE, a handsome, large, populous, and ancient town of France, in the department of Isere and late province of Dauphiny, with a bishop's see. It contains a great number of handsome structures, particularly churches. The cathedral is a fine ancient building in the Gothic taste; and St. Andrew's church is adorned with a curious spire, and a tomb of excellent workmanship. The leather and gloves that are made here are highly esteemed. It is seated on the river Isere, over which are two bridges to pass into that part called Perreire, a large street on the side of the river. It is 27 miles S. of Chambery, and 105 W. by N. of Turin. Lon. 5. 49. E. Lat. 45. 12. N.

GRESHAM (Sir Thomas), an opulent merchant of London, descended from an ancient and honourable family of Norfolk, was born in 1519. He was, as his father had been before him,

appointed king's agent at Antwerp, for taking up money of the merchants; and in 1551 he removed to that city with his family. This employment was suspended on the accession of queen Mary: but, on proper representations, was restored to him again. Queen Elizabeth conferred the honour of knighthood upon him, and made him her agent in foreign parts. It was at this time he thought proper to provide himself with a mansion-house in the city, suitable to his station and dignity; with which intention he built a large house on the west side of Bishopsgate-street, afterwards known by the name of *Grebbam-college*. His father had proposed building a house or exchange for the merchants to meet in, instead of walking in the open street; but this design remained for the son to accomplish. Sir Thomas went beyond his father: he offered, if the citizens would provide a proper piece of ground, to build a house at his own expence; which being accepted, he fulfilled his promise after the plan of the exchange at Antwerp. When the new edifice was opened, the queen (Jan. 29, 1570) came and dined with the founder; and caused a herald with a trumpet to proclaim it by the name of the *Royal Exchange*. In pursuance also of a promise to endow a college for the profession of the seven liberal sciences, he made a testamentary disposition of his house in London for that purpose: leaving one moiety of the royal exchange to the corporation of London, and the other to the mercers' company, for the salaries of seven lecturers in divinity, law, physic, astronomy, geometry, music, and rhetoric, at 50*l.* each *per annum*. He left several other considerable benefactions, and died in 1579. As to the college, it has been pulled down within these 18 or 20 years, in consequence of an application to parliament from the city, and the excise-office erected in its place. The lectures are read, or rather hurried through, in a chamber over the Royal Exchange. Those who have drawn Sir Thomas's character observe, that he had the happiness of a mind every way suited to his fortune, generous and benign; ready to perform any good actions, and encourage them in others. He was a great friend and patron of our celebrated martyrologist John Fox. He was well acquainted with the ancient and several modern languages; he had a very comprehensive knowledge of all affairs relating to commerce, whether foreign or domestic; and his success was not less, being in his time esteemed the richest commoner in England. He transacted queen Elizabeth's mercantile affairs so constantly, that he was called *the royal merchant*: and his house was sometimes appointed for the reception of foreign princes upon their first arrival in London.

GRETNA-GREEN, a village of Dumfriesshire in Scotland, near the mouth of the river Esk. It has been long noted as the resort of those young gentlemen and ladies in England, who choose to be married notwithstanding the prohibitions of their parents and guardians. The ceremony is performed by a blacksmith.

GREVILLE (Fulke), lord Brook, of Beauchamp's Court in Warwickshire, a poet and miscellaneous writer, was born in the year 1554, and descended from the noble families of Beauchamps of Powick and Willoughby de Brook. In company with his cousin Sir Philip Sidney, he began his education at a school in Shrewsbury: thence he went to Oxford, where he remained for some time a gentleman commoner, and then removed to Trinity-college in Cambridge. Having left the university, he visited foreign courts, and thus added to his knowledge of the ancient languages a perfect knowledge of the modern. On his return to England he was introduced to queen Elizabeth by his uncle Robert Greville, at that time in her majesty's service; and by means of Sir Henry Sidney, lord president of Wales, was nominated to some lucrative employments in that principality.

In the year 1581, when the French commissioners who came to treat about the queen's marriage with the duke of Anjou were sumptuously entertained with tilts and tournaments, Mr. Greville, who was one of the challengers, so signalized himself, as to "win the reputation of a most valiant knight." He continued a constant attendant at court, and a favourite with the queen to the end of her reign; during which he obtained the office of treasurer of marine causes, also a grant of the manor of Wednock, and likewise the honour of knighthood. In this reign he was several times elected member for the county of Warwick; and from the journals of the house seems to have been a man of business, as his name frequently appears in committees.

On the accession of king James I. he was installed knight of the Bath; and soon after obtained a grant of the ruinous castles of Warwick, which he repaired at a considerable expence, and where he probably resided during the former part of this reign: but in the year 1614, the twelfth of James I. he was made under treasurer and chancellor of the exchequer, one of the privy council, and gentleman of the bed-chamber; and in the year 1620 was raised to the dignity of a baron by the title of lord Brook of Beauchamp's Court. He was also privy-counsellor to king Charles I. in the beginning of whose reign he founded a history-lecture in Cambridge.

Having now attained the age of 74, through a life of continued prosperity, universally admired as a gentleman and a scholar, he fell by the hand of an assassin, one of his own domestics, who immediately stabbed himself with the same weapon with which he had murdered his master. This fellow's name was Haywood; and the cause is said to have been a severe reprimand for his presumption in upbraiding his master for not providing for him after his death. It seems he had been witness to lord Brook's will, and knew the contents. Some say he stabbed him with a knife in the back, others with a sword. This affair happened at Brooke-house in Holborne. Lord Brooke was buried with great pomp in St. Mary's church at Warwick, in his own vault, over which he had erected a monument of black and white marble, ordering at his death the following inscription to be engraved upon the tomb: "Fulke Greville, servant to queen Elizabeth, counsellor to king James, and friend to Sir Philip Sidney. *Trophæum Peccati*." He wrote several works both in verse and prose; among which are, 1. Two tragedies, Alaham and Mustapha. 2. A Treatise of Human Learning, &c. in verse, folio. 3. The Life of Sir Philip Sidney. 4. An Inquisition upon Fame and Honour, in 86 stanzas. 6. *Cæcilia*, a collection of 109 songs. 7. His Remains, consisting of political and philosophical poems.

GREVIUS. See GRÆVIUS.

GREW (Nehemiah), a learned English writer, in the 17th century, had a considerable practice as a physician in London, and succeeded Mr. Oldenburgh in the office of secretary to the royal society. In this capacity, pursuant to an order of council, he drew up a catalogue of the natural and artificial rarities belonging to the society, under the title of *Musæum Regalis Societatis*, &c. 1681. He also wrote, besides several pieces in the Philosophical Transactions, 1. The Comparative Anatomy of the Stomach and Guts, folio. 2. The Anatomy of Plants, folio. 3. *Tractatus de sulis cathartici natura et usu*. 4. *Cosmologia Sacra*, or a Discourse of the Universe as it is the Creature and Kingdom of God, folio. He died suddenly in 1721.

GREWIA, in botany; a genus of the polyandria order, belonging to the gynandria class of plants, and in the natural method ranking under the 37th order, *Columniferae*. The calyx is pentaphyllous; there are five petals, each with a nectariferous scale at the base; the berry is quadrilocular. The *Species* are,

1. The *occidentalis*, with oval crenated leaves, has long been preserved in many curious gardens both in England and Holland. It is a native of the Cape of Good Hope, and grows to the height of 10 or 12 feet. The stem and branches greatly resemble those of the small-leaved elm, the bark being smooth, and of the same colour with that when young. The leaves are also very like those of the elm, and fall off in autumn. The flowers are produced singly along the young branches from the wings of the leaves, and are of a bright purple colour. 2. The *Africana*, with oval spear-shaped serrated leaves, is a native of Senegal in Africa, from whence its seeds were brought by Mr. Adanson. In this country it rises with a shrubby stalk five or six feet high, sending out many lateral branches, with a brown hairy bark, and garnished with spear-shaped serrated leaves; but the plants have not flowered in Britain.

The first sort, though a native of a warm climate, will bear the open air in this country; only requiring to be sheltered in a green-house during the winter-time. It may be propagated by cuttings or layers planted in pots filled with soft loamy earth. The second sort is tender, and must be kept constantly in a warm bark-stove. In summer, they require a large share of the free air to be admitted to them, and should have water three or four times a-week in warm weather; but in the winter they must be sparingly watered. The negroes of Senegal consider a decoction of the bark of this last species, as a never-failing remedy against venereal complaints.

GREY, or GRAY colour. See GRAY.

GREY (Lady Jane), a most illustrious and unfortunate lady, descended of the blood-royal of England by both parents, was the eldest daughter of Henry Grey marquis of Dorset and Frances the daughter of Charles Brandon lord Suffolk, by Mary the dowager of Louis XII. king of France, who was the youngest daughter of Henry VII. king of England. She was born in the year 1537, at Broadgate, her father's seat in Leicestershire. She discovered an early propensity to all kinds of good literature; and having a fine genius, improved under the tuition of Mr. Elmer, she made a most surprising progress in the languages, arts, and sciences. She understood perfectly both kinds of philosophy, and could express herself very properly at least in the Latin and Greek tongues; and we are informed by Sir Thomas Chaloner (in Strype's Memorials, Vol. III. p. 93.) that she was well versed in Hebrew, Chaldee, Arabic, French, and Italian; "and (he adds) she played well on instrumental music, wrote a curious hand, and was excellent at the needle." Chaloner also tells us, that she accompanied her musical instruments with a voice exquisitely sweet in itself, assisted by all the graces that art could bestow.

In the year 1553, the dukes of Suffolk and Northumberland, who were now, after the fall of Somerset, arrived at the height of power, began, on the decline of the king's health, to think how to prevent that reverse of fortune which, as things then stood, they foresaw must happen upon Edward's death. To obtain this end, no other remedy was judged sufficient but a change in the succession of the crown, and transferring it into their own families, by rendering Lady Jane queen. Those most excellent and amiable qualities which had rendered her dear to all who had the happiness to know her, joined to her near affinity to the king, subjected her to become the chief tool of an ambition so notoriously not her own. Upon this very account she was married to lord Guilford Dudley, fourth son of the duke of Northumberland, without discovering to her the real design of the match; which was celebrated with great pomp in the latter end of May, so much to the king's satisfaction, that he contributed bounteously to the expence of it from the royal wardrobe. The young king Edward VI. died in July following; and our fair scholar, with infinite reluctance, overpowered

by the solicitations of her ambitious friends, allowed herself to be proclaimed queen of England, on the strength of a deed of settlement extorted from that prince by her father-in-law the duke of Northumberland, which set aside the succession of queen Mary, queen Elizabeth, and Mary queen of Scots. Her regal pageantry continued but a few days. Queen Mary's undoubted right prevailed; and the unfortunate Lady Jane Grey and her husband were committed to the Tower, and on the 13th of November arraigned and found guilty of high treason. On the 12th of February following they were both beheaded on Tower-hill. Her magnanimity in this dreadful catastrophe was astonishing. Immediately before her execution, she addressed herself to the weeping multitude with amazing composure and coherence: she acknowledged the justice of the law, and died in charity with that wretched world which she had so much reason to execrate. Thus did the pious Mary begin her reign with the murder of an innocent young creature of 18; who for simplicity of manners, purity of heart, and extensive learning, was hardly ever equalled in any age or country. But, alas! Jane was an obstinate heretic.—A few days before her execution, Fleckenham, the queen's chaplain, with a pious intention to rescue her poor soul from eternal misery, paid his frequent visits in the Tower, and used every argument in his power to convert her to the Popish religion: but he found her so much his superior in argument, that he gave up the contest; resigning her body to the block, and her soul to the devil:

Her writings are, 1. Four Latin Epistles; three to Bullenger, and one to her sister lady Catharine. The last was written, the night before her execution, in a blank leaf of a Greek Testament. Printed in a book intitled *Epistolæ Helveticæ Reformato-ribus, vel ad eos scriptæ, &c.* Tiguri, 1742, 8vo. 2. Her Conference with Fleckenham. (Ballard). 3. A letter to Dr. Harding, her father's chaplain. Printed in the Phœnix, vol. ii. p. 28. 4. A Prayer for her own use during her confinement. In Fox's Acts and Monuments. 5. Four Latin verses; written in prison with a pin. They are as follows:

Non aliena putes, homini quæ obtingere possunt:

Sors bodierna mihi, tunc erit illa tibi. JANE DUDLEY.

Deo juvante, nil nocet labor malus:

Et non juvante, nil juvat labor gravis.

Post tenebras spero lucem.

6. Her Speech on the Scaffold. (Ballard). It began thus: "My Lords, and you good Christian people who come to see me die; I am under a law, and by that law, as a never-erring judge, I am condemned to die: not for any thing I have offended the queen's majesty; for I will wash my hands guiltless thereof, and deliver to my God a soul as pure from such trespasses as innocence from injustice; but only for that I consented to the thing I was enforced unto, constraint making the law believe I did that which I never understood," &c.—Hollinshed, Sir Richard Baker, Bale, and Fox, tell us that she wrote several other things, but do not mention where they are to be found.

GREY-Hound. See GRE-Hound.

GRIAS, in botany; a genus of the monogynia order, belonging to the polyandria class of plants, and in the natural method ranking with those of which the order is doubtful. The corolla is tetrapetalous; the calyx quadri-lobed; the stigma sessile and cruciform: the fruit is a plum with an eight-furrowed kernel. There is but one species, the cauliflora or anchovy-pear, a native of Jamaica. The leaves are nearly oval, and about three feet long. It has a straight stem, upon the upper part of which come forth the flowers. The fruit is large, and contains a stone with eight furrows. These fruits are eaten by the inhabitants.

GRIBALDUS (Matthew), a learned civilian of Padua, left Italy in the 16th century, in order to make a public profession of the Protestant religion. After having been for some time professor of the civil law at Tübingen, he was obliged to make his escape to avoid the punishment he would have incurred had he been convicted of differing from Calvin with respect to the doctrine of the Trinity; but he was seized at Berne, where he would have met with very severe treatment had he not pretended to renounce his opinions; but as he relapsed again, he would certainly have been put to death, had he not died of the plague in 1664. He wrote *De methodo ac ratione studendi in jure civili*; and several other works which are esteemed.

GRIBNER (Michael Henry), a learned civilian of Germany, was born at Leipzig in 1682. After writing some time in the journal of Leipzig, he was made professor of law at Wittenberg: whence he passed to Dresden, and was at last recalled to Leipzig to succeed M. Mencke. He died in 1734. Besides several academical dissertations, he wrote, 1. *Principia processus judicarii*. 2. *Principia jurisprudentiæ naturalis*, a small work much esteemed: 3. *Opuscula juris publici et privati*.

GRIELUM, in botany; a genus of the pentagynia order, belonging to the decandria class of plants. The calyx is quinquefid; there are five petals; the filaments persisting; and there are five monospermous seed-cases.

GRIERSON (Constantia), born of poor parents in the county of Kilkenny in Ireland, was one of the most learned women on record, though she died at the age of 27, in 1733. She was an excellent Greek and Latin scholar, and understood history, divinity, philosophy, and mathematics. She proved her skill in Latin by her dedication of the Dublin edition of Tacitus to lord Carteret, and by that of Terence to his son; to whom she also addressed a Greek epigram. She wrote many elegant English poems, several of which were inserted by Mrs. Barber among her own. When lord Carteret was lord lieutenant of Ireland, he obtained a patent for Mr. Grierson to be the king's printer; and, to reward the uncommon merit of his wife, caused her life to be included in it.

GRIFFON, **GRYPHUS**, γρυψ, in the natural history of the ancients, the name of an imaginary bird of prey, of the eagle kind. They represented it with four legs, wings, and a beak; the upper part representing an eagle, and the lower a lion; they supposed it to watch over gold mines, hidden treasures, &c. This animal was consecrated to the sun; and the ancient painters represented the chariot of the sun as drawn by griffons. M. Spanheim observes the same of those of Jupiter and Nemesis. The griffon in Scripture is that species of the eagle called in Latin *ossifraga*, the "osprey;" and פֶּרֶם, of the verb פָּרַם *paras*, "to break." The griffon is frequently seen on ancient medals: and is still borne in coat-armour. Guillim blazons it rampant; alleging, that any very fierce animal may be so blazoned as well as the lion. Sylvester, Morgan, and others, use the terms *segriciant* instead of rampant. The griffon is also an ornament of architecture in constant use among the Greeks, and was copied from them, with the other elegancies of architectural enrichments, by the Romans. See **SPHYNX**.

GRIFLEA, in botany; a genus of the monogynia order, belonging to the octandria class of plants, and in the natural method ranking under the 17th order, *Calycanthemæ*. The calyx is quadrifid; and there are four petals, one from each incisure of it. The filaments are very long, ascending or turning upwards; the capsule is globose, superior, unilocular, and polyspermous.

GRIMALDI (Francisco), an eminent painter, generally known by the appellation of *Bolognese*, was born at Bologna in 1606, where he became a disciple of Annibal Caracci, and proved an honour to that illustrious master. From the school of Annibal he went to complete his studies at Rome, and im-

proved himself daily, by copying the works of those artists in which he observed the greatest excellence, until his superior talents recommended him to the favour of Innocent X. who afforded him immediate opportunities of exerting his genius in the gallery of his palace at Monte Cavallo, and also in the Vatican. The merit of his performances very soon engaged the attention and applause of the public, and increased the number of his admirers and friends; among whom were the prince Pamphilio, and many of the principal nobility of Rome. His reputation reached cardinal Mazarine at Paris, who sent for him, settled a large pension on him, and employed him for three years in embellishing his palace and the Louvre, by the order of Louis XIII. The troubles of the state, and the clamours raised against the cardinal, whose party he warmly espoused, put him so much in danger, that his friends advised him to retire among the Jesuits. He did so, and was of use to them; for he painted them a decoration for the exposition of the sacrament during the holy days, according to the custom of Rome. This piece was mightily relished at Paris: the king honoured it with two visits, and commanded him to paint such another for his chapel at the Louvre. Grimaldi after that returned to Italy; and on his arrival at Rome found his great patron Innocent X. dead: but his two successors Alexander VII. and Clement IX. honoured him equally with their friendship, and found him variety of employment. Grimaldi was amiable in his manners, as well as skilful in his profession: he was generous without profusion, respectful to the great without meaness, and charitable to the poor. The following instance of his benevolence may serve to characterise the man. A Sicilian gentleman, who had retired from Messina with his daughter during the troubles of that country, was reduced to the misery of wanting bread. As he lived over-against him, Grimaldi was soon informed of it; and in the dusk of the evening, knocking at the Sicilian's door, without making himself known, tossed in money and retired. The thing happening more than once, raised the Sicilian's curiosity to know his benefactor; who finding him out, by hiding himself behind the door, fell down on his knees to thank the hand that had relieved him. Grimaldi remained confused, offered him his house, and continued his friend till his death. He died of a dropsy at Rome in 1680, and left a considerable fortune among six children. The genius of Grimaldi directed him chiefly to landscape, which he executed most happily. His colouring is strong; his touch light and delicate: his situations are uncommonly pleasing; and the leasing of his trees is admirable. Sometimes, indeed, his colouring appears rather too green: but those landscapes, which he painted in the manner of the Caracci, may serve as models for all those who admire the style of that school; and he designed his figures in an elegant taste. The pictures of this master are very unfrequent, especially those of his best time; and whenever they are to be purchased, they sell for large prices. Of his children above mentioned, the youngest, named *Alexander*, proved a good painter, in the same style and taste with his father, though very far inferior to him: some of the pictures of Alexander, however, are either artfully, or injudiciously, ascribed to Francisco.

Great GRIMSBY, a large borough of Lincolnshire, with a market on Wednesday and Saturday. It had formerly a castle and two parish churches, with a commodious harbour, now almost choked up. It has now only one church, a large handsome structure, like a cathedral. It is 35 miles N. E. by E. of Lincoln, and 170 N. of London. Lon. 0. 6. E. Lat. 53. 34. N.

GRINDING, or **TRITURATION**, the act of breaking or comminuting a solid body, and reducing it into powder. See **PULVERISATION** and **LEVIGATION**. Painters' colours are ground on a marble or porphyry, either with oil or gum water. *Grinding* is also used for rubbing or wearing off the irregular parts

of the surface of a body, and reducing it to the destined figure, whether that be flat, concave, or the like. The grinding and polishing of glass is a considerable art; for which see *GLASS-Grinding*.

GRINDON-RIGG, a river in Northumberland, near Berwick, famous for the victory which was gained over the Scots in 1558 by the earl of Northumberland and his brother, when many of the Scots were drowned in this river. On a rising ground near Grindon, about a quarter of a mile S. from Sandybank, are four upright stone pillars, funeral monuments of the chieftains slain in that action.

East **GRINSTEAD**, a borough in Suffex, with a market on Thursday. The assizes for the county are sometimes held here. It is 18 miles N. of Lewes, and 29 S. of London. Lon. 0. 2. E. Lat. 51. 12. N.

GRIPSWALD, a strong and considerable town of Germany, in Pomerania, formerly imperial, but now subject to the Swedes, with a good harbour, and a university. It is seated near the sea, 15 miles S. E. of Stralsund, and 55 N. W. of Stettin. Lon. 13. 44. E. Lat. 54. 4. N.

GRISGRIS, a superstition greatly in vogue among the negroes in the interior parts of Africa. The grisgris, according to Le Maire, are certain Arabic characters mixed with magical figures drawn by the Marabuts or priests upon paper. Labat affirms, that they are nothing else than scraps of the alcoran in Arabic; but this is denied by Barbut, who brought over one of these grisgris to Europe, and showed it to a number of persons deeply skilled in oriental learning. None of these could find the least trace of any character they understood. Yet, after all, this might be owing to the badness of the hand-writing; and the words are probably of the Mandingo language, though the characters are an attempt to imitate the Arabic. The poorest negro never goes to war without his grisgris, as a charm against wounds; and if it proves ineffectual, the priest transfers the blame on the immorality of his conduct. These priests invent grisgris against all kinds of dangers, and in favour of all desires and appetites; by virtue of which the possessors may obtain or avoid whatever they like or dislike. They defend them from storms, enemies, diseases, pains, and misfortunes; and preserve health, long life, wealth, honour, and merit, according to the Marabuts. No clergy in the world are more honoured and revered by the people than these impostors are by the negroes; nor are any people in the world more impoverished by their priests than these negroes are, a grisgris being frequently sold at three slaves and four and five oxen. The grisgris intended for the head is made in the form of a cross, reaching from the forehead to the neck behind, and from ear to ear; nor are the arms and shoulders neglected. Sometimes they are planted in their bonnets in the form of horns; at other times, they are made like serpents, lizards, or some other animals, cut out of a kind of pasteboard, &c. There are not wanting Europeans, and otherwise intelligent seamen and merchants, who are in some degree infected with this weakness of the country, and believe that the negro forcerers have an actual communication with the devil, and that they are filled with the malignant influence of that evil spirit, when they see them distort their features and muscles, make horrid grimaces, and at last imitate all the appearance of epileptics.

GRISONS, a people situated among the Alps, and allies of the Swiss. Their country is bounded on the north by the counties of Surgans and Bludenz, the canton of Glaris, and the principality of Lichtenstein; on the south by the canton's Italian bailiwicks, the county of Chavenne, and the Valteline; on the east by the territories of Venice and Milan; and on the west by some of the Italian bailiwicks, and the canton of Uri. It is divided into three leagues, viz. the *Grison* or *grey league*, the *league of the house of God*, and that of the *ten jurisdictions*;

which unite and form one republic. The two first lie towards the south, and the third towards the north. The length of the whole is above 70 miles, and the breadth about 60. The inhabitants are said to have had the name of *Grifons* from the grey coats they wore in former times. This country, lying among the Alps, is very mountainous; but the mountains yield good pasture for cattle, sheep and goats, with some rye and barley: in the valleys there is plenty of grain, pulse, fruits, and wine. This country also abounds with hogs and wild-fowl; but there is a scarcity of fish and salt, and their horses are mostly purchased of foreigners. The principal rivers are the Rhine, the Inn, and the Adda. Here are also several lakes, most of which lie on the tops of the hills. The language of the Grifons is either a corrupt Italian or the German. Each of the leagues is subdivided into several lesser communities, which are so many democracies; every male above 16 having a share in the government of the community, and a vote in the election of magistrates. Deputies from the several communities constitute the general diet of the Grifon leagues, which meets annually, and alternately at the capital of each league; but they can conclude nothing without the consent of their constituents. This country was anciently a part of Rhetia. After the extinction of the Roman empire in the west, it was some time subject to its own dukes, or those of Swabia. Then the bishop of Coire, and other petty princes, dependent on the emperors of Germany, became masters of great part of it: at last, by the extinction of some, purchase, voluntary grants, and force, it got rid of all its lords, and erected itself into three distinct republics, each of which, as we observed already, is subdivided into a certain number of communities, which are a sort of republics, exercising every branch of sovereignty, except that of making peace or war, sending embassies, concluding alliances, and enacting laws relating to the whole country, which belong to the provincial diets of the several leagues. The communities may be compared to the cities of Holland, and the diets of the several leagues to the provincial states. The particular diets are composed of a deputy from each community; and both in them and the communities every thing is determined by a majority of votes. In the communities, every male above 16 has a vote. Besides the annual provincial diets for choosing the chiefs and other officers, and deliberating on the affairs of the respective leagues, there are general diets for what concerns all the three leagues or whole body. In both these, the representatives can do nothing of themselves, but are tied down to the instructions of their principals. There is a general seal for all the three leagues; and each particular league has a separate seal. Besides the stated times of meeting, extraordinary diets are sometimes summoned, when either the domestic affairs of the state or any foreign minister require it. In the general diets, the Grey League has 28 votes; that of the House of God, 23; and that of the Ten Jurisdictions, 15. These leagues, at different times, have entered into close alliances with the neighbouring cantons and their associates. The bailiwicks belonging in common to the three leagues are those of the Valteline, Chavenne, Bormio, Meyenfeld, Malans, and Jennins; the officers of which are nominated successively by the several communities every two years. The yearly revenue arising to the Grifons from their bailiwicks is said to amount to about 13,500 florins. The public revenues altogether are but small, though there are many private persons in the country that are rich. However, in case of any extraordinary emergency, they tax themselves in proportion to the necessity of the service and the people's abilities. They have no regular troops, but a well-disciplined militia; and upon occasion, it is said, can bring a body of 30,000 fighting men into the field: but their chief security arises from the narrow passes and high mountains by which they are surrounded.

Of the jurisprudence, religion, &c. of the Grifons, the follow-

ing account is given by Mr. Coxe in his Travels in Switzerland. Throughout the three leagues the Roman law prevails, modified by the municipal customs. The courts of justice in each community are composed of the chief magistrate, who presides, and a certain number of jurymen, chosen by the people: they have no regular salaries, but receive for their attendance a small sum, arising in some communities from the expences of the process, which are defrayed by the criminals; in others from a share of the fines. They enjoy the power of pardoning or diminishing the penalty, and of receiving a composition in money. This mode of proceeding supposes what is as absurd in theory as it is contrary to experience, that judges will incline to mercy when it is their interest to convict; or will impartially inflict punishment, even when injurious to their own private advantage. The prisoners are examined in private; frequently tortured for the purpose of forcing confession, when the judges either divide the fines, or remit the punishment for a composition. In some districts a criminal trial is a kind of festival to the judges, for whom a good repast is provided at the expence of the prisoner if convicted; and thus the following allusion, in Garth's Dispensary, applied with more wit than truth to our courts of justice, is literally fulfilled: "*And wretches hang, that jurymen may dine.*" Capital punishments, however, are extremely rare; a circumstance arising not from a want of severity in the penal statutes, or from a propensity to mercy in the judges, but because the latter draw more advantages from fining than executing an offender. In a word, to use the expression of Burnet, which is as true at present as it was in his time, "Many crimes go unpunished, if the persons who commit them have either great credit or much money." It is remarkable, that torture is more frequently applied, and for smaller delinquencies, in these independent republics, than in the subject provinces. The infliction of it depends entirely upon the arbitrary will of the judges; a majority of whom may order it for an offence which is not capital, nor even punishable by corporal penalties. Thus it is not uncommon, in those communities where fines are divided among the judges, to torture women of loose conduct, for the purpose of compelling them to confess with whom they have been connected; for as such offences are punishable by fines, the more persons are convicted, the larger share of money is distributed among the judges for the trouble of their attendance. Even in the districts where the fines are paid to the community, torture is often no less wantonly inflicted, because, when the prisoner is not found guilty, the expences of the process fall upon the public, and the judges receive little emolument. Even in the civil courts most causes are decided by bribing the judges; and appeals in those communities, wherein they are admitted, scarcely serve any other end than to enlarge the sphere of corruption. Coire, and a few other places, are excepted from this general reflection.

The religion of the Grisons is divided into catholic and reformed. The doctrines of the reformation were first preached about the year 1524, and received at Fläsch, a small village in the Ten Jurisdictions upon the confines of Sargans; from thence they were extended to Mayenfeld and Malantz, and soon afterwards through the whole valley of Pretigau. The new opinions spread with such celerity, that before the end of the 16th century they were embraced by the whole league of the Ten Jurisdictions (excepting part of the community of Alvenew), the greatest part of the House of God, and a few communities in the Grey League. The difference of religion nearly excited a civil war between the two sects, as well at the first introduction of the reformation as at the beginning of the troubles in the Valteline. In the latter instance, the two parties rose in arms; but the Catholics being overpowered by the Protestants, matters were amicably adjusted. Since that period all religious concerns have been regulated with perfect cordiality. According

to the general consent of the three leagues, each community being absolute within its little territory, has the power of appointing its own particular worship, and the inhabitants are free to follow either the Catholic or Reformed persuasion. In the administration of civil affairs religion has no interference: the deputies of the general diet may be members of either communion, as chosen by the communities which they represent. By this moderate and tolerating principle, all religious dissensions have been suppressed as much as possible; and the most perfect amity subsists between the two sects.

In spiritual concerns, the Catholics for the most part are under the jurisdiction of the bishop of Coire. For the affairs of the Reformed churches, each league is divided into a certain number of districts, the ministers whereof assemble twice every year: these assemblies are called *colloquia*. Each colloquium has its president, and each league a superintendant called a *dean*. The supreme authority in spiritual concerns is vested in the synod, which is composed of the three deans, and the clergy of each league; the synod assembles every year alternately in each of the three leagues. Candidates for holy orders are examined before the synod. The necessary qualifications for admission into the church ought to be the knowledge of Hebrew, Greek, and Latin; but this rule is not strictly adhered to; many being ordained without the least acquaintance with either of those languages. Formerly Latin was solely used, as well in the debates of the synod as for the purpose of examining the candidates: but at present that tongue grows more and more into disuse, and German is employed in its stead.

The number of reformed parishes in the whole three leagues amounts to 135, in the following proportion: In the Grey League 46, in that of God's House 53, and in the League of Ten Jurisdictions 36. The ministers of these churches enjoy but very small salaries. The richest benefices do not perhaps yield more than 20*l.* or at most 25*l. per annum*, and the poorest sometimes scarcely 6*l.* This scanty income is attended with many inconveniences. It obliges the clergy who have families to follow some branch of traffic, to the neglect of their ecclesiastical studies, and to the degradation of the professional character. Another inconvenience is superadded to the narrowness of their income. In most communities the ministers, though confirmed by the synod, are chosen by the people of the parish, and are solely dependent on their bounty. For these reasons, the candidates for holy orders are generally extremely ignorant. They cannot support that expence which is requisite to pursue their studies; they are not animated with the expectation of a decent competence; and, from the dependent mode of their election, are not encouraged to deserve their promotion by a consistent dignity of character.

GRIST, in country affairs, denotes corn ground, or in a state ready for grinding.

GRIT (*argillaceous*), a genus of argillaceous earths. Its texture is more or less porous, equable, and rough to the touch. It does not give fire with steel, nor effervesce with acids. When fresh broken and breathed upon, it exhales an earthy smell. Mr. Kirwan mentions two kinds; one from Hollington near Uttoxeter, of a yellowish or whitish grey, and about the specific gravity of 2288. Another, from Kneperly in Staffordshire, is of the specific gravity of 2568, and so insusible as to be used for fire stones. According to Fabroni the grit-stone is of greater or less hardness, mostly of a grey, and sometimes of a yellowish colour, composed of a siliceous and micaceous sand, but rarely of a sparry kind; with greater or smaller particles closely compacted by an argillaceous cement. It gives some sparks with steel, is indissoluble for the most part in acids, and vitrifiable in a strong fire. It is used for millstones and whetstones; and sometimes for filtering stones and for building.

GROAT, an English money of account, equal to four pence

Other nations, as the Dutch, Polanders, Saxons, Bohemians, French, &c. have likewise their groats, groots, groches, gros, &c. In the Saxon times, no silver coin bigger than a penny was struck in England, nor after the Conquest, till Edward III. who, about the year 1351, coined groffes, i. e. *groats*, or great pieces, which went for 4d. a-piece: and so the matter stood till the reign of Henry VIII. who in 1504 first coined shillings.

GROATS, in country affairs, oats after the hulls are off, or great oat-meal. In London they are called GRITS.

GROCERS, anciently were such persons as engrossed all merchandize that was vendible; but now they are incorporated, and make one of the companies of the city of London, which deals in sugar, foreign fruits, spices, &c.

GRODNO, the principal town, though not the capital, of Lithuania. It is a large and straggling place, but contains no more than 3000 Christians, excluding the persons employed in the manufactures, and 1000 Jews. It has greatly the appearance of a decayed town; containing a mixture of wretched hovels, falling houses, and ruined palaces, with magnificent gateways, remains of its ancient splendour. A few habitations in good repair make the contrast more striking. Some remains still exist of the old palace in which the kings used to reside during the holding of the diets. It stood on a hill; opposite to which is the new palace, built, but never inhabited, by Augustus III. In this palace are the apartments where the diets are sometimes held; particularly the last, in 1793, which was compelled, at the point of the bayonet, to consent to the second partition of Poland. Here is a college and physic garden; the king of Poland having established a royal academy of physic for Lithuania. Grodno is seated partly in a plain, on the river Niemen, and partly on a mountain, 125 miles N. E. of Warsaw. Lon. 24. 15. E. Lat. 53. 28. N.

GROGRAM, a kind of stuff made of silk and mohair.

GROIN, that part of the belly next the thigh. In vol. 67 of the Philosophical Transactions is an account of a remarkable case, where a peg of wood was extracted from the groin of a young woman of 21, after it had remained 16 years in the stomach and intestines, having been accidentally swallowed when she was about five years of age.

GROIN, among builders, is the angular curve made by the intersection of two semi-cylinders or arches, and is either regular or irregular. A *regular* groin is when the intersecting arches, whether semicircular or semielliptical, are of the same diameters and heights. An *irregular* groin is where one of the arches is semicircular and the other semielliptical.

GROMWELL, in botany. See LITHOSPERMUM.

GRONINGEN, a rich, populous, and handsome town of the Netherlands, capital of a lordship of the same name, which is one of the United Provinces, with a citadel and a university. It is seated on the rivers Hunes and Aa, 10 miles from the sea, and 85 N. E. of Amsterdam. Lon. 6. 31. E. Lat. 53. 10. N.

GRONINGEN, one of the Seven United Provinces, bounded on the E. by the river Ems, which separates it from E. Friesland, on the W. by Friesland, on the N. by the German ocean, and on the S. by Overijssel. It is divided into two parts, of which the town of Groningen and its district are one, and the Ommerlands the other. These two bodies assembled by their deputies, with the states of the province, make the sovereignty. Its government is not unlike that of ancient Rome. The excellence of this country consists in pastures, which feed a great number of large horses, fit for the coach.

GRONOVIA, in botany: a genus of the monogynia order, belonging to the pentandria class of plants, and in the natural method ranking under the 34th order, *Cucurbitacea*. There are five petals and stamina inserted into a campanulated calyx; the berry is dry, monospermous, and inferior.

GRONOVIVS (John Frederic), a very learned critic, was

born at Hamburgh in 1613; and having travelled through Germany, Italy, and France, was made professor of polite learning at Deventer, and afterwards at Leyden, where he died in 1671. He published, 1. *Diatriba in Statii*, &c. 2. *De sefertiiis*. 3. Correct editions of Seneca, Statius, T. Livy, Pliny's Natural History, Tacitus, Aulus Gellius, Phaedrus's Fables, &c. with notes; and other works.

GRONOVIVS (James), son of the preceding, and a very learned man, was educated first at Leyden, then went over to England, where he visited the universities, consulted the curious MSS. and formed an acquaintance with several learned men. He was chosen by the grand duke to be professor at Pisa, with a considerable stipend. He returned into Holland, after he had resided two years in Tuscany, and consulted the MSS. in the Medicean library. In 1679, he was invited by the curators of the university to a professorship; and his inaugural dissertation was so highly approved of, that the curators added 400 florins to his stipend, and this augmentation continued to his death in 1716. He refused several honourable and advantageous offers. His principal works are, *The treasure of Greek antiquities*, in 13 vols. folio; and a great number of dissertations, and editions of ancient authors. He was compared to Schioppus for the virulence of his style; and the severity with which he treated other great men who differed from him exposed him to just censure.

GROOM, a name particularly applied to several superior officers belonging to the king's household, as groom of the chamber, groom of the stole. See STOLE and WARDROBE.

GROOM is more particularly used for a servant appointed to attend on horses in the stable. The word is formed from the Flemish *grom*, "a boy."

GROOVE, among miners, is the shaft or pit sunk into the earth, sometimes in the vein, and sometimes not.

GROOVE, among joiners, the channel made by their plough in the edge of a moulding, stile, or rail, to introduce pannels in, in wainscoting.

GROSS, a foreign money, in some countries, answering to our groat.

Gross is used among us for the quantity of twelve dozen.

Gross *weight*, is the weight of merchandize and goods, with their dust and dross, as also of the bag, cask, chest, &c. wherein they are contained; out of which gross weight, allowance is to be made of tare and tret.

GROSS, or GROSSUS, in our ancient law writers, denote a thing absolute, and not depending on another. Thus, *villain in gross*, *villanus in grosso*, was a servant, who did not belong to the land, but immediately to the person of the lord; or a servile person not appendant or annexed to the land or manor, and to go along with the tenures as appurtenant to it; but like other personal goods and chattels of his lord, at his lord's pleasure and disposal.

GROSS, *advowson in*. See ADVOWSON.

GROSS-BEAN, in zoology, a name by which we commonly call the *coecotbraustes*, called also at other times the *baro-fuch*. This is the *LOXIA coecotbraustes* in the Linnæan system.

GROSS-BEAK, in ornithology; a species of *LOXIA*.

GROSSULARIA. See RIBES.

GROTESQUE, in sculpture and painting, something whimsical, extravagant, and monstrous; consisting either of things that are merely imaginary, and have no existence in nature; or of things so distorted, as to raise surprise and ridicule. The name arises hence, that figures of this kind were anciently much used to adorn the *grottos*, wherein the tombs of eminent persons or families were inclosed. Such was that of Ovid, whose grotto was discovered near Rome about one hundred years ago.

GROTIUS (Hugo), or more properly HUGO DE GROOT, one of the greatest men in Europe, was born at Delft in 1583.

He made so rapid a progress in his studies, that at the age of 15 he had attained a great knowledge in philosophy, divinity, and civil law; and a yet greater proficiency in polite literature, as appeared by the commentary he had made at that age on Martianus Capella. In 1598, he accompanied the Dutch ambassador into France, and was honoured with several marks of esteem by Henry IV. He took his degree of doctor of laws in that kingdom; and at his return to his native country, devoted himself to the bar, and pleaded before he was 17 years of age. He was not 24 when he was appointed attorney-general. In 1613 he settled in Rotterdam, and was nominated syndic of that city; but did not accept of the office, till a promise was made him that he should not be removed from it. This prudent precaution he took from his foreseeing, that the quarrels of the divines on the doctrine of grace, which had already given rise to many factions in the state, would occasion revolutions in the chief cities. The same year he was sent into England, on account of the divisions that reigned between the traders of the two nations, on the right of fishing in the northern seas; but he could obtain no satisfaction. He was afterwards sent to England, as it is thought, to persuade the king and the principal divines to favour the Arminians; and he had several conferences with King James on that subject. On his return to Holland, his attachment to Barneveldt involved him in great trouble; for he was seized, and sentenced to perpetual imprisonment in 1619, and to forfeit all his goods and chattels. But after having been treated with great rigour for above a year and a half in his confinement, he was delivered by the advice and artifice of his wife, who having observed that his keepers had often fatigued themselves with searching and examining a great trunk-full of foul linen which used to be washed at Gorkum, but now let it pass without opening it, she advised him to bore holes in it to prevent his being stifled, and then to get into it. He complied with this advice, and was carried to a friend's house in Gorkum; where dressing himself like a mason, and taking a rule and trowel, he passed through the market-place, and stepping into a boat went to Velvet in Brabant. Here he made himself known to some Arminians, and hired a carriage to Antwerp. At first there was a design of prosecuting his wife, who staid in the prison; and some judges were of opinion that she ought to be kept there in her husband's stead: however, she was released by a plurality of voices, and universally applauded for her behaviour. He now retired into France, where he met with a gracious reception from that court, and Louis XIII. settled a pension upon him. Having resided there eleven years, he returned to Holland, on his receiving a very kind letter from Frederic Henry prince of Orange: but his enemies renewing their persecution, he went to Hamburg; where, in 1634, Queen Christina of Sweden made him her counsellor, and sent him ambassador into France. After having discharged the duties of this office above eleven years, he returned, in order to give an account to Queen Christina of his embassy: when he took Holland in his way, and received many honours at Amsterdam. He was introduced to her Swedish majesty at Stockholm, and there begged that she would grant his dismissal, in order that he might return to Holland. This he obtained with difficulty: and the queen gave him many marks of her esteem, though he had many enemies at this court. As he was returning, the ship in which he embarked was cast away on the coast of Pomerania: and being now sick, he continued his journey by land; but was forced to stop at Roslock, where he died, on the 28th of August 1645. His body was carried to Delft, to be interred in the sepulchre of his ancestors. Notwithstanding the embassies in which he was employed, he composed a great number of excellent works; the principal of which are, 1. A treatise *De jure belli et pacis*, which is esteemed a master-piece. 2. A treatise on the truth of the Christian

religion. 3. Commentaries on the holy scriptures. 4. The history and annals of Holland. 5. A great number of letters. All which are written in Latin.

GROTSKAW, a town of Turkey in Europe, in the province of Servia, where a battle was fought between the Germans and Turks in the year 1739, in which the Germans were forced to retreat with loss. E. long. 21. 0. N. lat. 45. 0.

GROTSKAW, a strong town of Germany, capital of a province of the same name in Silesia. It is very agreeably seated in a fruitful plain. E. long. 17. 35. N. lat. 50. 42.

GROTTO, or GROTTA, a large deep cavern or den in a mountain or rock. The word is Italian, *grotta*, formed, according to Menage, &c. from the Latin *crypta*. Du Cange observes, that *grotta* was used in the same sense in the corrupt Latin. The ancient anchorites retired into dens and grottos, to apply themselves the more attentively to meditation. *Okey-hole*, *Elden-hole*, *Peake's-hole*, and *Pool's-hole*, are famous among the natural caverns or grottos of our country. The entrance to Okey-hole, on the south side of Mendip-hills, is in the fall of those hills, which is beset all about with rocks, and has near it a precipitate descent of near twelve fathoms deep, at the bottom of which there continually issues from the rocks a considerable current of water. The naked rocks above the entrance show themselves about 30 fathoms high, and the whole ascent of the hill above is about a mile, and is very steep. As you pass into this vault, you go at first upon a level, but advancing farther, the way is found to be rocky and uneven, sometimes ascending, and sometimes descending. The roof of this cavern, in the highest part, is about eight fathoms from the ground, but in many particular places it is so low, that a man must stoop to get along. The breadth is not less various than the height, for in some places it is five or six fathoms wide, and in others not more than one or two. It extends itself in length about two hundred yards. People talk much of certain stones in it, resembling men and women, and other things; but there is little matter of curiosity in these, being only shapeless lumps of a common spar. At the farthest part of the cavern there is a good stream of water, large enough to drive a mill, which passes all along one side of the cavern, and at length slides down about six or eight fathoms among the rocks, and then pressing through the clefts of them, discharges itself into the valley. The river within the cavern is well stored with cels, and has some trouts in it; and these cannot have come from without, there being so great a fall near the entrance. In dry summers, a great number of frogs are seen all along this cavern, even to the farthest part of it; and on the roof of it, at certain places, hang vast numbers of bats, as they do in almost all caverns, the entrance of which is either level, or but slightly ascending or descending; and even in the more perpendicular ones they are sometimes found, provided they are not too narrow, and are sufficiently high. The cattle that feed in the pastures through which this river runs have been known to die suddenly sometimes after a flood; this is probably owing to the waters having been impregnated, either naturally or accidentally, with lead ore.

Elden-hole is a huge profound perpendicular chasm, three miles from Buxton, ranked among the natural wonders of the Peak. Its depth is unknown, and is pretended to be unfathomable. Cotton tells us he founded 884 yards; yet the plummet still drew. But he might easily be deceived, unless his plummet was very heavy; the weight of a rope of that length might well make the landing of the plummet scarce perceivable.

Peake's-hole, and *Pool's-hole*, called also *the Devil's A---fi*, are two remarkable horizontal springs under mountains; the one near Castleton, the other just by Buxton. They seem to have owed their origin to the springs which have their current through them; when the water had forced its way through the

horizontal fissures of the strata, and had carried the loose earth away with it, the loose stones must fall down of course: and where the strata had few or no fissures, they remained entire; and so formed these very irregular arches, which are now so much wondered at. The water which passes through Pool's-hole is impregnated with particles of lime-stone, and has incruited the whole cavern in such a manner that it appears as one solid rock.

In grottos are frequently found crystals of the rock, stalactites, and other natural conglaciations, and those often of an amazing beauty. M. Homberg conjectures, from several circumstances, that the marble pillars in the grotto of Antiparos vegetate or grow. That author looks on this grotto as a garden, whereof the pieces of marble are the plants; and endeavours to show, that they could only be produced by some vegetable principle.

At Foligno in Italy is another grotto, consisting of pillars and orders of architecture of marble, with their ornaments, &c. scarcely inferior to those of art; but they all grow downwards: so that if this too be a garden, the plants are turned upside down.

GROTTO *del Cani*, a little cavern near Pozzuoli, four leagues from Naples, the steams whereof are of a mephitical or noxious quality; whence also it is called *bocca venenosa*, the poisonous mouth. See CHEMISTRY, p. 412. "Two miles from Naples (says Dr. Mead) just by the Lago de Agnano, is a celebrated mofeta, commonly called *la Grotta del Cani*, and equally destructive to all within the reach of its vapours. It is a small grotto about eight feet high, twelve long, and six broad; from the ground arises a thin, subtle, warm fume, visible enough to a discerning eye, which does not spring up in little parcels here and there, but in one continued stream, covering the whole surface of the bottom of the cave; having this remarkable difference from common vapours, that it does not, like smoke, disperse itself into the air, but quickly after its rise falls back again, and returns to the earth; the colour of the sides of the grotto being the measure of its ascent: for so far it is of a darkish-green, but higher only common earth. And as I myself found no inconvenience by standing in it, so no animal, if its head be above this mark, is the least injured. But when, as the manner is, a dog, or any other creature, is forcibly kept below it; or, by reason of its smallness, cannot hold its head above it, it presently loses all motion, falls down as dead, or in a swoon; the limbs convulsed and trembling, till at last no more signs of life appear than a very weak and almost insensible beating of the heart and arteries; which, if the animal be left a little longer, quickly ceases too, and then the case is irrecoverable; but if it be snatched out, and laid in the open air, it soon comes to life again, and sooner if thrown into the adjacent lake."

Respecting this steam, which, however, is nothing else than what is called *fixed air* (carbonic acid) issuing out of the earth in that place in very great quantity, from a cause not as yet known, see the articles BLOOD and DAMPS.

GROTTA *del Serpi*, is a subterraneous cavern near the village of Sassa, eight miles from the city of Braccano in Italy, described by Kircher thus: "The *grotta del serpi* is big enough to hold two persons. It is perforated with several fistular apertures, somewhat in manner of a sieve; out of which, at the beginning of the spring season, issues a numerous brood of young snakes of divers colours, but all free from any particular poisonous quality. In this cave they expose their lepers, paralytics, arthritics, and elephantiac patients, quite naked; where, the warmth of the subterraneous steams resolving them into a sweat, and the serpents clinging variously all around, licking and sucking them, they become so thoroughly freed of all their vitious humours, that, upon repeating the operation for some time, they become perfectly restored." This cave Kircher visited himself; and found it warm, and every way agreeable to

the description given of it. He saw the holes, and heard a murmuring hissing noise in them. Though he missed seeing the serpents, it not being the season of their creeping out, yet he saw a great number of their exuvia, or sloughs, and an elin growing hard by laden with them. The discovery of this cave was by the cure of a leper going from Rome to some baths near this place. Losing his way, and being benighted, he happened upon this cave. Finding it very warm, he pulled off his clothes; and, being weary and sleepy, had the good fortune not to feel the serpents about him till they had wrought his cure.

MILKY GROTTA, *Crypta Lactea*, a mile distant from the ancient village of Bethlehem, is said to have been thus denominated on occasion of the blessed Virgin, who let fall some drops of milk in giving suck to Jesus in this grotto. And hence it has been commonly supposed, that the earth of this cavern has the virtue of restoring milk to women that are grown dry, and even of curing fevers. Accordingly, they are always digging in it, and the earth is sold at a good rate to such as have folly enough to give credit to the fable. An altar has been built on the place, and a church just by it.

GROTTO is also used for a little artificial edifice made in a garden, in imitation of a natural grotto. The outsides of these grottos are usually adorned with rustic architecture, and their insides with shell-work, fossils, &c. finished likewise with jets d'eau or fountains, &c. A cement for artificial grottos may be made thus: Take two parts of white rosin, melt it clear, and add to it four parts of bees' wax; when melted together, add two or three parts of the powder of the stone you design to cement, or so much as will give the cement the colour of the stone. With this cement, the stones, shells, &c. after being well dried before the fire, may be cemented. Artificial red coral branches, for the embellishment of grottos, may be made in the following manner: Take clear rosin, dissolve it in a brass-pan; to every ounce of which add two drams of the finest vermilion: when you have stirred them well together, and have chosen your twigs and branches, peeled and dried, take a pencil and paint the branches all over whilst the composition is warm; afterwards shape them in imitation of natural coral. This done, hold the branches over a gentle coal-fire, till all is smooth and even as if polished. In the same manner white coral may be prepared with white lead, and black coral with lamp-black. A grotto may be built, with little expence, of glass, cinders, pebbles, pieces of large flint, shells, moss, stones, counterfeit coral, pieces of chalk, &c. all bound or cemented together with the above described cement.

GROVE, in gardening, a small wood impervious to the rays of the sun. Groves have been in all ages held in great veneration. The *proseuchæ*, and high-places of the Jews, whether they resorted for the purposes of devotion, were probably situated in groves: See Joshua xxiv. 26. The *proseuchæ* in Alexandria, mentioned by Philo, had groves about them, because he complains that the Alexandrians, in a tumult against the Jews, cut down the trees of their *proseuchæ*. The ancient Romans had a sort of groves near several of their temples, which were consecrated to some god, and called *luci* by antiphrasis, a *non lucendo*, as being shady and dark. The veneration which the ancient druids had for groves is well known. Modern groves are not only great ornaments to gardens, but are also the greatest relief against the violent heats of the sun, affording shade to walk under in the hottest parts of the day, when the other parts of the gardens are exposed; so that every garden is defective which has not some such shade.

Groves are of two sorts, *viz.* either *open* or *close*. *Open* groves are such as have large shady trees, which stand at such distances, as that their branches approach so near to each other as to prevent the rays of the sun from penetrating through them. *Close* groves have frequently large trees standing in them; but

the ground under these is filled with shrubs or underwood: so that the walks which are in them are private, and screened from winds; by which means they are rendered agreeable for walking, at those times when the air is either too hot or too cold in the more exposed parts of the garden. These are often contrived so as to bound the open groves, and frequently to hide the walls or other inclosures of the garden: and when they are properly laid out, with dry walks winding through them, and on the sides of these sweet-smelling shrubs and flowers irregularly planted, they have a charming effect.

GROUND, in painting, the surface upon which the figures and other objects are represented. The ground is properly understood of such parts of the piece as have nothing painted on them, but retain the original colour upon which the other colours are applied to make the representations. A building is said to serve as a ground to a figure when the figure is painted on the building. The ground behind a picture in miniature is commonly blue or crimson, imitating a curtain of sattin or velvet.

GROUND, in etching, denotes a composition of gums smeared over the surface of the metal to be etched, to prevent the aquafortis from eating, except in such places where this ground is cut through with the point of a needle. See the article **ETCHING**.

GROUND-Angling, fishing under water without a float, only with a plumb of lead, placed about nine inches from the hook; or a bullet, which is better, because it will roll on the ground. This method of fishing is most proper in cold weather, when the fish swim very low. The morning and evening are the proper times for the ground-line in fishing for trout: but if the day prove cloudy, or the water muddy, you may fish at ground all the day.

GROUND-Tackle, a ship's anchors, cables, &c. and in general whatever is necessary to make her ride safe at anchor.

GROUND-Ivy, in botany. See **GLECHOMA**.

GROUND-Pine, in botany. See **TEUCRIUM**.

GROUNDSEL. See **SENECIO**.

GROUP, in painting and sculpture, is an assemblage of two or more figures of men, beasts, fruits, or the like, which have some apparent relation to each other. See **PAINTING**. The word is formed of the Italian *gruppo*, a knot.

The Groups, a cluster of islands lately discovered in the South Sea. They lie in about S. lat. 18. 12. and W. lon. 142. 42. They are long narrow slips of land, ranging in all directions, some of them ten miles or upwards in length, but not more than a quarter of a mile broad. They abound in trees, particularly those of the cocoa-nut. They are inhabited by well-made people, of a brown complexion. Most of them carried in their hands a slender pole about 14 feet in length, pointed like a spear; they had likewise something shaped like a paddle, about four feet long. Their canoes were of different sizes, carrying from three to six or seven people, and some of them hoisted a sail.

GROUSE, or **GROUSE**. See **TETRAO**.

GROUTHEAD, or **GREATHED** (Robert), a learned and famous bishop of Lincoln, was born at Stow in Lincolnshire, or (according to others) at Stradbroke in Suffolk, in the latter part of the twelfth century. His parents were so poor, that when a boy he was reduced to do the meanest offices, and even to beg his bread; till the mayor of Lincoln, struck with his appearance and the quickness of his answers to certain questions, took him into his family, and put him to school. Here his ardent love of learning, and admirable capacity for acquiring it, soon appeared, and procured him many patrons, by whose assistance he was enabled to prosecute his studies, first at Cambridge, afterwards at Oxford, and at last at Paris. In these three famous seats of learning, he spent many years in the most indefatigable

pursuit of knowledge, and became one of the best and most universal scholars of the age. He was a great master not only of the French and Latin, but also of the Greek and Hebrew languages, which was a rare accomplishment in those times. We are assured by Roger Bacon, who was intimately acquainted with him, that he spent much of his time for almost forty years in the study of geometry, astronomy, optics, and other branches of mathematical learning, in all which he very much excelled. Theology was his favourite study, in which he read lectures at Oxford with great applause. In the mean time he obtained several preferments in the church, and was at length elected and consecrated bishop of Lincoln, A. D. 1235. This most excellent and learned prelate was a very voluminous writer, and composed a prodigious number of treatises on a great variety of subjects in philosophy and divinity, a catalogue of which is given by Bale.

GROWTH, the gradual increase of bulk and stature that takes place in animals or vegetables, to a certain period. The increase of bulk in such bodies as have no life, owing to fermentations excited in their substance, or to other causes, is called **EXPANSION**, **SWELLING**, &c. The growth of animals, nay even of the human species, is subject to great variations. A remarkable instance in the last was observed in France in the year 1729. At this time the Academy of Sciences examined a boy, who was then only seven years old, and who measured four feet eight inches and four lines high without his shoes. His mother observed the signs of puberty in him at two years old, which continued to increase very quick, and soon arrived at the usual standard. At four years old he was able to lift and toss the common bundles of hay in stables into the horses' racks; and at six years old could lift as much as a sturdy fellow of twenty. But though he thus increased in bodily strength, his understanding was no greater than is usual with children of his age, and their playthings were also his favourite amusements.

Another boy, a native of the hamlet of Bouzanquet, in the diocese of Alais, though of a strong constitution, appeared to be knit and stiff in his joints till he was about four years and a half old. During this time nothing farther was remarkable of him than an extraordinary appetite, which was satisfied no otherwise than by giving him plenty of the common aliments of the inhabitants of the country, consisting of rye-bread, chestnuts, bacon, and water; but his limbs soon becoming supple and pliable, and his body beginning to expand itself, he grew up in so extraordinary a manner, that at the age of five years he measured four feet three inches; some months after he was four feet eleven inches; and at six, five feet, and bulky in proportion. His growth was so rapid, that one might fancy he saw him grow: every month his clothes required to be made longer and wider; and what was still very extraordinary in his growth, it was not preceded by any sickness, nor accompanied with any pain in any part of his body. At the age of five years his voice changed, his beard began to appear, and at six he had as much as a man of thirty: in short, all the unquestionable marks of puberty were visible in him. It was not doubted in the country but this child was, at five years old, or five and a half, in a condition of begetting other children; which induced the rector of the parish to recommend to his mother that she would keep him from too familiar a conversation with children of the other sex. Though his wit was riper than is commonly observable at the age of five or six years, yet its progress was not in proportion to that of his body. His air and manner still retained something childish, though by his bulk and stature he resembled a complete man, which at first sight produced a very singular contrast. His voice was strong and manly, and his great strength rendered him already fit for the labours of the country. At the age of five years, he could carry to a good distance three measures of rye, weighing 84 pounds; when turned

of six, he could lift up easily on his shoulders and carry loads of 150 pounds weight a good way off: and these exercises were exhibited by him as often as the curious engaged him thereto by a reward. Such beginnings made people think that he would shoot up into a giant. A mountebank was already soliciting his parents for him, and flattering them with hopes of putting him in a way of making a great fortune. But all these hopes suddenly vanished. His legs became crooked, his body shrunk, his strength diminished, his voice grew sensibly weaker, and he at last sunk into a total imbecility.

In the Paris Memoirs also there is an account of a girl who had her menses at the age of three months. When four years old, she was four feet six inches in height, and had her limbs well proportioned to that height, her breasts large and plump, and the parts of generation like those of a girl of eighteen; so that there is no doubt but that she was marriageable at that time, and capable of being a mother of children. These things are more singular and marvellous in the northern than in the southern climates, where the females come sooner to maturity. In some places of the East Indies, the girls, it is said, have children at nine years of age.

Many other instances of extraordinary growth might be brought, but the particulars are not remarkably different from those already related. It is at first sight astonishing that children of such early and prodigious growth do not become giants: but when we consider, that the signs of puberty appear so much sooner than they ought, it seems evident that the whole is only a more than usually rapid expansion of the parts, as in hot climates; and accordingly it is observed, that such children, instead of becoming giants, always decay and die, apparently of old age, long before the natural term of human life.

GRUB, in zoology, the English name of the hexapode worms, produced from the eggs of beetles, and which at length are transformed into winged insects of the same species with their parents.

GRUBBING, in agriculture, the digging or pulling up of the stumps and roots of trees. When the roots are large, this is a very troublesome and laborious task; but Mr. Mortimer has shown how it may be accomplished in such a manner, as to save great expence by a very simple and easy method. He proposes a strong iron hook to be made, about two feet four inches long, with a large iron-ring fastened to the upper part of it. This hook must be put into a hole in the side of the root, to which it must be fastened; and a lever being put into the ring, three men, by means of this lever, may draw out the root, and twist the sap-roots asunder. Stubs of trees may also be taken up with the same hook, in which work it will save a great deal of labour, though not so much as in the other; because the stumps must be first cleft with wedges, before the hook can enter the sides of them, to wrench them out by pieces.

GRUBENHAGEN, a town and castle of Germany, in the circle of Lower Saxony, and the chief place of a principality of the same name, belonging to the house of Hanover. In the mountains near it are mines of silver, iron, copper, and lead. These mountains are covered with trees, some remains of the Hercynian forest. It is 45 miles S. of Hanover. E. lon. 10. 3. N. lat. 51. 31.

GRUINALES, from *grus* "a crane," the name of the fourteenth order in Linnæus's Fragments of a Natural Method, consisting of geranium, and a few other genera which the author considers as allied to it in their habit and external structure. See BOTANY, page 50.

GRUPPO, or Turned SHAKE, a musical grace, defined by Playford to consist in the alternate prolation of two tones in juxtaposition to each other, with a close on the note immediately beneath the lower of them. See SHAKE.

GRUS, in antiquity, a dance performed yearly by the young

Athenians around the temple of Apollo, on the day of the Delia. The motions and figures of this dance were very intricate, and variously interwoven; some of them being intended to express the windings of the labyrinth wherein the minotaur was killed by Theseus.

GRUS, in astronomy, a southern constellation, not visible in our latitude. The number of stars in this constellation, according to Mr. Sharp's Catalogue, is 13.

GRUS, in ornithology. See ARDEA.

GRUTER (James), a learned philologist, and one of the most laborious writers of his time, was born at Antwerp in 1560. He was but a child when his father and mother, being persecuted for the Protestant religion by the dukes of Parma, governors of the Netherlands, carried him into England. He imbibed the elements of learning from his mother, who was one of the most learned women of the age, and besides French, Italian, and English, was a complete mistress of Latin, and well skilled in Greek. He spent some years in the university of Cambridge; after which he went to that of Leyden to study the civil law; but at last applied himself wholly to polite literature. After travelling much, he became professor in the university of Heidelburgh; near which city he died in 1627. He wrote many works, the most considerable of which are, 1. A large collection of ancient inscriptions. 2. *Thesaurus criticus*. 3. *Deliciae poetarum Gallorum, Italorum, & Belgarum, &c.*

GRUYERES, a town of Switzerland, in the canton of Friburg, with a handsome castle, where the bailiff resides. It is famous for cheese, and is 15 miles S. W. of Friburg. A dangerous insurrection broke out here in 1781, which threatened the destruction even of Friburg, the capital, but was happily quelled by some troops from Bern. W. lon. 6. 43. N. lat. 46. 35.

GRY, a measure containing one-tenth of a line. A line is one-tenth of a digit, and a digit one-tenth of a foot, and a philosophical foot one-third of a pendulum, whose diadromes, or vibrations, in the latitude of 45 degrees, are each equal to one-second of time, or one-sixtieth of a minute.

GRYLLUS, in zoology, the name of the cricket and locust kinds, which, together with the grasshoppers, make only one genus of insects, belonging to the order of *hemiptera*. See plate 2. The general characters of the genus are these: The head is inflected, armed with jaws, and furnished with palpi: The antennæ in some of the species are setaceous, in others filiform: The wings are deflected towards and wrapped round the sides of the body; the under ones are folded up, so as to be concealed under the elytra. All the feet are armed with two nails; and the hind ones are formed for leaping. The genus is subdivided into five different sections, or families:

I. The ACRIDÆ, *Truxalides* of Fabricius, or CRICKET family properly so called; of which the characters are: The head is of a conical form, and longer than the thorax; and the antennæ are ensiform, or sword-shaped. Of this family there are eight species, none of them found in Britain.

II. The BULLÆ, or *Acydia* of Fabricius: These are distinguished by a kind of crest or elevation on the thorax; their antennæ are shorter than the thorax, and filiform; and their palpi are equal. The gryllus *bullæ-bipunctatus* is of a dark brown colour; sometimes besprinkled with spots of a lighter hue. But the chief and most obvious distinction of this species is the form of its thorax, which is prolonged, covering the whole body, and decreases to the extremity of the abdomen. This prolongation of the thorax stands instead of elytra, of which this insect is destitute. It has only wings under this projection of the thorax. Linnæus mentions a spot in the thorax; which, however, is often wanting. This species is every where to be met with, in the fields, in woods, &c. There are 10 or 11 other species, inhabitants of Europe and America.

III. The third family, called АСНЕТЪ, are distinguished by two bristles, situated above the extremity of their abdomen, by having three stemmata, and by the tarsi being composed of three articulations. This family is in many places called *Cricket*, on account of the sound which the insect makes. There are 28 species enumerated in the new edition of the *Systema Naturæ*; of which the most remarkable are,

1. The *gryllus domesticus*, or the *domesticus* and *campestris*, the domestic and the field gryllus being one and the same species; only that the former is paler and has more of the yellow cast, and the latter more of a brown. The antennæ are as slender as a thread, and nearly equal to the body in length. The head is large and round, with two large eyes, and three smaller ones of a light yellow colour, placed higher on the edge of the depression, from the centre of which originate the antennæ: The thorax is broad and short. In the *males*, the elytra are longer than the body, veined, as it were rumpled on the upper part, crossed one over the other, and enfolding part of the abdomen, with a projecting angle on the sides: They have also at their base a pale-coloured band. In the *females*, the elytra leave one-third of the abdomen uncovered, and scarcely cross each other; and they are all over of one colour, veined and not rumpled; nor do they wrap round so much of the abdomen underneath. The female, moreover, carries at the extremity of its body a hard spine, almost as long as the abdomen, thicker at the end, composed of two sheaths, which encompass two laminæ: This implement serves the insect to sink and deposit its eggs in the ground. Both the male and female have two pointed soft appendices at the extremity of the abdomen. Their hinder feet are much larger and longer than the rest, and serve them for leaping.

Towards sunset is the time the *field gryllus*, or *cricket*, as it is often called, likes best to appear out of its subterraneous habitation. In White's *Natural History of Selbourne*, Let. 46. a very pleasing account is given of the manners and economy of these insects; which, however, are so shy and cautious, he observes, that it is no easy matter to get a sight of them; for, feeling a person's footsteps as he advances, they stop short in the midst of their song, and retire backward nimbly into their burrows, where they lurk till all suspicion of danger is over. At first it was attempted to dig them out with a spade, but without any great success; for either the bottom of the hole was inaccessible from its terminating under a great stone; or else, in breaking up the ground, the poor insect was inadvertently squeezed to death. Out of one so bruised a multitude of eggs were taken, which were long and narrow, of a yellow colour, and covered with a very tough skin. More gentle means were then used, and proved successful: "a pliant stalk of grass, gently insinuated into the caverns, will probe their windings to the bottom, and quickly bring out the inhabitant; and thus the humane enquirer may gratify his curiosity without injuring the object of it. It is remarkable, that though these insects are furnished with long legs behind, and brawny thighs for leaping, like grasshoppers, yet when driven from their holes they show no activity, but crawl along in a shiftless manner, so as easily to be taken: and again, though provided with a curious apparatus of wings, yet they never exert them when there seems to be the greatest occasion. The males only make that shrilling noise perhaps out of rivalry and emulation, as is the case with many animals which exert some sprightly note during their breeding time: it is raised by a brisk friction of one wing against the other. They are solitary beings, living singly male or female, each as it may happen; but there must be a time when the sexes have some intercourse, and then the wings may be useful perhaps during the hours of night. When the males meet they will fight fiercely, as our author found by some which he put into the crevices of a dry stone-wall, where he wanted to have made them settle. For though they seemed distressed by being taken

out of their knowledge, yet the first that got possession of the chinks would seize on any that were obtruded upon them with a vast row of serrated fangs. With their strong jaws, toothed like the shears of a lobster's claws, they perforate and round their curious regular cells, having no fore-claws to dig, like the mole-cricket. When taken in the hand, they never offered to defend themselves, though armed with such formidable weapons. Of such herbs as grow before the mouths of their burrows they eat indiscriminately; and on a little platform, which they make just by, they drop their dung; and never, in the day-time, seem to stir more than two or three inches from home. Sitting in the entrance of their caverns they chirp all night as well as day, from the middle of the month of May to the middle of July; in hot weather, when they are most vigorous, they make the hills echo; and in the stiller hours of darkness may be heard to a considerable distance. In the beginning of the season their notes are more faint and inward; but become louder as the summer advances, and so die away again by degrees. In March the crickets appear at the mouth of their cells, which they then open and bore, and shape very elegantly. All that ever I have seen at that season were in their pupa state, and had only the rudiments of wings, lying under a skin or coat, which must be cast before the insect can arrive at its perfect state; from whence I should suppose that the old ones of last year do not always survive the winter. In August their holes begin to be obliterated, and the insects are seen no more till spring.—Not many summers ago I endeavoured to transplant a colony to the terrace in my garden, by boring deep holes in the sloping turf. The new inhabitants staid some time, and fed and sung; but wandered away by degrees, and were heard at a farther distance every morning; so that it appears that on this emergency they made use of their wings in attempting to return to the spot from which they were taken. One of these crickets, when confined in a paper cage and set in the sun, and supplied with plants moistened with water, will feed and thrive, and become so merry and loud as to be irksome in the same room where a person is sitting: if the plants are not wetted, it will die."

The *domestic gryllus*, or hearth-cricket, as it is called, does not require to be sought after for examination, nor is shy like the other sort: it slides altogether within our dwellings, intruding itself upon our notice whether we will or no. It delights in new-built houses; being, like the spider, pleased with the moisture of the walls; and besides, the softness of the mortar enables them to burrow and mine between the joints of the bricks or stones, and to open communications from one room to another. They are particularly fond of kitchens and bakers' ovens, on account of their perpetual warmth. "Tender insects that live abroad either enjoy only the short period of one summer, or else doze away the cold uncomfortable months in profound slumbers; but these (our author observes), residing as it were in a torrid zone, are always alert and merry: a good Christmas fire is to them like the heats of the dog-days. Though they are frequently heard by day, yet is their natural time of motion only in the night. As soon as it grows dusk, the chirping increases, and they come running forth, and are from the size of a flea to that of their full stature. As one should suppose, from the burning atmosphere which they inhabit, they are a thirsty race, and show a great propensity for liquids, being found frequently drowned in pans of water, milk, broth, or the like. Whatever is moist they affect: and therefore often gnaw holes in wet woollen stockings and aprons that are hung to the fire. These crickets are not only very thirsty, but very voracious; for they will eat the scummings of pots: yeast, salt, and crumbs of bread; and any kitchen offal or sweepings. In the summer we have observed them to fly, when it became dusk, out of the windows, and over the neighbouring roofs. This feat of activity accounts for the sudden manner in which

they often leave their haunts, as it does for the method by which they come to houses where they were not known before. It is remarkable, that many sorts of insects seem never to use their wings but when they have a mind to shift their quarters and settle new colonies. When in the air they move "*volatu undoso*," in waves or curves, like wood peckers, opening and shutting their wings at every stroke, and so are always rising or sinking. When they increase to a great degree, as they did once in the house where I am now writing, they become noisome pests, flying into the candles, and dashing into people's faces; but may be blasted by gunpowder discharged into their crevices and crannies. In families, at such times, they are like Pharaoh's plague of frogs,—'in their bedchambers, and upon their beds, and in their ovens, and in their kneading troughs.' Their shrilling noise is occasioned by a brisk attrition of their wings. Cats catch hearth-crickets, and, playing with them as they do with mice, devour them. Crickets may be destroyed, like wasps, by phials half filled with beer, or any liquid, and set in their haunts; for, being always eager to drink, they will crowd in till the bottles are full." A popular prejudice, however, frequently prevents their being driven away and destroyed: the common people imagine that their presence brings a kind of luck to the house while they are in it, and think it would be hazardous to destroy them.

2. *Gryllus gryllotalpa*, or mole cricket, is of a very unpleasant form. Its head, in proportion to the size of its body, is small and oblong, with four long thick palpi, and two long antennæ as slender as threads. Behind the antennæ are situated the eyes, and between those two eyes are seen three stemmata or lesser eyes, amounting to five in all, set in one line transversely. The thorax forms a kind of cuirass, oblong, almost cylindrical, which appears as it were velvety. The elytra, which are short, reach but to the middle of the abdomen, are crossed one over the other, and have large black or brown nervous fibres. The wings terminate in a point, longer not only than the elytra, but even than the abdomen. This latter is soft, and ends in two points or appendices of some length. But what constitutes the chief singularity of this insect are its fore-feet, that are very large and flat, with broad legs, ending outwardly in four large ferrated claws, and inwardly in two only; between which claws is situated, and often concealed, the tarsus. The whole animal is of a brown dusky colour. It haunts moist meadows, and frequents the sides of ponds and banks of streams, performing all its functions in a swampy wet soil. With a pair of fore-feet, curiously adapted to the purpose, it burrows and works under ground like the mole, raising a ridge as it proceeds, but seldom throwing up hillocks. As mole-crickets often infest gardens by the sides of canals, they are unwelcome guests to the gardener, raising up ridges in their subterraneous progress, and rendering the walks unsightly. If they take to the kitchen gardens, they occasion great damage among the plants and roots, by destroying whole beds of cabbages, young legumes, and flowers. When dug out they seem very slow and helpless, and make no use of their wings by day; but at night they come abroad, and make long excursions. In fine weather, about the middle of April, and just at the close of day, they begin to solace themselves with a low, dull, jarring note, continued for a long time without interruption, and not unlike the chattering of the fern-owl, or goat-sucker, but more inward. About the beginning of May they lay their eggs, as Mr. White informs us, who was once an eye-witness: "for a gardener at an house where he was on a visit, happening to be mowing, on the 6th of that month, by the side of a canal, his scythe struck too deep, pared off a large piece of turf, and laid open to view a curious scene of domestic economy. There were many caverns and winding passages leading to a kind of chamber, neatly smoothed and rounded, and about the size of a moderate snuff-

box. Within this secret nursery were deposited near 100 eggs of a dirty yellow colour, and enveloped in a tough skin, but too lately excluded to contain any rudiments of young, being full of a viscous substance. The eggs lay but shallow, and within the influence of the sun, just under a little heap of fresh-mowed mould, like that which is raised by ants.—When mole-crickets fly, they move "*curfu undoso*," rising and falling in curves, like the domestic species mentioned before. In different parts of this kingdom people call them *fen-crickets*, *churr-worms*, and *ewe-churrs*, all very apposite names."

IV. The TETTIGONIÆ, GRASSHOPPERS, or *Locusts* armed at the tail: The females of this family are distinguished by a tubular dart at the extremity of their abdomen: in both sexes the antennæ are setaceous, and longer than the abdomen; and the tarsi composed of four articulations. Of these insects there are 69 species enumerated in the *Systema Naturæ*. They leap by the help of their hinder legs, which are strong and much longer than the fore ones. Their walk is heavy, but they fly tolerably well. Their females deposit their eggs in the ground, by means of the appendices which they carry in their tail, which consist of two laminae, and penetrate the ground. They lay a great number of eggs at a time; and those eggs, united in a thin membrane, form a kind of group. The little larvæ that spring from them are wholly like the perfect insects, excepting in size, and their having neither wings nor elytra, but only a kind of knobs, four in number, which contain both, but undisplayed. The unfolding of them only takes place at the time of the metamorphosis, when the insect has attained its full growth. In these insects, when examined internally, besides the gullet, we discover a small stomach; and behind that, a very large one, wrinkled and furrowed within-side. Lower down, there is still a third: so that it is thought, and with some probability, that all the animals of this genus chew the cud, as they so much resemble ruminant animals in their internal conformation.

V. LOCUSTÆ (the *Grylli* of Fabricius), or *Locusts* unarmed at the tail. This family is distinguished by having the tail purple, without the setæ of the *Achetæ*, or the tube of the *Tettigoniæ*: their antennæ are filiform, and half shorter than the abdomen: they have three stemmata, and three joints to the tarsi. To part of this description, however, there is an exception in the *gryllus locusta-grossus*, the antennæ of which are of a cylindrical form. According to Mr. Barbutt, "few species vary so much in size and colours. Some of these insects are twice as long as others; the antennæ in most are filiform, but in this particular species cylindrical, composed of about 24 articulations, and but one-fourth of the length of the body. As to colour, the small individuals are nearly quite red spotted with black, with the under part of the body only of a greenish yellow. The larger subjects are all over of a greenish hue, the under part being of a deeper yellow, only the inside of the hinder thighs is red. But what characterises this species is, the form of the thorax, which has, above, a longitudinal elevation, attended by one on each side, the middle whereof drawing nigh to the first, forms a kind of X. Moreover, between the claws that terminate the feet there are small sponges, but larger in this species than the rest. This species is to be met with every where in the country. The larvæ or caterpillars very much resemble the perfect insects, and commonly dwell under ground." Of this tribe, 118 other species are enumerated in the *Systema Naturæ*, natives of different parts of the globe; besides a considerable number noted as unascertained, with regard to their being distinct species, or only synonymous, or varieties of some of the others.

All the GRYLLI, except the first family which feed upon other insects, live upon plants; the *achetæ* chiefly upon the roots, the *tettigoniæ* and *locustæ* upon the leaves.

The distinction of *Locusts* into families (IV. V.), as above

characterised, is extremely proper; and the difference of organisation upon which it is founded has been observed to be adapted to the mode and the places in which the insects lay their eggs. But by taking the wings into consideration, there might have been formed three tribes or divisions, instead of two, upon the same natural foundation. Thus, according to the observations of the Abbé Pouet in the Journ. de Physique for 1787, those which have their abdomen furnished with the tube or dart above mentioned, lay their eggs in a stiff sort of earth which that instrument perforates. During the operation, the dart opens; and, being hollow and grooved on each side within, the egg slides down along the grooves, and is deposited in the hole. Of those which have the tail simple, i. e. which have *no dart*, some have long wings, and some very short. The long-winged sort lay their eggs on the bare ground, and have no use for a perforating instrument; but they cover them with a glutinous substance, which fixes them to the soil, and prevents their being injured either by wind or wetness. Those again which have short wings deposit their eggs in the sand; and, to make the holes for this purpose, they have the power of elongating and retracting their abdominal rings, and can turn their body as on a pivot; in which operation long wings would have been a material impediment.

The annals of most of the warm countries are filled with accounts of the devastations produced by locusts, who sometimes make their appearance in clouds of vast extent. They seldom visit Europe in such swarms as formerly; yet in the warmer parts of it are still formidable. Those which have at uncertain intervals visited Europe in our memory, are supposed to have come from Africa: they are a large species about three inches long. The head and horns are of a brownish colour; it is blue about the mouth, as also on the inside of the larger legs. The shield which covers the back is greenish; and the upper side of the body brown, spotted black, and the under side purple. The upper wings are brown, with small dusky spots, and one larger spot at the tips. The under wings are more transparent, and of a light brown tinged with green, but there is a dark cloud of spots near the tips. These insects are bred in the warm parts of Asia and Africa, from whence they have often taken their flight into Europe, where they committed terrible devastations. They multiply faster than any other animal in the creation, and are truly terrible in the countries where they breed. Some of them were seen in different parts of Britain in the year 1748, and great mischiefs were apprehended: but happily for us, the coldness of our climate, and the humidity of our soil, are very unfavourable to their production; so that, as they are only animals of a year's continuance, they all perish without leaving a young generation to succeed them.

When the locusts take the field, it is said they have a leader at their head, whose flight they observe, and pay a strict regard to all his motions. They appear at a distance like a black cloud, which, as it approaches, gathers upon the horizon, and almost hides the light of day. It often happens, that the husbandman sees this imminent calamity pass away without doing him any mischief; and the whole swarm proceeds onward to settle upon some less fortunate country. In those places, however, where they alight, they destroy every green thing, stripping the trees of their leaves, as well as devouring the corn and grass. In the tropical climates they are not so pernicious as in the more southern parts of Europe. In the first, the power of vegetation is so strong, that an interval of three or four days repairs the damage; but in Europe this cannot be done till next year. Besides, in their long flights to this part of the world, they are fatigued by the length of their journey, and are therefore more voracious wherever they happen to settle. But as much damage is occasioned by what they destroy, as by what they devour. Their bite is thought to contaminate the plant, and either to

destroy or greatly to weaken its vegetation. To use the expression of the husbandmen, they burn wherever they touch, and leave the marks of their devastation for three or four years ensuing. When dead, they infect the air in such a manner that the stench is insupportable. Orosius tells us, that in the year of the world 3800, Africa was infested with a multitude of locusts. After having eaten up every thing that was green, they flew off and were drowned in the sea; where they caused such a stench as could not have been equalled by the putrefying carcases of 100,000 men.

In the year 1650 a cloud of locusts were seen to enter Russia in three different places; and from thence they spread themselves over Poland and Lithuania in such astonishing multitudes, that the air was darkened and the earth covered with their numbers. In some places they were seen lying dead, heaped upon each other to the depth of four feet; in others, they covered the surface like a black cloth; the trees bent with their weight, and the damage which the country sustained exceeded computation.

In Barbary, their numbers are formidable; and Dr. Shaw was a witness of their devastations there in 1724. Their first appearance was in the latter end of March, when the wind had been southerly for some time. In the beginning of April, their numbers were so vastly increased, that, in the heat of the day, they formed themselves into large swarms that appeared like clouds, and darkened the sun. In the middle of May they began to disappear, retiring into the plains to deposit their eggs. In June the young brood began to make their appearance, forming many compact bodies of several hundred yards square; which afterwards marching forward, climbed the trees, walls, and houses, eating every thing that was green in their way. The inhabitants, to stop their progress, laid trenches all over their fields and gardens, which they filled with water. Some placed large quantities of heath, stubble, and such-like combustible matter, in rows, and set them on fire on the approach of the locusts. But all this was to no purpose; for the trenches were quickly filled up, and the fires put out by the great numbers of swarms that succeeded each other. A day or two after one of these was in motion, others that were just hatched came to glean after them, gnawing off the young branches, and the very bark of the trees. Having lived near a month in this manner, they arrived at their full growth, and threw off their worm-like state, by casting their skins. To prepare themselves for this change, they fixed their hinder part to some bush or twig, or corner of a stone, when immediately, by an undulating motion used on this occasion, their heads would first appear, and soon after the rest of their bodies. The whole transformation was performed in seven or eight minutes time, after which they remained for a little while in a languishing condition; but as soon as the sun and air had hardened their wings, and dried up the moisture that remained after casting off their former sloughs, they returned to their former greediness, with an addition both of strength and agility. But they did not long continue in this state before they were entirely dispersed. After laying their eggs, they directed their course northward, and probably perished in the sea. In that country, however, the amazing fertility of the soil and warmth of the climate generally render the depredations of these insects of little consequence; besides that many circumstances concur to diminish their number. Though naturally herbivorous, they often fight with each other, and the victor devours the vanquished. They are the prey, too, of serpents, lizards, frogs, and the carnivorous birds. They have been found in the stomachs of the eagle and different kinds of owls. They are also used as food by the Moors; who go to hunt them, fry them in oil or butter, and sell them publicly at Tunis and other places.

In 1754, 1755, 1756, and 1757, great devastations were

committed in Spain by a species of locusts, of which we have the following description by Don Guillerino Bowles, published in *Dillon's Travels* through that country. "The locusts are continually seen in the southern parts of Spain, particularly in the pastures and remote uncultivated districts of Estremadura, but in general are not taken notice of, if not very numerous, as they commonly feed upon wild herbs, without preying upon gardens and cultivated lands, or making their way into houses. The peasants look at them with indifference while they are frisking about in the field, neglecting any measure to destroy them till the danger is immediate and the favourable moment to remedy the evil is elapsed. Their yearly number is not very considerable, as the males are far more numerous than the females. If an equal proportion were allowed only for ten years, their numbers would be so great as to destroy the whole vegetative system. Beasts and birds would starve for want of subsistence, and even mankind would become a prey to their ravenous appetites. In 1754 their increase was so great from the multitude of females, that all La Mancha and Portugal were covered with them and totally ravaged. The horrors of famine were spread even farther, and assailed the fruitful provinces of Andalusia, Murcia, and Valencia.

"The amours of these creatures are objects of surprise and astonishment, and their union is such that it is difficult to separate them. When this separation is voluntary, after having lasted some hours, they are so exhausted, that the male retires immediately to the water for refreshment, where, losing the use of his limbs, he soon perishes, and becomes an easy prey to the fish: having given life to his offspring at the expence of his own. The female, disembarrassed, though not without violent struggles, spends the remainder of her days in some solitary place, busy in forming a retreat under ground, where she can secure her eggs, of which she generally lays about 40, screening them by her sagacity from the intemperance of the air, as well as the more immediate danger of the plough or the spade, one fatal blow of which would destroy all the hopes of a rising generation.

"The manner of her building this cell is equally surprising. In the hinder part of her body, nature has provided her with a round smooth instrument, eight lines in length, which at its head is as big as a writing quill, diminishing to a hard sharp point, hollow within like the tooth of a viper, but only to be seen with a lens. At the root of this vehicle there is a cavity, with a kind of bladder, containing a glutinous matter, of the same colour, but without the consistency or tenacity of that of the silk-worm, as I found by an experiment, made for the purpose, by an infusion in vinegar, for several days, without any effect. The orifice of the bladder corresponds exactly with the instrument which serves to eject the glutinous matter. It is hid under the skin of the belly, and its interior surface is united to the moveable parts of the belly, and can partake of its motions, forming the most admirable contexture for every part of its operations, as she can dispose of this ingredient at pleasure, and eject the fluid, which has three very essential properties: first, being indissoluble in water, it prevents the young from being drowned; next, it resists the heat of the sun, otherwise the structure would give way and destroy its inhabitants; lastly, it is proof against the frost of winter, so as to preserve a necessary warmth within. For greater security, this retreat is always contrived in a solitary place: for though a million of locusts were to light upon a cultivated field, not one would deposit her eggs there; but wherever they meet a barren and lone some situation, there they are sure to repair and lay their eggs.

"These locusts seem to devour, not so much from a ravenous appetite, as from a rage of destroying every thing that comes in their way. It is not surprising, that they should be fond of the most juicy plants and fruits, such as melons, and all man-

ner of garden fruits and herbs, and feed also upon aromatic plants, such as lavender, thyme, rosemary, &c. which are so common in Spain, that they serve to heat ovens: but it is very singular, that they equally eat mustard seed, onions, and garlic; nay even hemlock, and the most rank and poisonous plants, such as the thorn apple and deadly nightshade. They will even prey upon crowfoot, whose causticity burns the very hides of beasts; and such is their universal taste, that they do not prefer the innocent mallow to the bitter furze, or rue to wormwood, consuming all alike, without predilection or favour, with this remarkable circumstance, that during the four years they committed such havoc in Estremadura, the love-apple, or *Lycopersicon solanum* of Linnæus, was the only plant that escaped their rapacious tooth, and claimed a respect to its root, leaves, flowers, and fruit. Naturalists may search for their motives, which I am at a loss to discover; the more as I saw millions of them light on a field near Almaden, and devour the woollen and linen garments of the peasants, which were lying to dry on the ground. The curate of the village, a man of veracity, at whose house I was, assured me, that a tremendous body of them entered the church, and devoured the silk garments that adorned the images of the saints, not sparing even the varnish on the altars. The better to discover the nature of such a phenomenon, I examined the stomach of the locust, but only found one thin and soft membrane, with which, and the liquor it contains, it destroys and dissolves all kinds of substances, equally with the most caustic and venomous plants; extracting from them a sufficient and salutary nourishment.

"Out of curiosity to know the nature of so formidable a creature, I was urged to examine all its parts with the utmost exactness: its head is of the size of a pea, though longer; its forehead pointing downwards like the handsome Andalusian horse, its mouth large and open, its eyes black and rolling, added to a timid aspect not unlike a hare. With such a dastardly countenance who would imagine this creature to be the scourge of mankind! In its two jaws it has four incisive teeth, whose sharp points traverse each other like scissars, their mechanism being such as to gripe or to cut. Thus armed, what can resist a legion of such enemies? After devouring the vegetable kingdom, were they, in proportion to their strength and numbers, to become carnivorous like wasps, they would be able to destroy whole flocks of sheep, even to the dogs and shepherds; just as we are told of ants in America, that will overcome the fiercest serpents.

"The locust spends the months of April, May, and June, in the place of its birth: at the end of June its wings have a fine rose colour, and its body is strong. Being then in their prime, they assemble for the last time, and burn with a desire to propagate their species: this is observed by their motions, which are unequal in the two sexes. The male is restless and solicitous, the female is coy, and eager after food, flying the approaches of the male, so that the morning is spent in the courtship of the one and the retreat of the other. About ten o'clock, when the warmth of the sun has cleared their wings from the dampness of the night, the females seem uneasy at the forwardness of the males, who continuing their pursuit, they rise together 500 feet high, forming a black cloud that darkens the rays of the sun. The clear atmosphere of Spain becomes gloomy, and the finest summer day of Estremadura more dismal than the winter of Holland. The rustling of so many millions of wings in the air seems like the trees of a forest agitated by the wind. The first direction of this formidable column is always against the wind, which if not too strong, the column will extend about a couple of leagues. The locusts then make a halt, when the most dreadful havoc begins; their sense of smell being so delicate, they can find at that distance a corn field or a garden, and, after demolishing it, rise again in pursuit of another;

this may be said to be done in an instant. Each seems to have, as it were, four arms and two feet: the males climb up the plants, as sailors do the shrouds of a ship, and nip off the tender buds, which fall to the females below.

"Many old people assured me, when so much mischief was done in 1754, it was the third time in their remembrance, and that they always are found in the pasture grounds of Estremadura, from whence they spread into the other provinces of Spain. They are certainly indigenous, being of a different shape from those of the North or the Levant, as is evident in comparing them with such in the cabinets of natural history. The locust of Spain is the only one that has rose-coloured wings: besides, it is impossible they can come from any other part. From the north it is clear they do not, by the observation of so many ages; from the south they cannot, without crossing the sea, which is hardly possible by the shortness of their flight: and, like birds of passage, they would be known. I once saw a cloud of them pass over Malaga, and move towards the sea, and go over it, for about a quarter of a league, to the great joy of the inhabitants, who concluded they would soon be drowned; but, to their disappointment, they suddenly veered about towards the coast, and pitched upon an uncultivated space surrounded with vineyards, which they soon after quitted. When once they appear, let the number demolished be ever so great, the proportion remaining is still too considerable: therefore, the only way to put an end to such a calamity is to attack them beforehand, and destroy their eggs, by which means they might be totally extirpated."

GRYNÆUS (Simon), son to a peasant of Suabia, born in 1493, was Greek professor at Heidelberg in 1523. He took a tour into England, and received great civility from the lord chancellor Sir Thomas More, to whom Erasmus had recommended him. He was a learned and laborious man, and did great service to the commonwealth of letters. He was the first who published the *Almagest* of Ptolemy in Greek. He also published a Greek *Euclid*, and Plato's works, with some commentaries of Proclus.

GRYPHIUS (Sebastian), a celebrated printer of Lyons in France, was a German, and born at Suabia near Augsberg in 1494. He restored the art of printing at Lyons, which was before exceedingly corrupted; and the great number of books printed by him are valued by the connoisseurs. He printed many books in Hebrew, Greek, and Latin, with new and very beautiful types; and his editions are no less accurate than beautiful. The reason is, that he was a very learned man, and perfectly versed in the languages of such books as he undertook to print. He died in 1556 in his 63d year: and his trade was carried on honourably in the same city by his son, Anthony Gryphius. One of the most beautiful books of Sebastian Gryphius is a Latin Bible: it was printed 1550, with the largest types that had then been seen, in 2 vols. folio.

GRYPHITES, in natural history, in English *crow's stone*, an oblong fossil shell, very narrow at the head, and becoming gradually wider to the extremity, where it ends in a circular limb; the head or beak of this is very hooked or bent inward. They are frequently found in our gravel or clay-pits in many counties. There are three or four distinct species of them; some are extremely rounded and convex on the back, others less so; and the plates of which they are composed are in some smaller and thinner, in others thicker and larger, in specimens of the same bigness. See the article *Fossil*, and plate 32. Vol. III.

GUADALAJARA, or GUADALAXARA, a town of Spain, in New Castile, on the river Herares, 30 miles N. E. of Madrid. Lon. 2. 47. W. Lat. 40. 36. N.

GUADALAJARA, the capital of a rich and fertile province of

the same name in N. America, with a bishop's see, 217 miles W. of Mexico. Lon. 104. 49. W. Lat. 20. 50. N.

GUADALAVIAR, a river of Spain, which rises on the confines of Arragon, crosses the province of Valencia, and falls into the Mediterranean, a little below the town of Valencia.

GUADALOUPE, a handsome town of Spain, in Estremadura, with a celebrated convent. It is seated on a rivulet of the same name. Lon. 5. 3. E. Lat. 39. 12. N.

GUADALOUPE, one of the Leeward Islands in the W. Indies, lying between Antigua and Dominica, in lon. 62. 0. W. and lat. 16. 20. N. It is divided into two parts by a narrow strait, called the Salt River. At this place the land on each side is not above four miles broad, and by this strait the sea on the N. W. communicates with that on the S. E. The N. W. part is 60 miles in length, and 24 in breadth. The S. E. part, in extent, is much the same. The French began to settle this island in 1632. It was taken by the English in 1759, but restored in 1763. It is said to be the best of all the Caribbee Islands, the soil being exceedingly good, and well watered near the sea, by rivulets which fall from the mountains. On this island is a hill called the Mountain of Sulphur: on the E. side of it are two mouths, which open into a pit of sulphur: they frequently emit thick clouds of black smoke, with sparks of fire: the Negroes who sell brimstone fetch it from this pit.

GUADALQUIVER, one of the most famous rivers of Spain, which rises in Andalusia, and falls into the gulf of Cadiz.

GUADIANA, a river of Spain, which rises in New Castile, separates Algarve from Andalusia, and falls into the bay of Cadiz, between Castro Marino and Agramonte.

GUADIX, a town of Spain, in the kingdom of Granada, with a bishop's see. It was taken from the Moors in 1253, who afterwards retook it; but the Spaniards again got possession of it in 1489. It is seated in a fertile country, in W. lon. 2. 12. N. lat. 37. 5.

GUAIACUM, LIGNUM VITÆ, or *Pockwood*; a genus of the monogynia order, belonging to the decandria class of plants, and in the natural method ranking under the 14th order, *Grui-nalis*. The calyx is quinquefid and unequal; the petals five, and inserted into the calyx; the capsule is angulated, and trilocular or quinquelocular. The *Species* are, 1. The *officinale*, or common lignum vitæ used in medicine, is a native of the West India Islands and the warmer parts of America. There it becomes a large tree, having a hard, brittle, brownish bark, not very thick. The wood is firm, solid, ponderous, very resinous, of a blackish yellow colour in the middle, and of a hot aromatic taste. The smaller branches have an ash coloured bark, and are garnished with leaves divided by pairs of a bright green colour. The flowers are produced in clusters at the end of the branches, and are composed of oval concave petals of a fine blue colour. 2. The *sanctum*, with many pairs of obtuse lobes, hath many small lobes placed along the mid rib by pairs of a darker green colour than those of the foregoing sort. The flowers are produced in loose bunches towards the end of the branches, and are of a fine blue colour, with petals fringed on the edges. This species is also a native of the West India islands, where it is called *bastard lignum vitæ*. 3. The *Afrum*, with many blunt-pointed leaves, is a native of the Cape of Good Hope. The plants retain their leaves all the year, but have never yet flowered in this country.

The first species can only be propagated by seeds, which must be procured from the countries where it naturally grows. They must be sown fresh in pots, and plunged into a good hot-bed, where they will come up in six or eight weeks. While young, they may be kept in a hot-bed of tan-bark under a frame during the summer; but in autumn they must be removed into the

bark stove, where they should constantly remain. The second sort may be propagated the same way; but the third is to be propagated by layers, and will live all the winter in a good greenhouse.

The wood of the first species is of very considerable use both in medicine and in the mechanical arts. It is so compact and heavy as to sink in water. The outer part is often of a pale yellowish colour; but the heart is blacker, or of a deep brown. Sometimes it is marbled with different colours. It is so hard as to break the tools which are employed in felling it, and is therefore seldom used as firewood, but is of great use to the sugar-planters for making wheels and cogs to the sugar-mill. It is also frequently wrought into bowls, mortars, and other utensils. It is brought over hither in large pieces of four or five hundred weight each; and from its hardness and beauty is in great demand for various articles of turnery ware.

The wood, gum, bark, fruit, and even the flowers of this tree, have been found to possess medicinal virtues; but it is only the three first, and more particularly the wood and resin, which are now in general use in Europe. The wood has little or no smell, except when heated, or while rasping, and then a slight aromatic one is perceived. When chewed, it impresses a mild acrimony, biting the palate and fauces. Its pungency resides in its resinous matter, which it gives out in some degree to water by boiling, but spirit extracts it wholly.

The resin is obtained by wounding the bark in different parts of the body of the tree, or by what has been called *jagging*. It exudes copiously from these wounds, though gradually; and when a quantity is found accumulated upon the several wounded trees, hardened by exposure to the sun, it is gathered and packed in small kegs for exportation. This resin is of a friable texture, of a deep greenish colour, and sometimes of a reddish hue; it has a pungent acrid taste, but little or no smell unless heated. The tree also yields a spontaneous exudation from the bark, which is called the *native gum*, and is brought to us in small irregular pieces, of a bright semipellucid appearance, and differs from the former in being much purer.

Guaiacum was first introduced into Europe as a remedy for the venereal disease, and appears to have been used in Spain so early as 1508. The great success attending its administration before the proper use of mercury was known, brought it into such repute, that it is said to have been sold for seven old crowns a-pound. It did not, however, continue to maintain its reputation; but was found generally to fail where the disease was inveterate, and was at length superseded by mercury, to which it now only serves occasionally as an adjuvant. The general virtues of guaiacum are those of a warm stimulating medicine; strengthening the stomach and other viscera, and remarkably promoting the urinary and cuticular discharges: hence, in cutaneous eruptions, it is deemed eminently useful; as well as in the rheumatism when given in a sufficient dose. The resin is the most active, and the efficacy of the wood, &c. depends upon the quantity of this contained in them. The resin is given from a few grains to a scruple or half a dram, which last dose proves for the most part considerably purgative. Dissolved in spirit of wine, and afterwards combined with water, by means of mucilage or the yolk of egg, or in form of the simple or volatile tincture, it is much employed in gout and chronic rheumatism. These last have been given to the extent of half an ounce twice a day, and are sometimes usefully combined with tincture of opium.

GUALDO, a town of Italy, in the marquisate of Ancona, eight miles N. W. of Nocera. In 1751 it was almost destroyed by an earthquake. Lon. 12. 43. E. Lat. 43. 6. N.

GUALEOR, **GUALIOR**, or *Gowalior*, a large town of Hindostan in Asia, and capital of a province of the same name, with an ancient and celebrated fortress of great strength. It is

situated in the very heart of Hindostan Proper, being about 80 miles to the south of Agra, the ancient capital of the empire, and 130 from the nearest part of the Ganges. From Calcutta it is, by the nearest route, upwards of 800 miles, and 910 by the ordinary one; and about 280 from the British frontiers. Its latitude is 26. 14. and longitude 78. 26. from Greenwich. The fortress of Gualior stands on a vast rock of about four miles in length, but narrow, and of unequal breadth, and nearly flat at the top. The sides are so steep as to appear almost perpendicular in every part; for where it was not naturally so, it has been scraped away; and the height from the plain below is from 200 to 300 feet. The rampart conforms to the edge of the precipice all round; and the only entrance to it is by steps running up the side of the rock, defended on the side next the country by a wall and bastions, and farther guarded by seven stone gateways, at certain distances from each other. The area within is full of noble buildings, reservoirs of water, wells, and cultivated land; so that it is really a little district in itself. At the north-west foot of the mountain is the town, pretty large, and well built; the houses all of stone.

GUAM, the chief of the Ladrone Islands, in the N. Pacific Ocean, 100 miles in circumference. It is subject to the Spaniards, who have a garrison here; but the inhabitants are almost all natives of the country, and reputed to be very skilful in building boats. It abounds with excellent fruit, and the air is wholesome; notwithstanding which the natives are subject to a kind of leprosy. Lon. 15. 15. E. Lat. 13. 5. N.

GUAMANGA, a town of S. America, capital of a province of the same name in Peru, with a bishop's see. It is remarkable for its sweetmeats, manufactures, and mines of gold, silver, loadstones, and particularly quicksilver. It is 200 miles E. of Lima. Lon. 73. 25. W. Lat. 12. 40. S.

GUANAHAMI, or **CAT ISLAND**, one of the Bahama Islands, the first discovered by Christopher Columbus, in 1492, and named by him St. Salvador. Lon. 75. 5. W. Lat. from 24. 10. to 24. 40. N.

GUANUGO, a rich town of S. America, capital of a district of the same name, that abounds in all the necessaries of life. It is 112 miles N. E. of Lima. Lon. 74. 55. W. Lat. 9. 55. S.

GUANAZAVELCA, a rich town of S. America, in Peru, in a country abounding in mines of quicksilver. It is 159 miles from Pisco. Lon. 74. 39. W. Lat. 12. 36. S.

GUARANTEE, or **WARRANTEE**, in law, a term relative to warrant or warranter, properly signifying him whom the warranter undertakes to indemnify or secure from damage. *Guarantee*, however, is more frequently used for a warranter, or a person who undertakes and obliges himself to see a second person perform what he has stipulated to the third. See **WARRANTY**.

GUARD, in the military art, is a duty performed by a body of men, to secure an army or place from being surprised by an enemy. In garrison the guards are relieved every day: hence it comes that every soldier mounts guard once every three or four days in time of peace, and much oftener in time of war. See **HONOURS**.

Advanced Guard, called also *Van Guard*, is a party of either horse or foot that marches before a more considerable body, to give notice of any approaching danger. These guards are either made stronger or weaker, according to situation, the danger to be apprehended from the enemy, or the nature of the country.

Artillery Guard, is a detachment from the army to secure the artillery when in the field. Their *corps de garde* is in the front of the artillery park, and their sentries dispersed round the same. This is generally a 48-hours guard; and upon a march, this guard marches in the front and rear of the artillery,

and must be sure to leave nothing behind: if a gun or waggon breaks down, the officer that commands the guard is to leave a sufficient number of men to assist the gunners in getting it up again. *Artillery Quarter-GUARD*, is frequently a non-commissioned officer's guard from the royal regiment of artillery, whose *corps de garde* is always in the front of their incampment. *Artillery Rear GUARD*, consists of a corporal and six men, posted in the rear of the park.

Corps de GARDE, are soldiers entrusted with the guard of a post under the command of one or more officers. This word also signifies the place where the guard mounts.

Grand GUARD, three or four squadrons of horse, commanded by a field officer, posted at about a mile or a mile and a half from the camp, on the right and left wings, towards the enemy, for the better security of the camp.

Forage GUARD, a detachment sent out to secure the foragers, and who are posted at all places, where either the enemy's party may come to disturb the foragers, or where they may be spread too near the enemy, so as to be in danger of being taken. This guard consists both of horse and foot, and must remain on their posts till the foragers are all come off the ground.

Main GUARD, is that from which all other guards are detached. Those who are for mounting guard assemble at their respective captain's quarters, and march from thence to the parade in good order; where, after the whole guard is drawn up, the small guards are detached to their respective posts: then the subalterns draw lots for their guards, who are all under the command of the captain of the main guard. This guard mounts in garrison at different hours, according as the governor pleases.

Piquet GUARD, a good number of horse and foot, always in readiness in case of an alarm: the horses are generally saddled all the time, and the riders booted. The foot draw up at the head of the battalion, frequently at the beating of the tat-too; but afterwards return to their tents, where they hold themselves in readiness to march upon any sudden alarm. This guard is to make resistance in case of an attack, until the army can get ready.

Baggage GUARD, is usually an officer's guard, who has the care of the baggage on a march. The waggons should be numbered by companies, and follow one another regularly: vigilance and attention in the passage of hollow ways, woods, and thickets, must be strictly observed by this guard.

Quarter GUARD, is a small guard commanded by a subaltern officer, posted in the front of each battalion, at 222 feet before the front of the regiment.

Rear GUARD, that part of the army which brings up the rear on a march, generally composed of all the old grand guards of the camp. The rear-guard of a party is frequently eight or ten horse, about 500 paces behind the party. Hence the advance-guard going out upon a party, form the rear guard in their retreat. *Rear Guard*, is also a corporal's guard placed in the rear of a regiment, to keep good order in that part of the camp.

Standard GUARD, a small guard under a corporal, out of each regiment of horse, who mount on foot in the front of each regiment, at the distance of 20 feet from the streets, opposite the main street of an encampment.

Trench GUARD, only mounts in the time of a siege, and sometimes consists of three, four, or six battalions, according to the importance of the siege. This guard must oppose the besieged when they sally out, protect the workmen, &c.

Provost GUARD, is always an officer's guard that attends the provost in his rounds, either to prevent desertion, marauding, noting, &c. See *PROVOST*.

GUARD, in fencing, implies a posture proper to defend the body from the sword of an antagonist.

GUARDS, also imply the troops kept to guard the king's person, and consist both of horse and foot,

Horse GUARDS, in England, were gentlemen chosen for their bravery, to be entrusted with the guard of the king's person; and were divided into four troops, called *the 1st, 2d, 3d, and 4th troops of horse guards*. The first troop was raised in the year 1660, and the command given to lord Gerard; the second in 1661, and the command given to Sir Philip Howard; the third in 1693, and the command given to earl Feversham; the fourth in 1792, and the command given to earl Newburgh. Each troop had one colonel, two lieutenant-colonels, one cornet and major, one guidon and major, four exempts and captains, four brigadiers and lieutenants, one adjutant, four sub-brigadiers and cornets, and 60 private men. But the four troops are now turned into two regiments of life-guards.

Horse-Grenadier GUARDS, are divided into two troops, called *the 1st and 2d troops of horse-grenadier guards*. The first troop was raised in 1693, and the command given to lieutenant-general Cholmondeley; the second in 1702, and the command given to lord Forbes. Each troop has one colonel, lieutenant-colonel, one guidon or major, three exempts and captains, three lieutenants, one adjutant, three cornets, and 60 private men.

Yeomen of the GUARD, first raised by Henry VII. in the year 1485. They are a kind of pompous foot-guards to the king's person, and are generally called by a nickname the *Beef Eaters*. They were anciently 250 men of the first rank under gentry, and of larger stature than ordinary, each being required to be six feet high. At present there are but 100 in constant duty, and 70 more not on duty; and when any one of the 100 dies, his place is supplied out of the 70. They go dressed after the manner of king Henry VIII's time. Their first commander or captain was the earl of Oxford, and their pay is 2s. 6d. per day.

Foot-GUARDS, are regiments of foot appointed for the guard of his majesty and his palace. There are three regiments of them, called *the 1st, 2d, and 3d regiments of foot-guards*. They were raised in the year 1660; and the command of the first given to colonel Ruffel, that of the second to general Monk, and the third to the earl of Linlithgow. The first regiment is at present commanded by one colonel, one lieutenant-colonel, three majors, 23 captains, one captain-lieutenant, 31 lieutenants, and 24 ensigns; and contains three battalions. The second regiment has one colonel, one lieutenant-colonel, two majors, 14 captains, one captain lieutenant, 18 lieutenants, 16 ensigns; and contains only two battalions. The third regiment is the same as the second.

GUARD Boat, a boat appointed to row the rounds amongst the ships of war which are laid up in any harbour, &c. to observe that their officers keep a good look-out, calling to the guard-boat as she passes, and not suffering her crew to come on board, without having previously communicated the watch-word of the night.

GUARD-Ship, a vessel of war appointed to superintend the marine affairs in a harbour or river, and to see that the ships which are not commissioned have their proper watch-word kept duly, by sending her guard-boats around them every night. She is also to receive seamen who are impressed in the time of war.

GUARDIAN, in law, a person who has the charge of any thing; but more commonly it signifies one who has the custody and education of such persons as have not sufficient discretion to take care of themselves and their own affairs, as children and idiots. Their business is to take the profits of the minor's lands to his use, and to account for the same: they ought to sell all moveables within a reasonable time, and to convert them into land or money, except the minor is near of age, and may want such things himself; and they are to pay interest for the money in their hands, that might have been so placed out; in which case it will be presumed that the guardians made use of it

themselves. They are to sustain the lands of the heir, without making destruction of any thing thereon, and to keep it safely for him: if they commit waste on the lands, it is a forfeiture of the guardianship, 3 Edw. 1. And where persons, as guardians, hold over any land, without the consent of the person who is next intitled, they shall be adjudged trespassers, and shall be accountable. 6 Ann. cap. xviii.

GUARDIAN or *Warden of the Cinque ports*, is an officer who has the jurisdiction of the cinque-ports, with all the power that the admiral of England has in other places. Camden relates, that the Romans, after they had settled themselves and their empire in our island, appointed a magistrate, or governor, over the east parts, where the Cinque ports lie, with the title of *comes littoris Saxonici per Britanniam*; having another who bore the like title on the opposite side of the sea. Their business was to strengthen the sea coast with munition, against the outrages and robberies of the barbarians; and that antiquary takes our warden of the Cinque-ports to have been erected in imitation thereof. The wardenship is a place of value, supposed worth 7000*l. per annum*.

GUARDIAN of the *Spiritualities*, the person to whom the spiritual jurisdiction of any diocese is committed, during the time the see is vacant. A guardian of the spiritualities may likewise be either such in law, as the archbishop is of any diocese within his province; or by delegation, as he whom the archbishop or vicar-general for the time appoints. Any such guardian has power to hold courts, grant licences, dispensations, probates of wills, &c.

GUAREA, in botany; a genus of the monogynia order, belonging to the octandria class of plants. The calyx is quadrid; the petals four: the nectarium cylindric, having the anther in its mouth; the capsule is quadrilocular and quadrivalvular; the seeds solitary.

GUARINI (Battista), a celebrated Italian poet, born at Ferrara in 1538. He was great-grandson to Guarino of Verona, and was secretary to Alphonso Duke of Ferrara, who intrusted him with several important commissions. After the death of that prince, he was successively secretary to Vincenzo de Gonzaga, to Ferdinand de Medicis grand duke of Tuscany, and to Francis Maria de Feltri duke of Urbino. But the only advantages he reaped under these various masters were great encomiums on his wit and compositions. He was well acquainted with polite literature, and acquired immortal reputation by his Italian poems, especially by his *Pastor Fido*, the most known and admired of all his works, and of which there have been innumerable editions and translations. He died in 1612.

GUARDAFUI, a cape of Africa, at the eastern extremity of Adel, and the entrance of the strait of Babelmandel. Lon. 52. 5. E. Lat. 11. 46. N.

GUARDIA, or **GUARDA**, a town of Portugal, in the province of Beira, with a bishop's see. It contains about 2300 inhabitants, is fortified both by art and nature, and has a stately cathedral. W. long. 5. 17. N. lat. 40. 20.

GUARDIA-Alferez, a town of Italy, in the kingdom of Naples, and in the Contado-di-Molise, with a bishop's see. E. long. 15. 53. N. lat. 51. 50.

GUARGALA, or **GUERGUELA**, a town of Africa, and capital of a small kingdom of the same name, in Biledulgerid, to the south of Mount Atlas. E. long. 9. 55. N. lat. 28. 0.

GUARIBA, in natural history, the name of a species of monkey found in the West Indies. See **SIMIA**.

GUASTALLA, a strong town of Italy, in the duchy of Mantua, ceded to the duke of Parma in 1748. Here the imperial general Konigseg attacked the French army in 1734, but was repulsed with the loss of 5000 men. It is seated near the river Po, 15 miles N. of Reggio. Lon. 10. 38. E. Lat. 44. 56. N.

GUATIMALA, *the Audience of*, in North America, and in New Spain, is above 750 miles in length, and 450 in breadth. It abounds in chocolate, which they make use of instead of money. It has 12 provinces under it: and the native Americans, under the dominions of Spain, profess Christianity; but it is mixed with a great many of their own superstitions. There is a great chain of high mountains, which run across it from E. to W. and it is subject to earthquakes and storms. It is, however, very fertile; and produces, besides chocolate, great quantities of cochineal and cotton.

GUATIMALA, a province of North America, in New Spain, and in the Audience of the same name; bounded on the W. by Soconusco, on the N. by Verapaz and Honduras, on the E. by Nicaragua, and on the S. by the south sea. St. Jago de Guatimala is the capital of the whole Audience.

GUATIMALA, a large and rich town of North America, in New Spain; and capital of a government of the same name, with a bishop's see, and an university. It carries on a great trade, especially in chocolate. W. long. 91. 30. N. lat. 14. 0.

GUATIMALA (the Volcano of), is a mountain, which throws out fire and smoke. St. Jago de Guatimala was almost ruined by it in 1541. It was afterwards rebuilt at a good distance from this dreadful mountain. A few years ago, however, it was again destroyed, with circumstances more terrible perhaps than any mentioned in history.

GUAVA, in botany. See **PSIDIUM**.

GUAXACA, a province of North America, in New Spain, which is very fertile in wheat, Indian corn, cochineal, and castia. It is bounded by the gulph of Mexico on the north, and by the South-Sea on the south. It contains mines of gold, silver, and crystal. Guaxaca is the capital town.

GUAXACA, a town of North America, in the Audience of Mexico, and capital of a province of the same name, with a bishop's see. It is without walls, and does not contain above 2000 inhabitants; but it is rich, and they make very fine sweetmeats and chocolate. It has several rich convents, both for men and women. W. long. 100. N. lat. 17. 45.

GUAYRA, a district of the province of La Plata, in South America, having Brasil on the east, and Paraguay on the west.

GUBEN, a handsome town of Germany, in Lower Lusatia, seated on the river Neisse, and belonging to the house of Sax-Merfenburg. E. long. 14. 59. N. lat. 51. 55.

GUBER, a kingdom of Africa, in Negroland. It is surrounded with high mountains; and the villages, which are many, are inhabited by people who are employed in taking care of their cattle and sheep. There are also abundance of artificers and linen-weavers, who send their commodities to Tombuto. The whole country is overflowed every year by the inundations of the Niger, and at that time the inhabitants sow their rice. There is one town which contains almost 6000 families, among whom are many merchants.

GUBIO, a town of Italy, in the territory of the church, and in the duchy of Urbino, with a bishop's see. E. long. 12. 41. N. lat. 43. 18.

GUDGEON, in ichthyology; a species of cyprinus. See **BABEL**. This fish, though small, is of so pleasant a taste, that it is very little inferior to a smelt. They spawn twice in the summer-season; and their feeding is much like the barbels in streams and on gravel, slighting all manner of flies: but they are easily taken with a small red worm, fishing near the ground; and being a leather-mouthed fish, will not easily get off the hook when struck. The gudgeon may be fished for with float, the hook being on the ground; or by hand, with a running line on the ground, without cork or float. But although the small red worm above mentioned is the best bait for this fish, yet wasps, gentles, and carl-baits will do very well. Some fish for gudgeons with two or three hooks at once, and find very plea-

fant sport, where they rise any thing large. In angling for them, it is necessary to stir up the sand or gravel with a long rake; this will make them gather to that place, and bite with more eagerness.

Sea-GUDGEON, Rock-fish, or Black Goby. See **G O B I U S**.

GUDGEON, in mechanics, a kind of catch used in various machines to assist their operations. In vol. XI. of the *Trans.* of the Society for the Encouragement of Arts, &c. we have the following account of a *gudgeon* on an improved construction, for the upright shafts of mills. "This gudgeon is formed of hard steel, and works on a hard steel bed; is circular, three inches diameter, and three-fourths of an inch thick: from its upper side a rib projects, which, being fixed in the bottom of an upright shaft, the gudgeon works horizontally on a square bed: and that now in the possession of the Society has worked in a mill whose wheel and shaft weighed nearly six tons; and, though it had continued in work seven years, had lost very little of its surface. It ran in a square box of cast iron, having oil therein: and a notch along the whole of the face of the gudgeon admits the oil to insinuate itself between the gudgeon and the bed."

GUEBRES, or GABRES. See **G A B R E S**.

GUELPHS, or GUELFs, a celebrated faction in Italy, antagonists of the Gibelins. See **G I B E L I N S**. The Guelphs and Gibelins filled Italy with blood and carnage for many years. The Guelphs stood for the Pope against the emperor. Their rise is referred by some to the time of Conrad III. in the twelfth century; by others, to that of Frederic I.; and by others, to that of his successor Frederic II. in the thirteenth century. The name of *Guelph* is commonly said to have been formed from *Welfe*, or *Welfo*, on the following occasion: The emperor Conrad III. having taken the duchy of Bavaria from Welfe VI. brother of Henry duke of Bavaria, Welfe, assisted by the forces of Roger king of Sicily, made war on Conrad, and thus gave birth to the faction of the Guelfs. Others derive the name *Guelfs* from the German *Wolff*, on account of the grievous evils committed by that cruel faction: others deduce the denomination from that of a German called *Guelfe*, who lived at Pistoye; adding, that his brother, named *Gibel*, gave his name to the Gibelins.

GUELDERLAND, or GUELDRES, a territory of the Netherlands. That part which is a district of the town of Gueldres belongs to the king of Prussia; Ruremond and its dependencies to the house of Austria; and Venlo and Stevenswaert to the States General.

GUELDRES, a strong town of the Netherlands, in the duchy of the same name, ceded to the king of Prussia by the peace of Utrecht. It is 10 miles N. E. of Venlo. Lon. 6. 0. E. Lat. 51. 26. N.

GUERAND, a town of France, in the department of Lower Loire and late province of Brittany. It carries on a considerable trade in white salt, and is three miles from the sea, and 250 W. S. W. of Paris. Lon. 2. 20. W. Lat. 47. 20. N.

GUERCINO. See **B A R B I E R I**.

GUERET, a town of France, in the department of Creuse and late province of Marche, seated on the river Gartampe; 35 miles N. E. of Limoges, and 170 S. of Paris. Lon. 1. 56. E. Lat. 46. 10. N.

GUELDICKE, or GUERICHL, (Otho), the most celebrated mathematician of his time, was born in 1602. He was the inventor of the air-pump; and author of several works in natural philosophy, the chief of which is *Experimenta Magdeburgica*. He died in 1686.

GUERNSEY, an island on the coast of Normandy, subject to Great Britain. It is naturally strong, being surrounded by high rocks, and is well situated for trade in time of peace, and in time of war to annoy the French with our privateers. It

is 10 miles in length, as much in breadth, and contains 10 parishes. The natives speak French, it having been a part of Normandy, and is still governed by the Norman laws. Lon. 2. 37. W. Lat. 49. 32. N.

GUETTARDA, in botany; a genus of the heptandria order, belonging to the monœcia class of plants, and in the natural method ranking under the 38th order, *Tritœae*. The male calyx is cylindrical; the corolla cleft into seven parts, and funnel-shaped. The female calyx cylindrical; the corolla cleft into seven parts; one pistil, and the fruit a dry plum.

GUIANA, a country of S. America, between the rivers Oronoko and Amazon, and to the E. of Peru. The interior parts of the country are inhabited by savages, who have different languages and customs; and some of them build their houses on trees, to be secure from the inundations of the rivers. The French possess a part of the coast, which is called Equinoctial France, and the Dutch another. Here is a perpetual spring, and it produces large quantities of sugar-canes. It is between the equator and eight degrees of N. lat. See **C A Y E N N E** and **S U R I N A M**.

GUIAQUIL, a town, bay, and harbour of S. America, in Peru, capital of an audience of the same name. It faces a low island close by the river, partly on the side, and partly at the foot of a hill, which descends gently toward the river. It is divided by the stream into two parts, called the Old and the New, joined by a bridge for foot passengers, half a mile long. The situation is in such a boggy ground, and so dirty in winter, that, without the bridge, there would be scarce any passing from one house to another. It has but one regular street, along the river side. Before the church of St. Jago is a handsome parade, but the church itself is gone to decay. There are three other churches, well-adorned with altars and pictures. It is 140 miles N. E. of Païta. Lon. 81. 6. W. Lat. 2. 11. N.

GUIARA, a sea-port town of South America, and on the Caracca coast. The English attempted to take it in 1739 and 1743; but they were repulsed both times. W. long. 66. 5. N. lat. 10. 35.

GUICCIARDINI (Francisco), a celebrated historian, born at Florence in 1482. He professed the civil law with reputation, and was employed in several embassies. Leo X. gave him the government of Modena and Reggio, and Clement VII. that of Romagna and Bologna. Guicciardini was also lieutenant-general of the pope's army, and distinguished himself by his bravery on several occasions; but Paul III. having taken from him the government of Bologna, he retired to Florence, where he was made counsellor of state, and was of great service to the house of Medicis. He at length retired into the country to write his history of Italy, which he composed in Italian, and which comprehends what passed from the year 1494 to 1532. This history is greatly esteemed, and was continued by John Baptist Adriani, his friend. He died in 1540.

GUICCIARDINI (Lewis), nephew of the foregoing, composed a history of the Low Countries, and memoirs of the affairs of Europe, from 1530 to 1560. He wrote with great spirit against the persecution of the duke d'Alva, for which the latter imprisoned him. He died in 1583.

GUIDI (Alexander), an eminent Italian poet, born at Pavia in 1650. Having a desire to see Rome, he there attracted the notice of queen Christina of Sweden, who retained him at her court; he also obtained a considerable benefice from pope Innocent XI. and a pension from the duke of Parma. For a good office he did the state of Milan with prince Eugene, he was enrolled among the nobles and decurions of that town; and died in 1712. Nature had been kinder to his intellects than to his exterior form: his body was small and crooked, his head was large, and he was blind of his right eye. A collection of his works was published at Verona in 1726.

GUIDO (Reni), an illustrious Italian painter, born at Bologna in 1595. In his early age he was the disciple of Denis Calvert, a Flemish master of good reputation; but afterwards entered himself in the school of the Caracci. He first imitated Ludovico Caracci; but fixed at last in a peculiar style of his own, that secured him the applause of his own time and the admiration of posterity. He was much honoured, and lived in splendor: but an unhappy attachment to gaming ruined his circumstances; the reflection of which brought on a languishing disorder, that put an end to his life in 1642. There are several designs of this great master in print, etched by himself.

GUIDON, a sort of flag or standard borne by the king's life-guard; being broad at one extreme, and almost pointed at the other, and slit or divided into two. The guidon is the ensign or flag of a troop of horse-guards. See **GUARD**. The term *Guidon* also denotes the officer who bears the guidon. The guidon is in the horse-guards what the ensign is in the foot. The guidon of a troop of horse takes place next below the cornet.

GUIDONS, *guidones*, or *schola guidonum*, was a company of priests established by Charlemagne, at Rome, to conduct and guide pilgrims to Jerusalem, to visit the holy places: they were also to assist them in case they fell sick, and to perform the last offices to them in case they died.

GUIENNE, a late province of France, which now forms the department of Gironde and that of Lot and Garonne.

GUILANDINA, the **NICKAR TREE**; a genus of the monogynia order, belonging to the decandria class of plants, and in the natural method ranking under the 33d order, *Lomentaceæ*. The calyx is nophyllous and salver-shaped; the petals, inserted into the neck of the calyx, nearly equal. The seed-vesSEL a legumen. The *Species* are, 1. The *bonduc*, or yellow nickar. 2. The *bonducell*, or gray nickar. These are climbing plants, natives of the West Indies, where they rise to the height of twelve or fourteen feet: the flowers come out at the wings of the stalks, and are composed of five concave yellow petals. They are succeeded by pods about three inches long and two broad, closely armed with slender spines, opening with two valves, each inclosing two hard seeds about the size of children's marbles, of a yellowish colour. 3. The *moringa*, or morunga nickar, is a native of the island of Ceylon, and some places on the Malabar coast. It rises to the height of 25 or 30 feet, having flowers produced in loose bunches from the sides of the branches, and composed of an unequal number of petals.

These plants being natives of warm climates require to be kept through the winter in a stove in this country. They are propagated by seeds; but those of the first sort are so hard, that unless they are soaked two or three days in water before they are put into the ground, or placed under the pots in the tan-bed to soften their covers, they will remain for years without vegetating.—The roots of the third sort are scraped when young, and used by the inhabitants of Ceylon and Malabar as those of horse-radish are in Europe. The wood dyes a beautiful blue colour. It is the *lignum nephrificum* of the dispensatories, and is brought over in large, compact, ponderous pieces, without knots, of a whitish or pale yellow colour on the outside, and dark coloured or reddish within: the bark is usually rejected. This wood imparts to water or rectified spirit a deep tincture; appearing, when placed between the eye and the light, of a golden colour; in other situations blue: pieces of another wood are sometimes mixed with it, which give only a yellow colour to water. The nephritic wood has scarce any smell, and very little taste. It stands recommended in difficulty of urine, and all nephritic complaints, and is said to have this peculiar advantage, that it does not, like the warmer diuretics, heat or irritate the urinary passages. Practitioners, however, have not found these praises warranted by experience.

GUILD (from the Saxon *gildan* "to pay"), signifies a fraternity or company, because every one was *gildare*, i. e. to pay something towards the charge and support of the company. As to the original of these guilds or companies: It was a law among the Saxons, that every freeman of fourteen years of age should find sureties to keep the peace, or be committed: upon which certain neighbours, consisting of ten families, entered into an association, and became bound for each other, either to produce him who committed an offence, or to make satisfaction to the injured party: that they might the better do this, they raised a sum of money among themselves, which they put into a common stock; and when one of their pledges had committed an offence, and was fled, then the other nine made satisfaction out of this stock, by payment of money, according to the offence. Because this association consisted of ten families, it was called a *decennary*: and from hence proceeded later kinds of fraternities. But as to the precise time when these guilds had their origin in England, there is nothing of certainty to be found; since they were in use long before any formal licence was granted to them for such meetings. It seems to have been about the close of the eleventh century, says Anderson, in his History of Commerce, vol. i. p. 70, that merchant-guilds, or fraternities, which were afterwards styled corporations, came first into general use in many parts of Europe. Mr. Madox, in his *Firma Burgi*, chap. i. § 9. thinks they were hardly known to our Saxon progenitors, and that they might be probably brought into England by the Normans; although they do not seem to have been very numerous in those days. The French and Normans might probably borrow them from the free cities of Italy, where trade and manufactures were much earlier propagated, and where possibly such communities were first in use. These guilds are now companies joined together, with laws and orders made by themselves, by the licence of the prince.

GUILD, in the royal boroughs of Scotland, is still used for a company of merchants, who are freemen of the borough. See **BOROUGH**. Every royal borough has a dean of *guild*, who is the next magistrate below the bailiff. He judges of controversies among men concerning trade; disputes between inhabitants touching buildings, lights, water courses, and other nuisances; calls courts, at which his brethren of the *guild* are bound to attend; manages the common stock of the *guild*; and amerces and collects fines.

GUILD, *Gild*, or *Geld*, is also used among our ancient writers, for a compensation or mulct for a fault committed.

GUILD-HALL, the great hall of judicature for the city of London. In it are kept the mayor's court, the sheriff's court, the court of hustings, court of conscience, court of common council, chamberlain's court, &c. Here also the judges sit upon *miscellaneous*, &c.

GUILFORD, a large borough in Surry, with a market on Saturday. It is seated on the river Wey, and on the declivity of a hill. It had a large castle, of which some of the walls are still standing. The summer assizes for the county are alternately held here and at Croydon. The Wey is navigable to the Thames, and much corn and timber are carried upon it. It is 17 miles S. W. of Kingston, and 30 S. W. of London. Lon. 0. 30. W. Lat. 51. 16. N.

GUILLEMOT, in ornithology. See **COLYMBUS**.

GUILIM (John), of Welch extraction, was born in Herefordshire, about the year 1565. Having completed his education at Brazen-nose college, Oxford, he became a member of the college of arms in London, and was made rouge croix pur-suivant, in which post he died in 1621. He published in 1610 a celebrated work intitled *The Display of Heraldry*, folio, which has gone through many editions. To the fifth, which came out in 1679, was added *A treatise of honour civil and military*, by captain John Loggan.

GUILLOTINE, an instrument calculated for the expeditious decapitation of criminals, and much used during the revolutionary murders committed lately in France. This machine consists of two upright posts, ten feet high, joined at the top by an horizontal piece of timber. At four feet from the bottom is a cross-bar on which the neck of the criminal is laid, and over that, there falls a similar bar, shaped to receive the neck like the front board of our pillory. On the inner faces of the frame are grooves, along which the extreme edges of an axe slide up and down. The axe is in shape somewhat like the italic capital letter *K*, the oblique stroke representing the sharp edge, which in falling, with a heavy mass of lead affixed to its upper part, severs the culprit's head from his body by a sliding cut. The upright side of the axe is wholly included in the groove which guides it, by means of a cord and pulley, up to a catch or pin, to which a separate cord is connected. The criminal is prepared for his fate by the executioner, who, having first cut off his hair, ties him in a standing posture to a board, which he afterwards inclines, so as to lay the body horizontally with the face downwards, and with the head advanced over a basket placed for its reception. The string being pulled by the executioner, the axe descends, and the head is severed in an instant. Louis XVI, his queen and aunt, and multitudes of persons of both sexes, and of all ranks, who were attached to the Royal cause in France, suffered death in this way. See Plate 2.

A similar machine once existed in England, but was confined in its use to the province of Hardwick, or the places within its precinct. The execution was generally at Halifax. This machine is now destroyed; but one of the same kind is in a room under the parliament-house at Edinburgh, where the use of it was introduced by the Earl of Morton, who took a model of it as he passed through Halifax, and had the misfortune at length to suffer by it himself. In England and Scotland it is called a *Maiden*. Its name, *La Guillotine*, is taken from the name of the person who brought it into use in Paris, as at Lille it is called *Louison*, for the same reason.

There are several engravings of this instrument to be seen; one in wood in 1520; another to a German translation of the works of Petrarch in 1520, and some others: in all which, the axe is straight or semicircular, but always horizontal.—The sloping position of the French axe appears the best for celerity of execution.

The *Guillotine*, it farther appears, was an instrument used by the Romans under the name of *Tympanum*. Enphorion, of Chalcis, quoted by Athenæus, p. 154, tells us, that to be tympanized was to have your head cut off by an axe. According to Photius, the tympanum was a machine of wood, with which the criminal was struck and decollated.

GUINEA, a country of Africa, of which little is known except the coast, thence called the coast of Guinea. It is divided into the Lower and Upper. This last comprehends the Malaguetta Coast, the Tooth Coast, the Gold Coast, Whidah, Great Adra, and Benin. The lower part is commonly called Congo. It is very unhealthy for Europeans, though the negroes live a considerable time. The water is so bad, that it often occasions worms, of a white silver colour, to breed between the skin and the flesh. The inhabitants in general go almost naked, and there seems to be little religion or honesty among them. The commodities purchased there are gum-sebeca, at Senegal; grain, upon the Grain Coast; elephant's teeth, upon the Tooth Coast; the greatest plenty of gold upon the Gold Coast; and all, in general, furnish slaves, more or less: indeed, some of all these commodities are to be had in all parts of it. The English, Dutch, French, Danes, and other nations, have factories upon this coast, and purchase slaves and other commodities. There are abundance of little states, whose chiefs the sailors have dignified with the name of kings; but there are very few who de-

serve that title. When they are at war with each other, as they often are, the people taken, on both sides, are sold for slaves; and it is not uncommon for the nearest of kin to sell each other. These unnatural and horrid practices will probably continue, so long as guilty Europeans persevere in their odious traffic in human flesh.

New GUINEA, an island of the S. Pacific Ocean, to the N. of New Holland, from which it is separated by Endeavour Strait. The length of this strait, from N. E. to S. W. is 10 leagues, and its breadth about five, except at the N. E. entrance, where it is contracted to somewhat less than two miles by the islands called Prince of Wales' Islands. Except this strait and the land of Cape Deliverance, the whole coast and the circumjacent islands seem to have been minutely examined both by the Dutch and Spaniards. Some traces of a passage between New Holland and New Guinea are also to be found in the accounts of former voyages; but Captain Cook in 1770 had the merit of establishing the fact beyond dispute. New Guinea was thus found to be a long narrow island, extending S. E. from the equator to 12° S. lat. and from 131° to 153° E. long. The land in general is low, but covered with such luxuriance of wood and herbage as can scarcely be conceived. The cocoa-nut, the bread-fruit, and the plantain-tree, beside most of the trees, shrubs, and plants, that are common to all the South Sea islands, are found here in the greatest perfection. The inhabitants make much the same appearance as the New Hollanders.

GUINEA, a gold coin, struck and current in Britain. The value or rate of guineas has varied: it was first struck on the footing of 20s. but by the scarcity of gold it was afterwards advanced to 21s. 6d. It afterwards sunk to 21s. The pound weight troy of gold is cut into 44 parts and a half; each part makes a guinea.—This coin took its denomination *guinea*, because the gold whereof the first was struck was brought from that part of Africa called *Guinea*; for which reason it likewise bore the impression of an elephant.

GUINEA Company. See *African COMPANY*.

GUINEA-Hen, in ornithology. See *NUMIDA*.

GUINEA Pig, in zoology. See *MUS*.

GUINEA-Whet. See *ZEA*.

GUINCAMP, a town of France, in the department of the North Coast and late province of Bretagne, 258 miles W. of Paris. Lon. 2. 56. W. Lat. 48. 36. N.

GUIPUSCOA, a province in the N. of Spain, bounded on the E. by Basques; on the N. by the ocean; on the W. by Biscay; and on the S. by Navarre. Tolosa is the capital.

GUISE, a small town of France, in the department of Aisne, with a strong castle, seated on the river Oise, 15 miles N. E. of St. Quentin, and 95 N. E. of Paris. Lon. 3. 42. E. Lat. 49. 54. N.

GUISE (Henry) of Lorrain, duke of Guise (eldest son of Francois of Lorrain duke of Guise), memorable in the history of France as a gallant officer, but an imperious, turbulent, seditious subject, who placed himself at the head of an armed force, and called his rebel band *The League*. The plan was formed by the cardinal, his younger brother; and under the pretext of defending the Roman Catholic religion, the king Henry III. and the freedom of the state, against the design of the Huguenots, or French Protestants, they carried on a civil war, massacred the Huguenots, and governed the king, who forbid his appearance at Paris; but Guise now became an open rebel, entered the city against the king's express order, and put to the sword all who opposed him. The streets being barricaded to prevent his progress, this fatal day is called in the French history *The day of the barricades*. Masters of Paris, the policy of the Guises failed them: for they suffered the king to escape to Blois, though he was deserted in his palace at Paris by his

very guards. At Blois, Henry convened an assembly of the states of France; the duke of Guise had the boldness to appear to a summons sent him for that purpose: a forced reconciliation took place between him and the king, by the advice of this assembly; but it being accidentally discovered that Guise had formed a design to dethrone the king, that weak monarch, instead of resolutely bringing him to justice, had him privately assassinated, December 23, 1558, in the 38th year of his age. His brother the cardinal shared the same fate the next day.

GUITAR, GUITARRA, a musical instrument of the stringed kind, with five double rows of strings, of which those that are brais are in the middle, except it be for the burden, an octave lower than the fourth. This instrument was first used in Spain and by the Italians. In the former country it is still greatly in vogue. There are few of that nation who cannot play on the guitar; and with this instrument they serenade their mistresses at night. At Madrid and other cities in that country, it is common to meet in the streets young men equipped with a guitar and a dark lanthorn, who, taking their station under the windows, sing, and accompany their voices with this instrument; and there is scarce an artificer or day-labourer in any of the cities or principal towns who does not entertain himself with his guitar.

GULDENSTAEDT (John Anthony), was born at Riga, April 26, 1745; received the rudiments of his education in that town; and in 1763 was admitted into the medical college at Berlin. He completed his studies at Frankfort upon the Oder, and in 1767 received the degree of M. D. in that university. On account of his knowledge of foreign languages, and the considerable progress he had made in natural history, he was considered as a fit person to engage in the expeditions which were planned by the imperial academy. Being invited to St. Petersburg, he arrived in that city in 1768, was created adjunct of the academy, and afterwards, in 1770, member of that society, and professor of natural history. In June 1761 he set out upon his travels, and was absent seven years. From Moscow, where he continued till March 1769, he passed to Voronetz, Tzaritzin, Astracan, and Kiilar, a fortress upon the western shore of the Caspian, and close to the confines of Persia. In 1770 he examined the districts watered by the rivers Terek, Sunsha, and Alkai, in the eastern extremity of Caucasus; and in the course of the ensuing year penetrated into Ossitia, in the highest part of the same mountain, where he collected vocabularies of the languages spoken in those regions, made inquiries into the history of the people, and discovered some traces of Christianity among them. Having visited Cabarda and the northern chain of the Caucasus, he proceeded to Georgia, and was admitted to an audience of prince Heraclius, who was encamped about ten miles from Tesslis. Having passed the winter here and in examining the adjacent country, he followed in spring the prince to the province of Koketia, and explored the southern districts inhabited by the Turcoman Tartars in the company of a Georgian magnate, whom he had cured of a dangerous disorder. In July he passed into Imeretia, a country which lies between the Caspian and Black Seas, and is bounded on the east by Georgia, on the north by Ossitia, on the west by Mingrelia, and on the south by the Turkish dominions. He penetrated into the middle chain of mount Caucasus, visited the confines of Mingrelia, Middle Georgia, and Eastern and Lower Imeretia; and, after escaping many imminent dangers from the banditti of those parts, fortunately returned to Kiilar on the 18th of November, where he passed the winter, collecting various information concerning the neighbouring Tartar tribes of the Caucasus, and particularly the Lesgees. In the following summer he journeyed to Cabarda Major, continued his course to mount Beilton, the highest point of the first ridge of the Caucasus: inspected the mines of Maj-

shar, and went to Tcherkaski upon the Don. From thence he made expeditions to Azof and Taganrog, and then, along the new limits to the Dnieper, he finished this year's route at Kremenstluk in the government of New Russia. In the ensuing spring, he was proceeding to Crim Tartary; but receiving an order of recall, he returned through the Ukraine to Moscow and St. Petersburg, where he arrived in the month of March 1775. Upon his return, he was employed in arranging his papers; but before he could finish them for the press, was seized with a violent fever, which carried him to the grave in March 1781. His writings which have been hitherto published consist of a number of curious treatises, of which a list is given in Coxe's Travels, Vol. I. p. 162.

GULA, in anatomy, the œsophagus or gullet; that conduit by which animals take down food into the stomach. See ANATOMY, page 188.

GULE of AUGUST, the day of St. Peter *ad vincula*, which is celebrated on the first of August. It is called the *gule of August*, from the Latin *gula*, "a throat," for this reason, that one Quirinus, a tribune, having a daughter that had a disease in her throat, went to Pope Alexander, the sixth from St. Peter, and desired of him to see the chains that St. Peter was chained with under Nero; which request being granted, and she, kissing the chains, was cured of her disease; whereupon the Pope instituted this feast in honour of St. Peter; and, as before, this day was termed only the calends of August, it was on this occasion called indifferently either the day of St. Peter *ad vincula*, from what wrought the miracle, or the *gule of August*, from that part of the virgin whereon it was wrought.

GULES, in heraldry, a corruption of the French word *gules*, which in this science signifies "red," and is represented in engraving by perpendicular lines. This colour is by the generality of the English heralds ranked before azure; but French heralds, N. Upton and his followers, prefer azure to it.

GULL, in ichthyology. See LARUS.

GULF, or GULPH, a broad and capacious bay comprehended between two promontories, and sometimes taking the name of a sea when it is very extensive; but particularly when it only communicates with the sea by means of a strait. Such are the Euxine or Black Sea, otherwise called the *Gulf of Constantinople*; the Adriatic Sea, called also the *Gulf of Venice*; the gulf of Sidra near Barbary; and the gulf of Lyons near France. All these gulfs are in the Mediterranean. There are besides, the gulf of Mexico, the gulf of St. Lawrence, and the gulf of California, which are in North America. There are also the gulf of Persia, otherwise called the *Red Sea*, between Persia and Arabia; the gulf of Bengal in India; and the gulfs of Cochinchina and Kamtschatka, near the countries of the same name. The word comes from the French *golfe*, and that from the Italian *golfo*, which signify the same. Some deduce these further from the Greek γολφός, which Guishart again derives from the Hebrew גולב *gob*. Du Cange derives them from the barbarous Latin *gulfum*, or *gulfus*, which signify the same thing.

GULLET. See GULA.

GUM, a concrete vegetable juice, of no particular smell or taste, becoming viscous and tenacious when moistened with water; totally dissolving in water into a liquid, more or less glutinous in proportion to the quantity of the gum; not dissolving in vinous spirits or in oils; burning in the fire to a black coal, without melting or catching flame; suffering no dissipation in the heat of boiling water. The true gums are gum arabic, gum tragacanth, gum senegal, the gum of cherry and plum trees, and such like. All else have more or less of resin in them, and are thence called *gum resins*.

GUM Arabic is the produce of a species of MIMOSA; which see. The medical character of gum arabic is its glutinous quality,

in consequence of which it proves useful in tickling coughs, hoarsenesses, in dysenteries attended with gripes, and where the mucus is abraded from the bowels or from the urethra. In a dysuria the true gum arabic should be preferred to any other of the vegetable gums. One ounce of it renders a pint of water considerably glutinous: four ounces give it a thick syrupy consistence: but for mucilage, one part gum to two parts water is required; and for some purposes, an equal proportion will be necessary. In Dr. Percival's *Essays*, Vol. I. p. 319, &c. we have a curious account, by Mr. Henry, of the faculty which this gum hath of dissolving and keeping suspended in water, not only resinous but also other substances which should seem not likely to be at all affected by it.

In Mr. Haffelquist's *Travels* we have an instance of the extraordinary nutritive virtues of gum arabic. "The Abyssinians (says he) make a journey every year to Cairo, to sell the products of their country. They must travel over terrible deserts, and their journey depends as much on the weather as a voyage at sea: consequently they know as little as a seaman how long they must be on their journey; and the necessaries of life may chance to fail them when the journey lasts too long. This happened to the Abyssinian caravan in the year 1740, their provisions being consumed when they had still two months to travel. They were then obliged to search for something among their merchandise wherewith they might support nature; and found nothing more proper than gum arabic, of which they had carried a considerable quantity along with them. This served to support above 1000 persons for two months; and the caravan at last arrived at Cairo without any great loss of people either by hunger or diseases."

Gum Seneca, is a gum extremely resembling gum arabic. It is brought to us from the country through which the river Senega runs, in loose or single drops: but these are much larger than those of the gum arabic usually are; sometimes it is of the bigness of an egg, and sometimes much larger: the surface is very rough or wrinkled, and appears much less bright than the inner substance where the masses are broken. It has no smell, and scarce any taste. It is probably produced from a tree of the same kind with the former. The virtues of it are the same with the gum arabic; but it is rarely used in medicine, unless as mixed with the gum arabic: the dyers and other artificers consume the great quantities of it that are annually imported hither. The negroes dissolve it in milk, and in that state make it a principal ingredient in many of their dishes, and often feed on it thus alone.

The consumption of this article in our manufactories is so considerable, as to make it an object to find any kind of substitute that is cheaper and that will answer the purpose. In the *Repertory*, Vol. iii. we find the following patent receipt for making a gum, which the inventor recommends under the name of the "*Britannic Elastic Gum*," and which, among a variety of less important uses, is said to be suitable "for painting, pencilling, and staining, silks, calicoes, &c. and in dressing of silk, linen, and cotton, in the loom." The receipt is, linseed or nut-oil, one gallon; bees'-wax, one pound; glue or size, six pounds; verdigrise, four ounces; and the same of litharge. These he directs to be put into an iron kettle with two quarts of water, and the whole melted down together. The mode of employing this gum Mr. Angell's patent does not specify.

Another invention is described in the same Work, professedly as a "*substitute for gum, in thickening colours for printing*." The patent was granted to Mr. Blakie, of Glasgow, in 1788, and he describes his invention in the following words: "The gum substitute, to thicken colours for linen and callico-printing, and making up or furnishing printers' colour-tubs, and which may also be applied to several other uses, is prepared by boiling any quantity of flax-seed in a sufficient quantity of water,

until the whole substance be extracted thereby; and, having strained it through a linen or woollen cloth, again boil down the liquor to the consistence of a jelly. Put it into a close vessel, and, for preservation, put in a little strong spirits, or pour a little sweet-oil on the top of it; bitters may also be used to preserve it. In using the substitute, the printer may either put a certain quantity into a gallon of colour, according to the nature of it, and the particular kind of work to be done, and regulate himself by trial, as is common in using gum; or reduce the substitute, by boiling in water to the consistence wanted."

Gum Tragacanth, the gum of the tragacanth, a thorny bush growing in Crete, Asia, and Greece. See *ASTRAGALUS*.

Other substances known by the name of *gums* are as follow:

Gum Ammoniac. See *AMMONIAC*.

Gum Elemi. See *AMYRIS*.

Gum Keno or *Kino*. See *KENO*.

Gum Guaiacum. See *GUAIACUM*.

Gum Lacca. See *COCCUS* and *LACCA*.

GUM, among gardeners, denotes a kind of gangrene incident to fruit-trees of the stone kind, in which its viscid juices are made to extravasate and ooze out upon the bark in the form of gum. When this distemper surrounds the branch, it admits of no remedy; but in slighter cases, it is only necessary to remove the decayed parts and apply a coating of tar. See *ORCHARD*.

GUMMA, a sort of venereal excrescence on the periosteum of the bones.

GUMS, in anatomy, the hard fleshy substance in either jaw, through which the teeth pass from the jawbone. The gums are apt to become spongy, and to separate from the teeth; and the cause is frequently a stony tartarous kind of crust, which forms itself there, but which when separated by an operation which the dentists call *scaling*, the gums soon return to their former state. If rubbed daily with a brush composed of very stiff bristles, the tartar will not only be prevented from accumulating, but the gums, from being tender and apt to bleed, will become hard and firm. Cold water is as useful as any other wash, but some choose to join with it one part in four of tincture of myrrh. The scurvy is another disorder which affects the gums; indeed, when a scorbutic disorder invades the whole habit, its first symptom is a putrid state of the gums.

GUN, a fire-arm, or weapon of offence, which forcibly discharges a ball or other matter through a cylindrical tube, by means of inflamed gun-powder.

The word *gun* now includes most of the species of fire-arms; mortars and pistols being almost the only ones excepted from this denomination. They are divided into great and small guns: the former including all that are usually called cannon, ordnance, or artillery; and the latter includes musquets, firelocks, carabines, musquetoons, blunderbusses, fowling-pieces, &c.

It is not certainly known at what time these weapons were first invented. And though the introduction of guns into the western part of the world is but of modern date, comparatively speaking, yet it is certain that in some parts of Asia they have been used for many ages, though in a very rude and imperfect manner. Philostratus speaks of a city near the river Hyphasis in the Indies, which was said to be impregnable, and that its inhabitants were relations of the gods, because they threw thunder and lightning upon their enemies; and other Greek authors, as also Quintus Curtius, speak of the same thing having happened to Alexander the Great. Hence some have imagined that guns were used by the eastern nations in his time, while others suppose the thunder and lightning alluded to by those authors were only certain artificial fire-works, or rockets,

such as we know are used in the wars by the Indians even in the present day against the Europeans. Be this however as it may, it is asserted by many modern travellers, that guns were used in China as far back as the year of Christ 85, and have continued in use ever since.

The first hint of the invention of guns in Europe is in the works of Roger Bacon, who flourished in the 13th century. In a treatise written by him about the year 1220, he proposes to apply the violent explosive force of gun-powder for the destruction of armies. And though it is certainly known that the composition of gun-powder is described by Bacon in the said work, yet the invention has usually, though improperly, been ascribed to Bartholdas Schwartz, a German monk, who it is said discovered it only in the year 1320; and the accident is related in the following manner. Schwartz having, for some purpose, pounded nitre, sulphur, and charcoal together, in a mortar, which he afterwards covered imperfectly with a stone, a spark of fire accidentally fell into the mortar, which setting the mixture on fire, the explosion blew the stone to a considerable distance. Hence it is probable that Schwartz might be taught the simplest method of applying it in war; for it rather seems that Bacon conceived the manner of using it to be by the violent effort of the flame unconfined, and which is indeed capable of producing astonishing effects. (See GUNPOWDER). And the figure and name of *mortars* given to a species of old artillery, and their employment, in throwing large stone bullets at an elevation, very much favour this conjecture.

Soon after the time of Schwartz, we find guns commonly used as instruments of war. These were originally made of iron-bars foldered together, and fortified with strong iron hoops or rings; several of which are still to be seen in the Tower of London, and in the Warren at Woolwich. Others were made of thin sheets of iron rolled up together and hooped: and on particular emergencies some have been made of leather, and of lead, with plates of iron or copper. These first pieces were executed in a rude and imperfect manner, like the first essays of most new inventions. Stone balls were thrown out of them, and a small quantity of powder used on account of their weakness. They were of a cylindrical form, without ornaments, and were placed on their carriages by rings.

When or by whom they were first made is uncertain. It is known however that the Venetians used cannon at the siege of Claudia Jessa, now called Chioggia, in 1366, which were brought thither by two Germans, with some powder and leaden balls; as likewise in their wars with the Genoese in 1379. But before that, king Edward III. made use of cannon at the battle of Cressly in 1346, and at the siege of Calais in 1347. Cannon were employed by the Turks at the siege of Constantinople, then in possession of the Christians, in 1394, and in that of 1452, which threw a weight of 100lb.; but they commonly burnt at the 1st, 2d, or 3d firing. Louis XII. had one cast at Tours, of the same size, which threw a ball from the Bastile to Charenton: one of these extraordinary cannon was taken at the siege of Dieu in 1546, by Don John de Castro, and is now in the castle of St. Julian da Barra, 10 miles from Lisbon: the length of it is 20 feet 7 inches, its diameter at the middle 6 feet 3 inches, and it threw a ball of 100lb. weight. It has neither dolphins, rings, nor button; is of an unusual kind of metal; and it has a large Indian inscription upon it, which says it was cast in 1400.

Formerly cannon were dignified with uncommon names. Thus Lewis XII. in 1503 had 12 brass cannon cast, of an extraordinary size, called after the names of the 12 peers of France. The Spanish and Portuguese called them after their saints. The emperor Charles V. when he marched against Tunis, founded the 12 apostles. At Milan there is a 70 pounder, called the Pimontelle; and one at Bois-le-due, called the

Devil. A 60 pounder at Dover-castle, called Queen Elizabeth's pocket pistol. An 80 pounder in the Tower of London, brought there from Edinburgh-castle, called Mount's-meg. An 80 pounder in the royal arsenal at Berlin, called the Thunderer. An 80 pounder at Malaga, called the Terrible. Two enormous 60 pounders in the arsenal at Bremen, called the Messenger of bad news. And lastly an uncommon 70 pounder in the castle of St. Angelo at Rome, made of the nails that fastened the copper-plates which covered the ancient Pantheon, with this inscription upon it, *Ex clavis trabalibus porticus Agrippa*. In the beginning of the 15th century these uncommon names were generally abolished, and the following more universal ones took place, viz.

Names.	Wt. of piece	
	Wt. of ball, Pounds.	in cwt., about Cwt.
Cannon royal, or carthoun,	48	- 90
Bastard cannon, or $\frac{3}{4}$ carthoun,	36	- 79
Demi-carthoun,	24	- 60
Whole culverins,	18	- 50
Demi-culverins,	9	- 30
Falcon,	6	- 25
Sacker {	largest size	8
	ordinary	6
	lowest fort	5
Basilisk	48	- 85
Serpentine	4	- 8
Aspic	2	- 7
Dragon	6	- 12
Syren	60	- 81
Falconet	3, 2, and 1	15, 10, 5
Rabinet	1	
Moyens	10 or 12 oz.	

These curious names of beasts and birds of prey were adopted on account of their swiftness in motion, or of their cruelty; as the falconet, falcon, sacker, and culverin, &c. for their swiftness in flying; the basilisk, serpentine, aspic, dragon, syren, &c. for their cruelty. But, at present, cannon take their names from the weight of their proper ball. Thus a piece that discharges a cast-iron ball of 24 pounds is called a 24 pounder; one that carries a ball of 12 pounds is called a 12 pounder; and so of the rest, divided into the following sorts, viz. *Ship-guns*, consisting in 42, 36, 32, 24, 18, 12, 9, 6, and 3 pounders. *Garrison-guns*, in 42, 32, 24, 18, 12, 9, and 6 pounders. *Battering-guns*, in 24, 18, and 12 pounders. *Field-pieces*, in 12, 9, 6, 3, 2, $1\frac{1}{2}$, 1, and $\frac{1}{2}$ pounders.

Mortars, it is thought, have been at least as ancient as cannon. They were employed in the wars of Italy, to throw balls of red-hot iron, stones, &c. long before the invention of shells. These last, it is supposed, were of German invention, and the use of them in war shewn by the following accident: viz. A citizen of Venlo, at a festival celebrated in honour of the duke of Cleves, throwing a number of shells, one of them fell on a house and set it on fire, by which misfortune the greatest part of the town was reduced to ashes. The first account of shells used for military purposes is in 1435, when Naples was besieged by Charles VIII. History informs us, with more certainty, that shells were thrown out of mortars at the siege of Wachtendonk in Guelderland in 1588, by the earl of Mansfield; and Cyprian Lucar wrote upon the method of filling and throwing such shells, in his Appendix to the Colloquies of Tartaglia, printed at London in 1588; where also the compounding and throwing of carcasses and various sorts of fire works are shewn.

Mr Malter, an English engineer, first taught the French the art of throwing shells, which they practised at the siege of Motte in 1634. The method of throwing red-hot balls out

of mortars was first certainly put in practice at the siege of Stralsund in 1675 by the elector of Brandenburg: though some say in 1653 at the siege of Bremen.

Another species of ordnance has been long in use, by the name of *Howitzer*, which is a kind of medium as to its length between the cannon and the mortar, and is a very useful piece for discharging either shells or large balls, which is done either at point-blance or at a small elevation.

A new species of ordnance was introduced by the Carron company, and thence called a *Carronade*, which is only a very short howitzer, and which seems to possess the advantage of being light and easy to work. They are not, however, found so useful as was expected.

The species of guns before mentioned are now made chiefly of cast iron: except the howitzer, which is of brass, as well as some cannon and mortars.

Muskets were first used at the siege of Rhege in the year 1511. The Spaniards were the first who armed part of their foot with these weapons. At first they were very heavy, and could not be used without a rest. They had match-locks, and did execution at a great distance. On their march the soldiers carried only the rests and ammunition, having boys to bear their muskets after them. They were very slow in loading, not only by reason of the unwieldiness of their pieces, and because they carried the powder and ball separate, but from the time it took to prepare and adjust the match; so that their fire was not near so brisk as ours is now. Afterwards a lighter match-lock musket came in use: and they carried their ammunition in bandeliers, to which were hung several little cases of wood covered with leather, each containing a charge of powder. The muskets with rests were used as late as the beginning of the civil wars in the time of Charles the First. The lighter kind succeeded them, and continued till the beginning of the present century, when they also were disused, and the troops throughout Europe armed with firelocks. These are usually made of hammered iron. For the dimensions, construction, and practice of various species of guns, &c. see the various articles CANNON, MORTAR, HOWITZER, &c. &c. See also GUNNERY.

GUNDELIA, in botany; a genus of the polygamia frégate order, belonging to the syngenesia class of plants, and in the natural method ranking under the 49th order, *Compositæ*. There is scarce any calyx but quinqueflorous, with tubular hermaphrodite florets; the receptacle bristly, with scarce any pappus.

GUNELLUS, in ichthyology. See **BLENNIUS**.

GUNNERS, officers of the Tower and other garrisons, whose business it is to manage and look after the ordnance mounted on the lines and batteries, which are all fixed and ready with cartouches and ball for service on the shortest warning. They carry a field-staff, and a large powder-horn in a string over the left shoulder; in which equipage they march by the guns.

GUNNER, in the artillery, till of late denoted exclusively the second rank of private men in the royal regiment of artillery. The privates were then called the *Matrosses*, a name which is now changed for that of *second Gunner*.

GUNNER of a ship of war, is an officer appointed to take charge of the artillery and ammunition on board; to observe that the former are kept in order, and fitted with tackle and other furniture, and to teach the sailors the exercise of the guns: he is assisted by a mate, &c.

GUNNERA, in botany; a genus of the diandria order, belonging to the gynandria class of plants. The amentum consists of unisporous scales; there is neither calyx nor corolla; the germen is bicelled, with two styles and one seed.

GUNNERY, the art of charging, directing, and exploding all kinds of fire-arms, as cannon, mortars, muskets, &c. to the best advantage. Gunnery is sometimes considered as a part of the military art, and sometimes as a part of pyrotechny. To the art of gunnery too belongs the knowledge of the force and effect of gunpowder, the dimensions of the pieces, and the proportions of the powder and ball they carry, with the methods of managing, charging, pointing, spunging, &c. Also some parts of gunnery are brought under mathematical consideration, which among mathematicians are called absolutely by the name *Gunnery*, viz. the rules and method of computing the range, elevation, quantity of powder, &c. so as to hit a mark or object proposed, and is more particularly called *Projectile*. See **PROJECTILES**.

Long before the invention of gunpowder, and of gunnery properly so called, the art of artillery, or projectiles, was actually in practice. For, not to mention the use of spears, javelins, or stones thrown with the hand, or of bows and arrows, all which are found among the most barbarous and ignorant people, accounts of the larger machines for throwing stones, darts, &c. are recorded by the most ancient writers. Thus one of the kings of Judah, 800 years before the Christian æra, erected engines of war on the towers and bulwarks of Jerusalem, for shooting arrows and great stones for the defence of the city. 2 Chron. xxvi. 15. Such machines were afterwards known among the Greeks and Romans by the names of **BALLISTA**, **CATAPULTA**, &c. which produced effects by the action of a spring of a strongly twisted cordage, formed of tough and elastic animal substances, no less terrible than the artillery of the moderns. Such warlike instruments continued in use down to the 12th and 13th centuries, and the use of bows still longer; nor is it probable that they were totally laid aside till they were superseded by gunpowder and the modern ordnance.

The first application of gunpowder to military affairs, it seems, was made soon after the year 1300, for which the proposal of friar Bacon, about the year 1280, for applying its enormous explosion to the destruction of armies, might give the first hint; and Schwartz, to whom the invention of gunpowder has been erroneously ascribed, on account of the accident mentioned under the article **GUN**, might have been the first who actually applied it in this way, that is, in Europe; for as to Asia, it is probable that the Chinese and Indians had something of the kind many ages before. Thus, only to mention the prohibition of fire-arms in the code of Gentoo laws, printed by the East India Company in 1776, which seems to confirm the suspicion suggested by a passage in Quintus Curtius, that Alexander the Great found some weapons of that kind in India: Cannon in the Shanerit idiom is called *Shet aghnee*, or the weapon that kills a hundred men at once.

However, the first pieces of artillery, which were charged with gunpowder and stone bullets of a prodigious size, were of very clumsy and inconvenient structure and weight. Thus, when Mahomet the Second besieged Constantinople in 1453, he battered the walls with stones of this kind, and with pieces of the calibre of 1200 pounds; which could not be fired more than four times a day. It was however soon discovered that iron bullets, of much less weight than stone ones, would be more efficacious if impelled by greater quantities of stronger powder. This occasioned an alteration in the matter and form of the cannon, which were now cast of brass. These were lighter and more manageable than the former, at the same time that they were stronger in proportion to their bore. This change took place about the close of the fifteenth century.

By this means came first into use such powder as is now employed over all Europe, by varying the proportion of the materials. But this change of the proportion was not the only improvement it received. The practice of graining it is doubtless of considerable advantage. At first the powder had been always used in the form of fine meal, such as it was reduced to by grinding the materials together. And it is doubtful whether the first graining of powder was intended to increase its strength, or only to render it more convenient for filling into small charges and the charging of small arms, to which alone it was applied for many years, whilst meal-powder was still used for cannon. But at last the additional strength which the grained powder was found to possess, doubtless from the free passage of the air between the grains, occasioned the meal-powder to be entirely laid aside.

For the last 200 years, the formation of cannon has been very little improved; the best pieces of modern artillery differing little in their proportion from those used in the time of Charles the Fifth. Indeed lighter and shorter pieces have been often proposed and tried; but though they have their advantages in particular cases, it is agreed they are not sufficient for general service. Yet the size of the pieces has been much decreased; the same purposes being now accomplished by smaller pieces than what were formerly thought necessary. Thus the battering cannon now approved are those that formerly were called demi-cannon, carrying a ball of 24 pounds weight; this weight having been found fully sufficient. The method also of making a breach, by first cutting off the whole wall as low as possible before its upper part is attempted to be beaten down, seems to be a considerable modern improvement in the practical part of gunnery. But the most considerable improvement in the practice is the method of firing with small quantities of powder, and elevating the piece but a little, so that the bullet may just go clear of the parapet of the enemy, and drop into their works, called ricochet firing: for by this means the ball, coming to the ground at a small angle, and with a small velocity, does not bury itself, but bounds or rolls along a great way, destroying all before it. This method was first practised by M. Vauban at the siege of Aeth, in the year 1692. A practice of this kind was successfully practised by the king of Prussia at the battle of Rosbach in 1757. He had several six-inch mortars, made with trunnions, and mounted on travelling carriages, which were fired obliquely on the enemy's lines, and among their horse. These being charged with only 8 ounces of powder, and elevated at one degree and a quarter, did great execution: for these shells rolling along the lines with burning fuses made the stoutest of the enemy not wait for their burbling.

The use of fire-arms was however long known before any theory of projectiles was formed. The Italians were the first people that made any attempts at the theory, which they did about the beginning of the 16th century, and amongst them it seems the first who wrote professedly on the flight of cannon shot was Nicholas Tartalia, of Brescia, the same author who had so great a share in the invention of the rules for cubic equations. In 1537 he published at Venice his *Nova Scientia*, and in 1546 his *Questi et Inventioni diversi*, in both which he treats professedly on these motions, as well as in another work, translated into English with additions by Cyprian Lucar, under the title of *Colloquies concerning the Art of Shooting in great and small Pieces of Artillery*, and published at London in 1588. He determined, that the greatest range of a shot was when discharged at an elevation of 45° : and he asserted, contrary to the opinion of his contemporaries, that no part of the path described by a ball is a right line; although the curvature in the first part of it is so small, that it need not be at-

tended to. He compared it to the surface of the sea; which, though it appears to be a plane, is yet doubtless incurvated round the centre of the earth. He says he invented the gunner's quadrant, for laying a piece of ordnance at any point or degree of elevation; and though he had but little opportunity of acquiring any practical knowledge by experiments, he yet gave shrewd guesses at the event of some untried methods.

The philosophers of those times also took part in the questions arising upon this subject; and many disputes on motion were held, especially in Italy, which continued till the time of Galileo, and probably gave rise to his celebrated *Dialogues on Motion*. These were not published till the year 1638; and in the interval there were many theories of the motion of military projectiles, as well as many tables of their comparative ranges, though for the most part very fallacious, and inconsistent with the motion of these bodies.

It is remarkable however that, during these contests, so few of those who were intrusted with the care of artillery thought it worth while to bring their theories to the test of experiment. Mr. Robins informs us, in the preface to his *New Principles of Gunnery*, that he had met with no more than four authors who had treated experimentally on this subject. The first of these is Collado, in 1642, who has given the ranges of a falconet, carrying a three-pound shot, to every point of the gunner's quadrant, each point being the 12th part, or 7° and a half. But from his numbers it is manifest that the piece is not charged with its usual allotment of powder. The result of his trials shews the ranges at the point-blanc, and the several points of elevation, as below.

Collado's Experiments.

Points.	Elevation at	Deg.	Range in
	or		paces.
0	or	0	268
1	-	$7\frac{1}{2}$	594
2	-	15	794
3	-	$22\frac{1}{2}$	994
4	-	30	1010
5	-	$37\frac{1}{2}$	1040
6	-	45	1053
7	-	$52\frac{1}{2}$	between the 3d and 4th.
8	-	60	between the 2d and 3d
9	-	$67\frac{1}{2}$	between the 1st and 2d
10	-	75	between the 0 and 1st
11	-	$82\frac{1}{2}$	fell very near the piece.

The next was by Wm. Bourne in 1643, in his *Art of Shooting in Great Ordnance*. His elevations were not regulated by the points of the gunner's quadrant, but by degrees; and he gives the proportions between the ranges at different elevations and the extent of the point-blanc shot, thus: If the extent of the point-blanc shot be represented by 1, then the proportions of the ranges at several elevations will be as below, viz.

Bourne's Proportion of Ranges.

Elevation.	Range.
0°	1
5	$2\frac{2}{9}$
10	$3\frac{1}{3}$
15	$4\frac{1}{3}$
20	$4\frac{2}{9}$
and the greatest random $5\frac{1}{2}$;	

which greatest random, he says, in a calm day is at 42° elevation; but according to the strength of the wind, and as it favours or opposes the flight of the shot, the elevation may be from 43° to 36° . He does not say with what piece he made his trials; though from his proportion it seems to have been a small one. This however ought to have been mentioned, as the relation between the extent of different ranges varies extremely according to the velocity and density of the bullet.

After him, Eldred and Anderson, both Englishmen, also published treatises on this subject. The former of these was many years gunner of Dover Castle, where most of his experiments were made, the earliest of which are dated in 1611, though his book was not published till 1646, and was intitled *The Gunner's Glass*. His principles were sufficiently simple, and within certain limits very near the truth, though they were not rigorously so. He has given the actual ranges of different pieces of artillery at small elevations, all under 10 degrees. His experiments are numerous, and appear to be made with great care and caution; and he has honestly set down some, which were not reconcileable to his method: upon the whole he seems to have taken more pains, and to have had a juster knowledge of his business, than is to be found in most of his practical brethren.

Galileo printed his Dialogues on Motion in the year 1646. In these he pointed out the general laws observed by nature in the production and composition of motion, and was the first who described the action and effects of gravity on falling bodies: on these principles he determined, that the flight of a cannon-shot, or of any other projectile, would be in the curve of a parabola, unless so far as it should be diverted from that track by the resistance of the air. He also proposed the means of examining the inequalities which arise from thence, and of discovering what sensible effects that resistance would produce in the motion of a bullet at some given distance from the piece.

Notwithstanding these determinations and hints of Galileo, it seems that those who came after him never imagined that it was necessary to consider how far the operations of gunnery were affected by this resistance. Instead of this, they boldly asserted, without making the experiment, that no great variation could arise from the resistance of the air in the flight of shells or cannon-shot. In this persuasion they supported themselves chiefly by considering the extreme rarity of the air, compared with those dense and ponderous bodies; and at last it became an almost generally established maxim, that the flight of these bodies was nearly in the curve of a parabola.

Thus Robert Anderson, in his *Genuine Use and Effects of the Gunne* published in 1674, and again in his book *To hit a Mark* in 1690, relates a great many experiments; but proceeding on the principles of Galileo, he strenuously asserts that the flight of all bullets is in the curve of a parabola; undertaking to answer all objections that could be brought to the contrary. The same thing was also undertaken by Blondel, in his *Art de jeter les Bombes*, published in 1683; where, after long discussion, he concludes, that the variations from the air's resistance are so slight as not to deserve any notice. The same subject is treated of in the *Philos. Trans.* No. 216, p. 68, by Dr. Halley; who also, swayed by the very great disproportion between the density of the air and that of iron or lead, thought it reasonable to believe that the opposition of the air to large metal-shot is scarcely discernible; although in small and light shot he owns that it must be accounted for.

But though this hypothesis went on smoothly in speculation, yet Anderson, who made a great number of trials, found it impossible to support it without some new modification. For though it does not appear that he ever examined the compara-

tive ranges of either cannon or musket shot when fired with their usual velocity, yet his experiments on the ranges of shells thrown with velocities that were but small in comparison of those above mentioned convinced him that their whole track was not parabolical. But instead of making the proper inferences from hence, and concluding that the resistance of the air was of considerable efficacy, he framed a new hypothesis; which was, that the shell or bullet at its first discharge flew to a certain distance in a right line, from the end of which line only it began to describe a parabola: and this right line, which he calls the line of the impulse of the fire, he supposes is the same for all elevations. So that, by assigning a proper length to this line of impulse, it was always in his power to reconcile any two shots made at any two different angles; though the same method could not succeed with three shots; nor indeed does he ever inform us of the event of his experiments when three ranges were tried at one time.

But after the publication of Newton's *Principia*, it might have been expected, that the defects of the theory would be ascribed to their true cause, which is the great resistance of the air to such swift motions; as in that work he particularly considered the subject of such motions, and related the result of experiments, made on slow motions at least; by which it appeared, that in such motions the resistance increases as the square of the velocities, and he even hints a suspicion that it will increase above that law in swifter motions, as is now known to be the case. So far however were those who treated this subject scientifically, from making a proper allowance for the resistance of the atmosphere, that they still neglected it, or rather opposed it, and their theories still differed most egregiously from the truth. Huygens alone seems to have attended to this principle: for in the year 1690 he published a treatise on gravity, in which he gave an account of some experiments tending to prove that the track of all projectiles, moving with very swift motions, was widely different from that of a parabola. The rest of the learned generally acquiesced in the justness and sufficiency of Galileo's doctrine, and accordingly very erroneous calculations concerning the ranges of cannon were given. Nor was any farther notice taken of these errors till the year 1716, at which time Mr. Reffons, a French officer of artillery, of great merit and experience, gave in a memoir to the Royal Academy, importing that, "although it was agreed that theory joined with practice did constitute the perfection of every art; yet experience had taught him that theory was of very little service in the use of mortars: That the works of M. Blondel had justly enough described the several parabolic lines, according to the different degrees of the elevation of the piece; but that practice had convinced him there was no theory in the effect of gunpowder; for having endeavoured, with the greatest precision, to point a mortar according to these calculations, he had never been able to establish any solid foundation upon them." One instance only occurs in which D. Bernoulli applies the doctrine of Newton to the motions of projectiles, in the *Com. Acad. Petrop.* tom. 2, p. 338, &c. Besides which nothing further was done in this business till the time of Mr. Benjamin Robins, who published a treatise in 1742 intitled *New Principles of Gunnery*, in which he treated particularly not only of the resistance of the atmosphere, but also of the force of gunpowder, the nature and effects of different guns, and almost every thing else relating to the flight of military projectiles; and indeed he carried the theory of gunnery nearly to its utmost perfection.

The first thing considered by Mr. Robins, and which is indeed the foundation of all other particulars relating to gunnery, is the explosive force of gunpowder. M. De la Hire, in the *Hist. of the Acad. of Sciences* for the year 1702, supposed that this force may be owing to the increased elasticity

of the air contained in and between the grains, in consequence of the heat and fire produced at the time of the explosion: a cause not adequate to the 200th part of the effect. On the other hand, Mr. Robins determined, by irrefragable experiments, that this force was owing to an elastic fluid, similar to our atmosphere, existing in the powder in an extremely condensed state, which, being suddenly freed from the powder by the combustion, expanded with an amazing force, and violently impelled the bullet, or whatever might oppose its expansion.

The intensity of this force of exploded gunpowder Mr. Robins ascertained in different ways, after the example of Mr. Hawksbee, related in the *Philos. Trans.* No. 295, and in his *Physico-Mechan. Exper.* p. 81. One of these is by firing the powder in the air thus: A small quantity of the powder is placed in the upper part of a glass tube, and the lower part of the tube is immersed in water, the water being made to rise so near the top, that only a small portion of air is left in that part where the powder is placed: then in this situation the communication between the upper part of the tube and the external air being closed, the powder is fired by means of a burning glass, or otherwise; the water descends upon the explosion, and stands lower in the tube than before, by a space proportioned to the quantity of powder fired.

Another way was by firing the powder in vacuo, viz. in an exhausted receiver, by dropping the grains of powder upon a hot iron included in the receiver. By this means a permanent elastic fluid was generated from the fired gunpowder, and the quantity of it was always in proportion to the quantity of powder that was used, as was found by the proportional sinking of the mercurial gage annexed to the air pump. The result of these experiments was, that the weight of the elastic air thus generated was equal to $\frac{3}{15}$ of the compound mass of the gunpowder which yielded it; and that its bulk, when cold and expanded to the rarity of common atmospheric air, was about 240 times the bulk of the powder; and consequently in the same proportion would such fluid at first, if it were cold, exceed the force or elasticity of the atmosphere. But as Mr. Robins found, by another ingenious experiment, that air heated to the extreme degree of the white heat of iron has its elasticity quadrupled, or is 4 times as strong; he thence inferred that the force of the elastic air generated as above, at the moment of the explosion, is at least 4 times 240, or 960, or in round numbers about 1000 times as strong as the elasticity or pressure of the atmosphere on the same space.

Having thus determined the force of the gunpowder, or intensity of the agent by which the projectile is to be urged, Mr. Robins next proceeds to determine the effects it will produce, or the velocity with which it will impel a shot of a given weight from a piece of ordnance of given dimensions; which is a problem strictly limited, and perfectly soluble by mathematical rules, and is in general this: Given the first force, and the law of its variation, to determine the velocity with which it will impel a given body in passing through a given space, which is the length of the bore of the gun.

In the solution of this problem, Mr. Robins assumes these two postulates, viz. 1, That the action of the powder on the bullet ceases as soon as the bullet is out of the piece; and 2d, That all the powder of the charge is fired and converted into elastic fluid before the bullet is sensibly moved from its place: assumptions which, for good reasons, are found to be in many cases very near the truth. It is to be noted also, that the law by which the force of the elastic fluid varies is this, viz. that its intensity is directly as its density, or reciprocally proportional to the space it occupies, being so much the stronger as the space is less: a principle well known, and common to all elastic fluids. Upon these principles then Mr. Robins resolves

this problem, by means of the 39th prop. of Newton's *Principia* in a direct way, and the result is equivalent to this theorem, when the quantities are expressed by algebraic symbols; viz. the velocity of the ball

$$v = 27130 \sqrt{\frac{10a}{cd} \times \log. \frac{b}{a}}$$

$$\text{or} = 100 \sqrt{\frac{223ad^2}{w} \times \log. \frac{b}{a}}$$

where v is the velocity of the ball,
 a the length of the charge of powder,
 b the whole length of the bore,
 c the spec. grav. of the ball, or wt. of a cubic foot,
of the same matter in ounces,
 d the diam. of the bore,
 w the wt. of the ball in ounces.

For example, suppose $a = 2\frac{5}{8}$ inc., $b = 45$ inches,
 $c = 11345$ oz. for a ball of lead, and $d = \frac{3}{4}$ inches;

$$\text{then } v = 27130 \sqrt{\frac{7}{2269} \times \log. \frac{120}{7}} = 1674 \text{ feet per second,}$$

the velocity of the ball.

Or, if the wt. of the bullet be $w = 1\frac{9}{16}$ oz. = $\frac{20}{8}$ oz.

$$\text{Then } v = 100 \sqrt{\frac{1115 \times 189}{29 \times 32} \times \log. \frac{120}{7}} = 1674 \text{ feet, as}$$

before.

“ Having in this proposition (says Mr. Robins) shewn how the velocity which any bullet acquires from the force of powder, may be computed upon the principles of the theory laid down in the preceding propositions, we shall next shew, that the actual velocities with which bullets of different magnitudes are impelled from different pieces, with different quantities of powder, are really the same with the velocities assigned by these computations; and consequently that this theory of the force of powder, here delivered, does unquestionably ascertain the true action and modification of this enormous power.

“ But in order to compare the velocities communicated to bullets by the explosion with the velocities resulting from the theory by computation, it is necessary that the actual velocities with which bullets move should be capable of being discovered, which yet is impossible to be done by any methods hitherto made public. The only means hitherto practised by others for that purpose have been either by observing the time of the flight of the shot through a given space, or by measuring the range of the shot at a given elevation, and thence computing on the parabolic hypothesis what velocity would produce this range. The first method labours under this insurmountable difficulty, that the velocities of these bodies are often so swift, and consequently the time observed is so short, that an imperceptible error in that time may occasion an error in the velocity thus found, of 2, 3, 4, 5, or 600 feet in a second. The other method is so fallacious by reason of the resistance of the air (to which inequality the first is also liable), that the velocities thus assigned may not be perhaps the 10th part of the actual velocities sought.

“ To remedy then these inconveniencies, I have invented a new method of finding the real velocities of bullets of all kinds; and this to such a degree of exactness (which may be augmented too at pleasure), that in a bullet moving with the velocity of 1700 feet in 1'', the error in the estimation of it need never amount to its 500th part; and this with-

out any extraordinary nicety in the construction of the machine."

Mr. Robins then gives an account of the machine by which he measures the velocities of the balls, which machine is simply this, viz. a pendulous block of wood suspended freely by a horizontal axis, against which block are to be fired the balls whose velocities are to be determined.

"This instrument thus fitted, if the weight of the pendulum be known, and likewise the respective distances of its centre of gravity and of its centre of oscillation from its axis of suspension, it will thence be known what motion will be communicated to this pendulum by the percussion of a body of a known weight moving with a known degree of celerity, and striking it in a given point; that is, if the pendulum be supposed at rest before the percussion, it will be known what vibration it ought to make in consequence of such a determined blow; and, on the contrary, if the pendulum, being at rest, is struck by a body of a known weight, and the vibration which the pendulum makes after the blow is known, the velocity of the striking body may from thence be determined.

"Hence then, if a bullet of a known weight strikes the pendulum, and the vibration which the pendulum makes in consequence of the stroke be ascertained, the velocity with which the ball moved is thence to be known."

Mr. Robins then explains his method of computing velocities from experiments with this machine; which method is rather troublesome and perplexed, as well as the rules of Euler and Antoni, who followed him in this business; but a much plainer rule is given in Hutton's Tracts, vol. 1, p. 119, where such experiments are explained at full length, and this rule is expressed by either of the two following formulas,

$$v = 5.6727cg \times \frac{p+b}{bir} \sqrt{o} = 614.58cg \times \frac{p+b}{birn},$$

the velocity; where v denotes the velocity of the ball when it strikes the pendulum, p the weight of the pendulum, b the weight of the ball, c the chord of the arc described by the vibration to the radius r , g the distance below the axis of motion to the centre of gravity, o the distance to the centre of oscillation, i the distance to the point of impact, and n the number of oscillations the pendulum will perform in one minute, when made to oscillate in small arcs. The latter of these two theorems is much the easiest, both because it is free of radicals, and because the value of the radical \sqrt{o} , in the former, is to be first computed from the number n , or number of oscillations the pendulum is observed to make.

With such machines Mr. Robins made a great number of experiments, with musket barrels of different lengths, with balls of various weights, and with different charges or quantities of powder. He has set down the results of 61 of these experiments, which nearly agree with the corresponding velocities as computed by his theory of the force of powder, and which therefore establish that theory on a sure foundation.

From these experiments, as well as from the preceding theory, many important conclusions were deduced by Mr. Robins; and indeed by means of these it is obvious that every thing may be determined relative both to the true theory of projectiles, and to the practice of artillery: for, by firing a piece of ordnance charged in a similar manner against such a ballistic pendulum from different distances, the velocity lost by passing through such spaces of air will be found, and consequently the resistance of the air, the only circumstance that was wanting to complete the theory of gunnery, or military projectiles; and of this kind I have since made a great number of experiments with cannon balls, and have thereby obtained the whole series of resistances to such a ball when moving with every degree of velocity; from 0 up to 2000 feet per second of time. In the struc-

ture of artillery, they may likewise be of the greatest use: for hence may be determined the best lengths of guns; the proportions of the shot and powder to the several lengths; the thickness of a piece, so as it may be able to confine, without bursting, any given charge of powder; as also the effect of wads, chambers, placing of the vent, ramming the powder, &c. For the many other curious circumstances relating to this subject, and the various other improvements in the theory and practice of gunnery made by Mr. Robins, consult the first vol. of his Tracts, collected and published by Dr. Wilson in the year 1761, where ample information may be found.

Soon after the first publication of Robins's New Principles of Gunnery in 1742, the learned in several other nations, treading in his steps, repeated and farther extended the same subject, sometimes varying and enlarging the machinery; particularly Euler in Germany, D'Antoni in Italy, and Messrs. D'Arcy and Le Roy in France. But most of these, like Mr. Robins, with small fire-arms, such as muskets and fuzils.

"But (says Dr. Hutton, in his Phil. Dict. p. 556) in the year 1755, in conjunction with several able officers of the Royal Artillery, and other ingenious gentlemen, I undertook a course of experiments with the ballistic pendulum, in which we ventured to extend the machinery to cannon shot of 1, 2, and 3 pounds weight. An account of these experiments was published in the Philos. Trans. for 1778, and for which the Royal Society honoured me with the prize of the gold medal. These were the only experiments that I know of which had been made with cannon balls for this purpose, although the conclusions to be deduced from such are of the greatest importance to those parts of natural philosophy which are dependent on the effects of fired gunpowder; nor do I know of any other practical method of ascertaining the initial velocities within any tolerable degree of the truth. The knowledge of this velocity is of the utmost consequence in gunnery: by means of it, together with the law of the resistance of the medium, every thing is determinable relative to that business; for, besides its being an excellent method of trying the strength of different sorts of powder, it gives us the law relative to the different quantities of powder, to the different weights of shot, and to the different lengths and sizes of guns. Besides these, there does not seem to be any thing wanting to answer any inquiry that can be made concerning the flight and ranges of shot, except the effects arising from the resistance of the medium. In these experiments the weights of the pendulums employed were from 300 to near 600 pounds. In that paper is described the method of constructing the machinery, of finding the centres of gravity and oscillation of the pendulum, and of making the experiments, which are all set down in the form of a journal, with all the minute and concomitant circumstances; as also the investigation of the new and easy rule, set down just above, for computing the velocity of the ball from the experiments. The charges of powder were varied from 2 to 8 ounces, and the shot from 1 to near 3 pounds. And from the whole were clearly deduced these principal inferences, viz.

1. First, That gunpowder fires almost instantaneously.
2. That the velocities communicated to balls or shot, of the same weight, by different quantities of powder, are nearly in the subduplicate ratio of those quantities: a small variation, in defect, taking place when the quantities of powder became great.
3. And when shot of different weights are employed, with the same quantity of powder, the velocities communicated to them are nearly in the reciprocal subduplicate ratio of their weights.
4. So that, universally, shot which are of different weights, and impelled by the firing of different quantities of powder, require velocities which are directly as the square roots

of the quantities of powder, and inversely as the square roots of the weights of the shot, nearly. 5. It would therefore be a great improvement in artillery, to make use of shot of a long form, or of heavier matter; for thus the momentum of a shot, when fired with the same weight of powder, would be increased in the ratio of the square root of the weight of the shot. 6. It would also be an improvement to diminish the windage; for by so doing, one-third or more of the quantity of powder might be saved. 7. When the improvements mentioned in the last two articles are considered as both taking place, it is evident that about half the quantity of powder might be saved, which is a very considerable object. But important as this saving may be, it seems to be still exceeded by that of the article of the guns; for thus a small gun may be made to have the effect and execution of another of two or three times its size in the present mode, by discharging a shot of two or three times the weight of its natural ball or round shot. And thus a small ship might discharge shot as heavy as those of the greatest now made use of.

“ Finally, as the above experiments exhibit the regulations with regard to the weights of powder and balls, when fired from the same piece of ordnance, &c.; so by making similar experiments with a gun, varied in its length, by cutting off from it a certain part before each course of experiments, the effects and general rules for the different lengths of guns may be certainly determined by them. In short, the principles on which these experiments were made are so fruitful in consequences, that, in conjunction with the effects resulting from the resistance of the medium, they seem to be sufficient for answering all the enquiries of the speculative philosopher, as well as those of the practical artillerist.”

In the year 1786 was published the first volume of Dr. Hutton's Traacts, in which is detailed, at great length, another very extensive course of experiments which were carried on at Woolwich in the years 1783, 1784, and 1785, by order of the Duke of Richmond, Master General of the Ordnance. The objects of this course were very numerous, but the principal of them were the following:

“ 1. The velocities with which balls are projected by equal charges of powder, from pieces of the same weight and calibre, but of different lengths.

“ 2. The velocities with different charges of powder, the weight and length of the gun being the same.

“ 3. The greatest velocity due to the different lengths of guns, to be obtained by increasing the charge as far as the resistance of the piece is capable of sustaining.

“ 4. The effect of varying the weight of the piece; every thing else being the same.

“ 5. The penetration of balls into blocks of wood.

“ 6. The ranges and times of flight of balls; to compare them with their initial velocities for determining the resistance of the medium.

“ 7. The effect of wads;
of different degrees of ramming;
of different degrees of windage;
of different positions of the vent;
of chambers, and trunnions, and every other circumstance necessary to be known for the improvement of artillery.”

All these objects were obtained in a very perfect and accurate manner; excepting only the article of ranges, which were not quite so regular and uniform as might be wished. The balls too were most of them of one pound weight; but the powder was increased from 1 ounce, up till the bore was quite full; and the pendulum was from 600 to 800 lb. weight. The conclusions from the whole were as follow:

“ 1. That the former law, between the charge and velocity

of ball, is again confirmed, viz. that the velocity is directly as the square root of the weight of powder, as far as to about the charge of 8 ounces: and so it would continue for all charges, were the guns of an indefinite length. But as the length of the charge is increased, and bears a more considerable proportion to the length of the bore, the velocity falls the more short of that proportion.

“ 2. That the velocity of the ball increases with the charge to a certain point, which is peculiar to each gun, where it is greatest; and that by farther increasing the charge, the velocity gradually diminishes, till the bore is quite full of powder. That this charge for the greatest velocity is greater as the gun is longer, but not greater however in so high a proportion as the length of the gun is; so that the part of the bore filled with powder bears a less proportion to the whole in the long guns, than it does in the short ones; the part of the whole which is filled being indeed nearly in the reciprocal subduplicate ratio of the length of the empty part. And the other circumstances are as in this table.

TABLE of Charges producing the greatest Velocity.

Gun. Num.	Length of the bore.	Length filled.	Part of the whole.	Wt. of the powder.
	inches.	inches.		oz.
1	28.2	8.2	$\frac{3}{10}$	12
2	38.1	9.5	$\frac{1}{12}$	14
3	57.4	10.7	$\frac{1}{8}$	16
4	79.9	12.1	$\frac{1}{6}$	18

“ 3. It appears that the velocity continually increases as the gun is longer, though the increase in velocity is but very small in respect of the increase in length, the velocities being in a ratio somewhat less than that of the square roots of the length of the bore, but somewhat greater than that of the cube roots of the length, and is indeed nearly in the middle ratio between the two.

“ 4. The range increases in a much less ratio than the velocity, and indeed is nearly as the square root of the velocity, the gun and elevation being the same. And when this is compared with the property of the velocity and length of gun in the foregoing paragraph, we perceive that very little is gained in the range by a great increase in the length of the gun, the charge being the same. And indeed the range is nearly as the 5th root of the length of the bore; which is so small an increase, as to amount only to about $\frac{1}{3}$ th part more range for a double length of gun.

“ 5. It also appears that the time of the ball's flight is nearly as the range; the gun and elevation being the same.

“ 6. It appears that there is no sensible difference caused in the velocity or range, by varying the weight of the gun, nor by the use of wads, nor by different degrees of ramming, nor by firing the charge of powder in different parts of it.

“ 7. But a great difference in the velocity arises from a small degree of windage. Indeed with the usual established windage only, namely, about $\frac{1}{20}$ th of the calibre, no less than between $\frac{1}{2}$ and $\frac{1}{4}$ of the powder escapes and is lost. And as the balls are often smaller than that size, it frequently happens that half the powder is lost by unnecessary windage.

“ 8. It appears that the resisting force of wood to balls fired into it is not constant. And that the depths penetrated by different velocities or charges are nearly as the logarithms of the charges, instead of being as the charges themselves, or, which is the same thing, as the square of the velocity.

“ 9. These, and most other experiments, show that balls are greatly deflected from the direction they are projected in; and that so much as 300 or 400 yards in a range of a mile, or almost $\frac{1}{4}$ th of the range, which is nearly a deflection of an angle of 15 degrees.

“ 10. Finally, these experiments furnish us with the following concomitant data, to a tolerable degree of accuracy, namely, the dimensions and elevation of the gun, the weight and dimensions of the powder and shot, with the range and time of flight, and the first velocity of the ball. From which it is to be hoped, that the measure of the resistance of the air to projectiles may be determined, and thereby lay the foundation for a true and practical system of gunnery, which may be as well useful in service as in theory.”

“ Since the publication of those Tracts (says Dr. Hutton), we have prosecuted the experiments still farther from year to year, gradually extending our aim to more objects, and enlarging the guns and machinery, till we have arrived at experiments with the 6 pounder guns, and pendulums of 1800 pounds weight. One of the new objects of enquiry was the resistance the atmosphere makes to military projectiles; to obtain which, the guns have been placed at many different distances from the pendulum, against which they are fired, to get the velocity lost in passing through those spaces of air; by which, and the use of the whirling machine, described near the end of the 1st vol. of Robins's Tracts, for the slower motions, I have investigated the resistance of the air to given balls moving with all degrees of velocity, from 0 up to 2000 feet per second; as well as the resistance for many degrees of velocity, to planes and figures of other shapes, and inclined to their path in all varieties of angles; from which I have deduced general laws and formulas for all such motions.

“ Mr. Robins made also similar experiments on the resistance of the air; but being only with musket bullets, on account of their smallness, and of their change of figure by the explosion of the powder, I find they are very inaccurate, and considerably different from those above mentioned, which were accurately made with pretty considerable cannon balls, of iron. For this reason we may omit here the rules and theory deduced from them by Mr. Robins, till others more correct shall have been established. All these experiments indeed agree in evincing the very enormous resistance the air makes to the swift motions of military projectiles, amounting in some cases to 20 or 30 times the weight of the ball itself; on which account, the common rules for projectiles, deduced from the parabolic theory, are of little or no use in real practice; for from these experiments it is clearly proved, that the track described by the flight even of the heaviest shot is neither a parabola, nor yet approaching any thing near it, except when they are projected with very small velocities; in so much that some balls, which in the air range only to the distance of one mile, would, *in vacuo*, when projected with the same velocity, range above 10 or 20 times as far.” For the common rules of the parabolic theory, see PROJECTILES; and for a small specimen of experiments on resistances, see the 2d vol. of the Edinburgh Philos. Transf.; as also Hutton's Conic Sections and Select Exercises.

Mr. Benjamin Thompson (now Count Rumford) instituted a very considerable course of experiments of the same kind as those of Mr. Robins, with musket barrels, which was published in the Philos. Transf. vol. 71, for the year 1781. In these experiments, the conclusions of Mr. Robins are generally confirmed, and several other curious circumstances in this business are remarked by Mr. Thompson. This gentleman also pursues a hint thrown out by Mr. Robins, relative to the determining the velocity of a ball from the recoil of the pendulous gun itself. Mr. Robins, in prop. 11. remarks, that the effect of the exploded powder upon the recoil of the gun is the same whether the gun is charged with a ball or without one; and that the

chord, or velocity, of recoil with the powder alone, being subtracted from that of the recoil when charged with both powder and ball, leaves the velocity which is due to the ball alone. From thence Mr. Thompson observes, that the inference is obvious, viz. that the momentum thus communicated to the gun by the ball alone, being equal to the momentum of the ball, this becomes known; and therefore being divided by the known weight of the ball, the quotient will be its velocity. Mr. Thompson sets a great value on this new rule, the velocities by means of which he found to agree nearly with several of those deduced from the motion of the pendulum; and in the other cases, in which they differed greatly from these, he very inconsistently supposes that these latter ones are erroneous. In the experiments however contained in Dr. Hutton's Tracts, a great multitude of those cases are compared together, and the inaccuracy of that new rule is fully proved.

Having in the 9th prop. compared together a number of computed and experimented velocities of balls, to verify his theory; Mr. Robins, in the 10th prop. assigns the changes in the force of powder, which arise from the different state of the atmosphere, as to heat and moisture, both which he finds have some effect on it, but especially the latter. In prop. 11. he investigates the velocity which the flame of gunpowder acquires by expanding itself, supposing it fired in a given piece of artillery, without either a bullet or any other body before it. This velocity he finds is upwards of 7000 feet per second. But the celebrated Euler, in his commentary on this part of Mr. Robins's book, thinks it may be still much greater; and in this prop. too it is, that Mr. Robins declares his opinion above alluded to, viz. that the effect of the powder upon the recoil of the gun is the same in all cases, whether fired with a ball or without one. In prop. 12. he ascertains the manner in which the flame of powder impels a ball which is laid at a considerable distance from the charge; showing here that the sudden accumulation and density of the fluid against the ball is the reason that the barrel is so often burst in those cases. In prop. 13. he enumerates the various kinds of powder, and describes the properest methods of examining its goodness. He here shows that the best proportion of the ingredients is when the saltpetre is $\frac{2}{3}$ of the whole compound mass of the powder, and the sulphur and charcoal the other $\frac{1}{3}$ between them, in equal quantities. In this prop. Mr. Robins takes occasion to remark upon the use of eprouvettes, or methods of trying powder; condemning the practice of the English in using what is called the vertical eprouvette; as well as that of the French, in using a small mortar, with a very large ball, and a small charge of powder; and instead of these, he strongly recommends the use of his ballistic pendulum, for its great accuracy. But for still more dispatch, he says he should use another method, which however he reserves to himself, without giving any particular description of it. From what has been done by Mr. Robins upon this head, several persons have introduced his method of suspending the gun as a pendulum, and noting the quantity of its oscillating recoil when fired with a certain quantity of powder; and of this kind Dr. Hutton has contrived a machine, which possesses several advantages over all others, being extremely simple, accurate, and expeditious; so much so indeed; that the weighing out of the powder is the chief part of the trouble. See GUNPOWDER and POWDER-PROVER.

The other or 2d chapter of Mr. Robins's work, in 8 propositions, treats “ of the resistance of the air, and of the track described by the flight of shot and shells.” And of these, prop. 1. describes the general principles of the resistance of fluids to solid bodies moving in them. Here Mr. Robins discriminates between continued and compressed fluids, which immediately rush into the space quitted by a body moving in them, and whose parts yield to the impulse of the body without condensing and accumulating before it; and such fluids as are

imperfectly compressed, rushing into a void space, with a limited velocity, as in the case of our atmosphere, which condenses more and more before the ball as this moves quicker, and also presses the less behind it, by following it always with only a given velocity: hence it happens, that the former fluid will resist moving bodies in proportion to the square of the velocity, while the latter resists in a higher proportion. Prop. 2. is "to determine the resistance of the air to projectiles by experiments." One of the methods for this purpose is by the ballistic pendulum, placing the gun at different distances from it, by which he finds the velocity lost in passing through certain spaces of air, and consequently the force of resistance to such velocities as the body moves with in the several parts of its path. And another way was by firing balls, with a known given velocity, over a large piece of water, in which the fall and plunge of the ball could be seen, and consequently the space it passed over in a given time. By these means Mr. Robins determined the resistances of the air to several different velocities, all which showed that there was a gradual increase of the resistance, over the law of the square of the velocity, as the body moved quicker. In the remaining propositions of this chapter, he proceeds a little farther in this subject of the resistance of the air; in which he lays down a rule for the proportion of the resistance between two assigned velocities; and he shows, that when a 24 pound ball, fired with its full charge of powder, first issues from the piece, the resistance it meets with from the air is more than 20 times its weight. He farther shows, that "the track described by the flight of shot or shells is neither a parabola, nor nearly a parabola, unless they are projected with small velocities;" and that "bullets in their flight are not only depressed beneath their original direction by the action of gravity, but are also frequently driven to the right or left of that direction by the action of some other force: and in the 8th or last proposition, he pretends to show that the depths of penetration of balls into firm substances are as the squares of the velocities. But this is a mistake; for neither does it appear that his trials were sufficiently numerous or various, nor were his small leaden balls fit for this purpose; and it has appeared, from a number of trials with iron cannon balls, that the penetrations are in a much lower proportion, and that the resisting force of wood is not uniform. See Dr. Hutton's TRACTS.

In the following small tracts, added to the principles, in this volume, Mr. Robins prosecutes the subject of the resistance of the air much farther, and lays down rules for computing ranges made in the air. But these must be far from accurate, as they are founded on the two following principles, which are known, from numerous experiments, to be erroneous: viz. 1st, "That till the velocity of the projectile surpasses that of 1100 feet in a second, the resistance may be esteemed to be in the duplicate proportion of the velocity. 2d, That if the velocity be greater than that of 11 or 1200 feet in a second, then the absolute quantity of that resistance in these greater velocities will be near three times as great as it should be by a comparison with the smaller velocities." For, instead of leaping at once from the law of the square of the velocities, and ever after being about three times as much, experiments prove that the increase of the resistance above the law of the square of the velocity, takes place at first in the smallest motions, and increases gradually more and more, to a certain point, but never rises so high as to be three times that quantity, after which it decreases again. To render this evident, Dr. Hutton has inserted the following table of the actual quantities of resistances, which are deduced from accurate experiments, and which show also the nature of the law of the variations, by means of the columns of differences annexed; reserving the detail of the experiments themselves to another occasion. These resistances are, upon a ball of 1.965 inc. diameter, in avoirdupois ounces, and are for all velocities from 0 up to that of 2000 feet per second of time.

The quantity of the resistance of the air to a ball of 1.965 inc. diameter.

The additional tracts of Mr. Robins, in the latter part of this volume, which contain many useful and important matters, are numbered and titled as follows, viz. Number 1, "Of the resistance of the air. Number 2, Of the resistance of the air; together with the method of computing the motions of bodies projected in that medium. Number 3, An Account of the experiments relating to the resistance of the air, exhibited at different times before the Royal Society, in the year 1746. Number 4, Of the force of fired gunpowder, together with the computation of the velocities thereby communicated to military projectiles. Number 5, A comparison of the experimental ranges of cannon and mortars with the theory contained in the preceding papers. Practical Maxims relating to the effects and management of artillery, and the flight of shells and shot. A proposal for increasing the strength of the British navy, by changing all the guns, from the 18 pounders downwards, into others of equal weight, but of a greater bore." With several letters, and other papers, "On pointing, or the directing of cannon to strike distant objects; Of the nature and advantage of rifled barrel pieces," &c.

"I have (continues Dr. Hutton) dwelt thus long on Mr. Robins's New Principles of Gunnery, because it is the first work that can be considered as attempting to establish a practical system of gunnery, and projectiles, on good experiments, on the force of gunpowder, on the resistance of the air, and on the effects of different pieces of artillery. Those experiments are however not sufficiently perfect, both on account of the smallness of the bullets, and for want of good ranges, to form a proper theory upon. I have supplied some of the necessary desiderata for this purpose, viz. the resistance of the air to cannon balls moving with all degrees of velocity, and the velocities communicated by given charges of powder to different balls, and from different pieces of artillery. But there are still

wanting good experiments with different pieces of ordnance, giving the ranges and times of flight, with all varieties of charges, and at all different angles of elevation. A few however of those I have obtained, as in the following small table, which are derived from experiments made with a medium one-pounder gun, the iron ball being nearly 2 inches in diameter :

Powder	Elev. of gun	Veloc. of ball	Range	Time of flight
oz	9	feet	feet	"
2	15	860	4100	9
4	15	1230	5100	12
8	15	1640	6000	14 $\frac{1}{2}$
12	15	1680	6700	15 $\frac{1}{2}$
2	45	860	5100	21

The celebrated Mr. Euler added many excellent dissertations on the subject of gunnery, in his translation of Robins's Gunnery into the German language ; which were again farther improved in Brown's translation of the same into English, in the year 1777. See also Antoni's *Examen de la Poudre* ; the experiments of MM D'Arcy and Le Roy, in the *Memoirs of the Academy* in 1751 ; and D'Arcy's *Essai d'une theorie d'artillerie* in 1760 : Dr. Hutton's Tracts ; and paper on the force of fired gunpowder in the *Philos. Transf.* for 1778 : and Thompson's paper on the same subject in 1781. Of the common or parabolic theory of gunnery, Mr. Simpson gave a very neat and concise treatise in his *Select Exercises*. For a representation of various implements in GUNNERY, see pl. 2. also the article MORTAR, &c.

GUNPOWDER, a composition of nitre, sulphur, and charcoal, mixed together, and usually granulated. This easily takes fire ; and when fired, it rarefies or expands with great vehemence, by means of its elastic force. It is to this powder that we owe all the effect and action of guns, and ordnance of all sorts. So that fortification, with the modern military art, &c. in a great measure depends upon it. The above definition however is not general ; for, instead of the nitre, it has lately been discovered that the marine acid answers much better.

The invention of gunpowder is ascribed by Polydore Virgil to a chemist ; who having accidentally put some of this composition in a mortar, and covered it with a stone, it happened to take fire, and blew up the stone. Thevet says, that the person here spoken of was a monk of Friburg, named Constantine Anelzen ; but Belleforet, and other authors, with more probability, hold it to be Bartholdus Schwartz, or the Black, who discovered it, as some say, about the year 1320 ; and the first use of it is ascribed to the Venetians, in the year 1380, during the war with the Genoese. But there are earlier accounts of its use, after the accident of Schwartz, as well as before it. For Peter Mexia, in his *Various Readings*, mentions that the Moors being besieged in 1343, by Alphonus the Eleventh, king of Castile, discharged a kind of iron mortars upon them, which made a noise like thunder ; and this is seconded by what is related by Don Pedro, bishop of Leon, in his chronicle of king Alphonus, who reduced Toledo, viz. that in a sea-combat between the king of Tunis and the Moorish king of Seville, about that time, those of Tunis had certain iron tubs or barrels, with which they threw thunderbolts of fire. Du-Cange adds, that there is mention made of gunpowder in the registers of the chambers of accounts in France as early as the year 1338.

But it appears that Roger Bacon knew of gunpowder near 100 years before Schwartz was born. He tells us, in his *Treatise De Secretis Operibus Artis & Naturæ, & de Nullitate Magiæ*, cap. 6, (which is supposed by some to have been published at Oxford in 1216, and which was undoubtedly written before his *Opus Majus*, in 1267), " that from saltpetre, and other ingredients, we are able to make a fire that shall burn at what distance we please." And Dr. Plott, in his *History of*

Oxfordshire, p. 236, assures us, that these " other ingredients were explained in a MS. copy of the same treatise, in the hands of Dr. G. Langbain, and seen by Dr. Wallis, to be sulphur and wood coal." Farther, in the life of Friar Bacon in the *Biographia Britannica*, vol. 1, we are told that Bacon himself has divulged the secret of this composition in a cipher, by transposing the letters of the two words in chap. xi. of the said treatise ; where it is thus expressed : *sed tamen salis petra LURA MOPE CAN UBRE (i. e. carbonum pulvere) et sulphuris ; et sic facies tonitrum & corruscationem, si scias artificium* : and from hence the biographer apprehends the words *carbonum pulvere* were transferred to the 6th chapter of Langbain's MS. In this same chapter, Bacon expressly says, that sounds like thunder, and corruscations, may be formed in the air, much more horrible than those that happen naturally : and farther adds, that there are many ways of doing this, by which a city or an army might be destroyed : and he supposes that by an artifice of this kind Gideon defeated the Midianites with only 300 men : Judges, chap. 7. There is also another passage to the same purpose, in the treatise *De Scientia Experimentalis*. See Dr. Jebb's edition of the *Opus Majus*, p. 474.

Mr. Robins, in the preface to his *Gunnery*, apprehends that Bacon describes gunpowder, not as a new composition first proposed by himself, but as the application of an old one to military purposes, and that it was known long before his time.

But Mr. Dutens carries the antiquity of gunpowder still much higher, and refers to the writings of the ancients themselves for the proof of it. " Virgil, says he, and his commentator Servius (*Æneid*, lib. 6, v. 585), Hyginus (*Fabul.* 61 and 650), Eustathius (*ad Odyss.* λ, 234, p. 1682, lib. 1), La Cerda (*in Virgil. loc. cit.*), Valerius Flaccus (*lib. i.* 662), and many other authors (as Raphael Volatarran, in *Commentar. Cornelius Agrippa poster. Oper. de Verbo Dei*, c. 100, p. 237. Gruteri *Fax Artium Liberal.* tom. 2, p. 1236), speak in such a manner of Salmonesus's attempts to imitate thunder, as suggest to us that this prince used for that purpose a composition of the nature of gunpowder. Eustathius in particular speaks of him on this occasion, as being so very expert in mechanics, that he formed machines, which imitated the noise of thunder ; and the writers of fable, whose surprise in this respect may be compared to that of the Mexicans when they first beheld the fire-arms of the Spaniards, give out that Jupiter, incensed at the audacity of this prince, slew him with lightning, as he was employing himself in launching his thunder. But it is much more natural to suppose, that this unfortunate prince, the inventor of gunpowder, gave rise to these fables, by having accidentally fallen a victim to his own experiments. Dion (*Hist. Rom. in Caligula*, p. 662), and Joannes Antiochenus, (*in Chronico, &c. a Valesio edita*, Paris 1634, p. 804), report the very same thing of Caligula, assuring us that this emperor imitated thunder and lightning by means of certain machines, which at the same time emitted stones. Themistius informs us, that the Brachmans encountered one another with thunder and lightning, which they had the art of launching from on high at a considerable distance ; (*Themist. Oratio* 27, p. 337). And in another place he relates, that Hercules and Bacchus, attempting to assault them in a fort where they were entrenched, were so roughly received by reiterated strokes of thunder and lightning, launched upon them from on high by the besieged, that they were obliged to retire, leaving behind them an everlasting monument of the rashness of their enterprise. Agathias the historian reports of Anthemius Tralensis, that having fallen out with his neighbour Zeno the rhetorician, he set fire to his house with thunder and lightning. It appears from all these passages, that the effects ascribed to these engines of war, especially those of Caligula, Anthemius, and the Indians, could be only brought about by gunpowder. And what is still more, we find in Julius Africanus a receipt for an ingenious composition to be

thrown upon an enemy, which very nearly resembles that powder. But what places this beyond all doubt is a clear and positive passage of an author called Marcus Græcus, whose work in manuscript is in the national library at Paris, intitled *Liber Ignium*. Dr. Mead had the same also in manuscript, and a copy of that is now in Dr. Hutton's hands. The author describes several ways of encountering an enemy, by launching fire upon him; and among others gives the following: "Mix together one pound of live sulphur, two of charcoal of willow, and six of saltpetre; reducing them to a very fine powder in a marble mortar." He adds, "that a certain quantity of this is to be put into a long, narrow, and well-compacted cover, and so discharged into the air. Here we have the description of a rocket. The cover with which thunder is imitated, he represents as short, thick, but half-filled, and strongly bound with packthread; which is exactly the form of a cracker. He then treats of different methods of preparing the match, and how one squib may set fire to another in the air, by having it inclosed within it. In short, he speaks as clearly of the composition and effects of gunpowder, as any person in our times could do. Our inquiries have not yet been able precisely to determine when this author lived, but probably it was before the time of the Arabian physician Mesue, who speaks of him, and who flourished in the beginning of the 9th century. Nay, there is reason to believe that he is the same of whom Galen speaks; in which case he will be of antiquity sufficient to support what I advance." It appears too, from many authors, and many circumstances, that this composition has been known to the Chinese and Indians for thousands of years. See what is said on this head under the article *GUN*.

To this history of gunpowder it may be added, that it has lately been discovered that saltpetre or nitre is not essential to this composition, but that its place may be supplied by other substances; for new gunpowder, of double the strength of the old, has lately been made in France, by the chemists in that country, without any nitre at all; and in 1790 Dr. Hutton tried some of this new powder, that was made at Woolwich, with his eprouvette, when he found it about double the strength of the ordinary sort. This is effected by substituting, instead of the nitre, a like quantity of the marine acid.

But perhaps this new composition may not come into common and general use; both because of the great expence in procuring or making the acid, and of the trouble and danger of preventing it from taking fire by the heat in making it; for it is found to catch fire and explode from a very small degree of heat, and without the aid of a spark.

As to the preparation of gunpowder, there are various compositions of it, with respect to the proportions of the three ingredients, to be met with in pyrotechnical writings; but the process of making it up is much the same in all.

For some time after the invention of artillery, gunpowder was of a much weaker composition than that now in use, or that described by Marcus Græcus; which was chiefly owing to the weakness of their first pieces. See *GUN*. Of 23 different compositions, used at different times, and mentioned by Tartaglia in his *Quest. and Inv. lib. 3, ques. 5*, the first, which was the oldest, contained equal parts of the three ingredients. But when guns of modern structure were introduced, gunpowder of the same composition as the present came also into use. In the time of Tartaglia the cannon powder was made of 4 parts of nitre, one of sulphur, and one of charcoal; and the musket powder of 48 parts of nitre, 7 parts of sulphur, and 8 parts of charcoal; or of 18 parts of nitre, 2 parts of sulphur, and 3 parts of charcoal. But the modern composition is 6 parts of nitre, to one of each of the other two ingredients. Though Mr. Napier says, he finds the strength commonly to be greatest when the proportions are, nitre 3 lb. charcoal about 9 oz. and sulphur about 3 oz. See his paper on gunpowder in the *Trans-*

actions of the Royal Irish Academy, vol. 2. The cannon powder was in meal, and the musket powder grained. And it is certain that the graining of powder, which is a very considerable advantage, is a modern improvement. See the preface to Robins's *Math. Tracts*, p. 32.

To make gunpowder well, regard is to be had to the purity or goodness of the ingredients, as well as to the proportions of them; for the strength of the powder depends much on that circumstance, and also on the due working or mixing of them together.

To purify the nitre, by taking away the fixt or common salt, and earthy part. Dissolve it in a quantity of hot water over the fire; then filtrate it through a flannel bag into an open vessel, and set it aside to cool, and to crystallize. These crystals may in like manner be dissolved and crystallized again; and so on, till they become quite pure and white. Then put the crystals into a dry kettle over a moderate fire, which gradually increase till it begins to smoke, evaporate, lose its humidity, and grow very white: it must be kept continually stirring with a ladle, lest it should return to its former figure, by which its greasiness would be taken away: after that, so much water is to be poured into the kettle as will cover the nitre; and when it is dissolved, and reduced to the consistence of a thick liquor, it must be continually stirred with a ladle till all the moisture is again evaporated, and it be reduced to a dry and white meal.

The like regard is to be had to the sulphur; choosing that which is in large lumps, clear and perfectly yellow; not very hard, nor compact, but porous; nor yet too much shining; and if, when set on fire, it freely burns all away, it is a sign of its goodness: so likewise, if it be pressed between two iron plates that are hot enough to make it run, and in the running it appear yellow, and that which remains of a reddish colour, it is then fit for the purpose. But in case it be foul, it may be purified in this manner: Melt the sulphur in a large iron ladle, or pot, over a very gentle coal fire, well kindled, but not flaming; then scum off all that rises on the top, and swims upon the sulphur; take it presently after from the fire, and strain it through a double linen cloth, letting it pass leisurely; so will it be pure, the gross matter remaining behind in the cloth.

For the charcoal, the third ingredient, such should be chosen as is large, clear, and free from knots, well burnt, and cleaving. The charcoal of light woods is mostly preferred, as of willow, and that of the branches or twigs of a moderate thickness, as of an inch or two in diameter. Dogwood is now much esteemed for this purpose. And a method of charring the wood in a large iron cylinder has lately been recommended, and indeed proved, as yielding better charcoal than formerly. The charcoal not only concurs with the sulphur in supplying the inflammable matter, which causes the detonation of the nitre, but also greatly adds to the explosive power of it by the quantity of elastic vapour expelled during its combustion.

These three ingredients, in their purest state, being procured, long experience has shewn that they are then to be mixed together in the proportion before mentioned, to have the best effect, viz. three-quarters of the composition to be nitre, and the other quarter made up of equal parts of the other two ingredients; or, which is the same thing, 6 parts nitre, 1 part sulphur, and 1 part charcoal.

But it is not the due proportion of the materials only, which is necessary to the making of good powder; another circumstance, not less essential, is the mixing them well together: if this be not effectually done, some parts of the composition will have too much nitre in them, and others too little; and in either case there will be a defect of strength in the powder. On this subject Dr. Hutton refers to Robins, p. 119.

After the materials have been reduced to fine dust, they are mixed together, and moistened with water, or vinegar, or urine,

or spirit of wine, &c. and then beaten together with wooden pebbles for 24 hours, either by hand, or by mills, and afterwards pressed into a hard, firm, and solid cake. When dry, it is grained or corned; which is done by breaking the cake of powder into small pieces, and so running it through a sieve; by which means the grains may have any size given them, according to the nature of the sieve employed, either finer or coarser; and thus also the dust is separated from the grains, and again mixed with other manufacturing powder, or worked up into cakes again.

Powder is smoothed, or *glazed*, as it is called, for small arms, by the following operation: A hollow cylinder or cask is mounted on an axis, turned by a wheel; this cask is half filled with powder, and turned for 6 hours; and thus, by the mutual friction of the grains of powder, it is smoothed, or glazed. The fine mealy part, thus separated or worn off from the rest, is moistened and again granulated.

The Nature, Effects, &c. of Gunpowder.—When the powder is prepared as above, if the least spark be struck upon it from a steel and flint, the whole will immediately inflame, and burst out with extreme violence. This effect is not hard to account for: the charcoal part of the grain upon which the spark falls, catching fire like tinder, the sulphur and nitre are readily melted, and the former also breaks into flame; the contiguous grains at the same time undergoing the same change.

Sir Isaac Newton reasons thus upon the point: The charcoal and sulphur in gunpowder easily take fire, and kindle the nitre; and the spirit of the nitre, being thereby rarefied into vapour, rushes out with an explosion much after the manner that the vapour of water rushes out of an eolipile; the sulphur also, being volatile, is converted into vapour, and augments the explosion: add, that the acid vapour of the sulphur, namely that which distils under a bell into oil of sulphur, entering violently into the fixt body of the nitre, lets loose the spirit of the nitre, and excites a greater fermentation, by which the heat is farther augmented, and the fixt body of the nitre is also rarefied into fume; and the explosion is thereby made more vehement and quick. For if salt of tartar be mixed with gunpowder, and that mixture be warmed till it takes fire, the explosion will be far more violent and quick than that of gunpowder alone; which cannot proceed from any other cause than the action of the vapour of the gunpowder upon the salt of tartar, by which that salt is rarefied.

The explosion of gunpowder therefore arises from the violent action, by which all the mixture, being quickly and vehemently heated, is rarefied and converted into fume and vapour; which vapour, by the violence of that action becoming so hot as to shine, appears in the form of a flame.

M. De la Hire, in the History of the French Academy for 1702, ascribes all the force and effect of gunpowder to the spring or elasticity of the air inclosed in the several grains of it, and in the intervals or spaces between the grains: the powder being kindled, sets the springs of so many little parcels of air a-playing, and dilates them all at once, whence the effect; the powder itself only serving to light a fire which may put the air in action; after which the whole is done by the air alone.

But it appears from the experiments and observations of Mr. Robins, that if this air be in its natural state at the time when the powder is fired, the greatest addition its elasticity could acquire from the flame of the explosion, would not amount to five times its usual quantity, and therefore could not suffice for the 200th part of the effort which is exerted by fired powder.

To understand the force of gunpowder, it must be considered that, whether it be fired in a vacuum or in air, it produces by its explosion a permanently elastic fluid. See *Philos. Transf.*

number 295; also Hauksbee's *Phys. Mech. Exp.* p. 81. It also appears from experiment, that the elasticity or pressure of the fluid produced by the firing of gunpowder, is, *cæteris paribus*, directly as its density.

To determine the elasticity and quantity of this elastic fluid, produced from the explosion of a given quantity of gunpowder, Mr. Robins premises, that the elasticity of this fluid increases by heat, and diminishes by cold, in the same manner as that of the air; and that the density of this fluid, and consequently its weight, is the same with the weight of an equal bulk of air, having the same elasticity and the same temperature. From these principles, and from the experiments by which they are established (for a detail of which we must refer to the book itself, so often cited in these articles), he concludes, that the fluid produced by the firing of gunpowder is nearly $\frac{3}{5}$ of the weight of the generating powder itself; and that the volume or bulk of this air or fluid, when expanded to the rarity of common atmospheric air, is about 244 times the bulk of the said generating powder.—Count Saluce, in his *Miscel. Phil. Mathem. Soc. Priv. Taurin.* p. 125, makes the proportion as 222 to 1; which he says agrees with the computation of Mess. Hauksbee, Amontons, and Belidor.

Hence it appears, that any quantity of powder fired in any confined space, which it adequately fills, exerts, at the instant of its explosion against the sides of the vessel containing it, and the bodies it impels before it, a force at least 244 times greater than the elasticity of common air, or, which is the same thing, than the pressure of the atmosphere; and this without considering the great addition arising from the violent degree of heat with which it is endued at that time; the quantity of which augmentation is the next head of Mr. Robins's enquiry. He determines, that the elasticity of the air is augmented in a proportion somewhat greater than that of 4 to 1, when heated to the extreme heat of red hot iron; and supposing that the flame of fired gunpowder is not of a less degree of heat, increasing the former number a little more than 4 times, makes nearly 1000; which shews that the elasticity of the flame, at the moment of explosion, is about 1000 times stronger than the elasticity of common air, or than the pressure of the atmosphere. But, from the height of the barometer, it is known that the pressure of the atmosphere upon every square inch, is on a medium 14 $\frac{3}{4}$ lb.; and therefore 1000 times this, or 14750 lb. is the force or pressure of the flame of gunpowder, at the moment of explosion, upon a square inch, which is very nearly equivalent to 6 tons and a half. This great force however diminishes as the fluid dilates itself, and in that proportion, viz. in proportion to the space it occupies, it being only half the strength when it occupies a double space, one third the strength when triple the space, and so on.

Mr. Robins farther supposes the degree of heat above mentioned to be a kind of medium heat; but that in the case of large quantities of powder the heat will be higher, and in very small quantities lower; and that therefore in the former case the force will be somewhat more, and in the latter somewhat less, than 1000 times the force of the atmosphere.

He farther found that the strength of powder is the same in all variations in the density of the atmosphere. But that the moisture of the air has a great effect upon it; for the same quantity which in a dry season would discharge a bullet with a velocity of 1700 feet in one second, will not in damp weather give it a velocity of more than 12 or 1300 feet in a second, or even less, if the powder be bad, and negligently kept. See Robins's *Tracts*, vol. 1. p. 101, &c. Farther, as there is a certain quantity of water, which, when mixed with powder, will prevent its firing at all, it cannot be doubted but every degree of moisture must abate the violence of the explosion; and hence the effects of damp powder are not difficult to account for.

It is to be observed, that the moisture imbibed by powder does not render it less active when dried again. Indeed, if powder be exposed to very great damps without any caution, or when common salt abounds in it, as often happens through negligence in refining the nitre, in such cases the moisture it imbibes may perhaps be sufficient to dissolve some part of the nitre: which is a permanent damage that no drying can retrieve. But when tolerable care is taken in preserving powder, and the nitre it is composed of has been well purged from common salt, it will retain its force for a long time; and it is said that powder has been known to have been preserved for 50 years without any apparent damage from its age.

The velocity of expansion of the flame of gunpowder, when fired in a piece of artillery, without either bullet or other body before it, is prodigiously great, viz. 7000 feet per second, or upwards, as appears from the experiments of Mr. Robins. But Mr. Bernoulli and Mr. Euler suspect it is still much greater. And Dr. Hutton suspects it may not be less, at the moment of explosion, than 4 times as much.

It is this prodigious celerity of expansion of the flame of fired gunpowder which is its peculiar excellence, and the circumstance in which it so eminently surpasses all other inventions, either ancient or modern: for as to the momentum of these projectiles only, many of the warlike machines of the ancients produced this in a degree far surpassing that of our heaviest cannon shot or shells; but the great celerity given to these bodies cannot be in the least approached by any other means than the explosion of powder.

To prove Gunpowder. There are several ways of doing this. 1. By sight: thus, if it be too black, it is a sign that it is moist, or else that it has too much charcoal in it; so also if rubbed upon white paper, it blackens it more than good powder does: but if it be of a kind of azure colour, somewhat inclining to red, it is a sign of good powder. 2. By touching: for if in crushing it with the fingers ends, the grains break easily, and turn into dust, without feeling hard, it has too much coal in it; or if, in pressing it under the fingers upon a smooth hard board, some grains feel harder than the rest, it is a sign the sulphur is not well mixed with the nitre. Also, by thrusting the hand into a parcel of powder, and grasping it, as if to take out a handful, you will feel if it is dry and equally grained, by its evading the grasp, and running softly out of the hand. 3. By burning; and here the method most commonly followed for this purpose with us, says Mr. Robins, is to fire a small heap of it on a clean board, and to attend nicely to the flame and smoke it produces, and to the marks it leaves behind on the board: but besides this uncertain method, there are other contrivances made use of, such as powder-triers acting by a spring, commonly sold at the shops, and others again that move a great weight, throwing it upwards, which is a very bad sort of epreuve. But these machines, says Mr. Robins, though more perfect than the common powder-triers, are yet liable to great irregularities; for as they are all moved by the instantaneous stroke of the flame, and not by its continued pressure, they do not determine the force of the fired powder with sufficient certainty and uniformity. Another method is to judge from the range given to a large solid ball, thrown from a very short mortar, charged with a small quantity of powder; which is also an uncertain way, both on account of the great disproportion between the weight of the ball and powder, and the unequal resistance of the air; not to mention that it is too tedious to prove large quantities of powder in this way; for, "if each barrel of powder was to be proved in this manner, the trouble of charging the mortar, and bringing back the ball each time, would be intolerable, and the delay so great, that no business of this kind could ever be finished; and if a number of barrels are received on the merit of a few, it is great odds but some

bad ones would be amongst them, which may prove a great disappointment in time of service." These exceptions do "no-ways hold, continues Mr. Robins, against the method by which I have tried the comparative strength of different kinds of powder, which has been by the actual velocity given to a bullet, by such a quantity of powder as is usually esteemed a proper charge for the piece: and as this velocity, however great, is easily discovered by the motion which the pendulum acquires from the stroke of the bullet, it might seem a good amendment to the method used by the French (viz. that of the small mortar above mentioned) to introduce this trial by the pendulum instead of it. But though I am satisfied, that this would be much more accurate, less laborious, and readier than the other, yet, as there is some little attention and caution required in this practice, which might render it of less dispatch than might be convenient, when a great number of barrels were to be separately tried, I should myself choose to practise another method not less certain, but prodigiously more expeditious; so that I could engage, that the weighing out of a small parcel of powder from each barrel should be the greatest part of the labour; and, doubtless, three or four hands could, by this means, examine 500 barrels in a morning: besides, the machines for this purpose, as they might be made of cast iron, would be so very cheap, that they might be multiplied at pleasure." Robins, page 123. It is not certainly known what might be the particular construction of the epreuve here hinted at, but it was probably a piece of ordnance suspended like a pendulum, as he had made several experiments with a barrel in that manner. Be this however as it may, several persons, from those ideas and experiments of Mr. Robins, have made epreuves on this principle, which seems to be the best of any; and on this idea also Dr. Hutton has lately made a machine for this purpose, which has several peculiar contrivances, and advantages over all others, both in the nature of its motion, and the divisions on its arc, &c. It is a small cannon, the bore of which is about one inch in diameter, and is usually charged with 2 ounces of powder, and with powder only, as a ball is not necessary, and the strength of the powder is accurately shewn by the arc of the gun's recoil. The whole machine is so simple, easy, and expeditious, that, as Mr. Robins observed above, the weighing of the powder is the chief part of the trouble; and so accurate and uniform, that the successive repetitions or firings with the same quantity of the same sort of powder, hardly ever yield a difference in the recoil of the 100th part of itself.

To recover damaged Powder. The method used by the powder merchants is this: They put part of the powder on a sail-cloth, to which they add an equal weight of what is really good; then with a shovel they mingle it well together, dry it in the sun, and barrel it up, keeping it in a dry and proper place.

Others again, if it be very bad, restore it by moistening it with vinegar, water, urine, or brandy; then they beat it fine, sift it, and to every pound of powder add an ounce, or an ounce and a half, or two ounces (according as it is decayed), of melted nitre; and afterwards these ingredients are to be moistened and well mixed, so that nothing may be discerned in the composition; which may be known by cutting the mass, and then they granulate it as usual. In case the powder be quite spoiled, the only way is to extract the saltpetre with water, in the usual way, by boiling, filtrating, evaporating, and crystallizing: and then, with fresh sulphur and charcoal, to make it up again. On the subject of gunpowder, see Euler on Robins's Gunnery, Antoni Examen de la Poudre, Baume's Chemistry, and Thompson's Experiments in the Philos. Trans. for 1781.

According to Boerhaave, gunpowder affords a vapour capable of resisting the plague and other contagious diseases. It is also reckoned of service as a topic in cutaneous diseases.

It is enacted by 5 and 11 of Geo. I. and 5 Geo. II. c. 20. that gunpowder be carried to any place in a covered carriage; the barrels being close-jointed; or in casks and bags of leather, &c. And persons keeping more than 200 pounds weight of gunpowder at one time, within the cities of London and Westminster, or the suburbs, &c. are liable to forfeitures if it be not removed; and justices of peace may issue warrants to search for, seize, and remove the same.

GUN-Shot Wounds. See SURGERY.

GUN-Smith, a maker of small fire-arms, as muskets, fowling-pieces, pistols, &c.

GUN-Smithery, the business of a gun-smith, or the art of making fire-arms of the smaller sort, as muskets, fowling-pieces, pistols, &c. The principal part of these instruments is the barrel, which ought to have the following properties. 1. Lightness, that it may incommode the person who carries it as little as possible. 2. Sufficient strength and other properties requisite to prevent its bursting by a discharge. 3. It ought to be constructed in such a manner as not to recoil with violence. And, 4. it ought to be of sufficient length to carry the shot to as great a distance as the force of the powder employed is capable of doing.

The manufacture of fire-arms is now carried to such a degree of perfection by different European nations, that it may perhaps be justly doubted whether any farther improvement in the requisites just mentioned can be made. For the materials, the softest iron that can be procured is to be made use of. The best in this country are formed of *stubs*, as they are called, or old horse-shoe nails; which are procured by the gun-smiths from farriers, and from poor people who subsist by picking them up on the great roads leading to London. These are sold at about 10s. per cwt. and 28 pounds are requisite to form a single musket barrel. The method of manufacturing them from this material is as follows: A hoop of about an inch broad, and six or seven inches diameter, is placed in a perpendicular situation, and the stubs, previously well cleaned, piled up in it with their heads outermost on each side, till the hoop is quite filled and wedged tight with them. The whole then resembles a rough circular cake of iron; which being heated to a white heat, and then strongly hammered, coalesces into one solid lump. The hoop is now removed, and the heatings and hammerings repeated till the iron is rendered very tough and close in the grain; when it is drawn out into pieces of about 24 inches in length, half an inch or more in breadth, and half an inch in thickness.

Four of these pieces are employed for one barrel; but in the ordinary way a single bar of the best soft iron is employed. The workmen begin with hammering out this into the form of a flat ruler, having its length and breadth proportioned to the dimensions of the intended barrel. By repeated heating and hammering this plate is turned round a tempered iron rod called a *mandril*, the diameter of which is considerably smaller than the intended bore of the barrel. One of the edges of the plate being laid over the other about half an inch, the whole is heated and welded by two or three inches at a time, hammering it briskly, but with moderate strokes, upon an anvil which has a number of semicircular furrows in it, adapted to barrels of different sizes. Every time the barrel is withdrawn from the fire, the workman strikes it gently against the anvil once or twice in an horizontal direction. By this operation the particles of the metal are more perfectly consolidated, and every appearance of a seam in the barrel is obliterated. The mandril being then again introduced into the cavity of the barrel, the latter is very strongly hammered upon it in one of the semicircular hollows of the anvil, by small portions at a time; the heatings and hammerings being repeated until the whole barrel has undergone the operation, and its parts rendered as

perfectly continuous as if they had been formed out of a single piece. To effect this completely, three welding heats are necessary when the very best iron is made use of, and a greater number for the coarser kinds. The French workmen imagine, that by giving the barrel, while in the fire, slight horizontal strokes with the hammer, so as to communicate a vibratory motion to the iron, those particles are thrown off which are in a state of fusion and cannot easily be converted into malleable iron: but considering the great number of operations already described which the metal has undergone, we can scarce suppose this to be of much consequence.

The next operation in forming the barrels is the boring of them, which is done in the following manner: Two beams of oak, each about six inches in diameter, and six or seven feet long, are placed horizontally and parallel to one another: having each of their extremities mortised upon a strong upright piece about three feet high, and firmly fixed. A space of three or four inches is left between the horizontal pieces, in which a piece of wood is made to slide by having at either end a tenon let into a groove which runs on the inside of each beam throughout its whole length. Through this sliding piece a strong pin or bolt of iron is driven or screwed in a perpendicular direction, having at its upper end a round hole large enough to admit the breach of the barrel, which is secured in it by means of a piece of iron that serves as a wedge, and a vertical screw passing through the upper part of the hole. A chain is fastened to a staple in one side of the sliding piece which runs between the two horizontal beams; and passing over a pulley at one end of the machine, has a weight hooked on to it. An upright piece of timber is fixed above this pulley and between the ends of the beams, having its upper end perforated by the axis of an iron crank furnished with a square socket; the other axis being supported by the wall, or by a strong post, and loaded with a heavy wheel of cast iron to give it force. The axes of this crank are in a line with the hole in the bolt already mentioned.—The borer being then fixed into the socket of the crank, has its other end, previously well oiled, introduced into the barrel, whose breech part is made fast in the hole of the bolt: the chain is then carried over the pulley, and the weight hooked on; the crank being then turned with the hand, the barrel advances as the borer cuts its way, till it has passed through the whole length.—The boring bit consists of an iron rod somewhat longer than the barrel, one end of which fits the socket of the crank; the other is adapted to a cylindrical piece of tempered steel about an inch and a half in length, having its surface cut after the manner of a perpetual screw, with five or six threads, the obliquity of which is very small. The breadth of the furrows is the same with that of the threads, and their depth sufficient to let the metal cut by the threads pass through them easily. Thus the bit gets a strong hold of the metal; and the threads, being sharp at the edges, scoop out and remove all the inequalities and roughness from the inside of the barrel, and render the cavity smooth and equal throughout. A number of bits, each a little larger than the former, are afterwards successively passed through the barrel in the same way, until the bore has acquired the magnitude intended. By this operation the barrel is very much heated, especially the first time the borer is passed through it, by which means it is apt to warp. To prevent this in some measure, the barrel is covered with a cloth kept constantly wetted, which not only preserves the barrel from an excess of heat, but likewise preserves the temper of the bit from being destroyed. The borer itself must also be withdrawn from time to time; both to clean it from the shavings of the metal and to oil it, or repair any damages it may have sustained. Every time a fresh bit has been passed through the barrel, the latter must be carefully examined, to see if it has warped; and likewise if there are any spots, by the work-

men called *blacks*, on its inside. When warped, it must be straightened on the anvil; for which a few slight strokes on the convex parts will be sufficient; and this is termed *setting up* the barrel. When black spots are perceived, the corresponding part on the outside must be marked, and driven in by gentle strokes with the hammer, when they will be completely removed by passing the borer another time through the piece.

The equality of the bore is of the utmost consequence to the perfection of a barrel; inasmuch that the greatest possible accuracy in every other respect will not make amends for any deficiency in this respect. The method used by gunsmiths to ascertain this is by a cylindrical plug of tempered steel highly polished, about an inch in length, and fitting the bore exactly. This is screwed upon the end of an iron rod, and introduced into the cavity of the barrel, where it is moved backwards and forwards; and the places where it passes with difficulty being marked, the boring bit is repeatedly passed until it moves with equal ease through every part. Any person who wishes to know the merit of his piece in this respect, may do it with tolerable accuracy by means of a plug of lead cast on a rod of iron; or even by a musket ball filed exactly to the bore, and pushed through the barrel by a ramrod; taking care, however, not to use much force lest the ball be flattened, and its passage thus rendered difficult.

The last step towards the perfection of the inside of the barrel is termed *fine boring*; by which is meant the smoothing it in such a manner as to remove all marks and inequalities left by the borer. The fine-borer resembles the other in its general construction; but instead of the piece of steel cut in form of a screw which belongs to that, it is furnished with a square broach 10 or 12 inches long, highly polished, and very sharp, by which means it cuts the metal very smoothly. It is found to answer the purpose best when only two of its edges are allowed to work; the other two are covered with slips of oiled paper, one or more additional slips being put on each time that the instrument is passed through the barrel. The fine-borer is frequently passed through, from the muzzle to the breech, and from the breech to the muzzle, until the whole inside presents a perfectly equal and polished surface; the barrel being likewise examined and set up, if requisite, after each time. It is absolutely necessary that this instrument should be perfectly true, and not in the least cast or warped in the tempering.

Besides the operations above described, another, called *polishing*, is usually performed on gun-barrels, though it is doubtful whether this last be attended with any good effect or not. It is performed by a cylinder of lead, five or six inches long, cast upon a rod of iron, and filed exactly to the bore. The lead being then covered with very fine emery and oil, is wrought backwards and forwards through the whole length of the barrel, until the inside has acquired the requisite degree of polish. The disadvantages of this operation are, that it is scarce possible to perform it without pressing more upon one part than another, and thus producing some degree of inequality on the inside, which is of the very worst consequence to fire-arms. The polish thus given is likewise very perishable; so that the fine-boring may justly be considered as the last operation necessary for the inside of a barrel; and it is then proper to give the external form and proportions by means of a file. For this purpose, four faces are first formed upon it, then eight, then 16; and so on till it be quite round, excepting the part next the breech, called the *reinforced part*, which is always left of an octagonal form. It being absolutely necessary that the barrel should be equally thick on every side, gunsmiths employ, for accomplishing this purpose, a particular tool named a *compass*. This consists of an iron-rod bent in such a manner as to form two parallel branches about an inch distant from one another. One of these branches is introduced into the barrel,

and kept closely applied to the side, by means of one or more springs with which it is furnished; the other descends parallel to this on the outside, and has several screws passing through it with their points directed to the barrel. By screwing these until their points touch the surface of the barrel, and then turning the instrument round within the bore, we perceive where the metal is too thick, and how much it must be reduced, in order to render every part perfectly equal throughout its circumference. It may be made long enough to reach the whole length of the barrel, though it will be more convenient to have it only half as much, and to introduce it first at one end and then at the other. Instead of rounding the barrel by means of a file and compass, however, some people do so by turning it in a lathe; which is no doubt more expeditious, though neither so certain nor exact. A spindle as long as a gun-barrel cannot, without great difficulty, be prevented from springing considerably under the tool employed to reduce or smooth it in turning; whence it is found, that by this operation barrels are more frequently warped than by all the borings they undergo; and there is now this farther inconvenience, that they cannot be set up as formerly, without danger of destroying them entirely.

The barrels being thus bored and formed externally, it is customary with the gunsmiths in France to folder on the loops and aim before they breech the barrel. The English, however, do not restrict themselves in this manner: for as soft folder is sufficient for fastening on these, they never use any other; while the French, who use hard folder, must of consequence employ a great heat. Thus the inside is roughened sometimes so considerably, that it is necessary to repeat the fine boring; which could not be done without injuring the threads of the screw formed for the breech, if the barrel were prepared for the latter without foldering on the former.

The first tool employed in forming the breech-screw is a plug of tempered steel, somewhat conical, with the threads of a male screw upon its surface, and by the workman termed a *screw tap*. This being introduced into the barrel, and worked from left to right and back again, until it has marked out the four first threads of the screw, another less conical tap is introduced; and when this has carried the impression of the screw as far as it is intended to go, a third one, nearly cylindrical, is made use of, scarcely differing from the plug of the breech intended to fill the screw thus formed in the barrel. The plug itself has its screw formed by means of a screw-plate of tempered steel, with several female screws, corresponding with the taps employed for forming that in the barrel. Seven or eight threads are a sufficient length for a plug: they ought to be neat and sharp, so as completely to fill the turns made in the barrel by the tap. The breech-plug is then to be case-hardened, or to have its surface converted into steel, by covering it with shavings of horn, or the parings of the hoofs of horses, and keeping it for some time red hot; after which it is plunged in cold water.

The only thing now requisite for completing the barrels is to give them a proper colour; as a preparation for which their outside is first to be neatly polished with oil and emery. This being done, it was formerly the custom to give such a degree of heat as would make them blue throughout; but as this cannot be effected without a partial calcination of the surface, which of consequence affects the inside also, the blue colour has been for some time disused, and a brown one substituted in its place. To give this colour, the pieces are first rubbed over with aquafortis or spirit of salt diluted with water; after which they are laid by till a complete coat of rust is formed upon them: a little oil is then applied; and the surface being rubbed dry, is polished by means of a hard brush and bees-wax.

Thus the common musket-barrels for the purposes especially of sportsmanship are made; but there are some other methods

of manufacture, by which the barrels are made to differ in some respects from those just described, and are thought to be considerably improved. One kind of these are called *twisted barrels*; and by the English workmen are formed out of the plates made of *stubs* as above described. Four of these, of the size already mentioned, are requisite to make one barrel. One of them heated red hot for five or six inches is turned like a cork-screw by means of the hammer and anvil; the remaining parts being treated successively in the same manner until the whole is turned into a spiral, forming a tube, the diameter of which corresponds with the bore of the intended barrel. Four are generally sufficient to form a barrel of the ordinary length, *i. e.* from 32 to 38 inches; and the two which form the breech or strongest part, called the *reinforced part*, are considerably thicker than those which form the muzzle or fore part of the barrel. One of these tubes is then welded to a part of an old barrel to serve as an handle; after which the turns of the spiral are united by heating the tube two or three inches at a time to a bright white heat, and striking the end of it several times against the anvil in a horizontal direction with considerable strength, which is called *jumping the barrel*; and the heats given for this purpose are called *jumping heats*. The next step is to introduce a mandril into the cavity, and to hammer the heated portion lightly in order to flatten the ridges or burrs raised by the jumping at the place where the spirals are joined. As soon as one piece is jumped throughout its whole length, another is welded to it, and treated in the same manner, until the four pieces are united, when the part of the old barrel is cut off, as being no longer of any use. The welding is repeated three times at least, and is performed exactly in the same manner as directed for plain barrels; and the piece may afterwards be finished according to the directions already given.

The operation for the French twisted barrels is very different from that just mentioned, and much more exceptionable. It consists in heating the barrel by a few inches at a time to a strong red heat; one end is then screwed into a vice, and a square piece of iron with an handle like an augre is introduced into the other. By means of these the fibres of the heated portion are twisted into a spiral direction, which is supposed to resist the effort of the inflamed powder better than the other. To render this operation complete, however, it must be observed, that when once the several portions of the barrel have been twisted, the subsequent heats ought not to be very great, or the grain of the metal will regain its former state, and the barrel be no better for the twisting than before. To twist a barrel in this manner, also, it will be necessary to forge it at least half a foot longer than it is intended to be, that a sufficient length may be kept cold at each end to give a sufficient purchase to the vice and twisting instrument; and these portions must afterwards be cut off before the barrel is bored, or two pieces of an old barrel may be welded to the muzzle and breech of that which is to be twisted, and cut off when the operation is over. These pieces may also be made stronger than usual to resist the force of the vice and twisting instrument; and in order to give the latter a firmer hold, the cavity of the muzzle may be made of a square form. The English workmen are unanimously of opinion that this method of twisting is really injurious to the barrel, by straining the fibres of the metal. At any rate, from the injudicious methods followed by the French artists, the greatest part of their barrels, said to be twisted, are not so in reality; there being at least six or seven inches at the muzzle, and seven or eight at the breech, which are not affected by the operation.

The French *ribbon barrels* have a great resemblance to the English twisted ones; but the process for making them is much more operose, though it seems not to possess any real advantage over that used by the English gun-smiths. A plate

of iron, about the twelfth part of an inch in thickness, is turned round a mandril, and welded its whole length in the same manner as a plain barrel. Upon this slight barrel, which is called the *lining*, a plate of iron about an inch in breadth, and bevelled off at the edges, is by means of successive heats rolled in a spiral direction; after which it is termed the *ribbon*, and must have a thickness corresponding with that part of the barrel which it is to form. As it would, however, be difficult to form a ribbon of sufficient length for the whole barrel, it is made in several pieces; and when one piece is rolled on, another is welded to its end, and the operation continued until the lining be entirely covered. The edges are so much bevelled, that the one folds over the other about a quarter of an inch. After the ribbon is all rolled on, the barrel must be heated by two or three inches at a time, and the turns of the spiral united to each other and to the lining by being welded in the same manner as the twisted barrel; though, from what has been said of the construction of these barrels, it is plain that the operation of *jumping* cannot be admitted in them. The barrel is afterwards bored in such a manner that almost the whole of the lining is cut out, and scarce any thing left but the ribbon with which the lining was covered.

The superiority of twisted and ribbon barrels over the plain kind gave occasion to a third sort named *wired barrels*. These were invented by an ingenious workman at Paris named *Barrois*; whose method was as follows: Upon a thin barrel, filed and dressed as usual, he rolled, as close as possible, and in a spiral direction, a tempered iron wire about the thickness of a crow-quill, the first layer covering only the reinforced part. The turns of the wire were foldered to each other and to the barrel with a composition which he kept a secret. The wired part was then filed smooth and bright, but not so much as to weaken it; a second layer of wire was applied over the first, extending two-thirds of the length of the barrel; and this being smoothed and brightened like the first, a third layer was applied, which covered the two former and reached quite to the muzzle. The barrels made after this manner are supposed to be much superior to others, though the supposition seems not to be well founded.

The Spanish barrels have been long held in great estimation; yet as the Spanish iron is universally allowed to be unusually good, it is probable that the superiority of their barrels is owing more to the goodness of the materials than to the skill of the workmen. It must be observed, however, that instead of making the plates overlap *a little* in the place where they join, they give one of them a complete turn; so that every Spanish barrel may be said to be double throughout its whole length. The different portions of the iron are also forged in such a manner, that the grain of the iron is disposed in a spiral manner; whence it has the same effect with a ribbon or twisted barrel. The outside is finished by turning them in a lathe; whence probably they are always less elegantly wrought than the French and English pieces. The great value put upon them is also thought to be more owing to fancy than to any real good qualities they possess. Formerly they were made from three to three feet and a half long; their bore being such as to admit a bullet from 22 to 24 in the pound; and their weight from three to three pounds and an half. The reinforced part extends two-fifths of the length; and at 10 or 12 inches from the breech is placed a *sight*, such as is usually put upon rifle-barrels, or those intended only for ball. According to Espinas, arquebuss-bearer to Philip IV. the weight of a Spanish barrel ought to be four pounds and an half when the length is 42 inches; but both in weight and length they are now much reduced, and seldom exceed the dimensions already mentioned. Next to the barrels made at Madrid, the most esteemed are those of Bustindui and St. Olabe at Placentia in

Biscay; and of Jeun and Clement Padwesteva, Eudal Pous, and Martin Marechal, at Barcelona; the usual price of them being about 3l. 10s. sterling.

Having now described the method of forging barrels, we shall next proceed to give an account of those imperfections to which they are sometimes liable, and which render them apt to burst or recoil with violence. The principal imperfections are the *chink*, *crack*, and *flaw*. The first is a small rent in the direction of the length of the barrel; the second across it; and the third is a kind of scale or small plate adhering to the barrel by a narrow base, from which it spreads out like the head of a nail from its shank, and, when separated, leaves a pit or hollow in the metal. The chink or flaw are of much worse consequence than the crack in fire-arms, the force of the powder being exerted more upon the circumference than the length of the barrel. The flaw is much more frequent than the chink, the latter scarce ever occurring but in plain barrels formed out of a single plate of iron, and then only when the metal is deficient in quality. When flaws happen on the outside, they are of no great consequence; but in the inside they are apt to lodge moisture and foulness which corrode the iron, and thus the cavity enlarges continually till the piece bursts. This accident, however, may arise from many other causes besides the defect of the barrel itself. The best pieces will burst when the ball is not sufficiently rammed home, so that a space is left between it and the powder. A very small windage or passage for the inflamed powder between the sides of the barrel and ball will be sufficient to prevent the accident; but if the ball has been forcibly driven down with an iron ramrod, so as to fill up the cavity of the barrel very exactly, the piece will almost certainly burst, if only a very small space be left between it and the powder; and the greater the space is, the more certainly does the event take place. Of this Mr. Robins has given a remarkable instance, accounting at the same time for the phenomenon. "A moderate charge of powder (says he), when it has expanded itself through the vacant space and reaches the ball, will, by the velocity each part has acquired, accumulate itself behind the ball, and will thereby be condensed prodigiously: whence, if the barrel be not of an extraordinary strength in that part, it must infallibly burst. The truth of this I have experienced in a very good Tower musket forged of very tough iron: for charging it with 12 pennyweight of powder, and placing the ball loosely 16 inches from the breech; on the firing of it, the part of the barrel just behind the bullet was swelled out to double its diameter like a blown bladder, and two large pieces of two inches in length were burst out of it." A piece will frequently burst from having its mouth stoppered up with earth or snow; which accident sometimes happens to sportsmen in leaping a ditch, in which they have assisted themselves with their fowling-piece, putting the mouth of it to the ground; and when this did not happen, it is only to be accounted for from the stoppage being extremely slight. For the same reason a musket will certainly burst if it be fired with the muzzle immersed only a very little way in water. It will also burst from an overcharge; but when such an accident happens in other circumstances, it is most probably to be attributed to a defect in the workmanship, or in the iron itself. These defects are principally an imperfection in the welding, a deep flaw having taken place, or an inequality in the bore; which last is the most common of any, especially in the low-priced barrels. The reason of a barrel's bursting from an inequality in the bore is, that the elastic fluid, set loose by the inflammation of the powder, and endeavouring to expand itself in every direction, being repelled by the stronger parts, acts with additional force against the weaker ones, and frequently bursts through them, which it would not have done had the sides been equally thick and strong throughout. With regard to defects arising from

the bad quality of the iron, it is impossible to say any thing certain. As the choice of the materials depends entirely on the gunsmith, the only way to be assured of having a barrel made of proper metal is to purchase it from an artist of known reputation, and to give a liberal price for the piece.

The recoil of a piece becomes an object of importance only when it is very great; for every piece recoils in some degree when it is discharged. The most frequent cause of an excessive recoil is an inequality in the bore of the barrel; and by this it will be occasioned even when the inequality is too small to be perceived by the eye. The explanation of this upon mechanical principles indeed is not very easy: for as it is there an invariable law, that action and reaction are equal to one another, we should be apt to suppose that every time a piece is discharged it should recoil with the whole difference between the velocity of the bullet and that of the inflamed powder. The cause to which too great a recoil in muskets has been usually attributed, is the placing of the touch-hole at some distance from the breech plug; so that the powder is fired about the middle, or towards its fore-part, rather than at its base. To avoid this, some artists form a groove or channel in the breech-plug as deep as the second or third turn of the screw; the touch-hole opening into this channel, and thus firing the powder at its very lowest part. It appears, however, from a number of experiments made upon this subject by M. le Clerc, that it made very little difference with regard to the recoil, whether the touch-hole was close to the breech or an inch distant from it. The only circumstance to be attended to with respect to its situation therefore is, that it be not quite close to the breech-plug; as in such a case it is found to be more apt to be choked up than when placed about a quarter of an inch from it.

The only other circumstance now to be determined with regard to musket-barrels is their proper length. Formerly it was supposed that the longer they were made, the greater would be the distance to which they carried the shot, and that without any limitation. This opinion continued to prevail till about half a century ago, when it was first proposed as a doubt whether long barrels carried farther than short ones. With regard to cannon, indeed, it had long before this time been known that they might be made too long; and Balthazar Killar, a celebrated cannon-founder in the reign of Louis XIV. was able to account for it. When asked by Mons. Suriry de St. Remy, why the culverin of Nancy, which is 22 feet long, did not carry a ball equally far with a shorter piece? he replied, that "the powder, when inflamed, ought to quit the cavity of the piece in a certain time, in order to exert its whole force upon the bullet; by a longer stay, part of the force is lost; and the same cause may produce an inequality in the shots, by giving a variation to the bullet, so as to destroy its rectilinear course, and throw it to one side or other of the mark." Mr. Robins, who on this, as well as every other question in gunnery, has almost exhausted the subject, informs us, that "if a musket-barrel, of the common length and bore, be fired with a leaden bullet and half its weight of powder, and if the same barrel be afterwards shortened one half and fired with the same charge, the velocity of the bullet in this shortened barrel will be about one-sixth less than what it was when the barrel was entire; and if, instead of shortening the barrel, it be increased to twice its usual length, when it will be near eight feet long, the velocity of the bullet will not hereby be augmented more than one-eighth part. And the greater the length of the barrel is in proportion to the diameter of the bullet, and the smaller the quantity of powder, the more inconsiderable will these alterations of velocity be." From these considerations it appears, that the advantages gained by long barrels are by no means equivalent to the disadvantages arising from the weight and incumbrance of using them; and from a multitude of experiments it is now apparent, that

any one may choose what length he pleases, without any sensible detriment to the range of his piece. The most approved lengths are from 32 to 38 inches.

An opinion has generally prevailed among sportsmen, that by some unknown manœuvre the gunsmith is able to make a piece, loaded with small shot, throw the contents so close together, that even at the distance of 40 or 50 paces the whole will be confined within the breadth of a hat. From such experiments as have been made on this subject, however, it appears, that the closeness or wideness with which a piece throws its shot is liable to innumerable variations from causes which no skill in the gunsmith can possibly reach. So variable are these causes, that there is no possibility of making the same piece throw its shot equally close twice successively. In general, however, the closer the wadding is, the better disposed the shot seems to be to fall within a small compass. The closeness of the shot therefore would seem to depend in a great measure on preventing the flame of the powder from insinuating itself among its particles: whence the following method is said to be practised with success by those who shoot for a wager at a mark with small shot; *viz.* to put in the shot by small quantities at a time, ramming down a little tow or thin paper over each; so as to fill the interstices of the grains, and thus prevent the flame from getting in amongst the grains and scattering them. In firing with small shot, a curious circumstance sometimes occurs, *viz.* that the grains, instead of being equally distributed over the space they strike, are thrown in clusters of 10, 12, 15, or more; whilst several considerable spaces are left without a grain in them. Sometimes one-third or one half of the charge will be collected into a cluster of this kind; nay, sometimes, though much more rarely, the whole charge will be collected into one mass, so as to pierce a board near an inch thick at the distance of 40 or 45 paces. Small barrels are said to be more liable to this clustering than large ones; and M. de Marolles informs us, that this is especially the case when the barrels are new, and likewise when they are fresh-washed; though he acknowledges that it did not always happen with the barrels he employed even after they were washed. It is probable, therefore, that the closeness of the shot depends on some circumstance relative to the wadding rather than to the mechanism of the barrel.

GUNTER (Edmund), an excellent English mathematician and astronomer, was born in Hertfordshire in 1581, and studied at Westminster-school; from whence he removed to Oxford, where he took the degree of master of arts in 1606, and afterwards entered into holy orders. In 1615 he took the degree of bachelor of divinity: but being peculiarly eminent for his knowledge in the mathematics, he had two years before been chosen professor of astronomy in Gresham-college, London; where he distinguished himself by his lectures and writings. He invented a small portable quadrant; and also the famous line of proportions, which, after the inventor, is called *Gunter's scale*. He likewise published *Canon Triangulorum*; and a work, intitled, *Of the Sector, Cross-staff, and other Instruments*. This last was published, with an English translation of his *Canon Triangulorum*, in 4to, by Samuel Foster professor of Gresham-college. Mr. Gunter died at that college in 1626.

GUNTER'S *Line*, a logarithmic line, usually graduated upon scales, sectors, &c. It is also called the *line of lines* and *line of numbers*: being only the logarithms graduated upon a ruler, which therefore serves to solve problems instrumentally in the same manner as logarithms do arithmetically. It is usually divided into 100 parts, every tenth whereof is numbered, beginning with 1 and ending with 10: so that if the first great division, marked 1, stand for one tenth of any integer, the next division, marked 2, will stand for two-tenths, 3, three-tenths,

and so on; and the intermediate divisions will in like manner represent 100th-parts of the same integer. If each of the great divisions represent 10 integers, then will the lesser divisions stand for integers; and if the greater divisions be supposed each 100, the subdivisions will be each 10.

Use of GUNTER'S Line. 1. *To find the product of two numbers.* From 1 extend the compasses to the multiplier; and the same extent, applied the same way from the multiplicand, will reach to the product. Thus if the product of 4 and 8 be required, extend the compasses from 1 to 4, and that extent laid from 8 the same way will reach to 32, their product. 2. *To divide one number by another.* The extent from the divisor to unity will reach from the dividend to the quotient: thus, to divide 36 by 4, extend the compasses from 4 to 1, and the same extent will reach from 36 to 9, the quotient sought. 3. *To three given numbers to find a fourth proportional.* Suppose the numbers 6, 8, 9: extend the compasses from 6 to 8; and this extent, laid from 9 the same way, will reach to 12, the fourth proportional required. 4. *To find a mean proportional between any two given numbers.* Suppose 8 and 32: extend the compasses from 8, in the left-hand part of the line, to 32 in the right; then bisecting this distance, its half will reach from 8 forward, or from 32 backward, to 16, the mean proportional sought. 5. *To extract the square-root of any number.* Suppose 25: bisect the distance between 1 on the scale and the point representing 25; then the half of this distance, set off from 1, will give the point representing the root 5. In the same manner the cube root, or that of any higher power, may be found by dividing the distance on the line between 1 and the given number into as many equal parts as the index of the power expresses; then one of those parts, set from 1, will find the point representing the root required.

GUNTER'S *Quadrant*, one made of wood, brass, &c. containing a kind of stereographic projection of the sphere, on the plane of the equinoctial; the eye being supposed placed in one of the poles.

GUNTER'S *Scale*, called by navigators simply the *gunter*, is a large plain scale, generally two feet long, and about an inch and a half broad, with artificial lines delineated on it, of great use in solving questions in trigonometry, navigation, &c.

GUNWALE, or GUNNEL, is the uppermost wale of a ship, or that piece of timber which reaches on either side from the quarter-deck to the fore-castle, being the uppermost bend which finishes the upper works of the hull, in that part in which are put the stanchions which support the waste-trees.

GURK, an episcopal town of Carinthia in Germany, seated on the river Gurk, in E. long. 14. 15. N. lat. 47. 10.

GURNARD, in ichthyology. See TRIGLA.

GUSTAVIA, in botany; a genus of the polyandria order, belonging to the monadelphia class of plants. There is no calyx; the petals very numerous; the berry multilocular; the seeds appendaged.

GUTTA ROSACEA, in medicine, denotes a red or pimpled face; a disease which, though not always owing its existence to hard drinking, is nevertheless most incident to tipplers of strong beer, wines, spirits, &c.

GUTTA SERENA, a disease in which the patient, without any apparent fault in the eye, is deprived of sight. See SURGERY.

GUTTA, in architecture, are ornaments in the form of little cones used in the Doric cornice, or on the architrave underneath the triglyphs, representing a sort of drops or bells.

GUTTY, in heraldry, a term used when any thing is charged or sprinkled with drops. In blazoning, the colour of the drops is to be named; as gutty of sable, of gules, &c.

GUY (Thomas), an eminent bookseller, founder of the hospital for sick and lame in Southwark bearing his name, was the son of Thomas Guy, lighterman and coal-dealer in Horsley-

down, Southwark. He was put apprentice, in 1660, to a bookfeller in the porch of Mercer's-chapel; and set up trade with a stock of about 200*l.* in the house that forms the angle between Corn-hill and Lombard-street. The English Bibles being at that time very badly printed, Mr. Guy engaged with others in a scheme for printing them in Holland, and importing them; but this being put a stop to, he contracted with the university of Oxford for their privilege of printing them, and carried on a great bible-trade for many years to a considerable advantage. Thus he began to accumulate money, and his gains rested in his hands; for, being a single man, and very penurious, his expences could not be great when it was his custom to dine on his shop-counter with no other table-covering than an old newspaper: he was moreover as little scrupulous about the style of his apparel. The bulk of his fortune, however, was acquired by purchasing seamen's tickets during queen Anne's wars, and by South-Sea stock in the memorable year 1720. To show what great events spring from trivial causes, it may be observed, that the public owe the dedication of the greatest part of his immense fortune to charitable purposes, to the indifereet officiousness of his maid-servant in interfering with the mending of the pavement before the door. Guy had agreed to marry her; and, preparatory to his nuptials, had ordered the pavement before his door, which was in a neglected state, to be mended, as far as to a particular stone which he pointed out. The maid, while her matter was out, innocently looking on the paviers at work, saw a broken place that they had not repaired, and mentioned it to them: but they told her that Mr. Guy had directed them not to go so far. Well, says she, do you mend it: tell him I bade you, and I know he will not be angry. It happened, however, that the poor girl presumed too much on her influence over her careful lover, with whom a few extraordinary shillings expence turned the scale totally against her: the men obeyed; Guy was enraged to find his orders exceeded, his matrimonial scheme was renounced, and so he built hospitals in his old age. In the year 1707 he built and furnished three wards, on the north side of the outer court of St. Thomas's Hospital in Southwark, and gave 100*l.* to it annually for eleven years preceding the erection of his own hospital: and, some time before his death, erected the stately iron gate, with the large houses on each side, at the expence of about 3000*l.* He was 76 years of age when he formed the design of building the hospital contiguous to that of St. Thomas's, which bears his name, and lived to see it roofed in; dying in the year 1724. The charge of erecting this vast pile amounted to 18,793*l.* and he left 219,499*l.* to endow it; a much larger sum than had ever been dedicated to charitable uses in this kingdom by any one man. He erected an alms-house with a library at Tamworth in Staffordshire (the place of his mother's nativity, and for which he was representative in parliament) for 14 poor men and women; and for their pensions, as well as for the putting out poor children apprentices, bequeathed 125*l.* a-year. Lastly, he bequeathed 1000*l.* to every one who could prove themselves in any degree related to him.

GUY, a rope used to keep steady any weighty body whilst it is hoisting or lowering, particularly when the ship is shaken by a tempestuous sea.

GUY is likewise a large slack rope, extending from the head of the main-mast to the head of the fore-mast, and having two or three large blocks fastened to the middle of it. This is chiefly employed to sustain the tackle used to hoist in and out the cargo of a merchant ship, and is accordingly removed from the mast-head as soon as the vessel is laden or delivered.

GUY'S CLIFF, in Warwickshire, a great cliff on the west side of the Avon and the north side of Warwick, where in the Britons' time was an oratory, and in that of the Saxons an hermitage, where Guy earl of Warwick, who is said to have re-

tired to it after his fatigues by the toils and pleasures of the world, built a chapel, and colihabited with the hermit; and that from thence it had the name. This hermitage was kept up to the reign of Henry VI. when Richard Beauchamp earl of Warwick established a chantry here, and in memory of the famous Guy erected a large statue of him in the chapel eight feet in height, and raised a roof over the adjacent springs. The chapel is in the parish of St. Nicholas, in the suburbs of Warwick.

GUYON (Johanna Mary Bouriers de la Mothe), a French lady, memorable for her writings, and for her sufferings in the cause of Quietism, was descended from a noble family, and born at Montargis in 1648. She shewed some extraordinary symptoms of illumination from her earliest infancy, and tried to take the veil before she was of age to dispose of herself; but her parents obliged her to marry a gentleman to whom they had promised her. She was a widow at the age of 28; when distinguishing herself in, and making many converts to, the way of contemplation and prayer known by the name of *Quietism*, complaints were made of her spiritualism, and she was confined by order of the king, and severely examined for eight months. She was discharged; but was afterwards involved in the persecution of the archbishop of Cambrai, and thrown into the Bastille, where she underwent many examinations: but nothing being made out against her, she once more obtained her liberty, and lived private till her death, in 1717. She spent her latter years in mystical reveries; covering her tables, ceilings, and every thing that would receive them, with the traces of a visionary imagination. Her pious verses were collected after her death in 5 vols. intitled, *Cantiques spirituels, ou d'Emblemes sur l'Amour Divin*. Her publications were, *Le moyen court et tres facile de faire Oraisons*; and *Le Cantique des Cantiques de Salomon interprete selon le sens mystique*; which were condemned by the archbishop of Paris.

GWINIAD, in ichthyology. See SALMO.

GYARUS, in the ancient geography, one of the Cyclades, 12 miles in compass, lying to the east of Delos. It was a desert island, and allotted for a place of banishment by the Romans.

GYBING, the act of shifting any boom sail from one side of the mast to the other. In order to understand this operation more clearly, it is necessary to remark, that by a boom-sail is meant any sail whose bottom is extended by a boom, the fore-end of which is hooked to its respective mast; so as to swing occasionally on either side of the vessel, describing an arch, of which the mast will be the centre. As the wind or the course changes, it also becomes frequently necessary to change the position of the boom, together with its sail, which is accordingly shifted to the other side of the vessel as a door turns upon its hinges. The boom is pushed out by the effort of the wind upon the sail, and is restrained in a proper situation by a strong tackle communicating with the vessel's stern, and called the *sheet*. It is also confined on the fore-part by another tackle called the *guy*.

GYGES, in fabulous history, a Lydian, to whom Candaules king of the country showed his wife naked. The queen was so incensed at this instance of imprudence and infirmity in her husband, that she ordered Gyges either to prepare for death himself, or to put Candaules to death. He chose the latter; and, marrying the queen, ascended the vacant throne about 718 years before the Christian era. He was the first of the Mermnadæ who reigned in Lydia. He reigned 38 years, and distinguished himself by the immense presents which he made to the oracle of Delphi (*Herod.* 1. c. 8.) According to Plato, Gyges descended into a chasm of the earth, where he found a brazen horse, whose sides he opened, and saw within the body the carcase of a man of uncommon size, from whose finger he

took a brazen ring. This ring, when he put it on his finger, rendered him invisible; and by means of its virtue he introduced himself to the queen, murdered her husband, and married her and usurped the crown of Lydia. *Cic. Off.* iii. c. 9.

GYMNASIARCH, in antiquity, the director of the gymnasium. He had two deputies under him; the one called *xyfarch*, who presided over the *athletæ*, and had the oversight of wrestling; the other was *gymnastes*, who had the direction of all other exercises.

GYMNASIUM, in Grecian antiquity, a place fitted for performing exercises of the body, &c. The word is Greek, formed of *γυμνός*, "naked;" by reason they anciently put off their clothes, to practise with the more freedom. *Gymnasia*, according to Potter, were first used at Lacedæmon, but were afterwards very common in all parts of Greece; and imitated, very much augmented, and improved, at Rome. There were three principal gymnasia at Athens; the Academy, where Plato taught; the Lyceum, noted for Aristotle's lectures; and the Cynosarges, allotted for the populace.

Vitruvius describes the structure and form of the ancient gymnasia, lib. v. cap. 11. They were called *gymnasia*, because several of the exercises were performed naked; and *palæstræ*, from wrestling, which was one of the most usual exercises there: the Romans sometimes also called them *thermæ*, because the baths and bagnios made a principal part of the building. It appears that they did not perform their exercises quite naked so early as the time of Homer, but always in drawers; which they did not lay aside before the 32d Olympiad. One Orsipus is said to have been the first who introduced the practice: for having been worsted by means of his drawers undoing and entangling him, he threw them quite aside, and the rest afterwards imitated him. They were not single edifices, but a knot of buildings united, being sufficiently capacious to hold many thousands of people at once; and having room enough for philosophers, rhetoricians, and the professors of all other sciences to read their lectures; and wrestlers, dancers, and all others who had a mind to exercise; at the same time without the least disturbance or interruption. They consisted of a great many parts. Vitruvius recites no less than 12, viz. 1. The *exterior porticos*, where the philosophers, rhetoricians, mathematicians, physicians, and other virtuosi, read public lectures, and where they also disputed and rehearsed their performances. 2. The *ephebeum*, where the youth assembled very early, to learn their exercises in private, without any spectators. 3. The *coryceum*, apodyterion, or gymnasterion, a kind of wardrobe, where they stripped, either to bathe or exercise. 4. The *elæothesium*, alipterion, or unctuarium, appointed for the unctions, which either preceded or followed the use of the bath, wrestling, pancratia, &c. 5. The *conisterium* or conistra, in which they covered themselves with sand or dust, to dry up the oil or sweat. 6. The *palæstra*, properly so called, where they practised wrestling, the pugillate, pancratia, and various other exercises. 7. The *spharisterium* or tennis-court, reserved for exercises wherein they used balls. 8. Large *unpaved alleys*, which comprehended the space between the porticos and the walls wherewith the edifice was surrounded. 9. The *xyfili*, which were porticos for the wrestlers in winter or bad weather. 10. *Other xyfili* or open alleys, allotted for summer or fine weather, some of which were quite open, and others planted with trees. 11. The *baths*, consisting of several different apartments. 12. The *stadium*, a large space of a semicircular form, covered with sand, and surrounded with seats for the spectators.

For the administration of the gymnasia, there were different officers: the principal were, 1. The *gymnasiarcha*, who was the director and superintendant of the whole. 2. The *xyfarcha*, who presided in the *xyfistus*, or stadium. 3. The *gymnasta*, or

master of the exercises, who understood their different effects, and could accommodate them to the different complexions of the *athletæ*. 4. The *pædotriba*, whose business was mechanically to teach the exercises, without understanding their theory or use. Under these four officers were a number of subalterns, whose names distinguished their different functions.

The gymnastic exercises may be reduced to two general classes; as they depend either on the action of the body alone, or as they require external agents or instruments. The latter consisted chiefly in mounting the horse, driving the chariot, and swimming. The former were chiefly of two kinds; orcheftice, and palæstrice. The *orcheftice* comprehended, 1. Dancing. 2. Cubitice, or the art of tumbling. 3. Sphæristice or tennis, including all the exercises with pilæ or balls. The *palæstrice* comprised all exercises under the denomination *palæstræ*; as wrestling, boxing, pancratia, hoplomachia, running, leaping, throwing the discus, the exercise of the javelin, and that of the hoop, denominated by the Greeks *τροχός*, which consisted in rolling an iron hoop five or six feet in diameter, beset with iron rings, the noise of which apprising the people to give way, afforded them also an amusement. Both strength and skill were requisite in directing this hoop, which was to be driven with an iron rod. To these must also be added the exercises belonging to the medicinal gymnastics; as, 1. Walking. 2. Vociferation, or shouting. 3. Holding the breath. Hoffman enumerates no fewer than 55 sorts of exercises that were practised in the gymnasia.

GYMNASTICS, GYMNASTICE, or the GYMNASTIC art, denotes the art of performing exercises of the body, whether for defence, health, or diversion. See GYMNASIUM. Several modern writers have treated of this art. M. Burette has given the history of gymnastics in the Memoirs of the Royal Academy of Inscriptions. On the first establishment of society, men, being apprised of the necessity of military exercises for repelling the insults of their neighbours, instituted games and proposed prizes to animate their youth to combats of divers kinds. And as running, leaping, strength and dexterity of arm in throwing the javelin, driving a ball, or tossing a quoit, together with wrestling, &c. were exercises suited to the manner of fighting in those days, so the youth vied to excel in them, in the presence of the aged, who sat as their judges, and dispensed prizes to the conquerors; till what was originally only amusement became at length a matter of such importance as to interest great cities and entire nations in its practice. Hence arose an emulation and eagerness to excel, in hopes one day of being proclaimed and crowned conquerors in the public games, which was the highest honour a mortal could arrive at: nay, they went so far as to imagine, that even gods and demigods were not insensible of what men were so captivated with; and, in consequence hereof, to introduce the greatest part of these exercises into their religious ceremonies, the worship of their gods, and the funeral honours done to the manes of the dead.

Though it be hard to determine the precise epocha of the gymnastic art, yet it appears from several passages in Homer, and particularly the 23d book of the Iliad, where he describes the games celebrated at the funeral of Patroclus, that it was not unknown at the time of the Trojan war. From that description, which is the earliest monument now extant of the Grecian gymnastics, it appears that they had chariot-races, boxing, wrestling, foot-races, gladiators, throwing the discus, drawing the bow, and hurling the javelin; and it should seem, from the particular account Homer gives of these exercises, that even then the gymnastic art wanted little of perfection: so that when Galen says there was no gymnastic art in Homer's days, and that it began to appear no earlier than Plato, he is to be understood of the medicinal gymnastics only. This last,

indeed, had its rise later; because, while men continued sober and laborious, they had no occasion for it; but when luxury and idleness had reduced them to the sad necessity of applying to physicians, these, who had found that nothing contributed so much to the preservation and re-establishment of health as exercises proportioned to the different complexions, ages, and sexes, did not fail to refer them to the practice of gymnastics.

According to Plato, one Herodicus, prior a little time to Hippocrates, was the first who introduced this art into physic; and his successors, convinced by experience of its usefulness, applied themselves in earnest to improve it. Hippocrates, in his book of Regimen, has given instances of it, where he treats of exercise in general, and of the particular effects of walking, with regard to health; also of the different sorts of races, either on foot or horseback; leaping, wrestling, the exercise of the suspended ball, called *corycus*, chironomy, unctions, frictions, rolling in the sand, &c. But as physicians did not adopt all the exercises of the gymnastic art in their practice, it came to be divided between them and the masters of martial and athletic exercises, who kept schools, the number of which was greatly increased in Greece. At length the Romans also caught the same taste; and, adopting the military and athletic exercises of the Greeks, they improved and advanced them to the utmost pitch of magnificence, not to say extravagance. But the declension of the empire involved the arts in its ruin, and, among others, gymnastics and medicine; which last unhappily then relinquished the title it had to the former, and has neglected to resume it ever since.

GYMNOPYRIS, in natural history, a name given by Dr. Hill to the pyritæ of a simple internal structure, and not covered with a crust. See PYRITES. Of these there are only two species. 1. A green variously shaped kind. 2. A botryoid kind. The first species is the most common of all the pyritæ, and appears under a great diversity of shapes. It is very hard and heavy, very readily gives fire with steel, but will not at all ferment with aquafortis. The second species is very elegant and beautiful, and its usual colour is a very agreeable pale green; but what most distinguishes it from all other pyritæ is, that its surface is always beautifully elevated into tubercles of various sizes, resembling a cluster of grapes.

GYMNOSOPHISTS, a set of Indian philosophers, famous in antiquity, so denominated from their going barefoot. The word is formed of the Greek *γυμνοσοφιστης*, q. d. a sophist or philosopher who goes naked. This name was given to the Indian philosophers, whom the excessive heat of the country obliged to go naked; as that of *Peripateticus* was given to those who philosophised walking. The gymnosophists, however, did not go absolutely naked; but only clothed themselves no farther than modesty required. There were some of these sages in Africa; but the most celebrated clan of them was in India. The African gymnosophists dwelt upon a mountain in Ethiopia, near the Nile, without the accommodation either of house or cell. They did not form themselves into societies like those of India; but each had his private recess, where he studied and performed his devotions by himself. If any person had killed another by chance, he applied to these sages for absolution, and submitted to whatever penances they enjoined. They observed an extraordinary frugality, and lived only upon the fruits of the earth. Lucan ascribes to these gymnosophists several new discoveries in astronomy.

As to the Indian gymnosophists, they dwelt in the woods, where they lived upon the wild products of the earth, and never drank wine, nor married. Some of them practised physic, and travelled from one place to another; these were particularly famous for their remedies against barrenness. Some of them,

likewise, pretended to practise magic, and to foretell future events.

In general, the gymnosophists were wise and learned men: their maxims and discourses, recorded by historians, do not in the least favour of a barbarous education, but are plainly the result of great sense and deep thought. They kept up the dignity of their character to so high a degree, that it was never their custom to wait upon any body, not even upon princes themselves. They believed the immortality and transmigration of the soul: they placed the chief happiness of man in a contempt of the goods of fortune and the pleasures of sense, and gloried in having given faithful and disinterested counsels to princes and magistrates. It is said, that when they became old and infirm, they threw themselves into a pile of burning wood, in order to prevent the miseries of an advanced age. One of them, named *Calamus*, thus burnt himself in the presence of Alexander the Great.

Apuleius (Florid. lib. 1.) describes the gymnosophists thus: "They are all devoted to the study of wisdom, both the elder masters and the younger pupils; and what to me appears the most amiable thing in their character is, that they have an aversion to idleness and indolence: accordingly, as soon as the table is spread, before a bit of victuals be brought, the youths are all called together from their several places and offices, and the masters examine them what good they have done since the sun-rise: here one relates something he has discovered by meditation; another has learned something by demonstration; and as for those who have nothing to allege why they should dine, they are turned out to work fasting." The great leader of the gymnosophists, according to Jerome, was one *Buddas*, so called by Clemens Butta, who is ranked by Suidas among the Brahmins. That last author makes Buddas, the preceptor of Manes the Persian, the founder of the gymnosophists.

GYMNOSPERMIA, in botany, from *γυμνος* "naked," and *σπέρμα* "seed;" the first order in Linnæus's class of didynamia. It comprehends those plants of that class which have naked seeds. The seeds are constantly four in number, except in one genus, viz. *phryma*, which is monospermous. See BOTANY, p. 42.

GYMNOTUS, in ichthyology, a genus of fishes belonging to the order of apodes. They have two tentacula at the upper lip; the eyes are covered with the common skin; there are five rays in the membrane of the gills; the body is compressed, and carinated on the belly with a fin. There are five species, the most remarkable of which is the *electricus*, or electric eel, called by the French *anguille tremblante*. See pl. 2. This species is peculiar to Surinam, and is found in the rocky parts of the river, at a great distance from the sea. The most accurate description we have of this fish is in the Philosophical Transactions for 1775, where Alex. Garden, M. D. gives an account of three of them brought to Charlestown in South Carolina. The largest was about three feet eight inches in length, and might have been from 10 to 14 inches in circumference about the thickest part of its body. The head was large, broad, flat, and smooth; impressed here and there with holes, as if perforated with a blunt needle, especially towards the sides, where they were more regularly ranged in a line on each side. There were two nostrils on each side; the first large, tubular, and elevated above the surface; the others small, and level with the skin. The eyes were small, flattish, and of a blueish colour, placed about three quarters of an inch behind the nostrils. The whole body, from about four inches below the head, was clearly distinguished into four longitudinal parts or divisions. The upper part or back was of a dark colour, and separated from the other parts on each side by the *lateral lines*. These lines took their rise at the base of the head, just above

the pectoral fins, and run down the sides, gradually converging as the fish grew smaller to the tail. The second division was of a lighter and clearer colour than the first, inclining to blue. It seemed to swell out on each side; but towards the under part it is again contracted and sharpened into the third part or *carina*. This part is easily distinguished from the other two by its thinness, its apparent laxness, and by the reticulated skin of a more grey and light colour, with which it is covered. The *carina* begins about six or seven inches below the base of the head; and, gradually deepening or widening as it goes along, reaches down to the tail, where it is thinnest. The fourth part is a long, deep, soft, and wavy fin, which takes its rise about three or four inches at most below the head, and thus runs down the sharp edge of the *carina* to the extremity of the tail. The situation of the anus was very singular, being an inch more forward than the pectoral fins. Externally it seemed to be a pretty large *rima*; but the formed excrements were only the size of a quill or those of a common fowl. There were two pectoral fins situated just behind the head, scarcely an inch in length; of a very thin, delicate consistence, and orbicular shape. They seemed to be chiefly useful in supporting and raising the head of the fish when he came up to breathe; which he was obliged to do every four or five minutes. Across the body were a number of small bands, annular divisions, or rather *rugæ* of the skin. By means of these the fish seemed to partake of the vermicular nature, had the power of lengthening or shortening its body like a worm, and could swim backwards as well as forwards, which is another property of the vermicular tribe. Every now and then it laid itself on one side in the water, as if to rest.—For an account of the singular properties of this fish, see TORPEDO and ELECTRICITY, p. 264.

GYNÆCEUM, among the ancients, the apartment of the women, a separate room in the inner part of the house, where they employed themselves in spinning, weaving, and needle-work.

GYNÆCOCRACY, denotes the government of women, or a state where women are capable of the supreme command. Such are Britain and Spain.

GYNÆOCRATUMENI, an ancient people of Sarmatia Europæa, inhabiting the eastern banks of the river Tanais, near its opening into the Palus Mæotis; thus called, as authors relate, because they had no women among them; or, rather, because they were under the dominion of women. The word is formed of *γυνή* woman, and *καταουμένο*: *vanquished*, of *καταύω* I overcome, q. d. overcome by women. Fa. Hardouin, in his notes on Pliny, says they were thus called, because, after a battle which they lost against the Amazons, on the banks of the Thermoodon, they were obliged to have venereal commerce with them, in order to get them children: *Et quod victricibus obsequantur ad procurandam eis sobolem*.—Hardouin calls them the husbands of the Amazons, *Amazonum connubia*; for, as the author observes, the word *unde* must be retrenched from Pliny, having been foisted into the text by people who were not masters of the author's meaning, *unde Amazonum connubia*. See AMAZONS. They who take the Amazons for a fabulous people will conclude the same of the Gynæocratumensians.

GYNANDRIA, from *γυνή* a "woman," and *άνδρ* a "man," the name of the 20th class in Linnæus's sexual system, consisting of plants with hermaphrodite flowers, in which the stamina are placed upon the style, or, to speak more properly, upon a pillar-shaped receptacle resembling a style, which rises in the middle of the flower, and bears both the stamina and pointal; that is, both the supposed organs of generation. See BOTANY, p. 46. The flowers of this class, says Linnæus, have a monstrous appearance, arising, as he imagines, from the singular and unusual situation of the parts of fructification.

GYPSIES, or EGYPTIANS, an outlandish tribe of vagabonds, who disguising themselves in uncouth habits, smearing their faces and bodies, and framing to themselves a canting language, wander up and down, and, under pretence of telling fortunes, curing diseases, &c. abuse the common people, trick them of their money, and steal all that they can come at.

They are a strange kind of commonwealth among themselves of wandering impostors and jugglers, who made their first appearance in Germany about the beginning of the 16th century. Munster, it is true, who is followed and relied upon by Spelman, fixes the time of their first appearance to the year 1417: but as he owns that the first whom he ever saw were in 1529, it is probably an error of the press for 1517; especially as other historians inform us, that when Sultan Selim conquered Egypt in the year 1517, several of the natives refused to submit to the Turkish yoke, and revolted under one Zinganeus; whence the Turks call them Zinganees; but being at length surrounded and banished, they agreed to disperse in small parties all over the world, where their supposed skill in the black art gave them an universal reception in that age of superstition and credulity. In the compass of a very few years they gained such a number of idle profelytes (who imitated their language and complexion, and betook themselves to the same arts of chiromancy, begging and pilfering), that they became troublesome, and even formidable, to most of the states of Europe. Hence they were expelled from France in the year 1560, and from Spain in 1591. And the government of England took the alarm much earlier: for in 1530 they are described by Stat. 22 Hen. VIII. c. 10. as "an outlandish people calling themselves Egyptians, using no craft nor feat of merchandize, who have come into this realm, and gone from shire to shire, and place to place, in great companies, and used great, subtle, and crafty means to deceive the people; bearing them in hand, that they by palmistry could tell men's and women's fortunes; and so many times by craft and subtilty have deceived the people of their money, and also have committed many heinous felonies and robberies." Wherefore they are directed to avoid the realm, and not to return under pain of imprisonment, and forfeiture of their goods and chattels; and upon their trials for any felony which they may have committed, they shall not be entitled to a jury *de medietate lingue*. And afterwards it is enacted, by statutes 1st and 2d Ph. and Mary, c. 4. and 5th Eliz. c. 20. that if any such persons shall be imported into the kingdom, the importer shall forfeit 40l. And if the Egyptians themselves remain one month in the kingdom, or if any person being 14 years old, whether natural-born subject or stranger, which hath been seen or found in the fellowship of such Egyptians, or which hath disguised him or herself like them, shall remain in the same one month at one or several times, it is felony without benefit of clergy. And Sir M. Hale informs us, that at one Suffolk assizes, no less than 13 persons were executed upon these statutes a few years before the restoration. But, to the honour of our national humanity, there are no instances more modern than this of carrying these laws into practice; and the last sanguinary act is itself now repealed by 23 Geo. III. c. 54.

In Scotland they seem to have enjoyed some share of indulgence; for a writ of privy seal, dated 1594, supports John Faw, lord and earl of Little Egypt, in the execution of justice on his company and folk, conformable to the laws of Egypt, and in punishing certain persons there named who rebelled against him, left him, robbed him, and refused to return home with him. James's subjects are commanded to assist in apprehending them, and in assisting Faw and his adherents to return home. There is a like writ in his favour from Mary Q. of Scots 1553, and in 1554 he obtained a pardon for the murder of Nunan Small. So that it appears he had staid long in Scotland,

and perhaps some of the time in England; and from him this kind of strolling people might receive the name of *Faw Gang*, which they still retain.

A very circumstantial account of this singular race of vagrants has been lately given in an express *Enquiry* concerning them, written in German by H. M. G. Grellman, and translated by Mr. Raper. It is incredible to think how this regular swarm of banditti has spread itself over the face of the earth. They wander about in Asia, in the interior parts of Africa, and, like locusts, have over-run most of the European nations. In the reigns of Henry VIII. and queen Elizabeth, as we have seen, they were set up as a mark of general persecution in England; yet their numbers do not appear to have much diminished. Spain is supposed by Mr. Twiss to contain 40,000 of these vagrants; but by others 60,000; and by some even double that number. They became less numerous in France in consequence of the strictness of the police. In Italy they abound, especially in the dominions of the church, on account of the bad police and the prevalence of superstition, which permit and entice them to deceive the ignorant. They are scattered, though not in great numbers, through Germany, Denmark, Sweden, and Russia; but their chief population is in the south-east parts of Europe, which seem to be the general rendezvous of the gypsy nation. At a moderate computation Europe contains more than seven hundred thousand of these vagabonds. For near four centuries they have wandered through the world; and in every region, and among every people, whether barbarous or civilized, they have continued equally unchanged by the lapse of time, the variation of climate, and the force of example. Their singular physiognomy and particular manners are the same in every country. Their swarthy complexion derives no darker shade from the burning sun of Africa, nor any fairer tincture from the temperate climates of Europe; they contract no additional laziness in Spain, nor acquire any new industry in England; in Turkey they behold the mosque and the crescent with equal indifference as they do the reformed and the catholic church in Europe. In the neighbourhood of civilized life they continue barbarous; and, beholding around them cities and settled inhabitants, they live in tents or holes in the earth, and wander from place to place as fugitives and vagabonds.

They are passionately fond of ornaments; in which, however, they consult neither propriety nor consistency; they will wear an old laced coat, while the rest of the garments scarcely hang together. In Hungary and Transylvania, their summer habitations are tents; their winter ones, holes 10 or 12 feet deep in the earth, except such as keep inns, or exercise trades. They are fond of plate, particularly silver cups, which they bury under the hearth for security. Their principal occupations are, smith's work, or tinkers, or wooden ware, and horse-dealing; and in Hungary and Transylvania they are executioners of criminals, slayers of dead beasts, and washers of gold. The women deal in old clothes, prostitution, wanton dances, and fortune-telling. Notwithstanding these occupations, the majority of this people are lazy, beggars, and thieves. They bring up their children to their own professions, and are very fond of them. They have few disorders, except the measles and small-pox, and weaknesses in their eyes, occasioned by the smoke, and live to an advanced age, with a strong attachment to life. Their physic is saffron in their soups, or bleeding.

These people, however, appear to be distinguished by different singularities in different countries. At least in the following circumstances the German gypsies differ widely from those we commonly meet with in England. It is a great feast to them, our author says, whenever they can procure a roast of cattle that died of any distemper. It is all one to them, whether it be carrion of a sheep, hog, cow, or other beast, horse-

flesh only excepted; they are so far from being disgusted with it, that to eat their fill of such a meal is to them the height of epicurism. When any one censures their taste, or shows surprise at it, they answer, "The flesh of a beast which God kills must be better than that of one killed by the hand of man." They therefore take every opportunity of getting such dainties. That they take carrion from a laystall, as is affirmed of the gypsies in Hungary, is by no means certain, any more than that they eat horse-flesh. But if a beast out of an herd dies, and they find it before it becomes rotten and putrified; or if a farmer gives them notice of a cow dead, they proceed, without hesitation, to get possession of this booty. Their favourite object is animals that have been destroyed by fire; therefore, whenever a conflagration has happened, either in town or country, the next day the gypsies, from every neighbouring quarter, assemble and draw the suffocated half-consumed beasts out of the ashes. Men, women, and children, in troops, are extremely busy, joyfully carrying the flesh home to their dwelling-places; they return several times, provide themselves plentifully with this roast meat, and gluttonize in their huts as long as their noble fare lasts.

The gypsies have, at least in Transylvania, a sort of regular government, rather nominal than real or effective. They have their leaders or chiefs, whom they distinguish by the Slavonian title, *Waywode*. To this dignity every person is eligible who is of a family descended from a former waywode; but the preference is generally given to those who have the best clothes and the most wealth, who are of a large stature, and not past the meridian of life. Of religion, however, they have no sense; though, with their usual cunning and hypocrisy, they profess the established faith of every country in which they live. They also speak the languages of the respective countries, yet have a language of their own; from whence derived, authors differ. The only science which they have attained is music. Their poetry is ungrammatical indecent rhyme.

Their general character and capacities are thus described: Imagine people of a childish way of thinking; their minds filled with raw, undigested conceptions; guided more by sense than reason; using understanding and reflection so far only as they promote the gratification of any particular appetite; and you have a perfect sketch of the gypsy character. They are lively, uncommonly loquacious and chattering; frèkle in the extreme, consequently inconstant in their pursuits; faithless to every body, even their own cast; void of the least emotion of gratitude, frequently rewarding benefits with the most insidious malice. Fear makes them slavishly compliant when under subjection; but having nothing to apprehend, like other timorous people, they are cruel. Desire of revenge often causes them to take the most desperate resolutions. To such a degree of violence is their fury sometimes excited, that a mother has been known, in the excess of passion, to take her small infant by the feet, and therewith strike the object of her anger, when no other instrument has readily presented itself. They are so addicted to drinking, as to sacrifice what is most necessary to them, that they may feast their palates with spirits. They have, too, what one would little expect, an enormous share of vanity, which shows itself in their fondness for fine clothes, and their gait and deportment when dressed in them. One might imagine, that this pride would have the good effect to render a gypsy cautious not to be guilty of such crimes as subject him to public shame; but here comes in the levity of character, for he never looks to the right nor to the left in his transactions. In an hour's time he forgets that he is just untied from the whipping-post. But their pride is grounded on mere idle conceit, as appears plainly from their making it a point of honour to abuse their companions, and put on a terrible appearance in the public market, where they are sure to have

many spectators; they cry out, make a violent noise, challenge their adversary to fight, but very seldom any thing comes of it. Thus the gypsey seeks honour, of which his ideas coincide very little with those of other people, and sometimes deviate entirely from propriety.

“Nothing (continues our author) can exceed the unrestrained depravity of manners existing among these people, I allude particularly to the other sex. Unchecked by any idea of shame, they give way to every desire. The mother endeavours, by the most scandalous arts, to train up her daughter for an offering to sensuality; and *this* is scarce grown up before she becomes the seducer of others. Laziness is so prevalent among them, that were they to subsist by their own labour only, they would hardly have bread for two of the seven days in the week. This indolence increases their propensity to stealing and cheating, the common attendants on idleness. They seek to avail themselves of every opportunity to satisfy their lawless desires. Their universal bad character therefore for fickleness, infidelity, ingratitude, revenge, malice, rage, depravity, laziness, knavery, thievishness, and cunning, though not deficient in capacity and cleverness, render these people of no use in society, except as soldiers to form marauding parties. Persons in their company, and under their disguise, have formed dangerous designs against cities and countries. They have been banished from almost all civilized states in their turn, except Hungary and Transylvania, and to little purpose. Our author is of opinion, that as Turkey would allow them toleration, it would be better for the European states to take some steps for cultivating and civilizing them, and making them useful. But while they are insensible of religion and strongly attached to their own manners, it is to be feared the attempt will be impracticable. This appears from a very intelligent Hungarian lady's experience on the subject, communicated in a letter as follows: ‘There are a great number of them on my estates, but I have permitted two families in particular to establish themselves at the place of my own residence, under the express condition that no others shall come here and join them. I took all possible pains to make them reasonable creatures. I set the elder ones to work; the younger ones to tend the cattle. I observed that they were more fond of horses than any thing else; for which reason I placed a gypsey under each groom. I had their children clothed, that none of them might be ruming about naked, according to their usual practice. It appeared, however, that custom was become nature with them. The old ones worked diligently so long as any body stood over them; the moment their back was turned they all got together in a circle, their legs aëros, facing the sun, and chattered. Thus they cannot possibly earn more, indeed hardly so much, as would find them bread, although very cheap with us; for the bread I give them does not stand me in half a kretzer the pound. Even in winter they cannot bear a hat on their head nor shoes on their feet. The boys run like wild things wherever they are sent, either on foot or on horseback; but they spoil the horses unmercifully, beat them on the head, or jerk the bits in their mouths, so as to make them run down with blood. They cannot be brought by any means whatever to dress horses. Clothe them as you will, they always sell or lose their clothes. In a word, one cannot but consider them as void of reason; it is really shocking to see even well grown children put whatever they find into their mouths, like infants before they can speak; wherefore they eat every thing, even carrion, let it stink never so much. Where a mortality happens among the cattle, there these wretched beings are to be found in the greatest numbers.’

The origin of this people, as we have seen, has been generally supposed to be Egyptian; and that belief is as old as their existence in Europe. Thomasius, Salmon the English geogra-

pher, and lately Signior Griselini, have endeavoured to prove it by satisfactory evidence. This theory, however, according to our author, is without foundation. The Egyptian descent of these people, he thinks, is not only destitute of proofs, but the most positive evidence is found to contradict it. Their language differs entirely from the Coptic; and their customs are very different from those of the Egyptians. They are indeed to be found in Egypt; but they wander about there as strangers, and form a distinct people as in other countries. The expressions of Bellonius are strong and decisive: “No part of the world, I believe, is free from those banditti, wandering about in troops, whom we by mistake call *Egyptians* and *Bohemians*. When we were at Cairo, and in the villages bordering on the Nile, we found troops of these strolling thieves sitting under palm-trees; and they are esteemed foreigners in Egypt as well as among us.”

The Egyptian descent of the gypsies being rejected, our author next endeavours to show that they come from Hindostan. The chief basis of his theory, however, is no other than that very dubious one, a similarity of language. He adds a long vocabulary of the gypsey and the Hindostanic languages; in which, it must be confessed, many words are the same; but many are different. A principal proof which he adduces on this head is from the relation of Captain Szekely von Doba, to whom a printer in 1763 related, that a preacher of the Reformed church, when a student at Leyden, being intimately acquainted with three young Malabar students, took down 1000 of their words, which he fancied corresponded with the gypsey language; and they added, that a tract of land in their island was named *Ozigania*. He repeated these words to the Raber gypsies, who explained them without trouble or hesitation. This account was published in the Vienna Gazette. Supposing these three young men to be sons of Bramins, who use the Sanscrit, the common language of Hindostan comes as near to that as modern Italian to pure Latin. The comparison of the two languages takes up above 30 pages; and Mr. Grellman thinks it establishes his system. The same opinion is maintained by Mr. Marsden, in a paper upon this subject in the 7th volume of the *Archæologia*. The numerals, however, both in Hindostanic and gypsey, differ greatly as stated by the two authors. And here, as in other such comparisons, one is astonished at the credulity of the comparers of orthoepy and orthography (as a periodical critic observes), which can have no connection in languages with which we are not perfectly familiar, even were both languages reduced to writing by their respective people: how much less, then, where one of the two languages is never reduced to writing, as is the case of the gypsey, but is blended with the language of the country where the clan resides? This appears from the correspondence of several words in all languages with the gypsey. Mr. Grellman acknowledges the two gypsey versions of the Lord's Prayer, at different periods, differ so widely, that one would almost be inclined to doubt whether they were really the same language. We think we can discern a few words differently indeed written, but probably pronounced alike. Nor can we, in all the languages in which Chamberlayne gives the Lord's Prayer, perceive the least resemblance to the gypsey name of father, *Dade* and *Dad*, except in the Welch, *Taad*. In prosecuting his argument, Mr. Grellman does not insist on the similarity of colour between the two people, nor on the cowardice common to both, nor on the attachment of the Indians to tents, or letting their children go naked; all these being traits to be met with in other nations: but he dwells on the word *Po'gar*, the name of one of the first gypsey leaders, and of the Hindostanic god of marriage; also on the correspondence between the travelling smiths in the two people, who carry two pair of bellows; the Indian's boy blows them in India, the wife or child of the

gypsey in Europe : as if every travelling tinker, in every nation where tinkers travel, had not the same journeyman. In lascivious dances and chiromancy the two people agree ; nor are these uncommon in other parts of the globe. The excessive loquacity of the two people is produced as similar ; as if no other nations in the world were loquacious. Fainter resemblances are, a fondness for saffron, and the intermarrying only with their own people. The last position in the author's theory is, that the gypsies are of the lowest class of Indians, namely, *Parias*, or, as they are called in Hindostan, *Suders*. He compares the manners of this class with those of the gypsies, and enumerates many circumstances in which they agree : some of the comparisons are frivolous, and prove nothing ; as an instance of which we may take the following : ' Gypsies are fond of being about horses : the *Suders* in India likewise, for which reason they are commonly employed as horse-keepers by the Europeans resident in that country.' This reasoning does not prove that the gypsies are *Suders*, any more than that they are Arabians or Yorkshire farmers.

The objections, however, to which this learned and industrious author's theory is liable, are such as only show it to be by no means satisfactory ; but do not prove that this is wrong. It may possibly be right ; and upon this supposition the cause of their emigration from their country, he conjectures, not without probability, to be the war of Timur Beg in India. In the years 1408 and 1409 this conqueror ravaged India ; and the progress of his arms was attended with devastation and cruelty. All who made resistance were destroyed ; those who fell into the enemy's hands were made slaves ; of those very slaves 100,000 were put to death. As on this occasion an universal panic took place, what could be more natural than that a great number of terrified inhabitants should endeavour to save themselves by flight ?—In the last place, the author endeavours to trace the route by which the gypsies came from Hindostan to Europe : but here he justly acknowledges that all that can be said on the subject is mere surmise ; and, upon the whole, after perusing all the preceding details, the reader will probably be of opinion that there still hangs a cloud over the origin of this extraordinary race.

GYP SOPHILA, in botany ; a genus of the digynia order, belonging to the decandria class of plants, and in the natural method ranking under the 22d order, *Caryophylleii*. The calyx is monophyllous, campanulate, and angulated ; the petals are five in number, ovate, and sessile ; the capsule globose and unilocular.

GYP SUM, **PLASTER-STONE**, or *Alabaster* ; a natural combination of the calcareous earth with vitriolic acid. See **ALABASTER**. The properties of gypsum, according to Cronstedt, are, 1. It is looser and more friable than a calcareous earth. 2. It does not effervesce with acids either in its crude or calcined state ; or at most but in a very slight degree, in proportion to what it wants of the vitriolic acid for the complete saturation of its base. 3. It falls into powder in the fire very readily. 4. When burnt without being made red-hot, its powder readily concretes with water into a mass which soon hardens ; but without any sensible heat being excited in the operation. 6. According to our author, it is nearly as difficult of fusion as limestone, and shows almost the same effects upon other bodies with limestone, though the acid of vitriol seems to promote the vitrification. M. Magellan, however, informs us, that he has found most of the gypseous kind, particularly the fibrous, to melt in the fire pretty easily by themselves. 7. When melted in the fire with borax, it puffs and bubbles very much, and for a long time during the fusion. According to M. Magellan, when a small quantity of any gypsum is melted together with borax, the glass becomes colourless and transparent ; but some sorts of alabaster and sparry gypsum, when

melted in quantity with borax, yield a fine yellow transparent coloured glass, resembling that of the best topazes ; but if too much of the gypsum is used in proportion to the borax, the glass becomes opaque, just as it happens with the pure limestone. 8. When burnt with any inflammable matter it emits a sulphureous smell, and may thus be decomposed, as well as by either of the fixed alkaline salts ; but if this last method is followed, there ought to be five or six times as much salt as there is of gypsum. 9. On being decomposed in this manner, the residuum commonly shows some signs of iron.

The species are, 1. *Friable gypseous earth* of a white colour, found in Saxony. 2. *Indurated gypsum* of a solid texture, the particles of which are not visible, commonly called *alabaster*. This is sometimes found unsaturated with vitriolic acid ; in which case only it will effervesce with aquafortis. For its properties, &c. see the article **CHEMISTRY**. It is very easily sawed or cut, and takes a dull polish. It is of several kinds ; as, white ; clear and transparent from Persia, opaque from Italy and Trapano in Sicily ; of a yellow colour, of which there are likewise two kinds, transparent and opaque ; the former being met with in the eastern countries, the latter in Spain. Brunnick informs us, that in this country there are a great many fine varieties of the species we treat of ; and from hence he supposes that the ancients obtained the beautiful alabasters they used. Fabroni tells us, that a great variety of fine alabasters are met with in Italy. Twenty-four quarries of them, each of a different colour, are now worked out at Volterra ; but he is of opinion that the Romans brought the greatest part of the alabasters they made use of from Greece. 3. *Gypsum of a scaly texture*, or common plaster of Paris. This is found in many different countries, of two kinds, viz. white with coarse scales, or with small scales yellowish or greyish. According to Bergman, plaster contains $\frac{4}{100}$ of vitriolic acid, $\frac{3}{100}$ of pure calcareous earth, and 22 of water. It is soluble in 500 times its weight of warm water, or 450 times its weight of boiling water. It is well known by its property of forming a hard mass with water after being slightly burned ; and during this consolidation a slight degree of heat is produced, though less than when lime is slaked. It is often employed in building ; and may be taken off and used again and again for the same purpose. 4. *Fibrous gypsum*, or plaster-stone, has likewise two varieties, viz. with coarse or with fine fibres. It is of a white colour. 5. *Selenites*, or spar-like gypsum, by some also called *glacies mane*, and confounded with the clear and transparent mica. It is found of two kinds, clear and transparent, or yellowish and opaque. 6. *Crystallized gypsum*, or gypseous drusen. This is found composed of wedge-shaped and sometimes of capillary crystals, sometimes white and sometimes yellowish. 7. *Stalactitical gypsum* is found of a great many different forms and colours. When found in large pieces, it commonly varies between white and yellow, and likewise in its transparency in different parts of the same mass. It is used as alabaster in several works.

Besides the countries already mentioned, England abounds with substances of a gypseous nature. There are plenty in Derbyshire and Nottinghamshire, so fine as to be used like alabaster, that is, to take a fine polish. In the counties just mentioned there are large pits of this kind, also in most of the cliffs of the Severn, especially at the Old Passage in Somersetshire. A very fine semipellucid solid alabaster is found in Derbyshire. Very fine fibrous tales are found in the above-mentioned pits of stone, and many other places. Selenites every where abound, so that it is impossible to enumerate the different places. Very fine gypseous drusen are found in Sheppey Isle, and some exceedingly beautiful, large and clear as crystal, have been dug from the salt-rocks at Nantwich in Cheshire. The selenites rhomboidales is found in plenty in England, though rare is

other countries. Shotover-hill in Oxfordshire is remarkable for them. The Isle of Sheppey affords a kind of spar-like gypsum, of a fibrous nature, and always accreting like the radiations of a star on the septaria, and thence called *stella septarii*.

The principal use of gypsum is a material for small statues and figures of various kinds, also for moulds for casting wax-work, &c. It has also been introduced as a manure in France and America, though its success in this respect has not yet been sufficiently experienced.

GYR-FALCO, in zoology, the name of a large and fierce species of falcon, called in English the *jer-falcon*. See FALCO. It is a very bold and daring bird, attacking all other fowls without reserve, particularly the heron and stork kinds. The other falcons are all afraid of this.

GYRINUS, in zoology; a genus of insects of the coleoptera

order. See pl. 4. vol. iii. The generic characters are: The antennæ are cylindrical, stiff, and shorter than the head: and the eyes are four, two on the upper and two on the under part of the head. Mr. Barbut, however, says that the eyes only appear on the upper and under parts of the head, but that they are not four. The natator, or common water-flea, is of a bright black colour; the feet are yellow, flat, and large; the insect is in length one-third of an inch. It runs with great celerity in circles on the surface of waters, and is very difficult to catch, plunging down instantaneously when attempted to be taken. There are eight other species, which frequent the waters in different parts of the globe.

GYSHORN, a town of Germany, in the duchy of Lunenburg, situated on the river Aller, in E. lon. 10. 45. N. lat. 52. 50.

H.

H A B

H, The eighth letter and sixth consonant in our alphabet; though some grammarians will have it to be only an aspiration, or breathing. But nothing can be more ridiculous than to dispute its being a distinct sound, and formed in a particular manner by the organs of speech, at least in our language: witness the words *eat* and *beat*, *arm* and *harm*, *ear* and *bear*, *at* and *bat*, &c. as pronounced with or without the *h*. It is pronounced by a strong expiration of the breath between the lips, closing, as it were, by a gentle motion of the lower jaw to the upper, and the tongue nearly approaching the palate. There seems to be no doubt but that our *h*, which is the same with that of the Romans, derived its figure from that of the Hebrew ה. And indeed the Phœnicians, most ancient Greeks and Romans, used the same figure with our *H*, which in the series of all these alphabets keeps its primitive place, being the eighth letter.

H, used as a numeral, denotes 200; and with a dash over it, *H̄*, 200,000.

As an abbreviation, *H* was used by the ancients to denote *homo*, *hæres*, *hora*, &c. Thus *H. B.* stood for *hæres bonorum*; and *H. S.* corruptly for *L. L. S. festerce*; and *H. A.* for *Hadrrianus*.

HAAG, or HAG, a town of the duchy of Bavaria in Germany, seated on a hill on the west side of the river Inn, in E. lon. 12. 23. N. lat. 48. 16.

HABAKKUK, one of the twelve lesser prophets, whose prophecies are taken into the canon of the Old Testament. The name is written in the Hebrew with the *הבבב*, and signifies "a wrestler." There is no precise time mentioned in Scripture when this Habakkuk lived; but from his predicting the ruin of the Jews by the Chaldeans, it may be concluded that he prophesied before Zedekiah, or about the time of Manasseh. He is reported to have been the author of several prophecies which are not extant: but those that are indisputably his are contained in three chapters. In these the prophet complains very pathetically of the disorders which he observed in the kingdom of Judea. God reveals to him, that he would shortly punish them in a very terrible manner by the arms of the Chaldeans. He foretells the conquests of Nebuchadnezzar, his metemorphosis,

H A B

and death. He foretells, that the vast designs of Jehoiakim would be frustrated. He speaks against a prince (probably the king of Tyre) who built with blood and iniquity; and he accuses another king (perhaps the king of Egypt) of having intoxicated his friend, in order to discover his nakedness. The third chapter is a song or prayer to God, whose majesty he describes with the utmost grandeur and sublimity of expression.

HABAT, a province of Africa, in Barbary, and in the kingdom of Fez. It is surrounded by the Mediterranean, the Straits of Gibraltar, and the Atlantic Ocean. The principal towns are Arzilla, Tetuan, and Ceuta; which last is in possession of the Spaniards.

HABDALA, a ceremony of the Jews observed on the evening of the sabbath, when every one of the family is come home. At that time they light a taper or lamp, with two wicks at least. The master of the family then takes a cup, with some wine, mixed with fragrant spices, and having repeated a passage or two of scripture, as for example, "I will take the cup of salvation," &c. Psal. cxvi. and "The Jews had light and gladness," &c. Esth. viii. he blesses the wine and spices. Afterwards he blesses the light of the fire; and then casts his eyes on his hands and nails, as remembering that he is going to work. The whole is intended to signify, that the sabbath is over, and is from that moment divided from the day of labour which follows. For this reason the ceremony is called *Habdala*, which signifies "distinction." After the ceremony is over, and the company breaks up, they wish one another, not "a good night," but "a good week."

HABEAS CORPUS, in law, is the great remedy in cases of False IMPRISONMENT. The incapacity of the three other remedies referred to under that article, to give complete relief in every case, hath almost entirely antiquated them, and hath caused a general recourse to be had, in behalf of persons aggrieved by illegal imprisonment, to the present writ, the most celebrated in the English law. Of this there are various kinds made use of by the courts at Westminster, for removing prisoners from one court into another for the more easy administration of justice. Such is the *habeas corpus ad respondendum*, when a man hath a cause of action

against one who is confined by the process of some inferior court; in order to remove the prisoner, and charge him with this new action in the court above. Such is that *ad satisfaciendum*, when a prisoner hath judgment against him in an action, and the plaintiff is desirous to bring him up to some superior court to charge him with process of execution. Such also are those *ad prosequendum, testificandum, deliberandum, &c.*; which issue when it is necessary to remove a prisoner, in order to prosecute or bear testimony in any court, or to be tried in the proper jurisdiction wherein the fact was committed. Such is, lastly, the common writ *ad faciendum et recipiendum*, which issues out of any of the courts of Westminster-hall, when a person is sued in some inferior jurisdiction, and is desirous to remove the action into the superior court; commanding the inferior judges to produce the body of the defendant, together with the day and cause of his caption and detainer (whence the writ is frequently denominated an *habeas corpus cum causa*), to do and receive whatsoever the king's court shall consider in that behalf. This is a writ grantable of common right, without any motion in court; and it instantly supercedes all proceedings in the court below. But, in order to prevent the surreptitious discharge of prisoners, it is ordered by statute 1 & 2 P. & M. c. 13. that no *habeas corpus* shall issue to remove any prisoner out of any gaol, unless signed by some judge of the court out of which it is awarded. And, to avoid vexatious delays by removal of frivolous causes, it is enacted by statute 21 Jac. I. c. 23. that, where the judge of an inferior court of record is a barrister of three years standing, no cause shall be removed from thence by *habeas corpus* or other writ, after issue or demurrer deliberately joined: that no cause, if once remanded to the inferior court by writ of *procedendo* or otherwise, shall ever afterwards be again removed: and that no cause shall be removed at all, if the debt or damages laid in the declaration do not amount to the sum of five pounds. But an *expedient* having been found out to elude the latter branch of the statute, by procuring a nominal plaintiff to bring another action for five pounds or upwards (and then by the course of the court the *habeas corpus* removed both actions together), it is therefore enacted by statute 12 Geo. I. c. 29. that the inferior court may proceed in such actions as are under the value of five pounds, notwithstanding other actions may be brought against the same defendant to a greater amount.

But the great and efficacious writ, in all manner of illegal confinement, Judge Blackstone observes, is that of *habeas corpus ad subjiciendum*; directed to the person detaining another, and commanding him to produce the body of the prisoner, with the day and cause of his caption and detention, *ad faciendum, subjiciendum, et recipiendum*, to do, submit to, and receive whatsoever the judge or court awarding such writ shall consider in that behalf. This is a high prerogative writ, and therefore by the common law issuing out of the court of king's bench, not only in term-time, but also during the vacation, by a *fiat* from the chief justice, or any other of the judges, and running into all parts of the king's dominions: for the king is at all times entitled to have an account why the liberty of any of his subjects is restrained, wherever that restraint may be inflicted. If it issues in vacation, it is usually returnable before the judge himself who awarded it, and he proceeds by himself thereon; unless the term should intervene, and then it may be returned in court. Indeed, if the party were privileged in the courts of common pleas and exchequer, as being an officer or suitor of the court, an *habeas corpus ad subjiciendum* might also have been awarded from thence; and, if the cause of imprisonment were palpably illegal, they might have discharged him: but if he were committed for any criminal matter, they could only have remanded him, or taken bail for his appearance in the court of king's bench; which occasioned the common-pleas to discountenance

such applications. It hath also been said, and by very respectable authorities, that the like *habeas corpus* may issue out of the court of chancery in vacation: but upon the famous application to lord Nottingham by Jenks, notwithstanding the most diligent searches, no precedent could be found where the chancellor had issued such a writ in vacation; and therefore his lordship refused it.

In the court of king's-bench it was, and is still, necessary to apply for it by motion to the court, as in the case of all other prerogative writs (*certiorari, prohibition, mandamus, &c.*) which do not issue as of mere course, without showing some probable cause why the extraordinary power of the crown is called in to the party's assistance. For, as was argued by lord chief justice Vaughan, "it is granted on motion, because it cannot be had of course; and there is therefore no necessity to grant it: for the court ought to be satisfied that the party hath a probable cause to be delivered." And this seems the more reasonable, because, when once granted, the person to whom it is directed can return no satisfactory excuse for not bringing up the body of the prisoner. So that, if it issued of mere course, without showing to the court or judge some reasonable ground for awarding it, a traitor or felon under sentence of death, a soldier or mariner in the king's service, a wife, a child, a relation, or a domestic, confined for insanity or other prudential reasons, might obtain a temporary enlargement by suing out an *habeas corpus*, though sure to be remanded as soon as brought up to the court. And therefore Sir Edward Coke, when chief justice, did not scruple, in 13 Jac. I. to deny a *habeas corpus* to one confined by the court of admiralty for piracy; there appearing, upon his own showing, sufficient grounds to confine him. On the other hand, if a probable ground be shown, that the party is imprisoned without just cause, and therefore hath a right to be delivered, the writ of *habeas corpus* is then a writ of right, which "may not be denied, but ought to be granted to every man that is committed, or detained in prison, or otherwise restrained, though it be by the command of the king, the privy-council, or any other."

It has been shewn that the personal liberty of the subject is a natural inherent right, which cannot be surrendered or forfeited unless by the commission of some great and atrocious crime, and which ought not to be abridged in any case without the special permission of law: a doctrine coeval with the first rudiments of our constitution; and handed down to us from the Anglo-Saxons, notwithstanding all their struggles with the Danes, and the violence of the Norman conquest: asserted afterwards and confirmed by the conqueror himself and his descendants: and though sometimes a little impaired by the ferocity of the times, and the occasional despotism of jealous or usurping princes, yet established on the firmest basis by the provisions of *magna charta*, and a long succession of statutes enacted under Edward III. To assert an absolute exemption from imprisonment in all cases is inconsistent with every idea of law and political society; and in the end would destroy all civil liberty, by rendering its protection impossible: but the glory of the English law consists in clearly defining the times, the causes, and the extent, when, wherefore, and to what degree, the imprisonment of the subject may be lawful. This it is which induces the absolute necessity of expressing upon every commitment the reason for which it is made; that the court, upon an *habeas corpus*, may examine into its validity; and according to the circumstances of the case may discharge, admit to bail, or remand the prisoner.

And yet, early in the reign of Charles I. the court of king's-bench, relying on some arbitrary precedents (and those perhaps misunderstood), determined (State Trials, viii. 136) that they could not upon an *habeas corpus* either bail or deliver a prisoner, though committed without any cause assigned, in case he was

committed by the special command of the king, or by the lords of the privy-council. This drew on a parliamentary inquiry, and produced the *petition of right*, 3 Car. I. which recites this illegal judgment, and enacts that no freeman hereafter shall be so imprisoned or detained. But when, in the following year, Mr. Selden and others were committed by the lords of the council, in pursuance of his majesty's special command, under a general charge of "notable contempts and stirring up sedition against the king and government," the judges delayed for two terms (including also the long vacation) to deliver an opinion how far such a charge was bailable; and when at length they agreed that it was, they however annexed a condition of finding sureties for the good behaviour, which still protracted their imprisonment; the chief justice, Sir Nicholas Hyde, at the same time declaring, that "if they were again remanded for that cause, perhaps the court would not afterwards grant a *habeas corpus*, being already made acquainted with the cause of the imprisonment." But this was heard with indignation and astonishment by every lawyer present; according to Mr. Selden's own account of the matter, whose resentment was not cooled at the distance of four and-twenty years.

These pitiful evasions gave rise to the statute 16 Car. I. c. 10. § 8. whereby it is enacted, that if any person be committed by the king himself in person, or by his privy council, or by any of the members thereof, he shall have granted unto him, without any delay upon any pretence whatsoever, a writ of *habeas corpus*, upon demand or motion made to the court of king's bench or common-pleas; who shall thereupon, within three court days after the return is made, examine and determine the legality of such commitment, and do what to justice shall appertain, in delivering, bailing, or remanding such prisoner. Yet still in the case of Jenks, before alluded to, who in 1576 was committed by the king in council for a turbulent speech at Guildhall, new shifts and devices were made use of to prevent his enlargement by law; the chief justice (as well as the chancellor) declining to award a writ of *habeas corpus ad subjiciendum* in vacation, though at last he thought proper to award the usual writs *ad deliberandum*, &c. whereby the prisoner was discharged at the Old Bailey. Other abuses had also crept into daily practice, which had in some measure defeated the benefit of this great constitutional remedy. The party imprisoning was at liberty to delay his obedience to the first writ, and might wait, till a second and a third, called an *alias* and a *pluries*, were issued, before he produced the party: and many other vexatious shifts were practised to detain state-prisoners in custody. But whoever will attentively consider the English history, may observe, that the flagrant abuse of any power, by the crown or its ministers, has always been productive of a struggle; which either discovers the exercise of that power to be contrary to law, or (if legal) restrains it for the future. This was the case in the present instance. The oppression of an obscure individual gave birth to the famous *habeas corpus* act, 31 Car. II. c. 2. which is frequently considered as another *magna charta* of the kingdom; and by consequence has also in subsequent times reduced the method of proceeding on these writs (though not within the reach of that statute, but issuing merely at the common law) to the true standard of law and liberty.

The statute itself enacts, 1. That the writ shall be returned and the prisoner brought up, within a limited time, according to the distance, not exceeding in any case twenty days. 2. That such writs shall be endorsed, as granted in pursuance of this act, and signed by the person awarding them. 3. That on complaint and request in writing by or on behalf of any person committed and charged with any crime (unless committed for treason or felony expressed in the warrant, or for suspicion of the same, or as accessory thereto before the fact, or convicted or

charged in execution by legal process), the lord chancellor, or any of the twelve judges in vacation, upon viewing a copy of the warrant, or affidavit that a copy is denied, shall (unless the party has neglected for two terms to apply to any court for his enlargement) award a *habeas corpus* for such prisoner, returnable immediately before himself or any other of the judges; and upon the return made shall discharge the party, if bailable, upon giving security to appear and answer to the accusation in the proper court of judicature. 4. That officers and keepers neglecting to make due returns, or not delivering to the prisoner or his agent, within six hours after demand, a copy of the warrant of commitment, or shifting the custody of a prisoner from one to another without sufficient reason or authority (specified in the act), shall for the first offence forfeit 100l. and for the second offence 200l. to the party grieved, and be disabled to hold his office. 5. That no person, once delivered by *habeas corpus*, shall be recommitted for the same offence, on penalty of 500l. 6. That every person committed for treason or felony shall, if he requires it, the first week of the next term, or the first day of the next session of *oyer* and *terminer*, be indicted in that term or session, or else admitted to bail; unless the king's witnesses cannot be produced at that time: and if acquitted, or if not indicted and tried in the second term or session, he shall be discharged from his imprisonment for such imputed offence: but that no person, after the assizes shall be opened for the county in which he is detained, shall be removed by *habeas corpus*, till after the assizes are ended; but shall be left to the justice of the judges of assize. 7. That any such prisoner may move for and obtain his *habeas corpus*, as well out of the chancery or exchequer as out of the king's-bench or common-pleas; and the lord chancellor or judges denying the same, on sight of the warrant, or oath that the same is refused, forfeit severally to the party grieved the sum of 500l. 8. That the writ of *habeas corpus* shall run into the counties palatine, cinque ports, and other privileged places, and the islands of Jersey and Guernsey. 9. That no inhabitant of England (except persons contracting, or convicted praying to be transported; or having committed some capital offence in the place to which they are sent) shall be sent prisoner to Scotland, Ireland, Jersey, Guernsey, or any places beyond the seas, within or without the king's dominions: on pain that the party committing, his advisers, aiders, and assistants, shall forfeit to the party grieved a sum not less than 500l. to be recovered with treble costs; shall be disabled to bear any office of trust or profit; shall incur the penalties of *præmunire*; and shall be incapable of the king's pardon.

This is the substance of that great and important statute: which extends (we may observe) only to the case of commitments for such criminal charge as can produce no inconvenience to public justice by a temporary enlargement of the prisoner; all other cases of unjust imprisonment being left to the *habeas corpus* at common law. But even upon writs at the common law it is now expected by the court, agreeable to ancient precedents and the spirit of the act of parliament, that the writ should be immediately obeyed, without waiting for any *alias* or *pluries*; otherwise an attachment will issue. By these admirable regulations, judicial as well as parliamentary, the remedy is now complete for removing the injury of unjust and illegal confinement;—a remedy the more necessary, because the oppression does not always arise from the ill nature, but sometimes from the mere inattention, of government. For it frequently happens in foreign countries (and has happened in England during the temporary suspensions of the statute), that persons apprehended upon suspicion have suffered a long imprisonment, merely because they were forgotten.

HÄBERDASHER, in commerce, a feller of hats and other small wares. The matter and wardens of the company of haberdashers in London, calling to their assistance one of the com-

pany of cappers, and another of the hat-makers, and mayors, &c. of towns, may search the wares of all hatters who work hats with foreign wool, and who have not been apprentices to the trade, or who dye them with any thing but copperas and galls, or woad and madder: in which cases they are liable to penalties by stat. 8 Eliz. cap. 7. and 5 Geo. II. cap. 22. For the etymology of this denomination, see BERDASH.

HABERGION, or HAUBERGEON, HABERGETUM, a coat of mail; an ancient piece of defensive armour, in form of a coat, descending from the neck to the middle, and formed of little iron rings or meshes, linked into each other. The word is also written *haberge*, *hauberge*, *haubere*, *haubert*, *hauber*, *boutbert*, and *hauberk*. Spelman takes it to have been formed from the ancient French *haut*, "high," and *berg*, "armour, covering;" as serving to defend the upper part of the body. Du Cange and Skinner choose to derive it from the Belgic *hals*, or Teutonic *hals*, "neck," and *bergen*, "to cover;" as if it were a peculiar defence for the neck. Others will have it formed of *al*, *alli*, q. d. *all*, and *bergen*, "to cover;" as importing it a cover for the whole body.

HABICOT (Nicholas), a celebrated surgeon, born at Ponny in Gatinois, acquired great reputation by his skill in his profession, and by his writings; and died in 1624. He wrote a treatise on the plague, and several other curious works.

HABINGTON (William), an English poet and historian, was the son of Thomas Habington, Esq. He was born in 1605, at Hendlip in Worcestershire; and was educated at St. Omers and at Paris. He died in 1654, and left several manuscripts in the hands of his son. His printed works are, 1. Poems under the title of *Castura*. 2. The Queen of Arragon, a tragic comedy. 3. Observations upon History. 4. The History of Edward IV. King of England, written and published at the desire of Charles I. This work is composed in a very florid style.

HABIT, in philosophy, an aptitude or disposition either of mind or body, acquired by a frequent repetition of the same act. See CUSTOM and Habit.

HABIT is also used for a dress or garb, or the composition of garments, wherewith a person is covered. The principal part of the dress worn by the Jews and Greeks was the *μαλλιον* and the *χιτων*. The *μαλλιον* was an upper garment, consisting of a loose square piece of cloth wrapped round the body; the *χιτων* was an under garment, or tunic, which was fastened round the body and embraced it closely, falling down to the mid-thigh. It is proper in this place to observe, that a person divested of this upper garment or *μαλλιον*, in the eastern language, is styled *naked*, and in this sense David danced naked before the ark. The several sorts of garments in use with both sexes, amongst the Romans, were the toga, tunica, peluna, lacerna, chlamys, paludamentum, læna, stola, pallium or palla. See TOGA, &c. For the habits of the priests amongst the Jews, Greeks, and Romans, see the article PRIESTS.

HABIT is particularly used for the uniform garments of the religious, conformable to the rule and order whereof they make profession: as the habit of St. Benedict, of St. Augustine, &c. In this sense we say absolutely, such a person has taken the habit; meaning he has entered upon a noviciate in a certain order. So he is said to quit the habit when he renounces the order. See VOW. The habits of the several religious are not supposed to have been calculated for singularity or novelty: the founders of the orders, who were at first chiefly inhabitants of deserts and solitudes, gave their monks the habit usual among the country people. Accordingly, the primitive habits of St. Anthony, St. Hilarion, St. Benedict, &c. are described by the ancient writers as consisting chiefly of sheep skins, the common dress of the peasants, shepherds, and mountaineers, of that time; and the same they gave to their disciples.

The orders established in and about cities and inhabited places took the habit worn by other ecclesiastics at the time of their institution. Thus, St. Dominic gave his disciples the habit of regular canons, which he himself had always worn to that time. And the like may be said of the Jesuits, Barnabites, Theatins, Oratorians, &c. who took the common habit of the ecclesiastics at the time of their foundation. And what makes them differ so much from each other, as well as from the ecclesiastical habit of the present times, is, that they have always kept invariably to the same form; whereas the ecclesiastics and laics have been changing their mode on every occasion.

HABITUDE, among schoolmen, the respect or relation one thing bears to another. See RELATION.

HABSBURG, or HAPSBERG, an ancient castle of Switzerland, in the canton of Bern. It is the place where the ancient counts of Hapsburg resided, and is seated near the lake of Lucern, and to the east of the town of that name. E. lon. 8. 10. N. lat. 47. 22.

HACHA, a sea port town of South America, in Terra Firma, seated at the mouth of a river of the same name. Here the Spanish galleons touch at their arrival in South America, from whence expresses are sent to all the settlements to give them notice of it. W. lon. 72. S. N. lat. 11. 30.

HACKET (John), bishop of Lichfield and Coventry, was born in 1592. In 1623 he was made chaplain to James I. and prebendary of Lincoln; and soon after obtained the rectory of St. Andrew's, Holborn, with that of Cheam in Surry; his patron telling him he intended Holborn for wealth, and Cheam for health. In 1642 he was presented to a prebendary and residentiary; but was deprived of the enjoyment of them, as well as of St. Andrew's, by the ensuing troubles. He then lived retired at Cheam with little disturbance, until he recovered his preferments by the restoration of Charles II. by whom he was preferred to the see of Lichfield and Coventry in 1661. Finding the beautiful cathedral of Lichfield almost battered to the ground, he in eight years finished a complete church superior to the former, at his own expence of 20,000l. excepting 1000l. he had from the dean and chapter, with what he could procure from private benefactors. He laid out 1000l. on a prebendal house, his palaces at Lichfield and Eccleshall having been demolished during the civil wars: and, beside these acts of munificence, left several other benefactions at his death in 1670. He published, before he entered into orders, a comedy intitled *Loyola*, which was twice acted before king James the First. After his death there appeared a "Century of his sermons on several remarkable subjects," in folio; and "The Life of Archbishop Williams," in folio, which was abridged in 1700 by Ambrose Philips.

HACKNEY, a parish of Middlesex, on the north-east side of London, containing no less than 12 hamlets. At the bottom of Hackney-Marsh, through which the river Lea runs, between Old-Ford and the Wyck, there have been discovered the remains of a great stone causeway, which, by the Roman coins, &c. found there, was no doubt one of the famous highways made by the Romans. The old church is of a very ancient foundation, so old as Edward II. and the number of houses above 800. That part next London is called *Maré Street*; the middle, *Church Street*; and the north part *Clupton*; Dorleston and Shacklewell are on the west, and Hommerton, which leads to the Marsh, on the east. Here are three meeting-houses and several boarding-schools, besides the free-school in the church-yard, a charity-school, and 17 almshouses. It was from this place that the coaches let to the people in London first received their name; for in the last century, many people having gone on visits to see their friends at Hackney, it occasioned them often to hire horses or carriages, so that in time it became a common name for such horses, coaches, and chairs, as were let to the people of Lon-

don; and the name is now general through Britain and Ireland. A large church has been lately built near the old one.

HACKNEY-Coaches, those exposed to hire in the streets of London, and some other great towns and cities, as Edinburgh, Liverpool, Bristol, &c. at certain rates fixed by authority. See **COACH**. These first began to ply in the streets of London, or rather waited at inns, in the year 1625, and were originally no more than 20 in number. The following is an abstract of the several acts of parliament relating to hackney-coaches in London.

The king may appoint a number of commissioners, not exceeding five, to license and regulate hackney-coaches within the cities of London and Westminster, the suburbs thereof, and other places within the bills of mortality, not exceeding 1000, every proprietor paying ten shillings per week by monthly payments. This however includes the additional duty of five shillings per week, which took place in 1784.

Every coach shall have its number on each side; and if any proprietor shall presume to alter his number, he shall forfeit 5l. half to the king, and half to the informer. The horses to be used with hackney-coaches shall not be under 14 hands high.

No person shall drive or let to hire any hackney-coach without licence, on pain of 5l. and from and after the 4th of September 1784, if any person shall drive a mourning coach or hearse to any funeral within the cities of London and Westminster, or the suburbs thereof, or within five miles of Temple Bar, without a licensed number fixed on its fore-standard, he shall be liable to a penalty of 5l.

Any coachman plying for hire, may be obliged, on every day of the week, to go at reasonable times any where within the distance of ten miles from the city of London or Westminster; and if he has not a cheque string, placed in a proper part of his coach, he shall forfeit five shillings. If the owners of hackney-coaches, or their proper drivers, neglect to attend the commissioners upon the third summons, they forfeit their licence.

From and after the 1st of August 1786, the several rates or fares formerly paid, were repealed, and the following are now substituted in their stead.

	<i>Miles.</i>	<i>s. d.</i>
For any distance not exceeding - - -	1 $\frac{1}{4}$	— 1 0
Do. above 1 $\frac{1}{4}$ mile and not exceeding - - -	2	— 1 6
Do. above 2 miles and not exceeding - - -	2 $\frac{1}{2}$	— 2 0
Do. above 2 $\frac{1}{2}$ miles and not exceeding - - -	3	— 2 6
Do. above 3 miles and not exceeding - - -	3 $\frac{1}{2}$	— 3 0
Do. above 3 $\frac{1}{2}$ miles and not exceeding - - -	4	— 3 6
Do. above 4 miles and not exceeding - - -	4 $\frac{1}{2}$	— 4 0
Do. above 4 $\frac{1}{2}$ miles and not exceeding - - -	5	— 4 6

And so on to the extent of 10-miles from London or Westminster, at the rate of sixpence for each additional half mile, the last of which is to be paid if entered upon.

If the coach is kept in waiting, or paid by time, the fares will be—

	<i>s. d.</i>
For any time not exceeding 3 quarters of an hour - - -	1 0
From 3 quarters of an hour and not exceeding 1 hour - - -	1 6
From 1 hour 00 min. - - - to 1 hour 20 min. - - -	2 0
From 1 hour 20 min. - - - to 1 hour 40 min. - - -	2 6
From 1 hour 40 min. - - - to 2 hours 00 min. - - -	3 0
From 2 hours 00 min. - - - to 2 hours 20 min. - - -	3 6
From 2 hours 20 min. - - - to 2 hours 40 min. - - -	4 0
From 2 hours 40 min. - - - to 3 hours 00 min. - - -	4 6
From 3 hours 00 min. - - - to 3 hours 20 min. - - -	5 0
From 3 hours 20 min. - - - to 3 hours 40 min. - - -	5 6
From 3 hours 40 min. - - - to 4 hours 00 min. - - -	6 0
From 4 hours 00 min. - - - to 4 hours 20 min. - - -	6 6
From 4 hours 20 min. - - - to 4 hours 40 min. - - -	7 0
From 4 hours 40 min. - - - to 5 hours 00 min. - - -	7 6

And so on for any additional time at the rate of sixpence for every 20 minutes; the last of which is to be paid for if entered upon.

For a day of 12 hours - - - - - 14 6
 For any time after the said 12 hours the coach is to be considered as a coach in waiting, and paid for accordingly.

All the space betwixt the stand and the taking up of the fare is to be reckoned into the fare, and the coachman is at liberty to take either for the length of ground or time, but not for both; nor can he charge more than one shilling for any time within the first 3 quarters of an hour, unless he has gone above one mile and a quarter; his stopping and waiting at various places, driving slow by desire, or returning from whence he came, make no addition to the fare.

Any coachman refusing to go at, or exacting more for his hire than according to the foregoing rates, shall forfeit a sum not exceeding 3l. or under 10s. and in case of misbehaviour by abusive language or otherwise, the commissioners may revoke his licence, or inflict a penalty not exceeding 3l. to the poor, and on non-payment, to be committed and kept to hard labour for 30 days.

Any person refusing to pay the fare, or defacing the coach, may be brought by warrant before any justice, who, on proof upon oath, may award satisfaction to the party; and in case of refusal to pay, may bind him over to the next sessions.

Rents and penalties to be levied by distress, and, in default thereof, imprisonment till paid; and if any rent is fourteen days unpaid, the licence may be withdrawn.

A coach should be taken *possession* of, before the coachman is told where to drive; if he then refuses to proceed he is liable to be punished; and if at any time you apprehend that more than the proper fare is demanded, you may offer whatever is asked, but charge the coachman to take no more than is due; and if he then persists in the overcharge and takes it, you may take his number and apply for redress at the hackney coach office, in Somerset-place; though the penalties are equally recoverable before the Alderman of every ward of the city, or any justice of peace.

The duty arising from licences to hackney coaches and chairs in London forms a branch of the national revenue.

HADDINGTON, a populous borough of Scotland, in the county of the same name. It is seated on the Tyne, to the inundations of which it has been sometimes subject. The Franciscan monastery here has been a very handsome building. Part of it is occupied as a parish church. At a small distance are the ruins of a nunnery, founded in 1178. Haddington is 18 miles E. of Edinburgh. Lon. 3. 39. W. Lat. 55. 58. N.

HADDINGTONSHIRE, or **EAST LOTHIAN**, a county of Scotland, bounded on the W. by Edinburghshire, on the N. by the fiith of Forth, on the E. by the German Ocean, and on the S. by the county of Berwick. It is about 25 miles long from E. to W. and 15 miles where broadest. A great tract of this county, extending to the S. and E. is for the most part champaign, and very fertile and beautiful. The soil is, in many places, doubly productive. Rich crops are raised on the surface; and the mines of coal are inexhaustible. The southern part of this county is very mountainous, comprehending the N. side of Lammermuir Hills. These high grounds, however, feed many sheep.

HADDOCK, the English name of a species of **GADUS**.
HADDON (Dr. Walter), a great restorer of the learned languages in England, was born in 1516. He distinguished himself particularly by writing Latin in a fine style, which he acquired by constantly studying Cicero. He was a strenuous promoter of the reformation under king Edward; and was therefore thought a proper person to succeed bishop Gardiner in

the mastership of Trinity-hall, Cambridge, on his deprivation. He lay concealed during the reign of queen Mary; but acquired the favour of Elizabeth, who constituted him one of the masters of the court of requests, and sent him one of the three agents to Bruges in 1566, to restore commerce between England and the Netherlands. He was also engaged, with Sir John Cheke, in drawing up in Latin that useful code of ecclesiastical law, published in 1571 by the learned John Fox, under the title of *Reformatio legum ecclesiasticarum*; his other works are collected and published under the title of *Lucubrations*. He died in 1572.

HADERSLEBEN, a sea-port town of Denmark, in the duchy of Sleswick, with a strong citadel, built upon a small island. It is seated on a bay of the Baltic Sea, and has a well-frequented harbour. E. lon. 9. 35. N. lat. 55. 24.

HADES, in the scriptures, is used in various senses. Sometimes it signifies the invisible regions of the dead, sometimes the place of the damned, and sometimes the grave. In Greek authors, it is used to signify, in general, the regions of the dead. See HELL.

HADHRAMUT, a town and province of Arabia Felix, 115 miles W. of Careßen. Lon. 45. 30. E. Lat. 15. 0. N.

HADLEY, a large town in Suffolk, with a market on Monday. It is seated on the river Preston, and has a very handsome church. Large quantities of yarn are spun here for the Norwich manufacture; and this town had once a considerable woollen manufactory, which is now decayed. It is 20 miles S. E. of Bury, and 64 N. E. of London. Lon. 1. 6. E. Lat. 52. 10. N.

HÆMAGOGOS, among the old physicians, a compound medicine, consisting of fetid and aromatic simples mixed with black hellebore, and prescribed in order to promote the menstrua and hæmorrhoidal fluxes; as also to bring away the lochia.

HÆMANTHUS, the BLOOD-FLOWER; a genus of the monogynia order, belonging to the hexandria class of plants; and in the natural method ranking under the ninth order, *Spatheæ*. The involucre is hexaphyllous and multiflorous; the corolla sexpartite superior; the berry trilocular. The species are, 1. The *coccineus*, with plain tongue-shaped leaves, rises about a foot high, with a stalk supporting a cluster of bright red tubulous flowers. It hath a large bulbous root, from which in the autumn come out two broad flat leaves of a fleshy consistence, shaped like a tongue, which turn backward on each side, and spread on the ground, so that they have a strange appearance all the winter. In the spring these decay; so that from May to the beginning of August they are destitute of leaves. The flowers are produced in the autumn just before the leaves come out. 2. The *carinatus*, with keel-shaped leaves, has a taller stalk and paler flowers than the former; its leaves are not flat, but hollowed like the keel of a boat. 3. The *funicus*, with large spear-shaped waved leaves, grows about a foot high, and hath flowers of a yellowish red colour. These are succeeded by berries, which are of a beautiful red colour when ripe. All these plants are natives of the Cape of Good Hope, and do not propagate very fast in Europe, their roots seldom putting forth many off-sets. The best method of managing them is to have a bed of good earth in a bricked pit, where they may be covered with glasses, and in hard frosts with mats and straw. The earth in the frame should be two feet deep, and the frame should rise two feet above the surface, to allow height for the flower-stems to grow. The roots should be planted nine or ten inches asunder; and in winter, if they are protected from frost, and not suffered to have too much wet, but in mild weather exposed to the air, they will flower every year, and the flowers will be much stronger than with any other management. The third sort requires to be constantly kept in a dry stove.

HÆMATITES, or BLOOD-STONE, a hard mineral substance, red, black, or purple, but the powder of which is always red. It is found in masses sometimes spherical, semi-spherical, pyramidal, or cellular, that is, like a honeycomb. It contains a large quantity of iron. Forty pounds of that metal have been extracted from a quintal of stone; but the iron is of such a bad quality, that this ore is not commonly smelted. The great hardness of hæmatites renders it fit for burnishing and polishing metals.

HÆMATOPUS, the SEA-PYE, in ornithology, a genus belonging to the order of grallæ. The beak is compressed, with an equal wedge-shaped point; the nostrils are linear; and the feet have three toes without nails. There is but one species, viz. the ostralegus, or oyster-catcher, a native of Europe and America. See plate 3. It feeds upon shell-fish near the sea-shore, particularly oysters, and limpets. On observing an oyster which gapes wide enough for the insertion of its bill, it thrusts it in, and takes out the inhabitant: it will also force the limpets from their adhesion to the rocks with sufficient ease. Occasionally, it feeds on marine insects and worms. With us these birds are often seen in considerable flocks in winter: in the summer they are met with only in pairs, though chiefly in the neighbourhood of the sea or salt rivers. The female lays four or five eggs, on the bare ground, on the shore, above high-water mark: they are of a greenish grey, blotched with black. The young are said to be hatched in about three weeks. These birds are rather wild when in flocks; yet are easily brought up tame, if taken young.

HÆMATOXYLUM, LOGWOOD, or *Campeachy Wood*; a genus of the monogynia order, belonging to the decandria class of plants; and in the natural method ranking under the 33d order, *Lomentaceæ*. The calyx is quinquepartite; the petals five; the capsule lanceolated; unilocular, and bivalved; the valves navicular or keeled like a boat. Of this genus there is only one species, viz. the *campechianum*, which grows naturally in the bay of Campeachy at Honduras, and other parts of the Spanish West Indies, where it rises from 16 to 24 feet high. The stems are generally crooked, and very deformed; and seldom thicker than a man's thigh. The branches, which come out on each side, are crooked, irregular, and armed with strong thorns, garnished with winged leaves, composed of three pair of obscure lobes indented at the top. The flowers come in a racemus from the wings of the leaves, standing erect, and are of a pale yellowish colour, with a purple empalement. They are succeeded by flat oblong pods, each containing two or three kidney-seeds. Dr. Wright informs us, that this tree was introduced into Jamaica from Honduras in 1715; and is at this time too common, as it has overrun large tracts of land, and is very difficult to root out. It makes a beautiful and strong fence against cattle. If pruned from the lower branches, it grows to a sizeable tree, and, when old, the wood is as good as that from Honduras. The trees are cut up into billets or junks, the bark and white sap of which are chipped off, and the red part, or heart, is sent to England for sale.

Logwood is used in great quantities for dyeing purple, but especially black colours. All the colours, however, which can be prepared from it, are of a fading nature, and cannot by any art be made equally durable with those prepared from some other materials. Of all the colours prepared from logwood, the black is the most durable. Dr. Lewis recommends it as an ingredient in making ink. "In dyeing cloth (says he), vitriol and galls, in whatever proportions they are used, produce only browns of different shades: I have often been surprised that with these capital materials of the black dye I never could obtain any true blackness in white cloth, and attributed the failure to some unheeded mismanagement in the process, till I found it to be a known fact among the dyers. Logwood is the material

which adds blackness to the vitriol and gall-brown; and this black dye, though not of the most durable kind, is the most common. On blue cloth a good black may be dyed by vitriol and galls alone; but even here, an addition of logwood contributes not a little to improve the colour." Mr. Delaval, however, in his Essay on Colours, informs us, that with an infusion of galls and iron-silings, he not only made an exceeding black and durable ink, but also dyed linen cloth of a very deep black. See COLOUR-Making; DYEING, p. 112; and INK. Logwood is also found to have a considerable astringent virtue as a medicine, and an extract of it is sometimes given with great success in diarrhœas.

HÆMOPTYSIS, HÆMARTYSIS, or HÆMORTOE'; a spitting of blood. See MEDICINE.

HÆMORRHAGY, compounded of *αιμα* "blood," and *ερρωειν* "I burst forth," in medicine, a flux of blood at any part of the body; arising either from a rupture of the vessels, as when they are too full or too much pressed; or from an erosion of the same, as when the matter of an abscess becomes corrosive. The hæmorrhagy, properly speaking, as understood by the Greeks, was only a flux of blood at the nose; but the moderns extend the name to any kind of flux of blood, whether by the nose, mouth, lungs, stomach, intestines, fundament, matrix, or any other part. See MEDICINE and SURGERY.

HÆMORRHOIDAL, an appellation given by anatomists to the arteries and veins of the intestinum rectum.

HÆMORRHOIDS, or **PILES**, an hæmorrhage or issue of blood from the hæmorrhoidal vessels. See SURGERY.

HÆMUS, in ancient geography, a vast ridge, running from Illyricum towards the Euxine, (Pliny); so high as to afford a prospect both of the Euxine and Adriatic. Here, in after ages, was constituted a province called *Hæmimons* or *Hæmimontus*.

HÆRETICO COMBURENDO, a writ which anciently lay against an heretic, who, having once been convicted of heresy by his bishop, and having abjured it, afterwards falling into it again, or into some other, is thereupon committed to the secular power. This writ is thought by some to be as ancient as the common law itself; however, the conviction of heresy by the common law was not in any petty ecclesiastical court, but before the archbishop himself in a provincial synod, and the delinquent was delivered up to the king to do with him as he pleased: so that the crown had a control over the spiritual power. But by 2 Hen. IV. cap. 15. the diocesan alone, without the intervention of a synod, might convict of heretical tenets; and unless the convict abjured his opinions, or if after abjuration he relapsed, the sheriff was bound *ex officio*, if required by the bishop, to commit the unhappy victim to the flames, without waiting for the consent of the crown. This writ remained in force, and was actually executed on two Anabaptists in the seventh of Elizabeth, and on two Arians in the ninth of James I. Sir Edward Coke was of opinion, that this writ did not lie in his time; but it is now formally taken away by statute 29 Car. II. cap. 9. But this statute does not extend to take away or abridge the jurisdiction of Protestant archbishops or bishops, or any other judges of any ecclesiastical courts, in cases of atheism, blasphemy, heresy, or schism, and other damnable doctrines and opinions; but they may prove and punish the same according to his majesty's ecclesiastical laws, by excommunication, deprivation, degradation, and other ecclesiastical censures, not extending to death, in such sort and no other, as they might have done before the making of this act. Sec. 2. See HERESY.

HÆRLEM. See HARLEM.

HAG, in zoology. See MYXINE.

HAGARENS, the descendants of Ishmael. They are called also *Ishmaelites* and *Saracens*; and lastly, by the general name of *Arabians*. As to the Hagarens, they dwell in Arabia the

Happy, according to Pliny. Strabo joins them with the Nabathæans, and Chavlotæans, whose habitation was rather in Arabia Deserta. Others think their capital was Petra, otherwise Agra, and consequently they should be placed in Arabia Petraea. The author of the lxxxiiiid Psalm, ver. 6. joins them with the Moabites; and in the Chronicles it is said (1 Chr. v. 10.), that the sons of Reuben, in the time of Saul, made war against the Hagarens, and became masters of their country eastward of the mountains of Gilead. This therefore was the true and ancient country of the Hagarens. When Trajan came into Arabia, he besieged the capital of the Hagarens, but could not take it. The sons of Hagar valued themselves of old upon their wisdom, which appears by Baruch iii, 23.

HAGEDORN (Frederick de), a celebrated German poet, was born at Hamburg, where his father was resident for the king of Denmark, in 1708. He finished his studies at Jena; and in 1728 published a number of poetical pieces in Germany, which were well received. He afterwards came to England, where he obtained the friendship of many of the learned; and, at his return, was made secretary to the English Hamburg company, a lucrative employment that left him sufficient time for cultivating the Muses. In 1738 he published his Fables and Tales, the first collection of the kind of which Germany can boast. He afterwards published other pieces of poetry of different kinds, as Moral Poems, Epigrams, and five books of Songs: which of all his poetical pieces are most esteemed. He died in 1754.

HAGGAI, the tenth of the small prophets, was born, in all probability, at Babylon, in the year of the world 3457, from whence he returned with Zerubbabel. It was this prophet who by command from God (Ezra v. 1, 2, &c.) exhorted the Jews, after their return from the captivity, to finish the rebuilding of the temple, which they had intermitted for 14 years. His remonstrances had their effect; and to encourage them to proceed in the work, he assured them from God, that the glory of this latter house should be greater than the glory of the former house; which was accordingly fulfilled, when Christ honoured it with his presence: for with respect to the building, this latter temple was nothing in comparison of the former. We know nothing certain of Haggai's death. The Jews pretend, that he died in the last year of the reign of Darius, at the same time with the prophets Zechariah and Malachi, and that thereupon the spirit of prophecy ceased among the children of Israel. Epiphanius will have it, that he was buried at Jerusalem among the priests. The Greeks keep his festival on the 16th of December, and the Latins on the 4th of July.

HAGIOGRAPHIA, a name given to part of the books of scripture, called by the Jews *Cetuvim*. The word is compounded of *αγιος* "holy;" and *γραφω* "I write." The name is very ancient: St. Jerom makes frequent mention of it: before him, St. Epiphanius called these books simply *Γραφαια*. The Jews divide the sacred writings into three classes: The Law, which comprehends the five books of Moses: The Prophets, which they call *Nevim*: And the *Cetuvim* **כְּתוּבִים**, called by the Greeks, &c. *Hagiographa*: comprehending the book of Psalms, Proverbs, Job, Daniel, Ezra, including also the book of Nehemiah, Chronicles, Canticles, Ruth, the Lamentations, Ecclesiastes, and Esther. The Jews sometimes call these books the *Writings*, by way of eminence, as being written by immediate inspiration of the Holy Spirit. Thus says Kimchi, in his preface to the Psalms, Maimonides, in More Nevoch, and Elias Levita in his Thibsi, under the word **כְּתוּבִים**. They distinguish the *bagiographers*, however, from the Prophets; in that the authors of the former did not receive the matters contained in them by the way called *Prophecy*, which consists in dreams, visions, whispers, ecstasies, &c. but by mere inspiration and direction of the Spirit.

HAGUE, a town of the United Provinces, in Holland, situated in E. lon. 4. 10 N. lat. 48. 49. In Latin it is called *Haga Comitis*; in French, *La Haye*; in Dutch, *der Haag*, or *'S Graavenhage*, i. e. the Earl's Grove or Wood, from the wood near which it is built, and in which the earls of Holland had a country-house. Though it sends no deputies to the states, it is one of the most considerable towns in Holland, pleasantly situated, and exceedingly beautiful. It may indeed compare with almost any city in Europe, though geographers account it but a village. The inhabitants also breathe a better air than those of the other cities, as it stands on a dry soil, somewhat higher than the rest of the country. It has no gates or walls, but is surrounded by a moat over which there are many draw-bridges. Two hours are required to walk round it, and it contains about 40,000 or 50,000 souls. It is a place of much splendor and business, being the seat of the high colleges of the republic and province of Holland, and the residence of the stadtholder and foreign ambassadors; and there are a great many fine streets and squares in it. In the inner court all the high colleges and courts of justice hold their assemblies: there likewise the foot-guards do duty, as the horse-guards in the outer, when the states are sitting. De Plaats is an open airy place, in form of a triangle, adorned with neat and beautiful buildings: the Vyverberg is an eminence, laid out into several fine shady walks, with the Vyver, a large basin of water, at the bottom: the Voorhout is the most celebrated part of the Hague, and consists of the mall, and three ways for coaches on each side, planted with trees, being much the same as St. James's park at London: the palace of Opdam, or Wassenaar, is built in a very elegant taste: the prince and princess grafts are fine streets: the Plan, in Dutch *Het Pleyn*, is a beautiful grove, laid out in several cross walks, and surrounded with stately houses. The Jewish synagogue is well worth being seen by a curious traveller; and also the palaces of the prince of Orange, the hotel of Spain, the new Voorhout, the mausoleum of the baron of Opdam in the great church, and the several hospitals. The environs of the Hague are exceedingly pleasant. Among other agreeable objects are the wood, with the palace of Orange at the extremity of it, called the *housé in the wood*; the village of Scheveling; and the sand-hills, along the north sea; with the village of Voorburg, and the charming seats and fine gardens round it. Two miles from the Hague is Ryfwick, a village: and a quarter of a mile from that, a noble palace belonging to the prince of Orange, famous for the treaty of peace concluded there in 1697. Loosduynen, where Margaret, countess of Henneburg, and daughter of Florence IV. count of Holland and Zealand, is said to have been delivered of 365 children at a birth in 1276, is about five miles from the Hague. Five miles beyond Loosduynen, and not far from the beautiful village of Gravesande, is Honslardyck, another palace belonging to the prince of Orange, and one of the finest structures in the Low Countries.

HAGUENAU, a town of France, in the department of Lower Rhine and late province of Alsace. It was formerly a free imperial city; but it was taken by the French in 1673. The great general Montecuculi was obliged to raise the siege of it in 1675. It was several times taken and retaken in the subsequent wars; the last of all by the French in 1706. It is seated on the river Motter, which divides it into two parts, 12 miles N. of Strasbourg, and 255 E. of Paris. Lon. 7. 53. E. Lat. 48. 47. N.

HAHN (Simon Frederick), a celebrated German historian. At ten years of age he was not only far advanced in the Latin, but understood several living languages. Four years after, he pronounced a speech on the origin of the cloyster at Bergen, the place of his birth, which was printed with some other pieces; and in 1708 he published a Continuation of Meibomius's Chronicle of Bergen. After having for several years given public

lectures at Hall, he became, at the age of 24, professor of history at Helmstadt; and was at length counsellor, historiographer, and librarian, to the king of Great Britain, elector of Hanover. He died in 1729, aged 37. Besides the above, and some other works, he wrote, 1. The first volume of the History of the Empire. 2. *Collectio monumentorum veterum et recentium ineditorum*, 2 vols. 8vo.

HAI-TANG, a beautiful Chinese shrub, originally brought from the bottom of the rocks which border the sea-coast. It has been cultivated in China for more than 14 centuries; and is celebrated as often in the works of the Chinese poets, as roses and lilies are in those of ours. Painters and embroiderers ornament almost all their works with its foliage and flowers. The stalk of the hai-tang is of a cylindric form, and shoots forth a number of branches of a purple tint towards their bases, and full of knots, which are also of a purple colour round the edges. It produces a number of shoots, the tallest of which are about two feet and a half in height. Its leaves (which are much indented, of an oval form towards the stalk, pointed at their upper extremities, and full of small prickles) grow almost opposite one another on the branches, and at the same distance as the knots. Their colour above is a deep-green; that below is much lighter, and almost effaced by their fibres, which are large, and of a delicate purple: all these leaves together have a beautiful effect to the eye. The flowers grow in bunches at the extremities of the branches. Each flower is composed of four petals, two great and two small, resembling in colour the bloom of a peach-tree, and which have almost the same figure as the blossom of our cherry-trees. The two large are cemented one upon the other, in the form of a purse; and when they blow, the two small blow also in their turn; and then the whole four represent a cross. The pistil is composed of very bright yellow grains, which separate gradually one from another by the lengthening of the filaments to which they adhere; they then open into little bells, and compose a small yellow tuft, supported by a slender stalk, which rises above the petals. The calyx, which sustains each of the flowers, is composed of two purple-coloured leaves, united in form of a purse. In proportion as the flowers grow and increase in size, the two leaves of the calyx open, become pale and dry, and drop off. The flowers, supported by small stalks, separate one from the other, and produce of themselves other flowers, which rise up from a new calyx. This plant is propagated from seed, but with difficulty. It thrives best in a sandy soil; dung or mould destroys it; and great care must be taken to refresh it only with the purest water. As it cannot endure the sun in any season, it is always planted below walls that are exposed to the north. It generally begins to flower about the end of August. After it has produced seed, all its branches are cut; and it commonly shoots forth new ones before the spring following; but it is necessary to heap up gravel and pieces of brick round its roots, to prevent them from rotting. Notwithstanding all the care that is taken to cultivate this tree at Peking, it does not thrive so well there as in the southern provinces. The smell of its leaves has an affinity both to that of the rose and the violet; but it is weaker, and never extends to any great distance.

HAIL, in natural history, a meteor generally defined frozen rain, but differing from it in that the hailstones are not formed of single pieces of ice, but of many little spherules agglutinated together. Neither are these spherules all of the same consistence; some of them being hard and solid like perfect ice; others soft, and mostly like snow hardened by a severe frost. Sometimes the hailstone hath a kind of core of this soft matter; but more frequently the core is solid and hard, while the outside is formed of a softer matter. Hailstones assume various figures, being sometimes round, at other times pyramidal, crenated, angular, thin, and flat,

and sometimes stellated, with six radii like the small crystals of snow.

Natural historians furnish us with various accounts of surprising showers of hail, in which the hailstones were of extraordinary magnitude. Mezeray, speaking of the war of Louis XII. in Italy, in the year 1510, relates, that there was for some time an horrible darkness, thicker than that of night; after which the clouds broke into thunder and lightning, and there fell a shower of hailstones, or rather (as he calls them) pebblestones, which destroyed all the fish, birds, and beasts of the country. It was attended with a strong smell of sulphur; and the stones were of a blueish colour, some of them weighing an hundred pounds. *Hist. de France*, tom. II. p. 339.

At Lille in Flanders in 1686, fell hailstones of a very large size; some of which contained in the middle a dark-brown matter, which, thrown on the fire, gave a very great report, Phil. Transf. No. 203.

Dr. Halley and others also relate, that in Cheshire, Lancashire, &c. April 29, 1697, a thick black cloud coming from Carnarvonshire, disposed the vapours to congeal in such a manner, that for about the breadth of two miles, which was the limit of the cloud, in its progress for the space of 60 miles, it did inconceivable damage; not only killing all sorts of fowls and other small animals, but splitting trees, knocking down horses and men, and even ploughing up the earth; so that the hailstones buried themselves under ground an inch or an inch and a half deep. The hailstones, many of which weighed five ounces, and some half a pound, and being five or six inches about, were of various figures; some round, others half round; some smooth, others embossed and crenated: the icy substance of them was very transparent and hard, but there was a snowy kernel in the middle of them.

In Hertfordshire, May 4, the same year, after a severe storm of thunder and lightning, a shower of hail succeeded, which far exceeded the former: some persons were killed by it, their bodies beat all black and blue; vast oaks were split, and fields of rye cut down as with a scythe. The stones measured from 10 to 13 or 14 inches about. Their figures were various, some oval, others picked, and some flat. *Philosoph. Transf. No. 229.*

It is remarkable, that, so far as we know, hail is a meteor which never produces any beneficial effect. The rain and dew invigorate and give life to the whole vegetable tribe; the frost, by expanding the water contained in the earth, pulverises and renders the soil fertile; snow covers and preserves the tender vegetables from being destroyed by too severe a frost. But hail does none of all these. In winter, it lies not sufficiently close to cover vegetables from the nipping frosts; and in spring and summer it not only has a chilling and blasting effect from its coldness, but often does great damage to the more tender plants by the weight of the stones, and in great hail-storms the damage done in this manner is prodigious.

Hail is one of the natural phenomena for which it is almost impossible to account in any satisfactory manner. It is certain, that on the tops of mountains, hailstones, as well as drops of rain, are very small, and continually increase in bulk till they reach the lower grounds. It would seem, therefore, that during their passage through the air, they attract the congealed vapour, which increases them in size. But here we are at a loss how they come to be solid hard bodies, and not always soft, and composed of many small stars like snow. The flakes of snow, no doubt, increase in size as they descend, as well as the drops of rain or hailstones; but why should the one be in soft crystals, and the other in large hard lumps, seeing both are produced from congealed vapour? Some modern philosophers ascribe the formation of hail to electricity. Signor Beccaria supposes hail to be formed in the higher regions of the air, where the cold is intense, and where the electric matter is very copious. In these circumstances,

a great number of particles of water are brought near together, where they are frozen, and in their descent collect other particles, so that the density of the substance of the hailstone grows less and less from the centre; this being formed first in the higher regions, and the surface being collected in the lower. Agreeably to this, it is observed, that, in mountains, hailstones, as well as drops of rain, are very small, there being but little space through which they can fall and increase their bulk. Drops of rain and hail also agree in this, that the more intense the electricity that forms them, the larger they are. Motion is known to promote freezing, and so the rapid motion of the electrified clouds may produce that effect. A more intense electricity also, he thinks, unites the particles of hail more closely than the more moderate electricity does those of snow. In like manner we see thunder-clouds more dense than those that merely bring rain; and the drops of rain are larger in proportion, though they fall not from so great a height.

HAILING, the salutation or accosting of a ship at a distance, either at sea or in a harbour. The usual expression is, "Ho, the ship ahoy!" To which she answers, "Hollo! Whence came ye? Where are ye bound? Good voyage! What cheer? All well! How fare ye?" &c.

HAILLAN (Bernard de Girard, lord of), a celebrated French historian. After having made some figure in the literary world, and as a translator, he applied himself to history with such success, that in 1571 Charles IX. made him historiographer of France. His history of France extends from Pharamond to the death of Charles VII. and is the first complete history of that kingdom composed in the French tongue. He was honoured by Henry III. with several marks of favour; and proposed to continue his history to the reign of Henry IV. but did not perform his promise. He died at Paris in 1610.

HAIMSUCKEN. See **HAMESECKEN**.

HAINAN, a considerable island of Asia, belonging to China, to the N. of the gulf of Cochin-China, and to the S. of the province of Canton, from which it is 12 miles distant. It is 400 miles in circumference. The soil of the N. part is level; but in the S. and E. are mountains, among which are valleys that produce two crops of rice every year. The inhabitants are mostly a wild sort of people, and great cowards, for 50 Chinese will put a thousand of them to flight. In general, they are a short and deformed people, and the colour of their skins is red dish. They are clothed from the waist downward only, and paint their faces like other savages. There are mines of gold and lapis lazuli, which last is carried to Canton, to paint the porcelain with. It produces the same fruits as China, beside sugar, tobacco, cotton, and indigo. Among the animals is a great black ape, with features resembling those of the human face; but they are very scarce. The common sort of apes are grey, and very ugly. Some of the inhabitants of the sea-coast have submitted to the Chinese.

HAINAULT, a province of the Netherlands; bounded on the N. by Brabant, on the N. W. by Flanders, on the W. by Artois, on the S. by Cambresis, Picardy, and Champagne, and on the E. by the territory of Liege, and the county of Namur. It is divided into Austrian Hainault, of which the capital is Mons; and French Hainault, which is included in the department of the North.

HAINAULT, a forest of Essex, lying to the S. E. of Epping Forest, and supposed to be so called from some of the deer, with which it was stocked, having been brought from the province of the same name in the Netherlands. In this forest is a celebrated oak, known through many centuries by the name of Fairlop. Beneath its shade, which overspreads an area of 300 feet in circuit, an annual fair has been long held on the 22d of July. A society of archers, called the Hainault Foresters, and consisting of some of the principal gentlemen and ladies of the county,

march round this tree, at certain stated times, dressed in elegant uniforms, and attended by a band of music.

HAIR, small filaments issuing out of the pores of the skins of animals; and serving most of them as a tegument or covering. In lieu of hair, the nakedness of some animals is covered with feathers, wool, scales, &c. Hair is found on all parts of the human body, except the soles of the feet and the palms of the hands. But it grows longest on the head, chin, breast, in the arm-pits, and about the privities.

The ancients held the hair a sort of excrement, fed only with excrementitious matters, and no proper part of a living body. They supposed it generated of the fuliginous parts of the blood, exhaled by the heat of the body to the surface, and there condensed in passing through the pores. Their chief reasons were, that the hair being cut, will grow again apace, even in extreme old age, and when life is very low: that in hectic and consumptive people, where the rest of the body is continually emaciating and attenuating, the hair shall thrive: nay, and that it will grow again in dead carcases. They added, that hair does not feed and grow like the other parts, by intusception, i. e. by a juice circulating within it; but, like the nails, by juxtaposition, each part next the root thrusting forward that immediately before it.

But the moderns are agreed, that every hair does properly and truly live, and receive nutriment to fill and distend it like the other parts: which they argue hence, that the roots do not turn grey in aged persons sooner than the extremities, but the whole changes colour at once, and the like is observed in boys, &c.; which shows that there is a direct communication, and that all the parts are affected alike.

It may be observed, however, that, properly speaking, the life and growth of hairs is of a different kind from that of the rest of the body; and is not immediately derived therefrom, or reciprocated therewith. It is rather of the nature of vegetation. They grow as plants do out of the earth; or as some plants shoot from the parts of others; from which though they draw their nourishment, yet each has, as it were, its several life and a distinct economy. They derive their food from some juices in the body, but not from the nutritious juices of the body; whence they may live, even though the body be starved. Wulferus, in the *Philosophical Collections*, gives an account of a woman buried at Norimberg, whose grave being opened 43 years after her death, there was hair found issuing forth plentifully through the clefts of the coffin; inasmuch, that there was reason to imagine the coffin had some time been covered all over with hair. The cover being removed, the whole corpse appeared in its perfect shape; but, from the crown of the head to the sole of the foot, covered over with a thick-set hair, long and curled. The sexton going to handle the upper part of the head with his fingers, the whole structure fell at once, leaving nothing in his hand but an handful of hair: there was neither skull nor any other bone left; yet the hair was solid and strong enough. Mr. Arnold, in the same collection, gives a relation of a man hanged for theft, who, in a little time, while he yet hung upon the gallows, had his body strangely covered over with hair. Some moderns, however, deny the authenticity of these and other similar relations.

The hairs ordinarily appear round or cylindrical; but the microscope also discovers triangular and square ones; which diversity of figure arises from that of the pores, to which the hairs always accommodate themselves. Their length depends on the quantity of the fluids which feed them, and their colour on some property in that humour; whence it is that at different stages of life, the colour usually changes. Their extremities split into two or three branches, especially when kept dry, or suffered to grow too long; so that what appears only a single hair to the naked eye, seems a brush to the microscope.

The hair of a mouse, viewed by Mr. Derham with a microscope, seemed to be one single transparent tube, with a pith made up of fibrous substances, running in dark lines, in some hairs transversely, in others spirally. The darker medullary parts or lines, he observes, were no other than small fibres convolved round, and lying closer together than in the other parts of the hair. They run from the bottom to the top of the hair; and, he imagines, may serve to make a gentle evacuation of some humour out of the body. Hence the hair of hairy animals, this author suggests, may not only serve as a fence against cold, &c. but as an organ of insensible perspiration.

Though the external surface of the body is the natural place for hairs, we have many well-attested instances of their being found also on the internal surface. Amatus Lusitanus mentions a person who had hair upon his tongue. Pliay and Valerius Maximus concur in their testimonies, that the heart of Aristomenes the Messenian was hairy. Cælius Rhodiginus relates the same of Hermogenes the rhetorician; and Plutarch, of Leonidas the Spartan. Hairs are said to have been frequently found in the breasts of women, and to have occasioned the distemper called *trichiasis*; but some authors are of opinion, that these are small worms, and not hairs. There have been, however, various and indisputable observations of hairs found in the kidneys, and voided by urine.

Hippocrates is of opinion, that the glandular parts are the most subject to hair; but bundles of hair have been found in the muscular parts of beef, and in such parts of the human body as are equally firm with that. Hair has been often found in abscesses and imposthumations. Schultetus, opening the abdomen of a woman, found 12 pints of water, and a large lock or bundle of hair swimming loose in it. But of all the internal parts, there is none so much subject to an unnatural growth of hair as the ovaries of females, and that as well of the human species as of other animals. Of this Dr. Tyson relates three remarkable instances: two of these were young women, and the other was a bitch. The animal had been much emaciated in its hinder parts; the hair was about an inch and a half long; but the most remarkable particular was, that hair was also found lying loose in the cavities of the veins. We have several instances of mankind being affected in the same manner. Cardan relates, that he found hair in the blood of a Spaniard: and Slonatus in that of a gentlewoman of Cracovia; and Schultetus declares from his own observation, that those who are afflicted with the *plica polonica* have very often hair in their blood; but these accounts are incredible.

Diseases of the Hair. Almost the only disease of the hair, besides the remarkable one called *plica polonica*, is its falling off, or *balduess*. For this many remedies have been recommended, but scarce any of them can be depended upon. The juice of burdock, and the lixivial salts of vine ashes, are said to be efficacious; also the powder of hermodactyls, and the decoction of boxwood. A remarkable instance of the efficacy of this last is given in the *Encycl. Brit.* under the article *Buxus*. Some authors give instances of the hair changing its colour in a short time, through grief, or by reason of a fright, &c.

Hair as an Ornament, or as an Ensign of Dignity or of Religion. By the Jews hair was worn naturally long, just as it grew; but the priests had theirs cut every fortnight, while they were in waiting at the temple; they made use of no razors, however, but scissars only. The Nazarites, while their vow continued, were forbidden to touch their heads with a razor. See NAZARITE.

The falling of the hair, or a change of its colour, was regarded amongst the Hebrews as a sign of the leprosy. Black hair was esteemed by them as the most beautiful. Absalom's hair was cut once a-year, and is said to have weighed 200 shekels, by the king's weight, which is about 31 ounces. The

law of God hath left no particular ordinances with respect to the hair.

The hair of both Jewish and Grecian women engaged a principal share of their attention, and the Roman ladies seem to have been no less curious with respect to theirs. They generally wore it long, and dressed it in a variety of ways, ornamenting it with gold, silver, pearls, &c. On the contrary, the men amongst the Greeks and Romans, and amongst the later Jews, wore their hair short, as may be collected from books, medals, statues, &c. This formed a principal distinction in dress betwixt the sexes. This observation illustrates a passage in 1 Cor. xi. 14, 15. St. Paul forbids the Corinthian women, when praying by divine inspiration, to have their hair dishevelled; probably because this made them resemble the heathen priestesses, when actuated by the pretended influence of their gods.

Amongst the Greeks, both sexes, a few days before marriage, cut off and consecrated their hair as an offering to their favourite deities. It was also customary among them to hang the hair of the dead on the doors of their houses previous to interment. They likewise tore, cut off, and sometimes shaved their hair, when mourning for their deceased relations or friends, which they laid upon the corpse or threw into the pile, to be consumed together with the body. The ancients imagined that no person could die till a lock of hair was cut off; and this act they supposed was performed by the invisible hand of death, or Iris, or some other messenger of the gods. This hair, thus cut off, they fancied consecrated the person to the infernal deities, under whose jurisdiction the dead were supposed to be. It was a sort of first fruits which sanctified the whole. See *Virg. Æn.* 4. 694.

Whatever was the fashion, with respect to the hair, in the Grecian states, slaves were forbidden to imitate the freemen. The hair of the slaves was always cut in a particular manner, called *θηξ ἀνδραποδοῦνης*, which they no longer retained after they procured their freedom.

It was esteemed a notable honour among the ancient Gauls to have long hair, and hence came the appellation *Gallia comata*. For this reason Julius Cæsar, upon subduing the Gauls, made them cut off their hair as a token of submission. It was with a view to this, that such as afterwards quitted the world to go and live in cloisters, procured their hair to be shaven off; to show that they bid adieu to all earthly ornaments, and made a vow of perpetual subjection to their superiors.

Gregory of Tours assures us, that in the royal family of France, it was a long time the peculiar mark and privilege of kings and princes of the blood to wear long hair, artfully dressed and curled; every body else was obliged to be polled, or cut round, in sign of inferiority and obedience. Some writers assure us, that there were different cuts for all the different qualities and conditions; from the prince who wore it at full length, to the slave or villain who was quite cropt. To cut off the hair of a son of France, under the first race of kings, was to declare him excluded from the right of succeeding to the crown, and reduced to the condition of a subject.

In the eighth century, it was the custom of people of quality to have their children's hair cut the first time by persons they had a particular honour and esteem for; who, in virtue of this ceremony, were reputed a sort of spiritual parents or godfathers thereof: Though this practice appears to have been more ancient; inasmuch as we read, that Constantine sent the pope the hair of his son Heraclius, as a token that he desired him to be his adoptive father.

The parade of long hair became still more and more obnoxious in the progress of Christianity, as something utterly inconsistent with the profession of persons who bore the cross. Hence numerous injunctions and canons to the contrary. Pope Anicetus is commonly supposed to have been the first who forbade

the clergy to wear long hair: but the prohibition is of an older standing in the churches of the east; and the letter wherein that decree is written, is of a much later date than that pope. The clerical tonsure is related by Isidore Hispalensis, as of apostolical institution.

Long hair was anciently held so odious, that there is a canon still extant of the year 1096, importing, that such as wore long hair should be excluded coming into church while living, and not be prayed for when dead. We have a furious declamation of Luitprand against the emperor Phocas, for wearing long hair, after the manner of the other emperors of the east, all except Theophilus, who, being bald, enjoined all his subjects to shave their heads.

The French historians and antiquaries have been very exact in recording particulars of the hair of their several kings. Charlemagne wore it very short, his son shorter; Charles the Bald had none at all. Under Hugh Capet it began to appear again: this the ecclesiastics took in dudgeon, and excommunicated all who let their hair grow. Peter Lombard expostulated the matter so warmly with Charles the Young, that he cut off his hair; and his successors for some generations wore it very short. A professor of Utrecht, in 1650, wrote expressly on the question, Whether it be lawful for men to wear long hair? and concluded for the negative. Another divine, named Reves, who had written for the affirmative, replied to him.

The ancient Britons were extremely proud of the length and beauty of their hair, and were at much pains in dressing and adorning their heads. Some of them carried their fondness for and admiration of their hair to an extravagant height. It is said to have been the last and most earnest request of a young warrior, who was taken prisoner and condemned to be beheaded, that no slave might be permitted to touch his hair, which was remarkably long and beautiful, and that it might not be stained with his blood. We hardly ever meet with a description of a fine woman or beautiful man, in the poems of Ossian, but their hair is mentioned as one of their greatest beauties. Not contented with the natural colour of their hair, which was commonly fair or yellow, they made use of certain washes to render it still brighter. One of these washes was a composition of lime, the ashes of certain vegetables, and tallow. They made use of various arts also to make the hair of their heads grow thick and long; which last was not only esteemed a great beauty, but was considered as a mark of dignity and noble birth. Boadicia queen of the Iceni is described by Dio with very long hair, flowing over her shoulders, and reaching down below the middle of her back. The Britons shaved all their beards, except their upper lips; the hair of which they, as well as the Gauls, allowed to grow to a very inconvenient length.

In after-times, the Anglo-Saxons and Danes also considered fine hair as one of the greatest beauties and ornaments of their persons, and were at no little pains in dressing it to advantage. Young ladies before marriage wore their hair uncovered and untied, flowing in ringlets over their shoulders; but as soon as they were married, they cut it shorter, tied it up, and put on a head-dress of some kind or other according to the prevailing fashion. To have the hair entirely cut off was so great a disgrace, that it was one of the greatest punishments inflicted on those women who were guilty of adultery. The Danish soldiers who were quartered upon the English, in the reigns of Edgar the Peaceable and of Ethelred the Unready, were the beaux of those times, and were particularly attentive to the dressing of their hair; which they combed at least once every day, and thereby captivated the affections of the English ladies. The clergy, both secular and regular, were obliged to shave the crowns of their heads, and keep their hair short, which distinguished them from the laity; and several canons were made against their concealing their tonsure, or allowing their hair to grow

long. The shape of this clerical tonsure was the subject of long and violent debates between the English clergy on the one hand, and those of the Scots and Picts on the other; that of the former being circular, and that of the latter only semicircular. It appears very plainly, that long flowing hair was universally esteemed a great ornament; and the tonsure of the clergy was considered as an act of mortification and self-denial, to which many of them submitted with reluctance, and endeavoured to conceal as much as possible. Some of them who affected the reputation of superior sanctity inveighed with great bitterness against the long hair of the laity; and laboured earnestly to persuade them to cut it short, in imitation of the clergy. Thus the famous St. Wulfstan, bishop of Worcester, is said to have declaimed with great vehemence against luxury of all kinds, but chiefly against long hair as most criminal and most universal. "The English (says William of Malmesbury in his Life of St. Wulfstan) were very vicious in their manners, and plunged in luxury, through the long peace which they had enjoyed in the reign of Edward the Confessor. The holy prelate Wulfstan reproved the wicked of all ranks with great boldness; but he rebuked those with the greatest severity who were proud of their long hair. When any of those vain people bowed their heads before him to receive his blessing, before he gave it he cut a lock of their hair with a little sharp knife, which he carried about him for that purpose; and commanded them, by way of penance for their sins, to cut all the rest of their hair in the same manner. If any of them refused to comply with this command, he denounced the most dreadful judgments upon them, reproached them for their effeminacy, and foretold, that as they imitated women in the length of their hair, they would imitate them in their cowardice when their country was invaded; which was accomplished at the landing of the Normans."

This continued to be long a topic of declamation among the clergy, who even represented it as one of the greatest crimes, and most certain marks of reprobation. Anselm archbishop of Canterbury went so far as to pronounce the then terrible sentence of excommunication against all who wore long hair; for which pious zeal he is very much commended. Serlo, a Norman bishop, acquired great honour by a sermon which he preached before Henry I. A. D. 1104, against long and curled hair; with which the king and all his courtiers were so much affected, that they consented to resign their flowing ringlets, of which they had been so vain. The prudent prelate gave them no time to change their minds, but immediately pulled a pair of shears out of his sleeve, and performed the operation with his own hand. Another incident happened about 25 years after, which gave a temporary check to the prevailing fondness for long hair. It is thus related by a contemporary historian: "An event happened, A. D. 1129, which seemed very wonderful to our young gallants; who, forgetting that they were men, had transformed themselves into women by the length of their hair. A certain knight, who was very proud of his long luxuriant hair, dreamed that a person suffocated him with his curls. As soon as he awoke from his sleep, he cut his hair to a decent length. The report of this spread over all England, and almost all the knights reduced their hair to the proper standard. But this reformation was not of long continuance; for in less than a year all who wished to appear fashionable returned to their former wickedness, and contended with the ladies in length of hair. Those to whom nature had denied that ornament supplied the defect by art." The Greeks, and, after their example, the Romans, wore false hair.

Commerce of HAIR. Hair makes a very considerable article in commerce, especially since the mode of perukes has obtained. The hair of the growth of the northern countries, as England, &c. is valued much beyond that of the more southern ones, as Italy, Spain, the south parts of France, &c. The

merit of good hair consists in its being well fed, and neither too coarse nor too slender; the bigness rendering it less susceptible of the artificial curl, and disposing it rather to frizzle, and the smallness making its curl of too short duration. Its length should be about 25 inches; the more it falls short of this the less value it bears. There is no certain price for hair; but it is sold from five shillings to five pounds an ounce, according to its quality.

The scarceness of grey and white hair has put the dealers in that commodity upon the methods of reducing other colours to this. This is done by spreading the hair to bleach on the grass like linen, after first washing it out in a lixivious water. This lye, with the force of the sun and air, brings the hair to so perfect a whiteness, that the most experienced person may be deceived therein; there being scarce any way of detecting the artifice, but by boiling and drying it, which leaves the hair of the colour of a dead walnut-tree leaf. There is also a method of *dyeing hair* with bismuth, which renders such white hair as borders too much upon the yellow, of a bright silver colour: boiling is the proof of this too, the bismuth not being able to stand it.

Hair may be also changed from a red, grey, or other disagreeable colour, to a brown or deep black, by a solution of silver. The liquors sold under the name of *hair-waters*, are, in fact, no more than solutions of silver in aquafortis, largely diluted with water, with the addition perhaps of other ingredients, which contribute nothing to their efficacy. The solution should be fully saturated with the silver, that there may be no more acid in it than is necessary for holding the metal dissolved; and besides dilution with water, a little spirit of wine may be added for the further decomposition of the acid. It must be observed, that for diluting the solution, distilled water, or pure rain-water, must be used; the common spring-waters turning it milky, and precipitating a part of the dissolved silver. It is to be observed also, that if the liquor touches the skin, it has the same effect on it as on the matter to be stained, changing the part moistened with it to an indelible black.—Hair may also be dyed of any colour in the same manner as wool. See DYEING.

Hair which does not curl or buckle naturally, is brought to it by art, by first boiling and then baking it in the following manner: After having picked and sorted the hair, and disposed it in parcels according to lengths, they roll them up and tie them tight down upon little cylindrical instruments, either of wood or earthen ware, a quarter of an inch thick, and hollowed a little in the middle, called *pipes*; in which state they are put in a pot over the fire, there to boil for about two hours. When taken out, they let them dry; and when dried, they spread them on a sheet of brown paper, cover them with another, and thus send them to the pastry-cook; who making a crust or coffin around them of common paste, sets them in an oven till the crust is about three-fourths baked.

The end by which a hair grew to the head is called the *bead of the hair*; and the other, with which they begin to give the buckle, the *joint*. Formerly the peruke-makers made no difference between the ends, but curled and wove them by either indifferently: but this made them unable to give a fine buckle; hair woven by the point never taking a right curl. Foreigners own themselves obliged to the English for this discovery, which was first carried abroad by a peruke-maker of our country.

Hair is also used in various other arts and manufactures. In particular, the hair of beavers, hares, rabbits, &c. is the principal matter whereof hats are made. Spread on the ground, and left to putrefy on corn-lands, hair, like all other animal substances, *viz.* horns, hoofs, blood, garbage, &c. proves good manure.

HAIR, in farriery, is generally called the *coat*; and, with re-

gard to horses, deserves some consideration. The hair growing on the fetlock serves as a defence to the prominent part of it in travelling in stony ways or in frosty weather. If the hair of a horse's neck, and the parts most uncovered, be close, smooth, and sleek, it is an indication of his being in health and good case. In order to make the hide of an horse soft and sleek, he must be kept in warm clothing. Some, in order to effect this, bleed him and rub him all over with his own blood, and, after repeating it two or three days, curry and dress him well, which makes his coat shine as if it were covered with a fine varnish. If hair fall off from the mane or tail, it is caused either by his having a dry mange, or from some furfeit or cold. To cure the mange, anoint the horse's mane and crest with black soap; or with a strong lye of ashes, and wash the part all over with it. But if a canker should grow on a horse's tail, then the part should be dressed with verdegris, or blue vitriol, and treated as an ill-conditioned wound. See FARRIERY.

If you would take away hair from any part of a horse's body, it may be done by applying the caustic called *Kalipurum*, which should be slightly rubbed over the surface so as just to destroy the skin; but care should be taken not to employ it too profusely, as it will in that case act more deeply than is required.

HAIR, or *Down*, of Plants; a general term expressive of all the hairy and glandular appearances on the surface of plants, to which they are supposed by naturalists to serve the double purpose of defensive weapons and vessels of secretion. These hairs are minute threads of greater or less length and solidity; some of them visible to the naked eye; whilst others are rendered visible only by the help of glasses. Examined by a microscope, almost all the parts of plants, particularly the young stalks or stems, appear covered with hairs. Hairs on the surface of plants present themselves under various forms: in the leguminous plants, they are generally cylindric; in the mallow tribe, terminated in a point; in agrimony, shaped like a fish-hook; in nettle, awl-shaped and jointed; and in some compound flowers with hollow or funnel-shaped florets, they are terminated in two crooked points. Probable as some experiments have rendered it, that the hairs on the surface of plants contribute to some organical secretion, their principal use seems to be to preserve the parts in which they are lodged from the bad effects of violent frictions, from winds, from extremes of heat and cold, and such like external injuries. M. Guettard, who has established a botanical method from the form, situation, and other circumstances of the hairy and glandular appearances on the surface of plants, has demonstrated, that these appearances are generally constant and uniform in all the plants of the same genus. The same uniformity seems to characterise all the different genera of the same natural order. The different sorts of hairs which form the down upon the surface of plants were imperfectly distinguished by Grew in 1682, and by Malpighi in 1686. M. Guettard just mentioned was the first who examined the subject both as a botanist and a philosopher. His observations were published in 1747.

HAIR-Clotbs, in military affairs, are large pieces of cloth made with horse hair. They are used for covering the powder in waggons, or upon batteries; as also for covering charged bombs or hand grenades, and many other uses in magazines.

HAIR-Powder. See STARCH.

HAIR-Worm. See GORDIUS.

HAKE, in ichthyology, the English name of a fish common in the English and some other seas, and called by authors the *merlucius* and *lucius marinus*. This fish was used of old dried and salted. Hence the proverb obtains in Kent, *As dry as a bake*.

HAKLUYT (Richard), a naval historian, is supposed to have been born in London about the year 1553, and descended of a

genteel family in Herefordshire, as the name frequently occurs in the list of high-sheriffs for that county in former reigns. He was educated at Westminster-school; and thence, in 1570, removed to Christ-church, Oxford; where he applied himself particularly to the study of cosmography, and read public lectures in that science. Sir Edward Stafford being sent ambassador to France in 1583, Mr. Hakluyt was one of his attendants, probably in the capacity of chaplain. He was at this time master of arts and professor of divinity. In 1585 he obtained the royal mandate for the next vacant prebend of Bristol, to which preferment he succeeded during his residence at Paris. Constantly attentive to his favourite cosmographical inquiries, in searching the French libraries, he found a valuable history of Florida, which had been discovered about 20 years before by Captain Loudonniere and others: this he caused to be published, at his own expence, in the French language, and soon after revised and republished Peter Martyr's book *De orbe novo*. After five years residence in France, Mr. Hakluyt returned to England in company with lady Sheffield, sister to the lord admiral Howard. In the year 1589 he published his *Collection of Voyages* in one folio volume, which in 1598 was republished in three. In 1605 our author was made prebendary of Westminster; which, with the rectory of Wetheringsfet in the county of Suffolk, seems to have been the summit of his preferment. He died in 1616, and was buried in Westminster-abbey; bequeathing to his son Edmund his manor of Bridge-Place, and several houses in Tothil-street, Westminster. He was an indefatigable and faithful historian. His works are, 1. A *Collection of Voyages and Discoveries*, a small volume. 2. *History of Florida*, above mentioned. 3. *The principal Navigations, Voyages, and Discoveries of the English Nation, made by Sea or over Land to the farthest distant Quarters of the Earth, at any Time within the Compass of these 1500 Years*, in three vols. folio. 4. *The Discoveries of the World, from the first Original to the Year 1555*, written in the Portugal Tongue by Ant. Galvano; corrected, much amended, and translated into English, by Richard Hakluyt. 5. *Virginia richly valued*, by the Description of the Main Land of Florida, her next Neighbour, &c. written by a Portugal Gentleman of Elvas, and translated by Richard Hakluyt. Besides these, he left several manuscripts, which were printed in Purchas's collection.

HALBERSTADT, a handsome town of Germany, in the circle of Lower Saxony, and capital of a principality of the same name. It was formerly capital of the bishopric of Halberstadt, now secularized. The cathedral is a superb structure, with a fine peal of bells; and there are two regular abbeys within the town, and one without. There are also two nunneries. The Jews are tolerated here, and carry on a great trade; and the inhabitants brew excellent beer. It is subject to the king of Prussia, and is seated on the river Hotheim, 32 miles S. E. of Brunswick. Lon. 11. 24. E. Lat. 52. 6. N.

HALBERT, or **HALBARD**, in the art of war, a well-known weapon carried by the sergeants of marching regiments. It is a sort of spear, the shaft of which is about five feet long, and made of ash or other wood. Its head is armed with a steel point, not unlike the point of a two edged sword. But, besides this sharp point which is in a line with the shaft, there is a cross piece of steel, flat and pointed at both ends; but generally with a cutting edge at one extremity, and a bent sharp point at the other; so that it serves equally to cut down or to push withal. It is also useful in determining the ground between the ranks, and adjusting the files of a battalion. The word is formed of the German *hal*, "hall," and *bard*, "an hatchet." Vollius derives it from the German *halletaert*, of *bel*, "clarus, splendens," and *bart*, "ax." The *halbert* was anciently a common weapon in the army, where there were companies of halberdiers. It is said to have been used by the

Amazons, and afterwards by the Rhætians and Vindelicians about the year 570. It was called the *Danish ax*, because the Danes bore an halbert on the left shoulder. From the Danes it was derived to the Scots, from the Scots to the English Saxons, and from them to the French.

HALCYON, in ornithology, a name given by the ancients to the alcedo or king's fisher. See *ALCEDO*.

HALCYON *Days*, in antiquity, a name given to seven days before and as many after the winter solstice; by reason the halcyon, invited by the calmness of the weather, laid its eggs in nets built in the rocks, close by the brink of the sea, at this season.

HALDÉ (John Baptist du), a learned French Jesuit, born at Paris in 1674. He was extremely well versed in Asiatic geography; and we have of his compilation a work intitled *Grand description de la Chine & de la Tartarie*, from original memoirs of the Jesuitical missionaries, in 4 vols. folio. He was also concerned in a collection of letters begun by father Gobien, called *Des lettres edifiantes*, in 18 vols; and published some Latin poems and orations. He died in 1743.

HALDENSTEIN, a free and independent barony of the country of the Grisons. It consists of a small semicircular plain, which lies between the Rhine and the foot of Mount Calendar, about five miles in length, and scarcely one in breadth. It occupies also part of the mountain, which is so steep as not to be inhabited. It contains only two villages, Haldenstein and Sewils; and the whole number of the baron's subjects does not exceed 400. The ancient castle is now in ruins; but the baron resides in a house built in 1545, which commands a fine view of the town of Coire and the adjacent country.

HALE, in the sea language, signifies *pull*; as, to hale up, is to pull up; to hale in or out, is to pull in or out. To over-hale a rope, is to hale it too stiff, or to hale it the contrary way.

Keel-HALE. See *DUCKING*.

HALE (Sir Matthew), lord chief justice of the king's-bench in the reign of Charles II. was the son of Robert Hale, Esq. a barrister of Lincoln's Inn, and was born in 1609. He was educated at Oxford, where he made a considerable progress in learning; but was afterwards diverted from his studies by the levities of youth. From these he was reformed by Mr. John Glanvill serjeant at law; and applying to the study of the law, entered into Lincoln's Inn. Noy the attorney-general took early notice of him, and directed him in his studies. Mr. Selden also took much notice of him; and it was this acquaintance that first set Mr. Hale on a more enlarged pursuit of learning, which he had before confined to his own profession. During the civil wars, he behaved so well as to gain the esteem of both parties. He was employed in his practice by all the king's party; and was appointed by the parliament one of the commissioners to treat with the king. The execution of king Charles gave him very sensible regret. However, he took the engagement; and was appointed, with several others, to consider of the reformation of the law. In 1653 he was by writ made serjeant at law, and soon after appointed one of the justices of the common pleas. Upon the death of Oliver Cromwell he refused to accept of the new commission offered him by Richard his successor. He was returned one of the knights of Gloucestershire, in the parliament which called home Charles II. Soon after he was made lord chief baron of the exchequer; but declined the honour of knighthood, till lord chancellor Hyde, sending for him upon business when the king was at his house, told his majesty, that "there was his modest chief baron;" upon which he was unexpectedly knighted. He was one of the principal judges that sat in Clifford's Inn about settling the difference between landlord and tenant, after the fire of London, in which he behaved to the satisfaction of all parties concerned,

and also in his post of chief baron acted with inflexible integrity. One of the first peers went once to his chamber and told him, "That having a suit in law to be tried before him, he was then to acquaint him with it, that he might the better understand it when it should come to be tried in court." Upon which the lord chief baron interrupted him, and said, "He did not deal fairly to come to his chambers about such affairs; for he never received information of such causes but in open court, where both parties were to be heard alike." Upon which his grace (for it was a duke) went away not a little dissatisfied, and complained of it to the king as a rudeness that was not to be endured: but his majesty bid him content himself that he was used no worse; and said, "That he verily believed he would have used him no better if he had gone to solicit him in any of his own causes." Another remarkable incident happened in one of his circuits. A gentleman who had a trial at the assizes had sent him a buck for his table. When judge Hale therefore heard his name, he asked "if he was not the same person who had sent him the venison?" and finding that he was the same, told him, that "he could not suffer the trial to go on till he had paid him for his buck." The gentleman answered, that "he never sold his venison; and that he had done nothing to him which he did not do to every judge who had gone that circuit:" which was confirmed by several gentlemen present. The lord chief baron, however, would not suffer the trial to proceed till he had paid for the present: upon which the gentleman withdrew the record. In short, he was in 1671 advanced to be lord chief justice of the king's bench; but about four years after this promotion, his health declining, he resigned his post in February 1675-6, and died in December following. This excellent man, who was an ornament to the bench, to his country, and to human nature, wrote, 1. An Essay on the Gravitation and Non-gravitation of Fluid Bodies. 2. Observations touching the Torricellian Experiment. 3. Contemplations, moral and divine. 4. The Life of Pomponius Atticus, with political and moral Reflections. 5. Observations on the Principles of natural Motion. 6. The primitive Origination of Mankind. He also left a great number of manuscripts, in Latin and English, upon various subjects; among which are, his Pleas of the Crown, since published by Mr. Emlyn in two volumes folio; and his Original Institution, Power, and Jurisdiction of Parliaments.

HALEN, a town of Austrian Brabant, on the river Geet, 24 miles W. of Maestricht. Lon. 5. 4. E. Lat. 50. 58. N.

HALES (Stephen), D. D. a celebrated divine and philosopher, was born in 1677. He was the sixth son of Thomas Hales, Esq. the eldest son of Sir Robert Hales, created a baronet by king Charles II. and Mary the heiress of Richard Langley of Abbot's-Wood in Hertfordshire. In 1696 he was entered a pensioner at Bennet-college, Cambridge; and was admitted a fellow in 1703, and became bachelor of divinity in 1711. He soon discovered a genius for natural philosophy. Botany was his first study; and he used frequently to make excursions among Gogmagog hills, in company with Dr. Stukely, with a view of prosecuting that study. In these expeditions he likewise collected fossils and insects, having contrived a curious instrument for catching such of the latter as have wings. In company with this friend he also applied himself to the study of anatomy, and invented a curious method of obtaining a representation of the lungs in lead. They next applied themselves to the study of chemistry; in which, however, they did not make any remarkable discoveries. In the study of astronomy Mr. Hales was equally assiduous. Having made himself acquainted with the Newtonian system, he contrived a machine for showing the phenomena on much the same principles with that afterwards made by Mr. Rowley, and, from the name of his patron, called an *Orrery*.

About the year 1710 he was presented to the perpetual cure of Teddington near Twickenham, in Middlesex; and afterwards accepted of the living of Porlock in Somersetshire, which vacated his fellowship in the college, and which he exchanged for the living of Faringdon in Hampshire. Soon after, he married Mary, the daughter and heiress of Dr. Newce, who was rector of Halitham in Sussex, but resided at Much-Haddam in Hertfordshire. On the 13th of March 1718, he was elected member of the Royal Society; and on the 5th of March, in the year following, he exhibited an account of some experiments he had lately made on the effect of the sun's warmth in raising the sap in trees. This procured him the thanks of the society, who also requested him to prosecute the subject. With this request he complied with great pleasure; and on the 14th of June 1725 exhibited a treatise in which he gave an account of his progress. This treatise being highly applauded by the society, he farther enlarged and improved it; and in April 1727 he published it under the title of *Vegetable Statics*. This work he dedicated to his late majesty king George II. who was then prince of Wales; and he was the same year chosen one of the council of the Royal Society, Sir Hans Sloane being at the same annual election chosen their president. The book being well received, a second edition of it was published in 1731. In a preface to this edition Mr. Hales promised a sequel to the work, which he published in 1733 under the title of *Statical Essays*, &c. In 1732 he was appointed one of the trustees for establishing a new colony in Georgia. On the 5th of July 1733 the university of Oxford honoured him with a diploma for the degree of doctor in divinity; a mark of distinction the more honourable, as it is not usual for one university to confer academical honours on those who were educated at another. In 1734, when the health and morals of the lower and middling class of people were subverted by the excessive drinking of gin, he published, though without his name, A friendly Admonition to the Drinkers of Brandy and other spirituous Liquors; which was twice reprinted. The latter end of the same year he published a sermon which he preached at St. Bride's before the rest of the trustees for establishing a new colony in Georgia. His text was, "Bear ye one another's burthens, and so fulfil the law of Christ;" Galatians vi. 2. In 1739 he printed a volume in 8vo, intitled, Philosophical Experiments on Sea-water, Corn, Flesh, and other Substances. This work, which contained many useful instructions for voyagers, was dedicated to the lords of the admiralty. The same year he exhibited to the Royal Society an account of some farther experiments towards the discovery of medicines for dissolving the stone in the kidneys and bladder, and preserving meat in long voyages, for which he received the gold medal of Sir Godfrey Copley's donation. The year following he published some account of Experiments and Observations on Mrs. Stephens's Medicines for dissolving the Stone, in which their dissolvent power is inquired into and demonstrated.

In 1741 he read before the Royal Society an account of an instrument which he invented, and called a *ventilator*, for conveying fresh air into mines, hospitals, prisons, and the close parts of ships: he had communicated it to his particular friends some months before; and it is very remarkable, that a machine of the same kind, for the same purpose, was in the spring of the same year invented by one Martin Triewald, an officer in the service of the king of Sweden, called *captain of mechanics*, for which the king and senate granted him a privilege in October following, and ordered every ship of war in the service of that state to be furnished with one of them; a model also of this machine was sent into France, and all the ships in the French navy were also ordered to have a ventilator of the same sort. It happened also, that about the same time one Sutton, who kept a coffee house in Aldersgate-street, invented a ventila-

tor of another construction to draw off the foul air out of ships by means of the cook-room fire: but poor Sutton had not interest enough to make mankind accept the benefit he offered them; though its superiority to Dr. Hales's contrivance was evident, and among others Dr. Mead and the late ingenious Mr. Benjamin Robins gave their testimony in its favour. See *Air-Pipes*. The public, however, is not less indebted to the ingenuity and benevolence of Dr. Hales, whose ventilators came more early into use for many purposes of the greatest importance to life, particularly for keeping corn sweet, by blowing through it fresh showers of air; a practice very soon adopted by France, a large granary having been made, under the direction of Duhamel, for the preservation of corn in this manner, with a view to make it a general practice.

In 1743, Dr. Hales read before the Royal Society a description of a method of conveying liquors into the *abdomen* during the operation of tapping, and it was afterwards printed in their Transactions. In 1745, he published some experiments and observations on tar-water, which he had been induced to make by the publication of a work called *Siris*, in which the late learned and most excellent Dr. Berkley, bishop of Cloyne, had recommended tar-water as an universal medicine: on this occasion several letters passed between them on the subject, particularly with respect to the use of tar-water in the disease of the horned cattle. In the same year he communicated to the public, by a letter to the editor of the Gentleman's Magazine, a description of a *back-beaver*, which will winnow and clean corn much sooner and better than can be done by the common method. He also, at the same time, and by the same channel, communicated to the public a cheap and easy way to preserve corn sweet in sacks; an invention of great benefit to farmers, especially to poor leasers, who want to keep small quantities of corn for some time, but have no proper granary or repository for that purpose. He also the same year took the same method to publish directions how to keep corn sweet in heaps without turning it, and to sweeten it when musty. He published a long paper, containing an account of several methods to preserve corn by ventilators; with a particular description of several sorts of ventilators, illustrated by a cut, so that the whole mechanism of them may be easily known, and the machine constructed by a common carpenter. He published also in the same volume, but without his name, a detection of the fallacious boasts concerning the efficacy of the liquid shell in dissolving the stone in the bladder. In 1746 he communicated to the Royal Society a proposal for bringing small passible stones soon, and with ease, out of the bladder: and this was also printed in their Transactions. In the Gentleman's Magazine for July 1747, he published an account of a very considerable improvement of his back-beaver, by which it became capable of clearing corn of the very small grain, seeds, blacks, smut-balls, &c. to such perfection as to make it fit for seed-corn. In 1748 he communicated to the Royal Society a proposal for checking, in some degree, the progress of fires, occasioned by the great fire which happened that year in Cornhill: and the substance of this proposal was printed in their Transactions. In the same year he also communicated to the Society two memoirs, which are printed in their Transactions; one on the great benefit of ventilators, and the other on some experiments in electricity. In 1749 his ventilators were fixed in the Savoy prison, by order of the right hon. Henry Fox, Esq; then secretary at war, afterwards lord Holland; and the benefit was so great, that though 50 or 100 in a year often died of the gaol-distemper before, yet from the year 1749 to the year 1752 inclusive, no more than four persons died, though in the year 1750 the number of prisoners was 240; and of those four, one died of the small-pox, and another of intemperance. In the year 1750 he published some considerations on the causes of earthquakes; occasioned by the

flight shocks felt that year in London. The substance of this work was also printed in the Philosophical Transactions. The same year he exhibited an examination of the strength of several purging waters, especially of the water of *Jessop's well*, which is printed in the Philosophical Transactions.

Dr. Hales had now been several years honoured with the esteem and friendship of his royal highness Frederick prince of Wales; who frequently visited him at Teddington, from his neighbouring palace at Kew, and took a pleasure in surprising him in the midst of those curious researches into the various parts of nature which almost incessantly employed him. Upon the prince's death, which happened this year, and the settlement of the household of the princess-dowager, he was, without his solicitation, or even knowledge, appointed clerk of the closet, or almoner, to her royal highness. In 1751 he was chosen by the college of physicians to preach the annual sermon called *Crowne's lecture*: Dr. William Crowne having left a legacy for a sermon to be annually preached on "the wisdom and goodness of God displayed in the formation of man." Dr. Hales's text was, *With the ancient is wisdom, and in length of days understanding*, Job xii. 12. This sermon, as usual, was published at the request of the college. In the latter end of the year 1752, his ventilators, worked by a windmill, were fixed in Newgate, with branching trunks to 24 wards; and it appeared that the disproportion of those that died in the gaol before and after this establishment was as 16 to 7. He published also a farther account of their success, and some observations on the great danger arising from foul air, exemplified by a narrative of several persons seized with the gaol-fever by working in Newgate.

On the death of Sir Hans Sloane, which happened in the year 1753, Dr. Hales was elected a member of the Academy of Sciences at Paris in his room. The same year he published in the Gentleman's Magazine some farther considerations about means to draw the foul air out of the sick rooms of occasional army-hospitals, and private houses in town. He also published many other curious particulars relative to the use and success of ventilators. The same year a description of a sea-gage, which the doctor invented to measure unsathomable depths, was communicated to the public in the same miscellany: this paper was drawn up about the year 1732 or 1733, by the doctor, for the late Colin Campbell, Esq. who employed the ingenious Mr. Hawksbee to make the machine it describes, which was tried in various depths, and answered with great exactness, yet was at last lost near Bermuda. In 1754, he communicated to the Royal Society some experiments for keeping water and fish sweet with lime-water, an account of which was published in the Philosophical Transactions. He also continued to enrich their memoirs with many useful articles from this time till his death, particularly a method of forwarding the distillation of fresh from salt water by blowing showers of fresh air up through the latter during the operation. In 1757 he communicated to the editor of the Gentleman's Magazine an easy method of purifying the air, and regulating its heat in melon-frames and green-houses; also further improvements in his method of distilling sea-water.

His reputation and the interest of his family and friends might easily have procured him farther preferment: but of farther preferment he was not desirous; for, being nominated by his late Majesty to a canonry of Windsor, he engaged the princess to request his majesty to recall his nomination. That a man so devoted to philosophical studies and employments, and so conscientious in the discharge of his duty, should not desire any preferment which would reduce him to the dilemma either of neglecting his duty, or foregoing his amusement, is not strange: but that he would refuse an honourable and profitable appointment, for which no duty was to be done that would interrupt his habits of life, can scarce be imputed to his

temperance and humility without impeaching his benevolence; for, if he had no wish of any thing more for himself, a liberal mind would surely have been highly gratified by the distribution of so considerable a sum as a canonry of Windsor would have put into his power, in the reward of industry, the alleviation of distress, and the support of helpless indigence. He was, however, remarkable for social virtue and sweetness of temper; his life was not only blameless, but exemplary in a high degree; he was happy in himself, and beneficial to others, as appears by this account of his attainments and pursuits; the constant serenity and cheerfulness of his mind, and the temperance and regularity of his life, concurred, with a good constitution, to preserve him in health and vigour to the uncommon age of fourscore and four years. He died at Teddington in 1761; and was buried, pursuant to his own directions, under the tower of the parish-church, which he built at his own expence not long before his death.—Her royal highness the princess of Wales erected a monument to his memory in Westminster abbey.

HALESIA, in botany; a genus of the monogynia order, belonging to the dodecandria class of plants; and in the natural method ranking under the 18th order, *Bicornes*. The calyx is quadridentated, superior; the corolla quadrifid; the nut quadrangular and dispermous.

HALES OWEN, a town in Shropshire, inclosed by Worcester-shire, six miles E. of Stourbridge.

HALESWORTH, a town in Suffolk, with a market on Tuesday. It is seated on a neck of land between two branches of the river Blyth, is a thriving place, and has a trade in linen-yarn and sail-cloth. About the town is raised a great deal of hemp. It is 28 miles N. E. of Ipswich, and 101 N. E. of London. Lon. 1. 40. E. Lat. 52. 25. N.

HALF-BLOOD, in law, is where a man marries a second wife, the first being dead, and by the first venter he has a son, and by his second venter has likewise a son; the two brothers, in this case, are but of half-blood. See CONSANGUINITY and DESCENT.

HALF-Merk; a noble, or 6s. 8d.

HALF-Moon, in fortification; an outwork composed of two faces, forming a salient angle, whose gorge is in form of a crescent or half-moon, whence the name. See FORTIFICATION.

HALFPENNY, a well known copper coin, whose value is expressed by its name, in reference to the penny.

HALI-BEIGH, first dragoman or interpreter at the Grand Signior's court in the 17th century, was born of Christian parents in Poland; but having been taken by the Tartars when he was young, they sold him to the Turks, who brought him up in their religion in the seraglio. His name, in his native country, was Bobowiki. He learnt many languages, and Sir Paul Ricaut owns he was indebted to him for several things which he relates in his *Present state of the Ottoman empire*. He held a great correspondence with the English, who persuaded him to translate some books into the Turkish language; and he had a mind to return into the bosom of the Christian church, but died before he could accomplish the design. Dr. Hyde published his book, *Of the liturgy of the Turks, their pilgrimages to Mecca, their circumcision and visiting of the sick*. He translated the catechism of the church of England, and the bible, into the Turkish language. The MS. is lodged in the library of Leyden. He wrote likewise a Turkish grammar and dictionary.

HALIBUT ISLAND, an island in the N. Pacific Ocean, so named by captain Cook in his last voyage, on account of the number of fish of that name they caught there, some of which weighed upward of a hundred pounds, and none less than twenty. It is seven leagues in circumference, and very low and barren. Lon. 164. 15. W. Lat. 54. 48. N.

HALICARNASSUS, in ancient geography, a principal town of Caria, said to be built by the Argives, and situated be-

tween two bays, the Ceramicus and Jafius. It was the royal residence (called *Zephyra* formerly); especially of Mausolus, made more illustrious by his monument. This monument was one of the seven wonders, and erected by Artemisia. Halicarnassus, or Halicarnassensis, was the gentilitious name of Herodotus and Dionysius. The former was called the Father of History; and the latter was not only a good historian but also a critic.

HALLÆTUS, in ornithology. See **FALCO**.

HALIEUTICS, **HALIEUTICA**, **ἁλιευτική**, formed of *ἄλιος*, *fisherman*, which is derived from *ἅλιος*, *sea*; books treating of fishes, or the art of fishing. We have still extant the halieutics of Oppian.

HALIFAX, a town of Nova Scotia, in North America, on Chebucto Bay. It has a good harbour, large and safe enough to shelter a squadron of ships throughout the winter. The town has an entrenchment, and is strengthened with forts of timber. It is commodiously situated for the fishery, 789 miles N. E. of New York. W. lon. 63. 30. N. lat. 44. 45.

HALIFAX, a town in the west riding of Yorkshire, with a market on Saturday. It is seated in a hilly country, of rather difficult access, but full of people. It is the great market for stuffs, such as shalloon, calamancos, everlastings, &c. It has a large market-house, called *The New Piece Hall*, as well as various others for particular goods. It is a very large parish, and contains 12 chapels of ease, and upwards of 12,000 inhabitants. The town is handsome, with houses built of stone, and good streets, and is 40 miles W. S. W. of York, and 197 N. by W. of London. W. lon. 1. 45. N. lat. 53. 45.

HALIOTIS, the **EAR-SHELL**, a genus of insects belonging to the order of *vermes testacea*. This is an animal of the snail kind, with an open shell resembling an ear. There are seven species, distinguished by the figure of their shells. See plate 3.

HALITZ, a town of Poland, and capital of a territory of the same name, in Red Russia, with a castle. It is seated on the river Dnieister. E. lon. 26. 0. N. lat. 49. 20.

HALL, in architecture, a large room at the entrance of a fine house and palace. Vitruvius mentions three kinds of halls; the tetrastyle, with four columns supporting the platfond or ceiling; the Corinthian, with columns all round let into the wall, and vaulted over; and the Egyptian, which had a peristyle of insulated Corinthian columns, bearing a second order with a ceiling. The hall is properly the finest as well as first member of an apartment: and in the houses of ministers of state, magistrates, &c. is the place where they dispatch business, and give audience. In very magnificent buildings, where the hall is larger and loftier than ordinary, and placed in the middle of the house, it is called a *saloon*. The length of a hall should be at least twice and a quarter its breadth; and in great buildings, three times its breadth. As to the height of halls, it may be two-thirds of the breadth; and, if made with an arched ceiling, it will be much handfomer, and less liable to accidents by fire. In this case, its height is found by dividing its breadth into six parts, five of which will be the height from the floor to the under side of the key of the arch.

HALL is also particularly used for a court of justice; or an edifice wherein there is one or more tribunals. In *Westminster-hall* are held the great courts of England, viz. the king's bench, chancery, common-pleas, and exchequer. In adjoining apartments is likewise held the high court of parliament. *Westminster-hall* was the royal palace or place of residence of our ancient kings; who ordinarily held their parliaments and courts of judicature in their dwelling-houses (as is still done by the kings of Spain), and frequently sat in person in the courts of judicature, as they still do in parliament. A great part of this palace was burnt under Henry VIII. What remains is still reserved for the said judicatories. The great hall, wherein the courts of king's-

bench, &c. are kept, is said to have been built by William Rufus; others say by Richard I. or II. It is reckoned superior in point of dimensions to any hall in Europe; being 300 feet long and 100 broad.

HALL (Joseph), an eminent prelate of the church of England, was born in 1574, and educated at Cambridge. He became professor of rhetoric in that university, and then successively was made rector of Halsted in Suffolk, presented to the living of Waltham in Essex, made prebendary of Wolverhampton, dean of Worcester, bishop of Exeter, and lastly of Norwich. His works testify his zeal against Popery, and are much esteemed. He lamented the divisions of the Protestants, and wrote something concerning the means of putting an end to them. July 1616 he attended the embassy of lord Donecaster into France, and upon his return was appointed by his majesty to be one of the divines who should attend him into Scotland. In 1618 he was sent to the synod of Dort with other divines, and pitched upon to preach a Latin sermon before that assembly. But being obliged to return from thence before the synod broke up, on account of his health, he was by the states presented with a gold medal. He wrote, 1. Miscellaneous epistles. 2. *Mundus alter et idem*. 3. A just censure of travellers. 4. The Christian Seneca. 5. Satires, in six books. 6. A century of meditations; and many other works, which, besides the above satires, make in all five volumes in folio and quarto. He died in 1656.

HALL (John), a poet of distinguished learning, was born at Durham, and educated at Cambridge, where he was esteemed the brightest genius in that university. In 1646, when he was but 19 years of age, he published his *Horæ Vacivæ*, or *Essays*; and the same year came out his poems. He translated from the Greek "Hierocles upon the golden verses of Pythagoras;" before which is an account of the ingenious translator and his works, by John Davies of Kidwelly. He died in 1656, aged 29.

HALLAGE, a fee or toll paid for cloth brought to be sold in Blackwell-hall, London.

HALLAMAS, in our old writers, the day of all-hallows, or all-saints, viz. November 1. It is one of the erofs quarters of the year which was computed, in ancient writings, from Hallamas to Candlemas.

HALLAND, a province of Gothland, in Sweden, on the W. coast of that kingdom. It is 60 miles along the coast, but not above 12 in breadth. Halmstadt is the capital.

HALLATON, a town of Leicestershire, with a market on Thursday. It is 12 miles S. E. of Leicester, and 90 N. by E. of London. E. lon. 0. 50. N. lat. 52. 32.

HALLE, a little dismantled town of Austrian Hainault. The church contains an image of the Virgin Mary, held in great veneration. It is seated on the river Senne, eight miles S. W. of Brussels. E. lon. 4. 20. N. lat. 50. 46.

HALLE, a handsome and considerable town of Germany, in the circle of Upper Saxony, and duchy of Magdeburg, with a famous university and salt-works. It is seated on the river Sale, 40 miles E. of Magdeburg. E. lon. 12. 8. N. lat. 51. 36.

HALLE, a free imperial town of Germany, in Suabia, famous for its salt-pits; seated on the river Kocher, among rocks and mountains, 37 miles N. E. of Stutgard. E. lon. 9. 52. N. lat. 49. 20.

HALLE, a town of Germany, in Tyrol, six miles N. E. of Inspruck. E. lon. 11. 33. N. lat. 47. 12.

HALLEIN, a town of Germany, in the archbishopric of Saltzburg; seated on the river Saltza, among the mountains, wherein are mines of salt, which are the chief riches of the town and country. It is seven miles S. E. of Saltzburg. E. lon. 13. 12. N. lat. 47. 33.

HALLELUIA, or HALLELUJAH, a term of rejoicing, sometimes sung or rehearsed at the end of verses on such occasions. The word is Hebrew; or rather, it is two Hebrew words joined together: one of them הללו, *hallelu*, and the other יהוה *jab*; an abridgement of the name of God, יהוה, *Jehovah*. The first signifies *laudate*, "praise ye;" and the other *Dominum*, "the Lord." St. Jerome first introduced the word hallelujah into the church service: for a considerable time it was only used once a year in the Latin church, viz. at Easter; but in the Greek church it was much more frequent. St. Jerome mentions its being sung at the interments of the dead, which still continues to be done in that church, as also on some occasions in the time of Lent. In the time of Gregory the Great, it was appointed to be sung all the year round in the Latin church, which raised some complaints against that pope; as giving too much into the Greek way, and introducing the ceremonies of the church of Constantinople into that of Rome. But he excused himself by alleging, that this had been the ancient usage of Rome; and that it had been brought from Constantinople at the time when the word hallelujah was first introduced under pope Damascus.

HALLER (Albert Van), an eminent physician, was born at Bern, on the 16th of October 1708. He was the son of an advocate of considerable eminence in his profession. His father had a numerous family, and Albert was the youngest of five sons. From the first period of his education, he showed a very great genius for literature of every kind: to forward the progress of his studies, his father took into his family a private tutor, named *Abraham Billodt*; and such was the discipline exerted by this pedagogue, that the accidental sight of him, at any future period of life, excited in Haller very great uneasiness, and renewed all his former terrors. According to the accounts which are given us, the progress of Haller's studies, at the earliest periods of life, was rapid almost beyond belief. When other children were beginning only to read, he was studying Bayle and Moreri; and at nine years of age he was able to translate Greek, and was beginning the study of Hebrew. Not long after this, however, the course of his education was somewhat interrupted by the death of his father; an event which happened when he was in the 13th year of his age. After this he was sent to the public school at Bern, where he exhibited many specimens of early and uncommon genius. He was distinguished for his knowledge in the Greek and Latin languages; but he was chiefly remarkable for his poetical genius: and his essays of this kind, which were published in the German language, were read and admired throughout the whole empire. In the 16th year of his age he began the study of medicine at Tubingen, under those eminent teachers Duvernoy and Camerarius; and continued there for the space of two years, when the great reputation of the justly celebrated Boerhaave drew him to Leyden. Nor was this distinguished teacher the only man from whose superior abilities he had there an opportunity of profiting. Ruysch was still alive, and Albinus was rising into fame. Animated by such examples, he spent all the day, and the greatest part of the night, in the most intense study; and the proficiency which he made, gained him universal esteem both from his teachers and fellow-students. From Holland, in the year 1727, he came to England. Here, however, his stay was but short; and it was rather his intention to visit the illustrious men of that period, than to prosecute his studies at London. He formed connections with some of the most eminent of them. He was honoured with the friendship of Douglas and Cheselden; and he met with a reception proportioned to his merit from Sir Hans Sloane, president of the Royal Society. After his visit to Britain, he went to France; and there, under those eminent masters, Winslow and Le Dran, with the latter of whom he resided during his stay in Paris, he had opportunities

of prosecuting anatomy, which he had not before enjoyed. But the zeal of our young anatomist was greater than the prejudices of the people at that period, even in the enlightened city of Paris, could admit of. An information being lodged against him to the police for dissecting dead bodies, he was obliged to cut short his anatomical investigations by a precipitate retreat. Still, however, intent on the farther prosecution of his studies, he went to Basil, where he became a pupil to the celebrated Bernoulli.

Thus improved and instructed by the lectures of the most distinguished teachers of that period, by uncommon natural abilities, and by unremitting industry, he returned to the place of his nativity in the 26th year of his age. Not long after this, he offered himself a candidate, first for the office of physician to an hospital, and afterwards for a professorship. But neither the character which he had before he left his native country, nor the fame which he had acquired and supported while abroad, was sufficient to combat the interest opposed to him. He was disappointed in both; and it was even with difficulty that he obtained, in the following year, the appointment of keeper of a public library at Bern. The exercise of this office was indeed by no means suited to his great abilities: but it was agreeable to him, as it afforded him an opportunity for that extensive reading by which he has been so justly distinguished. The neglect of his merit, which marked his first outset, neither diminished his ardour for medical pursuits, nor detracted from his reputation either at home or abroad. And soon after he was nominated a professor in the university of Gottingen, by king George II. The duties of this important office he discharged, with no less honour to himself than advantage to the public, for the space of 17 years: and it afforded him an ample field for the exertion of those great talents which he possessed. Extensively acquainted with the sentiments of others respecting the economy of the human body, struck with the diversity of opinions which they held, and sensible that the only means of investigating truth was by careful and candid experiment, he undertook the arduous task of exploring the phenomena of human nature from the original source. In these pursuits he was no less industrious than successful, and there was hardly any function of the body on which his experiments did not reflect either a new or a stronger light. Nor was it long necessary for him, in this arduous undertaking, to labour alone. The example of the preceptor inspired his pupils with the spirit of industrious exertion. Zinn, Zimmermann, Caldani, and many others, animated by a generous emulation, laboured with indefatigable industry to prosecute and to perfect the discoveries of their great master. And the mutual exertion of the teacher and his students, not only tended to forward the progress of medical science, but placed the philosophy of the human body on a more sure, and an almost entirely new, basis. But the labours of Dr. Haller, during his residence at Gottingen, were by no means confined to any one department of science. He was not more anxious to be an improver himself, than to instigate others to similar pursuits. To him, the Anatomical Theatre, the School of Midwifery, the Chirurgical Society, and the Royal Academy of Sciences at Gottingen, owe their origin. Such distinguished merit could not fail to meet with a suitable reward from the sovereign under whose protection he then taught. The king of Great Britain not only honoured him with every mark of attention which he himself could bestow, but procured him also letters of nobility from the Emperor. On the death of Dillenius, he had an offer of the professorship of botany at Oxford; the states of Holland invited him to the chair of the younger Albinus; the king of Prussia was anxious that he should be the successor of Maupertuis at Berlin. Marshal Keith wrote to him in the name of his sovereign, offering him the chancellorship of the university of Halle, vacant by the death of the celebrated Wolff. Count Orlov invited him to Russia, in the name of his

mistress the empress, offering him a distinguished place at St. Petersburg. The king of Sweden conferred on him an unsolicited honour, by raising him to the rank of knighthood of the order of the polar star; and the emperor of Germany did him the honour of a personal visit; during which he thought it no degradation of his character to pass some time with him in the most familiar conversation.

Thus honoured by sovereigns, revered by men of literature, and esteemed by all Europe, he had it in his power to have held the highest rank in the republic of letters. Yet, declining all the tempting offers which were made to him, he continued at Göttingen, anxiously endeavouring to extend the rising fame of that medical school. But after 17 years residence in that university, an ill state of health rendering him less fit for the duties of the important office which he held, he solicited and obtained permission from the regency of Hanover to return to his native city of Bern. His fellow-citizens, who might at first have fixed him among themselves, with no less honour than advantage to their city, were now as sensible as others of his superior merit. A pension was settled upon him for life, and he was nominated at different times to fill the most important offices in the state. These occupations, however, did not diminish his ardour for useful improvements. He was the first president, as well as the greatest promoter, of the Oeconomical Society at Bern; and he may be considered as the father and founder of the Orphan Hospital of that city. Declining health, however, restrained his exertions in the more active scenes of life, and for many years he was confined entirely to his own house. Even this, however, could not put a period to his utility: for, with indefatigable industry, he continued his favourite employment of writing till within a few days of his death; which happened in the 70th year of his age, on the 12th of December 1777. His *Elementa Physiologicæ* and *Bibliotheca Medicinæ* will afford, to latest posterity, undeniable proofs of his indefatigable industry, penetrating genius, and solid judgment. But he was not less distinguished as a philosopher than beloved as a man; and he was not more eminent for his improvement in every department of medical science, than for his piety to God, and benevolence to all mankind.

HALLERIA, in botany; a genus of the angiospermia order, belonging to the didynamia class of plants; and in the natural method ranking under the 40th order, *Perfovatæ*. The calyx is trifid; the corolla quadrifid; the filaments longer than the corolla; the berry inferior and bilocular (the fruit not yet fully described).

HALLEY (Dr. Edmund), an eminent astronomer, was the only son of a soap-boiler in London, and was born in 1656. He first applied himself to the study of the languages and sciences, but at length gave himself up wholly to that of astronomy. In 1676 he went to the island of St. Helena to complete the catalogue of fixed stars, by the addition of those that lie near the south pole; and having delineated a planisphere in which he laid them all down in their exact places, he returned to England in 1678. In the year 1680 he took what is called *the grand tour*, accompanied by his friend the celebrated Mr. Nelson. In the midway between Calais and Paris, Mr. Halley had a sight of a remarkable comet, as it then appeared a second time that year, in its return from the sun. He had the November before seen it in its descent; and now hastened to complete his observations upon it, in viewing it from the royal observatory of France. His design in this part of his tour was, to settle a friendly correspondence between the two royal astronomers of Greenwich and Paris; and in the mean time to improve himself under so great a master as Cassini. From thence he went to Italy, where he spent great part of the year 1681; but his affairs calling him home, he returned to England. In 1683 he published his *Theory of the Variation of the Magnetical Compass*; in which

he supposes the whole globe of the earth to be a great magnet, with four magnetical poles, or points of attraction: but afterwards thinking that this theory was liable to great exceptions, he procured an application to be made to king William, who appointed him commander of the Paramour pink, with orders to seek by observations the discovery of the rule of variations, and to lay down the longitudes and latitudes of his majesty's settlements in America. He set out on this attempt on the 24th of November 1698: but having crossed the line, his men grew sickly; and his lieutenant mutinying, he returned home in June 1699. Having got the lieutenant tried and cashiered, he set sail a second time in September following, with the same ship, and another of less bulk, of which he had also the command. He now traversed the vast Atlantic ocean from one hemisphere to the other, as far as the ice would permit him to go; and having made his observations at St. Helena, Brazil, Cape Verd, Barbadoes, the Madeiras, the Canaries, the coast of Barbary, and many other latitudes, arrived in September 1700; and the next year published a general chart, showing at one view the variation of the compass in all those places. Captain Halley, as he was now called, had been at home little more than half a year, when he was sent by the king to observe the course of the tides, with the longitude and latitude of the principal head-lands in the British channel; which having executed with his usual expedition and accuracy, he published a large map of the British channel. Soon after, the emperor of Germany resolving to make a convenient harbour for shipping in the Adriatic, Captain Halley was sent by queen Anne to view the two ports on the coast of Dalmatia. He embarked on the 22d of November 1702; passed over to Holland; and going through Germany to Vienna, he proceeded to Istria: but the Dutch opposing the design, it was laid aside; yet the emperor made him a present of a rich diamond-ring from his finger, and honoured him with a letter of recommendation, written with his own hand, to queen Anne. Presently after his return, he was sent again on the same business; when passing through Hanover, he supped with king George I. then electoral prince, and his sister the queen of Prussia. On his arrival at Vienna, he was the same evening presented to the emperor, who sent his chief engineer to attend him to Istria, where they repaired and added new fortifications to those of Trieste. Mr. Halley returned to England in 1703; and the same year was made professor of geometry in the university of Oxford, in the room of Dr. Wallis, and had the degree of doctor of laws conferred on him by that university. He is said to have lost the professorship of astronomy in that city, because he would not profess his belief of the Christian religion. He was scarcely settled at Oxford, when he began to translate into Latin from the Arabic, *Apollonius de sectione rationis*; and to restore the two books *De sectione spatii* of the same author, which are lost, from the account given of them by Pappus; and he published the whole work in 1706. Afterwards he had a share in preparing for the press Apollonius's Conics; and ventured to supply the whole eighth book, the original of which is also lost. He likewise added Serenus on the section of the cylinder and cone, printed from the original Greek, with a Latin translation, and published the whole in folio. In 1713 he was made secretary of the Royal Society; in 1720 he was appointed the king's astronomer at the royal observatory at Greenwich in the room of Mr. Flamsteed; and in 1729, was chosen as a foreign member of the Academy of Sciences at Paris. He died at Greenwich in 1742. His principal works are, 1. *Catalogus stellarum in firmamento*. 2. *Tabulae astronomicae*. 3. An abridgment of the astronomy of comets, &c. We are also indebted to him for the publication of several of the works of the great Sir Isaac Newton, who had a particular friendship for him, and to whom he frequently communicated his discoveries.

HALLEY'S *Quadrant*. See QUADRANT.

HALLIARDS, the ropes or tackles usually employed to hoist or lower any sail upon its respective mast or stay. See JEARS.

HALMOTE, or HALIMOTE, is the same with what we now call a *court-baron*, the word implying a meeting of the tenants of the same hall or manor. The name is still retained at Luston, and other places in Herefordshire. See MOTE.

HALMSTADT, a strong seaport of Sweden, capital of the province of Halland, situated on a bay of the North Sea, 80 miles S. S. E. of Gotheborg. E. lon. 12. 48. N. lat. 56. 39.

HALO, or CORONA, in natural history, a coloured circle appearing round the body of the sun, moon, or any of the large stars. See CORONA.

HALORAGUS, in botany; a genus of the tetragynia order, belonging to the octandria class of plants. The calyx is quadrifid above; there are four petals; a dry plum, and a quadrilocular nut.

HALSTEAD, a town in Essex, with a market on Friday. It has long had a share in the manufactory of bays and says; and is seated on the declivity of a hill, at the foot of which runs the river Coln, 16 miles N. of Chelmsford, and 47 N. E. of London. E. lon. 0. 45. N. lat. 51. 59.

HALT, in war, a pause or stop in the march of a military body. Some derive the word from the Latin *balitus*, "breath;" it being a frequent occasion of halting to take breath: others from *alto*, because in halting they raised their pikes on end, &c.

HALTER, in the manege, a head-stall for a horse, of Hungary leather, mounted with one, and sometimes two straps, with a second throat-band, if the horse is apt to unhalter himself. The rope by which death is usually inflicted on criminals, is also called a *halter*.

HALTER-Cast, is an excoriation of the pastern, occasioned by the halter's being entangled about the foot, upon a horse's endeavouring to rub his neck with his hinder foot. For the cure of this, anoint the place, morning and evening, with equal quantities of linseed oil and brandy, mixed together.

HALTEREN, a town of Germany, in the bishopric of Munster; seated on the river Lippe, 25 miles S. W. of Munster. E. lon. 7. 27. N. lat. 51. 40.

HALTERISTÆ, in antiquity, a kind of players at discus; denominated from a peculiar kind of discus called by the Greeks *αλτηρ*, and by the Latins *halter*. See DISCUS. Some take the discus to have been a leaden weight or ball which the vaulters bore in their hands, to secure and keep themselves the more steady in their leaping. Others will have the halter to be a lump or mass of lead or stone, with an hole or handle fixed to it, by which it might be carried; and that the halteristæ were those who exercised themselves in removing these masses from place to place. Hier. Mercurialis, in his treatise *De arte gymnastica*, l. ii. c. 12. distinguishes two kinds of halteristæ; for though there was but one halter, there were two ways of applying it. The one was to throw or pitch it in a certain manner; the other only to hold it out at arm's end, and in this posture to give themselves divers motions, swinging the hand backwards and forwards, according to the engraven figures thereof given us by Mercurialis. The halter was of a cylindrical figure, smaller in the middle, where it was held, by one diameter, than at the two ends. It was above a foot long, and there was one for each hand: it was either of iron, stone, or lead. Galen, *De tuend. valetud.* lib. i. v. & vi. speaks of this exercise, and shows of what use it is in purging the body of peccant humours; making it equivalent both to purging and phlebotomy.

HALTON, or HAULTON, i. e. *Higb-Town*, a town of Cheshire, 186 miles from London. It stands on a hill, where a castle was built anno 1071, and is a member of the duchy of Lancaster; which maintains a large jurisdiction in the county

round it, by the name of *Halton-Fee*, or the *honour of Halton*, having a court of record, prison, &c. within themselves. About Michaelmas every year, the king's officers of the duchy keep a law-day at the castle, which still remains a stately building; once a fortnight a court is kept here, to determine all matters within their jurisdiction; but felons and thieves are carried to the sessions at Chester, to receive their sentence. By the late inland navigation, it has communication with the rivers Mersey, Dee, Ribble, Ouse, Trent, Darwent, Severn, Humber, Thames, Avon, &c. which navigation, including its windings, extends above 500 miles, in the counties of Lincoln, Nottingham, York, Lancaster, Westmoreland, Stafford, Warwick, Leicestershire, Oxford, Worcester, &c.

HALTWHISTLE, a well-built town of Northumberland, whose market is disused. It is 37 miles W. of Newcastle, and 315 N. N. W. of London. E. lon. 2. 17. N. lat. 55. 2.

HALYMOTE, properly signifies an holy or ecclesiastical court. See HALMOTE. There is a court held in London by this name before the lord mayor and sheriffs, for regulating the bakers. It was anciently held on Sunday next before St. Thomas's day, and for this reason called the *Halymote*, or *Holy-court*.

HALYS, in ancient geography, the noblest river of the Hither Asia, through which it had a long course, was the boundary of Cræsus's kingdom to the east. Running down from the foot of mount Taurus, through Cataonia and Cappadocia, it divided almost the whole of the Lower Asia, from the sea of Cyprus down to the Euxine, according to Herodotus; who seems to extend its course too far. According to Strabo, himself a Cappadocian, it had its springs in the Great Cappadocia. It separated Paphlagonia from Cappadocia; and received its name *απο του αλο*; from salt, because its waters were of a salt and bitter taste, from the nature of the soil over which they flowed. It is famous for the defeat of Cræsus king of Lydia, who was misled by the ambiguous words of this oracle: *Χροισος αλυν διασας μεγαλην αρχην διαλυσει*. "If Cræsus passes over the Halys he shall destroy a great empire." That empire was his own.

HALYWERC FOLK, in old writers, were persons who enjoyed land, by the pious service of repairing some church, or defending a sepulchre. This word also signified such persons in the diocese of Durham, as held their lands to defend the corpse of St. Cuthbert, and who from thence claimed the privilege of not being forced to go out of the bishopric.

HAM, a Saxon word used for "a place of dwelling;" a village or town: hence the termination of some of our towns, *Nottingham*, *Buckingham*, &c. Also a home close, or little narrow meadow, is called a *ham*.

HAM, is also a part of the leg of an animal; being the inner or hind part of the knee, or the ply or angle in which the leg and thigh, when bent, incline to each other.

HAM, in commerce, &c. denotes a leg or thigh of pork, dried, seasoned, and prepared, to make it keep and to give it a favourable agreeable flavour. *Westphalia* hams, so much in vogue, are prepared by salting them with saltpetre, pressing them in a press eight or ten days, then steeping them in juniper-water, and drying them by the smoke of juniper-wood. A common ham may be salted in imitation of those of Westphalia, by sprinkling it with salt for one day, in order to fetch out the blood; then wiping it dry, and rubbing it with a mixture of a pound of brown sugar, a quarter of a pound of saltpetre, half a pint of bay salt, and three pints of common salt, well stirred together in an iron pan over the fire till they are moderately hot: let it lie three weeks in this salting, and be frequently turned, and then dry it in a chimney.

HAM, a strong town of Germany, in Westphalia, capital of the county of Marck. It is seated on the river Lippe, twenty-

four miles south of Munster. E. lon. 7. 50. N. lat. 51. 36.

HAM, a town of France, in the department of Somme and late province of Picardy, seated on the river Somme, 10 miles N. of Noyon, and 48 N. of Paris. E. lon. 3. 6. N. lat. 49. 45.

HAM, a village in Surry, between Peterham and Kingston, the houses of which surround a pleasant common. Near it is Ham House, the seat of the earl of Dyfart, and Ham Walks, celebrated by Thomson and others. This village, which is a hamlet to Kingston, is 11 miles W. S. W. of London,

West HAM, a village of Essex, where are the remains of an opulent abbey, founded in 1135. This village is seated on the river Lea, about four miles E. by N. of London.

East HAM, a village in Essex, adjoining to West Ham. In this parish is a spring called Miller's Well, the excellent water of which has never been known to freeze, or to vary in its height. A part of Kent, in the parish of Woolwich, lies on this side of the Thames, and divides the parish of East Ham from that river.

HAMADAN. See AMADAN.

HAMADRYADES, of *ἄμα* together, and *δρυας* dryad, of *δρυς* oak, in antiquity, certain fabulous deities revered among the ancient heathens, and believed to preside over woods and forests, and to be inclosed under the bark of oaks. The hamadryades were supposed to live and die with the trees they were attached to; as is observed by Servius on Virgil, Eclog. x. ver. 62. after Mnesimachus, the scholiast of Apollonius, &c. who mentions other traditions relating thereto. The poets, however, frequently confound the Hamadryads with the Naiads, Napææ, and rural nymphs in general; witness Catullus, Carm. lxxviii. ver. 23. Ovid, Fast. iv. 229. Met. i. ver. 695. xiv. ver. 628. Propertius, Eleg. xx. 32. Virg. Eccl. x. ver. 64. Georg. iv. ver. 382, 383. Festus calls them *Querquetulanæ*, as being issued or sprung from oaks. An ancient poet, Pherenicus, in Athenæus, lib. iii. calls the vine, fig-tree, and other fruit-trees, *hamadryades*, from the idea of their mother the oak. This common idea among the ancients, of nymphs or intellectual beings annexed to trees, will account for their worshipping of trees; as we find they did, not only from their poets but their historians. Livy speaks of an ambassador's addressing himself to an old oak, as to an intelligent person and a divinity. Lib. iii. § 25.

HAMAH, a large town of Asia, in Syria, seated among the hills. The houses being built on the ascent of a hill, one above another, make a very agreeable appearance. Many of the best houses are half ruined; but those that are still standing, with the mosques, are built of black and white stones, as well as the castle. The river Afi, formerly called Orontes, runs close by the castle, and fills the ditches about it, which are cut deep into the solid rock. The market-places are pretty good; and they have a trade for linen of their own manufacture. It is 78 miles S. W. of Aleppo. E. lon. 34. 55. N. lat. 36. 15.

HAMAMELIS, WITCH HAZEL; a genus of the digynia order, belonging to the tetrandria class of plants; and in the natural method ranking with those of which the order is doubtful. The involucre is triphyllous, the proper calyx is tetraphyllous; there are four petals; the nut horned and bilocular. There is but one species, a native of Virginia. It hath a shrubby or woody stem, branching three or four feet high; oval, indented, alternate leaves, resembling those of common hazel; and flowers growing in clusters from the joints of the young branches, but not succeeded by seeds in this country. The plant is hardy, and is admitted as a variety in our gardens; but its flowers are more remarkable for their appearing in November and December, when the leaves are fallen, than for their beauty. It may be propagated either by seeds or layers.

HAMAM LEEF, a town 12 miles east from Tunis, noted for its hot baths, which are much resorted to by the Tunifans, and deemed efficacious in the rheumatism and many other complaints. Here the Bey has a very fine bath, which he frequently permits the consuls and other persons of distinction to use.

HAMAMET, a town of Africa, in Barbary, seated on a gulf of the same name, 45 miles from Tunis. E. lon. 10. 15. N. lat. 36. 35.

HAMAXOBII, HAMAXOBIANS, in the ancient geography, a people who had no houses, but lived in carriages. The word is formed from *ἀμαξία* a carriage or chariot, and *βίωσις* life. The *Hamaxobii*, called also *Hamaxobitæ*, were an ancient people of Sarmatia Europæa, inhabiting the southern part of Muscovy, who instead of houses had a sort of tents made of leather, and fixed on carriages to be ready for shifting and travel.

HAMB DEN (John), a celebrated patriot, descended of the ancient family of Hambden in Buckinghamshire, was born in 1594. From the university he went to the inns of court, where he made a considerable progress in the study of the law. He was chosen to serve in the parliament which began at Westminster February 5, 1626; and served in all the succeeding parliaments in the reign of Charles I. In 1636 he became universally known, by his refusal to pay ship-money, as being an illegal tax; upon which he was prosecuted, and his carriage throughout this transaction gained him a great character. When the long parliament began, the eyes of all men were fixed on him as their *pater patriæ*. On January 3, 1642, the king ordered articles of high treason and other misdemeanours to be prepared against Lord Kimbolton, Mr. Hambden, and four other members of the House of Commons, and went to that house to seize them: but they were then retired. Mr. Hambden afterwards made a speech in the house to clear himself of the charge laid against him. In the beginning of the wars he commanded a regiment of foot, and did good service to the parliament at the battle of Edge-hill. He received a mortal wound in an engagement with Prince Rupert, in Chalgrave-field in Oxfordshire, and died in 1643. He is said to have had the art of Socrates to a great degree, of interrogating, and under the notion of doubts, insinuating objections, so that he infused his own opinions into those from whom he pretended to learn and receive them. He was, say his panegyrists, a very wise man and of great parts; and possessed of the most absolute spirit of popularity to govern the people, that ever was in any country: He was master over all his appetites and passions, and had thereby a very great ascendant over other men's: He was of an industry and vigilance never to be tired out, of parts not to be imposed upon by the most subtle, and of courage equal to his best parts.

HAMBURGH, one of the largest towns in Germany, consisting of the Old Town and the New Town; both nearly of an equal size. Most of the houses are built after the manner of the Dutch, and richly furnished within. The principal streets of the Old Town have long and broad canals, which are filled twice every 24 hours by the tide. These are not only useful for trade, but serve to keep the houses and the streets clean. It is seated on the river Elbe, which is of vast advantage to the inhabitants; and on the side of Holstein is the Alster, which, before it enters the town by sluices, forms a fine basin that cannot be equalled in Germany. Hamburgh is well fortified, and on the ramparts are handsome walks. The burghers mount guard themselves, and are divided into several companies. The streets are well lighted every night; and there is a guard which patrols all over the city. This is a pleasant place for foreigners: because, beside the cheapness of provisions, they are sure to meet with people of their own nation; and there are operas, plays, assemblies, balls, concerts, masquerades, and other parties of pleasure for their diversion. The senate of this town is composed of four

burgo-masters, of whom one only is a tradesman; 4 syndics; 24 senators, of whom 11 are men of letters, and the rest tradesmen; four secretaries, one of whom is a protonotary, and another belongs to the archives; so that the whole senate consists of 36 persons. The town is divided into five parishes; and out of each are formed several colleges, or companies, who take care of public affairs, unless there is any thing too high for their determination, and then it is judged by a sort of general assembly. It is a place of great trade; which they carry on with Portugal, Spain, France, England, Denmark, Norway, Sweden, Italy, and Russia. They also send vessels every year to Greenland to catch whales; and there are not less than 200 ships at a time, belonging to foreign merchants, at anchor before the city: and there is a handsome exchange. The inhabitants are all Lutherans, and none but the English have the liberty of performing divine service in a chapel of their own. Other religions are tolerated at Altena, a large town near the harbour of Hamburg; except the Jews, who have no synagogue. Beside the 5 principal churches, they have 11 smaller ones for particular occasions, some of which belong to hospitals. The cathedral of Our Lady is a very fine structure, and has a chapter, consisting of 12 canons, who are all Protestants. It is 55 miles N. E. of Bremen. E. lon. 9. 55. N. lat. 53. 34.

HAMEL (John Baptiste du), a very learned French philosopher and writer in the 17th century. At 18 he wrote a treatise, in which he explained in a very simple manner, Theodosius's three books of Spherics; to which he added a tract upon trigonometry, extremely perspicuous, and designed as an introduction to astronomy. Natural philosophy, as it was then taught, was only a collection of vague, knotty, and barren questions; when our author undertook to establish it upon right principles, and published his *Astronomia Physica*. In 1666 Mr. Colbert proposed to Louis XIV. a scheme, which was approved of by his majesty, for establishing a royal academy of sciences; and appointed our author secretary of it. He published a great many books; and died at Paris in 1706, of mere old age, being almost 83. He was regius professor of philosophy, in which post he was succeeded by M. Varignon. He wrote Latin with purity and elegance.

HAMELBURGH, a town of Germany, in Franconia, and in the territory of the abbey of Fuld; seated on the river Saab, 28 miles S. E. of Fuld. E. lon. 10. 12. N. lat. 50. 16.

HAMELIN, a strong town of Germany, in the duchy of Calenberg in Lower Saxony. It is situated at the extremity of the duchy of Brunswick, to which it is the key, near the confluence of the rivers Hamel and Weser, in E. lon. 9. 55. N. lat. 52. 13.

HAMELLIA, in botany; a genus of the monogynia order, belonging to the pentandria class of plants; and in the natural method ranking with those of which the order is doubtful. The corolla is quinquefid; the berry quinquelocular, inferior, polyspermous.

HAMSECKEN. BURGLARY, or *Nocturnal House breaking*, was by the ancient English law called *Hamsceken*, as it is to this day in Scotland; where violating the privilege of a man's house is as severely punished as ravishing a woman.

HAMI, or HA-MI, a country of Asia, subject to the Chinese. It is situated to the north-east of China, at the extremity of that desert which the Chinese call *Chamo*, and the Tartars *Cobi*; and is only 90 leagues distant from the most westerly point of the province of Chenti. This country was inhabited in the early ages by a wandering people, named *long*. About the year 950 before the Christian era, they sent deputies to pay homage to the emperor of China, and presented some sabres by way of tribute. The civil wars by which China was torn about

the end of the dynasty of Tcheou having prevented assistance from being sent to these people, they fell under the dominion of the Hiongnou, who appear to have been the same as the Huns, and who at that time were a formidable nation. The Chinese several times lost and recovered the country of Hami. Though surrounded by deserts, this country is accounted one of the most delightful in the world. The soil produces abundance of grain, fruits, leguminous plants, and pasture of every kind. The rice which grows there is particularly esteemed in China; but the most useful and most esteemed production of this country is its dried raisins, which are of two kinds: The first, much used in Chinese medicine, have a near resemblance to those known in Europe by the name of Corinthian. The second, which are in much greater request for the table, are smaller and more delicate than those of Provence. The emperor caused plants of both kinds to be transported from Hami to Peking; and as these have been cultivated with extraordinary care, the raisins produced by them have a most exquisite flavour. Although the country of Hami (the latitude of which is 42° 53' 20") lies farther towards the north than several of the departments of France, its climate is said to be more favourable to the culture of vines. The kingdom contains a great number of villages and hamlets; but it has properly only one city, which is its capital, and has the same name. The country is very abundant in fossils and valuable minerals: the Chinese have, for a long time, procured diamonds, and a great deal of gold from it; at present it supplies them with a kind of agate, on which they set a great value. The inhabitants of this small state are brave, capable of enduring fatigue, very dexterous in all bodily exercises, and make excellent soldiers; but they are fickle and soon irritated, and when in a passion they are extremely ferocious and sanguinary.

HAMILTON, a town of Lanerksire, in Scotland, which contains many handsome houses, with the ruins of a collegiate church, founded in 1451. Near this town is Hamilton House, the magnificent seat of the duke of Hamilton, seated between the Clyde and Avon, and surrounded by venerable oaks. The town also is situated on the Clyde, 10 miles S. E. of Glasgow. W. lon. 4. 16. N. lat. 55. 58.

HAMILTON (Anthony, count), descended from a noble family in Scotland, was born in Ireland, and settled in France. He wrote several poetical pieces; and was the first who composed romances in an agreeable taste, without imitating the burlesque of Scarron. He is also said to be the author of the *Memoirs of the Count de Grammont*, one of the best written pieces in the French language. His works were printed in 6 vols. 12mo. He died at St. Germain en-Laye, in 1720.

HAMLET, HAMEL, or *Hampsel*, (from the Saxon *ham*, i. e. *domus*, and the German *let*, i. e. *membrum*), signifies a little village, or part of a village or parish; of which three words the first is now only used, though Kitchen mentions the two last. By Spelman there is a difference between *villam integram*, *villam dimidiam*, and *hamletam*; and Stow expounds it to be the seat of a freeholder. Several county towns have hamlets, as there may be several hamlets in a parish; and some particular places may be out of a town or hamlet, though not out of the county.

HAMLET, a prince, celebrated in the annals of Denmark; and whose name has been rendered familiar in this country, and his story interesting, by being the subject of one of the noblest tragedies of our immortal Shakespeare. Adjoining to a royal palace, which stands about half a mile from that of Cronborg in Elsinour, is a garden, which, Mr. Coxe informs us, is called Hamlet's Garden, and is said by tradition to be the very spot where the murder of his father was perpetrated. The house is of modern date, and is situated at the foot of a sandy ridge near the sea. The garden occupies the side of the hill, and is laid out in ter-

passes rising one above another. Elſineur is the ſcene of Shakeſpeare's Hamlet; and the original hiſtory from which our poet derived the principal incidents of his play is founded upon facts, but ſo deeply buried in remote antiquity, that it is difficult to diſcriminate truth from fable. Saxo-Grammaticus, who flouriſhed in the 12th century, is the earlieſt hiſtorian of Denmark that relates the adventures of Hamlet. His account is extracted, and much altered, by Belleforeſt a French author; an Engliſh tranſlation of whoſe romance was publiſhed under the title of the Hiſtorye of Hamblet: and from this tranſlation Shakeſpeare formed the ground-work of his play, though with many alterations and additions. The following ſhort ſketch of Hamlet's hiſtory, as recorded in the Daniſh annals, will enable the reader to compare the original character with that delineated by Shakeſpeare.

Long before the introduction of Chriſtianity into Denmark, Horwendillus, preſect or king of Jutland, was married to Geruthra, or Gertrude, daughter of Ruric king of Denmark, by whom he had a ſon called *Amlettus*, or *Hamlet*. Fengo murders his brother Horwendillus, marries Gertrude, and aſcends the throne. Hamlet, to avoid his uncle's jealousy, counterfeits folly; and is repreſented as ſuch an abhorrer of falſhood, that though he conſtantly frames the moſt evaſive and even abſurd anſwers, yet artfully contrives never to deviate from truth. Fengo, ſuſpecting the reality of his madneſs, endeavours, by various methods, to diſcover the real ſtate of his mind: amongſt others, he departs from Elſineur, concerts a meeting between Hamlet and Gertrude, concluding that the former would not conceal his ſentiments from his own mother; and orders a courtier to conceal himſelf, unknown to both, for the purpoſe of overhearing their converſation. The courtier repairs to the queen's apartment, and hides himſelf under a heap of ſtraw. Hamlet, upon entering the cabinet, ſuſpecting the preſence of ſome ſpy, imitates, after his uſual affectation of folly, the crow of a cock, and, ſhaking his arms like wings, jumps upon the heap of ſtraw; till, feeling the courtier, he draws his ſword and inſtantly diſpatches him. He then cuts the body to pieces, boils it, and gives it to the hogs. He then avows to his mother that he only perſonated a fool, reproaches her for her inceſtuous marriage with the murderer of her huſband; and concludes his remonſtrances by ſaying, "Inſtead, therefore, of condoling my insanity, deplore your own infamy, and learn to lament the deformity of your own mind." The queen is ſilent; but is recalled to virtue by theſe admonitions. Fengo returns to Elſineur, ſends Hamlet to England under the care of two courtiers, and requeſts the king by a letter to put him to death. Hamlet diſcovers and alters the letter; ſo that, upon their arrival in England, the king orders the two courtiers to immediate execution, and betrothes his daughter to Hamlet, who gives many aſtoniſhing proofs of a moſt tranſcendent underſtanding. At the end of the year he returns to Denmark, and alarms the court by his unexpected appearance; as a report of his death had been ſpread, and preparations were making for his funeral. Having re-aliſhed his affected insanity, he purpoſely wounds his fingers in drawing his ſword, which the byſtanders immediately faſten to the ſcabbard. He afterwards invites the principal nobles to an entertainment, makes them intoxicated, and in that ſtate covers them with a large curtain, which he faſtens to the ground with wooden pegs: he then ſets fire to the palace; and the nobles, being enveloped in the curtain, periſh in the flames. During this tranſaction he repairs to Fengo's apartment; and, taking the ſword which lay by the ſide of his bed, puts his own in its place: he inſtantly awakens and informs him, that Hamlet is come to revenge the murder of his father. Fengo ſtarts from his bed, ſeizes the ſword; but, being unable to draw it, falls by the hand of Hamlet. The next morning, when the populace were aſſembled to view the ruins of the palace, Ham-

let ſummons the remaining nobles; and in a maſterly ſpeech, which is too long to inſert in this place, lays open the motives of his own conduct, proves his uncle to have been the aſſaſſin of his father; and concludes in the following words: "Tread upon the aſhes of the monſter, who, polluting the wife of his murdered brother, joined inceſt to parricide, and ruled over you with the moſt oppreſſive tyranny. Receive me as the miniſter of a juſt revenge, as one who felt for the ſufferings of his father and his people. Conſider me as the perſon who has purged the diſgrace of his country; extinguished the infamy of his mother; freed you from the deſpotiſm of a monſter, whoſe crimes, if he had lived, would have daily increaſed, and terminated in your deſtruction. Acknowledge my ſervices; and if I have deſerved it, preſent me with the crown. Behold in me the author of theſe advantages: no degenerate perſon, no parricide; but the rightful ſucceſſor to the throne, and the pious avenger of a father's murder. I have reſcued you from ſlavery, reſtored you to liberty, and re-eſtabliſhed your glory: I have deſtroyed a tyrant, and triumphed over an aſſaſſin. The recompenſe is in your hands: you can eſtimate the value of my ſervices, and in your virtue I reſt my hopes of reward." This ſpeech has the deſired effect: the greater part of the aſſembly ſhed tears, and all who are preſent unaniſmouſly proclaim him king amid repeated acclamations.

Hamlet, ſoon after his elevation, ſails to England, and orders a ſhield to be made on which the principal actions of his life are repreſented. The king receives him with feigned demonſtrations of joy, falſely aſſures him that his daughter is dead, and recommends him to repair to Scotland as his ambaffador, and to pay his addreſſes to the queen Hermetruda. He gives this inſidious advice with the hopes that Hamlet may periſh in the attempt; as the queen, who was remarkable for her chaſtity and cruelty, had ſuch an averſion to all propoſals of marriage, that not one of her ſuitors had eſcaped falling a ſacrifice to her vengeance. Hamlet, in oppoſition to all difficulties, performs the embaffy; and, by the aſſiſtance of his ſhield, which inſpires the lady with a favourable opinion of his wiſdom and courage, obtains her in marriage, and returns with her to England. Informed by the princeſs to whom he had been betrothed that her father meditates his aſſaſſination, Hamlet avoids his fate by wearing armour under his robe; puts to death the king of England; and ſails to Denmark with his two wives, where he is ſoon afterwards killed in a combat with Vigletus ſon of Ruric. Hamlet, adds the hiſtorian, was a prince, who, if his good fortune had been equal to his deſerts, would have rivalled the gods in ſplendor, and in his actions would have exceeded even the labours of Hercules.

HAMMER, a well-known tool uſed by mechanics, conſiſting of an iron head, fixed croſſwiſe upon a handle of wood. There are ſeveral ſorts of hammers uſed by blackſmiths; as, 1. The *band-hammer*, which is of ſuch weight that it may be wielded or governed with one hand at the anvil. 2. The *up-band ſledge*, uſed with both hands, and ſeldom liſted above the head. 3. The *about-ſledge*, which is the biggeſt hammer of all, and held by both hands at the fartheſt end of the handle; and, being ſwung at arm's length over the head, is made to fall upon the work with as heavy a blow as poſſible. 4. There is alſo another hammer uſed by ſmiths, called a *rivetting-hammer*; which is the ſmalleſt of all, and is ſeldom uſed at the forge unleſs upon ſmall work. Carpenters and joiners have likewiſe hammers accommodated to their ſeveral purpoſes.

HAMMERING, the act of beating or extending and fashioning a body under the hammer. When it is performed on iron heated for the purpoſe, the ſmiths uſually call it *forging*. In coining a piece of money, or a medal, it is ſaid to be *hammered*, when it is ſtruck, and the impreſſion given with a hammer, and not with a mill.

HAMMERSMITH, a large village of Middlesex, in the parish of Fulham, four miles W. of London, and a little to the N. of the Thames.

HAMERSTEIN, a fortress of Germany, upon the Rhine, opposite Coblenz, belonging to the elector of Treves.

HAMMOCK, or HAMAC, a kind of hanging bed, suspended between two trees, posts, hooks, or the like, much used throughout the West Indies, as also on board of ships. The Indians hang their hammocks to trees, and thus secure themselves from wild beasts and insects, which render lying on the ground there very dangerous. According to F. Plumier, who has often made use of the hammock in the Indies, it consists of a large strong coverlet or sheet of coarse cotton, about six feet square: on two opposite sides are loops of the same stuff, through which a string is run, and thereof other loops are formed, all which are tied together with a cord; and thus is the whole fastened to two neighbouring trees in the field, or two hooks in houses. This kind of couch serves at the same time for bed, quilts, sheets, pillow, &c. The hammock used on board of ships is made of a piece of canvas six feet long and three feet wide, gathered or drawn together at the two ends. There are usually from fourteen to twenty inches in breadth allowed between decks for every hammock in a ship of war; but this space must in some measure depend on the number of the crew, &c. In time of battle the hammocks and bedding are firmly corded and fixed in the nettings on the quarter-deck, or wherever the men are too much exposed to the view or fire of the enemy.

HAMMOND (HENRY), D. D. one of the most learned English divines in the 17th century, was born in 1605. He studied at Oxford, and in 1629 entered into holy orders. In 1633 he was inducted into the rectory of Penshurst in Kent. In 1643 he was made archdeacon of Chichester. In the beginning of 1645 he was made one of the canons of Christ church, Oxford, and chaplain in ordinary to king Charles I. who was then in that city; and he was also chosen public orator of the university. In 1647 he attended the king in his confinement at Woburn, Cavesham, Hampton-Court, and the Isle of Wight, where he continued till his majesty's attendants were again put from him. He then returned to Oxford, where he was chosen sub-dean; and continued there till the parliament-visitors first ejected him, and then imprisoned him for several weeks in a private house in Oxford. During this confinement he began his Annotations on the New Testament. At the opening of the year 1660, when every thing visibly tended to the restoration of the royal family, the doctor was desired by the bishops to repair to London to assist there in the composition of the breaches of the church, his station in which was designed to be the bishopric of Worcester; but on the 4th of April he was seized by a fit of the stone, of which he died on the 25th of that month, aged 55. Besides the above work, he wrote many others; all of which have been published together in four volumes folio.

HAMMOND (Anthony, Esq.), an ingenious English poet, descended from a good family of Somersham Place in Huntingdonshire, was born in 1668. After a liberal education at St. John's-college, Cambridge, he was chosen member of parliament, and soon distinguished himself as a fine speaker. He became a commissioner of the royal navy, which place he quitted in 1712. He published a Miscellany of original Poems by the most eminent hands; in which himself, as appears by the poems marked with his own name, had no inconsiderable share. He wrote the life of Walter Moyle, Esq. prefixed to his works; being the intimate friend of that gentleman. Mr. Hammond died about the year 1726.

HAMMOND (James), known to the world by the Love-Elegies which some years after his death were published by the earl of Chesterfield, was the son of Anthony Hammonnd above-

mentioned, and was preferred to a place about the person of the late prince of Wales, which he held till an unfortunate accident deprived him of his senses. The cause of this calamity was a passion he entertained for a lady, who would not return it: upon which he wrote those love-elegies which have been so much celebrated for their tenderness. The editor observes, that he composed them before he was 21 years of age: a period, says he, when fancy and imagination commonly riot at the expence of judgment and correctness. He was sincere in his love, as in his friendship; and wrote to his mistress, as he spoke to his friends, nothing but the genuine sentiments of his heart. Tibullus seems to have been the model our author judiciously preferred to Ovid; the former writing directly from the heart to the heart, the latter too often yielding and addressing himself to the imagination. Mr. Hammond died in the year 1743, at Stow, the seat of lord Cobham, who, as well as the earl of Chesterfield, honoured him with a particular intimacy.

HAMONT, a town of Germany, in the bishopric of Liege, 17 miles W. of Ruremonde. Lon. 5. 31. E. Lat. 51. 17. N.

HAMPSHIRE, HANTS, or Southampton, a county of England, bounded on the N. by Berks, on the E. by Surry and Sussex, on the S. by the English Channel, and on the W. by Dorsetshire and Wilts. It extends, exclusive of the Isle of Wight, 42 miles from N. to S. and 38 from E. to W. It is divided into 39 hundreds, and contains one city, 20 market-towns, and 253 parishes; and sends, with the Isle of Wight, 26 members to parliament. It is one of the most agreeable, fertile, and populous counties in England. The air, in the higher parts, is clear and pure; toward the sea, mild, and inclined to moisture. Its products are the finest corn (especially wheat), hops, cattle, sheep, wool, excellent bacon, honey, and timber. For the last it has been particularly famous, on account of its great woods, of which the principal are the New Forest, and the forest of East Bere. The principal rivers are the Avon, Test, Itchen, and Stour.

NEW HAMPSHIRE, one of the United States of North America, bounded on the N. by Canada; on the N. E. by the province of Main; on the S. E. by the Atlantic Ocean; on the S. by Massachusetts; and on the W. and N. W. by the river Connecticut, which separates it from Vermont. It is divided into the five counties of Rockingham, Stafford, Hillsborough, Cheshire, and Grafton. The land near the sea is generally low, but, advancing into the country, it rises into hills. The air is serene and healthful; the weather not so subject to variation as in the more southern climes. From the vicinity of some mountains, whose summits are covered with snow three quarters of the year, this country is intensely cold in winter. In summer the heat is great, but of short duration. The capital is Portsmouth.

HAMPSTEAD, a village of Middlesex, formerly famous for its medicinal waters. It is seated on the declivity of a hill, on the top of which is a fine heath that commands a delightful prospect of the metropolis and all the adjacent country. It is four miles N. N. W. of London.

HAMPTON, a town in Gloucestershire, with a market on Tuesday. It is seated on the Cotswold Hills, 14 miles S. of Gloucester, and 90 W. of London. Lon. 2. 15. W. Lat. 51. 36. N.

HAMPTON, a seaport of N. America, in New Hampshire, 40 miles N. of Boston. Lon. 74. 0. W. Lat. 43. 5. N.

HAMPTON, a town of Middlesex, famous for a royal palace, called Hampton Court, built by cardinal Woolsey, who gave it to Henry VIII. The buildings, gardens, and parks, to which king William made many additions, are four miles in circumference, and seated on the N. side of the Thames, 14 miles S. W. of London. Lon. 0. 9. W. Lat. 51. 25. N.

HAMESOKEN, or HAMESECKEN. See HAMESECKEN

HANAPER, or **HAMPER**, an office in chancery, under the direction of a master, his deputy, and clerks, answering, in some measure, to the *sifcus* among the Romans. The *Clerk of the Hanaper* is sometimes styled *Warden of the hanaper*. He receives all money due to the king for seals of charters, patents, commissions, and writs, and attends the keeper of the seal daily in term time, and at all times of sealing, and takes into his custody all sealed charters, patents, and the like, which he receives into bags; but anciently, it is supposed, into hampers, which gave denomination to the office. There is also a *comptroller* of the hanaper.

HANAU, a handsome and strong town of Germany, in the circle of the Lower Rhine, capital of a county of the same name. It belongs to its own prince. It is divided into two towns, the Old and the New, and is seated near the river Maine, 18 miles N. E. of Darmstadt. Lon. 8. 55. E. Lat. 49. 56. N.

HANAU, the county of, bounded on the E. by the county of Rhinec and the territory of Fuld; on the W. by the counties of Weissemburg and Solms; and on the N. and S. by the territories of Mentz and Francfort. It is 45 miles in length, but its breadth is small. Its soil is very fruitful.

HAND, a part or member of the body of man, making the extremity of the arm. See **ANATOMY**, page 167. The mechanism of the hand is excellently contrived to fit it for various uses and occasions. It consists of a compages of muscles, tendons, and little bones connected with each other, which give it a great degree of strength, and at the same time an unusual flexibility, to enable it to handle adjacent bodies, lay hold of them, and grasp them, in order either to draw them toward us or thrust them off. Anaxagoras is represented by ancient authors, as maintaining, that man owes all his wisdom, knowledge, and superiority over other animals, to the use of his hands. Galen represents the matter otherwise: man, according to him, is not the wisest creature, because he has hands; but he had hands given him because he was the wisest creature. He truly said it was not our hands that taught us arts, but our reason which directed us in the use of our hands.

In scripture, the word *hand* was variously applied. To pour water on any one's hand, signified to *serve* him. To wash the hands was a ceremony made use of to denote innocency from murder or manslaughter. To kiss the hand was an act of adoration. To fill the hand signified taking possession of the priesthood, and performing its functions. To lean upon any one's hand was a mark of familiarity and superiority. To give the hand signifies to grant peace, swear friendship, promise security, or make alliance. The right hand was the place of honour and respect. Amongst the Greeks and Romans it was customary for inferiors to walk on the left hand of superiors, that their right hand might be ready to afford protection and defence to their left side, which was, on account of the awkwardness of the left hand, more exposed to danger.

Imposition or *laying on* of **HANDS**, signifies the conferring of holy orders; a ceremony wherein the hands are laid on the head of another, as a sign of a mission, or of a power given him to exercise the functions of the ministry belonging to the order. The apostles began to appoint missionaries by the imposition of hands. See **IMPOSITION**.

HAND, in falconry, is used for the foot of the hawk. To have a clean, strong, slender, glutinous hand, well clawed, are some of the good qualities of a hawk or falcon.

HAND, in the manege, sometimes stands for the fore-feet of a horse. It is also used for a division of the horse into two parts, with respect to the rider's hand. The fore-hand includes the head, neck, and fore-quarters; the hind hand is all the rest of the horse.

HAND is likewise used for a measure of four inches, or of a clenched fist, by which the height of a horse is computed.

HAND is also figuratively used in painting, sculpture, &c. to indicate the *manner* or style of this or that master.

HANDS are borne in coat-armour, *dexter* and *sinister*; that is, right and left, expanded or open; and after other manners. A bloody hand in the centre of the escutcheon is the badge of a baronet of Great Britain.

HAND-Breadth, a measure of three inches.

HANDEL (George Frederic), a most eminent master and composer of music, was born at Hall, a city of Upper Saxony in Germany. His father was a physician and surgeon of that place, and was upwards of 60 years of age when Handel was born. During his infancy young Handel is said to have amused himself with musical instruments, and to have made considerable progress before he was seven years of age, without any instructions. His propensity for music at last became so strong, that his father, who designed him for the study of the civil law, thought proper to forbid him, even at this early period of life, to touch a musical instrument, and would suffer none to remain in his house. Notwithstanding this prohibition, however, Handel found means to get a little clavichord privately conveyed to a room in the uppermost story of the house, to which room he constantly stole when the family were asleep; and thus made such advances in his art, as enabled him to play on the harpsichord. He was first taken notice of by the duke of Saxe Weisensels, on the following occasion. His father went to pay a visit to another son by a former wife, who was valet de chambre to the duke, and resided at his court. Young Handel, being then in his seventh year, earnestly desired permission to go along with him; but being refused, he followed the chaise on foot, and overtook it, the carriage being probably retarded by the roughness of the way. His father at first chid him for his disobedience, but at last took him into the chaise along with him. While he was in the duke's court, he still continued to show the same inclination for music: it was impossible to keep him from harpsichords; and he used sometimes to get into the organ-loft at church, and play after service was over. On one of these occasions, the duke happening to go out later than usual, found something so uncommon in Handel's manner of playing, that he inquired of his valet who it was; and receiving for answer that it was his brother, he desired to see him. This nobleman was so much taken with the musical genius shown by young Handel, that he persuaded his father to let him follow the bent of his inclination. He made the boy a present; and told him, that if he minded his studies, no encouragement should be wanting.

On his return to Hall, Handel was placed under one Zackaw, the organist of the cathedral church; and our young musician was even then able to supply his master's place in his absence. At nine years of age he began to compose church-services for voices and instruments, and continued to compose one such service every week for three years successively. At the age of 14, he far excelled his master, as he himself owned; and he was sent to Berlin, where he had a relation in some place about the court, on whose care and fidelity his parents could rely. The opera was then in a flourishing condition, being encouraged by the grandfather of the late king of Prussia, and under the direction of many eminent persons from Italy, among whom were Buononcini and Attilio. Buononcini being of a haughty disposition, treated Handel with contempt; but Attilio behaved to him with great kindness, and he profited much by his instructions. His abilities soon recommended him to the king, who frequently made him presents, and at last proposed to send him into Italy under his own patronage, and to take him under his immediate protection as soon as his studies should be com-

pleted. But Handel's parents not thinking proper to submit their child to the caprice of the king, declined the offer; upon which it became necessary for him to return to Hall.

Handel having now obtained ideas in music far excelling every thing that could be found in Hall, continued there very unwillingly, and it was resolved to send him into Italy: but as the expence of this journey could not then be spared, he went to Hamburg, where the opera was little inferior to that of Berlin. Soon after his arrival in this city, his father died; and his mother being left in narrow circumstances, her son thought it necessary to procure some scholars, and to accept a place in the orchestra; by which means, instead of being a burden, he became a great relief to her.

At this time, the first harpsichord in Hamburg was played by one Kefer, a man who also excelled in composition; but he, having involved himself in some debts, was obliged to abscond. Upon this vacancy, the person who had been used to play the second harpsichord claimed the first by right of succession; but was opposed by Handel, who founded a claim to the first harpsichord upon his superior abilities. After much dispute, in which all who supported or directed the opera engaged with much vehemence, it was decided in favour of Handel; but this good success had almost cost him his life. His antagonist resented the supposed affront so much, that, as they were coming out of the orchestra together, he made a push at Handel's breast with a sword, which must undoubtedly have killed him, had there not fortunately been a music-book in the bosom of his coat.

Handel, though yet but in his 15th year, became composer to the house; and the success of *Almeria*, his first opera, was so great, that it ran 30 nights without interruption. Within less than a twelvemonth after this, he set two others, called *Florenda* and *Norene*, which were received with the same applause. During his stay here, which was about four or five years, he also composed a considerable number of sonatas, which are now lost. Here his abilities procured him the acquaintance of many persons of note, particularly the prince of Tuscany, brother to John Galton de Medicis the grand duke. This prince pressed him to go with him to Italy, where he assured him that no convenience should be wanting; but this offer Handel thought proper to decline, being resolved not to give up his independency for any advantage that could be offered him.

In the 19th year of his age, Handel took a journey to Italy on his own bottom; where he was received with the greatest kindness by the prince of Tuscany, and had at all times access to the palace of the grand duke. His serene highness was impatient to have something composed by so great a master; and notwithstanding the difference between the style of the Italian music and the German, to which Handel had hitherto been accustomed, he set an opera called *Roderigo*, which pleased so well, that he was rewarded with 100 sequins and a service of plate. After staying about a year in Florence, he went to Venice, where he is said to have been first discovered at a masquerade. He was playing on a harpsichord in his visor, when Scarlatti, a famous performer, cried out, that the person who played could be none but the famous Saxon, or the devil. But a story similar to this is reported of many eminent persons whose abilities have been discovered in disguise. Here he composed his opera called *Agrippina*, which was performed 27 nights successively, with the most extravagant applause.

From Venice our musician proceeded to Rome, where he became acquainted with cardinal Ottoboni and many other dignitaries of the church, by which means he was frequently attacked on account of his religion; but Handel declared he would live and die in the religion in which he had been educated, whether it was true or false. Here he composed an oratorio called *Resur-*

rections, and 150 cantatas, besides some sonatas, and other music. Ottoboni also contrived to have a trial of skill between him and Dominici Scarlatti, who was considered as the greatest master on the harpsichord in Italy. The event is differently reported. Some say that Scarlatti was victorious, and others give the victory to Handel; but when they came to the organ, Scarlatti himself yielded the superiority to Handel.

From Rome, Handel went to Naples; after which, he paid a second visit to Florence; and at last, having spent six years in Italy, set out for his native country. In his way thither, he was introduced at the court of Hanover with so much advantage by the baron Kilmanseck, that his electoral Highness offered him a pension of 1500 crowns a-year as an inducement for him to continue there. This generous offer he declined on account of his having promised to visit the court of the Elector Palatine, and likewise to come over to England in compliance with the repeated invitations of the duke of Manchester. The elector, however, being made acquainted with this objection, generously ordered him to be told, that his acceptance of the pension should neither restrain him from his promise nor resolution: but that he should be at full liberty to be absent a year or more if he chose it, and to go wherever he thought fit. Soon after, the place of master of the chapel was bestowed upon Handel; and our musician having visited his mother, who was now extremely aged and blind, and his old master Zackaw, and staid some time at the court of the Elector Palatine, set out for England, where he arrived in 1710.

At that time operas were a new entertainment in England, and were conducted in a very absurd manner; but Handel soon put them on a better footing; and set a drama called *Rinaldo*, which was performed with uncommon success. Having staid a year in England, he returned to Hanover; but in 1712 he again came over to England; and the peace of Utrecht being concluded a few months afterwards, he composed a grand *Te Deum* and *Jubilate* on the occasion. He now found the nobility very desirous that he should resume the direction of the opera-house in the Hay Market; and the queen having added her authority to their solicitations, and conferred on him a pension of 200l. a-year, he forgot his engagements to the elector of Hanover, and remained in Britain till the death of the queen in 1714. On the arrival of king George I. Handel, conscious of his ill behaviour, durst not appear at court; but he was extricated from his dilemma by the baron Kilmanseck. Having engaged several of the English nobility in his behalf, the baron persuaded the king to a party of pleasure on the water. Handel was apprised of the design, and ordered to prepare some music for the occasion. This he executed with the utmost attention, and on the day appointed it was performed and conducted by himself. The king with pleasure and surprise inquired whose it was, and how the entertainment came to be provided without his knowledge. The baron then produced the delinquent; and asked leave to present him to his majesty, as one too sensible of his fault to attempt an excuse, but sincerely desirous to atone for it. This intercession was accepted. Handel was restored to favour, his water music was honoured with the highest approbation, and the king added a pension of 200l. a-year to that formerly bestowed on him by queen Anne; which he soon after increased to 400l. on his being appointed to teach the young princesses music.

In the year 1715, Handel composed his opera of *Amadige*; but from that time to the year 1720 he composed only *Tiffo* and *Pastor Fido*, Buononcini and Attilio being then composers for the operas. About this time a project was formed by the nobility for erecting a kind of academy at the Hay Market, with a view to secure to themselves a constant supply of operas to be composed by Handel, and performed under his direction.

No less than 50,000*l.* was subscribed for this scheme, of which the king himself subscribed 1000*l.* and it was proposed to continue the undertaking for 14 years. Handel went over to Dresden, in order to engage singers, and returned with Senesino and Durisanti. Buononcini and Attilio had still a strong party in their favour, but not equal to that of Handel; and therefore in 1720 he obtained leave to perform his opera of *Radamisto*. The house was so crowded that many fainted through excessive heat; and 40*s.* were offered by some for a seat in the gallery, after having in vain attempted to get one elsewhere. The contention, however, still ran very high between Handel's party and that of the two Italian masters; and at last it was determined that the rivals should be jointly employed in making an opera, in which each should take a distinct act, and he who by the general suffrage was allowed to have given the best proof of his abilities should be put in possession of the house. This opera was called *Muzio Scevola*, and Handel set the last act. It is said that Handel's superiority was owned even in the overture before it; but when the act came to be performed, there remained no pretence of doubt or dispute. The academy was now therefore firmly established, and Handel conducted it for nine years with great success; but about that time an irreconcilable enmity took place between Handel himself and Senesino. Senesino accused Handel of tyranny, and Handel accused Senesino of rebellion. The merits of the quarrel are not known: the nobility, however, became mediators for some time; and having failed in that good design, they became parties in the quarrel. Handel was resolved to dismiss Senesino, and the nobility seemed also resolved not to permit him to do so. The haughtiness of Handel's temper would not allow him to yield, and the affair ended in the total dissolution of the academy.

Handel now found that his abilities, great as they were, could not support him against the powerful opposition he met with. After the dismissal of Senesino, his audience sensibly dwindled away, and Handel entered into an agreement with Mr. Heidegger to carry on operas in conjunction with him. New singers were engaged from Italy; but the offended nobility raised a subscription against him, to carry on operas in the play-house in Lincoln's-Inn fields. Handel bore up four years against this opposition; three in partnership with Heidegger, and one by himself: but though his musical abilities were superior to those of his antagonists, the astonishing powers of the voice of Farinelli, whom the opposite party had engaged, determined the victory against him. At last Handel, having spent all he was worth in a fruitless opposition, thought proper to desist. His disappointment had such an effect upon him, that for some time he was disordered in his understanding, and at the same time his right arm was rendered useless by a stroke of the palsy. In this deplorable situation, it was thought necessary that he should go to the baths of Aix-la-Chapelle; and from them he received such extraordinary and sudden relief, that his cure was looked upon by the nuns as miraculous.

In 1736, Handel again returned to England; and soon after his return his *Alexander's Feast* was performed with applause at Covent Garden. The success and splendor of the Hay Market was by this time so much reduced by repeated mismanagements, that lord Middlesex undertook the direction of it himself, and once more applied to Handel for composition. He accordingly composed two operas called *Faramondo*, and *Alessandro Severo*, for which in 1737 he received 1000*l.* In 1738 he received 1500*l.* from a single benefit; and nothing seemed wanting to retrieve his affairs, excepting such concessions on his part as his opponents had a right to expect. These concessions, however, he could not be prevailed upon to make; and that he might no longer be under obligations to act as he was directed by others, he refused to enter into any engagements upon subscription. After having tried a few more operas at Covent Garden without

success, he introduced another species of music called *oratorios*, which he thought better suited to the native gravity of an English audience. But as the subjects of these pieces were always taken from sacred history, it was by some thought to be a profanation to set them to music and perform them at a playhouse. In consequence of this prejudice, the oratorios met with very indifferent success; and in 1741 Mr. Handel found his affairs in such a bad situation, that he was obliged to quit England, and go to Dublin.

He was received in Ireland in a manner suitable to his great merit; and his performing his oratorio called the *Messiah*, for the benefit of the city-prison, brought him into universal favour. In nine months time he had brought his affairs into a better situation; and on his return to England in 1742, he found the public much more favourably disposed. His oratorios were now performed with great applause: his *Messiah*, which before had been but coldly received, became a favourite performance; and Handel, with a generous humanity, determined to perform it annually for the benefit of the Foundling Hospital, which at that time was only supported by private benefactions. In 1743 he had a return of his paralytic disorder; and in 1751 became quite blind by a *gutta serena* in his eyes. This last misfortune for some time sunk him into the deepest despondency; but at last he was obliged to acquiesce in his misfortune, after having without any relief undergone some very painful operations. Finding it now impossible to manage his oratorios alone, he was assisted by Mr. Smith, who at his request frequently played for him, and conducted them in his stead; and with this assistance they were continued till within eight days of his death. During the latter part of his life, his mind was often disordered; yet at times it appears to have resumed its full vigour, and he composed several songs, choruses, &c. which from their dates may be considered almost as the last sounds of his dying voice. From about October 1758 his health declined very fast; his appetite, which had been remarkably keen, and which he had gratified to a great degree, left him; and he became sensible of the approach of death. On the 6th of April 1759, his last oratorio was performed, at which he was present, and he died on the 14th of the same month. On the 20th he was buried by the right reverend Dr. Pearce, bishop of Rochester, in Westminster-abbey; where, by his own order, and at his own expence, a monument was erected to his memory.

With regard to the character of this most eminent musician, he is universally allowed to have been a great epicure: In his temper he was very haughty, but was seldom or never guilty of mean actions. His pride was uniform; he was not by turns a tyrant and a slave. He appears to have had a most extravagant love for liberty and independence; inasmuch, that he would, for the sake of liberty, do things otherwise the most prejudicial to his own interest. He was liberal even when poor, and remembered his former friends when he was rich. His musical powers can perhaps be best expressed by Arbuthnot's reply to Pope, who seriously asked his opinion of him as a musician; "Conceive (said he) the highest you can of his abilities, and they are much beyond any thing you can conceive."

A musical exhibition took place in Westminster-abbey some years ago, under the name of the *Commemoration* of Handel. It may justly be considered the grandest of the kind ever attempted in any nation. Of the rise and progress of the design, together with the manner in which the first celebration was executed, an accurate and amusing detail is given in the 4th volume of the *History of Music*, by Dr. Burney, who closes his observations on this memorable occasion with these words: "As this commemoration is not only the first instance of a band of such magnitude being assembled together, but of any band at all numerous, performing in a similar situation without the assistance of a conductor to regulate the measure, the performances in Westminster-

abbey may be safely pronounced no less remarkable for the multiplicity of voices and instruments employed, than for accuracy and precision. When all the wheels of that huge machine, the orchestra, were in motion, the effect resembled clock-work in every thing but want of feeling and expression. And as the power of gravity and attraction in bodies is proportioned to their mass and density, so it seems as if the magnitude of this band had commanded and impelled adhesion and obedience beyond that of any other of inferior force. The pulsations in every limb, and ramifications of veins and arteries in an animal, could not be more reciprocal, isochronous, and under the regulation of the heart, than the members of this body of musicians under that of the conductor and leader. The totality of sound seemed to proceed from one voice and one instrument; and its powers produced not only new and exquisite sensations in judges and lovers of the art, but were felt by those who never received pleasure from music before. These effects, which will long be remembered by the present public, perhaps to the disadvantage of all other choral performances, run the risk of being doubted by all but those who heard them, and the present description of being pronounced fabulous if it should survive the present generation."

HANG-TCHEOU-FOU, the metropolis of the province of **TCHÉ-KIANG** in China. It is, according to the Chinese, the paradise of the earth; and may be considered as one of the richest, best situated, and largest cities of the empire. It is four leagues in circumference, exclusive of its suburbs; and the number of its inhabitants amounts to more than a million. It is computed, that there are a thousand workmen within its walls employed in manufacturing silk. What renders this city delightful, is a small lake, called *Si-bou*, which washes the bottom of its walls on the western side; its water is pure and limpid, and its banks are almost every where covered with flowers. Halls and open galleries, supported by pillars, and paved with large flag stones, have been erected here on piles, for the convenience of those who are fond of walking; causeways, cased with cut stone, traverse the lake in different directions; and the openings which are left in them at intervals, for the passage of boats, are covered by handsome bridges. In the middle of the lake are two islands, to which company generally resort after having amused themselves with rowing, and in which a temple and several pleasure-houses have been built for their reception. The emperor has a small palace in the neighbourhood. This city has a garrison of 3000 Chinese under the command of the viceroy, and 3000 Tartars commanded by a general of the same nation. It has under its jurisdiction seven cities of the second and third class.

HANGING, a common name given to the method of inflicting death on criminals by suspending them by the neck. Physicians are not agreed as to the manner in which death is brought on by hanging. De Haen hanged three dogs, whom he afterwards opened. In one, nothing remarkable appeared in the lungs. In another, from whom half an ounce of blood was taken from the jugular vein, the *dura* and *pia mater* were of the natural appearance; but the lungs were much inflamed. In the third, the meninges were found, and there was no effusion of blood in the ventricles of the brain, but the left lobe of the lungs was turgid with blood. Wepfer, Littræus, Alberti, Bruhierius, and Boerhaave, affirm that hanged animals die apoplectic. Their arguments for this are chiefly drawn from the livid colour of the face; from the turgescency of the vessels of the brain; the inflammation of the eyes; and from the sparks of fire which those who have survived hanging allege they have seen before their eyes. On the contrary, Bonetus, Petit, Haller, and Laucisi, from observing that death is occasioned by any small body falling into the glottis, have ascribed it to the stoppage of respiration. Others, deeming both these causes ill-founded, have ascribed it to a *luxation* of the *vertebræ* of the neck, which,

however, it is well known, scarcely ever takes place. De Haen adduces the authority of many eminent authors to prove the possibility of recovering hanged persons; and observes, in general, that with bleeding in the jugular vein, and anointing the neck with warm oil, the same remedies are to be employed in this case as for the recovery of drowned people. See **DROWNING**.

HANGINGS, denote any kind of drapery hung up against the walls or wainscoting of a room. See **PAPER-Hangings**, **TAPESTRY**, &c.

HANGCLIFF, a remarkable point of land on the east coast of the largest of the Shetland Islands. It is frequently the first land seen by ships in northern voyages. Captain Phipps determined its situation to be in W. lon. $0^{\circ} 56' 30''$. N. lat. $60^{\circ} 9'$.

HANNIBAL, a famous Carthaginian general, of whose exploits an account is given in the histories of **CARTHAGE** and **ROME**. After having had the misfortune to lose a sea-fight with the Rhodians, through the cowardice of Apollonius one of the admirals of Antiochus the Great, he was forced to fly into Crete, to avoid falling into the hands of the Romans. On his arrival in this island, he took sanctuary among the Gortynii; but as he had brought great treasure along with him, and knew the avarice of the Cretans, he thought proper to secure his riches by the following stratagem. He filled several vessels with melted lead, just covering them over with gold and silver. These he deposited in the temple of Diana, in the presence of the Gortynii, with whom, he said, he trusted all his treasure: Justin tells us, that he left this with them as a security for his good behaviour, and lived for some time very quietly in these parts. He took care, however, to conceal his riches in hollow statues of brass; which, according to some, he always carried along with him; or, as others will have it, exposed in a public place as things of little value. At last he retired to the court of Prusias king of Bithynia, where he found means to unite several of the neighbouring states with that prince into a confederacy against Eumenes king of Pergamus, a professed friend to the Romans; and during the ensuing war gave Eumenes several defeats, more through the force of his own genius than the valour of his troops. The Romans having received intelligence of the important services performed by Hannibal, immediately dispatched T. Quintius Flaminius as an ambassador to Prusias, in order to procure his destruction. At his first audience, he complained of the protection given to that famous general, representing him "as the most inveterate and implacable enemy the Romans ever had; as one who had ruined both his own country and Antiochus, by drawing them into a destructive war with Rome." Prusias, in order to ingratiate himself with the Romans, immediately sent a party of soldiers to surround Hannibal's house, that he might find it impossible to make his escape. The Carthaginian, having before discovered that no confidence was to be reposed in Prusias, had contrived seven secret passages from his house, in order to evade the machinations of his enemies, even if they should carry their point at the Bithynian court. But guards being posted at these, he could not fly, though, according to Livy, he attempted it. Perceiving, therefore, no possibility of escaping, he had recourse to poison, which he had long reserved for such a melancholy occasion. Then taking it in his hand, "Let us (said he) deliver the Romans from the disquietude with which they have long been tortured, since they have not patience to wait for an old man's death. Flaminius will not acquire any reputation or glory by a victory gained over a betrayed and defenceless person. This single day will be a lasting testimony of the degeneracy of the Romans. Their ancestors gave Pyrrhus intelligence of a design to poison him, that he might guard against the impending danger, even when he was at the head of a powerful army in

Italy; but they have deputed a person of consular dignity to excite Prusias impiouly to murder one who has taken refuge in his dominions, in violation of the laws of hospitality." Then having denounced dreadful imprecations against Prusias, he drank the poison, and expired at the age of 70 years. Cornelius Nepos acquaints us, that he put an end to his life by a subtle poison which he carried about with him in a ring. Plutarch relates, that, according to some writers, he ordered a servant to strangle him with a cloak wrapped about his neck; and others say, that, in imitation of Midas and Themistocles, he drank bull's blood.

With respect to the character of this general, it appears to have been in military affairs what Demosthenes was in oratory, or Newton in mathematics; namely, absolutely perfect, in which no human wisdom could discover a fault, and to which no man could add a perfection. Rollin hath contrasted his character with that of Scipio Africanus. He enumerates the qualities which make a complete general; and having then given a summary of what historians have related concerning both commanders, is inclined to give the preference to Hannibal. "There are, however (he says), two difficulties which hinder him from deciding; one drawn from the characters of the generals whom Hannibal vanquished; the other from the errors he committed. May it not be said (continues our author), that those victories which made Hannibal so famous, were as much owing to the imprudence and temerity of the Roman generals, as to his bravery and skill? When a Fabius and a Scipio were sent against him, the first stopped his progress, the other conquered him." These reasons however were answered by Mr. Hooke, who has taken some pains to vindicate Hannibal's character, by fully and fairly comparing it with that of Scipio Africanus, and other Roman commanders.

HANNO, general of the Carthaginians, was commanded to sail round Africa. He entered the ocean through the Straits of Gibraltar, and discovered several countries. He would have continued his navigation, had it not been for want of provisions. He wrote an account of his voyage, which was often quoted, but not much credited. Sigismund Gelenius published it in Greek at Basil, by Frobenius, in 1533. He lived, according to Pliny, when the affairs of the Carthaginians were in the most flourishing condition; but this is a very indeterminate expression.

HANOVER, a town of Germany, capital of the king of Great Britain's German dominions. The electors resided here before George I. ascended the British throne. The regency is administered in the same manner as if the sovereign were present. It is a large well-built town, and well fortified. The established religion is the Lutheran; but the Roman Catholics are tolerated, and have a handsome church. It has suffered greatly by the French, who got possession of it in 1757; but they were soon after expelled. Hanover is noted for a particular sort of beer, reckoned excellent by the people of this electorate. It is seated on the river Leina, which divides it in two; 25 miles W. of Brunsvick. E. lon. 10. 5. N. lat. 52. 25.

HANOVER, an electorate of Germany, which comprehended, at first, nothing but the county of Lawenbroad; but now it contains the duchy of Zell, Saxe-Lawenburg, Bremen, Lunenburg, the principality of Verden, Crubenhagen, and Oberwald. George I. king of Great Britain, was the first that gained possession of all these states, which lie mostly between the rivers Weser and Elbe, and extend 200 miles in length from S. W.; but the breadth is different, being in some places 150 miles, and in others but 50. Their produce is timber, cattle, hogs, mum, beer, and bacon; a little silver, copper, lead, iron, vitriol, brimstone, quicksilver, and coppers.

HANOVER, a fine large island, opposite the N. W. extremity of New Ireland. It is high, and covered with trees, among

which are many plantations, presenting a very beautiful appearance; and still further westward, in lon. 147° E. lie the Admiralty Islands, between 20 and 30 in number, many of them of considerable extent.

HANSE. or HANS, an ancient name for a society or company of merchants; particularly that of certain cities in Germany, &c. hence called *Hanse towns*. The word *hanse* is obsolete High Dutch or Teutonic; and signifies "alliance, confederacy, association," &c. Some derive it from the two German words, *am-see*, that is, "on the sea;" by reason the first hanse towns were all situated on the sea-coast: whence the society is said to have been first called *am see stenen*, that is, "cities on the sea;" and afterwards, by abbreviation, *hansee*, and *hanse*.

HANSE-TOWNS. The hanseatic society was a league between several maritime cities of Germany, for the mutual protection of their commerce. Bremen and Amsterdam were the two first that formed it; whose trade received such advantage by their fitting out two men of war in each to convoy their ships, that more cities continually entered into the league: even kings and princes made treaties with them, and were often glad of their assistance and protection; by which means they grew so powerful both by sea and land, that they raised armies as well as navies, enjoyed countries in sovereignty, and made peace or war, though always in defence of their trade, as if they had been an united state or commonwealth.

At this time also abundance of cities, though they had no great interest in trade, or intercourse with the ocean, came into their alliance for the preservation of their liberties: so that in the year 1200 we find no less than 72 cities in the list of the towns of the Hanse; particularly Bremen, Amsterdam, Antwerp, Rotterdam, Dort, Bruges, Ostend, Dunkirk, Middleburgh, Calais, Rouen, Rochelle, Bourdeaux, St. Malo, Bayonne, Bilboa, Lisbon, Seville, Cadiz, Carthage, Barcelona, Marseilles, Leghorn, Naples, Messina, London, Lubec, Rostock, Stralsund, Stetin, Wisnar, Konigsberg, Dantzic, Elbing, Marienburg.

The alliance was now so powerful, that their ships of war were often hired by other princes to assist them against their enemies. They not only awed, but often defeated, all that opposed their commerce; and, particularly in 1258, they took such revenge of the Danish fleet in the Sound, for having interrupted their commerce, that Waldemar III. then king of Denmark, for the sake of peace, gave them up all Schonen for 16 years; by which they commanded the passage of the Sound in their own right.—In 1428 they made war on Erick king of Denmark with 250 sail, carrying on board 12,000 men. These so ravaged the coast of Jutland, that the king was glad to make peace with them.

Many privileges were bestowed upon the hanse towns by Louis XI. Charles VIII. Louis XII. and Francis I. kings of France; as well as by the emperor Charles V. who had divers loans of money from them; and by king Henry III. who also incorporated them into a trading body, in acknowledgment for money which they advanced to him, as well as for the good services they did him by their naval forces in 1206.

These towns exercised a jurisdiction among themselves; for which purpose they were divided into four colleges or provinces, distinguished by the names of their four principal cities, viz. Lubec, Cologne, Brunsvic, and Dantzic, wherein were held their courts of judicature. They had a common stock or treasury at Lubec, and power to call an assembly as often as necessary. They kept magazines or warehouses for the sale of their merchandises in London, Bruges, Antwerp, Berg in Norway, Revel in Livonia, Novogorod in Muscovy, which were exported to most parts of Europe, in English, Dutch, and Flemish bottoms. One of their principal magazines was at London, where

a society of German merchants was formed, called the *steelyard company*. To this company great privileges were granted by Edward I. but revoked by act of parliament in 1552, in the reign of Edward VI. on a complaint of the English merchants that this company had so engrossed the cloth-trade, that in the preceding year they had exported 50,000 pieces, while all the English together had shipped off but 1100. Queen Mary, who ascended the throne the year following, having resolved to marry Philip the emperor's son, suspended the execution of the act for three years; but after that term, whether by reason of some new statute, or in pursuance of that of king Edward, the privileges of that company were no longer regarded, and all efforts of the hanse-towns to recover this loss were in vain.

Another accident that happened to their mortification was while queen Elizabeth was at war with the Spaniards. Sir Francis Drake happening to meet 60 ships in the Tagus, laden with corn, belonging to the hanse-towns, took out all the corn as contraband goods which they were forbid to carry by their original patent. The hanse-towns having complained of this to the diet of the empire, the queen sent an ambassador thither to declare her reasons. The king of Poland likewise interested himself in the affair, because the city of Dantzic was under his protection. At last, though the queen strove hard to preserve the commerce of the English in Germany, the emperor excluded the English company of merchant-adventurers, who had considerable factories at Stade, Embden, Bremen, Hamburg, and Elbing, from all trade in the empire. In short, the hanse-towns, in Germany in particular, were not only in so flourishing, but in so formidable a state, from the 14th to the 16th centuries, that they gave umbrage to all the neighbouring princes, who threatened a strong confederacy against them; and, as the first step towards it, commanded all the cities within their dominion or jurisdiction to withdraw from the union or hanse, and be no farther concerned therein. This immediately separated all the cities of England, France, and Italy, from them. The hanse, on the other hand, prudently put themselves under the protection of the empire: and as the cities just now mentioned had withdrawn from them; so they withdrew from several more, and made a decree among themselves, that none should be admitted into their society but such as stood within the limits of the German empire, or were dependent thereon; except Dantzic, which continued a member, though in nowise dependent on the empire, only it had been summoned formerly to the imperial diet. By this means they maintained their confederacy for the protection of their trade, as it was begun, without being any more envied by their neighbours. Hereby likewise they were reduced to Lubec, Bremen, Hamburg, and Dantzic; in the first of which they kept their register, and held assemblies once in three years at least. But this hanse or union has for some time been dissolved; and now every one of the cities carries on a trade separately for itself, according to the stipulation in such treaties of peace, &c. as are made for the empire betwixt the emperor and other potentates.

HANUYE, a town of Austrian Brabant, 20 miles S. E. of Louvain. E. lon. 5. 16. N. lat. 50. 41.

HANWAY (Jonas), eminent for his benevolent designs and useful writings, was born at Portsmouth in Hampshire on the 12th of August 1712. His father, Mr. Thomas Hanway, was an officer in the naval service, and for some years store-keeper to the dock-yard at that place. He was deprived of his life by an accident; and left his widow with four children, Jonas, William, Thomas, and Elizabeth, all of a very tender age. Mrs. Hanway, coming to London after the death of her husband, put Jonas to school, where he learned writing and accounts, and made some proficiency in Latin. At the age of 17 he was sent to Lisbon, where he arrived in June 1729, and was bound ap-

prentice to a merchant in that city. His early life, we are informed, was marked with that discreet attention to business, and love of neatness and regularity, which afterwards distinguished his character. At Lisbon his affections were captivated by a lady, then celebrated for her beauty and mental accomplishments; but she, preferring another for her husband, returned to England, and spent the latter part of her life in London with her family, on terms of friendship with Mr. Hanway. On the expiration of Mr. Hanway's apprenticeship, he entered into business at Lisbon as a merchant or factor; but did not remain there long before he returned to London.

He soon after connected himself as a partner in Mr. Dingley's house in St. Petersburg; where he arrived on the 10th of June 1743. The trade of the English nation over the Caspian Sea into Persia at this period had been entrusted to the care of Mr. Elton, who, not content with the pursuit of commercial affairs, had injudiciously engaged in the service of Nadir Shah to build ships on the Caspian after the European manner. This had alarmed the merchants in the Russian trade, and a resolution was formed that one of their body should make a journey into Persia. On this occasion Mr. Hanway offered his service, and was accepted. He set out on the 10th of September; and after experiencing a variety of hazards in that kingdom during a course of 12 months, returned to St. Petersburg, January 1, 1745, without being able to establish the intended trade by the Caspian, partly through the jealousy of the Russian court on account of Elton's connections with the Persians, and partly by the troubles and revolutions of the latter kingdom.

Though Mr. Hanway's conduct during this expedition seems to have been directed by the strictest rules of integrity, yet some difficulties arose in settling his demands on his employers. These, however, in the end were referred to the determination of impartial arbitrators, who at length decided in his favour. "I obtained (he says) my own; and as to any other personal advantage, it consisted in exercising my mind in patience under trials, and increasing my knowledge of the world." He now settled at St. Petersburg; where he remained five years, with no other variations in his life than such as may be supposed to occur in the dull round of a mercantile employment. During this time he interested himself greatly in the concerns of the merchants who had engaged in the Caspian trade: but the independence he had acquired having excited a desire to see his native country, he, after several disappointments which prevented him from accomplishing his wish, left St. Petersburg on the 9th of July 1750. On his arrival in his native country, he did not immediately relinquish his mercantile connections, though he seems to have left Russia with that view. He employed himself some time as a merchant; but afterwards, more beneficially to the world, as a private gentleman. In 1753 he published "An Historical Account of the British Trade over the Caspian Sea; with a Journal of Travels from London through Russia into Persia; and back again through Russia, Germany, and Holland. To which are added, the Revolutions of Persia during the present Century, with the particular History of the great Ufurper Nadir Kouli," 4 vols. 4to: a work which was received, as it deserved to be, with great attention from the public. In 1754 we find Mr. Hanway commending a plan offered for the advantage of Westminster, and suggesting hints for the further improvement of it, in "A Letter to Mr. John Spranger, on his excellent Proposal for Paving, Cleansing, and Lighting the Streets of Westminster, &c." 8vo. A few years afterwards, when a scheme of the like kind was carried into effect, many of Mr. Hanway's ideas, thrown out in this pamphlet, were adopted. In 1756, he printed "A Journal of Eight Days Journey from Portsmouth to Kingston upon Thames, with an Essay on Tea;" which was afterwards reprinted in 2 vols. 8vo, 1757.

At this juncture, Great Britain being on the eve of a war with France, the event of which was very important to the nation at large, and required every effort of patriotism and prudence to ward off the impending danger, Mr. Hanway published "Thoughts on the Duty of a good Citizen with regard to War and Invasion, in a Letter from a Citizen to his Friend," 8vo. About the same time, several gentlemen formed a plan, which was matured and made perfect by the assiduity of Mr. Hanway, for providing the navy with sailors, by furnishing poor children with necessaries to equip them for the service of their country. The success and propriety of this scheme soon became apparent. Mr. Hanway wrote and published three pamphlets on this occasion; and the treasurer of the Society, accompanied by Mr. Hanway, having waited on the king, the Society received 1000l. from his majesty, 400l. from the Prince of Wales, and 200l. from the Princess Dowager. This excellent institution through life was the favourite object of Mr. Hanway's care, and it continued to flourish under his auspices greatly to the advantage of the community. In 1758 he became an advocate for another charitable institution, which derived considerable emolument from his patronage of it. This was the Magdalen Charity; and, to assist it, he published "A Letter to Robert Dingley, Esq. being a Proposal for the Relief and Employment of Friendless Girls and Repenting Prostitutes," 4to. He also printed other small performances on the same subject.

In 1759 Mr. Hanway wrote "Reasons for an Augmentation of at least Twelve Thousand Mariners, to be employed in the Merchants Service and Coasting Trade, in 33 Letters to Charles Gray, Esq. of Colchester," 4to. The next year he published several performances: viz. 1. "A candid historical Account of the Hospital for the Reception of exposed and deserted young Children; representing the present Plan of it as productive of many Evils, and not adapted to the Genius and Happiness of this Nation," 8vo; which being answered by an anonymous Letter from Halifax in "Candid Remarks, 8vo. 1760," Mr. Hanway replied to it, and the Remarker rejoined. 2. "An Account of the Society for the Encouragement of the British Troops in Germany and North America, &c." 8vo. 3. "Eight Letters to — Duke of —, on the Custom of Vails-giving in England," 8vo. This practice of giving vails had arrived at a very extravagant pitch, especially among the servants of the great. It was Mr. Hanway who answered the kind reproach of a friend in a high station for not coming oftener to dine with him, by saying, "Indeed I cannot afford it." The nobleman to whom the above letters were addressed was the duke of Newcastle. The letters are written in that humorous style which is most attractive of general notice, and was best adapted to the subject. It was Sir Timothy Waldo that first put Mr. Hanway on this plan. Sir Timothy had dined with the duke of N——, and, on his leaving the house, was contributing to the support and insolence of a train of servants who lined the hall; and at last put a crown into the hand of the cook, who returned it, saying, "Sir, I do not take silver."—"Don't you indeed?" said the worthy baronet, putting it in his pocket; "then I do not give gold." Among the ludicrous circumstances in Mr. Hanway's letters is one which happened to himself. He was paying the servants of a respectable friend for a dinner which their master had invited him to, one by one as they appeared; "Sir, your great-coat;" a shilling—"Your hat;" a shilling—"Stick;" a shilling—"Umbrella;" a shilling—"Sir, your gloves;" "Why, friend, you may keep the gloves; they are not worth a shilling." In 1761, Mr. Hanway produced "Reflections, Essays, and Meditations on Life and Religion; with a Collection of Proverbs, and 28 Letters written occasionally on several Subjects," in 2 vols. 8vo.

The many useful and public-spirited plans which Mr. Han-

way had promoted for the welfare of the community, had now rendered his character most respectably popular, while his disinterestedness, and the sincerity of his intentions, were conspicuous to all. Five citizens of London, of whom the late Mr. Hoare the banker was one, waited on lord Bute, at that time the minister; and, in their own names, and the names of their fellow-citizens, requested that some notice might be taken of a man, who, at the expence of his own private fortune, and unremitting application, had rendered so many and such meritorious services to his country. In consequence of this request, he was in July 1762 appointed by a patent one of the commissioners for victualling the navy; a post which he held above 21 years. The next act of public beneficence in which we find him engaged is the collection of money for the sufferers by the fire which happened at Montreal, in the province of Quebec, in May 1765, when a fourth part of the city was consumed. On this occasion Mr. Hanway, in conjunction with two other gentlemen, collected 8415l. The very next year a dreadful fire broke out in Bridge Town in Barbadoes, which consumed buildings and property to the amount of near 100,000l. A subscription was opened, in which Mr. Hanway was a principal actor, and 14,886l. were collected, and transmitted to a committee appointed at Barbadoes to distribute it to the unfortunate sufferers. At subsequent periods he continued to interest himself in various other plans for relieving the distressed, and promoting the good, of different classes of the community. His attention was particularly directed towards alleviating the miseries of young chimney-sweepers. Besides the distressed of these helpless beings, which are open to general observation, such as a contortion of the limbs, and the prevention of their growth, they are liable to a disease peculiar to their occupation, now known by the name of the *chimney-sweeper's cancer*. Four children have been brought together into a workhouse, all afflicted with this dreadful and incurable disease. After much inquiry and consideration, he published, in 1773, "The State of the Chimney-sweepers young Apprentices; showing the wretched Condition of these distressed Boys; the ill Conduct of such Masters as do not observe the Obligation of Indentures; the Necessity of a strict Inquiry in order to support the civil and religious Rights of these Apprentices," 12mo. This small pamphlet has already been productive of some advantage to the objects intended to be benefited by it. The succeeding year, 1774, he enlarged a former publication, entitled "Advice from a Farmer to his Daughter, &c." and republished it under the title of "Virtue in humble Life; containing Reflections on the reciprocal Duties of the Wealthy and Indigent, the Master and the Servant," 2 vols. 8vo. a work deserving the particular consideration of every magistrate. This edition in a few months being sold, he reprinted it in two quarto volumes, with a dedication to Mrs. Montague.

In 1783, finding his health decline, he determined to resign his office at the victualling board, which he did on the 2d of October that year; and immediately received a grant of his whole salary by way of a pension, to continue for life. This favour he owed to the esteem which his majesty, to whom he was personally known, entertained of him; excited by his various exertions in behalf of his country and mankind. He was now released from his most material business, but did not think it would conduce to his happiness to lead an idle life. He engaged again in behalf of the chimney-sweepers boys; and promoted, by every means in his power, the establishment of Sunday-schools, which are now indeed generally adopted in every county in England. He likewise promoted a subscription for the relief of the many black poor people who wandered about the metropolis in extreme distress; and the lords of the treasury seconded the design, by directing money, as far as 14l. a-head, to be issued to the committee, to enable them to send the blacks to such places abroad as might be fixed on. After encounter-

ing many obstacles, about 300 negroes were sent, properly accommodated with provisions and necessaries, to Africa, under the conduct of a person approved for that station. The object of this plan, besides relieving the misery of these poor people, was to prevent in time the unbecoming connections between black persons and white, the evident consequences of which make their appearance frequently in our streets.

In the summer of 1786, Mr. Hanway's health declined so visibly that he thought it necessary to attend only to that. As he was extremely susceptible of cold, he took various precautions to defend himself from the effects of bad weather; and, among other expedients, was the first who ventured to carry an umbrella in the streets of London; a practice which has since become so universal.

With regard to his various publications, although they were defective in point of arrangement and abounding in digressions, yet those who are judges of literary composition allow, that his language is well calculated to have the effect he desired on the reader, and to impress him with the idea that the author was a man of inflexible integrity, and wrote from the pure dictates of the heart. It is plain and unornamented, without the appearance of art, or the affectation of singularity. Its greatest defect (say they) is a want of conciseness; its greatest beauty, an unaffected and genuine simplicity. He spoke French and Portuguese, and understood the Rus and modern Persic imperfectly. Latin he had been taught at school, but had not much occasion to cultivate it after he entered into life.

Mr. Hanway, although never married himself, was yet an advocate for marriage, and recommended it to all young people as the most effectual restraint on licentiousness. In his transactions with the world, he was always open, candid, and sincere. Whatever he said might be depended on with implicit confidence. In his department of commissioner for victualling the navy he was uncommonly assiduous and attentive; and kept the contractors and persons who had dealings with the office at a great distance. He would not even accept a hare or pheasant, or the smallest present, from any of them, but, with some mild answer, had them returned to the donors.

Besides the works already mentioned in the course of this article, Mr. Hanway was the author of a great number of others; his different publications amounting all together to between sixty and seventy. A complete list of them is given by his biographer Mr. Pugh, from whose grateful and well-written performance this article has been chiefly extracted.

HAP, or HAPP, in law, signifies to catch or snatch a thing. Thus we meet with, to hap the possession of a deed-poll. Littleton, fol. 8. also, to hap the rent. If partition be made between two parceners, and more land be allowed the one than the other, she that hath most of the land charges it to the other, and happeth the rent whereon assize is brought.

HAPAE, the name of four of the Friendly Islands in the S. Pacific Ocean. They are of a similar height and appearance, and connected by a reef of coral rocks, dry at low water. The plantations are very numerous and extensive; and some of them are inclosed in such a manner, that the fences, running parallel to each other, form spacious public roads, that would appear ornamental in countries, where rural conveniences have been carried to the greatest perfection. These islands extend about 19 miles. See FRIENDLY ISLANDS.

HAPSAL, a sea-port of the government of Revel, or Esthonia, in the Russian empire. It is seated on the Baltic, five miles S. W. of Revel, opposite the island of Dago. E. lon. 22. 47. N. lat. 59. 4.

HAPSBURG, an ancient castle, now in ruins, on a lofty eminence, near the town of Schintznach, not far from the river Aar, in the canton of Berne in Switzerland. This place was the cradle, as it were, of the house of Austria, whose an-

cestors may be traced back to the beginning of the 13th century, when they were no more than simple barons of Swisserland; and this castle commands an unbounded view over hills and dales, plains and forests, rivers and lakes, towns and villages, mountains and alps, emblems of that extent of power to which the talents of one man, who derived his title from this castle (Rodolph count of Hapsburg) raised himself and his descendants. What is left of this castle is now inhabited by the family of a peasant. There is another castle of the same name, near the lake of Lucern, which some authors have erroneously asserted to be that from which the counts derived their title. See GER-MANY.

HAQUE, in our old writers, a little hand-gun, prohibited to be used for destruction of game, &c. by statute 33 Hen. VIII. cap. 6. and 2 & 3 Ed. VI. cap. 14. There is also the half-haque, or demi-haque, within the said acts.

HARAM. See SERAGLIO.

HARANGUE, a modern French name for a speech or oration made by an orator in public. Menage derives the word from the Italian *aranga*, which signifies the same; formed, according to Ferrari, from *arringo*, "a just, or place of justing." Others derive it from the Latin *ara*, "altar;" by reason the first harangues were made before altars: whence the verse of Juvenal, "*Aut Lugdunensis rhetor dicturus ad aram.*" Harangues were usually made by the generals previous to an engagement both amongst the Greeks and Romans. An harangue on such occasions was called *allocutio*. See ALLOCUTIO. The word is also frequently used in a ludicrous sense, viz. for a too pompous, prolix, or unseasonable speech or declamation.

HARBINGER, an officer of the king's household, having four yeomen under him, who ride a day's journey before the court when it travels, to provide lodgings, &c.

HARBOROUGH, (MARKET), a town of Leicestershire, with a market on Tuesday. It is seated on the river Welland, which separates it from Northamptonshire, and is 14 miles S. of Leicester, and 83 N. by W. of London. W. lon. 0. 52. N. lat. 52. 28.

HARBOUR, a general name given to any sea-port or haven; as also to any place convenient for mooring shipping, although at a great distance from the sea. The qualities requisite in a good harbour are, that the bottom be entirely free from rocks or shallows; that the opening be of sufficient extent to admit the entrance or departure of large ships without difficulty; that it should have good anchoring-ground, and be easy of access; that it should be well defended from the violence of the wind and sea; that it should have room and convenience to receive the shipping of different nations, and those which are laden with different merchandises; that it be furnished with a good light-house, and have variety of proper rings, posts, moorings, &c. in order to remove or secure the vessels contained therein; and, finally, that it have plenty of wood, and other materials for firing, besides hemp, iron, mariners, &c.

HARBURG, a town of Germany, in the duchy of Lunenburg, with a strong castle, seated on the Elbe, opposite Hamburg, 37 miles N. W. of Lunenburg.

HARCOURT, a town of France, in the department of Calvados and late province of Normandy. Hence a late noble family in France derived their ducal title; and hence originally came the noble family of the same name in England. It is 12 miles S. of Caen.

HARDENING, the giving a greater degree of hardness to bodies than they had before. There are several ways of hardening iron and steel, as by hammering them, quenching them in cold water, &c. See STEEL.

Case-HARDENING. See CASE-HARDENING.

HARDERWICK, a town of the United Provinces, in Guelderland, with a university. It is seated on the Zui-

der-ze, 32 miles E. of Amsterdam. E. lon. 5. 40. N. lat. 52. 23.

HARDNESS, in bodies, a property directly opposite to fluidity; by which they resist the impression of any other substance, sometimes in an extreme degree. As fluidity has been found to consist in the motion of the particles of a body upon one another in consequence of a certain action of the universal fluid or elementary fire among them; we must conclude that hardness consists in the absence of this action, or a deficiency of what is called *latent heat*. This is confirmed by observing, that there is an intermediate state betwixt hardness and fluidity, in which bodies will yield to a certain force, though they still make a considerable resistance. This is principally observed in the metals, and is the foundation of their ductility. It appears, indeed, that this last property, as well as fluidity, is entirely dependent on a certain quantity of latent heat absorbed, or otherwise acting within the substance itself; for all the metals are rendered hard by hammering, and soft by being put again into the fire and kept there for some time. The former operation renders them hot as well as hard; probably, as Dr. Black observes, because the particles of metal are thus forced nearer one another, and those of fire squeezed out from among them. By keeping them for some time in the fire, that element insinuates itself again among the particles, and arranges them in the same manner as before, so that the ductility returns. By a second hammering this property is again destroyed, returning on a repetition of the heating, or *annealing* as it is called; and so on, as often as we please.

Hardness appears to diminish the cohesion of bodies in some degree, though their fragility does not by any means keep pace with their hardness. Thus, glass is very hard and very brittle; but flint, though still harder than glass, is much less brittle. Among the metals, however, these two properties seem to be more connected, though even here the connection is by no means complete. Steel, the hardest of all the metals, is indeed the most brittle; but lead, the softest, is not the most ductile. Neither is hardness connected with the specific gravity of bodies; for a diamond, the hardest substance in nature, is little more than half the weight of the lightest metal. As little is it connected with the coldness, electrical properties, or any other quality with which we are acquainted: so that though the principle above laid down may be accepted as a general foundation for our inquiries, a great number of particulars remain yet to be discovered before we can offer any satisfactory explanation.

All bodies become harder by cold; but this is not the only means of their doing so, for some become hard by heat as well as cold. Thus, water becomes hard by cold when it is frozen, but it becomes much harder when its steam is passed over red-hot iron, and it enters the substance of the metal, by an union with which it becomes almost as hard as glass.

Mr. Quist and others have constructed tables of the hardness of different substances. The method pursued in constructing these tables was by observing the order in which they were able to cut or make any impression upon one another. The following table, extracted from M. Magellan's edition of Cronstedt's Mineralogy, was taken from Dr. Quist, Bergman, and Mr. Kirman. The first column shows the hardness, and the second the specific gravity.

Diamond from Ormus	-	20	—	3,7
Pink diamond	-	19	—	3,4
Blueish diamond	-	19	—	3,3
Yellowish diamond	-	19	—	3,3
Cubic diamond	-	18	—	3,2
Ruby	-	17	—	4,2
Pale ruby from Brazil	-	16	—	3,5
Ruby spinell	-	13	—	3,4

Deep blue sapphire	-	-	16	—	3,8
Ditto paler	-	-	17	—	3,8
Topaz	-	-	15	—	4,2
Whitish ditto	-	-	14	—	3,5
Bohemian ditto	-	-	11	—	2,8

Chalk	-	-	3	—	2,7

HARDOUIN (John), a learned French Jesuit in the beginning of the 18th century, known by the remarkable paradoxes he advanced in his writings; this in particular, That all the works of the ancient profane writers, except Cicero's works, Virgil's Georgics, Horace's satires and epistles, and Pliny's natural history, are mere forgeries. He died at Paris in 1729, aged 83. His principal works are, 1. An edition of Pliny's natural history, with notes, which is much esteemed. 2. An edition of the Councils, which made much noise. 3. Chronology restored by medals, 4to. 4. A commentary on the New Testament, folio; in which he pretends that our Saviour and his apostles preached in Latin, &c.

HARE, in zoology. See **LEPUS**. The hare is a beast of venery, or of the forest, but peculiarly so termed in the second year of her age. There are reckoned four sorts of them, from the place of their abode: some live in the mountains, some in the fields, some in marshes, and some wander about every where. The mountain-hares are the swiftest, the field-hares are not so nimble, and those of the marshes are the slowest: but the wandering hares are the most dangerous to follow; for they are cunning in the ways and mazes of the fields, and, knowing the nearest ways, run up the hills and rocks, to the confusion of the dogs, and the discouragement of the hunters. See the article **HUNTING**.

Hares and rabbits are very mischievous to new planted orchards, by peeling off the barks of the tender and young trees for their food. They do also the same sort of mischief to nurseries; for the prevention of which, some bind ropes about the trees up to such a height as they are able to reach: some daub them with tar; but though this keeps off the hares, it is itself mischievous to the trees; but this hurtful property of it is in some degree taken off by mixing any kind of fat or grease with it, and incorporating them well over the fire. This mixture is to be rubbed over the lower part of the trees in November, and will preserve them till that time the next year, without any danger from these animals. It is only in the hard weather in the winter season, when other food is scarce, that these creatures feed on the barks of trees.

People who have the care of warrens, pretend to an odd way of making hares fat when they get them there. This is the stopping up their ears with wax, and rendering them deaf. The

hare is so timorous a creature, that she is continually listening after every noise, and will run a long way on the least suspicion of danger: so that she always eats in terror, and runs herself out of flesh continually. These are both prevented by her feeding in a safe place, and that without apprehension; and they say she will always readily be fattened in this way.

See HARE. See MUS.

HARE'S Ear, in botany. See RUPELLURUM.

HARE (Dr. Francis), an English bishop, of whose birth we have no particulars, was bred at Eton school, and from that foundation became a member of King's-college, Cambridge; where he had the tuition of the marquis of Blandford, only son of the illustrious duke of Marlborough, who appointed him chaplain-general to the army. He afterwards obtained the deanery of Worcester, and from thence was promoted to the bishopric of Chichester, which he held with the deanery of St. Paul's to his death, which happened in 1740. He was dismissed from being chaplain to George I. in 1718, by the strength of party prejudices, in company with Dr. Mols and Dr. Sherlock, persons of distinguished rank for parts and learning. About the latter end of queen Anne's reign he published a remarkable pamphlet, intitled, *The Difficulties and Discouragements which attend the Study of the Scriptures*, in the Way of private Judgment: in order to shew, that since such a study of the Scriptures is an indispensable duty, it concerns all Christian societies to remove, as much as possible, those discouragements. In this work, his manner appeared to be so ludicrous, that the Convocation fell upon him, as if he were really against the study of the holy scriptures: and Whiston says, that finding this piece likely to hinder that preferment he was seeking for, he aimed to conceal his being the author. He published many pieces against bishop Hoadley, in the Bangorian Controversy, as it is called; and also other learned works, which were collected after his death, and published in four vols. 8vo. 2. An edition of Terence, with notes, in 4to. 3. The book of Psalms in the Hebrew, put into the original poetical metre, 4to. In this last work, he pretends to have discovered the Hebrew metre, which was supposed to be irretrievably lost. But his hypothesis, though defended by some, yet has been confuted by several learned men, particularly by Dr. Lowth in his *Metricæ Hæcæne brevis Confutatio*, annexed to his lectures *De Sacra Poesi Hebræorum*.

HARESBURY, a town of Wiltshire, on the Willy, near Warminster, 94 miles from London, is in old records called *Heigtsbury*, or *Heytsbury*; and now it is written Hatchbury. It was once the seat of the empress Maud. Here are fairs May 14th, and September 15th; and it has sent members to parliament ever since Henry VI. it being an ancient borough by prescription. There is an alms-house here for 12 poor men and a woman. Here is a collegiate church with four prebendaries, and a free-school, and the place is governed by a bailiff and burgoises.

HARFLEUR, a town of France, in the department of Lower Seine and late province of Normandy. Its fortifications have been long demolished, and its harbour choked up. The English took it by assault in 1415. It stands at the mouth of the Seine, 36 miles N. W. of Rouen. E. lon. 0. 19. N. lat. 49. 30.

HARIOT, or **HERIOT**, in law, a due belonging to a lord at the death of his tenant, consisting of the best beast, either horse or cow, or ox, which he had at the time of his death; and in some manors the best goods, piece of plate, &c. are called harriots.

HARLECH, a town of Merionethshire, with a market on Saturday. It is seated on a rock, on the sea-shore, and but a poor place, though the county town, and governed by a mayor, &c. It is distinguished by a castle built by Edward I. which is

almost entire. It is 223 miles W. N. W. of London. W. lon. 4. 6. N. lat. 52. 54.

HARLEIAN COLLECTION. A most valuable collection of useful and curious manuscripts, begun near the end of the last century, by Robert Harley of Brampton Bryan, Esq. in Herefordshire, afterwards earl of Oxford and lord high-treasurer; and which was conducted upon the plan of the great Sir Robert Cotton. He published his first considerable collection in August 1705, and in less than ten years he got together near 2500 rare and curious MSS. Soon after this, the celebrated Dr. George Hicks, Mr. Anstis garter king at arms, bishop Nicolson, and many other eminent antiquaries, not only offered him their assistance in procuring MSS. but presented him with several that were very valuable. Being thus encouraged to perseverance by his success, he kept many persons employed in purchasing MSS. for him abroad, giving them written instructions for their conduct. By these means the MS. library was, in the year 1721, increased to near 6000 books, 14,000 original charters, and 500 rolls. On the 2d of May 1724 lord Oxford died: but his son Edward, who succeeded to his honours and estate, still farther enlarged the collection; so that when he died, June 16th 1741, it consisted of 8000 volumes, several of them containing distinct and independent treatises, besides many loose papers which have been since sorted and bound up in volumes; and above 40,000 original rolls, charters, letters patent, grants, and other deeds and instruments of great antiquity. The principal design of making this collection was the establishment of a MS. English historical library, and the rescuing from destruction such national records as had eluded the diligence of preceding collectors; but lord Oxford's plan was more extensive; for his collection abounds also with curious MSS. in every science. This collection is now in the British Museum; and an enumeration of its contents may be seen in the Annual Register, Vol. vi. p. 140, &c.

HARLEM, a large and populous town of the United Provinces, in Holland, memorable for the siege it held out against the Spaniards in 1573, for ten months; the townsmen, before they capitulated, being reduced to eat the vilest animals, and even leather and grass. The church, which is the largest in Holland, is adorned with the finest organ in Europe. It consists of 8000 pipes; the largest 38 feet long, and 16 inches in diameter; and there are 68 stops, of which the most wonderful is the vox humana. Harlem is seated on the lake of the same name; and to the S. of the town is a wood, cut into delightful walks and vistas. This place claims the invention of printing; and, in fact, the first attempts in the art are indisputably to be attributed to Laurentius Costar, a magistrate of the city. It is situated 10 miles W. of Amsterdam. E. lon. 4. 38. N. lat. 52. 24.

HARLEM MERE, a lake of Holland, near Harlem, about 14 miles long and the same broad. It lies between Leyden, Harlem, and Amsterdam; and is navigable, but subject to dangerous storms; on which account, the canals from Leyden to Amsterdam were made, as a safer though more tedious passage.

HARLEQUIN, in the Italian comedy, a buffoon, dressed in party-coloured clothes; answering much the same purpose as a merry-andrew or jack-pudding in our drolls, on mountebanks' stages, &c. We have also introduced the harlequin upon our theatres; and this is one of the standing characters in the modern grotesque or pantomime entertainments. The term took its rise from a famous Italian comedian who came to Paris under Henry III. and who frequenting the house of M. de Harlay, his companions used to call him Harlequino, q. d. little Harlay; a name which has descended to all those of the same rank and profession.

HARLEY (Robert), earl of Oxford and Mortimer, was the eldest son of Sir Edward Harley, and born in 1661. At the

Revolution, Sir Edward and his son raised a troop of horse at their own expence; and after the accession of king William and queen Mary, he obtained a seat in parliament. His promotions were rapid: in 1702 he was chosen speaker of the house of commons; in 1704 he was sworn of queen Anne's privy council, and the same year made secretary of state; in 1706 he acted as one of the commissioners for the Treaty of Union; and in 1710 was appointed a commissioner of the treasury, and chancellor and under treasurer of the exchequer. A daring attempt was made on his life, March 8, 1711, by the marquis of Guiscard, a French papist; who, when under an examination before a committee of the privy council, stabbed him with a penknife. Of this wound, however, he soon recovered; and was the same year created earl of Oxford, and lord high-treasurer, which office he resigned just before the queen's death. He was impeached of high treason in 1715, and committed to the Tower; but was cleared by trial, and died in 1724. His character has been variously represented, but cannot be here discussed. He was not only an encourager of literature, but the greatest collector in his time of curious books and MSS. his collection of which makes a capital part of the British Museum. See *HARLEIAN Collection*.

HARLING, a town in Norfolk, with a market on Tuesday. It is seated on a rivulet, and the market is chiefly for linen cloth. It is a pretty, neat, genteel town, but has no church, and only a small chapel in the middle of the place, and a presbyterian meeting-house. It manufactures a little linen-cloth, and is 24 miles S. W. of Norwich, and 88 N. E. of London.

HARLINGEN, a seaport of the United Provinces, in Friesland, of which, next to Lewarden, it is the largest and most populous. It is 13 miles W. of Lewarden. E. lon. 5. 14. N. lat. 53. 9.

HARLOCH, or **HARLEICH**, a town of Merionethshire, in North Wales, 223 miles from London, on the sea coast, near the north-west point of the county. It is naturally strong, a garrison being kept here for the security of the coast. Its castle lies now in ruins. The town, though a corporation and governed by a mayor, makes but a very mean appearance. It has a market on Saturdays, and four fairs in the year.

HARLOT, a woman given to incontinency, or that makes a habit or trade of prostituting her body. The word is supposed to be used for the diminutive *whorelet*, a "little whore."—Others derive it from *Arlotta*, mistress to Robert duke of Normandy, and mother to William the Conqueror: Camden derives it from one *Arlotba*, concubine to William the Conqueror: Others from the Italian *Arlotta*, "a proud whore." Harlots were tolerated amongst the Jews, Greeks, and Romans. Fornication indeed was prohibited among the Jews, under severe penalties; but these they explained as extending only to women of their own nation. The public stews were therefore stocked with foreign prostitutes, who seem to have been taken under the protection of government. Hence appears the reason why the word *strange woman* is often found to signify a harlot. Prostitutes at first wore veils or masks; but by and by their modesty was entirely put to flight, and they went abroad bare faced. At Athens the prostitutes were generally strangers; and such as debauched an Athenian female were liable to a penalty. To frequent the public stews was not held disgraceful! The wisest of the Heathen sages allowed it! Solon permitted common whores to go publicly to the young men who had engaged them, and encouraged the youth of Athens to gratify their lust with these, rather than seduce and debauch the wives or daughters of citizens. Cato the Censor was of the same sentiments; and Cicero challenges all persons to name a time when men were either reproved for this practice, or not countenanced in it. Amongst the Jews, the harlots used to ply in the highways and

streets of cities; at Athens they frequented the *ceramicus*, *sciros*, and the old forum. In some places they were distinguished by their dress from other women. Corinth was a remarkable nursery of harlots, and gave birth to the noted *Lais*. Their accomplishments were oftentimes great, in all the polite and elegant parts of female education, viz. philosophy, dancing, singing, rhetoric, &c. *Aspasia*, the mistress of Pericles, was admired by Socrates for her learning. The more accomplished prostitutes frequently amassed large fortunes; a remarkable instance of which we have in Phryne, who offered to rebuild the walls of Thebes, when destroyed by Alexander, on condition that they would perpetuate her memory and profession by an inscription. Prostitutes at Rome were obliged to fix a bill over their doors, indicating their character and profession. It was also customary for them to change their names, after they had signified to the prætor their intention of leading such a dissolute life: this they did, because their trade was unbecoming their birth and condition; but they re-assumed their family names when they quitted their infamous mode of living. Women whose grandfather, father, or husband, had been a Roman knight, were forbidden by the laws to make a public profession of lewdness.

HARLOW, a town in Essex, whose market is now dissolved; but, on a common, two miles from the town, is a famous annual fair, on the 9th of September, for horses, cattle, &c. It is called Harlow Bush Fair, and is much frequented by the neighbouring gentry. Harlow is 17 miles W. of Chelmsford, and 23 N. E. of London. E. lon. 0. 12. N. lat. 51. 49.

HARMATTAN, the name of a remarkable periodical wind which blows from the interior parts of Africa towards the Atlantic ocean. Of this wind we have the following account in the *Philosophical Transactions*, vol. 71. furnished by Mr. Norris, a gentleman who had frequent opportunities of observing its singular properties and effects.

"On that part of the coast of Africa which lies between Cape Verd and Cape Lopez, an easterly wind prevails during the months of December, January, and February, which by the Fantees, a nation on the Gold coast, is called the *Harmattan*. Cape Verd is in 15 N. latitude, and Cape Lopez in 1 S. latitude; and the coast between these two Capes runs, in an oblique direction, nearly from W.S.W. to E.S.E. forming a range of upwards of 2100 miles. At the isles de Los, which are a little to the northward of Sierra Leone, and to the southward of Cape Verd, it blows from the E. S. E. on the Gold coast from the N. E. and at Cape Lopez, and the river Gabon, from the N. N. E. This wind is by the French and Portuguese, who frequent the Gold coast, called simply the N. E. wind, the quarter from which it blows. The English, who sometimes borrow words and phrases from the Fantee language, which is less guttural and more harmonious than that of their neighbours, adopt the Fantee word *Harmattan*.

The *harmattan* comes on indiscriminately at any hour of the day, at any time of the tide, or at any period of the moon, and continues sometimes only a day or two, sometimes five or six days, and it has been known to last fifteen or sixteen days. There are generally three or four returns of it every season. It blows with a moderate force, not quite so strong as the sea-breeze (which every day sets in during the fair season from the W. W. S. W. and S. W.); but somewhat stronger than the land wind at night from the N. and N. N. W.

1. A fog or haze is one of the peculiarities which always accompanies the *harmattan*. The gloom occasioned by this fog is so great, as sometimes to make even near objects obscure. The English fort at Whydah stands about the midway between the French and Portuguese forts, and not quite a quarter of a mile from either, yet very often from thence neither of the other forts can be discovered. The sun, concealed the greatest part

of the day, appears only a few hours about noon, and then of a mild red, exciting no painful sensation in the eye.

2. Extreme dryness makes another extraordinary property of this wind. No dew falls during the continuance of the harmattan; nor is there the least appearance of moisture in the atmosphere. Vegetables of every kind are very much injured; all tender plants, and most of the productions of the garden, are destroyed; the grass withers, and becomes dry like hay; the vigorous ever-greens likewise feel its pernicious influence; the branches of the lemon, orange, and lime-trees droop, the leaves become flaccid, wither, and if the harmattan continues to blow for 10 or 12 days, are so parched, as to be easily rubbed to dust between the fingers: the fruit of these trees, deprived of its nourishment, and stunted in its growth, only appears to ripen, for it becomes yellow and dry, without acquiring half the usual size. The natives take this opportunity of the extreme dryness of the grass and young trees to set fire to them, especially near their roads, not only to keep those roads open to travellers, but to destroy the shelter which long grass, and thickets of young trees, would afford to skulking parties of their enemies. A fire thus lighted flies with such rapidity as to endanger those who travel: in that situation, a common method of escape is, on discovering a fire to windward, to set the grass on fire to leeward, and then follow your own fire. There are other extraordinary effects produced by the extreme dryness of the harmattan.

The parching effects of this wind are likewise evident on the external parts of the body. The eyes, nostrils, lips, and palate, are rendered dry and uneasy; and drink is often required, not so much to quench thirst, as to remove a painful aridity in the fauces. The lips and nose become sore, and even chapped; and though the air be cool, yet there is a troublesome sensation of prickling heat on the skin. If the harmattan continues four or five days, the scarf skin peels off, first from the hands and face, and afterwards from the other parts of the body if it continues a day or two longer. Mr. Norris observed, that when sweat was excited by exercise on those parts which were covered by his clothes from the weather, it was peculiarly acrid, and tasted, on applying his tongue to his arm, something like spirits of hartshorn diluted with water.

3. Salubrity forms a third peculiarity of the harmattan. Though this wind is so very prejudicial to vegetable life, and occasions such disagreeable parching effects on the human species, yet it is highly conducive to health. Those labouring under fluxes and intermitting fevers generally recover in an harmattan. Those weakened by fevers, and sinking under evacuations for the cure of them, particularly bleeding, which is often injudiciously repeated, have their lives saved, and vigour restored, in spite of the doctor. It stops the progress of epidemics: the small-pox, remittent fevers, &c. not only disappear, but those labouring under these diseases, when an harmattan comes on, are almost certain of a speedy recovery. Infection appears not then to be easily communicated even by art. In the year 1770, there were on board the Unity, at Whydah, above 300 slaves; the small-pox broke out among them, and it was determined to inoculate; those who were inoculated before the harmattan came on, got very well through the disease. About 70 were inoculated a day or two after the harmattan set in, but no one of them had either sickness or eruption. It was imagined that the infection was effectually dispersed, and the ship clear of the disorder; but in a very few weeks it began to appear among those seventy. About 50 of them were inoculated the second time; the others had the disease in a natural way: an harmattan came on, and they all recovered, excepting one girl, who had an ugly ulcer on the inoculated part, and died some time afterwards of a locked jaw."

This account differs remarkably from that given by Dr. Lind,

who calls the harmattan a malignant and fatal wind: (See his *Diseases of Hot Climates*.) As to the nature of the soil over which it blows, it appears, that, excepting a few rivers and some lakes, the country about and beyond Whydah is covered for 400 miles back with verdure, open plains of grass, clumps of trees, and some woods of no considerable extent. The surface is sandy, and below that a rich reddish earth: it rises with a gentle ascent for 150 miles from the sea, before there is the appearance of a hill, without affording a stone of the size of a walnut. Beyond these hills there is no account of any great ranges of mountains.

HARMODIUS, a friend of Aristogiton, who delivered his country from the tyranny of the Pisistratidæ. (See ARISTOGITON.) The Athenians, to reward the patriotism of these illustrious citizens, made a law that no one should ever after bear the name of Aristogiton and Harmodius.

HARMONIA, in fabulous history, the wife of Cadmus, both of whom were turned into serpents. See CADMUS. Though many of the ancient authors make Harmonia a princess of divine origin, there is a passage in Athenæus from Euhemerus, the Vanini of his time, which tells us, that she was by profession a player on the flute, and in the service of the prince of Zidon previous to her departure with Cadmus. This circumstance, however, might encourage the belief, that as Cadmus brought letters into Greece, his wife brought *harmony* thither; as the word ἀρμονία, *harmonia*, has been said to have no other derivation than from her name: which makes it very difficult to ascertain the sense in which the Greeks made use of it in their music; for it has no roots by which it can be decomposed, in order to deduce from them its etymology. The common account of the word, however, that is given by lexicographers, and generally adopted by the learned, does not confirm this opinion. It is generally derived from ἀρμολῶ, and this from the old verb ἀρῶ ἀρῶ, to fit or join.

HARMONIC. As an adjective, it signifies in general any thing belonging to harmony; though in our language the adjective is more properly written *harmonical*. In this case it may be applied to the *harmonical* divisions of a monochord; or, in a word, to consonances in general. As a substantive neuter, it imports all the concomitant or accessory sounds which, upon the principles resulting from the experiments made on sonorous bodies, attend any given sound whatever, and render it appetible. Thus all the aliquot parts of a musical string produce *harmonical* sounds, or *harmonics*.

HARMONICA. This word, when originally appropriated by Dr. Franklin to that peculiar form or mode of musical glasses, which he himself, after a number of happy experiments, had constituted, was written *Armonica*. In this place, however, we have ventured to restore it to its native plenitude of sound, as we have no antipathy against the moderate use of aspirations. It is derived from the Greek word ἀρμονία. The radical word is ἀρῶν, to suit or fit one thing to another. By the word ἀρμονία the Greeks expressed *aptitudes* of various kinds; and from the use which they made of that expression, we have reason to conclude, that it was intended to import the highest degree of refinement and delicacy in those relations which it was meant to signify. Relations or aptitudes of sound, in particular, were understood by it; and in this view, Dr. Franklin could not have selected a name more expressive of its nature and genius for the instrument which we are now to describe; as, perhaps, no musical tone can possibly be finer, nor consequently susceptible of juster concords, than those which it produces.

It has been said, that the elements or first approaches to music by glasses were conveyed in an old English book, from which rude and barbarous hints perhaps, Mr. Puckeridge afterwards improved. But, for a farther account of him, of the state in which he left the instrument, and of the state to which it

was afterwards carried, we must refer to the following extracts from Dr. Franklin and others.

“ Perhaps (says the Doctor in his letter to Father Beccaria) it may be agreeable to you, as you live in a musical country, to have an account of the new instrument lately added here to the great number that charming science was possessed of before. As it is an instrument that seems peculiarly adapted to Italian music, especially that of the soft and plaintive kind, I will endeavour to give you such a description of it, and of the manner of constructing it, that you or any of your friends may be enabled to imitate it, if you incline so to do, without being at the expense and trouble of the many experiments I have made in endeavouring to bring it to its present perfection.

“ You have doubtless heard the sweet tone that is drawn from a drinking-glass, by pressing a wet finger round its brim. One Mr. Puckeridge, a gentleman from Ireland, was the first who thought of playing tunes formed of these tones. He collected a number of glasses of different sizes; fixed them near each other on a table; and tuned them, by putting into them water, more or less as each note required. The tones were brought out by pressing his fingers round their brims. He was unfortunately burnt here, with his instrument, in a fire which consumed the house he lived in. Mr. E. Delaval, a most ingenious member of our Royal Society, made one in imitation of it, with a better choice and form of glasses, which was the first I saw or heard. Being charmed with the sweetness of its tones, and the music he produced from it, I wished to see the glasses disposed in a more convenient form, and brought together in a narrower compass, so as to admit of a greater number of tones, and all within reach of hand to a person sitting before the instrument; which I accomplished, after various intermediate trials, and less commodious forms, both of glasses and construction, in the following manner:

“ The glasses are blown as near as possible in the form of hemispheres, having each an open neck or socket in the middle. The thickness of the glass near the brim is about the tenth of an inch, or hardly so much, but thicker as it comes nearer the neck; which in the largest glasses is about an inch deep, and an inch and a half wide within; these dimensions lessening as the glasses themselves diminish in size, except that the neck of the smallest ought not to be shorter than half an inch. The largest glass is nine inches diameter, and the smallest three inches. Between these there are 23 different sizes, differing from each other a quarter of an inch in diameter. To make a single instrument there should be at least six glasses blown of each size; and out of this number one may probably pick 37 glasses (which are sufficient for three octaves with all the semitones) that will be each either the note one wants, or a little sharper than that note, and all fitting so well into each other as to taper pretty regularly from the largest to the smallest. It is true that there are not 37 sizes; but it often happens that two of the same size differ a note or half a note in tone, by reason of a difference in thickness, and these may be placed one in the other without sensibly hurting the regularity of the taper form.

“ The glasses being chosen, and every one marked with a diamond the note you intend it for, they are to be tuned by diminishing the thickness of those that are too sharp. This is done by grinding them round from the neck towards the brim, the breadth of one or two inches as may be required; often trying the glass by a well-tuned harpsichord, comparing the note drawn from the glass by your finger with the note you want, as sounded by that string of the harpsichord. When you come near the matter, be careful to wipe the glass clean and dry before each trial, because the tone is something flatter when the glass is wet than it will be when dry; and grinding a very little between each trial, you will thereby tune to great exactness. The more care is necessary in this, because if you go below

your required tone, there is no sharpening it again but by grinding somewhat off the brim, which will afterwards require polishing, and thus increase the trouble.

“ The glasses being thus tuned, you are to be provided with a case for them, and a spindle on which they are to be fixed. My case is about three feet long, eleven inches every way wide within at the biggest end, and five inches at the smallest end; for it tapers all the way, to adapt it better to the conical figure of the set of glasses. This case opens in the middle of its height, and the upper part turns up by hinges fixed behind. The spindle is of hard iron, lies horizontally from end to end of the box within, exactly in the middle, and is made to turn on brass gudgeons at each end. It is round, an inch diameter at the thickest end, and tapering to a quarter of an inch at the smallest. A square shank comes from its thickest end through the box, on which shank a wheel is fixed by a screw. This wheel serves as a fly to make the motion equable, when the spindle, with the glasses, is turned by the foot like a spinning-wheel. My wheel is of mahogany, 18 inches diameter, and pretty thick, so as to conceal near its circumference about 25 lb. of lead. An ivory pin is fixed in the face of this wheel, about four inches from the axis. Over the neck of this pin is put the loop of the string that comes up from the moveable step to give it motion. The case stands on a neat frame with four legs.

“ To fix the glasses on the spindle, a cork is first to be fitted in each neck pretty tight, and projecting a little without the neck, that the neck of one may not touch the inside of another when put together, for that would make a jarring. These corks are to be perforated with holes of different diameters, so as to suit that part of the spindle on which they are to be fixed. When a glass is put on, by holding it stiffly between both hands, while another turns the spindle, it may be gradually brought to its place. But care must be taken that the hole be not too small, lest in forcing it up the neck should split; nor too large, lest the glass, not being firmly fixed, should turn or move on the spindle, so as to touch or jar against its neighbouring glass. The glasses thus are placed one in another; the largest on the biggest end of the spindle, which is to the left hand: the neck of this glass is towards the wheel; and the next goes into it in the same position, only about an inch of its brim appearing beyond the brim of the first; thus proceeding, every glass when fixed shows about an inch of its brim (or three quarters of an inch, or half an inch, as they grow smaller) beyond the brim of the glass that contains it; and it is from these exposed parts of each glass that the tone is drawn, by laying a finger on one of them as the spindle and glasses turn round.

“ My largest glass is G a little below the reach of a common voice, and my highest G, including three complete octaves. To distinguish the glasses more ready to the eye, I have painted the apparent parts of the glasses within-side, every semitone white, and the other notes of the octave with the seven prismatic colours; viz. C, red; D, orange; E, yellow; F, green; G, blue; A, indigo; B, purple; and C, red again; so that the glasses of the same colour (the white excepted) are always octaves to each other.

“ This instrument is played upon by sitting before the middle of the set of glasses, as before the keys of a harpsichord, turning them with the foot, and wetting them now and then with a sponge and clean water. The fingers should be first a little soaked in water, and quite free from all greasiness; a little fine chalk upon them is sometimes useful, to make them catch the glass and bring out the tone more readily. Both hands are used, by which means different parts are played together. Observe, that the tones are best drawn out when the glasses turn from the ends of the fingers, not when they turn to them.

“ The advantages of this instrument are, that its tones are

incomparably sweet beyond those of any other; that they may be swelled and softened at pleasure by stronger or weaker pressures of the finger, and continued to any length; and that the instrument, being once well tuned, never again wants tuning."

Such was the state in which this learned and ingenious author found, and such the perfection to which he carried, that celestial instrument of which we now treat. We call it *celestial*; because, in comparison with any other instrument which we know, the sounds that it produces are indeed heavenly. Some of them, however, are still constructed in the same imperfect manner as the instrument of Mr. Puckeridge. They are contained in an oblong chest; their positions are either exactly or nearly rectilinear; the artificial semitones by which the full notes are divided, form another parallel line; but the distances between each of them are much greater than those between the notes of the natural scale, as they take their places, not directly opposite to the notes which they are intended to heighten or depress, but in a situation between the highest and lowest, to show, that in ascending they are sharps to the one, and in descending flats to the other. This structure, however, is doubly inconvenient; for it not only increases the labour and difficulty of the performer, but renders some musical operations impracticable, which upon the *Harmonica*, as constituted by Dr. Franklin, may be executed with ease and pleasure. In this fabric, if properly formed and accurately tuned, the instrument is equally adapted to harmony and melody. But as no material structure could ever yet be brought to the perfection even of human ideas, this instrument still in some measure retains the perverse nature of its original stamina. Hence it is not without the utmost difficulty that the glasses can be tuned by grinding; and the least conceivable redundancy or defect renders the discord upon this instrument more conspicuous and intolerable than upon any other. Hence likewise that inexpressible delicacy to be observed in the manner of the friction by which the sound is produced; for if the touch be too gentle, it cannot extort the tone; and if too strong, besides the mellow and delicate sound which ought to be heard, we likewise perceive the finger jarring upon the glass, which, mingled with those softer sounds by which the senses had been soothed, gives a feeling similar to iron grating upon iron, but more disagreeable. In wind-instruments the operation of the tongue, in harpsichords the stroke of the quill, and on the violin the motion of the bow, gives that strong and sensible interruption of sound which may be called *articulation*, and which renders the rhythmus or measure of an air more perceptible: but, upon the glasses, the touch of the finger is too soft to divide the notes with so much force; so that, unless the mind be steadily attentive, they seem to melt one into another, by which means the idea of rhythmus is almost lost. There is no way of performing a slur but by forbearing to stop the first sound, when that which is immediately subsequent commences. Thus, when the slur is of any length, and regularly descends or rises by the interval of a second, all the notes in the slur must be heard together, and produce no agreeable dissonance; yet if it rises or descends by perfect chords, the effect is pleasing. The open shake, or thrill, is another unhappy operation upon musical glasses; which can only be performed by the alternate pulsations of two continued sounds, differing from each other only by a note or semitone. But as these pulsations thus managed cannot be distinct, the result is far from being pleasant; nor is there any succedaneum for the close shake, which in the violin is performed by alternately depressing the string to the finger-board, and suffering it to rise without entirely removing the finger from it, and which, by giving the note that tremulous sound produced by the human voice affected with grief, is a grace peculiarly adapted to pathetic and plaintive airs. We proceed, however, to a farther account of the same instrument,

extracted from the Annual Register, vol. iv. p. 149. "Besides those tones (says the author of that account) which every elastic string produces by a vibration of all its parts, it is capable of another set of tones, in which only a part of the string is supposed to vibrate. These sounds are produced by the lightest touches, either by air, as in Oswald's lyre, or by rubbing the bow in the softest manner on the string of a fiddle.

"Analogous to these sounds are those produced by bells: in those last, besides those tones produced by their elliptical vibrations, there are a set of tones which may be brought by gently rubbing their edges, and in which the whole instrument does not appear to vibrate in all its parts as before.

"Take, for instance, a bell finely polished at the edges; or, what will perhaps be more convenient, a drinking-glass: let the edges be as free from any thing oily as possible; then, by moistening the finger in water (I have found alum-water to be best), and rubbing it circularly round the edge of the glass, you will at length bring out the tone referred to.

"This note is possessed of infinite sweetness; it has all the excellencies of the tone of a bell without its defects. It is loud, has a sufficient body, is capable of being swelled and continued at pleasure; and, besides, has naturally that vibratory softening which musicians endeavour to imitate by mixing with the note to be played a quarter tone from below.

"To vary these tones, nothing more is required than to procure several bells or glasses of different tones, tuned as nearly as possible, which may be done by thinning the edges of either: or, for immediate satisfaction, the glasses may be tuned by pouring in water; the more water is poured in, the graver the tone will be.

"Let us suppose then a double octave of those glasses, thus tuned, to be procured. Any common tune may be executed by the fingers rubbing upon each glass successively; and this I have frequently done without the least difficulty, only choosing those tunes which are slow and easy. Here then are numbers of delicate tones, with which musicians have been till very lately unacquainted; and the only defect is, that they cannot be made to follow each other with that celerity and ease which is requisite for melody. In order to remedy this, I took a large drinking-glass, and by means of a wheel and gut, as in the electrical machine, made it to turn upon its axis with a moderately quick but equable motion; then moistening the finger as before, nothing more was required than merely to touch the glass at the edge, without any other motion, in order to bring out the tone.

"Instead of one glass only turning in this manner, if the whole number of glasses were so fixed as to keep continually turning by means of a wheel, it follows, that upon every touch of the finger a note would be expressed; and thus, by touching several glasses at once, an harmony of notes might be produced, as in an harpsichord.

"As I write rather to excite than satisfy the curious, I shall not pretend to direct the various ways this number of glasses may be contrived to turn; it may be sufficient to say, that if the glasses are placed in the segment of a circle, and then a strap, as in a cutler's wheel, be supposed to go round them all, the whole number will by this means be made to turn by means of a wheel.

"Instead of the finger, I have applied moistened leather to the edge of the glass, in order to bring out the tone: but, for want of a proper elasticity, this did not succeed. I tried cork, and this answered every purpose of the finger; but made the tone much louder than the finger could do. Instead, therefore, of the finger, if a number of corks were so contrived as to fall with a proper degree of pressure on the edge of the glass, by means of keys like the jacks of an organ, it is evident, that in such a case a new and tolerably perfect instrument would be

produced ; not so loud indeed as some, but infinitely more melodious than any.

“ The mouths of the glasses or bells used in this experiment should not resemble the mouth of a trumpet, but should rather come forward with a perpendicular edge. The corks used in this case should be smooth, even, free from those blemishes which are usually found in them, and at the same time the more elastic the better.”

In the two accounts here given, seems to be comprehended every thing valuable which has been said upon the subject. It remains, however, our decided opinion, that the form and structure designed and recommended by Dr. Franklin is by much the most eligible ; nor can we admit, that a cork, however successfully applied, will produce the same mellowness and equality of tone in general with the finger. It appears also, that, by this kind of voluntary attrition, a note may be sunk or swelled with much more art and propriety than by the substitution of any thing else extrinsic to the hand ; and when chords are long protracted, that degree of friction, which renders every sound in the chord sensible to the ear, without harshness, must be the most agreeable. For this reason, likewise, we should recommend alum-water in preference to chalk.

From what has already been said, it will easily be perceived, that this instrument requires to be tuned with the nicest degree of delicacy which the laws of TEMPERAMENT will possibly admit. For these laws the reader will naturally have recourse to the article MUSIC ; and it is only necessary farther to observe, that the same rules which conduct the process of tuning a harpsichord, will be equally effectual in tuning the *Harmonica* ; with this only difference, that greater delicacy in adjusting the chords should, if practicable, be attempted.

In plate 3, we have given a representation of an instrument of this kind, made by Mr. Dobb. Dr. Edmund Cullen of Dublin has attempted an improvement on the harmonica of Dr. Franklin, but, we think, with no great share of success.

HARMONY. The sense which the Greeks gave to this word in their music, is so much less easy to be determined, because, the word itself being originally a substantive proper, it has no radical words by which we might analyse it, to discover its etymology. In the ancient treatises which remain to us, *harmony* appears to be that department whose object is the agreeable succession of sounds, merely considered as high or low ; in opposition to the two others called *rhythmica* and *metrica*, which have their principle in time and measure. This leaves our ideas concerning that aptitude of sound vague and undetermined ; nor can we fix them without studying for that purpose all the rules of the art ; and even after we have done so, it will be very difficult to distinguish harmony from melody, unless we add to the last the ideas of rhythmus and measure ; without which, in reality, no melody can have a distinguishing character : whereas harmony is characterised by its own nature, independent of all other quantities except the chords or intervals which compose it.

It appears by a passage of Nicomachus, and from others, that they likewise gave the name of *harmory* to the chord of an octave, and to concerts of voices and instruments, which performed in the distance of an octave one from the other, and which is more commonly called *antique*.

Harmony, according to the moderns, is a succession of chords agreeable to the laws of modulation. For a long time this harmony had no other principle but such rules as were almost arbitrary, or solely founded on the approbation of a practised ear, which decided concerning the agreeable or disagreeable succession of chords, and whose determinations were at last reduced to calculation. But father Meiffene and M. Saver having found that every sound, however simple in appearance, was always accompanied with other sounds less sensible, which constitute

with itself a perfect chord-major ; with this experiment M. Rameau set out, and upon it formed the basis of his harmonic system, which he has extended to a great many volumes, and which at last M. D'Alembert has taken the trouble of explaining to the public.

Signior Tartini, taking his route from an experiment which is newer and more delicate, yet not less certain, has reached conclusions similar enough to those of Rameau, by pursuing a path whose direction seems quite opposite. According to M. Rameau, the treble is generated by the bass ; Signior Tartini makes the bass result from the treble. One deduces harmony from melody, and the other supposes quite the contrary. To determine from which of the two schools the best performances are likely to proceed, no more is necessary than to investigate the end of the composer, and discover whether the air is made for the accompaniments, or the accompaniments for the air. At the word SYSTEM in Rousseau's Musical Dictionary, is given a delineation of that published by Signior Tartini. Here he continues to speak of M. Rameau, whom he has followed through this whole work, as the artist of greatest authority in the country where he writes.

He thinks himself obliged, however, to declare, that this system, however ingenious it may be, is far from being founded upon nature ; an affirmation which he incessantly repeats : “ that it is only established upon analogies and congruities, which a man of invention may overturn to-morrow, by substituting others more natural : that, in short, of the experiments from whence he deduces it, one is detected fallacious, and the other will not yield him the consequences which he would extort from it. In reality, when this author took it in his head to dignify with the title of *demonstration* the reasonings upon which he established his theory, every one turned the arrogant pretence into ridicule. The Academy of Sciences loudly disapproved a title so ill founded, and so gratuitously assumed ; and M. Estive, of the Royal Society at Montpellier, has shown him, that even to begin with this proposition, That according to the law of nature, sounds are represented by their octaves, and that the octaves may be substituted for them, there was not any one thing demonstrated, or even firmly established, in his pretended demonstration.” He returns to his system.

“ The mechanical principle of resonance presents us with nothing but independent and solitary chords ; it neither prescribes nor establishes their succession. Yet a regular succession is necessary ; a dictionary of selected words is not an oration, nor a collection of legitimate chords a piece of music ; there must be a meaning, there must be connections in music as well as in language : it is necessary that what has preceded should transmit something of its nature to what is subsequent, so that all the parts conjoined may form a whole, and be stamped with the genuine character of unity.

“ Now, the complex sensation which results from a perfect chord must be resolved into the simple sensation of each particular sound which composes it, and into the sensation of each particular interval which forms it, ascertained by comparison one with another. Beyond this there is nothing sensible in any chord ; from whence it follows, that it is only by the relation between sounds, and by the analogy between intervals, that the connection now in question can be established ; and this is the genuine, the only source, from whence flow all the laws of harmony and modulation. If, then, the whole of harmony were only formed by a succession of perfect chords-major, it would be sufficient to proceed by intervals similar to those which compose such a chord ; for then some one or more sounds of the preceding chord being necessarily protracted in that which is subsequent, all the chords would be found sufficiently connected, and the harmony would, at least in this sense, be one.

“ Put besides that these successions must exclude all melody by excluding the diatonic series which forms its foundation, it would not arrive at the real end of the art ; because, as music is a system of meanings like a discourse, it ought, like a discourse, to have its periods, its phrases, its suspenses, its cadences, its punctuation of every kind ; and because the uniformity of a harmonical procedure implies nothing of all this, diatonic procedures require that major and minor chords should be intermixed ; and the necessity of dissonances has been felt in order to distinguish the phrases, and render the cadences sensible. Now, a connected series of perfect chords-major can neither be productive of perfect chords-minor nor of dissonances, nor can sensibly mark any musical phrase, and the punctuation must there be found entirely defective.

“ M. Rameau being absolutely determined, in his system, to deduce from nature all the harmony practised among us, had recourse, for this effect, to another experiment of his own invention, of which I have formerly spoken, and which by a different arrangement is taken from the first. He pretended, that any simple sound whatever afforded in it multiplies a perfect minor or flat chord, of which it was the dominant or fifth, as it furnished a perfect chord major by the vibration of its aliquot parts, of which it is the tonic or fundamental sound. He has assumed as a certain fact, that a vocal string caused two others lower than itself to vibrate through their whole extent, yet without making them produce any sound, one to its twelfth major, and the other to its seventeenth ; and from this joined to the former fact, he has very ingeniously deduced, not only the application of the minor mode and of dissonances in harmony, but the rules of harmonic phrases and of all modulation, such as they are found at the words *Chord, Accompaniment, Fundamental Bass, Cadence, Dissonance, Modulation*.

“ But first (continues Rousseau) the experiment is false. It is discovered, that the strings tuned beneath the fundamental sound do not entirely vibrate when this fundamental sound is given ; but that they are divided in such a manner as to return its unison alone, which of consequence can have no harmonics below. It is moreover discovered, that the property of strings in dividing themselves, is not peculiar to those which are tuned by a twelfth and seventeenth below the principal sound ; but that oscillations are likewise produced in the lower strings by all its multiples. Whence it follows, that, the intervals of the twelfth and seventeenth below not being singular phenomena of their kind, nothing can be concluded in favour of the perfect minor chord which they represent.

“ Though the truth of this experiment were granted, even this would by no means remove the difficulty. If, as M. Rameau alleges, all harmony is derived from the resonance of sonorous bodies, it cannot then be derived only from the vibrations of such bodies as do not resound. In reality, it is an extraordinary theory, to deduce from bodies that do not resound the principles of harmony ; and it is a position in natural philosophy no less strange, that a sonorous body should vibrate without resounding, as if sound itself were any thing else but the air impelled by these vibrations. Moreover, sonorous bodies do not only produce, besides the principal sound, the other tones which with itself compose a perfect chord ; but an infinite number of other sounds, formed by all the aliquot parts of the bodies in vibration, which do not enter into that perfect harmony. Why then should the former sounds produce consonances, and why should the latter not produce them, since all of them equally result from nature ?

“ Every sound exhibits a chord truly perfect, since it is composed of all its harmonics, and since it is by them that it becomes a sound. Yet these harmonics are not heard, and nothing is distinguished but a simple sound, unless it be exceedingly strong : whence it follows, that the only good harmony is

an unison ; and that, as soon as the consonances can be distinguished, the natural proportion being altered, the harmony has lost its purity.

“ That alteration is in this case produced two different ways. First, by causing certain harmonics to resound, and not the others, the proportion of force which ought to prevail in all of them is altered, for producing the sensation of a single sound ; whence the unity of nature is destroyed. By doubling these harmonics, an effect is exhibited similar to that which would be produced by suppressing all the others ; for in that case we cannot doubt, but that, along with the generating sound, the tones of the other harmonics which were permitted to sound would be heard : whereas, in leaving all of them to their natural operations, they destroy one another, and conspire together in forming and strengthening the simple sensation of the principal sound. It is the same effect which the full sound of a stop in the organ produces, when, by successively removing the stopper or register, the third and fifth are permitted to sound with the principal ; for then that fifth and third, which remained absorbed in the other sounds, are separately and disagreeably distinguished by the ear.

“ Moreover, the harmonics which we cause to sound have other harmonics pertaining to themselves, which cannot be such to the fundamental sound. It is by these additional harmonics that the sounds which produce them are distinguished with a more sensible degree of harshness ; and these very harmonics which thus render the chord perceptible, do not enter into its harmony. This is the reason why the most perfect chords are naturally displeasing to ears whose relish for harmony is not sufficiently formed ; and I have no hesitation in thinking, that even the octave itself might be displeasing, if the mixture of male and female voices did not inure us to that interval from our infancy.

“ With dissonance it is still worse ; because, not only the harmonics of the sound by which the discord is produced, but even the sound itself, is excluded from the natural harmony of the fundamental : which is the cause why discord is always distinguished amongst all the other sounds in a manner shocking to the sense.

“ Every key of an organ, with the stop fully opened, gives a perfect chord with its third major, which are not distinguished from the fundamental sound, if the hearer is not extremely attentive, and if he does not sound the whole stop in succession ; but these harmonic sounds are never absorbed in the fundamental, but on account of the prodigious noise, and by such a situation of the registers as may cause the pipes which produce the fundamental sound to conceal by their force the other sounds which produce these harmonics. Now, no person observes, nor can observe, this continual proportion in a concert ; since, by the manner of inverting the harmony, its greatest force must in every instant be transferred from one part to another ; which is not practicable, and would destroy the whole melody.

“ When we play upon the organ, every key in the bass causes to resound the perfect chord major ; but because that bass is not always fundamental, and because the music is often modulated in a perfect minor chord, this perfect chord-major is rarely struck with the right hand ; so that we hear the third minor with the major, the fifth with the triton, the seventh redundant with the octave, and a thousand other cacophonies, which, however, do not much disgust our ears, because habit renders them tractable ; but it is not to be imagined that an ear naturally just would prove so patient of discords, when first exposed to the test of this harmony.

“ M. Rameau pretends, that trebles composed with a certain degree of simplicity naturally suggest their own basses ; and that any man having a just, though unpractised ear, would spontaneously sing that bass. This is the prejudice of a musician, re-

futed by univerfal experience. Not only would he, who has never heard either bafs or harmony, be of himfelf incapable of finding either the bafs or the harmony of M. Rameau, but they would be difpleafing to him if he heard them, and he would greatly prefer the fimple unifon.

“ When we confider, that, of all the people upon earth, who have all of them fome kind of mufic and melody, the Europeans are the only people who have a harmony confifting of chords, and who are pleafed with this mixture of founds; when we confider that the world has endured for fo many ages, whilft, of all the nations which cultivated the fine arts, not one has found out this harmony: that not one animal, not one bird, not one being in nature, produces any other chord but the unifon, nor any other mufic but melody: that the eaftern languages, fo fonorous, fo mufical; that the ears of the Greeks, fo delicate, fo fenfible, praftifed and cultivated with fo much art, have never conducted this people, luxurious and enamoured of pleafure as they were, towards this harmony which we imagined fo natural: that without it their mufic produced fuch aftonifhing effects; that with it ours is fo impotent: that, in fhort, it was referved for the people of the north, whofe grofs and callous organs of fenfation are more affeeted with the noife and clamour of voices, than with the fweetnefs of accents and the melody of inflections, to make this grand difcovery, and to vend it as the effential principle upon which all the rules of the art were founded; when, in fhort, attention is paid to all thefe obfervations, it is very difficult not to fufpect that all our harmony is nothing but a Gothic and barbarous invention, which would never have entered into our minds, had we been truly fenfible to the genuine beauties of art, and of that mufic which is unqueftionably natural.

“ M. Rameau afferts, however, that harmony is the fource of the moft powerful charms in mufic. But this notion is contradictory both to reafon and to matter of fact. To fact it is contradictory; becaufe, fince the invention of counter-point, all the wonderful effects of mufic have ceafed, and it has loft its whole force and energy. To which may be added, that fuch beauties as purely refult from harmony are only perceived by the learned; that they affect none with transport but fuch as are deeply converfant in the art: whereas the real beauties of mufic, refulting from nature, ought to be, and certainly are, equally obvious to the adept and the novice. To reafon it is contradictory; fince harmony affords us no principle of imitation by which mufic, in forming images and expreffing fentiments, can rife above its native excellence till it becomes in fome meafure dramatic or imitative, which is the higheft pitch of elevation and energy to which the art can afpire; fince all the pleafures which we can receive from the mere mechanical influence of founds are extremely limited, and have very little power over the human heart.”

Thus far we have heard M. Rouffeau, in his obfervations on harmony, with patience; and we readily grant, that the *fyftem of harmony* by M. Rameau is neither demonftrated, nor capable of demonftration. But it will not follow, that any man of invention can fo eafily and fo quickly fubvert thofe aptitudes and analogies on which the fyftem is founded. Every hypothesis is admitted to poffefs a degree of probability proportioned to the number of phenomena for which it offers a fatisfactory folution. The firft experiment of M. Rameau is, that every fonorous body, together with its principal found and its octave, gives likewife its twelfth and feventeenth major above; which being approximated as much as poffible, even to the chords immediately represented by them, return to the third, fifth, and octave, or, in other words, produce perfect harmony. This is what nature, when foli-cited, fpontaneously gives; this is what the human ear, unprepared and uncultivated, imbibes with ineffable avidity and pleafure. Could any thing which claims a

right to our attention, and acceptance from nature, be imprefsed with more genuine or more eligible fignatures of her fanection than this? We do not contend for the truth of M. Rameau's fecond experiment. Nor is it neceffary we fhould. The firft, expanded and carried into all its confequences, refolves the phenomena of harmony in a manner fufficient to eftablifh its authenticity and influence. The difficulties for which it affords no folution are too few and too trivial either to merit the regard of an artift, or a philofopher, as M. D'Alembert in his *Elements* has clearly fhown. The facts with which M. Rouffeau confronts this principle, the armies of multiplied harmonics generated in *infinitum*, which he draws up in formidable array againft it, only fhew the thin partitions which fometimes may divide philofophy from whim. For, as bodies are infinitely divifible, according to the philofophy now eftablifhed, or, as, according to every philofopher, they muft be indefinitely divifible, each infinitesimal of any given mafs, which are only harmonics to other principal founds, muft have fundamental tones and harmonics peculiar to themfelves; fo that, if the reafoning of Rouffeau has any force againft M. Rameau's experiment, the ear muft be continually diftracted with a chaos of inappretiable harmonics, and melody itfelf muft be loft in the confufion. But the truth of the matter is, that, by the wife institution of nature, there is fuch a conformity eftablifhed between our fenfes and their proper objects, as muft prevent all thefe difagreeable effects. Rouffeau and his opponent are agreed in this, that the harmonics confpire to form one predominant found; and are not to be detected but by the nicest organs, applied with the deepeft attention. It is equally obvious, that, in an artificial harmony, by a proper management of this wife precaution of nature, diffonances themfelves may be either entirely concealed or confiderably foftened. So that, fince by nature fonorous bodies in actual vibration are predisposed to exhibit perfect harmony; and fince the human ear is, by the fame wife regulation, fabricated in fuch a manner as to perceive it; the harmonical chaos of M. Rouffeau muft have excluſively operated on his own brain, where indeed it met probably with the warmeft reception. Nor has it availed him to pretend, that before the harmonics can be diftinguifhed, fonorous bodies muft be impelled with a force which alters the chords, and deftroys the purity of the harmony; for this pofition is equally falfe both in theory and praftice. In theory, becaufe an impulle, however forcible, muft proportionally operate on all the parts of any fonorous body, fo far as it extends: in praftice, becaufe the human ear actually perceives the harmony to be pure. What effects his various manœuvres upon the organ may have, we leave to fuch as have leifure and curioſity enough to try the experiments: but it is apprehended, that when tried, their refults will leave the fyftem of Rameau, particularly as remodelled by D'Alembert, in its full force.

Of all the whims and paradoxes maintained by this great philofopher, none is more extravagant than his affertion, that every chord, except the fimple unifon, is difpleafing to the human ear: nay, that we are only reconciled to octaves themfelves, by being inured to hear them from our infancy. Strange, that nature fhould have fixed this invariable proportion between male and female voices, whilft at the fame time ſhe infpired the hearers with fuch violent prepoſſeſſions againft it as were invincible but by long and confirmed habit! The tranſlator of *D'Alembert's Elements* has been at peculiar pains to inveſtigate his earlieſt recollections upon this ſubject; and has had ſuch opportunities, both of attending to his original perceptions, and of recognizing the fidelity of his memory, as are not common. He can remember, even from a period of early childhood, to have been pleafed with the fimpleſt kinds of artificial harmony; to have diftinguifhed the harmonics of fonorous bodies with delight; and to have been ſtruck with horror at the found of ſuch

bodies as, by their structure, or by the cohesion of their parts, exhibited these harmonics false. This is the chief, if not the only cause, of the tremendous and disagreeable sensation which we feel from the sound of the Chinese gong. The same horrible cacophony is frequently, in some degree, produced by a drum unequally braced: from this sound the translator often remembers to have started and screamed, when carried through the streets of the town in which he was borne in the arms of his nursery-maid; and as he is conscious, that the acoustic organs of many are as exquisite as his own, he cannot doubt but they may have had the same sensations, though perhaps they do not recollect the facts. So early and so nicely may the sensations of harmony and discord be distinguished. But after all, it seems that harmony is no more than a modern invention, and even at this late period only known to the Europeans. We should, however, be glad to know, from what oracle our philosopher learned that harmony was not known to antiquity; since, from what remains of their works, no proof of his position can possibly be derived. But though Rousseau's mighty objections were granted, that harmony can only be endured by such ears as are habitually formed and cultivated; that the period of its prevalence has been short, and the extent of its empire limited to Europe; still his conclusion, that it is a Gothic and barbarous invention, is not fairly deducible even from these premises. Must we affirm, that epic poetry has no foundation in nature, because, during the long interval which happened from the beginning of the world to the destruction of Troy, no epic poem seems to have appeared? Or because a natural and mellifluous versification is less relished by an unpolished taste, than the uncouth rhymes of a common ballad, shall we infer, that the power of numbers is merely supposititious and arbitrary? On the contrary, we will venture to affirm, that though harmony cannot, as Rameau supposes, be mathematically demonstrated from the nature and vibrations of sonorous bodies; yet the idea of its constituent parts, and of their coalescence, is no less established, no less precise and definite, than any mode or property of space or quantity to be investigated by geometrical researches or algebraical calculations. It is certain, that the mimetic or imitative power of music chiefly consists in melody; but from this truth, however evident, it cannot be fairly deduced, that harmony is absolutely unsusceptible of imitation. Perhaps every musical sound, even to the most simple, and all modulations of sound, are more or less remotely connected with some sentiment or passion of the human heart. We know, that there are instinctive expressions of pain or pleasure in their various modes and degrees, which, when uttered by any sensitive, and perceived by any conscious being, excite in the mind of the percipient a feeling sympathetic with that by which they are prompted. We likewise know from experience, that all artificial sounds modulated in the same manner, have similar, though not equal, effects. We have seen, that, in order to render harmony compatible with itself, the melody of each part must be congenial; and, for that reason, one kindred melody result from the whole. So far, therefore, as any composer has it in his power to render the general melody homogeneous; so far the imitation may be preserved, and even heightened; for such objects as are majestic and august, or the feelings which they excite, are more aptly expressed by a composition of kindred sounds, than by any simple tone whatever. They who suppose the mimetic powers of music to be consummated in the imitation of mere unmeaning sounds or degrees of motion, must entertain limited and unworthy ideas of its province. It is naturally a representative almost of every sentiment or affection of the soul: and, when this end is gained, the art must have reached its highest perfection, and produced its noblest effects. But these effects, however sensible among the ancients, may in us be superseded by other causes which remain yet unexplored. Theatrical per-

formances are likewise, by them, said to have produced the most wonderful effects; yet these we do not recognise amongst ourselves, though we have dramatic entertainments perhaps not inferior to theirs — M. Rousseau proceeds to tell us, that among the ancients the *enharmonic* species of music was sometimes called *harmony*.

Direct HARMONY, is that in which the bass is fundamental, and in which the upper parts preserve among themselves, and with that fundamental bass, the natural and original order which ought to subsist in each of the chords that compose this harmony.

Inverted HARMONY, is that in which the fundamental or generating sound is placed in some of the upper parts, and when some other sound of the chord is transferred to the bass beneath the others.

HARMONY of the Spheres, or *Celestial harmony*, a sort of music much talked of by many of the ancient philosophers and fathers, supposed to be produced by the sweetly tuned motions of the stars and planets. This harmony they attributed to the various proportionate impressions of the heavenly globes upon one another, acting at proper intervals. It is impossible, according to them, that such prodigious large bodies, moving with so much rapidity, should be silent: on the contrary, the atmosphere, continually impelled by them, must yield a set of sounds proportionate to the impression it receives; consequently, as they do not all run the same circuit, nor with one and the same velocity, the different tones arising from the diversity of motions, directed by the hand of the Almighty, must form an admirable symphony or concert. They therefore supposed, that the moon, as being the lowest of the planets, corresponded to *mi*; Mercury, to *fa*; Venus, to *sol*; the Sun, to *la*; Mars, to *si*; Jupiter, to *ut*; Saturn, to *re*; and the orb of the fixed stars, as being the highest of all, to *mi*, or the octave.

HARMOSTES, or HARMOSTA, in antiquity, a sort of magistrate among the Spartans, whereof there were several, whose business was to look to the building of citadels, and repairing the forts and fortifications of the cities. The word is ἀρμοστής, formed of ἀρμόζω, *apto, concino*, "I adapt, concert," &c.

HARMOSYNIANS, ἀρμόσυνοι, in antiquity, were magistrates among the Spartans, who, after the death of Lycurgus, were appointed to enforce the observance of that law of the Spartan legislator which required married women to wear a veil when they appeared in the streets, whereby they were distinguished from single females, who were allowed to appear abroad with their faces uncovered.

HARNESS, a complete armour, or the whole equipage and accoutrements of a cavalier heavily armed; as casque, cuirass, &c. The word is formed of the French *harnois*; which some derive from the Greek ἀρνίς, "a lamb's skin," because they anciently covered themselves therewith. Du Cange observes, that the word *harnesium* is used in the corrupt Latin in the same sense, and that it comes from the High Dutch *harnas* or *harnisch*. Others derive it from the Italian *arnese*; others from the Celtic *harnes*, "a cuirass." Under king Richard II. it was expressly forbidden all men to ride in harness with lances. *Vide* stat. 7 Ric. II. cap. 13. In the statute 2 Hen. VI. cap. 14. harness seems to include all kinds of furniture for offence as well as defence, both of men and horse; as swords, buckles for belts, girdles, &c.

HARNESS is also used for the furniture put on a horse to draw in a coach or waggon, or other carriage; such as collars, leathers, traces, &c.

HARO, HAROU, or *Harol*, in the Norman customs, *Clamour de baro* is a cry or formula of invoking the assistance of justice against the violence of some offender, who, upon hearing the word *baro*, is obliged to desist, on pain of being severely punished for his outrage, and to go with the party before the

judge. The word is commonly derived of *ba* and *roul*, as being supposed an invocation of the sovereign power, to assist the weak against the strong, on occasion of Raoul first duke of Normandy, about the year 912, who rendered himself venerable to his subjects by the severity of his justice; so that they called on him even after his death when they suffered any oppression. Some derive it from Harola king of Denmark, who in the year 826 was made grand conservator of justice at Mentz. Others from the Danish *aa rau*, q. d. "help me;" a cry raised by the Normans in flying from a king of Denmark named Roux, who made himself duke of Normandy. The letters of the French chancery have usually this clause, *Non obstant clamor de baro*, &c. The haro had anciently such vast power, that a poor man of the city of Caen named Aslelin, in virtue hereof, arrested the corpse of William the Conqueror, in the middle of the funeral procession, till such time as his son Henry had paid the value of the land in question, which was that whereon the chapel was built wherein he was interred.

HARP, a musical instrument of the stringed kind, of a triangular figure, and held upright between the legs of the performer. Papias, and Du Cange after him, will have the harp to have taken its name from the Arpi, a people of Italy, who were supposed the first that invented it; and from whom, they say, it was borrowed by other nations. Menage, &c. derive the word from the Latin *barpa*, and that from the German *berp* or *barp*. Others bring it from the Latin *carpo*, because touched or thrummed with the fingers. Dr. Hickes derives it from *barpa* or *bearpa*, which signify the same thing; the first in the language of the Cimbri, the second in that of the Anglo-Saxons. The English priest who wrote the life of St. Dunstan, and who lived with him in the tenth century, says, cap. ii. n. 12. *Sumpsit secum ex more citbaram suam, quam paterna lingua hearpan vocamus*; which intimates the word to be Anglo-Saxon.

The harp was the favourite musical instrument of the Britons and other northern nations in the middle ages; as is evident from their laws, and from every passage in their history, in which there is the least allusion to music. By the laws of Wales, a harp was one of the three things that were necessary to constitute a gentleman, i. e. a freeman; and none could pretend to that character who had not one of these favourite instruments, or could not play upon it. By the same laws, to prevent slaves from pretending to be gentlemen, it was expressly forbidden to teach, or to permit them to play upon the harp; and none but the king, the king's musicians, and gentlemen, were allowed to have harps in their possession. A gentleman's harp was not liable to be seized for debt; because the want of it would have degraded him from his rank, and reduced him to a slave. The harp was in no less estimation and universal use among the Saxons and Danes. Those who played upon this instrument were declared gentlemen by law; their persons were esteemed inviolable, and secured from injuries by very severe penalties; they were readily admitted into the highest company, and treated with distinguished marks of respect wherever they appeared.

There is some diversity in the structure of harps. That called the *triple harp* has 97 strings or chords in three rows, extending from C in the tenor clef to double G in alt, which make five octaves: the middle row is for the semitones, and the two outside rows are perfect unisons. On the bass side, which is played with the right hand, there are 36 strings; on the treble side, 26; and in the middle row, 35 strings. There are two rows of pins or screws on the right side, serving to keep the strings tight in their holes, which are fastened at the other end to three rows of pins on the upper side. The harp, within the last 40 years, has been in some degree improved by the addition of eight strings to the unison, viz. from E to double F in alt. This

instrument is struck with the finger and thumb of both hands. Its music is much like that of the spinet, all its strings going from semitone to semitone; whence some call it an *inverted spinet*. It is capable of a much greater degree of perfection than the lute.

There are among us two sorts of this instrument, viz. the *Welsh harp*, being that just described; and the *Irish harp*. Plate 3. fig. 1. represents the harp of Brian Boiromh, king of all Ireland, slain in battle with the Danes A. D. 1014, at Clontarf. His son Donagh having murdered his brother Teige, A. D. 1023, and being deposed by his nephew, retired to Rome, and carried with him the crown, harp, and other regalia of his father, which he presented to the Pope in order to obtain absolution. Adrian IV. surnamed Breakspear, alleged this circumstance as one of the principal titles he claimed to this kingdom in his bull transferring it to Henry II. These regalia were kept in the Vatican till the Pope sent the harp to Henry VIII. with the title of Defender of the Faith; but kept the crown, which was of massive gold. Henry gave the harp to the first earl of Clanricard; in whose family it remained till the beginning of this century, when it came by a lady of the De Burgh family into that of Mac Mahon of Clenagh in the county of Clare, after whose death it passed into the possession of commissioner Mac Namara of Limerick. In 1782 it was presented to the right honourable William Conyngham, who deposited it in Trinity college library. It is 32 inches high, and of extraordinary good workmanship; the sounding-board is of oak, the arms of red sally; the extremity of the uppermost arm in part is capped with silver, extremely well wrought and chiseled. It contains a large crystal set in silver, and under it was another stone now lost. The buttons or ornamental knobs at the sides of this arm are of silver. On the front arm are the arms chased in silver of the O'Brien family, the bloody-hand supported by lions. On the sides of the front arm within two circles are two Irish wolf dogs cut in the wood. The holes of the sounding-board where the strings entered are neatly ornamented with escutcheons of brass carved and gilt; the larger sounding-holes have been ornamented, probably with silver, as they have been the object of theft. This harp has 28 keys, and as many string-holes, consequently there were as many strings. The foot piece or rest is broken off, and the parts round which it was joined are very rotten. The whole bears evidence of an expert artist.

King David is usually painted with a harp in his hands; but we have no testimony in all antiquity that the Hebrew harp, which they call *chinnor*, was any thing like ours. On a Hebrew medal of Simon Maccabæus we see two sorts of musical instruments; but they are both of them very different from our harp, and only consist of three or four strings. All authors agree, that our harp is very different from the lyra, cithara, or barbiton, used among the Romans. Fortunatus, lib. vii. carm. 8. witnesses, that it was an instrument of the barbarians:

*Romanusque lyra, plaudat tibi barbarus harpa,
Græcus Acbilliacha, crotta Britanna canat.*

Of ancient harps, two are represented on the same plate. Fig. 2. is a *trigonum* or triangular harp. It is taken from an ancient painting in the museum of the king of Naples, in which it is placed on the shoulder of a little dancing Cupid, who supports the instrument with his left hand, and plays upon it with his right. The *trigonum* is mentioned by Athenæus, lib. iv. and by Julius Pollux, lib. iv. cap. 9. According to Athenæus, Sophocles calls it a *Phrygian instrument*; and one of his disciples tells us, that a certain musician, named *Alexander Alexandrinus*, was such an admirable performer upon it, and had given such proofs of his abilities at Rome, that he made the inhabitants *μυσομανειν*, "musically mad." Fig. 3. and 4. are va-

rieties of the same instrument. Fig. 5. is the Theban harp, according to a drawing made from an ancient painting in one of the sepulchral grottos of the first kings of Thebes, and communicated by Mr. Bruce to Dr. Burney. (Hist. of Music, p. 224.) The performer is clad in a habit made like a skirt, such as the women still wear in Abyssinia, and the men in Nubia. It reaches down to his ancles; his feet are without sandals, and bare; his neck and arms are also bare; his loose white sleeves are gathered above his elbows; and his head is close shaved. His left hand seems employed in the upper part of the instrument among the notes in *alto*, as if in an arpeggio; while, stooping forwards, he seems with his right hand to be beginning with the lowest string, and promising to ascend with the most rapid execution: this action, so obviously rendered by an indifferent artist, shows that it was a common one in his time; or, in other words, that great hands were then frequent, and consequently that music was well understood and diligently followed.

On this instrument Dr. Burney makes the following observations: "The number of strings, the size and form of this instrument, and the elegance of its ornaments, awaken reflections, which to indulge would lead us too far from our purpose, and indeed out of our depth. The mind is wholly lost in the immense antiquity of the painting in which it is represented. Indeed the time when it was executed is so remote, as to encourage a belief, that arts, after having been brought to great perfection, were again lost and again invented long after this period. — With respect to the number of strings upon this harp, if conjectures may be allowed concerning the method of tuning them, two might be offered to the reader's choice. The first idea that presented itself at the sight of 13 strings was, that they would furnish all the semitones to be found in modern instruments within the compass of an octave, as from C to c, D to d, or E to e. The second idea is more Grecian, and conformable to antiquity; which is, that if the longest string represented *proslambanomenos*, or D, the remaining 12 strings would supply all the tones, semitones, and quarter tones of the diatonic, chromatic, and enharmonic genera of the ancients, within the compass of an octave: but for my part, I would rather incline to the first arrangement, as it is more natural, and more conformable to the structure of our organs, than the second. For, with respect to the genera of the Greeks, though no historic testimony can be produced concerning the invention of the diatonic and chromatic, yet ancient writers are unanimous in ascribing to Olympus the Phrygian the first use of the enharmonic: and though in the beginning the melody of this genus was so simple and natural as to resemble the wild notes and rude essays of a people not quite emerged from barbarism; yet, in after-times, it became overcharged with finical fopperies and fanciful beauties, arising from such minute divisions of the scale as had no other merit than the great difficulty of forming them. It seems a matter of great wonder, with such a model before their eyes as the Theban harp, that the form and manner of using such an instrument should not have been perpetuated by posterity; but that, many ages after, another of an inferior kind, with fewer strings, should take place of it. Yet if we consider how little we are acquainted with the use and even construction of the instruments which afforded the greatest delight to the Greeks and Romans, or even with others in common use in a neighbouring part of Europe only a few centuries ago, our wonder will cease; especially if we reflect upon the ignorance and barbarism into which it is possible for an ingenious people to be plunged by the tyranny and devastation of a powerful and cruel invader.

Bell HARP, a musical instrument of the string kind, thus called from the common players on it swinging it about, as a bell on its basis. It is about three feet long; its strings, which

are of no determinate number, are of brass or steel wire, fixed at one end, and stretched across the sound-board by screws fixed at the other. It takes in four octaves, according to the number of the strings, which are struck only with the thumbs, the right hand playing the treble, and the left hand the base: and in order to draw the sound the clearer, the thumbs are armed with a little wire pin. This may perhaps be the *lyra*, or *cythara* of the ancients; but we find no mention made of it under the name it now bears, which must be allowed to be modern.

HARP of Æolus. See *ACOUSTICS*, p. 25.

HARPAGINES, in antiquity, were hooks of iron, hanging on the top of a pole, which, being secured with chains to the masts of ships, and then let down with great velocity into the enemy's vessels, caught them up into the air. By way of defence against these machines, they covered their ships with hides, which broke and blunted the force of the iron. The harpagines, by the Greeks called *Ἀρπαγε*, owe their invention to Anacharsis the Scythian philosopher.

HARPALUS, a Greek astronomer, who flourished about 480 B. C. corrected the cycle of eight years invented by Cleostratus; and proposed a new one of nine years, in which he imagined the sun and moon returned to the same point. But Harpalus's cycle was afterwards altered by Meton, who added ten full years to it.

HARPIES (*Ἀπιτῖαι*, *HARPYLÆ*), in antiquity, a rapacious impure sort of monsters of the bird kind, mentioned among the poets. They are represented (Virg. *Æn.* iii.) with wings, ears like bears, bodies like vultures, faces like women, and feet and hands hooked like the talons of birds of prey. The ancients looked on the harpies as a sort of genii or demons. Some make them the daughters of Tellus and Oceanus, the *earth* and *ocean*; whence, says Servius, it is, that they inhabit an island, half on land and half in water. Valerius Flaccus makes them the daughters of Typhon.

There were three harpies, Aello, Ocypete, and Celæno, which last Homer calls *Podarge*. Hesiod, in his *Theogony*, ver. 267. only reckons two, Aello and Ocypete, and makes them the daughters of Phæomas and Electra, affirming that they had wings, and went with the rapidity of the wind. Zephyrus begat of them Balius and Xanthus, Achilles's horses. Pherecydes relates, that the Boreades expelled them from the Ægean and Sicilian seas, and pursued them as far as the islands which he calls *Plotæ* and Homer *Calynæ*; and which have since been called the *Strophades*. Vossius, *De Idolol.* lib. iii. cap. 99. p. 63. thinks, that what the ancients have related of the harpies, agrees to no other birds so well as the bats found in the territories of Darien in South America. These animals kill not only birds, but dogs and cats, and prove very troublesome to men by their peckings. But the ancients, as the same Vossius observes, knew nothing of these birds. By the harpies, therefore, he thinks, they could mean nothing else but the winds; and that it was on this account they were made daughters of Electra, the daughter of Oceanus. Such is the opinion of the scholiasts of Apollonius, Hesiod, and Eustathius. Their names, Aello, Ocypete, Celæno, are supposed to suggest a farther argument of this.

Mr. Bryant supposes that the harpies were a college of priests in Bithynia, who, on account of their repeated acts of violence and cruelty, were driven out of the country: their temple was called *Arpi*, and the environs *Arpiai*, whence the Grecians formed *Ἀρπυῖαι*; and he observes farther, that *Harpya*, *Ἀρπυῖα*, was certainly of old the name of a place.

HARPINGS, the fore-parts of the wales which encompass the bow of a ship, and are fastened to the stem, being thicker than the after part of the wales, in order to reinforce the ship in this place, where she sustains the greatest shock of resistance

Hippopotamus.

Hookah.

Fig. 1.

Gun Harpoon.

in plunging into the sea, or dividing it, under a great pressure of sail.

HARPOCRATES, in mythology, the son of Isis and Osiris. This is an Egyptian deity, whose distinguishing attribute is, that he is represented with his fingers applied to his mouth, denoting that he is the god of silence. The statue of this idol was fixed in the entrance of most of the Egyptian temples, and he was commonly exhibited under the figure of a young man naked, crowned with an Egyptian mitre, holding in one hand a cornucopia, and in the other the flower of lotus, and sometimes bearing a quiver.

HARPOCRATION (Valerius), a celebrated ancient rhetorician of Alexandria, who has left us an excellent *Lexicon upon the ten orators of Greece*. Aldus first published this lexicon in the Greek at Venice in 1613. Many learned men have laboured upon it; but the best edition was given by James Gronovius at Leyden in 1696.

HARPOON, or **HARPING-IRON**, a spear or javelin used to strike the whales in the Greenland fishery. The harpoon, which is sometimes called the *harping-iron*, is furnished with a long staff, having at one end a broad and flat triangular head, sharpened at both edges, so as to penetrate the whale with facility: to the head of this weapon is fastened a long cord, called the *whale line*, which lies carefully coiled in the boat, in such a manner as to run out without being interrupted or entangled. See **BALÆNA**, *Whale-FISHERY*, and pl. 4.

Gun-HARPOON, a kind of fire-arm for discharging harpoons at whales, and thereby killing them more easily and expeditiously than formerly when the harpoons were thrown by the hand. Though this method was projected a good many years ago, it has but lately come into use; and premiums have been annually offered by the society for encouraging arts, &c. to the persons who first struck a fish in this manner. In the Transactions of that Society for 1786, we have an account of the first fish struck in this manner in 1784. The gun was of the blunderbuss construction, loaded with four common tobacco-pipes full of glazed powder; the fish was shot at the distance of ten fathoms, the harpoon going into her back up to the ring; and she was killed in about an hour. In 1785 three whales were killed in this manner: four in 1786, and three in 1787. Since that time the gun harpoon has come more into use, and will probably soon supersede the other method entirely. In the Transactions of the Society for 1789, we have accounts of a number of whales killed in this manner. The instrument appears to be extremely useful in calm still weather, as the whale, though a timorous creature, will frequently allow a boat to approach it to the distance of 20, 15, or even 10 fathoms, all of which distances are within reach of the gun harpoon, though not within the reach of that thrown by the hand. The greatest inconvenience was in case of rain or snow, by which the lock was apt to get wet. To remedy this, a case of leather was made to fit round the gun and over the lock, lined with tin, and big enough to fire the gun when it was on. The fish struck with an harpoon discharged in this manner are soon killed by reason of its penetrating their bodies to a great depth, not less than five or six feet, which no man's strength would be able to accomplish. In the volume just quoted, we have an account of one which was shot through the tail. The harpoon broke in the slit, but five fathoms of line went through the tail. The fish was killed in eight hours, which is perhaps the only instance of a fish struck in that part being caught. In another, the harpoon carried six feet of line into its body; the creature died in ten minutes. Others were killed in 15 minutes or half an hour, and one had a rib broken by the violence of the stroke. In the Transactions of the Society for 1790, there are other accounts similar to the foregoing, and all agreeing as to the great usefulness of the instrument both for striking the fish at

a considerable distance, and for killing them in a very short time. See pl. 4.

HARPSICHORD, the most harmonious of all the musical instruments of the string-kind. It is played on after the manner of the organ, and is furnished with a set, and sometimes with two sets of keys; the touching or striking of these keys moves a kind of little jacks, which also move a double row of chords or strings, of brass or iron, stretched over four bridges on the table of the instrument.

HARQUEBUSS, a piece of fire-arms, of the length of a musket, usually cocked with a wheel. It carried a ball that weighed one ounce seven-eighths.

There was also a larger sort, called the great harquebuss, used for the defence of strong places, which carried a ball of about three ounces and a half: but they are now but little used, except in some old castles, and by the French in some of their garrisons.

HARRIER, a kind of hound, endowed with an admirable gift of smelling, and very bold in the pursuit of his game. See **CANIS**.

HARRINGTON (Sir John), an ingenious English poet, was the son of John Harrington, Esq. who was committed to the Tower by queen Mary for holding a correspondence with her sister Elizabeth; who, when she came to the crown, stood godmother to this son. Before he was 30, he published a translation of Ariosto's Orlando Furioso, a work by which he was principally known; for though he afterwards published some epigrams, his talent did not seem to have lain that way. He was created knight of the bath by James I.; and presented a MS. to prince Henry, levelled chiefly at the married bishops. He is supposed to have died about the latter end of James's reign.

HARRINGTON (James), a most eminent English writer in the 17th century, bred at Oxford, travelled into Holland, France, Denmark, and Germany, and learned the languages of those countries. Upon his return to England, he was admitted one of the privy-chamber extraordinary to king Charles I. He served the king with great fidelity, and made use of his interest with his friends in parliament to procure matters to be accommodated with all parties. The king loved his company, except when the conversation happened to turn upon commonwealths. He found means to see the king at St. James's; and attended him on the scaffold, where, or a little before, he received a token of his majesty's affection. After the death of king Charles, he wrote his *Oceana*; a kind of political romance, in imitation of Plato's Commonwealth, which he dedicated to Oliver Cromwell. It is said, that when Oliver perused it, he declared, that "the gentleman had wrote very well, but must not think to cheat him out of his power and authority; for that what he had won by the sword, he would not suffer himself to be scribbled out of." This work was attacked by several writers, against whom he defended it. Beside his writings to promote republican principles, he instituted likewise a nightly meeting of several ingenious men in the New Palace-Yard, Westminster; which club was called the *Rota*, and continued till the secluded members of parliament were restored by general Monk. In 1661 he was committed to the Tower for treasonable designs and practices; and chancellor Hyde, at a conference with the lords and commons, charged him with being concerned in a plot. But a committee of lords and commons could make nothing of that plot. He was conveyed to St. Nicolas's island, and from thence to Plymouth, where he fell into an uncommon disorder of the imagination. Having obtained his liberty by means of the earl of Bath, he was carried to London, and died in 1677. He published, besides the above works, several others, which were first collected by Toland, in one volume folio, in 1700; but a more complete edition was published, in 1737, by the reverend Dr. Birch.

HARRIOT (Thomas), a celebrated algebraist, was born at Oxford in 1560, where he was also educated. In 1579 he completed his bachelor's degree; and, being already distinguished for his mathematical learning, was soon after recommended to Sir Walter Raleigh as a proper person to instruct him in that science. He was accordingly received into the family of that gentleman; who, in 1585, sent him with the colony, under Sir Richard Grenville, to Virginia; of which country, having remained there about a year, he afterwards published a topographical description. About the year 1588 Mr. Harriot was introduced, by his patron Sir Walter Raleigh, to Henry Percy earl of Northumberland, who allowed him a pension of 120*l. per annum*. He spent many years of his life in Sion college; where he died in July 1621, of a cancer in his lip, and was buried in the church of St. Christopher, where a handsome monument was erected to his memory. Anthony Wood tells us, he was a deist, and that the divines looked upon his death as a judgment. Be his religious opinions what they might, he was doubtless one of the first mathematicians of the age in which he lived, and will always be remembered as the inventor of the present improved method of algebraical calculation. His improvements in algebra were adopted by Des Cartes, and for a considerable time imposed upon the French nation as his own invention; but the theft was at last detected, and exposed by Dr. Wallis, in his History of Algebra, where the reader will find our author's invention accurately specified. His works are, 1. A brief and true report of the new-found land of Virginia; of the commodities there found, and to be raised, &c. 2. *Artis analyticae praxis ad æquationes algebraicas nova expedita, et generali methodo resolvendas, e posthumis Thomæ Harrioti, &c.* 3. *Epbemeris chymometrica*, a manuscript, in the library of Sion college. He is said to have left several other manuscripts, which are probably lost.

HARRIS (James, Esq.), an English gentleman of very uncommon parts and learning; was the son of James Harris, Esq. by a sister of lord Shaftesbury author of *The Characteristics*. He was born in the Close at Salisbury 1709; and educated at the grammar-school there. In 1726 he was removed to Wadham college in Oxford, but took no degree. He cultivated letters, however, most attentively; and also music, in the theory and practice of which he is said to have had few equals. He was member for Christ-church Hants, which he represented in several successive parliaments. In 1763 he was appointed one of the lords commissioners of the admiralty, and soon after removed to the board of treasury. In 1774 he was made secretary and comptroller to the queen, which post he held until his death. He died Dec. 21, 1780, in his 72d year, after a long illness, which he bore with calmness and resignation.—He is the author of some valuable works. 1. *Three Treatises: concerning Art; Music, Painting, and Poetry; and Happiness*, 1745, 8vo. 2. *Hermes; or, A Philosophical Enquiry concerning Universal Grammar*. 3. *Philosophical Arrangements*. 4. *Philological Inquiries*, 1782, 2 vols. 8vo. finished just before his death, and published since. These *Inquiries* show much ingenuity and learning; but being the amusement of his old age rather than an exertion of genius, they have not the philosophic tone of his former productions.

HARRIS, one of the Hebrides or Western Islands of Scotland. It is 20 miles in length, and 10 in breadth. Upon the east side it is mostly rock; but on the west there are some tolerable farms, and the number of people amounts to 2000. It has Lewis on the north, and North Uist on the south, from which it is separated by a channel of four miles in width, called the *Sound of Harris*. This channel is navigable for vessels of burden, but it requires a skilful pilot. It is the only passage between the Butt of the Lewis and Bara for vessels of burden passing to and from the west side of the Long Island. The sound

is greatly incumbered with rocks and islands, some of which are considerable, as Bernera, Pabay, Enfay, Killegray. These, with Scalpay, Taransay, and Scarp, compose the inhabited islands on the coast of Harris. Some of them produce good crops of grain, and all of them good pasture. Harris and its islands sell from 400 to 500 tons of kelp annually; it abounds on the east side in excellent lochs or bays, and its shores on both sides form one continued fishery. The fish on this coast, and along the whole shores of the Long Island, are more numerous, and of larger dimensions, than those on the opposite continent; on which account, two royal fishing stations were begun in the reign of Charles I. one in Loch Maddie, and the other in the Sound of Harris.

HARRISON (William), a writer much esteemed and patronised by the literati of his time, was fellow of New-college, Oxford, and had no other income than 40*l.* a year as tutor to one of the duke of Queensberry's sons. In this employment he fortunately attracted the favour of Dr. Swift, whose solicitations with Mr. St. John obtained for him the reputable employment of secretary to lord Raby, ambassador at the Hague, and afterwards earl of Strafford. A letter of his whilst at Utrecht, dated Dec. 16, 1712, is printed in the Dean's works. Mr. Harrison, who did not long enjoy his rising fortune, was dispatched to London with the Barrier-treaty; and died Feb. 15, 1712-13. See the Journal to Stella, of that and the following day; where Dr. Swift laments his loss with the most unaffected sincerity. Mr. Tickel has mentioned him with respect in his *Prospect of Peace*; in *English Poets*, vol. xxvi. p. 113; and Dr. Young in the beautiful close of an Epistle to Lord Lansdowne, vol. lii. p. 185, most pathetically bewails his loss. Dr. Birch, who has given a curious note on Mr. Harrison's Letter to Swift, has confounded him with *Thomas Harrison*, M. A. of Queen's-college. In Nichols's *Select Collection* are some pleasing specimens of his poetry; which, with *Woodstock-Park* in *Doddsley's Collection*, and an Ode to the Duke of Marlborough, 1707, in *Duncombe's Horace*, are all the poetical writings that are known of this excellent young man; who figured both as an humourist and a politician in the fifth volume of the *Tatler*, of which (under the patronage of Bolingbroke, Henley, and Swift) he was professedly the editor. See the Supplement to Swift. There was another *William Harrison*, author of *The Pilgrim*, or *The happy Convert*, a Pastoral Tragedy, 1709.

HARRISON (John), a most accurate mechanic, the celebrated inventor of the famous *time-keeper* for ascertaining the longitude at sea, and also of the compound, or, as it is commonly called, the *gridiron pendulum*; was born at Foulby, in the parish of Wragby, near Pontefract in Yorkshire, in 1693. The vigour of his natural abilities, if not even strengthened by the want of education, which confined his attention to few objects, at least amply compensated the deficiencies of it; as fully appeared from the astonishing progress he made in that branch of mechanics to which he devoted himself. His father was a carpenter, in which profession the son assisted; occasionally also, according to the miscellaneous practice of country artists, surveying land, and repairing clocks and watches. He was, from his early childhood, attached to any machinery moving by wheels, as appeared while he lay sick of the small-pox about the sixth year of his age, when he had a watch placed open upon his pillow to amuse himself by contemplating the movement. In 1700, he removed with his father to Barrow in Lincolnshire; where, though his opportunities of acquiring knowledge were very few, he eagerly improved every incident from which he might collect information; frequently employing all or great part of his nights in writing or drawing: and he always acknowledged his obligations to a clergyman who came every Sunday to officiate in the neighbourhood, who lent him a MS. copy of professor Saunderson's Lectures; which he carefully and

neatly transcribed, with all the diagrams. His native genius exerted itself superior to these solitary disadvantages; for in the year 1726 he had constructed two clocks, mostly of wood, in which he applied the escapement and compound pendulum of his own invention: these surpassed every thing then made, scarcely erring a second in a month. In 1728 he came up to London with the drawings of a machine for determining the longitude at sea, in expectation of being engaged to execute one by the board of longitude. Upon application to Dr. Halley, he referred him to Mr. George Graham; who, discovering he had uncommon merit, advised him to make his machine before he applied to the board of longitude. He returned home to perform this task; and in 1735 came to London again with his first machine; with which he was sent to Lisbon the next year for a trial of its properties. In this short voyage he corrected the dead reckoning about a degree and a half; a success that proved the means of his receiving both public and private encouragement. About the year 1739 he completed his second machine, of a construction much more simple than the former, and which answered much better; this, though not sent to sea, recommended Mr. Harrison yet stronger to the patronage of his private friends and of the public. His third machine, which he produced in 1749, was still less complicated than the second, and superior in accuracy, as erring only three or four seconds in a week. This he conceived to be the *ne plus ultra* of his attempts; but in an endeavour to improve pocket-watches, he found the principles he applied to surpass his expectations so much, as to encourage him to make his fourth time-keeper, which is in the form of a pocket watch, about six inches diameter. With this time-keeper his son made two voyages, the one to Jamaica, and the other to Barbadoes: in both which experiments it corrected the longitude within the nearest limits required by the act of the 12th of queen Anne; and the inventor therefore, at different times, though not without infinite trouble, received the proposed reward of 20,000l. These four machines were given up to the board of longitude. The three former were not of any use, as all the advantages gained by making them were comprehended in the last; they were worthy, however, of being carefully preserved as mechanical curiosities, in which might be traced the gradations of ingenuity combined with the most delicate workmanship; whereas they now lie totally neglected in the royal observatory at Greenwich. The fourth machine, emphatically distinguished by the name of *The time-keeper*, has been copied by the ingenious Mr. KENDAL; and that duplicate, during a three years' circumnavigation of the globe in the southern hemisphere by captain Cook, answered as well as the original. The latter part of Mr. Harrison's life was employed in making a fifth improved time-keeper on the same principles with the preceding one; which, at the end of a ten weeks' trial, in 1772, at the king's private observatory at Richmond, erred only $4\frac{1}{4}$ seconds. Within a few years of his death, his constitution visibly declined; and after frequent fits of the gout, a disorder that never attacked him before his 77th year, he died at his house in Red-Lion Square, in 1776, aged 83. The reclusé manner of his life in the unremitted pursuit of his favourite object, was by no means calculated to qualify him as a man of the world; and the many discouragements he encountered in soliciting the legal reward of his labours, still less disposed him to accommodate himself to the humours of mankind. In conversing on his profession, he was clear, distinct, and modest; yet, like many other mere mechanics, found a difficulty in delivering his meaning by writing; in which he adhered to a peculiar and uncouth phraseology. This was but too evident in his *Description concerning such mechanism as will afford a nice or true mensuration of time*, &c. 8vo. 1775; which his well-known mechanical talents will induce the public to ac-

count for from his unacquaintance with letters, from his advanced age, and attendant mental infirmities; among which may be reckoned his obstinate refusal to accept of any assistance whatever in this publication. This small work includes also an account of his new musical scale; or mechanical division of the octave, according to the proportion which the radius and diameter of a circle have respectively to the circumference. He had in his youth been the leader of a distinguished band of church-singers, had a very delicate ear for music; and his experiments on sound, with a most curious monochord of his own improvement, are reported to have been not less accurate than those he was engaged in for the mensuration of time.

HARROGATE, a village in the West Riding of Yorkshire, in the parish of Knaresborough, 206 miles from London, remarkable for its medicinal springs. These are three in number, all different in their qualities, notwithstanding their contiguity. 1. The *Terret water* or Sweet Spa, a vitriolic spring of a sort of milky taste used in gravelly cases, was discovered by Mr. Slingby 1638. 2. The stinking or sulphur spring, useful in dropical, scorbutic, and gouty cases, rises in the town, and is received into four basons, under four different buildings; at one it is drunk, at the others used for hot or cold baths. It is perfectly clear; but the taste and smell a composition of rotten eggs, sea-water, and sulphur, and extremely salt. Bathing is the most general mode of using it. It is the strongest sulphur water in Great Britain; and from the superior strength of the impregnating sulphur, it does not lose the sulphureous smell even when exposed to a scalding and almost boiling heat; and in distilling it, when three pints had been taken off from a gallon of it, the last was as strong as the first, and stunk intolerably. It is discutient and attenuating, and a warm bath of it is of great benefit in pains and aches, strains and lameness; dissolving hard swellings, helping old ulcers and scrophulous complaints, and is a powerful cleanser of the stomach and bowels. 3. *St. Mungo's well*, is so called from Kentigern a Scotch saint much honoured hereabouts, whom his tutor Servanus bishop of Orkney, out of affection for him, called *Mongab*, which in the Norish or Norway language signifies a dear friend. The Harrogate season is from May to Michaelmas; and the company assemble and lodge in five or six large houses or inns on the heath, a mile from the village, each house having a long room and an ordinary: the best company used to lodge at Knaresborough, which is three miles off.

HARROW-ON-THE-HILL, a town of Middlesex, so called from its situation on the highest hill in the county, is 10 miles north-west of London. This parish is noted for a free school, founded in the reign of queen Elizabeth. A silver arrow is shot for here once a year, viz. August 4, by a select number of the scholars, who are dressed for the purpose in the habit of archers.

HARROW, in agriculture. See HUSBANDRY.

HART, a stag, or male deer, in the sixth year. See CERVUS.

HART-Beest, or Quanga. See CAPRA.

HART'S-Horns, the horns of the common male deer. The scrapings or raspings of the horn of this animal are medicinal, and used in decoctions, pitans, &c. Hartshorn jelly is nutritive and strengthening, and is sometimes given in diarrheas; but a decoction of burnt hartshorn in water is more frequently used for this purpose, and is called *barshorn drink*. The coal of hartshorn, by being calcined with a long-continued and strong fire, is changed into a very white earth, till of late called *calcined barshorn*. This earth levigated is the basis of Sydenham's white decoction, which is commonly prescribed in dysenteries. When levigated, it is employed as an absorbent. The salt of hartshorn is a great sudorific, and given in fevers with success; and hartshorn also yields, by distillation, a very

penetrating volatile spirit. The chemical properties of the deer's horn, however, yields none of these in greater perfection than may be procured from the horns, or even the bones, of any other animal.

HARTLAND, a town in Devonshire, with a market on Saturday. It is seated on the Bristol Channel, near a promontory, called Hartland-point, 28 miles W. of Barnstaple, and 213 W. by S. of London. Lon. 4. 31. W. Lat. 51. 12. N.

HARTLEPOOL, a seaport of the county of Durham, with a market on Monday. It is commodiously seated on the sea-shore, and is partly surrounded by rocks and hills. It is a pretty large place, but the market is come to nothing. It is 16 miles S. E. of Durham, and 254 N. by W. of London. Lon. 1. 4. W. Lat. 54. 47. N.

HARTLEY, a town of Northumberland, on the coast, situated north west of Tynemouth, where Lord Delaval has constructed a pretty haven, whence coals are shipped for London. Here are large salt-works and copperas-works, and likewise considerable glass-works; and there is here a canal cut through a solid rock to the harbour, 52 feet deep, 30 broad, and 900 long. These works are the sole property of Lord Delaval, and yield a revenue of above 20,000*l. per annum.*

HARTLEY (David), M. A. born at Ilingworth, where his father was curate, received his academical education at Jesus college, Cambridge, of which he was a fellow. He first began to practise physic at Newark, in Nottinghamshire; from whence he removed to St Edmund's Bury, in Suffolk. After this, he settled for some time in London; and lastly went to live at Bath, where he died in 1757, aged 53, leaving two sons and a daughter. He published "A view of the present evidence for and against Mrs. Stephens's medicine as a solvent for the stone, containing 155 cases, with some experiments and observations;" London, 1739. He is said to have also written against Dr. Warren, of St. Edmund's Bury, in defence of inoculation; and some letters of his are to be met with in the Philosophical Transactions. The doctor was certainly a man of learning, and reputed a good physician; but too fond of nostrums. But his most considerable literary production is a work intitled, "Observations on man, his frame, his duty, and his expectations, in two parts;" London, 1749, 2 vols. 8vo. The first part contains observations on the frame of the human body and mind, and on their mutual connections and influences. The second part contains observations on the duty and expectations of mankind.

HARTMANN (John Adolphus), a learned divine and historian, was born at Munster in 1680. After being a Jesuit for several years, he became a Calvinist at Cassel, in 1715; and soon after was made a professor of philosophy and poetry, and in 1722 professor of history and eloquence, at Marburg, where he died in 1744. The most esteemed of his works are, 1. The state of the sciences at Hesse, in Germany. 2. *Historia Hassiaca*, 3 vols. 3. *Præcepta eloquentiæ rationalis*, &c.—He ought not to be confounded with *George Hartmann*, a German mathematician, who, in 1540, wrote a book on perspective; nor with *Wolfgang Hartmann*, who, in 1596, composed the Annals of Augsbürg.

HARTOGIA, in botany; a genus of the pentandria order, belonging to the monœcia class of plants; and in the natural method ranking under the 48th order, *Aggregatæ*. The male calyx is pentaphyllous, the petals five; the female calyx triphyllous, with five petals, and five barren and five castrated stamina. There are three capsules; and the seeds are arillated, or inclosed in a deciduous case.

HARUSPICES, pretenders to divination by certain signs or omens among the Romans. The Roman haruspices were at first all taken from Hetruria, where their art had most credit.

Afterwards young Romans were sent into Hetruria, in order to be brought up in the science. It consisted in foretelling future events by attending to various circumstances of the victims. First, It was an ill omen when the victim would not come to the altar without dragging, when it broke its rope, fled away, avoided the stroke, struggled much after it, made a great bel-lowing, was long a-dying, or bled but little. Secondly, Pre-fages were drawn from inspecting the noble parts of the victim when opened; as the heart, lungs, spleen, and especially the liver. If all these were found, if the top of the liver was large and well-made, and if its fibres were strong, it presaged well for the affair in question. Thirdly, Knowledge was also drawn by the haruspices from the manner in which the fire consumed the victim. If the flame brightened immediately, was pure and clear, rose up in a pyramid without noise, and did not go out till the victim was consumed, these were happy signs. Fourthly, The smoke also was considered, whether it whirled about in curls, or spread itself to the right or the left, or gave a smell different from the common one of broiled meat. Fifthly, It was a lucky omen if the incense they burned melted all at once, and gave a most agreeable smell.

HARVEST, probably derived from a Saxon word signifying *berb-fraß*, is that season of the year when the corn is ripe and fit to be reaped and gathered into barns.

HARVEST Fly, in zoology, a large four-winged fly of the cicada kind, very common in Italy, and erroneously supposed to be a grasshopper. See **CICADA**.

HARVEST-Home, denotes the feast often observed at the close of harvest, and also the song used on that occasion. See **DECEMBER**.

HARVEY (Dr. William), an eminent English physician in the 17th century, was incorporated Doctor of physic in Cambridge, afterwards admitted into the college of physicians in London, and was appointed lecturer of anatomy and chirurgery in that college. In these lectures he opened his discovery relating to the circulation of the blood; which, after a variety of experiments, he communicated to the world in his *Exercitatio anatomica de motu cordis et sanguinis*. He was physician to king James I. and to king Charles I. and adhered to the royal cause. His works have eternized his memory. In 1651 he published his *Exercitationes de generatione animalium*, a very curious work; but it would have been more so had not his papers been destroyed during the civil wars. In 1654 he was chosen president of the college of physicians in his absence: but his age and weakness were so great, that he could not discharge the duty of that office; and therefore desired them to choose Dr. Pringle. As he had no children, he settled his paternal estate upon the college. He had three years before built a combination-room, a library, and a museum; and in 1656 he brought the deeds of his estate, and presented them to the college. He was then present at the first feast, instituted by himself, to be continued annually, together with a commemoration-speech in Latin; to be spoken on the 18th of October, in honour of the benefactors to the college; he having appointed a handsome stipend for the orator, and also for the keeper of the library and museum, which are still called by his name. He died in 1657: This great physician had the happiness, in his life-time, to find the clamours of ignorance, envy, and prejudice against his doctrine, totally silenced, and to see it universally established. It has, by length of time, been more and more confirmed; and every man now sees and knows it from his own experience. It appears to be of the utmost importance in medicine; as it is perhaps impossible to define health and sickness in fewer words, than that the one is a free, and the other an obstructed, circulation. Dr. Harvey was not only an excellent physician, but an excellent man; his modesty, candour, and

piety were equal to his knowledge; the farther he penetrated into the wonders of nature, the more he was inclined to venerate the Author of it.

HARWICH, a seaport and borough of Essex, with a market on Tuesday and Friday. It is seated on a tongue of land, opposite the united mouths of the Stour and Orwell. It is not very large, but is well inhabited and frequented, and here the packet-boats are stationed that go to Holland. It has a capacious harbour, and a dock for the building of men of war. The entrance into the harbour is defended by a strong fortress, called Land-guard Fort, which is built on a sandy point on the Suffolk side of the water, but within the jurisdiction of Essex. Here is only a chapel of ease, the mother-church being at Dover-court, two miles distant. Harwich is 42 miles E. by N. of Chelmsford, and 72 E. N. E. of London. E. lon. 1. 25. N. lat. 52. 0.

HARWOOD, a small but pretty town in the North Riding of Yorkshire, with a costly stone-bridge of 11 arches over the Wharfe, which runs in a bed of stone, and is as clear as rock-water. Near it are the ruins of an ancient castle, built soon after the conquest; and which remained a neat strong building in Canibden's time. It had a variety of masters; one of whom, in the reign of king John, obtained a grant for a market and fair here. In the reign of Edward III. it was valued at 400 marks a year. This castle was ruined in the civil wars. It has eight or nine dependent constabularies, wherein are many antiquities. The remains of the castle, which seems to have been the keep, are in a condition to exist long. The castle itself covered near an acre of ground. Near it is now Harwood-House, one of the first houses in the county for elegance and superior embellishments; built on part of the site of Gawthorp-Hall, now no more. In the church are some ancient monuments, particularly that of lord chief-justice Gascoigne, who committed the Prince of Wales to prison for striking him on the bench.

HASLEMERE, a small borough of Surry, with a market on Tuesday. It is 12 miles S. W. of Guildford, and 42 S. W. of London.

HASSELQUISTA, in botany; a genus of the digynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 45th order, *Umbellatæ*. The fruits are quite smooth; the seeds of the radius oval, plane, marginated, and convex in the middle; those in the disk hemispherical and urceolated or bladder-shaped.

HASSELT, a handsome town of the United Provinces, in Overijssel, seated on the river Vecht, five miles from Zwoll.

HASSELT, a town of Germany, in the territory of Liege, seated on the river Demer, 14 miles N. W. of Maestricht.

HASSIDEANS, or **ASSIDEANS**. See **ASSIDEANS**.

HASSOCK, a kind of baf or cushion made of rushes, to kneel or rest the feet upon in churches.

HASTA, or **HASTA Pura**, among medallists, signifies a kind of spear or javelin, not shod or headed with iron; or rather an ancient sceptre, somewhat longer than ordinary, occasionally given to all the gods. The hasta is supposed a symbol of the goodness of the gods, and of the conduct of Providence, which is equally mild and forcible.

HASTA, in some countries, is a measure or quantity of ground amounting to thirty paces: thus called, according to M. Du-Cange, from the hasta or rod wherewith it was measured.

HASTATED LEAF. See **BOTANY**, p. 48 and 49.

HASTING-PEAR, a name given by the gardeners to a species of pear, called also by some the *green chissel pear*. This is a moderately large pear, and is longish towards the pedicle; its skin is thin, and of a whitish green; the pulp is melting, and of a sugary flavour. It ripens in July.

HASTINGS, a borough of Suffex, with a market on Wed-

nesday and Saturday. It is one of the Cinque-ports, and noted for being the place where William the Conqueror landed. It is seated between a high cleft toward the sea, and a high hill toward the land side. The chief employment of the people is fishing. It had once a strong castle, now in ruins, and its harbour is maintained by a small river. It is 24 miles E. of Lewes, and 64 S. E. of London. E. lon. 0. 46. N. lat. 50. 52.

HASTIVE, a French term, sometimes used in English for early, forward, or something that comes before the ordinary time or season. The hative fruits are strawberries and cherries. We have hative peas, &c.

HAT, a covering for the head, worn by the men throughout the western part of Europe. Hats are said to have been first seen about the year 1400, at which time they became of use for country wear, riding, &c. F. Daniel relates, that when Charles II. made his public entry into Rouen, in 1449, he had on a hat lined with red velvet, and surmounted with a plume or tuft of feathers: he adds, that it is from this entry, or at least under this reign, that the use of hats and caps is to be dated, which henceforward began to take place of the chaperoons and hoods that had been worn before. In the process of time, from the laity, the clergy also took this part of the habit; but it was looked on as a great abuse, and several regulations were published, forbidding any priest or religious person to appear abroad in a hat without coronets, and enjoining them to keep to the use of chaperoons, made of black cloth, with decent coronets; if they were poor, they were at least to have coronets fastened to their hats, and this upon penalty of suspension and excommunication. Indeed the use of hats is said to have been of a longer standing among the ecclesiastics of Brittany, by two hundred years, and especially among the canons; but these were no other than a kind of caps, and from hence arose the square caps worn in colleges, &c. Lobineau observes, that a bishop of Dol, in the 12th century, zealous for good order, allowed the canons alone to wear such hats; enjoining, that if any other person come with them to church, divine service should immediately be suspended. Hats make a very considerable article in commerce: the finest, and those most valued, are made of pure hair of an amphibious animal, called the castor or beaver, frequent in Canada and other provinces of North America. See **BEAVER**.

HAT-making. Hats are made either of wool, or hair of various animals, particularly of the castor, hare, rabbit, camel, &c. The process is much the same in all; for which reason we shall content ourselves to instance that of the beaver. The skin of this animal is covered with two kinds of hair; the one long, stiff, glossy, and rather thin set; this is what renders the skin or fur of so much value: the other is short, thick, and soft, which alone is used in hats. To tear off one of these kinds of hair, and cut the other, the hatters, or rather the women employed for that purpose, make use of two knives, a large one like a shoemaker's knife for the long hair; and a smaller not unlike a vine-knife, wherewith they shave or scrape off the shorter hair.

When the hair is off, they mix the stuff; to one third of dry castor putting two-thirds of old coat, i. e. of hair which has been worn some time by the savages, and card the whole with cards, like those used in the woollen manufactory; only finer; this done, they weigh it, and take more or less according to the size or thickness of the hat intended. The stuff is now laid on the hurdle, which is a square table, parallel to the horizon, having longitudinal chinks cut through it; on this hurdle, with an instrument called a *boru*, much like that of a violin, but larger, whose string is worked with a little bow tick, and thus made to play on the furs, they fly and mix together; the dust and filth at the same time passing through the chinks. This they reckon one

of the most difficult operations in the whole, on account of the justness required in the hand to make the stuff fall precisely together, and that it may be every where of the same thickness. In lieu of a bow, some hatters make use of a sieve or searce of hair, through which they pass the stuff.

After this manner they form gores, or two capades, of an oval form, ending in an acute angle at top; and with what stuff remains, they supply and strengthen them in places where they happen to be slenderer than ordinary; though it is to be remembered, that they designedly make them thicker in the brim, near the crown, than toward the circumference, or in the crown itself.

The capades thus finished, they go on to harden them into closer and more consistent flakes by pressing down a hardening skin or leather thereon; this done, they are carried to the bason, which is a sort of bench with an iron plate fitted therein, and a little fire underneath it; upon which laying one of the hardened capades, sprinkled over with water, and a sort of mould being applied thereon, the heat of the fire, with the water and pressing, imbody the matter into a slight hairy sort of stuff or felt; after which, turning up the edges all round the mould, they lay it by, and thus proceed to the other: this finished, the two next are joined together, so as to meet in an angle at the top, and only form one conical cap, after the manner of a manica Hippocratis, or flannel bag.

The hat thus basoned, they remove it to a large kind of receiver or trough, resembling a mill-hopper, going sloping or narrowing down from the edge or rim to the bottom, which is a copper kettle filled with water and grounds, kept hot for that purpose. On the descent or sloping side, called the *plank*, the basoned hat, being first dipped in the kettle, is laid; and here they proceed to work it, by rolling and unrolling it again and again, one part after another, first with the hand, and then with a little wooden roller, taking care to dip it from time to time, till at length, by thus fulling and thickening it four or five hours, it is reduced to the extent or dimensions of the hat intended. To secure the hands from being injured by this frequent rolling, &c. they usually guard them with a sort of thick gloves.

The hat thus wrought, they proceed to give it the proper form, which is done by laying the conical cap on a wooden block, of the intended size of the crown of the hat, and thus tying it round with a packthread, called a *commander*: after which, with a piece of iron, or copper bent for that purpose, and called a *stamper*, they gradually beat or drive down the commander all round, till it has reached the bottom of the block, and thus is the crown formed; what remains at bottom below the string being the brim.

The hat being now set to dry, they proceed to finge it, by holding it over a flare of straw or the like; then it is pounced, or rubbed over with pumice, to take off the coarser knap; then rubbed over afresh with seal-skin to lay the knap a little finer; and lastly, carded with a fine card to raise the fine cotton, with which the hat is afterwards to appear.

Things thus far advanced, the hat is thus sent, upon its block, and tied about with a packthread as before, to be dyed. The dye being completed, the hat is returned to the hatter, who proceeds to dry it, by hanging it in the top or roof of a stove or oven, at the bottom of which is a charcoal fire; when dry, it is to be stiffened, which is done with melted glue or gum senegal, applied thereon by first smearing it, and beating it over with a brush, and then rubbing it with the hand. The next thing is to steam it on the steaming bason, which is a little hearth or fire-place, raised three feet high, with an iron-plate laid over it, exactly covering the hearth; on this plate they first spread cloths, which being sprinkled over with water to secure the hat from burning, the hat is placed brim downwards thereon; when moderately hot, the workman strikes gently on

the brim with the flat of his hand, to make the joinings incorporate and bind so as not to appear; turning it from time to time, this way and that way, and at last overturning and setting it in the crown. When steamed sufficiently, and dried, they put it again on the block, and brush and iron it on a table or bench for the purpose, called the *stall-board*; this they perform with a sort of irons like those commonly used in ironing linen, and heated like them; which being rubbed over and over each part of the hat, with the assistance of the brush, smooths and gives it a gloss, which is the last operation; nothing now remaining but to clip the edges even with scissars, and sew a lining to the crown.

Dyeing of HATS. The instructions of Mr. Colbert direct hats to be first strongly galled, by boiling them a long time in a decoction of galls with a little logwood, that the dye may penetrate the better into their substance; after which a proper quantity of vitriol and decoction of logwood, with a little verdigris, are added, and the hats continued in this mixture also for a considerable time. They are afterwards to be put into a fresh liquor of logwood, galls, vitriol, and verdigris; and where the hats are of great price, or of a hair which difficultly takes the dye, the same process is to be repeated a third time. For obtaining the most perfect colour, the hair or wool is to be dyed blue previously to its being formed into hats. The present practice is more compendious, and affords, as we may daily see, a very good black. According to Dr. Lewis, it does not materially differ from that of the *Encyclopédie*, which is as follows.

An hundred pounds of logwood, 12 pounds of gum, and six pounds of galls, are boiled in a proper quantity of water for some hours; after which, about six pounds of verdigris and ten of green vitriol are added, and the liquor kept just simmering, or of a heat a little below boiling. Ten or twelve dozen of hats are immediately put in, each on its block, and kept down by cross bars for about an hour and an half: they are then taken out and aired, and the same number of others put in their room. The two sets of hats are thus dipped and aired alternately, eight times each; the liquor being refreshed each time with more of the ingredients, but in less quantity than at first.

This process (says Dr. Lewis) affords a very good black on woollen and silk stuffs as well as on hats, as we see in the small pieces of both kinds which are sometimes dyed by the hatters. The workmen lay great stress upon the verdigris, and affirm that they cannot dye a black hat without it: it were to be wished that the use of this ingredient were more common in the other branches of the black dye; for the hatters' dye, both on silk and woollen, is reckoned a finer black than what is commonly produced by the woollen and silk-dyers.

HATS are also made for women's wear, not only of the above stuffs, but of chips, straw, or cane, by plaiting, and sewing the plaits together; beginning with the centre of the crown, and working round till the whole is finished. Hats for the same purpose are also wove and made of horse-hair, silk, &c.

HAT is also figuratively used for the dignity of cardinal, or a promotion to that dignity. In this sense they say, "to expect the hat; to claim, or have pretensions to, the hat," &c. Pope Innocent IV. first made the hat the symbol or cognizance of the cardinals, enjoining them to wear a red hat at the ceremonies and processions, in token of their being ready to spill their blood for Jesus Christ.

HATCH, or HATCHWAY, a square or oblong opening in the deck of a ship, of which there are several, forming the passages from one deck to another, and into the hold or lower apartments. See pl. 90, Vol. II.; where A represents the main-hatchway of the lower deck; NN the fore-hatchway; and OO the after-hatchway. There are likewise hatches of a smaller kind, called *scuttles*. See UU in the same figure; as also the article SCUTTLE. Hatches is also, though improperly,

a name applied by sailors to the covers or lids of the hatchway.

HATCHEL, **HITCHEL**, or **HECKLE**, in the manufactory of flax, hemp, &c. a tool, not unlike a card, for dressing and combing them into fine hairs. They consist of sharp-pointed iron pins, or teeth, set orderly in a board. Of these there are several sorts, some with finer and shorter, others with coarser and longer teeth. See **FLAX**.

HATCHES, in mining, a term used in Cornwall, to express any of the openings of the earth either into mines or in search of them. The fruitless openings are called *essay-hatches*; the real mouths of the veins, *tin-hatches*; and the places where they wind up the buckets of ore, *wind-hatches*.

HATCHES also denote flood-gates set in a river, &c. to stop the current of the water, particularly certain dams or mounds made of rubbish, clay, or earth, to prevent the water that issues from the stream-works and tin-washes in Cornwall from running into the fresh rivers.

HATCHET, a small light sort of axe, with a basil edge on its left side, and a short handle, calculated to be used with one hand. Hatchets are used by various artificers, and more particularly in hewing of wood.

HATCHING, the maturing and fecundating eggs, whether by the incubation and warmth of the parent bird, or by artificial heat, so as to produce young chickens alive. The art of hatching chickens by means of ovens has long been practised in Egypt; but it is there only known to the inhabitants of a single village named *Berne*, and to those that live at a small distance from it. Towards the beginning of autumn they scatter themselves all over the country; where each person among them is ready to undertake the management of an oven, each of which is of a different size; but, in general, they are capable of containing from forty to fourscore thousand eggs. The number of these ovens placed up and down the country is about 386, and they usually keep them working for about six months: as, therefore, each brood takes up in an oven, as under a hen, only 21 days, it is easy in every one of them to hatch eight different broods of chickens. Every Bermean is under the obligation of delivering to the person who intrusts him with an oven, only two-thirds of as many chickens as there have been eggs put under his care; and he is a gainer by this bargain, as more than two-thirds of the eggs usually produce chickens. In order to make a calculation of the number of chickens yearly so hatched in Egypt, it has been supposed that only two-thirds of the eggs are hatched, and that each brood consists of at least 30,000 chickens; and thus it would appear, that the ovens of Egypt give life yearly to at least 92,640,000 of these animals.

This useful and advantageous method of hatching eggs was originally discovered in France by the ingenious Mr. Reaumur; who, by a number of experiments, reduced the art to certain principles. He found by experience, that the heat necessary for this purpose is nearly the same with that marked 32 on his thermometer, or that marked 96 on Fahrenheit's. This degree of heat is nearly that of the skin of the hen, and, what is remarkable, of the skin of all other domestic fowls, and probably of all other kinds of birds. The degree of heat which brings about the development of the cygnet, the gosling, and the turkey-pout, is the same as that which fits for hatching the canary songster, and, in all probability, the smallest humming-bird: the difference is only in the time during which this heat ought to be communicated to the eggs of different birds; it will bring the canary bird to perfection in 11 or 12 days, while the turkey pout will require 27 or 28.

After many experiments, Mr. Reaumur found, that stoves heated by means of a baker's oven succeeded better than those made hot by layers of dung: and the furnaces of glass-houses

and those of the melters of metals, by means of pipes to convey heat into a room, might, no doubt, be made to answer the same purpose. As to the form of the stoves, no great nicety is required. A chamber over an oven will do very well. Nothing more will be necessary than to ascertain the degree of heat; which may be done by melting a lump of butter of the size of a walnut, with half as much tallow, and putting it into a phial. This will serve to indicate the heat with sufficient exactness: for when it is too great, this mixture will become as liquid as oil; and when the heat is too small, it will remain fixed in a lump: but it will flow like a thick syrup, upon inclining the bottle, if the stove be of a right temper. Great attention therefore should be given to keep the heat always at this degree, by letting in fresh air, if it be too great, or shutting the stove more close if it be too small: and that all the eggs in the stove may equally share the irregularities of the heat, it will be necessary to shift them from the sides to the centre; and thus to imitate the hens, who are frequently seen to make use of their bills, to push to the outer parts those eggs that were nearest to the middle of their nests, and to bring into the middle such as lay nearest the sides.

Mr. Reaumur has invented a sort of low boxes, without bottoms, and lined with furs. These, which he calls *artificial parents*, not only shelter the chickens from the injuries of the air, but afford a kindly warmth, so that they presently take the benefit of their shelter as readily as they would have done under the wings of a hen. After hatching, it will be necessary to keep the chickens, for some time, in a room artfully heated and furnished with these boxes; but afterwards they may be safely exposed to the air in the court-yard, in which it may not be amiss to place one of these artificial parents to shelter them if there should be occasion for it.

As to the manner of feeding the young brood, they are generally a whole day after being hatched, before they take any food at all; and then a few crumbs of bread may be given them for a day or two, after which they will begin to pick up insects and grass for themselves. But to save the trouble of attending them, capons may be taught to watch them in the same manner as hens do. Mr. Reaumur alleges, that he has seen above 200 chickens at once, all led about and defended only by three or four such capons. Nay, cocks may be taught to perform the same office; which they, as well as the capons, will continue to do all their lives after.

HATCHING, or **HACHING**, in designing, &c. the making of lines with a pen, pencil, graver, or the like; and the intersecting or going across those lines with others drawn a contrary way, is called *counter-hatching*. The depths and shadows of draughts are usually formed by hatching. Hatching is of singular use in heraldry, to distinguish the several colours of a shield, without being illumined: thus, gules or red is hatched by lines drawn from the top to the bottom; azure, by lines drawn across the shield; and so of other colours.

HATCHMENT, in heraldry, the coat-of-arms of a person dead, usually placed on the front of a house, whereby may be known what rank the deceased person was of when living: the whole distinguished in such a manner as to enable the beholder to know whether he was a bachelor, married man, or widower; with the like distinctions for women.

HATFIELD, a town of Herts, with a market on Thursday. It formerly belonged to the see of Ely, but was alienated to the crown in the reign of queen Elizabeth. It had before been an occasional royal residence, notwithstanding it was the property of the church. William of Hatfield, second son of Edward III. was born here; and hence Elizabeth, on the death of Mary, was conducted to ascend the throne. King James exchanged this royal demesne with Sir Robert Cecil, afterwards earl of Salisbury, for Theobalds. On the site of the ancient episcopal

palace, that nobleman built the present magnificent seat of the marquis of Salisbury, called Hatfield House. It is seated on the river Lea, 20 miles N. N. W. of London. W. lon. 0. 10. N. lat. 51. 48.

HATFIELD BROAD-OAK, or *Hatfield-Regis*, a town of Essex, with a market on Saturday. It is 30 miles E. N. E. of London.

HATHERLY, a town of Devonshire, with a market on Friday. It is 26 miles N. W. of Exeter, and 201 W. by S. of London. W. lon. 4. 9. N. lat. 50. 52.

HATTEM, a town of the United Provinces, in Guelderland, seated on the river Yssel, five miles S. W. of Zwoll. It was taken by the French in 1672, who demolished the fortifications.

HATTEMISTS, in ecclesiastical history, the name of a modern Dutch sect, so called from Pontian Van Hattem, a minister in the province of Zealand, towards the close of the last century, who being addicted to the sentiments of Spinoza, was on that account degraded from his pastoral office. The Verschorists and Hattemists resemble each other in their religious systems, though they never so entirely agreed as to form one communion. The founders of these sects deduced from the doctrine of absolute decrees a system of fatal and uncontrollable necessity; they denied the difference between moral good and evil, and the corruption of human nature: from hence they farther concluded, that mankind were under no sort of obligation to correct their manners, to improve their minds, or to obey the divine laws; that the whole of religion consisted not in acting, but in suffering; and that all the precepts of Jesus Christ are reducible to this one, that we bear with cheerfulness and patience the events that happen to us through the divine will, and make it our constant and only study to maintain a permanent tranquillity of mind. Thus far they agreed; but the Hattemists farther affirmed, that Christ made no expiation for the sins of men by his death, but had only suggested to us by his mediation, that there was nothing in us that could offend the Deity; this, they say, was Christ's manner of justifying his servants, and presenting them blameless before the tribunal of God. It was one of their distinguished tenets, that God does not punish men for their sins, but by their sins. These two sects, says Mosheim, still subsist, though they no longer bear the names of their founders.

HATTOCK, a shock of corn containing twelve sheaves; others make it only three sheaves laid together.

HATUAN, a town and fort of Upper Hungary, in the county of Novigrod, 28 miles N. E. of Buda. It was taken by the Imperialists in 1685. It is seated on a mountain, in E. lon. 19. 48. N. lat. 47. 52.

HAVANNA, a sea port on the N. W. part of the island of Cuba, opposite Florida. It is famous for its harbour, which is so large that it may hold 1000 vessels; and yet the mouth is so narrow, that only one ship can enter at a time. This is the place where all the ships that come from the Spanish settlements rendezvous on their return to Spain. It is near two miles in circumference, and, in 1700, was computed to contain 26,000 inhabitants, Spaniards, Mulattoes, and Negroes; a number which must have been considerably increased since. The entrance into the harbour is well defended by forts and platforms of great guns. The buildings are elegant, built of stone, and some of them superbly furnished; and the churches are rich and magnificent. Here is the residence of the governor and captain-general of Cuba, and of the royal officers, as well as of an assessor for the assistance of the governor and captain-general of the West Indies, of the bishop of St. Jago de Cuba, and of most of the men of fashion and fortune belonging to the island. It was taken by the English in 1762, but restored to the Spaniards by the treaty of peace in 1763. It is seated on the W.

side of the harbour, and is watered by two branches of the river Lagida. W. lon. 82. 13. N. lat. 23. 12.

HAVANT, a town of Hampshire, with a market on Saturday. It is seven miles N. E. of Portsmouth, and 64 W. by S. of London. E. lon. 0. 58. N. lat. 50. 52.

HAVEL, a river of Brandenburg, which proceeds from a lake in the duchy of Mecklenburg, and running through the middle Marche, and through Brandenburg and other towns, runs north, and falls into the Elbe.

HAVELBERG, a town of Germany, in the circle of Lower Saxony, and in the electorate of Brandenburg, with a bishop's see, secularized in favour of the house of Brandenburg. It is seated on the river Havel, in E. lon. 12. 43. N. lat. 53. 4.

HAVEN, a sea-port or harbour for ships. See PORT and HARBOUR. The word is derived from the Saxon *havenc*, or the German *bafen*, or the French *bavre*; which all signify the same thing.

HAVERCAMP (Sigibert), a celebrated Dutch scholar and critic, professor of history, eloquence, and the Greek tongue, at Leyden. He was particularly skilled in medals; and was the author of some esteemed works in that way, beside giving good and elegant editions of several Greek and Latin authors. He died at Leyden in 1742, aged 58.

HAVERFORDWEST, a town of Pembrokehire, with a market on Tuesday and Saturday. It is a town and county of itself, seated on the side of a hill, on a creek of Milford-Haven, over which is a stone bridge. It is a large handsome place, inhabited by many genteel families, and contains three parish churches. It has a considerable trade, with several vessels belonging to it, and sends one member to parliament. The assizes and county gaol are kept here; and it had once a wall and castle, now demolished. It is 15 miles S. by E. of St. David's, and 239 W. by N. of London. W. lon. 5. 0. N. lat. 51. 50.

HAVERRILL, a town of Suffolk, with a market on Wednesday. It has a great manufactory of checks, cottons, and fustians, and is 59 miles N. E. of London.

HAUL, or HALE, an expression peculiar to seamen, implying to pull a single rope, without the assistance of blocks or other such mechanical powers. When a rope is otherwise pulled, as by the application of tackles, or the connection with blocks, &c. the term is changed into *bowing*. To HAUL the Wind, is to direct the ship's course nearer to that point of the compass from which the wind arises. Thus, supposing a ship to sail south-west, with the wind northerly, and some particular occasion requires to haul the wind more westward; to perform this operation, it is necessary to arrange the sails more obliquely with her keel; to brace the yards more forward, by slackening the starboard and pulling in the larboard braces, and to haul the lower sheets further aft; and, finally, to put the helm a-port, *i. e.* over to the larboard side of the vessel. As soon as her head is turned directly to the westward, and her sails are trimmed accordingly, she is said to have hauled the wind four points; that is to say, from south-west to west. She may still go two points nearer to the direction of the wind, by disposing her sails according to their greatest obliquity, or, in the sea-phrase, by *trimming all sharp*; and in this situation she is said to be close hauled, as sailing west-north-west.

HAUM, HALM, or *Hawm*, among farmers, denotes the stem or stalk of corn, pease, beans; &c. from the root to the ear.

HAUNCH, or HANCH, the *Hip*, or that part of the body between the last ribs and the thigh. The haunches of a horse are too long, if when standing in the stable he limps, with his hind-legs farther back than he ought; and when the top or onset of his tail is not in a perpendicular line to the tip of his

hocks, as it always does in horses whose haunches are of a just length. There are some horses which, though they have too long haunches, yet commonly walk well: such are good to climb hills, but are not at all sure upon a descent; for they cannot ply their hams, and never gallop slowly, but always nearly upon a full speed. The art of riding the great horse has not a more necessary lesson than that of putting a horse upon his haunches; which, in other words, is called *coupling him well*, or putting him well together, or compact. A horse that cannot bend or lower his haunches, throws himself too much upon his shoulder, and lies heavy upon the bridle.

HAVRE, in geography, &c. a French term signifying the same with haven or harbour.

HAVRE de Grace, a large, populous, and well-built commercial town of France, in the department of Lower Seine and late province of Normandy. It has an excellent harbour, a strong citadel, and a good arsenal. It was bombarded by the English in 1694 and 1759, and is seated at the mouth of the Seine, 45 miles W. of Rouen, and 112 N. W. of Paris. E. lon. 0. 11. N. lat. 49. 29.

HAURIANT, in heraldry, a term peculiar to fishes; and signifies their standing upright, as if they were refreshing themselves by sucking in the air.

HAUTEFEUILLE (John), an ingenious mechanic, born at Orleans in 1647. Though he embraced the state of an ecclesiastic, and enjoyed several benefices, he applied almost his whole life to mechanics, in which he made a great progress. He had a particular taste for clock-work, and made several discoveries in it that were of singular use. It was he who found out the secret of moderating the vibration of the balance by means of a small steel spring, which has since been made use of. This discovery he laid before the members of the Academy of Sciences in 1674; and these watches are, by way of eminence, called *pendulum-watches*; not that they have real pendulums, but because they nearly approach to the justness of pendulums. M. Huygens perfected this happy invention; but having declared himself the inventor, and obtained from Louis XIV. a patent for making watches with spiral springs, the abbé Feuille opposed the registering of this privilege, and published on the subject against M. Huygens. He wrote a great number of other pieces, most of which are small pamphlets consisting of a few pages, but very curious; as, 1. His perpetual pendulum, quarto. 2. New inventions, quarto. 3. The art of breathing under water, and the means of preserving a flame shut up in a small place. 4. Reflections on machines for raising water. 5. His opinion on the different sentiments of Mallebranche and Regis relating to the appearance of the moon when seen in the horizon. 6. The magnetic balance. 7. A placet to the king on the longitude. 8. Letter on the secret of the longitude. 9. A new system on the flux and reflux of the sea. 10. The means of making sensible experiments that prove the motion of the earth; and many other pieces. He died in 1724.

HAUTBOY, a musical instrument of the wind kind, shaped much like the clarinet. It spreads and widens towards the bottom, and is sounded through a reed. The treble is two feet long; the tenor goes a fifth lower when blown open: it has only eight holes; but the bass, which is five feet long, has eleven. The word is French, *baut bois*, q. d. "high wood;" and is given to this instrument because its tone ascends higher than that of the violin.

HAW, a sort of berry, the fruit of several species of *mespilus*, thence denominated *hawthorns*. See *MESPILUS*.

HAW, among farriers, an excrescence resembling a gristle, growing under the nether eye-lid and eye of a horse, which, if not timely removed, will cause blindness. See *FARRIERY*, page 423.

HAW, a small parcel of land so called in Kent, as a *Hemp-*

barw, or *Beanbarw*, lying near the house, and inclosed for these uses. But Sir Edward Coke, in an ancient plea concerning FEVERSHAM in Kent, says *barwes* are houses.

HAW-Finch. See *LOXIA*.

HAWGH, or HOWGH, signifies a green plot in a valley as they use it in the north of England.

HAWK, in ornithology. See *FALCO*.

HAWKERS, anciently were fraudulent persons, who went from place to place buying and selling brass, pewter, and other merchandize, which ought to be uttered in open market. In this sense the word is mentioned *anno* 25 Hen. VIII. cap. 6. and 33 *ejusdem*, cap. 4. The appellation *hawkers* seems to have arisen from their uncertain wandering, like those who, with hawks, fought their game where they could find it. The term is now used as synonymous with pedlar; a person who travels about the country selling wares. Former acts of parliament require every hawkker to take out an annual licence, paying for it 4l. and if he travel with a horse, ass, or mule, for every one of them 8l. If he travel without a licence, or contrary to it, he forfeits for every offence to the informer, and the poor of the parish where discovered, 10l. The acts relating to hawkkers do not extend to makers of goods or their agents; or to those who sell goods in fairs or markets; to the sellers of fish, fruit, or other victuals; nor to the venders of books and newspapers, 9 and 10 W. cap. 27. 3 and 4 Anne, cap. 4. But hawkkers shall not, by virtue of such licence, sell or offer to sale any tea or spirituous liquors, though with a permit, under the penalty of having the same seized, and imprisonment and prosecution of the offender. 9 Geo. II. cap. 35. Hawkkers who were licensed on June 23, 1785, may set up any business in the place where they are resident inhabitants, though not brought up thereto, and may employ therein persons who have not been apprentices. Additional duties are, however, imposed on hawkkers, by subsequent acts; viz. 29 Geo. III. c. 26. and 35 Geo. III. c. 91. which likewise subject them to various regulations not enjoined by former acts.

HAWKERS is a term also applied to those who go up and down London streets and country towns, selling newspapers, pamphlets, &c.

HAWKESWORTH (John), a celebrated English writer, was born about the year 1719; though his epitaph, as we find it in the Gentleman's Magazine for Aug. 1781, makes him to have been born in 1715. He was brought up to a mechanical profession, that of a watchmaker as is supposed. He was of the Presbyterian persuasion, and a member of the celebrated Tom Bradbury's meeting, from which he was expelled for some irregularities. He afterwards devoted himself to literature, and became an author of considerable eminence. In the early part of life his circumstances were rather confined. He resided some time at Bromley in Kent, where his wife kept a boarding-school. He afterwards became known to a lady who had great property and interest in the East India company, and through her means was chosen a director of that body. As an author, his *Adventurer* is his capital work; the merits of which, if we mistake not, procured him the degree of LL.D. from Herring archbishop of Canterbury. When the design of compiling a narrative of the discoveries in the South Seas was on foot, he was recommended as a proper person to be employed on the occasion: but in truth he was not a proper person, nor did the performance answer expectation. Works of taste and elegance, where imagination and the passions were to be affected, were his province; not works of dry, cold, accurate narrative. However, he executed his task, and is said to have received for it the enormous sum of 6000l. He died in 1773; some say, of high living; others, of chagrin from the ill reception of his *Narrative*: for he was a man of the keenest sensibility, and obnoxious to all the evils of such irritable natures. A handsome marble me-

ument was erected to his memory at Bromley in Kent. The latter part of the inscription is taken from the last number of *The Adventurer*; it runs thus: "The hour is hastening, in which whatever praise or censure I have acquired will be remembered with equal indifference. Time, who is impatient to date my last paper, will shortly moulder the hand which is now writing it in the dust, and still the breast that now throbs at the reflection. But let not this be read as something that relates only to another; for a few years only can divide the eye that is now reading from the hand that has written."

HAWKING, the exercise of taking wild-fowl by means of hawks. The method of reclaiming, manning, and bringing up a hawk to this exercise, is called *falcoury*. See *FALCONRY*. There are only two countries in the world where we have any evidence that the exercise of hawking was very anciently in vogue. These are Thrace and Britain. In the former, it was pursued merely as the diversion of a particular district, if we may believe Pliny, (b. x. 8.) whose account is rendered obscure by the darkness of his own ideas of the matter. The primæval Britons, with a fondness for the exercise of hunting, had also a taste for that of hawking; and every chief among them maintained a considerable number of birds for that sport. It appears also from a curious passage in the poems of Ossian, (vol. i. p. 115.) that the same diversion was fashionable at a very early period in Scotland. The poet tells us, that a peace was endeavoured to be gained by the proffer of 100 managed steeds, 100 foreign captives, and "100 hawks with fluttering wings, that fly across the sky." To the Romans this diversion was scarce known in the days of Vespasian; yet it was introduced immediately afterwards. Most probably they adopted it from the Britons; but we certainly know that they greatly improved it by the introduction of spaniels into the island. In this state it appears among the Roman Britons in the sixth century. Gildas, in a remarkable passage in his first epistle, speaks of Maglocunus, on his relinquishing the sphere of ambition, and taking refuge in a monastery; and proverbially compares him to a dove, that hastens away at the noisy approach of the dogs, and with various turns and windings takes her flight from the talons of the hawk.

In after times, hawking was the principal amusement of the English: a person of rank scarce stirred out without his hawk on his hand; which, in old paintings, is the criterion of nobility. Harold, afterwards king of England, when he went on a most important embassy into Normandy, is painted embarking with a bird on his fist, and a dog under his arm: and in an ancient picture of the nuptials of Henry VI. a nobleman is represented in much the same manner; for in those days, *it was thought sufficient for noblemen to wind their horn, and to carry their hawk fair, and leave study and learning to the children of mean people*. The former were the accomplishments of the times; Spenser makes his gallant Sir Trifram boast,

No is there hawk which mantleth her on perch,

Whether high towring, or accoasting low,

But I the measure of her flight doe search,

And all her prey, and all her diet know. B. vi. Canto 2.

In short, this diversion was, among the old English, the pride of the rich, and the privilege of the poor; no rank of men seems to have been excluded the amusement: we learn from the book of St. Alban's, that every degree had its peculiar hawk, from the emperor down to the *boly-water clerk*. Vast was the expence that sometimes attended this sport. In the reign of James I. Sir Thomas Monson is said to have given 1000l. for a cast of hawks: we are not then to wonder at the rigour of the laws that tended to preserve a pleasure that was carried to such an extravagant pitch. In the 34th of Edward III. it was made felony to steal a hawk; to take its eggs, even in a person's own

ground, was punishable with imprisonment for a year and a day, besides a fine at the king's pleasure: in queen Elizabeth's reign, the imprisonment was reduced to three months; but the offender was to find security for his good behaviour for seven years, or lie in prison till he did. Such was the enviable state of the times of old England; during the whole day, the gentry were given to the fowls of the air and the beasts of the field; in the evening they celebrated their exploits with the most abandoned and brutish sottishness; at the same time, the inferior rank of people, by the most unjust and arbitrary laws, were liable to capital punishments, to fines, and loss of liberty, for destroying the most noxious of the feathered tribe.

According to Olearius, the diversion of hawking is more followed by the Tartars and Persians than ever it was in any part of Europe. *Il n'y avoit point de butte* (says he) *qui n'eust son aigle ou son faucon*.

The falcons or hawks that were in use in these kingdoms are now found to breed in Wales, and in North Britain and its isles. The peregrine falcon inhabits the rocks of Caernarvonshire. The same species, with the gyrfalcon, the gentil, and the gohawk, are found in Scotland, and the lanner in Ireland.

We may here take notice, that the Norwegian breed was, in old times, in high esteem in England: they were thought bribes worthy a king. Jeoffrey Fitzpierre gave two good Norway hawks to king John, to obtain for his friend the liberty of exporting 100 wt. of cheese; and Nicholas the Dane was to give the king a hawk every time he came into England, that he might have free liberty to traffic throughout the king's dominions.

They were also made the tenures that some of the nobility held their estates by, from the crown. Thus Sir John Stanley had a grant of the Isle of Man from Henry IV. to be held of the king, his heirs, and successors, by homage and the service of two falcons, payable on the day of his or their coronation. And Philip de Haftang held his manor of Combertoun in Cambridgeshire, by the service of keeping the king's falcons.

Hawking, though an exercise now much disused among us, in comparison of what it anciently was, does yet furnish a great variety of significant terms, which still obtain in our language. Thus, the parts of a hawk have their proper names. The legs, from the thigh to the foot, are called *arms*; the toes, the *petty singles*; the claws, the *pouces*. The wings are called the *sails*; the long feathers thereof, the *beans*; the two longest, the *principal feathers*; those next thereto, the *flags*. The tail is called the *train*; the breast-feathers, the *mails*; those behind the thigh, the *pendant feathers*. When the feathers are not yet full grown, she is said to be *unsummed*; when they are complete, she is *summed*: The craw, or crop, is called the *gorge*: The pipe next the fundament, where the feces are drawn down, is called the *pannel*: The slimy substance lying in the pannel is called the *glut*: The upper and crooked part of the bill is called the *beak*; the nether part, the *clap*; the yellow part between the beak and the eyes, the *scar* or *scere*; the two small holes therein, the *nares*.

As to her furniture: The leathers, with bells buttoned on her legs, are called *beavits*. The leathern thong, whereby the falconer holds the hawk, is called the *leafe* or *leafe*; the little straps, by which the leafe is fastened to the legs, *jeses*; and a line or pack-thread fastened to the leafe, in disciplining her, a *creance*. A cover for her head, to keep her in the dark, is called a *hood*; a large wide hood, open behind, to be wore at first, is called a *ruster hood*: To draw the strings, that the hood may be in readiness to be pulled off, is called *unstriking the hood*. The blinding a hawk just taken, by running a thread through her eye-lids, and thus drawing them over the eyes, to prepare her for being hooded, is called *feeling*. A figure or resemblance

of a fowl, made of leather and feathers, is called a *lure*. Her resting-place, when off the falconer's fist, is called the *perch*. The place where her meat is laid, is called the *back*; and that wherein she is set, while her feathers fall and come again, the *meu*.

Something given a hawk, to cleanse and purge her gorge, is called *casting*. Small feathers given her to make her cast, are called *plumage*: Gravel given her to help to bring down her stomach, is called *rangle*: Her throwing up filth from the gorge after casting, is called *gleaming*. The purging of her greafe, &c. *enseaming*. Her being stuffed, is called *gurgiting*. The inserting a feather in her wing, in lieu of a broken one, is called *imping*. The giving her a leg, wing, or pinion of a fowl to pull at, is called *tiring*: The neck of a bird the hawk preys on, is called the *inke*: What the hawk leaves of her prey, is called the *pill* or *pelf*.

There are also proper terms for her several actions. When she flutters with her wings, as if striving to get away, either from perch or fist, she is said to *bate*. When, standing too near, they fight with each other, it is called *crabbing*: When the young ones quiver, and shake their wings in obedience to the elder, it is called *cowering*: When she wipes her beak after feeding, she is said to *feak*: When she sleeps, she is said to *jouk*: From the time of exchanging her coat, till she turn white again, is called her *intermewing*: Treading is called *caroking*: When she stretches one of her wings after her legs, and then the other, it is called *mantling*: Her dung is called *muting*; when she mutes a good way from her, she is said to *slize*; when she does it directly down, instead of yerking backwards, she is said to *slime*; and if it be in drops, it is called *dropping*. When she as it were sneezes, it is called *sniting*. When she raises and shakes herself, she is said to *rouze*: When, after mantling, she crosses her wings together over her back, she is said to *warble*.

When a hawk seizes, she is said to *bind*: When, after seizing, she pulls off the feathers, she is said to *plume*. When she raises a fowl aloft, and at length descends with it to the ground, it is called *truffing*. When, being aloft, she descends to strike her prey, it is called *stooping*. When she flies out too far from game, she is said to *rake*. When, forsaking her proper game, she flies at pyes, crows, &c. that chance to cross her, it is called the *check*. When, missing the fowl, she betakes herself to the next check, she is said to *fly on bead*. The fowl or game she flies at is called the *quarry*. The dead body of a fowl killed by the hawk, is called a *pelt*. When she flies away with the quarry, she is said to *carry*. When in stooping she turns two or three times on the wing, to recover herself ere she seizes, it is called *cancelliering*. When she hits the prey, yet does not trufs it, it is called *ruff*. The making a hawk tame and gentle, is called *reclaiming*. The bringing her to endure company, *manning* her. An old staunch hawk, used to fly and set example to a young one, is called a *make-hawk*.

The reclaiming, manning, and bringing up a hawk to the sport, is not easy to be brought to any precise set of rules. It consists in a number of little practices and observances, calculated to familiarize the falconer to his bird, to procure the love thereof, &c. See the article FALCONRY.

When your hawk comes readily to the lure, a large pair of luring bells are to be put upon her; and the more giddy-headed and apt to rake out your hawk is, the larger must the bells be. Having done this, and she being sharp-set, ride out in a fair morning, into some large field unencumbered with trees or wood, with your hawk on your fist; then having loosened her hood, whistle softly, to provoke her to fly; unhood her, and let her fly with her head into the wind; for by that means she will be the better able to get upon the wing, and will naturally climb upwards, flying a circle. After she has flown three or four turns, then lure her with your voice, casting the lure about your head, having first tied a pullet to it; and if your falcon come in and

approach near you, cast out the lure into the wind, and if she stoop to it reward her.

You will often find, that when she flies from the fist, she will take stand on the ground: this is a fault which is very common with soar-falcons. To remedy this, fright her up with your wand; and when you have forced her to take a turn or two, take her down to the lure, and feed her. But if this does not do, then you must have in readiness a duck sealed, so that she may see no way but backwards, and that will make her mount the higher. Hold this duck in your hand, by one of the wings near the body; then lure with the voice, to make the falcon turn her head; and when she is at a reasonable pitch, cast your duck up just under her; when, if she strike, stoop, or trufs the duck, permit her to kill it, and reward her by giving her a reasonable gorge. After you have practised this two or three times, your hawk will leave the stand, and, delighted to be on the wing, will be very obedient.

It is not convenient, for the first or second time, to show your hawk a large fowl; for it frequently happens, that they escape from the hawk, and she, not recovering them, rakes after them: this gives the falconer trouble, and frequently occasions the loss of the hawk. But if she happens to pursue a fowl, and, being unable to recover it, gives it over, and comes in again directly, then cast out a sealed duck; and if she stoop and trufs it across the wings, permit her to take her pleasure, rewarding her also with the heart, brains, tongue, and liver. But if you have not a quick duck, take her down with a dry lure, and let her plume a pullet and feed upon it. By this means a hawk will learn to give over a fowl that rakes out, and, on hearing the falconer's lure, will make back again, and know the better how to hold in the head.

Some hawks have a disdainful coynefs, proceeding from their being high fed: such a hawk must not be rewarded though she should kill: but you may give her leave to plume a little; and then taking a sheep's heart cold, or the leg of a pullet, when the hawk is busy in pluming, let either of them be conveyed into the body of the fowl, that it may favour of it; and when the hawk has eaten the heart, brains, and tongue of the fowl, take out what is inclosed, call her to your fist, and feed her with it: afterwards give her some of the feathers of the fowl's neck, to scower her, and make her cast.

If your hawk be a stately high-flying one, she ought not to take more than one flight in a morning; and if she be made for the river, let her not fly more than twice; when she is at the highest, take her down with your lure; and when she has plumed and broken the fowl a little, feed her, by which means you will keep her a high-flier, and fond of the lure.

HAWKWOOD (Sir John), a famous English general, was the son of a tanner at Heddingham-Sibil in Essex, where he was born in the reign of Edward III. He was bound apprentice to a taylor in London; but being fortunately pressed into the army, was sent abroad, where his genius soon expanded itself, and surmounted the narrow prejudices which adhered to his birth and occupation. He signalized himself as a soldier in France and Italy, and particularly at Pisa and Florence. He commanded with great ability and success in the army of Galeacia duke of Milan; and was in such high esteem with Barnabas his brother, that he gave him Domitia his natural daughter in marriage, with an ample fortune. He died at Florence, full of years and military fame, in 1394.

HAWSE, or HAUSE, is generally understood to imply the situation of the cables before the ship's stem, when she is moored with two anchors out from forward, viz. one on the starboard, and the other on the larboard bow. Hence it is usual to say, *she has a clear hawse*, or *a foul hawse*. It also denotes any small distance ahead of a ship, or between her head and the anchors employed to ride her, as, "He has anchored in our hawse, The brig fell athwart our hawse," &c. A ship is said to ride

with a clear hawse, when the cables are directed to their anchors, without lying athwart the stem; or crossing, or being twisted round each other by the ship's winding about, according to the change of the wind, tide, or current. A foul hawse, on the contrary, implies that the cables lie across the stem, or bear upon each other, so as to be rubbed and chafed by the motion of the vessel. The hawse accordingly is foul, by having either a cross, an elbow, or a round turn. If the larboard cable, lying across the stem, points out on the starboard side, while the starboard cable at the same time grows out on the larboard side, there is a cross in the hawse. If, after this, the ship, without returning to her former position, continues to wind about the same way, so as to perform an entire revolution, each of the cables will be twisted round the other, and then directed out from the opposite bow, forming what is called a round turn. An elbow is produced when the ship stops in the middle of that revolution, after having had a cross: or, in other words, if she rides with her head northward with a clear hawse, and afterwards turns quite round so as to direct her head northward again, she will have an elbow.

Hawse-Holes, certain cylindrical holes cut through the bows of a ship on each side of the stem, through which the cables pass in order to be drawn into or let out of the vessel as occasion requires. They are fortified on each side by the

Hawse-Pieces, a name given to the foremost timbers of a ship, whose lower ends rest on the knuckle-timber, or the foremost of the cant-timbers. They are generally parallel to the stem, having their upper ends sometimes terminated by the lower part of the beakhead; and otherwise, by the top of the bow, particularly in small ships and merchantmen.

Hawser, a large rope which holds the middle degree between the *cable* and *tow-line*, in any ship whereto it belongs, being a size smaller than the former, and as much larger than the latter.

HAY, any kind of grafs cut and dried for the food of cattle. The time of mowing grafs for hay must be regulated according to its growth and ripeness; nothing being more prejudicial to the crop than mowing it too soon; because the sap is not then fully come out of the root, and when made into hay, the grafs shrinks away to nothing. It must not, however, be let stand too long till it have shed its seeds. When the tops of the grafs look brown, and begin to bend down, and the red honey-suckle flowers begin to wither, you may conclude it ripe for mowing.

Sain-Foin HAY, is of several sorts, which may be distinguished by the following terms, viz. 1. The virgin. 2. The blossomed. 3. The full-grown. And, 4. The threshed hay. The first of these is beyond comparison the best. It must be cut before the blossoms generally appear; for when it stands till it is full blown, the most spirituous and nourishing parts of its juice are spent, the sap is much impoverished, and the sain-foin can never recover that richness it had in its virgin state. But this fine hay cannot well be had of uncultivated sain-foin, because that may not be much above an handful high when it is in a condition to be cut; it would then make a very light crop, and would be a great while before it sprang up again: but the rich will have two or three tons to an acre, and spring again immediately for a second crop; so that little or none in quantity would be lost by so great an improvement of its quality.

The second sort is that cut in the flower, which, though much inferior to the virgin hay, far exceeds any other kind as yet commonly propagated in Britain; and if it be a full crop, it may amount to three tons an acre. This is that sain-foin which is commonly made; and the larger it is, the more nourishing it is for horses.

The next sort of sain-foin is the full grown, cut when the blossoms are gone or going off: this also is good hay, though it falls short by many degrees of the goodness of the other two

sorts; but it makes a greater crop than either of them, because it grows to its full bulk, and shrinks little in drying.

The last sort is the threshed hay; which, when not damaged by wet weather, has been found more nourishing to horses than coarse water-meadow hay; and, when it is cut small by an engine, is good for cattle, and much better than the chaff of corn. The best time to cut it, is when the greatest part of the feed is well filled; the first-blown ripe, and the last-blown beginning to be full.

The goodness of the hay depends greatly upon the manner of managing it. The best hay in all England is made of sain-foin, without ever spreading it. This method, though it be longer before it be finished, costs less labour than the other. If sain-foin be laid up pretty green, it will take no damage, provided it be set in small round ricks, with a large basket drawn up in the middle of each, to have a vent-hole, through which the superfluous moisture of the hay may transpire. As soon as its heating is over, these ricks ought to be thatched; and all sain-foin ricks, that are made when the hay is full dried in the cocks, ought to be thatched immediately after the making them. That which is laid up most dried, will come out of the rick of a green colour; but that which has been much heated in the rick, will be brown.

The seed affords the owner another opportunity of making a profit of his sain-foin: but this, if the hoeing husbandry were general, would not be vendible in great quantities for planting; because the ordinary crop of an acre will produce seed enough to drill an hundred acres, which would not want planting for a long time. The other use then of this seed is for provender; and it has been affirmed by some who have made trials of it, that three bushels of good sain-foin seed given to horses, will nourish them as much as four bushels of oats; and when well ordered, it is so sweet, that most sorts of cattle are greedy of it.

HAY-Making. See *HUSBANDRY*.

HAY, a town of Brecknockshire, in Wales, seated near the confluence of the rivers Wye and Dulas. It was a town of good note in the time of the Romans; it being then fortified with a castle and a wall, which were ruined in the rebellion of Owen Glendower. It is at present a pretty good town; and the market is large for corn, cattle, and provisions. W. lon. o. 56. N. lat. 52. 10.

HAY (William, Esq.), an agreeable English writer, was born at Glenburne in Sussex, about 1700, as is conjectured; and educated at Headley-school. In 1730 he published a poem called *Mount Caburn*, dedicated to the dukes of Newcastle; in which he describes the beauties of his native country, and celebrates the virtues of his friends. When lord Hardwicke was called up to the house of lords in 1734, he was chosen to succeed him in representing the borough of Seaford among the commons: and he represented this borough for the remainder of his life. He defended the measures of Sir Robert Walpole, and was the supposed author of a ministerial pamphlet, intitled, *A Letter to a Freholder on the late Reduction of the Land-tax to one Shilling in the Pound*; which had been printed in 1732. In 1735 he published *Remarks on the Laws relative to the Poor, with Proposals for their better Relief and Employment*; and at the same time brought in a bill for the purpose. He made another attempt of this kind, but without effect. In May 1738, he was appointed a commissioner of the Victualling-office. In 1753 appeared *Religio Philosophi*; or, the Principles of Morality and Christianity, illustrated from a View of the Universe, and of Man's Situation in it. This was followed, in 1754, by his *Essay on Deformity*; in which he rallies his own imperfection in this respect with much liveliness and good humour. "Bodily deformity (says he) is very rare. Among 558 gentlemen in the House of Commons, I am the only one that is so. Thanks to my worthy constituents, who never objected to my person, and I hope never to give them

cause to object to my behaviour." The same year, he translated Hawkins Browne *De Immortalitate Animi*. In 1755, he translated and modernized some Epigrams of Martial; but survived this publication only a short time, dying June 19, the same year. A little time before, he had been appointed keeper of the Records in the Tower; and it is said that his attention and assiduity during the few months he held that office were eminently serviceable to his successors. He left a son, who inherited the imperfect form of his father. This gentleman went into the service of the East India company, where he acquired rank, fortune, and reputation; but being one of those who opposed Cossim Ally Kawn, and unfortunately falling into his hands, was, with other gentlemen, ordered to be put to death at Patna, Oct. 5, 1763.

HAYES (Charles, Esq.), a very singular person, whose great erudition was so concealed by his modesty, that his name is known to very few, though his publications are many. He was born in 1678, and became distinguished in 1704 by A Treatise of Fluxions, folio: the only work to which he ever set his name. In 1710 came out a small 4to pamphlet of 19 pages, intitled, A new and easy Method to find out the Longitude, from observing the Altitudes of the Celestial Bodies: and, in 1723, The Moon, a Philosophical Dialogue; tending to show, that the moon is not an opaque body, but has original light of her own. During a long course of years, the management of the late Royal African company lay in a manner wholly upon Mr. Hayes, he being annually either sub-governor or deputy-governor; notwithstanding which, he continued his pursuit after general knowledge. To a skill in the Greek and Latin as well as modern languages, he added the knowledge of the Hebrew; and published several pieces relating to the translation and chronology of the scriptures. The African company being dissolved in 1752, he retired to Down in Kent, where he gave himself up to study. In May 1753 he began to compile in Latin his *Chronographia Asiatica & Ægyptiaca*, which he lived to finish, but not to publish; which, however, was published afterwards. In August 1758 he left his house in Kent, and took chambers in Gray's-Inn, where he died December 18, 1760, in his 82d year. The title of his posthumous works runs thus: *Chronographiæ Asiaticæ & Ægyptiæ Specimen*; in quo, 1. *Origo Chronologiæ LXX Interpretum investigatur.* 2. *Conspectus totius operis exhibetur*, 8vo.

HAYS, particular nets for taking rabbits, hares, &c. common to be bought in shops that sell nets, and they may be had larger or shorter as you think fit: from 15 to 20 fathoms is a good length, and for depth a fathom. As rabbits often straggle abroad about mid-day for fresh grass, where you perceive a number gone forth to any remote brakes or thickets, pitch two or three of these hays about their burrows; lie close there: but in case you have not nets enough to inclose all their burrows, some may be stopped up with stones, &c. Then set out with the coney-dog to hunt up and down at a good distance, and draw on by degrees to the man who is with you, and lies close by the hay, who may take them as they bolt into it.

HAYWARD, the person who keeps the common herd or cattle of a town. He is appointed by the lord's court; and his office is to see that the cattle neither break nor crop the hedges of inclosed grounds.

HAYWARD (Sir John), an eminent English historian and biographer in the beginning of the 17th century, was educated in the university of Cambridge, where he took the degree of doctor of laws. In 1610 he was appointed one of the historiographers of a college then at Chelsea; and, in 1619, received the honour of knighthood. He wrote, 1. The lives of the three Norman kings of England, William I. and II. and Henry I. 2. The first part of the life and reign of king Henry IV. 3. The life and reign of king Edward VI.; and several theological works. He died in 1627.

HAZARD, or CHANCE, in gaming. See GAMING.

HAZARD, a game on dice, without tables, is very properly so called; since it speedily makes a man, or undoes him. It is played with only two dice; and as many may play at it as can stand round the largest round table. Two things are chiefly to be observed, viz. *main* and *chance*; the latter belonging to the caster, and the former, or main, to the other gamblers. There can be no main thrown above nine, nor under five; so that five, six, seven, eight, and nine, are the only mains flung at hazard. Chances and nicks are from four to ten: thus four is a chance to nine, five to eight, six to seven, seven to six, eight to five; and nine and ten a chance to five, six, seven, and eight: in short, four, five, six, seven, eight, nine, and ten, are chances to any main, if any of these nick it not. Now nicks are either when the chance is the same with the main, as five and five, or the like; or six and twelve, seven and eleven, eight and twelve. Here observe, that twelve is out to nine, seven, and five; eleven is out to nine, eight, six, and five: and ames-ace and duce-ace are out to all mains whatever.

HAZLE, or HAZEL, in botany. See CORYLUS. The kernels of the fruit have a mild, farinaceous, oily taste, agreeable to most palates. Squirrels and mice are fond of them, as well as some birds, such as jays, nutcrackers, &c. A kind of chocolate has been prepared from them, and there are instances of their having been formed into bread. The oil expressed from them is little inferior to the oil of almonds; and is used by painters and by chemists for receiving and retaining odours. The charcoal made of the wood is preferred by painters for drawing. Some of the Highlanders, where superstition is not totally subsided, look upon the tree itself as unlucky; but are glad to get two of the nuts naturally conjoined, which is a good omen. These they call *cho-chomlaich*, and carry them as an efficacious charm against witchcraft. Evelyn tells us, that no plant is more proper for thickening of copes than the hazle, for which he directs the following expeditious method. Take a pole of hazle (ash or poplar may also be used) of 20 or 30 feet in length, the head a little lopped into the ground, giving it a chop near the ground to make it succumb; this fastened to the earth with a hook or two, and covered with some fresh mould at a competent depth (as gardeners lay their carnations), will produce a great number of suckers, and thicken and furnish a cope speedily.

HAZLE-EARTH, or Hazley-Earth, a kind of red loam, which is said to be an excellent mixture with other sorts of earth; uniting what is too loose, cooling what is too hot, and gently retaining the moisture.

Witch-HAZEL. See HAMAMALIS.

HEAD, the uppermost or superior part of the body of an animal. See ANATOMY, p. 163.

HEAD ACH, a most troublesome sensation in the head, produced by various causes, and attended with different symptoms, according to its different degrees and the place where it is seated. See MEDICINE.

Dragon's HEAD, in astronomy, is the ascending node of the moon or other planet.

HEAD of a Ship, an ornamental figure erected on the continuation of a ship's stem, as being expressive of her name, and emblematical of war, navigation, commerce, &c. The term *bead* is also used in a more enlarged sense to signify the whole front or forepart of the ship, including the bows on each side. The head therefore opens the column of water through which the ship passes when advancing. Hence we say, head-fails, head-sea, head-way, &c.

Thus, fig. 1. Plate 3. represents one side of the fore-part or head of a 74 gun ship, together with part of the bow, keel, and gunnel. The names of the several pieces, exhibited therein, are as follow: A A Fore-part of the keel, with a a The two false keels beneath it. A C The stem. a a The cat-head. b b

The supporter of the cat-head. *cc* The knight-head, or bollard-timber, of which there is one on each side, to secure the inner end of the bowsprit. *dd* The haufe holes. *ee* The naval-hoods, *i. e.* thick pieces of plank laid upon the bow to strengthen the edges of the haufe-holes. *f* The davit-chock, by which the davit is firmly wedged while employed to fish the anchor. *gg* The bulk-head, which terminates the fore-castle on the fore-side, being called the *beak-head bulk-head* by shipwrights. *H* The gun-ports of the lower deck. *b* The gun-ports of the upper deck and fore-castle. *I I* The channels, with their dead eyes and chain plates. *i* The gripe, or fore-foot, which unites the keel with the stem, forming a part of either. *kk* These dotted lines represent the thickness and descent of the different decks from the fore-part of the ship towards the middle. The lowest of the three dotted lines *l* expresses the convexity of the beams, or the difference between the height of the deck in the middle of its breadth and at the ship's side. This is also exhibited more clearly in the *MIDSHIP-FRAME*; where the red curve of the beam is delineated. (N. B. These lines must be always parallel to the lines which terminate the gun-ports above and below.) *mm* The timbers of the head, and part of the bowsprit. *XX* The rails of the head which lie across the timbers. *QZ* Fore-part of the main wale. *RX* Fore part of the channel-wale. *UC* The load water line.

Fig. 2. Represents a head-view of a ship, with the projection of her principal timbers, and all her planks laid on one side. It is evident that the fore-part of a ship is called its *head*, from the affinity of motion and position it bears to a fish, and in general to the horizontal situation of all animals whilst swimming.

By the *HEAD*; the state of a ship, which is laden deeper at the fore-end than the after-end.

HEAD Borow, or *HEAD-Borough*, signifies the person who is the chief of the frank-pledge, and had anciently the principal direction of those within his own pledge. He was also called *burrow-head*, *burshoulder*, now *borsholder*, *third-borow*, *tytbingman*, *chief-pledge*, and *borow elder*, according to the diversity of speech in different places. This office is now usually called a *high-constable*. The head-borow was the chief of ten pledges: the other nine were called *band-lorows*, or *plegii manuales*, &c.

HEAD-Mould-shot, a disease in children, wherein the sutures of the skull, generally the coronal, *ride*; that is, have their edges shot over one another; and are so close locked together, as to compress the internal parts, the meninges, or even the brain itself. The disease is supposed to occasion convulsions, and to admit of no cure, unless room could be given by manual operation or a divulsion of the sutures. The head mould-shot is the disorder opposite to the horse-shoe head.

HEAD-PENCE, an exaction of a certain sum formerly collected by the sheriff of Northumberland from the inhabitants of that county, without any account to be made to the king. This was abolished by the statute 23 Hen. VI. cap. 7.

HEAD-Tin, in metallurgy, is a preparation of tin-ore toward the fitting it for working into metal. When the ore has been pounded and twice washed, that part of it which lies uppermost, or makes the surface of the mass in the tub, is called the *head tin*; this is separated from the rest, and after a little more washing becomes fit for the blowing-house.

HEAD-Traff, a rope employed to fasten a ship to a wharf, chain, or buoy, or to some other vessel along-side.

HEAD-Land, a name frequently given to a cape or promontory.

HEAD-Dress, amongst the Jewish, Grecian, and Roman ladies, as among ourselves, was various, according to the different periods of time, and the fluctuation of fashion. In general, it principally consisted of their hair differently tricked out. It was usually divided before, with a bodkin, into two equal parts; sometimes it was covered with a net, or put into a kind of purse, or tied behind in the form of a knot, or bound back

and plaited with ribbands. It was washed with great care; essence and perfumes were applied to it, and gold-dust sometimes made use of as powder. Pearls and jewels made a part of their ornaments; and pendants were worn in the ear. To cover the defect of hair, perukes were made use of by the gentlemen of Rome. And we read that Otho had a covering of false hair, because he had not much of his own. See *HAIR*, and *JEWELS*. Both the Grecian and Roman ladies wore *têtes*.

HEADMOST, the situation of any ship or ships which are the most advanced in a fleet, or line of battle.

HEAD Rope, that part of the bolt-rope which terminates any of the principal sails on the upper edge, which is accordingly sewed thereto. See the article *BOLT-ROPE*.

HEAD-Sails, a general name for all those sails which are extended on the fore-mast and bowsprit, and employed to command the fore-part of the ship: such are the fore-sail, fore-top-sail, fore-top gallant sail, jib, fore stay-sail, and the sprit-sail with its top-sail. This term is used in opposition to *after-sails*, viz. all those which are extended on the mizen-mast, and on the stays between the mizen and main-masts.

HEAD-to-wind; the situation of a ship or boat, when her head is turned to windward.

HEAD-Way, the motion of advancing at sea. It is generally used when a ship first begins to advance; or when it is doubtful whether she is in a state of rest or motion. It is in both senses opposed to retreating, or moving with the stern foremost. See the article *STERNWAY*.

HEALFANG, *HEALSFANG*, or *HALSFANG*, in our ancient customs, signifies *collistrigium*, or "the punishment of the pillory." The word is compounded of two Saxon words; *balp* "neck," and *pangen* "to contain:" *Pœna scilicet qua alicui collum stringatur*. The healfang, however, cannot signify a pillory in the charter of Canutus, De Forestis, cap. xiv. *Et pro culpa solvat regi duos solidos, quos Dani vocant halfeshang*.

HEALFANG is also taken for a pecuniary punishment or mulct, to commute for standing in the pillory; and is to be paid either to the king or the chief lord. *Qui falsum testimonium dedit, reddat regi vel terræ domino healfang*.

HEALING, in its general sense, includes the whole process of curing or removing a disorder, and recovering health. In this sense medicine is defined the art of healing. In its more restrained sense, as used in surgery, &c. healing denotes the uniting or consolidating the lips of a wound or ulcer.

HEALING, in architecture, denotes the covering the roof of a building. The healing is various; as of lead, tiles, slate, Horshamstone, shingles, or reed and straw.

HEALTH, is a right disposition of the body, and of all its parts; consisting in a due temperature, a right conformation, just connection, and ready and free exercise of the several vital functions. Health admits of latitude, as not being the same in all subjects, who may yet be said to enjoy health. That part of medicine which shows the means of preserving health, is termed *hygieine*. See *MEDICINE*. The Greeks and Romans deified Health, representing it under the figure of a woman, whom they supposed to be the daughter of *Æsculapins*. We find the name of the goddess *Salus*, or Health, on many medals of the Roman emperors, with different inscriptions; as, *SALUS PUBLICA*, *SALUS REIPUBLICÆ*, *SALUS AUGUSTI*, &c.

HEAM, in beasts, denotes the same with *after-birth* in women. Thyme, penny-royal, winter-savory, and common horehound, boiled in white-wine, and given to a mare, are esteemed good to expel the heam.

HEARING, the act or faculty of perceiving sounds. Hearing is reckoned among our external senses. Its organ is the ear, and particularly the auditory nerve diffused through the same; and its object, certain motions or vibrations of the air. Hence hearing may be more scientifically defined, a sensation, whereby, from a due motion impressed on the fibrillæ of the auditory

nerve, and communicated thence to the sensory, the mind perceives and gets the idea of sounds. See ANATOMY, p. 211.

HEARING in different animals. See COMPARATIVE-ANATOMY, ENTOMOLOGY, and ICHTHYOLOGY.

HEARNE (Thomas), a celebrated antiquarian, eminent for his writings and editions of MSS. His father was parish-clerk of Little Waltham in Berkshire, where he was born in 1680. He had a liberal education under the patronage of a neighbouring gentleman; and even from a boy discovered a strong propensity to the study of antiquities. He rendered great services to the Bodleian library, and died in 1735.

HEARSE, among hunters, a hind in the second year of her age. See HUNTING.

HEARSE is the name of a well known carriage, used for conveying the dead to the grave. The word is also used by Shakespeare in his Henry VI. for a monument erected over a grave.

HEART, in anatomy, the most important of the viscera in the human body. It is situated in the thorax, on the anterior part of the diaphragm, between the two laminæ of the mediastinum. The veins all terminate in it, and from it all the arteries arise; and, by its alternate contraction and dilatation, it becomes the chief instrument of the circulation of the blood, and the organ of life. See ANATOMY, page 193.

Philosophers have, from time to time, attempted to make estimates of the force of the blood in the heart and arteries; but they have as widely differed from each other, as they have from the truth, for want of a sufficient number of data to argue upon. This set the truly ingenious Dr. Hales upon making proper experiments, in order to ascertain the force of the blood in the veins and arteries of several animals. If, according to Dr. Keil's estimate, the left ventricle of a man's heart throws out in each systole an ounce or 1.638 cubic inches of blood, and the area of the orifice of the aorta be = 0.4187, then

dividing the former by this, the quotient 3.9 is the length of the cylinder of blood which is formed in passing through the aorta in each systole of the ventricle; and in the 75 pulses of a minute, a cylinder of 292.5 inches in length will pass: this is at the rate of 1462 feet in an hour. But the systole of the heart being performed in one third of this time, the velocity of the blood in that instant will be thrice as much, viz. at the rate of 4386 feet in an hour, or 73 feet in a minute. And if the ventricle throws out one ounce in a pulse, then in the 75 pulses of a minute, the quantity of blood will be equal to 4.4lb. 11oz. and, in 34 minutes, a quantity equal to a middle-sized man, viz. 158 lb. will pass through the heart. But if, with Dr. Harvey and Dr. Lower, we suppose two ounces of blood; that is, 3.276 cubic inches, to be thrown out at each systole of the ventricle, then the velocity of the blood in entering the orifice of the aorta will be double the former, viz. at the rate of 146 feet in a minute, and a quantity of blood equal to the weight of a man's body will pass in half the time, viz. 17 minutes.

If we suppose, what is probable, that the blood will rise $7 + \frac{1}{2}$ feet high in a tube fixed to the carotid artery of a man, and that the inward area of the left ventricle of his heart is equal to 15 square inches, these multiplied into $7 + \frac{1}{2}$ feet, give 1350 cubic inches of blood, which presses on that ventricle, when it first begins to contract, a weight equal to 15.5 pounds.

What the doctor thus calculates, from supposition, with regard to mankind, he actually submitted to experiment in horses, dogs, fallow-does, &c. by fixing tubes in orifices opened in their veins and arteries; by observing the several heights to which the blood rose in these tubes, as they lay on the ground; and by measuring the capacities of the ventricles of the heart and orifices of the arteries. And, that the reader may the more readily compare the said estimates together, he has given a table of them, ranged in the following order.

The several animals.	Weight of each.	Height of the blood in the tube from the jugular vein.	Height of the blood in tubes fixed to arteries.	Capacity of the left ventricle of the heart.	Area of the orifice of the aorta.	Velocity of the blood in the aorta.	Quantities of blood equal to the weight of the animal, in what time.	How much in a minute.	Weight of the blood sustained by the left ventricle contracting.	No. of pulses in a minute.	Area of transverse section of descending aorta.	Area of the transverse section of ascending aorta.
	Pounds. Ounces.	Inches.	Feet. Inches.	Cubic inches.	Square inches.	Feet and inches in a minute.	Minutes.	Pounds.	Pounds.		Square inches.	Square inches.

HEART-burn, a disease usually called *cardialgia* by physicians. In surfeits, or upon swallowing without due mastication; when meats are eat tough and fat, or with farinaceous substances unfermented; or when by any accident the saliva is not intimately mixed with the food, the stomach swells with air; and this extraordinary commotion being attended with an unusual heat, brings on the uneasiness called the *heart-burn*; which is remedied by whatever promotes a greater secretion of saliva, or helps to mix it with our aliment. Magnesia, or the testaceous powders, as oyster-shells, crabs eyes, chalk, &c. are the usual remedies for this complaint.

HEARTH, that part of the floor or pavement of a room on which the fire is immediately placed.

HEARTH-Money. See *CHIMNEY-Money*.

HEAT, the opposite to cold, being a relative term denoting the property of fire, or of those bodies we denominate hot; being in us a sensation excited by the action of fire. See *CHEMISTRY*, p. 372, 373, &c. Heat, as it exists in the hot body, or that which constitutes and denominates a body hot, and enables it to produce such effects on our organs, is variously considered by the philosophers; some making it a quality, others a substance, and others only a mechanical affection. The former principle is laid down by Aristotle and the Peripatetics. While the Epicureans, and other corpuscularians, define heat not as an accident of fire, but as an essential power or property of it, the same in reality with it, and only distinguished from it in the manner of our conception. So that heat, on their principles, is no other than the volatile substance of fire itself, reduced into atoms, and emitted in a continual stream from ignited bodies; so as not only to warm the objects within its reach, but also, if they be inflammable, to kindle them, turn them into fire, and conspire with them to make flame. In effect, these corpuscles, say they, flying off from the ignited body, constitute fire while yet contained within the sphere of its flame; but when fled, or got beyond the same, and dispersed every way, so as to escape the apprehension of the eye, and only to be perceived by the feeling, they take the denomination of heat, inasmuch as they excite in us that sensation. The Cartesians, improving on this doctrine, assert that heat consists in a certain motion of the insensible particles of a body, resembling the motion by which the several parts of our body are agitated by the motion of the heart and blood.

Our latest and best writers of mechanical, experimental, and chemical philosophy, differ very considerably about heat. The chief difference is, whether it be a peculiar property of one certain immutable body, called fire, or phlogiston, or electricity; or whether it may be produced mechanically in other bodies, by inducing an alteration in their particles. The former tenet, which is as ancient as Democritus, and the system of atoms, had given way to that of the Cartesians, and other mechanists; but is now with great address retrieved, and improved on, by some of the latest writers, particularly Homburg, the younger Lemery, Gravefande, Boerhaave in his lectures on fire, Black, Crawford, and other chemical philosophers.

The thing called fire, according to Boerhaave, is a body sui generis, created such ab origine, unalterable in its nature and properties, and not either producible de novo from any other body, nor capable of being reduced into any other body, or of ceasing to be fire. This fire, he contends, is diffused equably every where, and exists alike, or in equal quantity, in all the parts of space, whether void, or possessed by bodies; but that naturally, and in itself, it is perfectly latent and imperceptible; being only discovered by certain effects which it produces, and which are cognizable by our senses. These effects are heat, light, colour, rarefaction, and burning, which are all indications of fire, as being none of them producible by any other cause: so that wherever we observe any of these, we may safely infer the

action and presence of fire. But though the effect cannot be without the cause, yet the fire may remain without any of these effects; any, we mean, gross enough to affect our senses, or become objects of them: and this, he adds, is the ordinary case; there being a concurrence of other circumstances, which are often wanting, necessary to the production of such sensible effects.

The mechanical philosophers, particularly Bacon, Boyle, and Newton, conceive otherwise of Heat; considering it not as an original inherent property of any particular sort of body; but as mechanically producible in any body. The former, in an express treatise *De Forma Calidi*, from a particular enumeration of the several phenomena and effects of heat, deduces several general properties of it; and hence he defines heat, an expansive undulatory motion in the minute particles of the body; by which they tend, with some rapidity, towards the circumference, and at the same time incline a little upwards.

Mr. Boyle, in a Treatise on the Mechanical Origin of Heat and Cold, strongly supports the doctrine of the producibility of heat, with new observations and experiments; as in the instance of a smith briskly hammering a small piece of iron, which, though cold before, soon becomes exceedingly hot.

This system is also farther supported by Newton, who does not conceive fire as any particular species of body, originally endued with such and such properties. Fire, according to him, is only a body much ignited, that is heated hot, so as to emit light copiously: what else, says he, is red-hot iron but fire? and what else is a burning charcoal but red-hot wood? or flame itself, but red-hot smoke? It is certain that flame is only the volatile part of the fuel heated red-hot, i. e. so hot as to shine; and hence only such bodies as are volatile, that is, such as emit a copious fume, will flame; nor will they flame longer than they have fume to burn. In distilling hot spirits, if the head of the still be taken off, the ascending vapours will catch fire from a candle, and turn into a flame. And in the same manner several bodies, much heated by motion, attrition, fermentation, or the like, will emit lucid fumes, which, if they be copious enough, and the heat sufficiently great, will be flame; and the reason why fused metals do not flame, is the smallness of their fume; this is evident, because spelter, which fumes most copiously, does likewise flame. Add, that all flaming bodies, as oil, tallow, wax, wood, pitch, sulphur, &c. by flaming, waste and vanish into burning smoke. And do not all fixed bodies, when heated beyond a certain degree, emit light, and shine? and is not this emission performed by the vibrating motion of their parts? and do not all bodies, which abound with terrestrial and sulphureous parts, emit light as often as those parts are sufficiently agitated; whether that agitation be made by external fire, or by friction, or percussion, or putrefaction, or by any other cause? Thus, sea water, in a storm; quicksilver agitated in vacuo; the back of a cat, or the neck of a horse, obliquely rubbed in a dark place; wood, flesh, and fish, while they putrefy; vapours from putrefying waters, usually called *ignes fatni*; stacks of moist hay or corn; glow-worms; amber and diamonds by rubbing; fragments of steel struck off with a flint, &c. all emit light. Are not gross bodies and light convertible into one another? and may not bodies receive much of their activity from the particles of light which enter their composition? I know no body less apt to shine than water; and yet water, by frequent distillations, changes into fixed earth, which, by a sufficient heat, may be brought to shine like other bodies.

Add, that the sun and stars, according to Newton's conjecture, are no other than great earths vehemently heated: for large bodies, he observes, preserve their heat the longest, their parts heating one another; and why may not great, dense, and fixed bodies, when heated beyond a certain degree, emit light so copiously, as by the emission and reaction of it, and the

reflections and refractions of the rays within the pores, to grow still hotter, till they arrive at such a period of heat as is that of the sun? Their parts also may be farther preserved from summing away, not only by their fixity, but by the vast weight and density of their atmospheres incumbent on them, thus strongly compressing them, and condensing the vapours and exhalations arising from them. Hence we see warm water, in an exhausted receiver, shall boil as vehemently as the hottest water open to the air: the weight of the incumbent atmosphere, in this latter case, keeping down the vapours, and hindering the ebullition, till it has conceived its utmost degree of heat. So also a mixture of tin and lead, put on a red-hot iron in vacuo, emits a fume and flame; but the same mixture in the open air, by reason of the incumbent atmosphere, does not emit the least sensible flame.

Thus much for the system of the producibility of heat.

On the other hand, M. Homberg, in his *Essai du Soufre Principe*, holds, that the chemical principle or element, sulphur, which is supposed one of the simple, primary, pre-existent ingredients of all natural bodies, is real fire; and consequently that fire is co-eval with body. *Mem. de l'Acad. an. 1705.*

Dr. Gravesande goes upon much the same principle. According to him, fire enters the composition of all bodies, is contained in all bodies, and may be separated or procured from all bodies, by rubbing them against each other, and thus putting their fire in motion. But fire, he adds, is by no means generated by such motion. *Elem. Phys. tom. 2, cap. 1.* Heat, in the hot body, he says, is an agitation of the parts of the body, made by means of the fire contained in it; by such agitation a motion is produced in our bodies, which excites the idea of heat in our minds: so that heat, in respect of us, is nothing but that idea, and in the hot body nothing but motion. If such motion expel the fire in right lines, it may give us the idea of light; if in a various and irregular motion, only of heat.

Lemery, the younger, agrees with these two authors, in asserting this absolute and ingenerable nature of fire; but he extends it farther. Not contented with confiding it as an element to bodies, he endeavours to shew, that it is equally diffused through all space: that it is present in all places, even in the void spaces between the bodies, as well as in the insensible interstices between their parts. And this last sentiment falls in with that of Boerhaave above delivered. *Mem. de l'Acad. an. 1713.*

Philosophers have lately distinguished heat into absolute, and sensible. By absolute heat, or fire, they mean that power or element which, when it is in a certain degree, excites in animals the sensation of heat; and by sensible heat, the same power considered in its relation to the effects which it produces: thus, two bodies are said to have equal quantities of sensible heat, when they produce equal effects upon the mercury in the thermometer; but as bodies of different kinds have different capacities for containing heat, the absolute heat in such bodies will be different, though the sensible heat be the same. Thus, a pound of water and a pound of antimony, of the same temperature, have equal sensible heat; but the former contains a much greater quantity of absolute heat than the latter.

M. De Luc has evinced, by a variety of experiments, that the expansions of mercury between the freezing and boiling points of water, correspond precisely to the quantities of absolute heat applied, and that its contractions are proportionable to the diminution of this element within these limits. And from hence it may be inferred, that if the mercury were to retain its fluid form, its contractions would be proportionable to the decrements of the absolute heat, though the diminution were continued to the point of total privation. But the comparative quantities of absolute heat, which are communicated to different bodies, or separated from them, cannot be determined in a direct manner by the thermometer.

Some philosophers have apprehended that the quantities of absolute heat in bodies, are in proportion to their densities. While others, as Boerhaave, imagined that heat is equally diffused through all bodies, the densest as well as the rarest, and therefore that the quantities of heat in bodies are in proportion to their bulk or magnitude: and, at his desire, Fahrenheit attempted to determine the fact by experiment. For this purpose, he took equal quantities of the same fluid, and gave them different degrees of heat; then, upon mixing them intimately together, he found that the temperature of the mixture was a just medium, or arithmetical mean, between the two. But if this experiment be made with water and mercury, in the same circumstances, viz. in equal bulks, the result will be different, as the temperature of the mixture will not be a mean between the two, but always nearer to that of the water than to the quicksilver; so that, when the water is the hotter, the temperature of the mixture is above the mean, and below it when the water is the colder. And from experiments of this kind it has been inferred, that the comparative quantities of the absolute heats of these fluids, are reciprocally proportional to the changes which are produced in their sensible heats, when they are mixed together at different temperatures: and this fact has been publicly taught, for several years, by Dr. Black, and Dr. Irvine, in the universities of Edinburgh and Glasgow. This rule, however, does not apply to those substances which, in mixture, excite sensible heat by chemical action.

From the experiments and reasoning employed by Dr. Crawford, it more fully appears, that the quantities of absolute heat in different bodies, are not as their densities; or that equal weights of heterogeneous substances, as air and water, having the same temperature, may contain unequal quantities of absolute heat: he also shews, that if phlogiston be added to a body, a quantity of the absolute heat of that body will be extricated; and if the phlogiston be separated again, an equal quantity of heat will be absorbed. So that heat and phlogiston appear to be two opposite principles in nature. But this ingenious writer has not presumed absolutely to decide the question that has been long agitated, whether heat be a substance or a quality.—He inclines to the former opinion however, and observes, that if we adopt the opinion, that heat is a distinct substance, or an element sui generis, the phenomena will be found to admit of a simple and obvious interpretation, and to be perfectly agreeable to the analogy of nature. See Crawford's *Experiments and Observations on Animal Heat and the Inflammation of Combustible Bodies.*

Animal HEAT. The heat of animals is very various, both according to the variety of their kinds, and the difference of the seasons: accordingly, zoologists have divided them into hot and cold blooded, reckoning those to be hot that are near or above our own temperature, and all others cold whose heat is below ours, and consequently affect us with the sense of cold; thus making the human species a medium between the hot and cold blooded animals, or at least the lowest order of the hot blooded.

The heat of the human body, in its natural state, according to Dr. Boerhaave, is such as to raise the mercury in the thermometer to 92° or at most to 94°; and Dr. Piteairn makes the heat of the human skin the same. Indeed it is evident that different parts of the human body, and its different states, as well as the different seasons, will make it shew of different temperatures. Thus, by various experiments at different times, the heat of the human body is made various by the following authors:

Boerhaave and Piteairn	-	-	92°
Amontons	-	-	91, 92, or 93
Sir Isaac Newton	-	-	95½
Fahrenheit and Musschenbroek, the blood,	-	-	96
Dr. Martine, the skin	-	-	97, or 98
—————, the urine	-	-	99

shows, that in the process of inflammation a very great quantity of heat is derived from the air. But, on the contrary, no part of the heat can be derived from the combustible body; because this body, during the inflammation, being deprived of its phlogiston, undergoes a change similar to that of the blood by the process of respiration, in consequence of which its capacity of containing heat is increased; and therefore it will not give off any part of its absolute heat, but, like the blood in its passage through the lungs, it will absorb heat.

A similar theory of heat has lately been published by Mr. Elliot. See his *Philosophical Observations on the Senses of Vision and Hearing*; to which is added, an *Essay on Combustion and Animal Heat*, 8vo, 1780.

HEAT, in geography, is that which relates to the earth. There is a great variety in the heat of different places and seasons. Naturalists have commonly laid it down, that the nearer any place is to the centre of the earth, the hotter it is found: but this does not hold strictly true; and if it were, the effect might be otherwise accounted for, and more satisfactorily, than from their imagined central fire.

Mr. Boyle, who had been at the bottom of some mines himself, with more probability suspects that this degree of heat, at least in some of them, may arise from the peculiar nature of the minerals there produced. And he instances a mineral of the vitriolic kind, dug up in large quantities, in several parts of England, which, by the bare affusion of common water, will grow so hot as almost to take fire. To which may be added, that such places, in the bowels of the earth, usually feel hot, from the confined and stagnant state of the air in them, in which the heat is retained, through the want of a current or change of air to carry the heat off.

On the other hand, on ascending high mountains, the air grows more and more cold and piercing. Thus, the tops of the Pike of Teneriffe, the Alps, and several other mountains, even in the most sultry countries, are found always invested with snow and ice, which the heat is never sufficient to thaw. In some of the mountains of Peru there is no such thing as running water, but all ice: plants vegetate a little about the bottom of the mountains, but near the top no vegetable can live, for the intenseness of the cold. This effect is attributed to the thinness of the air, and the little surface of the earth there is to reflect the rays, as well as the great distance of the general surface of the earth which reflects the rays back into the atmosphere.

As to the diversity in the heat of different climes and seasons, it arises from the different angles under which the sun's rays strike upon the surface of the earth. In the *Philos. Trans.* Abr. vol. 2, p. 165, Dr. Halley has given a computation of this heat, on the principle, that the simple action of the sun's rays, like other impulses or strokes, is more or less forcible, according to the sines of the angles of incidence, or to the sines of the sun's altitudes, at different times or places.

Hence it follows, that, the time of continuance, or the sun's shining on any place, being taken for a basis, and the sines of the sun's altitudes perpendicularly erected upon it, and a curve line drawn through the extremities of those perpendiculars, the area thus comprehended will be proportional to the collection of all the heat of the sun's beams in that space of time.

Hence it will likewise follow, that, at the pole, the collection of all the heat of a tropical day, is proportional to the rectangle or product of the sine of $23\frac{1}{2}$ degrees in 24 hours, or the circumference of a circle, or as $\frac{8}{5}$ into 12 hours, the sine of $23\frac{1}{2}$ degrees being nearly $\frac{4}{5}$ of radius. Or the polar heat will be equal to that of the sun continuing 12 hours above the horizon at 53 degrees height; and the sun is not 5 hours more elevated than this under the equinoctial.

But as it is the nature of heat to remain in the subject, after

the luminary is removed, and particularly in the air, under the equinoctial the 12 hours absence of the sun abates but little from the effect of his heat in the day; but under the pole, the long absence of the sun for 6 months has so chilled the air, that it is in a manner frozen; and after the sun has risen upon the pole again, it is long before his beams can make any impression, being obstructed by thick clouds and fogs.

From the foregoing principle Dr. Halley computes the following table, exhibiting the heat to every 10th degree of latitude, for the equinoctial and tropical sun, and from which an estimate may easily be made for the intermediate degrees.

Lat.	Sign that the Sun is in.		
	Υ or \sphericalangle	ϱ	ϑ
0	20000	18341	18341
10	19696	20290	15834
20	18794	21737	13166
30	17321	22651	10124
40	15321	23048	6944
50	12855	22991	3798
60	10000	22773	1075
70	6840	23543	0
80	3473	24673	0
90	0	25055	0

From the same principles, and table, also are deduced the following corollaries, viz.

1. That the equatorial heat, when the sun becomes vertical, is as twice the square of the radius.—2. That, at the equator, the heat is as the sine of the sun's declination.—3. That, in the frigid zones, when the sun sets not, the heat is as the circumference of a circle into the sine of the altitude at 6: and consequently that, in the same latitude, these aggregates of heat are as the sines of the sun's declination; and at the same declination of the sun, they are as the sines of the latitudes; and generally they are as the sines of the latitudes into the sines of declination.—4. That the equatorial day's heat is everywhere as the cosine of the latitude.—5. In all places where the sun sets, the difference between the summer and winter heats, when the declinations are contrary, is equal to a circle into the sine of the altitude at 6, in the summer parallel; and consequently those differences are as the rectangles of the sines of the latitude and declination.—6. The tropical sun has the least force of any at the equator; and at the pole it is greatest of all.

Many objections have been urged against this theory of Dr. Halley. Some have objected, that the effect of the sun's heat is not in the simple, but in the duplicate ratio of the sines of the angles of incidence; like the law of the impulse of fluids. And indeed, the quantity of the sun's direct rays received at any place, being evidently as the sine of the angle of incidence, or of the sun's altitude, if the heat be also proportional to the force with which a ray strikes, like the mechanical action or impulse of any body, then it will follow that the heat must be in the compound ratio of both, that is, as the square of the sine of the sun's altitude. But this last principle is here only assumed gratis, as we do not know a priori that the heat is proportional to the force of a striking body; and it is only experiment that can determine this point.

It is certain that heat communicated by the sun to bodies on the earth, depends also much upon other circumstances beside the direct force of his rays. These must be modified by our atmosphere, and variously reflected and combined by the action of the earth's surface itself, to produce any remarkable effects of heat. So that if it were not for these additional circum-

stances, it is probable the naked heat of the sun would not be very sensible.

Dr. Halley himself was well apprised, that many other circumstances, besides the direct force of the sun's rays, contributed to augment or diminish the effect of this, and the heat resulting from it, in different climates; and therefore no calculation, formed on the preceding theory, can be supposed to correspond exactly with observation and experiment. It has also been objected, that, according to the foregoing theory, the greatest heat in the same place should be at the summer solstice, and the most extreme cold at the winter solstice; which is contrary to experience. To this objection it may be replied, that heat is not produced in bodies by the sun instantaneously, nor do the effects of his heat cease immediately when his rays are withdrawn; and therefore those parts which are once heated, retain the heat for some time; which, with the additional heat daily imparted, makes it continue to increase, though the sun declines from us: and this is the reason why July is hotter than June, although the sun has withdrawn from the summer tropic; as we also find it is generally hotter at one, two, or three in the afternoon, when the sun has declined towards the west, than at noon, when he is on the meridian. As long as the heating particles, which are constantly received, are more numerous than those which fly away or lose their force, the heat of bodies must continually increase. So, after the sun has left the tropic, the number of particles, which heat our atmosphere and earth, constantly increases, because we receive more in the day than we lose at night, and therefore our heat must also increase. But as the days decrease again, and the action of the sun becomes weaker, more particles will fly off in the night-time than are received in the day, by which means the earth and air will gradually cool. Farther, those places which are well cooled, require time to be heated again; and therefore January is mostly colder than December, although the sun has withdrawn from the winter tropic, and begun to emit his rays more perpendicularly upon us.

But the chief cause of the difference between the heat of summer and winter is, that in summer the rays fall more perpendicularly, and pass through a less dense part of the atmosphere; and therefore with greater force, or at least in greater number in the same place: and besides, by their long continuance, a much greater degree of heat is imparted by day than can fly off by night.

For the calculations and opinions of several other philosophers on this head, see Keill's *Astron.* lect. 8; Ferguson's *Astron.* ch. 10; Long's *Astron.* § 777; Mem. Acad. Scienc. 1719.

As to the temperature or heat of our atmosphere, it may be observed, that the mercury seldom falls under 16° in Fahrenheit's thermometer; but we are apt to reckon it very cold at 24° , and it continues coldish to 40° and a little above. However, such colds have been often known as bring it down to 0° , the beginning of the scale, or nearly the cold produced by a mixture of snow and salt, often near it, and in some places below it. Thus, the degree of the thermometer has been observed at various times and places as follows:

Places.	Latit.	Year.	Thermom.
Pennsylvania	$40^{\circ} 0'$	1732	5°
Paris	$48 50$	1709 & 1710	8
Leyden	$52 10$	1729	5
Utrecht	$52 8$	—	4
London	$51 31$	1709 & 1710	0
Copenhagen	$55 43$	1709	0
Upsal	$59 56$	1732	—1
Petersburg	$59 56$	—	—28
Torneo	$65 51$	1736-7	—33
Hudson's Bay	$52 24$	1775	—37

The middle temperature of our atmosphere is about 48° , being nearly a medium of all the seasons. The French make it somewhat higher, reckoning it equal to the cave of their royal observatory, or 53° . In cold countries, the air is found agreeable enough to the inhabitants while it is between 40 and 50° . In our climate we are best pleased with the heat of the air from 50 to 60° ; while in the hot countries the air is generally at a medium about 70° . With us, the air is not reckoned warm till it arrives at about 64° , and it is very warm and sultry at 80° . It is to be noted, that the foregoing observations are to be understood of the state of the air in the shade; for as to the heat of bodies acted upon by the direct rays of the sun, it is much greater: thus, Dr. Martine found dry earth heated to above 120° ; but Dr. Hales found a very hot sun shine heat in 1727 to be about 140° ; and Musschenbroek once observed it so high as 150° ; but at Montpellier the sun was so very hot, on one day in the year 1705, as to raise M. Amontons's thermometer to the mark of boiling water itself, which is our 212° .

It appears from the register of the thermometer kept at London by Dr. Heberden for 9 years, viz. from the end of 1763 to the end of 1772, that the mean heat at 8 in the morning was $47^{\circ} 4$; and by another register kept at Hawkhill, near Edinburgh, that the mean heat in that place, during the same period of time, was 46° . Also by registers kept in London and at Hawkhill, for the three years 1772, 1773, 1774, it appears that the mean heat of these three years in London, at 8 in the morning, was $48^{\circ} 5$, and at 2 in the afternoon 56° , but the mean of both morning and afternoon $52^{\circ} 2$; while the mean heat at Hawkhill for the same time,

at 8 in the morning, was	$45^{\circ} 4$
and at 2 in the afternoon	$50^{\circ} 1$
and the mean of both	$47^{\circ} 7$.

The mean heat of springs near Edinburgh seems to be 47° , and at London 51° . *Philos. Transf.* vol. 65, art. 44.

Lastly, from the meteorological journals of the Royal Society, published in the *Philos. Transf.* it appears that the mean heights of the thermometer, for the whole years, kept without and within the house, are as below:

	Therm. Without	Therm. Within
For 1775	$51^{\circ} 5$	$52^{\circ} 7$
1776	$51^{\circ} 1$	$52^{\circ} 9$
1777	$51^{\circ} 0$	$53^{\circ} 0$
1778	$52^{\circ} 0$	$53^{\circ} 1$
mean of all	$51^{\circ} 4$	$52^{\circ} 9$

HEATH, in botany. See ERICA.

Berry-bearing HEATH. See EMPETRUM.

HEATH (James), an English historian, was born 1629 at London; where his father, who was the king's cutler, lived. He was educated at Westminster-school, and became a student of Christ-church, Oxford, in 1646. In 1648 he was ejected from thence by the parliament visitors for his adherence to the royal cause; lived upon his patrimony till it was almost spent; and then marrying, was obliged to write books and correct the press in order to maintain his family. He died of a consumption and dropsy at London in August 1664, and left several children to the parish. His principal publications were, 1. A brief Chronicle of the late Intestine War in the Three Kingdoms of England, Scotland, and Ireland, &c. 1661, 8vo; afterwards enlarged by the author, and completed from 1637 to 1663, in four parts, 1663, in a thick 8vo. To this was again added a continuation from 1663 to 1675 by John Philips, nephew by the mother to Milton, 1676, folio. 2. Flagellum: or, the Life and Death, Birth and Burial, of Oliver Cromwell, the late Usurper, 1663. The third edition came out with additions in

1665, 8vo. 3. A New Book of Loyal English Martyrs and Confessors, who have endured the Pains and Terrors of Death, Arraignment, &c. for the Maintenance of the just and legal Government of these Kingdoms both in Church and State, 1663, 12mo. The reason why such writers as our author continue to be read, and will probably always be read, is not only because *Historia quoquo modo scripta deletat*; but also because in the meanest historian there will always be found some facts, of which there will be no cause to doubt the truth, and which yet will not be found in the best. Thus Heath, who perhaps had nothing but pamphlets and newspapers to compile from, frequently relates facts that throw light upon the history of those times, which Clarendon, though he drew every thing from the most authentic records, has omitted.

HEATH (Thomas), an alderman of Exeter, and father of John Heath, Esq; one of the Judges of the Common Pleas, was author of An Essay towards a new English Version of the book of Job from the original Hebrew, with some account of his Life, 1755, 8vo. His brother Benjamin, a lawyer of eminence, and town clerk of Exeter, was likewise an author; and wrote, 1. An Essay towards a demonstrative Proof of the Divine Existence, Unity, and Attributes; to which is premised, A short Defence of the Argument commonly called *a priori*, 1740. 2. The Case of the County of Devon with respect to the Consequences of the New Excise Duty on Cyder and Perry. Published by the direction of the Committee appointed at a General Meeting of that County to superintend the Application for the Repeal of that Duty, 1763, 4to. 3. *Notæ sive Lectiones ad Tragicorum Græcorum veterum, Æschyli, &c.* 1752, 4to; a work which places the author's learning and critical skill in a very conspicuous light. The same solidity of judgment apparent in the preceding, distinguished the author's last production. 4. A Revival of Shakespeare's Text, wherein the alterations introduced into it by the more modern editors and critics are particularly considered, 1765, 8vo.

HEATHENS, in matters of religion. See PAGANS.

HEAVEN, an azure transparent orb investing our earth, where the celestial bodies perform their motions. It is of various denominations, as the highest or empyrean Heaven, the ethereal or starry Heaven, the planetary Heaven, &c. Formerly the Heavens were considered as solid substances, or else as spaces full of solid matter; but Newton has abundantly shown that the Heavens are void of almost all resistance, and consequently of almost all matter: this he proves from the phenomena of the celestial bodies; from the planets persisting in their motions, without any sensible diminution of their velocity; and the comets freely passing in all directions towards all parts of the Heavens. Heaven, taken in this general sense, or the whole expanse between our earth and the remotest regions of the fixed stars, may be divided into two very unequal parts, according to the matter occupying them; viz. the atmosphere or aerial Heaven, possessed by air; and the ethereal Heaven, possessed by a thin and unresisting medium, called ether.

HEAVEN is more particularly used, in Astronomy, for an orb, or circular region, of the ethereal Heaven. The ancient astronomers assumed as many different Heavens as they observed different celestial motions. All these they made solid, thinking they could not otherwise sustain the bodies fixed in them; and of a spherical form, as being the most proper for motion. Thus they had seven Heavens for the seven planets; viz. the Heavens of the Moon, Mercury, Venus, the Sun, Mars, Jupiter, and Saturn. The 8th was for the fixed stars, which they particularly called the firmament. Ptolemy added a 9th Heaven, which he called the primum mobile. After him two crystalline Heavens were added by king Alphonsus, &c. to account for some irregularities in the motions of the other Heavens. And lastly an empyrean Heaven was drawn over the whole for the residence

of the Deity; which made the number 12. But others admitted many other Heavens, according as their different views and hypotheses required. Eudoxus supposed 23, Calippus 30, Regiomontanus 33, Aristotle 47, and Fracastor no less than 70. The astronomers however did not much concern themselves whether the Heavens they thus allowed, were real or not; provided they served a purpose in accounting for any of the celestial motions, and agreed with the phenomena.

HEBDOMADARY, HEBDOMADARIUS, or HEBDOMADIUS, a member of a chapter or convent, whose week it is to officiate in the choir, to rehearse the anthems and prayers, and to perform the usual functions which the superiors perform at solemn feasts, and on other extraordinary occasions. The word is formed of the Greek ἑβδομας, which signifies the number seven; of ἑβρα, seven. The hebdomadary generally collates to the benefices which become vacant during his week; though it is usually looked upon as an abuse. In cathedrals, the hebdomadary was a canon or prebendary, who had the peculiar care of the choir, and the inspection of the officers for his week. In monasteries, the hebdomadary is he who waits at table for a week, or other stated period; directs and assists the cook, &c.

HEBDOME, a solemnity of the ancient Greeks, in honour of Apollo, in which the Athenians sung hymns to his praise, and carried in their hands branches of laurel. The word signifies the *seventh day*, this solemnity being observed on the seventh day of every lunar month.

HEBE, in ancient mythology, a goddess, the idea of whom, among the Romans, seems to have been much the same with that of eternal youth, or an immortality of bliss; agreeably to which, she is represented, on a gem in the great duke's collection at Florence, with a young airy look, and drinking out of a little bowl; or, according to Milton's expression, "Quaffing immortality and joy." She is fabled to have been a daughter of Jupiter and Juno. According to some she was the daughter of Juno only, who conceived her after eating lettuces. As she was fair and always in the bloom of youth, she was called the goddess of youth, and made by her mother cup-bearer to all the gods. She was dismissed from her office by Jupiter, because she fell down in an indecent posture as she was pouring nectar to the gods at a grand festival; and Ganymedes, the favourite of Jupiter, succeeded her as cup-bearer. She was employed by her mother to prepare her chariot, and to harness her peacocks whenever requisite. When Hercules was raised to the rank of a god, he was reconciled to Juno by marrying her daughter Hebe, by whom he had two sons, Alexiars and Anicetus. As Hebe had the power of restoring gods and men to the vigour of youth, she, at the instance of her husband, performed that kind office to Iolaus his friend. Hebe was worshipped at Sicyon under the name of Dia, and at Rome under that of Juventas.

HEBENSTRETTIA, in botany; a genus of the angiosperma order, belonging to the didynamia class of plants; and in the natural method ranking under the 48th order, *aggregata*. The calyx is emarginated, and divided below; the corolla unilabiate; the lip rising upwards, and quadrid; the capsule dispersing; the stamina inserted into the margin of the limb of the corolla.

HEBER, the son of Salah, and father of Peleg, from whom the Hebrews derived their name, according to Josephus, Eusebius, Jerome, Bede, and most of the interpreters of the sacred writings; but Huet bishop of Avranches, in his Evangelical Demonstration, has attempted to prove, that the Hebrews took their name from the word *heber*, which signifies *beyond*, because they came from beyond the Euphrates. Heber is supposed to have been born 2281 years B. C. and to have lived 464 years.

HEBRAISM, an idiom, or manner of speaking, peculiar to the Hebrew language. See the next article.

HEBREW, something relating to the Hebrew. See HEBREWS. Thus we say, HEBREW Bible. See BIBLE.

HEBREW Character. There are two kinds of Hebrew characters: the ancient, called also the *square*; and the modern, or rabbinical characters.

1. The square Hebrew takes its denomination from the figure of its characters, which stand more square, and have their angles more exact and precise than the other. This character is used in the text of holy scripture, and their other principal and most important writings. When both this and the rabbinical character are used in the same work, the former is for the text, or the fundamental part; and the latter for the accessory part, as the gloss, notes, commentaries, &c. The best and most beautiful characters of this kind, are those copied from the characters in the Spanish manuscripts; next, those from the Italian manuscripts; then those from the French; and lastly, those of the Germans, whose characters are much the same, with respect to the other genuine square Hebrew characters, that the Gothic or Dutch characters are with respect to the Roman.

Several authors contend, that the square character is not the real ancient Hebrew character, written from the beginning of the language to the time of the Babylonish captivity; but that it is the Assyrian, or Chaldee character, which the Jews assumed, and accustomed themselves to, during the captivity, and retained afterwards. They say, that the Jews, during their captivity, had quite disused their ancient character; so that Ezra found it necessary to have the sacred books transcribed into the Chaldean square character. These authors add, that what we call the Samaritan character, is the genuine ancient Hebrew. Of this opinion are Scaliger, Bochart, Casaubon, Vossius, Grotius, Walton, Capellus, &c. and among the ancients Jerome and Eusebius. On this side it is urged, that the present characters are called Assyrian by the ancient Jewish writers of the Talmud, and therefore must have been brought from Assyria; but to this argument it is replied, that there were two sorts of characters anciently in use, viz. the sacred or present square character, and the profane or civil, which we call Samaritan; and that the sacred is called Assyrian, because it first began in Assyria to come into common use. It is farther alleged, that the Chaldee letters, which the Jews now use, were unknown to the ancient Jews before the captivity, from Dan. i. 4. Moreover, it is inferred from 2 Kings, xvii. 28, whence we learn that a Jewish priest was sent to teach the Samaritans the worship of Jehovah; on which occasion he must have taught them the law; and yet no mention occurs of his teaching them the language or character that the law was then written in, the character which the Samaritans used. But the chief argument is taken from some ancient Jewish shekels, with a legend on one side "The shekel of Israel," and on the other "Jerusalem the holy," both in Samaritan characters. These shekels, it is said, must have been coined before the division of the two kingdoms of Judah and Israel, or at least before the Assyrian captivity, because the Samaritans never afterwards reckoned Jerusalem holy. On the other side, or for the primitive antiquity of the square character, are the two Buxtorfs, Leusden, Calovius, Hottinger, Spanheim, Lightfoot, &c. They urge, from Matthew v. 18. that *jod* is really the least of the consonants in the present Hebrew, whereas it is one of the largest characters in the Samaritan alphabet: but Walton replies, that if our Saviour here speaks of the least letter of the alphabet, we can only infer, that the Chaldee character was used in our Saviour's time, which is not denied by those who maintain the Samaritan to be the original. They also allege, that the Jews were too obstinate and superstitious to allow their sacred character to be altered; but if this was done under the direction and authority of Ezra, the argument will be much invalidated. Farther, they say that Ezra

could not alter the ancient character, because it was impossible to make the alterations in all their copies. This argument, however, is contradicted by fact; since the old English black letter is actually changed for the Roman. They say, likewise, that Ezra was not disposed to profane the sacred writings with a heathen character: but this supposes that Ezra was so superstitious as to imagine, that there was some peculiar sanctity in the shape of the letters. Moreover, the advocates for this opinion appeal to ancient coins found in Judæa, with a legend in the Chaldee or Assyrian character. But the genuineness of these coins is much suspected.

The learned Jesuit Souciet maintains, with great address, that the ancient Hebrew character is that found on the medals of Simon, and others, commonly called *Samaritan medals*; but which, he asserts, were really Hebrew medals, struck by the Jews, and not the Samaritans.

Buxtorf endeavours to reconcile these two opinions, by producing a variety of passages from the rabbies to prove that both these characters were anciently used; the present square character being that in which the tables of the law, and the copy deposited in the ark, were written; and the other character being used in the copies of the law which were written for private and common use, and in civil affairs in general; and that after the captivity, Ezra enjoined the former to be used by the Jews on all occasions, leaving the latter to the Samaritans and apostates. But it can hardly be allowed by any who consider the difference between the Chaldee and Samaritan characters, with respect to convenience and beauty, that they were ever used at the same time. After all, it is of no great moment which of these, or whether either of them, were the original characters; since it appears, that no change of the words has arisen from the manner of writing them, because the Samaritan and Jewish Pentateuch almost always agree after so many ages. It is most probable that the form of these characters has varied in different periods; this appears from the testimony of Montfaucon, in his *Hexapla Origenis*, vol. i. p. 22. &c. and is implied in Dr. Kennicot's making the characters in which manuscripts are written one test of their age.

2. The modern, or rabbinical, is a good neat character, formed of the square Hebrew, by rounding it, and retrenching most of the angles or corners of the letters, to make it the more easy and flowing. The letters used by the Germans are very different from the rabbinical character used every where else, though all formed alike from the square character, but the German in a more slovenly manner than the rest. The rabbins frequently make use either of their own, or the square Hebrew character, to write the modern languages in. There are even books in the vulgar tongues printed in Hebrew characters; instances whereof are seen in the late French king's library.

HEBREW Language, that spoken by the Hebrews, and wherein the Old Testament is written. This appears to be the most ancient of all the languages in the world, at least we know of none older; and some learned men are of opinion, that this is the language in which God spoke to Adam in Paradise. Dr. Sharpe adopts the opinion that the Hebrew was the original language; not indeed that the Hebrew is the unvaried language of our first parents, but that it was the general language of men at the dispersion; and however it might have been improved and altered from the first speech of our first parents, it was the original of all the languages, or almost all the languages, or rather dialects, that have since arisen in the world.

The books of the Old Testament are the only pieces to be found, in all antiquity, written in pure Hebrew; and the language of many of these is extremely sublime: it appears perfectly regular, and particularly so in its conjugations. Indeed, properly speaking, it has but one conjugation; but this is varied in each seven or eight different ways, which has the effect

of so many different conjugations, and affords a great variety of expressions to represent by a single word the different modifications of a verb, and many ideas which in the modern and in many of the ancient and learned languages cannot be expressed without a periphrasis.

The primitive words, which are called *roots*, have seldom more than three letters or two syllables.

In this language there are 22 letters, only five of which are usually reckoned vowels, which are the same with ours, viz. *a, e, i, o, u*; but then each vowel is divided into two, a long and a short, the sound of the former being somewhat grave and long, and that of the latter short and acute: it must however be remarked, that the two last vowels have sounds that differ in other respects besides quantity and a greater or less elevation. To these 10 or 12 vowels may be added others, called *semi-vowels*, which serve to connect the consonants, and to make the easier transitions from one to another. The number of accents in this language are indeed prodigious: of these there are near 40, the use of some of which, notwithstanding all the inquiries of the learned, are not yet perfectly known. We know, in general, that they serve to distinguish the sentences like the points called *commas, semicolons, &c.* in our language; to determine the quantity of the syllables; and to mark the tone with which they are to be spoken or sung. It is no wonder, then, that there are more accents in the Hebrew than in other languages, since they perform the office of three different things, which in other languages are called by different names.

As we have no Hebrew but what is contained in the Scripture, that language to us wants a great many words; not only because in those primitive times the languages were not so copious as at present; but also on this account, that the inspired writers had no occasion to mention many of the terms that might be in the language.

The Chaldee, Syriac, Ethiopic, &c. languages, are by some held to be only dialects of the Hebrew; as the French, Italian, Spanish, &c. are dialects of the Latin. It has been supposed by many very learned men, that the Hebrew characters or letters were often used hieroglyphically, and that each had its several distinct sense understood as a hieroglyphic. Neumann, who seems to have taken infinite pains to find out this secret meaning of these letters, gives the following explication: *א aleph*, he says, is a character denoting motion, readiness, and activity; *ב bet*, signifies, 1. Matter, body, substance, thing; 2. Place, space, or capacity; and, 3. In, within, or contained: *ג gimel*, stands for flexion, bending, or obliquity of any kind: *ד dalet*, signifies any protrusion made from without, or any promotion of any kind: *ה he*, stands for presence, or demonstrative essence of any thing: *ו vau*, stands for copulation or growing together of things: *ז zain*, expresses vehement protrusion and violent compression, such as is occasioned by at once violently discharging and constringing a thing together; it also signifies sometimes the straitening of any figure into a narrow point at the end: *ח cheth*, expresses association, society, or any kind of composition or combination of things together: *ט tet*, stands for the withdrawing, drawing back, or recess of any thing: *י yod*, signifies extension and length, whether in matter or in time: *כ cap*, expresses a turning, curvedness, or concavity: *ל lamech*, stands for an addition, access, impulse, or adversation, and sometimes for pressure: *מ mem*, expresses amplitude, or the amplifying any thing in whatever sense; in regard to continuous qualities, it signifies the adding length, breadth, and circumference; and in disjunct qualities it signifies multitude: *נ nun*, signifies the propagation of one thing from another, or of the same thing from one person to another: *ס samech*, expresses circumscription and coarctation: *ע ain*, stands for observation, objection, or obviation: *פ pe*, stands for a crookedness or an

angle of any figure: *צ tsade*, expresses contiguity and close succession: *ק koph*, expresses a circuit or ambit: *ר resh*, expresses the egress of any thing, as also the exterior part of a thing, and the extremity or end of any thing: *ש shin*, signifies the number three, or the third degree, or the utmost perfection of any thing: *ת tau*, expresses a sequel, continuation, or succession of any thing.

According to this explication, as the several particular letters of the Hebrew alphabet separately signify the ideas of motion, matter, space, and several modifications of matter, space, and motion, it follows, that a language, the words of which are composed of such expressive characters, must necessarily be of all languages the most perfect and expressive; as the words formed of such letters, according to their determinate separate significations, must convey the idea of all the matters contained in the sense of the several characters, and be at once a name and a definition, or succinct description of the subject; and all things material as well as spiritual, all objects in the natural and moral world, must be known as soon as their names are known, and their separate letters considered.

The words *urim* and *thummim* are thus easily explained, and found, perhaps, the most apposite and expressive words that were ever formed.

Rabbinical, or modern HEBREW, is the language used by the rabbins in the writings they have composed. The basis or body hereof is the Hebrew and Chaldee, with divers alterations in the words of these two languages, the meanings whereof they have considerably enlarged and extended. Abundance of things they have borrowed from the Arabic; the rest is chiefly composed of words and expressions, chiefly from the Greek; some from the Latin; and others from the other modern tongues, particularly that spoken in the place where each rabbin lived or wrote.

The rabbinical Hebrew must be allowed to be a very copious language. M. Simon, in his *Hist. Crit. du Vieux Testam.* liv. iii. chap. 27. observes, that there is scarce any art or science that the rabbins have not treated of in it. They have translated most of the ancient philosophers, mathematicians, astronomers, and physicians; and have written themselves on most subjects: they do not want even orators and poets. Add, that this language, notwithstanding it is so crowded with foreign words, has its beauties visible enough in the works of those who have written well in it.

HEBREWS, the descendants of Heber, commonly called *Jews*. See **HEBER** and **Jews**.

HEBREWS, or *Epistle to the Hebrews*, a canonical book of the New Testament. Though St. Paul did not prefix his name to this epistle, the concurrent testimony of the best authors ancient and modern affords such evidence of his being the author of it, that the objections to the contrary are of little or no weight. The Hebrews, to whom this epistle was written, were the believing Jews of Palestine; and its design was to convince them, and by their means all the Jewish converts wheresoever dispersed, of the insufficiency and abolishment of the ceremonial and ritual law.

HEBRIDES, or **WESTERN ISLANDS**, a large cluster of islands on the W. coast of Scotland, the principal of which are Skye, St. Kilda, Lewis and Harris, N. and S. Uist, Cannay, Staffa, Mull, Jura, Ithly, &c. which see.

HEBRIDES, **NEW**, a group of islands first discovered by Quiros in 1606, and considered as part of a great southern continent, under the name of *Tierra Australia del Espíritu Santo*. They were next visited by M. de Bougainville in 1768, who did no more than discover that the land was not connected, but composed of islands, which he called the Great Cyclades. Captain Cook, in 1774, ascertained the extent and situation of the whole group, and gave them the name they now bear. They are situ-

ated between the latitudes of 14. 29. and 20. 4. S. and between the longitudes of 166. 41. and 170. 21. E. extending 125 leagues. The principal islands are Tierra del Espíritu Santo and Malicollo, beside several of less note, some of which are from 18. to 25 leagues in circuit. In general, they are high and mountainous, abounding with wood, water, and the usual productions of the tropical islands. The inhabitants are of very different appearances at different islands. They are, in general, of a slender make and dark colour, and most of them have frizzled hair. Their canoes and houses are small, and poorly constructed; and, except their arms, they have scarcely any manufacture, not even for clothing. They are, however, hospitable and good-natured, when not prompted to a contrary conduct by the jealousy which the unusual appearance of European visitors may naturally be supposed to excite.

HEBRUS, in ancient geography, the largest river of Thrace, rising from mount Scombrus; running in two channels till it comes to Philippopolis, where they unite. It empties itself at two mouths into the Ægean Sea, to the north of Samothrace. It was supposed to roll its waters upon golden sands. The head of Orpheus was thrown into it after it had been cut off by the Ciconian women.

HECATE, in fabulous history, a daughter of Perseus and Asteria, the same as Proserpine or Diana. She was called Luna in heaven, Diana on earth, and Hecate or Proserpine in hell; whence her name of *Diva triformis, tergemina, triceps*. She was supposed to preside over magic and enchantments. She was generally represented like a woman, with the head of a horse, a dog, or a boar; and sometimes she appeared with three different bodies, and three different faces, with one neck. Dogs, lambs, and honey, were generally offered to her, especially in ways and cross roads; whence she obtained the name of *Trivia*. Her power was extended over heaven, the earth, sea, and hell; and to her kings and nations supposed themselves indebted for their prosperity.

HECATESIA, a yearly festival observed by the Stratonicensians in honour of Hecate. The Athenians paid also particular worship to this goddess, who was deemed the patroness of families and of children. From this circumstance the statues of the goddesses were erected before the doors of the houses; and upon every new moon a public supper was always provided at the expense of the richest people, and set in the streets, where the poorest of the citizens were permitted to retire and feast upon it, while they reported that Hecate had devoured it. There were also expiatory offerings, to supplicate the goddesses to remove whatever evils might seem to threaten the public, &c.

HECATOMB, in antiquity, a sacrifice of an hundred beasts of the same kind, at an hundred altars, and by an hundred priests or sacrificers. The word is formed of the Greek *κατὰ μίαν*, which properly signifies a sumptuous or magnificent sacrifice. Others derive it from the Greek *κατόν centum*, "a hundred," and *βός bos*, "bullock," &c.; on which footing the hecatomb should be a sacrifice of 100 bullocks. Others derive the word from *κατόν* and *πῶς pes* "foot;" and on that principle hold, that the hecatomb might consist of only 25 four-footed beasts. They add, that it did not matter what kind of beasts were chose for victims, provided the quota of feet were but had. Pythagoras is said to have sacrificed a hecatomb to the muses, of 100 oxen, in joy and gratitude for his discovering the demonstration of the 47th proposition of the first book of Euclid, viz. that in a rectangled triangle the square of the hypotenuse is equal to the squares of the two other sides. For the origin of hecatombs: Strabo relates, that there were 100 cities in Laconia, and that each city used to sacrifice a bullock every year for the common safety of the country; whence the institution of the celebrated sacrifice of 100 victims, called *hecatombs*. Others refer the origin of hecatombs to a plague, wherewith the 100 cities of Peloponnesus

were afflicted; for the removal whereof, they jointly contributed to so splendid a sacrifice. Julius Capitolinus relates, that for a hecatomb they erected 100 altars of turf, and on these sacrificed 100 sheep and 100 hogs. He adds, that when the emperors offered sacrifices of this kind, they sacrificed 100 lions, 100 eagles, and 100 other beasts of the like kind.

HECATOMBÆON was the first month of the Athenian year, consisting of 30 days; beginning on the first new moon after the summer solstice, and consequently answering to the latter part of our June and the beginning of July. It had its name from the great number of hecatombs sacrificed in it. See *HECATOMB*.

HECATOMPOLIS, a surname of the island of Crete, from its 100 cities. The territory of Laconia also had anciently this name for the same reason; and the custom of these 100 cities was to sacrifice a hecatomb annually.

HECATOMPYLOS, the metropolis of Parthia, and royal residence of Arsaces, situated at the springs of the Araxes. Thebes in Egypt had also the same name, from its 100 gates.

HECK, an engine to take fish. A salmon heck is a grate for catching that sort of fish.

HECKLE, among hemp-dressers. See *HATCHEL*.

HECLA, a volcano of Iceland, and one of the most furious in the world, situated on the southern part of the island. See *ICELAND*. It was visited in the year 1772 by Dr. Van Troil, a Swedish gentleman, along with Sir Joseph Banks, Dr. Solander, and Dr. James Lind of Edinburgh. On their first landing they found a tract of land 60 or 70 miles in extent entirely ruined by lava, which appeared to have been in the highest state of liquefaction. Having undertaken a journey to the top of the mountain, they travelled 300 or 360 English miles over an uninterrupted tract of lava; and had at length the pleasure of being the first who had arrived at the summit of the mountain.

Hecla, according to the accounts of these gentlemen, is situated in the southern part of the island, about four miles from the sea-coast, and is divided into three parts at the top, the middle point being the highest; and, according to an exact observation with Ramsden's barometer, is 5000 feet above the level of the sea. They were obliged to quit their horses at the first opening from which the fire had burst. They describe this as a place with lofty glazed walls and high glazed cliffs, unlike any thing which they had ever seen before.

A little higher up they found a large quantity of grit and stones; and still farther on, another opening, which, though not deep, descended lower than that of the highest point. Here they imagined they plainly discerned the effects of boiling water; and not far from thence the mountain began to be covered with snow, excepting some spots which were bare. The reason of this difference they soon perceived to be the hot vapour ascending from the mountain. As they ascended higher they found these spots become larger; and about 200 yards below the summit, a hole about a yard and an half in diameter was observed, from whence issued so hot a steam, that they could not measure the degree of heat with the thermometer. The cold now began to be very intense; Fahrenheit's thermometer, which, at the foot of the mountain was at 54, now fell to 24; the wind also became so violent, that they were sometimes obliged to lie down for fear of being blown down the most dreadful precipices. On the very summit they experienced at the same time a high degree of heat and cold; for, in the air, Fahrenheit's thermometer stood constantly at 24, but when set on the ground, rose to 153; the barometer stood at 22.247. Though they were very much inclined to remain here for some time, it could by no means be done with safety; for which reason they were obliged to descend very quickly.

The mountain seems to be made up, not of lava, but of sand, grit, and ashes; which are thrown up with the stones partly

discoloured, and partly melted by the fire. Several forts of pumice stones were found on it, among which was one with some sulphur. Sometimes the pumice was so much burnt, that it was as light as tow. Its form and colour were sometimes very fine, but at the same time so soft, that it was difficult to remove it from one place to another. The common lava was found both in large pieces and small bits; as likewise a quantity of black jasper burned at the extremities, and resembling trees and branches. Some slate of a strong red colour was observed among the stones thrown out by the volcano. In one place the lava had taken the form of chimney-stacks half broken down. As they descended the mountain they observed three openings. In one, every thing looked as red as brick; from another, the lava had flowed in a stream about 50 yards broad, and after proceeding for some way, had divided into three large branches. Further on they perceived an opening, at the bottom of which was a mountain in form of a sugar loaf, in throwing up of which the fire appeared to have exhausted itself.

We have already observed, that our travellers were the first who ascended to the top of this mountain. The reason that no one before them had ever done so was partly founded in superstition, and partly the steepness and difficulty of the ascent, which was greatly facilitated by an eruption in 1766. Most kinds of lava found in other volcanic countries are to be met with about Hecla, or other Iceland volcanoes; as the grey, dark perforated kind, similar to the Derbyshire loadstone; the Iceland agate, pumex vitreus both the *niger* and *viridis*. Some have conjectured this to be the lapis obsidianus of the ancients, which they formed into statues.

The lava is seldom found near the openings whence the eruptions proceed, but rather loose grit and allies; and indeed the greater part of the Icelandic mountains consist of this matter; which, when it is grown cold, generally takes an arched form. The upper crust frequently grows hard and solid, whilst the melted matter beneath it continues liquid. This forms great cavities, whose walls, bed, and roof, are of lava, and where great quantities of stalactite lava are found. There are a vast number of these caves in the island, some of which are very large, and are made use of by the inhabitants for sheltering their cattle. The largest in the island is 5034 feet long, and from 50 to 54 in breadth, and between 34 and 36 in height. There are some prodigious clefts left by the eruptions, the largest of which is called *Almeneggaa*, near the water of Tingalla, in the south-western part of the island. It is 105 feet broad and very long. The direction of the chasm itself is from north to south. Its western wall, from which the other has been perpendicularly divided, is 107 feet six inches in height, and consists of many strata, of about 10 inches each in height, of lava grown cold at different times. The eastern wall is only 45 feet four inches in height, and that part of it which is directly opposite to the highest part of the other side is no more than 36 feet five inches high.

HECTIC FEVER. See MEDICINE.

HECTOR, the son of Priam and Hecuba, and the father of Astyanax, is celebrated for the valour with which he defended the city of Troy against the Greeks. He was killed by Achilles, who dragged his body, fastened to his chariot, thrice round the walls of Troy, and afterwards restored it to Priam for a large ransom. See TROY.

HEDERA, IVY, in botany; a genus of the monogynia order, belonging to the pentandria class of plants; and in the natural method giving name to the 46th order, *Hederaceæ*. There are five oblong petals; the berry is pentaspermous, girt by the calyx. The species are, 1. The *bilix*, or common ivy, grows naturally in many parts of Britain; and, where it meets with any support, will rise to a great height, sending out roots on every side, which strike into the joints of walls or the bark of

trees. If there is no support, they trail on the ground, and take root all their length, so that they closely cover the surface, and are difficult to eradicate. While these stalks are fixed to any support, or trail upon the ground, they are slender and flexible; but when they have reached to the top of their support, they shorten and become woody, forming themselves into large bushy heads, and their leaves are larger, more of an oval shape, and not divided into lobes like the lower leaves, so that it hath a quite different appearance. There are two varieties of this species, one with silver-striped leaves, the other with yellowish leaves on the tops of the branches; and these are sometimes admitted into gardens. 2. The *quinquefolia*, or Virginia creeper, is a native of all the northern parts of America. It was first brought to Europe from Canada; and has been long cultivated in the British gardens, chiefly to plant against walls or buildings to cover them: which these plants will do in a short time; for they will shoot almost 20 feet in one year, and will mount up to the top of the highest building: but as the leaves fall off in autumn, the plants make but an indifferent appearance in winter, and therefore are proper only for such situations as will not admit of better plants; for this will thrive in the midst of cities, and is not injured by smoke or the closeness of the air.

The first species is easily propagated by its trailing branches, and will thrive in almost any soil or situation. The second may be propagated by cuttings; which if planted in autumn in a shady border will take root, and by the following autumn will be fit to plant in those places where they are designed to remain.

The roots of the ivy are used by leather-cutters to whet their knives upon. Apricots and peaches covered with ivy during the month of February, have been observed to bear fruit plentifully. The leaves have a nauseous taste; Haller says, they are given to children in Germany as a specific for the atrophy. The common people of England apply them to issues; and an ointment made from them is in great esteem among the Highlanders of Scotland as a ready cure for burns. The berries have a little acidity. In warm climates, a resinous juice exudes from the stalks, which is said to be a powerful resolvent, and an excellent ingredient in plasters and ointments. Horses and sheep eat the plant; goats and cows refuse it. Caspar Bauhine and Tournefort mention a sort of ivy that grows in many of the islands of the Archipelago, to which they have given the name of the *poet's ivy*, because the ancients are said to have made crowns of this plant for adorning the brows of their poets. By others it is called *hedera dionysias*, because they made use of the same sort of ivy in their public rejoicings and feasts in honour of Bacchus. The berries are of a fine gold colour, whence this species has been termed by others *chrysoearpos*.

HEDERACEÆ, from *hedera* "ivy," the name of the 46th order in Linnæus's fragments of a natural method; consisting of ivy, and a few other genera, which from their general habit and appearance seem nearly allied to it. See BOTANY, p. 53.

HEDGE, in agriculture, a fence inclosing a field, garden, &c. made of branches of trees interwoven. The word is formed of the German *bag* or *baeg*, or the Anglo-Saxon *begge*, or *bege*, which signifies simply *inclosure*, *circumference*.

Quickset-HEDGES are so called from being made of quick or live trees, which have taken root, in contradistinction to those made of dead substances, as faggots, hurdles, dry boughs, &c. The hawthorn is esteemed the best of all the English shrubs for quickset hedges. The best method of raising this for use, is to put the haws into the ground as soon as ripe, and cover them with earth, and by the spring twelvemonth the young shoots will be of a due size to transplant from the seed-pot into hedge rows. The crab-tree is a common mixture with the hawthorn

in hedges; but it grows faster than the hawthorn, and requires cutting to keep the hedge even. The young hawthorns raised from seed always thrive better than those picked up wild in the fields.

The great consideration in making quickset hedges is to bring the plants from a worse soil than that in which it is intended to set them. They must be about the thickness of a goose quill, well rooted and strong, and must be planted about four or five inches out of the ground. If there be a ditch to the hedge, it should be six feet wide at the top, one and a half at the bottom, and three feet deep. If the bank be without a ditch, the plants should be set in two rows, at a foot distance below one another. The turf is to be laid, with the grass-side downward, on that side of the ditch on which the bank is designed to be made, and some of the best mould must be laid upon it to bed the quick: then the quick is to be laid upon it a foot asunder, so that the end of it may be inclining upwards; and, at equal distances of thirty feet, plant an ash, oak, crab or elm, to grow with the quick. When the first row of quick is laid, it must be covered with mould, and the turf laid upon it as before, and some more mould upon that; so that, when the bank is a foot high, another row of sets may be laid against the spaces of the lower quick. These must be then covered as the former, and the bank is to be then topped with the bottom of the ditch, and a dry or dead hedge laid to shade the under plantation. There should then be stakes driven into the loose earth quite down to the firm ground, at about two feet and a half distance from each other; oak stakes are accounted the best of all for this use, and the next to this those of black thorn or fallow. Small bushes are to be laid below, but not too thick, only to cover the quick from being injured as it shoots.

The young plants must be constantly weeded, and great care must be taken to preserve them from being bitten by cattle, especially sheep. If they have been cropped, or are not found to grow well, it is a good custom among the farmers to cut them down in February to the ground, or within an inch of it, for after this they usually send out new roots, and shoot very vigorously.

When the hedge is of eight or nine years growth, it may be plashed or laid down, by giving the shoots or branches a cut with a knife or a bill half through, and then weaving them about the stakes, and trimming off the small superfluous branches. See FENCE. The crab, black-thorn or sloe, and holly, are sometimes planted for hedges.

Instead of building a garden wall facing the north-east, Mr. Lawrence advises, that to save charge, &c. a crab tree hedge of three rows be planted; which will be a good mound, and quickly grow up to be a better fence than a wall against the west and south-west winds, which make the greatest destruction in a garden, and which blow two parts in three of the whole year; besides the stock of fruit such a hedge, grafted with red-streak or gennet moyl, will yield.

Hedges for ornament in gardens, are sometimes planted with evergreens, in which case the *bolly* is preferable to any other. Next to this most people prefer the *yew*, on account of its growing very close; but the dead colour of its leaves renders these hedges less agreeable. The *laurel* is one of the most beautiful evergreens, but the shoots are so luxuriant, that it is difficult to keep it in any tolerable shape; but hedges that are formed of laurel, which has large leaves, should be pruned with a knife, cutting the shoots just down to a leaf; and this method is much better than that of cutting them with shears. The *laurustinus* is also a very fine plant for the purpose of ornamental hedges; but this is liable to the same objection as the laurel; it ought, therefore, to be pruned with a knife, in April, when the flowers are going off; but the new shoots of the same spring must by no means be shortened. The small-leaved and rough *laurustines*

are the best plants for this purpose. The true *phyllirea* is the next best plant for hedges, which may be led up to the height of ten or twelve feet; and if they are kept narrow at the top, that the snow may not have room to lodge upon them, they will become close and thick, and make a fine appearance. The *ilex*, or evergreen oak, is also planted for hedges, and is a fit plant for those that are designed to be very tall. The deciduous trees, which are usually planted to form hedges in gardens, are the hornbeam, which may be kept neat with less trouble than most other plants; the beech; and the small-leaved English elm, which should not be planted closer than seven or eight, or even ten feet: the lime tree has also been recommended for this purpose; but, as hedges thus formed become thin at bottom, and the leaves turn of a black disagreeable colour, it is now disused. The alder is frequently used for hedges; and where the soil is moist, it is preferable to any of the deciduous trees, because its leaves are of a lively green till late in autumn, and when they decay their litter is soon over. Many of the flowering shrubs have been planted for hedges, such as roses, honey-suckles, sweet-brier, &c. but these are difficult to train; and if they are cut to keep them within compass, their flowers, which are their greatest beauty, will be entirely destroyed. However, these hedges are by no means to be recommended for pleasure-gardens, either as ornamental or useful.

By 43 Eliz. cap. 7. hedge-breakers are bound to pay such damages as a justice of the peace shall think fit; and if not able to pay, they shall be committed to the constable to be whipped. And hedge-stealers may be apprehended, and the justice shall adjudge a penalty, not exceeding 10s. to the poor; or, in want of payment, they shall be sent to the house of correction for a month. 15 Car. II. cap. 2. And persons convicted of buying stolen wood, shall forfeit treble the value.

HEDGE-Hog. See ERINACEUS.

HEDGE-Sparrow. See MOTACILLA.

HEDYCARYA, in botany; a genus of the polyandria order, belonging to the diœcia class of plants. The calyx of the male is cleft in eight or ten parts; there is no corolla, nor are there any filaments; the antheræ are in the bottom of the calyx, four furrowed, and bearded at top. The calyx and corolla of the female are as in the male; the germs pedicellated; the nuts pedicellated and monospermous.

HEDYOTIS, in botany; a genus of the monogynia order, belonging to the tetrandria class of plants; and in the natural method ranking under the 47th order, *Stellatæ*. The corolla is monopetalous and funnel-shaped; the capsule is bilocular, polyspermous, inferior.

HEDYSARUM, in botany; a genus of the decandria order, belonging to the diadelphina class of plants; and in the natural method ranking under the 32d order, *Papilionacæ*. The carina of the corolla is transversely obtuse; the seed-vessel a legumen with monospermous joints. There are 59 species of this plant, of which the most remarkable are, 1. The *gyrans*, or sensitive hedyfarum, a native of the East Indies, where it is called *burru chundalli*. It arrives at the height of four feet, and in autumn produces bunches of yellow flowers. The root is annual or biennial. It is a trifolious plant, and the lateral leaves are smaller than those at the end, and all day long they are in constant motion without any external impulse. They move up and down and circularly. This last motion is performed by the twisting of the footstalks; and while the one leaf is rising, its associate is generally descending. The motion downwards is quicker and more irregular than the motion upwards, which is steady and uniform. These motions are observable for the space of 24 hours in the leaves of a branch which is lopped off from the shrub if it is kept in water. If from any obstacle the motion is retarded, upon the removal of that obstacle it is resumed with a greater degree of velocity. 2. The

aromatium, or common biennial French honeysuckle, hath large deeply-striking biennial roots; upright, hollow, smooth, very branchy stalks, three or four feet high, garnished with pinnated leaves; and from between the leaves proceed long spikes of beautiful red flowers, succeeded by jointed seed-pods. The first species, being a native of hot climates, requires the common culture of tender exotics; the second is easily raised from seed in any of the common borders, and is very ornamental.

HEEL, in anatomy, the hind part of the foot. See ANATOMY, p. 158.

HEEL of a Horse, the lower hinder part of the foot comprehended between the quarters and opposite to the toe. The heel of a horse should be high and large, and one side of it should not rise higher than the other upon the pastern. It is of the utmost importance, by a judicious manner of shoeing, to keep the heels of a horse from contracting. See FARRIERY, Part IV.

HEEL of a Horseman. This being the part that is armed with the spur, the word is used for the spur itself: "This horse understands the heel well." To ride a horse from one heel to another, is to make him go sideways, sometimes to one heel and sometimes to the other.

HEEL, in the sea-language. If a ship leans on one side, whether she be aground or afloat, then it is said the heels a-starboard, or a-port; or that she heels offwards, or to the fore; that is, inclines more to one side than to another.

HEELER, or Bloody HEEL Cock, a fighting cock, that strikes or wounds much with his spurs. Cock-fighters know such a cock, even while a chicken, by the striking of his two heels together in his going.

HEEM (John David), an able painter, born at Utrecht in 1604. He excelled in painting flowers, fruit, vases, and instruments of music, which he performed in such a perfect manner, that a person was apt to attempt taking them in his hand. His colouring is agreeable, and the insects in his pictures appear alive. He died at Antwerp in 1674. Cornelius de HEEM, his son, was also a good painter, though inferior to his father.

HEGIRA, in chronology, a celebrated epoch among the Mahometans. The word is Arabic, formed of *هجره*, *bagirab*, *flight*; of *هجر*, *to fly, quit one's country, family, friends, &c.* The event which gave occasion to this epocha, was Mahomet's flight from Mecca. The magistrates of that city, fearing his impostures might raise a sedition, resolved to expel him: this, accordingly, they effected in the year of our Lord 622, on the evening of the 15th or 16th of July. To render this epocha more creditable, the Mahometans affect to use the word *begira* in a peculiar sense for an act of religion, whereby a man forsakes his country, and gives way to the violence of persecutors and enemies of the faith: they add, that the Corashites, being then the strongest party in the city, obliged their prophet to fly, as not being able to endure his abolishing of idolatry. This flight was not the first of Mahomet's, but it was the most famous. It happened in the 14th year from his assuming the character of prophet and apostle, and promulgating his new religion.

The orientals do not agree with us as to the time of the hegira. Among the Mahometans, Amasi fixes it to the year of Christ 630, and from the death of Moses 2347; and Ben Cassim to the year of the world 5800: according to the Greek computation, among the Christians, Said Ebn Batrik refers the hegira to the year of Christ 614, and of the creation 6114. Khoundemir relates, that it was Omar, the second caliph, that first established the hegira as an epocha, and appointed the years to be numbered from it: at the time he made this decree, there were already seven years elapsed. This establishment was made in imitation of the Christians, who, in those times, reckoned their years from the persecution of Dioclesian. But there is another hegira, and that earlier too, though of less eminence.

Mahomet, in the 14th year of his mission, was obliged to relinquish Medina: the Corashites had all along opposed him very vigorously, as an innovator and disturber of the public peace; and many of his disciples, not enduring to be reputed followers of an impostor, desired leave of him to abandon the city, for fear of being obliged to renounce their religion. This retreat makes the first hegira. These two hegiras the Mahometans, in their language, call *begiratan*.

The years of the hegira consist only of 354 days. To reduce these years to the Julian calendar, i. e. to find what Julian year a given year of the hegira answers to, reduce the year of the hegira given into days, by multiplying by 354, divide the product by 365, and from the quotient subtract the intercalations, i. e. as many days as there are four years in the quotient; and lastly, to the remainder add 622. See YEAR.

HEIDEGGER (John James), was the son of a clergyman, and a native of Zurich in Switzerland, where he married, but left his country in consequence of an intrigue. Having had an opportunity of visiting the principal cities of Europe, he acquired such a taste for elegant and refined pleasures, as peculiarly fitted him for the management of public amusements. In 1708, when he was near 50 years old, he came to England on a negotiation from the Swiss at Zurich; but, failing in his embassy, he entered as a private soldier in the guards for protection. By his sprightly conversation and insinuating address, he soon worked himself into the good graces of our young people of fashion; from whom he obtained the appellation of "the Swiss Count." He had the address to procure a subscription, with which, in 1709, he was enabled to furnish out the opera of "Thomyris," which was written in English, and performed at the queen's theatre in the Haymarket. The music, however, was Italian; that is to say, airs selected from sundry of the foreign operas by Bunoncini, Scarlatti, Steffani, Gasparini, and Albinoni. Heidegger by this performance alone was a gainer of 500 guineas. The judicious remarks he made on several defects in the conduct of our operas in general, and the hints he threw out for improving the entertainments of the royal theatre, soon established his character as a good critic. Appeals were made to his judgment; and some very magnificent and elegant decorations introduced upon the stage in consequence of his advice, gave such satisfaction to George II. who was fond of operas, that, upon being informed to whose genius he was indebted for these improvements, his majesty was pleased from that time to countenance him, and he soon obtained the chief management of the opera house in the Haymarket. He then set about improving another species of diversion, not less agreeable to the king, which was the masquerades, and over these he always presided at the king's theatre. He was likewise appointed master of the revels. The nobility now cared less for him so much, and had such an opinion of his taste, that all splendid and elegant entertainments given by them upon particular occasions, and all private assemblies by subscription, were submitted to his direction. From the emoluments of these several employments, he gained a regular considerable income, amounting, it is said, in some years, to 5000l. which he spent with much liberality; particularly in the maintenance of a somewhat too luxurious table; so that it may be said he raised an income, but never a fortune. At the same time his charities ought not to pass unnoticed, which were frequent and ample. After a successful masquerade, he has been known to give away several hundred pounds at a time. "You know poor objects of distress better than I do," he would frequently say to a particular acquaintance; "be so kind as to give away this money for me." This well known liberality, perhaps, contributed much to his carrying on that diversion with so little opposition as he met with. He died in 1749, at the advanced age of 90 years.

This extraordinary man was long the *Arbiter Elegantiarum* of England. He is alluded to in many publications of his time, and many ludicrous anecdotes have been related concerning him. Heidegger's countenance was peculiarly unpleasing, from an unusual harshness of features. There is a mezzotinto of him by J. Faber, 1742, from a painting by Vanloo, a striking likeness; and his face is introduced in more than one of Hogarth's prints. Heidegger was, however, the first to joke upon his own ugliness; and he once laid a wager with the earl of Chesterfield, that within a certain given time his lordship would not be able to produce so hideous a face in all London. After a strict search, a woman was found, whose features were at first sight thought stronger than Heidegger's; but upon clapping her head-dress upon himself, he was universally allowed to have won the wager. Jolly, a well-known taylor, carrying his bill to a noble duke; his grace, for evasion, said, "Damn your ugly face, I never will pay you till you bring me an uglier fellow than yourself!" Jolly bowed and retired, wrote a letter, and sent it by a servant to Heidegger; saying, "His grace wished to see him the next morning on particular business." Heidegger attended, and Jolly was there to meet him; and in consequence, as soon as Heidegger's visit was over, Jolly received the cash.

Being once at supper with a large company, when a question was debated, Which nationalist of Europe had the greatest ingenuity? to the surprise of all present, he claimed that character for the Swiss, and appealed to himself for the truth of it. "I was born a Swiss (said he), and came to England without a farthing, where I have found means to gain 5000l. a-year, and to spend it. Now I defy the most able Englishman to go to Switzerland, and either to gain that income or to spend it there." Heidegger is said to have had so remarkable a memory, that he once walked from Charing-cross to Temple-bar, and back again; and when he came home, wrote down every sign on each side of the street.

HEIDENHEIM, a town of Germany, in Suabia, and in the territory of Brentzhall, with a handsome palace, belonging to the house of Wirtemberg, 22 miles N. of Ulm. E. lon. 10. 9. N. lat. 48. 47.

HEIDELBERG, a considerable and populous town of Germany, capital of the Lower Palatinate, with a celebrated university. It is noted for its great tun, which holds 800 hog-heads, generally kept full of good Rhenish wine. It stands in a pleasant rich country, and was a famous seat of learning; but it has undergone so many calamities, that it is nothing now to what it was formerly. It was first reduced to a heap of ruins in 1622 by the Spaniards; and the rich library was transported, partly to Vienna, and partly to the Vatican at Rome. After this it enjoyed the benefits of peace, till the Protestant electoral house became extinct, and a bloody war ensued, in which the castle was ruined. This happened in 1693; and the people of the Palatinate were obliged to leave their dwellings, and to go for refuge into foreign countries. To add to these misfortunes, the elector resided at Mannheim, and carried most of the people of distinction with him. The great tun was broke to pieces in 1693 by the French, and, at a great expence, in 1729, was repaired. The town stands on the river Neckar, over which is a handsome bridge, 12 miles N. E. of Spire. E. lon. 8. 48. N. lat. 49. 26.

HEIGHT, in general, signifies the difference between the ground and the top of any object measured perpendicularly. For the *Methods of measuring HEIGHTS*, see GEOMETRY, TRIGONOMETRY, BAROMETER, &c.

HEILA, a town of Western Prussia, seated at the mouth of the Vistula, on the Baltic Sea, 12 miles N. of Dantzick. E. lon. 19. 25. N. lat. 54. 53.

HEILEGEN-HAVE, a seaport of Germany, in Holstein,

seated on the Baltic, opposite the island of Femenen. E. lon. 10. 57. N. lat. 54. 30.

HEINECCIUS (John Gotlieb), one of the greatest civilians of the 18th century, was born at Eisenberg, in the principality of Altenburg, in 1681. After having studied at Goflar and Leipsick, he was designed for the ministry, and began to preach; but disliking that profession, he laid it aside, and applied himself entirely to the study of philosophy and the civil law. In 1710 he became professor of philosophy at Hall; and in 1721 he was made professor of civil law, with the title of *counsellor of the court*. His great reputation made the States of Friesland invite him to Franeker in 1724; but three years after the king of Prussia prevailed on him to accept of a professorship of law at Francfort on the Oder, where he distinguished himself till the year 1733. Becoming again professor at Hall, he remained there till his death, which happened in 1741, notwithstanding his being invited to Marpurg, Denmark, and three academies in Holland. He wrote many works, all of them much esteemed. The principal are, 1. *Antiquitatum Romanarum jurisprudentiam illustrantium syntagma*. It was this excellent abridgement that gave rise to his reputation in foreign countries. 2. *Elementa juris civilis secundum ordinem institutionum & pandectarum*. 3. *Fundamenta styli cultioris*. There are few works so useful as this for forming a Latin style. 4. *Elementa philosophiæ rationalis & moralis, quibus præmissa historia philosophica*. 5. *Historia juris civilis Romani ac Germanici*. 6. *Elementa juris naturæ & gentium, &c.*

HEINETKEN (Christian), an extraordinary child, the prodigy of the North, was born at Lubeck in 1721. He spoke his maternal tongue fluently at 10 months. At one year old, he knew the principal events of the pentateuch; in two months more he was master of the entire history of the Old and New Testaments; at two years and an half he answered the principal questions in geography and in ancient and modern history; and he spoke Latin and French with great facility before the commencement of his fourth year. His constitution was so delicate, that he was not weaned till a few months before his death. M. Martini of Lubeck published a pamphlet in 1730, in which he endeavoured to give natural reasons for the extraordinary capacity of this infant, who died in his fifth year.

HEINSIUS (Daniel), professor of politics and history at Leyden, and librarian to the university there, was born at Gand in Flanders in 1580. He became a scholar to Joseph Scaliger at Leyden, and was indebted to the encouragement and care of that great man for the perfection to which he attained in literature, and which at the beginning of his life there was little reason to hope from him. He distinguished himself as a critic by his remarks on many classical authors; and was highly honoured: as well abroad as at home: Gustavus Adolphus king of Sweden gave him a place among his counsellors of state; the republic of Venice made him a knight of the order of St. Mark; and pope Urban VIII. made him great offers, if he would come, as he expressed it, "to rescue Rome from barbarism." He died in 1666, leaving several works of his own, both in poetry and prose.

HEINSIUS (Nicholas), the son of Daniel Heinsius, was born at Leyden; and became as great a Latin poet, and a greater critic, than his father. His poems have been several times printed, but the best edition is that of Amsterdam in 1666. He gave editions of several of the classics, with notes; his Claudian is dedicated in a Latin poem to queen Christina of Sweden, and his Ovid to Thuanus. At his death, which happened in 1681, he disclaimed all his works, and expressed the utmost regret at having left behind him so many "monuments of his vanity," as he called them. He was as much distinguished by his great employments in the state, as by his talents, learning, and good qualities.

HEIR, in law, signifies the person who succeeds another by

descent to lands, tenements, and hereditaments, being an estate of inheritance, or an estate in fee; because nothing passes by right of inheritance but in fee. See the articles CONSANGUINITY, DESCENT, FEE, SUCCESSION; and LAW. *HEIR-Apparent*, is a person so called in the lifetime of his ancestor, at whose death he is heir at law. *HEIR-Presumptive*, is one who, if the ancestor should die immediately, would, in the present circumstances of things, be his heir; but whose right of inheritance may be defeated by the contingency of some nearer heir being born.

HEIR Loom, formed of *heir* and the Saxon *loom*, denoting *limb* or *members*, in our law-books, signifies such goods and personal chattels as are not inventoried after the owner's decease, but necessarily come to the heir along with the house. Heir-loom comprehends various implements; as tables, presses, cupboards, bedsteads, furnaces, wainscot, and such like; which in some countries have belonged to a house for certain descents, and are never inventoried after the decease of the owner, as chattels are, but accrue by custom, not by common law, to the heir, with the house itself. The ancient jewels of the crown are held to be heir-looms, and are not deviseable by will, but descend to the next successor.

HEIRESS, a female heir to one who has an estate in lands, &c. See **HEIR**. The stealing an heiress is made highly penal by the laws of England. See *FORCIBLE Marriage*.

HEISTERIA, in botany; a genus of the monogynia order, belonging to the decandria class of plants; and in the natural method ranking under the 12th order, *Holoraceæ*. The calyx is quinquefid, the petals five; the fruit is a plum on a very large coloured calyx.

ST. HELENA, an island in the Atlantic Ocean, belonging to the English East India Company. Its circumference is about 20 miles. It has some high mountains, particularly one called Diana's Peak, which is covered with woods to the very top. There are other hills also, which bear evident marks of a volcanic origin; and some have huge rocks of lava and a kind of half vitrified slags. The country, however, is far from being barren, the interior valleys and even mountains being pleasant and fertile. Mr. Forster, who made an excursion about half a mile into the country, informs us, that he was transported with one of the finest prospects he had ever seen, consisting of several little hills, covered with rich verdure, and interspersed with fertile valleys, which contained gardens, orchards, and various plantations. Many pastures, he adds, were surrounded by inclosures of stone, and filled with a small but fine breed of cattle, and with English sheep. Every valley was watered by a rivulet. The mountains, in the centre of the island, were hung with woods. The soil, which covered the rocks and mountains, was, in general, a rich mould, from six to ten inches deep, clothed with a variety of plants and shrubs, among which was a tree which the inhabitants call a cabbage-tree (though only used for fuel), gum trees, and red wood. In the governor's garden, three miles from the town, he saw several plants of Europe, Africa, and America, and particularly a profusion of roses and lilies, interspersed with myrtle and laurel. Several walks of peach-trees were loaded with fruit, which had a peculiar rich flavour, different from that of our peaches; but the other European fruit-trees throve but indifferently, and never bore fruit. Vines had been planted several times, but had not succeeded, on account of the climate. Cabbages and other greens thrive extremely well, but are devoured by caterpillars; and the barley, and other kinds of corn, are generally devoured by rats, which are inconceivably numerous. The ground, for that reason, was laid out chiefly in pastures, the verdure of which was surprising; and the island can support 3000 head of their small cattle. The beef is juicy, delicious, and very fat. The island abounds with goats, rabbits, a

small breed of horses, ring-pheasants, red-legged partridges, rice-birds, pigeons, &c. of some of which the breed is indigenous, but others have been brought from Africa, Europe, or the East Indies. The number of inhabitants on the island does not exceed 2000, including near 500 soldiers, and 600 slaves, who are supplied with all sorts of manufactures by the company's ships, in return for refreshments; and many of the slaves are employed in catching fish, which are very plentiful. To Mr. Forster's account may be added, that the town is small, and stands in a valley at the bottom of a bay on the S side of the island, between two steep dreary mountains. The buildings, both public and private, are plain, but neat, and the town is well defended by forts and batteries. This island was discovered by the Portuguese, in 1502, on St. Helena's Day, whence it had its name. Afterward the Dutch were in possession of it till 1600, when they were expelled by the English. In 1673 the Dutch retook it by surprise: but it was soon after recovered by the brave captain Munden. This island is situated between the continents of Africa and S. America, about 1200 miles W. of the former, and 1800 E. of the latter. W. lon. 5. 49. S. lat. 15. 55.

HELEN, in fabulous history, the daughter of Tyndarus and Leda, was married to Menelaus king of Sparta, but was stolen from him by Theseus, 1235 B. C. She was restored soon after; but carried off again by Paris, the Trojan prince; which occasioned the famous Trojan war.

ST. HELENS, a town of the Isle of Wight, in East-Medina, has a bay which runs a considerable way within land, and in a war with France is often the station and place of rendezvous for the royal navy. At the mouth of the bay is that cluster of rocks called the *Mixen*. It had an old church situated at the extremity of the coast, which was in danger of being washed away, as was a great part of the church-yard, which occasioned a new church to be built in 1719. The priory to which the old church belonged is now converted into a gentleman's seat; is in a remarkably pleasant situation, and commands a fine prospect of Portsmouth and the Road at Spithead. St. Helen's appears to have been of more consideration in former times than at present.

HELENIUM, **BASTARD SUN FLOWER**; a genus of the polygamia superflua order, belonging to the syngenesia class of plants; and in the natural method ranking under the 49th order, *Compositæ*. The receptacle is naked in the middle; under the radius, paleaceous; the pappus consists of five short awns; the calyx is simple and multipartite; the florets of the radius semitrid. The *species* are, 1. The *autumnale*, with spear-shaped narrow leaves. 2. The *latifolium*, with pointed, spear-shaped, sawed leaves. Both these are natives of North America, where they grow wild in great plenty. They rise to the height of seven or eight feet in good ground. The roots, when large, send up a great number of stalks, which branch toward the top; the upper part of the stalk sustains one yellow flower, shaped like the sun-flower, but much smaller, having long rays, which are jagged pretty deep into four or five segments. These plants may be propagated by seeds, or by parting their roots; the latter is generally practised in this country. The best season to transplant and part the old roots is in October when their leaves are past, or in the beginning of March just before they begin to shoot. They delight in a soil rather moist than dry, provided it is not too strong, or does not hold the wet in winter.

HELENUS, in fabulous history, a celebrated soothsayer, son of Priam and Hecuba. He was greatly respected by all the Trojans. When Deiphobus was given in marriage to Helen in preference to himself, he resolved to leave his country, and retired to mount Ida, where Ulysses took him prisoner by the advice of Calchas. As he was well acquainted with futurity, the Greeks made use of prayers, threats, and promises, to induce

him to reveal the secrets of the Trojans; and either the fear of death, or gratification of resentment, seduced him to disclose to the enemies of his country, that Troy could not be taken whilst it was in possession of the Palladium, nor before Polydectes came from his retreat at Lemnos and assisted to support the siege. After the ruin of his country, he fell to the share of Pyrrhus the son of Achilles, and saved his life by warning him to avoid a dangerous tempest, which in reality proved fatal to all those who set sail. This endeared him to Pyrrhus; and he received from his hand Andromache the widow of his brother Hector, by whom he had a son called *Cestrimus*. This marriage, according to some, was consummated after the death of Pyrrhus, who lived with Andromache as with a wife. Helenus was the only one of Priam's sons who survived the ruin of his country. After the death of Pyrrhus he reigned over part of Epirus, which he called *Chaonia* in memory of his brother Chaon, whom he had inadvertently killed. Helenus received Æneas as he voyaged towards Italy, and foretold him some of the calamities which attended his fleet. The manner in which he received the gift of prophecy is doubtful.

HELEPOLIS, in the ancient art of war, a machine for battering down the walls of a place besieged, the invention of which is ascribed to Demetrius Poliorcetes. Diodorus Siculus says, that each side of the Helepolis was 405 cubits in breadth and 90 in height; that it had nine stages, and was carried on four strong solid wheels eight cubits in diameter; that it was armed with large battering rams, and had two roofs capable of supporting them; that in the lower stages there were different sorts of engines for casting stones; and in the middle they had large catapultas for discharging arrows, and smaller ones in those above, with a number of expert men for working all these machines.

HELIADES, in mythology, the daughters of the Sun and Clymenes, according to the poets. They were so afflicted, as they say, with the death of their brother Phaeton, that the gods, moved with compassion, transformed them into poplars on the banks of the river Eridanus.

HELIACAL, in astronomy, a term applied to the rising and setting of the stars; or, more strictly speaking, to their emersion out of and immersion into the rays and superior splendor of the sun. A star is said to rise heliacally, when, after having been in conjunction with the sun, and on that account invisible, it comes to be at such a distance from him as to be seen in the morning before sun-rising; the sun, by his apparent motion, receding from the star towards the east. On the contrary, the heliacal setting is when the sun approaches so near a star as to hide it with his beams, which prevent the fainter light of the star from being perceived; so that the terms *apparition* and *occultation* would be more proper than *rising* and *setting*.

HELIAEA, in Grecian antiquity, was the greatest and most frequented court in Athens for the trial of civil affairs. See **HELIASTÆ**.

HELIANTHUS, the GREAT SUNFLOWER; a genus of the polygamia fruticosa order, belonging to the syngenesia class of plants; and in the natural method ranking under the 49th order, *Compositæ*. The receptacle is paleaceous and plane; the pappus diphylous; the calyx imbricated; the scales standing a little out at the tops. There are 12 species, most of which are now very common in our gardens, though all of them are natives of America. They are all very hardy, and will thrive in almost any soil or situation. They may be propagated either by seeds or by parting their roots.

HELIASTÆ, in antiquity, the judges of the court **HELIAEA**. They were so called, according to some authors, from a Greek word which signifies *to assemble in a great number*; and, according to others, from another word which signifies *the sun*, because they held their assemblies in an open place. They com-

posed not only the most numerous, but likewise the most important of the Athenian tribunals; for their province was either to explain the obscure laws, or to give new vigour and authority to those which had been violated. The *Thesmothetæ* convoked the assembly of the *Heliastæ*, which sometimes amounted to 1000, sometimes to 1500, judges. Mr. Blanchard is of opinion, that, to make this number, the *Thesmothetæ* sometimes summoned those of each tribe who had last quitted the public offices which they had exercised in another court. However that may be, it appears that the assemblies of the *Heliastæ* were not frequent, as they would have interrupted the jurisdiction of the stated tribunals and the common course of affairs.

The *Thesmothetæ* paid to each member of this assembly, for his attendance, three oboli: which are equal to two Roman sesterces, or to half a drachma. Hence Aristophanes terms them *the brothers of the triobulus*. They were likewise condemned to pay a fine if they came too late; and if they did not present themselves till after the orators had begun to speak, they were not admitted. Their attendance was requited out of the public treasury, and their pay was called *misthos heliasticus*.

The assembly met at first, according to Aristophanes, at the rising of the sun. If the judges were obliged to meet under cover on account of frost and snow, they had a fire; but there is not a passage in any ancient author which informs us of the place where these assemblies were held either in the rigorous or in the mild seasons. We only learn, that there was a double inclosure around the assembly, that it might not be disturbed. The first was a kind of arbour-work, from space to space, separated by doors, over which were painted in red the ten or twelve first letters of the Greek alphabet, which directed the entrance of the officers who composed the tribunal, each of them entering under the letter which distinguished his tribe. The beadles of the court, to whom they showed the wands which had been sent them by the *Thesmothetæ* as a summons to meet, examined its mark, to see if it was authentic, and then introduced them. The second inclosure, which was at the distance of 20 feet from the former, was a rope or cord; that the people who stood round the first inclosure, and were desirous to see what passed within the second, might not be prevented from gratifying their curiosity at a proper distance. Thus the attention of the judges was not interrupted by the concourse of the multitude, many of whom were heated by views of interest or of party.

To each of the members of the assembly were distributed two pieces of copper; one of which was perforated, not certainly that it might be distinguished from the other by feeling, for these assemblies met at the rising and were dissolved at the setting of the sun. Those pieces of copper had been substituted for little sea-shells, which were at first in use. The king was present at the assembly, at whose command it had been summoned. The *Thesmothetæ* read the names of those who were to compose it, and each man took his place as he was called. The *Thesmothetæ* were then sent for, whose function it was to observe prodigies and to superintend the sacrifices; and if they gave their sanction, the deliberations were begun. It is well known, that the officers called *Execretæ* were often corrupted by those who were interested in the debates of the assembly; and that they excited such tumults as were raised by the Roman tribunal in the popular assemblies convoked by the consuls.

Of all the monuments which remain relating to the *Heliastæ*, the most curious is the oath which those judges took before the *Thesmothetæ*: Demosthenes hath preserved it in his oration against Timocrates, who having been bribed by those who had been intrusted with the effects taken on board a vessel of Naucratis, and refused to give an account of them, got a law passed, by which an enlargement was granted to prisoners for public debts on giving bail. Demosthenes, in making his oration

against that law, ordered the oath of the Heliastæ to be read aloud, as a perpetual auxiliary to his arguments, and happily calculated to interest the multitude and inflame their passions. This oath bore ample testimony how respectable a tribunal that of the Heliastæ was, and how important were their decisions.

Aristotle informs us of another motive for the meeting of this assembly; this was, by the public authority deputed to them, to elect a magistrate in the room of one dead. It is surprising that Pausanias, who enters so often into details, gives us no particular account of this assembly. All that he says of it is, that the most numerous of the Athenian assemblies was called *Helicæ*.

We are told by Diogenes Laertius, in his Life of Solon, that it was before one of these Heliastic assemblies that Pisistratus presented himself, covered with wounds and contusions (for thus he had treated himself and the mules which drew his car), to excite the indignation of the people against his pretended enemies, who, jealous, as he alleged, of the popularity he had acquired by asserting the rights of his poorer fellow-citizens, in opposition to the men in power, had attacked him while he was hunting, and had wounded him in that barbarous manner. His design succeeded: a guard was appointed him; by the assistance of which he acquired the sovereignty or tyranny of Athens, and kept it 33 years. The power of the assembly appeared remarkably on that occasion; for Solon, who was present, opposed it with all his efforts, and did not succeed.

As to the manner in which the judges gave their suffrages, there was a sort of vessel covered with an osier mat, in which were placed two urns, the one of copper, the other of wood. In the lid of these urns there was an oblong hole, which was large at the top, and grew narrower downwards, as we see in some old boxes of our churches. The suffrages which condemned the accused person were thrown into the wooden urn, which was termed *kyrios*. That of copper, named *akyros*, received those which absolved him.

Aristotle observes, that Solon, whose aim was to make his people happy, and who found an aristocracy established by the election of the nine archons (annual officers, whose power was almost absolute), tempered their sovereignty, by instituting the privilege of appealing from *them* to the people, who were to be assembled by lot to give their suffrage: after having taken the oath of the Heliastæ, in a place near the Panathenæum; where Hippias had, in former days, calmed a sedition of the people, and bound them to unanimity by an oath. It has likewise been remarked, that the god Apollo was not invoked in the oath of the Heliastæ, as in the oaths of the other judges. We have observed, that he who took the oath of the Heliastæ, engaged that he would not be corrupted by solicitation or money. Those who violated this part of their oath were condemned to pay a severe fine. The decemvirs at Rome made such corruption a capital crime. But Asconius remarks, that the punishment denounced against them was mitigated in later times; and that they were expelled the senate, or banished for a certain time, according to the degree of their guilt.

HELICON, in ancient geography, the name of a mountain in the neighbourhood of Parnassus and Cytheron, sacred to Apollo and the muses, who are thence called *Heliconides*. It is situated in Livadia, and now called *Zagura* or *Zaguya*. Helicon was one of the most fertile and woody mountains in Greece. On it the fruit of the adrachnus, a species of the arbutus or of the strawberry-tree, was uncommonly sweet; and the inhabitants affirmed, that the plants and roots were all friendly to man, and that even the serpents had their poison weakened by the innoxious qualities of their food. It approached Parnassus on the north, where it touched on Phocis; and resembled that mountain in loftiness, extent, and magnitude.

Here was the shady grove of the muses and their images; with statues of Apollo and Bacchus, of Linus and Orpheus, and the illustrious poets who had recited their verses to the harp. Among the tripods, in the second century, was that consecrated by Hesiod. On the left-hand going to the grove was the fountain Aganippe; and about twenty stadia, or two miles and a half, higher up, the violet-coloured Hippocrene. Round the grove were houses. A festival was celebrated there by the Thespianians with games called *Musea*. The valleys of Helicon are described by Wheler as green and flowery in the spring; and enlivened by pleasing cascades and streams, and by fountains and wells of clear water. The Bœotian cities in general, two or three excepted, were reduced to inconsiderable villages in the time of Strabo. The grove of the muses was plundered under the auspices of Constantine the Great. The Heliconian goddesses were afterwards consumed in a fire at Constantinople, to which city they had been removed. Their ancient seat on the mountain, Aganippe and Hippocrene, are unascertained.

HELICONIA, in botany; a genus of the monogynia order, belonging to the pentandria class of plants. The spathe is universal and partial; there is no calyx; the corolla has three petals, and the nectarium two leaves; the capsule is three-grained.

HELICTERES, the SCREW-TREE; a genus of the decandria order, belonging to the gynandria class of plants; and in the natural method ranking under the 37th order, *Columniferæ*. The calyx is monophyllous and oblique; there are five petals, and the nectarium consists of five petal-like leaflets; the capsules are intorted or twisted inwards. There are four species, all natives of warm climates. They are shrubby plants, rising from five to fourteen feet in height, adorned with flowers of a yellow colour. They are propagated by seeds; but are tender, and in this country must be kept in a stove during the winter.

ST. HELIER, the capital of the island of Jersey, in the English Channel, seated in the bay of St. Aubin, where it has a harbour, and a stone pier, having the sea on the S. W. and hills on the N. that shelter it from the cold. Another large hill projects in a manner over the town, and has a pleasant walk, that affords an extensive prospect. The streets are wide and well-paved. The inhabitants are computed to be 2000. In the church, prayers are read alternately in English and French. At the top of the market-place is the statue of George II. in bronze, gilt. In the church is a monument, erected at the public expence, to the memory of Major Pierson, who fell in the moment of victory, in the attack of the French troops, who had made a descent on this island; in which action, the French general also was mortally wounded. W. lon. 2. 10. N. lat. 49. 11. See JERSEY.

St. HELIER, a little island, near the town of the same name, in the bay of St. Aubin, on the S. side of Jersey. It took its name from Elerius, or Helier, a holy man, who lived in this island many centuries ago, and was slain by the Pagan Normans, at their coming here. He is mentioned among the martyrs in the Martyrology of Coutances. His little cell, with the stone bed, is still shown among the rocks; and, in memory of him, a noble abbey was founded in this island. On the site of this abbey now stands Elizabeth Castle, a very large and strong fortification. It is the residence of the governor and garrison of St. Helier, and occupies the whole island, which is near a mile in circuit, and surrounded by the sea at every half flood; and hence, at low water, is a passage to the town of St. Helier, called the Bridge, half a mile long and formed of sand and stones.

HELIOCARPUS, in botany; a genus of the digynia order, belonging to the dodecandria class of plants; and in the natural method ranking under the 37th order, *Columniferæ*. The

calyx is tetraphyllous; the petals four; the styles simple; the capsule bilocular, compressed, and radiated lengthwise on each side.

HELIOCENTRIC LATITUDE of a Planet, the inclination of a line drawn between the centre of the sun and the centre of a planet to the plane of the ecliptic. The heliocentric place of a planet is the place of the ecliptic, wherein the planet would appear to a spectator placed at the centre of the sun.

HELIOCOMETES, a phenomenon sometimes observed about sun-setting; being a large luminous tail or column of light proceeding from the body of the sun, and dragging after it, not unlike the tail of a comet; whence the name.

HELIODORUS of PHOENICIA, bishop of Trica in Thesaly, better known by the romance he composed in his youth intitled *Ethiopics*, and relating the amours of Theagenes and Chariclea. Some say he was deposed by a synod because he would not consent to the suppressing that romance. The fable has a moral tendency, and particularly inculcates the virtue of chastity. As it was the first of this species of writing, he is styled the *Father of Romances*. He was also a good Latin poet. He lived in the 4th century.

HELIOMETER, formed of *ἥλιος* sun, and *μέτρον* I measure, the name of an instrument called also *astrometer*, invented by M. Bouguer in 1747, for measuring with particular exactness the diameters of the stars, and especially those of the sun and moon. This instrument is a kind of telescope, consisting of two object-glasses of equal focal distance, placed one of them by the side of the other, so that the same eye-glass serves for both. The tube of this instrument is of a conic form, larger at the upper end, which receives the two object glasses, than at the lower, which is furnished with an eye-glass and micrometer. By the construction of this instrument two distinct images of an object are formed in the focus of the eye-glass, whose distance, depending on that of the two object-glasses from one another, may be measured with great accuracy: nor is it necessary that the whole disc of the sun or moon come within the field of view; since, if the images of only a small part of the disc be formed by each object-glass, the whole diameter may be easily computed by their position with respect to one another: for if the object be large, the images will approach, or perhaps lie even over one another; and the object-glasses being moveable, the two images may always be brought exactly to touch one another, and the diameter may be computed from the known distance of the centres of the two glasses. Besides, as this instrument has a common micrometer in the focus of the eye-glass, when the two images of the sun or moon are made in part to cover one another, that part which is common to both the images may be measured with great exactness, as being viewed upon a ground that is only one half less luminous than itself; whereas, in general, the heavenly bodies are viewed upon a dark ground, and on that account are imagined to be larger than they really are. By a small addition to this instrument, provided it be of a moderate length, M. Bouguer thought it very possible to measure angles of three or four degrees, which is of particular consequence in taking the distance of stars from the moon. With this instrument M. Bouguer, by repeated observation, found, that the sun's vertical diameter, though somewhat diminished by the astronomical refraction, is longer than the horizontal diameter; and, in ascertaining this phenomenon, he also found, that the upper and lower edges of the sun's disc are not so equally defined as the other parts; on this account his image appears somewhat extended in the vertical direction. This is owing to the decomposition of light, which is known to consist of rays differently refrangible in its passage through our atmosphere. Thus the blue and violet rays, which proceed from the upper part of the disc at the same time with those of other colours, are somewhat more refracted than the others, and therefore seem to us to have

proceeded from a higher point; whereas, on the contrary, the red rays, proceeding from the lower edge of the disc, being less refracted than the others, seem to proceed from a lower point; so that the vertical diameter is extended, or appears longer, than the horizontal diameter. Mr. Servington Savery discovered a similar method of improving the micrometer, which was communicated to the Royal Society in 1743. See **MICROMETER**.

HELIOPHILA, in botany; a genus of the siliquosa order, belonging to the tetradynamia class of plants; and in the natural method ranking under the 39th order, *Siliquesæ*. There are two nectaria recurvated towards the vesicular base of the calyx.

HELIOPHOBI, a name given to the white negroes or albinos, from their aversion to the light of the sun. See **ALBINO**.

HELIOPOLIS, in ancient geography, so called by Herodotus and Diodorus Siculus, by Moses *On*, and in Jeremiah *Beth-femes*; a city of Egypt, to the south-east of the Delta, and east of Memphis; of a very old standing, its origin terminating in fable. Here stood the temple of the Sun, held in religious veneration. The city stood on an extraordinary mount, but in Strabo's time was desolate. It gave name to the *Nomos Heliopolites*. There was another *Heliopolis* in Cælosyria, near the springs of the Orontes; so called from the worship of the Sun, which was in great vogue over all Syria.

HELIOSCOPE, in optics, a sort of telescope, peculiarly fitted for viewing the sun without hurting the eyes. See **TELESCOPE**. As the sun may be viewed through coloured glasses without hurt to the eyes, if the object and eye-glasses of a telescope be made of coloured glass, as red or green, such a telescope will become an helioscope. But Mr. Huygens only used a plain glass, blacked at the flame of a candle on one side, and placed between the eye-glass and the eye; which answers the design of an helioscope very well.

HELIOSTATA, in optics, an instrument invented by the late learned Dr. S. Gravesande; who gave it this name from its fixing, as it were, the rays of the sun in an horizontal direction across the dark chamber all the while it is in use. See **OPTICS**.

HELIOTROPE, *heliotropium*, among the ancients, an instrument or machine for showing when the sun arrived at the tropics and the equinoctial line. This name was also used for a sun-dial in general.

HELIOTROPE is also a precious stone, of a green colour, streaked with red veins. Pliny says it is thus called, because, when cast into a vessel of water, the sun's rays falling thereon seem to be of a blood colour; and that, when out of the water, it gives a faint reflection of the figure of the sun; and is proper to observe eclipses of the sun as a helioscope. The heliotrope is also called *oriental jasper*, on account of its ruddy spots. It is found in the East Indies, as also in Ethiopia, Germany, Bohemia, &c. Some have ascribed to it the faculty of rendering people invisible, like Gyges's ring.

HELIOTROPIUM, **TURNSOLE**; a genus of the polygynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 41st order, *Asperifoliae*. The corolla is salver-shaped and quinquefid, with lesser dents interjected alternately; the throat closed up by small arches formed in the corolla itself. There are a number of species, all of them natives of warm countries. Only one, called the *triccocum*, grows in Europe; and is a native of France, Spain, and Italy. It is only remarkable for the property of its berries. See **COLOUR Making**.

HELIX, in geometry, a spiral line. See **SPIRAL**. The word is Greek, *εἰλιξ*, and literally signifies "a wreath or winding;" of *εἰλω* *involve*, "I environ." In architecture some authors make a difference between the helix and the spiral. A

stair-case, according to Daviler, is in a helix, or is helical, when the stairs or steps wind round a cylindrical newel; whereas the spiral winds round a cone, and is continually approaching nearer and nearer its axis. *Helix* is also applied, in architecture, to the caulicules or little volutes under the flowers of the Corinthian capital; called also *willæ*.

HELIX, in anatomy, is the whole circuit or extent of the auricle or border of the ear outwards. In opposition to which, the inner protuberance surrounded thereby, and answering thereto, is called *antihelix*. See ANATOMY, p. 211.

HELIX, the *Snail*, in zoology, a genus belonging to the order of vermes testacea. The shell consists of one spiral, brittle, and almost diaphanous valve; and the aperture is narrow. There are 60 species, principally distinguished by the figure of their shells. They are of various sizes, from that of a small apple to less than half a pea. Some of them live on land, frequenting woods and gardens, or inhabiting clefts of rocks and dry sand-banks. Others of them are aquatic, inhabiting ponds, deep rivers, and the ocean.

The principal species are, 1. The *jantbina*, with a violet-coloured shell, is remarkable for the extreme thinness of its texture, which breaks with the least pressure, and seems therefore entirely calculated to keep the open sea, or at least to shun rocky shores. It inhabits the seas of Europe, especially the Mediterranean; those of Asia and Africa; and also the ocean. The living animal, when touched, exudes a juice which stains the hands of a violet colour. Dr. Hawkesworth, in his account of Cook's voyage, mistakes this shell for that which yielded the *purpura* of the ancients. But whoever looks into Pliny, can never have the least idea that the thin shell aforementioned could be the same with it. They had several shells which yielded the purple dye: but these were all rock-shells (see **BUCCINUM** and **MUREX**), and very different both in figure and hardness from the little helix janthina; which is not calculated for the neighbourhood of rocks, as already mentioned. *Vid.* Plin lib. v. cap. 1. and lib. ix. cap. 60, 61. See also Don Ant. Ulloa's Voyage to South America, book iv. ch. 8. 2. The *pomatia*, or exotic snail, with five spires, most remarkably ventricose, and fasciated with a lighter and a deeper brown, is a native of France, where it inhabits the woods; but has been naturalized in England, where it inhabits the woods of the southern counties. It was introduced, it is said, by Sir Kenelm Digby; whether for medical purposes, or as food, is uncertain: tradition says, that to cure his beloved wife of a decay was the object. They are quite confined to our southern counties. An attempt was made to bring them into Northamptonshire, but they would not live there. These are used as a food in several parts of Europe during Lent; and are preserved in an escargatoire, or a large plate boarded in, with a floor covered half a foot deep with herbs, in which the snails nestle and fatten. They were also a favourite dish with the Romans, who had their *cochlearia*, a nursery similar to the above. Fulvius Hirpinus was the first inventor of this luxury, a little before the civil wars between Cæsar and Pompey. The snails were fed with bran and sodden wine. If we could credit Varro, they grew so large, that the shells of some would hold ten quarts! People need not admire the temperance of the supper of the younger Pliny, which consisted of only a lettuce a-piece, three snails, two eggs, a barley-cake, sweet wine and snow, in case his snails bore any proportion in size to those of Hirpinus. Its name is derived not from any thing relating to an orchard, but from *πωμα*, an *operculum*, it having a very strong one. This seems to be the species described by Pliny, lib. viii. c. 39. which he says was scarce; that it covered itself with the opercle, and lodged under ground; and that they were at first found only about the maritime Alps, and more lately near Velitræ. See plate 3. where the figure appears of half the natural size. 3. The *bortensis*, or garden-snail,

is in form like the last, but less, and not umbilicated and clouded, or mottled with browns. It abounds with a viscid slimy juice, which it readily gives out by boiling in milk or water, so as to render them thick and glutinous. The decoctions in milk are apparently very nutritious and demulcent, and have been recommended in a thin acrimonious state of the humours, in consumptive cases and emaciations.

The eyes of snails are lodged in their horns, one at the end of each horn, which they can retract at pleasure. The manner of examining these eyes, which are four in number, is this: When the horns are out, cut off nimbly the extremity of one of them; and placing it before the microscope, you may discover the black spot at the end to be really a semiglobular eye. The dissection of this animal is very curious; for by this means the microscope not only discovers the heart beating just against the round hole near the neck, which seems the place of respiration, but also the liver, spleen, stomach, and intestines, with the veins, arteries, mouth and teeth, are plainly observable. The guts of this creature are green, from its eating of herbs, and are branched all over with fine capillary white veins: the mouth is like a hare's or rabbit's, with four or six needle-teeth, resembling those of leeches, and of a substance like horn. Snails are all hermaphrodites, having both sexes united in each individual. They lay their eggs with great care in the earth, and the young ones are hatched with shells completely formed. Cutting off a snail's head, a little stone appears, which is supposed to be a great diuretic, and good in all nephritic disorders. Immediately under this stone the heart is seen beating; and the auricles are evidently distinguishable; and are membranous, and of a white colour; as are also the vessels which proceed from them.

Snails discharge their excrements at a hole in their neck; they also breathe by this hole, and their parts of generation are situated very near it. The penis is very long, and in shape resembles that of a whale. In the process of generation, it has been observed, that with the male and female part there issues, at the aperture of the neck, a kind of spear, shaped like the head of a lance, and terminating in a very acute point: and when the two snails turn the clefts in their necks towards each other, the spear issuing from one pricks the other, and then either drops to the ground or is carried off by the snail it has pricked. The snail instantly withdraws, but soon after rejoins the other, which it pricks in its turn; and after such mutual puncture, the copulation never fails of being consummated. Snails are said to couple three times at the distance of about fifteen days from each other, nature producing a new spear for each time of copulation, which last ten or twelve hours. At the end of about eighteen days they bring forth their eggs by the aperture of their neck.

So small an animal as the snail is not free from the plague of supporting other smaller animals on its body; and as in other animals we find these secondary ones either living only on their surface, as lice, &c. or only in the intestines, as worms, it is very remarkable that this creature infests the snail in both these manners; being found sometimes on the surface of its body and sometimes within its intestines. There is a part of the common garden snail, and of other of the like kinds, commonly called the *collar*. This surrounds the neck of the snail, and is considerably thick, and is the only part that is visible when the animal is retired quietly into its shell. In this state of the animal these insects which infest it are usually seen in considerable numbers marching about very nimbly on this part: besides, the snail, every time it has occasion to open its anus, gives them a place by which to enter into its intestines, and they often seize the opportunity.

Snails are great destroyers of fruit in our gardens, especially the better sorts of wall-fruit. Lime and ashes sprinkled on the

ground where they most resort will drive them away, and destroy the young brood of them: it is a common practice to pull off the fruit they have bitten; but this should never be done, for they will eat no other till they have wholly eat up this if it be left for them.

HELL, the place of divine punishment after death. As all religions have supposed a future state of existence after this life, so all have their hell or place of torment in which the wicked are supposed to be punished. The hell of the ancient heathens was divided into two mansions; the one called *Elysium*, on the right hand, pleasant and delightful, appointed for the souls of good men; the other called *Tartarus*, on the left, a region of misery and torment appointed for the wicked. The latter only was hell, in the present restrained sense of the word. See ELYSIUM.

The philosophers were of opinion, that the infernal regions were at an equal distance from all the parts of the earth; nevertheless it was the opinion of some, that there were certain passages which led thither, as the river Lethe near the Syrtis, and the Acherusian cave in Epirus. At Hermione it was thought, that there was a very short way to hell; for which reason the people of that country never put the fare into the mouths of the dead to pay their passage.

The Jews placed hell in the centre of the earth, and believed it to be situated under waters and mountains. According to them, there are three passages leading to it: the first is in the wilderness, and by that Korah, Dathan, and Abiram, descended into hell; the second is in the sea, because Jonah, who was thrown into the sea, cried to God out of the belly of hell; the third is in Jerusalem, because it is said the fire of the Lord is in Zion, and his furnace is in Jerusalem. They likewise acknowledged seven degrees of pain in hell, because they find this place called by seven different names in scripture. Though they believed that infidels, and persons eminently wicked, will continue for ever in hell; yet they maintained, that every Jew who is not infected with some heresy, and has not acted contrary to the points mentioned by the rabbins, will not be punished therein for any other crimes above a year at most.

The Mahometans believe the eternity of rewards and punishments in another life. In the Koran it is said, that hell has seven gates, the first for the Mussulmans, the second for the Christians, the third for the Jews, the fourth for the Sabians, the fifth for the Magians, the sixth for the Pagans, and the seventh for the Hypocrites of all religions.

Among Christians, there are two controverted questions in regard to hell; the one concerns locality, the other the duration of its torments. 1. The locality of hell, and the reality of its fire, began first to be controverted by Origen. That father, interpreting the scripture account metaphorically, makes hell to consist, not in external punishments, but in a consciousness or sense of guilt, and a remembrance of past pleasures. Among the moderns, Mr. Whiston advanced a new hypothesis. According to him, the comets are so many hells appointed in their orbits alternately to carry the damned into the confines of the sun, there to be scorched by its violent heat, and then to return with them beyond the orb of Saturn, there to starve them in these cold and dismal regions. Another modern author, not satisfied with any hypothesis hitherto advanced, assigns the sun to be the local hell. 2. As to the second question, viz. the duration of hell-torments, we have Origen again at the head of those who deny that they are eternal; it being that father's opinion, that not only men, but devils, after a due course of punishment suitable to their respective crimes, shall be pardoned and restored to heaven. The chief principle upon which Origen built his opinion, was the nature of punishment, which he took to be emendatory, applied only as physic for the recovery of the patient's health. The chief objection to the eternity of hell torments

among modern writers, is the disproportion between temporary crimes and eternal punishments. Those who maintain the affirmative, ground their opinions on scripture accounts, which represent the pains of hell under the figure of a worm which never dies, and a fire which is not quenched; as also upon the words, "These shall go away into everlasting punishment, but the righteous into life eternal."

HELLANICUS of Mitylene, a celebrated Greek historian, born before Herodotus, flourished about 480 B. C. He wrote a history of the ancient kings and founders of cities, but which hath not come down to us.

HELLAS, in ancient geography, an appellation comprising, according to the more ancient Greeks and Romans, Achaia and Peloponnesus, but afterwards restrained to Achaia. It was bounded on the west by the river Achelous, on the north by mounts Othrys and Oëta, on the east by the Egean sea, and on the south by the Saronic and Corinthian bays, and by the isthmus which joins it to Peloponnesus. It was called *Hellas*, from Hellen the son of Deucalion; or from Hellas, a district of Thesfaly; whence *Hellenes*, the gentilitious name, denoting Greeks. Now called *Livadia*.

HELLE, in fabulous history, a daughter of Athamas king of Thebes by Nephele. She fled from her father's house with her brother Phryxus, to avoid the cruel oppression of her mother-in-law Ino. According to some accounts she was carried through the air on a golden ram which her mother had received from Neptune, and in her passage she became giddy and fell from her seat into that part of the sea which from her received the name of *Hellefont*. Others say that she was carried on a cloud, or rather upon a ship, from which she fell into the sea and was drowned. Phryxus, after he had given his sister a burial on the neighbouring coasts, pursued his journey and arrived in Colchis.

HELLEBORE. See HELLEBORUS.

White-HELLEBORE. See VERATRUM.

HELLEBORUS, HELLEBORE; a genus of the polygynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 26th order, *Multifloræ*. There is no calyx; but five or more petals: the nectaria are bilabiated and tubular; the capsules polyspermous, and a little erect.

The most remarkable species described of this plant is the niger, commonly called *Christmas rose*. It hath roots composed of many thick fleshy spreading fibres, crowned by a large cluster of lobed leaves, consisting each of seven or eight obtuse fleshy lobes, united to one foot-stalk; and between the leaves several thick fleshy flower stalks three or four inches high, surmounted by large beautiful white flowers of five roundish petals, and numerous filaments, appearing in winter, about or soon after Christmas.

This plant may be propagated either by seeds or parting the roots. It prospers in the open borders, or may be planted in pots to move when in bloom in order to adorn any particular place; but it always flowers fairest and most abundantly in the front of a warm sunny border. The plants may be removed, and the roots divided for propagation, in September, October, or November; but the sooner in autumn it is done, the stronger will the plants flower at their proper season.

The root of this plant was anciently used as a cathartic. The taste of it is acrid and bitter. Its acrimony, as Dr. Grew observes, is first felt on the tip of the tongue, and then spreads itself immediately to the middle, without being much perceived in the intermediate part. On chewing the root for a few minutes, the tongue seems benumbed, and affected with a kind of paralytic stupor, as when burnt by eating any thing too hot. The fibres are more acrimonious than the head of the root from whence they issue. Black hellebore root, taken from 15 to 30 grains, proves a strong cathartic; and, as such, has been celebrated for

the cure of maniacal disorders, and such also as were attributed to what the ancients called the *atra bilis*. In mania, however, this root appears by no means to be possessed of any specific power. It does not indeed appear, that our black hellebore acts with so much violence as that of the ancients; whence many have supposed it to be a different species of plant: and indeed the descriptions which the ancients have left us of their hellebore, do not agree with those of any of the sorts usually taken notice of by modern botanists. Another species has been discovered in the eastern countries, which Tournefort distinguishes by the name of *belleborus niger orientalis*, *amplissimo folio, caule prostrato, flore purpurascente*, and supposes to be the true ancient hellebore, from its growing in plenty about mount Olympus, and in the island of Anticyra, celebrated of old for the production of this antimaniacal drug: he relates, that a scruple of this sort, given for a dose, occasioned convulsions. Our hellebore is looked upon principally as an alterative; and is sometimes employed, in small doses, for promoting the uterine and urinary discharges, &c. It proves a powerful emmenagogue in plethoric habits, where steel is ineffectual or improper. In some parts of Germany, a species of black hellebore has been made use of, which frequently produced violent, and sometimes deleterious, effects. It appears to be the fetid kind of Linnæus, called in English *settlewort*, *fatterwort*, or *bastard hellebore*. The roots of this may be distinguished from those of the true kind, by their being less black.

HELLEN, the son of Deucalion, is said to have given the name of Hellenists to the people before called *Greeks*, 1521 B. C.

HELLENISM, in language, a phrase in the idiom, genius, or construction of the Greek tongue. This word is only used when speaking of the authors who, writing in a different language, express themselves in a phraseology peculiar to the Greek.

HELLENISTIC LANGUAGE, that used by the Grecian Jews who lived in Egypt and other parts where the Greek tongue prevailed. In this language it is said the Septuagint was written, and also the books of the New Testament; and that it was thus denominated to show that it was Greek filled with Hebraisms and Syriacisms.

HELLENISTS, *Hellenistæ*, a term occurring in the Greek text of the New Testament, and which in the English version is rendered Grecians. The critics are divided as to the signification of the word. Œcumenius, in his Scholia on Acts vi. i. observes, that it is not to be understood as signifying those of the religion of the Greeks, but those who spoke Greek, τῆς ἑλληνικῆς φωνῆς ὁμιλοῦντες. The authors of the Vulgate version, indeed, render it like ours, *Greci*; but Messieurs Du Port Royal more accurately, *Juifs Grecs*, Greek or Grecian Jews; it being the Jews who spoke Greek that are here treated of, and who are hereby distinguished from the Jews called *Hebrews*, that is, who spoke the Hebrew tongue of that time. The Hellenists, or Grecian Jews, were those who lived in Egypt and other parts where the Greek tongue prevailed. It is to them we owe the Greek version of the Old Testament, commonly called the *Septuagint*, or that of the Seventy. Salmasius and Vossius are of a different sentiment with regard to the Hellenists. The latter will only have them to be those who adhered to the Grecian interests. Scaliger is represented, in the Scaligerana, as asserting the Hellenists to be the Jews who lived in Greece and other places, and who read the Greek Bible in their synagogue, and used the Greek language *in sacris*; and thus they were opposed to the Hebrew Jews, who performed their public worship in the Hebrew tongue; and in this sense St. Paul speaks of himself as a Hebrew of the Hebrews, Phil. iii. 5. i. e. a Hebrew both by nation and language. The Hellenists are thus properly distinguished from the *Hellenes* or *Greeks*, mentioned John

xii. 20. who were Greeks by birth and nation, and yet professed to the Jewish religion.

HELLENODICÆ, ἑλληνοδικαί, in antiquity, the directors of the Olympian games. At first there was only one, afterwards the number increased to two and to three, and at length to nine. They assembled in a place called ἑλληνοδικαίον, in the Elean forum, where they were obliged to reside ten months before the celebration of the games, to take care that such as offered themselves to contend, performed their προγυμνασματα, or preparatory exercises, and to be instructed in all the laws of games by certain men called νομοφύλακες, i. e. "keepers of the laws." And the better to prevent all unjust practices, they were farther obliged to take an oath, that they would act impartially, would take no bribes, nor discover the reason for which they disliked or approved of any of the contenders. At the solemnity they sat naked, having before them the victorial crown till the exercises were finished, and then it was presented to whomsoever they adjudged it. Nevertheless, there lay an appeal from the hellenodicæ to the Olympian senate.

HELLESPONT, a narrow strait between Asia and Europe, near the Propontis, which received its name from HELLE, who was drowned there in her voyage to Colchis. It is celebrated for the love and death of Leander, and for the bridge of boats which Xerxes built over it when he invaded Greece. The folly of this great prince is well known in beating and fettering the waves of the sea, whose impetuosity scattered his ships, and rendered all his labours ineffectual. It is now called the *Dardanelles*. It is about 33 miles long, and in the broadest parts the Asiatic coast is about one mile and a half distant from the European, and only half a mile in the narrowest, according to modern investigation, and the cocks are heard crowing from the opposite shores.

HELM, a long and flat piece of timber, or an assemblage of several pieces, suspended along the hind part of a ship's stern-post, where it turns upon hinges to the right, or left, serving to direct the course of the vessel, as the tail of a fish guides the body. The helm is usually composed of three parts, viz. the rudder, the tiller, and the wheel, except in small vessels, where the wheel is unnecessary. As to the form of the rudder, it becomes gradually broader in proportion to its distance from the top, or to its depth under the water. The back, or inner part of it, which joins to the stern-post, is diminished into the form of a wedge throughout its whole length, so as that the rudder may be more easily turned from one side to the other, where it makes an obtuse angle with the keel. It is supported upon hinges, of which those that are bolted round the stern-post to the after extremity of the ship, are called *googings*, and are furnished with a large hole on the after-part of the stern-post. The other parts of the hinges, which are bolted to the back of the rudder, are called *pintles*, being strong cylindrical pins, which enter into the googings, and rest upon them. The length and thickness of the rudder is nearly equal to that of the stern-post.

The rudder is turned upon its hinges by means of a long bar of timber, called the *tiller*, which is fixed horizontally in its upper end within the vessel. The movements of the tiller to the right and left, accordingly, direct the efforts of the rudder to the government of the ship's course as she advances; which, in the sea-language, is called *steering*. The operations of the tiller are guided and assisted by a sort of tackle, communicating with the ship's side, called the *tiller-rope*, which is usually composed of untarred rope-yarns for the purpose of traversing more readily through the blocks or pulleys.

In order to facilitate the management of the helm, the tiller-rope, in all large vessels, is wound about a wheel, which acts upon it with the powers of a crane or windlass. The rope employed in this service being conveyed from the fore-end of the tiller *k*, to a single block *i*, on each side of the ship, (see DECK

pl. 90. vol. ii.), is farther communicated to the wheel, by means of two blocks suspended near the mizzen-mast, and two holes immediately above, leading up to the wheel, which is fixed upon an axis on the quarter-deck, almost perpendicularly over the fore-end of the tiller. Five turns of the tiller-rope are usually wound about the barrel of the wheel; and, when the helm is amidship, the middle turn is nailed to the top of the barrel, with a mark by which the helmsman readily discovers the situation of the helm, as the wheel turns it from the starboard to the larboard side. The spokes of the wheel generally reach about eight inches beyond the rim or circumference, serving as handles to the person who steers the vessel. As the effect of a lever increases in proportion to the length of its arm, it is evident that the power of the helmsman to turn the wheel will be increased according to the length of the spokes beyond the circumference of the barrel.

When the helm, instead of lying in a right line with the keel, is turned to one side or the other, as represented in BD, pl. 3. it receives an immediate shock from the water, which glides along the ship's bottom in running *ast* from A to B; and this fluid pushes it towards the opposite side, whilst it is retained in this position: so that the stern, to which the rudder is confined, receives the same impression, and accordingly turns from B to *b* about some point *c*, whilst the head of the ship passes from A to *a*. It must be observed, that the current of water falls upon the rudder obliquely, and only strikes it with that part of its motion which acts according to the sine of incidence, pushing it in the direction NP, with a force which not only depends on the velocity of the ship's course, by which this current of water is produced, but also upon the extent of the sine of incidence. This force is by consequence composed of the square of the velocity with which the ship advances, and the square of the sine of incidence, which will necessarily be greater or smaller according to circumstances; so that if the vessel runs three or four times more swiftly, the absolute shock of the water upon the rudder will be nine or 16 times stronger under the same incidence: and, if the incidence is increased, it will yet be augmented in a greater proportion, because the square of the sine of incidence is more enlarged. This impression, or, what is the same thing, the power of the helm, is always very feeble, when compared with the weight of the vessel; but as it operates with the force of a long lever, its efforts to turn the ship are extremely advantageous. For the helm being applied to a great distance from the centre of gravity G, or from the point about which the vessel turns horizontally, if the direction PN of the impression of the water upon the rudder be prolonged, it is evident that it will pass perpendicularly to R, widely distant from the centre of gravity G: thus the absolute effort of the water is very powerful. It is not therefore surprising, that this machine impresses the ship with a considerable circular movement, by pushing the stern from B to *b*, and the head from A to *a*; and even much farther whilst she sails with rapidity, because the effect of the helm always keeps pace with the velocity with which the vessel advances.

Amongst the several angles that the rudder makes with the keel, there is always one position more favourable than any of the others, as it more readily produces the desired effect of turning the ship, in order to change her course. To ascertain this, it must be considered, that if the obliquity of the rudder with the keel is greater than the obtuse angle ABD, so as to diminish that angle, the action of the water upon the rudder will increase, and at the same time oppose the course of the ship in a greater degree; because the angle of incidence will be more open, so as to present a greater surface to the shock of the water, by opposing its passage more perpendicularly. But at that time the direction NP of the effort of the helm upon the ship will pass with a smaller distance from the centre of gravity G to-

wards R, and less approach the perpendicular NL, according to which it is absolutely necessary that the power applied should act with a greater effect to turn the vessel. Thus it is evident, that if the obtuse angle ABD is too much inclosed, the greatest impulse of the water will not counterbalance the loss sustained by the distance of the direction NP from NL, or by the great obliquity which is given to the same direction NP of the absolute effort of the helm with the keel AB. If, on the contrary, the angle ABD is too much opened, the direction NP of the force of the action of the helm will become more advantageous to turn the vessel, because it will approach nearer the perpendicular NL; so that the line prolonged from NP will increase the line GR, by removing R to a greater distance from the centre of gravity G: but then the helm will receive the impression of the water too obliquely, for the angle of incidence will be more acute; so that it will only present a small portion of its breadth to the shock of the water, and by consequence will only receive a feeble effort. By this principle it is easy to conceive, that the greatest distance GR from the centre of gravity G, is not sufficient to repair the diminution of force occasioned by the too great obliquity of the shock of the water. Hence we may conclude, that when the water either strikes the helm too directly, or too obliquely, it loses a great deal of the effect it ought to produce. Between the two extremes there is therefore a mean position, which is the most favourable to its operations.

The diagonal NP of the rectangle IL represents the absolute direction of the effort of the water upon the helm. NI expresses the portion of this effort which is opposed to the ship's head-way, or which pushes her astern, in a direction parallel to the keel. It is easily perceived, that this part NI of the whole power of the helm contributes but little to turn the vessel; for, if IN is prolonged, it appears that its direction approaches to a very small distance GV from the centre of gravity G; and that the arm of the lever BN = GV, to which the force is applied, is not in the whole more than equal to half the breadth of the rudder: but the relative force NL, which acts perpendicular to the keel, is extremely different. If the first NI is almost useless, and even pernicious, by retarding the velocity; the second NL is capable of a very great effect, because it operates at a considerable distance from the centre of gravity G of the ship, and acts upon the arm of a lever GE, which is very long. Thus it appears, that between the effects NL and NI, which result from the absolute effort NP, there is one which always opposes the ship's course, and contributes little to her motion of turning; whilst the other produces only this movement of rotation, without operating to retard her velocity.

Geometricians have determined the most advantageous angle made by the helm with the line prolonged from the keel, and fixed it at $54^{\circ} 44'$, presuming that the ship is as narrow at her floating-line, or at the line described by the surface of the water round her bottom, as at the keel. But as this supposition is absolutely false, inasmuch as all vessels augment their breadth from the keel upward to the extreme breadth, where the floating-line or the highest water-line is terminated; it follows, that this angle is too large by a certain number of degrees. For the rudder is impressed by the water, at the height of the floating-line, more directly than at the keel, because the fluid exactly follows the horizontal outlines of the bottom; so that a particular position of the helm might be supposed necessary for each different incidence which it encounters from the keel upwards. But as a middle position may be taken between all these points, it will be sufficient to consider the angle formed by the sides of the ship, and her axis, or the middle-line of her length, at the surface of the water, in order to determine afterwards the mean point, and the mean angle of incidence.

It is evident that the angle $54^{\circ} 44'$ is too open, and very unfavourable to the ship's head-way, because the water acts upon

the rudder there with too great a sine of incidence, as being equal to that of the angle which it makes with the line prolonged from the keel below: but above, the shock of the water is almost perpendicular to the rudder, because of the breadth of the bottom, as we have already remarked. If then the rudder is only opposed to the fluid, by making an angle of 45° with the line prolonged from the keel, the impression, by becoming weaker, will be less opposed to the ship's head-way, and the direction NP of the absolute effort of the water upon the helm drawing nearer to the lateral perpendicular, will be placed more advantageously, for the reasons above mentioned. On the other hand, experience daily testifies, that a ship steers well when the rudder makes the angle DBE equal to 35° only.

It has been already remarked, that the effect of moving the wheel to govern the helm increases in proportion to the length of the spokes; and so great is the power of the wheel, that if the helmsman employs a force upon its spokes equivalent to 30 pounds, it will produce an effect of 90 or 120 pounds upon the tiller. On the contrary, the action of the water is collected into the middle of the breadth of the rudder, which is very narrow in comparison with the length of the tiller; so the effort of the water is very little removed from the fulcrum B upon which it turns; whereas the tiller forms the arm of a lever 10 or 15 times longer, which also increases the power of the helmsman in the same proportion that the tiller bears to the lever upon which the impulse of the water is directed. This force then is by consequence 10 or 15 times stronger; and the effort of 30 pounds, which at first gave the helmsman a power equal to 90 or 120 pounds, becomes accumulated to one of 900 or 1800 pounds upon the rudder. This advantage then arises from the shortness of the lever upon which the action of the water is impressed, and the great comparative length of the tiller, or lever, by which the rudder is governed; together with the additional power of the wheel that directs the movements of the tiller, and still farther accumulates the power of the helmsman over it. Such a demonstration ought to remove the surprise with which the prodigious effect of the helm is sometimes considered, from an inattention to its mechanism: for we need only to observe the pressure of the water, which acts at a great distance from the centre of gravity G, about which the ship is supposed to turn, and we shall easily perceive the difference there is between the effort of the water against the helmsman, and the effect of the same impulse against the vessel. With regard to the person who steers, the water acts only with the arm of a very short lever NB, of which B is the fulcrum: on the contrary, with regard to the ship, the force of the water is impressed in the direction NP, which passes to a great distance from G, and acts upon a very long lever EG, which renders the action of the rudder extremely powerful in turning the vessel; so that, in a large ship, the rudder receives a shock from the water of 2700 or 2800 pounds, which is frequently the case when she sails at the rate of three or four leagues by the hour; and this force being applied in E, perhaps 100 or 110 feet distant from the centre of gravity G, will operate upon the ship, to turn her about, with 270,000 or 308,000 pounds; whilst, in the latter case, the helmsman acts with an effort which exceeds not 30 pounds upon the spokes of the wheel.

After what has been said of the helm, it is easy to judge, that the more a ship increases her velocity with regard to the sea, the more powerful will be the effect of the rudder; because it acts against the water with a force, which increases as the square of the swiftness of the fluid, whether the ship advances or retreats; or, in other words, whether she has head-way or stern-way; with this distinction, that in these two circumstances the effects will be contrary. For if the vessel retreats, or moves astern, the helm will be impressed from I to N; and instead of being pushed, according to NP, it will receive the effort of the

water from N towards R; so that the stern will be transported to the same movement, and the head turned in a contrary direction. When the helm operates by itself, the centre of rotation of the ship, and her movement, are determined by estimating the force of this machine; that is to say, by multiplying the surface of the rudder by the square of the ship's velocity.

There are several terms in the sea-language relating to the helm; as, *Bear up the helm*; that is, Let the ship go more large before the wind. *Helm a mid-ship*, or *right the helm*: that is, Keep it even with the middle of the ship. *Port the helm*, Put it over the left side of the ship. *Starboard the helm*, Put it on the right side of the ship.

HELMET, an ancient defensive armour worn by horsemen both in war and in tournaments. It covered both the head and face, only leaving an aperture in the front secured by bars, which was called the *visor*. In achievements, it is placed above the escutcheon as the principal ornament, and is the true mark of chivalry and nobility. Helmets vary according to the different degrees of those who bear them. They are also used as a bearing in coats of arms. See HERALDRY.

HELMINTHOLITHUS, in natural history, a name given by Linnæus to petrified bodies resembling worms. Of these he reckons four genera. 1. Petrified lithophyta, found in the mountains of Sweden. 2. Petrified shells. 3. Petrified zoophytes: 4. Petrified reptiles.

HELMONT (John Baptist Van), a celebrated Flemish gentleman, was born at Brussels in 1577. He acquired such skill in natural philosophy, physic, and chemistry, that he was accounted a magician, and thrown into the inquisition: but having with difficulty justified himself, as soon as he was released he retired to Holland; where he died in 1644. He published, 1. *De magnetica corporum curatione*. 2. *Febrium doctrina inaudita*. 3. *Ortus medicinæ*. 4. *Paraloxa de aquis spadanis*; and other works, printed together in one volume folio.

HELMONT, a small town in the Netherlands, in Dutch Brabant, and capital of the district of Peeland, with a good castle. It is seated on the river Aa, in E. long. 5. 37. N. lat. 51. 31.

HELMSDALE, a river of Sutherland-shire, in Scotland, which descends from the mountains bordering on Caithness-shire, and rolling over its rocky bottom toward the Ord of Caithness, becomes, at that place, deep, rapid, and dangerous, there being no bridge over the river. At its mouth, in the German Ocean, is a good salmon fishery.

HELMSLEY, or HELMSLEY-BLACKMORE, a town of the N. riding of Yorkshire, seated on the river Rye. The houses are well built of stone, and covered with slate. It had formerly a castle, and has now a market on Saturday. It is 20 miles N. of York, and 220 N. by W. of London. W. lon. 1. 9. N. lat. 54. 19.

HELMSTADT, a town of Germany, in the duchy of Brunswick, with a university; 22 miles N. E. of Brunswick. E. lon. 11. 16. N. lat. 52. 16.

HELONIAS, in botany, a genus of the trigynia order, belonging to the hexandria class of plants; and in the natural method ranking under the 10th order, *Coronarie*. The corolla is hexapetalous; there is no calyx; and the capsule is trilobular.

HELOISE, famous for her unfortunate affection for her tutor Abelard, and for her Latin letters to him after they had retired from the world. She died abbess of Paraclet in 1163. See ABELARD.

HELOS, in ancient geography, a maritime town of Laconia, situated between Trinasus and Acrisæ, in Pausanias's time in ruins. The district was called *Helotes*, and the people *Helotes*, *Helotæ*, *Helci*, and *Helotæ*, by Stephanus; and *Ilota*, by Livy. Being subdued by the Lacedæmonians, they were all

reduced to a state of public slavery, or made the slaves of the public, on these conditions, viz. that they neither could recover their liberty, nor be sold out of the territory of Sparta. Hence the term *ελωττειν*, in Harpoeration, for being in a state of slavery; and hence also the Lacedæmonians called the slaves of all nations whatever *belotes*. *Heloticus* is the epithet.

HELOTS, in Grecian antiquity, the slaves of the Spartans. See **HELOS**. The freemen of Sparta were forbidden the exercise of any mean or mechanical employment, and therefore the whole care of supplying the city with necessaries devolved upon the Helots.

HELSINBURG. See **ELSIMBURG**.

HELSINGFORS, a town of Swedish Finland, in a romantic situation, on a rising shore, near several rocks and huge fragments of granite. The harbour is in the gulf of Finland, and is the most commodious of any in the province of that name. Helsingfors is 150 miles E. of Abo. E. lon. 25. 0. N. lat. 60. 20.

HELSINGIA, a province of Sweden, bounded on the north by Jempterland and Medelpadia, on the east by the Bothnic gulf, and on the south and west by Dalecarlia and Gestricia. It is full of mountains and forests, and the inhabitants are almost constantly employed in hunting and fishing. It has no cities: the principal towns are, Hudwickvald, Alta, and Dilsbo.

HELSINGIC CHARACTER, a peculiar kind of character found inscribed on stones in the province of Helsingia. The Runic and Helsingic characters may be easily transformed into each other.

HELSTON, a borough of Cornwall, with a market on Monday. It is seated on the river Cober, near its influx into the sea. It is one of those appointed for the coinage of the tin. A little below the town is a tolerable good harbour, where several of the tin ships take in their lading. It is well inhabited, and governed by a mayor, four aldermen, a town-clerk, and deputy recorder. Here is the largest market-house in the county. It is 11 miles S. W. of Falmouth, and 274 W. by S. of London. E. lon. 5. 15. N. lat. 50. 2.

HELVELLA, in botany; a genus of the natural order of fungi, belonging to the cryptogamia class of plants. The fungus is of the shape of a top.

HELVETIC, something that has a relation to the Switzers, or inhabitants of the Swiss cantons, who were anciently called *Helvetii*. The Helvetic body comprehends the republic of Switzerland, consisting of 13 cantons, which make so many particular commonwealths. By the laws and customs of the Helvetic body, all differences between the several states and republics are to be decided within themselves, without the intervention of any foreign power. The government of this body is chiefly democratic, with some mixture of the aristocratic.

HELVETII, a people of Belgica, in the neighbourhood of the Allobroges and the Provincia Romana; famed for bravery and a turn for war. Called *Civitas Helvetia*, and divided into four Pagi or Cantons; situated to the south and west of the Rhine, by which they were divided from the Germans; and extending towards Gaul, from which they were separated by mount Jura on the west, and by the Rhodanus and Lacus Lemanus on the south, and therefore called a Gallic nation (Tacitus, Cæsar, Strabo, Ptolemy, Pliny). Formerly a part of Celtic Gaul, but by Augustus assigned to Belgica.

HELVETIUS (Adrian), an eminent physician, born in Holland. After having studied physic at Leyden, he went to Paris, where he acquired great reputation in his profession. He introduced in France the use of ipeacacuanha in the cure of dysenteries; a remedy which he at first kept secret, but was

ordered to make it public, and on that account received a gratification from the king of 1000 louis d'ors. He was made inspector-general of the hospitals in Flanders, physician to the duke of Orleans regent of France, &c.; and died at Paris in 1727, aged 65. He wrote a treatise on the most common diseases, and the remedies proper for their cure (the best edition of which is that of 1724, in two volumes octavo); and other works.

HELVETIUS (John-Claude), son of the above, was born in 1685, and died in 1755. He was physician to the queen, and greatly encouraged by the town as well as court. He was, like his father, inspector-general of the military hospitals. He was of the Academy of Sciences at Paris, of the Royal Society in London, and of the Academies of Prussia, Florence, and Bologne. He is the author of, 1. *Idée Générale de l'économie animale*, 1722, 8vo. 2. *Principia Physico-Medica, in tyronum Medicinæ gratiam conscripta*, 2 vols. 8vo. It may be proper farther to mention, that he is the father of the Mons. **HELVETIUS**, who wrote the celebrated book *De l'Esprit*; and whom Voltaire calls "a true philosopher;" but whose book was stigmatized by the authors of the *Journal de Trevoux*, and suppressed by the government.

HELVICUS (Christopher), professor of divinity, Greek, and the Oriental tongues, in the university of Gissen, died in the flower of his age in 1617; after having published several books, and projected more. The Hebrew language was so familiar to him, that he spoke it as fluently as his mother tongue. He was not only a good grammarian, but also an able chronologer. His chronological tables have been greatly esteemed, though they are not free from errors.

HELVIDIANS, a sect of ancient heretics, denominated from their leader Helvidius, a disciple of Auxentius the Arian, whose distinguishing principle was, that Mary, the mother of Jesus, did not continue a virgin, but had other children by Joseph.

HELVOETSLUYS, a seaport of the United Provinces, in Holland, on the island of Voorn. It is frequented by a great number of ships, particularly by the English packet-boats, from Harwich. It is five miles S. of the Briel. E. lon. 4. 23. N. lat. 51. 45.

HEMATITES. See **HÆMATITES**.

HEMELAR (John), an eminent antiquarian, and canon of Antwerp, in the 17th century, was born at the Hague; and wrote a work, entitled, *Expositio Numismatum imperatorum Romanorum à Julio Cæsare ad Heraclium*; which is very scarce, though it has had several editions.

HEMEROBAPTISTS, a sect among the ancient Jews, thus called from their washing and bathing every day in all seasons; and performing this custom with the greatest solemnity, as a religious rite necessary to salvation. Epiphanius, who mentions this as the fourth heresy among the Jews, observes, that in other points these heretics had much the same opinions as the Scribes and Pharisees; only that they denied the resurrection of the dead, in common with the Sadducees, and retained a few other of the improprieties of these last. The sects who pass in the East under the denomination of Sabians, calling themselves *Mendai Iabi*, or *the disciples of John*, and whom the Europeans entitle *the Christians of St. John*, because they yet retain some knowledge of the gospel, is probably of Jewish origin, and seems to have been derived from the ancient Hemerobaptists; at least it is certain, that that John, whom they consider as the founder of their sect, bears no sort of similitude to John the Baptist, but rather resembles the person of that name whom the ancient writers represent as the chief of the Jewish Hemerobaptists. These ambiguous Christians dwell in Persia and Arabia, and principally at Bassora; and their religion consists in bodily washings, performed frequently,

and with great solemnity, and attended with certain ceremonies which the priests mingle with this superstitious service.

HEMEROBIUS, in zoology; a genus of insects of the neuroptera order; the characters of which are these. The mouth is furnished with two teeth; the palpi are four; the wings are deflected, but not plaited; and the antennæ are bristly, and longer than the breast. There are 15 species; principally distinguished by their colours. This insect takes the name of *hemerobius* from the shortness of its life, which, however, continues several days. In the state of larva it is a great devourer of plant-lice, for which it has had bestowed upon it the appellation of *lion of the plant-lice*. The hemerobii, even after their transformation, preserve their carnivorous inclination. Not satisfied with making war upon the plant-lice, who tamely let themselves be devoured, they do not spare each other. The eggs of this insect are borne upon small pedicles, which are nothing but a gum spun out by the hemerobius by raising up the hinder part of its abdomen, and by that means the egg remains fastened to the upper part of the thread. Those eggs are deposited upon leaves, and set in the form of bunches. They have been taken for parasitic plants. The larva, when hatched, finds there its food in the midst of plant-lice. In 15 or 16 days it has attained to its full growth. With its spinning-wheel at its tail, it makes itself a small, round, white, silky cocoon, of a close texture. In summer, at the end of three weeks, the hemerobius issues forth with its wings; but when the cocoon has not been spun till autumn, the chrysalis remains in it the whole winter, and does not undergo its final metamorphosis till the ensuing spring. The flight of this insect is heavy: some species have an excrementitious smell. One goes by the name of the *water-hemerobius*, because it lives mostly at the water-side.

HEMEROCALLIS, DAY-LILY, or *lily-asphodel*; a genus of the monogynia order, belonging to the hexandria class of plants; and in the natural method ranking under the 10th order, *Coronarieæ*. The corolla is campanulated, with the tube cylindrical; the stamina decussating downwards. The *Species* are, 1. The *flava*, or yellow day-lily, with strong fibrous roots, sending up large hollow keel-shaped leaves, two feet long, upright, leafless firm stalks two feet high; dividing at top into several foot-stalks, each terminated by one large liliaceous yellow flower of an agreeable odour. Of this there is a variety called the *hemerocallis minor*, or small yellow day-lily. 2. The *fulva*, reddish, or copper-coloured day-lily, hath roots composed of strong fleshy fibres and large oblong tubes; radical, keel-shaped, hollow, pointed leaves, a yard long, reflected at top; with leafless stalks three or four feet high, and large copper-coloured liliaceous flowers. These have large stamina, charged with a kind of brown-coloured farina; which, on being touched or smelled to, is discharged in great plenty all over the hands and face. Both these species are hardy, and will thrive any where. They may be easily propagated by parting their roots in autumn, or almost any time after flowering, or before they begin to flower.

HEMERODROMI, compounded of *ἡμερα* "day," and *δρομη* "course," &c. among the ancients, were sentinels or guards appointed for the security and preservation of cities and other places. They went out of the city every morning, as soon as the gates were opened, and kept all day patrolling round the place; sometimes also making excursions farther into the country, to see that there were no enemies lying in wait to surprize them.

HEMERODROMI were also a sort of couriers among the ancients, who only travelled one day, and then delivered their packets or dispatches to a fresh man, who ran his day, and so on to the end of the journey. The Greeks had of these sort of couriers, which they derived from the Persians, who were

the inventors thereof, as appears from Herodotus. Augustus had the same; at least he established couriers, who, if they did not relieve each other from day to day, yet did it from space to space, and that space was not very great.

HEMEROTROPHIS, in antiquity, a measure of capacity, the same with the chœnix. It was so called from its holding one day's food. The word is compounded of *ἡμερα* a day, and *τροφη* food.

HEMI, a word used in the composition of various terms. It signifies the same with *femi* or *demi*, viz. "half;" being an abbreviature of *ἡμισυς* *hemisys*, which signifies the same. The Greeks retrenched the last syllable of the word *ἡμισυς* in the composition of words; and, after their example, we have done so too in most of the compounds borrowed from them.

HEMICRANIA, in medicine, a species of cephalalgia, or head-ach; wherein only one side of the head is affected. It is said to be owing to a congestion of blood in the vessels of that side, but it more frequently arises from sympathy with the stomach.

HEMICYCLE, **HEMICYCLUM**, compounded of *ἡμισυς* half, and *κυκλος* circle, a semicircle. This term is particularly applied, in architecture, to vaults in the cradle form; and arches or sweeps of vaults, constituting a perfect semicircle. To construct an arch of hewn stone, they divide the hemisphere into so many vouffoires; taking care to make them an uneven number, that there be no joint in the middle, where the key-stone should be. See **KEY** and **BRIDGE**.

HEMICYCLUM was also a part of the orchestra in the ancient theatre. Scaliger, however, observes, it was no standing part of the orchestra; being only used in dramatic pieces, where some person was supposed to be arrived from sea, as in Plautus's *Rudens*. The ancients had also a sort of sundial, called *hemicyclium*. It was a concave semicircle, the upper end or cusp whereof looked to the north. There was a style, or gnomon, issuing from the middle of the hemisphere, whereof that point corresponding to the centre of the hemisphere represented the centre of the earth; and its shadow projected on the concavity of the hemisphere, which represented the space between one tropic and another, the sun's declination, the day of the month, hour of the day, &c.

HEMIMERIS, in botany; a genus of the angiospermia order, belonging to the didynamia class of plants. The capsule is bilocular, with one of the cells more gibbous than the other: the corolla is wheel-shaped; with one division greater, and inverse heart-shaped; the interstice of the divisions nectar-bearing.

HEMINA, in Roman antiquity, a liquid measure, which, according to Arbutnot, was equal to half a wine-pint English measure; its contents being 2.818 solid inches.

HEMIOBOLON, a weight often mentioned by the ancient writers in medicine, and expressing the half of their obolus, or the twelfth part of a dram, that is, five grains.

HEMIONITIS, in botany; a genus of the natural order of filices, belonging to the cryptogamia class of plants. The fructifications are in lines decussating or crossing each other.

HEMIPLEGIA, or **HEMIPLEXIA**, among physicians, a palsy of one half of the body. See **MEDICINE**.

HEMIPTERA, derived from *ἡμισυς* half, and *πτερον* wing, in the Linnæan system, the second order of insects, comprehending twelve genera, viz. the *blattæ*, *mantis*, *gryllus*, *fulgora*, *cicada*, *rotoneta*, *u. p. c. mex*, *aphis*, *chermes*, *coccus*, and *thrips*, and a great number of species. See **ENTOMOLOGY**, **INSECTS**, and **ZOOLOGY**.

HEMISPHERE, **HEMISPHERIUM**, compounded of *ἡμισυς* half, and *σφαيرا* sphere, in geometry, is one half of a globe or sphere, when divided into two by a plane passing through its centre. This term, in astronomy, is particularly used for one

half of the mundane sphere. The equator divides the sphere into two equal parts, called the *northern* and *southern hemispheres*. The horizon also divides the sphere into two parts, called the *upper* and the *lower hemispheres*.

HEMISPHERE is also used for a map, or projection, of half the terrestrial globe, or half the celestial sphere, on a plane. Hemispheres are frequently called *planispheres*.

HEMISTICH, in poetry, denotes half a verse, or a verse not completed. Of this there are frequent examples in Virgil's *Æneid*; but whether they were left unfinished by design or not, is disputed among the learned: such are, *Ferò accincta vocat*, *Æn.* II. v. 614. And, *Italiam non sponte sequor*, *Æn.* IV. v. 361. In reading common English verses, a short pause is required at the end of each hemistich or half-verse.

HEMITONE, in the ancient music, was what we now call a half note or semitone.

HEMITRITÆUS, in medicine, a kind of fever, denoting the same as semi-tertian, returning twice every day. The word is Greek, and compounded of ἡμις "half," and τριταῖος "third or tertian."

HEMLOCK, in botany. See *CICUTA* and *CONIUM*.

HEMOIPTOTON. See *ORATORY*.

HEMP. See *CANNABIS*. It does not appear that the ancients were acquainted with the use of hemp, in respect of the thread it affords. Pliny, who speaks of the plant in his natural history, lib. xx. cap. 23. says not a word of this; contenting himself with extolling the virtues of its stem, leaves, and root. In effect, what some writers of the Roman antiquities remark, viz. that the hemp necessary for the use of war was all stored up in two cities of the western empire, viz. at Ravenna and Vienne, under the direction of two procurators, called *procuratores lini-ficii*, must be understood of linum or flax.

The use of hemp is so extensive and important, that vast quantities of it are annually imported into this and other kingdoms from those countries where it grows in greatest plenty, of which Russia is one. In the year 1763, the quantity imported into England alone amounted to 11,000 tons. Sir John Sinclair informs us (*Annals of Agriculture*, vol. xiii. p. 508), that in the year 1785 the quantity exported from Petersburg in British ships was as follows:

	Poods.
Clean hemp	1,038,791
Outshot	37,382
Half-clean	18,374
Hemp-codille	19,251
	<hr/>
	1,113,798

Now, allowing 63 poods to a ton, the quantity just mentioned will amount to 17,695 tons; and supposing it to take five acres to produce a ton of hemp, the whole quantity of ground requisite for this purpose would amount to 88,475 acres.

By other accounts, the annual export of hemp to England is valued at 400,000l.; but by a computation of the whole imported into Britain and Ireland in 1788, it would seem that a considerably greater quantity must fall to the share of England. In that year the quantity amounted to no less than 58,464 tons; which at 20l. per ton amounted to 1,269,280l. We cannot wonder at this vast consumption, when it is considered that the sails and cordage of a first rate man of war require 180,000lb. of rough hemp for their construction; but even this will scarce account for the enormous consumption in France, which in the year 1783 is said to have amounted to upwards of 400 millions of pounds, or 200,000 tons; of which more than one third was imported.

Only the coarser kinds of hemp are employed in making cordage, the better sorts being used for linen, which, though it

can never be made so fine as that from flax, is yet incomparably stronger, and equally susceptible of bleaching both in the old and new way. Cloths made of hemp have also this property, that their colour improves by wearing, while that of linen decays. The prices of hemp-linen are various; from 10d. to 4s. 6d. per yard. The low-priced kinds are very generally worn in Suffolk (where hemp is cultivated) by husbandmen, servants, &c. those from 1s. 6d. to 2s. by farmers and tradesmen; and those from 2s. 6d. to 4s. 6d. are frequently preferred by gentlemen to flax-linen, on account of their strength and warmth. The English hemp is much superior in strength to that which grows in any other country. Next to it is the Russian, from which sacking is usually made, as it is sometimes also from the offal of the English kind, but none of the Suffolk hemp is ever made into cordage, on account of its fineness. A considerable quantity of Russia sheeting is imported into England merely on account of its strength, and is much coarser at the price than any other foreign linen.

Besides these uses of hemp, it is said to possess a property as a plant which renders it almost invaluable; viz. that of driving away almost all insects that feed upon other vegetables. Hence in some places of the continent they secure their crops from these mischievous attacks, by sowing a belt of hemp round their gardens, or any particular spot which they wish to preserve.

The important uses of hemp, and the superiority of that produced in Britain to other kinds, have rendered the culture of it an object of attention to government. Accordingly in the year 1787, a bounty of three-pence per stone was allowed on all the hemp raised in England; and probably with a view to encourage the growth of English hemp, duties have been laid on that which comes from abroad. Dressed hemp in a British ship pays 2l. 4s. per cwt. import duty; in a foreign one, 2l. 6s. 9d.; and in both cases a drawback of 1l. 19s. is allowed. Undressed hemp in a British ship pays 3s. 8d.; and in a foreign one 3s. 11d. In both cases the drawback is 3s. 4d. The export of British hemp is free.

The usual height of the plant when growing is from five to six feet, but this varies very considerably according to circumstances. That which is cultivated near Bischwiller in Alsace is sometimes more than 12 feet high, and upwards of three inches in circumference, the stalks being so deeply rooted that a very strong man can scarce pull them up. Mr. Arthur Young, in a tour through Catalonia in Spain, says, that where the country is well watered, the crops of hemp are extraordinary; and that the plants generally rise to the height of seven feet. In Italy hemp is generally cultivated, though the Bolognese only can pretend to any superiority in the management of it. It is there sown upon their best lands, which are rich strong loams; and on which they are at all possible pains to procure a fine friable surface. For manure they use dung, pieces of rotten cloth, feathers, and horns brought from Dalmatia. The plant, however, may be cultivated upon ground of every kind; the poorer land producing that which is finer in quality, though in smaller quantity; whereas strong and rich land produces a great quantity, but coarser. It does not exhaust the land on which it grows, like flax; whence it is probable, that if properly managed, and care taken in the cultivation, it might be found to supersede flax entirely. A Sussex manufacturer, who writes on this subject in the *Annals of Agriculture*, informs us, that it may be raised for many years successively on the same ground, provided it be well manured. An acre requires from nine to twelve pecks, according to the nature of the soil; the latter being the most usual, though a variation in the quality of the soil makes an alteration both in the quantity and quality of the hemp. An acre produces on an average 36 or 38 stone. The abbé Brulle, in a *Treatise upon the Culture and Management of*

Hemp, printed by order of the lords of the committee of council for trade and foreign plantations, informs us, that the season for sowing it extends from the 25th of March to the 15th of June. The seed ought always to be sown thin, not exceeding two bushels to an acre; and if you have the advantage of a drill plough, still less will answer. As there are two kinds of hemp, the male and female, of which the former only produces seed, some regard must be had to this circumstance. In Suffolk the male and female are pulled together about 13 weeks after the sowing, but in the fens they are frequently separated. This last method is recommended by the abbé Brulle, who, for the more easy accomplishment of it, directs that little paths should be made lengthwise through the field at about seven feet distance from each other, to allow a passage for the person who pulls up the female hemp from among the other; the latter requiring to stand more than a month after for the purpose of ripening the seeds. The female hemp is known to be ripe by the fading of the flowers, the falling of the farina secundans, and some of the stalks turning yellow. After the whole of this kind is pulled, it must be manufactured according to the directions to be afterwards given, and ought to be worked if possible while green; the hemp thus produced being much finer than that which is previously dried. The reason of this is, that the plant contains a great quantity of glutinous matter; which being once dried, agglutinates the fibres in such a manner that they can never be afterwards perfectly separated. The female hemp, however, is always in smaller quantity than the male; and therefore, where the crop is large, it will be impossible to work the whole as fast as it is pulled or cut. It is known to be ripe by the stems becoming pale; but it must be remembered, that hemp of any kind will be much less injured by pulling the plants before they are ripe than by letting them stand too long.

The male hemp being stripped of its leaves, &c. as afterwards directed, will soon be dry for storing by the heat of the atmosphere, though sometimes it may be necessary to use artificial means; but where these are used, the utmost care must be taken, hemp when dry being exceedingly inflammable. The stored or dried hemp must be steeped and treated in every other respect as though it had been green; whence it is evident that this operation ought never to be used but in cases of necessity. It is likewise impossible to make hemp which has been dried previous to its being steeped, so white as that which has been worked green.

With regard to the perfecting of hemp-seed for a subsequent season, it would seem proper to set apart a piece of ground for this purpose; for M. Aimen, from 40 plants raised in the common way, had only a pound and an half of seed, though the plants from which it was taken might be deemed fine; whereas, from a single plant which grew by itself, he had seven pounds and an half. Some are of opinion, that by putting the clusters which contain the hemp-seed to heat and sweat, the quality is improved; as many of those seeds which would otherwise wither and die, may thus arrive at perfection. This, however, seems to be very problematical; as there are no experiments which show that seeds, when separated from the vegetable producing them, have any power of meliorating themselves.

After the hemp is pulled, it must be taken in large handfuls, cutting off the roots (though this is not absolutely necessary), the leaves, seeds, and lateral branches, being dressed off with a wooden sword or ripple. It is then to be made up into bundles of twelve handfuls each, in order to be steeped, like flax, in water. This, or something similar, is absolutely necessary, in order to separate the bark; which is properly the hemp, from the reed or woody part. In Suffolk, this operation is called *water-retting*; but sometimes a mere exposure to the air is substituted in its place, turning the hemp frequently during the

time it is exposed. This is called *dew-retting*; but the former method is universally deemed preferable. Such hemp as is designed for seed is seldom water-retted, though in the opinion of the manufacturer already quoted, it would be better if it were so. Dew-retted hemp is generally stacked and covered during the winter; in January and February it is spread upon meadow land, and whitens with the frost and snow; though it is always much inferior to the other, and proper for coarser yarns only.

The length of time required for steeping hemp is various, and a complete knowledge of it can only be attained by practice. In Suffolk it is usual to continue the immersion four, five, or six days; standing water is preferred, and the same water will steep hemp three times during the season, but the first has always the best colour. The abbé Brulle prefers clear and running water, especially if overhung with trees. The bundles are to be laid crosswise upon each other, taking particular notice of the manner in which they lie when put in, that they may be taken out without difficulty. His time of steeping is from six to 11 days; and here we must observe, that it is much better to let it remain too long in the water than too short a time. The slenderest hemp requires the most soaking. The operation is known to be finished by the reed separating easily from the bark.

After the hemp is thoroughly steeped, the next operation is to separate the bark from the reed or woody part; and this may be done in two ways, viz. either pulling out the reed from every stalk with the hand, or drying and breaking it like flax. The abbé Brulle is very particular in his directions for this last operation, which he calls *reeding*, and which may be performed either in a trough under water or upon a table. The whole, however, may be reduced to the following, viz. pressing down the bundles either in the trough or on a table by proper weights, to keep the hemp steady on the middle and top end. Then beginning at the upper part of the bundle, pull out the reeds one by one. As you proceed, the rind which remains will press closely upon the remaining unreeded hemp, and keep it more steady; so that you may take two, four, or even six stalks at a time. The weight is then to be removed from the top, and all the pieces of reed which remain there having broken off in the former operation, are to be taken out. Lastly, the middle weight is to be taken off, and any small pieces which remain there taken out. If the reeding is performed on a table, the bundle must be weeded frequently, though slightly; a continual dropping of water would perhaps be the best method.

After the hemp is reeded, it must next be freed from the mucilaginous matter with which it still abounds. This is done by pouring water through it, squeezing out the liquid after every affusion, but taking care not to let the threads twist or entangle each other, which they will be very apt to do. The abbé is of opinion, that soft soap should be dissolved in the last water, in the proportion of an ounce to three pounds of dry hemp; which though not absolutely necessary, contributes much to the softening and rendering the hemp easy and pleasant to dress.

Hemp is broken by machinery, after being steeped, in a manner similar to flax; but the instruments used for this purpose in Suffolk are all worked by the hand. That which breaks in the operation is called *shorts*, and is about half the value of the long hemp. The best water-retted hemp sells for about 8s. 6d. per stone; the other kind from one to two shillings lower.

Beating of hemp is the next operation, which formerly was performed entirely by hand, but now in most places by a water-mill, which raises three heavy beaters that fall upon it alternately; the hemp being turned all the while by a boy in order to receive the strokes equally. The finer it is required to make

the tow, the more beating is necessary. It is then dressed or combed by drawing it through heckles formed like the combs of wool-manufacturers, only fixed. Sometimes it is divided into two or three sorts of tow, and sometimes the whole is worked together into one sort; the prices varying from 6d. to 1s. 6d. per pound.

The hemp thus manufactured is sold to spinners, who reel their yarn as follows:

2 Yards make	-	1 thread.
40 Threads	-	1 lea.
20 Leas	-	1 skain.
3 Skains	-	1 clue of 4800 yards.

It is next delivered to the bleachers, who return it bleached on receiving 20 or 21 clues for every 120 bleached. The prices of the hemp-yarn are as follows:

1 Clue from a pound	-	7d. or 6½d.
1½ from do.	-	8½d. or 8d.
2 from do.	-	9½d. or 9d.
2½ from do.	-	10½d. or 10d.
3 from do.	-	12d.

Chinese HEMP, a newly discovered species of *Cannabis*, of which an account is given in the 72d volume of the Philosophical Transactions, p. 46. In that paper Mr. Fitzgerald, vice-president of the society for encouraging arts, mentions his having received the seeds from the late Mr. Elliot; which being sown, according to his directions, produced plants 14 feet high, and nearly seven inches in circumference. These being pulled up in November, and steeped for a fortnight in water, were placed against a southern wall to dry. After this the hemp was found to separate easily from the woody part; and so great was the produce, that 32 plants yielded three pounds and a quarter. In consequence of this success, Mr. Fitzgerald applied to the directors of the India company to procure some of the seeds from China; which being complied with, the society were furnished, in 1785, with some more of the seeds, which were distributed to several of the members; but, notwithstanding their endeavours, few of the plants appear to have ripened their seeds in this country. Two of the species of hemp, tried by the duke of Northumberland, rose to the height of 14 feet seven inches, and would have been much larger, had they not been hurt by an high wind: another kind arose only to that of three feet and an half, the stem about the size of a common wheat straw; but though it flowered well, did not produce any seed. These kinds were sown in an hot-bed, where the heat was very strong, on the 14th of April. They appeared above ground in four days, and were transplanted into pots on the 25th. They were then put under an hot-bed frame where the heat had been gone off, to harden them for the natural ground, in which they were planted on the 30th, by turning them whole out of the pots; letting them, three together, be planted at two feet distance every way; covering them at times for about ten days, until they were supposed to be rooted. Only a few seeds were preserved from plants which had been kept constantly in a stove.

Other trials were attended with little better success; but, in 1786, the Rev. Dr. Hinton, of Northwold near Brandon, made a successful experiment with some seeds he received from the secretary of the society. They were sown on the 17th of May, and appeared on the 6th of June. The plants were few and sickly; and notwithstanding some fine showers, they continued to languish so much that the experiment was entirely abandoned, and buckwheat was harrowed into the ground for a fallow crop. In the beginning of October, however, the persons employed in cutting the buck-wheat discovered some seed in the heads of a few straggling hemp plants which had been suffered to grow in the crop; which being carefully threshed, afforded three pints of seed tolerably bright and heavy. These seeds were sown on

the 10th of May 1787. On the 19th they appeared above the ground numerous and healthy. The male hemp was drawn on the 13th of August, but the female not till the 9th of October; the spot on which the plants were sown measured only 322 square yards, and produced of marketable hemp no less than 95 stone 7 pounds 12 ounces; being upwards of one third more than the best crops of English hemp are ever known to produce. Thus it appeared, that the seeds of the Chinese hemp had retained their superiority over those of the English; though how long they would continue to do so cannot be determined but by experience. For this experiment Dr. Hinton received a silver medal from the society. Few of the seeds, either of Chinese, or any other hemp, will vegetate if two years old at the time of sowing; and to this circumstance the Doctor attributes the failure of other trials of Chinese hemp.

HEMP-Agrimony, a species of eupatorium. See *EUPATORIUM*.

HEMPSTED, or *HEMEL HEMPSTED*, a town of Herts, with a market on Thursday; seated among the hills, on a branch of the river Coln, 18 miles S. W. of Hertford, and 23 N. W. of London. W. lon. 0. 15. N. lat. 51. 47.

HEMSKERCK (Egbert), called the *Old*, a celebrated Flemish painter of drolls and conversations, of whom, though so universally known, we have no information as to the time in which he flourished, or the school in which he was taught. Though the taste of his compositions is but low, yet it ought to be considered that he took his subjects from nature; from persons in the meanest occupations, whose dress, actions, and manners, could not furnish the imagination with any ideas of elegance: and to express their passions and undisguised humours, seems to have been the utmost of his ambition. By frequenting fairs, merry-meetings, gaming-houses, and inns, he acquired a surprising power of connecting humorous circumstances. He designed and drew correctly, and his pictures have a strong effect from his accurate management of the chiaro oscuro. Some of his pictures have suffered from unskilful cleaners, and many things are sold as his which dishonour him; but his genuine works, well preserved, have a clearness and force equal to any of the Flemish artists.

HEMSKERCK (Egbert), called the *Young*, was the disciple of Peter Grebber, but imitated the manner of Brouwer and of the elder Hemskerck. He was born at Haerlem in 1645, but settled at London, where for a long time his works were exceedingly esteemed, though they are now much sunk in their value. He had a whimsical imagination, and delighted in composing uncommon and fanciful subjects; such as the temptation of St. Anthony, nocturnal intercourses of witches and spectres, enchantments, &c. which he executed with a free pencil and a spirited touch. It was customary with him to introduce his own portrait among the conversations he designed; and for that purpose had a small looking-glass placed near his case. He died in 1704.

HEN, in ornithology. See *PHASIANUS*.

Guinea-HEN. See *NUMIDA*.

HEN-Bane. See *HYOSCIAMUS*.

HEN-Harrier. See *FALCO*.

HEN-Mould-soil, in agriculture, a term used by the husbandmen in Northamptonshire, and other counties, to express a black, hollow, spongy, and mouldering earth, usually found at the bottoms of hills. It is an earth much fitter for grazing than for corn, because it will never settle close enough to the grain to keep it sufficiently steady while it is growing up, without which, the farmers observe, it either does not grow well, or, if it seems to thrive, as it will in some years, the growth is rank, and yields much straw, but little ear. It is too moist, and to that is principally to be attributed this rankness of the crop in some years; and the occasion of its retaining so much moist-

ture is, that it usually has a bed of stiff clay, which will not let the water run off into the under strata. In some places they also give this name to a black, rich, and dense earth, with streaks of a whitish mould in many parts. This sort of hen-mould is usually found very rich and fertile.

HENAUT (Charles John Francis), was son of John Remi Henault lord of Moutly, and born at Paris in 1685. He early discovered a sprightly benevolent disposition, and his penetration and aptness soon distinguished itself by the success of his studies. Claude de Lisle, father of the celebrated geographer, gave him the same lessons in geography and history which he had before given to the duke of Orleans, afterwards regent; and which have been printed in seven volumes, under the title of "Abridgment of Universal History." On quitting college, Henault entered the Oratory, where he soon attached himself to the study of eloquence: and, on the death of the abbé René, reformer of La Trappe, he undertook to pronounce his panegyric; which not meeting the approbation of father Massillon, he quitted the Oratory after two years, and his father bought for him, of marechal Villeroy, the "lieutenance des chasses," and the government of Corbeil. At the marshal's he formed connections, and even intimate friendships, with many of the nobility, and passed the early part of his life in agreeable amusements, and in the liveliest company, without having his religious sentiments tainted. He associated with the wits till the dispute between Rousseau and de la Motte soon gave him a disgust for these trifling societies. In 1707 he gained the prize of eloquence at the French academy; and another next year at the academy des Jeux Floraux. About this time M. Reaumur, who was his relation, came to Paris, and took lessons in geometry under the same master, Guinée. Henault introduced him to the abbé Bignon, and this was the first step of his illustrious course. In 1713 he brought a tragedy on the stage, under the disguised name of Fuselier. As he was known to the public only by some slighter pieces, "Cornelia the Vestal" met with no better success. He therefore locked it up without printing. In his old age his passion for these subjects reviving, and Mr. Horace Walpole being at Paris in 1768, and having formed a friendship with him as one of the most amiable men of his nation, obtained this piece, and had it printed at a press which he had at his country seat, from whence a beautiful edition of Lucan had before issued. In 1751 M. Henault, under a borrowed name, brought out a second tragedy, intituled, "Marius," which was well received and printed. He had been admitted counsellor in parliament in 1706, with a dispensation on account of age; and in 1710 president of the first chamber of inquests. These important places, which he determined to fill in a becoming manner, engaged him in the most solid studies. The excellent work of M. Domat charmed him, and made him eager to go back to the fountain-head. He spent several years in making himself master of the Roman law, the ordonnances of the French king, their customs, and public law. M. de Morville, procureur-general of the great council, being appointed ambassador to the Hague in 1718, engaged M. Henault to accompany him. His personal merit soon introduced him to the acquaintance of the most eminent personages at that time there. The grand pensionary, Heinsius, who, under the exterior of Lacedemonian simplicity, kept up all the haughtiness of that people, lost with him all that hauteur which France itself had experienced from him in the negotiations of the treaty of Utrecht. The agitation which all France felt by Law's system, and the consequent sending of the parliament into exile, was a trial to the wise policy of the president Henault. His friendship for the first president, De Mesmes, led him to second all the views of that great magistrate: he took part in all the negotiations, and was animated purely by the public good, without any private advantage. On the death of the cardinal du Bois, in 1723, he succeeded in his

place at the French academy. Cardinal Fleury recommended him to succeed himself as director, and he pronounced the eulogy of M. de Malezieux.

History was M. Henault's favourite study; not a bare collection of dates, but a knowledge of the laws and manners of nations; to obtain which he drew instructions from private conversations, a method he so strongly recommends in his preface. After having thus discussed the most important points of our public law, he undertook to collect and publish the result of his inquiries, and he is deservedly accounted the first framer of chronological abridgements; in which, without stopping at detached facts, he attends only to those which form a chain of events that perfect or alter the government and character of a nation, and traces only the springs which exalt or humble a nation, extending or contracting the space it occupies in the world. His work has had the fortune of those literary phenomena, where novelty and merit united excite minds eager after glory, and fire the ardour of young writers to press after a guide whom few can overtake. The first edition of the work, the result of 40 years reading, appeared in 1744, under the auspices of the chancellor Daguesseau, with the modest title of *an Essay*. The success it met with surprised him. He made continual improvements in it, and it has gone through nine editions, and been translated into Italian, English, and German, and even into Chinese. As the best writings are not secure from criticism, and are indeed the only ones that deserve it, the author read to the academy of Belles Lettres a defence of his abridgement. All the ages and events of the French monarchy being present to his mind, and his imagination and memory being a vast theatre whereon he beheld the different movements and parts of the actors in the several revolutions, he determined to give a specimen of what passed in his own mind, and to reduce into the form of a regular drama, one of the periods of French history, the reign of Francis II. which, though happy only by being short, appeared to him one of the most important by its consequences, and most easy to be confined within the stage bounds. His friend the chancellor highly approved the plan, and wished it to be printed. It accordingly went through five editions; the harmony of dates and facts is exactly observed in it, and the passions interested without offence to historic truth.

In 1755 he was chosen an honorary member of the academy of Belles Lettres, being then a member of the academies of Nanci, Berlin, and Stockholm. The queen appointed him superintendent of her house. His natural sprightliness relieved her from the serious attendance on his private morning lectures. The company of persons most distinguished by their wit and birth, a table more celebrated for the choice of the guests than its delicacies, the little comedies suggested by wit, and executed by reflection, united at his house all the pleasures of an agreeable and innocent life. All the members of this ingenious society contributed to render it agreeable, and the president was not behind any. He composed three comedies: *La Petite Maison*, *Le Jaloux de Soi-même*, and *Le Réveil d'Épiménide*. The subject of the last was the Cretan philosopher, who is pretended to have slept 27 years. He is introduced fancying that he had slept but one night, and astonished at the change in the age of all around him: he mistakes his mistress for his mother; but discovering his mistake, offers to marry her, which she refuses, though he still continues to love her. The queen was particularly pleased with this piece. She ordered the president to restore the philosopher's mistress to her former youth: he introduced Hebe, and this episode produced an agreeable entertainment. He was now in such favour with her majesty, that on the place of superintendent becoming vacant by the death of M. Bernard de Conbert master of requests, and the sum he had paid for it being lost to his family, Henault solicited it in favour of several persons, till at last the queen bestowed it on himself, and con-

mented that he should divide the profits with his predecessor's widow. On the queen's death he held the same place under the dauphiness.

A delicate constitution made him liable to much illness; which, however, did not interrupt the serenity of his mind. He made several journeys to the waters of Plombières: in one of these he visited the deposed king Stanislaus at Luneville; and in another accompanied his friend the marquis de Pauliny, ambassador to Switzerland. In 1763 he drew near his end. One morning, after a quiet night, he felt an oppression, which the faculty pronounced a suffocating cough. His confessor being sent to him, he formed his resolution without alarm. He afterwards said, that he recollected having then said to himself, "What do I regret?" and called to mind that saying of Madame de Sevigne, "I leave here only dying creatures." He received the sacraments. It was believed the next night would be his last; but by noon next day he was out of danger. "Now (said he) I know what death is. It will not be new to me any more." He never forgot it during the following seven years of his life, which, like all the rest, were gentle and calm. Full of gratitude for the favours of Providence, resigned to its decrees, offering to the Author of his being a pure and sincere devotion; he felt his infirmities without complaining, and perceived a gradual decay with unabated firmness. He died Dec. 24, 1771, in his 86th year. He married in 1714 a daughter of M. le Bas de Montargis keeper of the royal treasure, &c. who died in 1728 without leaving any issue.

HENBURY, a village in Gloucestershire, near Bristol, two miles from St. Vincent's Rock. In this parish is a camp, with three rampires and trenches, supposed to have been British. In digging up this hill in 1707, great numbers of Roman coins were found.

HENDECAGON, in geometry, a figure that hath eleven sides and as many angles.

HENED-PENNY, in our old writers, a customary payment of money instead of hens at Christmas. It is mentioned in a charter of king Edward III. Mon. Angl. tom. ii. p. 327. Duncange is of opinion it may be *ben-penny*, *gallinagium*, or a composition for eggs; but Cowel thinks it is misprinted *bened-penny* for *beved-penny*, or *bead-penny*.

HENLEY, a town of Oxfordshire, with a market on Wednesday, Friday, and Saturday. It is seated on the Thames, over which is a handsome bridge, and sends malt, corn, &c. to London, by barges. It is 24 miles S. E. of Oxford, and 35 W. of London. W. lon. o. 46. N. lat. 51. 35.

HENLEY, a town in Warwickshire, with a market on Tuesday. It is seated on the river Alne, 10 miles N. W. of Warwick, and 102 W. N. W. of London. W. lon. o. 50. N. lat. 52. 23.

HENLEY (John), better known by the appellation of *Orator Henley*, a very singular character, was born at Melton-Moubray, Leicestershire, in 1691. His father, the Rev. Simon Henley, and his grandfather by his mother's side (John Dowel, M. A.), were both vicars of that parish. Having passed his exercises at Cambridge, and his examination for the degree of B. A. with the particular approbation of Mr. Field, Mr. Smales, and the master of the college, he returned to his native place, where he was first desired by the trustees of the school in Melton to assist in, and then to take the direction of that school; which he increased and raised from a declining to a flourishing condition. He established here a practice of improving elocution by the public speaking of passages in the classics, morning and afternoon, as well as orations, &c. Here he was invited by a letter from the Rev. Mr. Newcombe to be a candidate for a fellowship in St. John's; but as he had long been absent, and therefore lessened his personal interest, he declined appearing for it. Here likewise he began his "Universal Grammar," and finished

ten languages, with dissertations prefixed, as the most ready introduction to any tongue whatever. In the beginning of this interval he wrote his poem on "Esther," which was approved by the town, and well received. He was ordained a deacon by Dr. Wake, then bishop of Lincoln; and after having taken his degree of M. A. was admitted to priest's orders by Dr. Gibson, his successor in that see. He formed an early resolution to improve himself in all the advantages of books and conversation the most effectually, on the first opportunity, at London. But he laid the basis of future proficiency in assisting at the curacy of his native town; where he preached many occasional sermons, particularly one at the assizes of Leicester: he then gave a voluntary warning for the choice of a new master and curate, and came to town recommended by above 30 letters from the most considerable men in the country, both of the clergy and laity; but against the inclination of his neighbours and his school, which was now, as from his first entrance upon it, still advancing: and his method being established and approved, one of his own scholars was appointed to succeed him. In town he published several pieces, as a translation of Pliny's Epistles, of several works of Abbe Vertot, of Montfaucon's Italian Travels in folio, and many other lucubrations. His most generous patron was the earl of Macclesfield, who gave him a benefice in the country, the value of which to a resident would have been above 80l. a-year: he had likewise a lecture in the city; and preached more charity sermons about town, was more numerously followed, and raised more for the poor children, than any other preacher, however dignified or distinguished. But when he pressed his desire and promise from a great man of being fixed in town, it passed in the negative. He took the people (it seems) too much from their parish-churches; and as he was not so proper for a London divine, he was very welcome, notwithstanding all difficulties, to be a rural pastor. But it was not for a second rustication, as he informs us, that he left the fields and the swains of Arcadia to visit the great city: and as he knew it was as lawful to take a licence from the king and parliament at Hicks's-hall as at Doctors Commons (since the ministerial powers of this kingdom are and ought to be parliamentary only), he freely, without compulsion, or being desired or capable of being compelled to reside in the country, gave up his benefice and lecture, certainties for an uncertainty; believing the public would be a more hospitable protector of learning and science, than some of the upper world in his own order.

Mr. Henley, in answer to a cavil (that he borrowed from books), proposed, "that if any person would single out any celebrated discourse of an approved writer, dead or living, and point out what he thought excellent in it, and the reasons; he would submit it to the world, whether the most famed composition might not be surpassed in their own excellency, either on that or any different subject."

Henley preached on Sundays upon theological matters, and on Wednesdays upon all other sciences. He declaimed some years against the greatest persons, and occasionally, says Warburton, did Pope that honour. The poet in return thus blazons him to infamy:

"But, where each science lifts its modern type,
 "History her pot, Divinity his pipe,
 "While proud Philosophy repines to show,
 "Dishonest fight! his breeches rent below;
 "Imbrown'd with native bronze, lo Henley stands,
 "Tuning his voice, and balancing his hands.
 "How fluent nonsense trickles from his tongue!
 "How sweet the periods, neither said nor sung!
 "Still break the benches, Henley! with thy strain,
 "While Kennet, Hare, and Gibson preach in vain.

“ O great restorer of the good old stage,
 “ Preacher at once and Zany of thy age !
 “ O worthy thou of Ægypt's wife abodes,
 “ A decent priest where monkeys were the gods !
 “ But Fate with butchers plac'd thy priestly stall,
 “ Meek modern Faith to murder, hack and maul :
 “ And bade thee live, to crown Britannia's praise,
 “ In Toland's, Tindal's, and in Woolston's days.”

This extraordinary person (who died October 14, 1756) struck medals, which he dispersed as tickets to his subscribers : a star rising to the meridian, with this motto, *Ad summa* ; and below, *Inveniam viam, aut faciam*. Each auditor paid 1s. He was author of a weekly paper called the Hyp Doctor, for which he had 100l. a-year given him. Henley used every Saturday to print an advertisement in the Daily Advertiser, containing an account of the subjects he intended to discourse on the ensuing evening at his Oratory near Lincoln's-inn-fields, with a sort of motto before it, which was generally a sneer at some public transaction of the preceding week. Dr. Cobden, one of Geo. II.'s chaplains, having, in 1748, preached a sermon at St. James's from these words, “ Take away the wicked from before the king, and his throne shall be established in righteousness ;” it gave so much displeasure, that the Doctor was struck out of the list of chaplains ; and the next Saturday the following parody of his text appeared as a motto to Henley's advertisement :

“ Away with the wicked before the king,
 “ And away with the wicked behind him ;
 “ His throne it will bless
 “ With righteousness,
 “ And we shall know where to find him.”

His audience was generally composed of the lowest ranks ; and it is well known that he even collected an infinite number of shoe makers, by announcing that he could teach them a speedy mode of operation in their business, which proved only to be, the making of shoes by cutting off the tops of ready-made boots.

HENNA, or ALHENNA. See LAWSONIA.

HENNEBERG, a county of Germany, in the circle of Franconia. It is bounded on the N. by Thuringia, on the W. by Hesse, on the S. by the bishopric of Wurtzburg, and on the E. by that of Bamberg. It abounds in mountains and woods, and is populous and fertile. It is divided among no less than seven different sovereigns. Mainungen is the capital.

HENNEBERG, a town of Germany, in the circle of Franconia, and county of the same name, with a castle. It is 34 miles N. W. of Bamberg. E. lon. 10. 38. N. lat. 50. 40.

HENNEBON, a town of France, in the department of Morbihan and late province of Bretagne, seated on the river Blavet, 260 miles W. by S. of Paris, and 22 N. W. of Vannes. W. lon. 3. 4. N. lat. 47. 50.

HENOTICUM, *ἑνωτικόν*, q. d. “ reconciliative ;” of *ενωω* “ I unite,” in church history, a famous edict of the emperor Zeno, published A. D. 482, and intended to reconcile and reunite the Eutychians with the Catholics. It was procured of the emperor by means of Acacius, patriarch of Constantinople, with the assistance of the friends of Peter Mongus and Peter Trullo. The sting of this edict lies here ; that it repeats and confirms all that had been enacted in the councils of Nice, Constantinople, Ephesus, and Chalcedon, against the Arians, Nestorians, and Eutychians, without making any particular mention of the council of Chalcedon. It is in form of a letter, addressed by Zeno to the bishops, priests, monks, and people of Egypt and Libya. It was opposed by the Catholics, and condemned in form by pope Felix II.

HENRICHEMONT, a small town of France, in the de-

partment of Cher and late province of Berry, situated on the river Sandre. It was the capital of a district which Henry IV. gave to his illustrious minister the duke of Sully. Its original name was Bois-Belle ; but Sully gave it the present name, in gratitude for the privileges which the king had annexed to it. As the soil in the environs is not excellent, the town is in a manner deserted ; and the uniform houses, with which Sully had adorned it, are in a wretched condition. The family alienated it to Louis XV. in 1767. The town is 15 miles from Bourges.

HENRICIANS, in ecclesiastical history, a sect so called from Henry its founder, who, though a monk and hermit, undertook to reform the superstition and vices of the clergy. For this purpose he left Laufanne in Switzerland, and removing from different places, at length settled at Thoulouse in the year 1147, and there exercised his ministerial function, till being overcome by the opposition of Bernard abbot of Clairval, and condemned by pope Eugenius III. at a council assembled at Rheims, he was committed to a close prison in 1148, where he soon ended his days. This reformer rejected the baptism of infants ; severely censured the corrupt manners of the clergy ; treated the festivals and ceremonies of the church with the utmost contempt, and held clandestine assemblies for inculcating his peculiar doctrines.

HENRY (Cape), the S. cape of Virginia, at the entrance of Chesapeak Bay. W. lon. 76. 5. N. lat. 36. 56.

HENTINGS, in agriculture, a term used by the farmers for a particular method of sowing before the plough ; the corn being cast in a straight line just where the plough is to come, is by this means presently ploughed in. By this way of sowing they think they save a great deal of seed and other charge, a dexterous boy being as capable of sowing this way out of his hat as the most skilful seedsmen. Henting is also a term used by the ploughmen, and others, to signify the two furrows that are turned from one another at the bottom, in the ploughing of a ridge. The word seems to be a corruption of ending, because those furrows made an end of ploughing the ridges. The tops of the ridges they call *weerings*.

HEPAR SULPHURIS, *Alkaline*, or *Liver of Sulphur* ; a combination of alkali and sulphur. See CHEMISTRY, p. 384. With the fume arising on the decomposition of hepar sulphuris by an acid, Mr. Bergman found a method of imitating the hot or sulphureous mineral waters, to as great perfection as the cold ones are now imitated by fixed air. The process consists simply in adding the vitriolic acid to hepar sulphuris, and impregnating water with the peculiar species of air that arises from this mixture ; in the same manner as when water is impregnated with the fixed air arising from the mixture of that or any other acid with chalk. This *hepatic air*, as the author calls it, is very readily absorbed by water ; to which it gives the smell, taste, and all the other sensible qualities of the sulphureous waters. A Swedish cantharus of distilled water, containing 12½ Swedish cubic inches, will absorb about 60 cubic inches of this hepatic air ; and on dropping into it the nitrous acid, it will appear, that a real sulphur is contained, in a state of perfect solution, in this water, to the quantity of eight grains. It does not appear that any other acid, except what the author calls the *dephlogisticated marine acid*, will produce this effect. When any particular sulphureous water is to be imitated, we scarce need to observe, that the saline, or other contents peculiar to it, are to be added to the artificial hepatic water. Instead of the liver of sulphur, the operator may use a mixture of three parts of filings of iron and two parts of sulphur melted together.

It may, perhaps, be thought, that water thus prepared does not differ from that in which a portion of the hepar sulphuris has been dissolved : but it appears evidently to differ from it in this material circumstance ; that in the solution of hepar sul-

phuris, the sulphur is held in solution by the water, through the means of the alkali combined with it: whereas, in Mr. Bergman's process, it does not appear probable that the hepar sulphuris rises substantially in the form of air; for, in that case, its presence in the hepatic water might be detected by means of the weakest of the acids (even the inephitic), which would precipitate the sulphur from it. Nor can it be supposed that any portion or constituent part of the alkali itself (except a part of its remaining fixed air) can come over. The water, therefore, must owe its impregnation to the sulphur, raised, in some peculiar manner, into the state of an elastic vapour; permanent, when the experiment is made in quicksilver; but condensable in water, and rendered soluble in that fluid through the means of some unknown principle combined with it, and which the author supposes to be the matter of heat combined with it through the medium of phlogiston.

HEPATIC, in medicine and anatomy, any thing belonging to the liver.

HEPATIC Air, a permanently elastic fluid, of a very disagreeable odour somewhat like that of rotten eggs, obtained in plenty from combinations of sulphur with earths, alkalies, metals, &c. and sometimes from combinations of alkalies with substances which do not appear to contain any sulphur. The nature of this fluid has been particularly examined by Mr. Kirwan, of whose experiments we have an account in the 76th volume of the Philosophical Transactions.

From considering the results, that gentleman concludes, that hepatic air consists merely of sulphur rarefied by elementary fire, or the matter of heat. Some have supposed that it consists of liver of sulphur itself volatilized; but this our author denies, for the following reasons: 1. It is evidently, though weakly, acid; reddening litmus, and precipitating acetous baro-selenite, though none of the other solutions of earths do. 2. It may be extracted from materials which either contain no alkali at all, or next to none; as iron, sugar, oil, charcoal, &c. 3. It is not decomposed by marine or fixed air; by which nevertheless liver of sulphur may be decomposed.

Our author informs us, that he was formerly of opinion that sulphur was held in solution in hepatic air, either by means of vitriolic or marine air: but neither of these is essential to the constitution of hepatic air as such, since it is producible from materials that contain neither of these acids; and from whatever substance it is obtained, it always affords the same character, viz. that of the vitriolic acid exceedingly weakened, such an acid as we may suppose sulphur itself to be. This substance indeed, even in its concrete state, manifests the properties of an acid, by uniting with alkalies, calcareous and ponderous earths, as well as with most metals, which a very weak acid might be supposed to do. See CHEMISTRY, p. 384 and 409.

HEPATIC Ales, the inspissated juice of a species of ALOE.

HEPATIC Stone. See LIVER Stone.

HEPATIC Water. See HEPAR Sulphuris.

HEPATICA, in botany, a species of ANEMONE.

HEPATITIS, in medicine, an inflammation of the liver.

See MEDICINE.

HEPATOSCOPIA, formed of ἥπαρ liver, and σκοπεω I consider, in antiquity, a species of divination, wherein predictions were made by inspecting the livers of animals. Hepatoscopia is also used as a general name for divination by entrails.

HEPHÆSTIA, in Grecian antiquity, an Athenian festival in honour of Vulcan, the chief ceremony of which was a race with torches. It was performed in this manner: The antagonists were three young men, one of whom, by lot, took a lighted torch in his hand, and began his course; if the torch was extinguished before he finished the race, he delivered it to the second; and he in like manner to the third: the victory was his

who first carried the torch lighted to the end of the race; and to this successive delivering of the torch we find many allusions in ancient writers.

HEPHTHEMIMERIS, composed of ἑπτα seven, ἡμισυ half, and μετ part, in the Greek and Latin poetry, a sort of verse consisting of three feet and a syllable; that is, of seven half feet.

Such are most of the verses in Anacreon:

Θ:λω	γελειν	Ατρει	δας
Θελω	δε Καδ	μυα	δω; &c.

And that of Aristophanes, in his Plutus: Επεσε μετρη χορη. They are also called *trimetri catalectici*.

HEPHTHEMIMERIS, or *Hephtthemimeres*, is also a cæsura after the third foot; that is, on the seventh half-foot. It is a rule, that this syllable, though it be short in itself, must be made long on account of the cæsura, or to make it an *hephtthemimeris*. As in that verse of Virgil—*Et furis agilitatus amor, et conscia virtus*. It may be added, that the cæsura is not to be on the fifth foot, as it is in the verse which Dr. Harris gives us for an example: *Ille latus nitcum molli fultus Hyacintho*. This is not a hephtthemimeris cæsura, but a *henneamimeris*, i. e. of nine half feet.

HEPTACHORD, in the ancient poetry, signified verses that were sung or played on seven chords, that is, on seven different notes. In this sense it was applied to the lyre when it had but seven strings. One of the intervals is also called an *heptachord*, as containing the same number of degrees between the extremes.

HEPTAGON, in geometry, a figure consisting of seven sides, and as many angles. In fortification, a place is termed an *heptagon*, that has seven bastions for its defence.

HEPTAGONAL NUMBERS, in arithmetic, a sort of polygonal numbers, wherein the difference of the terms of the corresponding arithmetical progression is 5. One of the properties of these numbers is, that if they be multiplied by 40, and 9 be added to the product, the sum will be a square number.

HEPTANDRIA, in botany, from ἑπτα seven, and ἀνδρῶν a man; the seventh class in Linnæus's sexual method, consisting of plants with hermaphrodite flowers, which have seven stamina or male-organs. The orders are four, derived from the number of styles or female organs. See BOTANY, p. 40.

HEPTANGULAR, in geometry, an appellation given to figures which have seven angles.

HEPTARCHY, compounded of the Greek ἑπτα "seven," and αρχη, imperium, "government," a government composed of seven persons, or a country governed by seven persons, or divided into seven kingdoms. The Saxon heptarchy included all England, which was cantoned out into seven petty independent kingdoms, peopled and governed by different clans and colonies; viz. those of Kent, the South Saxons, West Saxons, East Saxons, Northumberland, the East Angles, and Mercia. The heptarchy was formed by degrees from the year 455, when first the kingdom of Kent was erected, and Hengist assumed the title of king of Kent immediately after the battle of Eglesford; and it terminated in 827 or 828, when king Egbert reunited them into one, made the heptarchy into a monarchy, and assumed the title of king of England. It must be observed, however, that though Egbert became monarch of England, he was not perfectly absolute. The kingdom which he actually possessed consisted of the ancient kingdoms of Wessex, Susses, Kent, and Essex, that had been peopled by Saxons and Jutes. As for the other three kingdoms, whose inhabitants were Angles, he contented himself with preserving the sovereignty over them, permitting them to be governed by kings, who were his vassals and tributaries. The government of the heptarchy, reckoning from the founding of the kingdom of Mercia, the last of the

seven Anglo-Saxon kingdoms, lasted 243 years; but if the time spent by the Saxons in their conquests from the arrival of Hengist in 449 be added, the heptarchy will be found to have lasted 378 years from its commencement to its dissolution. The causes of the dissolution of the heptarchy were, the great inequality among the seven kingdoms, three of which greatly surpassed the others in extent and power; the default of male heirs in the royal families of all the kingdoms, that of Wessex excepted; and the concurrence of various circumstances which combined in the time of Egbert.

HERACLEA, an ancient seaport of Turkey in Europe, in Romania, with a Greek archbishop's see. It was formerly very famous; and there are still considerable remains of antiquity. It is 50 miles W. of Constantinople. E. lon. 27. 58. N. lat. 40. 59.

HERACLEONITES, a sect of Christians, the followers of Heracleon, who refined upon the Gnostic divinity, and maintained that the world was not the immediate production of the Son of God, but that he was only the occasional cause of its being created by the demiurgus. The Heracleonites denied the authority of the prophecies of the Old Testament, maintaining that they were mere random sounds in the air; and that St. John the Baptist was the only true voice that directed to the Messiah.

HERACLEUM, **MADNESS**; a genus of the digynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 45th order, *Umbellatæ*. The fruit is elliptical, emarginated, compressed, and striated, with a thin border. The corolla is difform, inflexed, and emarginated; the involucre dropping off. There are five species, of which the most remarkable is the spondylium, or cow-parsnip. This is common in many parts of Britain, and other northern parts of Europe and Asia. Gmelin, in his *Flora Siberica*, p. 214. tells us, that the inhabitants of Kamtschatka, about the beginning of July, collect the foot-stalks of the radical leaves of this plant, and, after peeling off the rind, dry them separately in the sun, and then, tying them in bundles, dry them carefully in the shade: in a short time afterwards, these dried stalks are covered over with a yellow saccharine efflorescence, tasting like liquorice: and in this state they are eaten as a great delicacy. The Russians not only eat the stalks thus prepared, but procure from them a very intoxicating spirit. They first ferment them in water with the greater bilberries (*vaccinium uliginosum*), and then distil the liquor to what degree of strength they please; which Gmelin says is more agreeable to the taste than spirits made from corn. This may therefore prove a good succedaneum for whisky, and prevent the consumption of much barley, which ought to be applied to better purposes. Swine and rabbits are very fond of this plant. In the county of Norfolk it is called *hog-weed*.

HERACLIDÆ, the descendants of Hercules, greatly celebrated in ancient history. Hercules, at his death, left to his son Hyllus all the rights and demands which he had upon the Peloponnesus, and permitted him to marry Iole as soon as he came of age. The posterity of Hercules were not more kindly treated by Euristheus than their father had been, and they were obliged to retire for protection to the court of Ceyx, king of Trachinia. Euristheus pursued them thither; and Ceyx, afraid of his resentment, begged the Heraclidæ to depart from his dominions. From Trachinia they came to Athens, where Theseus the king of the country, who had accompanied their father in some of his expeditions, received them with great humanity, and assisted them against their common enemy Euristheus. Euristheus was killed by the hand of Hyllus himself, and his children perished with him, and all the cities of the Peloponnesus became the undisputed property of the Heraclidæ. Their triumph, however, was short; their numbers were lessened by

a pestilence; and the oracle informed them, that they had taken possession of the Peloponnesus before the gods permitted their return. Upon this they abandoned Peloponnesus, and came to settle in the territories of the Athenians, where Hyllus, obedient to his father's commands, married Iole the daughter of Euristheus. Soon after he consulted the oracle, anxious to recover the Peloponnesus; and the ambiguity of the answer determined him to make a second attempt. He challenged to single combat Atreus, the successor of Euristheus on the throne of Mycenæ; and it was mutually agreed that the undisturbed possession of the Peloponnesus should be ceded to whosoever defeated his adversary. Echemus accepted the challenge for Atreus, and Hyllus was killed, and the Heraclidæ a second time departed from Peloponnesus. Cleodæus the son of Hyllus made a third attempt, and was equally unsuccessful; and his son Aristomachus some time after met with the same unfavourable reception, and perished in the field of battle. Aristodemus, Temenus, and Chresphontes, the three sons of Aristomachus, encouraged by the more expressive word of an oracle, and desirous to revenge the death of their progenitors, assembled a numerous force, and with a fleet invaded all Peloponnesus. Their expedition was attended with much success; and after some decisive battles, they became masters of all the peninsula. The recovery of the Peloponnesus by the descendants of Hercules forms an interesting epoch in ancient history, which is universally believed to have happened 80 years after the Trojan war, or 1190 years before the Christian era. This conquest was totally achieved about 120 years after the first attempt of Hyllus, who was killed about 20 years before the Trojan war. As it occasioned a world of changes and revolutions in the affairs of Greece, insomuch that scarce a state or people but were turned upside down thereby, the return of the Heraclidæ is the epocha of the beginning of profane history: all the time that preceded it is reputed fabulous. Accordingly, Ephorus, Cumanus, Calisthenes, and Theopompus, only begin their histories from hence.

HERACLIDES of PONTUS, a Greek philosopher, the disciple of Speusippus, and afterwards of Aristotle, flourished about 326 B. C. His vanity prompted him to desire one of his friends to put a serpent into his bed just as he was dead, in order to raise a belief that he was ascended to the heavens among the Gods; but the cheat was discovered. All his works are lost.

HERACLITUS, a famous Ephesian philosopher, who flourished about the 69th Olympiad, in the time of Darius Hystaspes. He is said to have continually bewailed the wicked lives of men, and, as often as he came among them, to have fallen a-weeping; contrary to Democritus, who made the follies of mankind a subject of laughter. He retired to the temple of Diana, and played at dice with the boys there; saying to the Ephesians who gathered round him, "Worst of men, what do ye wonder at? Is it not better to do thus than to govern you?" Darius wrote to this philosopher to come and live with him; but he refused the offer: at last, out of hatred to mankind, he retired to the mountains, where he contracted a dropsy by living on herbs, which destroyed him at 70 years of age. His writings gained him to great reputation, that his followers were called *Heraclicians*. Laertius speaks of a treatise upon nature, divided into three books, one concerning the universe, the second political, the third theological. This book he deposited in the temple of Diana; and it is said, that he affected to write obscurely, lest it should be read by the vulgar, and become contemptible. The fundamental doctrine of his philosophy was, that fire is the principle of all things; and the ancient philosophers have collected and preserved admirable apophthegms of this philosopher.

HERALD, says Vertegau, is derived from the Saxon word *Herebault*, and by abbreviation *Heralt*, which in that language

signifies the champion of an army; and, growing to be a name of office, it was given to him who, in the army, had the special charge to denounce war, to challenge to battle and combat, to proclaim peace, and to execute martial messages. But the business of heralds with us is as follows, viz. To marshal, order, and conduct all royal cavalcades, ceremonies at coronations, royal marriages, installations, creations of dukes, marquises, earls, viscounts, barons, baronets, and dubbing of knights; embalmings, funeral processions, declarations of war, proclamations of peace, &c.: to record and blazon the arms of the nobility and gentry; and to regulate any abuses therein through the English dominions, under the authority of the Earl Marshal, to whom they are subservient. The office of Windsor, Chester, Richmond, Somerset, York, and Lancaster heralds, is to be assistants to the kings at arms, in the different branches of their office; and they are superior to each other, according to creation, in the above order.

Heralds were formerly held in much greater esteem than they

are at present; and were created and christened by the king, who, pouring a gold-cup of wine on their head, gave them the herald-name: but they are now made by the Earl Marshal. They could not then arrive at the dignity of herald without having been seven years purpivant; nor could they quit the office of herald, but to be made king at arms. Richard III. was the first who formed them, in this kingdom, into a college; and afterwards great privileges were granted them by Edward VI. and Philip and Mary.

The origin of heralds is very ancient. Stentor is represented by Homer as herald of the Greeks, who had a voice louder than 50 men together. The Greeks called them *κερικες*, and *επιρυθι λακες*; and the Romans, *feciales*. The Romans had a college of heralds, appointed to decide whether a war were just or unjust; and to prevent its coming to open hostilities, till all means had been attempted for deciding the difference in a pacific way.

H E R A L D R Y,

A SCIENCE which teaches how to blazon, or explain in proper terms, all that belongs to coats-of-arms: and how to marshal, or dispose regularly, divers arms on a field. It also teaches whatever relates to the marshalling of solemn cavalcades, processions, and other public ceremonies at coronations, installations, creations of peers, nuptials, christening of princes, funerals, &c.

Arms, or coats-of-arms, are hereditary marks of honour, made up of fixed and determined colours and figures, granted by sovereign princes, as a reward for military valour, or some signal public service performed. These are intended to denote the descent and alliance of the bearer, or to distinguish states, cities, societies, &c. civil, ecclesiastical, and military.

Although arms appear thus to be the proper object of the science of Heraldry, yet they differ much both in their origin and antiquity. Heraldry, according to Sir George Mackenzie, "as digested into an art, and subjected to rules, must be ascribed to Charlemagne and Frederick Barbarossa, for it did begin and grow with the feudal law." Sir John Ferne is of opinion, that we did borrow *arms* from the Egyptians; meaning, from their hieroglyphics. Sir William Dugdale mentions, that arms, as marks of honour, were first used by great commanders in war, necessity requiring that their persons should be notified to their friends and followers. The learned Alexander Nisbet, in his excellent System of Heraldry, says, that arms owe their rise and beginning to the light of nature, and that signs and marks of honour were made use of in the first ages of the world, and by all nations, however simple and illiterate, to distinguish the noble from the ignoble. We find in Homer, Virgil, and Ovid, that their heroes had divers figures on their shields, whereby their persons were distinctly known. Alexander the Great, desirous to honour those of his captains and soldiers who had done any glorious action, and also to excite an emulation among the rest, did grant them certain badges to be borne on their armour, pennons, and banners; ordering, at the same time, that no person or potentate, through his empire, should attempt or presume to give or tolerate the bearing of those signs upon the armour of any man, but it should be a power reserved to himself; which prerogative has been claimed ever since by all other kings and sovereign princes within their dominions.

After these and many other different opinions, all that can be said with any certainty is, that, in all ages, men have made

use of figures of living creatures, or symbolical signs, to denote the bravery and courage either of their chief or nation, to render themselves the more terrible to their enemies, and even to distinguish themselves or families, as names do individuals. The famous C. Agrippa, in his treatise of the vanity of sciences, cap. 81. has collected many instances of these marks of distinction, anciently borne by kingdoms and states that were any way civilized. Thus, the Egyptians bore an Ox; the Athenians, an Owl; the Goths, a Bear; the Romans, an Eagle; the Franks, a Lion; and the Saxons, a Horse. The last is still borne in the arms of his present Britannic Majesty. As to hereditary arms of families, William Cambden, Sir Henry Spelman, and other judicious heralds, agree, that they began no sooner than towards the latter end of the 11th century. According to Father Menestrier's opinion, a French writer, whose authority is of great weight in this matter, Henry l'Oiseleur (the falconer), who was raised to the imperial throne of the West in 920, by regulating tournaments in Germany gave occasion to the establishment of family-arms, or hereditary marks of honour, which undeniably are more ancient and better observed among the Germans than in any other nation. Moreover, this last author asserts, that with tournaments first came up coats-of-arms; which were a sort of livery, made up of several lists, fillets, or narrow pieces of stuff of many colours, from whence came the fess, the bend, the pale, &c. which were the original charges of family-arms; for they who never had been at tournaments, had not such marks of distinction. They who enlisted themselves in the Croisades, took up also several new figures hitherto unknown in armorial ensigns; such as ale-riens, bezants, escalop-shells, martlets, &c. but more particularly crosses, of different colours for distinction's sake. From this it may be concluded, that heraldry, like most human inventions, was insensibly introduced and established; and that, after having been rude and unsettled for many ages, it was at last methodized, perfected, and fixed, by the Croisades and tournaments.

These marks of honour are called *arms*, from their being principally and first worn by military men at war and tournaments, who had them engraved, embossed or depicted on shields, targets, banners, or other martial instruments. They are also called *coats-of-arms*, from the custom of the ancients embroidering them on the coats they wore over their arms, as heralds do to this day.

Arms are distinguished by different names, to denote the causes of their bearing; such as, arms of Dominion;—of Pretension;—of Concession;—of Community;—of Patronage;—of Family;—of Alliance;—of Succession.

Arms of *Dominion*, or sovereignty, are those which emperors, kings, and sovereign states do constantly bear; being, as it were, annexed to the territories, kingdoms, and provinces they possess. Thus the three lions are the arms of England, the harp those of Ireland, &c.

Arms of *Pretension*, are those of such kingdoms, provinces, or territories, to which a prince or lord has some claim, and which he adds to his own, although the said kingdoms or territories be possessed by a foreign prince or other lord. Thus the kings of England have quartered the arms of France with their own ever since Edward III. laid claim to the kingdom of France, which happened in the year 1330, on account of his being son to Isabella, sister to Charles the Handsome, who died without issue.

Arms of *Concession*, or augmentation of honour, are either entire arms, or else one or more figures, given by princes as a reward for some extraordinary service. We read in history, that Robert Bruce, king of Scotland, allowed the earl of Winton's ancestor to bear, in his coat-armour, a crown supported by a sword, to show that he, and the clan Seaton, of which he was the head, supported his tottering crown. The late Queen Anne granted to Sir Cloudefley Shovel, rear-admiral of Great Britain, a cheveron between two fleurs-de-lis in chief, and a crescent in base, to denote three great victories he had gained; two over the French, and one over the Turks.

Arms of *Community*, are those of bishoprics, cities, universities, academies, societies, companies, and other bodies corporate.

Arms of *Patronage*, are such as governors of provinces, lords of manors, patrons of benefices, &c. add to their family-arms, as a token of their superiority, rights, and jurisdiction. These arms have introduced into heraldry, castles, gates, wheels, ploughs, rakes, harrows, &c.

Arms of *Family*, or *paternal arms*, are those that belong to one particular family, that distinguish it from others, and which no person is suffered to assume without committing a crime, which sovereigns have a right to restrain and punish.

Arms of *Alliance*, are those which families, or private persons, take up and join to their own, to denote the alliances they have contracted by marriage. This sort of arms is either impaled, or borne in an *escutcheon of pretence*, by those who have married heiresses.

Arms of *Succession*, are such as are taken up by them who inherit certain estates, manors, &c. either by will, entail, or donation, and which they either impale or quarter with their own arms; which multiplies the titles of some families out of necessity, and not through ostentation, as many imagine.

These are the eight classes under which the different sorts of arms are generally ranged; but there is a sort which blazoners call *assumptive arms*, being such as are taken up by the caprice or fancy of upstarts, though of ever so mean extraction, who, being advanced to a degree of fortune, assume them without a legal title. This, indeed, is a great abuse of heraldry; and common only in Britain, for on the continent no such practice takes place.

We now proceed to consider the essential and integral parts of arms, which are these: 1. The ESCUTCHEON. 2. The TINCTURES. 3. The CHARGES. 4. The ORNAMENTS.

C H A P. I.

Of the SHIELD or ESCUTCHEON.

THE Shield or Escutcheon is the field or ground whereon are

represented the figures that make up a coat of arms: for these marks of distinction were put on bucklers or shields before they were placed on banners, standards, flags, and coat-armour; and wherever they may be fixed, they are still on a plane or superficies whose form resembles a shield.

Shields, in heraldry called *escutcheons* or *scutcheons*, from the Latin word *scutum*, have been, and still are, of different forms, according to different times and nations. Amongst ancient shields, some were almost like a horse-shoe, such as is represented by a few of the figures of escutcheons; others triangular, somewhat flat or rounded at the bottom. The people who inhabited Mesopotamia, now called *Diarbeck*, made use of this sort of shield, which it is thought they had of the Trojans. Sometimes the shield was heptagonal, that is, had seven sides. The first shield of this shape is said to have been used by the famous triumvir M. Antony. That of knights banneret was perfectly square, like a banner. As to modern escutcheons, those of the Italians, particularly of ecclesiastics, are generally a long oval. The English, French, Germans, and other nations, have their escutcheons formed different ways, according to the carver's or painter's fancy: of these, various examples are contained in our Plates of Heraldry. But the shield of maids, widows, and of such as are born ladies, and are married to private gentlemen, is of the form of a lozenge: See Plate 8. Sir George Mackenzie mentions one Muriel, countess of Strathern, who carried her arms in a lozenge, *anno* 1284, which shows how long we have been versant in heraldry.

Armorists distinguish several parts or points in escutcheons, in order to determine exactly the position of the bearings they are charged with; they are here denoted by the first nine letters of the alphabet, ranged in the following manner:

- A B C the chief.
- D the honour point.
- E the fess point.
- F the nombril point.
- G H I the base.

The knowledge of these points is of great importance, and ought to be well observed, for they are frequently occupied with several things of different kinds. It is necessary to observe, that the dexter side of the escutcheon is opposite to the left hand, and the sinister side to the right hand of the person that looks on it.

C H A P. II.

Of TINCTURES, FURS, LINES, and DIFFERENCES.

SECT. I. Of Tinctures.

BY *Tinctures* is meant that variable hue of arms which is common both to shields and their bearings. According to the French heralds, there are but seven tinctures in armory; of which two are metals, the other five are colours, viz.

The Proper Colours.	By Tinctures for Commoners.	By Prec. Stones for Peers.	By Planets for Princes, Kings, and Emperors.
Yellow	Or	Topaz	Sol
White	Argent	Pearl	Jovis
Red	Gules	Ruby	Mars
Blue	Azure	Sapphires	Jupiter
Purple	Purpure	Amethyst	Mercury
Black	Sable	Diamond	Saturn
Green	Vert	Emerald	Venus

When natural bodies, such as animals, plants, celestial bodies, &c. are introduced into coats of arms, they frequently retain their natural colours, which is expressed in this science by the word *proper*.

Besides the colours above mentioned, some of the English writers on heraldry have admitted two others, *viz.*

Orange, } termed { *Tenny*.
Blood-colour, } *Sanguine*.

But these two are rarely to be found in British bearings.

These tinctures are represented in engravings and drawings (the invention of the ingenious Silvester Petra Sancta, an Italian author of the last century) by dots and lines, as represented in Pl. 5.

Or is expressed by dots. *Argent* needs no mark, and is therefore plain. *Azure*, by horizontal lines. *Gules*, by perpendicular lines. *Vert*, by diagonal lines from the dexter chief to the sinister base points. *Purple*, by diagonal lines from the sinister chief to the dexter base points. *Sable*, by perpendicular and horizontal lines crossing each other.

Of the other two, *Tenny* is represented by diagonal lines from the sinister chief to the dexter base points, traversed by horizontal lines.

Sanguine is shewn by lines crossing each other diagonally from dexter to sinister, and from sinister to dexter.

The English heralds give different names to the roundle, according to its colour. See *Roundles* the Plate.

The French, and all other nations, do not apply such a multiplicity of names to this figure; but call them *Bezants*, after an ancient coin struck at Constantinople, once *Byzantium*, if they are *Or* and *Torteaux*; if of any other tincture, expressing the same.

SECT. II. Of Furs.

FURS represent the hairy skin of certain beasts prepared for the doublings or linings of robes and garments of state: and as shields were anciently covered with furred skins, they are therefore used in heraldry, not only for the linings of the mantles, and other ornaments of the shields, but also in the coats of arms themselves.

There are three different kinds in general use, *viz.*

1. *Ermine*; which is a field argent, powdered with black spots, their tails terminating in three hairs. See the Plate.

2. *Erminites*, where the field is sable, and the powdering white.

3. *Erminois*; the field is *Or*, the powdering *Sable*. For the use of this fur Guillim cites Bara, p. 14. but no such fur is to be found in Bara.

4. *Pean*; the field is *Sable*, the powdering *Or*. The French use no such term: but they call all furs or doublings *des pannes*, or *pennes*; which term has possibly given rise to this mistake, and many others, in those who do not understand the French language.

5. *Vair*, which is expressed by blue and white skins, cut into the forms of little bells, ranged in rows opposite to each other, the base of the white ones being always next to that of the blue ones. *Vair* is usually of six rows; if there be more or fewer, the number ought to be expressed; and if the colours are different from those above mentioned, they must likewise be expressed.

6. *Potent*, anciently called *Vairy-cuppy*, as when the field is filled with crutches or potents counter-placed.

Vair and *Potent* may consist of any two colours.

It may not be improper to observe, that the use of the tinctures took its rise from the several colours used by warriors whilst they were in the army, which S. de Petra Sancta proves by many citations. And because it was the custom to embroider gold and silver on silk, or silk on cloth of gold and silver,

the heralds did therefore appoint, that in imitation of the clothes so embroidered, colour should never be used upon colour, or metal upon metal.

SECT. III. Of the Lines used in the parting of Fields.

ESCUTCHEONS are either of one tincture, or more than one. Those that are of one only, that is, when some metal, colour, or fur, is spread all over the surface or field, such a tincture is said to be predominant: but in such as have on them more than one, as most have, the field is divided by lines; which, according to their different forms, receive various names.

Lines may be either straight or crooked. Straight lines are carried evenly through the escutcheon: and are of four different kinds; *viz.* a perpendicular line |; a horizontal, —; a diagonal dexter, \; a diagonal sinister, /.

Crooked lines are those which are carried unevenly through the escutcheon with rising and falling. French armorists reckon 11 different sorts of them; Guillim admits of seven only; but there are fourteen distinct kinds, the figures and names of which are as represented in the Plate. They are, 1. The *engrailed*. 2. The *inverted*. 3. The *wavy*. 4. The *embattled*, or *crenelle*. 5. The *nebule*. 6. The *raguly*. 7. The *indented*. 8. The *dancette*. 9. The *dove-tail*. 10. The *embattled aronde*. 11. The *battled embattled*. 12. *Champaine*.

The principal reason why lines are thus used in heraldry, is to difference bearings which would be otherwise the same; for an escutcheon charged with a chief engrailed, differs from one charged with a chief wavy, as much as if the one bore a cross and the other a saltier.

As the fore-mentioned lines serve to divide the field, it must be observed, that if the division consists of two equal parts made by the perpendicular line, it is called *parted per pale*; by the horizontal line, *parted per fess*; by the diagonal dexter, *parted per bend*; by the diagonal sinister, *parted per bend sinister*; examples of which will be given in the sequel of this treatise.

If a field is divided into four equal parts by any of these lines, it is said to be *quartered*; which may be done two ways, *viz.*

Quartered or *parted per cross*; which is made by a perpendicular and horizontal line, which, crossing each other at the centre of the field, divide it into four equal parts called *quarters*. See Plate 7.

Quartered or *parted per saltier*; which is made by two diagonal lines, dexter and sinister, that cross one another in the centre of the field, and likewise divide it into four equal parts. *Ibid.*

The escutcheon is sometimes divided into a greater number of parts, in order to place in it the arms of the several families to which one is allied; and in this case it is called a *genealogical achievement*. These divisions may consist of 6, 8, 12, and 16, quarters [as the royal arms], and even sometimes of 20, 32, 64, and upwards; there being examples of such divisions frequently exhibited at pompous funerals. An extraordinary instance of this kind was exhibited at the pompous funeral of the late worthy viscountess Townshend, whose corpse was brought from Dublin castle in Ireland to Rainham-hall in Norfolk, one of the principal tenants on horseback carrying before the hearse a genealogical banner, containing the quarterings of his lordship's and her ladyship's family, to the amount of upwards of 160 coats. Sir George Booth, rector of the valuable living of Ash-ton under Line, bears six distinct coats of arms in his shield; *viz.* those for Booth, Barton, Venables, Mountfort, Ashton, Egerton; and has besides a right to 37 other coats: but Sir William Dugdale very justly objects to so many arms being clustered together in one shield or banner, on account of the difficulty of discerning and knowing asunder one coat of arms from another.

SECT. IV. *Of the DIFFERENCES of Coats of Arms.*

ARMORISTS have invented many differences or characteristic marks, whereby bearers of the same coat of arms are distinguished each from others, and their nearness to the principal bearer demonstrated. According to J. Guillim, these differences are to be considered either as ancient or modern.

1. Those he calls *ancient differences* consist in *bordures*; which is a bearing that goes all round, and parallel to the boundary of the escutcheon, in form of a hem, and always contains a fifth part of the field in breadth. *Bordures* were used in ancient times for the distinguishing not only of one nation or tribe from another, but also to note a diversity between particular persons descended of one family and from the same parents. This distinction, however, was not expressly signified by invariable marks; nor were *bordures* always appropriated to denote the different degrees of consanguinity: for, as Sir Henry Spelman observes in his *Aspilogia*, p. 140, ancient heralds, being fond of conspicuous differences, often inverted the paternal tincture, or sometimes inserted another charge in the escutcheon, such as bends, crosslets, cantons, or the like; which irregularity has, probably, induced modern armorists to invent and make use of others.

There are *bordures* of different forms and tinctures, as may be seen in the examples exhibited in Plate 5. *Bordures* are generally used as a *difference* between families of the same name, and likewise as marks of illegitimacy.

A *bordure* is never of metal upon metal, and seldom of colour upon colour, but rather of the tincture which the principal bearing or charge is of.

2. The *modern differences* which have been adopted not only for the distinguishing of sons issued out of one family, but also to denote the difference and subordinate degrees in each house from the original ancestors, are nine, *viz.* For the heir or first son, the Label. 2d son, the Crescent. 3d son, the Mullet. 4th son, the Martlet. 5th son, the Annulet. 6th son, the Flower-de-luce. 7th son, the Rose. 8th son, the Cross moline. 9th son, the Double Quater-foil. See Plate 5.

By these differences, the six sons of Thomas Beauchamp, the 15th earl of Warwick, who died in the 34th year of king Edward III. are distinguished in an old window of the church of St. Mary at Warwick; so that although they are called *modern differences*, their usage with the English is ancient.

It must be observed, that, of all the forementioned marks of distinction, none but the label is affixed on the coats of arms belonging to any of the royal family; which the introducers of this peculiarity have, however, thought proper to difference by additional pendants and distinct charges on them, as is shewn in the Plate, where

1. Prince of Wales and Duke of Cornwall has a Label Luna.
2. Duke of York—A Label Luna charged with a Cross Mars upon the middle Lambeaux.
3. Duke of Clarence—A Label Luna charged with a Cross Mars between two Anchors Jupiter.
4. Duke of Gloucester—A Label of 5 Points Luna, the middle one charged with a Fleur-de-lis Jupiter, the other four with a Cross Mars.

These differences are borne upon the Arms and Supporters.

As to the distinction to be made in the arms of the offspring belonging to each of the abovementioned brothers, it is expressed by figures on the top and margin of the TABLE of HOUSES given in the Plate. For instance, The heir or first son of the second house, beareth a crescent charged with a label during his father's life only. The second son of the second house, a crescent charged with another crescent. The third son of the second house, a crescent charged with a mullet. The fourth son of the second house, a crescent charged

with a martlet. The fifth son of the second house, a crescent charged with an annulet. The sixth son of the second house, a crescent charged with a flower-de-luce: and so on of the other sons, taking care to have them of a different tincture.

In what part of the escutcheon these differences should be borne is not certain; for Guillim, Morgan, and others, give us many different examples of their position. The honour-point would be the properest place, if the arms would admit of it; but that is not always the case, as that part may be charged with some figure in the paternal coat, which cannot with propriety receive the difference. There are instances where these are borne alone as perfect coats of arms.

In the *Examples of Differences* exhibited in Plate the 5th, 1. Is the mark of filiation for the fourth son of the sixth house. 2. Is the fourth son of the first generation; expressed by the martlet in chief.

Sisters, except of the blood-royal, have no other mark of difference in their coats of arms, but the form of the escutcheon (as observed before); therefore they are permitted to bear the arms of their father, even as the eldest son does after his father's decease. The reason of which is by Guillim said to be, that when they are married, they lose their surname, and receive that of their husbands.

Next to these diminutions, G. Leigh, J. Guillim, and after them Dr. Harris in his *Lexicon Technicum*, set forth at large various figures, which they pretend were formerly added to the coats of such as were to be punished and branded for cowardice, fornication, slander, adultery, treason, or murder, for which they give them the name of *abatements of honour*; but as they produce but one instance of such whimsical bearings, we have not inserted them here. Besides, arms being marks of honour, they cannot admit of any note of infamy; nor would any body now-a-days bear them if they were so branded. It is true, a man may be degraded for different crimes, particularly high treason; but in such cases the escutcheon is reversed, trod upon, and torn in pieces, to denote a total extinction and suppression of the honour and dignity of the person to whom it belonged.

C H A P. III.

Of the CHARGES.

WHATSOEVER is contained in the field, whether it occupy the whole or only a part thereof, is called a Charge. All charges are distinguished by the names of honourable ordinaries, sub-ordinaries, and common charges. *Honourable ordinaries*, the principal charges in heraldry, are made of lines only, which, according to their disposition and form, receive different names. *Sub-ordinaries* are ancient heraldic figures, frequently used in coats of arms, and which are distinguished by terms appropriated to each of them. *Common charges* are composed of natural, artificial, and even chimerical things; such as planets, creatures, vegetables, instruments, &c. See various instances in the Plates.

SECT. I. *Of Honourable Ordinaries.*

THE most judicious armorists admit only of nine honourable ordinaries, *viz.* The Chief—The Pale—The Bend—The Bend sinister—The Fess—The Bar—The Chevron—The Cross—and The Saltier.

Of these, but six have diminutives, which are called as follows: That of the chief is a *fillet*; the pale has a *pallet* and *endorse*; the bend, a *bendlet*, *cost*, and *ribband*; the bend sinister has the *scarp* and *baton*; the bar, the *closet* and *barulet*; the chevron, a *chevronel* and *couple-closet*. All which will be treated of in their order.

1. THE CHIEF is an ordinary determined by an horizontal

line, which, if it is of any other form but straight, must be expressed. It is placed in the upper part of the escutcheon, and containeth in depth the third part of the field. Its diminutive is a fillet, the content of which is not to exceed one fourth of the chief, and standeth in the lowest part thereof. This ordinary is subject to be charged with variety of figures; and may be indented, wavy, nebule, &c. Various examples are shewn in the Plates.

2. The PALE is an ordinary, consisting of two perpendicular lines drawn from the top to the base of the escutcheon, and contains the third middle part of the field. Its diminutives are, the pallet, which is the half of the pale; and the endorse, which is the fourth part of a pale. This ordinary and the pallet may receive any charge, but the endorse should not be charged. The endorse, besides, is never used, according to J. Leigh, but to accompany the pale in pairs, as cotices do the bend; but Sir John Ferne is of a different opinion.

3. The BEND is an ordinary formed by two diagonal lines, drawn from the dexter-chief to the sinister-base; and contains the fifth part of the field in breadth, if uncharged; but if charged, then the third. Its diminutives are, the bendlet, which is the half of a bend; the cost or cotice, when two of them accompany a bend, which is the fourth part of a bend; and the ribband, the moiety of a cost, or the eighth part of the field.

There is also the *bend-sinister*, which is of the same breadth as the bend, but drawn the contrary way: this is subdivided into a scrape, which is the half of the bend, and into a bâton, which is the fourth part of the bend, but does not extend itself to the extremities of the field, there being part of it seen at both ends. See the example, in Plate 6.

4. The FESS is an ordinary which is produced by two parallel lines drawn horizontally across the centre of the field, and contains in breadth the third part thereof. Some English writers say it has no diminutive, for the bar is a distinct ordinary of itself.

5. The BAR, according to their definition, is formed of two lines, and contains but the fifth part of the field: which is not the only thing wherein it differs from the fess; for there may be more than one in an escutcheon, placed in different parts thereof, whereas the fess is limited to the centre-point; but in this the French differed from them. The bar has two diminutives; the barulet, which contains the half of the bar; and the clofet, which is the half of the barulet. When the shield contains a number of bars of metal and colour alternate, of even number, that is called *barry* of so many pieces, expressing their number. See the examples.

6. The CHEVERON, which represents two rafters of a house well jointed together, or a pair of compasses half open, takes up the fifth part of the field with the English, but the French gave it the third. Its diminutives are, The cheveronel, which contains the half of a cheveron; and the couple-clofet, which is the half of a cheveronel, that is, its breadth is but the fourth part of a cheveron. Leigh observes, that this last diminutive is never borne but in pairs, or with a cheveron between two of them. The French have but one diminution of this ordinary called *Etaye*, containing the third part of its breadth. Examples of cheverons are given in the Plates.

7. The CROSS is an ordinary formed by the meeting of two perpendicular with two horizontal lines in the fess-point, where they make four right-angles; the lines are not drawn throughout, but discontinued the breadth of the ordinary, which takes up only the fifth part of the field when not charged; but if charged, then the third. It is borne as well engrailed, indented, &c. as plain.

There is so great a variety of crosses used in heraldry, that it would be a very difficult task to treat of them all. Guillim has mentioned 39 different sorts; De la Columbiere, 72; Leigh,

46; and Upton declares he dares not ascertain all the various crosses borne in arms, for that they are almost innumerable: therefore, as all their forms cannot be expected here, we will only delineate such as are most commonly seen at present in coats-of-arms. See Plate 6.

8. The SALTIER, which is formed by the bend and bend-sinister crossing each other in right angles, as the intersecting of the pale and fess forms the cross, contains the fifth part of the field; but if charged, then the third. In Scotland, this ordinary is frequently called a *St. Andrew's cross*. It may, like the others, be borne engrailed, wavy, &c. as also between charges or charged with any thing. See Plate 6.

SECT. II. Of SUB-ORDINARIES.

BESIDES the honourable ordinaries and the diminutions already mentioned, there are other heraldic figures, called *sub-ordinaries*, or *ordinaries* only, which, by reason of their ancient use in arms, are of worthy bearing, viz. The *Giron*, *Franc-quarter*, *Canton*, *Pairle*, *Fret*, *Pile*, *Orle*, *Inescutcheon*, *Trefure*, *Annulet*, *Flanches*, *Flasques*, *Voiders*, *Billet*, *Lozenge*, *Gutté*, *Fusil*, *Rustre*, *Masle*, *Papillone*, and *Diaper*. For examples of the most material of these, see Plates 5 and 6.

The *Giron* is a triangular figure formed by two lines, one drawn diagonally from one of the four angles to the centre of the shield; and the other is drawn either horizontal or perpendicular, from one of the sides of the shield, meeting the other line at the centre of the field. *Girone* is said, when the field is covered with six, eight, ten, or twelve girones in a coat-of-arms: but a French author would have the true girone to consist of eight pieces only. This may be instanced in the coat-of-arms of Flora Campbell countess of Loudon, &c. whose ancestor was created baron of Loudon in 1604 by James VI. and earl of the same place, May 12, 1633, the 9th of Charles I.

The *Franc-quarter* is a square figure, which occupies the upper dexter quarter of the shield. It is but rarely carried as a charge. Silvester Petra Sancta has given us a few instances, however, of its use.

The *Canton* is a square part of the escutcheon, somewhat less than the quarter, but without any fixed proportion. It represents the banner that was given to ancient knights-bannerets, and, generally speaking, possesses the dexter-chief-point of the shield, as in the fig.; but should it possess the sinister-corner, which is but seldom, it must be blazoned a *canton-sinister*. Coats reckons it as one of the nine honourable ordinaries, contrary to most heralds' opinions. It is added to coats-of-arms of military men as an augmentation of honour.

The *Pairle* is a figure formed by the conjunction of the upper half of the saltier with the under half of the pale.

The *Fret* is a figure representing two little sticks in saltier, with a masle in the centre interlaced. J. Gibbon terms it the *herald's true lover's knot*; but many dissent from his opinion. *Fretty* is said when the field or bearings are covered with a fret of six, eight, or more pieces, as in the figure. The word *fretty* may be used without addition, when it is of eight pieces; but if there be less than that number, they must be specified.

The *Pile*, which consists of two lines, terminating in a point, is formed like a wedge, and is borne engrailed, wavy, &c. It issues in general from the chief, and extends towards the base; yet there are some piles borne in bend, and issuing from other parts of the field.

The *Orle* is an ordinary composed of two lines going round the shield, the same as the bordure, but its breadth is but one-half of the latter, and at some distance from the rim of the shield.

The *Inescutcheon* is a little escutcheon borne within the shield; which, according to Guillim's opinion, is only to be

so called when it is borne single in the fess-point or centre; but modern heralds, with more propriety, give the name of *inescocheon* to such as are contained in Plate 6, and call that which is fixed on the fess-point *escocheon of pretence*, which is to contain the arms of a wife that is an heiress, as represented in the same Plate.

The *Tressure* is an ordinary commonly supposed to be the half of the breadth of an orle, and is generally borne flowery and counter-flowery, as it is also very often *double*, and sometimes treble. See the Plate. This double tressure makes part of the arms of Scotland, as marshalled in the coat armour of the kings of Great Britain, and was granted to the Scots kings by Charlemagne, being then emperor and king of France, when he entered into a league with Achaius king of Scotland, to show that the French lilies should defend and guard the Scottish lion.

The *Annulet*, or ring, is a well-known figure, and is frequently to be found in arms through every kingdom in Europe. The annulet is shewn in the Table of Houses, Plate 5.

The *Flanches* are formed by two curved lines, or semicircles, being always borne double. G. Leigh observes, that on two such Flanches two sundry coats may be borne.

The *Flasques* resemble the flanches, except that the circular lines do not go so near the centre of the field; (see the figure.) J. Gibbon would have these two ordinaries to be both one, and written *flank*; alleging, that the two other names are but a corruption of this last: but as G. Leigh and J. Guillim make them two distinct and subordinate ordinaries, we have noticed them here as such.

The *Voiders* are by Guillim considered as a subordinate ordinary, and are not unlike the flasques (see the figure), but they occupy less of the field.

The *Billet* is an oblong square figure, twice as long as broad. Some heralds imagine, that they represent bricks for building; others more properly consider them as representing folded paper or letters.

The *Lozenge* is an ordinary of four equal and parallel sides, but not rectangular; two of its opposite angles being acute, and the other two obtuse. Its shape is the same with those of our window-glasses, before the square came so much in fashion. See the figure in Plate 5.

Gutté, or drops, are round at bottom, waved on the sides, and terminate at the top in points. Herald's have given them different names according to their different tinctures; thus, they are called, if Yellow, *Gutté d'Or*; if White, *d'Eau*; if Red, *de Sang*; Blue, *de Larmes*; Green, *de Veri*; and if Black, *de Poix*. See Plate 5.

The *Fusil* is longer than the lozenge, having its upper and lower part more acute and sharp than the other two collateral middle parts, which acuteness is occasioned by the short distance of the space between the two collateral angles; which space, if the fusil is rightly made, is always shorter than any of the four equal geometrical lines whereof it is composed. See the figure, in Plate 5.

The *Rustre* is a lozenge pierced round in the middle. They are called by the Germans *ruten*. Menestrier gives an example of them in the arms of Lebaret in France, argent three rustres azure.

The *Masle* is pretty much like a lozenge, but voided or perforated through its whole extent, showing a narrow border, as in the figure. Authors are divided about its resemblance; some taking it for the mesh of a net, and others for the spots of certain flints found about Rohan. It is shewn in Plate 5.

Papillone is an expression used for a field or charge that is covered with figures like the scales of a fish. Monf. Baron gives as an example of it the arms of Monti Gueules Paplone

d'Argent. The proper term for it in English would be *escallop work*. See *escallop* in Plate 5.

Diapering is said of a field or charge shadowed with flourishings or foliage with a colour a little darker than that on which it is wrought. The Germans frequently use it; but it does not enter into the blazoning or description of an arms, but only serves to embellish the coat.

If the fore-mentioned ordinaries have any attributes, that is, if they are engrailed, indented, wavy, &c. they must be distinctly specified, after the same manner as the honourable ordinaries.

SECT. III. Of COMMON CHARGES borne in Coats-of-arms.

It has been already observed, that in all ages men have made use of the representation of living creatures, and other symbolical signs, to distinguish themselves in war; and that these marks, which were promiscuously used for hieroglyphics, emblems, and personal devices, gave the first notion of heraldry. But nothing shows the extent of human fancy more, than the great variety of these marks of distinction, since they are composed of all sorts of figures, some natural, others artificial, and many chimerical; in allusion, it is to be supposed, to the state, quality, or inclination of the bearer.

Hence it is, that the sun, moon, stars, comets, meteors, &c. have been introduced to denote glory, grandeur, power, &c. Lions, leopards, tigers, serpents, stags, &c. have been employed to signify courage, strength, prudence, swiftness, &c.

The application to certain exercises, such as war, hunting, music, &c. has furnished lances, swords, pikes, arms, fiddles, &c. Architecture, columns, cheverons, &c.; and the other arts several things that relate to them.

Human bodies, or distinct parts of them, also clothes, and ornaments, have, for some particular intention, found place in armory; trees, plants, fruits, and flowers, have likewise been admitted to denote the rarities, advantages, and singularities, of different countries.

The relation of some creatures, figures, &c. to particular names, has been likewise a very fruitful source of variety in arms. Thus the family of Coningsby bears three conies; of Arundel, six swallows; of Urson, a bear; of Lucic, three pikes; in Latin *tres lucios pisces*; of Starkey, a stork; of Castleman, a castle triple-towered; of Shuttleworth, three weaver's shuttles, &c.

Besides these natural and artificial figures, there are chimerical or imaginary ones used in heraldry, the result of fancy and caprice; such as centaurs, hydras, phenixes, griffons, dragons, &c. Which great variety of figures shows the impossibility of comprehending all common charges in a work of this nature; therefore such only shall be treated of as are most frequently borne in coats-of-arms.

I. Among the multitude of NATURAL FIGURES which are used in coats-of-arms, those most usually borne are, for the sake of brevity as well as perspicuity, distributed into the following classes, viz. *Celestial figures*; as, the sun, moon, stars, &c. and their parts. *Effigies* of men, women, &c. and their parts. *Beasts*; as, lions, stags, foxes, boars, &c. and their parts. *Birds*; as, eagles, swans, storks, pelicans, &c. and their parts. *Fishes*; as, dolphins, whales, sturgeons, trouts, &c. and their parts. *Reptiles and Insects*; as, tortoises, serpents, grasshoppers, &c. and their parts. *Vegetables*; as, trees, plants, flowers, herbs, &c. and their parts. *Stones*; as, diamonds, rubies, pebbles, rocks, &c.

These charges have, as well as ordinaries, divers attributes or epithets, which express their qualities, positions, and dispositions. Thus the sun is said to be *in his glory*, *eclipsed*, &c. The moon, *in her complement*, *increfcent*, &c. Animals are said

to be *rampant, passant, &c.* Birds have also their denominations, such as *close, displayed, &c.* Fishes are described to be *hauriant, naiant, &c.* Examples of these are contained in Plate 7. It is only therefore necessary to notice here, that lions are termed *lioncels* if more than two in the field, and eagles *eaglets*.

It must be observed also, that trees and plants are sometimes said to be *trunked, eradicated, fructuated, or raguled,* according as they are represented in arms.

2. Of ARTIFICIAL FIGURES borne in coats-of-arms, the following classes may be distinguished. See the Plate. *Warlike instruments*; as, swords, arrows, battering-rams, gauntlets, helmets, spears, pole-axes, &c. *Ornaments used in royal and religious ceremonies*; as, crowns, coronets, mitres, wreaths, croziers, &c. *Architecture*; as, towers, castles, arches, columns, plummets, battlements, churches, portcullisses, &c. *Navigation*; as, ships, anchors, rudders, pendants, sails, oars, masts, flags, galleys, lighters, &c.

All these bearings have different epithets, serving either to express their position, disposition, or make: *viz.* swords are said to be erect, pommeled, hilted, &c.; arrows, armed, feathered, &c.; towers, covered, embattled, &c.; and so on of all others, as will appear by the titles expressed in the Plate.

3. CHIMERICAL FIGURES form the last and oddest kind of bearings in coats of arms, as under the name of *chimerical*, heralds rank all figures of things which have no real existence, but are mere fabulous and fantastical inventions. These charges, griffons, martlets, and unicorns excepted, are so uncommon in British coats, that we have not thought it necessary to give more than a few examples of them; and these may be seen in Plate 7. Instances occur, however, of angels, cherubims, tritons, centaurs, martlets, griffons, unicorns, dragons, mermaids, satyrs, wiverns, harpies, cockatrices, phenixes, &c. and all these, like the foregoing charges, are subject to various positions and dispositions, which, from the principles already laid down, will be plainly understood.

To the forementioned figures may be added the *montegre*, an imaginary creature, supposed to have the body of a tiger with a satyr's head and horns; also those which have a real existence, but are said to be endowed with extravagant and imaginary qualities, *viz.* the salamander, beaver, camoleon, &c.

C H A P. IV.

Of the EXTERNAL ORNAMENTS of ESCUTCHEONS.

THE ornaments that accompany or surround escutcheons denote the birth, dignity, or office, of the person to whom the coat-of-arms appertaineth; and obtains both among the laity and clergy. Those most in use are of ten sorts, *viz.* crowns, coronets, mitres, helmets, mantles, chapeaux, wreaths, crests, scrolls, supporters.

SECT. I. *Of Crowns.*

THE first crowns were only diadems, bands, or fillets; afterwards they were composed of branches of divers trees, and then flowers were added to them. Among the Greeks, the crowns given to those who carried the prize at the Isthmian games, were of pine; at the Olympic, of laurel; and at the Nemean, of smalage. The Romans had various crowns to reward martial exploits and extraordinary services done to the republic; for which, see the article CROWN in this work, and Plate 8. Examples of some of these crowns are frequently met with in modern achievements.

Modern crowns are only used as an ornament, which emperors, kings, and independent princes set on their heads, in great solemnities, to denote their sovereign authority. These are described in heraldry as follows:

The imperial crown is made of a circle of gold, adorned with precious stones and pearls, heightened with fleurs-de-lis, bordered and seeded with pearls, raised in the form of a cap voided at the top, like a crescent. From the middle of this cap rises an arched fillet enriched with pearls, and surmounted of a mound, whereon is a cross of pearls.

The crown of the kings of Great Britain (see Plate 8.) is a circle of gold, bordered with ermine, enriched with pearls and precious stones, and heightened up with four crosses pattee and four large fleurs-de-lis alternately; from these rise four arched diadems adorned with pearls, which close under a mound, surmounted of a cross like those at bottom. Mr. Sandford, in his Genealogical History, p. 381, remarks, that Edward IV. is the first king of England that in his seal, or on his coin, is crowned with an arched diadem.

The crowns of Spain and Portugal are a ducal coronet, heightened up with eight arched diadems that support a mound, ensigned with a plain cross. Those of Denmark and Sweden are both of the same form; and consist of eight arched diadems, rising from a marquis's coronet, which conjoin at the top under a mound ensigned with a cross-botone. The crowns of most other kings in Europe are circles of gold, adorned with precious stones, and heightened up with large trefoils, and closed by four, six, or eight diadems, supporting a mound, surmounted of a cross.

The Great Turk bears over his arms a turban, enriched with pearls and diamonds, under two coronets, the first of which is made of pyramidal points heightened up with large pearls, and the uppermost is surmounted with crescents.

The Pope appropriates to himself a tiara or long cap of golden cloth, from which hang two pendants embroidered and fringed at the ends, *semée* of crosses of gold. This cap is inclosed by three marquis's coronets; and has on its top a mound of gold, whereon is a cross of the same, which cross is sometimes represented by engravers and painters pomotted, recrossed, flowery, or plain. It is a difficult matter to ascertain the time when these haughty prelates assumed the three forementioned coronets. A patched up succession of the holy pontiffs, engraved and published a few years ago by order of Clement XIII. the late Pope, for the edification of his good subjects in Great Britain and Ireland, represents Marcellus, who was chosen bishop of Rome anno 310. and all his successors, adorned with such a cap: but it appears, from very good authority, that Boniface VIII. who was elected into the see of Rome anno 1295, first compassed his cap with a coronet; Benedict XII. in 1335, added a second to it; and John XXIII. in 1411, a third; with a view to indicate by them, that the Pope is the sovereign priest, the supreme judge, and the sole legislator among Christians.

SECT. II. *Of Coronets.*

THE Coronet of the prince of Wales, or eldest son of the king of Great Britain (pl. 8.), was anciently a circle of gold set round with four crosses-patee, and as many fleurs-de-lis alternately; but since the Restoration, it has been closed with one arch only, adorned with pearls, and surmounted of a mound and cross, and bordered with ermine like the king's. But besides the coronet, his royal highness has another distinguishing mark of honour, peculiar to himself, *viz.* a plume of three ostrich feathers, with an ancient coronet of a prince of Wales. Under it, in a scroll, is this motto, *Ich Dien*, which in the German or old Saxon language signifies "I serve." This device was at first taken by Edward prince of Wales, commonly called the *black prince*, after the famous battle of Cressy, in 1346, where having with his own hand killed John king of Bohemia, he took from his head such a plume, and put it on his own.

The coronet of all the immediate sons and brothers of the kings of Great Britain, is a circle of gold, bordered with ermine, heightened up with four fleurs-de-lis, and as many crosses-patee alternate (see Plate 8.). The particular and distinguishing form of such coronets as are appropriated to princes of the blood-royal, is described and settled in a grant of Charles II. the 13th of his reign.

The coronet of the *princesses* of Great Britain is a circle of gold, bordered with ermine, and heightened up with crosses-patee, fleurs-de-lis, and strawberry leaves alternate; whereas a prince's coronet has only fleurs-de-lis and crosses.

A *duke's* coronet is a circle of gold bordered with ermine, enriched with precious stones and pearls, and set round with eight large strawberry or parsley leaves.

A *marquis's* coronet is a circle of gold, bordered with ermine, set round with four strawberry leaves, and as many pearls on pyramidal points of equal height, alternate.

An *earl's* coronet is a circle of gold, bordered with ermine, heightened up with eight pyramidal points or rays, on the tops of which are as many large pearls, that are placed alternately with as many strawberry leaves, but the pearls much higher than the leaves.

A *viscount's* coronet differs from the preceding ones as being only a circle of gold bordered with ermine, with large pearls set close together on the rim, without any limited number, which is his prerogative above the baron, who is limited.

A *baron's* coronet, which, it appears, was granted by king Charles II. is formed with six pearls set at equal distances on a gold circle, bordered with ermine, four of which only are seen on engravings, paintings, &c. to show he is inferior to the viscount. In the Plate, where representations of the foregoing may be seen, we have given one of the caps worn by the ancient barons before the year 1661.

The eldest sons of peers, above the degree of a baron, bear their father's arms and supporters with a label, and use the coronet appertaining to their father's second title; and all the younger sons bear their arms with proper differences, but use no coronets.

As the crown of the king of Great Britain is not quite like that of other potentates, so do most of the coronets of foreign noblemen differ a little from those of the British nobility.

SECT. III. *Of Mitres.*

THE archbishops and bishops of England and Ireland place a mitre over their coats-of-arms. It is a round cap pointed and cleft at the top, from which hang two pendants fringed at both ends; with this difference, that the bishop's mitre is only surrounded with a fillet of gold, set with precious stones, whereas the archbishop's issues out of a ducal coronet. See Plate 8.

This ornament, with other ecclesiastical garments, is still worn by all the archbishops and bishops of the church of Rome, whenever they officiate with solemnity; but it is never used in England, otherwise than on coats-of-arms, as before mentioned.

The first archbishop's consecration in England was in the year 568. No mitre but an archbishop's is borne upon a ducal coronet, except the bishop of Durham, that see being a principality.

The first bishop's consecration in England was in the year 516.

SECT. IV. *Of Helmets.*

THE helmet was formerly worn as a defensive weapon, to cover the head; and is now placed over a coat-of-arms as its chief ornament, and the true mark of gentility. There are

several sorts, distinguished by the matter they are made of, by their form, and by their position. 1st, As to the matter they are, or rather were, made of: The helmets of sovereigns were of burnished gold damasked; those of princes and lords, of silver figured with gold; those of knights, of steel adorned with silver; and those of private gentlemen, of polished steel. 2dly, As to their form: Those of the king and the royal family, and noblemen of Great Britain, are open-faced and grated, and the number of bars serves to distinguish the bearer's quality; that is, the helmet appropriated to the dukes and marquises is different from the king's, by having a bar exactly in the middle, and two on each side, making but five bars in all; (see Plate 8.) whereas the king's helmet has six bars, viz. three on each side. The other grated helmet with four bars is common to all degrees of peerage under a marquis. The open-faced helmet without bars denotes baronets and knights. The close helmet is for all esquires and gentlemen. 3dly, Their position is also looked upon as a mark of distinction. The grated helmet in front belongs to sovereign princes. The grated helmet in profile is common to all degrees of peerage. The helmet standing direct without bars, and the beaver a little open, denotes baronets and knights. Lastly, the side-standing helmet, with the beaver close, is the way of wearing it amongst esquires and gentlemen. See the various figures in the Plate.

SECT. V. *Of Mantlings.*

MANTLINGS are pieces of drapery shaped in various ways, which serve to ornament escutcheons. They were the ancient coverings of helmets, to preserve them, or the wearer, from the injuries of the weather, as also to prevent the ill consequences of their too much dazzling the eye in action. But Guillim very judiciously observes, that their shape must have undergone a great alteration since they have been out of use, and therefore might more properly be termed *flourishings* than *mantlings*.

The French heralds assure us, that these mantlings were originally no other than short coverings which commanders wore over their helmets, and that, going into battle with them, they often, on their coming away, brought them back in a ragged manner, occasioned by the many cuts they had received on their heads: and therefore the more hacked they were, the more honourable they were accounted; as our colours in time of war are the more esteemed for having been shot through in many places.

Sometimes skins of beasts, as lions, bears, &c. were thus borne, to make the bearer look more terrible; and that gave occasion to the doubling of mantlings with furs.

SECT. VI. *Of Chapeaux, Wreaths, and Crests.*

A CHAPEAU is an ancient hat, or rather cap, of dignity worn by dukes, generally scarlet-coloured velvet on the outside, lined and turned up with fur; of late frequently to be met with above an helmet, instead of a wreath, under gentlemen's and noblemen's crests. Heretofore they were seldom to be found, as of right appertaining to primate families; but by the grants of Robert Cooke, Clarencieux, and other succeeding heralds, these, together with ducal coronets, are now frequently to be met with in families, who yet claim not above the degree of gentlemen. See the representations of the chapeau, &c. in plate 8.

THE WREATH is a kind of roll made of two skins of silk of different colours twisted together, which ancient knights wore as a head-dress when equipped for tournaments. The colours of the silk are always taken from the principal metal and colour contained in the coat-of-arms of the bearer. They are still accounted as one of the lesser ornaments of escutcheons, and are

placed between the helmet and the crest (see the Plate.). In the time of Henry I. and long after, no man who was under the degree of a knight had his crest set on a wreath; but this, like other prerogatives, has been infringed so far that every body now-a-days wears a wreath.

The **CREST** is the highest part of the ornaments of a coat-of-arms. It is called *crest*, from the Latin word *crisla*, which signifies comb or tuft, such as many birds have upon their heads, as the peacock, pheasant, &c. in allusion to the place on which it is fixed.

Crests were formerly great marks of honour, because they were only worn by heroes of great valour, or by such as were advanced to some superior military command, in order that they might be the better distinguished in an engagement, and thereby rally their men if dispersed; but they are at present considered as a mere ornament. The crest is frequently a part either of the supporters, or of the charge borne in the escutcheon. Thus the crest of the royal achievement of Great Britain is a "Lion guardant crown'd." There are several instances of crests that are relative to alliances, employments, or names; and which on that account have been changed.

SECT. VII. *Of the Scroll and Supporters.*

THE **SCROLL** is the ornament usually placed below the crest, containing a motto, or short sentence, alluding thereto, or to the bearings; or to the bearer's name, as in the two following instances. The motto of the noble earl of Chohnondeley is, *Cassis tutissima virtus*; i. e. "Virtue is the safest helmet;" on account of the helmet in the coat of arms. The motto of the right hon. lord Fortescue is, *Fortis scutum salus ducum*; i. e. "A strong shield is the safety of the commanders;" alluding to the name of that ancient family. Sometimes it has reference to neither, but expresses something divine or heroic; as that of the earl of Scarborough, which is, *Murus arcus conscientia sana*; i. e. "A good conscience is a wall of brass." Others are ænigmatical; as that of the royal achievement, which is *Dieu et mon droit*, i. e. "God and my right;" introduced by Edward III. in 1340, when he assumed the arms and title of *king of France*, and began to prosecute his claim, which occasioned long and bloody wars, fatal, by turns, to both kingdoms. Mottos, though hereditary in the families that first took them up, have been changed on some particular occasions, and others appropriated in their stead, instances of which are sometimes met with in the history of families.

SUPPORTERS are figures standing on the scroll, and placed at the side of the escutcheon; they are so called, because they seem to support or hold up the shield. The rise of supporters is, by F. Menestrier, traced up to ancient tournaments, wherein the knights caused their shields to be carried by servants or pages under the disguise of lions, bears, griffons, blackamoors, &c. who also held and guarded the escutcheons, which the knights were obliged to expose to public view for some time before the lists were opened. Sir George Mackenzie, who differs from this opinion, says, in his *Treatise on the Science of Heraldry*, chap. xxxi. p. 93. "That the first origin and use of them was from the custom which ever was, and is, of leading such as are invested with any great honour to the prince who confers it: thus, when any man is created a duke, marquis, or knight of the garter, or any other order, he is supported by, and led to the prince betwixt, two of the quality, and so receives from him the symbols of that honour; and in remembrance of that solemnity, his arms are thereafter supported by any two creatures he chooses." Supporters have formerly been taken from such animals or birds as are borne in the shields, and sometimes they have been chosen as bearing some allusion to the names of those whose arms they are made to support. The supporters of the arms of Great Britain, since king James

the first's accession to the throne, are a *Lion rampant guardant crowned Or*, on the dexter-side, and an *Unicorn Argent, crowned, armed, unguled, maned and gorged with an antique Crown, to which a chain is affixed, all Or*, on the sinister.

It is to be observed, that bearing coats-of-arms supported, is, according to the heraldic rules of England, the prerogative, 1st, Of those called *nobiles majores*, viz. dukes, marquises, earls, viscounts, and barons; 2d, Of all knights of the garter, though they should be under the degree of barons; 3d, Of knights of the Bath, who both receive on their creation a grant of supporters; and, lastly, of such knights as the king chooses to bestow this honour upon; as in the instance of Sir Andrew Fountain, who was knighted by Philip earl of Pembroke when lord-lieutenant of Ireland, Fountain being then his secretary; and on his return to England, king William granted him supporters to his arms, viz. *two Griffons Gules and Or*.

C H A P. V.

Of the Laws of HERALDRY, and the Method of Marshalling Coats-of-arms.

THE several escutcheons, tinctures, charges, and ornaments of coats-of-arms, and their various properties, being now explained; it may not be improper to subjoin such rules for blazoning the same, as the ancient usage and laws of heraldry have established in Britain. 1. The first and most general rule is, to express heraldic distinctions in proper terms, so as not to omit any thing that ought to be specified, and at the same time to be clear and concise without tautology. 2. Begin with the tincture of the field, and then proceed to the principal charges which possess the most honourable place in the shield, such as Fess, Cheveron, &c. always naming that charge first which lies next and immediately upon the field. 3. After naming the tincture of the field, the honourable ordinaries, or other principal figures, you must specify their attributes, and afterwards their metal or colour. 4. When an honourable ordinary, or some one figure, is placed upon another, whether it be a Fess, Cheveron, Cross, &c. it is always to be named after the ordinary or figure over which it is placed, with one of these expressions, *surmount*, or *over all*. 5. In the blazoning of such ordinaries as are plain, the bare mention of them is sufficient; but if an ordinary should be made of any of the crooked lines mentioned above, its form must be specified; that is, whether it be Engrailed, Wavy, &c. 6. When a principal figure possesses the centre of the field, its position is not to be expressed (which amounts to the same thing) when a bearing is named, without specifying the point where it is placed, then it is understood to possess the middle of the shield. 7. The number of the points of mullets or stars must be specified when more than five; and also if a mullet or any other charge be pierced, it must be mentioned as such, to distinguish it from what is plain. 8. When a ray of the sun, or other single figure, is borne in any other part of the escutcheon than the centre, the point it issues from must be named. 9. The natural colour of trees, plants, fruits, birds, &c. is no otherwise to be expressed in blazoning but by the word *proper*; but if discoloured, that is, if they differ from their natural colour, it must be particularized. 10. When three figures are in a field, and their position is not mentioned in the blazoning, they are always understood to be placed two above, and one below. 11. When there are many figures of the same species borne in a coat-of-arms, their number must be observed as they stand, and must be distinctly expressed. See the plates of **CHARGES**.

There are positions called *irregular*; as for example, when three figures, which are naturally placed 2 and 1, are disposed 1 and 2, &c. It must also be observed, that when the field is

strewed with the same figures, this is expressed by the word *semée*: but, according to a French armorist's opinion, if the figures strewed on the field are whole ones, it must be denoted by the words *sans nombre*; whereas, if part of them is cut off at the extremities of the escutcheon, the word *semée* or *semi* is then to be used.

By MARSHALLING coats-of-arms, is to be understood the art of disposing divers of them in one escutcheon, and of distributing their contingent ornaments in proper places. Various causes may occasion arms to be thus conjoined, which J. Guillim comprises under two heads, viz. *manifest* and *obscure*. What this learned and judicious herald means by *manifest causes* in the marshalling of coats-of-arms, are such as betoken marriages, or a sovereign's gift, granted either through the special favour of the prince, or for some eminent services. Concerning marriages it is to be observed,

1. When the coats-of-arms of a married couple, descended of distinct families, are to be put together in one escutcheon, the field of their respective arms is conjoined Paleways, and blazoned *parted per Pale, Baron and Femme, two coats; first, &c.* In which case the baron's arms are always to be placed on the dexter-side, and the femme's arms on the sinister-side. See all the different examples of marshalling the wife's arms with those of the husband in pl. 8.

2. If a widower marry again, his late and present wife's arms are, according to G. Leigh, "to be both placed on the sinister-side, in the escutcheon with his own, and parted per Pale. The first wife's coat shall stand on the Chief, and the second on the Base; or he may set them both in Pale with his own, the first wife's coat next to himself, and his second outermost. If he should marry a third wife, then the two first matches shall stand on the Chief, and the third shall have the whole Base. And if he take a fourth wife, she must participate one half of the Base with the third wife, and so will they seem to be so many coats quartered." But it must be observed, that these forms of impaling are meant of hereditary coats, whereby the husband stands in expectation of having the hereditary possessions of his wife united to his patrimony. *Note.* If a man marry a widow, he marshalls her *maiden* arms only.

3. In the arms of femmes joined to the paternal coat of the baron, the proper differences by which they were borne by the fathers of such women must be inserted.

4. If a coat-of-arms that has a Bordure be impaled with another, as by marriage, then the Bordure must be wholly omitted in the side of the arms next the centre.

5. The person that marries an heiress, instead of impaling his arms with those of his wife, is to bear them in an escutcheon placed in the centre of his shield, which, on account of its showing forth his pretension to her estate, is called *an escutcheon of pretence*, and is blazoned *surmount*, i. e. *over-all*. But the children are to bear the hereditary coat-of-arms of their father and mother *quarterly*, which denotes a fixed inheritance, and so transmit them to posterity. The first and fourth quarters generally contain the father's arms, and the second and third the mother's; except the heirs should derive not only their estate, but also their title and dignity, from their mother.

6. If a maiden or dowager lady of quality marry a commoner, or a nobleman inferior to her rank, their coats of-arms may be set beside one another, in two separate escutcheons, upon one mantle or drapery, and the lady's arms ornamented according to her title. See pl. 5.

7. Archbishops and bishops impale their arms differently from the fore-mentioned coats, in giving the place of honour, that is, the dexter-side, to the arms of their dignity, as it is expressed in pl. 8, which represents the coats-of-arms of a supposed archbishop of Canterbury and bishop of an English See.

With respect to such armorial ensigns as the sovereign thinks

fit to augment a coat-of-arms with, they may be done in various ways, as may be seen in the arms of his Majesty of Rutland, and many others.

So far the causes for marshalling divers arms in one shield, &c. are *manifest*. As to such as are called *obscure*, that is, when coats-of-arms are marshalled in such a manner that no probable reason can be given why they are so conjoined, the explanation of them must be left to the heralds.

CHAP. VI.

Of the ORDERS of KNIGHTHOOD, &c.

AS we have noticed at length, under the articles KNIGHTHOOD, BARONET, *Knights of the GARTER*, BATH, &c. every thing necessary to be known on these subjects, we shall not here treat of them at any length. To the augmentations mentioned in the last chapter may be added, 1. The Baronet's mark of distinction, or the arms of the province of Ulster in Ireland, granted and made hereditary in the male line by king James I. who erected this dignity on the 22d of May 1611, in the 9th year of his reign, in order to propagate a plantation in the fore-mentioned province. This mark is *Argent, a sinister Hand couped at the Wrist, and erected Gules*; which may be borne either in a canton, or in an escutcheon, as will best suit the figures of the arms. See the Baronet's escutcheon in pl. 8. 2dly, The ancient and respectable badge of the most noble Order of the Garter, instituted by king Edward III. 1349, in the 27th year of his reign. This honourable augmentation is a deep blue garter, surrounding the arms of such knights, and inscribed with his motto, "*Honi soit qui mal y pense*." See the plate.

The arms of those who are knights of the orders of the Bath, of the Thistle, or of St. Patrick, are marshalled in the same manner, with this difference only, that the colour and motto accord with the order to which it belongs. Thus the motto "*Quis separabit 1783*" on the light blue ribbon of the order, surrounds the escutcheon of a knight of St. Patrick. "*Nemo me injure lacessit*," on a green ribbon, distinguishes a knight of the Thistle; and "*Tria juncta in uno*," on red, a knight of the Bath. It is to be observed, that none of the orders of *Knighthood* are hereditary. The honours of a Paronet of Ulster, and of a Baronet of Nova Scotia (created by patent in 1602), descend to the heirs-male.

With regard to the emblazoning of the wife's arms in the case of the husband being noble, or a knight of the Garter, of the Bath, &c. or where, on the other hand, the wife is noble in her own right, and the husband a commoner, these will be found fully exemplified in plate 5.

For representations of the BADGES of the several Orders of *Knighthood*, see plate 7.

CHAP. VII.

Of FUNERAL ESCUTCHIONS.

AFTER having treated of the essential parts of coats-of-arms, of the various charges and ornaments usually borne therewith, of their attributes and dispositions, and of the rules for blazoning and marshalling them, we shall next describe the several funeral escutcheons, usually called *batiments*; whereby may be known, after any person's decease, what rank either he or she held when living; and if it be a gentleman's hatchment, whether he was a bachelor, married man, or widower, with the like distinctions for gentlewomen.

The hatchment is usually affixed to the fronts of houses, when any of the nobility or gentry die. The arms, if the deceased be a private gentleman, are parted per Pale with those of his wife. The ground without the escutcheon being black, denotes the man to be dead; and the ground on the sinister side being white,

signifies that the wife is living, which is distinctly shown in plate 8, where also all the varieties of hatchments are displayed, according to the following descriptions.

When a *married gentlewoman* dies first, the hatchment is distinguished by a contrary colour from the former; that is, the arms on the sinister-side have the ground without the escutcheon black; whereas those on the dexter-side, for her surviving husband, are upon a white ground: the hatchment of a gentlewoman is, moreover, differenced by a cherub over the arms instead of a crest.

When a *bachelor* dies, his arms may be depicted single or quartered, with a crest over them, but never impaled as the two first are, and all the ground without the escutcheon is also black.

When a *maid* dies, her arms, which are placed in a lozenge, may be single, or quartered, as those of a bachelor: all the ground without the escutcheon is also black.

When a *widower* dies, his arms are represented impaled with those of his deceased wife, having a crest, and sometimes a helmet and mantling over them, and all the ground without the escutcheon black.

When a *widow* dies, her arms are also represented impaled with those of her deceased husband, but inclosed in a lozenge, and a cherub is placed over them; all the ground without the escutcheon is also black.

If a widower or bachelor should happen to be the last of his family, a death-head is generally annexed to each hatchment, to denote that death has conquered all.

By the fore-mentioned rules, which are sometimes neglected through the ignorance of illiterate people, may be known, upon the sight of any hatchment, what branch of the family is dead; and by the helmet, coronet, &c. what title and degree the deceased person held. The same rules are observed with respect to the escutcheons placed on the hearse and horses used in pompous funerals, except that they are not surmounted with any crest, as in the foregoing examples of hatchments, but are always plain. It is necessary, however, to ensign those of peers with coronets, supporters, &c. and that of a maiden lady with a knot of ribbands. For various other examples of hatchments see the plate already referred to.

C H A P. VIII.

Of PRECEDENCY.

IN forming the present Treatise, we can by no means omit giving some account of the laws which govern the *precedency of the different ranks* which compose the community of Great Britain. This, by permission of its author, George Naylor, Esq. York Herald, and Genealogist of the Order of the Bath, (to whose indulgence we are in like manner exclusively indebted for nearly the whole of the engravings that accompany this part of our publication), we take from an elegant engraved "*Chart of Blazonry*," which comprehends every thing necessary to be known in English heraldry, and is extremely convenient for hanging up in the libraries of noblemen and gentlemen. We shall divide these tables of precedency into two parts.

SECT. I. Of the Precedency of Men.

THE first personage in point of precedency, is of course—

The KING.

Prince of Wales.

King's Sons.

King's Brothers.

King's Uncles.

King's Grandsons.

King's Nephews.

Vicegerent, when any such Officer.

Archbishop of Canterbury, Lord Primate of all England.

Lord High Chancellor, or Lord Keeper.

Archbishop of York, Primate of England.

Lord High Treasurer.

Lord President of the Privy Council.

Lord Privy Seal.

Lord High Constable in commission.

Hereditary Earl Marshal.

Lord High Admiral.

Lord Steward of his Majesty's Household.

Lord Chamberlain of his Majesty's Household.

Dukes, according to Patents of Creation.

Marquises, according to their Patents.

Dukes' eldest Sons.

Earls, according to their Patents.

Marquises' eldest Sons.

Dukes' younger Sons.

Viscounts, according to their Patents.

Earls' eldest Sons.

Marquises' younger Sons.

Bishops of London, Durham, Winchester.

Bishops, according to seniority of consecration; but if any

Bishop be Principal Secretary of State, he shall be placed above all other Bishops not having any of the great offices before mentioned.

Barons, according to their Patents of Creation; but if any

Baron be Principal Secretary of State, he shall be placed above all Barons, unless they have any of the great offices before mentioned.

Speaker of the House of Commons.

Viscounts' eldest Sons.

Earls' younger Sons.

Barons' eldest Sons.

Knights of the most noble Order of the Garter.

Privy Councillors.

Chancellor of the Exchequer.

Chancellor of the Duchy of Lancaster.

Lord Chief Justice of the King's Bench.

Master of the Rolls.

Lord Chief Justice of the Common Pleas.

Lord Chief Baron of the Exchequer.

Judges, Barons, of the degree of the Coif of the said Courts, according to seniority.

Bannerets, made under the King's own Royal Standard, displayed in an Army Royal, in open War, by the King himself in person, for the term of their lives only.

Viscounts' younger Sons.

Barons' younger Sons.

Baronets.

Bannerets, not made by the King in person.

Knights of the most honourable Order of the Bath.

Knights Bachelors.

Baronets' eldest Sons.

Knights' of the Garter eldest Sons.

Bannerets' eldest Sons.

Knights' of the Bath eldest Sons.

Knights' eldest Sons.

Serjeants at Law, DD. LLD. MD. of English Universities.

Baronets' younger Sons.

Esquires of the King's creation, by the imposition of a collar of SS.

Esquires attending Knights of the Bath.

Esquires by office, as Justices of the Peace.

Captains, Gentlemen of the Privy Chamber, &c.

Knights' of the Garter younger Sons.

Bannerets' of both kinds younger Sons.

Knights' of the Bath younger Sons.

Colours.

Expressed by Engraving.

Yellow White Red Blue

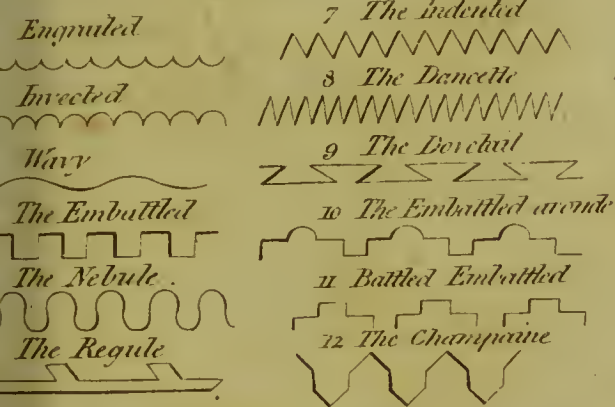

Purple Black Green

Roundles.

Plate Or Argent Vert Purpure Sable

Lines.

Lines.

their several Names when applied to Crests Feys &c

Chief only Feys Wavy Chief Ingrailed Chief Invected

Chief ended Feys Dancette Feys Nebulee Feys Embattled

Chief ended Chief Champvaue Plain Bordure Bordure Compaigne

Bordure chequy Bordure Barry Bordure Ermine

Furs.

Potent vair Ermine Ermines Erminois Pean

Gutte' or Drops.

Examples of Differences

Knight of the Garter (being a Commoner)

Earl & Barons in her own Right

Baroness in her own Right

Arms of a knight of the Bath being a Commoner & his Lady

Differences of the Royal Family.

Table of Houses.

Arms of a Commoner & his Lady being a Barons in her own Right, with supporters.

Table of Houses showing 6th, 5th, 4th, 3rd, 2nd, and 1st House variations for 1st through 6th sons.

CHARGES &c. used in Coat Armour.

Note. Most of these have their Diminutives when borne in greater number in the same escutcheon.

Baron and up.

Knights Bachelors' younger Sons.
Gentlemen entitled to bear arms.
Gentlemen by office, function, or profession.
Clergymen.
Attorneys at Law, &c.
Citizens.
Burgesses, &c.

SECT. II. *Precedency of Women.*

THE QUEEN.

Princess of Wales.
Princess Royal.
Daughters of the King.
Duchess of York, and
Wives of the King's younger Sons.
Wives of the King's Brothers.
Wives of the King's Uncles.
Wives of the eldest Sons of Dukes, of the Blood Royal.
Daughters of Dukes, of the Blood Royal.
Wives of the King's Brothers' or Sisters' Sons.
Duchesses.
Marchionesses.
Wives of the eldest Sons of Dukes.
Daughters of Dukes.
Countesses.
Wives of the eldest Sons of Marquisses.
Daughters of Marquisses.
Wives of the younger Sons of Dukes.
Viscountesses.
Wives of the eldest Sons of Earls.
Daughters of Earls.
Wives of the younger Sons of Marquisses.
Baronesses.
Wives of the eldest Sons of Viscounts.
Daughters of Viscounts.
Wives of the younger Sons of Earls.
Wives of the eldest Sons of Barons.
Daughters of Barons.
Wives of the younger Sons of Viscounts.
Wives of the younger Sons of Barons.
Dames, Wives of Baronets.
Wives of Knights of the Garter.
Wives of Bannerets of each kind.
Wives of Knights of the Bath.
Wives of Knights Bachelors.
Wives of the eldest Sons of Baronets.
Daughters of Baronets.
Wives of the eldest Sons of Knights of the Garter.
Daughters of Knights of the Garter.
Wives of the eldest Sons of Bannerets of each kind.

Daughters of Bannerets of each kind.
Wives of the eldest Sons of Knights of the Bath.
Daughters of Knights of the Bath.
Wives of the eldest Sons of Knights Bachelors.
Wives of Serjeants at Law, DD. LLD. MD. of English Universities.
Wives of the younger Sons of Baronets.
Daughters of Knights Bachelors.
Wives of Esquires, attendants on Knights of the Bath.
Wives of Esquires by office, as Justices of the Peace.
Wives of Captains, Gentlemen of the Privy Chamber, &c.
Wives of the younger Sons of Knights of the Garter.
Wives of the younger Sons of Bannerets of each kind.
Wives of the younger Sons of Knights of the Bath.
Wives of the younger Sons of Knights Bachelors.
Wives of Gentlemen lawfully bearing Coat Armour.
Daughters of Esquires lawfully bearing Coat Armour, who are Gentlewomen by birth.
Daughters of Gentlemen lawfully bearing Coat Armour, who are Gentlewomen by birth.
Wives of Gentlemen by office, function, or profession, as Clergymen, and Attorneys at Law, &c. &c.
Wives of Citizens.
Wives of Burgesses, &c.

SECT. III. *Of Styles.*

A SUBJECT nearly connected with precedence is that indicated by the title of this section. By the term *style* in heraldry, is meant that kind of language in which, according to its laws, a person of one rank is bound to address an individual of another; as at the commencement of a petition, memorial, or public address.

In this view, the KING is styled "Most High, Most Mighty, and Most Excellent Monarch."—PRINCE of WALES, "Most High, most Mighty, and most Illustrious Prince."—ARCHBISHOP, "Most Reverend Father in God."—DUKE, "Most High, Mighty, and most Noble Prince."—MARQUIS, "Most Noble and Mighty Prince."—EARL, "Most Noble and Mighty Lord."—BISHOP, "Right Reverend Father in God."—VISCOUNT and BARON, "Most Noble Lord."

Of Royal and Noble Female Personages, the QUEEN is styled "Most High, Most Mighty, and Most Excellent Princesses."—PRINCESS of the BLOOD ROYAL, "Most Illustrious Princesses."—DUCHESS, "Most High, Mighty, and most Noble Princesses."—MARCHIONESS, "Most Noble and Puissant Princesses."—COUNTESS, "Most Noble and Puissant Lady."—VISCOUNTESS and BARONESS, "Most Noble Lady."

The styles which custom confers on those inferior ranks of the community to whom heraldic distinctions belong, are too well known to need any description.

H E R

HERALDUS (Desiderius), in French *Herault*, a counsellor of the parliament of Paris, has given good proofs of uncommon learning by very different works. His *Adversaria* appeared in 1559; which little book, if the *Scaligerana* may be credited, he repented the having published. His notes on Tertullian's Apology, on Minutius Felix, and on Arnobius, have been esteemed. He also wrote notes on Martial's Epigrams. He disguised himself under the name of *David Leidbrufferus*, to write a political dissertation on the independence of kings, some time after the death of Henry IV. He had a controversy with Salmasius, *De jure Attico ac Romano*; but did not live to finish what he had written on that subject. What he had done, how-

H E R

ever, was printed in 1650. He died in June 1649. Guy Patin says, that "he was looked upon as a very learned man, both in the civil law and in polite literature, and wrote with great facility on any subject he pitched on." Daille, speaking of such Protestant writers as condemned the executing of Charles I. king of England, quotes the *Pacifique Royal en deuil*, by Herault. This author, son to our Desiderius Heraldus, was a minister in Normandy, when he was called to the service of the Walloon-church of London under Charles I. and he was so zealous a royalist that he was forced to fly to France, to escape the fury of the commonwealths men. He returned to England after the Restoration, and resumed his ancient employment in

the Walloon-church at London; some time after which he obtained a canonry in the cathedral of Canterbury, and enjoyed it till his death.

HERB, in botany; a name by which Linnæus denominates that portion of every vegetable which arises from the root, and is terminated by the fructification. It comprehends, 1. The trunk, stalk, or stem. 2. The leaves. 3. Those minute external parts called by the same author the *fulcra* or supports of plants. 4. The buds, or, as he also terms them, the *winter-quarters* of the future vegetable.

HERB-*Christopber*. See *ACTÆA*.

HERB-*Robert*, a species of *GERANIUM*. This plant is in great repute with some farmers on account of its supposed virtues against staling of blood and the bloody-flux in cattle, in which cases it is said to be of great service.

HERBACEOUS PLANTS, are those which have succulent stems or stalks that lie down to the ground every year. Of herbaceous plants, those are annual which perish stem and root and all every year; biennial, which subsist by the roots two years; perennial, which are perpetuated by their roots for a series of years, a new stem being produced every spring.

HERBAGE, in law, signifies the pasture provided by nature for the food of cattle; also the liberty to feed cattle in the forest, or in another person's ground.

HERBAL, signifies a book that treats of the classes, genera, species, and virtues of plants. The same term is sometimes also used for what is more usually called *hortus siccus*. See *HORTUS*.

HERBELOT (Bartholomew d'), a French writer, eminent for his oriental learning, was born at Paris in 1625. He travelled several times into Italy, where he obtained the esteem of some of the most learned men of the age. Ferdinand II. grand duke of Tuscany, showed him many marks of his favour: a library being exposed to sale at Florence, the duke desired him to examine the manuscripts in the oriental languages, to select the best of them, and to mark the price; which being done, that generous prince purchased them, and made him a present of them. M. Colbert, being at length informed of Herbelot's merit, recalled him to Paris, and obtained a pension for him of 1500 livres: he afterwards became secretary and interpreter of the oriental languages, and royal professor of the Syriac tongue. He died at Paris in 1695. His principal work is intitled *Bibliothèque Orientale*, which he first wrote in Arabic, and afterwards translated into French. It is greatly esteemed. M. Herbelot's modesty was equal to his erudition; and his uncommon abilities were accompanied with the utmost probity, piety, and charity, which he practised through the whole course of his life.

HERBERT (Mary), countess of Pembroke, was sister of the famous Sir Philip Sidney, and wife of Henry earl of Pembroke. She was not only a lover of the muses, but a great encourager of polite literature; a character not very common among ladies. Her brother dedicated his incomparable romance *Arcadia* to her, from which circumstance it hath been called *The Countess of Pembroke's Arcadia*. She translated a dramatic piece from the French, intitled *Antonius*, a tragedy; though it is said she was assisted by her lord's chaplain, Dr. Babington, afterwards bishop of Exeter. She also turned the psalms of David into English metre; but it is doubtful whether these works were ever printed. She died in 1621; and an exalted character of her is to be found in Francis Osborne's memoirs of king James I.

HERBERT (Edward), lord Herbert of Cherbury in Shropshire, an eminent English writer, was born in 1581, and educated at Oxford; after which he travelled, and at his return was made knight of the Bath. James I. sent him ambassador to Louis XIII. in behalf of the Protestants who were besieged in several

cities of France; and continued in this station till he was recalled, on account of a dispute between him and the constable de Luines. In 1625 he was advanced to the dignity of a baron in the kingdom of Ireland, by the title of lord Herbert of Castle-Island; and in 1631 to that of lord Herbert of Cherbury in Shropshire. After the breaking out of the civil wars, he adhered to the parliament; and in 1644 obtained a pension, on account of his having been plundered by the king's forces. He wrote A History of the Life and Reign of Henry VIII. which was greatly admired; a treatise *De veritate*; and several other works. He died at London in 1648. "Lord Herbert (says Mr. Granger) stands in the first rank of the public ministers, historians, and philosophers of his age. It is hard to say whether his person, his understanding, or his courage, was the most extraordinary; as the fair, the learned, and the brave, held him in equal admiration. But the same man was wise and capricious; redressed wrongs, and quarrelled for punètilias; hated bigotry in religion, and was himself a bigot in philosophy. He exposed himself to such dangers as other men of courage would have carefully declined: and called in question the fundamentals of a religion, which none had the hardiness to dispute besides himself."

HERBERT (George), an English poet and divine, was brother to the preceding. He was born in 1593, and educated at Cambridge. In 1619 he was chosen public orator of that university, and afterwards obtained a sinecure from the king. In 1626 he was collated to the prebend of Layton Ecclesia, in the diocese of Lincoln; and in 1630 was inducted into the rectory of Bamerton, near Sarum. The great lord Bacon had such an opinion of his judgment, that he would not suffer his works to be printed before they had passed his examination. He wrote a volume of devout poems, called *The Temple*, and another intitled *The Priest of the Temple*. This pious divine died about the year 1635.

HERBERT (William), earl of Pembroke, was born at Wilton in Wiltshire, 1580, and admitted of New-college in Oxford in 1592, where he continued about two years. In 1601 he succeeded to his father's honours and estate; was made K. G. in 1604; and governor of Portsmouth six years after. In 1626 he was elected chancellor of the university of Oxford; and about the same time made lord steward of the king's household. He died suddenly at his house called *Baynard's castle*, in London, April 10, 1630; according to the calculation of his nativity, says Wood, made several years before by Mr. Thomas Allen of Gloucester-hall. Clarendon relates concerning this calculation, that some considerable persons connected with lord Pembroke being met at Maidenhead, one of them at supper drank a health to the lord steward: upon which another said, that he believed his lordship was at that time very merry; for he had now outlived the day, which it had been prognosticated upon his nativity he would not outlive; but he had outlived it now, for that was his birth-day, which had completed his age to 50 years. The next morning, however, they received the news of his death. Whether the noble historian really believed this and other accounts relating to astrology, apparitions, providential interpositions, &c. which he has inserted in his history, we do not presume to say: he delivers them, however, as if he did not actually disbelieve them. Lord Pembroke was not only a great favourer of learned and ingenious men, but was himself learned, and endued with a considerable share of poetic genius. All that are extant of his productions in this way were published with this title: "Poems written by William Earl of Pembroke, &c. many of which are answered by way of reparation by Sir Benjamin Rudyard, with other Poems written by them occasionally and apart, 1660, 8vo.

HERBERT (Sir Thomas), an eminent gentleman of the Pembroke family, was born at York, where his father was an

alderman. William earl of Pembroke sent him to travel at his expence in 1626, and he spent four years in visiting Asia and Africa: his expectations of preferment ending with the death of the earl, he went abroad again, and travelled over several parts of Europe. In 1634 he published, in folio, A Relation of some Years Travel into Africa and the Great Asia, especially the Territories of the Persian Monarchy, and some parts of the Oriental Indies and Isles adjacent. On the breaking out of the civil war, he adhered to the parliament; and at Oldenby, on the removal of the king's servants, by desire of the commissioners from the parliament, he and James Harrington were retained as grooms of his bed-chamber, and attended him even to the block. At the restoration he was created a baronet by Charles II. for his faithful services to his father during his two last years. In 1678 he wrote *Tbrno-dia Carolina*, containing an account of the two last years of the life of Charles I.; and he assisted Sir William Dugdale in compiling the third volume of his *Monasticon Anglicanum*. He died at York in 1682, leaving several MSS to the public library at Oxford, and others to that of the cathedral at York.

HERCULANEUM is the name of an ancient city of Campania in Italy, which was destroyed by an eruption of Vesuvius in the first year of the emperor Titus, or the 79th of the Christian era, and lately rendered famous on account of the curious monuments of antiquity discovered in its ruins; an account of which has been published by order of the king of Naples, in a work of six volumes folio. The epocha of the foundation of Herculaneum is unknown. Dionysius Halicarnassensis conjectures that it may be referred to 60 years before the war of Troy, or about 1342 years before Christ; and therefore that it lasted about 1400 years.

The thickness of the heap of lava and ashes by which the city was overwhelmed, has been much increased by fiery streams vomited since that catastrophe; and now forms a mass 24 feet deep of dark grey stone, which is easily broken to pieces. By its non-adhesion to foreign bodies, marbles and bronzes are preserved in it as in a case made to fit them, and exact moulds of the faces and limbs of statues are frequently found in this substance. The precise situation of this subterraneous city was not known till the year 1713, when it was accidentally discovered by some labourers, who, in digging a well, struck upon a statue on the benches of the theatre. Many others were afterwards dug out and sent to France by the prince of Elbœuf. But little progress was made in the excavations till Charles, infant of Spain, ascended the Neapolitan throne; by whose unwearied efforts and liberality a very considerable part of Herculaneum has been explored, and such treasures of antiquity drawn out as form the most curious museum in the world. It being too arduous a task to attempt removing the covering, the king contented himself with cutting galleries to the principal buildings, and causing the extent of one or two of them to be cleared. Of these the theatre is the most considerable. On a balustrade which divided the orchestra from the stage, was found a row of statues; and, on each side of the pulpitum, the equestrian figure of a person of the Nonia family. They are now placed under porticos of the palace; and from the great rarity of equestrian statues in marble would be very valuable objects, were their workmanship even less excellent than it is: one of them in particular is a very fine piece of sculpture. Since the king of Spain left Naples, the digging has been continued, but with less spirit and expenditure: indeed the collection of curiosities brought out of Herculaneum and Pompeii is already so considerable, that a relaxation of zeal and activity becomes excusable. They are now arranged in a wing of the palace; and consist not only of statues, busts, altars, inscriptions, and other ornamental appendages of opulence and luxury,

but also comprehend an entire assortment of the domestic, musical, and chyrurgical instruments used by the ancients; tripods of elegant form and exquisite execution, lamps in endless variety, vases and basons of noble dimensions, chandeliers of the most beautiful shapes, pateras and other appurtenances of sacrifice, looking-glasses of polished metal, coloured glass so hard, clear, and well stained, as to appear emeralds, sapphires, and other precious stones; a kitchen completely fitted up with copper-pans lined with silver, kettles, cisterns for heating water, and every utensil necessary for culinary purposes; specimens of various sorts of combustibles, retaining their form though burnt to a cinder; corn, bread, fish, oil, wine, and flour: a lady's toilet, fully furnished with combs, thimbles, rings, paint, ear-rings, &c. Among the statues, which are numerous, comoisieurs allow the greatest share of merit to a Mercury and a sleeping faun: the busts fill several rooms; but very few of the originals whom they were meant to imitate are known. The floors are paved with ancient Mosaic. Few rare medallions have been found in these ruins; the most curious is a gold medallion of Augustus, struck in Sicily in the 15th year of his reign. The fresco paintings, which, for the sake of preservation, have been torn off the walls and framed and glazed, are to be seen in another part of the palace. "The elegance of the attitudes, and the infinite variety of the subjects (Mr. Swinburne observes), stamp them as performances worthy of the attention of artists and antiquarians; but no pictures yet found are masterly enough to prove that the Greeks carried the art of painting to as great a height of perfection as they did that of statuary. Yet can we suppose those authors incapable of appreciating the merits of an Apelles or a Zeuxis, who with so much critical discernment have pointed out the beauties of the works of a Phidias or a Praxiteles, beauties that we have still an opportunity of contemplating? would they have bestowed equal praises upon both kinds of performances, if either of them had been much inferior to the other? Certainly it is not probable; and we must presume, that the capital productions of the ancient painters, being of more perishable materials than busts and statues, have been destroyed in the fatal disasters that have so often afflicted both Greece and Italy. Herculaneum and Pompeii were but towns of the second order, and not likely to possess the master-pieces of the great artists, which were usually destined to adorn the more celebrated temples, or the palaces of kings and emperors." A more valuable acquisition than bronzes and pictures was thought to be made, when a large parcel of manuscripts was found among the ruins. Hopes were entertained that many works of the classics, which time has deprived us of, were now going to be restored to light, and that a new mine of science was on the point of being opened. But the difficulty of unrolling the burnt parchment, of pasting the fragments on a flat surface, and of decyphering the obscure letters, have proved such obstacles, that very little progress has been made in the work. A priest invented the method of proceeding; but it would require the joint labours of many learned to carry on so nice and tedious an operation with any success. The plan is dropped; and the manuscripts now lie in dusty heaps, as useless to the learned world as they had been for the preceding-seventeen centuries.

HERCULES, in fabulous history, a most renowned Grecian hero, who, after death, was ranked among the gods, and received divine honours. According to the ancients, there were many persons of the same name. Diodorus mentions three, Cicero six, and some authors extend the number to no less than forty-three. Of all these, one generally called the *Theban Hercules*, is the most celebrated; and to him, as may easily be imagined, the actions of the others have been attributed. He is reported to have been the son of Jupiter by Almena (wife to Amphitryon king of Argos), whom Jupiter

enjoyed in the shape of her husband while he was absent ; and in order to add the greater strength to the child, made that amorous night as long as three. Amphitryon having soon after accidentally killed his uncle and father-in-law Electryon, was obliged to fly to Thebes, where Hercules was born. The jealousy of Juno, on account of her husband's amour with Alcmena, prompted her to destroy the infant. For this purpose she sent two serpents to kill him in the cradle, but young Hercules strangled them both. He was early instructed in the liberal arts, and Castor the son of Tyndarus taught him how to fight, Eurytus how to shoot with a bow and arrows, Autolicus to drive a chariot, Linus to play on the lyre, and Eumolpus to sing. He, like the rest of his illustrious contemporaries, soon after became the pupil of the centaur Chiron, and under him he perfected and rendered himself the most valiant and accomplished of the age. In the 18th year of his age he resolved to deliver the neighbourhood of mount Cithæron from a huge lion which preyed on the flocks of Amphitryon his supposed father, and which laid waste the adjacent country. He went to the court of Thespius king of Thespiæ, who shared in the general calamity ; and he received here a tender treatment, and was entertained during 50 days. The 50 daughters of the king became mothers by Hercules during his stay at Thespiæ, and some say that it was effected in one night. After he had destroyed the lion of mount Cithæron, he delivered his country from the annual tribute of 100 oxen which it paid to Erginus. Such public services became universally known ; and Creon, who then sat on the throne of Thebes, rewarded the patriotic deeds of Hercules by giving him his daughter in marriage, and entrusting him with the government of his kingdom.

Eurystheus, the son of Amphitryon, having succeeded his father, soon became jealous of Hercules ; and fearing lest he might by him be deprived of his crown, left no means untried to get rid of him. Of this Hercules was not insensible, because he was perpetually engaging him on some desperate expedition ; and therefore went to consult the oracle. But being answered that it was the pleasure of the gods that he should serve Eurystheus 12 years, he fell into a deep melancholy, which at last ended in a furious madness ; during which, among other desperate actions, he put away his wife Megara, and murdered all the children he had by her. As an expiation of this crime, the king imposed upon him twelve labours surpassing the power of all other mortals to accomplish, which nevertheless our hero performed with great ease. The favours of the gods had indeed completely armed him when he undertook his labours. He had received a coat of armour and helmet from Minerva, a sword from Mercury, a horse from Neptune, a shield from Jupiter, a bow and arrows from Apollo, and from Vulcan a golden cuirass and brazen buskin, with a celebrated club of brass according to the opinion of some writers.

The first labour imposed upon him was the killing of a lion in Nemea, a wood of Achaia : whose hide was proof against any weapon, so that he was forced to seize him by the throat and strangle him. He carried the dead animal on his shoulders to Mycenæ, and ever after clothed himself with the skin. Eurystheus was so astonished at the sight of the beast, and at the courage of Hercules, that he ordered him never to enter the gates of the city when he returned from his expeditions, but to wait for his orders without the walls. He even made himself a brazen vessel, into which he retired whenever Hercules returned. The second labour was to destroy the Lernaean hydra, which had seven heads according to Apollodorus, 50 according to Simonides, and 100 according to Diodorus. This celebrated monster he first attacked with his arrows ; but soon after he came to a close engagement, and by means of his heavy club he destroyed the heads of his enemy. This, however, was pro-

ductive of no advantage ; for as soon as one head was beaten to pieces by the club, immediately two sprang up ; and the labour of Hercules would have remained unfinished, had not he commanded his friend Iolas to burn with a hot iron the root of the head which he had crushed to pieces. This succeeded ; and Hercules became victorious, opened the belly of the monster, and dipped his arrows in the gall to render the wounds which he gave fatal and incurable. He was ordered in his third labour to bring alive and unhurt into the presence of Eurystheus a stag, famous for its incredible swiftness, its golden horns, and brazen feet. This celebrated animal frequented the neighbourhood of Cœnoë ; and Hercules was employed for a whole year in continually pursuing it : at last he caught it in a trap, or when tired, or, according to others, by slightly wounding it and lessening its swiftness. The fourth labour was to bring alive to Eurystheus a wild boar, which ravaged the neighbourhood of Erymanthus. In this expedition he destroyed the centaurs, and caught the boar by closely pursuing him through the deep snow. Eurystheus was so frightened at the sight of the boar, that, according to Diodorus, he hid himself in his brazen vessel for some days. In his fifth labour Hercules was ordered to clean the stables of Augeas, where 3000 oxen had been confined for many years. For his sixth labour he was ordered to kill the carnivorous birds which ravaged the country near the lake Stympalis in Arcadia. In his seventh labour he brought alive into Peloponnesus a prodigious wild bull which laid waste the island of Crete. In his eighth labour he was employed in obtaining the mares of Diomedes, which fed upon human flesh. He killed Diomedes, and gave him to be eat by his mares, which he brought to Eurystheus. They were sent to mount Olympus by the king of Mycenæ, where they were devoured by the wild beasts ; or, according to others, they were consecrated to Jupiter, and their breed still existed in the age of Alexander the Great. For his ninth labour, he was commanded to obtain the girdle of the queen of the Amazons. In his tenth labour he killed the monster Geryon king of Gades, and brought to Argos his numerous flocks which fed upon human flesh. This was in Iberia or Spain ; in the furthest parts of which he erected his two pillars, as the utmost limits of the then known world. These ten labours he achieved, as the fable says, in about eight years. In this last expedition he is likewise affirmed to have killed Antæus, a famous giant of a monstrous size, who, when weary with wrestling or labour, was immediately refreshed by touching the earth. Hercules overcame him in wrestling, and slew him ; and after him the tyrant Busiris, in his way through Egypt. This bloody man used to sacrifice all his guests and strangers upon his altars ; and designing to have done the same by Hercules, was slain by him, together with all his attendants. His eleventh labour was the carrying away the Hesperian golden apples kept by a dragon (See HESPERIDES). The twelfth and last, and most dangerous of his labours, was to bring upon earth the three-headed dog Cerberus. Descending into hell by a cave on mount Tænarus, he was permitted by Pluto to carry away his friends Theseus and Pirithous, who were condemned to punishment in hell ; and Cerberus also was granted to his prayers, provided he made use of no arms but only force to drag him away. Hercules, as some report, carried him back to hell after he had brought him before Eurystheus.

Many other exploits are said to have been performed by Hercules ; in particular, he accompanied the Argonauts to Colchis before he delivered himself up to the king of Mycenæ. He assisted the gods in their wars against the giants, and it was through him alone that Jupiter obtained a victory. He conquered Laomedon, and pillaged Troy. When Iole, the daughter of Eurytus king of Cœchalia, of whom he was deeply ena-

moured, was refused to his entreaties, he became the prey of a second fit of insanity, and he murdered Iphytus, the only one of the sons of Eurytus who favoured his addresses to Iole. He was some time after purified of the murder, and his insanity ceased; but the gods persecuted him, and he was visited by a disorder which obliged him to apply to the oracle of Delphi for relief. The coldness with which the Pythia received him irritated him, and he resolved to plunder Apollo's temple and carry away the sacred tripod. Apollo opposed him, and a severe conflict was begun, which nothing but the interference of Jupiter with his thunderbolts could have prevented. He was upon this told by the oracle that he must be sold as a slave, and remain three years in the most abject servitude to recover from his disorder. He complied; and Mercury, by order of Jupiter, conducted him to Omphale, queen of Lydia, to whom he was sold as a slave. Here he cleared all the country from robbers; and Omphale, who was astonished at the greatness of his exploits, married him. Hercules had Agelaus and Lamon by Omphale, from whom Cræsus king of Lydia was descended. He became also enamoured of one of Omphale's female servants, by whom he had Alceus. After he had completed the years of his slavery, he returned to Peloponnesus, where he re-established on the throne of Sparta Tyndarus, who had been expelled by Hippocoon. He became one of Dejanira's suitors, and married her after he had overcome all his rivals. He was obliged to leave Calydon his father-in-law's kingdom, because he had inadvertently killed a man with a blow of his fist; and it was on account of this expulsion that he was not present at the hunting of the Calydonian boar. From Calydon he retired to the court of Ceyx king of Trachinia. The king received him and his wife with great marks of friendship, and purified him of the murder which he had committed at Calydon. Hercules was still mindful that he had once been refused the hand of Iole; he therefore made war against her father Eurytus, and killed him with three of his sons. Iole fell into the hands of her father's murderer, and found that she was loved by Hercules as much as before. She accompanied him on mount Cæta, where he was going to raise an altar and offer a solemn sacrifice to Jupiter. As he had not then the shirt and tunic in which he arrayed himself to offer a sacrifice, he sent Lichas to Trachin to his wife Dejanira, in order to provide himself a proper dress. Dejanira had some time before been attempted by the Centaur Nessus, as he was ferrying her over the river Euenus; and Hercules beholding it from the shore, had given him a mortal wound with an arrow. The monster finding himself dying, advised her to mix some oil with the blood which flowed from his wound, and to anoint her husband's shirt with it, pretending that it would infallibly secure him from loving any other woman; and she, too well apprized of his inconstancy, had actually prepared the poisoned ointment accordingly. Lychas coming to her for the garments, unfortunately acquainted her with his having brought away Iole; upon which she, in a fit of jealousy, anointed his shirt with the fatal mixture. This had no sooner touched his body, than he felt the poison diffuse itself through all his veins; the violent pain of which caused him to disband his army, and to return to Trachin. His torment still increasing, he sent to consult the oracle for a cure; and was answered, that he should cause himself to be conveyed to mount Cæta, and there rear up a great pile of wood, and leave the rest to Jupiter. By the time he had obeyed the oracle, his pains being become intolerable, he dressed himself in his martial habit, flung himself upon the pile, and desired the bystanders to set fire to it. Others say that he left the charge of it to his son Philoctetes; who having performed his father's command, had his bow and arrows given him as a reward for his obedience. At the same time Jupiter, to be as good as his word, sent a flash of light-

ning, which consumed both the pile and the hero; insomuch that Iolæus, coming to take up his bones, found nothing but ashes: from which they concluded, that he was passed from earth to heaven, and joined to the gods. His friends showed their gratitude to his memory by raising an altar where the burning pile had stood. Menætius the son of Actor offered him a sacrifice of a bull, a wild boar, and a goat, and enjoined the people of Opus yearly to observe the same religious ceremonies. His worship soon became as universal as his fame; and Juno, who had once persecuted him with such fury, forgot her resentment, and gave him her daughter Hebe in marriage. Hercules has received many surnames and epithets, either from the place where his worship was established, or from the labours which he achieved. His temples were numerous and magnificent, and his divinity revered. No dogs or flies ever entered his temple at Rome: and that of Gades, according to Strabo, was always forbidden to women and pigs. The Phœnicians offered quails on his altars; and as it was supposed that he presided over dreams, the sick and infirm were sent to sleep in his temples, that they might receive in their dreams the agreeable presages of their approaching recovery. The white poplar was particularly dedicated to his service.

It is observed, that there are none even of the twelve great gods of antiquity that have so many ancient monuments relating to them as Hercules. The famous statue of Hercules, in the Farnese palace at Rome, is well known to the connoisseurs: this represents him resting after the last of his twelve labours above recited, leaning on his club, and holding the apples of the Hesperides in his hand. In this statue, as in all the other figures of him, he is formed, by the breadth of his shoulders, the spaciousness of his chest, the largeness of his size, and the firmness of his muscles, to express strength and a capacity of enduring great fatigue, which constituted the chief idea of virtue among the ancient heathens. His other attributes are his lion's skin, his club, and his bow. Hercules is represented by the ancients as an exemplar of virtue: however, the *Hercules bibax*, or drunken Hercules, is no uncommon figure; and his amours are described both by the poets and artists. Thus, the Cupids are made to take away his club, and he is exhibited in the posture of bending under a little boy; by which actions we perceive, that he who conquered all difficulties was a slave to love. His children are as numerous as the labours and difficulties which he underwent; and indeed they became so powerful soon after his death, that they alone had the courage to invade all Peloponnesus. See HERACLIDÆ.

The apotheosis of Hercules, or the establishment of his altars in the principal cities of Greece, is fixed by Thrasylulus 29 years before the taking of Troy.

Hercules has been particularly honoured by the Greeks under the name of *Musagetes*, "the conductor of the Muses;" and at Rome under that of *Hercules Musarum*. He is represented on medals with a lyre in his hand; and the reverse is marked with the figure of the nine Muses, with their proper symbols.

HERCULES, in astronomy, one of the constellations of the northern hemisphere. The stars in the constellation Hercules in Ptolemy's catalogue are 29; in Tycho's 28; in the Britannic catalogue 113.

HERCULES'S *Pillars*, in antiquity, a name given to two lofty mountains, situated one on the most southern extremity of Spain, and the other on the opposite part of Africa. They were called by the ancients *Abyli* and *Cilpe*. They are reckoned the boundaries of the labours of Hercules; and, according to ancient tradition, they were joined together till they were severed by the arm of the hero, and a communication opened between the Mediterranean and Atlantic seas.

HERCYNIA SILVA, in ancient geography, the largest of

forests. Its breadth was a journey of nine days to the best traveller. Taking its rise at the limits of the Helvetii, Nemetes, and Rauraci, it ran along the Danube to the borders of the Daci and Anartes, a length of 60 days journey, according to Cæsar, who appears to have been well acquainted with its true breadth, seeing it occupied all Lower Germany. It may therefore be considered as covering the whole of Germany; and most of the other forests may be considered as parts of it, though distinguished by particular names: consequently the Hartz, in the duchy of Brunswic, which gave name to the whole, may be considered as one of its parts. The name *Hartz* denotes "resinous," or "pine-trees." By the Greeks it is called *Orcynius*, as a name common to all the forests in Germany; in the same manner as *Hercynius* was the name given by the Romans; and both from the German *Hartz*.

HERD, among hunters, an assemblage of black or fallow beasts, in contradistinction to *flock*. See FLOCK. In the hunting language there are various terms used for companies of the different kinds of game. We say a *herd* of harts or bucks, a *bevy* of roes, a *rovt* of wolves, a *richess* of martens, &c.

HEREDITAMENTS, whatever moveable things a person may have to himself and his heirs by way of inheritance; and which, if not otherwise bequeathed, descend to him who is next heir, and not to the executor as chattels do.

HEREDITARY, an appellation given to whatever belongs to a family by right of succession from heir to heir. The term *hereditary* is also figuratively applied to good or ill qualities, either of body or mind, supposed to be transmitted from father to son: thus we say virtue and piety are hereditary qualities in such a family; that in Italy the hatred of families is hereditary; and that the gout, king's evil, madness, &c. are hereditary diseases.

HEREDITARY *Right*, in the British constitution. The grand fundamental maxim upon which the *jus coronæ*, or right of succession to the throne of Britain depends, Sir William Blackstone takes to be this: That the crown is, by common law and constitutional custom, hereditary; and this in a manner peculiar to itself: but that the right of inheritance may from time to time be changed or limited by act of parliament; under which limitations the crown still continues hereditary.

1. The crown is in general hereditary, or descendible to the next heir, on the death or demise of the last proprietor. All regal governments must be either hereditary or elective: and as there is no instance wherein the crown of England has ever been asserted to be elective, except by the regicides on the occasion of the unparalleled trial of king Charles I. it must of consequence be hereditary. Yet in thus asserting an hereditary right, a *jure divino* title to the throne is by no means intended. Such a title may be allowed to have subsisted under the theocratic establishments of the children of Israel in Palestine: but it never yet subsisted in any other country; save only so far as kingdoms, like other human fabrics, are subjected to the general and ordinary dispensations of Providence. Nor indeed have a *jure divino* and an hereditary right any necessary connection with each other; as some have very weakly imagined. The titles of David and Jehu were equally *jure divino* as those of either Solomon or Ahab; and yet David slew the sons of his predecessor, and Jehu his predecessor himself. And when our kings have the same warrant as they had, whether it be to sit upon the throne of their fathers, or to destroy the house of the preceding sovereign, they will then, and not before, possess the crown of England by a right like theirs, immediately derived from heaven. The hereditary right, which the laws of England acknowledge, owes its origin to the founders of our constitution, and to them only. It has no relation to, nor de-

pends upon, the civil laws of the Jews, the Greeks, the Romans, or any other nation upon earth; the municipal laws of one society having no connection with, or influence upon, the fundamental polity of another. The founders of our English monarchy might perhaps, if they had thought proper, have made it an elective monarchy; but they rather chose, and upon good reason, to establish originally a succession by inheritance. This has been acquiesced in by general consent, and ripened by degrees into common law: the very same title that every private man has to his own estate. Lands are not naturally descendible, any more than thrones: but the law has thought proper, for the benefit and peace of the public, to establish hereditary succession in the one as well as the other.

It must be owned, an elective monarchy seems to be the most obvious, and best suited of any to the rational principles of government, and the freedom of human nature: and accordingly we find from history, that, in the infancy and first rudiments of almost every state, the leader, chief magistrate, or prince, hath usually been elective. And, if the individuals who compose that state could always continue true to first principles, uninfluenced by passion or prejudice, unassailed by corruption, and unawed by violence, elective succession were as much to be desired in a kingdom as in other inferior communities. The best, the wisest, and the bravest man, would then be sure of receiving that crown which his endowments have merited; and the sense of an unbiassed majority would be dutifully acquiesced in by the few who were of different opinions. But history and observation will inform us, that elections of every kind (in the present state of human nature) are too frequently brought about by influence, partiality, and artifice: and, even where the case is otherwise, these practices will be often suspected, and as constantly charged upon the successful, by a splanetic disappointed minority. This is an evil to which all societies are liable; as well those of a private and domestic kind, as the great community of the public, which regulates and includes the rest. But in the former there is this advantage, That such suspicions, if false, proceed no farther than jealousies and murmurs, which time will effectually suppress; and, if true, the injustice may be remedied by legal means, by an appeal to those tribunals to which every member of society has (by becoming such) virtually engaged to submit. Whereas, in the great and independent society, which every nation composes, there is no superior to resort to but the law of nature; no method to redress the infringements of that law, but the actual exertion of private force. As therefore between two nations, complaining of mutual injuries, the quarrel can only be decided by the law of arms; so in one and the same nation, when the fundamental principles of their common union are supposed to be invaded, and more especially when the appointment of their chief magistrate is alleged to be unduly made, the only tribunal to which the complainants can appeal is that of the God of battles, the only process by which the appeal can be carried on is that of a civil and intestine war. An hereditary succession to the crown is therefore now established, in this and most other countries, in order to prevent that periodical bloodshed and misery, which the history of ancient imperial Rome, and the more modern experience of Poland and Germany, may show us are the consequences of elective kingdoms.

2. But, secondly, as to the particular mode of inheritance. It in general corresponds with the feudal path of descents, chalked out by the common law in the succession to landed estates; yet with one or two material exceptions. Like them, the crown will descend lineally to the issue of the reigning monarch; as it did from king John to Richard II. through a regular pedigree of six lineal generations: as in them the preference of males to females, and the right of primogeniture among the males, are strictly adhered to. Thus Edward V,

ſucceeded to the crown, in preference to Richard his younger brother, and Elizabeth his elder ſiſter. Like them, on failure of the male line, it deſcends to the iſſue female; according to the ancient Britiſh cuſtom remarked by Tacitus, *Solent ſæminarum ductu bellare, et ſexum in imperiis non diſcernere*. Thus Mary I. ſucceeded to Edward VI.; and the line of Margaret queen of Scots, the daughter of Henry VII. ſucceeded, on failure of the line of Henry VIII. his ſon. But among the females, the crown deſcends by right of primogeniture to the eldeſt daughter only and her iſſue; and not, as in common inheritances, to all the daughters at once; the evident neceſſity of a ſole ſucceſſion to the throne having occaſioned the royal law of deſcents to depart from the common law in this reſpect: and therefore queen Mary, on the death of her brother, ſucceeded to the crown alone, and not in partnership with her ſiſter Elizabeth. Again, the doctrine of representation prevails in the deſcent of the crown, as it does in other inheritances; whereby the lineal deſcendants of any perſon deceaſed ſtand in the ſame place as their anceſtor, if living, would have done. Thus Richard II. ſucceeded his grandfather Edward III. in right of his father the Black Prince; to the excluſion of all his uncles, his grandfather's younger children. Laſtly, on failure of lineal deſcendants, the crown goes to the next collateral relations of the late king; provided they are lineally deſcended from the blood-royal, that is, from that royal ſtock which originally acquired the crown. Thus Henry I. ſucceeded to William II. John to Richard I. and James I. to Elizabeth; being all derived from the Conqueror, who was then the only regal ſtock. But herein there is no objection (as in the caſe of common deſcents) to the ſucceſſion of a brother, an uncle, or other collateral relation, of the half-blood; that is, where the relationship proceeds not from the ſame couple of anceſtors (which conſtitutes a kinsman of the whole blood), but from a ſingle anceſtor only; as when two perſons are derived from the ſame father, and not from the ſame mother, or *vice verſa*: provided only, that the one anceſtor, from whom both are deſcended, be that from whoſe veins the blood-royal is communicated to each. Thus Mary I. inherited to Edward VI. and Elizabeth inherited to Mary; all born of the ſame father, king Henry VIII. but all by different mothers. See the articles CONSANGUINITY, DESCENT, and SUCCESSION.

3. The doctrine of hereditary right does by no means imply an indefeasible right to the throne. No man will aſſert this, who has conſidered our laws, conſtitution, and hiſtory, without prejudice, and with any degree of attention. It is unqueſtionably in the breaſt of the ſupreme legiſlative authority of this kingdom, the king and both houſes of parliament, to defeat this hereditary right; and, by partiular entails, limitations, and proviſions, to exclude the immediate heir, and veſt the inheritance in any one elſe. This is ſtrictly conſonant to our laws and conſtitution; as may be gathered from the expreſſion ſo frequently uſed in our ſtatute-book, of “the king's majeſty, his heirs, and ſucceſſors.” In which we may obſerve, that as the word heirs neceſſarily implies an inheritance or hereditary right generally ſubſiſting in the royal perſon; ſo the word *ſucceſſors*, diſtinctly taken, muſt imply that this inheritance may ſometimes be broken through; or, that there may be a ſucceſſor, without being the heir of the king. And this is ſo extremely reaſonable, that without ſuch a power, lodged ſomewhere, our polity would be very defective. For, let us barely ſuppoſe ſo melancholy a caſe, as that the heir-apparent ſhould be a lunatic, an idiot, or otherwiſe incapable of reigning; how miſerable would the condition of the nation be, if he were alſo incapable of being ſet aſide! It is therefore neceſſary that this power ſhould be lodged ſomewhere; and yet the inheritance and regal dignity would be very precarious indeed, if this power were expreſſly and avowedly lodged in the

hands of the ſubject only, to be exerted whenever prejudice, caprice, or diſcontent, ſhould happen to take the lead. Conſequently it can no where be ſo properly lodged as in the two houſes of parliament, by and with the conſent of the reigning king; who, it is not to be ſuppoſed, will agree to any thing improperly prejudicial to the rights of his own deſcendants. And therefore in the king, lords, and commons, in parliament aſſembled, our laws have expreſſly lodged it.

4. But, fourthly, However the crown may be limited or transferred, it ſtill retains its deſcendible quality, and becomes hereditary in the wearer of it. And hence in our law the king is ſaid never to die in his political capacity; though, in common with other men, he is ſubject to mortality in his natural: becauſe immediately upon the natural death of Henry, William, or Edward, the king ſurvives in his ſucceſſor. For the right of the crown veſts, *eo iſtanti*, upon his heir; either the *heres natus*, if the courſe of deſcent remains unimpeded, or the *heres factus*, if the inheritance be under any partiular ſettlement. So that there can be no interregnum; but, as Sir Matthew Hale obſerves, the right of ſovereignty is fully inveſted in the ſucceſſor by the very deſcent of the crown. And therefore, however acquired, it becomes in him abſolutely hereditary, unleſs by the rules of the limitation it is otherwiſe ordered and determined: In the ſame manner as landed eſtates, to continue our former comparison, are by the law hereditary, or deſcendible to the heirs of the owner; but ſtill there exiſts a power, by which the property of thoſe lands may be transferred to another perſon. If this transfer be made ſimply and abſolutely, the lands will be hereditary in the new owner, and deſcend to his heir at law: but if the transfer be clogged with any limitations, conditions, or entails, the lands muſt deſcend in that channel, ſo limited and preſcribed, and no other. See SUCCESSION.

HEREFORD, the capital of Herefordſhire, with a market on Wednesday, Friday, and Saturday. It is almoſt encompassed by the Wye and two other rivers, over which are two bridges. It is an ancient decayed place, and had ſix pariſh-churches, but two of them were demolished in the civil wars. It is a biſhop's ſee; and the cathedral is an ancient and venerable ſtructure. The weſt tower, in partiular, was eſteemed a beautiful and magnificent piece of architecture: it was 125 feet high, and was built, in the 12th century, by Giles de Bruce, then biſhop of Hereford; but, in April 1786, the whole of this tower, with a part of the body of the church, fell down. A ſubſcription, however, having been ſet on foot, this tower has been ſince rebuilt. The chief manufacture is gloves. It is governed by a mayor, ſix aldermen, and a ſword-bearer; and is 24 miles W. N. W. of Glouceſter, and 130 W. N. W. of London. W. lon. 2. 35. N. lat. 52. 4.

HEREFORDSHIRE, a county of England, bounded on the E. by Glouceſterſhire and Woreeſterſhire, on the W. by Radnorſhire and Brecknockſhire, on the N. by Shropſhire, and on the S. by Monmouthſhire. It extends 35 miles from N. to S. and 47 from E. to W. It is divided into 11 hundreds; contains one city, eight market towns, and 176 pariſhes; and ſends eight members to parliament. The air is healthy and delightful; and the inhabitants generally live to a great age. The ſoil is exceedingly rich, producing excellent corn, wool, and fruit, as is evident from the Leominſter bread, Weobly ale, and Herefordſhire cider; the laſt of which is ſent to all parts of England. The apples producing the cider grow in greater abundance here than in any other county, being plentiful even in the hedge-rows. Of theſe are various kinds, yielding liquors of different ſtrength and qualities. The moſt celebrated is the redſtreak, which is ſaid to be peculiar to this county. The Styer cider is remarkable for a ſuperior ſtrength

and body, and for keeping very well. The sheep of Herefordshire are small, affording a fine silky wool, in quality approaching to the Spanish. The principal rivers are the Wye, Mynnow, and Lug; all which are well stored with fish. The salmon of this county are very remarkable; for, in other parts of England, they are so far out of season, after spawning, as to be unwholesome food, till they have been again at sea to recover themselves; but here they are always found, fat, and fit for the table.

HERENHAUSEN, a palace of Germany near Hanover, belonging to the king of Great Britain. Here are lodgings for all the court; and a garden of vast extent, in which are fine water-works, a labyrinth, and many other curiosities worthy the observation of a traveller.

HERENTHALS, a town of Austrian Brabant, seated on the river Nethe, 20 miles N. E. of Louvain. E. lon. 4. 54. N. lat. 51. 13.

HERESY, in law, an offence against Christianity, consisting in a denial of some of its essential doctrines, publicly and obstinately avowed; being defined, "*sententia rerum divinarum humano sensu excogitata, palam docta et pertinaciter defensa.*" And here it must be acknowledged that particular modes of belief or unbelief, not tending to overturn Christianity itself, or to sap the foundations of morality, are by no means the object of coercion by the civil magistrate. What doctrines shall therefore be adjudged heresy, was left by our old constitution to the determination of the ecclesiastical judge; who had herein a most arbitrary latitude allowed him. For the general definition of an heretic given by Lyndewode, extends to the smallest deviations from the doctrines of the holy church: "*hereticus est qui dubitat de fide catholica, et qui negligit servare ea, quæ Romana ecclesia statuit, seu servare decreverat.*" Or, as the statute 2 Hen. IV. c. 15. expresses it in English, "teachers of erroneous opinions, contrary to the faith and blessed determinations of the holy church." Very contrary this to the usage of the first general councils, which defined all heretical doctrines with the utmost precision and exactness. And what ought to have alleviated the punishment, the uncertainty of the crime, seems to have enhanced it in those days of blind zeal and pious cruelty. It is true that the sanctimonious hypocrisy of the canonists went at first no farther than enjoining penance, excommunication, and ecclesiastical deprivation, for heresy; though afterwards they proceeded boldly to imprisonment by the ordinary, and confiscation of goods *in pios usus*. But in the mean time they had prevailed upon the weakness of bigoted princes to make the civil power subservient to their purposes, by making heresy not only a temporal, but even a capital, offence: the Romish ecclesiastics determining, without appeal, whatever they pleased to be heresy, and shifting off to the secular arm the odium and drudgery of executions; with which they themselves were too tender and delicate to intermeddle. Nay, they pretended to intercede and pray, on behalf of the convicted heretic, *ut citra mortis periculum sententiæ circa eum moderetur*: well knowing that at the same time they were delivering the unhappy victim to certain death. Hence the capital punishments inflicted on the ancient Donatists and Manichæans by the emperors Theodosius and Justinian: hence also the constitution of the emperor Frederic mentioned by Lyndewode, adjudging all persons without distinction to be burnt with fire who were convicted of heresy by the ecclesiastical judge. The same emperor, in another constitution, ordained, that if any temporal lord, when admonished by the church, should neglect to clear his territories of heretics within a year, it should be lawful for good catholics to seize and occupy the lands, and utterly to exterminate the heretical possessors. And upon this foundation was built that arbitrary power, so long claimed and so fatally exerted by the Pope, of disposing even of the king-

doms of refractory princes to more dutiful sons of the church. The immediate event of this constitution was something singular, and may serve to illustrate at once the gratitude of the holy see, and the just punishment of the royal bigot; for, upon the authority of this very constitution, the pope afterwards expelled this very emperor Frederic from his kingdom of Sicily, and gave it to Charles of Anjou.

Christianity being thus deformed by the dæmon of persecution upon the continent, we cannot expect that our own island should be entirely free from the same scourge. And therefore we find among our ancient precedents a writ *de heretico comburendo*, which is thought by some to be as ancient as the common law itself. However, it appears from thence, that the conviction of heresy by the common law was not in any petty ecclesiastical court, but before the archbishop himself in a provincial synod; and that the delinquent was delivered over to the king to do as he should please with him: so that the crown had a controul over the spiritual power, and might pardon the convict by issuing no process against him; the writ *de heretico comburendo* being not a writ of course, but issuing only by the special direction of the king in council.

But in the reign of Henry IV. when the eyes of the Christian world began to open, and the seeds of the Protestant religion (though under the opprobrious name of *lollardy*) took root in this kingdom; the clergy, taking advantage from the king's dubious title to demand an increase of their own power, obtained an act of parliament, which sharpened the edge of persecution to its utmost keenness. For, by that statute, the diocesan alone, without the intervention of a synod, might convict of heretical tenets; and unless the convict abjured his opinions, or if after abjuration he relapsed, the sheriff was bound *ex officio*, if required by the bishop, to commit the unhappy victim to the flames, without waiting for the consent of the crown. By the statute 2 Hen. V. c. 7. *lollardy* was also made a temporal offence, and indictable in the king's courts; which did not thereby gain an exclusive, but only a concurrent, jurisdiction with the bishop's consistory.

Afterwards, when the final reformation of religion began to advance, the power of the ecclesiastics was somewhat moderated; for though what heresy *is*, was not then precisely defined, yet we are told in some points what it *is not*: the statute 25 Hen. VIII. c. 14. declaring that offences against the see of Rome are not heresy; and the ordinary being thereby restrained from proceeding in any case upon mere suspicion; that is, unless the party be accused by two credible witnesses, or an indictment of heresy be first previously found in the king's courts of common law. And yet the spirit of persecution was not yet abated, but only diverted into a lay channel. For in six years afterwards, by statute 31 Hen. VIII. c. 14. the bloody law of the six articles was made, which established the six most contested points of popery, transubstantiation, communion in one kind, the celibacy of the clergy, monastic vows, the sacrifice of the mass, and auricular confession; which points were "determined and resolved by the most godly study, pain, and travail of his majesty: for which his most humble and obedient subjects, the lords *spiritual* and temporal, and the commons, in parliament assembled, did not only render and give unto his highness their most high and hearty thanks;" but did also enact and declare all oppugners of the first to be heretics, and to be burnt with fire; and of the five last to be felons, and to suffer death. The same statute established a new and mixed jurisdiction of clergy and laity for the trial and conviction of heretics; the reigning prince being then equally intent on destroying the supremacy of the bishops of Rome, and establishing all other their corruptions of the Christian religion.

Without perplexing this detail with the various repeals and

revivals of these sanguinary laws in the two succeeding reigns, let us proceed to the reign of queen Elizabeth; when the reformation was finally established with temper and decency, unfulfilled with party-rancour, or personal caprice and resentment. By statute 1 Eliz. c. 1. all former statutes relating to heresy are repealed, which leaves the jurisdiction of heresy as it stood at common law; viz. as to the infliction of common censures, in the ecclesiastical courts; and in case of burning the heretic, in the provincial synod only. Sir Matthew Hale is indeed of a different opinion, and holds that such power resided in the diocesan also; though he agrees, that in either case the writ *de heretico comburendo* was not demandable of common right, but grantable or otherwise merely at the king's discretion. But the principal point now gained was, that by this statute a boundary is for the first time set to what shall be accounted heresy; nothing for the future being to be so determined, but only such tenets, which have been heretofore so declared, 1. by the words of the canonical scriptures; 2. by the first four general councils, or such others as have only used the words of the holy Scriptures; or, 3. which shall hereafter be so declared by the parliament, with the assent of the clergy in convocation. Thus was heresy reduced to a greater certainty than before; though it might not have been the worse to have defined it in terms still more precise and particular: as a man continued still liable to be burnt, for what perhaps he did not understand to be heresy, till the ecclesiastical judge so interpreted the words of the canonical scriptures.

For the writ *de heretico comburendo* remained still in force; and we have instances of its being put in execution upon two Anabaptists in the seventeenth of Elizabeth, and two Arians in the ninth of James I. But it was totally abolished, and heresy again subjected only to ecclesiastical correction, *pro salute animæ*, by virtue of the statute 29 Car. II. c. 9.: for, in one and the same reign, our lands were delivered from the slavery of military tenures; our bodies from arbitrary imprisonment by the *habeas corpus* act; and our minds from the tyranny of superstitious bigotry, by demolishing this last badge of persecution in the English law.

Everything is now less exceptionable, with respect to the spiritual cognizance, and spiritual punishment of heresy: unless perhaps that the crime ought to be more strictly defined, and no prosecution permitted, even in the ecclesiastical courts, till the tenets in question are by proper authority previously declared to be heretical. Under these restrictions, some think it necessary for the support of the national religion, that the officers of the church should have power to censure heretics; yet not to harass them with temporal penalties, much less to exterminate or destroy them. The legislature hath indeed thought it proper, that the civil magistrate should again interpose, with regard to one species of heresy, very prevalent in modern times; for by statute 9 and 10 W. III. c. 32. if any person educated in the Christian religion, or professing the same, shall by writing, printing, teaching, or advised speaking, deny any one of the persons in the holy Trinity to be God, or maintain that there are more gods than one, he shall undergo the same penalties and incapacities which were just now mentioned to be inflicted on apostacy by the same statute.

HERETIC, a general name for all such persons under any religion, but especially the Christian, as profess or teach religious opinions contrary to the established faith, or to what is made the standard of orthodoxy. See HERESY.

HERETOCHS, among our Saxon ancestors, signified the same with dukes or duces, denoting the commanders or leaders of their armies. It appears, from Edward the Confessor's laws, that the military force of this kingdom was in the hands of the dukes or heretochs, who were constituted through every province and county in the kingdom, being selected out of the

principal nobility, and such as were most remarkable for being *sapientes, fideles, & animosi*. Their duty was to lead and regulate the English armies, with a very unlimited power; and because of their great power, they were elected by the people in their full assembly, or folk-mote, in the same manner as sheriffs were elected.

HERFORDEN, or HERWARDEN, a free imperial town of Germany, in the circle of Westphalia, capital of the county of Ravensburgh, with a famous nunnery, belonging to the protestants of the confession of Augsburg, whose abbess is a princess of the empire, and has a voice and place in the diet. It is seated on the river Aa, 17 miles S. W. of Minden. E. lon. 8. 47. N. lat. 52. 9.

HERGRUNDT, a town of Upper Hungary, remarkable for its mines of vitriol, which are extremely rich. Those who work in the mines have built a subterraneous town, with a great number of inhabitants. It is 65 miles N. of Buda. E. lon. 18. 15. N. lat. 48. 30.

HERI, a pleasant island in the Indian Ocean, two miles N. N. W. of Ternate. It is pretty high, and not more than two miles in circumference. The cultivated parts, contrasted with the brown shade of the trees, and the interspersed situation of the houses, give this little spot a very picturesque appearance. It appears, as well as Ternate, to be in a perfect state of cultivation, and to be well inhabited.

HERIOT, in law, a customary tribute of goods and chattels, payable to the lord of the fee on the decease of the owner of the land. See TENURE. *Heriot* is of two sorts, viz. 1. *Heriot-custum*, where heriots have been paid time out of mind by custom, after the death of a tenant for life. In some places, there is a customary composition in money, as 10 or 20 shillings in lieu of a heriot, by which the lord and tenant are both bound, if it be an indisputably ancient custom: but a new composition of this sort will not bind the representatives of either party. 2. *Heriot-service*, when a tenant holds by such service to pay heriot at the time of his death; which service is expressed in the deed of feoffment. For this latter the lord shall distrain; and for the other he shall seize, and not distrain. If the lord purchase part of the tenancy, heriot-service is extinguished; but it is not so of heriot-custum.

HERISSON, in fortification, a beam armed with a great number of iron spikes with their points outwards, and supported by a pivot on which it turns. These serve as a barrier to block up any passage, and are frequently placed before the gates, and more especially the wicket-doors, of a town or fortress, to secure those passages which must of necessity be often opened and shut.

HERISHAW, an ancient town of Swisserland, the most considerable possessed by the protestants in the canton of Appenzel. It is seated on the river Bulbach.

HERK, a town of Germany, in the bishopric of Liege, seated on a river of the same name, near its confluence with the Demer, two miles W. of Maestricht. E. lon. 5. 38. N. lat. 50. 52.

HERMÆA, in antiquity, ancient Greek festivals in honour of the god Hermes or Mercury. One of these was celebrated by the Phegeatæ in Arcadia; a second by the Cyllenians in Elis; and a third by the Tanagræans, where Mercury was represented with a ram upon his shoulder, because he was said to have walked through the city in that posture in time of a plague, and to have cured the sick; in memory of which, it was customary at this festival for one of the most beautiful youths in the city to walk round the walls with a ram upon his shoulder. A fourth festival of the same name was observed in Crete, when it was usual for the servants to sit down at the table while their masters waited; a custom which was also observed at the Roman Saturnalia.

HERMAN (Paul), a famous botanist in the 17th century, was born at Hall in Saxony. He practised physic in the isle of Ceylon, and was afterwards made professor of botany at Leyden, where he died in 1695. He wrote a catalogue of the plants in the public garden at Leyden, and a work intitled *Floræ Lugduno-Batavæ flores*.

HERMANN (James), a learned mathematician of the academy at Berlin, and a member of the academy of sciences at Paris, was born at Basil in 1678. He was a great traveller, and for six years was professor of mathematics at Padua. He afterwards went to Muscovy, being invited thither by the Czar in 1724. At his return to his native country, he was made professor of morality and natural law at Basil; and died there in 1733. He wrote several mathematical works.

HERMANNIA, in botany; a genus of the pentandria order, belonging to the monadelphia class of plants; and in the natural method ranking under the 37th order, *Columniferæ*. The capsule is quinquelocular; the petals at the base are semitubulated and oblique. The *species* are, 1. The *lavendulifolia*, which hath a shrubby stalk and slender branches, very bushy, about a foot and an half high, small, spear-shaped, obtuse and hairy leaves, with clusters of small yellow flowers along the sides of the branches, continuing from June to Autumn. 2. The *althæifolia* hath a shrubby stalk, and soft woolly branches, growing two feet high, with numerous yellow flowers in loose spikes growing at the end of the branches, and making their appearance in July. 3. The *grossularifolia* hath a shrubby stalk and spreading branches, growing three or four feet high, with bright yellow flowers coming out in great numbers at the ends of all the shoots and branches in April or May. 4. The *alnifolia* hath a shrubby stalk and branches growing irregularly four or five feet high, with pale yellow flowers in short spikes from the sides and ends of the branches, appearing in April or May. 3. The *byssopifolia* hath a shrubby upright stalk, branching out laterally six or seven feet high, with pale yellow flowers in clusters from the sides of the branches, appearing in May and June. There are 14 other species. All these plants are natives of Africa, and therefore must be kept in a green-house during the winter in this country. They are propagated by cuttings of their young shoots, which may be planted in pots of rich earth any time from April to July.

HERMANSTADT, a handsome, large, populous, and strong town of Hungary, capital of Transylvania, with a bishop's see. It is seated on the river Ceben, 25 miles E. of Weissemburg, and 205 S. E. of Buda. E. lon. 24. 40. N. lat. 46. 25.

HERMANT (Godfrey), a learned doctor of the Sorbonne, born at Beauvais in 1617. He wrote many excellent works; the principal of which are, 1. The lives of St. Athanasius, St. Basil, St. Gregory Nazianzen, St. Chrysostom, and St. Ambrose. 2. Four pieces in defence of the rights of the university of Paris against the Jesuits. 3. A French translation of St. Chrysostom's treatise of Providence, and St. Basil's Ascetics. 4. Extracts from the councils; published after his death, under the title of *Clavis disciplinæ ecclesiasticæ*. He died suddenly at Paris in 1690.

HERMAPHRODITE, is generally understood to signify a human creature possessed of both sexes, or who has the parts of generation both of male and female. The term, however, is applied also to other animals, and even to plants. The word is formed of the Greek Ἑρμαφροδίτης, a compound of Ἑρμης Mercury, and Ἀφροδίτη Venus; *q. d.* a mixture of Mercury and Venus, *i. e.* of male and female. For it is to be observed, *Hermaphroditus* was originally a proper name, applied by the heathen mythologists to a fabulous deity, whom some represent as a son of *Hermes*, Mercury, and *Aphrodite*, Venus; and who, being desperately in love with the nymph *Salmasis*, obtained of the

gods to have his body and hers united into one. Others say, that the god *Hermaphroditus* was conceived as a composition of Mercury and Venus; to exhibit the union between eloquence, or rather commerce, whereof Mercury was god, with pleasure, whereof Venus was the proper deity. Lastly, others think this junction intended to show that Venus (pleasure) was of both sexes; as, in effect, the poet *Calvus* calls Venus a god; *Pollentemque Deum Venerem*. As also *Virgil*, *Æneid*. lib. ii.

*Discedo, ac ducente Deo flammam inter et hostes
Expedior*—————

M. Spon observes, *Hesychius* calls Venus *Aphroditos*; and *Theophrastus* affirms, that *Aphroditos*, or Venus, is *Hermaphroditus*; and that in the island of Cyprus she has a statue, which represents her with a beard like a man. The Greeks also call *hermaphroditos* ἀνδρογύνος *androgyni*, *q. d.* men-women. See the article *ANDROGYNES*.

In a paper by Mr. *Hunter*, in the 69th volume of the *Philosophical Transactions*, hermaphroditos are divided into *natural* and *unnatural* or monstrous. The first belongs to the more simple orders of animals, of which there are a much greater number than of the more perfect. The unnatural takes place in every tribe of animals having distinct sexes, but is more common in some than in others. The human species, our author imagines, has the fewest; never having seen them in that species, nor in dogs; but in the horse, sheep, and black cattle, they are very frequent.

From Mr. *Hunter's* account, however, it does not appear that such a creature as a perfect hermaphrodite has ever existed. All the hermaphroditos which he had the opportunity of seeing had the appearance of females, and were generally thought such. In the horse they are very frequent; and in the most perfect of this kind he ever saw, the testicles had come down out of the abdomen into the place where the udder should have been, and appeared like an udder, not so pendulous as the scrotum in the male of such animals. There were also two nipples, of which horses have no perfect form; being blended in them with the sheath or prepuce, of which there was none here. The external female parts were exactly similar to those of a perfect female; but instead of a common-sized clitoris, there was one about five or six inches long; which, when erect, stood almost directly backwards.

A foal-afs very similar to the above was killed, and the following appearances were observed on dissection. The testicles were not come down as in the former, possibly because the creature was too young. It had also two nipples; but there was no penis passing round the pubes to the belly, as in the perfect male afs. The external female parts were similar to those of the she-afs. Within the entrance of the vagina was placed the clitoris; but much longer than that of a true female, being about five inches long. The vagina was open a little farther than the opening of the urethra into it, and then became obliterated; from thence, up to the fundus of the uterus, there was no canal. At the fundus of the common uterus it was hollow, or had a cavity in it, and then divided into two, viz. a right and a left, called the *horns* of the uterus, which were also pervious. Beyond the termination of the two horns were placed the ovaria, as in the true female; but the Fallopian tubes could not be found. From the broad ligaments, to the edges of which the horns of the uterus and ovaria were attached, there passed towards each groin a part similar to the round ligaments in the female, which were continued into the rings of the abdominal muscles; but with this difference, that there were continued with them a process or theca of the peritonæum, similar to the tunica vaginalis communis in the male afs; and in these thecæ were found the testicles, but no vasa deferentia could be observed passing from them.

In most species of animals, the production of hermaphrodites appears to be the effect of chance; but in the black cattle it seems to be an established principle of their propagation. It is a well-known fact, and, as far as hath yet been discovered, appears to be universal, that when a cow brings forth two calves, one of them a bull, and the other a cow to appearance, the cow is unfit for propagation, but the bull-calf becomes a very proper bull. They are known not to breed; they do not even show the least inclination for the bull, nor does the bull ever take the least notice of them. Among the country people in England, this kind of calf is called a *free-martin*; and this singularity is just as well known among the farmers as either cow or bull. When they are preserved, it is for the purposes of an ox or spayed heifer; viz. to yoke with the oxen, or fatten for the table. They are much larger than either the bull or the cow, and the horns grow longer and bigger, being very similar to those of an ox. The bellow of a free-martin is similar to that of an ox, and the meat is similar to that of the ox or spayed heifer, viz. much finer in the fibre than either the bull or cow; and they are more susceptible of growing fat with good food. By some they are supposed to exceed the ox and heifer in delicacy of taste, and bear a higher price at market; this, however, does not always hold, and Mr. Hunter gives an instance of the contrary. The Romans, who called the bull *taurus*, spoke also of *tauræ*, in the feminine gender, different from cows. Stephens observes, that it was thought they meant by this word *barren cows*, who obtained the name because they did not conceive any more than bulls. He also quotes a passage from Columella, *lib. vi. cap. 22.* "And, like the *tauræ*, which occupy the place of fertile cows, should be rejected or sent away." He likewise quotes Varro, *De re rustica, lib. ii. cap. 5.* "The cow which is barren is called *taura*." From which we may reasonably conjecture, that the Romans had not the idea of the circumstances of their production.

Of these creatures Mr. Hunter dissected three, and the following appearances were observed in the most perfect of them. The external parts were rather smaller than in the cow. The vagina passed on as in the cow to the opening of the urethra, and then it began to contract into a small canal, which passed on to the division of the uterus into the two horns; each horn passing along the edge of the broad ligament laterally towards the ovaria. At the termination of these horns were placed both the ovaria and testicles, both of which were nearly about the size of a small nutmeg. No Fallopian tubes could be found. To the testicles were vasa deferentia, but imperfect. The left one did not come near the testicle: the right one came close to it, but did not terminate in the body called *epididymis*. They were both pervious, and opened into the vagina near the opening of the urethra. On the posterior surface of the bladder, or between the uterus and bladder, were the two bags called the *vesiculæ seminales* in the male, but smaller than what they are in the bull: the ducts opened along with the vasa deferentia.

Concerning hermaphrodites of the human species, much has been written, and many laws enacted about them in different nations; but the existence of them is justly disputed. Dr. Parsons has given us a treatise on the subject, in which he endeavours to explode the notion as a vulgar error. According to him, all the hermaphrodites that have appeared, were only women whose clitoris from some cause or other was overgrown; and, in particular, that this was the case with an Angola woman shown at London as an hermaphrodite some time ago.

Among the reptile tribe, indeed, such as worms, snails, leeches, &c. hermaphrodites are very frequent. In the memoirs of the French academy, we have an account of this very extraordinary kind of hermaphrodites, which not only have both sexes, but do the office of both at the same time. Such are earth-worms,

round-tailed worms found in the intestines of men and horses, land-snails, and those of fresh waters, and all the sorts of leeches. And, as all these are reptiles, and without bones, M. Poupert concludes it probable, that all other insects which have these two characters are also hermaphrodites.

The method of coupling practised in this class of hermaphrodites, may be illustrated in the instance of earth-worms. These little creatures creep, two by two, out of holes proper to receive them, where they dispose their bodies in such a manner as that the head of the one is turned to the tail of the other. Being thus stretched lengthwise, a little conical button or papilla is thrust forth by each, and received into an aperture of the other. These animals, being male in one part of the body, and female in another, and the body flexible withal, M. Homberg does not think it impossible but that an earth-worm may couple with itself, and be both father and mother of its young; an observation which appears rather extravagant.

Among the insects of the soft or boneless kind, there are great numbers indeed, which are so far from being hermaphrodites, that they are of no sex at all. Of this kind are all the caterpillars, maggots, and worms, produced of the eggs of flies of all kinds: but the reason of this is plain; these are not animals in a perfect state, but disguises under which animals lurk. They have no business with the propagating of their species, but are to be transformed into animals of another kind, by the putting off their several coverings, and then only they are in their perfect state, and therefore then only show the differences of sex, which are always in the distinct animals, each being only male or female. These copulate, and their eggs produce these creatures, which show no sex till they arrive at that perfect state again.

HERMAPHRODITE Flowers, in botany. These are so called by the sexualists on account of their containing both the antheræ and stigma, the supposed organs of generation, within the same calyx and petals. Of this kind are the flowers of all the classes in Linnæus's sexual method, except the classes *monœcia* and *diœcia*; in the former of which, male and female flowers are produced on the same root; in the latter, in distinct plants from the same seed. In the class *polygamia*, there are always hermaphrodite flowers mixed with male or female, or both, either on the same or distinct roots. In the plantain-tree the flowers are all hermaphrodite; in some, however, the anthera or male organ, in others the stigma or female organ, proves abortive. The flowers in the former class are styled *female hermaphrodites*; in the latter, *male hermaphrodites*. Hermaphrodites are thus as frequent in the vegetable kingdom as they are rare and scarce in the animal one.

HERMAS, an ecclesiastical author of the first century; and, according to Origen, Eusebius, and Jerome, the same whom St. Paul salutes in the end of his epistle to the Romans. He wrote a book in Greek some time before Domitian's persecution, which happened in the year 95. This work is intitled *The Pastor*, from his representing an angel speaking to him in it under the form of a shepherd. The Greek text is lost, but a very ancient Latin version of it is still extant. Some of the fathers have considered this book as canonical. The best edition of it is that of 1698, where it is to be found among the other apostolical fathers, illustrated with the notes and corrections of Cotelærius and Le Clerc. With them it was translated into English by Archbishop Wake, the best edition of which is that of 1710.

HERMAS, in botany; a genus of the *monœcia* order, belonging to the *polygamia* class of plants. The umbel in the hermaphrodite is terminal; there is an universal involucre and partial ones. The rays of the small umbels are lobed; the central one flower-bearing; there are five petals, and as many barren stamina; the seeds are two-fold and suborbicular. In the male

the lateral umbels have univerval and partial involucria; the small umbels are many-flowered; there are five petals, and five fertile stamina.

HERMES, or HERMA, among antiquaries, a sort of square or cubical figure of the god Mercury, usually made of marble, though sometimes of brass or other materials, without arms or legs, and planted by the Greeks and Romans in their cross-ways. Servius gives us the origin thereof, in his comment on the eighth book of the *Æneid*. Some shepherds, says he, having one day caught Mercury, called by the Greeks *Hermes*, asleep on a mountain, cut off his hands; from which he, as well as the mountain where the action was done, became denominated Cyllenius, from *κωλλος* *maimed*: and thence, adds Servius, it is that certain statues without arms are denominated *Hermeses* or *Hermæ*. But this etymology of the epithet of Cyllenius contradicts most of the other ancient authors; who derive it hence, that Mercury was born at Cyllene, a city of Elis, or even on the mountain Cyllene itself, which had been thus called before him.

Suidas gives a moral explication of this custom of making statues of Mercury without arms. The *Hermeses*, says he, were statues of stone placed at the vestibules or porches of the doors and temples at Athens; for this reason, that as Mercury was held the god of speech and of truth, square and cubical statues were peculiarly proper; having this in common with truth, that on what side soever they are viewed, they always appear the same. It must be observed, that Athens abounded more than any other place in *Hermeses*: there were abundance of very signal ones in various parts of the city, and they were indeed one of the principal ornaments of the place. They were also placed in the high roads and cross-ways, because Mercury, who was the courier of the gods, presided over the highways; whence he had his surname of Trivius, from *trivium*; and that of Viacus, from *via*.

From Suidas's account, above cited, it appears, that the *termini*, used among us in the door-cases, balconies, &c. of our buildings, take their origin from these Athenian *Hermeses*; and that it was more proper to call them *hermetes* than *termini*, because, though the Roman *termini* were square stones, whereon a head was frequently placed, yet they were rather used as land-marks and mere stones than as ornaments of building. See the articles *MERCURY* and *THOTH*.

HERMETIC, or HERMETICAL-*Art*, a name given to chemistry, on a supposition that Hermes Trismegistus was the inventor of the art, or that he excelled therein. See *THOTH*.

HERMETICAL *Philosophy* is that which undertakes to solve and explain all the phenomena of nature, from the three chemical principles, salt, sulphur, and mercury.

HERMETICAL *Physic*, or *Medicine*, is that system or hypothesis in the art of healing, which explains the causes of diseases, and the operations of medicine, on the principles of the hermetical philosophy, and particularly on the system of alkali and acid. It has been long exploded.

HERMETICAL *Seal*, a manner of stopping or closing glass vessels, for chemical operations, so very accurately, that nothing can exhale or escape, not even the most subtile spirits. It is performed by heating the neck of the vessel in the flame of a lamp till it be ready to melt, and then with a pair of pincers twisting it close together. This they call putting on *Hermes's Seal*. There are also other ways of sealing vessels hermetically; viz. by stopping them with a plug or stopple of glass, well luted into the neck of the vessel; or, by turning another ovum philosophicum upon that wherein the matter is contained.

HERMHARPOCRATES, or HERMARPOCRATES, in antiquity, a deity, or figure of a deity, composed of Mercury and Harpocrates the god of Silence. M. Spon gives us a *hermharpocrates* in his *Rech. Cur. de l'Antiquité*, p. 98. fig. 15. having

wings on his feet like Mercury, and laying his finger on his mouth like Harpocrates. It is probable they might mean by this combination, that Silence is sometimes eloquent.

HERMIANI, or HERMIATITÆ, a sect of heretics in the second century, thus called from their leader Hermias. They were also denominated *Seleuciani*. One of their distinguishing tenets was, that God is corporeal. Another, that Jesus Christ did not ascend into heaven with his body, but left it in the sun.

HERMIONE, in ancient geography, a considerable city of Argolis. It was in ruins, except a few temples, in the time of Pausanias; who says that the new city was at the distance of four stadia from the promontory on which the temple of Neptune stood. It gave name to the Sinus Hermionicus, a part of the Sinus Argolicus.

HERMIT, or EREMIT, *Eremita*, a devout person retired into solitude, to be more at leisure for prayer and contemplation, and to disencumber himself of the affairs of this world. The word is formed from the Greek *ερημος*, *desert* or *wilderness*; and, according to the etymology, should rather be written *Eremit*. Paul, surnamed the *Hermit*, is usually reckoned the first hermit; though St. Jerome at the beginning of the Life of that saint says, it is not known who was the first. Some go back to John the Baptist, others to Elias: others make St. Anthony the founder of the eremetical life; but others think that he only rekindled and heightened the fervour thereof, and hold that the disciples of that saint owned St. Paul of Thebes for the first that practised it. The persecutions of Decius and Valerian are supposed to have been the occasion. Several of the ancient hermits, as St. Anthony, &c. though they lived in deserts, had yet numbers of religious accompanying them. There are also various orders and congregations of religious distinguished by the title of *hermits*; as, hermits of St. Augustine, of St. John Baptist, of St. Jerom, of St. Paul, &c.

HERMIT (Gaytier Peter the), a French officer of Amiens in Picardy, who quitted the military profession, and commenced hermit and pilgrim. Unfortunately he travelled to the Holy Land about the year 1093; and making a melancholy recital of the deplorable situation of a few Christians in that country to Pope Urban II. and at the same time enthusiastically lamenting that Infidels should be in possession of the famous city where the Author of Christianity first promulgated his sacred doctrines, Urban gave him a fatal commission to excite all Christian princes to a general war against the Turks and Saracens, the possessors of the Holy Land. See *CRUSADES*.

HERMITAGE properly signifies a little hut or habitation, in some desert place, where a hermit dwells. *Hermitage* is a name also popularly applied to any religious cell, built and endowed in a private and reclusive place, and thus annexed to some large abbey, of which the superior was called *bermita*.

HERMODACTYL, in the materia medica, a root brought from Turkey. It is of the shape of a heart flattened, of a white colour, compact, yet easy to cut or powder; of a viscous sweetish taste, with a light degree of acrimony. *Hermodactyls* were of great repute among the ancients as a cathartic; but those we now meet with in the shops have very little purgative virtue; Neumann declares he never found them to have any effect at all. The *hermodactyl* is the root of the *Colchicum variegatum*, according to some; others suppose it to be the root of the *Iris tuberosa*.

HERMOGENES, the first and most celebrated architect of antiquity, was, according to Vitruvius, born at Alanbada, a city in Caria. He built a temple of Diana at Magnesia; another of Bacchus at Tros; and was the inventor of several parts of Architecture. He composed a book on the subject, which is lost.

HERMOGENES *Tarsensis*, a rhetorician and orator, and who

was in every respect a prodigy. At 17 years of age he published his system of rhetoric, and at 20 his philosophic ideas: but at 25 he forgot every thing he had known. It is said, that his body being opened after his death, his heart was found of an extraordinary size, and all over hairy. He died about 168 B. C.

HERMOGENIANS, a sect of ancient heretics, denominated from their leader Hermogenes, who lived towards the close of the second century. Hermogenes established matter as his first principle; and regarding matter as the fountain of all evil, he maintained that the world, and every thing contained in it, as also the souls of men and other spirits, were formed by the Deity from an uncreated and eternal mass of corrupt matter. The opinions of Hermogenes, with regard to the origin of the world and the nature of the soul, were warmly opposed by Tertullian. The Hermogenians were divided into several branches under their respective chieftains, viz. Hermiani, Seleucians, Materiali, &c.

HERMON, or **AERMON**, in ancient geography, a mountain of the Amorites, called *Sanior* by the Phœnicians, and *Sanir* or *Senir* by the Amorites, on the east of Jordan. It is also called *Sion*, (Moses); but must not be confounded with the *Sion* of Jerusalem. By the Sidonians it was called *Scirion*; in the Vulgate, it is called *Sarion*. Joshua informs us, that it was the dominion of Og king of Bashan; which must be understood of its south side. It is never particularly mentioned by profane writers; being comprised under the appellation *Libanus*, or *Antilibanus*, with which mountain it is joined to the east. It is also called *Hermonim* plurally, Psalm xlii. 6. because it was extensive, and contained several mountains.

HERMES, in ancient geography, a river of Ionia; which rising near Dorylæum, a town of Phrygia, in a mountain sacred to Dindymene or Cybele, touched Mysia, and ran through the Regio Combusta, then through the plains of Smyrna down to the sea, carrying along with it the Pactolus, Hyllus, and other less noble rivers. Its waters were said to roll down gold, by Virgil and other poets.

HERNANDRIA, **JACK-IN-A-BOX-TREE**; a genus of the triandria order, belonging to the monœcia class of plants; and in the natural method ranking under the 38th order, *Tricocœ*. The male calyx is tripartite; the corolla tripetalous; the female calyx is truncated, quite entire; the corolla hexapetalous; the plum hollow, and open at the mouth or upper part, with a loose kernel. The *Species* are, 1. The *sonora*, or common jack-in-a-box, is a native of both the Indies. It grows 20 or 30 feet high; and is garnished with broad peltated leaves, and monœcious flowers, succeeded by a large swollen hollow fruit formed of the calyx; having a hole or open at the end, and a hard nut within. The wind blowing into the cavity of this fruit makes a very whistling and rattling noise, whence comes the name. 2. The *ovigera* grows many feet high, garnished with large oval leaves not peltated; and monœcious flowers, succeeded by a swollen fruit open at the end, and a nut within. It is said, the *sonora* in Java affords a sure antidote against poison, if you either put its small roots on the wounds or eat them; as was discovered to Rumphius by a captive woman in the war between the people of Macassar and the Dutch in the year 1667. The soldiers of the former always carry this root about them, as a remedy against wounds with poisoned arrows. Both these plants being tender exotics, must be planted in pots of rich earth, and always kept in a hot-house; in which, notwithstanding all the care that can be taken, they seldom flower, and never grow beyond the height of common shrubs, though in the places where they are natives they arrive at the height of trees. They are propagated by seeds procured from the West Indies.

HERNE, a town of Kent, 6 miles from Canterbury, 12 from Margate, and 14 from Feverham. It formerly had a

market, and has now a fair on Easter-Tuesday. The church is a large ancient structure, with a tower of flint, and has six stalls of the cathedral kind, with divisions of the choir from the nave by a carved screen of oak. The church is 113 feet long. The stone front is very ancient. Here the great Dr. Ridley, the English martyr, was vicar. Herne has a commodious bay, frequented by colliers, &c.

HERNIA, in surgery, a descent of a portion of the intestines or omentum out of their natural place; or rather, the tumour formed by that descent, popularly called a rupture. The word is Latin, *hernia*, and originally signifies the same with *tumor scroti*, called also *ramax*. Priscian observes, that the ancient Marſi gave the appellation *hernia* to rocks; whence some will have hernias thus called *propter duritiem*, on account of their hardness. Scaliger chooses rather to derive the word from the Greek *ἔρνος*, *ramus*, a branch. See SURGERY.

HERNIARIA, **RUPTURE-WORT**; a genus of the digynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 11th order, *Sarmentacœa*. The calyx is quinquepartite; there is no corolla; there are five barren stamens, and a monospermous capsule. There are four *species*, of which the only remarkable one is the *glabra*, or smooth rupture-wort, a native of many parts of England. It is a low trailing plant, with leaves like the smaller chickweed; the flowers come out in clusters from the side of the stalks at the joints, and are of a yellowish green colour. This plant is a little saltish and astringent. The juice is useful to take away specks in the eye. Cows, sheep, and horses, eat the plant; goats and swine refuse it.

HERNOSAND, a seaport of Sweden, on the gulph of Bothnia. E. lon. 17. 58. N. lat. 62. 38.

HERO, in Pagani mythology, a great and illustrious person, of a mortal nature, though supposed by the populace to partake of immortality, and after his death to be placed among the number of the gods. The word is formed of the Latin *heros*, and that of the Greek *ἕρως* *semi-deus*, "demi-god." The Greeks erected columns and other monuments over the tombs of their heroes, and established a kind of worship in honour of the manes both of their heroes and heroines. The Romans also raised statues in honour of their heroes; but there were six of their heroes of a superior order, and who were supposed to be admitted into the community of the twelve great gods: these were Hercules, Bacchus, Esculapius, Romulus, Castor, and Pollux. Writers have distinguished between the worship which the ancients paid to their heroes and that offered to their gods. The latter, it is said, consisted of sacrifices and libations; the former was only a kind of funeral honour, in which they celebrated their exploits, concluding the rehearsal with feasts.

HERO is also used in a more extensive sense, for a great, illustrious, and extraordinary personage; particularly in respect of valour, courage, intrepidity, and other military virtues. F. Bouhours makes this distinction between a great man and a hero, that the latter is more daring, fierce, and enterprising; and the former more prudent, thoughtful, and reserved. In this sense we properly say, Alexander was a hero, Julius Cæsar a great man. Women who evince any extraordinary heroism of character are called *Heroines*.

HERO of a poem or romance, is the principal personage, or he who has the chief part in it. Thus the hero of the Iliad is Achilles; of the Odyssey, Ulysses; of the Æneid, Æneas; of Tasso's Jerusalem, Godfrey of Bulloign; of Milton's Paradise Lost, Adam; though Mr. Dryden will have the Devil to be Milton's hero, because he gets the better of Adam, and drives him out of Paradise.

HERO, in fabulous history, a famous priestess of Venus, lived at Abydos, in a tower situated on the banks of the Hellespont.

She being beloved by Leander, who lived at Sestos on the other side of the strait, he every night swam over to visit her, being directed by a light fixed on the tower. But the light being put out in a stormy night, the youth missed his way, and was drowned; on which Hero threw herself into the sea, and perished.

HERO, the name of two celebrated Greek mathematicians; the one called the *old*, and the other the *young*, *Hero*. The younger was a disciple of Ctesibius. They are known by two works translated into Latin by Barochius: *Spiralium liber*, by Hero senior; and *Tractat. artis et machin. militar.* by Hero junior. They flourished about 130 and 100 B. C.

HERODIAN, an eminent Greek historian, who spent the greatest part of his life at Rome, flourished in the third century, in the reigns of Severus, Caracalla, Heliogabalus, Alexander, and Maximin. His history begins from the death of Marcus Aurelius the philosopher; and ends with the death of Balbinus and Maximin, and the beginning of the reign of Gordian. It is written in very elegant Greek; and there is an excellent translation of it into Latin, by Angelus Politianus. Herodian has been published by Henry Stephens in 4to, in 1581; by Boecler, at Strasburg, in 1662, 8vo; and by Hudson, at Oxford, in 1699, 8vo.

HERODIANS, a sect among the Jews at the time of our Saviour: mentioned Matth. xxii. 16. and Mark iii. 6.

The critics and commentators are very much divided with regard to the Herodians. St. Jerom, in his Dialogue against the Luciferians, takes the name to have been given to such as owned Herod for the Messiah; and Tertullian and Epiphanius are of the same opinion. But the same Jerom, in his Comment on St. Matthew, treats this opinion as ridiculous; and maintains, that the Pharisees gave this appellation by way of ridicule to Herod's soldiers, who paid tribute to the Romans; agreeable to which the Syrian interpreters render the word by *the domestics of Herod*, i. e. "his courtiers." M. Simon, in his notes on the 22d chapter of Matthew, advances a more probable opinion. The name *Herodian* he imagines to have been given to such as adhered to Herod's party and interest; and were for preserving the government in his family, about which were great divisions among the Jews. F. Hardouin will have the Herodians and Sadducees to have been the same. Dr. Prideaux is of opinion, that they derived their name from Herod the Great, and that they were distinguished from the other Jews by their concurrence with Herod's scheme of subjecting himself and his dominions to the Romans, and likewise by complying with many of their heathen usages and customs. This symbolizing with idolatry upon views of interest and worldly policy, was probably that leaven of Herod, against which our Saviour cautioned his disciples. It is farther probable, that they were chiefly of the sect of Sadducees; because the leaven of Herod is also denominated the leaven of the Sadducees.

HERODOTUS, an ancient Greek historian of Halicarnassus in Caria, son of Lyxus and Dryo, was born in the first year of the 74th Olympiad, that is, about 484 B. C. The city of Halicarnassus being at that time under the tyranny of Lygdamis, grandson of Artemisia queen of Caria, Herodotus quitted his country and retired to Samos; from whence he travelled over Egypt, Greece, Italy, &c. and in his travels acquired the knowledge of the history and origin of many nations. He then began to digest the materials he had collected into order, and composed that history which has preserved his name among men ever since. He wrote it in the isle of Samos, according to the general opinion. Lucian informs us, that when Herodotus left Caria to go into Greece, he began to consider with himself,

What he should do to be for ever known,
And make the age to come his own,

in the most expeditious way, and with as little trouble as possible. His history, he presumed, would easily procure him fame, and raise his name among the Grecians, in whose favour it was written: but then he foresaw that it would be very tedious to go through the several cities of Greece, and recite it to each respective city; to the Athenians, Corinthians, Argives, Lacedemonians, &c. He thought it most proper therefore to take the opportunity of their assembling all together; and accordingly recited his work at the Olympic games, which rendered him more famous than even those who had obtained the prizes. None were ignorant of his name, nor was there a single person in Greece who had not seen him at the Olympic games, or heard those speak of him who had seen him there.

His work is divided into nine books; which, according to the computation of Dionysius Halicarnassensis, contain the most remarkable occurrences within a period of 240 years; from the reign of Cyrus the first king of Persia, to that of Xerxes when the historian was living. These nine books are called after the names of the nine muses, each book being distinguished by the name of a muse; and this has given birth to two disquisitions among the learned: 1. Whether they were so called by Herodotus himself; and, 2. For what reason they were so called. As to the first, it is generally agreed that Herodotus did not impose these names himself; but it is not agreed why they were imposed by others. Lucian tells us, that these names were given them by the Grecians at the Olympic games, when they were first recited, as the best compliment that could be paid the man who had taken pains to do them so much honour. Others have thought that the names of the *muses* have been fixed upon them by way of reproach; and were designed to intimate, that Herodotus, instead of true history, had written a great deal of fable. But, be this as it will, it is certain, that with regard to the truth of his history, he is accused by several authors; and, on the other hand, he has not wanted persons to defend him. Aldus Manutius, Joachim Camerarius, and Henry Stephens, have written apologies for him; and, among other things, have very justly observed, that he seldom relates any thing of doubtful credit without producing the authority on which his narration is founded; and, if he has no certain authority to fix it upon, uses always the terms *ut ferunt, ut ego audivi, &c.*

There is ascribed also to Herodotus, but falsely, a Life of Homer, which is usually printed at the end of his work. He wrote in the Ionic dialect, and his style and manner have ever been admired by all people of taste. There have been several editions of the works of this historian; two by Henry Stephens, one in 1570, and the other in 1592; one by Gale at London in 1679; and one by Gronovius at Leyden in 1715, which is the last and best, though not the best printed.

HEROIC, something belonging to a hero, or heroine. Thus we say, *heroic actions, heroic virtue, heroic style, heroic verse, heroic poet, heroic age, &c.*

HEROIC Age, is that age or period of the world wherein the heroes, or those called by the poets the *children of the gods*, are supposed to have lived. The heroic age coincides with the fabulous age.

HEROIC Poem is that which undertakes to describe some extraordinary action, or enterprise. Homer, Virgil, Statius, and Lucan, Tasso, Camoens, Milton, and Voltaire, have composed *heroic poems*. In this sense, *heroic poem* coincides with *epic poem*.

HEROIC Verse, is that wherein heroic poems are usually composed; or, it is that proper for such poems. In the Greek and Latin, hexameter verses are peculiarly denominated *heroic verses*, as being alone used by Homer, Virgil, &c. Alexandrine verses, of 12 syllables, were formerly called *heroic verses*, as being supposed the only verse proper for heroic poetry; but later writers use verses of ten syllables.

HERON, in ornithology. See **ARDEA**. This bird is a very great devourer of fish, and will do more mischief to a pond than even an otter. Some say that an heron will destroy more fish in a week than an otter will in three months; but that seems carrying the matter too far. People who have kept herons, have had the curiosity to number out the fish they fed them with into a tub of water; and counting them again afterwards, it has been found that a heron will eat 50 moderate-sized dace and roaches in a day. It has been found, that in carp-ponds visited by this bird, one heron will eat up 1000 store carp in a year, and will hunt them so close that very few can escape. The readiest method of destroying this mischievous bird is by fishing for him in the manner of pike, with a baited hook; the bait consisting of small roach or dace, and the hook fastened to one end of a strong line, made of silk and wire twisted together. To the other end of the line is fastened a stone of a pound weight; and several of these baited lines being sunk by means of the stone in different parts of the pond, in a night or two the heron will not fail of being taken by one or other of them.

HERPES, in surgery, a kind of sore or pustule, which breaking out upon the skin, spreads in various directions; or sometimes heals on one side, or in the middle, while it eats the sound parts. As these appearances vary, the herpes accordingly receives different denominations. See **SURGERY**.

HERRERA TORDESILLAS (Anthony), a Spanish historian, was secretary to Vespasian Gonzaga, viceroy of Naples, and afterwards historiographer of the Indies, under king Philip II. who allowed him a considerable pension. He wrote a general history of the Indies, in Spanish, from 1492 to 1554; and of the world (not so much esteemed), from 1554 to 1598. He died in 1625, aged about 66.

HERRERA (Ferdinand de), an eminent Spanish poet, of the 16th century, was born at Seville, and principally succeeded in the lyric kind. Besides his poems, he wrote notes on Garcilasso de la Vega, and an account of the war of Cyprus, and the battle of Lepanto, &c.

HERRING, in ichthyology, a species of **CLUPEA**. The name *herring* is derived from the German *beer*, an *army*, which expresses their number when they migrate into our seas. Herrings are found in great plenty from the highest northern latitudes as low as the northern coasts of France. They are also met with in vast shoals on the coast of America, as low as Carolina: they are found also in the sea of Kamtschatka, and possibly reach Japan: but their winter rendezvous is within the arctic circle, whither they retire after spawning, and where they are provided with plenty of insect food. For an account of the remarkable migration of herrings, and the history of the fishery, &c. see **CLUPEA** and *Herring-Fishery*. They are in full roe at the end of June, and continue in perfection till the beginning of winter, when they begin to deposit their spawn.

There are different names given to preserved herrings, according to the different manners wherein they are ordered: as, 1. *Sea-sticks*; which are such as are caught all the fishing season, and are but once packed. A barrel of these holds six or eight hundred; eight barrels go to the ton by law; a hundred of herrings is to be a hundred and twenty; a last is ten thousand, and they commonly reckon fourteen barrels to the last. 2. There are others, repacked on shore, called *repacked herrings*; 17 barrels of sea-sticks commonly make from 12 to 14 of repacked herrings. The manner of repacking them is, to take out the herrings, wash them out in their own pickle, and lay them orderly in a fresh barrel: these have no salt put to them, but are close packed, and headed up by a sworn cooper, with pickle, when the barrel is half full. The pickle is brine; so strong as that the herring will swim in it. 3. *Summers*, are such as the Dutch chafers or divers catch from June to the 15th of July.

These are sold away in sea-sticks, to be used presently, in regard of their fatness; because they will not endure repacking. They go one with another, full and shotten; but the repacked herrings are sorted, the full herrings by themselves. 4. The *shotten* and *sick herrings* by themselves; the barrel whereof is to be marked distinctly. 5. *Crux herrings*; which are such as are caught after the 14th of September. These are cured with that kind of salt called salt-upon-salt, and are carefully sorted out, all full herrings, and used in the repacking. 6. *Corved herrings*. These serve to make red herrings, being such as are taken in the Yarmouth seas, from the end of August to the middle of October; provided they can be carried ashore within a week, more or less, after they are taken. These are never gipped, but rowed in salt, for the better preserving of them, till they can be brought on shore; and such as are kept to make *red herrings* are washed in great vats in fresh water, before they are hung up in the *herring-hangs* or *red-herring* houses.

As for the *manner of salting herrings*. The nets being haled on board, the fishes are taken out, and put into the warbacks, which stand on one side of the vessels. When all the nets are thus unloaded, one fills the gippers baskets. The gippers cut their throats, take out their guts, and sling out the full herrings into one basket, and the shotten into another. One man takes the full basket when they are gipped, and carries them to the rower-back, wherein there is salt. One boy rows and flirs them about in the salt, and another takes them, thus rowed, and carries them in baskets to the packers. Four men pack the herrings into one barrel, and lay them, one by one, straight and even; and another man, when the barrel is full, takes it from the packers. It is left to stand a day or more open to settle, that the salt may melt and dissolve to pickle; after which it is filled up, and the barrel headed. The pickle is to be strong enough to sustain a herring; otherwise the fish decay in it.

HERRING (Thomas), archbishop of Canterbury, was the son of the rev. Mr John Herring, rector of Walsoken in Norfolk, where he was born in 1693. He was educated at Jesus college, Cambridge; was afterwards chosen fellow of Corpus Christi College, and continued a tutor there upwards of seven years. Having entered into priest's orders in 1719, he was successively minister of Great Shelford, Stow cum Qui, and Trinity in Cambridge; chaplain to Dr. Fleetwood, bishop of Ely; rector of Retringdon in Essex, and of Barly in Hertfordshire; preacher to the Society of Lincoln's Inn, chaplain in ordinary to his late majesty, rector of Blechingly in Surry, and dean of Rochester. In 1737 he was consecrated bishop of Bangor, and in 1743 translated to the archiepiscopal see of York. On the death of Dr. Potter in 1747, he was translated to the see of Canterbury; but in 1753 was seized with a violent fever, which brought him to the brink of the grave; and after languishing about four years, he died on the 13th of March 1757. He expended upwards of six thousand pounds in repairing and adorning the palaces of Croydon and Lambeth. This worthy prelate, in a most eminent degree, possessed the virtues of public life; his mind was filled with unaffected piety and benevolence, he was an excellent preacher, and a true friend to religious and civil liberty. After his death was published a volume of his sermons on public occasions.

HERRNHUT, or **HERRNHUTH**, the first and most considerable settlement of the United Brethren, commonly called *Moravians*, situated in Upper Lusatia, upon an estate belonging to the family of Nicolas Lewis Count Zinzendorf, about 50 miles east of Dresden. See the article *UNITED Brethren*. The building of this place was begun in 1727 by some emigrants from Moravia, who forsook their possessions on account of the persecution they suffered as Protestants from the Roman Catholics. It is situated upon the rise of an hill called the *Hutberg*,

or Watch-hill, from which they took occasion to call the new settlement *Herrnhut*, or the Watch of the Lord. The building, increase, and admirable regulations of this settlement occasioned no small surprize in the adjacent country; and caused, in 1732, 1736, and 1737, commissioners to be appointed to examine into the doctrines and proceedings of the brethren at Herrnhut. The commissioners made a favourable report; and ever since both Herrnhut and other settlements of the United Brethren in Saxony have been protected, and even several immunities offered them by the court, but not accepted. Herrnhut was visited in 1766 by the late emperor Joseph II. after his return from Dresden, by the present king of Prussia, and by several other royal personages, who expressed their satisfaction in examining its peculiar regulations. The United Brethren have settlements in Saxony, Silesia, and other parts of Germany; in Holland, Denmark, England, Ireland, and America. In England, their principal settlements are at Fulneck near Leeds, and Fairfield near Manchester. In Greenland, North and South America, the West Indies, and Russia, they have missions for the propagation of Christianity among the Heathens; and in many parts have had considerable success. See Busching's Account of the Rise and Progress of the Church of the Brethren, printed at Halle in 1781; and Crantz's History of the Brethren, London, 1780.

New HERRNHUT, the first mission settlement of the United Brethren in the island of St. Thomas in the West Indies, under Danish government, begun in 1739; their missionaries having endeavoured to propagate Christianity among the negro slaves ever since 1731, and suffered many hardships and persecutions, from which their converts were not exempted. Many of the planters finding in process of time that the Christian slaves were more tractable, moral, and industrious than the heathen, not only countenanced but encouraged their endeavours. These were also greatly facilitated by the protection of the king of Denmark, Christian VI. The settlement consists of a spacious negro church, a dwelling-house for the missionaries, negro-huts, out-houses, and gardens. From this place the islands of St. Croix and St. Jan were at first supplied with missionaries; and the Brethren have now two settlements in each. The negro converts belonging to their church amount in those three islands to near 8000 souls.

New HERRNHUT, is also the name of the oldest mission settlement of the United Brethren in Greenland. It is situated on Balls River, a few miles from the sea, near Davis's Streights, on the western coast of Greenland, not far from the Danish colony Godhaab. The two first missionaries were sent from Herrnhut in the year 1733, and their laudable intentions favoured by Christian VI. king of Denmark. They had to struggle in this uncultivated, frozen, and savage country, with inconceivable hardships, and found at first great difficulty in acquiring the language of the natives. However, after six years labour and perseverance, they had the satisfaction to baptize four persons, all of one family; and from that time the mission began to prosper, so that in the succeeding years two other settlements were begun, called Lichtenfels and Lichtenau: all of them continue in prosperity. About 1300 of the natives have been christianized since the beginning of this mission. See Crantz's History of Greenland, London, 1777.

HERSE, in fortification, a lattice, or portcullis, in form of an harrow, beset with iron spikes. The word *herse* is French, and literally signifies "harrow;" being formed of the Latin *herpex* or *irpex*, which denotes the same. It is usually hung by a rope fastened to a moulinet; to be cut, in case of surprize, or when the first gate is broken with a petard, that the herse may fall, and stop up the passage of the gate or other entrance of a fortress. The herse is otherwise called a *sarrafin*, or *cataraet*; and when it consists of straight stakes, without any cross-pieces, it is called *orgues*.

HERSE is also a harrow, which the besieged, for want of chevaux de frise, lay in the way, or in breaches, with the points up, to incommode the march as well of the horse as of the infantry.

HERSILLON, in the military art, a sort of plank or beam, ten or twelve feet long, whose two sides are driven full of spikes or nails, to incommode the march of the infantry or cavalry. The word is a diminutive of *herse*; the hersillon doing the office of a little herse. See *HERSE*.

HERTFORD, the county town of Herts, with a market on Saturday. In the beginning of the heptarchy it was considered as one of the principal cities of the E. Saxons. It is seated on the river Lea, which is now navigable for barges, but, at that period, was equally navigable for ships to this town. In 879, the Danes erected two forts here, for the security of their ships; but Alfred turned the course of the river, so that their vessels were left on dry ground. Edward, the eldest son of Alfred, built a castle here, which has been often a royal residence. It is still entire, and the habitation of a noble family. The town sends two members to parliament, and is governed by a high steward, mayor, and nine aldermen, a recorder, &c. Here were formerly five churches, but now only two. Hertford is two miles W. by S. of Ware, and 21 N. of London. E. lon. 0. 1. N. lat. 51. 50.

HERTFORDSHIRE, or *HERTS*, a county of England, bounded on the N. by Cambridgeshire, on the E. by Essex, on the N. W. by Bedfordshire, on the W. by Bucks, and on the S. by Middlesex. It is 36 miles long from N. to S. and 28 broad from E. to W. It is divided into eight hundreds, which contain 19 market towns, and 174 parishes, and sends six members to parliament. The northern skirts of this county are hilly, forming a scattered part of the chalky ridge which extends across the kingdom in this direction. A number of streams take their rise from this side, which, by their clearness, show the general nature of the soil to be inclined to hardness, and not abundantly rich. Flint stones are scattered in great profusion over the face of this county; and beds of chalk are frequently to be met with. It is found, however, with the aid of proper culture, to be extremely favourable to corn, both wheat and barley, which come to as great perfection here as in any part of the kingdom. The western part is, in general, a tolerably rich soil, and under excellent cultivation. Indeed, the traffic of the county is in corn and malt. The air is wholesome; and the principal rivers are the Lea, Stort, and Coln.

HERTGOVINZA, a territory of Turkey in Europe, in Dalmatia. Castel-Nuovo, the capital, belongs to the Venetians; and the rest, with a town of the same name, to the Turks.

HERTHA, or *HERTHUS*, in mythology, a deity worshipped by the ancient Germans. This is mentioned by Tacitus, in his book *De Moribus Germanorum*, cap. 40. Vossius conjectures, that this goddess was Cybele: but she was more properly Terra or the Earth; because the Germans still use the word *bert* for the earth, whence also the English *earth*.

HERTZBERG, a considerable town, in the electorate of Saxony, 35 miles N. W. of Dresden. E. lon. 13. 17. N. lat. 51. 41.

HERVEY (James), a clergyman of exemplary piety, was born in 1714, and succeeded his father in the livings of Weston Favell and Collingtree in Northamptonshire. These, being within five miles of each other, he attended alternately with his curate; till being confined by his ill health, he resided constantly at Weston; where he diligently pursued the labours of the ministry and his study, under the disadvantage of a weak constitution. He was remarkably charitable; and desired to die just even with the world, and to be, as he termed it, his own executor. This excellent divine died on Christmas-day 1758, leaving the little he possessed to buy warm clothing for the poor in that

severe season. No work is more generally or deservedly known than his Meditations and Contemplations: containing, Meditations among the Tombs, Reflections on a Flower-garden, a Descant on Creation, Contemplations on the Night and Starry Heavens, and a Winter-piece. The sublime sentiments in these pieces have the peculiar advantage of being conveyed in a flowing elegant language, and they have accordingly gone through many editions. He published besides, Remarks on Lord Bolingbroke's Letters on History; Theron and Aspasio, or a Series of Dialogues and Letters on the most important subjects; some sermons, and other tracts.

HERVEY *Island*, one of the South-Sea islands, discovered by captain Cook, September 23, 1773, who gave it that name in honour of the earl of Bristol. It is a low island, situated in W. lon. 158. 54. S. lat. 19. 8.

HESBON, ESEBON, or *Hesebon*, in ancient geography, the royal city of the Amorites, in the tribe of Reuben, according to Moses: though in Joshua xxi. 39. where it is reckoned among the Levitical cities, it is put in the tribe of Gad; which argues its situation to be on the confines of both.

HESDIN, a strong town of France, in the department of the Straits of Calais and late county of Artois, seated on the river Canche, 25 miles S. S. W. of St. Omer, and 165 N. of Paris. E. lon. 2. 6. N. lat. 50. 24.

HESIOD, a very ancient Greek poet; but whether cotemporary with Homer, or a little older or younger than him, is not yet agreed among the learned; nor is there light enough in antiquity to settle the matter exactly. His father, as he tells us in his *Opera et Dies*, was an inhabitant of Cumæ, one of the Eolian isles, now called *Taio Nova*; and removed from thence to Ascra, a little village of Bœotia, at the foot of mount Helicon, where Hesiod was probably born, and called, as he often is, *Ascræus*, from it. Of what quality his father was, is nowhere said; but that he was driven by his misfortunes from Cumæ to Ascra, Hesiod himself informs us. His father seems to have prospered better at Ascra than he did in his own country; yet Hesiod could arrive at no higher fortune than keeping sheep on the top of mount Helicon. Here the muses met with him, and entered him into their service:

Erewhile as they the shepherd swain behold,
Feeding beneath the sacred mount his fold,
With love of charming song his breast they fir'd,
There me the heav'nly muses first inspir'd;
There, when the maids of Jove the silence broke,
To Hesiod thus the shepherd swain they spoke, &c.

To this account, which is to be found in the beginning of his *Generatio Deorum*, Ovid alludes in these two lines:

*Nec mihi sunt visæ Clio, Cliusque sorores,
Servanti pecudes vallibus, Ascra, tuis.*

Nor Clio nor her sisters have I seen,
As Hesiod saw them in the Ascræan green.

On the death of the father, an estate was left, which ought to have been equally divided between the two brothers Hesiod and Perseus; but Perseus defrauded him in the division, by corrupting the judges. Hesiod was so far from resenting this injustice, that he expresses a concern for those mistaken mortals who place their happiness in riches only, even at the expence of their virtue. He lets us know, that he was not only above want, but capable of assisting his brother in time of need; which he often did though he had been so ill used by him. The last circumstance he mentions relating to himself is his conquest in a poetical contention. Archidamus, king of Eubœa, had instituted funeral games in honour of his own memory, which his sons afterwards took care to have performed. Here Hesiod was a competitor for the prize in poetry; and won a tripod, which he consecrated

to the muses. Hesiod having entered himself in the service of the muses, left off the pastoral life, and applied himself to the study of arts and learning. When he was grown old (for it is agreed by all that he lived to a very great age), he removed to Locris, a town about the same distance from mount Parnassus as Ascra was from Helicon. His death was tragical. The man with whom he lived at Locris, a Milesian born, ravished a maid in the same house; and though Hesiod was entirely ignorant of the fact, yet being maliciously accused to her brothers as an accomplice, he was injuriously slain with the ravisher, and thrown into the sea. The *Theogony*, and *Works and Days*, are the only undoubted pieces of this poet now extant: though it is supposed that these poems have not descended perfect and finished to the present time. A good edition of Hesiod's works was published by Mr. Le Clerc at Amsterdam in 1701.

HESPER, HESPERUS, in astronomy, the evening star; an appellation given to Venus when she follows or sets after the sun. The word is formed of the Greek Ἑσπερος; and is supposed to have been originally the proper name of a man, brother of Atlas, and father of the Hesperides. Diodorus, lib. iii. relates, that Hesperus, having ascended to the top of mount Atlas, the better to observe and contemplate the stars, never returned; and that hence he was fabled to have been changed into this star.

HESPERIA, an ancient name of Italy; so called by the Greeks from its western situation. *Hesperia* was also an appellation of Spain; but with the epithet *ultima* (Hor.), to distinguish it from Italy, which is called *Hesperia magna* (Virg.), from its extent of empire.

HESPERI CORNU, called the *Great Bay* by the author of Hanno's Periplus; but most interpreters, following Mela, understand a promontory; some Cape Verd, others Palmas Cape: Vossius takes it to be the former, since Hanno did not proceed so far as the latter cape. 50.

HESPERIDÆ, in botany, from the Hesperides; *golden* or *precious fruit*: the name of the 19th order in Linnæus's *Fragments of a Natural Method*. See BOTANY, p. 50.

HESPERIDES, in the ancient mythology, were the daughters of Hesper or Hesperus, the brother of Atlas. According to Diodorus, Hesperus and Atlas were two brothers who possessed great riches in the western parts of Africa. Hesperus had a daughter called Hesperia, who married her uncle Atlas, and from this marriage proceeded seven daughters, called *Hesperides* from the name of their mother, and *Atlantides* from that of their father. According to the poets, the *Hesperides* were three in number, Ægle, Arethusa, and Hesperithusa. Hesiod, in his *Theogony*, makes them the daughters of *Nox*, Night, and seats them in the same place with the Gorgons; viz. at the extremities of the west, near mount Atlas: it is on that account he makes them the daughters of Night, because the sun sets there. The Hesperides are represented by the ancients as having the keeping of certain golden apples, on the other side the ocean. And the poets give them a dragon to watch the garden where the fruit grows: this dragon, they tell us, Hercules slew and carried off the apples. Pliny and Solinus will have the dragon to be no other than an arm of the sea, wherewith the garden was encompassed, and which defended the entrance thereof; and Varro supposes, that the golden apples were nothing but sheep. Others, with more probability, say they were oranges. The *Gardens* of the HESPERIDES are placed by some authors at Larach, a city of Fez; by others, at Bernich a city of Barca, which accords better with the fable. Others take the province of Susa in Morocco for the island wherein the garden was seated. And, lastly, Rudbecks places the Fortunate Islands, and the gardens of the Hesperides, in his own country, Sweden.

HESPERIDUM INSULÆ, in ancient geography, islands near the Hesperii Cornu; but the accounts of them are so

much involved in fable, that nothing certain can be affirmed of them.

HESPERIS, ROCKET, *Dame's Violet*, or *queen's gilliflower*; a genus of the siliquosa order, belonging to the tetradynamia class of plants; and in the natural method ranking under the 39th order, *Siliquosæ*. The petals are turned obliquely; there is a glandule within the shorter stamina; the siliqua almost upright; the stigma forked at the base, connivent, or closing at the top; the calyx close. The species are, 1. The *matronalis*, or common sweet-scented garden rocket, having fibrous roots, crowned with a tuft of long, spear-shaped, rough leaves; upright, single, hairy stalks, two feet high; garnished with oval lanceolate, slightly indented, close-fitting leaves; and the stalk and branches terminated by large and long spikes of sweet-scented flowers of different colours and properties in the varieties, of which there are a great number. All the varieties of this species are so remarkable for imparting a fragrant odour, that the ladies were fond of having them in their apartments. Hence they derived the name of *dame's violet*; and, bearing some resemblance to a stock-gilliflower, were sometimes also called *queen's gilliflower*; but are now most commonly called *rocket*. 2. The *inodora*, or scentless rocket, hath a fibrous root; upright, round, firm stalks, two feet high, garnished with spear-shaped, acute-pointed, sharply indented, close-fitting, leaves; and all the branches terminated by large spikes of scentless flowers, with obtuse petals, of different colours and properties in the varieties. This species makes a fine appearance, but hath no scent. 3. The *trifida*, or dull-flowered night-smelling rocket, hath fibrous roots, upright, branching, spreading, bristly stalks, two feet high; spear-shaped pointed leaves; and spikes of pale purple flowers, of great fragrance in the evening.

All the species are hardy, especially the first and second, which prosper in any of the open borders, and any common garden-soil; but the third, being rather impatient of a severe frost, and of much moisture in winter, should have a dry warm situation, and a few may be placed in pots to be sheltered in case of inclement weather. They may be propagated either by seeds, by offsets, or by cuttings off the stalks.

HESPERUS, in fabulous history, son of Cephalus by Aurora, as fair as Venus, was changed into a star, called *Lucifer* in the morning, and *Hesperus* in the evening. See **HESPER**.

HESSE, a country in the circle of the Upper Rhine, in Germany, bounded on the N. by the bishopric of Paderborn and duchy of Brunswick; on the E. by Thuringia; on the S. by the territory of Fulde and Weteravia; and on the W. by the counties of Nassau, Witgenstein, Hartzfeldt, and Waldeck. The house of Hesse is divided into four branches, namely, Hesse-Cassel, Homberg, Darmstadt, and Rhinefeldt, each of which has the title of landgrave, and takes its name from one of the four principal towns. This country is about 100 miles in length, and 50 in breadth, and surrounded by woods and mountains, in which are mines of iron and copper. In the middle are fine plains, fertile in corn and pastures; and there is plenty of all sorts of fruit and honey. They likewise cultivate a large quantity of hops, which serve to make excellent beer. Birch trees are very common, and they make a great deal of wine of the sap. The landgrave of Hesse-Cassel is an absolute prince, and derives a considerable part of his revenue from his troops, which he lets out to such of the powers of Europe as may be induced to give him an advantageous subsidy.

HESSIAN FLY, a very mischievous insect, which a few years ago appeared in North America; and whose depredations threatened then to destroy the crops of wheat in that country entirely. It is, in its perfect state, a small winged insect; but the mischief it does is while in the form of a caterpillar; and the difficulty of destroying it is increased by its being as yet unknown where it deposits its eggs, to be hatched before the first

appearance of the caterpillars. These mischievous insects begin their depredations in autumn, as soon as the wheat begins to shoot up through the ground. They devour the tender leaf and stem with great voracity, and continue to do so till stopped by the frost; but no sooner is this obstacle removed by the warmth of the spring, than the fly appears again, laying its eggs now, as has been supposed, upon the stems of the wheat just beginning to spire. The caterpillars, hatched from these eggs, perforate the stems of the remaining plants at the joints, and lodge themselves in the hollow within the corn, which shows no sign of disease till the ears begin to turn heavy. The stems then break; and being no longer able to perform their office in supporting and supplying the ears with nourishment, the corn perishes about the time that it goes into a milky state. These insects attack also rye, barley, and timothy-grass, though they seem to prefer wheat. The destruction occasioned by them is described in the American Museum (a magazine published at Philadelphia) for February 1787, in the following words: "It is well known that all the crops of wheat in all the land over which it has extended, have fallen before it, and that the farmers beyond it dread its approach; the prospect is, that unless means are discovered to prevent its progress, the whole continent will be over-run;—a calamity more to be dreaded than the ravages of war."

This terrible insect appeared first in Long Island during the American war, and was supposed to have been brought from Germany by the Hessians; whence it had the name of the *Hessian-fly*. From thence it proceeded inland at the rate of about 15 or 20 miles annually; and by the year 1789 had reached 200 miles from the place where it was first observed. At that time it continued to proceed with unabating increase; being apparently stopped neither by rivers nor mountains. In the fly state it is likewise exceedingly troublesome; by getting into houses in swarms, falling into victuals and drink; filling the windows, and flying perpetually into the candles. It still continued to infest Long Island as much as ever; and in many places the culture of wheat was entirely abandoned.

Mr. Morgan, in a communication to the Philadelphia Society for promoting agriculture, informs us, that he had made himself acquainted with the fly by breeding a number of them from the chrysalis into the perfect state. The fly is at first of a white body with long black legs and whiskers, so small and motionless as not to be easily perceived by the naked eye, though very discernible with a microscope; but they soon become black and very nimble, both on the wing and feet, being about the size of a small ant. During the height of the brood in June, where 50 or 100 of the nits have been deposited on one stalk of wheat, he has sometimes discovered, even with the naked eye, some of them to twist and move on being disturbed: this is while they are white; but they do not then travel from one stalk to another, nor to different parts of the same stalk. The usual time of their spring-hatching from the chrysalis is in May. "Those (says he) who are doubtful whether the fly is in their neighbourhood, or cannot find their eggs or nits in the wheat, may satisfy themselves by opening their windows at night and burning a candle in the room. The fly will enter in proportion to their numbers abroad. The first night after the commencement of wheat harvest, this season, they filled my dining-room in such numbers as to be exceedingly troublesome in the eating and drinking vessels. Without exaggeration I may say, that a glass tumbler from which beer had been just drank at dinner, had 500 flies in it in a few minutes. The windows are filled with them when they desire to make their escape. They are very distinguishable from every other fly by their horns or whiskers."

The American States are likewise infested with another mischievous insect, named the *Virginian wheat-fly*. This, however,

has not yet passed the river Delaware; though there is danger of its being gradually inured to colder climates so as to extend its depredations to the northern colonies also. But it is by no means the same with the Hessian fly. The wheat fly is the same with that whole ravages in the Anguimois in France are recorded by M. Du Hamel; it eats the grain, and is a moth in its perfect state. On the other hand, the Hessian fly has hitherto been unknown to naturalists; it eats only the leaf and stalk; and, in its perfect state, is probably a tenthredo, like the black negro-fly of the turnip.

As great quantities of wheat were at this time imported from America into Britain, it became an object worthy of the attention of government to consider how far it was proper to allow of such importation, lest this destructive insect might be brought along with the grain. The matter, therefore, was fully canvassed before the privy council; and the following is the substance of the information relative to it; and in consequence of this, the importation of American wheat was at that time forbid by proclamation.

From a very extensive correspondence which was instituted on this subject, between Mr. Bond the British consul at Philadelphia, and many others, with Sir Joseph Banks, the latter drew up a report for the privy council, dated March 2, 1789, in which he states the following particulars: 1. The appearance of the fly in Long Island was first observed in 1779. We must suppose this to be meant, that its destructive effects became then first perceptible; for it seems undoubtedly to have been known in the year 1776. 2. The opinion of colonel Morgan, that it was imported by the Hessians, seems to be erroneous, as no such insect can be found to exist in Germany or any other part of Europe. 3. Since its first appearance in Long Island it has advanced at the rate of 15 or 20 miles a-year, and neither waters nor mountains have impeded its progress. It was seen crossing the Delaware like a cloud, from the Fall's Township to Makefield; had reached Saratoga, 200 miles from its first appearance, infesting the counties of Middlesex, Somerset, Huntington, Morris, Suffex, the neighbourhood of Philadelphia, all the wheat counties of Connecticut, &c. committing the most dreadful ravages; attacking wheat, rye, barley, and timothy-grass. 4. The Americans, who have suffered by this insect, speak of it in terms of the greatest horror. In colonel Morgan's letter to Sir John Temple, he uses the following expressions. "Were it to reach Great Britain, it would be the greatest scourge that island ever experienced; as it multiplies from heat and moisture, and the most intense frosts have no effect on the egg or aurelia. Were a single straw, containing the insect, egg, or aurelia, to be carried and safely deposited in the centre of Norfolk in England, it would multiply in a few years, so as to destroy all the wheat and barley crops of the whole kingdom. There cannot exist such an atrocious villain as to commit such an act intentionally. 5. No satisfactory account of the mode in which this insect is propagated has hitherto been obtained. Those who say that the eggs are deposited on the stalk from six or eight to 50, and by their growth compress and hinder the stalk from growing, are evidently deceived, and the authors of the assertion plainly mistake the animal itself for its eggs. It is sufficient to remember, that eggs do not grow or increase in bulk, to prove that what they observed were not eggs. 6. The landholder's opinion, that the eggs are deposited on the ripe grains of wheat, though contradicted by colonel Morgan, is not disproved, as the colonel advances no argument against it. 7. A letter dated New York, September 1, 1786, says that the eggs are deposited on the young blade, resembling what we call a *fly-blow* in meat; very small, and but one in a place: but this, though the only natural mode of accounting for the appearance of the insect, had it been true, must undoubtedly have been confirmed by numbers of observa-

tions. 8. Even though this should be found hereafter to be the case, there will still remain a danger of the aurelias' being beaten off by the scail from the straw in threshing the wheat, and imported into Britain along with it; the presence of these flies in barns having been fully proved by the observations of Messrs. Potts and Bond. 9. None of the remedies proposed against this destructive insect have been in any degree effectual, excepting that of sowing the yellow bearded wheat; the straw of which is sufficiently strong to resist the impression of the insect, and, even if its eggs are deposited upon it, receives little injury in point of produce in grain: this provides, however, no remedy for the loss of the barley crop, nor for that which must be incurred by sowing the yellow-bearded wheat on lands better suited by nature for the produce of other kinds: it appears also that this very kind is liable to degenerate, and probably from a different cause than that assigned by colonel Morgan, viz. the mixture with common wheat. 9. Though the Agricultural Society at Philadelphia, as well as colonel Morgan, have declared their opinions decisively that no danger can arise from wheat imported into Britain, as the insect has no immediate connection with the grain; yet with nearly if not exactly the same materials before him which these gentlemen were furnished with, Sir Joseph Banks could not avoid drawing an inference directly contrary; and he concludes his report with the words of Mr. Bond in a letter to the marquis of Caermarthen. "Satisfactory as it would be to my feelings to be able to say with precision, that I apprehend no danger of extending the mischief by seed, my duty urges me to declare, that I have not heard or seen any conclusive fact by which I could decide on a matter of such importance; and till that test occurs, the wisdom of guarding against so grievous a calamity is obvious."

On the 27th of April the same year, another paper, by way of appendix to the foregoing, was given in by Sir Joseph Banks. In this he again observes, that none of the descriptions of any European insect hitherto published answer exactly to the Hessian fly. In a letter from Mr. Bond to the marquis of Caermarthen, he mentions another kind of insect in the state of Maryland, called by way of eminence *the fly*; and which in some things resembles the Hessian fly, though it cannot be accounted the same. It makes its way into the mow, and bites the ends of the grain perceptibly, and no doubt deposits its eggs in the grain itself; since it has been observed, that wheat recently threshed, and laid in a dry warm place, will soon be covered with an extreme clammy crust, which binds the wheat on the surface together in such a way as to admit its being lifted in lumps; but the wheat beneath will not be hurt to any considerable depth. Such is the quality of this fly, that if the hand be inserted into the heap infested by it, watery blisters are immediately raised; and the farmers and slaves, riding upon bags of this infested wheat, never fail to be severely blistered thereby. "This insect (says he) is called in Maryland the *Revolution fly*, by the friends of the British government; but from all I can learn it is not the same insect which originated on Long Island, and is called the *Hessian fly* (by way of opprobrium) by those who favoured the revolution. All the papers I have read on the Hessian fly are very inaccurate, not to say contradictory; and I am convinced it is by no means a settled point at this moment in what manner and place the eggs of these insects are deposited."

In another letter to the same nobleman, Mr. Bond expresses himself to the following purpose: "I have not been able to collect any decided information which fixes the essential point, how far the insect may be communicated by seed. It is a matter at this time quite undecided here: nor have I heard or observed any very conclusive reason to suppose that the fly makes its way generally into barns and ricks. A very intelligent farmer in the county of Bucks informed me that it was the pre-

vailing opinion there, and so I found it, that the fly did not either in the field or in the mow affect the grain of the wheat: a neighbour of his, in threshing the little wheat he had saved last harvest, observed the fly rise from the straw in great numbers wherever it was struck by the flail; but though it was at first presumed that the fly had intimated itself into the mow for the purpose of depositing its eggs in the grain or in the straw, no trace of the egg could be discovered from the appearance of any mucus or dust, either in the grain or in the straw; hence it was inferred that all the mischief was done in the field."

HESYCHIUS, the most celebrated of all the ancient Greek grammarians whose works are now extant, was a Christian; and, according to some, the same with Hesy chius patriarch of Jerusalem, who died in 609. He wrote a Greek lexicon; which, in the opinion of Casaubon, is the most learned and useful work of that kind produced by the ancients. Schrevelius published a good edition of it in 1668, in 4to, with notes; but the best is that of John Alberti, printed at Leyden in 1746, in two vols. folio.

HETERIARCH, HÆTERIARCHIA, in antiquity, an officer in the Greek empire, whereof there were two species; the one called simply *b. teriarch*, and the other *great heteriarch*, who had the direction of the former. The word is Greek, ἑταιριάρχια, formed of the Greek ἑταίριος *focius*, "companion, ally," and ἀρχή *imperium*, "command." Their principal function was to command the troops of the allies; besides which, they had some other duties in the emperor's court, described by Codin. *De officiis*, cap. 5. n. 30, 31, 32, 37.

HETEROCLITE, HETEROCLITON, in grammar, an irregular or anomalous word, which either in declension, conjugation, or regimen, deviates from the ordinary rules of grammar. The word is Greek, ἑτεροκλιτον; formed of ἕτερος *alter*, "another, different," and κλίω, "I decline." Heteroclite is more peculiarly applied to nouns which vary or are irregular in point of declension; having fewer cases, numbers, &c. than ordinary; or that are of one declension in one number, and another in another: as, *Hoc vas, vasis; hæc vasa, vasorum*.

HETERODOX, in polemical theology, something that is contrary to the faith or doctrine established in the true church. The word is formed of the Greek ἑτεροδοξος; a compound of ἕτερος "alter," and δόξα "opinion." Thus we say a *heterodox* opinion, a *heterodox* divine, &c. The word stands in opposition to *orthodox*.

HETEROGENEITY, in physics, the quality or disposition which denominates a thing *heterogeneous*. The word is also used for the heterogeneous parts themselves; in which sense, the heterogeneities of a body are the same thing with the impurities thereof.

HETEROGENEOUS, or HETEROGENEAL, literally imports something of a different nature, or that consists of parts of different or dissimilar kinds; in opposition to *homogeneous*. The word is Greek; formed of ἕτερος, *alter*, "different," and γένος, *genus*, "kind;" *q. d.* composed of different kinds of parts.

HETEROGENEOUS *Light*, is by Sir Isaac Newton said to be that which consists of rays of different degrees of refrangibility. Thus the common light of the sun or clouds is heterogeneous, being a mixture of all sorts of rays.

HETEROGENEOUS *Nouns*, one of the three variations in irregular nouns; or such as are of one gender in the singular number, and of another in the plural.—Heterogeneous, under which are comprehended mixed nouns, are six-fold. 1. Those which are of the masculine gender in the singular number, and neuter in the plural; as, *hic tartarus, hæc tartara*. 2. Those which are masculine in the singular number, but masculine and neuter in the plural; as, *hic locus, hi loci, & hæc loca*. 3. Such as are feminine in the singular number, but neuter in the plural; as *hæc*

earbasus, & hæc earlasa. 4. Such nouns as are neuter in the singular number, but masculine in the plural; as, *hoc caelum, hi caeli*. 5. Such as are neuter in the singular, but neuter and masculine in the plural; as, *hoc rastrum, bi rastro, & hæc rastro*. And, 6. Such as are neuter in the singular, but feminine in the plural number; as, *hoc epulum, hæc epulæ*.

HETEROGENEOUS *Quantities*, are those which are of such different kind and consideration, as that one of them, taken any number of times, never equals or exceeds the other.

HETEROGENEOUS *Surds*, are such as have different radical signs; as, \sqrt{aa} , and $\sqrt[3]{bb}$; $\sqrt[5]{9}$, and $\sqrt[7]{19}$.

HETEROSCII, in geography, a term of relation, denoting such inhabitants of the earth as have their shadows falling but one way, as those who live between the tropics and polar circles; whose shadows at noon in north latitude are always to the northward, and in south latitude to the southward.

HETRURIA, and ETRURIA, a celebrated country of Italy, at the west of the Tyber. It originally contained 12 different nations, which had each their respective monarch. Their names were Veientes, Clusini, Perusini, Cortonenses, Arretini, Vetuloni, Volaterrani, Rufellani, Volscinii, Tarquinii, Falisci, and Cæretani. The inhabitants were particularly famous for their superstition and strict confidence in omens, dreams, auguries, &c. They all proved powerful and resolute enemies to the rising empire of the Romans, and were conquered only after much effusion of blood.

HEVÆI, in ancient geography, one of the seven people who occupied Canaan; a principal and numerous people, and the same with the *Kadmonæi*, dwelling at the foot of Hermon and partly of Libanus, or between Libanus and Hermon (Judges iii. 3.) To this Bochart refers the fables concerning Cadmus and his wife Harmonia, or Hermonia, changed to serpents; the name *Hevi* denoting a wild beast, such as is a serpent. Cadmus, who is said to have carried the use of letters to Greece, seems to have been a Kadmonean; of whom the Greeks say that he came to their country from Phœnicia.

HEUCHERA, in botany; a genus of the digynia order, belonging to the pentandria class of plants. There are five petals; the capsule is birostrated and bilocular.

HEVELIUS, or HEVELKE, (John), an eminent astronomer, was born at Dantzic in 1611. He studied in Germany, England, and France, and every where obtained the esteem of the learned. He was the first that discovered a kind of libration in the moon, and made several important observations on the other planets. He also discovered several fixed stars, which he named the *firmament of Sobieski*, in honour of John III. king of Poland. His wife was also well skilled in astronomy, and made a part of the observations published by her husband. In 1673 he published a description of the instruments with which he made his observations, under the title of *Machina Cælestis*: and in 1679 he published the second part of this work; but in September the same year, while he was at a seat in the country, he had the misfortune to have his house at Dantzic burnt down. By this calamity he is said to have sustained a loss of several thousand pounds; having not only his observatory and all his valuable instruments and apparatus destroyed, but also a great number of copies of his *Machina Cælestis*; which accident has made this second part very scarce, and consequently very dear. In the year 1690 were published *Firmamentum Sobiescianum, and Prodromus astronomiæ & novæ tabule solares, una cum catalogo fixarum*, in which he lays down the necessary preliminaries for taking an exact catalogue of the stars. But both these works are posthumous; for Hevelius died in 1687, on his birth-day, aged 76. He was a man greatly esteemed by his countrymen, not only on account of his great reputation and skill in astronomy, but as a very excellent and worthy magistrate. He was made a burgo-master of Dantzic; which office he is said to

have executed with the utmost integrity and applause. He was also very highly esteemed by foreigners; and not only by those skilled in astronomy and the sciences, but by foreign princes and potentates: as appears abundantly from a collection of their letters, which were printed at Dantzic in the year 1683.

HEVER, a town of Austrian Brabant, two miles S. of Louvain. E. lon. 4. 49. N. lat. 50. 51.

HEUKELUM, a town of the United Provinces, in Holland, seated on the river Linge, five miles from Gorcum. E. lon. 4. 55. N. lat. 51. 55.

HEUSDEN, a strong town of the United Provinces, in Holland, seated on the river Maese, with a handsome castle; eight miles N. W. of Bois-le-duc. E. lon. 5. 3. N. lat. 51. 44.

HEWSON (William), a very ingenious anatomist, was born in 1739. He became assistant to Dr. Hunter, and was afterwards in partnership with him; but, on their disagreement, read anatomical lectures at his own house (in which he was seconded by Mr. Falconer). He wrote *Inquiries into the Properties of the blood, and the Lymphatic system*, 2 vols; and disputed with Dr. Monro the discovery of the lymphatic system of vessels in oviparous animals. He died in 1774, in consequence of absorption from a wound received in dissecting.

HEXACHORD, in ancient music, a concord called by the moderns a *sixth*.

HEXAGON, in geometry, a figure of six sides and angles; and if these sides and angles are equal, it is called a *regular hexagon*.

HEXAHEDRON, in geometry, one of the five platonic bodies, or regular solids, being the same with a cube.

HEXAMETER, in ancient poetry, a kind of verse consisting of six feet; the first four of which may be indifferently either spondees or dactyls; the fifth is generally a dactyl, and the sixth always a spondee. Such is the following verse of Horace:

1 2 3 4 5 6
Aut pro|disse vo|lunt, aut| dele|tare po|ete.

HEXAMILION, HEXAMILI, or *Hexamilium*, a celebrated wall, built by the emperor Emanuel in 1413 over the isthmus of Corinth. It took its name from ἕξ *fix*, and μίλιον, which in the vulgar Greek signifies a *mile*, as being six miles long. The design of the hexamilion was to defend Peloponnesus from the incursions of the barbarians. Amurath II. having raised the siege of Constantinople in the year 1424, demolished the hexamilium, though he had before concluded a peace with the Greek emperor. The Venetians restored it in the year 1463, by 30,000 workmen, employed for 15 days, and covered by an army commanded by Bertoldo d'Este general of the land forces, and Louis Loredano commander of the sea. The infidels made several attempts upon it; but were repulsed, and obliged to retire from the neighbourhood thereof: but Bertoldo being killed at the siege of Corinth, which was attempted soon after, Fertino Calcinato, who took on him the command of the army, abandoned, upon the approach of the beglerbeg, both the siege and the defence of the wall which had cost them so dear; upon which it was finally demolished.

HEXANDRIA, in botany, from ἕξ *fix*, and ἀνρ *a man*; the name of the sixth class in Linnæus's sexual method, consisting of plants with hermaphrodite flowers, which are furnished with six stamina or male organs, that are of an equal length. See BOTANY, p. 39.

HEXAPLA, formed of ἕξ *fix*, and ἀπλω *I open, I unfold*, in church-history, a Bible disposed in six columns; containing the text, and divers versions thereof, compiled and published by Origen, with a view of securing the sacred text from future corruptions, and to correct those that had been already introduced. Eusebius, *Hist. Eccl. lib. vi. cap. 16.* relates, that Ori-

gen, after his return from Rome under Caracalla, applied himself to learn Hebrew, and began to collect the several versions that had been made of the sacred writings, and of these to compose his Tetrapla and Hexapla; others, however, will not allow him to have begun till the time of Alexander, after he had retired into Palestine, about the year 231.

To conceive what this Hexapla was, it must be observed, that, besides the translation of the sacred writings, called the Septuagint, made under Ptolemy Philadelphus, above 280 years before Christ, the Scripture had been since translated into Greek by other interpreters. The first of those versions, or (reckoning the Septuagint) the second, was that of Aquila, a proselyte Jew, the first edition of which he published in the 12th year of the emperor Adrian, or about the year of Christ 128; the third was that of Symmachus, published, as is commonly supposed, under Marcus Aurelius, but, as some say, under Septimius Severus, about the year 200; the fourth was that of Theodotion, prior to that of Symmachus, under Commodus, or about the year 175. These Greek versions, says Dr. Kennicott, were made by the Jews from their corrupted copies of the Hebrew, and were designed to stand in the place of the Seventy, against which they were prejudiced, because it seemed to favour the Christians. The fifth was found at Jericho, in the reign of Caracalla, about the year 217; and the sixth was discovered at Nicopolis, in the reign of Alexander Severus, about the year 228: lastly, Origen himself recovered part of a seventh, containing only the Psalms.

Now Origen, who had held frequent disputations with the Jews in Egypt and Palestine, observing that they always objected to those passages of Scripture quoted against themselves, and appealed to the Hebrew text; the better to vindicate those passages, and confound the Jews by showing that the Seventy had given the sense of the Hebrew, or rather to show by a number of different versions what the real sense of the Hebrew was, undertook to reduce all these several versions into a body along with the Hebrew text, so as they might be easily confronted, and afford a mutual light to each other.

He made the Hebrew text his standard; and allowing that corruptions might have happened, and that the old Hebrew copies might and did read differently, he contented himself with marking such words or sentences as were not in his Hebrew text, nor the later Greek versions, and adding such words or sentences as were omitted in the Seventy, prefixing an asterisk to the additions, and an obelisk to the others. In order to this, he made choice of eight columns: in the first he gave the Hebrew text in Hebrew characters; in the second the same text in Greek characters; the rest were filled with the several versions above mentioned; all the columns answering verse for verse, and phrase for phrase; and in the Psalms there was a ninth column for the seventh version.

This work Origen called ἑξάπλω, *Hexapla*, q. d. *sextuple*, or work of six columns, as only regarding the first six Greek versions. See TETRAPLA. Indeed, St. Epiphanius, taking in likewise the two columns of the text, calls the work *Octapla*, as consisting of eight columns. This celebrated work, which Montfaucon imagines consisted of fifty large volumes, perished long ago, probably with the library at Cæsarea, where it was preserved, in the year 653; though several of the ancient writers have preserved us pieces thereof: particularly St. Chrysostom on the Psalms, Philoponus in his *Hexameron*, &c. Some modern writers have earnestly endeavoured to collect fragments of the Hexapla, particularly Flaminius Nobilius, Drusius, and F. Montfaucon, in two folio volumes, printed at Paris in 1713.

HEXASTYLE, in architecture, a building with six columns in front.

HEXHAM, a town of Northumberland, with a market on Tuesday. It is seated on the river Tyne, and was formerly fa-

mous for an abbey and church, one of which is now decayed, and a great part of the other was pulled down by the Scots. Near this place, in 1463, was fought a bloody battle, between the houses of York and Lancaster, in which the latter was defeated. Hexham is noted for its manufactory of tanned leather, shoes, and gloves; and is 22 miles W. of Newcastle, and 28 $\frac{1}{2}$ N. N. W. of London. W. lon. 2. 1. N. lat. 55. 3.

HEYDON, a borough in the E. riding of Yorkshire, with a market on Thursday. It is seated on a river, which soon falls into the Humber; and was formerly a considerable town, but is now much decayed. It is six miles W. of Hull, and 181 N. by W. of London. W. lon. 0. 5. N. lat. 53. 45.

HEYDON (John), who sometimes assumed the name of *Eugenius Theodilactus*, was a great pretender to skill in the Rosicrucian philosophy and the celestial signs, in the reign of king Charles I.; and wrote a considerable number of chemical and astrological works, with very singular titles. This ridiculous author was much resorted to by the duke of Buckingham, who was infatuated with judicial astrology. He employed him to calculate the king's and his own nativity, and was assured that his stars had promised him great things. The duke also employed Heydon in some treasonable and seditious practices, for which he was sent to the Tower. He lost much of his former reputation by telling Richard Cromwell and Thurloe, who went to him disguised like cavaliers, that Oliver would infallibly be hanged by a certain time; which he out-lived several years.

HEYLIN (Dr. Peter), an eminent English writer, was born at Burford, in Oxfordshire, in 1600. He studied at Hart Hall, Oxford; where he took his degrees in arts and divinity, and became an able geographer and historian. He was appointed one of the chaplains in ordinary to king Charles I. was presented to the rectory of Hemingsford in Huntingdonshire, made a prebendary of Westminster, and obtained several other livings: but of these he was deprived by the parliament, who also sequestered his estate; by which means he and his family were reduced to great necessity. However, upon the Restoration, he was restored to his spiritualities; but never rose higher than to be subdean of Westminster. He died in 1662, and was interred in St. Peter's church in Westminster, where he had a neat monument erected to his memory. His writings are very numerous: the principal of which are, 1. *Microcosmus*, or a Description of the Great World. 2. *Cosmographia*. 3. The History of St. George. 4. *Ecclesia Vindicata*, or the Church of England justified. 5. Historical and Miscellaneous Tracts, &c.

HEYWOOD (John), one of our most ancient dramatic poets, was born at North-Mims, near St. Alban's in Hertfordshire, and educated at Oxford. From thence he retired to the place of his nativity; where he had the good fortune to become acquainted with Sir Thomas More, who, it seems, had a seat in that neighbourhood. This patron of genius introduced our comic poet to the princess Mary, and afterwards to her father Henry, who, we are told, was much delighted with his wit and skill in music, and by whom he was frequently rewarded. When his former patroness, queen Mary, came to the crown, Heywood became a favourite at court, and continued often to entertain her majesty, *exercising his fancy before her, even to the time that she lay languishing on her death-bed*. On the accession of Elizabeth, being a zealous Papist, he thought fit to decamp, with other favourites of her deceased majesty. He settled at Mechlin in Flanders, where he died in the year 1565. John Heywood was a man of no great learning, nor were his poetical talents by any means extraordinary; but he possessed talents of more importance in the times in which he lived, namely, the talents of a jester. He wrote several plays; 500 epigrams; *A Dialogue in Verse concerning English Proverbs*; and *The Spider and Fly*, a Parable, a thick 4to. Before the title of this last

work is a whole-length wooden print of the author; who is also represented at the head of every chapter in the book, of which there are 77. He left two sons, who both became Jesuits and eminent men: *viz.* Ellis Heywood, who continued some time at Florence under the patronage of cardinal Pole, and became so good a master of the Italian tongue, as to write a treatise in that language, intitled *Il Moro*; he died at Louvain about the year 1572. His other son was Jasper Heywood, who was obliged to resign a fellowship at Oxford on account of his immoralities: he translated three tragedies of Seneca, and wrote various poems and devices; some of which were printed in a volume intitled *The Paradise of Dainty Devices*, 4to, 1573. He died at Naples in 1597.

HEYWOOD (Eliza), one of the most voluminous novel writers this island ever produced; of whom we know no more than that her father was a tradesman, and that she was born about the year 1696. In the early part of her life, her pen, whether to gratify her own disposition or the prevailing taste, dealt chiefly in licentious tales, and memoirs of personal scandal: the celebrated *Atalantis* of Mrs. Manley served her for a model; and *The Court of Carimania*, *The new Utopia*, with some other pieces of a like nature, were the copies her genius produced. She also attempted dramatic writing and performance, but did not succeed in either. Whatever it was that provoked the resentment of Pope, he gave full scope to it by distinguishing her as one of the prizes to be gained in the games introduced in honour of Dulness, in his *Dunciad*. Nevertheless, it seems undeniable, that there is much spirit, and much ingenuity, in her manner of treating subjects, which the friends of virtue may perhaps wish she had never meddled with at all. But, whatever offence she may have given to delicacy or morality in her early works, she appears to have been soon convinced of, and endeavoured to atone for, in the latter part of her life; as no author then appeared a greater advocate for virtue. Among her riper productions may be specified, *The Female Spectator*, 4 vols; *The history of Miss Betsy Thoughtless*, 4 vols; *Jenny and Jenny Jessamy*, 3 vols; *The invisible spy*, 4 vols; with a pamphlet intitled *A present for a servant-maid*. She died in 1759.

HIAMEN, or EMOUY. See EMOUY.

HIATUS, properly signifies an opening, chasm, or gap; but it is particularly applied to those verses where one word ends with a vowel, and the following word begins with one, and thereby occasions the mouth to be more open, and the sound to be very harsh. The term *hiatus* is also used in speaking of manuscripts, to denote their defects, or the parts that have been lost or effaced.

HIBISCUS, SYRIAN MALLOW; a genus of the polyandria order, belonging to the monadelphia class of plants; and in the natural method ranking under the 37th order, *Columniferae*. The calyx is double, the exterior one polyphyllous, the capsule quinquelocular and polyspermous. Of this genus there are 36 species; the most remarkable are, 1. The *Syriacus*, commonly called *alibæa frutex*, is a native of Syria. It rises with shrubby stalks to the height of eight or ten feet, sending out many woody branches covered with a smooth grey bark, garnished with oval spear-shaped leaves, whose upper parts are frequently divided into three lobes. The flowers come out from the wings of the stalk at every joint of the same year's shoot. They are large, and shaped like those of the mallow, having five large roundish petals which join at their base, spreading open at the top, in the shape of an open bell. These appear in August; and if the season is not too warm, there will be a succession of flowers till September. The flowers are succeeded by short capsules, with five cells, filled with kidney-shaped seeds; but unless the season proves warm, they will not ripen in this country. Of this species there are four or five varieties, differing in the

colour of their flowers: the most common hath pale purple flowers with dark bottoms; another hath bright purple flowers with black bottoms; a third hath white flowers with purple bottoms; and a fourth variegated flowers with dark bottoms. There are also two with variegated leaves, which are by some much esteemed. All these varieties are very ornamental in a garden. 2. The *Rosa Sinensis*, with an arborefcnt stem, and egg-pointed sawed leaves. It is a native of the East Indies, whence it has got the name of *Cbina rose*; but the seeds having been carried by the French to their West India settlements, it hath thence obtained the name of *Martinico rose*. Of this there are the double and single flowering kinds; the seeds of the first frequently produce plants that have only single flowers, but the latter seldom vary to the double kind. 3. The *mutabilis*, or changeable rose, has a soft spungy stem, which by age becomes ligneous and pithy. It rises to the height of 12 or 14 feet, sending out branches towards the top, which are hairy, garnished with heart-shaped leaves, cut into five acute angles on their borders, and slightly sawed on their edges; of a lucid green on their upper side, but pale below. The flowers are produced from the wings of the leaves; the single are composed of five petals which spread open, and are at first white, but afterwards change to a blush rose colour, and as they decay turn purple. In the West Indies, all these alterations happen on the same day, and the flowers themselves are of no longer duration; but in Britain the changes are not so sudden. The flowers are surrounded by short, thick, blunt, capsules, which are very hairy; having five cells, which contain many small kidney-shaped seeds, having a fine plume of fibrous down adhering to them. 4. The *albemarfibus*, or musk-seeded hibiscus, is a native of the West Indies, where the French cultivate great quantities of it. The plant rises with an herbaceous stalk three or four feet high, sending out two or three side-branches, garnished with large leaves cut into six or seven acute angles, sawed on their edges, having long footstalks, and placed alternately. The stalks and leaves of this sort are very hairy. The flowers come out from the wings of the leaves upon pretty long footstalks which stand erect. They are large, of a sulphur colour, with purple bottoms; and are succeeded by pyramidical five cornered capsules, which open in five cells, filled with large kidney-shaped seeds of a very musky odour. 5. The *tiliaceus*, or maho-tree, is a native of both the Indies. It rises with a woody, pithy stem, to the height of ten feet, dividing into several branches towards the top, which are covered with a woolly down, garnished with heart-shaped leaves ending in acute points. They are of a lucid green on their upper side, and hoary on the under side, full of large veins, and are placed alternately. The flowers are produced in loose spikes at the end of the branches, and are of a whitish-yellow colour. They are succeeded by short acuminate capsules, opening in five cells, filled with kidney-shaped seeds. 6. The *trionum*, Venice mallow, or flower of an hour, is a native of some parts of Italy, and has long been cultivated in the gardens of this country. It rises with a branching stalk a foot and a half high, having many short spines, which are soft, and do not appear unless closely viewed: the leaves are divided into three lobes, which are deeply jagged almost to the midrib. The flowers come out at the joints of the stalks, upon pretty long foot-stalks. They have a double empalement; the outer being composed of ten long narrow leaves, which join at their base: the inner is of one thin leaf swollen like a bladder, cut into five acute segments at the top, having many longitudinal purple ribs, and is hairy. Both these are permanent, and inclose the capsule after the flower is past. The flower is composed of five obtuse petals, which spread open at the top; the lower part forming an open bell-shaped flower. These have dark purple bottoms, but are of a pale sulphur-colour above. In hot weather the flowers continue but a few hours open; however, there

is a succession of flowers that open daily for a considerable time. 7. The *esculentus*, or catable hibiscus, rises to five or six feet; has broad five-parted leaves, and large yellow flowers. The pod or okra is from two to six inches long, and one inch diameter. When ripe it opens longitudinally in five different places, and discharges a number of heart-shaped seeds.

The first sort may be *propagated* either by seeds or cuttings. The seeds may be sown in pots filled with light earth about the latter end of March, and the young plants transplanted about the same time next year. They will succeed in the full ground; but must be covered in winter whilst young, otherwise they are apt to be destroyed. The second, third, fifth, and seventh sorts are propagated by seeds, which must be sown in a hot-bed. The young plants are to be transplanted into small separate pots, and treated like other tender vegetables, only allowing them a good share of air. The fourth sort is annual in this country, though biennial in those places where it is native. It is propagated by seeds, and must be treated in the manner directed for Amaranth. The sixth sort is propagated by seeds, which should be sown where the plants are designed to remain, for they do not bear transplanting well. They require no other culture than to be kept free from weeds, and thinned where they are too close; and if the seeds are permitted to scatter, the plants will come up fully as well as if they had been sown.

The fourth sort is cultivated in the West Indies by the French for the sake of its seeds. These are annually sent to France in great quantities, and form a considerable branch of trade, but the purposes which they answer are not certainly known. The inner rind of the fifth sort is very strong, and of great esteem, which the following passage from Dampier may serve to illustrate: "They (the Musketo Indians) make their lines, both for fishing and striking, with the bark of Maho, which is a sort of tree or shrub that grows plentifully all over the West Indies, and whose bark is made up of strings or threads very strong: you may draw it off either in flakes or small threads, as you have occasion. It is fit for any manner of cordage, and privateers often make their rigging of it." See BARK.

The seventh sort is a native of the West Indies, where it is cultivated in gardens and inclosures as an article of food. The whole of it is mucilaginous, especially the pods. "These (Dr. Wright informs us) are gathered green, cut into pieces, dried, and sent home as presents, or are boiled in broths or soups for food. It is the chief ingredient in the celebrated pepper-pot of the West Indies, which is no other than a rich olla: the other articles are either flesh meat, or dried fish and capficum. This dish is very palatable and nourishing. As a medicine, okra is employed in all cases where emollients and lubricants are indicated."

HICETAS of Syracuse, an ancient philosopher and astronomer, who taught that the sun and stars were motionless, and that the earth moved round them. This is mentioned by Cicero, and probably gave the first hint of the true system to Copernicus. He flourished 344 B. C.

HICKES (George), an English divine of extraordinary parts and learning, born in 1642. In 1681 he was made king's chaplain, and two years after dean of Worcester. The death of Charles II. stopped his farther preferment; for though his church principles were very high, he manifested too much zeal against Popery to be any favourite with James II. On the revolution, he with many others was deprived for refusing to take the oaths to king William and queen Mary; and soon after, archbishop Sancroft and his colleagues considering how to maintain episcopal succession among those who adhered to them, Dr. Hickes carried over a list of the deprived clergy to king James; and with his sanction a private consecration was performed, at which it is said lord Clarendon was present. Among others, Dr. Hickes was consecrated suffragan bishop of Thetford, and died in 1715. He wrote, 1. *Institutiones Grammaticæ Angli-*

Saxonia, et Marfo-Gothica. 2. Antiqua literatura septentrionalis.
 3. Two treatises, one of the Christian priesthood, the other of the dignity of the episcopal order. 4. Jovian, or an answer to Julian the apostate. 5. Sermons: with many temporary controversial pieces on politics and religion.

HICKUP, or HICCUGH, a spasmodic affection of the stomach, œsophagus, and muscles subservient to deglutition, arising sometimes from some particular stimulus acting on the stomach, œsophagus, diaphragm, &c. and sometimes from a general affection of the nervous system. See MEDICINE.

HIDAGE, *Hidagium*, was an extraordinary tax payable to the kings of England for every hide of land. This taxation was levied not only in money, but in provision, armour, &c; and when the Danes landed in Sandwich in 994, king Ethelred taxed all his lands by hides; so that every 310 hides found one ship furnished, and every eight hides furnished one jack and one saddle, to arm for the defence of the kingdom, &c. Sometimes the word *hidage* was used for the being quit of that tax: which was also called *bidegit'd*; and interpreted, from the Saxon, "a price or ransom paid to save one's skin or hide from beating."

HIDALGO, in modern history, a title given in Spain to all who are of noble family. The Hidalgos claim a descent from those valiant soldiers who retired into Castile, and the mountains of Asturias, and other remote parts of Spain, on the invasion of the Moors, where having fortified themselves, they successively descended into the plains, in proportion to the success of their arms: from the notoriety of their persons, or the lands they became possessed of, they acquired the appellation of *Hidalgos notorios*, *Hidalgos de solar conocido*, or *de casa solariega*. Of these, according to Hernando Mexia, there are three sorts; the first being lords of places, villages, towns, or castles, from whence they took their surnames, as the Guzmans, Mendozas, Laras, Guivaras, and others; the second, who recovered any fortresses from the Moors, as the Ponces of Leon, and others; and the third sort, from the places where they resided, or held jurisdiction, as Rodrigo de Narvaez was called of Antequera, from being Alcalde there. But this definition is not considered as exact or conclusive by Otalora, another civilian, who says that the true meaning of *Hidalgos de solar conocido* is explained by the laws of Castile to be a well known mansion or possession, the nature of which is particularly explained in the laws of *Parditas*, lib. 5. tit. 35. which describe three sorts of tenures called *Devifa*, *Solar e. a.*, and *Behetria*. By the first, lands are devised by the ancestor; *Solar* is a tenure upon another person's manor, and obliges the owner to receive the lord of the fee when necessity obliges him to travel; and *Behetria* is in the nature of an *allod'um*. In proportion as these Aborigines gained ground on the Moors, and increased in their numbers, many private persons distinguished themselves by their valour, and obtained testimonies of their services, called *cartas de merced*, which served them as a foundation of their birth and good descent, without which documents their posterity could not make it appear; and if from a lapse of time, or other unavoidable accidents, such proof should happen to be lost or destroyed, the law affords them a remedy under these circumstances, by a declaration, importing, that such persons as are supposed to have had such certificates, may be relieved by making it appear that their ancestors, time immemorial, have always been held and reputed as Hidalgos, and enjoyed the privileges of such, from a strong presumption in their favour; the possession of land having equal force to any other document; which is fully set forth in the *Pragmatica* of Cordova. To these executory letters are granted *cartas executorias*, expressive of their privileges; and for the better regulation of their matters, proper officers are appointed in the chancery courts, called *alcaldes de los hidalgos*, who ought to be *hidalgos* themselves, and hold jurisdiction in these cases, and no others: but even here innovations have

taken place; for as these grants flow from the sovereign, who is the fountain of honour, some are declared *Hidalgos de sangre*, by right of descent, and others *de privilegio*, or by office, in which the will of the sovereign has made amends for any deficiency of blood.

There is a set of people near Segovia, at a place called Zamarrainala, who are exempt from tribute on account of the care they take in sending proper persons every night to the castle of Segovia to stand sentinel—One cries out, *Vela, vela, bzo!* and the other blows a horn, from whence they have been titled *Hidalgos by the horn*. In Catalonia, those gentlemen who are styled *Hombre de Pareja*, are considered the same as *hidalgos* in Castile, and were so called from the word *parejar*, to equip, this name being given as a distinction by Borelo the 4th count of Barcelona, at the siege of that city, in 965, who summoning all his vassals to come to his assistance against the Moors, nine hundred horsemen well mounted and equipped joined him, and with their aid he took the city; and this appellation has been given in honourable remembrance of this loyal action.

These noble hidalgos enjoy many privileges and distinctions: of which the following are the principal. 1. The first and greatest privilege which they hold by law is to enjoy all posts of dignity and honour in the church and state, with liberty, when churchmen, of having a plurality of benefices. They are qualified for receiving all orders of knighthood, and are to be preferred in all embassies, governments, and public commissions. 2. When they are examined as witnesses in civil and criminal cases, their depositions are to be taken in their own houses, without being obliged to quit them to go to those of others. 3. In all churches, processions, and other public acts or assemblies, they are to have the next place of honour and precedency after the officers of justice, conforming themselves to particular customs. 4. They are not obliged to accept of any challenge for combat, supposing such were allowed of, but from those who are their equals. 5. Though it is forbidden to guardians to purchase the estates of minors, this does not extend to Hidalgos, in whom the law does not suppose any fraud, and they may purchase them publicly. 6. They are permitted to be seated in courts of justice in presence of the judges, from the respect and honour due to them. They have also seats in the courts of chancery, in consideration of their birth, which gives them a right to be near the persons of princes. 7. Their persons are free from arrest for debt, nor can any attachment be laid on their dwelling-houses, furniture, apparel, arms, horses, or mules in immediate use: nor can they make a cession of their estates, nor be distressed in suits of law, farther than their circumstances will admit of, but are to be allowed a reasonable and decent maintenance for their support. 8. In cases of imprisonment for criminal matters, they are to be treated differently from others. They are generally confined to their own houses with a safe guard, or under arrest upon their honour, or allowed the city or town they lived in, and in particular cases are sent into castles. 9. When punishments are inflicted for criminal cases, they are to be less severe to them than to others, as they are not to suffer ignominious punishments, such as public shame, whipping, galleys; nor are they to be hanged, but beheaded, excepting in cases of treason or heresy. In cases that do not imply a corporal punishment, but a pecuniary one, they are treated with more rigour, and pay a larger fine than others. 10. They are not to be put to the rack or torture, excepting for such heinous crimes as are particularly specified by the laws. 11. When there are title-deeds or other writings or papers in which two or more persons have an equal right or property, and require a particular charge, they are to be given up by preference to the custody of an hidalgo, if any of the parties are such. 12. The daughter of an hidalgo enjoys every privilege of her birth, though married to a commoner; and a woman who is not an

hidalgo enjoys all these privileges when she is a widow, following the fortune of her husband. But if the widow is an hidalgo, and the late husband was a commoner, she falls into the state of her husband after his death, though she had the privileges of her birth during his life. 13. They are free from all duties, called *Pechos*, *Pedidos*, *Monedas*, *Marteniegas*, *Contribuciones*, as well royal as civil, and all other levies of whatever kind they may be, with a reserve for such as are for the public benefit, in which they are equally concerned, such as the repairing the highways, bridges, fountains, walls, destruction of locusts and other vermin. 14. They are free from personal service, and from going to the wars, excepting when the king attends in person; even then they are not to be forced, but invited, and acquainted that the royal standard is displayed. 15. No persons whatever can be quartered upon, or lodged in their houses, except when the king, queen, prince, or infantess are on the road, as in such cases even the houses of the clergy are not exempt. 16. They cannot be compelled to accept of the office of receiver of the king's rents, or any other employment which is considered as mean and derogatory to their dignity and rank. 17. By a particular custom confirmed by royal authority in that part of Castile beyond the Ebro, bastards succeed to their parents, and enjoy their honours, contrary to the royal and common law. 18. If a lady, who marries a commoner, should be a queen, duchess, marchioness, or countess (for they have no barons in Castile), she not only does not lose her rank, but conveys her titles to her husband, who holds them in right of his wife.

These are the general privileges which the hidalgos enjoy; there are some others of less consequence, as well as particular grants to certain persons and families. An ancient and ridiculous custom is said to be observed by noble ladies who are widows of plebeians, in order to recover their birthright; for which purpose they carry a pack-saddle on their shoulders to their husband's grave, then throwing it down and striking it three times, say, 'Vilain, take thy villeiny, for I will abide by my nobility:' and then they recover their privileges again.

HIDE, the skin of a beast; but the word is particularly applied to those of large cattle, as bullocks, cows, horses, &c. Hides are either raw, that is, just as taken off the carcase: salted, or seasoned with salt, alum, and saltpetre, to prevent their spoiling; or curried and tanned. See TANNING.

HIDE of Land, was such a quantity of land as might be ploughed with one plough within the compass of a year, or as much as would maintain a family; some call it 60, some 80, and others 100 acres.

HIDE Bound. See FARRIERY, page 427.

HIERACIUM, HAWKWEED; a genus of the polygamia æqualis order, belonging to the syngenesia class of plants; and in the natural method ranking under the 49th order, *Compositæ*. The receptacle is naked, the calyx imbricated and ovate; the pappus simple and sessile. The *Species* are, 1. The *aurantiacum*, commonly called *Grim the collier*, hath many oblong oval entire leaves crowning the root; an upright, single, hairy, and almost leafless stalk, a foot high, terminated by reddish orange-coloured flowers in a corymbus. These flowers have dark oval ash-coloured calyces; whence the name of *Grim the collier*. 2. The *pilosella*, or mouse-ear, hath blossoms red on the outside, and pale yellow within; the cups set thick with black hairs. The flowers open at eight in the morning, and close about two in the afternoon. 3. The *umbellatum*, grows to the height of three feet, with an erect and firm stalk, terminated with an umbel of yellow flowers. The first is the only species cultivated in gardens. It is propagated by seeds, or parting the roots. The seed may be sown in autumn or spring. In June, when the plants are grown two or three inches high, they may be picked out and planted in beds, where they must be left till the next autumn, and then transplanted where they are to remain.

VOL. IV.

The second species is commonly in dry pastures in England; it has a milky juice, but is less bitter and astringent than is usual with plants of that class. It is reckoned hurtful to sheep. An insect of the cochineal genus (*Coccus Polonicus*) is often found at the roots (*Act. Upsal. 1752*). Goats eat it; sheep are not fond of it; horses and swine refuse it. The third species is a native of Scotland, and grows in rough stony places, but is not very common. The flowers are sometimes used for dyeing yarn of a fine yellow colour.

HIERACITES, in church-history, Christian heretics in the third century: so called from their leader Hierax, a philosopher of Egypt; who taught that Melchisedek was the Holy Ghost, denied the resurrection, and condemned marriage.

HIERA PICRA. See PHARMACY.

HIERAPOLIS, in ancient geography, a town of Phrygia, abounding in hot springs, and having its name from the number of its temples. There are coins exhibiting figures of various gods who had temples here. Of this place was Epictetus the stoic philosopher. It is now called *Pambouk*; and is situated near the Scamander, on a portion of Mount Mesogis, distant six miles from Laodicea. Its site appears at a distance as a white lofty cliff; and upon arriving at it, the view which it presents is so marvellous, that the description of it, to bear even a faint resemblance, ought to appear romantic. See Dr. Chandler's Travels in Asia Minor, p. 229.

HIERARCHY, among divines, denotes the subordination of angels. Some of the rabbins reckon four, others ten, orders or ranks of angels; and give them different names according to their different degrees of power and knowledge. *Hierarchy* likewise denotes the subordination of the clergy, ecclesiastical polity, or the constitution and government of the Christian church considered as a society.

HIERES, a town of France, in the department of Var and late province of Provence, seated in a pleasant fruitful country; but its harbour being choked up, it is now much decayed. In no other part of France is nature so uniformly beautiful. During great part of the winter, the verdure is as fine as in the spring; and in many gardens, green peas may be gathered. The winters, however, have been sometimes very severe; particularly in 1709, 1768, and 1789. This town is the birth-place of Maffillon, the celebrated French preacher. It is 12 miles E. of Toulon, and 350 S. by E. of Paris. E. lon. 6. 20. N. lat. 43. 5.

HIERES, islands of France, on the coast of Provence. They are four in number; namely, Porquerollos, Porteros, and Bagueau, which are inhabited, and the isle of Titan, the largest of them, which is capable of cultivation. Between these islands and the continent, is the road of Hieres, which is so capacious and excellent, that it has afforded shelter for the largest squadrons, and no instance of a shipwreck has ever occurred here. It is defended by three forts.

HIEROCLES, a cruel persecutor of the Christians, and a violent promoter of the persecution under Dioclesian, flourished in 302. He wrote some books against the Christian religion; in which he pretends some inconsistencies in the Holy Scriptures, and compares the miracles of Apollonius Tyaneus to those of our Saviour. He was refuted by Lactantius and Eusebins. The remains of his works were collected into one volume octavo, by bishop Pearson; and published in 1654, with a learned dissertation prefixed to the work.

HIEROCLES, a Platonic philosopher of the fifth century, taught at Alexandria, and was admired for his eloquence. He wrote seven books upon Providence and Fate; and dedicated them to the philosopher Olympiodorus, who by his embassies did the Romans great services under the emperors Honorius and Theodosius the younger. But these books are lost, and we only know them by the extracts in Photius. He wrote also a

3 R

Commentary upon the golden verses of Pythagoras; which is still extant, and has been several times published with those verses.

HIEROGLYPHICS, in antiquity, mystical characters, or symbols, in use among the Egyptians, and that as well in their writings as inscriptions; being the figures of various animals, the parts of human bodies, and mechanical instruments. The word is composed of the Greek *ἱερός* *sacer*, "holy," and *γλυφίζω* *sculpero*, "to engrave;" it being the custom to have the walls, doors, &c. of their temples, obelisks, &c. engraven with such figures. Hieroglyphics are properly emblems or signs of divine, sacred, or supernatural things; by which they are distinguished from common symbols, which are signs of sensible and natural things. Hermes Trismegistus is commonly esteemed the inventor of hieroglyphics: he first introduced them into the heathen theology, from whence they have been transplanted into the Jewish and Christian. Sacred things, says Hippocrates, should only be communicated to sacred persons. Hence it was that the ancient Egyptians communicated to none but their kings and priests, and those who were to succeed to the priesthood and the crown, the secrets of nature, and the secrets of their morality and history; and this they did by a kind of cabbala, which, at the same time that it instructed them, only amused the rest of the people. Hence the use of hieroglyphics, or mystic figures, to veil their morality, politics, &c. from profane eyes. This author, it may be observed, and many others, do not keep to the precise character of a hieroglyphic, but apply it to profane as well as divine things.

Hieroglyphics are a kind of real characters, which do not only denote, but in some measure express, the things. Thus, according to Clemens Alexandrinus, Strom. v. a lion is the hieroglyphic of strength and fortitude; a bullock, of agriculture; a horse, of liberty; a sphinx, of subtilty, &c.

Such is the opinion that has generally been embraced, both by ancient and modern writers, of the origin and use of hieroglyphics. It has been almost uniformly maintained, that they were invented by the Egyptian priests in order to conceal their wisdom from the knowledge of the vulgar; but the late bishop Warburton hath, with much ingenuity and learning, endeavoured to show that this account is erroneous.

According to this writer, the first kind of hieroglyphics were mere pictures, because the most natural way of communicating our conceptions by marks or figures was by tracing out the images of things; and this is actually verified in the case of the Mexicans, whose only method of writing their laws and history was by this picture writing. But the hieroglyphics invented by the Egyptians were an improvement on this rude and inconvenient essay towards writing, for they contrived to make them both pictures and characters. In order to effect this improvement, they were obliged to proceed gradually, by first making the principal circumstance of the subject stand for the whole; as in the hieroglyphics of Horapollo, which represent a battle of two armies in array by two hands, one holding a shield and the other a bow: then putting the instrument of the thing, whether real or metaphorical, for the thing itself, as an eye and sceptre to represent a monarch, a ship and pilot the governor of the universe, &c.; and finally, by making one thing stand for or represent another, where their observations of nature or traditional superstitions led them to discover or imagine any resemblance: thus, the universe was designed by a serpent in a circle, whose variegated spots denoted the stars; and a man who had nobly surmounted his misfortune was represented by the skin of the hyæna, because this was supposed to furnish an invulnerable defence in battle.

The Chinese writing, he observes, was the next kind of improvement in the use of hieroglyphics. The Egyptians joined characteristic marks to images; the Chinese threw out the images

and retained only the contracted marks, and from these marks proceeded letters. The general concurrence of different people in this method of recording their thoughts can never be supposed to be the effect of imitation, sinister views, or chance; but must be considered as the uniform voice of nature speaking to the rude conceptions of mankind: for not only the Chinese of the East, the Mexicans of the West, and the Egyptians of the South, but the Scythians likewise of the North, and the intermediate inhabitants of the earth, viz. the Indians, Phœnicians, Ethiopians, &c. used the same way of writing by picture and hieroglyphic.

The bishop farther shows, that the several species of hieroglyphic writing took their rise from nature and necessity, and not from choice and artifice, by tracing at large the origin and progress of the art of speech. He proceeds to show how in process of time the Egyptian hieroglyphics came to be employed for the vehicle of mystery. They used their hieroglyphics two ways; the one more simple, by putting the part for the whole, which was the curiologic hieroglyphic; and the other more artificial, by putting one thing of resembling qualities for another, called the *tropical hieroglyphic*: thus the moon was sometimes represented by a half circle and sometimes by a cynocephalus. They employed their proper hieroglyphics to record openly and plainly their laws, policies, public morals, and history, and all kinds of civil matters: this is evident from their obelisks, which were full of hieroglyphic characters, designed to record singular events, memorable actions, and new inventions; and also from the celebrated inscription on the temple of Minerva at Sais, where an infant, an old man, a hawk, a fish, and a river-horse, expressed this moral sentence: "All you who come into the world and go out of it, know this, that the gods hate impudence." However, the tropical hieroglyphics, which were employed to divulge, gradually produced symbols which were designed to secrete or conceal: thus Egypt was sometimes expressed by the crocodile, sometimes by a burning censer with a heart upon it; where the simplicity of the first representation and the abstruseness of the latter show, that the one was a tropical hieroglyphic for communication, and the other a tropical symbol invented for secrecy.

Enigmatic symbols were afterwards formed by the assemblage of different things, or of their properties that were less known; and though they might have been intelligible at first, yet when the art of writing was invented, hieroglyphics were more generally disused; the people forgot the signification of them; and the priests, retaining and cultivating the knowledge of them because they were the repositories of their learning and history, at length applied them to the purpose of preserving the secrets of their religion.

Symbols were the true original of animal worship in Egypt, as Sir John Marsham conjectured, *Can. Chron.* p. 58. because in these hieroglyphics was recorded the history of their greater deities, their kings, and law-givers, represented by animals and other creatures. The symbol of each god was well known and familiar to his worshippers, by means of the popular paintings and engravings on their temples and other sacred monuments; so that the symbol presenting the idea of the god, and that idea exciting sentiments of religion, it was natural for them, in their addresses to any particular god, to turn to his representative mark or symbol; especially when we consider farther, that the Egyptian priests feigned a divine original for hieroglyphic characters, in order to increase the veneration of the people for them. These would of course bring on a relative devotion to these symbolic figures, which, when it came to be paid to the living animal, would soon terminate in an ultimate worship.

Another consequence of the sacredness of the hieroglyphic characters was, that it disposed the more superstitious to engrave them on gems, and wear them as amulets or charms. This magical

abuse seems not to have been much earlier than the established worship of the god Serapis, which happened under the Ptolemies, and was first brought to the general knowledge of the world by certain Christian heretics and natives of Egypt, who had mixed a number of Pagan superstitions with their Christianity. These gems, called *abraxas*, are frequently to be met with in the cabinets of the curious, and are engraven with all kinds of hieroglyphic characters. To these abraxas succeeded the talismans.

HIEROGRAMMATISTS, (*Hierogrammatei*), i. e. *holy registers*, were an order of priests among the ancient Egyptians, who presided over learning and religion. They had the care of the hieroglyphics, and were the expositors of religious doctrines and opinions. They were looked upon as a kind of prophets; and it is pretended, that one of them predicted to an Egyptian king, that an Israelite (meaning Moses), eminent for his qualifications and achievements, would lessen and depress the Egyptian monarchy. The hierogrammatei were always near the king, to assist him with their information and counsels. The better to fit them for this, they made use of the skill and knowledge they had acquired in the stars and the motions of the heavenly lights, and even of the writings of their predecessors, wherein their functions and duties were delivered. They were exempted from all civil employments, were reputed the first persons in dignity next the king, and bore a kind of sceptre in form of a ploughshare. After Egypt became a province of the Roman empire, the hierogrammatei sunk into neglect.

HIEROMANCY, in antiquity, that species of divination which predicted future events from observing the various things offered in sacrifice. See **DIVINATION** and **SACRIFICE**.

HIEROMNEMON, among the ancient Greeks, signified a delegate chosen by lot, and sent to the great council of the Amphictyons, where he was to take care of what concerned religion. The hieromnemonies were reckoned more honourable than the other members of that assembly, the general meetings of which were always summoned by them, and their names were prefixed to the decrees made by that council.

HIEROMNEMON, composed of *ἱερός* "sacred," and *μνημων* "one who advertises or puts in mind of," an officer in the ancient Greek church, whose principal function was to stand behind the patriarch at the sacraments, ceremonies, &c. and show him the prayers, psalms, &c. which he was to rehearse. He also clothed the patriarch in his pontifical robes, and assigned the places of all those who had a right to be around him when seated on his throne, as the master of the ceremonies now does to the pope.

HIERONYMUS. See **JEROME**.

HIEROPHANTES, or **HIEROPHANTA**, from *ἱερός* *holy*, and *φαίνω* *I appear*, in antiquity, a priest among the Athenians. The hierophantes was properly the chief person that officiated in the Eleusinia, that great solemnity sacred to Ceres. This office was first executed by Eumolpus, and continued in his family for 1200 years, though when any person was appointed to this dignity, he was required always to live in celibacy. St. Jerome says, that the hierophantes extinguished the fire of lust by drinking cicuta or the juice of hemlock, or even by making themselves eunuchs. Apollodorus observes, that it was the hierophantes who instructed persons initiated into their religion in the mysteries and duties thereof, and that it was hence he derived his name: for the same reason he was called *prophetes*, "the prophet." He had officers under him to do the same thing, or to assist him therein, who were also called *prophetes* and *exegetes*, i. e. "explainers of divine things." To the hierophantes it belonged to dress and adorn the statues of the gods, and to bear them in processions and solemn ceremonies.

HIEROPHYLAX, an officer in the Greek church, who was

guardian or keeper of the holy utensils, vestments, &c. answering to our sacrista or vestry-keeper.

HIESMES, a town of France, in the department of Orne and late province of Normandy, seated on a barren mountain, 10 miles from Seez, and 90 W. of Paris.

HIGH, a term of relation, importing one thing's being superior or above another: thus we say, a *high* mountain, the *high* court of parliament, *high* relieve, &c.

HIGH, in music, is sometimes used in the same sense with *loud*, and sometimes in the same sense with *acute*.

HIGH Dutch is the German tongue in its greatest purity, as it is spoken in Misnia, &c.

HIGH Operation, in surgery, a method of extracting the stone; thus called, because the stone was taken out at the upper part of the bladder, above the pubis. This operation is now, very properly, superseded by one much safer and more successful.

HIGH-Places, were eminences on which the heathens used to worship their gods, chosen for that purpose as being supposed to be nearer heaven, their constant residence. The Jews are frequently blamed for their attachment to high-places, after the manner of the Gentiles; though their *prosecutions* were frequently upon mountains with groves planted about them. Where high-places are reprobated in scripture, therefore, we should understand them as abused and prostituted to idolatrous purposes. Before the temple was built, there was indeed nothing in the high-places very contrary to the law, provided God only was adored there, and that no incense or victims were offered to idols. Under the judges they seem to have been tolerated; and Samuel offered sacrifices in several places besides the tabernacle, where the ark was not present. Even in David's time, they sacrificed to the Lord at Shilo, Jerusalem, and Gibeon; but after the temple was built, and a place prepared for the fixed settlement of the ark, it was no more allowed of to sacrifice out of Jerusalem. Solomon, in the beginning of his reign, went a pilgrimage to Gibeon; but from that time we see no lawful sacrifices offered out of the temple.

HIGH-Priest. See **PONTIFEX** and **PRIEST**.

HIGH-Way, a free passage for the king's subjects; on which account it is called *the king's high way*, though the freehold of the soil belong to the owner of the land. Those ways that lead from one town to another, and such as are drift or cart ways, and are for all travellers in great roads, or that communicate with them, are high ways only; and as to their reparation, are under the care of commissioners and surveyors.

HIGH-WAY-MEN, are robbers on the high way; for the apprehending and taking of whom, a reward of 40*l.* is given by the statute of 4 and 5 W. & M. to be paid within a month after conviction by the sheriff of the county; to which the statute 8 Geo. II. cap. 16. superadds 10*l.* to be paid by the hundred indemnified by such taking.

HIGHAM FERRERS, a borough of Northamptonshire, with a great market on Thursday and Saturday. It is seated on an ascent, on the river Nen, and sends one member to parliament. It had formerly a castle, now in ruins; and is 35 miles E. S. E. of Coventry, and 66 N. N. W. of London. W. lon. 0. 40. N. lat. 52. 19.

HIGHGATE, a large village in Middlesex, seated on a hill E. of that of Hampstead; on which account, these two hills have been poetically called "the sister-hills." Here lord chief-baron Cholmondeley built a free-school in 1562, which was enlarged in 1570, by Edwin Sandys, bishop of London, who added a chapel to it, which is a chapel of ease to the two parishes of St. Pancras and Hornsey. Highgate is four miles N. by W. of London.

HIGHLANDERS, a general appellation for the inhabitants of the mountainous parts of any country. In Britain, the name

is appropriated to the people who inhabit the mountainous parts of Scotland, to the north and north-west, including those of the Hebrides or Western Isles. They are a branch of the ancient Celtæ; and undoubtedly the descendants of the first inhabitants of Britain, as appears from the many monuments of their language still retained in the most ancient names of places in all parts of the island. The Highlanders, or, as they are often termed by ancient authors, the *Caledonians*, were always a brave, warlike, and hardy race of people; and, in the remotest times, seem to have possessed a degree of refinement in sentiment and manners then unknown to the other nations that surrounded them. This appears not only from their own traditions and poems, but also from the testimony of many ancient authors. This civilization was probably owing in a great measure to the order of the bards, or Druids, and some other institutions peculiar to this people.

The ancient Highlanders lived in the hunting state till some time after the era of Fingal, who was one of their kings towards the close of the third century. For some ages after that, they turned their chief attention to the pastoral life, which afforded a less precarious subsistence. Till of late, agriculture in most parts of the Highlands made but little progress.

The Highlanders always enjoyed a king and government of their own, till Kenneth M'Alpine (anno 845), after having subdued the Pictish kingdom, transferred thither the seat of royalty. This event proved very unfavourable to the virtues of the Highlanders, which from this period began to decline. The country, no longer awed by the presence of the sovereign, fell into anarchy and confusion. The chieftains began to extend their authority, to form factions, and to foment divisions and feuds between contending clans. The laws were either too feeble to bind them, or too remote to take notice of them. Hence sprung all those evils which long disgraced the country, and disturbed the peace of its inhabitants. Robbery or plunder, provided it was committed on any one of an adverse clan or tribe, was countenanced and authorized; and their reprisals on one another were perpetual. Thus quarrels were handed down from one generation to another, and the whole clan were bound in honour to espouse the cause of every individual that belonged to it. By this means the genius of the people was greatly altered; and the Highlanders of a few ages back were almost as remarkable for their irregular and disorderly way of life as their predecessors were for their civilization and virtue. It is from not attending to this distinction between the ancient Highlanders and their posterity in later times, that many have doubted the existence of those exalted virtues ascribed by their poets to the more ancient inhabitants of the country. But now that the power of the chieftains is again abolished, law established, and property secured, the genius of the people (where it is not hindered by some other extraneous cause) begins again to show itself in its genuine colours; and many of their ancient virtues begin to shine with conspicuous lustre. Justice, generosity, honesty, friendship, peace, and love, are perhaps no where more cultivated than among this people. But one of the strongest features which marked the character of the Highlanders in every age, was their hospitality and benevolence to strangers. At night the traveller was always sure to find a hearty welcome in whatever house he should go to; and the host thought himself happier in giving the entertainment than the guest in receiving it. Even with regard to their enemies, the laws of hospitality were observed with the most sacred regard. They who fought against each other in the day, could join in the night feast, and even sleep together, in the same house. From the same principle, they were, in most other cases, so faithful to their trust, that they rarely betrayed any confidence reposed in them. A promise they thought as binding as an oath, and held it equally inviolable and sacred.

The Caledonians in all ages have been much addicted to poetry and music. The poems of Ossian, so universally repeated, and so highly esteemed by every Highlander, are a strong proof of the early proficiency of this people in the poetical art. Even to this day, notwithstanding the many disadvantages they labour under, the most illiterate of either sex discover frequently a genius for poetry, which often breaks forth in the most natural and simple strains, when love, grief, joy, or any other subject of song, demands it. Wherever their circumstances are so easy as to allow them any respite from toil, or any cheerfulness of spirits, a good portion of their time, especially of the winter nights, is still devoted to the song and tale. This last species of composition is chiefly of the novel-kind, and is handed down by tradition like their poems. It was the work of the bards; and proved, while they existed, no contemptible entertainment. But since the extinction of that order, both the Gaelic poems and tales are in a great measure either lost or adulterated.—The genius and character of the Gaelic poetry is well known. It is tender, simple, beautiful, and sublime.

Among the ancient Highlanders, the harp was the chief instrument of music. It suited the mildness of their manners, and was well adapted to the peace and quiet which they enjoyed under their own kings. In a later period, however, when the constant quarrels of their chiefs, and the endless feuds of contending clans, turned all their thoughts to war, it was forced to give place to the bag-pipe, an instrument altogether of the martial kind, and therefore well suited to the state of the country at that time. But ever since the cause which had brought this instrument in vogue has ceased to operate, the attention to it has been on the decline; so that the harp, with very little encouragement, might again resume the seat from which it was once expelled.—The most, and especially the oldest of the Highland music, having been composed to the harp, is of a soft, tender, and elegiac cast, as best suited to the genius of that instrument. These pieces are generally expressive of the passions of love and grief. Other pieces, which were composed in their state of war, and adapted to a different instrument, are altogether bold and martial. And many are of a sprightly and cheerful cast, the offspring of mirth, and the sport of fancy in the season of festivity. Many of these last are of the chorus kind; and are sung in almost all the exercises in which a number of people are engaged, such as rowing, reaping, felling, &c. The time of these pieces is adapted to the exercises to which they are respectively sung. They greatly forward the work, and alleviate the labour. The particular music which is generally used by the Highlanders in their dances is well known by the name of *Strathsley reels*.

The language of the Highlanders is still the Gaelic; which, with many of their customs and manners, has been secured to them by their mountains and fastnesses, amidst the many revolutions which the rest of the island has undergone in so long a course of ages. The Gaelic seems to be the oldest and purest dialect which remains of the Celtic, as appears from its approaching the nearest to the names of places, &c. which that language left in most countries where it prevailed, and from its most obvious affinity to those tongues, ancient or modern, which have been in any measure derived from the old Celtic. The Gaelic has all the marks of an original and primitive language. Most of the words are expressive of some property or quality of the objects which they denote. This, together with the variety of its sounds (many of which, especially of those that express the soft and mournful passions, are peculiar to itself), renders it highly adapted for poetry. It is generally allowed to have been the language of court, in Scotland, till the reign of Malcolm Canmore. The Gaelic epithet of *Can-more*, or "large head," by which this king is distinguished, seems to intimate so much. In some particular parliaments at least, it was spoken much

later, as in that held by Robert the Bruce at Ardehattan. That it has been formerly a good deal cultivated, appears from the style and complexion of its poems and tales, and from several ancient MSS. that have come down to the present times. To strangers the Gaelic has a forbidding aspect, on account of the number of its quiescent consonants (which are retained to mark the derivation of words and their variation in case and tense), but its sound is abundantly musical and harmonious, and its genius strong and masculine. Its alphabet consists of 18 letters, of which one is an aspirate, 12 are consonants, and five are vowels.

The Highlanders have begun of late years to apply to learning, agriculture, and especially to commerce, for which their country, every where indented with arms of the sea, is peculiarly favourable. Cattle is the chief staple of the country; but it produces more grain than would supply its inhabitants, if so much of it were not consumed in whisky. The natives are beginning to avail themselves of their mines, woods, wool, and fisheries; and by a vigorous application, with the due encouragement of government, may become a prosperous and useful people.

The Highlanders are of a quick and penetrating genius, strongly tinctured with a thirst of knowledge, which disposes them to learn any thing very readily. They are active, persevering, industrious, and economical. They are remarkably bold and adventurous, which qualifies them for being excellent seamen and soldiers. They are generally of a middle size, rather above it than otherwise; their eyes are lively, their features distinctly marked, and their persons strong and well made. Their countenance is open and ingenuous, and their temper frank and communicative.

HIGHMORE (Joseph, Esq.) an eminent painter, was born in the parish of St. James, Garlick-hithe, London, June 13, 1692, being the third son of Mr. Edward Highmore a coal-merchant in Thames-street. Having such an early and strong inclination to painting, that he could think of nothing else with pleasure, his father endeavoured to gratify him in a proposal to his uncle, who was serjeant-painter to king William, and with whom Mr. (afterwards Sir James) Thornhill had served his apprenticeship. But this was afterwards for good reasons declined, and he was articled as clerk to an attorney, July 18th 1707; but so much against his own declared inclination, that in about three years he began to form resolutions of indulging his natural disposition to his favourite art, having continually employed his leisure hours in designing, and in the study of geometry, perspective, architecture, and anatomy, but without any instructors except books. In fact, as might be expected, he arrived at great perfection and success in the exercise of his favourite art, and painted many pictures which were not only valued highly in his own time, but are now the objects of admiration to painters.

On the first institution of the academy of painting, sculpture, &c. in London, in the year 1753, he was elected one of the professors; an honour which, on account of his many avocations, he desired to decline. In 1754 he published "A critical examination of those two Paintings [by Rubens] on the Ceiling of the Banqueting house at Whitehall, in which Architecture is introduced, so far as relates to Perspective; together with the Discussion of a Question which has been the Subject of Debate among Painters:" printed in 4to. In the solution of this question, he proved that Rubens and several other great painters were mistaken in the practice, and Mr. Kirby and several other authors in the theory. And in the 17th volume of the Monthly Review, he animadverted (anonymously) on Mr. Kirby's unwarrantable treatment of Mr. Ware, and detected and exposed his errors, even when he exults in his own superior science. Of the many portraits which Mr. High-

more painted, in a large practice of 46 years (of which several have been engraved), it is impossible and useless to discuss particulars. Some of the most capital in the historical branch, which was then much less cultivated than it is at present, shall only be mentioned, viz. "Hagar and Ishmael," a present to the Foundling-hospital: "The good Samaritan," painted for Mr. Shepherd of Campsey Ash: "The finding of Moses," purchased at his sale by colonel (now general) Lister: "The Harlowe family, as described in Clarissa," now in the possession of Thomas Watkinson Payler, Esq. at Heden in Kent: "Clarissa," the portrait mentioned in that work: "The Graces unveiling Nature," drawn by memory from Rubens: "The Clementina of Grandison, and the queen-mother of Edward IV. with her younger son, &c. in Westminster-abbey;" the three last in the possession of his son.

Mr. Highmore was the author of various publications which were well received; but his most capital work of the literary kind was his "Practice and Perspective, on the principles of Dr. Brook Taylor, &c." written many years before, but not published till 1763, in one vol. 4to. This not only evinced his scientific knowledge of the subject, but removed, by its perspicuity, the only objection that can be made to the system of Dr. Taylor. His "Epistle to an eminent Painter;" published in the Gentleman's Magazine for 1778, shows that his talents were by no means impaired at the age of 86. Indeed he retained them to the last, and had even strength and spirit sufficient to enable him to ride out daily on horseback the summer before he died. A strong constitution, habitual temperance, and constant attention to his health in youth as well as in age, prolonged his life, and preserved his faculties to his 88th year, when he declined gradually, and died March 3, 1780. He was interred in the south aisle of Canterbury cathedral, leaving one son, Anthony, educated in his own profession; and a daughter, named Susanna.

His abilities as a painter appear in his works, which will not only be admired by his contemporaries, but by their posterity; as his tints, like those of Rubens and Vandyck, instead of being impaired, are improved by time, which some of them have now withstood above 60 years. His idea of beauty, when he indulged his fancy, was of the highest kind; and his knowledge of perspective gave him great advantages in family-pieces, of which he painted more than any one of his time. He could take a likeness by memory as well as by a sitting, as appears by his picture of the duke of Lorraine (afterwards emperor), which Faber engraved; and those of king George II. (in York-assembly-room); queen Caroline, the two Miss Gunning's, &c. Like many other great painters, he had "a poet for his friend," in the late Mr. Browne. There was likewise a poem addressed to him in 1726, by the Rev. Mr. Bunce, at that time of Trinity-hall, Cambridge, who succeeded Mr. Highmore, and in 1780 was vicar of St. Stephen's near Canterbury.

HIGHNESS, a quality or title of honour given to princes. The kings of England and Spain had formerly no other title but that of *highness*; the first till the time of James I. and the second till that of Charles V. The petty princes of Italy began first to be complimented with the title of *highness* in the year 1630. In France, the duke of Orleans assumed the title of *royal highness* in the year 1631, to distinguish himself from the other princes. The princes of the blood in England are each distinguished in the same way.

HIGHWORTH, a town of Wilts, with a market on Wednesday. It is seated on the top of a hill, which stands in a rich plain, near the vale of White Horse. It is 36 miles N. of Salisbury, and 77 W. of London.

HILARIA, in antiquity, feasts celebrated every year by the Romans on the 8th of the calends of April, or the 25th of March, in honour of Cybele the mother of the gods. The li-

laria were solemnized with great pomp and rejoicing. Every person dressed himself as he pleased, and took the marks or badges of whatever dignity or quality he had a fancy for. The statue of the goddess was carried in procession through the streets of the city, accompanied by multitudes in the most splendid attire. The day before the festival was spent in tears and mourning. Cybele represented the earth, which at this time of the year begins to feel the kindly warmth of the spring; so that this sudden transition from sorrow to joy was an emblem of the vicissitude of the seasons, which succeeded one another.

The Romans took this feast originally from the Greeks, who called it *αναΐσις*, q. d. *ascensus*; the eve of that day they spent in tears and lamentations, and thence denominated it *καταΐσις*, *descensus*. Afterwards, the Greeks took the name *Ιλαρία* from the Romans; as appears from Photius, in his extract of the life of the philosopher Isidore.

Casaubon maintains, that beside this particular signification, the word *hilaria* was also a general name for any joyful or festival day, whether public or private and domestic. But Salmasius does not allow of this. Tristram, tom. i. p. 482, distinguishes between *hilaria* and *hilarie*. The former, according to him, were public rejoicings; and the latter, prayers made in consequence thereof; or even of any private feast or rejoicing, as a marriage, &c. The public lasted several days; during which, all mourning and funeral ceremonies were suspended.

HILARIUS, an ancient father of the Christian church, who flourished in the 4th century. He was born, as St. Jerome informs us; at Poitiers, of a good family; who gave him a liberal education in the Pagan religion, and which he did not forsake till he was arrived at maturity. He was advanced to the bishopric of Poitiers in the year 355, according to Baronius; and became a most zealous champion for the orthodox faith, particularly against the Arians, who were at that time gaining ground in France. He assembled several councils there, in which the determinations of the synods of Rimini and Seleucia were condemned. He wrote a treatise concerning synods; and a famous work in 12 books on the Trinity, which is much admired by the orthodox believers. He died in the latter end of the year 367. His works have been many times published; but the last and best edition of them was given by the Benedictines at Paris in 1693.

HILARODI, in the ancient music and poetry, a sort of poets among the Greeks, who went about singing little gay poems or songs, somewhat graver than the Ionic pieces, accompanied with some instrument. From the streets they were at last introduced into tragedy, as the *magodi* were into comedy. They appeared dressed in white, and were crowned with gold. At first they wore shoes; but afterwards they assumed the *crepida*, being only a sole tied over with a strap.

HILARY-TERM. See TERM.

HILDBURGHAUSEN, a town of Germany, in a duchy of the same name, in the circle of Franconia and principality of Cobourg. It is seated on the Werra, and is a handsome well-built place, subject to the duke of Saxe-Hildburghausen, who has a palace here. It is 22 miles N. by W. of Cobourg. E. lon. 11. 3. N. lat. 50. 53.

HILDESHEIM, a strong town of Germany, in the circle of Lower Saxony, and bishopric of the same name. It is free and imperial; and in the cathedral is the statue of Herman, the celebrated German chief. It is divided into the old and new towns, each of which has its separate council; and its inhabitants are a mixture of Lutherans and Papists. It is seated on the Irneste, 17 miles S. S. E. of Hanover. E. lon. 10. 10. N. lat. 52. 10.

HILL, a term denoting any considerable eminence on the earth's surface. It is sometimes synonymous with the word *mountain*; though generally it denotes only the lesser eminences,

the word *mountain* being particularly applied to the very largest. See MOUNTAIN.

HILL (Aaron), a poet of considerable eminence, the son of a gentleman of Malmesbury-abbey in Wiltshire, was born in 1685. His father's imprudence having cut off his paternal inheritance, he left Westminster-school at 14 years of age; and embarked for Constantinople, to visit lord Paget the English ambassador there, who was his distant relation. Lord Paget received him with surprise and pleasure, provided him a tutor, and sent him to travel: by which opportunity he saw Egypt, Palestine, and a great part of the east; and returning home with his noble patron, visited most of the courts of Europe. About the year 1709 he published his first poem intitled *Camillus*, in honour of the earl of Peterborough who had been general in Spain; and being the same year made master of Drury-lane theatre, he wrote his first tragedy, *Elfred*, or the *Fair Inconstant*. In 1710 he became master of the opera-house in the Hay-market; when he wrote an opera called *Rinaldo*, which met with great success, being the first that Mr. Handel set to music after he came to England. Unfortunately for Mr. Hill, he was a projector as well as poet, and in 1715 obtained a patent for extracting oil from beech-nuts; which undertaking, whether good or bad, miscarried after engaging three years of his attention. He was also concerned in the first attempt to settle the colony of Georgia; from which he never reaped any advantage: and in 1728 he made a journey into the Highlands of Scotland, on a scheme of applying the woods there to ship-building; in which also he lost his labour. Mr. Hill seems to have lived in perfect harmony with all the writers of his time, except Mr. Pope, with whom he had a short paper-war, occasioned by that gentleman's introducing him in the *Dunciad*, as one of the competitors for the prize offered by the goddess of Dullness, in the following lines:

"Then *Hill* essay'd; scarce vanish'd out of sight,
"He buoys up instant, and returns to light;
"He bears no token of the fabler streams,
"And mounts far off among the Swans of Thames."

This, though far the gentlest piece of satire in the whole poem, and conveying at the same time an oblique compliment, roused Mr. Hill to take some notice of it; which he did by a poem written during his peregrination in the north, intitled, "The progress of wit, a caveat for the use of an eminent writer;" which he begins with the following eight lines, in which Mr. Pope's too well-known disposition is elegantly, yet very severely characterized:

"Tuneful *Alexis* on the Thames' fair side,
"The Ladies' play-thing and the Muses' pride;
"With merit popular, with wit polite,
"Easy tho' vain, and elegant tho' light;
"Desiring and deserving others praise,
"Poorly accepts a Fame he ne'er repays:
"Unborn to cherish, sneakingly approves;
"And wants the soul to spread the worth he loves."

The *sneakingly approves*, in the last couplet, Mr. Pope was much affected by; and indeed through their whole controversy afterwards, in which it was generally thought that Mr. Hill had much the advantage, Mr. Pope seems rather to express his repentance by denying the offence, than to vindicate himself supposing it to have been given. Besides the above poems, Mr. Hill, among many others, wrote one, called *The Northern Star*, upon the actions of Czar Peter the Great; for which he was several years afterwards complimented with a gold medal from the empress Catharine, according to the Czar's desire before his death. He likewise altered some of Shakespear's plays, and translated some of Voltaire's. His last production was *Me-*

rope; which was brought upon the stage in Drury-lane by Mr. Garrick. He died on the 8th of February 1749, as it is said, in the very minute of the earthquake; and after his decease, four volumes of his works in prose and verse were published in octavo, and his dramatic works in two volumes.

HILL (Sir John), a voluminous writer, was originally bred an apothecary; but his marrying early, and without a fortune, made him very soon look round for other resources than his profession. Having, therefore, in his apprenticeship, attended the botanical lectures of the company, and being possessed of quick natural parts, he soon made himself acquainted with the theoretical as well as practical parts of botany; from whence being recommended to the late duke of Richmond and lord Petre, he was by them employed in the inspection and arrangement of their botanic gardens. Assisted by the liberality of these noblemen, he executed a scheme of travelling over the kingdom, to collect the most rare and uncommon plants; which he afterward published by subscription: but after great researches and uncommon industry, this undertaking turned out by no means adequate to his expectation. The stage next presented itself, as a soil in which genius might stand a chance of flourishing: but after two or three unsuccessful attempts, it was found he had no pretensions either to the sock or buskin; which once more reduced him to his botanical pursuits, and his business as an apothecary. At length, about the year 1746, he translated from the Greek a small tract, written by Theophrastus, on Gems, which he published by subscription; and which, being well executed, procured him friends, reputation, and money. Encouraged by this, he engaged in works of greater extent and importance. The first he undertook was A general natural history, in 3 vols. folio. He next engaged, in conjunction with George Lewis Scott, Esq. in furnishing a Supplement to Chambers's Dictionary. He at the same time started the British Magazine; and while he was engaged in a great number of these and other works, some of which seemed to claim the continued attention of a whole life, he carried on a daily essay, under the title of *Inspector*. Amidst this hurry of business, Mr. Hill was so laborious and ready in all his undertakings, and was withal so exact an economist of his time, that he scarcely ever missed a public amusement for many years: where, while he relaxed from the severer pursuits of study, he gleaned up articles of information for his periodical works. It would not be easy to trace Mr. Hill, now Dr. Hill (for he procured a diploma from the college of St. Andrew's), through all his various pursuits in life. A quarrel he had with the Royal Society, for being refused as a member, which provoked him to ridicule that learned body, in A review of the works of the Royal Society of London, 4to, 1751; together with his overwriting himself upon all subjects without reserve; made him sink in the estimation of the public nearly in the same pace as he had ascended. He found as usual, however, resources in his own invention. He applied himself to the preparation of certain simple medicines: such as the essence of water-dock, tincture of valerian, balsam of honey, &c. The well-known simplicity of these medicines made the public judge favourably of their effects, insomuch that they had a rapid sale, and once more enabled the doctor to figure in that style of life ever so congenial to his inclination. Soon after the publication of the first of these medicines, he obtained the patronage of the earl of Bute, through whose interest he acquired the management of the royal gardens at Kew, with an handsome salary: and to wind up the whole of an extraordinary life, having, a little before his death, seized an opportunity to introduce himself to the knowledge of the king of Sweden, that monarch invested him with one of the orders of his court, which title he had not the happiness of enjoying above two years. He died toward the close of the year 1775.

HILLEL, senior, of Babylon, president of the sanhedrim of Jerusalem. He formed a celebrated school there, in which he maintained the oral traditions of the Jews against Shamai, his colleague, whose disciples adhered only to the written law; and this controversy gave rise to the sects of Pharisees and Scribes. He was likewise one of the compilers of the Talmud. He also laboured much at giving a correct edition of the sacred text; and there is attributed to him an ancient manuscript bible, which bears his name. He flourished about 30 years B. C. and died in a very advanced age.

HILLEL, the nasi, or prince, another learned Jew, the grandson of Judas Hakkadosh, or the Saint, the author of the Mishna, lived in the fourth century. He composed a cycle; and was one of the principal doctors of the Gemara. The greatest number of the Jewish writers attribute to him the correct edition of the Hebrew text which bears the name of *Hillel*, which we have already mentioned in the preceding article. There have been several other Jewish writers of the same name.

HILLIA, in botany; a genus of the monogynia order, belonging to the hexandria class of plants; and in the natural method ranking with those of which the order is doubtful. The calyx is hexaphyllous; the corolla cleft in six parts, and very long; the berry inferior, bilocular, and polyspermous.

HILLSBOROUGH, a borough, fair, and post-town, in the county of Down, and province of Ulster, 69 miles from Dublin. Here is a fine seat of the earl of Hillsborough. The town is pleasantly situated and almost new built, in view of Liffburn, Belfast, and Carrickfergus-bay; the church is magnificent, having an elegant spire, as lofty as that of St. Patrick's in Dublin, and seven painted windows. Here is an excellent inn, and a thriving manufacture of muslins. It has three fairs, and sends two members to parliament. This place gives title of earl to the family of Hillsborough. W. lon. 6. 20. N. lat. 54. 30.

HILUM, among botanists, denotes the eye of a bean.

HIMERA, in ancient geography, the name of two rivers in Sicily; one running northwards into the Tuscan sea, now called *Fiume di Termini*; and the other southwards into the Lybian; dividing Sicily into two parts, being the boundary between the Syracusans to the east and Carthaginians to the west; not rising from the same, but from different springs. HIMERA was also the name of a town of Sicily, at the mouth of the Himera, which ran northwards, on its left or west side. It was a colony of Zancle, and afterwards destroyed by the Carthaginians. (Diodorus Siculus.)

HIMERENSES THERMAE, in ancient geography, a town of Sicily, on the east side of that Himera which runs to the north. After the destruction of the town of Himera by the Carthaginians, such of the inhabitants as remained, settled in the same territory, not far from the ancient town, now called Termini. It was made a Roman colony by Augustus.

HIMMALEH-MOUNT, a vast chain of mountains in Asia, which extends from Cabul along the N. of Hindoostan, and appears to be the general boundary of Thibet, through the whole extent from the Ganges to the river Teesta; inclosing between it and Hindoostan, a tract of country, from 100 to 180 miles in breadth, divided into a number of small states, none of which are understood to be either tributaries or feudatories of Thibet; such as Sirinagur, Napaul, &c. This ridge was known to the ancients by the names of Imaus and the Indian Caucasus. The natives now call it Hindoo-Ko (the Indian mountains) as well as Himmaleh; which last is a Sanscrit word, signifying *snowy*; its summit being covered with snow. See GANGES and GOGRA.

HIN, a Hebrew measure of capacity for things liquid, containing the sixth part of an ephah, or one gallon two pints English measure.

HINCHINBROOK ISLAND, one of the New Hebrides in the South Pacific Ocean. E. lon. 168. 33. S. lat. 17. 25.

HINCKLEY, a town of Leicestershire, with a market on Monday. It is adorned with a large handsome church, which has a lofty spire. Hinckley has a considerable stocking manufactory, and is 12 miles S. W. of Leicester, and 91 N. N. W. of London. W. lon. 1. 20. N. lat. 52. 34.

HIND, a female stag in the third year of its age. See CERVUS.

HINDELOPEN, or HINLOPEN, a seaport of the United Provinces, in Friesland, seated on the Zuider-Zee, between Stavoren and Worcum.

HINDON, a small town of Wiltshire in England, which sends two members to parliament. It is situated in E. lon. 2. 14. N. lat. 51. 12.

HINDOOS, or GENTOOS, the inhabitants of that part of India known by the name of *Hindoostan*, or the *Mogul's empire*, who profess the religion of the Bramins, supposed to be the same with that of the ancient Gymnosophists of Ethiopia.

From the earliest period of history these people seem to have maintained the same religion, laws, and customs, which they do at this day: and indeed they and the Chinese are examples of perseverance in these respects altogether unknown in the western world. In the time of Diodorus Siculus they are said to have been divided into seven *casts* or tribes; but the intercourse betwixt Europe and India was in his time so small, that we may well suppose the historian to have been mistaken, and that the same tenacity for which they are so remarkable in other respects has manifested itself also in this. At present they are divided only into four tribes; 1. The Bramin; 2. The Khatri; 3. The Bhyse; and, 4. The Soodera. All these have distinct and separate offices, and cannot, according to their laws, intermingle with each other; but for certain offences they are subject to the loss of their cast, which is reckoned the highest punishment they can suffer; and hence is formed a kind of fifth cast named *Pariahs* on the coast of Coromandel, but in the Sanscrit or sacred language *Chandalas*. These are esteemed the dregs of the people, and are never employed but in the meanest offices. There is besides a general division which pervades the four casts indiscriminately; and which is taken from the worship of their gods *Vishnou* and *Sheevab*; the worshippers of the former being named *Vishnou-bukht*; of the latter, *Sheevab-lukht*.

Of these four casts the bramins are accounted the foremost in every respect; and all the laws have such an evident partiality towards them, as cannot but induce us to suppose that they have had the principal hand in framing them. They are not, however, allowed to assume the sovereignty; the religious ceremonies and the instruction of the people being their peculiar province. They alone are allowed to read the *Veda* or sacred books; the *Khatrics*, or cast next in dignity, being only allowed to hear them read; while the other two can only read the *Saftras*, or commentaries upon them. As for the poor Chandalas, they dare not enter a temple, or be present at any religious ceremony.

In point of precedency the bramins claim a superiority even to the princes; the latter being chosen out of the Khatri or second cast. A rajah will receive with respect the food that is prepared by a brahman, but the latter will eat nothing that has been prepared by any member of an inferior cast. The punishment of a bramini for any crime is much milder than if he had belonged to another tribe; and the greatest crime that can be committed is the murder of a bramini. No magistrate must *desire* the death of one of these sacred persons, or cut off one of his limbs. They must be readily admitted into the presence even of princes whenever they please: when passengers in a boat, they must be the first to enter and to go out; and the wa-

termen must besides carry them for nothing; every one who meets them on the road being likewise obliged to give place to them.

All the priests are chosen from among this order, such as are not admitted to the sacerdotal function being employed as secretaries and accountants. These can never afterwards become priests, but continue to be greatly revered by the other casts.

The Khatri, or second cast, are those from among whom the sovereigns are chosen. The Bhyse or Banians, who constitute the third cast, have the charge of commercial affairs; and the Soodera, or fourth cast, the most numerous of all, comprehend the labourers and artisans. These last are divided into as many classes as there are followers of different arts; all the children being invariably brought up to the profession of their fathers, and it being absolutely unlawful for them ever to alter it afterwards.

No Hindoo is allowed to quit the cast in which he was born upon any account. All of them are very scrupulous with regard to their diet; but the bramins much more so than any of the rest. They eat no flesh, nor shed blood; which we are informed by Porphyry and Clemens Alexandrinus was the case in their time. Their ordinary food is rice and other vegetables, dressed with *ghre* (a kind of butter melted and refined so as to be capable of being kept for a long time), and seasoned with ginger and other spices. The food which they most esteem, however, is milk as coming from the cow; an animal for which they have the most extravagant veneration, inasmuch that it is enacted in the code of Gentoo laws, that any one who exacts labour from a bullock that is hungry or thirsty, or that shall oblige him to labour when fatigued or out of season, is liable to be fined by the magistrates. The other casts, though less rigid, abstain very religiously from what is forbidden them: nor will they eat any thing provided by a person of an inferior cast, or by one of a different religion. Though they may eat some kinds of flesh and fish, yet it is counted a virtue to abstain from them all. None of them are allowed to taste intoxicating liquor of any kind. Quintus Curtius indeed mentions a sort of wine made use of by the Indians in his time; but this is supposed to have been no other than toddy, or the unfermented juice of the cocoa-nut. This, when fermented, affords a spirit of a very unwholesome quality; but it is drunk only by the Chandalas and the lower class of Europeans in the country. So exceedingly bigoted and superstitious are they in their absurd maxims with regard to meat and drink, that some Sepoys in a British ship having expended all the water appropriated to their use, would have suffered themselves to perish for thirst rather than taste a drop of that which was used by the ship's company.

The religion of the Hindoos, by which these maxims are inculcated, and by which they are made to differ so much from other nations, is contained in certain books named *Veda*, *Vedams*, or *Beds*, written in a language called *Sanscrit*, which is now known only to the learned among them. The books are supposed to have been the work, not of the supreme God himself, but of an inferior deity named Brimha. They inform us, that Brama, or Brahma, the supreme God, having created the world by the word of his mouth, formed a female deity named Bawaney, who in an enthusiasm of joy and praise brought forth three eggs. From these were produced three male deities, named *Brimha*, *Vishnou*, and *Sheevab*. Brimha was endowed with the power of creating the things of this world, Vishnou with that of cherishing them, and Sheevah with that of restraining and correcting them. Thus Brimha became the creator of man; and in this character he formed the four casts from different parts of his own body, the Bramins from his mouth, the Khatri from his arms, the Banians from

his belly and thighs, and the Soodera from his feet. Hence, say they, these four different casts derive the different offices assigned them, the Bramins to teach; the Khatry to defend and govern; the Banians to enrich by commerce and agriculture; and the Soodera to labour, serve, and obey. Brama himself endowed mankind with passions, and understanding to regulate them; while Brimha, having created the inferior beings, proceeded to write the Vedans, and delivered them to be read and explained by the Bramins.

The religion of the Hindoos, though involved in superstition and idolatry, seems to be originally pure; inculcating the belief of an eternal and omnipotent Being; their subordinate deities Brimha, Vishnou, and Sheevah, being only representatives of the wisdom, goodness, and power, of the supreme God Brama. All created things they suppose to be *types* of the attributes of Brama, whom they call the *principle of truth*, the *spirit of wisdom*, and the *supreme being*; so that it is probable that all their idols were at first only designed to represent these attributes.

There are a variety of sects among the Hindoos; two great classes we have mentioned already, *viz.* the worshippers of Vishnou and those of Sheevah; and these distinguish themselves remarkably, the former by painting their faces with an horizontal line, the latter by a perpendicular one. There is, however, very little difference in point of religion between these or any other Hindoo sects. All of them believe in the immortality of the soul, a state of future rewards and punishments, and transmigration. Charity and hospitality are inculcated in the strongest manner, and exist among them not only in theory but in practice. "Hospitality (say they) is commanded to be exercised even towards an enemy, when he cometh into thine house; the tree doth not withdraw its shade even from the wood-cutter. Good men extend their charity even to the vilest animals. The moon doth not withhold her light even from the Chandalah." These pure doctrines, however, are intermixed with some of the vilest and most absurd superstitions; and along with the true God they worship a number of inferior ones, each distinguished by a name indicative of his particular attribute.

But besides these inferior deities, the Hindoos have a multitude of *demigods*, who are supposed to inhabit the air, the earth, and the waters, and in short the whole world; so that every mountain, river, wood, town, village, &c. has one of these tutelar deities, as was the case among the western heathens. By nature these demigods are subject to death, but are supposed to obtain immortality by the use of a certain drink named *Amrut*. Their exploits in many instances resemble those of Bacchus, Hercules, Theseus, &c. and in a beautiful epic poem named *Rancyun*, we have an account of the wars of Rain, one of the demigods, with Ravana tyrant of Ceylon.

All these deities are worshipped, as in other countries, by going to their temples, fasting, prayers, and the performance of ceremonies to their honour. They pray thrice a day, at morning, noon, and evening, turning their faces towards the east. They use many ablutions, and, like the Pharisees of old, they always wash before meals. Running water is always preferred for this purpose to such as stagnates. Fruits, flowers, incense, and money, are offered in sacrifice to their idols; but for the dead they offer a kind of cake named *Peenda*; and offerings of this kind always take place on the day of the full moon. Nothing sanguinary is known in the worship of the Hindoos at present, though there is a tradition that it was formerly of this kind; nay, that even human sacrifices were made use of: but if such a custom ever did exist, it must have been at a very distant period. Their sacred writings indeed make mention of bloody sacrifices of various kinds, not excepting even those of the human race: but so many peculiarities are mentioned with regard to the proper victims, that it is almost impossible to find

them. The only instance of bloody sacrifices we find on record among the Hindoos, is that of the buffalo to Bawaney, the mother of the gods.

Among the Hindoos there are two kinds of worship, distinguished by the name of the worship of the *invisible God* and of *idols*. The worshippers of the invisible God are, strictly speaking, deists: the idolaters perform many absurd and unmeaning ceremonies, too tedious to mention, all of which are conducted by a Bramin; and during the performance of these rites, the dancing-women occasionally perform in the court, singing the praises of the Deity in concert with various instruments. All the Hindoos seem to worship the fire; at least they certainly pay a great veneration to it. Bishop Wilkins informs us, that they are enjoined to light up a fire at certain times, which must be produced by the friction of two pieces of wood of a particular kind; and the fire thus produced is made use of for consuming their sacrifices, burning the dead, and in the ceremonies of marriage.

Great numbers of *devotees* are to be met with every where through Hindoostan. Every cast is allowed to assume this way of life excepting the Chandalahs, who are excluded. Those held most in esteem are named *Seniaffes* and *Yogey*s. The former are allowed no other clothing but what suffices for covering their nakedness, nor have they any worldly goods besides a pitcher and staff; but though they are strictly enjoined to meditate on the truths contained in the sacred writings, they are expressly forbidden to argue about them. They must eat but once a day, and that very sparingly, of rice or other vegetables; they must also show the most perfect indifference about hunger, thirst, heat, cold, or any thing whatever relative to this world; looking forward with continual desire to the separation of the soul from the body. Should any of them fail in this extravagant self-denial, he is rendered so much more criminal by the attempt, as he neglected the duties of ordinary life for those of another which he was not able to accomplish. The Yogey are bound to much the same rules, and both subject themselves to the most extravagant penances. Some will keep their arms constantly stretched over their heads till they become quite withered and incapable of motion; others keep them crossed over their breast during life; while others, by keeping their hands constantly shut, have them quite pierced through by the growth of their nails. Some chain themselves to trees or particular spots of ground, which they never quit; others resolve never to lie down, but sleep leaning against a tree: but the most curious penance perhaps on record is that of a Yogey, who measured the distance between Benares and Jaggernaut with the length of his body, lying down and rising alternately. Many of these enthusiasts will throw themselves in the way of the chariots of Vishnou or Sheevah, which are sometimes brought forth in procession to celebrate the feast of a temple, and drawn by several hundreds of men. Thus the wretched devotees are in an instant crushed to pieces. Others devote themselves to the flames, in order to show their regard to some of their idols, or to appease the wrath of one whom they suppose to be offended.

A certain set of devotees are named *Pandarams*; and another on the coast of Coromandel are named *Cary-Patra Pandarams*. The former rub themselves all over with cow-dung, running about the country singing the praises of the god Sheevah whom they worship. The latter go about asking charity at doors by striking their hands together, for they never speak. They accept of nothing but rice; and when they have got as much as will satisfy their hunger, never give themselves any trouble about more, but pass the rest of the day in the shade, in a state of such supine indolence as scarce to look at any object whatever. The Tadinams are another set of mendicants, who sing the incarnations of Vishnou. They have hollow brass rings

found their ankles, which they fill with pebbles; so that they make a considerable noise as they walk; they beat likewise a kind of tabor.

The greatest singularity in the Hindoo religion, however, is, that so far from persecuting those of a contrary persuasion, which is too often the case with other professors, they absolutely refuse even to admit of a profelyte. They believe all religions to be equally acceptable to the Supreme Being: assigning as a reason, that if the Author of the universe preferred one to another, it would have been impossible for any other to have prevailed than that which he approved. Every religion, therefore, they conclude to be adapted to the country where it is established; and that all in their original purity are equally acceptable.

Among the Hindoos, *marriage* is considered as a religious duty; and parents are strictly commanded to marry their children by the time they arrive at eleven years of age at farthest. Polygamy is allowed; but this licence is seldom made use of, unless there should be no children by the first wife. In case the second wife also proves barren, they commonly adopt a son from among their relations.

The Hindoos receive no dower with their wives; but, on the contrary, the intended husband makes a present to the father of his bride. Nevertheless, in many cases, a rich man will choose a poor relation for his daughter; in which case the bride's father is at the expence of the wedding, receives his son-in-law into his house, or gives him a part of his fortune. The bridegroom then quits the dwelling of his parents with certain ceremonies, and lives with his father-in-law. Many formalities take place between the parties even after the match is fully agreed upon; and the celebration of the marriage is attended with much expence; magnificent processions are made, the bride and bridegroom sitting in the same palankeen, attended by their friends and relations; some riding in palankeens, some on horses, and others on elephants. So great is their vanity indeed on this occasion, that they will borrow or hire numbers of these expensive animals to do honour to the ceremony. The rejoicings last several days; during the evenings of which, fireworks and illuminations are displayed, and dancing-women perform their feats; the whole concluding with alms to the poor, and presents to the Bramins and principal guests, generally consisting of shawls, pieces of muslin, and other cloths. A number of other ceremonies are performed when the parties come of age, and are allowed to cohabit together. The same are repeated when the young wife becomes pregnant; when she passes the seventh month without any accident; and when she is delivered of her child. The relations assemble on the tenth day after the birth, to assist at the ceremony of naming the child; but if the bramins be of opinion that the aspect of the planets is at that time unfavourable, the ceremony is delayed, and prayers offered up to avert the misfortune. When the lucky moment is discovered, they fill as many pots with water as there are planets, and offer a sacrifice to them; afterwards they sprinkle the head of the child with water, and the brammin gives it such a name as he thinks best adapted to the time and circumstances; and the ceremony concludes with prayers, presents to the bramins, and alms to the poor. Mothers are obliged to suckle their own children; nor can this duty be dispensed with except in case of sickness. New ceremonies, with presents to the bramins, take place, when a boy comes of age to receive the string which the three first casts wear round their waist.

Boys are taught to read and write by the bramins, who keep *schools* for that purpose throughout the country. They use leaves instead of books, and write with a pointed iron instrument. The leaves are generally those of the palm-tree, which being smooth and hard, and having a thick substance, may be kept for almost any length of time, and the letters are not sub-

ject to grow faint or be effaced. The leaves are cut into slips about an inch broad, and their books consist of a number of these tied together by means of a hole in one end. Sometimes the letters are rubbed over with a black powder, to render them more legible. When they write upon paper, they make use of a small reed. Sometimes they are initiated in writing by making letters upon sand strewed on the floor; and they are taught arithmetic by means of a number of small pebbles. The education of the girls is much more limited; seldom extending farther than the articles of their religion.

Among these people the custom of *burning the dead* prevails universally; and the horrid practice of wives burning themselves along with their deceased husbands was formerly very common, though now much less so. At present it is totally prohibited in the British dominions; and even the Mohammedans endeavour to discountenance a practice so barbarous, though many of their governors are accused of conniving at it through motives of avarice. At present it is most common in the country of the Rajahs, and among women of high rank.

This piece of barbarity is not enjoined by any law existing among the Hindoos; it is only said to be *proper*, and rewards are promised in the next world to those who do so. But though a wife chooses to outlive her husband, she is in no case whatever permitted to marry again, even though the marriage with the former had never been completed. It is unlawful for a woman to burn herself if she be with-child at the time of her husband's decease, or if he died at a distance from her. In the latter case, however, she may do so if she can procure his girdle or turban to be put on the funeral pile along with her. These miserable enthusiasts, who devote themselves to this dreadful death, suffer with the greatest constancy; and Mr. Holwel gives an account of one who, being told of the pain she must suffer (with a view to dissuade her), put her finger into the fire and kept it there for a considerable time; after which she put fire on the palm of her hand, with incense upon it, and fumigated the bramins who were present. Sometimes a chapel is erected on the place where one of these sacrifices has been performed; sometimes it is inclosed, flowers planted upon it, and images set up. In some few places the Hindoos bury their dead; and some women have been known to suffer themselves to be buried alive with their deceased husbands: but the instances of this are still more rare than those of burning. No woman is allowed any inheritance among the Hindoos; so that if a man dies without male issue, his estate goes to his adopted son, or to his nearest relation.

The Hindoos, though naturally mild and timid, will on many occasions meet death with the most heroic intrepidity. An Hindoo who lies at the point of death, will talk of his decease with the utmost composure, and if near the river Ganges, will desire to be carried out, that he may expire on its banks. Such is the excessive veneration they have for their religion and customs, that no person will infringe them even to preserve his own life. An Hindoo, we are told, being ill of a putrid fever, was prevailed upon to send for an European physician, who prescribed him the bark in wine; but this was refused with the greatest obstinacy even to the very last, though the governor himself joined in his solicitations, and in other matters had a considerable influence over him. In many instances these people, both in ancient and modern times, have been known, when closely besieged by an enemy whom they could not resist, to kill their wives and children, set fire to their houses, and then violently rush upon their adversaries till every one was destroyed. In the late war, some Sepoys in the British service, having been concerned in a mutiny, were condemned to be blown away from the mouths of cannon. Some grenadiers cried out, that as they had all along had the post of honour, they saw no reason why they should be denied it now; and therefore desired that they might

be blown away first. This being granted, they walked forward to the guns with composure, begged that they might be spared the indignity of being tied, and, placing their breasts close to the muzzles, were shot away. The commanding officer was so much affected with this instance of heroism, that he pardoned all the rest.

In ordinary life, the Hindoos are cheerful and lively; fond of conversation and amusements, particularly dancing. They do not, however, learn or practise dancing themselves, but have women taught for the purpose; and in beholding these they will spend whole nights. They disapprove of many parts of the education of European ladies, as supposing that they engage the attention too much, and draw away a woman's affection from her husband and children. Hence there are few women in Hindoostan who can either read or write. In general they are finely shaped, gentle in their manners, and have soft and even musical voices. The women of Kashmere, according to Mr. Forster, have a bright olive complexion, fine features, and delicate shape; a pleasing freedom in their manners, without any tendency to immodesty.

The dress of the modest women in Hindoostan consists of a close jacket, which covers their breasts, but perfectly shows their form. The sleeves are tight, and reach half way to the elbows, with a narrow border painted or embroidered all round the edges. Instead of a petticoat, they have a piece of white cotton cloth wrapped round the loins, and reaching near the ankle on the one side, but not quite so low on the other. A wide piece of muslin is thrown over the right shoulder; which, passing under the left arm, is crossed round the middle, and hangs down to the feet. The hair is usually rolled up into a knot or bunch towards the back part of the head; and some have curls hanging before and behind the ears. They wear bracelets on their arms, rings in their ears, and on their fingers, toes and ankles; with sometimes a small one in the nostril.

The dress of the dancing-women, who are deemed votaries of Venus, is very various. Sometimes they wear a jama, or long robe of wrought muslin, or gold and silver tissue; the hair plaited and hanging down behind, with spiral curls on each side of the face. They are taught every accomplishment which can be supposed to captivate the other sex, form a class entirely different from the rest of the people, and live by their own rules. Their clothes, jewels, and lodging, are considered as implements of their trade, and must be allowed them in cases of confiscation for debt: they may drink spirituous liquors, and eat any kind of meat except beef: their dances are said to resemble pretty exactly those of the ancient Bacchanians represented in some of the ancient paintings and bas reliefs. In some of their dances they attach gold and silver bells to the rings of the same metals they wear on their ankles.

The men generally shave their heads and beards, leaving only a pair of small whiskers and a lock on the back part of their head, which they take great care to preserve. In Kashmere and some other places, they let their beards grow to the length of two inches. They wear turbans on their heads; but the bramins, who officiate in the temples, commonly go with their heads uncovered, and the upper part of the body naked: round their shoulders they hang the sacred string called *Zennar*, made of a kind of perennial cotton, and composed of a certain number of threads of a determined length. The Khatries wear also a string of this kind, but composed of fewer threads; the Bhyse have one with still fewer threads, but the Sooderas are not allowed to wear any string. The other dress of the bramins consists of a piece of white cotton cloth wrapped about the loins, descending below the knee, but lower on the left than on the right side. In cold weather they sometimes put a red cap on their heads, and wrap a shawl round their bodies. The Kha-

tries, and most other of the inhabitants of this country, wear also pieces of cotton cloth wrapped round them, but which cover the upper as well as the lower part of the body. Earrings and bracelets are worn by the men as well as women; and they are fond of ornamenting themselves with diamonds, rubies, and other precious stones, when they can procure them. They wear slippers on their feet of fine woollen cloth or velvet, frequently embroidered with gold and silver; those of princes being sometimes adorned with precious stones. The lower classes wear sandals or slippers of coarse woollen cloth or leather. These slippers are always put off on going into any apartment, being left at the door, or given to an attendant; nevertheless the Hindoos make no complaints of the Europeans for not putting off their shoes when they come into their houses, which must certainly appear very uncouth to them.

Hindoo families are always governed by the eldest male, to whom great respect is shown. Filial veneration is carried to such an height among them, that a son will not sit down in the presence of his father until ordered to do so: and Mr. Forster observes, that during the whole time of his residence in India, he never saw a direct instance of undutifulness to parents; and the same is related by other writers.

The houses of the Hindoos make a worse appearance than could be supposed from their ingenuity in other respects. In the southern parts of the country, the houses are only of one story. On each side of the door, towards the street, is a narrow gallery covered by the slope of the roof which projects over it, and which, as far as the gallery extends, is supported by pillars of brick or wood. The floor of this gallery is raised about 30 inches above the level of the street; and the porters, or bearers of palankeens, with the foot-soldiers named *Peons*, who commonly hire themselves to noblemen, often lie down in this place. This entrance leads into a court, which is also surrounded by a gallery like the former. On one side of the court is a large room, on a level with the floor of the gallery; open in front, and spread with mats and carpets covered with white cotton cloth, where the master of the house receives visits and transacts business. From this court there are entrances by very small doors to the private apartments. In the northern parts, houses of two or three stories are commonly met with. Over all the country also we meet with the ruins of palaces, which evidently show the magnificence of former times.

The bramins of India were anciently much celebrated for their learning, though they now make a very inconsiderable figure in comparison with the Europeans. According to Philostratus, the Gymnosophists of Ethiopia were a colony of bramins, who, being obliged to leave India on account of the murder of their king near the banks of the Ganges, migrated into that country. The ancient bramins, however, may justly be supposed to have cultivated science with much greater success than their descendants can boast of, considering the ruinous wars and revolutions to which the country has been subjected. Metaphysics, as well as moral and natural philosophy, appear to have been well understood among them; but at present all the Hindoo knowledge is confined to those whom they call *Pundits*, "doctors or learned men." These only understand the language called *Sanscrit* or *Sanscrit*, (from two words signifying perfection); in which the ancient books were written.

The metaphysics of the bramins is much the same with that of some ancient Greek philosophers. They believe the human soul to be an emanation from the Deity, as light and heat from the sun. Gowtama, an ancient metaphysician, distinguishes two kinds of souls, the divine and vital. The former resembles the eternal spirit from which it came, is immaterial, indivisible, and without passions; the vital soul is a subtle element

which pervades all things, distinct from organized matter, and which is the origin of all our desires. The external senses, according to this author, are representations of external things to the mind, by which it is furnished with materials for its various operations; but unless the mind act in conjunction with the senses, the operation is lost, as in that absence of mind which takes place in deep contemplation. He treats likewise of reason, memory, perception, and other abstract subjects. He is of opinion, that the world could not exist without a first cause; chance being nothing but the effect of an unknown cause: he is of opinion, however, that it is folly to make any conjectures concerning the beginning or duration of the world. In treating of providence, he denies any immediate interposition of the Deity; maintaining that the Supreme Being having created the system of nature, allowed it to proceed according to the laws originally impressed upon it, and man to follow the impulse of his own desires, restrained and conducted by his reason. His doctrine concerning a future state is not different from what we have already stated as the belief of the Hindoos in general. According to bishop Wilkins, many of them believe that this world is a state of rewards and punishments as well as of probation; and that good or bad fortune are the effects of good or evil actions committed in a former state.

The science for which the bramins, however, were most remarkable, is that of *astronomy*; and in this their progress was so great, as even yet to furnish matter of admiration to the moderns. See the article BANARES.

The progress of the Hindoos in *geometry* as well as astronomy has been very great in ancient times. Of this a most remarkable instance is given by Dr. Playfair, in their finding out the proportion of the circumference of a circle to its diameter to a great degree of accuracy. This is determined, in the *Ayeen Akbary*, to be as 3927 to 1250; and which to do it arithmetically in the simplest manner possible, would require the inscription of a polygon 768 sides; an operation which cannot be performed without the knowledge of some very curious properties of the circle, and at least nine extractions of the square root, each as far as ten places of decimals. This proportion of 1250 to 3927 is the same with that of 1 to 3.1416; and differs very little from that of 113 to 155 discovered by Metrus. He and Vieta were the first who surpassed the accuracy of Archimedes in the solution of this problem; and it is remarkable that these two mathematicians flourished at the very time that the *Ayeen Akbary* was composed among the Hindoos. In geography, however, they are much deficient; and it is very difficult to find out the true situation of the meridians mentioned by their authors from what they have said concerning them.

The art of *painting* among the Hindoos is in an imperfect state; nor are there any remains of antiquity which evince its ever having been more perfect than it is now. Their principal defect is in drawing, and being almost totally ignorant of the rules of perspective. They are much better skilled in colouring; and some of their pictures are finished with great nicety. Their *sculptures* are likewise rude, and greatly resemble those of the Egyptians. They seem to follow no regular rules in architecture: their temples indeed are filled with innumerable columns, but most of them without any just shape or proportion. They are principally remarkable for their immense size, which gives them an air of majesty and grandeur.

The *music* of the Hindoos is but little known to Europeans; and the art seems to have made but little progress among them in comparison with what it has done in the western countries; though some of the Indian airs are said to be very melodious. Their musical instruments are very numerous: in war they use a kind of great kettle drum named *nagar*, carried by a camel,

and sometimes by an elephant. The dolo is a long narrow drum slung round the neck; and the tam-tam is a flat kind of drum resembling a tabor, but larger and louder. They use also the cymbal, which they name *talan*; and they have various sorts of trumpets, particularly a great one named *tary*, which emits a most doleful sound, and is always used at funerals, and sometimes to announce the death of persons of distinction.

The *jugglers* among the Hindoos are so expert, that many of the missionaries have ascribed their tricks to supernatural power; and even so late a traveller as Mr. Grose seems to be not of a very different opinion. Like the Egyptians, they seem to have the power of disarming serpents of their poison; and there are many strollers who go about with numbers of these animals in bags, having along with them a small bag-pipe called *magouty*, which they pretend is useful to bring them from their lurking-places. They take the serpents, though of the most poisonous kinds, out of the bags with their naked hands, and throw them on the ground, where they are taught to rear and move about to the sound of their music. They say that this is accomplished by means of certain incantations.
