The most striking result of this research has been the revelation of vast areas of diffused nebulous matter, so faint as to be beyond visual observation. One of these areas extends over a number of square degrees in the constellations Ophiuchus and Scorpio, and, like the Orion nebula, it attaches itself to individual stars, the principal condensation being about the quadruple star ρ Ophiuchi. The region is marked by an absence of faint stars, and dark lines may be traced beyond the confines of the nebulosity as yet seen on the plates.

REPORT OF THE NATAL OBSERVATORY.—The report of Mr. E. Nevill, Government astronomer of Natal, for the year 1903, gives a brief *résumé* of the work accomplished at the Durban Observatory during the period with which the report deals, and contains a mass of information respecting the meteorology of the colony.

The time signals have been sent out as in former years, and Borrelly's comet was observed regularly during its appearance, the orbit deduced from the observations agreeing with those obtained at other observatories.

It is proposed to utilise the tide observations made during the years 1884-8 in order to provide the port authorities with tide-tables, but, owing to the constructional changes in the harbour during the last few years, it will be necessary to reduce the more recent observations and this will require additional computing assistance.

In former years it has been customary to issue the meteorological data compiled from the returns of the subsidiary stations once each month, but in future the returns will be published daily. Among the numerous tables given in the report there occurs, for the first time, a summary of the meteorological observations made at the Botanical Gardens, Durban, during the period 1873–1883 inclusive, before the institution of the Government observatory.

THE JESUIT OBSERVATORY AT BELEN, HAVANA.—An interesting illustrated account of the observatory attached to the Jesuit College at Belen, Havana, has been written, in Spanish, by Father Mariano Gutiérrez, S.J., the sub-director, and contains a history of the installation of the institution in 1857, and its proceedings since that date.

The meteorological section was first founded under the direction of Father Antonio Cabré, S.J., in the year named, but its position was not secured until the installation of Father Vines as director, in 1870, to the memory of whom the author of the history pays a high tribute, and laments his death in 1893 as an irreparable loss.

The equipment of the observatory is fairly complete, and includes meteorological, seismological, magnetic, and astronomical instruments, most of which, including the 6-inch Cooke equatorial, are illustrated in the present volume.

THE DISCOVERY OF JUPITER'S SIXTH SATELLITE.

THE addition of a sixth satellite to the system of Jupiter marks another triumph in Prof. Perrine's employment of the modified Crossley reflector. As mentioned in a note published in "Our Astronomical Column" last week, Prof. Perrine first suspected the existence of the newly discovered body from observations made during December, 1904, but it was not until January 4 that a further observation confirmed his suspicion, and enabled him to open the new year with the announcement of this important discovery.

The new satellite, so far as one may gather from the meagre news yet to hand, is situated at a much greater distance from its primary than any of the five previously known. The telegram announcing the discovery gave this distance, on January 4, as 45′, whilst that of the outermost of the four satellites discovered by Galileo never exceeds 10′·5, and the fifth, the innermost of all, is not quite half the distance from Jupiter that the moon is from the earth.

Assuming, for the moment, that the above distance is the outward limit of the satellite's orbit, it should make one revolution about its primary in about half a year, whereas the time occupied by the fourth satellite is only 16·7 days; thus we see there is an immense gap between the two bodies which, according to precedent, may contain other satellites as yet undiscovered.

The recent discovery raises the number of satellites in the solar system, discovered during the past thirty years, to five, and it is worthy of note that the discovery of a satellite has usually occurred at times when a new instrument has been installed or old instruments or methods have been improved. This fact calls to mind, although beyond our thirty years' limit but still dealing with the Jovian system, that Jupiter's four moons, Io, Europa, Ganymede, and Callisto, or i., ii., iii., and iv. as they are usually designated, were the first members of the solar system to be *discovered*, resulting, as they did, from Galileo's first use of the telescope in January, 1610.

After these, and within the past thirty years, came Deimos and Phobos, the lilliputian attendants to Mars, which were discovered by Prof. Asaph Hall at Washington in August, 1877, and were the first fruits of the then recently mounted 26-inch refractor of the U.S. Naval Observatory.

The fifth satellite of Jupiter was discovered by Prof. Barnard on September 9, 1892, with the nearly new giant refractor of the Lick Observatory. It is, comparatively, a minute object and can only be seen with the largest telescopes under the most favourable conditions. Its diameter can scarcely be greater than 100 miles, whilst the diameters of the other four, in order of their distance from the planet, are 2400, between 2000 and 2200 (about the size of our own moon), 3000, and 3600 miles respectively. This object revolves between

Io—the first satellite and Jupiter in a period of 11h. 57m. 22·6s.

Following this discovery came the addition, to an already numerous family, of the ninth satellite of Saturn, which was found by Prof. W. H. Pickering. The search was commenced in 1888 with the 13-inch Boyden telescope of the Harvard College Observatory, but was not successful in bringing to light any previously unknown attendant on Saturn. On the installation of the new 24-inch Bruce telescope in the clear atmosphere of Arequipa the search, which was photographic throughout, was renewed, and on examining the plates taken on August 16, 17, and 18, 1898, Prof. Pickering was rewarded by the appearance of a short trail which apparently partook of the planet's motion among the stars, and was, therefore, to be considered as part of its system. The story of the subsequent doubts and difficulties has been too recently told (Harvard College *Annals*, No. 3, vol. liii.) to need re-telling here, but it may be recalled to mind that the subsequent observations showed that the satellite revolves in an orbit which is far more eccentric than that of any other satellite, or of any major planet, in the solar system, and that its motion in that orbit is opposite in direction to the orbital motions of the remaining eight of Saturn's moons. Like the fifth satellite of Jupiter, this object can only be observed visually with the largest telescopes and under the best conditions. As a matter of fact, it was not *seen* until its position was accurately known, and even then Profs. Barnard and H. H. Turner, using the 40-inch refractor at Yerkes Observatory, in August last, could not feel certain that they had really observed the object which had up to that time remained invisible to human eyes.

Whilst our knowledge of the most recently discovered satellite is as yet very scanty, Prof. Perrine's message tells us that on January 4 its position angle was 260°, and the daily rate of its apparent approach towards Jupiter was 45", *i.e.* about 100,000 miles.

The magnitude, 14, ascribed to it is one magnitude fainter than that of Barnard's fifth satellite, and this primarily suggests that the diameter may be less than that of the fifth, although a smaller reflecting power, or "albedo," may account for the relative faintness. Its distance from Jupiter on January 4 would probably be about 6 million miles. The statement that the motion was "retrograde" refers, of course, to the apparent motion in the sky, and must not be confounded with a retrograde orbital motion similar to that followed by Phœbe, Saturn's ninth satellite.

W. E. R.

ATMOSPHERIC AND OCEANIC CARBON DIOXIDE.

THE carbonic acid of sea-water is usually supposed to be present in combination with certain bases, which constitute the *alkalinity* of the water, partly in the form of normal carbonate and partly in the form of bicarbonate, the total amount present being insufficient to convert the whole of the base into the bicarbonate. Thus the water of the North Atlantic has been found to contain 49 c.c. of carbonic acid gas per litre, whilst 54 c.c. would be required to convert the base completely into bicarbonate. That this view is not quite correct has been shown by Dr. A. Krogh, of Copenhagen, in a series of investigations on the carbon dioxide of the air and ocean.[1]

The reaction between carbonic acid and a normal carbonate to form a bicarbonate is, like so many chemical reactions, reversible, and equilibrium is established while a certain amount of the carbonic acid is still free. This free carbonic acid exerts a definite gaseous pressure, which varies with the total amount of carbon dioxide present and with the alkalinity of the water. This pressure can very readily be determined by simply shaking the water with a small volume of air and then ascertaining by direct analysis the pressure of the carbon dioxide in this air, which is, of course, equal to the pressure of that in the water, since the two have been brought into equilibrium by the shaking. This process gives excellent results both with fresh- and sea-water, and can be carried out very rapidly by the aid of the apparatus of Haldane or Petterson and Sonden for the estimation of small quantities of carbon dioxide. As the result of a careful study of the behaviour of sea-water in this respect, it appears that a comparatively large amount of carbon dioxide may be absorbed, whilst the corresponding pressure only undergoes a very small absolute change, provided that the alkalinity remains constant. A water, for example, which has the alkalinity 23, and contains 36·7 c.c. of carbon dioxide per litre, is capable of absorbing 4·3 c.c. of the gas per litre, whilst the pressure, measured as described above, only rises from 0·015 per cent. to 0·0295 per cent. of an atmosphere. This means that the air shaken up with the original water would be found to contain 1·5 parts of carbon dioxide per 10,000, whilst after the further absorption the air similarly treated would contain 2·95 parts per 10,000.

Owing to this pressure of carbon dioxide constant interchange takes place between every water surface, whether of sea-water or of fresh-water, and the air above it, resulting in evolution from the water or absorption by it according as the pressure of carbon dioxide in the water or the air is the greater. The effect of this is that the ocean acts as a regulator on the amount of carbon dioxide in the air, tending to compensate for any deviation from the normal proportion. The pressure of carbon dioxide in the air is at present about 0·03 per cent. of an atmosphere (3 volumes per 10,000), the absolute amount in the whole atmosphere being calculated as $2·4 \times 10^{12}$ tons, whilst the quantity contained in the entire mass of the sea may be taken as twenty-seven times as great as this.

In order to increase the proportion of the atmospheric carbon dioxide to 0·04 per cent. it would be necessary, of course, in the first place to add one-third of the amount already present. The pressure thus attained would, however, be gradually decreased by absorption by the sea, and it follows from the author's experiments that in order to bring the ocean into equilibrium with the altered atmosphere a further addition of twice the amount originally present would be required, a total change involving the production of $5·6 \times 10^{12}$ tons of carbon dioxide! A calculation of this kind goes far to explain the constancy of composition of the atmosphere, which at first sight appears so remarkable, and to indicate the enormous changes required to produce any considerable variation in it.

The interchange of carbon dioxide between sea and air, moreover, is by no means a slow process, but takes place with remarkable rapidity. Thus a pressure difference between sea and air of only 0·001 of an atmosphere, *i.e.* the presence in the air of an additional 0·1 part of carbon dioxide per 10,000, leads to the absorption of 0·525 c.c. of this gas per square centimetre of ocean surface per year, or a total annual absorption of $3·85 \times 10^9$ tons.

The author considers from this point of view the effect on the composition of the atmosphere of the combustion of coal, which annually throws into the air about one-thousandth of the carbon dioxide already present in it, so that, apart from any regulating action of the sea, in a thousand years—if the coal lasted—the percentage proportion would be doubled, rising from 3 to 6 volumes per 10,000, and rendering the air almost unfit for continued respiration. Before the proportion rose to 3·1 volumes per 10,000, however, the sea would be able to absorb the gas as fast as it was produced, and, owing to the large volume required to bring the ocean water into equilibrium with the air, it is probable that at the expiration of the thousand years the proportion of carbon dioxide in the air would not be more than 3·5 volumes per 10,000.

Many other interesting questions of great importance in the economy of nature are capable of being attacked from this point of view and subjected to experimental investigation. Such are the rate of deposition of calcium carbonate from hard waters, the rate of solution of limestone and chalk in natural waters, the absorption of carbon dioxide by rocks and soils, &c.

On the great question as to whether the production of carbon dioxide is on the whole greater or less than its decomposition nothing certain is known. Indications are not wanting, however, that this constituent of the atmosphere is increasing in quantity. The chief evidence to this effect is derived from the fact that over the sea the pressure of

[1] "Meddelelser om Gronland," vol. xxvi. pp. 333, 409.

this gas is distinctly lower than over the land. This would appear to be most easily accounted for on the assumption that the pressure of carbon dioxide in the sea is constantly lower than that in the air, and that, therefore, the air must be steadily deriving supplies of the gas from some source, by means of which this difference of pressure is maintained.

A. Harden.

CONFERENCE OF PUBLIC SCHOOL SCIENCE MASTERS.

The annual meeting of the Public School Science Masters' Association was held for the second time at Westminster School on January 14, by kind permission of Dr. Gow, who had undertaken the duties of president and occupied the chair. A letter was read by the honorary secretary, Mr. W. A. Shenstone, from Sir Michael Foster explaining why he had not been able to act as president. The meeting then occupied itself with business matters, and Sir Oliver Lodge was unanimously elected president for the ensuing year.

In the short address with which Dr. Gow opened the conference, he expressed the opinion that every boy should be taught natural science, and this pronouncement, coming as it does from a classical headmaster, is of very great importance at the present moment, as Prof. Armstrong was not slow to point out. It was no doubt elicited by the subject of the first paper, namely, the importance of including both Latin and science in a scheme of general education. This was read by Mr. Douglas Berridge, of Malvern College. In the paper the necessity of a general education was discussed, and the report of the committee upon the education of army officers was taken as a guide. In this it is laid down that English, mathematics, one modern language, Latin, and science are essential to a sound general education; but what is very strange, the framers of the report proceed to propose that all future officers of our Army should be debarred from obtaining what was considered necessary by the proposal that Latin and science should be optional and alternative subjects. In addition to the injury which a one-sided education inflicts upon the individual, Mr. Berridge pointed out a greater and more far-reaching danger to our nation as a whole. He urged that the present trend of education, as represented by London University (in its matriculation and school leaving examination), by Oxford and Cambridge (in their school leaving examinations), and by the Civil Service Commissioners and the Army entrance examinations, is sharply to divide Englishmen into two classes, the one trained on literary lines, leavened only by a modicum of mathematics, the other on scientific lines, leavened only by a smattering of French. Could it be, Mr. Berridge asked, to the advantage of any nation that its future rulers and organisers should thus be grouped into two opposing camps, of which, while they mutually despise one another, neither is able to understand the very method of reasoning adopted by the other? Mr. Berridge was able to support his contention by figures, for on application to all our public schools he had found that for the Army and matriculation examinations 45·6 per cent. of the boys now learn Latin and 54·4 per cent. learn science.

The discussion showed that while the need of a literary as well as a scientific training was thoroughly recognised, many speakers did not agree with Mr. Berridge that Latin was the best means of acquiring the former. It is true that Father Cortie (Stonyhurst) found that the best classical boys were most successful in science, but Prof. Armstrong said that no honest attempt had ever been made in this country to afford a literary training through any other language, and though Latin had proved very efficient in a few instances, in the vast majority of cases it was not. He maintained, also, that Latin translation did not give style. Finally, Prof. Armstrong characterised the making of science alternative to Latin in Army examinations as illogical and preposterous. Dr. Gow said that he never regarded Latin as a literary training, but as a scientific one, and referred to his opening remarks, in which he had characterised the words as typical and exceptional genera and species, and parsing as scientific classification.

The paper dealing with recent proposals for school leaving certificates, by Mr. C. I. Gardiner, of Cheltenham, dealt with what has been done on the Continent, and afterwards with the regulations at present suggested to the Board of Education by its consultative committee. The paper welcomed, as did many of the speakers afterwards, what is not very happily expressed as State interference. Many of the Board of Education's proposals were characterised by Mr. Gardiner as too vague, upon very good grounds. In the discussion, surprise was expressed that Mr. Gardiner had not mentioned what has been done recently in Ireland. It was recommended, also, that the Board of Education should get to know the schools before it suggested too much, and that its interference should be taken in small doses. Mr. W. A. Shenstone fancied he saw the edge of red tape in some of the proposals, while Father Cortie thought there was a danger that education might become stereotyped, so that special traits of certain schools would not be given free play. He hoped that inspectors with fads or insufficient knowledge would not interfere as they had done in elementary schools, and would not say, for instance, "your 'labs' are not so good as those in the primary schools (which are built with the ratepayers' money), you must erect new ones."

The third paper dealt with the use and misuse of terms in science teaching. It was contributed by Mr. T. L. Humberstone, of Toynbee Hall, who took exception to the loose way in which words, law, theory, hypothesis, and so on were used. He pointed out what the real meanings of the words were, and objected strongly to the idea that the experiments in practical mathematics "proved" the laws that they were intended to illustrate. Prof. Tilden agreed with Mr. Humberstone in regard to the misuse of terms, and said that professional scientific men were just as much to blame as schoolmasters. He thought that if boys were taught a little logic before they left school many mistakes would be prevented. He was amazed at the statement incidentally made by Mr. Humberstone as to there being too much laboratory work done in schools, and he pointed out that every discovery of the organic chemists was additional evidence in favour of the atomic theory which Mr. Humberstone thought was tottering. Mr. Fletcher, of the Board of Education, said that there was a widespread misapprehension as to the place of practical work in geometry. It was not possible to prove anything by the experiments used, but it was most important to get approximations which could be idealised into conceptions. They were necessary to create a state of mind and to commend postulates to common sense. Mr. Sanderson thought that some of the practical work set to boys was superfluous, and might well be replaced by good experiments shown by the master. Mr. Humberstone, in answer to a question from Mr. Shenstone, said that he thought ten or twelve hours a week was longer than was required for laboratory work, and he further said, with regard to superfluous work, that when a boy had learned how to obtain one gas properly it was not necessary for him to produce all the others.

The last paper was by Mr. F. B. Stead, of Clifton, and was on the possibility of teaching scientific method to boys whose education is almost entirely literary, and who have no time for a regular course in chemistry and physics. It was suggested that older boys in the Vth form should be given some definite piece of work to be carried out in detail, in order that they might understand (1) the method of experiment and observation by which facts are ascertained; (2) the process of reasoning from particular instances to general laws; and (3) the use of explanatory theories and their verification.

Prof. Armstrong considered the paper to be one of very great value, and suggested that the term "experimental" should be used instead of "scientific," bearing in mind what Dr. Gow had said in connection with Latin as scientific training. He also asked what place there would be in the near future for boys who only had had a literary education.

Wilfred Mark Webb.

PRIZE AWARDS OF THE ROYAL SOCIETY OF EDINBURGH.

AT a meeting of the Royal Society of Edinburgh on January 9 the prizes awarded by the council were presented by the chairman, Prof. J. Geikie. We have received the following particulars of the awards :—

The Gunning Victoria Jubilee prize for 1900–4 was awarded to Sir James Dewar, LL.D., D.Sc., F.R.S., &c., for his researches on the liquefaction of gases, extending over the last quarter of a century, and on the chemical and physical properties of substances at low temperatures, his earliest papers being published in the *Transactions and Proceedings* of the society.

In 1867 Mr. James Dewar read a paper to this society on the oxidation of phenol to oxalic acid. This, his first contribution to the aromatic compounds, was followed by a more important one on the oxidation of picoline, which he gave to the British Association in 1868, and in a fuller form to this society in 1870. In this he proposed a graphic formula of pyridine, which expresses the relation between the constitution of benzene and that of pyridine, now universally recognised.

Dewar's experiments on the liquefaction of gases extend over the last quarter of a century, and have culminated in the production of liquid and solid hydrogen in large quantities, so that as thirty-five years ago he studied the chemical and physical properties of hydrogenium solidified in palladium, he has now given us the properties of the solid element, hydrogen itself. Having thus in his hands the means of preparing large quantities of liquefied gases, and having devised most ingenious arrangements for keeping these very volatile liquids for a long time with only a small loss from evaporation, he made good use of the opportunity for examining the chemical and physical properties of substances at extremely low temperatures. The results of these inquiries are of the highest interest and importance. For this long series of investigations in chemistry and physics, characterised by ingenuity, skill, and perseverance, and crowned with success, the council has awarded to Sir James Dewar the Gunning Victoria Jubilee prize.

The Keith prize for 1901–3 was awarded to Sir William Turner, K.C.B., LL.D., F.R.S., &c., for his memoir entitled "A Contribution to the Craniology of the People of Scotland," published in the *Transactions* of the society, and for his "Contribution to the Craniology of the People of the Empire of India," parts i., ii., likewise published in the *Transactions* of the society.

These memoirs, important as they are, form a comparatively small part of the work which Sir William Turner has done in the field of physical anthropology. More especially should notice be taken of the two elaborate reports which he published on the crania and other bones of the human skeleton which were collected by the *Challenger* Expedition. These reports are not only valuable on account of the information which they convey regarding the physical characters of many races of mankind, but also because they establish methods of craniological and anthropometrical research which have very generally been accepted in this country by workers in the same field.

Four great leaders have been chiefly instrumental in developing that branch of science which has received the name of physical anthropology: Broca in France, Huxley and Flower in England, Turner in Scotland.

The Makdougall-Brisbane prize for 1902–4 was awarded to Mr. John Dougall, M.A., for his paper on an analytical theory of the equilibrium of an isotropic elastic plate, published in the *Transactions* of the society.

The problem of the deformation of an isotropic elastic plate under given forces has occupied the attention of mathematicians from the time of Lamé. The solution given by Lamé himself is merely formal; the integrals by which that solution is expressed are not only very complicated, but are not convergent, and they do not lead to the approximate theory.

In his memoir Mr. Dougall makes a new departure, and develops a method that has important applications in other branches of applied mathematics. By an exceedingly skilful use of Cauchy's theory of contour integration, certain integrals, which in Lamé's solution are not convergent, are transformed into highly convergent series, and the modifications which are necessary to secure convergence lead at once to the most significant terms of the solution. The theorem of Betti is applied to develop a method, analogous to the method of Green's function in the theory of the potential, by which the properties of the solution for a finite plate can be deduced from that for an infinite plate, and here, as elsewhere throughout the memoir, numerous results are obtained which have great value both for pure and for applied mathematics. The memoir confirms the ordinary approximate theory, but extends it in various directions; for example, the edge conditions given by Kirchhoff in correction of Poisson are found directly from the mathematical investigation, without the aid of any special physical hypothesis, and are carried to a higher degree of approximation than by Kirchhoff himself. The memoir contains much acute analysis, and strikes out a new method of treating the problems of mathematical physics that seems likely to be of great value in future investigations.

The Neill prize for the period 1901–4 was awarded to Prof. John Graham Kerr, M.A., for his researches on *Lepidosiren paradoxa*, published in the *Philosophical Transactions* of the Royal Society, London.

This work includes an account of the embryological material collected during an expedition specially organised for the purpose to the Grand Chaco of South America in the years 1896–7. The general biology and habits of Lepidosiren are described, the external features of development are fully dealt with, and in a discussion of the general bearings of the phenomena considered reference is made to, amongst other things, the relations of the protosoma to the body of the vertebrate, to the origin of the spiral valve, and to the morphological significance of the external gills which it is suggested are the persisting representatives of the organs from which the limbs of vertebrates have been evolved.

After the presentation of the prizes, Sir James Dewar gave a lecture on the properties of liquid air, with special reference to charcoal vacua, being a sequel to a paper communicated to the society by Prof. Tait and himself in 1875 (see NATURE, vol. xii. p. 217). Many of the familiar properties of liquid air were demonstrated by a series of experiments. Of particular interest were its use as a calorimeter and its employment in cooling charcoal in a vacuum tube so as greatly to diminish the density of the rarefied gas. By this means the tube gradually passed through all the well known stages from the ordinary bright discharge to the condition of evident striation and so to the Röntgen ray stage, and finally to the non-conducting state. When the liquid air was removed the charcoal gradually heated up to the ordinary temperature, and the tube passed back again through the stages in the reverse order. The phosphorescence at very low temperatures of certain substances not phosphorescent at ordinary temperatures was also demonstrated; also the production of luminous effects due to the electrification of a certain crystal on being cooled down to the temperature of liquid air.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—Mr. R. H. Lock has been appointed assistant curator of the herbarium for four years from January 1. He succeeds Mr. Yapp, who was some time ago elected professor of botany at Aberystwyth.

Prof. Sorley has been appointed chairman of the examiners for the moral sciences tripos.

The Sedgwick Museum Building Syndicate has issued a final report, from which it appears that the total cost of the building and fittings is 49,389*l*. 2*s*. 3*d*., of which sum 26,125*l*. has been furnished by the Sedgwick memorial trustees, besides 1050*l*. appropriated to the bronze statue sculptured by Mr. Onslow Ford.

In connection with the recently established diploma and final examination for the degree in geography, the Board of Geographical Studies has issued a list of eight lectures which amply cover the syllabus for these examinations. Besides the lectures on geography in general by Mr. Yule Oldham, Mr. Hinks is lecturing on geographical surveying, Dr. Marr on geomorphology, and Dr. Haddon on anthropogeography.

The recently established board of anthropology announce some thirteen courses of lectures which seem to embrace the world, ancient and modern. Prof. Ridgeway deals with Greek and Roman numismatics, Mr. Green with Egyptology, Mr. Johns with Assyriology and the social customs of Babylonia, Mr. Chadwick with those of the Anglo-Saxons, whilst Dr. Haddon lectures on the ethnology of Southern Asia, Baron von Hügel on the Melanesians and Polynesians, and Mr. Minns on the ancient ethnology of eastern Europe. Special courses on the sacred character and magical functions of kings in early society, and on physical anthropology, are to be delivered by Mr. J. G. Frazer and Mr. Duckworth.

LONDON.—The Drapers' Company has voted to University College the sum of 400*l*. a year for the next five years towards assisting further the statistical work and higher teaching of the department of applied mathematics. The Mercers' Company has voted the sum of 1000*l*. for providing for the chair of physiology at the college. Dr. Atkinson has been appointed an honorary demonstrator in the department of organic chemistry.

EDINBURGH.—The Senate has submited a resolution to the University Court expressing the view that the time has come for the recognition of geography as a subject for graduation in arts and science, and requesting that the court should take steps as soon as possible to obtain such alteration of the ordinances as may be necessary to that end. It was agreed that when the framing of a new and amending ordinance in arts comes before the court, the question of giving an adequate position to geography shall be given due consideration.

DUBLIN.—The Provost and senior fellows of Trinity College have accepted an offer made by Sir John Nutting, of St. Helens, county Dublin, to endow for a period of five years ten annual entrance exhibitions each of the value of 100*l*. (50*l*. per annum for two years). The exhibitions are to be awarded without further examination, and at the discretion of the Board of Trinity College, to ten young men or women who have competed with success at the senior or middle grade examinations of the Board of Intermediate Education in Ireland. The exhibitions will be confined to pupils of Irish secondary schools (Protestant and Roman Catholic) which have no other endowment than the "results fees" of the Intermediate Board, any other endowment to act as a disqualification.

MR. STANLEY H. TURNER, assistant in political economy at Glasgow, has been appointed lecturer in political economy in the University of Aberdeen, and a full qualifying course of lectures will in future be given by him.

DR. KARL BOEHM, of Heidelberg, and Dr. Hugo Kaufmann, of Stuttgart Technical College, have been appointed extraordinary professors for mathematics and chemistry respectively.

MRS. MACLOGHLIN, of Southport, recently made an offer to the Royal College of Surgeons of England to found scholarships in memory of her husband, the late Mr. E. Percy P. Macloghlin. Mrs. Macloghlin proposes, in five years from the date of her husband's death, to give to the college a sum of 10,000*l*. for the purpose of endowing these scholarships, which are intended to assist young students in need of financial help to proceed with their professional studies. The council of the college has accepted Mrs. Macloghlin's munificent offer, and has agreed to administer the trust.

THE president of the Board of Education has appointed the Right Hon. R. B. Haldane, K.C., M.P., to be chairman of the departmental committee which is inquiring into the present and future working of the Royal College of Science and Royal School of Mines, South Kensington, in succession to Sir Francis Mowatt, G.C.B., who will, however, remain a member of the committee. It may be remembered that the terms of reference to the committee are as follows:—To inquire into the present working of the Royal College of Science, including the School of Mines; to consider in what manner the staff, together with the buildings and appliances now in occupation or in course of construction, may be utilised to the fullest extent for the promotion of higher scientific studies in connection with the work of existing or projected institutions for instruction of the same character in the metropolis or elsewhere; and to report on any changes which may be desirable in order to carry out such recommendations as they may make.

THE annual meeting of the Incorporated Association of Headmasters was held at the Guildhall on January 11 and 12. In his presidential address, the Rev. James Went said that, speaking broadly, the difference between the English and the German educational ideal has been that the Germans have recognised the paramount importance of secondary education and the English have not. It is, however, being recognised gradually that the word "secondary" connotes, not a social distinction, but one of attainment. The recognition of this fact is, Mr. Went believes, largely due to boys of ability and good character who, under the name of exhibitioners or county council scholars, have during the last thirty years been admitted freely into grammar schools, and of whom many have afterwards won the highest distinctions at the universities. It appears likely that the number of boys of this class will be increased as time goes on. The address also dealt with the education of pupil teachers at secondary schools and with the recent regulations for secondary schools issued by the Board of Education. The following resolution was adopted:—"That this association regards the new regulations for secondary schools with satisfaction in general, but regrets that the Board of Education does not provide (*a*) for the calculation of grants upon terminal attendance; (*b*) for the recognition of advanced courses to follow upon the existing four-years' course; (*c*) for ensuring comparative freedom of curricula to schools satisfying certain tests of a higher liberal education; (*d*) for an elastic percentage division of the whole school time when prescribing for groups of subjects, in place of the existing rigid minima of hours or periods in each week. A rider was adopted also declaring that the financial basis on which grants are calculated is not at all adequate, and protesting against any application of the new regulations to secondary schools hitherto earning grants from the board, which would result in such schools receiving grants on a lower basis than in the past.

AT the second day's meeting of the Incorporated Association of Headmasters the following resolutions were adopted after discussion:—(1) That in the opinion of this association it is desirable that the universities should institute a twofold entrance examination (*a*) for candidates proceeding to degrees in arts, in general as at present, but with a higher standard in literary subjects; (*b*) for candidates proceeding to degrees in mathematics and science, with a modern language, including translation at sight, composition, and an oral test, as an alternative for Greek. (2) That the provision for papers in English and history, and for the omission of Paley's "Evidences" from the Cambridge previous paper as laid down in the first report of the Cambridge Studies Syndicate, should be insisted upon in examinations under both (*a*) and (*b*) above. (3) That a new degree in mathematics and in science should be instituted, differing in title from the degree in arts, but of precisely the same university standing. The Rev. R. D. Swallow, in moving the resolutions, said he would not add anything to the arguments on either side of the vexed question as to whether the study of Greek is to be compulsory for students who sought admission to the ancient universities. It is a question which has often been debated by the association, and now in later years, as the subject has assumed a more prominent place in all questions about the curricula of the universities and the secondary schools, the association has gradually focussed its view of it in favour of relaxation for candidates for admission at the university who are able to prove themselves worthy of high honours in mathematics or natural science.

MR. ARNOLD-FORSTER, Secretary of State for War, attended on Monday the first lecture of a course on military history and strategy at the University of London; and at the conclusion of the lecture spoke on army education. In the course of his remarks, he said:—If we have had one thing more than another to admire in the great military example in the Far East, it is the way in which the officers' corps of a great and friendly nation have succeeded in combining the maximum of devotion with the maximum of intelligence in the effective service of their country. In our Army we can find officers in every rank and branch of the service who will challenge comparison with the officers of any army in the world; but the diffusion of intelligence and education throughout the officers of the Army is not so great as it ought to be. This is not peculiar to the Army; it is characteristic of every profession in the country; and what this country is now feeling acutely is that we have so long subsisted on an educational basis inadequate to the needs of modern life. The time has come for the public schools to render to the Army greater service than they do now. Numbers of young men come up for the Army from the public schools with a totally inadequate knowledge of the language of every country but their own, and with an inadequate knowledge of the history and literature of their own country, as well as of the history and literature of every other country. That must all be changed. Young men ought to come up from the public schools instructed in the great science of geography. Now they are practically without any knowledge whatever of one of the sciences which, more than any other, is the reasonable foundation for the studies of an officer in the Army. There is an extraordinary lack in this country—which of all others ought to be well posted in this branch of science—of a proper knowledge of geography. We might be compelled to establish in this country for the Army schools like those which have been already established for the Navy, or like the college at West Point in the United States. The time has almost come when it would be wise to establish a great college like West Point, where the equipment, staff, and method should be as complete as possible, and where candidates should be taken not only for the Army, but for all the great departments of the State, and where even those who have no intention of entering the service of the State may be allowed to receive instruction.

SOCIETIES AND ACADEMIES.

PARIS.

Academy of Sciences, January 9.—M. Troost in the chair.—The external or superficial conductivity representing for a given body the cooling power of a fluid current: J. **Boussinesq**.—The micrographical study of the meteorite of the Diablo Canyon: H. **Moissan** and F. **Osmond**. The micrographical study of this meteorite has shown that the metallic parts, apparently homogeneous, frequently contain irregular microscopic nuclei formed of superposed layers of phosphide and carbide of iron. A detailed examination of nodules which have not been submitted to external oxidation made it clear that they are formed of sulphide of iron surrounded by successive layers of iron phosphide and carbide. In certain cases the laminated structure of the nodules showed that they had been submitted to very considerable pressures.—Trypanosomiasis and the tsetse-fly in French Guinea: A. **Laveran**. Specimens of Glossina, or the tsetse-fly, have been found in all parts of French Guinea, and in places where the existence of diseases due to trypanosomes has been already demonstrated. These trypanosomes attack horses as well as human beings, and a detailed account of the course of the disease in a horse, together with the results of a *post-mortem* examination of the animal, are given.—Observations on the Borrelly comet (December 28, 1904) made with the large equatorial at the Observatory of Bordeaux: G. **Rayet**. Two sets of observations were made on December 31, 1904, and one on January 2. On the latter evening the sky was clear, and the comet appeared as a nearly round nebulosity of about $1'$ in diameter, possessing a stellar nucleus of the thirteenth magnitude.—On a method of reading large surfaces of mercury: A. **Berget**. A collimator with a well illuminated very narrow slit is placed behind the column to be read, and an ungraduated thermometer tube in front. A luminous line, the focal line of a cylindrical mirror, is formed, and ends with great sharpness at a fixed point, which can be read off in a cathetometer with an accuracy of 0·01 mm.—The attraction observed between liquid drops suspended in a liquid of the same density: V. **Crémieu**. Drops of olive oil, suspended in a mixture of alcohol and water of as nearly as possible the same density as the oil, ascend or descend in a vertical straight line, with extreme slowness, if precautions against changes of temperature and shaking are taken. If two or more drops are present in the dilute alcohol at the same time, there is an attraction between the two drops which is manifested by their following curved paths instead of vertically straight ones.—On the photogenic radio-active properties of calcined coral placed in a radiant vacuum and submitted to the influence of the kathode rays: Gaston **Séguy**. Amongst various substances examined calcined coral (carbonate of lime and magnesia) gave the most intense phosphorescence as measured by the action on a photographic plate. Phosphorescent coral excites the fluorescence of barium platinocyanide screens, and is very rich in ultra-violet rays.—Concerning the action of very low temperatures on the phosphorescence of certain sulphides: F. P. **Le Roux**. The maximum potential light energy which can be induced in a given phosphorescent body by a given light is independent of the temperature. Variations of temperature can only have an influence on the velocity of transformation of the potential into the actual light energy.—On a supposed demonstration of the existence of the *n*-rays by photographic methods: M. **Chanoz** and M. **Perrigot**. The authors have repeated an experiment of M. Bordier's on the photographic detection of the *n*-rays emitted by tempered steel, with contrary results. They find that two equal masses of lead and tempered steel, placed identically on screens comparable as to thickness and insolation, never give different halos, whatever may be the duration of the exposure.—The special sensibility of the physiological ear for certain vowels: M. **Marage**.—On the fluorides of indium and rubidium: C. **Chabrié** and A. **Bouchonnet**. The fluoride of indium was prepared by dissolving the hydroxide of the metal in hydrofluoric acid, and was found on analysis to possess the composition $In_2F_6.18H_2O$. It emits acid vapours, and is completely decomposed on ignition to redness. On treating rubidium carbonate with hydrofluoric acid and evaporating to dryness the acid fluoride RbF.HF is obtained.—The limit of the reaction between diazobenzene and aniline: Léo **Vignon**. Aminoazobenzene does not react with diazobenzene either in aqueous or alcoholic solution. Aniline reacts with diazoaminoazobenzene chloride in presence of potassium carbonate giving a diazoamine.—Camphene, camphenylone, isoborneol, and camphor: L. **Bouveault** and G. **Blanc**. The tertiary alcohol, methylcamphenylol, was prepared from camphenylone by Grignard's reaction. The reaction of this alcohol with pyruvic acid at 140°–150° C. has been studied.—On the diastatic coagulation of starch: J. **Wolff** and A. **Fernbach**.—The estimation of carbon monoxide in confined atmospheres: Albert **Lévy** and A. **Pécoul**. The authors utilise the reaction first indicated by M. Gautier between carbon monoxide and iodic anhydride at 80° C., modifying the method by receiving the vapours of iodine in a small quantity of pure chloroform. The amount of iodine set free is ascertained calorimetrically by comparison with a set of sealed tubes containing known quantities of iodine. It is possible in this way to measure in four litres of air only down to 1/200,000 of carbon monoxide by volume. A test analysis with an artificially prepared atmosphere is given to show the accuracy of the method.

—On the rational estimation of gluten in wheaten flour: E. **Fleurent.** It is shown that by taking certain precautions as to the temperature and lime contents of the wash water, and fixing the time of washing, it is possible to obtain results by the mechanical method which agree well with the chemical method.—Physicochemical researches on hæmolysis: Victor **Henri.**—The comet *e* 1904, discovered December 28, 1904, at the Observatory of Marseilles: M. **Borrelly.**—The provisional elements of the new Borrelly comet (1904 December 28): G. **Fayet** and E. **Maubant.**—On the isochronism of the pendulum in the astronomical clock: Ch. **Féry.** For an amplitude between 2° 13′ and 2° 29′, that is, for a variation of amplitude of about 9 mm., the variation of the rate was nil, or there was a minimum for the time of oscillation. This result is probably due to a want of isochronism of the escapement.—On the value of the magnetic elements on January 1: Th. **Moureaux.**—Osmotic communication in fishes between the internal and external media: Jean **Gautrelet.** Referring to a recent paper by M. Quinton, the author directs attention to a paper of his bearing on the same subject published in 1902.—On the infection of *Padda oryzivora* by *Trypanosoma paddae* and by *Halteridium Danilewskyi*: M. **Thiroux.**

INDIA.

Asiatic Society of Bengal, December 7, 1904.—The lizards of the Andamans, with the description of a new gecko and a note on the reproduced tail in *Ptychozoon homocephalum*: N. **Annandale.** Out of the nine geckos recorded from the Andamans, five or possibly six would seem to have been carried thither by man. The remaining three are indigenous. One of the three is very nearly related to forms on the nearest mainland, the second has Malabar affinities, and the third Madagascan. The author describes *Gonatodes Andersonii*—a new species. The scales of the reproduced part of the tail, dorsal and ventral surfaces, of *Ptychozoon homocephalum* are slightly smaller than those of the uninjured part, and the dorsal tubercles are absent; also the loose membrane is narrower, asymmetric, and not lobed. This last point is important, as Müller had thought the lobes of specific importance.—The occurrence of an aquatic glow-worm in India: N. **Annandale.** A glow-worm larva of aquatic habit has been found in a tank in the neighbourhood of Calcutta. The only other aquatic glow-worm recorded was found in Lower Siam.

DIARY OF SOCIETIES.

THURSDAY, JANUARY 19.

CONTENTS.

THURSDAY, JANUARY 26, 1905.

A MONOGRAPH OF THE HELIOZOA.

Les Heliozoaires d'Eau Douce. By E. Penard. Pp. 341; illustrated. (Geneva: Henry Kundig, 1904.)

THE Heliozoa or "sun-animalcules" have always been favourite objects with microscopists on account of their abundance, especially in fresh water, their relatively large size, and their beauty as objects for the microscope. From the scientific aspect, however, they have not attracted so much attention as many other groups of Protozoa, on account, perhaps, of their somewhat isolated position from the systematic or phylogenetic point of view, no less than from their perfect innocuousness, so far as mankind is concerned. The work before us is a monograph of the fresh-water Heliozoa, based upon investigations upon those found in the environs of Geneva. It was the author's original intention, he tells us, to have confined himself to a description of the forms occurring in that territory, but since he obtained there nearly all the species hitherto known from fresh water, he has added to his catalogue descriptions of the species which appear not to occur in the sphere of his personal investigations in order to give his monograph a wider basis.

The monograph is divided into four chapters. The first contains general considerations on the structure, reproduction, and affinities of the group; the second gives a systematic account of those fresh-water forms, the position of which among the Heliozoa is above suspicion; the third deals with the "Pseudo-Heliozoa," that is to say, with organisms commonly referred to this group, but of which the affinities and systematic position are dubious; and the fourth discusses synonymic species, namely, those which are of doubtful nature, or which have not been described in a manner adequate for identification. The work further commences with a short introduction and ends with a full bibliography, and is illustrated by numerous text figures.

In his general chapter the author gives first an account of the methods employed by him for collecting these organisms, and then proceeds to consider their body-structure. Under the latter heading he distinguishes two principal types of Heliozoa. The first, or Actinophrys-type, has a large spherical nucleus occupying the centre of the body, and lying, surrounded by a clear zone of protoplasm, in the granular and vacuolated endoplasm, which in its turn is enveloped by the very vacuolated ectoplasm containing a large contractile vacuole. The pseudopodia, seldom longer than the diameter of the body, are supported by relatively strong axial filaments, centred round the nucleus and radiating thence to the periphery of the spherical body. To this first type, which might be called the text-book Heliozoön, may be referred, besides Actinophrys, the genera Clathrulina and Hedriocystis, while Actinosphærium is derived from it by multiplication of the originally single nucleus. The second or Acanthocystis-type is much commoner; here the centre of the spherical body is occupied, not by the nucleus, but by a central granule, apparently somewhat of the nature of a centrosome, from which radiate the delicate axial filaments, each passing to the surface of the body to be continued into one of the slender pseudopodia, which usually exceed the diameter of the body in length. The central granule and nucleus are both contained in the endoplasm ordinarily so called, which itself is eccentric in position, so that the surrounding zone of ectoplasm becomes thin on one side of the body and is thickest at the pole opposite to this. The large nucleus is placed eccentrically in the endoplasm, being always near the region where the ectoplasmic zone is at its thinnest, and is therefore still more markedly eccentric in relation to the body as a whole. The author inclines to the opinion that the ordinary use of the terms ectoplasm and endoplasm is incorrect in the case of the Acanthocystis-type of Heliozoön. He thinks that the true ectoplasm is here limited to a narrow peripheral zone of the body, and that the remainder of what is commonly called ectoplasm should really be considered as endoplasm, of which that part to which the term endoplasm is usually applied is only a special region, containing nucleus and central granule, and perhaps homologous with the clear zone round the nucleus in Actinophrys.

In the classification the author keeps to the division into the four well known orders founded by Bütschli, and since repeated in every text-book, although he is decidedly of opinion that this classification "is artificial and does not always correspond to the real affinities of the species." If this is the case, it is a matter for regret that the author did not attempt to embody his ideas of the natural relationships of the Heliozoa in a scheme of classification more suited to express them. He contents himself, however, by making only minor improvements, such as transferring the genus Heterophrys from the Chlamydophora to the Chalarothoraca. He also separates from Bütschli's list certain forms which are placed by him under the heading "Pseudo-Heliozoa." This category, he is at pains to explain, is not intended to have any systematic value, but merely to serve as a mode of uniting "certain organisms which exhibit points of resemblance to Heliozoa sufficiently striking to tempt one to unite them with the latter, and which nevertheless do not belong to the group." Under the Pseudo-Heliozoa are placed various aberrant types the descriptions of which constitute one of the most valuable portions of the book to the student of Protozoa.

For the many interesting details of structure or mode of life of these animalcules described by the author the reader must be referred to the book itself. The following sentences, however, from the section headed "Psychology" merit quotation:—

"If we wish to adopt the chemico-physical theory, so much in favour now-a-days, according to which everything in the lower beings is but mechanical reaction, it is necessary to apply the theory consistently, to examine the higher animals as well as the others, and we shall then be forced to recognise that between the top and the bottom of the psychical scale there is only a descending gradation. Hence, according to this theory, the savant solving a problem should only differ from the Protist in the greater complexity of the physico-chemical reactions. If on the contrary one is led to see something more than matter in the highest manifestations of human thought, this something must likewise be admitted for the beings lowest in the scale. But then, we may add, on the supposition that the scale rests on pure matter, it is not on the lowest grade that we find the infinitely minute creatures, but already some way up, so much so that the gap separating them from the bottom is infinitely greater than that which they would have to traverse to arrive at the summit."

In conclusion, it may be said that everyone interested in the study of microscopic forms of life will welcome this work from the hand of an enthusiastic observer, who has a most intimate knowledge at first hand with the creatures about which he is writing, and who has achieved a wide reputation as an investigator of the fresh-water Protozoa. The work is weakest on the side which deals with the minuter phenomena of the cell and nucleus, especially in relation to reproduction, the study of which during the last decade has developed with such rapidity and has brought forth results of such fundamental importance in biology. The author is evidently more of a naturalist than of a cytologist, but it is perhaps too much to expect detailed cytological work in a systematic monograph even of a group of Protozoa. As a general survey of the peculiar forms dealt with it will be found most useful, not only as an exposition of the present state of knowledge, but even more as indicating how much still remains to be worked out with regard to the affinities of the Heliozoa and allied forms of life. By directing attention to the many interesting problems these lowly creatures present for solution, it may be hoped that this monograph will act as a guide and stimulus to investigators in all countries.

E. A. M.

TREES.

Trees. By Prof. H. Marshall Ward. Vol. i. Buds and Twigs. Pp. xiv+271. Vol. ii. Leaves. Pp. x+348. (Cambridge: University Press, 1904.) Price 4*s.* 6*d.* net each.

AS one might naturally expect from the scant attention which has hitherto been given to the study of forestry in this country, our literature on the subject is by no means what it ought to be. True, we have several standard works, excellent of their kind, which, however, deal with trees more from a sylvicultural than from a botanical aspect. Students of forestry, and especially students of forest botany, and all those interested in the growth and cultivation of trees, have long felt the great want of a suitable text-book or guide to their studies, but happily now, with the appearance of the above handbook from the facile pen of Prof. Marshall Ward, this want has become a thing of the past.

The work will consist of several parts—each part forming a volume—the first of which is already to hand, and treats of buds and twigs. The mere mention of buds and twigs might suggest to some a dry, uninteresting study of minute details; but never was a greater mistake made than to imagine such is the case. The study of our trees and shrubs in their winter condition has a fascination all its own, and, in addition to this, the clear and simple way in which the author treats the subject is sure to inspire many with interest and enthusiasm for the study of forest botany.

The study of the minute structure of plants in the laboratory has in many cases received the lion's share of attention, with the result that students have been taught to know the internal structure of plants before they were able to recognise these plants in the field. The author clearly recognises this fact, and plainly states that his object is to bring the student more into touch with the plant in its natural surroundings, where he may form a personal acquaintance with it and learn to observe and note facts for himself, and thereby lay a solid foundation for the further study of the biology of the living plant of whatever kind or nature. The opening chapter gives a short but clear account of the general segmentation of the plant. The next eight chapters are devoted to a consideration of buds. The different kinds, structure, position, arrangement, and function are described in a most masterly and interesting fashion. The next seven chapters deal with the different kinds of shoots—their tegumentary systems, leaf-casting and the formation of leaf scars, lenticels, twigs and other accessory characters.

The second portion of the book contains a very comprehensive classification of trees and shrubs according to characters afforded by their buds and twigs. The classification is accompanied by a complete set of illustrations, showing very clearly in pictorial form all those features by which the species may be determined in their winter condition. Most of those drawings have been done by Miss Dawson, of the County School, Cambridge, to whose artistic skill they do great credit. The other illustrations with which the volume teems have been obtained from various sources, and are all duly acknowledged by the author.

The work will be found indispensable to those students who wish to make an expert study of forest botany. At the same time it is expressed in language so clear and devoid of technicalities that the amateur who wishes to know something about our trees and shrubs will find this one of the most useful guides to which he can turn.

Succeeding volumes will deal with leaves, inflorescences and flowers, fruits and seeds, seedlings, and the habit and conformation of the tree as a whole, and each of those volumes, like the present one, will contain diagnostic tables at the end, devised for use in the field.

From the foregoing it will be seen that the work is a many-sided one, acting not only as a guide to the naturalist in the field, but also as a laboratory handbook, where the use of the lens and microscope may be employed to amplify the study of objects already observed in their natural habitats.

Botanists generally, and especially forest botanists, will welcome the appearance of this book as supplying a decided want, and filling a distinct gap in our literature of forest botany.

Since the above was written the second volume has appeared. As already stated, it deals with leaves, and, like vol. i., consists of a general and a special part.

The general part contains an admirable and exhaustive treatment of the external features of leaves, their form, composition and arrangement, together with the general characters of their venation, surface and texture; nor has the author omitted to go into the more detailed but equally important consideration of the anatomical structure and physiological functions of leaves. This part also contains many lists comprising those leaves which show the same common features as regards arrangement on the twig, form of venation, character of base, apex and margin of lamina, &c.

Part ii. of this volume, like that of vol. i., gives the classification of trees and shrubs, but, in this case, according to the character of their leaves. A useful glossary is given at the end of the volume, so that the beginner need have no difficulty in understanding the few but necessary technical terms which are used in the book.

ADVANCES IN PHYSICAL SCIENCE.

The Recent Development of Physical Science. By W. C. D. Whetham, F.R.S. Pp. xii+344. (London: John Murray, 1904.) Price 7s. 6*d.* net.

IT is now nearly thirty years since Prof. Tait published his lectures on "Recent Advances in Physical Science." The period that has since elapsed has been one of remarkable fruitfulness, and it is a suggestive fact that the fundamental problems of physical science which were dealt with by Prof. Tait have to so large an extent supplied the motive for the investigations now described by Mr. Whetham. Foremost amongst these perennial problems must be placed the structure of matter, the mutation of energy, and the nature of comets and nebulæ. Lord Kelvin's vortex-ring theory of the atom, so lucidly expounded by Prof. Tait, finds in the later volume its analogue in the electrical or corpuscular atom of Prof. J. J. Thomson, and the doctrine of the conservation of energy, which occupies the foremost position in the earlier volume, is again brought into prominence by the recent suggestions that the internal motion of the atom, be it that of a vortex ring or of a moving electron, may perhaps be drawn upon to supply the energy that is liberated from some hidden storehouse by the radio-active elements.

After an introductory chapter on the philosophical basis of the science, Mr. Whetham devotes two chapters to the liquefaction of gases and the phenomena of fusion and solidification. These two chapters afford striking examples of the way in which recent years have added to the equipment of the experimental sciences, not only by increasing the range of temperatures within which investigations may now be conducted, but also by providing the means of accurately measuring these temperatures. Under the heading of "Fusion and Solidification" Mr. Whetham has given a concise and readable account of the knowledge recently acquired with reference to the structure of metals and alloys. The examples, already classical, of the copper-tin alloys studied by Roberts-Austen and by Heycock and Neville, and the iron-carbon alloys studied by Osmond, le Chatelier, Roberts-Austen, and others are described. Photomicrographs of the former series of alloys are given. The most fascinating part of the chapter, however, is that which deals with Mr. Beilby's recent investigations of the surface structure of solids. These investigations have shown that even a brittle metal like antimony can be made at ordinary temperatures to flow like a liquid, so that when it is rubbed with fine emery paper the surface produced is not jagged or crystalline, but under the highest magnification appears rather like a freshly painted surface on which the rounded streaks left by the brush are still visible.

In the chapter on the problems of solution, the mechanism of electrolysis is discussed from the point of view of Arrhenius's theory of electrolytic dissociation, but the arguments in favour of this theory are stated with a moderation that is in marked contrast to the one-sided statements that have sometimes been put forward by ardent supporters of the theory. In considering the nature of colloidal solutions, a purely physical explanation is given of the coagulation of the proteids; the observation that "the direction of movement of certain proteids" under the influence of an electric current "could be changed by changing the solvent from a very dilute acid to a very dilute alkali" would be interpreted by the chemist as evidence of their power, as amino-acids, to function either as acid or as base, whilst the fact that "if the solvent was very carefully neutralised an isoelectric point was reached at which the solution became very unstable and coagulation seemed to occur spontaneously" would be ascribed to the tendency of the free amino-acid to condense and form a more complex molecule in the manner characteristic of this group of compounds.

The chapters on the conduction of electricity through gases and on radio-activity contain a concise account of the series of investigations that have been co-ordinated in the recently published works of Prof. J. J. Thomson and Prof. Rutherford. The chapter on atoms and æther derives its chief interest from the inclusion in it of the results of Prof. Thomson's recent investigations of the stability of a system of negatively charged corpuscles revolving in orbits within a positively charged sphere. The atomic model suggested by such a system gives, probably for the first time, a clear representation of the periodic properties of the elements, including the variation in valency, which is the most characteristic of these properties.

The final chapter, on astrophysics, contains an account of the more recent results of spectroscopic investigations of the sun and stars, and includes reproductions of three of the most striking of Prof. Hale's solar photographs. In the later part of the chapter the pressure due to radiation is considered and applied to the explanation of the curious phenomena of comets' tails, whilst the mutual repulsion of radiating particles is suggested as a possible explanation of the permanence of Saturn's rings.

The author has sought to express the results of recent physical investigations in a form which "might prove useful to students of science in general," and "also appeal to those who, with little definite scientific training, are interested in the more important conclusions of scientific thought." In the former part of his task he has been eminently successful. In his appeal to a wider public, it is to be hoped that the difficulties of "treating the wider and deeper generalisations of natural science as fit subject-matter for current thought and literature" will not deprive him of a further measure of well merited success.

T. M. L.

THE CYANIDE PROCESS.

Cyaniding Gold and Silver Ores. A Practical Treatise on the Cyanide Process; embracing Technical and Commercial Investigations, the Chemistry in Theory and in Practice, Methods of Working and the Costs, Design and Construction of the Plant and the Costs. By H. Forbes Julian and Edgar Smart. Pp. xx+405; illustrated. (London: C. Griffin and Co., Ltd., 1904.) Price 21*s.* net.

THE cyanide process is still in its teens, but it is a lusty stripling. Much of the enormous increase in the production of gold during the last few years is due to it, either directly or indirectly. There are few gold mines of any importance in the world at which the process is not installed, and it has been stated on high authority that the majority of these mines could not earn profits and pay dividends without its aid. Owing to the shortness of the time since the industry of cyaniding gold and silver ores began to spring up, there is a lack of data on the subject readily available to men at work far from centres of civilisation. There are many books on the cyanide process, but new ones are still welcome, particularly a work like that of Messrs. Julian and Smart, in which some degree of completeness is attained.

The authors were well equipped for their task, both having been engaged in the industry for a number of years. They have not, however, merely written down the results of their own practical experience, a course which usually leads to dogmatic assertion on doubtful points, but, on the contrary, have studied the voluminous literature of the subject with evident care, and displayed some judgment in their extractions. If they had added a bibliography, one shudders to think of the portentous length it would have attained.

Not content with this, they have made a number of laboratory experiments on the dissolution and precipitation of gold, and advance views based on these which are in part novel and somewhat unsatisfactory. Exception may fairly be taken to this portion of the book, for whether these views are right or wrong, they are out of place in a text-book until they have been discussed adequately. To the practical worker, for whom this book is intended, theories are useful only if they explain and elucidate phenomena with which he is confronted in the mill, or enable him to decide on a course of action in unusual cases. Much of the authors' theorising does not appear to answer this test very well.

The book begins with an interesting, if not an impartial, chapter on the early history of the cyanide process. The authors next proceed to describe the laboratory experiments which are necessary to determine the method of applying the process to any particular ore. In the useful discussion on sampling, the omission of any reference to recent work is noticeable, and the account of automatic machines is hardly adequate.

The most serious omission in this section, however, is in regard to laboratory work in connection with a mill in operation. The examination of mill solutions for gold and other metals, for available cyanide, for oxygen, or for dissolving power is not touched on. The only reference to the matter is in the sentences:—

"It must however be understood that there is no relation between the (total cyanide) found present and the dissolving action of the solution on gold and silver. For this reason two different solutions containing by the test the same quantity of cyanide may have very different dissolving effects."

This would be cold comfort to anyone who wished to learn what he could of the methods adopted to determine the condition of a mill solution. The gap should be filled in a future edition.

The later chapters, dealing with the methods and machinery used in practice, form by far the most interesting and useful part of the book. The authors seem to be quite at home in describing the design and construction of leaching vats, precipitation boxes, pumps, launders, sizing plant, and all the accessories of a modern cyanide mill. The methods of treating different classes of material are also handled with skill and judgment, and are fairly up to date. It is not the fault of the authors that progress in the industry continues to be rapid, and that any description is behind the times almost as soon as it is printed. The book ends with a couple of excellent chapters on the cost of constructing plants and of treating ores, and the index has been carefully prepared.

The volume is handsomely got up, and enough has probably been said to show that the merits of the work so far outweigh its faults that those interested in the cyaniding industry cannot do without it.

T. K. R.

OUR BOOK SHELF.

Fireside Astronomy. By D. W. Horner. Pp. 105. (London: Witherby and Co., 1904.) Price 1*s.* 6*d.* net.

"THE articles which go to make up this little book originally appeared in the 'English Mechanic and World of Science,' and caused some discussion therein." This we read in the preface of the book before us, and we are further told there that this "simple worded treatise" is intended for the "man in the street."

A perusal of these pages will, however, tend to bewilder the mind of this very practical personage considerably, for the text is not a specimen of clearness, and the illustrations are very far from being self-explanatory; in fact, the latter are as bad as it seems possible for illustrations to be.

In justification of these statements it may be remarked that the zodiac is mentioned on p. 3 and *defined* on p. 14. On p. 4 we have a very ambiguous statement about the various altitudes of the sun at different *seasons* of the year, no reference being made to the inclination of the earth's axis to the plane of the ecliptic, or to altitudes at *noon*. On p. 11 we read:—"By refraction we mean the property of the atmosphere to bend the rays of light from celestial bodies, and so make them appear at a point in the heavens some distance (greater according to the proximity to the horizon) from their true position." Such a statement, to the man in the street, could apply equally as well to a horizontal as a vertical change of position. On p. 19 is written:—". . . solid body of the Sun himself, which is probably a relatively dark body . . ."; for such readers as this book is intended a statement of this nature should have been carefully avoided.

On the same page we must conclude that for most days of the year, especially in years away from sunspot minimum, the earth is subject to nearly a continuous series of magnetic storms, for "the appearance of spots on the sun is nearly always accompanied by a 'magnetic storm' . . . ." The use here of the term "magnetic storm" is quite unnecessary and misleading.

Enough, perhaps, has been said about the text of this "simple worded treatise," and we leave intending readers to criticise the drawings themselves, their attention being specially directed to those on pp. 6, 25, 36, and 89.

Observations océanographiques et météorologiques dans la Région du Courant de Guinée (1855–1900). (1) Texte et Tableaux. Pp. iv+116. (2) Planches, viii. The Netherlands Meteorological Institute. (Utrecht: Kemink & Zoon, 1904.) Price 5 francs.

THESE volumes contain the results of a discussion of observations recorded by Dutch shipmasters. The area extends from the equator to latitude 25° N., and from the meridian of Greenwich to 40° W. The work is a revised and more complete edition, brought up to date, of "De Guinea—en Equatoriaal Stroomen," published in 1895. Currents, winds, temperature and specific gravity of the sea water, temperature and pressure of the air, frequency of rain days, records of current ripples, flying fish, phosphorescence, and of green, brown, and blue water have been tabulated for each month in spaces of 1° squares, then grouped into 5° squares for each month and the year, also for each of twelve three-monthly periods—December to February, January to March, &c.—and finally, the current and wind results in 5° squares for each month and the year for each octant. So far as they go, the results for the various elements are interesting and valuable. Unfortunately, throughout this long period of thirty-six years Dutch ships kept so very closely within the narrow limits of the recognised outward and homeward routes that the information immediately beyond has been exceedingly sparse; indeed, over an area of about 400,000 square miles in the south-western quarter of the region under discussion not a single observation was available for the four consecutive months August to November, a period of the year when the east-going counter-current would be met with in this locality. We are presented, therefore, with very incomplete results as to the seasonal extension and contraction of this important current. It is admitted that, having failed to devise a wholly satisfactory system of weighting the frequency of winds, a method "subject to some objections" has been followed, so that whether the wind has been logged from the same point once or six times in the day it has been counted as one observation, whereas if logged from six different points in the same interval six observations have been tabulated. Except in table iv., and planches vi. and vii., the absence of current or wind has been ignored.

(1) *Opere matematiche di Francesco Brioschi*. Vol. iii. Pp. x+435. (Milan: U. Hoepli, 1904.) Price 25 lire.

(2) *Opere matematiche di Eugenio Beltrami*. Vol. ii. Pp. 468. (Milan: U. Hoepli, 1904.) Price 25 lire.

THESE are the continuations of series of collected papers of which the previous volumes have already been reviewed in NATURE.

The mathematical papers of Francesco Brioschi are published under the auspices of a committee consisting of Profs. G. Ascoli, V. Cerruti, G. Colombo, L. Cremona, G. Negri, and G. Schiaparelli. Of the papers in the third volume, Nos. 90 to 100 were published in the *Annali di matematica pura ed applicata* from 1887 to 1897, Nos. 101 to 125 in the Lombardy *Rendiconti* between 1867 and 1896, the next two in the *Memorie* of the Modena Society in 1855, and the remainder (Nos. 128 to 144) in the *Atti* of the Lincei Academy between 1870 and 1886. The papers have been revised by Profs. Bianchi, Capelli, Cerruti, Gerbaldi, Loria, Pascal, Pittarelli, and Tonelli; the volume has been edited by Profs. Gerbaldi and Pascal, and the former is mainly responsible for the revision of the proofs.

The second volume of Beltrami's works, like the first, is brought out under the auspices of the faculty of science of the University of Rome, and contains nineteen papers arranged in chronological order, numbered 27 to 45, and published between the years 1867 and 1873. The series is to be completed in five volumes.

The Science Year Book for 1905. Edited by Major B. F. S. Baden-Powell. Pp. iv+393. (London: King, Sell and Olding, 1905.)

A PLACE should be found for this Year-book on the writing table of every astronomer and meteorologist, and the volume should be available for ready reference in laboratories and schools where science is studied. The first section of the work contains an astronomical ephemeris throughout the year, short notes relating to the movements of the earth, particulars as to paths of the principal planets this year, details of eclipses, many useful tables, and maps of constellations. There are also meteorological tables and diagrams, physical and chemical constants, and tables of weights and measures of various kinds. Another section is devoted to particulars of scientific societies at home and in America, and notes on prizes and awards offered for scientific research. This list, which at present occupies only two pages, might be made a very valuable part of the book; for, so far as we are aware, the information does not exist in a convenient form anywhere. Particulars might be given, for instance, of the subjects and values of the prizes offered each year by the Paris Academy of Sciences and many similar bodies. Short articles are contributed on the progress of different branches of pure and applied science last year, and there is a biographical directory which includes the names of fellows of the Royal Society and a few other men of science, but is not complete enough to be of much use as a directory.

The remainder of the volume consists of a diary with pages for every day, for monthly notes, cash account, &c. For each day astronomical particulars are printed at the top of the page, and there are columns in which to enter results of meteorological observations. It is very convenient to have all these matters brought together so handily for reference and record; and we have no hesitation in saying that all who are interested in natural phenomena or concerned with scientific progress will find this Year-book of great service.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Origin of Radium.

EIGHT months have elapsed since I wrote in your columns (NATURE, May 12, 1904) giving an account of some experiments designed to test the view advanced by Prof. Rutherford and myself that radium is a product of the radio-active change of uranium. I then stated that in 1 kilogram of uranium nitrate that had been under observation over a period of one year since it was completely freed from radium, the quantity of radium reproduced in that time was less than one-ten-thousandth of the quantity theoretically to be expected. This result has been widely quoted, more widely, perhaps, than I intended, for the result was a preliminary conclusion only, and, as I pointed out, obtained under very unfavourable conditions owing to the very powerful preparations of radium that had been in use in the laboratory for other researches. The necessity for publishing it was to a certain extent forced upon me by the attention the problem was beginning to attract from other investigators, and by the prospect of several months' absence abroad. I relied on the fact that the result being negative, the presence of the radium in the laboratory could have had no effect, but in this I was mistaken.

Since my return I have resumed the research in the new chemical laboratories recently erected here, into which no radium has so far been brought, and have found that the earlier result was affected by an error which invalidates the conclusion drawn. It is therefore my duty to point this out at once without waiting for any further results. I am now fairly satisfied that there is a steady production of radium from uranium, and although the quantity formed, as measured by the amount of radium emanation evolved, is of a lower order of magnitude than is indicated by the disintegration theory, it is much greater than the ten-thousandth part.

At the present time, about eighteen months since the commencement of the experiment, the kilogram of uranium nitrate in solution contains, so far as the amount of emanation evolved is a measure, about $1{\cdot}5\times10^{-9}$ gram of radium, and if the whole series of measurements from the commencement are re-calculated, eliminating the error alluded to, they are fairly consistent with there having been a steady production of radium at this rate continuously from the commencement. This gives the value 2×10^{-12} for the fraction of the uranium changing per year, whereas the most probable theoretical estimate is 10^{-9}. The new result is thus still only one-five-hundredth of the theoretical.

The error in the result published last May was not in the determination of the amount of radium emanation evolved from the uranium, but in the determination of the amount of emanation given by a known weight of radium, against which the first mentioned determination was compared. The measurements on the uranium are in good agreement with those recently obtained, whereas the comparative experiments with radium gave results too high owing to extraneous radium in the laboratory. For the effect from the uranium is so minute that to obtain a comparable effect with the radium emanation, the quantity of the latter obtainable from the smallest weighable quantity of pure radium bromide must be diluted and subdivided until only a millionth part at most remains. Thus if any emanation were present in the air of the laboratory used for the dilution, or if by mischance any of the gas apparatus, rubber tubing, or mercury had been used previously in experiments with powerful radium preparations, the results obtained would be completely false. It is now known (*vide* Rutherford, *Phil. Mag.*, November, 1904, p. 637) that even metals, as copper and silver, absorb the radium emanation appreciably and slowly evolve it. The utmost precautions have to be observed in standardising the rate of leak of the electroscope by the emanation from a known weight of radium, so that each successive dilution of the emanation is performed in an entirely new apparatus with new mercury and rubber connections. Otherwise emanation is absorbed from the gas rich in it and given out to the diluted gas, and when the final dilution should contain only one-millionth of the original emanation, as in these experiments, it will be in reality far richer. This explains the apparently paradoxical result I obtained that the determinations of the amount of radium produced were far too *low*, owing to the extraneous radium of the laboratory.

The research is being continued with the view of eliminating what appears a probable explanation of the too low rate of production. It may be that under the conditions of the experiment the greater part of the emanation is retained by the uranium solution and not evolved as gas. New methods are being tried, and it is hoped that they will give a positive answer to this question.

FREDERICK SODDY.

The University, Glasgow, January 20.

A New Radio-active Product from Actinium.

AT the suggestion of Prof. Rutherford, I have made an examination to see if there is any product in actinium corresponding to the product UrX in uranium or ThX in thorium. The investigations were made with a preparation of the emanating substance of Giesel (of activity 300 times that of uranium), which has been shown to be identical in radio-active properties with the actinium of Debierne.

Taking into consideration the similarity of actinium and thorium, both as regards their chemical and radio-active properties, I resolved to try if the method used by Rutherford and Soddy for the separation of ThX would not serve also to separate an analogous product from actinium. The experiments were at once successful. If ammonia was added to a solution of actinium in hydrochloric acid, the actinium was precipitated, while a small amount of a very active substance was left behind in the filtrate. This substance, which is so similar in properties to ThX, will be called actinium X (AcX).

The product AcX, immediately after its separation, weight for weight, was more than a hundred times more active than the original actinium. The activity increased in the first day after removal to about 15 per cent. of its original value, and then decayed with the time according to an exponential law, falling to half value in about ten days. The actinium from which the AcX had been removed, almost inactive immediately after separation, gradually recovered its lost activity. As in the case of thorium, the curve of recovery of the activity was complementary to the curve of decay of AcX.

The behaviour of the product AcX is thus completely analogous in all respects to that of ThX, only the constant of change has a different value, which is characteristic for AcX.

Special experiments, made for the purpose, showed that the emanation was produced from AcX, and not directly from the actinium. The latter, immediately after separation of AcX, gave off very little emanation, while AcX produces the emanation in large amount. The amount of emanation from AcX diminished with the time at the same rate that AcX loses its activity. At the same time the actinium gradually increased in emanating power, due to the production of fresh AcX, and finally reached an equilibrium value.

The product AcX gives out both α and β and probably γ rays. It is, however, difficult to determine whether the β rays arise directly from AcX or from the excited activity to which the emanation gives rise.

There is an interesting point of distinction between the radio-activity of thorium and actinium. After the separation of AcX, the actinium is almost completely inactive, only 4 per cent. of the maximum activity being observed. It is probable that this amount could be still further reduced by successive precipitations. Thorium and radium, on the other hand, always show a non-separable activity of about 25 per cent. of the maximum. This points to the fact that the activity from ordinary actinium is due entirely to AcX and its successive products, and that little, if any, is supplied directly by actinium itself. From the point of view of the theory of radio-active changes, this shows that the change of actinium into AcX is a "rayless" change.

A more complete account of these investigations will be published later.

A Simple Model for Illustrating Wave-motion.

MACH's model for illustrating the transversal as well as the longitudinal wave is known to work in a beautiful manner. The arrangement for exciting the wave-motion is not, however, very simple. The fact that the period of a pendulum varies with the length of the string may conveniently be åvailed of for producing a wave-motion in a row of pendulum-bobs.

As shown in the annexed figure, a series of pendulums of equal length is suspended at equal intervals. Each ball hangs on two strings, each of which passes through the corresponding one in the row of holes in one of two parallel horizontal rods M and N; the strings pass through the holes from inside to outside, and are tied together to a horizontal rod L placed symmetrically above the two rods. One end of the upper rod is pivoted, while the

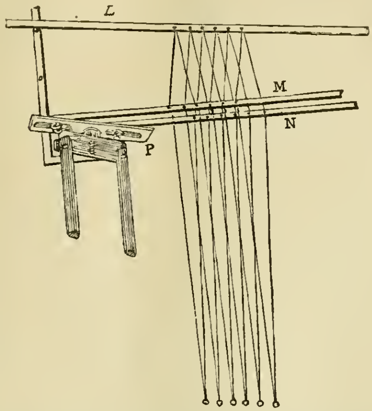

FIG. 1.

other can be raised to a suitable height. If this end be raised, the length of the pendulums increases from the end toward the other.

The two rods, M and N, can be separated or brought in contact by two links P and Q (not shown in the figure), attached to their ends. If the rods be in contact, the pendulums oscillate at right angles to the vertical plane containing the rod L; if they are separated, the pendulums oscillate in this plane. Hence, by the position of the links, the longitudinal as well as transversal oscillations of the pendulums can be excited at will.

To produce a wave-motion, the end of the upper rod L is raised, and then the two rods M and N are brought in contact. Then the pendulums are set in motion simultaneously by a long rod. After one or two minutes the phase-difference in each pendulum gradually increases, and a beautiful transversal wave-motion is produced. The wave-length becomes shorter and shorter; if a wave of a required wave-length is obtained, the rod L is lowered to its initial position. Each pendulum has then an equal length, so that wave-motion of a definite form incessantly proceeds from one end to another.

If the links be rotated, so as to separate the two bars M and N from each other, the plane of oscillation of each pendulum gradually changes, until the oscillation becomes at last longitudinal. Then a regular longitudinal wave is observed to proceed from one end to another.

On the other hand, a longitudinal wave can first be excited, and then be transformed into a transversal one. Raising the end of the upper rod, and separating the two horizontal rods M and N, each pendulum is simultaneously set in a longitudinal motion by a long rod with receiving holes for pendulum-bobs. A longitudinal wave is gradually formed; if a wave of a suitable length be obtained, the rod L is lowered to its initial position; then wave-motion of a definite form is established. By turning the links the longitudinal wave is transformed into a transversal one.
Tokyo, Japan.

Recently Observed Satellites.

MAY I ask whether the small, distant, eccentric, and possibly retrograde satellites of Jupiter and Saturn, which have been discovered and seem likely to be discovered, ought not more properly to be regarded as cometary bodies, or a shoal of meteors not yet too much drawn out for visibility at a distance? Would it not be possible for the larger planets to be attended by such bodies, the orbits of which have been made moderately elliptical by an accidental perturbation? It is known that the larger planets are able to capture comets for the sun; is it possible that with the aid of their satellites and subsequent tidal action they may be able to catch a few for themselves?
OLIVER LODGE.
The University, Birmingham, January 20.

Compulsory Greek at Cambridge.

MY experience of Greek at Cambridge is very similar to that of Mr. Willis, but the slight differences are, I think, instructive.

When I decided to go up to Cambridge to study mathematics and philosophy I was living abroad, and I crammed Greek just as Mr. Willis describes, except that I worked entirely alone. But on going in for the "Little Go," though I passed easily in translation, I failed by a few marks in Greek grammar. It was so near a thing that I thought I might pull through in December with a few hours more grind; but unfortunately I ran it too fine, and again failed by a few marks. This meant that I had to get up a complete new set of translation books for the following June, and to prevent further mistakes I went to a coach for the grammar part. I then passed, getting a second class. Like Mr. Willis, I can only say my present knowledge of the language is *nil*, although I had a double dose of it. It cannot for a moment be pretended that I got any insight into "Greek thought" which I could not have got equally well by reading a good translation. But I confess my opinion of the value of Greek thought was not raised by what I read—at best it only seemed to me creditable, considering how long ago it was written. But this may have been due to my resentment at being forced to waste time in an uncongenial study, when I was keen to get on to something else.
EDWARD T. DIXON.
Racketts, Hythe, Hants, January 20.

Super-cooled Rain Drops.

WALKING home from the university last night at about 8.45 p.m. an interesting phenomenon occurred.

Something was falling which at first appealed to one as hail, but I soon found that it was large rain drops evidently cooled below the freezing point; at the moment they struck objects such as one's hat, coat, or walking stick, &c., they instantly solidified in small hemispherical lumps; falling on the ground they gave it the appearance of a sheet of ice, but the roads were not slippery, as the solidified rain gave the road just a nice amount of roughness. The noise of the falling rain was very curious—a crackling noise, not unlike that of small electric sparks.
EDWARD E. ROBINSON.
The University, Birmingham, January 17.

Polar Plotting Paper.

MAY I be allowed to direct the attention of all interested in mathematical teaching in our schools and colleges to the polar plotting paper recently prepared by Mr. Ellice Horsburgh, lecturer on technical mathematics in Edinburgh University?

The special feature of this paper is that it is ruled radially with lines which subdivide the region about a point into aliquot parts of a radian. There are two forms of sheets now in the market. In one the origin is at the centre, and the radial subdivision is carried right round through four right angles. In the other, a reduced copy of which is here reproduced, the origin is taken near one corner, and the graduation is carried through a little more than a quadrant. Dotted radial lines show the backward continuation of the axis from which the radians are measured, and also the axis perpendicular to it. These dotted lines do not, of course, belong to the system of lines dividing the region into aliquot parts of a radian.

The radius of the fiftieth orthogonal circle is taken as the unit, and on the margins just outside the proper radian subdivisions small radial lines are drawn giving the usual division into degrees. The two circles drawn, the one on the axis as diameter and the other on the dotted perpendicular of unit length, serve to give by inspection the sines and cosines of the angles given in radians.

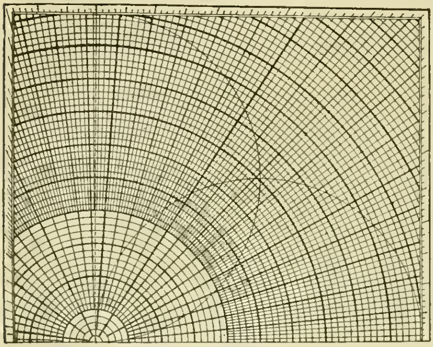

FIG. 1

Thus the paper contains on its own surface the means of plotting with great ease the polar equations of curves involving radians, sines and cosines, and a little calculation will enable the student to take account of other functions.

The first important use in the hands of the student is obviously to get a clear idea of the radian as the true scientific measure of angle; but a great many other important uses will at once occur to the teacher of practical mathematics, such, for example, as finding reciprocals, geometric means, mean proportionals, fourth proportionals, squares, square-roots, &c.

Another use is the evaluation of the integrals $\int r^2 d\theta$ and $\int r d\theta$. The former is got by simply counting the elements included in the area, and the latter by multiplying the total angle between the initial and final radius by the mean radius, the value of which may be obtained by a method similar to Simpson's rule.

From these few statements and indications the purpose of Mr. Horsburgh's patent will be readily appreciated. It is doubtful if the average student, taught along the usual lines, ever gets an accurate working knowledge of the radian or circular measure of an angle, indispensable though that is for all higher trigonometrical and analytical work. A few hours' systematised exercise with the polar paper will do more than days of arithmetical transformations in the usual academic style.

C. G. KNOTT.

Lissajous's Figures by Tank Oscillation.

THE oscillation of a rectangular water basin may be utilised for the illustration of the composition of two simple harmonic motions in two directions, perpendicular to each other.

A light pendulum was constructed of a thin aluminium rod, R (Fig. 1), 10 cm. long. The bob B was made of a disc of wood. On the upper end of the rod a light mirror M was attached. The rod could be supported at any desired point by a small gimbal G, so that the rod could oscillate as a spherical pendulum. A small brass weight W was attached to adjust the period of oscillation by raising or lowering it to a proper position.

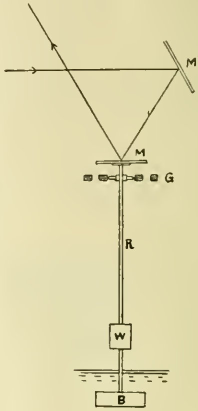

Fig. 1

The bob is sunk into the middle part of a suitable rectangular basin, filled with water to a proper depth. If the basin be tilted suddenly, and then let stand, the water is set in an oscillation which consists of two simple harmonic motions in perpendicular directions, the ratio of the periods varying as the ratio of the corresponding sides. The amplitudes of two component oscillations may be varied at pleasure. If the natural period of the pendulum is considerably shorter than that of the basin, the bob follows very nearly the motion of water, as judged by the motion of fine dust particles suspended in water. Now, if a beam of strong sun-light be sent as shown in the figure, the motion is projected on the ceiling of the room.

I have also obtained a photographic record of the motion of a small bead attached to the upper end of a small needle erected on the rod. By making the illumination intermittent by means of a perforated rotating disc, the difference of velocities at different phases may be shown.

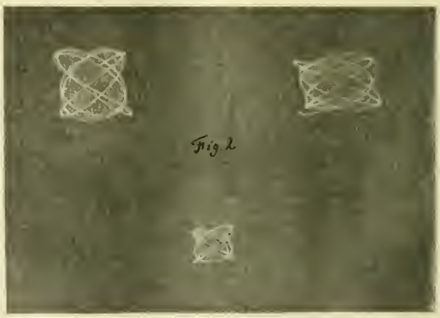

Fig 2

The motion of a kaleidophone may be projected in a similar manner.

T. TERADA.

Physical Laboratory, Tokyo, December 19, 1904.

NOTES ON STONEHENGE.

I.—CONDITIONS AND TRADITIONS.

AFTER Mr. Penrose, by his admirable observations in Greece, had shown that the orientation theory accounted as satisfactorily for the directions in which the chief temples in Greece had been built as I had shown it did for those in Egypt, it seemed important to apply the same methods of inquiry with all available accuracy to some example, at all events, of the various stone circles in Britain which have so far escaped destruction. Many attempts had been previously made to secure data, but the instruments and methods employed did not seem to be sufficient.

Much time has, indeed, been lost in the investigation of a great many of these circles, for the reason that in many cases the relations of the monuments to the chief points of the horizon have not been considered; and when they were, the observations were made only with reference to the magnetic north, which is different at different places, and besides is always varying; few indeed have tried to get at the astronomical conditions of the problem.

So far as I know, there has never been a complete inquiry into the stone circles in Britain, but Mr. Lewis, who has paid much attention to these matters, has dealt in a general manner with them (*Archaeological Journal*, vol. xlix. p. 136), and has further described (*Journal* Anthropological Institute, n.s., iii., 1900) the observations made by him of stone circles in various parts of Scotland. From an examination of a large number he concludes that they may be divided into different types, each of which has its centre in a different locality. The types are (1) the Western Scottish type, consisting of a rather irregular single ring or sometimes of two concentric rings. (2) The Inverness type, consisting of a more regular ring of better-shaped stones, surrounding a tumulus with a retaining wall, containing a built-up chamber and passage leading to it, or a kist without a passage. (3) The Aberdeen type, consisting of a similar ring with the addition of a so-called "altar-stone" and usually having traces of a tumulus and kist in the middle. In addition to these three types of circles, there are what Mr. Lewis calls sun and star circles, with their alignments of stones, and apparently proportioned measurements.

It may be useful here to state, with regard to megalithic remains generally, that they may be divided as follows:—

(*a*) Circles. These may be single or double, and either concentric or not.

(*b*) Menhirs, or single stones, in some cases still upright, but in many overthrown.

(*c*) Alignments, *i.e.* lines of stones in single, double, or in many parallel lines. If these alignments are short they are termed avenues.

(*d*) Cromlechs; this term generally means a collection of stones; the term is applied to irregular circles in Brittany. It also applies to a single stone raised on the summits of two or more pillar stones forming the end and sides of an irregular vault generally open at one end ("Dolmens of Ireland," Borlase, p. 429).

(*e*) Coves. A term applied by Dr. Stukeley and others to what they considered shrines formed by three upright stones, thus leaving one side open. I take them to be partially protected observing places. There are well-marked examples at Avebury, Stanton Drew, and Kit's Coity House.

(*f*) Dolmens, from Dol Men, a table stone. These consist of a flat stone resting on two or more upright stones forming a more or less complete chamber, which may or may not have been sepulchral. I note the following subdivisions, "Dolmen a galérie" having an entrance way of sufficient height, and "Galgal," similar but smaller. In the "Dolmen à l'allée couverte" there is a covered passage way to the centre. It is a more elaborate cove. For the relation between cromlechs and dolmens, see Borlase (*loc. cit.* and p. 424 *et seq.*).

With regard to dolmens, I give the following quotation from Mr. Penrose (NATURE, vol. lxiv., September 12, 1901):—

"Near Locmariaquer in the estuary named Rivière d'Auray, there is an island named Gavr' Inis, or Goat Island, which contains a good specimen of the kind of dolmen which has been named 'Galgal.'

"At the entrance our attention is at once arrested by the profusion of tracery which covers the walls. From the entrance to the wall facing us the distance is between 50 and 60 feet. The square chamber to which the gallery leads is composed of two huge slabs, the sides of the room and gallery being composed of upright stones, about a dozen on each side. The mystic lines and hieroglyphics similar to those above mentioned appear to have a decorative character.

"An interesting feature of Gavr' Inis is its remarkable resemblance to the New Grange tumulus at Meath. In construction there is again a strong resemblance to Mæs-Howe, in the island of Orkney. There is also some resemblance in smaller details."

While we generally have circles in Britain without, or with small, alignments, in Brittany we have alignments without circles, some of them being on an enormous scale[1]; thus at Menec (the place of stones) we have eleven lines of menhirs, terminating towards the west in a cromlech, and notwithstanding that great numbers have been converted to other uses, 1169 menhirs still remain, some reaching as much as 18 feet in height.

The alignments of Kermario (the place of the dead) contain 989 menhirs in ten lines. That of Kerlescant (the place of burning), which beginning with eleven rows is afterwards increased to thirteen, contains altogether 579 stones and thirty-nine in its cromlech, with some additional stones.

Both circles and alignments are associated with holidays and the lighting of fires on certain days of the year. This custom has remained more general in Brittany than in Britain.

At Mount St. Michael, near Carnac, the custom still prevails of lighting a large bonfire on its summit at the time of the summer solstice; others kindled on prominent eminences for a distance of twenty or thirty miles round reply to it. These fires are locally called "Tan Heol," and also by a later use, Tan St. Jean.

In Scotland there was a similar custom in the first week in May under the name of Bel Tan, or Baal's Fire; the synonym for summer used by Sir Walter Scott in the "Lady of the Lake":—

> Ours is no sapling chance-sown by the fountain
> Blooming at Beltane in winter to fade.

At Kerlescant the winter solstice is celebrated by a holiday, whilst Menec greets the summer solstice, and Kermario the equinoxes, with festivals. The adoration paid these stones yielded very slowly to Christianity. In the church history of Brittany the *Cultus Lapidum* was denounced in 658 A.D.

Many of the fallen menhirs in these alignments have been restored to their upright position by the French Government. Some of them may have been overturned in compliance with the decree of 658 A.D. above referred to. Several of the loftier menhirs are surmounted by crosses of stone or iron.

[1] "The French Stonehenge: an Account of the Principal Megalithic Remains in the Morbihan Archipelago." By T. Cato Worsfold, F.R.Hist.S. F.R.S.L. (London: Bemrose and Sons, Ltd.)

Regarding both circles and alignments in the light of the orientation theory, we may consider simple circles with a central stone as a collection of sight-lines from the central stone to one or more of the outer ones, or the interval between them, indicating the place of the rise or setting of either the sun or a star on some particular day of the year, which day will be a new year's day.

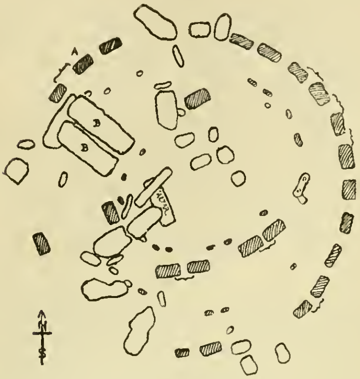

FIG. 1.—Plan of Stonehenge, standing stones shaded. A, Stone which fell in 1900; BB, Stones which fell in 1797.
(*Reproduced from "Man."*)

Alignments, on the other hand, will play the same part as the sight-lines in the circles.

Sometimes the sight-line may be indicated by a menhir outside, and even at a considerable distance from, the circle.

The dolmens have, I am convinced, been in many cases not graves originally, but darkened observing places whence to observe along a sight-line; this would be best done by means of an allée couverte, the predecessor of the darkened naos at Stonehenge, shielded by its covered trilithons.

FIG. 2.—View of Stonehenge from the west. A, Stone which fell in 1900; BB, Stones which fell in 1797.
(*Reproduced from an account of the fallen stones by Mr. Lewis in "Man."*)

In order to bring some measurements to test the orientation theory in Britain, I found that Stonehenge is the ancient monument in this country which lends itself to accurate theodolite work better than any other. Avebury and Stanton Drew are known to a great many archæologists; there are also other very wonderful stone circles near Keswick and in other parts of England; but unfortunately it is very much more difficult to get astronomical data from these ancient monuments than it is in the case of Stonehenge, one reason being that Stonehenge itself lies high, and the horizon round it in all directions is pretty nearly the same height, so that the important question of the heights of the hills along the sight-line—a matter which is very important from an astronomical point of view, although it has been neglected, so far as I can make out, by many who have made observations on these ancient monuments—is quite a simple one at Stonehenge. Hence it was much easier to determine a date there than by working at any of the other ancient remains to which I have referred.

In orientation generally, such orientation as has been dealt with by Mr. Penrose and myself in Egypt and in Greece, the question frequently was a change in direction in the axis of a temple, or the laying down of the axis of a temple, by means of observations of stars. Unfortunately for us as archæologists, not as astronomers, the changes of position of these stars, owing to certain causes, chiefly the precessional movement, are very considerable; so that if a temple pointed to a star in one year, in two or three hundred years it would no longer point to the same star, but to another one.

Acting on a very old tradition, the people from Salisbury and other surrounding places go to observe the sunrise on the longest day of the year at Stonehenge. We therefore are perfectly justified in assuming that it was a solar temple used for observation in the height of midsummer. But at dawn in midsummer in these latitudes the sky is so bright that it is not easy to see stars even if we get up in the morning to look for them; stars, therefore, were not in question, so that some other principle had to be adopted, and that was to point the temple directly to the position on the horizon at which the sun rose on that particular day of the year, and no other.

Now, if there were no change in the position of the sun, that, of course, would go on for ever and ever; but, fortunately for archæologists, there is a slight change in the position of the sun, as there is in the case of a star, but for a different reason; the planes of the ecliptic and of the equator undergo a slight change in the angle included between them. So far as we know, that angle has been gradually getting less for many thousands of years, so that, in the case of Stonehenge, if we wish to determine the date, having no stars to help us, the only thing that we can hope to get any information from is the very slow change of this angle; that, therefore, was the special point which Mr. Penrose and I were anxious to study at Stonehenge, for the reason that we seemed in a position to do it there more conveniently than anywhere else in Britain.

But while the astronomical conditions are better at Stonehenge than elsewhere, the ruined state of the monument makes accurate measures very difficult.

Great age and the action of weather are responsible for much havoc, so that very many of the stones are now recumbent, as will be gathered from the accompanying plan, for which I am indebted to Mr. Lewis, who described the condition of the monument in 1901 in *Man*.

But the real destructive agent has been man himself; savages could not have played more havoc with the monument than the English who have visited it at different times for different purposes. It is said the fall of one great stone in 1620 was caused by some excavations of the then Duke of Buckingham; the fall of another in 1797 was caused by gipsies digging a hole in which to shelter, and boil their kettle; many of the stones have been used for building walls and bridges; masses weighing from 56 lb. downwards have been broken off by hammers or cracked off as a result of fires lighted by excursionists.

It appears that the temenos wall or vallum, which is shown complete in Hoare's plan of 1810, is now broken down in many places by vehicles indiscriminately driven over it. Indeed, its original importance has now become so obliterated that many do not notice it as part of the structure—that, in fact, it bears the same relation to the interior stone circle as the nave of St. Paul's does to the Lady Chapel.

It is within the knowledge of all interested in archæology that not long ago Sir Edmund Antrobus, the owner of Stonehenge, advised by the famous Wiltshire local society, the Society for the Protection of Ancient Buildings and the Society of Antiquaries, enclosed the monument in order to preserve it from further wanton destruction, and—a first step in the way of restoration—with the skilled assistance of Prof. Gowland and Messrs. Carruthers, Detmar Blow, and Stallybrass, set upright the most important menhir, which threatened to fall or else break off at one of the cracks. This menhir, the so-called "leaning stone," once formed one of the uprights of the trilithon the fall of the other member of which was said to have been caused by the digging and researches of the Duke of Buckingham in 1620. The latter, broken in two pieces, and the supported lintel, now lie prostrate across the altar stone.

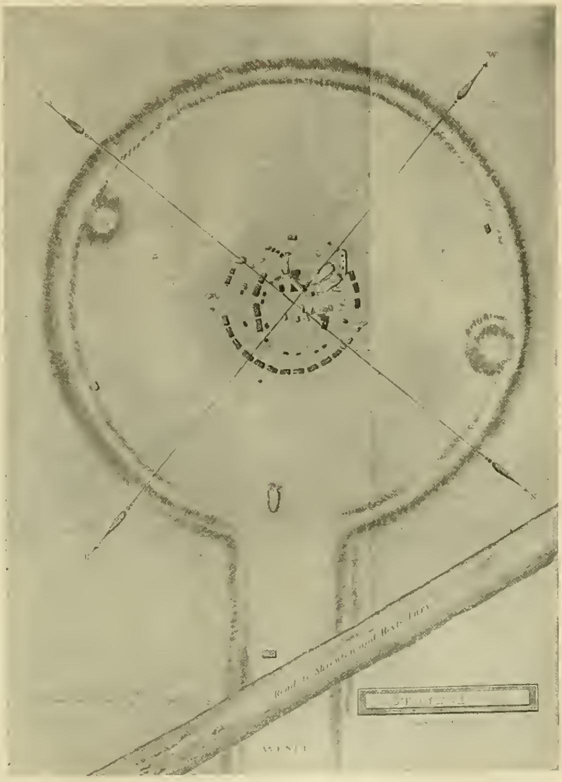

FIG. 3.—Copy of Hoare's plan of 1810, showing unbroken Vallum and its relation with the Avenue.

This piece of work was carried out with consummate skill and care, and most important conclusions, as we shall see in a subsequent "Note," were derived from the minute inquiry into the conditions revealed in the excavations which were necessary for the proper conduct of the work.

Let us hope that we have heard the last of the work of devastators, and even that, before long, some of the other larger stones, now inclined or prostrate, may be set upright.

Since Sir Edmund Antrobus, the present owner, has acted on the advice of the societies I have named to enclose the monument, with a view to guard it from destruction and desecration, he has been assailed on all sides. It is not a little surprising that the "unclimbable wire fence" recommended by the societies in question, the Bishop of Bristol being the president of the Wiltshire Society at the time, is by some regarded as a suggestion that the property is not national, the fact being that the nation has not bought the property, and that it has been private property for centuries, and treated in the way we have seen.

Let us hope also that before long the gaps in the vallum may be filled up. These, as I have already stated, take away from the meaning of an important part of one of the most imposing monuments of the world. In the meantime, it is comforting to know that, thanks to what Sir Edmund Antrobus has done, no more stones will be stolen, or broken by sledge-hammers; that fires; that excavations such as were apparently the prime cause of the disastrous fall of one of the majestic trilithons in 1797; that litter, broken bottles and the like, with which too many British sightseers mark their progress, besides much indecent desecration, are things of the past.

If Stonehenge had been built in Italy, or France or Germany, it would have been in charge of the State long ago.

I now pass from the monument itself to a reference to some of the traditions and historical statements concerning it.

Those who are interested in these matters should thank the Wiltshire Archæological and Natural History Society, which is to be warmly congratulated on its persistent and admirable efforts to do all in its power to enable the whole nation to learn about the venerable monuments of antiquity which it has practically taken under its scientific charge. It has published two most important volumes[1] dealing specially with Stonehenge, including both its traditions and history.

With regard to Mr. Long's memoir, it may be stated that it includes important extracts from notices of Stonehenge from the time of Henry of Huntingdon (12th century) to Hoare (1812), and that all extant information is given touching on the questions by whom the stones were erected, whence they came, and what was the object of the structure.

From Mr. Harrison's more recently published bibliography, no reference to Stonehenge by any ancient author, or any letter to the *Times* for the last twenty years dealing with any question touching the monuments, seems to be omitted.

It is very sad to read, both in Mr. Long's volume and the bibliography, of the devastation which has been allowed to go on for so many years and of the various forms it has taken.

As almost the whole of the notes which follow deal with the assumption of Stonehenge having been a solar temple, a short reference to the earliest statements concerning this view is desirable; and, again, as the approximate date arrived at by Mr. Penrose and myself in 1901 is an early one, a few words may be added indicating the presence in Britain at that time of a race of men capable of designing and executing such work. I quote from the paper communicated by Dr. Penrose and myself to the Royal Society:—

"As to the first point, Diodorus Siculus (ii., 47) has preserved a statement of Hecatæus in which Stonehenge alone can by any probability be referred to.

"We think that no one will consider it foreign to our subject to say a word respecting the Hyperboreans.

"Amongst the writers who have occupied themselves with the mythology of the ancients, Hecatæus and some others tell us that opposite the land of the Celts [ἐν τοῖς ἀντιπέραν τῆς Κελτικῆς τόποις] there exists in the Ocean an island not smaller than Sicily, and which, situated under the constellation of The Bear, is inhabited by the Hyperboreans; so called because they live beyond the point from which the North wind blows. . . . If one may believe the same mythology, Latona was born in this island, and for that reason the inhabitants honour Apollo more than any other deity. A sacred enclosure [νῆσον] is dedicated to him in the island, as well as a magnificent circular temple adorned with many rich offerings. . . . The Hyperboreans are in general very friendly to the Greeks.

"The Hecatæus above referred to was probably Hecatæus of Abdera, in Thrace, fourth century B.C.; a friend of Alexander the Great. This Hecatæus is said to have written a history of the Hyperboreans: that it was Hecatæus of Miletus, an historian of the sixth century B.C., is less likely.

"As to the second point, although we cannot go so far back in evidence of the power and civilisation of the Britons, there is an argument of some value to be drawn from the fine character of the coinage issued by British kings early in the second century B.C., and from the statement of Julius Cæsar ('De Bello Gallico,' vi., c. 13) that in the schools of the Druids the subjects taught included the movements of the stars, the size of the earth and the nature of things (Multa præterea de sideribus et eorum motu, de mundi magnitudine, de rerum natura, de deorum immortalium vi ac potestate disputant et juventuti tradunt).

"Studies of such a character seem quite consistent with, and to demand, a long antecedent period of civilisation."

Henry of Huntingdon is the first English writer to refer to Stonehenge, which he calls Stanenges. Geoffrey of Monmouth (1138) and Giraldus Cambrensis come next.

In spite of Inigo Jones's (1600) dictum that Stonehenge was of Roman origin, Stukeley came to the conclusion in 1723 that the Druids were responsible for its building, and Halley, who visited it in 1720—probably with Stukeley—concluded from the weathering of the stones that it was at least 3000 years old; if he only had taken his theodolite with him, how much his interest in the monument would have been increased!

Davies ("Celtic Researches," 1804) endorses Stukeley's view:—

"Amongst the pure descendants of the Celtae, the Druidism of Britain was in its highest repute. The principal seat of the order was found in Mona, an interior recess of that ancient race, which was born in the island. Into that sequestered scene, the Druids, who detested warfare, had gradually retired, after the irruption of the Belgae, and the further encroachment of the Romans. They had retired from their ancient magnificent seat at Abury, and from their *circular uncovered temple* on Salisbury Plain, in which the Hyperborean sages had once chaunted their hymns to Apollo and Plenyz."

NORMAN LOCKYER.

PROF. ERNST ABBE.

FORTY YEARS' PROGRESS, 1866–1905.

ERNST ABBE, born January 23, 1840, was the son of a foreman in a spinning mill at Eisenach. He was a student at Jena and Göttingen, graduating at the latter university with a thesis on the mechanical equivalent of heat. After teaching for some time at Frankfort-on-Main, he established himself at Jena in 1863 as a privat docent in mathematics, physics, and astronomy, taking for a special subject of instruction the theory of errors. In 1870 he was appointed an extraordinary professor. In 1874 there was a proposal to establish a physical laboratory at Jena, and Abbe was offered the professorship of physics, but his connection with Carl Zeiss had then begun, and he was compelled to decline the offer. He had married in 1871 the daughter of Prof. Snell, and has left two daughters.

Carl Zeiss had established himself at Jena in 1846 as a manufacturer of optical instruments; for some years the business prospered, his microscopes were as good as those of other makers, probably neither better nor worse; but Zeiss was not satisfied; he felt that the microscope ought to be improved, and in endeavouring to effect improvement he realised the deficiency of his own equipment; after one other unsuccessful attempt he enlisted Abbe's help in his work.

The partnership which has had so remarkable an effect on the manufacture of optical instruments began in 1866. Abbe's task was a hard one; the theory of the microscope was at that date only partially understood; the corrections to the lenses were made by a rough trial and error method, and the results were doubtful; the first step was to solve a mathematical problem of no small difficulty, and trace the path of the light through the complex lenses of a microscope objective.

Abbe soon found out the defects of the ordinary theory, and was led in 1870 to what is now known as the Abbe theory of microscopic vision; unfortunately, no complete account of that theory from his own pen has yet been printed, though the "Collected Papers of Ernst Abbe," of which the first volume was published last year under the skilful editorship of Dr. Czapski, and noticed in these pages recently (NATURE, vol. lxix. p. 497), go far to fill the gap, and it is to be hoped that Dr. Czapski himself or some other member of the Jena staff will now be in a position to give the complete theory to the world. It is not necessary here to discuss the controversy which has arisen over the matter, due in great measure to an incomplete representation of the problem and to a misconception of the theory.

It is clear that if we can treat the object as self-luminous, or if we know the distribution of light with respect to both intensity and phase over the object plane, then we may start from the object as our source, and the principles of the wave-theory, as Lord Rayleigh has shown, will allow us to determine the distribution in the view plane. If, however, the distribution in the object plane is unknown, we must go back to the source, consider how the light from the source is modified both by the object and the lenses, and from this infer what the resulting image will be like.

Diffraction patterns will be formed practically in the second focal plane of the object glass, and the distribution of the light in the image can, theoretically at any rate, be deduced from a knowledge of the intensity and phase of the disturbance in these patterns.

This theory, at any rate, led Abbe to most valuable results, and was one source of the success of the Zeiss microscope. From it, among other consequences, he deduced the importance of what is now known as the numerical aperture, the quantity $\mu \sin \alpha$, where μ is the refractive index of the first lens of the object glass, and 2α is the angle which that lens subtends at the point where the axis of the system cuts the object plane.

But the assistance given by the new theory was not alone sufficient to solve the problem. It had long been known that when the best glasses then obtainable were combined to form an achromatic system, a secondary spectrum remained, and until this could be removed it was hopeless to look for perfection in the image.

The experiments of Stokes and Harcourt had been directed to the discovery of glasses free from this defect, and Abbe and Zeiss in their early days made many attempts in the same direction, using in some cases liquid lenses to secure the desired end.

In 1876 the South Kensington Loan Exhibition of Scientific Apparatus took place, and Abbe came over to inspect it. In his report, published in 1878, he writes:—"The future of the microscope as regards further improvement in its dioptric qualities seems to lie chiefly in the hands of the glass maker," and then he explains in what direction changes are required and how difficult it is to introduce them.

This report of Abbe's fell into the hands of Dr. Otto Schott, a glass maker of Witten, in Westphalia. Schott communicated with Abbe in 1881, and commenced his investigations into the subject. Next year he removed to Jena, and, aided by a large grant from the Prussian Minister of Education, the experiments were satisfactorily concluded, and the firm of Schott and Co. was established; in 1884 he was in a position to commence the wholesale production of optical glass. The combination was now complete. "To-day it is difficult," as Prof. Auerbach writes in his recent work on the Carl Zeiss Stiftung in Jena, "to think of the Optical Works without the Glass Works, or *vice versâ*."

From this time onwards Abbe's time was fully occupied in developing the new undertaking; the history of his life would be the history of the works, and in the Zeiss instruments, known throughout the world, his monument is to be found.

But in many ways the latter years of his life are not the least interesting. Carl Zeiss died in 1888; next year his son Roderick retired from business, and Abbe was left sole proprietor of the optical works. In 1891 he created a kind of trust known as the Carl Zeiss Stiftung, to which he ceded all his proprietary rights, both in the optical and also in the glass works.

The story of the Carl Zeiss Stiftung as told by Prof. Auerbach is a very striking one. The statutes, due to Abbe himself, which were confirmed by the Grand Duke of Saxony in 1896, and have the force of law, can up to 1906 be modified by a simple procedure; afterwards legal action is practically required to render a change valid.

The works are a great cooperative concern. "To provide a large number of people with the most favourable opportunities for labour is both the means and the end of the Stiftung. The individuals who benefit by it are at the same time those who maintain and increase it. The officials and workmen employed at the optical works, the community and the university contribute their share towards the increase of the value of the property, and these, therefore, are entitled to participate in the benefits." The university alone will shortly have received 100,000*l.* from the scheme.

The Stiftung is managed by the Stiftung Administration; on this the Saxon Government appoints a representative or trustee whose duty it is to see that the statutes are obeyed; the works are supervised by boards of management appointed by the administration.

The employés possess the right of combination; they can be represented by their own committees, which may address the administration direct on any subject relating to the affairs of the concern. They are paid by piece-work, with a minimum time wage, and there is in the scheme a proviso by which no one, even though a member of the board of management, can receive a salary greater than ten times the average yearly earnings of workers of twenty-four years and over who have been at least three years with the firm. Moreover, when an employé has once received a certain wage and drawn it for one year his wage cannot be reduced because of slackness of trade. In addition to the wages calculated on the work done, every worker receives a share of the profits depending in any year on the net sum realised. There is also a liberal pension scheme, under which every employé who enters the works before his fortieth year is entitled, after five years' service, to a pension calculated at a rate which reaches 75 per cent. of his salary at the end of forty years' service, while the widows and orphans of employés have also pension rights. Finally, the working day is eight hours, and Abbe has put it on record in an address, delivered in 1901 to the Social Science Association, that in the case of 233 piece-workers about whom accurate statistics could be taken the total output was increased by 4 per cent. in the first year that followed the change from nine to eight hours.

Such has been Ernst Abbe's work; until 1903 he remained an active member of the board of management of the optical works; then he retired, partly on account of the state of his health, partly, if his health improved, to devote himself to his scientific work. The improvement hoped for never came, and he died last week, leaving it to the trained band of workers he had gathered round him to continue his task, and to show still further what can be done by the organised application of science to industry and manufactures.

R. T. G.

M. PAUL HENRI.

ABOUT the year 1864, two brothers entered the meteorological department of the Paris Observatory, and for nearly forty years laboured with zeal and success to promote the best interests of that institution and of astronomical science generally. In the autumn of 1903, one brother, M. Prosper Henri, died suddenly on a holiday tour, and we now have the melancholy duty of chronicling the death of the second brother, M. Paul Henri. It is necessary to recall the close and intimate relations that existed between these two, because the scientific life of one was that of the other. No one has ever thought of them separately, no one has ever attempted to discriminate between their successes and their triumphs. The same day (November 8, 1889) they were both elected associates of the Royal Astronomical Society, and other instances of similar recognition of their united work might be quoted. We may quote the words of the late M. Callandreau of these two:—"si unis que nous ne voyons souvent en eux qu' une seule personne pour ainsi dire, si oublieux de faire ressortir leur mérites respectifs qu' il est difficile de distinguer ce qui peut appartenir à chacun dans l'œuvre commune."

It is an oft-told tale to recall how these brothers, with whom mechanical art was a conspicuous gift, constructed their own instruments, and laboured to complete the ecliptic charts on which Chacornac had worked, how their systematic work and diligence added to the number of small planets, and how, finally, the necessity was forced upon them of adopting improved methods in registering the places of stars in the crowded regions of the heavens. The history of the "International Chart of the Heavens," which has taxed the resources of so many observatories, was the outcome of their skill and resource. Not only did they provide the optical parts of the instruments that were employed in many observatories, but they laboured zealously on the zone allotted to the Paris Observatory, and it is believed brought their share to a successful issue. They led the way in the photographic examination of clusters like the Pleiades, and showed to others how unsuspected nebulæ might be detected.

A new era of activity opened for astronomy in the general application of photography, and few have contributed more to the harvest of results that has followed that activity than have the brothers Henri. They not only supplied the instruments with which the negatives were taken, but they suggested devices for the construction of measuring machines by which these negatives could be discussed. The reputation of one and both rests on their photographic work. Smaller work, such as the careful and accurate delineation of planetary markings, the observation of minute satellites, and the more ordinary routine of observatory work, are all forgotten in the large share taken in the application of photography to celestial measurement. His colleagues in the observatory spoke of the many excellent qualities that distinguished M. Prosper Henri as a colleague and friend, and one is sure that no less kindly expressions will be used towards M. Paul Henri, who has enjoyed the confidence and respect of all the directors of the Paris Observatory who have followed M. Le Verrier.

W. E. P.

NOTES.

THE cross of officer of the Legion of Honour has been conferred, *La Nature* states, upon Dr. Otto Nordenskjöld for his South Polar explorations. Mrs. Bullock Workman has been appointed Officier de l'Instruction publique for her travels in the Himalayas.

THE autumn meeting of the Iron and Steel Institute is to be held this year in Sheffield for the first time. Mr. R. A. Hadfield has been elected to succeed Mr. Andrew Carnegie as president of the institute. The visit will take place during the week beginning September 25. The most influential members of the Sheffield steel industry have associated themselves with the invitation to the institute, and a committee has been formed, of which the Lord Mayor of Sheffield and the Master Cutler are chairman and vice-chairman respectively. Colonel H. Hughes, C.M.G., has been appointed chairman of the reception committee, with Mr. J. Rossiter Hoyle as honorary secretary. Mr. Frank Huntsman—who is, we learn from the *Times*, a descendant of the Huntsman who founded the Sheffield industry of melting steel in pots about 170 years ago—will act as honorary treasurer, and Mr. John Wortley as honorary assistant secretary.

ON Thursday next, February 2, Prof. W. Schlich will deliver the first of a course of two lectures at the Royal Institution on "Forestry in the British Empire." The discourse on Friday, February 3, will be delivered by Prof. T. Clifford Allbutt on "Blood Pressure in Man."

The International Congress of Psychology will meet this year at Rome on April 26–30. We learn from the *British Medical Journal* that there will be four sections. The section of experimental psychology, the president of which is Prof. G. Fano, of Florence, will deal with psychology in its relations to anatomy and physiology, psycho-physics, and comparative psychology. That of introspective psychology will, under the presidency of Prof. R. Ardigo, of Padua, devote itself to psychology in its relations to philosophical sciences. The section of pathological psychology, the president of which is Prof. E. Morselli, of Genoa, will discuss hypnotism, suggestion, and analogous phenomena, and psycho-therapeutics. The programme of the section of criminal, pædagogic, and social psychology, which is under the presidency of Prof. Lombroso, of Turin, has not yet been published. The president of the congress is Prof. Giuseppe Sergi, of Rome; the general secretary, Dr. Sante de Sanctis, to whom all communications relative to the meeting should be addressed at the Istituto Fisiologico, 92 Via Depretis, Rome.

We are informed that Dr. Carl Otto Weber, the well known chemical authority on india-rubber, died suddenly on January 14 at his residence in Massachusetts, U.S.A.

On November 16 last the University of Lehigh was bereaved of its president, Dr. Thomas Messinger Drown, and a brief obituary notice is contained in the *Popular Science Monthly* for January. Dr. Drown was born on March 19, 1842, at Philadelphia, and he graduated in medicine at Pennsylvania, subsequently studying chemistry in Germany and America. He held the chair of chemistry at Lafayette College for seven years, and at the Massachusetts Institute of Technology for seven years. He was secretary and editor of the American Institution of Mining Engineers for ten years from its foundation, and was elected president in 1897. His researches in quantitative analysis were devoted in the first place to devising standard methods in the analyses of iron and steel, and in the second place to water analysis, especially in connection with the natural waters of the State of Massachusetts, and the distribution of normal chlorine. He was elected president of Lehigh University in 1895, at a time when that institution's influence was at a low ebb, and since his appointment the efficiency of the college has developed in many important directions.

Reuter's Agency has been informed by the Pacific Cable Board that by an arrangement between the Washington and Sydney Observatories, with the cooperation of the telegraph administrations concerned, time signals were sent on New Year's Eve from the Washington Observatory to the Sydney Observatory at 3h., 4h., 5h., and 6h. The mean interval between the times when these signals were sent and when they were received was 2·90s. The distance separating Sydney and Washington is more than 12,000 miles. The signals through the Vancouver-Fanning cable, the longest cable span in the world (3457·76 nautical miles), were sent by automatic apparatus, and were recorded, as they passed, at the Vancouver station on an instrument placed in the artificial line which balances the cable for the purpose of duplex working. The signals consisted of second contacts, omitting the thirtieth and last five of each minute, except the last minute of the hour, when the thirtieth and all after the fiftieth second were omitted, the circuit closing with a long dash on the even hour. The signals were sent for five minutes before the hour from 3 p.m. to 6 p.m., Sydney time; equivalent to midnight to 3 a.m. Washington time.

Writing from Amsterdam, Dr. C. M. van Deventer desires to direct attention to an interesting fact observed by a schoolboy. Two years ago, during a lesson in physics given at the high school at Batavia, one of the boys, called Van Erpecum, told Dr. Deventer, as an observation of his own, that the water in a glass, filled to the brim with water and floating ice, does not flow over when the ice melts. The observation was communicated to Profs. Van der Waals and Zeeman, who judged it worthy of being the subject of a note presented by them to the Royal Academy of Amsterdam. Dr. Deventer says that the observation of his pupil tells only the half of the phenomenon—the truth being that the water neither rises nor sinks. He therefore states the proposition that "In a vessel containing water and floating ice, the level stays at the same height when the ice melts." Or, speaking more generally, "When a vessel contains a solid floating in its own liquid, the level of the latter does not change by the melting of the solid." This proposition Dr. Deventer proposes to call the "law of the permanent level." The law can be deduced from Archimedes's principle; but it is only rigorously exact when the weight of the air is neglected.

At the meeting of the Society of Antiquaries on January 19 Mr. A. J. Evans communicated an account of the tombs of Minoan Knossos. Mr. Evans's last season's work at Knossos was devoted largely to the search for the tombs in relation with the Minoan palace and city. On a hill about a mile north of the palace a cemetery was discovered. One hundred tombs were opened, and the contents showed that the bulk of them belonged to the period immediately succeeding the fall of the palace. The character of the art displayed by the relics found showed the unbroken tradition of the later palace style. The jewelry and gems discovered were of the typical "mature Mycenæan" class, and a scarab found in one of the graves is of a late eighteenth dynasty type. The tombs were of three main classes:—(*a*) Chamber tombs cut in the soft rock and approached in each case by a *dromos*; in many cases these contained clay coffins, in which the dead had been deposited in cists, their knees drawn towards the chin. (*b*) Shaft graves, each with a lesser cavity below, containing the extended skeleton, and with a roofing of stone slabs. (*c*) Pits giving access to a walled cavity in the side below; these also contained extended skeletons. A number of skulls have been secured, and are to be sent to England. On a high level called Sopata, about two miles north again of this cemetery, an important sepulchral monument was discovered. This consisted of a square chamber, about eight by six metres, constructed of limestone blocks, and with the side walls arching in "Cyclopean" fashion towards a high gable. The back wall was provided with a central cell opposite the blocked entrance. This entrance, arched on the same horizontal principle, communicated with a lofty entrance hall of similar construction, in the side walls of which, facing each other, were two cells that had been used for sepulchral purposes. A second blocked archway led from this hall to the imposing rock-cut *dromos*. A number of relics were found scattered about, including repeated clay impressions of what may have been a royal seal. Specially remarkable among the stone vessels is a porphyry bowl of Minoan workmanship, but recalling in material and execution that of the early Egyptian dynasties. Many imported Egyptian alabastra were also found, showing the survival of middle empire forms besides others of early eighteenth dynasty type. Beads of lapis lazuli were also found, and pendants of the same material, showing a close imitation of Egyptian models. The form of this mausoleum, with its square chamber, is unique, and contrasts with that of the tholos tombs of mainland Greece. The position in which it lies commands the whole south Ægean to Melos and Santorin, and Central Crete from Dicta to Ida.

WE have to welcome an addition to the already lengthy list of American biological serials in the form of a *Bulletin* issued by the Springfield (Mass.) Museum of Natural History, of which the first number is in our hands. This is devoted to the description of the early stages in the development of the ground-beetles of the family Carabidæ, as exemplified by a member of the genus Dicælus, in which the larva is of the ordinary predaceous type, and one of Brachinus, in which the larva is parasitic and degenerate. Of the adult beetles, the more specialised seems to be Brachinus. The authors of the paper are Messrs. Dimmock and Knab.

THE Albany Museum, according to the report for the first half of 1904, continues to make steady progress, and it is satisfactory to learn that arrangements are under consideration both for augmenting the staff and for increasing the size of the building. An important part of the museum's work is the investigation of the life-history of insects injurious to agriculture and horticulture, and the discovery of the best means of checking their ravages. For this purpose a piece of ground adjoining the museum has been enclosed, and it is hoped that funds will shortly be forthcoming for erecting in this enclosure an insect-house, without the aid of which the work can be carried on only with difficulty.

THE *Field Naturalists' Quarterly* for December, 1904, strikes us as being an unusually excellent number. It includes, in the first place, the second of the series of plates illustrating the development of the frog. Later on we have the first instalment of a set of articles by the editor (Dr. G. Leighton) explaining modern investigations on heredity in a manner calculated to bring home the fundamental truths of this complex subject to every intelligent reader, the development of the germ-plasm being the text of this contribution. In a preliminary note the editor expresses the hope that his articles will induce many persons who reside in the country to take up the practical investigation of some form of heredity for themselves. A third article to which we may direct attention is one by Mr. H. E. Forrest in which simple methods of distinguishing the various species of British bats are formulated. We notice that the author adheres to the old-fashioned nomenclature for the members of this group.

WE have received the January number of *Climate*, which contains an illustrated description of the Japanese soldier's outfit, and articles on blackwater fever, water and its connection with disease, the drinking habits of native races, climate and health in hot countries, &c. The medical articles are semi-popular in character, and should be useful to missionaries and others stationed in districts remote from medical aid.

THE *Journal* of the Royal Sanitary Institute (vol. xxv., part iii.) forms a bulky volume of some 600 pages. It contains a number of interesting and important papers and discussions thereon contributed to the congress of the institute at Glasgow last year. They are on such varied subjects as disinfection in phthisis (Prof. Kenwood and Dr. Allan), prevention of diphtheria (Dr. Cobbett), sewage disposal, school hygiene and ventilation, conditions of housing, &c.

THE December (1904) number of the Johns Hopkins Hospital *Bulletin* (vol. xv., No. 165) contains an account of the opening of the new surgical building and clinical amphitheatre of the Johns Hopkins Hospital, a description of a new chromogenic bacillus, *B. cyaneum*, and various papers of medical interest. In the new buildings a tablet has been erected to the memory of Dr. Jesse Lazear, who died from an attack of yellow fever while investigating that disease in Cuba.

IT is proposed to add to Reichenbach's "Icones Floræ Germanicæ et Helveticæ" a number of extra volumes containing monographs of critical genera. The publishers, Messrs. von Zezschwitz, of Gera, announce the immediate issue of the first of these, in which the genus Hieracium is treated by Dr. J. Murr and Mr. H. Zahn.

THE cultivation of mushrooms is not such an important business in the United States of America as in Great Britain and France. With the view of extending and improving the trade, Prof. B. M. Duggar has written a pamphlet on the subject, which has been issued by the U.S. Department of Agriculture as a *Farmers' Bulletin*. The preparation of English brick spawn and French flake spawn is dependent upon the haphazard collection of what is known as "virgin spawn" in the open. Prof. Duggar has for some time attempted to discover the conditions which are necessary for the germination of mushroom spores. He has already succeeded in germinating spores in pure cultures by means of chemical stimulation, and hopes shortly to make the process more practical. This will enable the grower to produce a definite strain, and if necessary to obtain improved varieties by selection.

THE *Ani-i-Akbari*, or annals of the Emperor Akbar, written in the Persian language, contain descriptions of various customs which prevailed during the Moghul period. Amongst these was the use of perfumes in religious observances, and the emperor took a personal interest in the preparation of the ingredients. A short summary of the principal substances and their sources is contributed by Mr. D. Hooper to the October (1904) number of the *Calcutta Review*. Among vegetable products, *Aquilaria agallocha*, aloe-wood, was then as now valued for the oleo-resin agar, and an oil known as chuwah; sandalwood was used as a powder, and perfumes were distilled from the rose, orange, jasmine, and broad-leaved willow, *Salix caprea*. Ambergris obtained from the sperm whale, the moist secretion of the civet cat, and the opercula of certain molluscs, known as "fingernails," were important animal products.

PAMPHLET series No. 32, issued by the Imperial Department of Agriculture for the West Indies, gives a summary of the results on the cultivation of seedling and other canes at the Barbados experiment stations in 1904. As in previous years the investigation has been conducted by Prof. d'Albuquerque and Mr. Bovell. Sixteen sugar estates in typical localities were selected, thirteen on black soils and three on red soils. The seedlings were treated in precisely the same manner as the ordinary canes. The season was favourable, there was very little root disease, and the crop consequently was above the average. Cane B 208 again gave uniformly good results, both as plant canes and ratoons, and it is recommended for a general trial on a field scale in all red soil districts. A newer cane, B 1529, however, takes the first place in the black soil list, coming out second to B 208 in the red soil list. Its cultivation will consequently be extended to as many experimental plots as possible. Cane B 147, at one time considered the most promising of the seedling varieties, did not give such good results as in previous years, but it appears to be cultivated with some success in the rather light soils in the parish of St. Philip.

THE Barbados *Official Gazette* of December 19, 1904, contains some correspondence relating to Cassava poisoning. Mr. Briggs, one of the district coroners, noted to the Colonial Secretary that witnesses in inquest cases frequently assert that if roasting and poison cassava grow closely side by side, the roasting cassava takes up some of the poison from the poison cassava; also that the roasting cassava gets a "spring in it," and that makes it poisonous. The Colonial Secretary submitted the note to Sir Daniel Morris, who replied that (1) "there can be no direct connection between the two plants, and it is impossible that the poison can pass through the soil from the poisonous cassava to the sweet," and (2) "if by the 'spring in it' is meant that the plant starts into second growth after heavy rain, it is probable that certain changes may take place inducing an increase of the poisonous quality." What probably happens when persons die from eating sweet or roasting cassava is that it is either too old or it has not been sufficiently cooked to drive out all the acid. It is only really wholesome when the roots are not too old, and when they have been cooked until they are quite soft. If the centre is hard it is probably more or less poisonous, and should not be eaten. Even properly cooked cassava which has been allowed to become cold is not fit to eat unless it is cooked a second time.

BECKELITE, a new mineral species named in honour of Prof. F. Becke, of Vienna, is described by Prof. J. Morozewicz in the December (1904) *Bulletin* of the Cracow Academy of Sciences. It occurs as an accessory constituent of a dyke-rock composed of albite, nephelite, ægirite, and magnetite in the elæolite-syenite complex near Mariupol, on the Sea of Azov. The wax-yellow octahedral or rhombic-dodecahedral crystals resemble pyrochlore in general appearance and physical characters, though the somewhat indistinct cleavage is cubic instead of octahedral. Chemically, however, the new mineral is quite distinct from pyrochlore, containing 17·13 per cent. of silica and 65·31 per cent. of rare earths, with no niobium or tantalum. The formula is $Ca_3(Ce,La,Di)_4Si_3O_{15}$, which presents a certain resemblance to the garnet formula with rare earths in place of alumina. From analogy to calcium "alumosilicate," the new mineral is described as a calcium cero-lanthano-didymo-silicate.

FOR the twenty-second time, the climatological records of the British Empire are summarised in the current number of *Symons's Meteorological Magazine*, viz. for the year 1903. The stations number twenty-five, but, as the editor points out, it is impossible to represent the average conditions of the climate of the Empire by so small a number of stations, however well distributed. Adelaide, which has almost constantly held the first place in the summary for extreme maximum temperature, now, as in 1902, gives way to Coolgardie, in Western Australia, where the shade temperature reached 113°·4 on January 27; the lowest shade temperature was −60°·8 at Dawson on January 26. Dawson had also the greatest yearly range (150°·3). The greatest mean daily range was 23°·5 at Winnipeg, and the least 8°·5 at Hong Kong. London had the highest relative humidity (82 per cent.) and Adelaide the lowest (62 per cent.). The greatest rainfall, 93·67 inches, was recorded at Hong Kong, and the least, 10·74 inches, at Dawson. We may mention, incidentally, that the present number of the magazine is the largest since its foundation in 1866; we hope to refer shortly to another of the interesting articles that it contains.

WE have received the *Journals* of the Meteorological Society of Japan for October and November last. They contain (as we see from the English titles) several interesting articles in Japanese. There is also one in English, on the duration of rainfall, by T. Okada. The object of the author is to show that Dr. Köppen's formula for the calculation of the probable duration of rainfall in a month, or any interval of time, from three or six observations daily, holds good for all climates. The calculation is very simple, and the formula in question, $(r/n)N$, is contained in an article by Dr. Köppen in the Austrian *Meteorologische Zeitschrift* for 1880; n is the total number of observations, r that of observations with rainfall, and N the total number of hours in a month (or other period). The author shows that the duration of rainfall, computed from tri-daily observations, does not differ materially from that computed from hourly observations—in the annual mean at most 4 per cent., and in the monthly mean 18 per cent. In the majority of cases the differences are much less; the method gives more approximate results than an ordinary self-recording rain-gauge, owing to the usual want of sensibility of such instruments.

IN the *Zeitschrift für physikalischen und chemischen Unterricht*, xvii., 5, Mr. Walter Stahlberg, of Steglitz, gives an account of the Zeiss "Verant" by which photographs are made to stand out in natural relief with monocular vision. The apparatus can hardly be correctly described as a stereoscope, since one of the most important features of the stereoscope depending on binocular vision is absent. The Verant is a single lens, the focal length of which should be equal to that of the camera used in taking the photographs, and this lens is convexo-concave, so that the axes of the pencils from different parts of the picture meet in the eye. From Mr. Stahlberg's account, we think the principle of the Verant may be roughly explained by the following illustration:—When a photograph of cloisters is taken from one corner in the interior the photograph gives the impression that the two colonnades meet at a very acute angle instead of at right angles. If the picture were seen through the Verant the angles would appear correct as they would to a person standing in the cloisters themselves. The now old-fashioned graphoscope appears to have had a somewhat similar purpose.

Two papers which are of importance in the study of superfusion phenomena are published by Drs. Tullio Gnesotto and Gino Zanetti in the *Atti* of the Royal Venetian Institute (1903, vol. lxii., p. 1377). By means of a modified ice calorimeter, the variation of the specific heat of superfused liquid sodium thiosulphate at temperatures between 0° C. and the melting point of the salt, 48°·8 C., was determined, the observations being also extended above this temperature up to 100° C. On calculating the specific heat at all temperatures within this range, it is seen that in the neighbourhood of the melting point a sudden diminution in its value occurs, but that slightly above this temperature the specific heat again increases, so that the curve resumes the same direction that it had below the melting point. The latent heat of fusion of the salt at 0° C. was also determined.

A VALUABLE paper on the properties of chrome-vanadium steels was read before the Institution of Mechanical Engineers on December 16, 1904, by Captain Riall Sankey and Mr. J. Kent Smith. These steels appear to be most valuable from their power of resisting rapid alternations of stress and sudden shock, especially after they have been subjected to special thermal treatment. The temperature of their recalescence is at about 715° C., and the effect of quenching in oil from 900° C. and subsequently reheating at 600° C. is to increase enormously the resistance of the alloy to shock, as measured by an impact test, and to alternations of stress, without affecting the tensile strength. A spring of chrome-vanadium steel which was prepared was found to have double the strength of an ordinary steel spring of the same dimensions, the extension being directly proportional to the load throughout a very much wider range. Like the nickel steels, those which contain vanadium and chromium are very efficient in withstanding bending tests.

MESSRS. DAWBARN AND WARD, LTD., have added a booklet, "How to Read a Workshop Drawing," by Mr. W. Longland, to their "Home-Worker's" series of practical handbooks.

A THIRD edition of Mr. M. M. Pattison Muir's translation of Prof. Lassar-Cohn's "Chemistry in Daily Life" has been published by Messrs. H. Grevel and Co. The book has been revised and enlarged.

A TEACHERS' edition of part ii. of "Elementary Algebra," by Messrs. W. M. Baker and A. A. Bourne, has been published by Messrs. George Bell and Sons. Teachers are likely to find the plan of printing the answers on the page opposite to the examples a convenience in class work.

THE Engineering Standards Committee has just issued the "British Standard Specification for Portland Cement." The specification deals with the quality and preparation of the cement, gives particulars as to sampling and preparation for testing and analysis, and goes on to enumerate what should be its fineness, specific gravity, chemical composition, &c. The specification also considers at length the various tests which a satisfactory cement should pass. Copies of the publication may be obtained from Messrs. Crosby Lockwood and Son, price 2*s*. 6*d*. net.

THE 1905 issue of "Hazell's Annual" has now been published. Twelve pages are devoted to scientific progress during 1904, and about five to scientific societies and institutions. Education in the United Kingdom in all its branches is given some fourteen pages.

OUR ASTRONOMICAL COLUMN.

THE REPORTED SIXTH SATELLITE OF JUPITER.—A telegram from the Kiel Centralstelle gives the position of a minor planet, P.V., photographed by Prof. Wolf on January 23·135 at the Konigstuhl Observatory, at 7h. 8·8m. (Konigstuhl M.T.), as

R.A. = 1h. 31m. 59s., dec. = +8° 36′ 13″.

The daily movement of this object is +23′ in R.A. and −9′ in declination, and it is suggested that the body may possibly be identical with the object announced by Prof. Perrine as a sixth satellite to Jupiter.

PERIODICAL COMETS DUE TO RETURN IN 1905.—In the January *Observatory* Mr. W. T. Lynn directs attention to the periodical comets which are due to return to perihelion this year. There are only two, of which the first, Encke's, has already been seen, and passed through perihelion on January 4. The second is that discovered by Prof. Max Wolf on September 17, 1884 (comet iii., 1884), which has a period, variously estimated, of about 6·76 years. This object returned as comet ii., 1891, and comet iv., 1898, its perihelion being passed during the latter return on July 4, although its nearest approach to the earth did not take place until the end of November. Accordingly it should again pass through perihelion early in April next.

CHANGES ON THE SURFACE OF JUPITER.—An interesting popular exposition of the knowledge acquired during the past twenty-five years concerning the conditions of, and the changes on, the visible surface of Jupiter is given by Prof. G. W. Hough in No. 1, vol. xiii., of *Popular Astronomy*.

Prof. Hough's own observations of Jupiter have extended over twenty-five years, and the present article summarises them and the conclusions to which they have led him. He particularly refers to the determined values for the rotation periods at different latitudes, and sees no evidence for the existence of any law connecting the two, giving diagrams which illustrate the point. Two other diagrams show the variations in the latitude and the rotation period of the great red spot from 1879 to 1903, whilst yet another illustrates the changes in the position and width of the equatorial belt during the period 1895–1904. From the latter diagram it is seen, very clearly, that the changes in the northern part of the belt are much more sudden and of a greater magnitude than those which take place in the southern portion.

STARS HAVING PECULIAR SPECTRA.—During the examination of the Henry Draper memorial plates, Mrs. Fleming has discovered some additional stars which are either variable or have peculiar spectra. Thirty-one of these are announced and briefly described in No. 92 of the Harvard College Observatory *Circulars*. Of those having peculiar spectra a few are worthy of special notice. For instance, λ Cephei (mag. 5·6) was found to have a spectrum identical with that of ζ Puppis, which hitherto has been regarded as unique. The stars D.M. −11° 1460 (Monoceros) and +64° 1527 (Cepheus), amongst others, show a bright Hβ line. In the former the other hydrogen and the helium lines are double, whilst in the latter they are single but broad. The spectrum of D.M. +39° 4368 (R.A. = 20h. 51·6m., dec. = +39° 55′, mag. = 7·2), as photographed on September 15, 1904, was continuous, showing no trace of lines, although the lines in the spectra of neighbouring stars were sharply defined; on other plates the hydrogen lines show faintly, although the spectrum was not so well defined.

REAL PATHS, HEIGHTS, AND VELOCITIES OF LEONIDS.—From the observational data submitted to him by various observers, Mr. Denning has computed the real paths, heights above the earth's surface, and velocities of several Leonids seen during the last shower. From three observations of the brightest meteor seen at Greenwich, at 16h. 24m. 42s., November 16, 1904, he finds that the height of this object was from 88 to 44 miles along a path extending not more than 60 miles from near Petersfield to Hungerford. The velocity was about 46 miles per second, and the radiant point was 151° + 22°.

A second meteor recorded by two observers was seen at Greenwich, at November 14d. 10h. 26m., and at Enniscorthy (Ireland), 280 miles away. This had a long horizontal flight from over the neighbourhood of Sheffield to near Carmarthen, and was 83 to 78 miles high, the velocity being about 40 miles per second. Another meteor travelled at a height of 79 to 58 miles from over Faringdon to Stroud, its visible path being 35 miles long and its velocity 39 miles per second (*Observatory*, January).

NEW METHOD FOR MEASURING RADIAL-VELOCITY SPECTROGRAMS.—At a meeting of the International Congress of Arts and Sciences held at St. Louis in September, 1904, Prof. J. Hartmann, of Potsdam, gave a brief outline of a new method whereby he proposes to reduce considerably the labour involved in measuring the displacements of lines in stellar spectra for the purpose of determining the radial velocities of the stars. Hitherto it has been customary to measure the displacement of each line separately, and subsequently to reduce the individual measures; but in Prof. Hartmann's new method the displacement of the whole of the lines in the star spectrum would be measured simultaneously. He proposes to photograph the spectrum of the star, with the terrestrial comparison spectrum alongside it, as usual, and then to photograph the solar spectrum and the same comparison with the same instrument. The two negatives are then placed in a specially devised measuring machine, and the solar plate moved by the micrometer screw until the similar lines in both the solar and the stellar spectra coincide. Then the solar plate is again moved by the screw until the lines in the comparison spectrum on it coincide with the analogous lines in the comparison spectrum on the stellar spectrogram. The difference between the two settings gives the displacement of the stellar lines, from which the radial velocity is computed. In the reduction, which is simple, the only assumption made is that the lines have the same wave-lengths in the solar and the stellar spectra, and this is permissible, at least with second-type stars for which the method was primarily devised (*Astrophysical Journal*, vol. xx., No. 5).

MEDICAL RESEARCH IN EGYPT.[1]

AN interval of three years has elapsed since the first volume of these "Records" was published. The present series of papers would alone afford abundant evidence of the activity of the members of the staff in the intervening period. But it is still more satisfactory to recollect that this does not represent the total output of research, for many other memoirs from the same source have already appeared elsewhere. There are evidently many problems of both local and general importance which require investigation, and the standard of excellence reached in the "Records" already published arouses a desire that succeeding volumes should appear more frequently.

The papers are naturally chiefly concerned with problems of special local importance. The three scourges of Egypt are said to be the malarial parasite, Ankylostoma and Bilharzia. The last seems to bring an extraordinary number of cases under the care of the surgical staff, some 16 per cent. of all surgical in-patients suffering directly from lesions produced by this parasite. From the pathological report by Dr. Symmers, it would appear that about 7 per cent. of the deaths are directly due to Bilharzia. In 100 consecutive admissions to the medical wards, 35 were found to have the eggs in their urine, though only two of these were suffering in any way from the infection. The surgical aspects of the disease are discussed in two interesting papers by Mr. Madden and Mr. Milton; they find that many pathological conditions turn out most unexpectedly to be due to the worm. At one period of life or another practically the whole of the native population is said to be infected. Unfortunately, no material progress has been made in elucidating the extra-corporeal history of the parasite; it is therefore impossible to take any direct preventive measures.

Dr. Phillips contributes an article on the relation of ascites to malaria. In at least one-third of the cases of ascites in Kasr-el-Ainy no cause could be found other than malaria, but the ætiological connection is not very clearly established. A definite malarial cirrhosis occurs in a certain number of the cases, but it is not always present, and the conditions found appear to be very variable.

Of ankylostomiasis there is nothing in this volume beyond incidental mention. But, as is well known, the most important recent contributions to our knowledge of this destructive world-disease have come from the Cairo Medical School. Dr. Looss, in a long series of papers, has most ably carried on the investigations begun by Griesinger in the same school fifty years ago, and we are disappointed to find here no sequel to his account of the Sclerostomidæ of horses and asses which appeared in the first volume of the "Records."

Dr. Wilson follows up his observations on the poisons of spiders by a very interesting study of the venom of Egyptian scorpions. An aqueous extract of the poison gland is treated with excess of alcohol, and from the precipitate thus obtained a substance may be extracted with normal saline which possesses toxic properties of a very high order. The toxic value is about ten million, that is, 1 milligram will kill 10 kilograms of guinea-pig—a figure of the same order as that obtained for similar preparations from the venoms of the more poisonous serpents. A full-grown specimen of the common Egyptian species (*Buthus quinque-striatus*) contains about $3\frac{1}{2}$ milligrams of this (impure) "toxin." If the susceptibility of man is the same as that of the laboratory animals, it follows that a single sting can kill at the utmost 35 kilograms. These calculations correspond very well with the fact that fatal cases of scorpion sting in adults are extremely rare, though the mortality in young children reaches 60 per cent. Scorpions are in this way on a different level from many of the poisonous snakes; as Captain Lamb has shown, the amount of toxin normally injected by a vigorous cobra is many times the minimum lethal dose for an adult man. Dr. Wilson finds that certain animals living in the desert (including the hedgehog) are naturally immune (at any rate relatively) to the venom; and Dr. Tallart has immunised goats and obtained an anti-toxic serum with curative properties.

An article by Dr. Tribe shows that phthisis in Egypt does not differ very much in frequency, incidence on rural and urban populations, and type from the same disease in western Europe; and Dr. Sobhy gives a curious account of the obstetric customs of the natives, which seem to have undergone no material change since very remote times. The volume concludes with the first instalment of what promises to be a monumental contribution to the morphology of the human brain, by Dr. Elliot Smith. The present section, which is fully illustrated, deals with the occipital region, and contains a great deal of original matter on the vexed questions of the significance and homologies of the convolutions.

The general printing of the volume is excellent, though the inevitable misprint has crept in here and there. The illustrations are good and useful, but we are sorry to see that the coloured plate illustrating Dr. Symmers's case of secondary sarcoma of brain could not be printed in Egypt.

A. E. B.

WIRELESS TELEGRAPHY IN WAR.

A VERY interesting account of the working of the wireless telegraphic war correspondence of the *Times* during the early part of the Russo-Japanese war was given by Captain James at a meeting of the Society of Arts last week. This is the second occasion on which the *Times* has played a prominent and important part in the practical development of wireless telegraphy. The first was when, shortly after Mr. Marconi had established communication between America and England, a regular correspondence was started between the two countries by means of wireless telegraphy—a correspondence which was not, however, destined to last for very many days. Very soon after its inception something went wrong, and though since that time the Marconi Company has greatly developed its Transatlantic signalling and has effectively demonstrated its utility and convenience for communicating with liners, the shore to shore correspondence has not been renewed.

The second case in which the *Times* intervened was also only of short duration; but here the cessation was due to its having met with too great success, the results achieved having demonstrated not that wireless telegraphy is useful for war correspondence, but that it is too effective to be permissible.

The system selected for the equipment of the *Haimun* was that of Dr. de Forest, a system which had already shown its efficiency during the yacht races of 1903; the reasons that led to the choice of this system were its freedom from interference and the speed at which it could be worked, it being possible to transmit thirty to thirty-five words a minute, as against ten to twelve words by any other system. The experiences of Captain James seem certainly to bear out the claim of freedom from interference. In spite of the fact that four other systems were at work in close proximity to the *Haimun*—the

Russian, Japanese, British, and Italian—Captain James never found his messages interfered with in any way. This notwithstanding that many of the messages sent were of considerable length, running from 1500 to 2000 words. To transmit these long messages under all the attendant difficulties was no mean achievement for wireless telegraphy and journalism alike.

Some of the incidents narrated by Captain James are both interesting and amusing. On one occasion, when the Japanese steamed in to attack Port Arthur, the *Haimun* telegraphed the news of the firing of the first shot to Wei-hai-wei, whence the message was forwarded express to London, with the result that two hours later the *Times* received the news, so that, on account of the difference in time, the journal knew that an engagement was taking place six hours before it started. On the occasion of the transmission of their first long message—one of 1500 words—which was sent from a distance of 130 miles from Wei-hai-wei, the operator listened anxiously at his telephone receiver, after the first section of 350 words had been transmitted, to know whether it had been satisfactorily received. For five minutes he waited; then his face lighted up, and he remarked, "Captain, we will deliver the goods, Wei-hai-wei says that it is coming in like a drum." It is a remarkable achievement, which journalists and men of science highly appreciate, that wireless telegraphy is capable even in adverse circumstances of transmitting messages that will "come in like a drum." Wireless telegraphy may still be in its infancy, but the results attained by its use have shown that it is no longer in an experimental stage. M. S.

FLOODS IN THE UNITED STATES.

IN our number for July 28 we gave particulars of the great flood that occurred in the Mississippi valley in 1903, and of the damage done in Kansas and other places, and also of floods in the Passaic River, the information being obtained from the reports issued by the Geological Department of the United States. We have recently received a further report on floods in other parts of the States.[1]

This report states that the year 1903 will be long remembered for its extreme local variations from normal climatic conditions. Besides the floods in the Mississippi valley already referred to, due to heavy and continuous rainfall, a cloud-burst at Heppner, in Oregon, caused the loss

FIG. 1.—Clifton before the Flood of 1903.

of 100 lives and of property valued at half a million dollars, one-third of the town being entirely destroyed. This flood was due to a very heavy storm of short duration covering a very small area, such storms being peculiar to this arid region, and locally called a "cloud burst." Such a storm is almost like a tornado in its suddenness, destructibility, and limited extent. The duration of this storm was only half an hour, and the resulting flood lasted less than an hour. It was estimated that the storm area was from two to four miles in width and eight to ten miles in length, and affected an area of twenty square miles.

This storm was accompanied by a very heavy fall of hail; some of the hailstones measured $1\frac{1}{4}$ inches in diameter.

FIG. 2.—Clifton after the flood of 1903.

Five days after the storm some that measured five-eighths by seven-sixteenths inch were removed from a house buried under silt and mud, and bodies were found in drifts of hail in nearly a perfect state of preservation.

Another destructive flood due to heavy rain occurred in South Carolina in the district situated on the southern slope of the Saluda Mountains, which includes the foothills and rolling country. About half of it is covered with timber, the remainder being cultivated and pasture land. The surface slopes are such that the water runs off rapidly, and there is very little storage.

Rain had occurred daily for some time previously, saturating the ground, and culminating in a fall of from $3\frac{1}{2}$ to 5 inches in twenty-four hours.

The greatest destruction caused by the flood due to this rainfall was the wrecking of three large cotton mills situated at Clifton (Figs. 1 and 2), on the river Pacolet. At one mill a chimney stack 137 feet high was washed down, and the mill, with shops, engine and boiler houses, and sixteen cottages, entirely destroyed. At another mill 110 feet of the main building and the wheelhouse were totally wrecked, and the machinery of the lower floors severely damaged by water, mud, and drift, and several cottages were destroyed. In another mill fifty-two women and children were drowned. Railway traffic was stopped for a week. The damage to the mills and other property was estimated at $3\frac{1}{2}$ millions of dollars.

[1] "Destructive Floods in the United States in 1903." By E. C. Murphy. Water Supply and Irrigation Papers, No. 96. (Washington.)

SEISMOLOGICAL NOTES.

THE third number of vol. x. of the *Bolletino* of the Italian Seismological Society contains the first instalment of the earthquake record for 1903. This is now in charge of Dr. G. Agamennone, and follows the same lines as in previous volumes, except that it has been found impossible to continue the attempt to reproduce all the records of earthquakes registered in Italy. This change is a consequence of the great increase in the number of stations where instruments devoted to the new seismology have been set up, and the consequent impracticability of collecting in one periodical all the records of even the limited number of great world-shaking earthquakes. Italy will, therefore, be content with publishing its own records, and at most a few lines will indicate those earthquakes which have also been recorded out of Italy.

Improvements are continually being made in the instruments used in every branch of science, and seismology is no exception. Prof. Omori publishes (*Publications* of the Earthquake Investigation Committee, No. 18) an account of a combination of light, inverted, vertical, with a heavy horizontal pendulum, with which it is claimed that a period of sixty seconds can easily be got from an instrument which does not exceed 1 metre in height and length of boom. Prof. Alippi, in the *Boll. Soc. Sismol. Ital.*, vol. x., No. 3, describes a simple device for overcoming the tendency to adherence in the electric contacts of delicate seismoscopes; it consists in placing an ordinary electric bell, without the gong, in the circuit, and fixing it so that the clapper beats against the stone slab on which the seismoscope rests. He finds that the vibration set up by this is sufficient to cause the two parts of the contact to separate, without in any way affecting the instrument, and suggests that it would be better to incorporate a small electric vibrator in the base of the seismoscope to act like the decoherer in wireless telegraphy.

The mysterious sounds known locally as mist-poeffers, barisal guns, &c., and now generally looked upon as seismic, are the subject of a short note by Prof. Alippi, who records two new localities and names. In the neighbourhood of Arezzo they are known as "baturlio della marina," and in the country between Bologna and Modena as "romba di Sassuolo." The multiplication of localities where these sounds are familiar, and of local names for them, is thought by Prof. Alippi to render a generic name desirable, and he suggests *brontid*, which has certainly the advantages of being descriptive and of implying no theory of origin (*Bol. Soc. Sismol. Ital.*, x., part iii.).

The relation between the variations in latitude at Tokio and the occurrence of earthquakes in Japan is the subject of a paper by Prof. Omori in No. 18 of the *Publications* of the Earthquake Investigation Committee; he finds that the destructive earthquakes of the last eight years all occurred during periods of high or low value of the latitude, and none at times when this was changing from one to the other. This result is said to be in harmony with the results obtained by Prof. Milne, but we may point out that this is not so; what Prof. Milne found was that the greatest frequency of world-shaking earthquakes coincided with the most rapid variation in the position of the pole, while Prof. Omori finds that the destructive earthquakes of Japan occurred at times when the latitude was stationary or only changing very slowly. What his investigation seems to show is that any connection which there may be between the occurrence of really great earthquakes and changes in the position of the axis of revolution, does not extend to local earthquakes.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

In accordance with the will of the late Mr. George Smith, of St. Louis, the treasurer of Harvard University has received, it is stated by *Science*, a payment of 51,500*l.* When this fund reaches 90,000*l.* by accumulation, three new dormitories are to be erected.

At the institute of archæology of the University of Liverpool, a course of lectures dealing with recent researches on the ancient sites of Greece and with the historical geography of western Asia, particularly Palestine, has been arranged, and will be delivered on successive Wednesdays of this spring term. The lecturers are Dr. Caton and the Rev. M. Linton Smith.

The President of the Board of Education has appointed Mr. T. S. Dymond, of the Essex County Technical Laboratories, Chelmsford, to an inspectorship under the Board, and to act as special adviser in matters of rural education, of nature-study in public elementary schools, of agricultural instruction in evening (including afternoon and Saturday) schools, and of the advancement of various forms of technical education in rural districts.

The Bucks Education Committee, under the presidency of the chairman, Lord Buckinghamshire, has decided that a communication should be issued to all school correspondents in the county requesting the managers to consider the desirability of introducing the teaching of the subjects of hygiene and temperance into the schools under their charge, and referring to the support given to the movement by 15,000 members of the medical profession.

About twenty scholarships ranging in value from 20*l.* to 50*l.* a year, and exhibitions for men and women tenable at University College, King's College, and the East London Technical College, in the faculties of arts, science, and engineering, will be offered for competition on June 27 and following days. Full particulars and forms of application may be obtained on application to the secretary of the Inter-Collegiate Scholarships' Board, King's College, Strand, W.C.

The conference on school hygiene, which will be held at the University of London on February 7–10, will be opened with an address by Sir Arthur W. Rucker, F.R.S., on "The Coordination of the Teaching of Hygiene." The subjects of papers for discussion include the following:—"Physical and Mental Development during School Life," Miss A. J. Cooper; "Physical Inspection," Dr. A. K. Chalmers; "Building and Equipment," Sir Aston Webb, R.A.; "Sanitary Inspection," Dr. J. F. J. Sykes; "Training of Teachers," Prof. C. S. Sherrington, F.R.S.; and "Training of Scholars," Prof. Findlay.

The *British Medical Journal* announces that the French Congress of School Hygiene will hold its second meeting in Paris this year at Whitsuntide. The following is the programme of discussions:—(1) the medical inspection of primary schools; (2) the education of families in school hygiene; (3) vacations and holidays; (4) tuberculosis and teachers; (5) the overloading of school courses and competitions for admission to large schools. Profs. Debove, Grancher, Landouzy, and Pinard are honorary presidents of the congress. All communications should be addressed to Dr. J. Ch. Roux, 46 rue de Grenelle, Paris.

The annual general meeting of the Association of Technical Institutions is to be held at the Manchester School of Technology on January 27. The business will include the address of the president, Sir Philip Magnus, consideration of the council's report, the election of officers, and the reading of papers. The subjects to be dealt with are:—"The Coordination of the Work of Evening Continuation Schools and Municipal Technical Institutions," "The Cooperation of Employers in the Technical Training of their Apprentices," and "The Registration of Teachers in Technical Institutions."

The annual general meeting of the members of the Association of Directors and Secretaries for Education was held in London on January 19 and 20. Mr. F. Wilkinson, the chairman for the year, presided, and in the course of his remarks dealt with the new regulations for secondary schools of the Board of Education. The following resolution was adopted by the association:—"That the policy at present pursued at South Kensington with reference to the erection, financing, and control of secondary day schools is calculated to cast a heavy burden upon the ratepayers, while at the same time depriving them of adequate control."

Mr. A. J. Gimson described before the Institution of Mechanical Engineers on January 20 his impressions of sixteen engineering workshops visited by him in America. In the course of his remarks, he said that a feature of the engineering industry that impressed him was "the close intercommunication of technical institutes and manufacturing workshops, of professors and manufacturers, and the presence, in minor positions of authority, of young men who had passed through a complete course of technical instruction." In this country, manufacturers as a rule have yet to learn the value of scientific investigation and scientific education as factors of industrial progress.

Sir William White delivered an address at the Battersea Polytechnic on January 21 on the systematic study of engineering. He expressed the opinion that in the teaching of those who have to work during the day and have only the evening in which to study, Great Britain is making progress. In many departments of technical education there is still much to learn, but in classes such as those in polytechnics England has led the way. The full value of such studies is often not attained, said Sir William White, because of the absence of a scientific method of teaching. Some teachers are uninformed themselves, and the consequences are serious to their students. The want of a good English elementary education has been recognised, but in secondary education there is much which still remains undone. He advised every student of engineering to apply himself to the study of mathematics and applied mechanics, without which an engineer must be at a disadvantage and have to work in the dark.

REFERENCE was made last week (p. 286) to the grant of 400*l.* a year, for the next five years, voted by the Drapers' Company for work in the department of applied mathematics at University College, London. The company has long taken an active part in the development of higher education, and the enlightened policy which has prompted it to make grants in aid of university work and scientific research in London will, we trust, be adopted by other city companies. No better testimony to the value of such grants could be obtained than is afforded by the memoirs which have been published containing the results of work carried on in Prof. Karl Pearson's laboratory (see, for instance, a note in NATURE of November 3, 1904, p. 15). In acknowledgment of the assistance given by the Drapers' Company to work of this kind, the council of University College passed the following resolution at its last meeting:—"That the council desire to convey to the Court of the Worshipful Company of Drapers their best thanks for the vote of 2000*l.* towards further assisting the statistical work and higher teaching of the department of applied mathematics at University College. By their original grant of 1000*l.* for this purpose the court has enabled the council to appoint an adequate staff and to purchase valuable apparatus for the work of the department. By generously continuing their aid the court will enable the work thus begun to be placed upon a more permanent footing, and will prepare the way for the establishment of a permanent statistical institute."

A RETURN showing the amount spent on technical education by local authorities in England and Wales—with the exception of four which have made no return—during the year 1902–3, has been prepared by the Board of Education and issued as a Blue-book. The return shows that the total amount of the residue received under the Local Taxation (Customs and Excise) Act, by the councils of counties and county boroughs in England (excepting the county of Monmouth), in 1902–3 was 879,405*l.*, of which 840,253*l.* was appropriated to educational purposes, and 39,152*l.* to relief of rates, the latter sum including 22,366*l.* devoted by the London County Council to relief of rates. Of the 49 county councils, 45 were applying the whole of the residue to technical education, and 3 a part of it to the same purpose. Of the councils of the 64 county boroughs, 61 were devoting the whole, and 3 a part of the residue to technical education. Further, 4 county councils and the councils of 31 county boroughs, 101 boroughs, and 211 urban districts, in England, were making grants out of the rates under the Technical Instruction Acts; and 31 local authorities were devoting funds to technical education out of the rate levied under the Public Libraries and Museums Acts. Thirty-three local authorities raised sums by loan on the security of the local rate under the Technical Instruction Acts. The total amount expended on technical education during the year was 1,149,216*l.* The total amount of the residue paid to the 13 county councils and the councils of the 3 county boroughs in Wales and Monmouth was 42,201*l.* These local authorities devoted the whole of it to intermediate and technical education, chiefly under the Welsh Intermediate Education Act, 1889. The total amount expended on technical education in Wales and Monmouth under the Technical Instruction Acts during the year was 42,781*l.*

SOCIETIES AND ACADEMIES.

LONDON.

Geological Society, January 4.—Dr. J. E. Marr, F.R.S., president, in the chair.—The marine beds in the Coal-measures of North Staffordshire: J. T. **Stobbs,** with notes on their palæontology by Dr. Wheelton **Hind.** The stratigraphical position of the marine beds can be located with exactness *in situ.* The horizons can be utilised for the subdivision of the Coal-measures. The known horizons at which marine fossils have been obtained were enumerated, and a map of the distribution of these beds was given. The Speedwell and Nettlebank bed appears to be the most important marine bed in the coalfield. A detailed table of the beds in North Staffordshire was given to show the exact position of the marine beds. Dr. Hind, in his notes on the palæontology, remarked that from the base of the Pendleside series to the top of the Coal-measures there is an unbroken succession of beds—at one time marine, at another estuarine, without unconformity.—The geology of Cyprus: C. V. **Bellamy,** with contributions by A. J. **Jukes-Browne.** The Kyrenia Mountains rise to heights of more than 3000 feet. They are composed of rocks tilted into a vertical position, altered by compression and intrusion, and are devoid of fossils. They are referred by Prof. Gaudry to the Cretaceous period, and are compared by him with the hippurite-limestones of Attica. The Kythræan rocks (Upper Eocene) are based on breccias and conglomerates made up of fragments of the Trypanian limestones. No fossils, except a few small tests of Globigerina, have been found in this series, which consists entirely of volcanic débris. The Idalian (Oligocene) series appears to rest conformably on the last. The gypsum-beds are largely developed in the south; the white chalky marls and limestones extend over nearly one-half of the island, and are always conspicuous from their intense whiteness. Foraminifera are abundant, and other fossils have been found which indicate that the beds are mainly of Oligocene age. Igneous rocks are most conspicuous in the centre of the island. They are intrusive into the formations already mentioned. The rocks include augite-syenite, rhyolite, liparite, olivine-dolerite, basalt, augite, and several varieties of serpentine. Miocene rocks have only been recognised in the south-east of the island. The Pliocene strata lie in horizontal or slightly inclined beds, resting unconformably upon all older rocks. The Pleistocene rocks sometimes attain a thickness of 50 feet. The cave-earths have yielded *Hippopotamus minutus* and *Elephas Cypriotes* to Miss D. M. Bate. An account of the chief economic mineral products of the island is given. Descriptions of some of the rocks, a note on the Miocene rocks, and a sketch of the physical history of the island are contributed by Mr. Jukes-Browne.

Mathematical Society, January 12.—Prof. A. R. Forsyth, president, in the chair.—Basic generalisations of well known analytic functions: Rev. F. H. **Jackson.** Recent investigations have led to generalised forms of the serial expressions of certain functions. The functional characters of the new series, the domains of convergence, and the possibility of finding linear differential equations satisfied by the generalised functions are the matters that next claim attention. The author explained the degree of success which he had attained in these lines of investigation.—Current flow in rectangular conductors: H. Fletcher **Moulton.** The paper deals with the resistance of a rectangular lamina between electrodes which occupy portions of opposite sides, and the distribution of currents which flow in a conducting lamina bounded internally and externally by squares.—On the kinematics and dynamics of a granular medium in normal piling: J. H. **Jeans.** The paper is occupied with problems suggested by Prof. O. Reynolds's "Sub-mechanics of the Universe." An attempt is made to examine the question of the permanence or non-permanence of peculiarities of piling such as Prof. Reynolds interpreted as matter, electricity, magnetism, &c. The results go to show that such peculiarities would be transient, and that a universe constructed as imagined by Prof. Reynolds would suffer instant dissolution, after which particles of matter, charges of electricity, &c., would appear fortuitously at rare intervals, and have no continuous existence either in time or space. If the æther were a granular medium in normal piling, it would be æolotropic with eighteen elastic constants, and the velocity of propagation of waves of high frequency would be much greater than that of waves of low frequency. Light transmitted from distant stars would consist largely of mirages and coloured spectra.—On a class of expansions in oscillating functions: Prof. A. C. **Dixon.** The paper deals with expansions of the kind discussed by Liouville and Sturm in which arbitrary functions are expanded in series of special functions which satisfy differential equations of a certain type. These expansions are used frequently in applications of mathematics to physics. The object of the paper is to give a rigorous proof of the possibility of such expansions in the case of functions which are analytic throughout the proposed range of validity of the expansions.—Generational relations for the abstract group simply isomorphic with the group $LF[2,p^n]$: Dr. W. H. **Bussey.**—On alternants and continuous groups: Dr. H. F. **Baker.** The paper is occupied with the proof of that fundamental theorem of non-commutative algebra which is usually written in the form $e^{A}e^{B}=e^{C}$, where A and B are non-commutative quantities, and C is a series of alternants of A and B. The proof is derived from a property of a matrix called the E-matrix, which involves the structure constants, and one set of the canonical variables, of the parameter group. This property is established independently of the theory of continuous groups. It is proved, further, that every alternant of E-matrices is an E-matrix, and thence is obtained a general expression for the equations of the first parameter group.—A generalisation of the Legendre polynomial: H. **Bateman.**—Isogonal transformation and the diameter transformation: H. L. **Trachtenberg.**

Royal Astronomical Society, January 13.—Prof. H. H. Turner, president, in the chair.—The eclipse of Agathocles in the year −309: Prof. **Newcomb.** The author considered that this eclipse had been identified by Celoria with an eclipse said by Cleomedes to have been total in the Hellespont. Assuming this to be the case, it would be necessary to make a diminution of 1″.5 in the secular acceleration.—The longitude of the moon's perigee: Mr. **Cowell.**—Magnetic storms and associated sun-spots: Rev. A. L. **Cortie.** Discussing Mr. Maunder's paper (read at the November, 1904, meeting), Father Cortie considered it was still possible to consider sun-spot phenomena and magnetic storms as produced by some common cause, and brought forward evidence from the Stonyhurst observations which he thought conflicted with some of Mr. Maunder's conclusions.—A paper on the same subject: Prof. **Schuster.** From Mr. Maunder's statistics, which Prof. Schuster discussed, it appeared that in some form or other magnetic storms recur at intervals apparently identical with that of the revolution of sun-spot zones. The author was unable, however, to accept Mr. Maunder's explanation of the cause of the storms, which he considered as of terrestrial origin, the earth's diurnal rotation being the real source of the energy. The energy thus drawn away from the earth would tend to diminish its velocity of rotation, but in a million years this diminution would not amount to more than a second a year. Without forming a definite theory on the subject, Prof. Schuster suggested that there is some solar effect, propagated in straight lines, which may increase the electric conductivity of the earth's atmosphere, and thus set a magnetic storm going without supplying its energy. The author concluded that Mr. Maunder had shown the urgent importance of further investigation, but that the facts have become more difficult to understand and explain. After a discussion, followed by a reply from Mr. Maunder, the meeting adjourned, many other papers being taken as read.

PARIS.

Academy of Sciences, January 16.—M. Troost in the chair.—On the generalisation of an elementary theorem of geometry: H. **Poincaré.** The theorem that the sum of the angles of a plane triangle is equal to two right angles is extended to the case of the tetrahedron.—On some theorems relating to algebraic surfaces of linear connection greater than unity: Émile **Picard.**—On some physical constants of calcium and on calcium amalgam: H. **Moissan** and M. **Chavanne.**—On the β-methyl-ϵ-alkylcyclohexanones and the corresponding alcohols, homologues of menthone and menthol: A. **Haller.** β-Methylcyclohexanone, which can be prepared either by the decomposition of pulegone or from metacresol by Sabatier and Senderens's method, is treated with sodium amide and the alkyl iodide. A mixture of various alkyl derivatives is obtained which up to the present has not been completely separated into its constituents.—On a synthesis of menthone and menthol: A. **Haller** and C. **Martine.** Methylcyclohexanone is treated successively with sodium amide and isopropyl iodide, the mass treated with water, extracted with ether, and the latter solution fractionated in a vacuum. The physical properties of the menthone obtained, as well as those of its oxime, semicarbazone, and other derivatives show that the synthetical is identical with the natural product.—Observations of the Borrelly comet (1904 *e*) made at the Observatory of Paris with the 30·5 cm. equatorial: G. **Bigourdan.**—On irregular algebraic surfaces: Federigo **Enriques.**—On some points in the theory of numbers: Georges **Rémoundos.**—On equations of the parabolic type: S. **Bernstein.**—On fluorescence: C. **Camichel.** The author has repeated some experiments of J. Burke on fluorescence with some additional precautions. His conclusion, which is opposed to that of Burke, is that the coefficient of absorption of uranium glass for the radiations which it emits during fluorescence is the same whether the fluorescence be excited or not.—Some combinations of samarium chloride with ammonia: C. **Matignon** and R. **Trannoy.** Samarium chloride forms eight different compounds with gaseous ammonia. The range of temperatures between which each of these compounds can exist, together with the heats of dissociation, were determined.—On a colloidal hydrate of iron obtained by electrodialysis and on some of its properties: J. **Tribot** and H. **Chrétien.** A solution of ferric hydrate in ferric chloride was placed in an ordinary Graham dialyser, and the amount of chlorine remaining in the solution determined at different intervals of time, in the first place on simple dialysis, and afterwards when a current of 1 ampere was passed through the solution. In the latter case the chlorine was more quickly and more completely removed; the theory of the two cases is given in detail, and the theoretical and actual results compared.—On an isomeride of trichloracetone: G. **Perrier** and E. **Prost.** Aluminium chloride is allowed to act upon alcohol in carbon bisulphide solution, and chloral is added. A liquid product possessing the composition and molecular weight of trichloracetone is obtained. The reactions, however, are quite different from this latter substance, and the formula  is provisionally proposed.—The migration of the ethylene linkage in unsaturated acyclic acids: E. E. **Blaise** and A. **Luttringer.** The migration of the ethylene linkage has been studied in the case of six alkylacrylic acids and normal $\alpha\beta$-hexenic acid. It appears to move into the longest chain, giving either an isomeric acid or a γ-lactone.—On the combination of natural leucine with carbamic acid: M. **Hugounenq** and Albert **Morel.**—On a new method of synthesising saturated ketones by the method of catalytic reduction: M. **Darzens.** It is shown that in applying the reaction of Sabatier and Senderens the temperature at which the reduced nickel is reduced is of equal importance with the temperature at which the reduction is carried out. If the nickel is prepared at 245° C. to 250° C., and the reduction is carried out at 180° C. to 190° C., unsaturated ketones can be readily reduced to the corresponding saturated compounds without the formation of considerable amounts of secondary alcohols as by-products. The reaction has been applied to mesityl oxide, methylhexanone, and methylheptenone.—Observations on the Borrelly comet (1904 *e*) made at the Observatory of Besançon: P. **Chofardet.**—Observations of the Borrelly comet (*e* 1904) made at the Observatory of Algiers with the 31·8 cm. equatorial:

MM. **Rambaud** and **Sy.**—Orogenic sketch of the chains of the Atlas mountains to the north-west of Chott el Hodna: M. **Savornin.**—On the existence and the abnormal tectonic situation of the Eocene deposits in New Caledonia: J. **Deprat** and M. **Piroutet.**—Geological observations collected by the Chari—Lake Chad expedition: H. **Courtet.**—Contribution to the chemical study of the soil, water, and mineral products of the region of Chari and of Lake Chad: Alex. **Hébert.**—On the spring at Hammam Moussa, near Tor, Sinai: R. **Fourtau** and N. **Georgiadès.** The water from this spring approximates to the water at Wiesbaden, containing sodium chloride and the sulphates of lime and magnesia. It has a slightly acid reaction.—Man and the mammoth at the Quaternary period in the soil of the Rue de Rennes, south of Saint-Germain-des-Prés: M. **Capitan.** Excavations in this district have led to the discovery in the Quaternary strata of several roughly executed flint heads and a well preserved tooth of the mammoth. It follows from this and previous discoveries that man, the elephant and the rhinoceros lived in the Seine valley, on the actual spot where Paris now stands.—Chlorophyll assimilation in the absence of oxygen: Jean **Friedel.** It is shown that the presence of oxygen in the atmosphere surrounding the leaf is not indispensable for the process of assimilation.—A gum bearing Stereospermum in Madagascar: Henri **Jumelle.**—The physiological effects of ovariotomy in the goat: P. **Oceanu** and A. **Babes.** Amongst the advantages of this operation in the goat are the disappearance of the characteristic smell of the milk, an increased secretion of the milk, and prolongation of the lacteal period.

DIARY OF SOCIETIES.

THURSDAY, JANUARY 26.

ROYAL SOCIETY, at 4.30.—On the Boring of the Simplon Tunnel, and the Distribution of Temperature that was Encountered: F. Fox.—On the Comparison of the Platinum Scale of Temperature with the Normal Scale at Temperatures between 444° and −190° C., with Notes on Constant Temperatures below the Melting Point of Ice: Prof. M. W. Travers, F.R.S., and A. S. C. Gwyer.—On the Modulus of Torsional Rigidity of Quartz Fibres, and its Temperature Coefficient: Dr. F. Horton.—On a Method of Finding the Conductivity for Heat: Prof. C. Niven, F.R.S.—On the Drift produced in Ions by Electromagnetic Disturbances, and a Theory of Radio-activity: G. W. Walker.—Exterior Ballistics. "Error of the Day" and other Corrections to Naval Range Tables: Prof. G. Forbes, F.R.S.—The Theory of Symmetrical Optical Objectives. Part ii.: S. D. Chalmers.—Coloration of Glass by Natural Solar and other Radiations: Sir William Crookes, F.R.S.—Note on the Cause of the Period of Chemical Induction in the Union of Hydrogen and Chlorine: C. H. Burgess and D. L. Chapman.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Fuel Economy in Steam Power Plants: W. H. Booth and J. B. C. Kershaw. (Conclusion of discussion.)

FRIDAY, JANUARY 27.

ROYAL INSTITUTION, at 9.—The Life-History of the Emperor Penguin: Dr. Edward A. Wilson.

PHYSICAL SOCIETY, at 5.—Action of a Magnetic Field on the Discharge through a Gas: Dr. R. S. Willows.—Action of Radium on the Electric Spark: Dr. R. S Willows and J. Peck.—The Slow Stretch in India-rubber, Glass, and Metal Wires when subjected to a Constant Pull: P. Phillips.—Determination of Young's Modulus for Glass: C. A. Bell. Some Methods for Studying the Viscosity of Solids: Dr. Boris Weinberg.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Concrete-Making on the Admiralty Harbour Works, Dover: T. L. Matthews.

SATURDAY, JANUARY 28.

MATHEMATICAL ASSOCIATION, at 3.—Models and their Use: E. M. Langley.—The New Geometry: W. H. Wagstaff.—Should Greek be Compulsory for Mathematicians at Cambridge? A. W. Siddons.

ESSEX FIELD CLUB (at Essex Museum of Natural History, Stratford), at 6.30.—On the Occurrence of Gypsum in Essex Soils: T. S. Dymond.—The Bog-Mosses (Sphagnaceæ) of Essex, a Contribution to the Flora of the County: F. J. Chittenden.

MONDAY, JANUARY 30.

SOCIETY OF ARTS, at 8.—Reservoir, Stylographic and Fountain Pens: J. P. Maginnis.

INSTITUTE OF ACTUARIES, at 5.—On Staff Pension Funds: G. King.

FARADAY SOCIETY, at 8.—Mass Analyses of Muntz's Metal by Electrolysis, and some Notes on the Electrolytic Properties of this Alloy: J. G. A. Rhodin.—On the Equilibrium between Sodium and Magnesium Sulphates: Dr. R. Beckett Denison.—"Refractory Materials": E. K. Scott.

TUESDAY, JANUARY 31.

ROYAL INSTITUTION, at 5.—The Structure and Life of Animals: Prof. L. C. Miall, F.R.S.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Floating Docks: L. E. Clark.

MINERALOGICAL SOCIETY, at 8.—(1) On Danalite from Cornwall: (2) Crystallographic Characters of Barium-radium Bromide: Prof. H. A. Miers, F.R.S.—On the Regular Growth of Crystals of one Substance upon Those of Another: T. V. Barker.—Apparatus for Determining the Density of Small Grains: K. A. K. Hallowes.

WEDNESDAY, FEBRUARY 1.

GEOLOGICAL SOCIETY, at 8.—On the Sporangia-like Organs of *Glossopteris Browniana*, Brongn.: E. A. Newell Arber.

SOCIETY OF PUBLIC ANALYSTS, at 8.—The Volumetric Estimation of Reducing Sugars: A. R. Ling and T. Rendle.—The Inversion of Cane Sugar in the presence of Milk Constituents: Hon. Francis Watts.—The Colorimetric Estimation of Salicylic Acid in Food Stuffs: F. T. Harry and W. R. Mummery.

SOCIETY OF ARTS, at 8.—The Navigation of the Nile: Sir William H. Preece, K.C.B.

THURSDAY, FEBRUARY 2.

ROYAL SOCIETY, at 4.30.—*Probable Papers:* On the Compressibility of Gases between One Atmosphere and Half an Atmosphere of Pressure: Lord Rayleigh, O.M., F.R.S.—On the "Blaze Currents" of the Gall Bladder of the Frog: Mrs. A. M. Waller:—The Theory of Photographic Processes; on the Chemical Dynamics of Development: S. E. Sheppard and C. E. K. Mees.—On the Relation between Variation of Atmospheric Pressure in North-East Africa, and the Nile Flood: Capt. H. G. Lyons.—Note on the Determination of the Volume Elasticity of Elastic Solids: Dr. C. Chree, F.R.S.—Theory of the Reflection of Light near the Polarising Angle: R. C. Maclaurin.

ROYAL INSTITUTION, at 5.—Forestry in the British Empire: Prof. W. Schlich.

THE QUINTESSENCE OF HAECKELISMUS.

The Wonders of Life. A Popular Study of Biological Philosophy. Supplementary volume to "The Riddle of the Universe." By Ernst Haeckel. Translated by Joseph McCabe. Pp. xiv+501. (London: Watts and Co., 1904.) Price 6s. net.

THIS new book by the indefatigable Haeckel is supplementary to his "Riddle of the Universe." That several hundred thousand copies of the "Riddle" were sold indicates the widespread interest taken in what the author calls "the construction of a rational and solid philosophy of life," or in what others would call an extremely biological way of looking at things. But the "Riddle" and its solutions raised storms of criticisms and evoked hundreds of reviews—both friendly and hostile—besides many large pamphlets and even a few books, not to speak of more than five thousand letters. To these collectively, friends and foes alike, Haeckel now replies in this "biological sketch-book," written uninterruptedly in the course of four months when he was completing his seventieth year in a vacation at Rapallo, a tiny coast-town of the Italian Riviera. He had leisure there to think over all the views on organic life which he had formed in the course of a many-sided experience of life and learning since the beginning of his academic studies (1852) and his teaching at Jena (1861). The constant sight of the blue Mediterranean, the animal inhabitants of which he knows so well, his solitary walks in the wild gorges of the Ligurian Apennines, and the moving spectacle of the "forest-crowned mountain altars," inspired him with "*a feeling of the unity of living nature*—a feeling that only too easily fades away in the study of detail in the laboratory." He hopes that his readers may be moved by his book "to penetrate deeper and deeper into the glorious work of Nature, and to reach the insight of our greatest German natural philosopher, Goethe:

> "What greater thing in life can man achieve
> Than that God-Nature be revealed to him?"

The work is described as "a popular study of biological philosophy"; it is divided into four sections—methodological, morphological, physiological, and genealogical, which deal respectively with the *knowledge* of life, the *nature* of life, the *functions* of life, and the *history* of life. It raises no end of perplexing problems—life and death, nutrition and reproduction, heredity and variation, sensation and intelligence, morality and religion. It discusses protoplasm and the cell, spontaneous generation and evolution in general, the "pro-morphology" of organisms and the intricate architecture of the brain, the recapitulation of phylogeny in ontogeny, the inheritance of acquired characters, the evolution of sensation, æsthesis, intelligence, and morality. In short, it comprises practically everything, including miracles, the religious thoughts of Mr. Romanes, the university curriculum, the increase of pauperism, the introduction of Spartan elimination-methods, the Apostles' Creed, the immaculate conception, immortality, and a belief in a personal God. A book with so large a purview is bound to be sketchy—and the author calls it "a biological sketch-book" but sketchiness in dealing with subjects so momentous is apt to be unsatisfactory, and, while Haeckel continually and quite fairly refers to what he has said elsewhere in his large family of books, the discriminating reader may justly complain that he has often to deal rather with an assertion of convictions than with a reasoned argument. What carries one on from page to page is the feeling that we have to listen to a veteran who is telling us frankly and fearlessly what he believes to be true in regard to the order of nature and our place in it.

From one point of view Haeckel's discussion of the "Wonders of Life" is an apology for "Monism" or "Hylozoism." In studies of "unequal value and incomplete workmanship," as the illustrious author confesses, an attempt is made to show how we may attain to the conception of one great harmoniously working universe—"whether you call this Nature or Cosmos, World or God"—without utilising any knowledge which is not of empirical origin and *a posteriori*. We must not allow metaphysical fictions to intrude on our philosophy—still less into our science; we may work with the "law of substance," but there is to be no hocus-pocusing with transcendental formulæ; science is sufficient unto herself, and is justified of her children; criticism of her postulates and categories is a waste of time when there is so much to do; psychology is "a branch of physiology," and it is unprofitable to think about thinking; a "theory of knowledge" is a luxury for the leisured. Everything seems to become plain sailing if we embark on the craft "Hylozoism," but we require faith to help us across the gangway.

From another point of view Haeckel's book may be taken as an expression of the outlook on man and nature which may be reached by a conscientious pursuit of the scientific method. Those who remain agnostic or positivist in regard to either monism or dualism in any of their forms will be interested in hearing once more of the order, unity and progressiveness of nature's tactics, and in considering the practical proposals which a thorough-going Darwinian has to offer in regard to incapables and incurables, pauperism and crime. We cannot do more than remark that these proposals preach elimination rather than eugenics; they are more akin to surgery than to preventive medicine. Much of the book is, naturally enough, an echo of previous works—the "Monera," the "Gastræa Theory," the "Natural History of Creation," the "Evolution of Man," and, what has always appeared to us the author's *magnum opus*, the "Generelle Morphologie" (1866); but all has been modernised and orientated afresh to illustrate what Haeckel was so much impressed with at Rapallo, *the unity of living nature*. An interesting illustration of the author's artistic enthusiasm and indifference to popularity will be found in the pages on promorphology, wherein he discusses the architectural symmetries of organisms, as he did forty years ago. The centrostigmatic, centraxonial, and centroplane types of architecture have some personal fascination for us, but they must be caviare to the general.

To illustrate more concretely the general tenor of the "Wonders of Life," we may refer, for a moment, to the first two chapters, on truth and on life. In the chapter on truth we are introduced to the "*phronema*," the organ of knowledge, a definite and limited part of the cerebral cortex, consisting of association-centres, the innumerable cells of which are the elementary organs of the cognitive process, the possibility of knowledge depending on their normal physical texture and chemical composition. *How* this august possibility depends on the organisation of the "phronetal cells" remains entirely obscure, and no amount of "bluffing" will lessen this obscurity. As to life in general, its phenomena are determined by the physicochemical organisation of the living matter; metabolism has its analogue in inorganic catalysis; reproduction is analogous to the "elective multiplication" of crystals; and sensation is a general form of the energy of substance, not specifically different in sensitive organisms and irritable inorganic objects (such as dynamite). It is unfortunate, however, for this view of things that we cannot at present interpret even the simplest vital phenomenon in terms of physical and chemical formulæ. But we must remember that while "there is no such thing as an immaterial soul," a "soul" in the atom "must necessarily be assumed to explain the simplest physical and chemical processes." It seems to us six of one and half a dozen of the other whether we recognise the soul at the top or at the bottom. In Aristotelian language, there is nothing in the end which was not also in the beginning; in plain English, we put into the beginning what we know to be in the end. In fact, when we pass from the descriptive, formulative, interpretative task of science to philosophical explanation—whether monistic or dualistic—we load our intellectual dice. The only alternative is positivism, which is not amusing, and refuses to play. Haeckel's monism, we are bound to confess, appears to us to be dualism in disguise. He predicates for his "substance"—which is from everlasting to everlasting—a trinity of fundamental attributes, matter, energy, *and* sensation.

It is one of Haeckel's pastimes to coin new words, and now and again he has hit on a term which has been really useful, and has come to stay. In his "Wonders" his verbose inventiveness is still manifest. For the sciences which deal with inanimate nature a term is needed, and we are invited to choose between abiology, anorganology, abiotik, and anorgik, each of which seems worse than its neighbour. "Ergology" we might digest, but when it comes to perilogy, metasitism, trophonomy, tocogony, gonimatology, plasmodomism, and metaplasmosisms, the suggestion of an emetic is so obvious that we cannot swallow them.

We wish to make a remark in regard to the translation. Haeckel's preface is dated June 17, 1904, and this means that the translation has been accomplished with quite remarkable rapidity. It is on the whole clear and vigorous, but it betrays inexpertness. Thus we would point out the undesirability of calling Acanthocephala "itch-worms," or Cirripedia "creeping-crabs" or "crawling crabs," or Arion "our common garden snail," or Holothurians "sea-gherkins," and we could add to this list considerably. There seems something wrong, too, in calling reproduction "*transgressive* growth," and we wonder what "wonder-snails" can be, or "the actinia among the tunicates." In regard to the articulation of the lower jaw in mammals, we learn that "this joint is temporal and so distinguished from the square joint of other vertebrates." "Square" is a quaint way of referring to the quadrate bone! The translator has not the vaguest idea what he is translating. Defective proof-reading introduces us to a number of strangers, such as an early microscopist "Crew" in England and a prominent modern biologist who is always referred to as "De Bries." We are interested also in a renowned physiologist called Felix Bernard, and in what Wilhelm Preyer did "for the plant." Such is fame! Beside these, misprints like Cecidomyca, Ichtyosauri, and diatomes are trivial. It is a very unusual proceeding to print every technical name of class, genus, or species in italics without capitals.

In conclusion, while we entirely disagree with Haeckel's treatment of philosophy, and believe that he has not justly realised what its office is, while we also disagree with some of Haeckel's science, *e.g.* the transmission of acquired characters, we desire to point out that this book expresses the sincere convictions of a veteran who has done much for biology, and that its aim is to help towards including "all the exuberant phenomena of organic life in one general scheme, and explaining all the wonders of life from the monistic point of view, as forms of one great harmoniously working universe—where you call this Nature or Cosmos, World or God." As Browning said, our reach should exceed our grasp, "else what's Heaven for?"

A USEFUL BOOK FOR FRUIT GROWERS.

The Culture of Fruit Trees in Pots. By Josh Brace. Pp. x + 110. (London: John Murray, 1904.) Price 5s. net.

IT is nearly half a century since the late Thomas Rivers built glass structures for the protection of his fruit trees in pots. He was led to do this because in several successive seasons the hardy fruit crops were almost destroyed by severe frosts, which occurred when the trees were in flower—a very critical stage in the growth of the trees. Mr. Rivers was convinced that in order to be certain of obtaining crops of first-rate fruit of peaches, nectarines, apricots, plums, cherries, and even apples and pears, it was necessary to have large glass structures to protect the trees at that period. These early houses were not provided with means of heating them artificially, because it was then thought that the extra expense this would have entailed was unnecessary; but subsequent experience proved that a flow and return hot water pipe in each house not only provided additional security against frost, but the slight heat thus obtainable, if employed in bad weather while the trees are in flower, has a good effect upon the pollen, and therefore assists in securing the fertilisation of the flowers.

Since that time the pot fruit trees cultivated in the Sawbridgeworth nurseries of Messrs. T. Rivers and Son have provided a unique object lesson to British fruit growers, and the system has been imitated in other commercial establishments and in many private gardens, a notable instance being the gardens belonging to Mr. Leopold de Rothschild at Gunnersbury House, Acton, where excellent results are obtained notwithstanding the fact that the gardens are in London. The author of the book under review has been charged with the care of the orchard houses at Sawbridgeworth for more than twenty years, and the details of cultivation he explains are those which have been practised with such conspicuous success in that establishment. It may be admitted that the orchard house is more necessary in the colder districts of midland and northern counties than in the south, but even in the south the season of ripe fruits can be prolonged by orchard house culture, and more perfectly developed apples and pears obtained for particular purposes. Who that has seen the exquisite specimens exhibited at the autumn fruit shows has not wished to cultivate fruits of similar excellence? It is the mission of Mr. Brace's book to assist the reader to accomplish this purpose.

In the first chapter the author has described very minutely the construction of the best type of houses, and the importance of commencing with suitable structures is so great that we are not disposed to complain that the subject occupies one-fifth of the book, as well as several diagrams. From every point of view houses with span-shaped roofs are best, and if Mr. Brace's instructions are studied, the cultivator, by moving his trees out of doors at suitable periods, will be able to make the most of the space afforded in the houses.

In chapter ii., in which the furnishing of the houses with trees is considered, the best methods of arranging them are described, so that as many trees may be grown as possible, and yet none be obscured by the others. If only one house is built, and this is of an appreciable size, it should be divided into sections, because peaches and nectarines can be treated more successfully when grouped by themselves, as the trees need to be syringed daily until the fruits begin to ripen, which would not be possible if cherries or plums, which ripen much earlier in the season, were associated with them in the same division.

Chapter iii. must be read very carefully, and should be frequently referred to by the inexperienced cultivator. It contains details of cultivation, explains the best forms of training for the different kinds of trees, the process of potting, methods of forcing, pruning, summer pinching, value of surface dressings to the roots, cost of trees, &c. In the cultivation of fruit trees in pots, whether half standards, or bush trees of peaches, nectarines, and plums, or pyramids of apples and pears, the work of pruning and pinching is of the greatest importance, and if it be done unskilfully not only will the trees be unshapely and the fruit spurs become longer than is desirable, but the trees will fail to contain sufficient fruitful wood to produce satisfactory crops.

The best varieties of the different kinds of fruits for pot culture are described in chapters iv. and vii., and in chapter v. the subject of insect pests is dealt with, and the measures to adopt against these and the peach mildew are explained. Chapter vi. consists of a brief calendar of operations in the unheated orchard house for each month of the year, which is sufficient to remind the practitioner of the correct time to carry out the operations which are more fully described in the previous pages.

In addition to other illustrations, the work is adorned with full-page plates representing pot fruit trees in bearing, being reproductions from photographs obtained in Messrs. Rivers' nursery. These are reproduced in the very best manner, and the printing throughout the book is clear, and the type large and distinct.

The book has little claim from a literary point of view, but the author has described in plain words a system of cultivating fruit trees in pots which, if faithfully followed, will be attended with absolute success.

R. H. P.

A TRAVELLER'S COMPANION.

Stanford's Geological Atlas of Great Britain (based on Reynolds's Geological Atlas). By Horace B. Woodward, F.R.S., F.G.S. Pp. x+140; with 34 coloured maps and 16 plates of fossils. (London: E. Stanford, 1904.) Price 12*s*. 6*d*. net.

THIS work is a re-written and revised edition of the well known atlas, which was long a familiar object to the students of shop-windows near Temple Bar, associated as it was with geological diagrams of a highly venerable aspect. It was always attractive by its very neatness and compactness, and has gained further in these respects under Mr. Stanford's care. The maps are printed in colours, and the concluding plates of fossils, reproducing for the most part Mr. Lowry's refined workmanship, are almost as delicate as the engraved originals, which were published in 1853. These plates, by the by, are not now arranged so consecutively as could be desired. Mr. H. B. Woodward has brought the text up to a modern standpoint, and we note references to the Pendleside series, to the Mesozoic rocks in a volcanic vent in Arran, and to the occurrence of Pliocene mammalian remains in a fissure in Derbyshire—all matters of very recent history. The Upper Greensand and Gault are described and mapped together as Selbornian, a combination of great stratigraphical convenience, however much it departs from the petrological and geognostic mapping of early days. Here we see at once how the philosophic view of "organised fossils," introduced by William Smith, has made two types of geological maps necessary, one for the students of the earth's history, and one for the engineers, landowners, and agriculturists, to whom Smith made his first appeal. Luckily, in our British Isles, our "drift" maps, on a reasonable scale, go far to satisfy both requirements.

Mr. Woodward's descriptions of the various counties contain rather too much matter that could be discovered from the maps themselves. Though dealing with a land of most fascinating variety, they do not always rise to the demands made by the salient scenic features. Yet these are the features that strike the common traveller, to whom this work must always be a boon. From his point of view we have read the account of Gloucestershire a second time, and, of course, discover nothing to add, while we are grateful for a good deal of graphic description, tersely worded. The matter probably only needs a new arrangement, so that the reader who descends in imagination or in memory from the steep side of the Forest of Dean, and wonders at the great scarp of the Cotteswolds, facing him ten miles off across the Severn, is not dragged aside to learn that Coal-measures were discovered in the Severn Tunnel, and the irritating fact that "sulphate of strontium is worked at Wickwar in the Keuper Marl." The traveller wants to move forward; the open landscape lies before him; when he has gained his first broad physiographic view, he will condescend to search for fossils, and to rejoice in geodes of celestine.

The exceptional knowledge of the country possessed by the author is apparent in all these careful pages. He has added, moreover, exceedingly practical descriptions of the geology that is to be learned along the main lines of British railways. His views on the nomenclature of fossils are known from his published writings; but, while most of us are sadly inconsistent, he yields perhaps too little to the purists. If Mr. Woodward goes so far as Doryderma and Cœlonautilus, where none will blame him, why does he retain Ammonites and Goniatites as unrestricted generic names? Why *Echinocorys scutatus*, which seems to surpass the historical acuteness of Mr. C. D. Sherborn (see "Index to Zones of the White Chalk," *Proc.* Geol. Association, June, 1904), and, side by side with it, *Galerites albogalerus*? We doubt also Protocardium for Protocardia; but these matters are outside the main intention of the atlas. As a companion in Great Britain, this handy book is to be recommended to every traveller. The complete revision of the Scotch map, which is now so admirable, despite its comparatively small scale, makes us hope that Ireland, as a country of equal interest and variety, may be included in the next edition. G. A. J. C.

THE TEACHING OF SCIENCE.

The Preparation of the Child for Science. By M. E. Boole. Pp. 157. (Oxford: Clarendon Press, 1904.) Price 2*s.* 6*d.*

Special Method in Elementary Science for the Common School. By Charles A. McMurry, Ph.D. Pp. ix + 275. (New York: The Macmillan Company, 1904.) Price 3*s.* 6*d.* net.

A GREAT change in the character of the books concerned with the teaching of science has taken place during the last twenty years or so. A quarter of a century ago the claims of science to a place in the school curriculum were being advocated vigorously, and men of science had still to convince reigning schoolmasters that no education was complete which ignored the growth of natural knowledge and failed to recognise that an acquaintance with the phenomena of nature is necessary to intelligent living. Speaking broadly, it may be said that most classicists even admit now that there are faculties of the human mind which are best developed by practice in observation and experiment. One consequence of the success which has followed the persistent efforts of Huxley and his followers—to secure in the school an adequate recognition of the educative power of science—has been that modern books on science teaching are concerned almost entirely with inquiries into the best methods of instructing young people, by means of practical exercises, how to observe accurately and to reason intelligently.

Mrs. Boole deals with the earliest education of the child, and gives a great deal of attention to the years which precede school life. Her book may be warmly recommended to parents anxious to adopt sane methods of educating their children and to teachers responsible for the training of the lowest classes of schools. Mrs. Boole rightly insists that the development in the child of the right attitude towards knowledge is of more importance during early years than the actual teaching. We agree with her, too, that "the best science teacher is usually a thorough-going enthusiast in the science itself, who in the intervals of regular teaching, gets his pupils to assist him in his own investigations or pursuits." But, unfortunately, the teaching profession is at present hardly attractive enough to secure the services of a sufficient number of ordinarily well educated men, and we shall have to wait a long time before we can expect to find many men of science engaged upon original research also teaching science to children in schools. Mrs. Boole's little book deserves to be read widely.

Like many other American educationists, Dr. McMurry attempts to do too much for the teacher. The larger part of his book is devoted to "illustrative lessons" and "the course of study," minute instructions being given as to what science subjects should be taught in each of the terms of each of the years spent by children in the elementary school. The teacher will deal most satisfactorily with those subjects of science he knows best, and in which he is most interested. From the point of view of the British teacher at least, it is inadvisable to attempt to impose a detailed scheme of work drawn up by somebody in another district and unfamiliar with the precise conditions and environment of the school in which the science teaching is to be done. Even if this were not the case, Dr. McMurry's scheme of work expects the class to accomplish far more in a term than can be studied satisfactorily in that period. Moreover, subjects too diverse, and hardly at all related one to the other, are prescribed for a single term. But Dr. McMurry's ideal is better than his practice; he says:—"it is easy for us to expect too much from formal method. The atmosphere which the teacher diffuses about him by his own interest and absorption in nature studies is more potent than any of the devices of method." A. T. S.

OUR BOOK SHELF.

The Basic Law of Vocal Utterance. By Emil Sutro. Pp. 124. (London: Kegan Paul and Co., Ltd., n.d.)

Duality of Voice and Speech. An Outline of Original Research. Pp. vi+224. (London: Kegan Paul and Co., Ltd., n.d.)

Duality of Thought and Language. An Outline of Original Research. Pp. viii +277. (London: Kegan Paul and Co., Ltd., n.d.)

THE first of these volumes, which was originally published in America in 1894, contains the starting point and main beliefs of the author; the second and third volumes form the amplification and illustration. Beginning with the practical problem of finding how a foreigner, especially a German, can learn to speak English correctly, Mr. Sutro has gone on until he has become convinced that he has discovered several most important scientific truths, and that he has a great mission to carry out in proclaiming them.

Among the discoveries stated in these volumes the following may be mentioned. There are two streams in the air which is breathed, which keep separate, one being for respiration, the other for sound. A person who breathed correctly might use the air supplied by the sound current in such a way as to speak for ever without taking breath, were it not for fatigue. For English speech we inspire through trachea and expire through œsophagus; for German the direction is reversed. The author has discovered a new vocal cord in the lower jaw. Air passages are diffused through the body; it is through these that the emotional nature of sound is produced. The original source of tone production has its location in the lungs, the kidneys, and the bladder for the most part. For the utterance of a word representing a flower there is an impression made on the right side of the thigh, while the expression is on the left side just opposite, the order being reversed for the corresponding German word. Just how we breathe into and out of the pelvis the author expects to explain satisfactorily in a future volume. Statements such as these, together with philosophical reflections and practical discussions as to the way in which the production of different sounds should be managed, fill the three volumes.

The volumes are not without a certain kind of interest that of observing the process by which a man, who is evidently in earnest, comes to elaborate and believe such nonsense. It is at the same time possible that there may be in the remarks regarding the way in which sounds should be produced something which would be suggestive to one engaged in the practical work of teaching in this subject. According to Mr. Sutro, America has left his works almost unnoticed, while Germany has given a more favourable reception to them. It appears that an International Physio-Psychic Society has been founded for the propagation of the views put forward in these volumes.

A Select Bibliography of Chemistry, 1492–1902. By H. C. Bolton. Second supplement. Pp. 462. (Washington: Smithsonian Institution, 1904.)

THE present volume of the "Select Bibliography" is the second supplement which has been published since the first issue in 1893, and carries the work down to 1902.

One can only admire the patient labour of the author, now unfortunately removed by death, who has placed in the hands of chemists all over the world a book of reference of such permanent value.

The supplement contains the titles of books published between 1898 and 1902 inclusive, in which the same subdivisions are preserved as in the first volume. It is just a question whether the last subdivision—academic dissertations—which fills nearly half the book, is worth the trouble it has entailed. It consists almost entirely of the titles of dissertations for the German doctorate, which in Germany often find their way into booksellers' hands, but are merely reprints of memoirs that have appeared in the scientific journals. The list is necessarily incomplete, and the trouble of indexing it must have been enormous. The proof-reading, as well as the preparation of the index, have been done by Mr. Axel Moth, of the New York Public Library. J. B. C.

Hints on Collecting and Preserving Plants. By S. Guiton. Pp. ii+55. (London: West, Newman and Co., 1905.) Price 1*s.*

THE collector of plants, whether he is merely pursuing a hobby or whether his object is to acquire specimens for reference which will enable him to get a better knowledge of systematic botany, ought to be acquainted with the best methods of preparing and arranging a herbarium. For information he will find this small book useful. Some of the suggested details are not absolutely necessary, but a little experience will soon show which are essential. In some respects Mr. Guiton tends to what one may call the collector's views, as, for instance, when he recommends gumming the specimens on cardboard; the more usual practice of fixing them by means of gummed slips on drawing paper is cheaper, and allows the specimens to be taken off for examination. The preference of iron grids in place of wooden ventilators, the advantages of cotton mattresses, and other such details which might be suggested are rather matters of individual taste; so long as a collector takes as much care as Mr. Guiton, his herbarium will be a pleasure, not only to himself, but also to kindred botanists.

Practical Retouching. By Drinkwater Butt. Pp. xv+78. (London: Iliffe and Sons, Ltd., 1904.) Price 1*s.* net

THIS book forms No. 10 of the *Photography* Bookshelf Series, and will be found a useful addition. The matter contained in it originally appeared in the pages of *Photography* in 1901, but the author has brought the information up to date and presented it in the present form, which will be found convenient for beginners. The chapters are eight in all, and after the preliminary ones dealing with things to be done and to be avoided, and the apparatus and material required for the work, we have those on general manipulations, manipulations in detail of portrait work and inanimate objects, concluding with the use of the back of the negative for further hand-work.

Stories from Natural History. By Richard Wagner. Translated from the German by G. S. Pp. viii+177. (London: Macmillan and Co., Ltd., 1904.) Price 1*s.* 6*d.*

THESE interesting stories dealing with subjects of natural history are presented in excellent English. The translator's style is graceful, and the language chosen is of a kind which will appeal to children; while the scientific information is sound as well as instructive. A young reader should learn incidentally a great deal about animal life, and at the same time be given sympathetic interest in it. The little volume is suitable for a reading book in the higher standards of the elementary school and for the lowest forms of a secondary school.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Compulsory Greek at Cambridge.

My own experiences are somewhat different from those of your correspondents, but the result is the same. I commenced Greek when about thirteen; I passed the London matriculation, the entrance examination at Trinity, and the Little-go without any difficulty; and I have read the three synoptic gospels in the original, several Greek plays, and a certain amount of Homer, Xenophon, and Thucydides. Now, if all the knowledge I thus acquired had been of any practical value to me in after life, I should, as a matter of ordinary common sense and worldly wisdom, have kept it up; but, finding Greek absolutely useless, my acquaintance with the language has so completely faded away that I can scarcely make out the sense of a Greek quotation in a historical or theological work.

It has often been a matter of profound regret to me that the time spent on Greek was not devoted to German, for if it had I should have been able to speak the language sufficiently well to enjoy during my whole life German society, German literature, and German places of amusement.

I have never been able to discover any educational value in a training which condemns boys to grind up pages of Greek declensions and irregular verbs. In my experience of life a youth who, after acquiring some knowledge of the grammar of a modern language, is made to read easy books on the manners, customs, and history of the country where the language is spoken (and nothing is better than a well-written novel) is far better equipped for the battle of life, and is a far more agreeable companion both intellectually and socially, than a man whose boyhood has been spent in studying musty old mythologies, which nobody troubles about nowadays except the select few who have made such subjects the hobby of their lives.

By all means let the bishops continue to require a knowledge of Greek (and also of Hebrew) on the part of candidates for orders, on the ground that these subjects ought to be considered part of the professional stock-in-trade of a clergyman; but special studies of this kind, like law in the case of barristers and solicitors, need not be commenced until a youth has decided upon the profession he intends to follow. A. B. BASSET.

Can Birds Smell?

EXAMINATION of the Bird's brain shows that the sense of smell can be but little developed. The olfactory bulbs are small. No medullated nerve-fibres unite them with the rest of the brain. Yet in no birds are the bulbs entirely absent, so far as I am aware. The olfactory membrane of birds presents certain structural peculiarities which are difficult to interpret. The nasal chambers which it lines are not large in any bird, but in some they are sufficiently extensive to suggest that olfaction is not completely in abeyance. The fact that they are better developed in birds which seek their food in the sea (petrels, the tropic bird, &c.), in which pursuit smell can, one would suppose, be of little service, than they are in most other birds seems to indicate that they have some function other than olfaction. Perhaps they serve to warm the inspired air; although here again we are confronted with the difficulty that, in the frigate bird (Fregata), in which the nasal chambers are relatively large, the nostrils are obliterated. Air may, of course, enter the nasal chambers through the cleft palate, but such a mechanism cannot provide for the warming of the air on its passage to the lungs. The teachings of anatomy being so obscure, it seemed to me desirable that direct observations should be made.

A study of the habits of flesh-eating birds shows that if they possess the sense of smell at all, it is not sufficiently acute to enable them to use it in finding food. All observers are agreed that when a carcase is hidden, by never so slight a screen, it is safe from the attacks of vultures and other carrion-seekers; but the most remarkable proof of the ineffectiveness of the sense (if it exist at all) is afforded by experiences which Dr. Guillemard was good enough to relate to me. Many times it has happened, he tells me, that, having shot a wildebeest or other game which was too heavy to carry home, he has disembowelled it, and has hidden the carcase in the hole of an "ant-bear." On returning with natives to carry it to camp, he has found a circle of vultures standing round the spot where the offal had been thrown, completely unaware of the carcase within a few yards of their beaks. Of observations proving the possession of the sense I know none, unless we are willing to accept as evidence the belief, which is very general among fanciers, that birds are attached to the smell of anise, and the similar belief of gamekeepers in some parts of the country that they are attracted by valerian. It is said that pigeons may be prevented from deserting the dove-cote by smearing their boxes with oil of anise. Poachers are supposed to lure hen-pheasants from a wood by anointing gate-posts with tincture of valerian.

With the view of testing the smelling powers of graminivorous birds, I placed a pair of turkeys in a pen which communicated with a large wired-in run. The pen was closed by means of a trap-door. In the run I placed, each day, two heaps of grain, right and left of the trap-door, but so far in front of it that they made with it an angle of about 50°. Various substances which give out a powerful odour were placed under one of the heaps, alternately the right and the left. The birds were lightly fed in the morning in their pen. At two o'clock the trap-door was raised, and they were admitted to the enclosure. It was curious to note that after the first few days the hen almost always came out first (in the last ten experiments this rule was broken but once), and invariably went to the heap on her right; the cock following went to the heap on the left. The cock usually tried the hen's heap after feeding for a short time from his own, but the hen never trespassed upon the preserve of the cock. In the earlier observations I placed beneath one of the heaps a slice of bread soaked with tincture of asafœtida, essence of anise, oil of lavender, or sprinkled with valerianate of zinc or powdered camphor. When the birds, plunging their beaks into the bread, took some of the tincture or essential oil into the mouth, the head was lifted up and shaken, but they immediately recommenced to peck at the grain. They were completely indifferent to the presence of camphor or valerianate of zinc. In several cases in which these substances were used, they consumed the bread. As a turkey does not steady the thing at which it is pecking, with its foot, but, seizing it in the beak, shakes it violently until a piece is detached, it is probable that most of the powder was shaken from the bread. As these experiments gave absolutely negative results, the birds showing neither preference for nor repugnance to any of the odorous substances used, I proceeded to stronger measures. The grain was placed upon a seven-inch cook's sieve, inverted. The odorous substance was placed beneath the sieve. Each of the following experiments was repeated three times, first with a small quantity of "smell," then with a great deal, and lastly with as much as possible. It is only necessary to describe the final tests. Four ounces of carbide was thrown into a saucer of water and placed beneath one of the sieves. There was no reason to think that the birds were aware of the existence of the acetylene which was evolved. The saucer was filled with bisulphide of carbon. The hen turkey finished her meal. When the grain was exhausted she knocked the sieve over with her foot. Both birds then lowered their beaks to within half an inch of the colourless liquid, which they appeared to examine. It is, perhaps, unfortunate that they had already satisfied their thirst at the water-trough. A bath sponge soaked in chloroform was placed under the sieve, the wire of which rested upon it. The hen finished her meal without leaving the sieve. Towards the end she pecked very slowly, and frequently raised her head and stretched her wings as if partially narcotised. This experiment was repeated on the cock, but I could not detect any indications of narcosis. The saucer was filled with hot dilute sulphuric acid, into which an ounce of powdered cyanide of potassium was thrown. The evolution of prussic acid was so violent that I considered the neighbourhood unsafe. My gardener, who was working thirty yards away, spoke to me of the "smell of almonds." For some minutes the cock turkey fed with his usual eagerness; then, suddenly, he began to stagger round the enclosure, crossing his legs and holding nis beak straight up in the air. He made his way back into the pen, where he stood with head down and wings outstretched. After ten minutes he returned to the enclosure, but did not eat any more grain. His comb and wattles were deeply suffused with blood.

In all observations on the sense of smell of animals we have an obvious difficulty to face. There is no reason for supposing that an animal enjoys an odour which pleases us or dislikes one which we find disagreeable. My dog appeared to be almost indifferent to bisulphide of carbon. He showed, however, great repugnance to chloroform and prussic acid. It is difficult to think that an animal which is unable to protect itself from the injurious effects of such drugs as these can possess the sense of smell.

I shall be very grateful to any of your readers who will give me information on this subject. Especially should I be glad to learn something about the habits of wingless birds, the mode of life of which, more or less, resembles that of a terrestrial mammal. In them, if in any birds, it would seem likely that the sense of smell would be efficient. In his memoir on the Apteryx, Owen stated that "the relative extent and complexity of the turbinated bones and the capacity of the posterior part of the nasal cavity exceed those of any other bird; and the sense of smell must be proportionately acute and important in its economy."

Downing College Lodge, January 26. Alex. Hill.

The Origin of Radium.

In the issue of Nature for January 26, Mr. Soddy describes the present position of his experiments on the production of radium from compounds of uranium, and announces a positive result.

Since I wrote on May 5, 1904, pointing out that, on the theory of Rutherford and Soddy, the quantity of radium developed by a few hundred grams of uranium should be measurable in a few months, a quantity of about 400 grams of uranium nitrate has been preserved in my laboratory.

I am not yet prepared to give definite quantitative results, but Mr. Soddy's announcement may perhaps excuse a preliminary statement that the quantity of radium emanation now evolved by my uranium salt is distinctly and appreciably greater than at first.

A rough calculation of the rate of growth of radium indicates a rate of change far slower than that suggested by the simplest theory of the process, but somewhat quicker than that given by Mr. Soddy, who finds that about 2×10^{-12} of the uranium is transformed per annum. As Mr. Soddy says, it is possible that the total amount of emanation is not secured, and the fraction obtained may depend to some extent on the particular method used by each experimenter. But another possibility should be borne in mind. If a non-radio-active product, intermediate between uranium and radium, exists, the rate of appearance of radium would be slower at first, and quicker as the experiment proceeds. My uranium salt was not purified so successfully as that used by Mr. Soddy, and, when the first measurement was made a month or so after preparation, the yield of radium emanation was appreciable. It may be that Mr. Soddy is tracing the process from its inception, and that I have started at a later stage, where the rate of formation is somewhat greater. Further observation may be expected to elucidate these and other questions. W. C. D. Whetham.

Cambridge, January 30.

Fact in Sociology.

I addressed a letter to the editor of Nature replying to what I allege to be misrepresentations and misstatements in a review of three of my books by "F. W. H." (December 29, 1904, p. 193). After a delay of some weeks due to the absence of "F. W. H." abroad, the editor of Nature has written to ask me to modify and shorten my protest.

"F. W. H." told the readers of Nature that my "Food of the Gods" "claimed to forecast the future." This was untrue, and I said so.

"F. W. H." mixed up my discussion of probabilities in "Anticipations" with my general review of educational influences in "Mankind in the Making," and presented this as my ideals. I pointed out that this was an unsound method of criticism.

"F. W. H." presented the following as my opinions:—"Germany will be cowed by the combined English and American Navies, and Anglo-Saxonism will eventually triumph. There remain the Yellow Races. Their star, too, will pale before that of the Anglo-Saxons." I repudiated this balderdash with some asperity. It is violently unlike my views.

He wrote of me, "he seems unaware of the part in the national life that is played by the lower stratum of society, the 'stagnant' masses as he would call them." I denied that I should, and pointed out that no one does know what part is played by any stratum of society in national reproduction. It is a field of unrecorded facts. I commented on "F. W. H.'s" assumption that he was in possession of special knowledge.

He wrote of "the fact that this stratum is an absolute necessity." This is *not* a fact. It may or may not be true. I commented on this use of the word "fact" in view of "F. W. H.'s" professorial sneer at my "imagination unclogged by knowledge."

He declared that I want to "get rid of the reckless classes, and depend solely on the careful classes," a statement which has not an atom of justification. He not only "guys" my suggestions, but foists an absolutely uncongenial phraseology upon me.

Finally, he wrote, "we are to introduce careful parentage, *that is*, put a stop to natural selection." I quoted this in view of his statement that I had "no very thorough grasp of the principles of evolution." I discussed what appeared to be his ideas about evolution. They appeared to me to be crude and dull, and I regret I cannot condense my criticisms to my present limits.

I expressed some irritation at his method of misstatement followed by reply, and hinted a doubt whether my own style of inquiry—in spite of the fact that romances blacken my reputation—was not really more scientific than his. H. G. Wells.

The Fertilisation of Jasminum nudiflorum.

This well known plant, in accordance with its usual habit, has been flowering in my garden at Stonehaven, Kincardineshire, since the third week in December, 1904, and amidst frost and snow and cold winds. There are no leaves, but there are thousands of bright yellow flowers. It is a puzzle to me how fertilisation is effected. The two stamens are situated about half-way down the tube of the corolla, and about four or five millimetres below the style, which is, in many cases, two millimetres longer than the tube of the corolla. It seems to me to be a plant requiring the aid of insects in its fertilisation, but there are no insects to be seen at this time of the year. On January 22, as there was some sunshine, I watched the plant for about four hours, but no insect paid it a visit. At the same time I found the oblong anthers had split and pollen grains were sticking to the stigma in many flowers. The brilliantly coloured flowers, although destitute of scent, are fitted to attract insects, and the form of the flower seems adapted for their visits. But there are no insects! Can anyone offer an explanation? The plant is beautifully figured in the *Botanical Magazine*, lxxviii., tab. 4649. John G. McKendrick.

University of Glasgow, January 24.

The Moon and the Barometer.

It is an old popular belief that weather tends to be more settled about full moon. Here are some sayings from Inward's "Weather Lore":—

"The three days of the change of the moon from the way to the wane we get no rain" (United States).

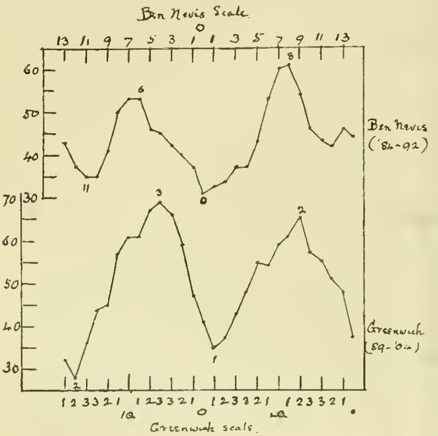
"The weather is generally clearer at the full than at the other ages of the moon" (Bacon).

"In Western Kansas it is said that when the moon is near full it never storms."

"The full moon brings fine weather." "The full moon eats clouds." (This disappearance of cloud Mr. G. F. Chambers pronounces "a thoroughly well authenticated fact.")

The following evidence in this connection seems to me instructive. It relates to Ben Nevis (1884–1892, nine years) and Greenwich (1889–1904, sixteen years), and to the summer half only (to be more exact, the six lunations commencing with that which had full moon in April).

The method was as follows:—In the case of Ben Nevis, fourteen columns were arranged for the fourteen days ending with full moon, and fourteen for those following full moon. Each day with barometer under 25·2 was re-



presented by a dot in those (graduated) columns; total 407. The dots in each column were then counted, and the sums obtained were added in groups of three (first to third, second to fourth, third to fifth, and so on). Thus we get the upper curve in the diagram.

In the case of Greenwich, the method was slightly different (see lower horizontal scale). The columns were for seven days about each of the four phases. For comparison with the Ben Nevis curve we commence with the first day after new moon. The days here considered were those with barometer under 29·6 inches; total, 476.

These two curves seem to tell much the same tale; *few* days of low barometer about (just after) full and new moon, *many* such days about (just after) the quarters. Thus, so far as the summer half in those twenty-one years is concerned, the popular belief would appear to be vindicated.

To give a fuller idea of the relations, I add a table of the maximum and minimum values (each number is, of course, the sum of three):—

	First min.	First max.	Second min.	Second max.
Ben Nevis	35	53	31	61
Greenwich	28	69	35	65

It will be seen that the chief maximum is about double the chief minimum in one case, and more than double in the other.

In a dot-diagram, where each day is represented separately according to its barometer (not merely grouped with others as below a certain limit), the contrast between the phases comes out still more clearly.

The view here given apparently finds support from various quarters. In the *Meteorologische Zeitschrift* for 1900, p. 421, Herr Börnstein gives a curve of pressure for Berlin (May to August in 1883–1900) which is of similar type to those in the diagram. Fr. Dechevrens informs me that the results above given agree with those of his own observations in China, Constantinople, and Jersey. M. Sainte Claire-Deville found the same variation at Cayenne, in French Guiana.

With regard to the winter half (October to March), the *régime* would appear to be somewhat different, but I cannot speak definitely of it at present.

Whether the facts presented be thought to indicate lunar influence or not, it may be of interest to watch future weather (in the summer half) from the point of view suggested. ALEX. B. MACDOWALL.

Reversal in Influence Machines.

THE method suggested for producing reversal on a Voss or Wimshurst will not be found always trustworthy. Atmospheric conditions make a great difference. I have been experimenting for more than a year with the view of finding a solution of the reversal problem, and think I have succeeded in tracing the cause, which is primarily connected with dielectric strain. A Wimshurst with the dischargers beyond sparking distance, working at full speed, will often reverse if the discharge is made by suddenly connecting the terminals, but there is no certainty in producing this effect. I have recently constructed an influence machine akin to the Voss except that the replenishment is from the back of the disc. Reversal is still the stumbling block, and must occur with fixed inductors, while no plan for controlling the reversal can be relied upon. I should be happy to give any of your correspondents fuller particulars of my experiments if they will communicate with me. CHARLES E. BENHAM.

Colchester, January 14.

Dates of Publication of Scientific Books.

MAY I through your columns suggest to publishers—especially of scientific and mathematical books—to give in their catalogues the dates of publication of their books? As a book often gets out of date very soon, such an addition would greatly help those who have no access to good libraries in selecting books to be purchased. I may say that this is done almost invariably in the catalogues of French and German publishers. To take an instance, the Clarendon Press still includes Price's "Infinitesimal Calculus" in its catalogue. Now, although to one who wants to study the subject in an exhaustive manner the book is very valuable, still, to one who wishes to know the principles only, the book is, to say the least, not worth the big price asked for; and if the date of publication were mentioned in the catalogue, the purchaser would at any rate know that he was not buying an up to date book. R. P. PARAIYPYE.

Fergusson College, Poona, India, January 1.

Super-cooled Rain Drops.

THE letter which appeared in your last issue (p. 295) from Mr. Robinson with reference to this interesting phenomenon reminds me of a similar case which I observed in Bournemouth during the winter of 1888, and I described in NATURE at the time under the title, "Is Hail thus Formed?" (vol. xxxvii., p. 295).

CECIL CARUS-WILSON.

PARA RUBBER.[1]

IN recent years the cultivation of rubber-yielding trees has attracted an increasing amount of notice. About 12,000 acres in Ceylon, and in the Malay Peninsula a still larger area, have been stocked with the Para rubber tree, *Hevea brasiliensis*, and other species of Hevea. The cultivation has also been successful in India and South America, and experimental plots are being tested in Uganda and the Gold Coast Colony.

In tropical Africa there are thousands of square miles of land suitable for growing the Para tree. But whilst the demand for rubber has been increasing with the development of the electrical and motor industries, the number of forest trees yielding the substance has been diminishing, year by year, as a consequence of the faulty methods of "tapping" employed by the natives. Hence a stimulus has been given to the production of rubber by cultivation; and with a view of fostering the industry in West Africa, Mr. Johnson was commissioned by Government in 1902 to visit Ceylon and study the methods employed there in the management of the plantations and the preparation of the rubber. He now gives, for the benefit of persons taking up the cultivation, some of the results of the visit in the form of such practical advice as would be likely to assist them in their undertaking.

The rubber trees are raised from the seeds, which may be obtained from Ceylon or the Straits Settlements at a cost of about 6*s*. 8*d*. per thousand. When the tree has attained a girth of twenty to twenty-four inches, the latex can safely be tapped; this may be in about five to seven years from the date of planting. The yield varies greatly, depending on the soil, the age of the tree, and the method of tapping. At present no really satisfactory data are available; but from such statistics as are given it would seem that about 1 lb. to 3 lb. of dry rubber *per annum* may be the average product of each tree. In addition, the seeds yield a drying oil somewhat resembling that obtained from linseed. As regards the latex-bearing "life" of the trees, it is stated, on the authority of the director of the Botanic Gardens, Straits Settlements, that trees are known to have been tapped, off and on, during fifty years, and to be still yielding a plentiful supply of latex.

The rubber-substance is contained in the latex of the plant in the form of minute globules, much as butter-fat exists in cow's milk. These globules can be made to coalesce by centrifugal action, just as cream is formed from milk in an ordinary separator; but the product thus obtained does not, apparently, compare favourably with the rubber given by the older methods of separation. These consist in coagulating the latex, either by simple exposure to the air or by the addition of an acid or a salt; the resulting coagulum is washed and rolled to free it from moisture and nitrogenous matters, and then dried by gently heating. The particular process suggested by the author is that of spontaneous coagulation of the latex in shallow saucers, followed, after washing and rolling, by exposure to the smoke of a wood fire as an antiseptic treatment. The price

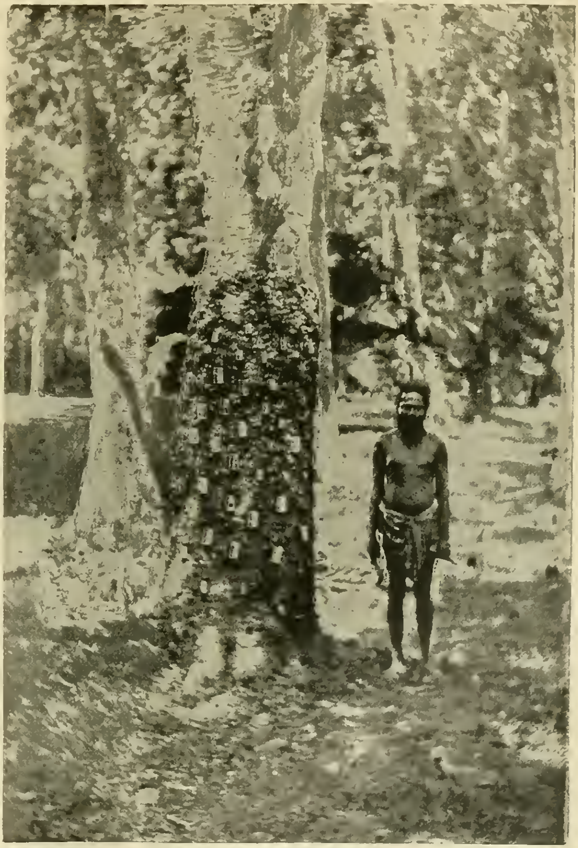


FIG. 1.—One of the Parent Trees of the Para Rubber Industry in the East, growing in the Botanic Gardens, Henaratgoda, Ceylon. (From "The Cultivation and Preparation of Para Rubber.")

obtained depends largely upon the care exercised in the preparation. For example, Congo rubbers, which some time ago realised only 1*s*. to 1*s*. 6*d*. a pound, now often fetch 4*s*. in consequence of being more carefully prepared. As showing what can be done in this direction, it is interesting to note that Ceylon Para rubber has recently commanded the "record" price of 5*s*. 6*d*. per pound.

The appurtenances required are of the simplest,

[1] "The Cultivation and Preparation of Para Rubber." By W. H. Johnson. Pp. xii+99. (London: Crosby Lockwood and Son, 1904.) Price 7*s*. 6*d*. net.

and no great demand is made upon the skill of the cultivator who desires to try his fortune in this direction. As regards the call upon his capital, some idea of the cost of opening and maintaining a plantation will be obtained from the estimates which the author supplies, showing the expenditure in Ceylon and the Malay Peninsula. As an alternative to tea-planting, orange-growing, and cattle-ranching, the production of rubber would seem to be well worth consideration by young Britons who go abroad in search of a competency. C. SIMMONDS.

PREHISTORIC ENGLAND.[1]

As this volume contains a notice by the publishers that they "will shortly begin" the issue of the series of "The Antiquary's Books," to which this belongs, it may be assumed that it is the first. For the reason that it is an earnest of the quality to be expected in its successors, the book, both in manner and matter, must be treated in somewhat more critical and judicial fashion than if the series had been already fairly launched. The responsibility of a publisher in placing an antiquarian library before the public is never light, and at the present time it suffers from the inequality of modern knowledge in respect to the various prehistoric and archæological periods. The later stages of the former class have vast floods of light thrown upon them by the constantly recurring discoveries in the Levant, and the comparative method has enabled us to classify many of our native antiquities by their means. In regard to the earlier stages of man's existence we are in the main still advancing at a painfully slow rate, and can scarcely be held to have more than a misty comprehension of the subject. In historic times the same want of balance of knowledge exists equally, though it is a far easier task to mask the difficulty, and to produce a nicely balanced tale from groups of facts of very different values.

The present volume deals only with the relics of man in Britain anterior to the coming of the Roman invaders, and in a sense, therefore, may be called prehistoric, for nothing in the nature of a native record can be quoted in support of any part of it. The author by his title, moreover, limits his field to the remains

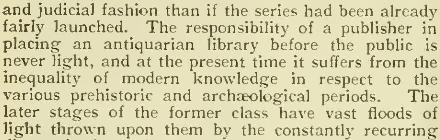

FIG. 1.—Section of Barrow with successive Interments. From "Remains of the Prehistoric Age in England."

of the dwellers in Britain, that is to say, to the monuments they raised, the implements they made, and the graves in which they deposited their dead. The racial characteristics, as shown by the physical characters, are treated very briefly, and the burning questions of the priority of Brythons and Goidels in the land, of the precise position of the Picts as an indigenous tribe, of the succeeding immigrations from the Continent bringing with them new types of people, of weapons, or of burial customs, are only incidentally mentioned.

By the elimination of all these questions Dr. Windle has set himself an infinitely lighter task; but it is to be questioned how far an intelligent reader can gain a true understanding of the conditions described without some fuller information on these points. It must be confessed, however, that the subject bristles with difficulties of all kinds and has tempting pitfalls for even the wary searcher, and, on the other hand, Dr. Windle has a right to set his own limits. Even within these limits he may be thought somewhat hardy, for to give an adequate account of all the material relics of man in Britain from the dawn of human life up to about 2000 years ago, within the compass of little more than three hundred pages, is not a thing to be undertaken with a light heart. One of the principal difficulties to be overcome is to avoid confusion in exposition and arrangement. In this matter Dr. Windle might have had more success. In

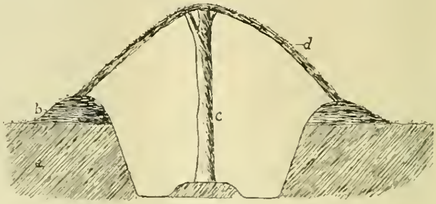

FIG. 2.—Ideal Section of Pit-dwelling. *a*, Natural soil; *b*, Bank of same heaped up around Pit; *c*, Central support of Roof; *d*, Roof of Turfs and Branches. From "Remains of the Prehistoric Age in England."

more cases than one, instances of special types of implements are quoted without giving the very necessary information that they belong to widely different periods. For instance, in dealing with "pygmy flints," a puzzling subject, Dr. Windle quotes a number of surface finds, and then goes on to say, "in France they have been discovered at Bruniquel." This can only mislead the inquirer or the student, for, so far as we know, the Bruniquel station, which is undoubtedly of the mammoth period, has no relation at all to such surface finds as have been made in Lincolnshire, Lancashire, India, or Belgium. Nothing is more certain than that mere type or form alone is the most unsafe criterion of age.

This elementary axiom may sound very like a platitude, but it is constantly neglected by men whose words carry weight, and cannot, therefore, be too much insisted upon. Such errors or vague statements affect the essentials of prehistoric science, and if persisted in inevitably retard the advance of knowledge instead of accelerating it, as Dr. Windle undoubtedly wishes to do. Again, it is very questionable wisdom to devote a chapter to "bone implements," the paragraphs dealing indiscriminately with the remains from the French caves, the Swiss lakes, and from a station like Grime's Graves. In the first place, there is again no relation between the sites quoted, and, so far as the French caves are concerned, the "bone" implements are mostly of horn. No doubt the information necessary to a proper understanding of the relative ages of the Dordogne caves, the Swiss lake dwellings, and the Norfolk flint pits is to be found elsewhere in the book; but for a popular work dealing with a difficult and complicated subject the first essential is clearness of exposition beyond all possibility of misunderstanding.

Further, Dr. Windle's authorities are occasionally antiquated. It is not treating the reader quite fairly to give him Dr. Thurnam's classification of barrows without qualification. Is it, for instance, quite certain in the light of recent knowledge that all round barrows are of the Bronze age? It is also a trifle hard to find the late Dr. Frazer quoted as an authority on

[1] "Remains of the Prehistoric Age in England." By Bertram C. A. Windle, Sc.D., F.R.S. Pp. xv + 320; illustrated. (London: Methuen and Co.) Price 7*s*. 6*d*. net.

gold in Ireland, while Salomon Reinach is not even mentioned. A little discrimination would have shown that Mr. Romilly Allen was making a curious statement (p. 293) when he said: "The bowls . . . seem to belong to the end of the Late Celtic period and the beginning of the Saxon." What becomes of the four hundred and odd years intervening between the two, when the Roman power was dominant in Britain? Such statements betray a carelessness that is not easily excused in a man of Dr. Windle's standing. The same want of precision is shown in "Hallstadt" for Halstatt, "Collie March" on one page and "Colley March" on another, the "forging" of bronze instead of "casting," and others of the same kind. In the circumstances it is a hard thing to say, but the illustrations leave much to be desired. The two figures we reproduce show diagrammatically a barrow with successive interments, and a restoration of a pit dwelling, from Mr. George Clinch's Kentish discoveries.

The book might easily have been so much better, for it has many good and useful points, that there is something exasperating in finding much to quarrel with. The index is a good and useful one, the lists of ancient remains an excellent departure, compiled with all modesty, and there is a great deal of clear treatment of some knotty questions, such as the so-called "Eolithic" period. As a series, the size of the volume is convenient and the print good, and in spite of the strictures we have felt bound to make, there is little doubt that the publishers will find a ready sale.

MEETING OF THE BRITISH ASSOCIATION IN SOUTH AFRICA.

The British Association will hold its meeting this year in South Africa. In these exceptional circumstances, the general officers of the association requested the council to appoint a strong committee to cooperate with them in carrying out the necessary arrangements. This "South African Committee" has held frequent sittings, and its work is so far advanced that it is now possible to make the following announcements.

Although the annual circular and programme have not yet been issued, pending the receipt of information from South Africa, many members have already intimated their intention of being present at the meeting. The "official party" of guests invited by the central executive committee at Cape Town, and nominated in the first instance by the council of the association, numbers upwards of 150 persons, comprising members of the council, past and present general officers and sectional presidents, the present sectional officers, and a certain proportion of the leading members of each section. To this list has yet to be added, on the nomination of the organising committees, the names of representative foreign and colonial men of science, the total number of the official party being restricted to 200, including the local officials. It is hoped, however, that many other members of the association will also attend the meeting.

The presidents-elect of the various sections are as follows:—

A (Mathematical and Physical Science), Prof. A. R. Forsyth, F.R.S.; B (Chemistry), Mr. G. T. Beilby; C (Geology), Prof. H. A. Miers, F.R.S.; D (Zoology), Mr. G. A. Boulenger, F.R.S.; E (Geography), Admiral Sir W. J. L. Wharton, K.C.B., F.R.S.; F (Economic Science and Statistics), Rev. W. Cunningham; G (Engineering), Colonel Sir Colin Scott-Moncrieff, G.C.S.I., K.C.M.G., R.E.; H (Anthropology), Dr. A. C. Haddon, F.R.S.; I (Physiology), Colonel D. Bruce, F.R.S.; K (Botany), Mr. Harold Wager, F.R.S.; L (Educational Science), Sir Richard C. Jebb, M.P.

The vice-presidents, recorders, and secretaries of the eleven sections have also now been appointed.

In view of the numerous towns to be visited by the association, and in which lectures or addresses will be given, the number of lecturers appointed is much larger than usual. The list of these, as at present arranged, is as follows:—

Cape Town: Prof. Poulton, on Burchell's work in South Africa; and Mr. C. V. Boys, on a subject in physics. *Durban*: Mr. F. Soddy, on radio-activity. *Maritzburg*: Prof. Arnold, on compounds of steel. *Johannesburg*: Prof. Ayrton, on distribution of power; Prof. Porter, on mining; and Mr. G. W. Lamplugh, on the geology of the Victoria Falls. *Pretoria* (or possibly *Bulawayo*): Mr. Shipley, on a subject in zoology. *Bloemfontein*: Mr. Hinks, on a subject in astronomy. *Kimberley*: Sir William Crookes, on diamonds.

As the wish has been conveyed to the council from South Africa that a few competent investigators should be selected to deliver addresses dealing with local problems of which they possessed special knowledge, a geologist, a bacteriologist, and an archæologist have been invited to undertake this work, involving in two cases special missions in advance of the main party. Whilst Colonel Bruce, F.R.S., will deal with some bacteriological questions of practical importance to South Africa, Mr. G. W. Lamplugh (by the courtesy of the Board of Education) will be enabled to investigate certain features in the geology of the Victoria Falls—particularly as regards the origin and structure of the cañon—and Mr. D. R. MacIver, who is at present exploring in Nubia, will proceed in March to Rhodesia in order to examine and report on the ancient ruins at Zimbabwe and also at Inyanga.

Most of the officials, and other members of the association, will leave Southampton on July 29 by the Union Castle Mail SS. *Saxon*, and arrive at Cape Town on August 15, the opening day of the meeting; but a considerable number will start from Southampton on the previous Saturday, either by the ordinary mail-boat or by the intermediate steamer sailing on that date.

The sectional meetings will be held at Cape Town (three days) and Johannesburg (three days). Between the inaugural meeting at the former and the concluding meeting at the latter town, opportunities will be offered to members to visit the Natal battlefields and other places of interest. Subsequently a party will be made up to proceed to the Victoria Falls (Zambesi); and, should a sufficient number of members register their names, a special steamer will be chartered for the voyage home, *viâ* Beira, by the east coast route, as an alternative to the return through Cape Town by the west coast route. Thus all the colonies and Rhodesia will be visited by the association. The tour will last 70 days *viâ* Cape Town, or a week longer *viâ* Beira (all-sea), leaving Southampton on July 29 and returning thither on October 7 or 14.

A central executive committee has been constituted at Cape Town, with Sir David Gill as chairman and Dr. Gilchrist as secretary; while local committees have been formed at Johannesburg and other important centres.

Prof. G. H. Darwin, F.R.S., is the president-elect, and among the vice-presidents-elect are the following:—the Rt. Hon. Lord Milner, the Hon. Sir Walter Hely-Hutchinson, Sir Henry McCallum, the Hon. Sir Arthur Lawley, Sir H. J. Goold-Adams, Sir David Gill, and Sir Charles Metcalfe.

Sir David Gill, Mr. Theodore Reunert, and others have taken a prominent part in the initial work. The South African Association for the Advancement of Science is cordially cooperating in the local organisation, and will join with the British Association in attending the meeting.

The aim of the council has been to secure the attendance of a representative body of British men of science, including specialists in various lines of investigation, and that, along with the generous support of the people and authorities in South Africa, should go far to ensure the success of the meeting and to stimulate local scientific interest and research.

THE ROYAL COMMISSION ON COAL SUPPLIES.

THE Royal Commission appointed on December 28, 1901, to inquire into the extent and available resources of the coalfields of the United Kingdom has issued its final report, which, in 38 pages, contains an able summary of the vast amount of valuable information submitted by the numerous witnesses examined. The Commission originally appointed consisted of Lord Allerton, Sir W. T. Lewis, Sir Lindsay Wood, Sir C. Le Neve Foster, and Messrs. T. Bell, W. Brace, A. C. Briggs, H. B. Dixon, J. S. Dixon, E. Hull, C. Lapworth, J. P. Maclay, A. Sopwith, J. J. H. Teall, and R. Young. Mr. A. Strahan was subsequently added to the Commission; Sir C. Le Neve Foster and Mr. Ralph Young died before the inquiry was completed.

On the whole the report is of a reassuring character. Adopting 4000 feet as the limit of practicable depth in working, and one foot as the minimum workable thickness, the commissioners estimate the available quantity of coal in the proved coalfields of the United Kingdom to be 100,914,668,167 tons, as compared with the 90,207,285,398 tons estimated by the Coal Commission of 1871, notwithstanding the fact that 5,694,928,507 tons have been raised in the meantime. The excess is accounted for by the more accurate knowledge of the coal-seams. It is also estimated that there are 39,483 million tons of coal in the concealed and unproved coalfields.

It is thought that in future thin seams will be worked more extensively than at present, and that the use of coal-cutting machines will facilitate this. The amount of unavoidable loss incident to coal-mining is a serious factor in estimating the available resources. Much coal is lost by leaving unnecessary barriers between properties, and a certain amount must necessarily remain in order to support the surface. The amount thus left might perhaps be reduced by the introduction of the methods employed on the Continent and in America of packing excavations with water-borne sand or other materials. The recovery of coal formerly abandoned might be facilitated by the establishment of central pumping stations.

The possible economies to which attention is directed comprise the adoption of coal-cutting machines, of which 483 were in use in 1902 and 643 in 1903, and the use of electricity for the transmission of power. The importance of cleaning, sizing, and sorting coal is also strongly urged, and the extended adoption of coking advocated. In this connection the advantages of by-product coke ovens are pointed out, and it is shown that washing and compression render it possible to coke many coals previously considered worthless. It is probable that briquettes will in future be more largely used for steam and domestic purposes, and there appears to be a promising field for research for the discovery of a less smoky and less costly binding material than pitch, which is now chiefly used.

In view of the dearth of statistics of coal consumption, the following estimate for 1903 is of special interest:—

	Tons
Railways ...	13,000,000
Coasting Steamers...	2,000,000
Factories ...	53,000,000
Mines ...	18,000,000
Iron and steel industries ...	28,000,000
Other metals and minerals ...	1,000,000
Brick works and potteries, glass works and chemical works ...	5,000,000
Gas works ...	15,000,000
Domestic ...	32,000,000
Total ...	167,000,000

It is calculated by Mr. Beilby that in this total there is a possible saving of 40 to 60 million tons. More particularly in connection with the raising of steam there are immense economies capable of realisation. Economy in the production of power may be effected by the combustion of gas obtained as a by-product. Information submitted by Mr. Bennett Brough points to increasing opportunities of utilising blast-furnace waste gases as a source of power Waste gases from coke ovens might similarly be utilised. Gas engines are referred to as the most economical of heat motors, but increased efficiency both thermally and mechanically is still possible. The importance of the development of producer-gas plants is strongly urged as rendering possible the utilisation of inferior coal. Interesting information is given regarding various other ways in which economies in consumption may be effected. Regret is expressed that the recommendations of the Mining Royalties Commission of 1893 and of the Departmental Committee of the Home Office in 1895 regarding mineral statistics had not been carried out. The commissioners recommend that accurate information on the coal industry should be published by one authority, and they think that it would be of great advantage if particulars of deep borings could be preserved in a Government office.

The report must necessarily attract great attention from mining engineers and economists; and it should also be carefully studied by students in mining classes. It is essentially a cautious document; and the general public will doubtless be disappointed that Lord Allerton and his colleagues have made no sensational prophecies as to the probable duration of our coal supplies, and have given no indication as to the way in which their estimate of the available tonnage of coal compares with that of other countries. Their report certainly shows that, while the coal resources are ample, the cost of coal is not likely to decrease, as the improved methods and appliances will probably be neutralised by the increased cost of working deeper and thinner seams. Where we should be glad of clearer light from the Royal Commission is on the question of the probable condition of competing coal-producing countries when the cost of production in Great Britain is considerably raised. It is futile to offer a detailed criticism of the final report until the sections containing the reports of the district commissioners, the report of the geological committee, and the minutes of evidence and appendices are published. The probable duration of the coalfields and the colonial and foreign coal resources appear to have been dealt with in special reports written respectively by Mr. R. Price-Williams and Mr. Bennett Brough, and to these the commissioners direct attention.

NOTES.

The Royal Meteorological Society has arranged for an exhibition of meteorological apparatus to be held on March 14–17. The exhibition will be chiefly devoted to recording instruments, but it will also include new meteorological apparatus invented or first constructed since the society's last exhibition, as well as photographs, drawings, and other objects possessing meteorological interest.

Science announces that Prof. Ernest Rutherford, of McGill University, has been appointed Silliman lecturer at Yale University for 1905. The previous Silliman lecturers have been Prof. J. J. Thomson and Prof. C. S. Sherrington.

As Prof. G. H. Bryan, F.R.S., is unable to lecture at the Royal Institution on Friday evening, March 24, Sir Oliver Lodge, F.R.S., will deliver a discourse on that date on "A Pertinacious Current."

A grant of 50*l.* has been awarded by the Berlin Academy of Sciences to Prof. R. Hagenbach, of Aachen, and Dr. Konen, of Bonn, for the publication of a spectrographic atlas.

The de Candolle prize of 20*l.* for the best monograph on a genus or family of plants is offered by the Physical and Natural History Society of Geneva. Papers may be written in Latin, French, German, Italian, or English, and should be sent before January 15, 1906, to M. le Président de la Société de Physique et d'Histoire naturelle de Genève, l'Athénée, Genève (Suisse). Members of the society are not admitted to this competition.

We are sorry to see in the *Athenaeum* the announcement of the death, on January 21, of Mr. E. Crossley, of Halifax, in his sixty-fourth year. Mr. Crossley published in 1879, in conjunction with Messrs. Gledhill and Wilson, a valuable "Handbook of Double Stars," which is complete in its information up to the time of publication. The Crossley reflector, with which excellent work is being done at the Lick Observatory, was presented to that observatory by Mr. Crossley, and contains one of the best mirrors made by the late Dr. Common.

Prof. J. W. Mason, professor of mathematics at the College of the City of New York from 1879 to 1903, died on January 10 at the age of sixty-nine years. The death is also announced of Dr. Guido Bodlaender, professor of physical chemistry and electrotechnics at the Brunswick Technical College.

We regret to see the announcements of the deaths of Dr. T. H. Behrens, professor of microchemistry at the Delft Polytechnic School, on January 14, at the age of sixty-two; of Dr. Albert von Reinach, the eminent geologist of Frankfurt, on January 12; of Prof. Benjamin W. Frazier, professor of mineralogy and metallurgy at Lehigh University since 1871; and of M. Joseph Chaudron, the Nestor of Belgian mining engineers, at the age of eighty-two. M. Chaudron's method of boring shafts was first employed in 1848, and its most recent application is now in progress at the colliery at Dover.

The annual general meeting of the Iron and Steel Institute will be held on May 11 and 12. The annual dinner will be held—under the presidency of Mr. R. A. Hadfield—in the Grand Hall of the Hotel Cecil on May 12. The autumn meeting will be held in Sheffield on September 25–29. Members of the institute are invited to participate in an International Congress of Mining, Metallurgy, Mechanics and Applied Geology, to be held at Liége on June 26 to July 1, in connection with the International Exhibition. The general secretary of the organising committee is M. Henri Dechamps, 16 Quai de l'Université, Liége.

Dr. F. T. Roberts will deliver the Harveian Oration of the Royal College of Physicians of London on June 21. Dr. W. H. Hamer has been appointed to deliver the Milroy lectures on State medicine and public hygiene for 1906; the lectures for this year will be delivered by Dr. T. M. Legge on "Industrial Anthrax," on March 7, 9, and 14; Dr. W. H. Allchin will deliver the Lumleian lectures, "Some Aspects of Malnutrition," on March 28, 30, and April 4; and the second Oliver-Sharpey lecture, "The Influence of Atmospheric Pressure on Man," will be delivered by Dr. L. E. Hill on April 6. Other lectures to be delivered during the year are the Croonian, by Prof. E. H. Starling, F.R.S.; the FitzPatrick, on "The History of Medicine," by Dr. Norman Moore; and the Bradshaw lecture, by Dr. G. R. Murray.

On Sunday, January 22, M. Victor Serrin died, at Neuilly-en-Tel, Department of Oise, aged seventy-five years. M. Serrin was the inventor of the first automatic regulator of the electric arc light used in the public service. The action is so satisfactory that the apparatus is still in use, after fifty years of scientific progress. M. Serrin produced other ingenious inventions, but no other has had the importance of his arc lamp. In 1852, M. Serrin was in charge of the rebuilding of the Pont St. Michel in Paris, and, as the work was urgent, men were kept busy night and day. At night an electric light, with hand-feed adjustment, was used, since no regulators existed. Provided with blue spectacles, Serrin watched the lamp and adjusted the carbons when necessary. He thus contracted ophthalmia, in consequence of which he nearly lost his sight. The idea of the regulator then occurred to him, and he made all the parts with his own hands. At the funeral the principal scientific societies of Paris sent wreaths.

The Johns Hopkins Hospital *Bulletin* for January (xvi., No. 166) contains a number of papers of pathological and medical interest, together with an interesting account by Dr. Platt of Fabricius Guilhelmus Hildanus, the "father" of German surgery, who lived in the latter part of the sixteenth and beginning of the seventeenth centuries.

We have received the January number of *Le Radium*, a monthly journal devoted to radio-activity and now commencing its second year of publication. It contains articles on Finsen's method of phototherapy, on the sensitisation of living tissues by the injection of certain fluorescent dyes whereby they become more susceptible to, and more penetrable by, the radium rays, and on the phenomena of induction, together with a comprehensive review of recent work. The publication is excellently printed and illustrated.

Messrs. Winslow and Belcher have carried out an investigation on the variations in the number of bacteria in samples of sewage kept in the laboratory (*Journal of Infectious Diseases*, i., No. 1). They find that the total number of bacteria rises rapidly during the first twenty-four hours of storage, increasing more than ten-fold, and then decreases steadily for at least six months. The rise and fall in the number of bacteria appear to affect the various organisms in an almost equal degree, there being no tendency towards the development of a pure culture of any dominant form.

A THIRD example of variation—among gold and silver pheasants—is discussed by Mr. F. Finn in the *Avicultural Magazine* for January. These variations, in the colour and markings of the plumage, would, in the author's opinion, be regarded as at least of subspecific value if the birds were wild instead of domesticated.

IN the *Proceedings* of the Royal Physical Society of Edinburgh for December last (vol. i. part i.) Dr. Gerald Leighton discusses the variation in the matter of scaling displayed by the common viper (*Vipera berus*), which he shows to be very extensive. His main thesis is apparently to demonstrate that squamation is an unsound feature upon which to rely in the discrimination of reptilian species, and consequently that the "small red viper" of the British Isles is entitled to be regarded as a distinct form. As regards mammals and birds, at all events, modern naturalists by no means accept it as "an axiom in zoological classification that morphological characters alone are to be taken into consideration."

VARIATION of another type forms the subject of a paper by Mr. O. C. Bradley in the above-mentioned issue of the *Proceedings* of the Edinburgh Physical Society. The trapezium of the carpus of the horse is the structure discussed in this communication, and it is shown that this bone is present, either in one or both limbs, in about 50 per cent. of the skeletons examined, while if each carpus be taken separately (that is, without reference to the condition in its fellow) the percentage is a little more than 40. This, in conjunction with its minute size, leads to the conclusion that in the evolution of the monodactyle foot of the horse the bone in question is following in the steps of the lateral metacarpal with which it was originally connected.

THE article on Dr. True's recent memoir on "The Whalebone Whales of the Western North Atlantic" which appeared in NATURE of November 14, 1904 (p. 84), has led Mr. F. A. Lucas, of the Brooklyn Institute Museum, to send us some results of measurements of whales made by him at Balena, Newfoundland. Mr. Lucas was one of the party sent to Newfoundland by the U.S. National Museum in 1903 to secure the skeleton and mould of a large sulphur-bottom whale in order that the skeleton and a reproduction of the whale might be prepared for the St. Louis Exposition. If whales grow slowly and require many years to reach their full size, there should naturally be examples of all sizes from small to large among those measured. As a matter of fact, Mr. Lucas remarks that, with the single exception of a female 64ft. long, all the sulphur-bottom whales examined by him were fairly large, and while some were immature and some old, the difference between the largest and smallest was, for such large animals, inconsiderable. With the exception noted the females, ten in number, varied from 68ft. 10in. to 75ft., the greatest jump being from 71ft. 8in. to 74ft. 4in. Fourteen males varied from 67ft. 7in. to 74ft. 8in., the greatest break being at the commencement of the series, from 67ft. 7in. to 68ft. 11in. No very small sulphur-bottom whale was taken during Mr. Lucas's stay, but several young humpbacks were brought in from 24ft. to 26ft. in length. These were still nursing and it seems fair to assume that a sulphur-bottom whale of the same age (a yearling?) would be from 30ft. to 35ft long. This seems to indicate that young sulphur-bottoms keep away from the coast of Newfoundland, while the fact that the 64ft. specimen was much younger than those 67ft. to 69ft. long would indicate that up to this point at least whales grow with great rapidity. As to the size of adult whales, Mr. Lucas remarks that, neglecting the wild statements of sailors and others, the length of the sulphur-bottom, *Balaenoptera musculus*, is given as being from 85ft. to 95ft. No whales so large as this were taken during the season of 1903. The largest four females ranged from 74ft. 4in. to 75ft. long, the largest three males 73ft. 4in. to 74ft. 8in., the measure being taken from the notch of the flukes, along the body, to opposite the tip of the nose. All these whales were not merely adult, but, as shown by an examination of their vertebræ, were old, the largest male, taken for a skeleton, having the epiphysial sutures obliterated save for a line or two on the thoracic vertebræ. Mr. Lucas consequently considers that it seems fair to assume that the average length of a fully grown sulphur-bottom is just under 80ft.

CONTINUING their notes on the Codiaceæ in the *Journal of Botany* (January), Mr. and Mrs. Gepp describe with figures a new species and a new variety of the incrusted alga Penicillus, also a new form of *Rhipocephalus Phoenix*, which were collected by Mr. M. A. Howe off the Bahamas. Mr. G. C. Druce publishes in the same journal a long list of flowering plants and ferns for which new localities in Berkshire have been recorded since the "Flora of Berkshire" was issued, and Mr. C. E. Salmon discusses *Limonium vulgare* and its varieties.

A LIST of the species of Compositæ from the Island of Formosa which are represented in the herbarium of Tokio University forms the concluding part of vol. xviii. of the *Journal* of the College of Science, Tokio. The author, Mr. B. Hayata, prefaces his list with an analysis of the genera, thirty-nine in number. Among these Blumea furnishes seven species, including, of course, *Blumea balsamifera*, the source of Ngai-camphor. Two new species, a Gynura and a Eupatorium, are described and figured.

THE limit of an Antarctic phytogeographical zone is discussed by Mr. C. Skottsberg, the botanist of the Swedish Antarctic Expedition, 1901–3, in an article in the *Geographical Journal* (December, 1904). It has been usual to include in the Antarctic flora the plants of Tierra del Fuego and the Falkland Islands, but Mr. Skottsberg prefers to confine the term Antarctic to a cold desert zone which comprises Graham Land and the islands lying north of it, also the South Shetlands and the South Orkneys, and to distinguish another, the Austral zone, in which the climate permits of the formation of forest or grassland. The two zones differ also with regard to their algal vegetation; the Austral flora contains algæ with floating fronds such as *Macrocystis pyrifera* and *Durvillea utilis*, but these are wanting in the Antarctic zone, where calcareous algæ predominate.

AN interesting summary of the rainfall of the British Isles for the year 1904 is given by Dr. H. R. Mill in *Symons's Meteorological Magazine* for January. Taking the British Isles as a whole, the year may be considered as a moderately dry one, the deficiency in the amount of rainfall does not seem to have exceeded 8 per cent.; the extremes noted were 120.3 inches at Seathwaite, and 16.1 inches at Shoeburyness. The whole of the Atlantic border from Cornwall to Shetland had more than the average amount; the excess was most marked in the west of Ireland, being as much as 18 per cent. in places, but the east of Ireland was so dry that the whole island exceeded the average by only 1 per cent. In England and Wales there was a deficiency of about 12 per cent. The driest region occupied the midlands and extended to the Severn on the south-west, the Humber on the north-east, and Yarmouth on the east. The whole of this area had a deficiency exceeding 20 per cent. For the whole of Scotland there was a deficiency of about 8 per cent.; this was due mainly to the exceptional dryness of the east coast. Dr. Mill loses no opportunity of enhancing the value of his published rainfall tables, and we are glad to learn that all values quoted in future will be referred to an average of thirty years, 1870–99.

PARTS xi. and xii. of vol. ciii. of the *Bulletin de la Société d'Encouragement* contain a review, by M. L. Gruner, of the metallurgical exhibits at the St. Louis Exhibition, and a general account, by M. H. Le Chatelier, of the uses of special steels in industry.

THE report for 1904 of the Board of Trade on its proceedings under the Weights and Measures Act contains particulars of a new denomination of Board of Trade standard of 50 pounds weight which has been made and verified in consequence of representations by the Liverpool Chamber of Commerce and the Mersey Docks and Harbour Board. The use in trade of this denomination of weight was authorised by an Order in Council of October 9, 1903. During the past year a number of "Board of Trade" standards, the accuracy of which is required by law to be re-determined once in each five years, have been verified in relation to the imperial and metric standards.

ALTHOUGH several investigations have been made during the past six years on the deviation of the kathode rays in an electric field, the true nature of the deviation has not yet been satisfactorily determined. In vol. xxxv. of the *Sitzungsberichte* of the Physico-medical Society of Erlangen, Mr. F. Schneider describes experiments from which, by excluding disturbing factors, he is able to decide that the deviation is of a purely electrostatic nature, and that the dark kathode space has no influence upon it. Variations in the deviation caused by differences of potential and by other circumstances were carefully measured. The same volume of the *Sitzungsberichte* also contains a discussion, by Dr. A. Wehnelt, of the production of negative ions by incandescent metallic oxides, and an interesting account, by Dr. Ferdinand Henrich, of Liebig's life as a student at Erlangen and Paris.

IN the December (1904) part of the *Bulletin de la Société d'Encouragement* (vol. ciii.), M. H. Le Chatelier criticises the method recently introduced by Mr. Gayley at the Carnegie Steel Works of using in the blast furnaces a current of air which has been freed from moisture by cooling it below 0° C. by means of an ammonia freezing machine. It is contended that Mr. Gayley's paper, recently read before the Iron and Steel Institute, contains statements which make it improbable that the alleged economy of 20 per cent. in the fuel used in this process is due solely to the mere desiccation of the air. The principal advantage of drying the air for the blast probably lies in its giving rise to a cast containing less sulphur than ordinary pig-iron, owing to the diminished formation in the absence of water of hydrogen sulphide capable of attacking the spongy iron. Preliminary experiments have shown the probability of this view.

WE have received from the firm of Ferdinand Ernecke, of Berlin, a catalogue of their lanterns for optical projection; this catalogue is noteworthy because of the description which it contains of methods for demonstrating by projection many optical phenomena, such as interference, diffraction, and the behaviour in polarised light of crystalline sections. Messrs. Ernecke, we notice, have acquired the sole right of manufacturing the various forms of the Wehnelt interrupter.

IN the course of an investigation on the anomalous dispersion of sodium vapour, Prof. R. W. Wood (*Proc. Amer. Acad.*, 1904, xl., 365) has observed that the vapour of sodium possesses a most remarkable viscosity which makes it possible to obtain at one part of an exhausted glass tube a mass of the heated vapour of great density separated by a high vacuum from the glass plates which close the ends of the tube. The tendency of the metal to distil into the colder parts of the tube is extraordinarily small; even after an hour hardly a trace of sodium vapour can be detected beyond the heated portion. The vapour appears to possess a cohesion similar to that of a liquid, and even in a vacuum tube it seems to have a free surface. Potassium, on the other hand, distils instantaneously into the colder parts of the tube. The dispersion of sodium vapour in the vicinity of the D_3-line of helium is almost incredibly great; if a prism could be constructed of sodium vapour giving the same deviation as a glass prism of 60°, two lines in the spectrum, separated by a distance equal to one twenty-third of that between the D-lines, would appear separated by a distance greater than that between the red and bluish-green of the spectrum formed by the glass prism. But even this dispersion is small compared with that which obtains within, say, one Angstrom unit of one of the D-lines of sodium. The variation of the index of refraction with wave-length is shown to conform throughout the range λ 2260–7500, except very close to the D-lines, with the simplest form of the dispersion formula developed from electromagnetic considerations for a medium with a single absorption band.

MM. H. MOISSAN AND CHAVANNE have taken advantage of the production of metallic calcium on a commercial scale to re-determine some of its physical properties. The specimens which they had under examination contained from 99.3 to 99.6 per cent. of the metal, and were only acted upon slowly by water. Calcium can be easily turned into cylinders possessing a brilliant lustre, tarnishing, however, as might be expected, in moist air. It is sufficiently tenacious to be drawn into wire as fine as 0.5mm. diameter, and these wires were utilised for the determination of the specific electrical conductivity, this proving to be about 16 per cent. of that of silver. The melting point was found to be 810° C. and the density 1.548. The metal was also utilised to prepare calcium amalgam in quantity; this is stable in dry air at the ordinary temperature, and does not absorb either nitrogen or oxygen. The crystalline amalgam corresponds very nearly to the compound Hg_nCa. It is interesting to note that, whilst in a recent list of Kahlbaum metallic calcium is quoted at 6*s*. 1*d*. for 15 grains, or about 9*l*. per oz., since its manufacture on an industrial scale it can be obtained at 1*s*. 6*d*. per oz.

THE January part of *L'Enseignement mathématique* contains a number of papers which should prove of interest to English mathematicians. Dr. J. S. Mackay, of Edinburgh, contributes an interesting account of the life and works of the late Prof. Tait. Prof. Gino Loria gives an account of the progress made and the methods adopted in Italy in the reform of teaching of elementary mathematics, and in particular geometry. Mathematical teaching for engineers forms the subject of a paper by Prof. Jules

Andrade, based on his own experiences in the University of Besançon, and finally, M. Louis Couturat, of Paris, contributes a paper on "The Definitions of Mathematics."

A SERIES of articles by Mr. E. Edser on the "Electromagnetic Theory" is appearing month by month in *Technics*, and should prove useful to students of physics. The article contributed to the January issue deals with the electric circuit. A very simple method is given of determining the force on a conductor carrying an electric current perpendicular to a magnetic field, and this result is used to obtain an expression for the electromotive force produced when a conductor cuts lines of force. The results, of course, are well known, and are used by every electrical engineer, but the reasoning by which they are obtained is not so widely understood. Most of the results are determined directly from the properties of lines of force, and the usefulness of the article is greatly increased by careful scale drawings.

MESSRS. R. AND J. BECK, LTD., supply, for one guinea, a glass trough, $4 \times 3 \times 0.8$ inches, which can be raised or depressed on a vertical metal upright a distance of from $1\frac{1}{2}$ inches to 10 inches from the table. This trough forms a simple form of light filter when filled with liquid, and will serve not only as a useful adjunct to a microscope, but for many other purposes where it is of advantage to use a screen for monochromatic light.

MESSRS. TAYLOR, TAYLOR AND HOBSON, LTD., have recently issued two series of rapid Cooke lenses that should prove of great service, not only in high-speed photography, but for the finest portraiture and for difficult subjects under fair conditions of lighting. They are known as the Series iv. and ii., and have full apertures of $f/5.6$ and $f/4.5$ respectively. The makers have fully developed in these new lenses the advantages of construction of their well-known Series iii. and v. Cooke lenses. The leaflet, which contains details and prices of these lenses, includes some striking illustrations of the work accomplished by them.

WE have received from Messrs. Burroughs Wellcome and Co. their photographic exposure record and diary, which is a most handy pocket book and contains many new features. The monthly light tables are now placed at the end of the book, and the order of the months has been reversed so that the current month faces the exposure calculator, each month being torn off as it passes. This renders the calculation of an exposure a very simple process indeed. There is also ample room for recording details of plates exposed, facts relating to positive exposures, and ordinary notes and memoranda, for each of which three separate sets of pages are available. In addition to these and other items of useful information for photographers, there is a serviceable article on exposure, giving complete instructions for using the calculator provided, a concise explanation of the factors governing correct exposure, and an up to date list of the speeds of all plates and films, including, besides British, a number of American and Continental brands. Bound in a neat cover, with pocket and pencil attached, this excellent, cheap, and compact little pocket encyclopædia of photography should be in great demand by all workers, whether amateur or professional.

MR. W. B. CLIVE has published new and enlarged editions of parts i. and ii. of Dr. G. H. Bailey's "Tutorial Chemistry." Both volumes have been edited by Dr. William Briggs.

THE Engineering Standards Committee has now issued its report on pipe flanges. It is entitled "British Standard Tables of Pipe Flanges," and is published by Messrs. Crosby Lockwood and Son at 2s. 6d. net.

THE Department of Revenue and Agriculture of the Government of India has published the agricultural statistics of India for the years 1898–9 to 1902–3, in two volumes. The first part is concerned with British India and the second with the native States. The voluminous particulars have been compiled under the supervision of the director-general of statistics.

SEVERAL catalogues of physical, chemical, and other scientific apparatus have been received from Messrs. Brady and Martin, Ltd., of Newcastle-upon-Tyne. Among interesting instruments described in a supplement that brings a larger catalogue up to date may be mentioned Sodeau's new form of gas analysis apparatus, and Seger's cones for the determination of the temperature of furnaces, kilns, &c. A special supplementary list of new apparatus for experiments in physics includes particulars of simple appliances described in recent text-books of practical physics which are largely used in the laboratories of schools and colleges.

THE story of the Zeiss works at Jena is of deep interest, both in its scientific and sociological aspects. Prof. F. Auerbach described the Jena enterprise in a volume published in 1903. This work has now been translated into English by Mr. S. F. Paul and Mr. F. J. Cheshire, and published by Messrs. Marshall, Brookes and Chalkley, Ltd., under the title "The Zeiss Works and the Carl-Zeiss Stiftung in Jena." A short account of the creation and progress of these great cooperative works was given in the obituary notice of Prof. Ernst Abbe which appeared in last week's NATURE (p. 301). Many other interesting particulars will be found in the English edition of Prof. Auerbach's book, which is a popular description of the development and importance of a concern that offers valuable lessons to students of physics, technology, and social science.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN FEBRUARY:—

Feb. 5. 9h. 7m. Minimum of Algol (β Persei).
8. 2h. Conjunction of the Moon and Venus. Venus 3° 20′ N.
,, 5h. 56m. Minimum of Algol (β Persei).
9. 18h. Conjunction of the Moon and Jupiter. Jupiter 2° 49′.
13. 5h. 12m. to 6h. 32m. Moon occults θ^2 Tauri (mag. 3·6).

28. 7h. 40m. Minimum of Algol (β Persei).

Jupiter's Sixth Satellite.—A further telegram respecting the recently discovered sixth satellite of Jupiter has been received from the Kiel Centralstelle. It contains a statement from Prof. Perrine that the object discovered by him is not identical with Prof. Wolf's minor planet 1905 P.V. The position of the satellite on January 17 at 8h. 44.3m. (Lick M.T.) was R.A. = 1h. 21m. 8s., dec. = $+7°\ 27'$.

A later telegram than the above, published in a supplement to No. 3990 of the *Astronomische Nachrichten*, states that Prof. Perrine observed the satellite on January 17.702 (G.M.T.), and found that its position with reference to Jupiter was 266° and its distance 36′.

Ephemeris for Comet 1904 *e*.—The following is the latter part of a daily ephemeris for comet 1904 *e* (Borrelly) published by Herr M. Ebell in No. 3989 of the *Astronomische Nachrichten.*

1905	α (true) h. m. s.	δ (true) ° ′	log r	log Δ	Brightness
Feb. 1	2 9 8	+15 17	0·2092	0·1501	0·58
2	2 11 7	+15 54			
3	2 13 6	+16 31			
4	2 15 7	+17 7			
5	2 17 8	+17 43	0·2133	0·1638	0·54

Brightness at time of discovery = 1.0 (= mag. 10.0).

From the above it will be seen that the comet is now travelling in a north-easterly direction through the constellation Aries, and is observable—although very faint—between sunset and midnight.

Solar Eclipse Problems.—In an address read at the International Congress of Arts and Sciences, held at St. Louis in September, Prof. Perrine enumerated and discussed a number of the outstanding problems which still confront solar eclipse observers.

The first problem mentioned was that relating to the existence of an intra-mercurial planet, and Prof. Perrine states that this year's eclipse ought to settle the problem so far as the existence of a body brighter than the tenth magnitude is concerned. Such a body would not be above 12 or 15 miles in diameter, and it would take about a million such to account for the anomalies in the motion of Mercury.

The movements and velocities of coronal matter are most important problems which should be settled, and, as stations situated so far apart as Labrador and Egypt may be utilised during the coming eclipse, this should offer an exceptional opportunity of solving the problem, because of the length of time between the passing of the shadow at these places. Prof. Perrine suggests the employment of cameras having focal lengths of 40 or 50 feet and pointed directly at the sun, or, where the atmospheric conditions are favourable, longer cameras, mounted horizontally, might be used. The rotational velocity of the corona as regards that of the sun's surface is another problem which he discusses. Finally, he points out the urgent need for a number of well-equipped and well-organised expeditions, and suggests that the interchange of plans and ideas before the eclipse takes place might lead to results of greater value being obtained.

The Conditions in the Solar Atmosphere during 1900–1.—An interesting discussion of the conditions obtaining in the solar atmosphere during the minimum epoch of 1900–1, as indicated by the author's eclipse photographs taken in Spain and Sumatra, is given in the January number of the *Bulletin de la Société de France* by M. N. Donitch, of St. Petersburg. He discusses in turn the spectra of the chromosphere, the prominences and the corona, the form of the corona, and the solar repulsion theory of Prof. Bredichin as applied to the latter.

In discussing the spectrum of the chromosphere, he refers to Sir Norman Lockyer's eclipse results, and, in directing special attention to the lines at λλ 5317.7 and 4233.8 (Donitch), he states that his results as to the non-agreement of these with the monochromatic coronal radiations incontestably confirm the conclusions arrived at from the English observations.

The spectra obtained by M. Donitch show that the prominences may be divided into two types, one composed entirely of calcium vapours, the second containing in addition hydrogen and helium.

Triangulation of the Pleiades Stars.—An important addition to the data concerning the positions, the intermutual distances, and the movements of the Pleiades stars is contained in parts vi. and vii., vol. i., of the *Transactions* of the Astronomical Observatory of Yale University.

During 1884–6 the director, Dr. Elkin, made a series of heliometer observations for the triangulation of the Pleiades, and published the results in part i. of the same volume of the *Transactions*. Since then, however, a new source of systematic error affecting such results has been discovered, and Dr. Elkin has, therefore, re-reduced his observations. The final values are given in part vi., and are therein compared with the similar results obtained at Königsberg in 1840 and those obtained during the more recent triangulation carried out at Yale. The results of these comparisons indicate a motion, in regard to the rest of the group, of 9 out of the 58 stars common to the three researches; the apparent displacements determined from the comparison of the Königsberg and Yale results are shown on a chart accompanying the present paper.

Part vii. of the publication contains an account of the second triangulation carried out at Yale by Mr. Mason F. Smith during the winters of 1900–1 and 1901–2, and shows the complete reduction of the observations, together with a final table in which the places of 58 Pleiades stars, for 1885.0, are given with the precession and secular variation values for each.

A Bright Meteor.—Mr. J. Ryan, writing from the Manor House, Kensal Green, N.W., states that he observed a very brilliant meteor at about 11.58 on the night of January 27. The meteor appeared about three degrees below Orionis as bright as a star of the first magnitude; it travelled slowly in a path nearly parallel to a line joining κ and β Orionis, increasing in size until it burst into a green ball when below β Orionis, and faded. The complete path was traversed in about 8 seconds.

THE GENERAL MOTION OF CLOUDS.

THE issue of the *Quarterly Journal of the Royal Meteorological Society* for October, 1904, contains a translation of the report on the international observations of clouds presented by Prof. H. H. Hildebrandsson to the Permanent International Committee during its session at Southport in 1903. It is not too much to say that this report is one of the most important contributions to our knowledge of the physics of the atmosphere which the last twenty-five years have brought forth, and the Royal Meteorological Society has rendered a substantial service by making the report accessible to English readers.

Our knowledge, from direct observations, of the average motion of the air over the greater part of the earth's surface has been in a sense complete for a considerable number of years, but of the currents in the upper air we have until recently had little or no direct information, and all schemes of a general circulation of the atmosphere as a whole have had to substitute hypothesis for fact in dealing with this part of the subject. It therefore became of the highest importance to see whether any direct evidence could be obtained on this point. The most obvious method of attacking the problem consisted in observing the direction and speed of drift of dust or water particles suspended in the atmosphere. Dust particles are seldom sufficiently numerous in the upper air to be of use in this connection, but clouds occur in all parts of the world, and their observation is comparatively easy. Even this method, however, has its limitations. Observations are clearly impossible on cloudless days, and it also frequently happens that the upper clouds are obscured by lower cloud forms.

To obtain any general results observations from every part of the earth's surface were essential, and to secure these the ponderous machinery of international cooperation had to be called into play. In the year 1878 a request was addressed to the Permanent International Committee to organise a comprehensive system of cloud observations. After some preliminary consultations a scheme, in which cloud forms were divided into two classes, viz. upper and lower clouds, was adopted, and observations on this plan were made for several years during the 'eighties. Comparison of the results, however, showed that the adopted classification was inadequate, and it became necessary to agree on a more complete subdivision of cloud forms. This task proved to be by no means an easy one, but eventually our present international classification of clouds into ten main types was adopted, and some years later, early in 1896, the international cloud atlas, which contains twenty-eight coloured plates illustrative of cloud forms, together with explanatory text in three languages, was published.

At the request of the committee, cloud observations were carried out at a large number of stations during the period from May 1, 1896, to the end of 1897. At the more important stations the height and the direction of motion of clouds were determined by means of the photogrammeter or with theodolites; at the remainder, direction only was observed with the help of nephoscopes.

The materials thus accumulated, as well as a large number of trustworthy observations of earlier date, are discussed by Prof. Hildebrandsson in the present report. The method adopted has been to work out, for each region of the earth's surface, the direction of the average monthly drift of the atmosphere at various heights with a "resultantometer" devised by Mr. Sandström. The results are set out in tables and diagrams, and in what follows attention will be directed to some of the most important points.

I.—*Tropical Zone.*

Observations at stations near the equator agree in showing a drift of the upper atmosphere from some easterly point at all seasons of the year. At Paramaribo (Dutch Guiana, lat. $5\frac{1}{2}°$ N.), out of 270 observations of upper clouds, only 6 were from south-east and five from north-east. This well marked easterly current in the uppermost regions of the air near the equator was revealed in a most singular manner during the eruption of Krakatoa in 1883. The optical effects produced by the fine dust, which was carried up to great heights, travelled round the earth from east to west in about twelve or thirteen days, indicating an upper east wind moving with the prodigious velocity of 83 miles per hour.

II.—*Trade-wind Zone.*

The generally accepted theory of the origin of the trade winds formulated by Halley and completed by Hadley teaches us to expect upper anti-trade winds from south-west or north-west in the northern and southern hemispheres respectively, and this expectation was found to be fully confirmed. At Mauritius, which lies in the centre of the region over which the south-east trade wind prevails, the cloud observations show a steady upper wind from the north-west throughout the year. We may therefore assume the existence of an upper wind from the south-west at corresponding latitudes in the northern hemisphere.

As more temperate regions are approached this south-westerly wind becomes deviated to the right, and at Teneriffe, and still more decidedly at San Fernando and Lisbon, the average drift at the cirrus level is from almost due west. No support is afforded to the assumption made by James Thomson and by Ferrel in their schemes of the general circulation of the atmosphere, that the anti-trade wind continues its course as an upper south-westerly wind until the Arctic regions are reached.

Special interest attaches to the observations from the region between the upper equatorial east wind and south-westerly or north-westerly anti-trade winds. On the northern side of the equator, at surface level, a broad band on the earth's surface is alternately covered in winter by the north-east trade wind and in summer by the tropical belt of calms. At higher levels a similar alternation is shown. In winter, when the trade wind prevails at the surface, the anti-trade from south-west blows above, but in summer the tropical upper east wind is found above the calm region at the surface. The observations from square No. 39 of the Atlantic Ocean, which is situated in 10°–20° lat. N., 20°–30° long. W., form the most complete example of this alternation in Prof. Hildebrandsson's report; some further very striking instances are to be found in the cloud results for the West Indies recently published by the U.S. Weather Bureau (*Monthly Weather Review*, vol. xxxii., No. 4, p. 166).

III.—*India.*

The wind circulation over India is exceedingly complex at the surface, but at higher altitudes a much simpler state of affairs is found to prevail. Prof. Hildebrandsson divides his observations into two groups, those from the north (Lahore to Calcutta) and those from the more central districts between Bombay and Cuttack. He finds that in the former the upper currents blow steadily from the west from December to April, but during the remainder of the year they tend to become easterly. Over Central India the upper westerly wind prevails throughout the year, except in August and September. Since the appearance of the report, Sir John Eliot has dealt with the detailed cloud observations taken at six Indian stations during the years 1896–1900 (*Indian Meteorological Memoirs*, vol. xv., part i.). These show a much steadier upper westerly current in the north. At Simla and Jaipur the average upper wind is westerly throughout the year; at Lahore and Allahabad an easterly component appears in the averages for August and September only. Further to the south we find an alternation similar to that described above. At Madras the equatorial upper current from the east prevails during the summer; in winter the upper currents vary between south and south-west.

IV.—*Temperate Zone.*

Throughout the temperate zone the direction of the average upper currents is from some westerly point all the year round in both hemispheres, though few observations are available from the south of the equator. In Europe and in North America there is thus substantial agreement between the general drift of the atmosphere at all levels, but when we turn to eastern Asia this is not the case. The excellent observations taken at the Observatory of Zikawei (Shanghai) show that at the surface and at the level of the lower clouds the prevailing direction is from the north during the winter and from the east, *i.e.* towards the low pressure system over the continent of Asia, during the summer; but already at the level of the intermediate clouds, and still more at higher levels, a steady drift from the west is found at all seasons. Similar results are shown by the observations from Japan.

Though there is substantial agreement in the mean direction of air motion over Europe at all levels, a general tendency for a component from the north to make its influence increasingly felt at higher altitudes is clearly shown. Thus at Upsala, during the winter months, the surface wind is from the south-west; the lower clouds travel from west-south-west and the intermediate ones from west-north-west, while at the cirrus level the direction of motion is from north-west. Further north, at Nora, in Swedish Lapland, cirrus moves from north-west throughout the year. Some particularly interesting results have been obtained from those of M. Teisserenc de Bort's balloon ascents in which the level of the highest cloud forms was exceeded. In all these cases the balloons were carried towards the south-east, showing that they met with a north-westerly wind in the uppermost layers of the atmosphere.

North-westerly winds at the cirrus level are also very prominent at Perpignan, Pola (Austria), Tiflis, and Madrid, stations which lie on the northern side of the tropical belt of high pressure, over which, as we have seen above, the direction of the anti-trade winds has become deviated from south-west to west.

Prof. Hildebrandsson sums up the results he has arrived at under the following headings:—

(1) Above the thermal equator and the equatorial calms there exists throughout the year a current from the east which appears to have a very high velocity at great altitudes.

(2) Above the trade winds, anti-trade winds from south-

west in the northern hemisphere and from north-west in the southern hemisphere prevail.

(3) These anti-trade winds do not extend beyond the polar limits of the trade winds; they are deviated to the right in the northern hemisphere and to the left in the southern, and become currents from the west above the tropical high pressure areas, where they descend to feed the trade winds.

(4) The air of the temperate zones is involved in vast "polar whirlpools," which rotate from west to east. This rotatory movement appears to be similar to that of ordinary cyclones; the air in the lower layers draws nearer to the centre of the whirl, while that in the upper layers recedes from it more and more as the height above the earth's surface increases up to the highest regions from which we have any observations.

(5) The layers of upper air of the temperate zones overflow the tropical high pressure areas, and there descend.

(6) The irregularities found at the surface of the earth, more particularly in the monsoon areas of India, disappear, as a general rule, at the level of the lower or intermediate clouds.

(7) The theory of a vertical circulation of the atmosphere between the tropics and the poles, which has hitherto been accepted (Ferrel, James Thomson), must be abandoned.

The report as published in the society's journal is very fully illustrated by reproductions of the diagrams of the original edition. M. Teisserenc de Bort's charts of the average distribution of pressure at the 4000-metre level for January and July are also given, and they illustrate in a very striking manner the scheme of general circulation of the upper air to which the results of Prof. Hildebrandsson's report point.

AMERICAN HYDROIDS.[1]

THE first part of this large work dealt with the plumularian hydroids. After an interval of four years, the second part, a folio of some 150 pages and 57 plates, has been issued. It appeals exclusively and intentionally to the student of systematic zoology; but owing to the wide distribution of the family—the "sea-firs" of our coasts—this account, though dealing primarily with American species, will assist students of sertularian taxonomy in almost any part of the world.

The plan of this book is that of the first part. There is first an anatomical account of the stem and its branches, then a *résumé* of the distribution, horizontal and vertical, in different seas, and finally a hundred pages of speciography. The most assiduous care has been employed in drawing up these descriptions and in illustrating them by well selected figures; and most critical and generous consideration is given to previous researches on this group of animals.

For some not very obvious reason, Prof. Nutting has decided to postpone the more interesting bearings of his subject to the final volume, and confines himself in the work before us rigidly to a consideration of the taxonomic and diagnostic features of the Sertularidæ. We look in vain for any explanation of the mode of distribution, though the occurrence of the majority in Alaskan and Arctic waters suggests a polar origin. There is no attempt to explain the absence of free medusæ, nor are we given any information as to the habits of these hydroids, their modes of growth and of repairing injury, the influence of light upon their branching and reproductive powers. There is not a single experiment recorded in the work, though it is to be expected from the plasticity of such cœlenterates that continuous and discontinuous variation may be induced by changes in environment. On the other hand, differentiating anatomical characters, such as the forms of branching, the shape of the gonidial sacs, and the opercula, are described and combined into a system with great care, and it is to be hoped that Prof. Nutting has laid the foundation of a permanent and authoritative classification.

[1] "American Hydroids. Part ii. Sertularidæ." By C. C. Nutting, Smithsonian Institution. U.S. National Museum. Special Bulletin. (Washington, 1904.)

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—The Vice-Chancellor has been informed that at a meeting of medical graduates recently held in London to consider the present provision in the university for the department of pathology, it was resolved (1) that steps should be taken to bring before the university the necessity of permanent and adequate support being received for the pathological department; (2) that a fund be started for the purpose of assisting in this object, and the primary object of this be the establishment and endowment of a professorship in pathology.

It was announced last term that the Rhodes trustees have made a grant for five years to Dr. Ritchie, the present reader in pathology, and New College has now elected him to an ordinary fellowship for seven years, provided that he continues his readership and does research work. Mr. Edward Whitley, Trinity College, has very generously given the university a thousand pounds towards the permanent endowment of a pathology chair.

CAMBRIDGE.—The Vice-Chancellor announces two important bequests which have been left to the university. The first consists of 5000*l.*, to be expended in improving the instrumental equipment of the Newall Observatory, and of a very valuable collection of illuminated manuscripts and early printed books and objects of mediæval and early art, to be placed in the Fitzwilliam Museum, left by Mr. Frank McClean, F.R.S., of Trinity College. The second bequest is left by the late editor of the *Athenaeum*, Mr. Norman Maccoll, of Christ's and Downing Colleges, and consists of 500*l.* to form some endowment for a lectureship in Spanish or Portuguese, together with a valuable library of books.

The number of commissions allotted to the university, the first half-yearly nomination to which will take place after the examination in September next, is one in the Royal Artillery, one in the Indian Army, and five in the cavalry, Foot Guards, infantry, or the Army Service Corps.

The regulations for administering the Gordon Wigan fund are announced. The revenue will be divided between the special board of physics and chemistry and the special board of biology and geology, to be used in promoting and encouraging scientific education and research. The bequest amounts to some 9000*l.*

LONDON.—Mr. William Loring, late director of education under the County Council of the West Riding of Yorkshire, has been appointed warden of the Goldsmiths' College, New Cross, and Mr. Edgar Schuster Francis Galton research fellow in national eugenics.

The Mercers' Company has voted a sum of 1000*l.* to the university for the promotion of the study of physiology at University College.

Mr. W. Williams has been awarded the degree of doctor of science through a thesis on "The Temperature Variations of the Electrical Resistances of Pure Metals," and other contributions.

Mr. H. M. Hobart has been appointed lecturer in electrical engineering design at the Northampton Institute in succession to Mr. E. K. Scott, who has been appointed lecturer in electrical engineering in the University of Sydney. Mr. M. H. Smith has been appointed chief assistant in the mechanical engineering department in succession to Mr. W. E. Curnock, who has been appointed head of the mechanical engineering department of the Technical College, Huddersfield.

MANCHESTER.—The new public health laboratories, which have been erected by the Victoria University and have cost 13,000*l.*, were opened on January 27 by Mr. W. J. Crossley. Lord Spencer, Chancellor of the University, presided at the ceremony, and the large gathering included the Lord Mayor of Manchester and the Mayor of Salford. Honorary degrees were afterwards conferred upon Prof. Calmelle, Lille University; Prof. Perroncito, Turin University; Prof. Salomonsen, Copenhagen University; and Captain R. F. Scott, R.N.

IT has been resolved to institute, in the United College, University of St. Andrews, a lectureship in organic chemistry, and to appoint Dr. James C. Irvine as the lecturer.

It is reported in *Science* that, by the will of the late Mr. E. W. Codman, of Boston and Nahant, Mass., an estate which may reach 200,000*l.* will be equally divided between Harvard University and the Massachusetts General Hospital.

The United States ambassador, Mr. Choate, has accepted the invitation of the governing body of the Battersea Polytechnic to distribute the awards and deliver an address on the occasion of the next annual distribution of prizes on Wednesday evening, February 22.

It is reported in *Science* that Harvard University and the University of Berlin have practically arranged a method by which a temporary exchange of professors will occur. It is further stated that a similar arrangement has been made between the Massachusetts Institute of Technology and the Berlin Institute of Technology.

Mr. J. D. Rockefeller has signified his willingness to contribute to the University of Chicago for the year beginning July 1, 1905, the sum of 49,000*l.* for current expenses, this being the same sum that he has contributed during the present year. Mr. Rockefeller has also contributed this year 12,000*l.* for the enlargement of the heating plant of the university.

A course of lectures and discussions has been arranged by the Childhood Society and the British Child-Study Association, to be delivered in the Parkes Museum, Margaret-street, W., and will commence on February 9. Among the subjects are :—Some physiological problems in education ; the proposed anthropometric survey ; mental faculty of the child : its growth and culture ; fatigue in children ; the health of children *qua* food and management ; and imitation.

At the annual conference of representative Mahomedans from all parts of India, held at Lucknow a month ago, it was agreed to form science faculties at Aligarh College. The list of subscriptions towards this object was headed by the Raja of Mahmudabad with a munificent donation of Rs.35,000. The aggregate subscriptions to the fund for promoting the advancement of Aligarh College to the status of a university, which will be the future university of Mahomedans in India, now amounts to Rs.1,04,000 (7000*l.*).

In connection with the fund instituted to supplement the resources of the Melbourne University, the Hon. F. S. Grimwade has given 1000*l.* for the purpose of founding an annual prize at the university, to be awarded in respect of research work in some branch of industrial chemistry. This donation, says the *Pharmaceutical Journal*, raises the fund to 11,000*l.*, and enables the university to claim a subscription of 1000*l.* promised by Mr. Andrew Carnegie. The whole of the money subscribed, which, with a Government grant of 12,000*l.*, now totals 24,000*l.*, is to be devoted to the purpose of building laboratories. The Government has promised a supplementary grant of 5000*l.* next year.

The need for a university in the south-west of England continues to be urged locally from time to time. At the recent ordinary general meeting of the governors of University College, Bristol, Mr. Henry Hobhouse said that it was unfortunate that the south-west of England was almost the only part of England and Wales that had no local university, and spoke of Bristol as the only possible centre for such an institution. Principal Lloyd Morgan, F.R.S., who returned recently from a visit to the United States, gave it as his opinion, after inspecting the equipment and work of the American university colleges, that when the amount of work done by the staff of Bristol University College is compared with the amount being done in any one of the American institutions he had visited, and the cost of the one is compared with the cost of the other, Bristol University College is ahead of them all. Several speakers urged the pressing need for more funds. In this connection we are glad to notice that the college received last year nearly 5000*l.* in donations outside the ordinary income.

The Association of Technical Institutions held its annual general meeting on January 27 at the Manchester School of Technology. Sir Philip Magnus was elected president of the association for 1905, and in the course of his address directed attention to the fact that in technical institutions the students who attend even the most elementary technological classes are too often insufficiently prepared to profit by the teaching. They are deficient in power of expression; they lack practical knowledge of arithmetic and the rudiments of science and the necessary skill in drawing. In a word, the training in the elementary schools of the country has not produced satisfactory results. The elementary teaching must be made more practical. The workroom will supersede the class room in elementary schools, continued Sir Philip Magnus, and manual training will become the central feature of the training around which other studies will be grouped. Numerous papers were read. Principal Reynolds, of Manchester, Mr. Wilkinson, of Bolton, and Principal Crowther, of Halifax, read papers on the co-ordination of the work of evening continuation schools and municipal technical institutions. The co-operation of employers in the technical training of their apprentices was the subject of a discussion opened by Principal Belcher, of Coventry, and Principal Gannon, of Norwich. The registration of teachers in technical institutions was dealt with by Principal Wells, of Battersea.

The report of the council of the Association of Technical Institutions was presented at the annual general meeting on January 27. The report states that, from the point of view of those specially concerned with technical education, the year 1904 has been marked chiefly by the development and coordination of local educational organisation and by the perfecting of matters of internal administration. It is too soon, the report states, to say what the effects of the abolition of the Technical Instruction and Local Taxation (Customs and Excise) Acts and the placing of all branches of education under one local authority may have upon the further extension of technical education. While recognising the possible danger to these interests of the large and growing demand for expenditure upon other branches of education, the association views with satisfaction the increasing recognition of the belief that technical education can only produce the best results when it builds upon the sure foundation of a sound secondary education. Among matters to which the association has given attention may be mentioned that of the possibility of obtaining a number of research scholarships, tenable by advanced students in technical institutions ; and that of the desirability of instituting a scheme for the issue by technical institutions of diplomas upon some common basis of award. This last question is of such importance that it has been referred to a subcommittee for further inquiry and report.

The annual meeting of the Mathematical Association was held at King's College on January 28. Prof. G. B. Mathews, F.R.S., was elected president for the ensuing year. Papers were read on models and their uses by Mr. E. M. Langley, and on the new geometry by Mr. W. H. Wagstaff, who does not think it is desirable to make all boys learn deductive geometry, but that some should learn logic instead, and that some training in practical geometry should be given to all. A discussion on the question : " Should Greek be Compulsory for Mathematicians at Cambridge? " was opened by Mr. A. W. Siddons, who urged that mathematicians should not have special arrangements made for them ; that, if Greek was compulsory for others, it should be for mathematicians also. Prof. A. R. Forsyth, F.R.S., said it is to his mind extraordinary that teachers of classics argue that, if Greek be made optional, therefore the subject will become extinct. The subject has a strong hold on the public schools and the universities ; every outside inducement to its continuation is still maintained, but in a large number of schools in the country Greek is now extinct. If the ancient universities maintain this barrier of Greek as a preliminary qualification for a degree, it means one of two things—either that all the boys in those schools where Greek is now extinct are cut off from the universities, and so those institutions cease to be contributing to the educational wealth of the country to the same extent as they used to do, or else that many boys often proceed to get up the subject from the point of view of satisfying a miserable minimum. What was asked for is a relaxation in favour of education in general and not in favour of any special class of people. The elimination of literary training in the country is not being sought.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, November 24, 1904.—"Preliminary Communication on Galvanic Cells produced by the Action of Light." By Dr. M. **Wilderman**. (From the Davy-Faraday Laboratory of the Royal Institution.)

The author finds that there is, under the action of light, a region of galvanic cells as wide and as varied as in the case of ordinary galvanic cells. He finds constant and inconstant cells, reversible and irreversible cells. The chemical reactions and chemical equilibrium in the galvanic combinations are now perfectly clear; they prove, however, to be all *sui generis*, all the phenomena being intermixed and characterised by phenomena of induction and deduction, peculiar to light cells only. The author also succeeded in placing this region of phenomena on a physico-mathematical basis, testing and proving the fundamental equations experimentally in all details. The principal results obtained are:—

(1) The total E.M.F. created by light consists of an E.M.F. produced by light at a constant temperature, owing to the increase of the chemical potential and of the solution pressure of the exposed plate, and of a thermo-E.M.F. caused by one of the plates in contact with the liquid being heated by light. Both E.M.F.'s are found to be directly proportional to the intensity of light; both give currents in the same direction, thus proving that light acts on the chemical potential as well as on the solution pressure of the electrode in the same way as does heat.

(2) The peculiar course of the induction and deduction periods enables one to distinguish constant and inconstant cells showing polarisation from one another. A consideration of the chemical composition and of the reactions going on in the systems under the action of the current leads to the same results.

(3) The induction period follows a law

$$d\pi/d\tau = c(\pi_0' - \pi)(\pi - \pi_0 + K),$$

giving at the same time also the fundamental law of photography relating to the connection between the amount of silver salts decomposed and the time of exposure. The deduction period follows a similar law

$$-d\pi/d\tau = -c'(\pi_0 - \pi)(\pi - \pi_0' + K').$$

(4) The fundamental equation for the E.M.F. of constant cells "reversible in respect of cation" (*e.g.* Ag plate in light, $AgNO_3$ solution in light, $AgNO_3$ solution in the dark, Ag plate in the dark) is

$$\Sigma E = 0{\cdot}860T\,(\log_e P_l/P_d - 2v/u + v \log_e p_l/p_d)10^{-4} \text{ volt},$$

and for constant cells "reversible in respect of the anion" (*e.g.* Ag-BrAg plate in light, KBr solution in light, KBr solution in the dark, Ag-BrAg plate in the dark) is

$$\Sigma E = 0{\cdot}860T(-\log_e P_l/P_d + 2u/u + v \log_e p_l/p_d)10^{-4} \text{ volt},$$

where P_l, P_d are the solution pressures of the electrodes in light and in dark, p_l, p_d are the osmotic pressures of the cation or anion in the solution in light and in dark, and T is the absolute temperature.

The theory of thermogalvanic cells is also given in the paper.

December 8, 1904.—"The *Rôle* of Diffusion during Catalysis by Colloidal Metals and Similar Substances." By Dr. Henry J. S. **Sand**. Communicated by Prof. J. H. Poynting, F.R.S.

This paper contains a criticism of the opinion expressed by Nernst (*Zeitschrift Phys. Chem.*, xlvii., 55) that the catalytic decomposition of hydrogen peroxide due to colloidal metals probably takes place practically instantaneously on the surface of the catalyser, so that the concentration of the hydrogen peroxide there is permanently maintained at zero, and the velocity of the reaction actually measured is that with which diffusion and convection renew the solute in contact with the catalytic particles.

As a result, it was shown that Nernst's hypothesis would lead us to expect the reaction to proceed as one of the first order, a conclusion which agrees with the experimental results found by Bredig and his pupils. The actual values of the experimental velocity-constants are, however, far too small to allow us to reconcile them with Nernst's suggestion, and the latter must therefore be rejected.

In order to arrive at this result, minimum theoretical values for the rate of the reaction were calculated on Nernst's hypothesis. For this purpose the particles were assumed to be spheres with a diameter of $0{\cdot}5\mu$, a value which, according to Bredig, is greater than any which was met with in his solutions. The particles were supposed to be in a state of continual movement, performing the so-called Brownian motions, but in travelling through the solution were assumed to take with them a film of adhering liquid. In order to obtain a minimum value for the reaction velocity the total volume of the films was supposed to be equal to that of the whole liquid. The diffusion-coefficient of hydrogen peroxide at 25° was taken as 10^{-5} cm.^{2}/sec., a value which is smaller than that of most substances with heavier molecules.

The great part played by convection due to the Brownian motions of the particles and stirring by gases, &c., was demonstrated, it being pointed out that the experimental results regarding the dependence of the velocity-constants on the concentration of the catalyser can only be reconciled with the idea of a heterogeneous reaction if convection plays an important part.

Lastly, it was shown that the experimental facts all agree with the assumption that the actual velocity of the reaction on the surfaces of the particles always has a finite value which is proportional to the concentration of the solute in immediate contact with them.

In conclusion, Nernst's views regarding reaction-velocities in heterogeneous systems were criticised from a thermodynamical point of view, and it was shown that whereas they may possibly be correct for the majority of physical processes, great caution should be exercised in applying them to processes of a chemical nature.

January 19.—"The Dual Force of the Dividing Cell. Part i.—The Achromatic Spindle-Figure, elucidated by Magnetic Chains of Force." By Prof. Marcus **Hartog**. Communicated by Sir William T. Thiselton-Dyer, K.C.M.G., C.I.E., F.R.S.

The essential points of this research are described as:—

(1) The introduction of a convenient apparatus for the study of the axial section of fields produced by isolated poles of a dual force.

(2) The formation of *chains of force* in a viscid material, the recognition of their character as a distinct type of material configuration, and the study of their properties.

(3) The application of the conception of *relative permeability*, and of the recognition of chains of force to the problem of the cell-figure.

Zoological Society, January 17.—Mr. G. A. Boulenger, F.R.S., vice-president, in the chair.—(1) Some notes on the cranial osteology of the mastigure (Uromastix); (2) a contribution to the anatomy of Chlamydosaurus and some other Agamidæ; and (3) a note on the brain of *Cynopithecus niger*: F. E. **Beddard**, F.R.S.—(1) A collection of sipunculids made at Singapore and Malacca; (2) a collection of gephyrean worms from Zanzibar; and (3) the sipunculids and echiurids collected during the "Skeat Expedition" to the Malay Peninsula: W. F. **Lanchester**. Four new species were described in the second paper and nine in the last.—On the oral and pharyngeal denticles of elasmobranchs: A. D. **Imms**. The author had found that these denticles were present in varied abundance over the mucous membrane lining both the oral and pharyngeal cavities in many of these fishes. Out of the specimens of the nineteen species (representing eighteen genera) examined, only five, belonging to as many genera, were found to be totally devoid of these structures.—The skull of a musk-ox from the river-gravels of the Severn Valley at Frampton-on-Severn, near Stonehouse, Gloucestershire: Dr. C. W. **Andrews.** The specimen consisted of the cranial portion of the skull of an old bull, and was found by Mr. W. T. Rennie, of Chepstow, who had presented it to the British Museum. Remains of this species were comparatively rare in Britain, and the nearest previously recorded locality to that described was Barnwood, near Gloucester.—Three new birds obtained by Colonel Waddell, C.B., on the recent expedition to Lhassa: H. E. **Dresser.** The birds exhibited and described were:—*Babax waddelli,* nearest to, but differing widely from, *Babax lanceolatus*; *Garrulax tibetanus,* a much darker and more uniformly coloured bird than *Garrulax sannio,* with the terminal part of the tail white; and *Lanius lama,* a much darker bird than *Lanius schach,* with less white on the forehead, no rufous on the back or scapulars, and no trace of an alar speculum.

Royal Meteorological Society, January 18.—Capt. D. Wilson-Barker, president, in the chair.—The **President** delivered an address on the connection of meteorology with other sciences. He said that meteorology and astronomy were doubtless the first of the sciences to attract the attention of men—which of the two exerts most influence on the well-being of humanity is a matter dependent on the position of the globe; in many regions people are but slightly affected by the weather, while the heavenly bodies, particularly the sun, exert an enormous influence on human life. Everywhere in nature we find the effects of meteorological agencies. After speaking upon the effects of evaporation, winds, rain, ice, snow, and pointing out the influence of weather on animal life, vegetation, health, &c., he said that meteorology is a science deserving more attention than it receives. He thought it ought to be recognised as a preliminary to the studies of geography, geology, and kindred subjects, and he was of opinion that meteorological observatories might very well be fitted up in schools, and pupils taught to observe. This could be done at a small cost of time or money. The tendency at present is to particularise in all scientific work, but the true path to progress lies in keeping a comprehensive outlook on the whole field of investigation. The United States have devoted much attention to meteorology with most satisfactory results. It is to be regretted that official help and encouragement are so deficient in this country. The baffling, difficult nature of meteorological problems should but serve as an incentive to their elucidation. The persistent observer gains much, not only in knowledge of the subject, but in the habits of close and accurate investigation which he insensibly acquires, and all workers in this field learn to appreciate the difficulties which confront their fellow-labourers and to recognise the value of what has been done by the meteorological organisations of the world.—Mr. Richard Bentley was elected president for the ensuing year.

Entomological Society, January 18.—Prof. E. B. Poulton in the chair.—Mr. F. Merrifield was elected president for the session 1904–5.—The president, Prof. **Poulton,** delivered an address in which he discussed the part played by the study of insects in the great controversy on the question, "Are acquired characters hereditary?" He argued that the decision whether Lamarck's theory of the causes of evolution is or is not founded on a mistaken assumption largely depends upon evidence supplied by the insect world, and finally concluded that the whole body of facts strongly supports Weismann's conclusions. At the end of his address the president urged that the study of insects is essential for the elucidation and solution of problems of the widest interest and the deepest significance.

Dublin.

Royal Dublin Society, December 20, 1904.—Mr. W. E. Wilson, F.R.S., in the chair.—Unrecognised factors in the transmission of gases through water: Dr. W. E. **Adeney.** The author has described in this communication an experimental investigation of the downward streaming which has been met with in experiments on diffusion of gases in water, when the gas is placed above the water. Hüfner has ascribed this downward streaming to the water becoming heavier as it dissolves the gas, and so forming concentration currents. The author shows from his experiments that the streaming is a gravitational effect, but that it is not due to concentrated solution currents as understood by Hüfner. He also shows that when the surface layers of long columns of water, of small cross section, are continuously agitated by mechanical stirrers, or by currents of air drawn through them, the streaming becomes very rapid, with the result that the columns of water are saturated with the gas in the course of a few hours. The streaming takes place more rapidly in sea-water than in distilled water.—Secondary radiation: Prof. J. A. **McClelland.**—The partial differential equations of mathematical physics: Prof. A. W. **Conway.** A new method of obtaining singular solutions of these equations was obtained, applicable to non-homogeneous equations. A new class of functions called "kinetic functions" was introduced.—The Primary rocks of Ireland with their intrusive rocks: G. H. **Kinahan.** The first part of the paper gave a general account of the rocks from the Permian to the Cambrian, specially mentioning their characteristic shore accumulations. The second and more important portion treated of all the occurrences of Irish Archæans with their exotic adjuncts, and their probable equivalents in England, Wales, Scotland, Canada, and the United States of America.

January 17.—Dr. W. E. Wilson, F.R.S., in the chair.—Improvements in equatorial telescope mountings: Sir Howard **Grubb,** F.R.S. The author described a new form of slow motion for large equatorial telescopes in which a small electric motor is used for actuating the differential wheels, which are ordinarily worked by an endless cord. This new form was first applied to the 24-inch photographic equatorial of the Radcliffe Observatory, Oxford, and is now being applied to the photographic equatorial at the Cape Town Observatory, which is of the same size. The working of the instrument, which was exhibited at the meeting, was demonstrated by the author, who also read a paper on a simplified form of his electrical control, which has lately been applied to several large instruments.—On the temperature of certain stars: W. E. **Wilson,** F.R.S. It seems probable that in the sun and some stars there are two quite distinct sources from which we can receive light which gives a continuous spectrum. First, the photospheric clouds, which are composed of droplets of matter in the solid form, probably carbon; secondly, layers of intensely hot gases which are under considerable pressure. Between these two sources of radiation lie principally the vapours of titanium and vanadium, and other elements of suitable atomic weight. In a sun-spot the temperature is locally so high that the photospheric clouds are volatilised, and we then get the radiation only from the gaseous layer below, the spectrum being darkened by the intervening layers, consisting principally of the vapours of titanium, &c., the lines of which are widened and darkened. It is then suggested that as a star like Arcturus, or type iv. stars, have a spectrum which is very similar to a sun-spot, in these bodies the temperature is so high that they have no photospheric clouds, and that their want of brilliancy is caused by their only receiving the radiations from the gaseous layers which lie at some depth in their atmospheres.—Mr. Richard J. **Moss** exhibited the absorption spectrum of liquid oxygen.

Manchester.

Literary and Philosophical Society, December 13, 1904.—Mr. W. H. Johnson in the chair.—Note on the dissemination of seeds by birds: C. **Oldham.** The opinion expressed by Mr. F. Nicholson at a recent meeting of the society that birds rarely act as disseminators of seeds, by voiding them in their excrement, is not in accord with the experience of many field naturalists. Nearly fifty years ago Darwin proved ("Origin of Species," chapter xii.) that certain seeds extracted from the excrement of small birds germinated, as did others from the ejected pellets and the excrement of carnivorous and piscivorous birds. The evidence of Wallace and other observers may be cited to the same effect. In mid-Cheshire, during the spell of hard weather at the end of November, 1904, an examination of the excrement of various birds showed that entire and apparently uninjured seeds are voided constantly. Redwings, fieldfares, and other thrushes were compelled during the frost to subsist largely upon hedgerow fruit, and entire seeds of the wild rose (Rosa) and hawthorn (Cratægus), among others, might have been collected from their droppings by thousands. From the excrement of smaller birds the author obtained many undigested seeds of the bramble (Rubus).—The Foraminifera from the coast of the island of Delos, part ii.: H. **Sidebottom.** Particular attention was directed to those species that are new to the Mediterranean. The dimorphic structure of many of the Foraminifera was also pointed out.

January 10.—Prof. W. Boyd Dawkins, F.R.S., in the chair.—On the supposed antagonism of Mendelian to biometric theory: A. D. **Darbishire.** The author, after referring to the conflict of the Mendelians and biometricians, explained the methods of investigation of the two schools. The biometricians apply statistical methods and deal with masses of individuals, and therefore with average characters; the Mendelians devote their attention to the study of the individual components of the mass, and endeavour by means of experiments to ascertain the nature and mode of modification of the characters of the units. Mr. Darbishire sought to show that the two views are not irreconcilable, but that the real truth was to be arrived at from a survey of both.—The cause of the period of chemical induction: C. H. **Burgess** and D. L. **Chapman.**

PARIS.

Academy of Sciences, January 23.—M. Troost in the chair.—New researches on the secular alterations of hydrocarbon of organic origin: M. **Berthelot.** Details are given of the chemical examination of a fatty substance found in an Egyptian vase of about 1600 B.C.—Some metals found in archæological excavations in Egypt: M. **Berthelot.** Analyses of two specimens of bronze dating from about the second dynasty.—On the increase of volume of molten cast iron, saturated with carbon in the electric furnace, at the moment of solidification: Henri **Moissan.** Iron which is free, or nearly free, from carbon, in passing from the liquid to the solid state, follows the ordinary law, its density increasing. On the contrary, when saturated with carbon at the temperature of the electric furnace, it increases in volume when solidifying.—Study of lunar photographs. Considerations on the course of solidification in the interior of a planet: MM. **Lœwy** and **Puiseux.** As the result of an examination of photographs of the moon's crust, the author has been led to support the geological view of the constitution of the earth, that of a thin crust with a liquid core, as against the rigid solid theory of the mathematicians.—Note on the three volumes of the *Annales de l'Observatoire de Nice*: M. **Bassot.**—On a recent ascent of Vesuvius: **J. Janssen.** Numerous specimens of gases from the fumerolles and of lava and scoria were collected, and photographs taken of the absorption spectra of the vapours issuing from the cone during an eruption. The description of a detailed examination of these is reserved for a future communication.—The calculation of ordinary and suspension bridges: M. **Considère.**—Observations of the Borrelly comet (1904 *e*) made by F. Courty with the large equatorial at the Observatory of Bordeaux: G. **Rayet.**—On families of surfaces with plane orthogonal trajectories: S. **Carrus.**—Remarks on the preceding communication: Gaston **Darboux.**—On the approximation of functions by polynomials considered in relation with the theory of partial differential equations: application to the problem of the initial state in mathematical physics: A. **Buhl.**—On a hyperelliptic surface: E. **Traynard.**—On the integrals of total differentials belonging to an irregular surface: G. **Castelnuovo.**—On linear differential equations of the second order containing one parameter: M. **Tzitzeica.**—On a theorem of M. Borel: F. **Riesz.**—On the deviation of falling bodies towards the south and on the curvature of lines of force: Maurice **Fouché.**—On the magnetic field to which a body in motion in an electric field is submitted: H. **Pellat.**—On the ions of the atmosphere: P. **Langevin.** The experiments of the author lead to the conclusion that there are only two kinds of ions present in the air, one having a mobility several thousand times smaller than the other. The apparatus used by Ebert only measures the first of these.—Contribution to the study of ionisation in flames: Pierre **Massoulier.**—On the specific coefficients of magnetisation of liquids: Georges **Meslin.**—The action of very low temperatures on the phosphorescence of certain sulphides: F. P. **Le Roux.** Remarks on a paper of MM. A. and L. Lumière dealing with the same subject.—On a new mineral containing radium: J. **Danne.** Some plumbiferous minerals, notably a pyromorphite, found in the neighbourhood of Issy-l'Évêque, have been found to contain radium, and it is a noteworthy fact that none of these minerals contain uranium. The amount of radium is variable, a ton of the mineral furnishing quantities of radium bromide of the order of a centigram.—The dissociation of strychnine salts as measured by the rotatory power. The rotatory power in homologous series. The influence of the double linkage: J. **Minguin.** The deviations were measured in the first place when the strychnine and acid were present in molecular quantities, and then in presence of an excess of acid. The differences observed point to a dissociation taking place.—On cæsium methylamide: E. **Rengade.** Cæsium dissolves in anhydrous liquid methylamine, forming at first a metal methylammonium; this soon evolves hydrogen and the methylamide is quantitatively formed. The amide detonates on heating, giving rise to cæsium cyanide and hydrogen. Water, allowed to act slowly, produces cæsium hydroxide and methylamine.—The action of phosphorus pentachloride upon some tertiary cyclic amines. Syntheses of colouring matters and formation of phosphorus: P. **Lemoult.**—The products of oxidation of anthracene octahydride: dihydro-oxanthranol and hexahydroanthrone: Marcel **Godchot.**—Thymomenthol and its derivatives: Léon **Brunel.** This is obtained from thymol by the Sabatier and Senderens reaction; its physical and chemical properties are given and the preparation of several derivatives described.—Contribution to the study of some derivatives of benzodihydrofurfurane: A. **Guyot** and J. **Catel.**—On the agricultural value of humic materials: J. **Dumont.**—On the elliptical character of the new Borrelly comet (*e* 1904): G. **Fayet.** It is shown that no parabola can satisfactorily represent all the observations, an elliptical orbit with a period of about eight years better representing the facts.—An electrical pendulum with free escapement: Ch. **Féry.** The arrangement described is remarkable for the small expenditure of electrical energy required to work it, less than 0.5 watt per annum. The diurnal variation of a clock beating half seconds fitted with the apparatus described is less than 0.3 second.—On the nitrates of potassium and ammonia and on the law of Bravais: Frédéric **Wallerant.**—The coal basin of French Lorraine: Francis **Laur.**—On the diatom-bearing level of the ravine of Égravats, near Mont Dore, Puy-de-Dôme: M. **Lauby.**—On the biology and anatomy of the suckers of *Osyris alba*: A. **Fraysse.**—On the biology of the Cestodæ: L. **James** and H. **Mandoul.**—The action of magnesium and of magnesia on micro-organisms: F. **Dienert.**

NEW SOUTH WALES

Royal Society, November 2, 1904.—Mr. C. O. Burge, president, in the chair.—Pot experiments to determine the limits of endurance of different farm crops for certain injurious substances, part iii., barley and rye: R. **Helms** and Prof. F. B. **Guthrie.** The authors describe experiments with barley and rye in continuation of those on wheat and maize (*Proc.* Roy. Soc. New South Wales, xxxvi. p. 191, and xxxvii. p. 165) to determine the tolerance of these plants to certain ingredients commonly present in the soils and water used for irrigating in certain parts of the State, namely, sodium chloride and sodium carbonate; also the effect produced upon their growth by the presence of small quantities of plant poisons occasionally met with in fertilisers, such as ammonium sulphocyanide, sodium chlorate, and arsenious acid.—The classification and systematic nomenclature of igneous rocks: H. Stanley **Jevons.** The author concludes that the most convenient general classification for the present time would be one constructed as follows:—(1) Based on alkali-lime-content of principal and minor mineral constituents. Produces two series: alkaline and calcic. (2) Based on similarity of principal mineral constituents. Produces seven sections, *e.g.* granitic, gabbroic, theralitic, &c. (3) Based on community of origin from similar parent magmas. The latter are defined by the presence of certain index minerals in the consolidated rocks (*e.g.* a granite, a granite-aplite, and a rhyolite, &c., may all be derived from one magma; other granites, rhyolites, &c., will be derived from similar magmas). Produces twelve orders, *e.g.* granates, essexates, &c. (4) Based on habit of mass. Produces seven families in each order, *e.g.* granophites, dioromicrites, gabbrolavites (basalts), &c. (5) Based on nature of minor mineral constituents. Produces a number of genera in each family, *e.g.* muscbigranophite, anaugi-hyper-peridotite (harzburgite). (6) Based on texture, but to be applied only in families where there is much variety of texture. Produces subgenera, *e.g.* spheri-mono-rhyolite, graphi-bi-rhyolite, &c. The system of nomenclature described is an elaboration of that already proposed by the author in a preliminary paper in the *Geological Magazine* (1901).

BENGAL.

Asiatic Society of Bengal, January 4.—Hierarchy of the Dalai Lama (1406–1726): Rai Sarat **Chandra Das**. The author gives a history of the origin and growth of power of the Dalai Lama.—On the prevalence of fevers in the Dinajpur district: Dr. L. **Rogers**. This paper deals with the results of a special inquiry into the causes of the very high mortality of above forty per thousand in the Dinajpur district. It is shown that the higher death rates in certain places are due mainly to malaria, the increased prevalence of which is closely related to a high ground water level due to unalterable physical conditions of the district. In the second part of the paper the varieties of fever met with and distribution of the anopheles which can carry the infection are dealt with, and the impracticability of mosquito destruction as a preventive measure in the district as a whole is pointed out. The wider distribution of quinine in each village through the agency of the primary schoolmasters so as to reach the children, who mainly die of the disease, is recommended as the only practicable method of lessening the death rates from malaria among the people of Lower Bengal.

DIARY OF SOCIETIES.

THURSDAY, FEBRUARY 2.

ROYAL SOCIETY, at 4.30.—On the Compressibility of Gases between One Atmosphere and Half an Atmosphere of Pressure: Lord Rayleigh, O.M., F.R.S.—On the "Blaze Currents" of the Gall Bladder of the Frog: Mrs. A. M. Waller.—The Theory of Photographic Processes: On the Chemical Dynamics of Development: S. E. Sheppard and C. E. K. Mees.—On the Relation between Variations of Atmospheric Pressure in North-East Africa, and the Nile Flood: Capt H. G. Lyons.—Note on the Determination of the Volume Elasticity of Elastic Solids: Dr. C. Chree, F.R.S.—Theory of the Reflection of Light near the Polarising Angle: Prof. R. C. Maclaurin.

ROYAL INSTITUTION, at 5.—Forestry in the British Empire: Prof. W. Schlich.

CIVIL AND MECHANICAL ENGINEERS' SOCIETY, at 8.—The Mechanics of Flour Milling: A. R. Tattersall.

LINNEAN SOCIETY, at 8.—Descriptions of New Chinese Plants (with lantern slides): W. J. Tutcher.—European Cirolaninæ (Isopoda): Dr. H. J. Hansen.

RONTGEN SOCIETY, at 8.15.—Some Points in the Construction of a High Frequency Machine: Dr. Clarence A. Wright.

CHEMICAL SOCIETY, at 8.—Studies in the Camphane Series. Part xvi. Camphorylcarbimide and Isomeric Camphorylcarbamides: M. O. Forster and H. E. Fierz.

FRIDAY, FEBRUARY 3.

ROYAL INSTITUTION, at 9.—Blood Pressure in Man: Prof. T. Clifford Allbutt, F.R.S.

GEOLOGISTS' ASSOCIATION, at 7.30.—Address on Modern Methods in the Study of Fossils: the President, Dr. A Smith Woodward, F.R.S.

MONDAY, FEBRUARY 6.

SOCIETY OF CHEMICAL INDUSTRY, at 8.—The Theory of Dyeing. Part ii. Pseudo-solution and Desolution: W. P. Dreaper.—The Fading of Inks and Pigments: J. W. Lovibond.

SOCIETY OF ARTS, at 8.—Fountain Pens: James P. Maginnis.

TUESDAY, FEBRUARY 7.

ROYAL INSTITUTION, at 5.—The Structure and Life of Animals: Prof. L. C. Miall, F.R.S.

ZOOLOGICAL SOCIETY, at 8.30.—On Abnormal Ranid Larvæ from Northeastern India: Nelson Annandale.—On a Second Collection of Fishes made by S. L. Hinde in the Kenya District, East Africa: G. A. Boulenger, F.R.S.—On some Points in the Anatomy of Diademodon: Dr. R. Broom.—Notes on the Mammals of Southern Cameroons and the Benito: George L. Bates.

INSTITUTION OF CIVIL ENGINEERS, at 8.—*Discussion*: Floating Docks: L. E. Clark.—*Papers*: Alfreton Second Tunnel: E. F. C. Trench.—The Reconstruction of Moncreiffe Tunnel: Dugald McLellan.

WEDNESDAY, FEBRUARY 8.

SOCIETY OF ARTS, at 8.—Time Development in Photography, and Modern Mechanical Methods of carrying it out: R. Child Bayley.

THURSDAY, FEBRUARY 9.

ROYAL SOCIETY, at 4.30.—*Probable Papers*: (1) On the Conversion of Electric Oscillations into Continuous Currents by means of a Vacuum Valve: (2) On a Kummeter for the Measurement of the Length of Long Electric Waves, and also small Inductances and Capacities: Prof. J. A. Fleming, F.R.S.—Report on an Area of Local Magnetic Disturbance in East Loch Roag, Lewes, Hebrides: Captain A. M. Field, R.N.—Phosphorescence caused by the Beta and Gamma Rays of Radium: G. T. Beilby.—(1) The Spectrum of Scandium and its Relation to Celestial Spectra; (2) Note on the Spectrum of μ Centauri; (3) On the Stellar Line near λ 4686: Sir Norman Lockyer, K.C.B., F.R.S., and F. E. Baxandall.—On Europium and its Ultra-Violet Spectrum: Sir William Crookes, F.R.S.

ROYAL INSTITUTION, at 5.—Forestry in the British Empire: Prof. W. Schlich, F.R.S.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Fuel Economy in Steam Power Plants: W. H. Booth and J. B. C. Kershaw. (Conclusion of discussion.)—The Value of Overhead Mains for Electric Distribution in the United Kingdom: G. L. Addenbrooke.

MATHEMATICAL SOCIETY, at 5.30.—General Theory of Transfinite Numbers and Order-types: Dr. E. W. Hobson.—On the Reducibility of Covariants of Binary Quantics of Infinite Order. Part ii: Mr. P. W. Wood.

FRIDAY, FEBRUARY 10.

ROYAL INSTITUTION, at 9.—The Art of the Ionian Greeks: Dr. Cecil Smith.

ROYAL ASTRONOMICAL SOCIETY, at 5.—Anniversary Meeting.

MALACOLOGICAL SOCIETY.—Annual General Meeting. Address by the President, Mr. E. R. Sykes, on Variation (including Teratology) in Recent Mollusca.

INSTITUTION OF CIVIL ENGINEERS, at 8.—The Reconstruction of the Santa Lucia River Bridge, Uruguay: P. J. Risdon.

CONTENTS.

THURSDAY, FEBRUARY 9, 1905.

SCIENTIFIC RESULTS OF THE BELGIAN ANTARCTIC EXPEDITION.

Résultats du Voyage du S.Y. Belgica en 1897, 1898, 1899, *sous le Commandemant de A. de Gerlache de Gomery.* Rapports scientifiques. (1) Zoology and Botany. (2) Astronomy and Meteorology. (Antwerp, 1902–4.)

(1) THE cruise of the steam-yacht *Belgica,* organised by the Belgian Government, may be regarded as the first of the series of expeditions fitted out during the last few years to explore the Antarctic and to collect systematically its zoological and botanical products. Consequently, it fell to the lot of this expedition to be the first to bring back specimens of certain animals previously known, more or less imperfectly, by examples obtained by the early expeditions to the South Polar regions, such as that of the *Erebus* and *Terror.* The most noticeable instance of this is afforded by the seal known as *Ommatophoca rossi,* which had been previously known only by two skulls and a skin brought home by the *Erebus* and *Terror* Expedition (1839–43). Fortunately, the fasciculus of the *Rapports* dealing with the seals (by Captain Barrett-Hamilton) was published in 1902, and ante-dates the British Museum report on the *Southern Cross* Expedition, thereby securing to the *Belgica* the full credit for having been the first to increase our knowledge of this interesting species.

The comparative slowness of the rate at which it has been found practicable to issue the result of the *Belgica's* work will, however, necessarily have discounted some of its claims to priority, seeing that the aforesaid report on the collections made by the *Southern Cross* was published in 1902, while at least one small instalment of the zoological results of the *Discovery* Expedition has already been made public. On the other hand, in many of the groups the new forms discovered by the *Belgica* expedition were described at an early date in the form of preliminary notices (in the case of the fishes as early as 1900), and as the later parts of the work before us contain reviews of the species described in the report of the *Southern Cross* Expedition, an advantage rather than a disadvantage has been gained by the delay in publication. This is particularly noticeable in the fasciculus devoted to fishes, which was published in 1904.

The characteristic of the reports on the *Belgica* collections is the wealth of detail with which the descriptions are worked out and the elaborate style in which they are issued. The entire work is, for instance, published in quarto form, in large type, with no apparent limitations to the extent of the letter-press, and a fair allowance of plates, most of which are admirably executed. Each section of the subject has been assigned to a specialist, and the mere mention of the fact that Captain Barrett-Hamilton is responsible for the seals, Mr. Racovitza (the naturalist to the expedition) for the cetaceans, Mr. Dollo for the fishes, and Dr. Pelseneer for the greater part of the molluscs, will be a sufficient indication of the care and wisdom with which the selection of these specialists has been made.

A total of more than sixty separate memoirs on the zoology of the expedition is promised, and of these no less than fourteen (ranging in their subjects from seals and cetaceans to corals and sponges) are now on the table before us. Within the limits of the space at our disposal it would obviously be impossible to attempt anything like a summary—much less a criticism—of the vast amount of work contained in this mass of literature. All that can be essayed is to record a few of the more striking results of some of these investigations, and at the same time to express our opinion, so far as we are capable of forming a judgment, of the high value and importance of the work generally.

As regards Mammalia, perhaps the most important result of the *Belgica* Expedition was a negative one, namely, the practical demonstration that no large forms of terrestrial mammalian life inhabit Antarctica. In his first expedition Mr. Borchgrevink was, indeed, inclined to attribute certain marks commonly seen on the hides of the Antarctic seals to the teeth of a land carnivore, but it is now believed, with much more probability, that they are due to sharks. Mr. Racovitza, it may be added, was the first to make us acquainted with the peculiar gular pouch and strange cry of Ross's seal.

In treating of the cetaceans, Mr. Racovitza, who (like Captain Hamilton in the case of the seals) has no new species to describe, makes some very interesting remarks with regard to the mode of life and physiology of these animals. Especially important are those relating to the depths to which whales are capable of descending. These the author believes to have been exaggerated very greatly, and he puts the extreme limit at one hundred, and the ordinary range at twenty-five metres. As he well remarks, it is practically impossible to imagine an animal the organisation of which would admit of its existence alike at the surface and under the pressure of abyssal depths. His arguments are supported by certain facts in regard to the depths at which cetaceans are captured by the Japanese.

In the bulky fasciculus on the fishes Mr. Dollo has incorporated the results of Mr. Boulenger's work on those obtained during the *Southern Cross* Expedition, and has thus been enabled to present his readers with what is practically a monograph of the Antarctic forms. The most remarkable representatives of this fauna are those constituting the family Nototheniidæ, of which the author recognises no less than eighteen generic types, three of these being named by himself. Whether he is justified in proposing the name *Cryodraco antarcticus* for the fish which he apparently admits to be identical with the one captured during the voyage of the *Erebus* and *Terror* and named Pagetodes, on account of the alleged insufficient definition of the latter, may be doubtful. In our opinion the original sketch of Pagetodes is amply sufficient for the generic definition.

Very few words must, unfortunately, suffice for the parts devoted to invertebrates. In the fasciculus on brachiopods, Prof. Joubin directs attention to the apparently small bodily size of the Antarctic representatives of the group, a feature which is the more notable on account of the contrast they present in this respect to the forms from the Straits of Magellan. Another important fact in connection with the fauna of the southern ocean is brought out by Prof. Koehler in his description of the echinoderms obtained to the south of lat. 69°, the furthest point from which these organisms had at the time been obtained. Practically all these echinoderms have proved to be new forms, but whether they belong to the sub-Antarctic or the true Antarctic fauna has not yet been definitely ascertained.

The other fasciculi at present to hand include the following monographs:—molluscs, by Messrs. Pelseneer and Joubin; myriopods, by Mr. C. von Attems; collembola, by Mr. V. Willems; copepods, by Dr. W. Giesbrecht; nematodes, by Dr. J. G. de Man; nemertines, by Dr. O. Bürger; bryozoans, by Mr. A. W. Waters; hydroids, by Dr. C. Hartlaub; zoophytes, by Messrs. von Marenzeller and Carlgren; and sponges, by Mr. E. Topsent. The botanical memoirs include one by Dr. E. A. Wainio on lichens; a second, by Mr. J. Cardot, on mosses; and a third, by Mr. T. Stephani, on liverworts.

In concluding this too brief notice of a most valuable series of monographs, we may congratulate the Belgian Government on its wise liberality in authorising their publication, and the committee of the *Belgica* on the manner in which they have carried out their share of the task. R. L.

(2) In the department of astronomy we have the discussion of the rates of the chronometers employed and a description of the methods by which time was ascertained during the long confinement of the Antarctic winter. We may say, and it is admitted by the author, M. G. Lecomte, that the astronomical equipment was inadequate. It consisted at the outset of three marine chronometers, a sextant, two artificial horizons, an astronomical telescope, and a theodolite. The size of the telescope is not stated, but it was a relic of the old whaleship, the *Patria,* and was that which had been used by the captain to observe seals when at some distance from the ship. With this instrument, three phenomena of Jupiter's satellites were observed and one occultation. Lunar distances were also observed, but the rates of the chronometers were generally determined from local observations. The accumulated error on return is not clearly stated, but the rates and errors are worked out apparently with great care.

Meteorology naturally claims a large part in the scientific results. The observations were under the charge of M. H. Arctowski, and he has presented the details with very great clearness, and accompanied the whole with many excellent charts, showing graphically the behaviour of the barometer, the hygrometrical measurements, and the variations of temperature. The lowest temperature recorded was $-43°.1$ C. ($-45°.6$ F.) on September 8, 1898. The whole result is to exhibit the factors on which the climate depended during the sojourn of the expedition on the shifting ice. The observations do not refer to a particular spot, the ship drifting with the ice some sixteen degrees in longitude and two degrees in latitude. The observation of the clouds and the discussion of the results were entrusted to M. Dobrowolski, who had to encounter many difficulties, due to fog and darkness, which occasion lacunæ in the record. An appendix gives a description, as complete as possible, of a considerable number of cloud systems, divided into three stages of cirrus, clouds at a mean height, and of clouds at low altitudes. The greatest care seems to have been taken in the description of these systems during the twelve months of residence, but here again the expedition might have been better provided with apparatus. The observer had to trust entirely to eye and the compass; no nephoscope was provided, or photographic camera, or means for determining the height of cloud.

The same author discusses the formation of snow and hoar frost, but in this department he appears to have been hampered by the want of instrumental means. He had no microphotographic apparatus, and it has been difficult and sometimes impossible to reproduce the varied structure which he encountered. Hand drawings have been extensively used, and the general result of his work has been to confirm that of modern investigators who have recognised but two types of forms of structure.

An interesting memoir is that of M. Arctowski discussing the optical phenomena witnessed during the expedition. In this section he treats of the deformation of figure of the sun and moon crossing the horizon, illuminations of the sky at twilight, the green ray seen at the moment of the sun's setting, halos, and other phenomena, the peculiarities of which are best studied in polar regions. The author apologises for the popular character of some of his notes, but though greater detail might have been added if a spectroscope had been included in the outfit, these notes afford very interesting reading. The discussion of the auroræ forms a volume by itself, due to the same physicist. Only sixty-two times in thirteen months was this phenomenon witnessed, owing to the facts that the period of minimum auroræ occurred about the time of the expedition, and the region in which the *Belgica* was ice-bound was far from the locality in which auroræ pass through the zenith. Two excellent plates are given in this section.

Oceanography is represented by two memoirs. In the first, M. Arctowski describes the method by which observations were made on the passage across the Pacific to the Straits of Magellan to determine the density of the surface water. Later during the wintering of the expedition samples were drawn from considerable depths below the ice, and examined in the physical laboratory on board. In the second memoir M. Thoulet, professor at the University of

Nancy, gives the results of some experiments made on the density of sea water in the course of an inquiry entrusted to him by the commission in connection with the results derived by M. Arctowski.

W. E. P.

ITALIAN CHEMISTRY.

Trattato di Chimica Inorganica Generale e Applicato all' Industria. By Dr. E. Molinari. Pp. xxii+693. (Milan: Ulrico Hoepli, 1905.) Price 12.50 lire.

DURING the greater part of last century the progress of science in Italy was retarded by the political troubles of the country; even after the nation had achieved its independence and unity, scientific education was hampered by ecclesiastical controversies and by the poverty of the newly created Government. Taxation has always fallen heavily on the Italian people, and the industry and energy of the north have been taxed unduly owing to the poverty and thriftlessness of the south. In spite of these disadvantages, Italy gave to science in the last century many names which will long be remembered in its history. In particular, the hypothesis of Count Avogadro, enunciated in 1811, forms the basis of the whole of the modern development of chemistry; for nearly fifty years, however, its importance was overlooked, and it was the peculiar merit of another Italian, Cannizzaro, by reviving it, to establish a new epoch in the development of chemical science and to introduce order where all was confused and contradictory.

In the course of the past twenty-five years a school of Italian chemists has arisen the quality of whose work is on a high level of excellence. Side by side with this, an astonishingly rapid development of all branches of the industry of Italy has occurred. The rapidity of the advance may be gauged from a few facts. In the six years 1893–9, the value of the chemical manufactures of Italy exactly doubled itself, increasing from about 1,000,000*l.* to 2,000,000*l.* per annum. In the twenty-five years from 1875 to 1900 the value of the raw silk annually produced tripled itself, and that of the woven silk, which in 1890 was 600,000*l.*, rose in 1900 to 4,000,000*l.* The cotton and wool industries have developed almost as rapidly, and a similar progress is seen in the case of new manufactures, such as that of steel rails, which have only recently been introduced into the country. In some instances Italian manufacturers have begun to compete in foreign markets, and this development bids fair to become still more rapid as Italy converts more and more of her abundant store of water power into electrical energy.

The author of the present treatise, who holds the position of professor of chemistry at the Society for the Encouragement of Arts and Crafts of Milan, has endeavoured in it to initiate a reform in the teaching of chemistry in Italian universities, a reform which has also been recently urged by Profs. Cannizzaro and Ciamician. Hitherto the chemistry taught has been of too academical a character, little attention being given to practical applications. The title of the present work defines its nature, which is that of a treatise on inorganic chemistry, with especial reference to chemical industry. The commoner elements and their compounds are dealt with in detail, but instead of illustrating the text with time-honoured drawings of lecture apparatus, the actual plant used in the manufacture of these substances is depicted. All the more recent processes of manufacture are described concisely but sufficiently, but the book does not degenerate into a mere treatise of technology. The principal physical and chemical properties of the substances are clearly defined, as well as the relation existing between them; owing to conciseness and to the character of the type employed, a large amount of information is imparted which is not to be found in the usual elementary text-books. A novel feature is that the average market price of each commercial article is stated, whilst statistics are given of the cost of manufacture and profit of many of the more important substances. In many cases the development of an industry is traced through the patents referring to it, for instance, in the case of the manufacture of sulphuric acid and of alkali.

Before undertaking the systematic treatment of the elements, 114 pages are devoted to general chemical theory. It is this part that is most liable to criticism. A portion might very profitably have been omitted. The description, for instance, on pp. 37 to 40, of as many as eight different methods of determining vapour density, serves no useful purpose in a book of this kind, while it is doubtful whether the method of deducing the relationship (pp. 72 to 73) between the osmotic pressure and the freezing and boiling points of dilute solutions will be intelligible to the student in its present form. The historical treatment adopted throughout the work is the cause of a few misstatements which should have been avoided. Why, for instance, revive the story, which has no basis in fact, that Priestley, after languishing in poverty, died of poison? In discussing the history of valency, no mention is made of Frankland and Kolbe, Wurtz and Graham only being referred to. It is, moreover, so far from being the truth (p. 136) that in 1809 Gay-Lussac and Thénard admitted that chlorine was probably an element that even in 1811 they contested Davy's view of its elementary nature. Strangely enough, the part played by Cannizzaro in reviving Avogadro's theory is passed over in silence (p. 33), and the credit given to Gerhardt and Laurent alone.

Dr. Molinari's treatise is especially adapted and is likely to be very serviceable to the student who intends devoting himself to chemical industry; for a similar text-book at an equally low price the English student has long sighed in vain. With a few slight alterations the work could be made equally useful to the engineer. In particular, more space might be given to considering materials of construction, whilst the treatment of alloys is far too brief to be satisfactory, considering the important part which they now play in engineering. Several pages of part i. might well be replaced by a general discussion of the remarkable influence of impurities and of thermal treatment on the physical properties of metals. The phase rule, which is briefly explained, could be given a practical application by referring to the nature of alloys, particularly in the case of carbon-iron mixtures.

As is the case with all the works published by the well known firm of Ulrico Hoepli, the printing and reproduction of the illustrations leave nothing to be desired. It is, however, a pity that so many proper names are wrongly spelt; thus Graham is uniformly spelt *Grahm*, and Van der Waals *Van der Vaals*. More than ten misprints of other names are observable.

W. A. D.

A NEW CRYSTALLOGRAPHY.

Grundzüge der Kristallographie. By Prof. C. M. Viola. Pp. iv+389. (Leipzig: W. Engelmann, 1904.) Price 11 marks; bound, 12 marks.

THE opinion is rapidly gaining ground that the theory of crystallography based on the laws of rational indices and symmetry no longer suffices without modification for the classification and description of crystals. It is recognised on the one hand that isomorphism of kindred substances shows itself (as in the Humite group of minerals) more in similarity of crystalline habit and angles than in identity of optical and geometrical symmetry, and on the other hand that vicinal faces with high indices may play an important part in the economy of crystals. Prof. Viola is evidently of opinion that the old methods cannot be adapted to meet the situation, and his book is as revolutionary as it well could be. Crystals are here divided into 7 sygonies, 10 fundamental forms, and 29 harmonies; symmetry is but a particular case of harmony; twins are two similar crystals with two predominant elements in common; the number of space-lattices is reduced to 10, and of space-groups to 156. The basis of classification is descriptive, not geometrical; blende, felspar, and garnet belong to the same fundamental form, chalcopyrite and tetrahedrite to the same harmony.

If the author had merely attacked the existing theory and advocated a classification expressing the results of direct observation alone, independent of any hypothesis, he might have had some success. Unfortunately, he has tried to build up a mathematical theory of his own, with disastrous results. The average shape of all crystals of a substance grown under approximately the same conditions is its "habit"; the average shape of all habits is its "fundamental form." The rate of growth in any direction is proportional to the "cohesion" in that direction (measured, apparently, by the force needed to break a rod of the substance the length of which lies in the given direction), and cleavage takes place perpendicular to the lines in which minima of cohesion are well marked. It follows that the fundamental form has always a centre of symmetry. These assumptions are hardly justified by the cleavage and usual habit of many crystals, *e.g.* fluorite and tetrahedrite, but the mathematical development of these hypotheses is, if possible, still more unfortunate than the premises themselves. It is argued (p. 14, *cf.* Fig. 20) that if two faces grow outwards with velocities c_1 and c_2, (1) their intersection moves with the velocity c_3, compounded of c_1 and c_2, (2) therefore the face perpendicular to c_3 grows with velocity c_3, (3) c_3 is a maximum or a minimum when c_1 and c_2 are minima. Of these statements (1) and (3) are untrue, and (2) absolutely unproven. Thus the fundamental principles on which nearly the whole of the book is based are wrong. Much of the reasoning is of the same fallacious nature, or is, at best, only an appeal to probability; but one more example must suffice.

The author sets himself (p. 251) the impossible task of proving that a symmetry-axis of a homogeneous medium is 2-al, 3-al, 4-al, or 6-al without employing either the law of rational indices or a molecular structure. He accomplishes this by assuming that if the medium is brought to self-coincidence by a rotation through an angle 2γ about an axis C, it cannot be brought to self-coincidence by a rotation about C through any angle less than 2γ.

Prof. Viola apparently considers the space-lattice as only a convenient geometrical expression of the physical properties of a crystal, not as corresponding to any reality of crystal-structure. It is true that he proves (by assuming that the densities of the molecule and of the crystal as a whole are equal, see pp. 280, 335) that the unit of crystalline structure must be the same as the chemical molecule; but on pp. 322 and 334 he uses arguments which would prove the existence of an infinite number of such units in a finite volume.

Crystallographers owe a debt of gratitude to the author for his clear and complete lists of references to the literature of the various subjects with which he deals; the historical notes are also very valuable. The chapters on the two-circle goniometer and the stereographic projection contain much that is interesting and not in the usual text-books. The appearance of the book is attractive, but there is a large number of misprints, some of which quite obscure the author's meaning.

Harold Hilton.

OUR BOOK SHELF.

The Arris and Gale Lectures on the Neurology of Vision. By J. Herbert Parsons, B.S., D.Sc., F.R.C.S. Pp. 70. (London: Hodder and Stoughton, 1904.) Price 2s. 6d. net.

The two lectures delivered by Mr. Parsons in the spring of last year before the Royal College of Surgeons deal with some points on the neurology of the eye which are of extreme interest. The first lecture has for its subject the course of the afferent impulses from the retina to the central nervous system, and their final distribution in the cerebral cortex. Since the delivery of these lectures there have been several important contributions to this latter subject. The case of Dr. Beevor and Dr. Collier, reported in the summer number of *Brain*, seems to go conclusively against the more restricted visual area for which Henschen argues. In this case, despite the fact that the lingual lobe, the depths of the calcarine fissure, and the lower cuneal lobe were all affected, the restriction of the field of vision was simply quadrantic. The truth seems to be that the limits of the visual cortical area correspond to the limits of the layer of Gennari, and that this varies markedly in its relations to the surface in different cases.

The second lecture deals with an equally important subject, the nervous control of pupillary movements. A review of the work done on the question of the course of the pupillo-dilator fibres is given. These fibres pass from the cervical sympathetic as a separate tract along the carotid towards the Gasserian ganglion, and run thence with the ophthalmic division of the trigeminal along the nasal branch to the long ciliary nerves, thus avoiding the ciliary ganglion. The final portion of the lecture is devoted to a discussion of the cortical localisation of pupillary movements. We agree with Mr. Parsons that a very critical spirit is necessary in dealing with this subject. Here, more than anywhere else, is to be found the "elusive factor" which upsets all hypotheses. The term "synkinesis" seems to have a sufficiently useful application in neurological nomenclature to justify its invention. The limits of this notice do not allow of more detailed criticism. We must, however, congratulate Mr. Parsons on the singularly lucid, though necessarily inconclusive, fashion in which he has dealt with subjects of great complexity and importance.

The Twentieth Century Atlas of Microscopical Petrography. Part ii. With four plates. (London: Thos. Murby, 1904.)

Since the note on this work appeared in Nature (vol. lxxi. p. 38), we have been informed that the "editor" of it is Mr. E. Howard Adye, who is, in fact, responsible both for the text and for the very delicate plates. The second part includes two igneous rocks from Edinburgh, the Carboniferous oolite of Clifton, and the beautiful green quartzite of Ightham, described by Prof. Bonney in 1888. This last rock, we believe, usually contains altered glauconite in addition to the minerals mentioned by the author. We fancy that Mr. Adye is familiar with biological writing, which makes his descriptions rather more severely technical than is customary among English geologists. We thus read of a "dark brown fenestrated region at the periphery," "hypo-odontoid outgrowths," "biogenetic formation," and so forth. We do not know, moreover, what degree of extraordinary accuracy is suggested by the phrases "completely polarised light" and "fully-crossed Nicols." The text, however, is usually clear and graphic. The four rock-sections accompanying the part, and issued through the laboratory of Mr. J. R. Gregory, are absolutely perfect specimens of an art rarely cultivated in the British Isles. G. A. J. C.

Abbildungen der in Deutschland und den angrenzenden Gebieten vorkommenden Grundformen der Orchideen-arten. 60 Tafeln nach der Natur gemalt und in Farbendruck ausgefuhrt von Walter Müller (Gera) mit beschreiben dem Text von Dr. F. Kränzlin (Berlin). Pp. xiv+60+plates. (Berlin: R. Friedländer und Sohn, 1904.) Price 10 marks.

This is a series of sixty coloured plates representing the orchids which occur in Central Europe. The introduction and the text are from the pen of Dr. Kränzlin, who tells us at the outset that the book is not intended for professed botanists, but for those who take an interest in botany, or who possess a love of flowers. For this reason it is, we suppose, that the minutiæ of anatomical structure and the details of physiology are but lightly touched on. The reader, however, has put before him in a very clear way the principal points in the morphology of this most interesting group, together with an account of the conformation of each species.

A general statement is made as to the geographical distribution of the several plants, but no precise indications of particular localities are given. Most of our European orchids are terrestrial and have tuberous roots, but *Liparis Loeselii,* a species very rare in Britain, has a distinct pseudo-bulb such as characterises most of the tropical epiphytes of this order, and a similar form of stem occurs in *Microstylis monophyllos,* so that the formation of a pseudo-bulb is not correlated solely with the epiphytic habit. Both the tuber and the pseudo-bulb serve as food stores for the growing plant. In *Goodyera repens* there is a creeping underground stem which also recalls that of its tropical congeners. These points and others of a similar character are well represented in the plates. These illustrations were executed from life by Mr. Walter Müller, and they are so truthful that we may commend them to the notice of orchid lovers. Our field botanists will find all the British species represented, as well as a few others that are not members of the British Flora.

Intensification and Reduction. By Henry W. Bennett. Pp. xv+124. (London: Iliffe and Sons, Ltd., 1904.)

This issue, No. 15 of the *Photography* Bookshelf Series, will form a useful addition to an already valuable set of handbooks. The author has wisely restricted himself to setting forth in a clear and concise manner the better methods employed in intensification and reduction, and has not burdened the beginner with an elaborate index to all possible methods past and present. The processes dealt with are treated in some detail, so for this reason the reader should gain a good working knowledge of the manipulations he has in hand. The distinctive qualities of each method are clearly brought out, making the selection of any one for a particular negative quite an easy matter.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of Nature. *No notice is taken of anonymous communications.]*

Slow Transformation Products of Radium.

In a recent number of the *Philosophical Magazine* (November, 1904), I have shown that radium, after passing through four rapid changes, finally gives rise to two slow transformation products, which, on the scheme of changes there outlined, were called radium D and radium E.

These two products can be separated from each other by suitable physical and chemical methods. Radium D, which is the parent of E, gives out only β rays, while E gives out only α rays. It was calculated that D should be half transformed in forty years, and E in about one year. Evidence was also shown that radium D was the active constituent in the radio-active lead of Hofmann, and that radium E was the active substance present in both the polonium of Mme. Curie and the radio-tellurium of Marckwald.

Later work has confirmed these conclusions. I have examined the rates of decay of the activity of radium E and of radio-tellurium, and have found them to be identical. Each loses half its activity in about 150 days, instead of the calculated period of one year. The specimen of radio-tellurium was obtained from Sthamer, of Hamburg, in the form of a thin film deposited on a polished bismuth rod. I find that the same value for the decay and activity of radio-tellurium has recently been obtained by Meyer and Schweidler (*Akad. d. Wiss. Wien.*, December 1, 1904).

I was, unfortunately, unable at the same time to determine accurately the decay of the activity of polonium. A specimen of polonium (ratio-active bismuth) had been in my possession for three years, and had during that time lost a large proportion of its original activity. On testing it, the activity was found to have reached a small and nearly constant value. Rough observations, however, which I had made from time to time indicated that the rate of decay of this polonium was certainly not very different from that of radium E. More accurate experiments will be required to settle the question definitely, but I think there is little doubt but that their rates of decay will be found to be the same.

Polonium, radio-tellurium, and radium E have very similar radio-active and chemical properties. Each gives out only α rays, and each is deposited on a bismuth plate placed in the active solution. The probable identity of their rates of decay, taken into conjunction with the similarity of their radiations and chemical properties, shows that the radio-active constituent present is in each case the same. We may thus conclude that the active substance present in polonium and radio-tellurium is a decomposition product of radium and is the sixth (or, as we shall see later, probably the seventh) member of the radium family.

The main objection, in the past, against the identity of polonium and radio-tellurium has rested on the statement of Marckwald that a very active preparation of his substance did not lose its activity to an appreciable extent in six months. Unless very special methods were employed, it would be difficult to determine with accuracy the variation of the activity for such very active material. The specimen of radio-tellurium obtained both by Meyer and Schweidler and by myself undoubtedly does lose its activity fairly rapidly.

I have recently examined more carefully the product radium D, and have found strong evidence that it is not a single product, but contains two distinct substances. The parent product, radium D, does not give out rays at all, but changes into a substance which gives out only β rays, and is half transformed in about six days. Unless observations are made on the product radium D shortly after its separation, this rapid change is likely to escape detection. The work on this subject is still in progress, but the evidence at present obtained indicates that the active deposit from the emanation, after passing through the three rapid stages, represented by radium A, B, and C, is transformed into a "rayless" product D, which changes extremely slowly. D continuously produces from itself another substance—which may for the time be termed D_1—which is transformed in the course of a few weeks and emits only β rays. This product D_1 gives rise to E (polonium).

Since the activity of D_1 reaches a maximum value a few weeks after the production of D, and will then decay at the same rate as D, the conclusion, previously arrived at, viz., that D is half transformed in about forty years, still holds good.

The view that radium D is the active constituent present in the so-called radio-lead of Hofmann has been very strongly supported by some experimental results recently obtained by Hofmann, Gonder and Wölfl (*Annal. der Physik*, vol. xv., 3, 1904).

They found that preparations of radio-lead continuously produced an α ray product, which could be separated on a bismuth plate. This active product is probably radium E, for they found it lost a large proportion of its activity in one year. They found, in addition, that by certain chemical methods another distinct product could be separated which gave out only β rays, and lost much of its activity in six weeks. This substance is probably the new radium product D_1 already referred to.

Debierne recently concluded that radio-lead and polonium were identical, and proposed that the name radio-lead should be dropped in favour of polonium. In the light of the above results, this position is not tenable. There is no doubt that the preparation of radio-lead in my possession, and also that experimented on by Hofmann, contains a distinct substance which, as the parent of polonium, has certainly as much right to a name as its offspring. The radio-active substance in "radio-lead" has no more connection with lead than Marckwald's active matter "radio-tellurium" has with tellurium. The names both arose because the active matter was initially found associated with these substances.

In order to avoid confusion, I have called the new radium product "radium D_1." If no further intermediate products of radium are brought to light, it would be simpler to call it radium E and to call the α ray product (polonium) radium F.

E. RUTHERFORD.

McGill University, Montreal, January 24.

Indian and South African Rainfalls, 1892-1902.

MR. J. R. SUTTON, of Kimberley, rendered a signal service to South African meteorology in his "Introduction to the Study of South African Rainfall" (*Trans.* S.A. Philosophical Soc., December, 1903), but when he states that south-east winds are rare on the south-east coast of South Africa, and that the rainfall of the greater part of the tableland and south-east coast comes from some northern direction (NATURE, November 3, 1904), it is difficult to follow his conclusions. Most, if not all, of those who have studied South African rainfall will, I think, agree with me that the facts do not bear this interpretation. Least of all is it the case that there has been nothing that can properly be called a drought, in the sense of Sir J. Eliot's address, within the past fifteen years in South Africa. In all the summer rainfall areas of South Africa, viz., over the bulk of the subcontinent, drought has prevailed during recent years, and in some localities it has been terribly severe.

During twenty years I have travelled over every part of South Africa except the desert areas, and I have resided continuously in those parts where there is most rain and forest. I have heard the rain and its mode of arrival discussed in every locality and from every point of view, and these facts have convinced me that the summer rains have their origin in the moist winds from the Indian Ocean. The precipitation of the moisture contained in these humid air currents is caused by barometric depressions with normal cyclonic wind circulation, and it is the winds proper to these depressions that give the appearance of rains coming from the north, north-west, west, &c.

The following gives a brief account of the various storm types. In Cape Colony storms travel from west to east at all times of the year. As one would expect, they are more regular and better developed in the south than in the north, and in Rhodesia than in the Northern Transvaal. In the north during summer they may be replaced by westward travelling tropical storms. Usually it is the secondary with its thunderstorms, a whirl within a whirl, which precipitates the greater amount of moisture. In the southern portion of the subcontinent these storms in most cases pass across from west to east with their centres to the south, and thus their wind circulation shows at first winds from the north and north-west, then from the west and south-west, and finally from the south and south-east. In summer, when the south-east trade blows on to the subcontinent with a monsoon effect, the wind remains longer in the south-east quarter, and heavy rains come frequently from the south-east or the south-west quarter. The portion of the barometric depression and its accompanying circulation which brings the wind will depend on the position of the locality, but I have never known the facts not to conform more or less closely to this type of wind circulation. A range of mountains across the south-east rain-producing wind will, of course, increase the precipitation, and when once rain has started in the south-east quarter it will often continue for days with a steady south-east wind blowing like a south-west monsoon wind in India. All this takes place on the eastern side of South Africa. The rain is greatest in amount where the east wind from the Indian Ocean first strikes the highest eastern land, and the rain gradually decreases in amount until the western deserts are reached. It is generally the north-west wind which starts the precipitation, but it is quite certain notwithstanding that the humid currents do not come from the north-west. If, as Mr. Sutton has suggested, the high upper current of the north-west anti-trade were the source of South African rains, then it would be natural to suppose that the rains would be best developed on the north and western sides of South Africa, which is exactly the reverse of what actually takes place.

South Africa lies on the border of the south-east trade area. In summer South Africa, from Cape Town to the Zambezi, comes entirely under the influence of the south-east trade winds; but in winter the southern portion of

Cape Colony is subject to another type of weather, due to the passage of storms from the South Atlantic, the "roaring forties" of mariners. It is necessary very carefully to distinguish between these two weather systems. In the one the storms bring winter rains to a small part of the subcontinent, *i.e.* Cape Town and the south-west; in the other the storms precipitate the abundant moisture brought by the trade winds from the Indian Ocean, more or less over the whole subcontinent.

This much of explanation is necessary in order to understand clearly the connection between the weather of India and that of South Africa. In studying this connection we have at the outset to eliminate the winter weather of the south-west with its winter rains coming from the South Atlantic.

Sir John Eliot, in his reply to Mr. Sutton, very properly excludes the area of winter rains. I go further, and exclude what Mr. Sutton has termed the area of spring and autumn rains. The latter are areas where, with the winter storms still prevailing and the summer south-easters coming in from the Indian Ocean, there is the most marked precipitation in spring and autumn. We are not in a position to say how far these rains have been produced by the tail-end of the retreating Atlantic storms or by the head of the advancing humid south-east trade currents. The fertile country watered directly by the south-east trade is comprised in sections x. to xv. of Mr. Sutton's rainfall areas, viz. the east of Cape Colony, Kaffraria, Basutoland, the Orange River Colony and Natal, and, in addition, all the Transvaal, Rhodesia, and the Portuguese territory; in fact, it is the whole of fertile South Africa with the exception of the southern and south-west coasts. In the table below I give the mean of Mr. Sutton's figures for his sections x. to xv., comprising Eastern Cape Colony, Transkei, Basutoland, Orangia, and Natal, and I add the yearly rainfall from typical stations in the Transvaal and Rhodesia, as correct general average figures for these territories are not available.

Percentages of Rainfall in the Summer Rainfall Areas, 1891 to 1902: Mean of Sutton's Sections x. to xv.

	1891	1892	1893	1894	1895	1896	1897	1898	1899	1900	1901	1902
Per cent.	136	106	132	97	103	102	74	107	89	82	98	93

And correcting Sir John Eliot's table to purely summer rainfalls it will read thus:—

Period of general excess of rain.

Year.	Percentage variation Summer rainfall. India	S. Africa.
1892	12	+ 6
1893	22	+ 32
1894	16	− 3

Period of general deficiency of rain.

Year.	Percentage variation Summer rainfall. India	S. Africa.
1895	− 5	+ 3
1896 (famine)	− 12	+ 2
1897	normal	− 26
1898	1	+ 7
1899 (famine)	− 27	− 11
1900	− 1	− 18
1901	− 10	− 2
1902	− 5	− 7

These figures show more strikingly than those already quoted by Sir John Eliot the intimate connection between the rainfall of India and South Africa during the period 1892 to 1902, and the connection would have shown better if seasonal instead of calendar years had been taken, since the calendar year cuts into two unequal portions the South African summer rainfall. It will be noted that each Indian famine year has been followed by one or two particularly bad years of drought in South Africa.

It is a somewhat remarkable coincidence that, while the number of Nature containing this discussion was on the sea on its way to the Cape, I prepared my yearly forecast of South African weather, and in that took occasion to point out the very close connection of the two rainfalls during this period. I may perhaps crave your indulgence to reproduce it, since it confirms so singularly Sir John Eliot's view. Speaking of certain typical stations I said:—

"Sir John Eliot's paper shows that 1892, 1893, and 1894 were years of good rainfall in India. These were the last years of general good rainfall we had in South Africa. In 1895 the drought set in at most South African stations. Further, in this droughty period there were two years of bad famine, viz., 1896 and 1899. These two years of famine in India were the two worst years of drought at many typical South African stations. At present we are not in a position to obtain average figures for the whole of South Africa, but nearly the same purpose will be served by taking certain typical stations thus:

"At Bulawayo (Hope Fountain), in 1890–1, there was the heaviest rain on record, viz., 45 inches; all the following years have been years of drought except three years when the rainfall was barely above the average.

"At Johannesburg there were good rains in 1894, when there were good rains in India, fair rains in 1895, and then drought, when there was drought in India. 1896 (one of the Indian famine years) was the worst year of drought in Johannesburg. The great Indian famine of 1899 was represented by a bad drought 1898–9 preceding the failure of the Indian monsoon by four months. . . .

"Natal rainfalls correspond closely with the Indian rainfalls. While 1899 was the worst famine for many years in India, 1899 and 1900 were the two worst years of drought ever experienced at Durban, in Natal, since meteorological observations were begun there in 1866. In 1900, the Durban rainfall was only 27 inches against an average of 41 inches. At Maritzburg, representing the inland Natal districts, 1899 was also a year of drought, but the greatest deficiency was registered the following year (probably chiefly due to the calendar year dividing the seasonal year).

"Again, at Grahamstown, Cape Colony, in 1899 there was under 20 inches against an average of 29 inches; at King William's Town in 1899, only 16 inches against an average of 25 inches; while at Graaff-Reinet in 1899 there was only 9 inches against an average of 15 inches. At all these South African stations, 1899, the great Indian famine year, was the worst year of drought in recent times!"

The rainfall curves for Umtata, Evelyn Valley, and Katberg show similar features, viz., severe South African droughts corresponding to the years of Indian famine, and a general deficiency of rainfall corresponding with the years of general deficiency of Indian rainfall. The rainfall curve of Evelyn Valley (Fig. 1), however, is very remarkable. This is a forest station, and the observer a particularly good one. I have elsewhere compared this station to Cherapunji, in India. I founded this station in 1887, and it has since shown the heaviest rainfall on the summer register. It lies in a *cul de sac* of the mountains facing the south-east at an elevation of 4200 feet. I have long regarded it as the typical southern station for the summer rainfalls. A study of its yearly rainfall curve shows how rain failed here in the most striking manner previous to the Indian famine of 1896, and during and after the Indian famine of 1899.

With regard to Mr. Sutton's statement that there has been no severe drought during recent years in South Africa, there is abundant evidence to the contrary.

A year ago I wrote: "In the Karoo the present drought is considered the worst during the last half-century. At Hanover (Upper Karoo) during nearly a year there has fallen only three-quarters of an inch, the normal yearly rainfall being 15 inches. The drought has lasted on and off since 1896–8, and during the worst years cattle and sheep have perished in millions. In British Central Africa the drought has lasted since about 1898; it is reported that the Shiré Lake is now nearly dry. Last summer's crops in the Transvaal, so sorely needed after the war, were a complete failure, while in Natal, Rhodesia, and the country to the north there was in many places famine, and people dying in places too remote to be reached by Government aid.

"When will the drought end? is now the great question for the country.

"Good rains have fallen recently all down the eastern side and on the south coast of South Africa. This rain has come as a precious mitigation of the drought. It may be looked on as a favourable indication for a good season —perhaps more favourable if it had come later.

"The local and other indications of an early ending of the drought are favourable. It has definitely broken up in Australia." (Weather forecast, dated November 23, 1903.)

Writing a year later, November 23rd, 1904, I said: "My weather forecast for last year (published in the *Cape Times* of November 23, 1903) indicated the expectation of a more or less complete break-up of the drought. This forecast has been fulfilled. In many parts of South Africa, particularly towards the north, the drought has broken, and good seasons were experienced last year. In other parts the rains were insufficient to really break the drought. This was the case in the fertile 'conquered territory' of Orangia, and over wide areas in Cape Colony. In the Transkei drought remains unbroken. It is described as a drought of terrible severity, and one that has stopped all ploughing and killed from 50 to 60 per cent. of the sheep in some of the districts. As was remarked by a correspondent in the *Cape Times* a few days since,

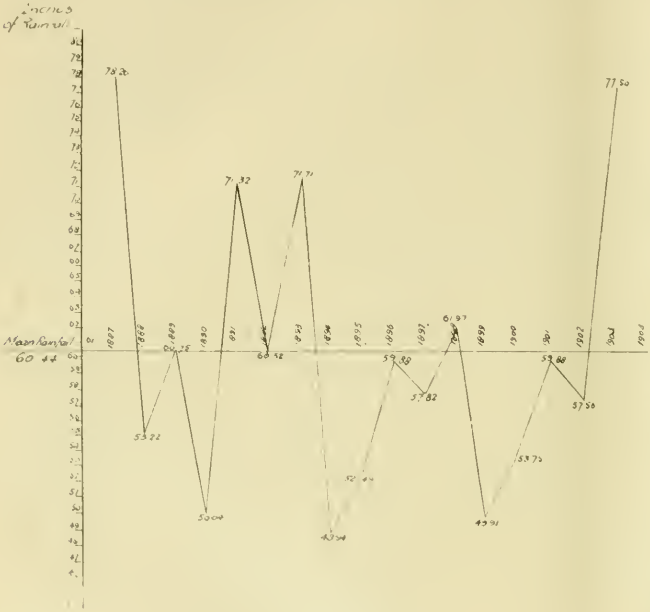

FIG. 1.—Rainfall, Evelyn Valley.

'No one not living here has any idea of the terrible condition existing in the Karoo and Eastern Province. The springs on most of the farms have utterly disappeared. On one farm in the Cradock district with large lands, orchards, and a water-mill at the junction of two kloofs in the Sneeuwberg, the river beds are as dry as a street; the farmer has sold all his stock, and I actually saw the water for household use brought some distance in a barrel. In former years the water-mill was in constant use for all the surrounding country.' "

Writing to me recently from Zomba, in British Central Africa, Mr. Clounie, the head of the scientific department, speaking of last summer's rains, says: "The wet season from November to April last has been remarkably good, and crops everywhere have been excellent. I think everything points to the end of the drought and a return to a period of good rains."

As regards the drought further north, the reader may turn to NATURE of November 3, 1904 (p. 15). I produce the extract for ready reference:—

"Appendix iii. of a report upon the basin of the Upper Nile, with proposals for the improvement of the river by Sir William Garstin, contains an interesting account of the variations of level of Lake Victoria Nyanza contributed by Captain H. G. Lyons, the director of the Survey Department of Egypt. This lake has a water surface of about 68,000 square kilometres, and is situated about 1129 metres above sea-level. It is believed to be of shallow depth, and lies for the most part of the year in the region of the equatorial rain and cloud belt, the excess water draining off at the Ripon Falls by the Victoria Nile. After reference to the geology and climate of the region, a brief historical summary is given of the early lake levels as observed by travellers and others visiting or residing by it; this is followed by a detailed study and discussion of the various gauges. Some of the results obtained are as follows:—The annual oscillation of the lake is from 0·30 metre to 0·90 metre. Between 1896 and 1902 there was a fall of 70cm. in the average level, since followed by a rise of 56cm. The epochs of high and low levels are given as:—1878, high level; 1880–90, falling level; 1892–5, temporary high level; 1896–1902, falling level; 1903, rising level."

The kernel of this quotation lies in the last six words: it shows the same correspondence with the Indian rainfall figures as the summer rainfall figures of South Africa.

Cape Town, December 8.

Compulsory Greek at Cambridge.

SOME years ago a young lady who was studying at Girton came to Bristol to spend a part of her first vacation after passing the "Little-go." She had never learnt Greek at school, but had been coached by an elder brother, who was at that time in residence at Cambridge; in about two months she obtained a knowledge of Greek sufficient to meet the requirements of the authorities at Cambridge.

While she was with us we paid a visit to the neighbouring city of Bath, and I directed her attention to the motto which is inscribed on the Roman baths there, viz.:

ἄριστον μὲν ὕδωρ.

Remembering her recent success in the "Little-go," I jokingly asked her the meaning of this inscription—not imagining for a moment that Cambridge compulsory Greek would be unequal to such an easy task; she was, however, unable to give the meaning of the words; she did not think she had ever seen ἄριστον, but was of opinion that she had in the course of her reading met the word ὕδωρ, but did not remember what it meant.

It may be well to add that the lady in question has great linguistic ability, and in due course obtained a good place in the Modern Languages Tripos.

Do our ultra-classical friends really think that compulsory "Greek" of this type is worth preserving?

J. WERTHEIMER.

Merchant Venturers' Technical College, Bristol, January 30.

NOTES ON STONEHENGE.[1]

II.—ARCHÆOLOGICAL OBSERVATIONS AT STONEHENGE, 1901.

SOON after Mr. Penrose and myself had made our astronomical survey of Stonehenge in 1901, some archæological results of the highest importance were obtained by Prof. Gowland. The operations which secured them were designed and carried out in order to re-erect the leaning stone which threatened to fall, a piece of work recommended to Sir Edmund Antrobus by the Society of Antiquaries and other learned bodies, and conducted at his desire and expense.

They were necessarily on a large scale, for the great monolith, "the leaning stone," is the largest in England, Cleopatra's Needle excepted. It stood behind the altar stone, over which it leant at an angle of 65 degrees, resting at one point against a small stone of syenite. Half-way up it had a fracture one-third across it; the weight of stone above this fracture was a dangerous strain on it, so that both powerful machinery and great care and precautions had to be used. Prof. Gowland was charged by the Society of Antiquaries with the conduct of the excavations necessary in the work. The engineering operations were planned by Mr. Carruthers, and Mr. Detmar Blow was responsible for the local superintendence. Mr. Blow thus describes the arrangements (*Journal* Institute of British Architects, 3rd series, ix., January, 1902):—

"A strong cradle of 12-inch square baulks of timber was bolted round the stone, with packing and felt, to prevent any marking of the stone. To the cradle were fixed two 1-inch steel eyebolts to receive the blocks for two six-folds of 6-inch ropes. These were secured and wound on to two strong winches fifty feet away, with four men at each winch. When the ropes were thoroughly tight, the first excavation was made as the stone was raised on its west side."

The method employed by Prof. Gowland in the excavation should be a model for all future work of the kind. I have to express my thanks to the council of the Society of Antiquaries and Prof. Gowland for permission to use the accompanying illustrations showing the operations and results.

Above each space to be excavated was placed a frame of wood, bearing on its long sides the letters A to H, and on its short sides the letters R M L, each letter being on a line one foot distant from the next. By this means the area to be excavated was divided into squares, each having the dimension of a square foot. A long rod divided into 6-inch spaces, numbered from 1 to 16, was also provided for indicating the depth from the datum line of anything found. In this way a letter on the long sides of the frames, together with one on the short sides, and a number on the vertical rod, indicated the position of any object found in any part of the excavation.

FIG. 4. The arrangements for raising the stone.

Excavations were necessary because to secure the stone for the future the whole of the adjacent soil had to be removed down to the rock level, so that it could be replaced by concrete.

All results were registered by Prof. Gowland in relation to a datum line 337·4 feet above sea level. The material was removed in buckets, and carefully sifted through a series of sieves 1-inch, ½-inch, ¼-inch, and ⅛-inch mesh, in order that the smallest object might not be overlooked.

From the exhaustive account of his work given by Prof. Gowland to the Society of Antiquaries (*Archaeologia*, lviii.), I gather three results of the highest importance from the point of view I am considering. These were, first, the finding of an enormous number of implements; secondly, the disposition and relative quantities of the chippings of the sarsen and blue stones; and thirdly, the discovery of the method by which the stones were originally erected.

I will take the implements first. This, in a con-

[1] Continued from p. 300.

densed form, is what Prof. Gowland says about them:—

More than a hundred flint implements were found, and the greater number occurred in the stratum of chalk rubble which either directly overlaid or was on a level with the bed rock. They may all be arranged generally in the following classes:—

Class I.—Axes roughly chipped and of rude forms, but having well-defined, more or less sharp cutting edges.

Class II.—Hammerstones, with more or less well-chipped, sharp curved edges. Most may be correctly termed hammer-axes.

Class III.—Hammerstones, more or less rounded. Some specimens appear to have once had distinct working edges, but they are now much blunted and battered by use.

In addition to the above flint implements were found about thirty hammerstones, consisting of large pebbles or small boulders of the hard quartzite variety of sarsen. Some have been roughly broken into convenient forms for holding in the hand, whilst a few have been rudely trimmed into more regular shapes. They vary in weight from about a pound up to six and a half pounds. To these we have to add mauls, a more remarkable kind of hammerstone than those just enumerated. Their weights range from about 40 lb. to 64 lb.

FIG. 5.—Some of the flint implements.

How came these flints and stones where they were found? Prof. Gowland gives an answer which everybody will accept. The implements must be regarded as the discarded tools of the builders of Stonehenge, dumped down into the holes as they became unfit for use, and, in fact, used to pack the monoliths as they were erected. We read:—"Dealing with the cavity occupied by No. 55 before its fall, the mauls were found wedged in below the front of its base to act together with the large blocks of sarsen as supports (p. 54)." Nearly all bear evidence of extremely rough usage, their edges being jagged and broken, just as we should expect to find after such rough employment. We evidently have to deal with builders doing their work in the Stone and not in the Bronze age. But was the age Palæolithic or Neolithic?

Prof. Gowland writes:—

"Perhaps the most striking features of the flint implements is their extreme rudeness, and that there is not a single ground or polished specimen among them. This, at first sight and without due consideration, might be taken to indicate an extremely remote age. But in this connection it must be borne in mind that in the building of such a stupendous structure as Stonehenge, the tools required must have been numbered by thousands. The work, too, was of the roughest character, and for such only rude tools were required. The highly finished and polished implements which we are accustomed to consider, and rightly so, as characteristic of Neolithic man, would find no place in such work. They required too much labour and time for their manufacture, and, when made, could not have been more effective than the hammer-axes and hammerstones found in the excavations, which could be so easily fashioned by merely rudely shaping the natural flints, with which the district abounds, by a few well directed blows of a sarsen pebble."

On this ground Prof. Gowland is of opinion that, notwithstanding their rudeness, they may be legitimately ascribed to the Neolithic age, and, it may be, near its termination, that is, before the Bronze age, the commencement of which has been placed at 1400 B.C. by Sir John Evans for Britain, though he is inclined to think that estimate too low, and 2000 B.C. by Montelius for Italy.

Prof. Gowland guardedly writes:—

"In my opinion, the date when copper or bronze was first known in Britain is a very remote one, as no country in the world presented greater facilities for their discovery. The beginning of their application to practical uses should, I think, be placed at least as far back as 1800 B.C., and that date I am inclined to give, until further evidence is forthcoming, as the approximate date of the erection of Stonehenge."

Now the date arrived at by Mr. Penrose and myself on astronomical grounds was about 1700 B.C. It is not a little remarkable that independent astronomical and archæological inquiries conducted in the same year should have come so nearly to the same conclusion. If a general agreement be arrived at regarding it, we have a firm basis for the study of other similar ancient monuments in this country.

I have previously in these "Notes" referred to the fact that the trilithons of the naos and of the outer circle are all built up of so-called "sarsen" stones. To describe their geological character, I cannot do better than quote, from Mr. Cunnington's "Geology of Stonehenge,"[1] their origin according to Prestwich:—

"Among the *Lower Tertiaries* (the Eocene of Sir Charles Lyell), are certain sands and mottled clays, named by Mr. Prestwich the Woolwich and Reading beds, from their being largely developed at these places, and from these he proves the sarsens to have been derived; although they are seldom found *in situ*, owing to the destruction of the stratum to which they belonged.

"The abundance of these remains, especially in some of the valleys of North Wilts, is very remarkable. Few persons who have not seen them can form an adequate idea of the extraordinary scene presented to the eye of the spectator, who, standing on the brow of one of the hills near Clatford, sees stretching for miles before him, countless numbers of these enormous stones, occupying the middle of the valley, and winding like a mighty stream towards the south."

These stones, then, may be regarded as closely associated with the local geology.

The exact nature of the stones, called "blue stones," can best be gathered from a valuable "Note" by Prof. Judd which accompanies Prof. Gowland's paper. These blue stones are entirely unconnected with the local geology; they must, therefore, represent boulders of the Glacial drift, or they must have been brought by man, from distant localities. Prof. Judd inclines to the first opinion.

The distinctions between these two kinds of stone are well shown by Prof. Gowland:—

"The large monoliths of the outer circle, and the trilithons of the horse-shoe are all sarsens—sandstones, consisting of quartz-sand, either fine or coarse, occasionally mixed with pebbles and angular bits of flint, all more or less firmly cemented together with silica. They range in structure from a granular rock resembling loaf sugar in internal appearance to one of great compactness similar to quartzite."

"The monoliths and trilithons all consist of the granular rock. The examples of the compact quartzite variety were, almost without exception, either hammerstones that had been used in shaping and dressing the monoliths, or fragments which had been broken from off them."

"The small monoliths, the so-called 'blue stones,' which form the inner circle and the inner horseshoe, are, with the undermentioned exceptions, all of diabase more or less porphyritic. Two are porphyrite (formerly known as felstone or hornstone). Two are argillaceous sandstone."

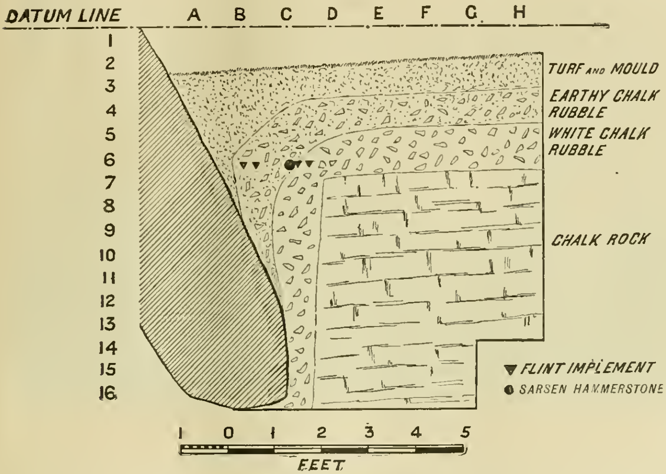

Fig. 6.—Face of rock against which a stone was made to rest.

"Mr. William Cunnington, in his valuable paper, 'Stonehenge Notes,' records the discovery of two stumps of 'blue stones' now covered by the turf. One of these lies in the inner horseshoe between Nos. 61 and 62, and 9 feet distant from the latter. It is diabase. The other is in the inner circle between Nos. 32 and 33, 10 feet from the former, and consists of a soft calcareous altered tuff, afterwards designated for the sake of brevity fissile rock.

The altar stone is of micaceous sandstone."

I now come to the second point, to which I shall return in subsequent "Notes."

In studying the material obtained from the excavations, it was found in almost every case that the number of chippings and fragments of blue stone largely exceeded that of the sarsens; more than this, diabase (blue stone) and sarsen were found together in the layer overlying the solid chalk (p. 15). Chippings of diabase were the most abundant, but there were few large pieces of it. Sarsen, on the other hand, occurred most abundantly in lumps (p. 20); very few small chips of sarsen were found (p. 42). Hence Prof. Gowland is of opinion that the sarsen blocks were roughly hewn where they were found (p. 40); the local tooling, executed with the small quartzite hammers and mauls, would produce dust.

Finally, I reach the third point of importance from the present standpoint; the excavations produced clear evidence touching the mode of erection. Prof. Gowland's memoir deals only with the leaning stone, but I take it for granted that the same method was employed throughout. This method was this:—

(1) The ground on the site it was to occupy was removed, the chalk rock being cut into in such a

[1] *Wilts Archaeological and Natural History Magazine*, xxi. pp. 141–149.

manner as to leave a ledge, on which the base of the stone was to rest, *and a perpendicular face rising from it, against which as a buttress* one side would bear when set up. From the bottom of this hole an inclined plane was cut to the surface, down which the monolith which had already been dressed was slid until its base rested on the ledge.

(2) It was then gradually raised into a vertical position by means first of levers and afterwards of a ropes. The levers would be long trunks of trees, to one end of which a number of ropes were attached (this method is still employed in Japan), so that the weights and pulling force of many men might be exerted on them. The stronger ropes were probably of hide or hair, but others of straw, or of withes of hazel or willow, may have been in use for minor purposes.

(3) As the stone was raised, it was packed up with logs of timber and probably also with blocks of stone placed beneath it.

(4) After its upper end had reached a certain elevation, ropes were attached to it, and it was then hauled by numerous men into a vertical position, *so that its back rested against the perpendicular face of the chalk which had been prepared for it.* During this part of the operation, struts of timber would probably be placed against its sides to guard against slip.

As regards the raising of the lintels, and imposts, and the placing of them on the tops of the uprights, there would be even less difficulty than in the erection of the uprights themselves.

It could be easily effected by the simple method practised in Japan for placing heavy blocks of stone in position. The stone, when lying on the ground, would be raised a little at one end by means of long wooden levers. A packing of logs would then be placed under the end so raised, the other extremity of the stone would be similarly raised and packed, and the raising and packing at alternate ends would be continued until the block had gradually reached the height of the uprights. It would then be simply pushed forward by levers until it rested upon them.

I shall deal later on with several interesting conclusions to which these investigations lead.

NORMAN LOCKYER.

FIG. 7.—The present aspect of the monument with the leaning stone raised.

GEOLOGY OF THE MOON.

FOR many years past geologists have turned wistfully to the moon in the hope of gaining from a study of its surface some insight into planetary evolution, and more especially into some of the stages in the history of our own globe. It must be confessed, however, that as yet few satisfactory data have been obtained, either in the facts observed or in the deductions drawn from them. The great majority of those who have studied the subject have formed the opinion that our satellite was once a liquid mass, such as we believe the earth itself to have also been, and that its so-called "craters" represent extensive and prolonged volcanic activity, when the gases and lava of the heated interior escaped to the surface, probably on a scale of magnitude greatly surpassing that on which subterranean energy has ever been manifested in the geological history of our planet. But another explanation has been proposed for these lunar features, according to which, as worked out by Mr. G. K. Gilbert, of the United States Geological Survey, the moon was formed by the aggregation of a ring of meteorites which once encircled the earth, and the "craters," instead of arising from the escape of volcanic energy from within, were produced by the impact of the last meteoric bodies that fell from without. These bodies, arriving with planetary velocity, would be melted or reduced to gas, while a portion of the lunar surface around them would also be liquefied. Mr. Gilbert believes that the lunar topography bears witness to such a meteoritic bombardment rather than to gigantic volcanic explosions.

The latest contribution to the discussion was recently presented to the Academy of Sciences of Paris by MM. Lœwy and Puiseux. These eminent astronomers direct attention to the evidence furnished by the latest photographic charts of the "Atlas Lunaire" in regard to the conditions in which a planetary body passes from the liquid to the solid state, and to the stage in this transformation which has been reached respectively by the earth and the moon.

With respect to the evolution of the earth two opposite theories have been propounded. The great body of geologists have maintained that the interior of the planet is an incandescent mass which is slowly cooling and consolidating from the surface inward, and is enclosed within a comparatively thin solid crust. Some distinguished physicists, however, have contended that the first formed crust would break up, sink down, and be re-melted; and thus that permanent consolidation would begin at the centre, and would gradually extend outwards, until eventually the whole globe became practically solid, with only here and there large vesicular spaces whence active volcanoes are supplied. The densest and least fusible materials would thus tend to accumulate towards the centre, and the lightest and most fusible towards the outside. The geological belief rests upon a large body of evidence from the structure of the terrestrial crust, which it is difficult or impossible to explain except on the supposition of an internal mass which at least in its outer parts is sufficiently liquid to emerge at the surface as molten lava. The physical argument rests on certain mathematical assumptions the validity of which has been contested. One of these assumptions is that if the interior were liquid, tides would be set up in its mass, and the crust would rise and fall with the passage of the internal tidal wave. Another objection is based on the supposition that huge mountain-chains could not possibly be supported by a thin crust, but would sink down into the interior. More recently the idea has been suggested that the internal core of the earth is gaseous. At the high temperatures and enormous pressures in the interior of the planet, gaseous iron or lava must be more incompressible than steel is at the surface. On the outside of this gaseous mass it is believed that the materials pass into the liquid form or magma which extends as a comparatively thin envelope round the gaseous core, and shades off outward into a solid crust which may not be more than twenty-five or thirty miles in thickness. The most recent earthquake observations have been quoted in support of this view.

Messrs. Lœwy and Puiseux approach the subject impartially from a study of the phenomena presented by the surface of the moon as recorded in a series of photographs. They accept the general belief that our satellite was once a liquid globe, and that traces of its passage from that condition to its present state of consolidation can be clearly recognised. They cannot say whether its temperature increases with depth from the surface, or if there is any variation in density, but they find in their photographs various particulars which, in their opinion, show that the solidification started from the surface.

The differences of level on the surface of the moon are relatively greater and more abrupt than those on the surface of the earth, and they display in many ways the dynamic effects which a liquid when in movement exerts on its solid containing walls, such as the superficial outpourings which have covered two-fifths of the visible lunar surface and have turned these tracts into continuous plains, round the margins of which numerous remains of the previous relief have been left. Other effects are seen in the traces of instability in the mountain ranges, the fractures, sharply-defined terraces and marginal fissures so often observable. The neighbourhood of a great sheet of liquid material is required to account for the undulations and horizontal displacements which have affected large tracts of the surface, such as the breaking down of the crest of the Apennines, the separation of the rectangular blocks of the Caucasus, and the formation of the rectilinear valleys of Rheita, the Alps, and Ariadæus.

The most decisive argument in favour of the gradual cooling of the moon from the outside towards the interior appears to be furnished by some facts which are brought out with great clearness by the recent photographs. Thus the two French astronomers have satisfied themselves that after the first establishment of a thin crust the inward retreat of the liquid took place gradually, until the fatal moment arrived when it partly lost connection with the overlying solidified crust, so that an intermediate vacant space was left between them. This temporary interval, being filled with gas at a high pressure, formed a cushion which was sufficiently elastic to prevent any falling-in, but was too limited in extent to affect isostatic compensations, so that the internal tides might be developed without endangering the external figure of the moon. When, for some unknown reason, as happens also on our globe, the lunar eruptive forces assumed special vigour, the crust, yielding to the pressures along its least resisting parts, was overflowed by the liquid interior. Such local subsidences gave rise to the great cirques and various other features in the polar region, where the cooling was most rapid, and where, for easily intelligible reasons, the crust reached a considerably greater thickness. But in the equatorial zone, where the tides and the centrifugal force are most powerful, these violent perturbations led to vast subsidences which now form the lunar "seas." The survival of remains of the earlier topographical relief, still visible along the borders of these tracts, bears witness to the nature of the gigantic changes. Each eruptive movement has marked, by the level bottom of the formations, the height of the level of the subjacent liquid. Five such stages in the subsidence of the molten matter are displayed in the photographs. We can understand that the process would be repeated with diminishing energy until the gradually thickening crust presented too great an obstacle to the eruptive action. Various striking examples are cited by the authors; in particular one where the five platforms are separated from each other by a step-like interval of several thousand metres. Had the consolidation begun at the centre of the moon, it is contended, the result would have been altogether different, for then only the latest level should have been seen, and the eruptive forces would have had neither an opportunity of manifesting themselves nor the means of leaving permanent traces at very different stages.

MM. Lœwy and Puiseux examine the argument from the tides in favour of the consolidation of a planet from the centre outwards, and remark that it must be considered as doubtful, because we do not know how far the coefficient of viscosity or internal friction, which has been employed in the calculations, agrees with the reality. They suggest that as the materials in the interior are under enormous pressure they may quite possibly have such viscosity, and yield so slowly to planetary influences, which are continually changing in direction in consequence of the diurnal movement, that no appreciable tidal deformation may result. In the case of the moon it is admitted that the tides in the still liquid mass would for a long time delay the formation of an outer crust, which before its final establishment must have undergone many violent disruptions, when its broken-up sheets were overflowed by the molten matter from within. But in the course of time it has ended by attaining a great thickness in consequence of continual cooling and the contraction of the outer layers.

The argument that on the supposition of a comparatively thin crust the existence of mountainous masses would be impossible is less applicable to the moon, where the force of gravity is six times less than on the earth. But in the opinion of the two French astronomers the argument need not be seriously considered, either for our planet or for our satellite, inasmuch as it depends on a problematic theory which is entirely based on an inaccurate hypothesis of homogeneity. Mountainous excrescences, so far from weakening the general stability, really conduce to it; they are not only held up by the tenacity of the neighbouring parts, but, as Airy suggested, they probably have roots which plunge down into material of greater density and permit them to float.

The authors affirm, in conclusion, that their detailed study of the moon appears to them to confirm geologists in their preference for the theory of a thin crust and to indicate that the transition to solidity, still incomplete for the moon, is far from having reached its end upon the earth. ARCH. GEIKIE.

NOTES.

WE regret to announce that Prof. G. B. Howes, F.R.S., died on Saturday last, February 4, at fifty-one years of age.

IT is proposed to erect a monument at Laibach, in Austria, to the memory of Vega, author of the well-known table of logarithms, which is now in its eightieth edition.

FROM the American Mathematical *Bulletin* for January we learn of the death of Dr. Francesco Chizzoni, professor of geometry at Modena, and of Prof. Achsah M. Ely (Miss Ely), head of the department of mathematics at Vassar College, U.S.A.

THE Wilde medal of the Manchester Literary and Philosophical Society has been awarded to Prof. C. Lapworth, F.R.S. The medal will be presented on February 28, when the Wilde lecture of the society will be delivered by Dr. D. H. Scott, F.R.S., on "The Early History of Seed-bearing Plants, as recorded in the Carboniferous Flora."

FOR the past year, a station for solar research has been maintained on Mount Wilson, California, by the Yerkes Observatory, with the aid of a grant from the Carnegie Institution of Washington. This station has now been replaced by a new solar observatory which has been established by the Carnegie Institution, and the following staff, formerly of the Yerkes Observatory, has been appointed:—Prof. G. E. Hale (director), Prof. G. W. Ritchey, Mr. F. Ellerman, and Mr. W. S. Adams.

PROF. VALDEMAR STEIN, leader of a well known Copenhagen analytical and chemical laboratory, where for a number of years official and private tests and investigations in Denmark have taken place, died on February 1, aged 69 years. He took over in 1863 the laboratory founded by H. C. Örsted and altered it to its present shape, making it a valuable public institution. Beside his work there Stein was Government adviser in chemical agriculture, and wrote many scientific articles on chemical and agricultural subjects.

THE Imperial Academy of Sciences, St. Petersburg, at the last annual meeting, awarded the Lomonosoff prize of 100*l.* to Prof. N. A. Menschutkin for his well-known and extensive researches in the domain of theoretical chemistry. The Ivanoff prize was awarded to Prof. P. N. Lebedeff, of Moscow, for his remarkable experimental researches on the pressure of light. At the same meeting, Prof. S. Th. Oldenburg declared, in his yearly review of the work of the academy, that the Polar Committee had given up all hope of the return of Baron Edward Toll, F. G. Seeberg, and their two companions. The party was probably lost during the Arctic night while trying to cross the ice-fields lying between Bennett Island and the New Siberian archipelago.

A NATIONAL exhibition of brewing materials and products will be held in Paris during March, 1906.

AT the meeting of the French Physical Society on January 20, under the presidency of M. d'Arsonval, the following officers were elected:—Vice-president, M. Amagat; general secretary, M. Henri Abraham; treasurer, M. de la Touanne. The office of president falls on M. Dufet.

THE *Times* correspondent at Colombo states that Sir H. A. Blake, Governor of Ceylon, announced at the last meeting of the Asiatic Society that Sinhalese medical books of the sixth century described 67 varieties of mosquitoes and 424 kinds of malarial fever caused by mosquitoes.

AT the meeting of the Anthropological Institute to be held on Tuesday next, February 14, Dr. A. C. Haddon, F.R.S., will exhibit a series of kinematograph pictures of native dances from the Torres Straits, taken by him when in New Guinea. Applications for admission should be addressed to the Secretary of the Institute at 3 Hanover-square, W.

A LARGE and influential international committee has been formed in Heidelberg, under the presidency of His Excellency Dr. A. Freiherr von Dusch, Minister of Education, &c., of the Grand Duchy of Baden, with the object of honouring the memory of the late Prof. Carl Gegenbaur, who for nearly thirty years was the director of the Anatomical Institute of Heidelberg. The committee has decided upon a life-size bust of Gegenbaur, to be executed in marble by Prof. C. Seffner, Leipzig. The bust will be placed in the vestibule of the Anatomical Institute, probably in the early summer, at a date not yet fixed. The committee invites former pupils of the deceased master, and all those who have benefited from his epoch-making works on human and comparative anatomy, to send monetary contributions, with their addresses and titles, to Prof. M. Fuerbringer, or to Prof. E. Goeppert, both in Heidelberg. Every contributor will receive a picture of the bust, and casts may be obtained, on special application, from Prof. C. Seffner.

AFTER an interval of two years the fifth conference of West Indian agriculturists was held at Port-of-Spain, Trinidad, from January 4 to 13. It was attended by official, scientific, commercial, and practical representatives from all parts. In his presidential address, Sir Daniel Morris gave an interesting survey of the great economic change which is in progress. Taken in the aggregate, sugar cultivation must still be regarded as the backbone of the colonial industries, but in some of the islands it has already become of comparatively little or no importance. Trinidad is now a cacao-producing island, its exports of this commodity having risen to the value of a million sterling per annum. Grenada's cacao exports are valued at 250,000*l.*, and Jamaica's at 80,000*l.* Cotton growing, too, has been successfully re-established in several islands, and remunerative prices for the raw cotton are being obtained from Lancashire merchants. The exportations of fruit far exceed in value those of the staple industry. The development of the tobacco, rubber, sisal hemp, fish-curing, and other industries also came under review, and Sir Daniel dwelt upon the importance of agricultural shows and on the provision made by his department for teaching elementary science and the principles of agriculture in the various colleges and elementary schools. Numerous papers were read and discussed, Prof. d'Albuquerque, Dr. Watts, Prof. Harrison, and others supplying valuable information relating to sugar; Mr. Hart, Mr. de Gannes, &c., on cacao; Mr. Bovell, Mr. Sands, &c., on cotton; and so on.

For practical purposes visits were paid to several cacao and sugar estates. Owing to its more than usually representative character the conference is declared to have been the most successful of the series.

THE very high barometric readings over the British Isles during the latter part of January last are noteworthy. The weather report for the week ending January 28 issued by the Meteorological Office stated that on Wednesday (25) the eastern edge of an anticyclone had appeared over the west of Ireland; this system, moving slowly eastward, and continually increasing in intensity, covered the whole kingdom by Thursday, its maximum pressure being about 30·7 inches. It subsequently moved southward and south-westward, and continued to increase in energy until Saturday (28), when the barometer rose to 31 inches or more over the south-western parts of the United Kingdom. The highest reading was reported from Scilly, at 2h. p.m. on January 28, 31·06 inches, and appears to have been the highest on record for that part of the kingdom. Very high readings also occurred over the eastern portion of the North Atlantic. Recent cases of very high readings occurred in January, 1902, January, 1896, and January, 1882. The highest reading on record in the British Isles is 31·11 inches at Ochtertyne (Scotland), in January, 1896, and the lowest 27·33 inches at the same place, in January, 1887. It will be observed that all these extreme readings have occurred in the month of January.

WE have to acknowledge the receipt of a copy of the *Transactions* of the Hull Scientific and Field Naturalists' Club for 1904 (vol. iii. part ii.). The most important item in its contents is a list, with references, of the land and freshwater molluscs of the East Riding, drawn up by Mr. T. Petch, occupying fifty-two pages.

THE salmon and trout of Japan form the subject of an article by Mr. T. Kitahara in vol. v. part iii. of *Annotationes Zoologicae Japonensis*. In place of the nine species of these fishes admitted by Messrs. Jordan and Evermann, the author recognises only seven from Japanese waters, of which the majority belong to Oncorhynchus.

THE contents of the *Biologisches Centralblatt* for January 15 include an article on the structure of certain ants' nests, by Mr. C. Ernst, and a criticism, by Dr. C. Schröder, of Mr. C. Schaposchnikow's theory of the colouring of the hind-wing of the butterflies of the genus Catocala, to which allusion has been already made in our columns.

THE *Zoologist* commences the year well with an excellent article on budding in animals by Prof. McIntosh, of St. Andrews, in which the various forms of propagation by gemmation are described in a clear and popular manner. In the same issue appears Mr. Southwell's account of sealing and whaling for 1904. Eleven right whales were captured during the season by British vessels and at British stations; but the Americans are reported to have taken no less than forty-nine. The price demanded for sizable whalebone is 2500*l*. per ton. Fin-whale hunting is being pursued with great energy, and as the demand for the products of these whales is limited, the author suggests that the market may be glutted.

THE *Nature Study Review* is the title of a journal published in New York of which the first volume is before us. "The aims and plans of the editorial committee," it is stated in the introduction, "are based upon an interpretation of nature-study in its literal and widest sense as including all phases, physical as well as biological, of studies of natural objects and processes in elementary schools." Several eminent writers have united to give their views as to the scope and limitations of nature-study; while others have done their best to refute hostile criticism of the movement. "Faddism," the bane of the movement, is strongly deprecated. In wishing the new venture a successful career, we may take the opportunity of recording our full sympathy with the effort to make scholars actually acquainted with natural objects, instead of attempting to learn about them through books alone. But the interpretation of the movement must be a liberal one, and it must be realised that a visit to a museum is just as much nature-study as is a saunter through a country lane.

THE double number of the *American Naturalist* for November and December last contains a suggestive article by Mr. W. D. Matthew on the arboreal ancestry of mammals. Strong arguments have been brought forward during the last few years by Mr. Dollo in Belgium and by Mr. Bensley in America to show that the ancestors of marsupials were probably arboreal; and in the present communication the author seeks to show that the same holds good for mammals in general. It is urged that the mammals of the Cretaceous were all of small size and mostly of a primitive type from which both marsupials and placentals might well have been derived. These early mammals were probably arboreal; and if so, the opposable thumb and hallux of certain living types is an archaic and not an acquired feature. Support to the view as to the arboreal habits of the ancestral mammals is afforded by the Upper Cretaceous upland flora, which first permitted the existence of an extensive terrestrial land mammalian fauna. If the theory be true, it entirely upsets the old idea that arboreal mammals had taken to their distinctive mode of life to escape persecution on the ground.

WE have received a copy of an important memoir by Dr. O. Abel, published in the *Abhandlungen* of the Austrian Geological Survey (vol. xix. part ii.), on the fossil sirenians of the Mediterranean formation of Austria, into the merits of which the limitations of space do not admit of our entering so fully as we desire. The title of the memoir scarcely does justice to its contents, for although the prime object is the description of the species known as *Metaxytherium krahuletzi*, the author also describes a number of remains of the much more primitive genus Eotherium, from the Eocene of the Mokattam Range, near Cairo. The most important feature connected with the latter (if the remains be rightly identified) is the discovery that Eotherium possessed a complete pelvis, showing a well-marked obturator foramen. In this respect the genus differs from all other known members of the order, and is thus brought into connection with less specialised mammals. The three Egyptian Eocene genera Eotherium, Eosiren, and Protosiren (new) are regarded as the earliest known ancestors of the dugong group; and to these succeed Halitherium in the Oligocene, Metaxytherium in the Miocene, and Felsinotherium in the Pliocene. In seeking to illustrate the origin of the downward flexure of the muzzle of the dugong by a malformed horse skull, we think the author has been ill-advised, as there is a much simpler and more natural explanation of the feature. In connection with the memoir by Dr. Abel, we may refer to a paper on the pelvis of Steller's sea-cow (*Rhytina stelleri*) by Dr. L. von Lorenz, published in part iii. of vol. xix. of the *Abhandlungen* of the Vienna Geologisches Reichsanstalt. The description and figure of this rudimentary bone supplement Dr. Abel's account of sirenian osteology in general.

Dr. Strong, the director of the Biological Laboratory, Manila, has published a valuable experimental study of the subject of protective inoculation against Asiatic cholera (No. 16, Bureau of Government Laboratories, Manila). After detailing the various methods of producing experimentally immunity against the cholera microbe, he discusses the use of Haffkine's prophylactic, which has been extensively employed in India with encouraging results, but an objection to which is the marked reaction that follows the inoculation, causing the inoculated person to be somewhat ill for two or three days. To remove this objection, Dr. Strong has obtained a prophylactic fluid by suspending the cholera microbes obtained from agar cultures in sterile water, keeping this suspension at 60° C. for several hours, then incubating at 37° C. for three or four days, and finally filtering through a porous porcelain filter. The fluid so obtained (a product of the autolytic digestion of the cholera microbes) was found to produce a high immunity in animals against cholera, and when injected into man was found to be free from danger, and to produce practically no general or local disturbance.

In the *Victorian Naturalist* for November, 1904, it is mentioned that, at the October meeting of the Field Naturalists' Club in Melbourne, a number of collections of wild flowers were sent from State schools in the country, including some so far away as Hawkesdale. Dimboola, and Mansfield. These were of great interest to teachers and children from the schools in Melbourne, who were allowed to take away named specimens for study. Would it not be possible to include in one of the exhibitions, such as the Grand Horticultural Exhibition held last June in the gardens of the Royal Botanic Society, similar collections from country schools for the benefit of schools in the metropolis?

It is remarkable how many comparative experiments conducted in tropical countries, with some or all of the established rubber plants, have demonstrated the superiority of *Hevea brasiliensis*, the source of Para rubber. One of the latest accounts is that by Mr. W. H. Johnson, director of agriculture, Gold Coast, issued as one of the miscellaneous series of *Colonial Reports*. Experiments in the Botanic Gardens, Aburi, were unsuccessful with the West African vine, *Landolphia owariensis*, Ceara, *Manihot glaziovii*, Assam, *Ficus elastica*, and Central American rubber, *Castilloa elastica*; fairly satisfactory results were obtained with the indigenous *Funtumia elastica*, but Hevea excelled in quantity and quality of rubber, in its rate of growth, and has been remarkably free from insect and fungus pests.

There seems to be good reason to believe that exploration of the more remote parts of Eastern Asia will add very considerably to the number of botanical species already known. In vol. iv. of the *Records* of the Botanical Survey of India, Sir Joseph Hooker states that the number of species of Impatiens, the second largest genus of Indian flowering plants, recorded for India has increased from 124 to 200 in thirty years, and that many more may be expected from the less accessible districts of Burma, Nepal, and the Eastern Himalayas. In the hope of inducing forest officers or other officials in India to take up the collection, or better, the study of this genus, Sir Joseph Hooker is publishing in the *Records* an epitome of the known species, and he also directs attention to two points of interest, the anomalous structure of the flower, and the remarkable details of segregation of the species.

It is always of interest to note a distinct novelty in the photographic line, but in the new Lambex system of daylight loading and film and plate changing, which has been introduced by Messrs. R. and J. Beck, Ltd., in a new class of cameras called the Lambex cameras, we have quite a new invention. The makers have sent us for inspection one of these cameras with the so-called Lambex skeleton and its envelope. The method of exposing is most simple and ingenious, and is one that will no doubt find considerable favour among photographers. The skeleton, less than half an inch thick, is the name of the folded strip of paper with a tag attached at each fold; in each of the folds, twelve in number, a film or plate, of any description or make, is held by a flap at the top and two corner slots at the bottom, and an opaque card is attached to the front. This skeleton is contained in a double length opaque envelope, the unexposed films remaining in the lower portion, and the exposed films being pulled one by one into the upper portion by the attached tags. The lower portion of the envelope is provided with an opening to correspond to the size of the film through which the exposure is made, and surrounding this opening is a stiff projecting edge of card into which the envelope with its skeleton is slid into a frame in the camera. The makers claim many advantages for this system, such as daylight loading, any plates or films may be used, the skeletons can be recharged, no scratching of films, no mechanism, &c. The compactness of this system renders it applicable to both folding, pocket, and box cameras, and the makers have now prepared a series of well-made Lambex cameras, constructed in several forms and sizes, and fitted with their well-known lenses. Limitations of space prevent us from entering more into detail, but the handbook of instructions in the form of a neat pocket-book contains all the necessary information.

To the February number of the *Monthly Review*, Sir William Ramsay contributes an article having the title "What is an Element?" It contains a popular account of the changes introduced into conceptions of the nature of elements owing to the discovery of the inert gases of the atmosphere and of radium and the radio-active elements.

The remarkable power of aluminium to absorb completely the vapour of mercury even when highly diluted with air, and at the ordinary temperature, is the subject of a paper by N. Tarugi in the *Gazzetta* for January 14. This property is made the basis of an extremely delicate test for mercury, and of a preventive measure against poisoning by mercury vapour. A species of respirator has been patented in which the air that is inhaled is made to pass through a mass of finely divided aluminium; in this passage every trace of mercury is absorbed, the action being so complete that the dense vapours evolved by heated mercuric chloride may be breathed with impunity. The respirator has already been introduced with good results into the mercury mines of Monte Amiata.

A striking instance of the intimate connection existing between the configuration of chemical substances and their susceptibility to fermentation is to be found in a paper by C. Ulpiani and M. Cingolani in the *Gazzetta* for January 14. The *Bacillus acidi urici*, which has the property of decomposing uric acid into carbon dioxide and urea by a process of successive hydrolysis and oxidation, is without action on the closely allied substances α-methyluric acid, guanine, caffeine, and theobromine. On the other hand the bacillus is capable of rapidly and completely oxidising such acids as tartronic, malonic, and mesoxalic acids, which contain the same carbon chain as that constituting the central axis of uric acid, whilst, in addition, the ureides of these acids, namely, barbituric acid, dialuric acid, and alloxan, are converted by the ferment quantitatively into urea and carbon dioxide. Moreover, just as in the case of the sugars only the hexoses are capable of undergoing fermentation, the bacillus of uric acid is indifferent to acids containing fewer or more than three carbon atoms.

THE *Psychological Bulletin* (vol. ii., No. 1) for January contains a notice of the meeting of the north central section of the American Psychological Association which was held at Chicago on November 26, under the presidency of Prof. W. D. Scott, of the North-western University. The following papers were read:—Is subjective idealism a necessary point of view for psychology? by Mr. Stephen S. Colvin; the genesis of meaning, by Mr. I. E. Miller; relation of sensation and revived mental processes, by Messrs. T. H. Haines and J. C. Williams; the vehicle of cognition, by Mr. B. H. Bode; psychological method, by Mr. C. A. Blanchard; an Iowa case of complete congenital cataracts cured after twenty-two years, by Mr. James Burt Miner; the relations of psychology to logic, by Miss Harriet S. Penfield; the functional theory in psychology and the concept of transcendence, by Mr. J. H. Farley; the psychology of linguistic development in the individual, by Mr. M. V. O'Shea; is the beauty of art a higher type than that of nature? by Mr. George Rebec; the reality and the symbol in education, by Miss Julia H. Gulliver; and a motor theory of rhythm, by Mr. R. H. Stretton

THE Walter Scott Publishing Company will shortly issue a translation of "Science and Hypothesis," by Prof. Poincaré. Prof. J. Larmor, Sec.R.S., has written a preface to this edition of Prof. Poincaré's work.

A COPY of the report of the librarian of the U.S. Congress for the fiscal year ending June 30, 1903, has been received from Washington. The report runs to 600 pp., and includes elaborate details concerning every department of the library's activities. A select list of recent purchases during 1901–1903 constitutes part ii. of the volume, and a third section is devoted to a report on copyright legislation.

MR. JOHN A. BERGSTRÖM, of Indiana, writing in the *Psychological Bulletin*, describes a spring suspension for laboratory motors used for driving colour mixing or other experimental apparatus, with the object of reducing the noise and vibration produced by motors resting on a fixed base.

THE third English edition of Prof. Mendeléeff's "Principles of Chemistry" has been published in two volumes by Messrs. Longmans, Green and Co. The new volumes are a translation from the seventh Russian edition by Mr. George Kamensky, edited by Mr. Thomas H. Pope. There are three appendices to the work. The first of these is the Royal Institution lecture delivered by Prof. Mendeléeff on May 31, 1889, entitled "An Attempt to apply to Chemistry one of the Principles of Newton's Natural Philosophy"; the second, on the "Periodic Law of the Chemical Elements," is Prof. Mendeléeff's 1899 Faraday lecture to the Chemical Society; the last is entitled "An Attempt towards a Chemical Conception of the Ether," and its contents were described in an article which appeared in NATURE on November 17, 1904 (vol. lxxi., No. 1829). The work is one of the classics of chemical science, and the new edition will be widely welcomed

OUR ASTRONOMICAL COLUMN.

EPHEMERIS FOR COMET 1904 *e*.—Given below is an extract from a daily ephemeris computed by Dr. E. Strömgren from the elliptic elements calculated by M. Fayet for comet 1904 *e*.

12*h*. (*M.T. Berlin*).

1905	α (h. m. s.)	δ (° ′)	log r	log Δ
Feb. 9	2 29 38	+21 14	0·1582	0·0816
,, 11	2 34 23	+22 27		
,, 13	2 39 14	+23 38	0·1613	0·0940
,, 15	2 44 10	+24 47		
,, 17	2 49 12	+25 54	0·1647	0·1067

On February 7 the comet was very near to, but south-west of, ν Arietis (*Astronomische Nachrichten*, No. 3991, supplement).

EPHEMERIS FOR COMET 1904 *d*.—The following is an extract from the daily ephemeris for comet 1904 *d* published in No. 3991 of the *Astronomische Nachrichten* by Herr M. Ebell.

12*h*. (*M.T. Berlin*).

1905	α (true) (h. m. s.)	δ (true) (° ′)	log r	log Δ	Brightness
Feb. 9	19 22 32	+54 50	0·3492	0·3584	0·82
,, 13	19 41 49	+56 28	0·3542	0·3643	0·78
,, 17	20 1 45	+57 57	0·3593	0·3710	0·74
,, 21	20 22 13	+59 17	0·3645	0·3784	0·70

Brightness at time of discovery = 1·0.

An observation made by Herr Pechüle at 16h. 24·3m. (Copenhagen M.T.) on January 14 gave corrections to this ephemeris of −4s. and −0′·5.

On February 9 the comet will be to the north-west of, and near to, κ Cygni, then, travelling in a north-easterly direction, it will pass into the constellation Cepheus.

ORBIT OF COMET 1904 *e* (BORRELLY).—From the observations made at Königsberg on December 31 and at Paris on January 11, M. Fayet has made an investigation of the probable orbit of Borrelly's comet (1904 *e*). In the first place three different sets of parabolic elements were computed, but, although the arc traversed by the comet whilst under observation was very small, and the results obtained were therefore not very trustworthy, the non-agreement of the parabolic elements with the observational results was too great to be admitted. M. Fayet therefore computed a set of elements on the assumption that the orbit was elliptical, and these were much more satisfactory, indicating a short period of about six years.

The following set of elliptic elements was finally adopted as giving a fairly satisfactory agreement between the observed and computed positions:—

$$T = 1905 \text{ Jan. } 15{\cdot}77425 \text{ (M.T. Paris)}$$

$$\left.\begin{aligned} ☊ &= 76^\circ\ 6'\ 43''{\cdot}97 \\ i &= 30^\circ\ 55'\ 21''{\cdot}25 \\ \omega &= 351^\circ\ 35'\ 27''{\cdot}11 \end{aligned}\right\} 1905$$

$$\log q = 0{\cdot}149236$$

$$\log e = 9{\cdot}818195$$

These results give a value for μ of 423″·915, and therefore indicate that the comet is of the short-period type, making one revolution in its orbit in about eight years (*Comptes rendus*, No. 4, 1905).

OBSERVATIONS OF THE LEONID SHOWER OF 1904.—In a note published in No. 3989 of the *Astronomische Nachrichten*, Mr. Denning gives a few details of his observations of the late Leonid shower at Bristol.

During a watch of about one and a half hours between 13h. 30m. and 15h. 45m. on November 14, 55 meteors, of which 33 were Leonids, were seen, and Mr. Denning estimated that, at that time, the latter were appearing at the rate of about 25 per hour, for one observer, from a radiant situated at R.A. = 151°, decl. = +23°. No increase in the horary rate was apparent at 16h., and as the fog became denser the observations were discontinued.

Two of the Leonids seen were as bright as Jupiter, whilst several others were as bright as, or brighter than, first magnitude stars. One of these flashed out in the north-west at 14h. 38m., traversed the path $315^\circ+57^\circ$ to $318^\circ+50\frac{1}{2}^\circ$, and left a short streak which lasted for about 30 seconds.

A few slow, yellow meteors from a radiant in Aries at $43^\circ+21^\circ$, and some swift streaking meteors from a radiant in Leo Minor at $144^\circ+37^\circ$, were also seen.

SPECTRA OF γ CYGNI, α CANIS MINORIS AND ϵ LEONIS.—In part vii. vol. cxiii. of the *Sitzungsberichte der Kais. Akad. der Wissenschaften*, Herren E. Haschek and K. Kostersitz publish the results of the reductions of the spectra of γ Cygni, Procyon and ϵ Leonis. After discussing in detail the methods of measurement and identification employed in the reduction, and the general and specific characteristics of each spectrum studied, the authors give a table of the wave-lengths and intensities of the lines for each star. The coincidences of each line with lines in the arc and spark spectra of terrestrial elements, as determined by Exner and Haschek, are also given, and in the last column of each table the "probable origins" of many of the lines are set down. Amongst the latter may be noted the rarer elements Yb, Pr, Sa, Nd, La, Pt, Wo, Gd, Eu, &c.

About 140 lines between λ 4250 and λ 4534, 190 lines between λ 4126 and λ 4550, and about 270 lines between λ 4215 and λ 4702 are given in the spectra of γ Cygni, α Canis Minoris and ϵ Leonis respectively.

SYSTEMATIC SURVEY OF DOUBLE STARS.—No. 99, vol. xvi., of the *Publications* of the Astronomical Society of the Pacific is devoted to an address on double stars read before the International Congress of Arts and Sciences at St. Louis by Prof. R. G. Aitken.

After discussing the work already performed in this field, Prof. Aitken described a systematical survey undertaken by Prof. Hussey and himself. All stars down to the ninth magnitude as given in the Bonn Durchmusterung were placed on the observing list, and the sky from the North Pole to -22° declination was equally divided for observation between the two observers.

The programme arranged for the observation of each star on the list on at least one good night, and all double stars discovered with a separation of 5″ or less were to be measured on at least two nights and catalogued. On September 10, Prof. Hussey had discovered 1035 and Prof. Aitken more than 875 new pairs. Seventy-three per cent. of these are separated by 2″ or less, and 142 are very close pairs in which the separation does not exceed 0″·25. Of similar pairs to the latter the previously published catalogues do not contain 100.

Prof. Aitken has examined, during this research, more than 12,000 stars, and finds that the doubles discovered form about 3 per cent. of this total. Including those previously discovered, the ratio of double stars, with distances of less than 5″, to the whole of the stars down to the ninth magnitude is apparently 1 : 18 to 1 : 20. This ratio is not, however, the same for all parts of the sky, for whilst in some regions observed double stars are very scarce, in others the ratio increases to about 1 : 8.

Other details concerning the survey, its prosecution and the reasons for carrying it out are given in Prof. Aitken's interesting paper.

REPORT OF THE YALE OBSERVATORY, 1900–4.—Dr. Elkin's reports to the board of managers of the Yale University Observatory for the years 1900–4, inclusive, occupy eight pages, and briefly describe the large amount of work performed at the observatory during that period.

Heliometer observations are the chief feature of the work and special attention has been paid to the determination of the parallaxes of stars having large proper motions. Practically all the stars in the northern hemisphere having known motions of 0″.5, or more, have now been observed at Yale. A second triangulation of the Pleiades and determinations of the parallax of Arcturus have also been made. Another feature of the work is the photography of meteor trails, and numerous trails of meteors from the principal showers have been obtained.

PRIZE SUBJECTS OF THE BATAVIAN SOCIETY OF EXPERIMENTAL PHILOSOPHY.

AT a recent general meeting of the Batavian Society of Experimental Philosophy of Rotterdam the following subjects were proposed for competition. The gold medal of the society, of the weight of thirty ducats, or its value, will be awarded for the best answer to one or other of the suggested questions. Answers may be written in the Dutch, French, English, German, or Latin languages, in another handwriting than that of the competitor, and must reach the secretary, Dr. G. T. W. Bremer, at Rotterdam not later than February 1, 1906.

Chemistry.—An experimental investigation of the atomic weight of an element which has not yet been satisfactorily fixed; a research on the causes of departure from Ostwald's dilution law; measurements of the osmotic pressure in solutions at concentrations corresponding with deviations from the simple gas laws; a study of the origin and physiological significance of the green pigment in the body of green articulated animals; experiments elucidating the formation and transformations of the sap in india-rubber plants; a re-investigation of the variations from the laws of electrolytic dissociation observed by Kahlenberg in 1901; an explanation of the thallioquinic test for quinine.

Physics.—An investigation of the electrical properties of some metallic alloys; of the variation with temperature of the specific heat of mercury; of the specific heat of sulphur and phosphorus in their various allotropic forms; of the indices of refraction of substances showing anomalous dispersion; of the cause of phosphorescence, particularly in the case of the lower organisms.

Biology.—A description of the life-history and properties of one or several species of moulds, ferments, or bacteria which are of industrial importance; the action of sulphur and of copper salts on plant parasites, and of mineral salts on the development of fungi; the *rôle* of micro-organisms in the formation of humus in the soil.

Physiology.—An investigation of the permeability of red blood corpuscles to the ions of NaCl, $NaNO_3$, Na_2SO_4; and of the localisation of functions in the cerebellum.

Geology.—An exposition of the theory of the origin of the Netherlands; a critical investigation of the volcanoes of the East Indian Archipelago.

Civil Engineering.—Statistical investigations of the Dutch "polders"; or an investigation of one of the principal rivers of Holland.

THE PIC DU MIDI OBSERVATORY.

IN a recent number of *La Nature*, M. L. Rudaux gave an interesting account of the present condition and operations of this important mountain station. France is well provided with high level stations, and the observations from seven of them are published daily in the *Bulletin International* of the French Meteorological Office. An account of the very favourable position of the Pic du Midi station, and of the almost insuperable difficulties experienced by its original founder, General de Nansouty, was given, in considerable detail, by M. R. Radau, in his useful little work on "Mountain Observatories" (Paris, 1876), and has been summarised by Mr. A. L. Rotch in the *American Meteorological Journal*. The summit, which has an elevation of 2877 metres (the observatory being 17 metres lower), is situated on the outskirts of the Pyrenees, in lat. 42° 56′ N., and long. 2° 12′ W. of Paris, and affords one of the finest views in Europe. Towards the north an immense plain stretches as far as the eye can see, and to the north-west, on very clear days, the blue waters of the Atlantic are visible, at a distance of 160 km. It lies directly in the path of the great atmospheric disturbances which traverse the Bay of Biscay, while the summit mostly enjoys a clear and luminous atmosphere, being some 200 metres above the level at which thunderstorm clouds usually gather. These advantages early attracted the attention of astronomers and scientific men; M. F. de Plantade died in 1741 while observing at the ridge which has since taken his name.

The project of a permanent meteorological station was first mooted in 1869, and provisional observations were commenced by General de Nansouty and his coadjutors in 1873, at the foot of the Pic, about 2300 metres above the sea, and were continued under great hardships, and at considerable personal expense for about eight years. The present station was established in 1880, by public and private subscriptions. The accompanying illustration gives a general view of the station as it now exists. On the left the thermometer screen may be distinguished near the erection on which the anemometer and actinometer are placed; at the other end of the terrace is the equatorial building, and the apparatus for celestial photography. The magnetic instruments are placed in vaults underneath the terrace. The meteorological observations are regularly published in the annals of the Central Meteorological Office; useful predictions have been given to the inhabitants of the plains of impending thunderstorms, and of probable floods owing to the sudden melting of the snow on the mountains. Amongst the miscellaneous observations undertaken under the able direction of M. Marchand, we may specially mention those relating to the zodiacal light, to solar phenomena, and the connection of the latter with magnetic disturbances. His observations in this direction have shown that whenever a terrestrial magnetic disturbance occurs, spots or faculæ exist on the central meridian of the sun. Important spectroscopic results have also been obtained respecting the atmospheres of Venus and Mars.

Fig. 1.—General View of the Pic du Midi Observatory in 1904.

AGRICULTURAL NOTES.

An important new feature of the annual report on the distribution of grants for agricultural education and research is a return giving the character of the instruction in agriculture provided by the county councils of England and Wales. The return shows that most counties are now spending considerable sums on agricultural education—altogether 88,893*l.* in 1902–3, and to this sum 9200*l.* was added by the Board of Agriculture in the form of grants to collegiate centres. It is estimated that some 22,000 persons have attended the various local lectures provided, while 1000 students entered for the courses offered by agricultural colleges. The expenditure of the counties is given in detail, and presents some curious anomalies; thus the London County Council assigned to agricultural education 742*l.*, while the authorities of one of the most fertile divisions of Lincolnshire, in which agriculture is practically the only industry, voted 65*l.* for the purpose! Again, East Sussex, with a total income from the "Residue Grant" of 7773*l.*, spent 6116*l.* in grants to agricultural colleges or schools, while West Sussex, with an income of 4503*l.*, gave nothing for collegiate instruction, and was satisfied with an expenditure of 275*l.* upon horticulture and poultry keeping. Conditions vary from county to county, but differences in the needs of the agriculturist do not explain the widely different educational policy of the local authorities. Under the new committees, it is to be hoped that the unsystematic and spasmodic efforts that have been too common in the past may disappear, and though it is probable that in the immediate future less money will be spent on agricultural education, it is likely to be expended to greater advantage. The Board of Agriculture's report should be studied by all members of county education committees who are interested in agricultural education.

A piece of work which has just been completed in the library of the U.S. Department of Agriculture has greatly enhanced the value of the leading Continental agricultural journals for English-speaking students. Complete card catalogues of "Annales de la Science agronomique," "Landwithschaftliche Jahrbücher," and "Die landwithschaftlichen Versuchs-stationen" have been prepared. Each index card gives author's name, title of article, and a brief outline of the scope of the article. The catalogues may be purchased in two series, either "author entry" sets, permitting papers to be indexed under the authors' names, or "complete" sets, furnishing two or more cards for each paper, which may then be indexed under the author's name, and also under the subject or subjects to which the article relates. The cost of the three sets of catalogues in the latter and more useful form is about 12*l*. The sets now issued bring the indexing down to 1903, but the work will be continued, and supplementary sets will be printed from time to time. Students who do not desire references to all branches of agricultural science may obtain sets of cards dealing with special subjects, such as soils, plant diseases, or forestry. Particulars of the eighteen subject-groups under which the cards are classified are given in *Bulletin* No. 9, issued by the Catalogue Division of the Library of Congress, Washington, D.C.

In the fourth report on the Woburn fruit farm, the Duke of Bedford and Mr. Spencer Pickering, F.R.S., discuss the results of several years' experiments in the manuring of fruit crops. In an introduction the soil of the fruit station is described, and chemical and mechanical analyses are given; the report then describes experiments on strawberries, gooseberries, currants, raspberries, and apples. For various reasons the experiments on currants and raspberries were unsatisfactory, but trustworthy data were obtained in the work on the other crops. It was found that 12 tons of farmyard manure per acre increased the strawberry crop by 12 per cent. to 15 per cent., and that the size and quality of the fruit were greatly improved. A mixed artificial manure supplying about the same quantities of nitrogen, phosphoric acid, potash and magnesia as the dung similarly increased the yield, but did not improve the quality. Farmyard manure much increased the gooseberry crop, but the artificial mixture failed to do so, and it is explained that the increase in the former case was probably due to the greater quantity of moisture retained by the dunged soil. Nitrate of soda applied in summer was found to benefit apples in certain seasons, but with this exception no kind of manure had any marked effect on the apple crop.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

BIRMINGHAM.—Mr. Chamberlain, the Chancellor of the University, presided at the annual meeting of the Court of Governors held on February 6. Speaking after the adoption of the annual report, Mr. Chamberlain said that when the governors of Mason College met some five or six years ago and came to the decision that the time had come to give Birmingham its own university, it was thought that the least sum of money which would justify them in applying for a charter was 100,000*l*. But very shortly afterwards they found that there was a great opportunity, not only for themselves, but for other great provincial cities, to create a series of universities which in the first place would bring home to all the population the advantages of the highest education, and in the second place, would specialise this highest education with some more definite idea of its application to science than hitherto had been found to be possible. The moment they decided on a departure of that kind they found that it meant something quite different from what they had previously supposed. New buildings had to be specially devised, a very large and expensive equipment had to be provided, and new chairs had to be created; altogether a completely new ideal had to be developed. And then they put their demand—a demand which, indeed, they did not strictly limit themselves to, but they thought it would probably be sufficient for the present generation—they put their demand at the expenditure of one million of money. They had received at once nearly half that sum, largely from Birmingham. And he might say in passing that the liberality of the local contribution was a ground for the claim which they made for some further State support. "It is something," he said, "that we have found that the Government are becoming alive to our needs and to our deserts, and that they have been able to double the sum previously given for the university education. But we may bear in mind at the same time that the present Chancellor of the Exchequer has promised to double it again in his next Budget, and, therefore, I anticipate that from that source we shall receive a very considerable addition. I do not at all accept it as in any way a satisfaction of our demands, because it is my conviction that public opinion will soon insist upon larger sums being devoted to this purpose. When I think that we are spending 13 millions a year at least on primary education I say the sum now given for the purpose of the highest education, the most profitable of all the investments we can make in that direction, is altogether inadequate."

CAMBRIDGE.—The voting on the report of the Studies and Examinations Syndicate will take place on Friday, March 3, and on Saturday, March 4, on both days from 1–3 p.m. and from 5–7 p.m. No votes will be taken after 7 p.m. on Saturday, March 3.

In view of the discussion on the report the syndicate has issued the report in an amended form. The chief changes include as alternatives in the papers in classical languages (1) passages for translation from a selected book or books; (2) unprepared passages for translation, a vocabulary of unusual words being supplied, also the abolition of distinct grammar papers, although questions on syntax and accidence will be set in connection with the translation papers; further, one of the Synoptic Gospels is Greek, is now proposed as an alternative to one of the Synoptic Gospels, together with the Acts of the Apostles in English, and logic is included amongst the optional subjects in part iii. These proposals are embodied by the Council in five graces. It is on the second of these, which deals with the question of compulsory Greek, that attention will be centred.

LONDON.—Sir Michael Foster has consented to offer himself for re-election to the next Parliament as member for the University of London. He seeks re-election as a representative of science and higher education; if re-elected he will take his seat as a member of the Liberal Party. A committee, with Sir Thomas Barlow as chairman, has been formed to promote his election. This committee comprises graduates belonging to different political parties who are supporting Sir M. Foster on the ground of his many public services and in the belief that his special knowledge will continue to prove of great value to the House of Commons.

OXFORD.—Mr. George Longstaff, New College, has presented 50*l*. to the Hope Department of Zoology, and has offered to provide an extra assistant in the department for the years 1905 and 1906.

A SHEFFIELD gentleman, who does not wish his identity to be disclosed, has, says the *Sheffield Telegraph*, intimated in connection with the Sheffield University movement that he is prepared to subscribe 10,000*l*. towards the endowment fund, provided four other sums of 10,000*l*. are contributed. As an alternative, he is willing to give 5,000*l*. provided nine similar donations are promised. Under either condition a sum of 50,000*l*. would be raised, and, roughly, this is the amount still required to complete the fund.

AT a public meeting held under the auspices of the University of Leeds on February 6th, Mr. Alfred Mosely, C.M.G., gave an address on "Some Lessons learned by the recent Mosely Commission of Educationists to the United States." In the course of his remarks he said: Much remains in England to be done so that she may be brought into line with the United States and Germany in the matter of education. In America the people realise that if the nation is to be made and saved it must be through the medium of education. The time has come for us to reconsider our position, and above all to realise that the Board schools and the primary schools are but the prelude to secondary education, which in the United States has made such satisfactory strides—as it has also in Germany. The great difference in the education of the United States and that in our own country is the appreciation there of everybody, from the highest to the lowest, of the value of education. The Government has realised its obligations, and private citizens pour out their money like water. The University at Chicago, for instance, has been built up through the liberality of one man, who has given millions of pounds sterling. Why is there not the same spirit in England?

THE current number of the *Quarterly Review* contains an article entitled "The Direction and Method of Education." The writer passes in review many of the official publications of the English Board of Education and the

Scotch Education Department, Prof. Sadler's report on secondary education in Liverpool, and other publications. Men of science would do well to note what is given as the sum and substance of official activity in education since the passing of the recent Education Act. The writer says, "If we were asked to describe in one word the whole tendency of English education as manifested at the present time, we should speak of a humanistic renaissance." And again later, "English education, we believe, is working round to the humanistic ideal." Literary studies are included in every satisfactory scheme of elementary and secondary education, and the man of science recognises fully the value of the humanities in the work of schools and colleges. But whatever "humanistic renaissance" there may be dawning upon the world of education, it is to be hoped that the danger of a return to the conditions of fifty years ago, when instruction in the methods of science was unknown in our schools, and no opportunity to become acquainted with natural objects was offered, will be borne in mind by all education committees and other authorities.

THE Hon. Maude Lawrence has been appointed to a newly-established post of Chief Woman Inspector under the Board of Education. Miss Lawrence will direct a staff of women inspectors of special qualifications and varied experience, who will assist the Board in dealing with many questions for the treatment of which they have hitherto been somewhat imperfectly equipped. Instruction in various domestic subjects, such as needlework, cookery, laundry work, household management, and hygiene, has for some time past been given under the regulations of the Board for schools of different grades. But the report of the Inter-Departmental Committee on Physical Deterioration points to the need of a reform in the methods now commonly employed in the teaching of these subjects. It is considered that this instruction has been less effective than it should have been, because it has been too theoretical and has not been kept sufficiently in touch with the needs and habits of daily life. The new branch of the inspectorate will be employed to assist local authorities in providing, as part of their educational system, ample opportunities for girls of various ages to obtain a training for home life simple, practical, and adapted, where necessary, to the special circumstances of each locality. There are also many questions of importance involving the national physique, as affected by the studies, the life, and the treatment of children, and especially of very young children, from day to day in elementary schools, which women inspectors are specially qualified to investigate and to advise upon.

THE council of the Association of Technical Institutions has published its report of an inquiry, undertaken in May, 1904, as to the conditions of admission to evening classes in technical institutions and evening continuation schools throughout the country. The council considers that the returns and expert opinions recorded in this report justify the following conclusions:—(1) That it is undesirable to establish any general system of free admission to evening continuation schools, or of free admission or admission at specially reduced fees to evening classes in technical institutions. (2) That it is unnecessary to grant entirely free admission, to evening classes in technical institutions, to any special class or body of students or workers engaged in skilled industries, such as apprentices or persons under twenty-one years of age. (3) That there is need for the establishment in all technical institutions of sufficient "free studentships" or "scholarships" to secure the admission of all qualified and deserving students who are unable, by reason of their limited means, to pay the usual class fees without more sacrifice than should reasonably be expected of them. The plan to secure information adopted by the council was to issue a letter and form of inquiry to the education authorities and technical institutions throughout the United Kingdom asking for information as to the existence of the following conditions of admission to evening classes: (*a*) entirely free, (*b*) at less than normal fee, (*c*) by scholarships, (*d*) by arrangement with employers. Replies were received with reference to sixty evening continuation school areas and from eighty-three technical institutions. Of the technical institutions, fifty-five are not in favour of free admission, and one only in favour of it. The remaining institutions gave no definite answer. Thirty-eight education committees are against free admission to evening continuation schools, two are in favour of it, sixteen expressed no opinion, and four suggest scholarships.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, November 24, 1904.—"The Flow of Water through Pipes.—Experiments on Stream-line Motion and the Measurement of Critical Velocity." By Dr. H. T. **Barnes** and Dr. E. G. **Coker**. Communicated by Prof. Osborne Reynolds, F.R.S.

In a brief note published in the *Physical Review* (vol. xii. p. 372, 1901), the authors described a thermal method of observing the change from stream-line to eddy motion for water flowing through pipes of different diameters.

The impossibility of heating a column of water uniformly throughout while flowing in stream-line motion has been previously observed. It was shown that, when water is heated electrically while flowing through a tube of two or three millimetres diameter by a central wire conductor, the heat is carried off by the rapidly moving stream, which forms a cloak of hot water around the wire, and leaves the walls of the tube almost entirely unheated.

The change from stream-line to eddy motion can be very clearly observed in a tube heated on the outside, since the temperature of the emerging stream immediately increases when the flow rises above the critical point. The point of change is very sharp, and the disappearance of the stream-lines instantaneous.

It is clear from a study of the work of Osborne Reynolds that the change from stream-line to eddy motion may take place within a wide range of velocities. Critical velocity is measured in two ways: either by observing the velocity at which the stream-lines break up into eddies, or by obtaining the velocity at which the eddies from initially disturbed water do not become smoothed out into stream-lines in a long uniform pipe. The first change may be at any velocity within certain limits depending on the initial steadiness of the inflowing water, while in the second, the change can take place at only one velocity.

Osborne Reynolds's experiments were carried out by the method of colour bands in a long rectangular tank. By using a very much larger tank under a high head of water the authors were able to obtain a higher degree of steadiness than was obtained in the comparatively small tank used by Reynolds. A large number of experiments were obtained, an account of which forms the main part of the present paper.

Briefly, the result of the work may be summarised as follows:—

(1) The attainment of exceedingly high velocities of stream-line flow for certain sizes of pipes fed by perfectly quiet water under a high head.

(2) The re-formation of stream-lines in certain cases after eddies had formed, with a subsequent breaking up of the stream-lines at a very much higher velocity.

(3) A small divergence from the law of the change in viscosity with temperature for the upper-limit of stream-line flow.

(4) A verification of the viscosity temperature law for the lower-limit of stream-line flow by separate methods.

January 19.—"Further Histological Studies on the Localisation of Cerebral Function.—The Brains of Felis, Canis, and Sus compared with that of Homo." By Dr. A. W. **Campbell**. Communicated by Prof. Sherrington, F.R.S.

This addendum to a work on cerebral localisation, presented by the same author to the Royal Society in November, 1903, aims at elucidating certain obscure functional analogies and structural homologies pertaining to the brain.

The points emphasised are as follows:—Giant cells characterise the cortex of the lower mammalian cruciate zone, and this represents the motor area, as defined by Profs. Sherrington and Grünbaum in the anthropoid ape, and by the author in man. The compensatory ansate and coronal sulci are respectively interchangeable with the upper and lower constituents of the primate fissure of Rolando. The common sensory area forms a morphological buffer behind the cruciate zone. Quite one-sixth of the lower animal's brain surface is allotted to visual cortex. The "true calcarine" fissure is the antecedent of the human anterior calcarine, the intercalary sulcus undergoes retrograde changes, and the suprasplenial sulcus is the derivative of the "sulcus intrastriatus lateralis." In the limbic region, human types of cortex are repeated, and the genual fissure is the homologue of the calloso-marginal. Parietal cortex is older, in the sense of phylogeny, than frontal. The lateral sulcus is the forerunner of the intraparietal. Out of the ectosylvian region of lower animals is developed the Sylvian region, including the insula, and much of the temporal lobe of primates.

It is concluded that the stability of the architectural plan of any given field of cortex is directly related to the phylogenic age of that cortex, and to the importance, as a means to survival, of the function it subserves; and, that while the human brain has expanded more decisively in some parts than in others, yet that expansion, if we except the visual and olfactory areas, has been general in kind.

January 26.—"On a Method of Finding the Conductivity for Heat." By Prof. C. **Niven**, F.R.S.

The first part of the paper contains a detailed account of the methods employed for finding the difference of temperature, and a description of the apparatus used. The results of some experiments made with it are also given, and compared with those found by other observers. The second part of the paper contains a solution of the mathematical problem of the diffusion of heat in an infinite solid from a line at which it is supplied at a constant rate, and the solution of some other allied questions. One result of the investigation suggests a method of finding the diffusivity directly, when the substance is of sufficiently great extent.

"The Boring of the Simplon Tunnel, and the Distribution of Temperature that was encountered." By Francis **Fox**. Communicated by C. V. Boys, F.R.S.

February 2.—"On the Compressibility of Gases between One Atmosphere and Half an Atmosphere of Pressure." By Lord **Rayleigh**, O.M., F.R.S.

The present memoir contains a detailed account of the observations referred to in the Preliminary Notice of February, 1904. In addition, results are now given for air, carbonic anhydride, and nitrous oxide. In the following table are recorded the values of B for the various gases at specified temperatures, B denoting the quotient of the value of pv at half an atmosphere by the value at the whole atmosphere:—

Gas	B.	Temperature
Oxygen	1·00038	11·2
Hydrogen	0·99974	10·7
Nitrogen	1·00015	14·9
Carbonic oxide	1·00026	13·8
Air	1·00023	11·4
Carbon dioxide	1·00279	15·0
Nitrous oxide	1·00327	11·0

By means of a formula given by D. Berthelot the compressibilities at 0° C. are inferred, and applied to deduce the ratio of densities as they would be observed at 0° C. under very low pressures. According to Avogadro's law these are the relative molecular weights. From the densities of nitrogen and oxygen we get N = 14·008, if O = 16. Again, from the densities of oxygen and nitrous oxide we find N = 13·998. The former is probably the more trustworthy.

Chemical Society, January 18.—Prof. W. A. Tilden, F.R.S., president, in the chair.—Nitrogen halogen derivatives of the sulphonamides: F. D. **Chattaway**. A number of the nitrogen halogen derivatives of the sulphonamides, which are obtained by the action of hypochlorous acid on the suphonamides and the alkylsulphonamides, were described, and the ease with which they can be prepared and crystallised demonstrated.—Electrolytic oxidation of the aliphatic aldehydes: H. D. **Law**. The chief product of oxidation of the lower members of the saturated aliphatic aldehydes is the corresponding organic acid, but small quantities of carbon dioxide and monoxide and saturated hydrocarbons are also formed in some cases.—The diazo-derivatives of the benzenesulphonylphenylenediamines: G. T. **Morgan** and F. M. G. **Micklethwait**. A description is given of the substances produced by the interaction of nitrous acid with the benzenesulphonyl derivatives of *o*-, *m*- and *p*-phenylenediamines, illustrating the different behaviour of these isomerides with this reagent.—The molecular condition in solution of ferrous potassium oxalate: S. E. **Sheppard** and C. E. K. **Mees**. Ferrous oxalate was shown to dissolve in alkali oxalates forming double salts, such as $K_2Fe(C_2O_4)_2$, which dissociate according to the scheme $2\overset{+}{K} + \overset{-\ -}{Fe(C_2O_4)_2}$. Spectrophotometric measurements indicated that the formation of ferrous ions at moderate dilutions was negligibly small.—A further analogy between the asymmetric nitrogen and carbon atoms: H. O. **Jones**. The author showed that, during the formation of an asymmetric nitrogen atom in a compound containing an asymmetric carbon atom, two isomerides, which are called the α- and β-compounds, are produced. For this purpose methyl-*l*-amylaniline has been combined with allyl and benzyl iodides.—The formation of magnesia from magnesium carbonate by heat and the effect of temperature on the properties of the product: W. C. **Anderson**. Experiments were made with native and artificial magnesium carbonates to ascertain (1) the lowest temperature at which the evolution of carbon dioxide could be distinctly recognised; (2) the comparative rates at which the expulsion of the gas takes place at higher temperatures under atmospheric pressure; and (3) the extent to which the magnesia obtained dissolves in water after being kept at different known temperatures for a fixed period. It is inferred from the results that polymerisation takes place when magnesia is heated, and that this goes on more quickly in the "heavy" oxide than in "light" magnesia.—Transformations of derivatives of *s*-tribromodiazobenzenes: K. J. P. **Orton**.—The addition of sodium hydrogen sulphite to ketonic compounds: A. W. **Stewart**.—The reduction products of anisic acid: J. S. **Lumsden**. When anisic acid, dissolved in amyl alcohol, is reduced by sodium, the products are hexahydrobenzoic acid and δ-keto-hexahydrobenzoic acid.—The physical properties of heptoic, hexahydrobenzoic, and benzoic acids and their derivatives: J. S. **Lumsden**.—The influence of solvents on the rotation of optically active compounds. Part vii. Solution-volume and rotation of menthol and menthyl tartrates: T. S. **Patterson** and F. **Taylor**.

Royal Microscopical Society, January 18.—Dr. Dukinfield H. Scott, F.R.S., president, in the chair.—The **President** delivered his annual address, the subject of which was an inquiry as to "What were the Carboniferous Ferns?"

Geological Society, January 18.—Dr. J. E. Marr, F.R.S., president, in the chair.—On the geology of Arenig Fawr and Moel Llyfnant: W. G. **Fearnsides**. This paper contains a detailed description of the succession of beds in Sedgwick's typical area of development of his Arenig series. The author discusses the relationship of the various divisions he describes to corresponding beds of other areas. He gives a description of the intrusive igneous rocks, and some account of the structure of the district and the nature of its glaciation.

Physical Society, January 27.—Dr. R. T. Glazebrook, F.R.S., president, in the chair.—Action of a magnetic field on the discharge through a gas: Dr. R. S. **Willows**. It has been shown previously that a transverse magnetic field, if applied at the kathode, may in some cases reduce the potential difference at the terminals of the tube. It is shown in the paper that the pressure at which this decrease commences corresponds to the pressure at which the voltage required to maintain this discharge, under normal conditions, is a minimum. This is also found to be the pressure at which the positive column is first completely striated. Reasons why such action takes place are given.—Action of radium on the electric spark: Dr. R. S. **Willows** and J. **Peck**. In certain cases the authors have found that the spark from a Wimshurst machine is extinguished by the action of the radiations from radium and that the current passing is decreased. The action is altogether different according to the direction of the discharge. Using a spark-gap longer than 2 cm. and making the larger knob, of the machine used, positive, the radiations had practically no influence. With the smaller knob positive the radium, in most cases, extinguished the spark. The phenomenon is found to be due to the action of the β rays. Röntgen rays do not produce this effect, even if their ionising power at the spark-gap is some thousands of times greater than that of the radium. Lenard rays are, however, effective.—The slow stretch in indiarubber, glass, and metal wires subjected to a constant pull: P. **Phillips.** When indiarubber is subjected to a sustained pull of constant amount it yields at quite a large rate, the stretch at any time (t), after the establishment of the pull, being given by $x=a+b \log t$, a and b being constants for the particular pull exerted. For different pulls b is proportional to the pull. When the pull is removed the indiarubber slowly returns to its original length, the extension still remaining at a time t_0 after the removal being given by

$$x=b \log (t/t_0),$$

t being the time which has elapsed since the pull was established. These two results, for the slow stretching and slow recovery of indiarubber, have also been established for glass fibres subjected to sustained pull, but the magnitude of the slow yielding is very much smaller. When annealed wires of copper, silver, gold, or platinum are subjected to a sustained pull they behave in some ways similarly to indiarubber and glass, but there are some very decided differences. If the pull is greater than a certain amount (in the actual experiments about one-third to one-quarter of the breaking weight) the stretch at any time (t) after the establishment of the pull is given by the same law $x=a+b \log t$, but below this value of the pull b is zero. This law obtains up to the breaking strain of the wire, b increasing very rapidly a little before the breaking strain is reached. When the pull is removed, there is no appreciable slow recovery like that occurring in indiarubber and glass. Iron and steel wires show themselves to be exceptions to these rules.—Determination of Young's modulus (adiabatic) for glass: C. A. **Bell,** with an appendix by Dr. C. **Chree,** F.R.S. In this paper it is shown that errors in the acoustical determination of Young's modulus for glass, due to irregularities in the rods or tubes employed, may be eliminated by applying to the measured length of each free-free rod a correction given by the formula

$$\Delta l=\int_0^l \frac{\delta S}{S_0} \cos \frac{2\pi z}{l}\, dz,$$

in which δS is the difference between the cross section at the point z and its mean value, S_0, for the whole rod.—Some methods for studying the viscosity of solids: Dr. Boris **Weinberg.** The author has been carrying out investigations similar to those described by Prof. Trouton and Mr. Andrews in their paper on the viscosity of pitch-like substances (*Proc.* Phys. Soc., 1903). The details of his experiments are, however, different. He has worked principally with lead and has employed three distinct methods for determining the coefficient of viscosity.

PARIS.

Academy of Sciences, January 30.—M. Troost in the chair.—On some new experiments relating to the preparation of the diamond: Henri **Moissan.** In connection with the study of the Cañon Diablo meteorite, it appeared desirable to repeat the experiments on the formation of diamonds in rapidly cooled cast iron, with especial reference to the effect of sulphur and silicon in the ingot. The results obtained with an ingot to which iron sulphide had been added immediately before cooling were similar to those of the earlier experiments, except that the yield of diamonds was slightly greater. The addition of silicon had the same effect, except that the formation of the dense silicon carbide rendered the separation of the microscopic diamonds rather more difficult. Drawings of four typical crystals are given.—Synthesis in the anthracene series: MM. **Haller** and A. **Guyot.** γ-hydroxy-γ-triphenyl-dihydroanthracene condenses very readily with amines and phenols, giving compounds of the type

$$(C_6H_5)_2C\begin{matrix} \diagup C_6H_4 \diagdown \\ \diagdown C_6H_4 \diagup \end{matrix}C(C_6H_5)(C_6H_4R),$$

in which R may be $N(CH_3)_2$, $N(C_2H_5)_2$, NH_2, or OH. A description of these substances is given.—The mixed treatment of trypanosomiasis by arsenious acid and trypan-red: A. **Laveran.** The injection of these substances has caused the disappearance of the *Tr. gambiense* in certain animals, and hence the author regards this disease as curable in certain cases, the most efficacious treatment being the successive injection of arsenious acid and trypan-red. As the curative doses of these substances are not far removed from their toxic doses, this toxicity being variable with the animal species, the doses to be prescribed must be rigorously determined. This will be especially difficult for man.—On the faculty possessed by cement strengthened with iron of supporting large elongations: M. **Considère.** Some doubt having been thrown on the earlier work of the author on this subject by German and American writers, details are given of some further experiments, the results of which are in complete accordance with those of the earlier work.—On the new short period comet 1904 *e* (Borrelly, December 28, 1904): G. **Fayet.** Observations on this comet having now been carried on for a month, the calculation of its orbit can be made with more certainty. The results confirm those previously published, the time of revolution being now determined at about seven years.—A secondary shadow observed on the rings of Saturn in October, November, and December, 1904: M. **Amann** and Cl. **Rozet.** Between October 20 and the end of December, besides the shadow of Saturn projected on its ring a second shadow, narrower and less well marked than this, was observed. It traversed the rings throughout in the form of a curved line, and it was noted that the portion of the rings between the shadow of the planet and that now described appeared to be more brilliant than the other illuminated portions of the rings. It is not clear to what this extra shadow can be due.—Remarks on a generalisation of M. Riesz: Émile **Borel.**—On the zeros of integral functions of infinite order, not transfinite: Ed. **Maillet.**—On the precision of geographical positions obtained in the field with the prism astrolabe: M. **Driencourt.** This instrument, invented by A. Claude, has already been tested in the Observatory of Montsouris, with very satisfactory results; it remained to be seen whether the same accuracy could be maintained in field observations. Details are given of some measurements made in Madagascar showing the remarkable saving of time, without loss of precision, resulting from its use.—On the self-registration of the ions of the atmosphere: P. **Langevin** and M. **Moulin.** Owing to the existence of two kinds of ions in air differing greatly in mobility, it is not possible to register these on the same apparatus, although the same principle is applicable. The theory of the apparatus with some details of its construction are given.—On the tempering of bronzes: Léon **Guillet.** The mechanical properties of bronzes of varying content of copper, and after tempering at varying temperatures, correspond very closely with the changes of constitution brought out by the experiments of Heycock and Neville.—A brown modification of colloidal ferric oxide: P. **Nicolardot.**—On the chlorination of methyl-ethyl-ketone: André **Kling.** After trying the various methods of chlorination of ketones, the method found to give the best yield is described in detail, the action of chlorine in the presence of water and marble. The chief product was $CH_3.CHCl.CO.CH_3$, boiling at 114° to 117°, and furnishing the glycol $CH_3.CH.(OH).CH(OH).CH_3$ on reduction.—The action of dilute nitric acid upon vegetable fibres: M. **Jardin.** The use of a weak solution of nitric acid, 5 parts of acid in 1000, is suggested for bleaching flax. It presents certain advantages in regard to the time and the amount of labour required, and leaves a fibre which takes the dye in a perfectly homogeneous manner.—On fiedlerite: A. **de Schulten.** This mineral is a hydrated oxychloride of lead, of a composition corresponding to $2PbOHCl,PbCl_2$.—On the salts of the Tchad region: H. **Courtet.**—On the parasitism of *Osyris alba*: A. **Fraysse.** In a preceding note some conclusions have been given on the biology of *Osyris alba* and on the anatomy of its suckers. In the present note is an account of the general physiology of these suckers and the relations existing between the parasite and its host.—On the changes of composition of the fruit of the Cucurbitaceæ: Leclerc **du Sablon.**—On the chemical composition and the signification of the aleurone grains: S. **Posternak.** The analyses of aleurone grains obtained from four different species of plants showed practically the same composition, noteworthy points being the invariable presence of silicon and the absence of sodium and chlorine. The manganese was more variable in amount than the other elements.—The preparation of practically sterile musts from apples: G. **Perrier.**—The mode of dorsal fixation of *Lernaeenicus Sardinae* on its host: Marcel **Baudouin.**—The existence of intra-uterine rickets: MM. **Charrin** and **Le Play.**—On the folded layers near Saint-Jean-de-Buèges (Herault): René **Nicklès.**—On the ascents of captive balloons carried out on the Mediterranean and on the Atlantic Ocean from the yacht of the Prince of Monaco in 1904: H. **Hergesell.** A study of the atmospheric conditions above the ocean, measurements being taken of the temperature, relative humidity, and direction of the wind at varying heights above the sea level.—On the existence of high terraces in the North Ural: L. **Duparc** and F. **Pearce.**

DIARY OF SOCIETIES.

THURSDAY, FEBRUARY 9.

ROYAL SOCIETY, at 4.30.—(1) On the Conversion of Electric Oscillations into Continuous Currents by means of a Vacuum Valve: (2) On an Instrument for the Measurement of the Length of Long Electric Waves, and also small Inductances and Capacities: Prof. J. A Fleming, F.R.S.—Report on an Area of Local Magnetic Disturbance in East Loch Roag, Lewes, Hebrides: Captain A. M. Field, R.N.—Phosphorescence caused by the Beta and Gamma Rays of Radium: G. T. Beilby.—(1) The Spectrum of Scandium and its Relation to Celestial Spectra; (2) On the Stellar Line near λ 4686; (3) Note on the Spectrum of μ Centauri: Sir Norman Lockyer, K.C.B., F.R.S., and F. E. Baxandall.—Europium and its Ultra-Violet Spectrum: Sir William Crookes, F.R.S.

CONTENTS.

THURSDAY, FEBRUARY 16, 1905.

THE HISTORY OF COAL MINING.

Annals of Coal Mining and the Coal Trade. Second Series. By R. L. Galloway. Pp. xvi+409. (London: Colliery Guardian Co., Ltd., 1904.)

IN a former volume (noticed in NATURE, vol. lix. p. 337) the author carried his annals of coal mining down to the period of the Select Committee of the House of Commons on Accidents in Mines in 1834. He now continues the subject to the passing of the Coal Mines Inspection Act of 1850, and to the establishment of the Royal School of Mines. This volume, like its predecessor, is comprehensive and accurate, and a monument of industry and of thorough technical knowledge.

The period of fifteen years reviewed is one of much interest. After ten years of stagnation came a remarkable increase of activity in the coal and iron industries. The chief causes that imparted the impetus were the rapid extension of steam navigation and the mania for constructing railways. Fresh life had been given to the manufacture of iron by the introduction of hot blast, and, owing to its increasing cheapness, the metal was being more largely used in collieries. Steel, however, was still a scarce commodity. The chief seat of mining operations at this period was in the Wear and South Durham district. In South Wales a considerable development of the steam-coal district took place, owing largely to the opening of the West Bute Dock at Cardiff in 1839. In Yorkshire the greatest depth attained in 1841 was at Barnsley, where the coal lay 594 feet below the surface. In Lancashire two pits were begun in 1838 at Pendleton, which reached the coal at 1392 feet, whilst at Apedale, in North Staffordshire, there was a mine with the exceptional depth of 2177 feet. Frequent instances of spontaneous issues of fire-damp are recorded. Full details of the various explosions are given by the author, and the gradual improvements in mining operations are traced. The author's records show that the men who did most to advance mining progress at this period were John Buddle, of Wallsend (1773–1843), Dr. W. R. Clanny (1776–1850), Sir Henry De la Beche (1796–1855), Michael Faraday (1791–1867), Sir Goldsworthy Gurney (1793–1875), Lord Playfair (1818–1898), Sir Warington Smyth (1817–1890), and James Young, of Bathgate (1811–1883), the founder of the Scotch mineral oil industry.

Incidentally, Mr. Galloway gives interesting etymological details of some local terms the origin of which is uncertain. Thus, in South Staffordshire and Scotland the word "butty" signifies a comrade or associate. Assuming neighbourhood to have been the original idea, a root for the word is suggested by the author in the term "but" as used in the expression "but and ben," applied to a divided house shared by two occupants. Again, what appear to be traces of a primitive state of servitude existed in Staffordshire, where the labourers employed in the haulage of coal continued to be known as "bondsmen"—a name probably coming down from a remote period; a supposition which receives support from a peculiar service required of them, known as "buildases." This consisted in working at times in the morning without receiving any payment beyond a drink of ale. This custom of exacting labour without pay is supposed to represent some ancient service required from their tenants by the monks of the Abbey of Buildwas, in Shropshire, whence the name was derived. Another etymology would have buildas, a contraction of build-house, because the money obtained by means of this unpaid labour enabled the butties to build rows of cottages. Another curious term was that applied to the small stools which in the north of England formed a regular part of the collier's accoutrements. This stool was known as a "cracket," a word which appears to be a variety of cricket.

In reviewing the history of this interesting period it is surprising to find what a large number of recent inventions had been anticipated. For example, the pneumatic system of haulage, successfully applied by Blanchet at Epinac, in France, in 1877, was patented in 1845 by Knowles and Woodcock in Lancashire. The use of reciprocating rods to raise vessels containing coal adopted on the Continent by Méhu, and subsequently by Guibal, was made the subject of a patent by Slade in 1836. The process of raising mineral in successive stages, proposed for working the deep-level mines of the Witwatersrand, appears to have been not uncommon during the first half of the nineteenth century. Winding by endless chain, as proposed by O. C. von Verbo in a book published a few months ago, was patented as early as 1789; and in 1839 an automatic arrangement for cutting off the steam and applying the brake, invented by John Wild, was in operation in Lancashire. The well known ventilator patented by W. P. Struvé was identical in principle with the hydraulic air-pump used in the Hartz mines since the Middle Ages. Iron props, adopted in France in 1880, were used in Derbyshire collieries in 1811, as were also pieces of timber built up two and two crosswise so as to form a square pillar. This so-called pig-sty timbering was introduced as a novelty by the Australian miners at the Day Dawn mine, in Queensland, ten years ago.

In one respect the work is open to criticism. The title "Annals of Coal Mining" should more properly have been "Annals of British Coal Mining," inasmuch as Continental and American practice is barely mentioned. This is to be regretted, as during the period under review several events happened abroad to which reference might usefully have been made. Thus, the first Belgian railway was opened in May, 1835, the first German railway in December, 1835, the first French railway in 1837, and the first Austrian railway in 1838. The first railways made in the United States were coal roads to the mines. In 1835 Thomas and Laurens suggested heating boilers with blast-furnace gas. In 1835 Kind improved the methods of deep boring. In 1846 Schönbein discovered gun cotton, and nitroglycerin was invented in the following year. In 1830 the modern mine-theodolite was invented by F. W. Breithaupt, of Cassel, and in 1845, in France, the trust-like company of the Loire was formed, that was the prototype of the coal trusts and syndicates of to-day. Events such as these had a far-reaching influence on the development of the coal-mining industry.

Special commendation is due to the author for the scrupulous accuracy with which references to original authorities are given, and for the care with which the proof-sheets have been read. Two trifling misprints have, however, escaped detection. Freiberg appears as "Freyburg" (p. 292), and Sir Marc Isambard Brunel as "M. J. Brunel" (p. 291).

BENNETT H. BROUGH.

MATHEMATICS OF BILLIARDS.

Billiards Mathematically Treated. By G. W. Hemming, K.C. Second edition. Pp. 61. (London: Macmillan and Co., Ltd., 1904.) Price 3s. 6d. net.

MORE fortunate, or more careful, than most authors, Mr. Hemming, whose recent death will be regretted by many, did not find it necessary in his second edition to make any material alterations in his original work. He added two appendices, iii. and iv., with which alone it is necessary to deal in the present notice.

Appendix iii. discusses the comparative advantages of fine and through strokes, with regard to the margin of error permissible in the respective cases. In the figure opposite p. 47, A is the player's ball, O the object ball, and the stroke is to make A, after striking O, pass within a distance of the point P depending on the nature of the stroke, namely, for a cannon a distance equal to the diameter of a ball, for a losing hazard the necessary distance from the centre of the pocket, which may vary between different tables. The angle AOP is given by the conditions of the problem, and in the notation adopted is $\pi-\Delta$. The angle of aim, OAS, is the thing to be determined. It shall be denoted by α, as in appendix ii. of the first edition. In the present appendix A_1 is also used for the same angle. S denotes the position of the centre of the striking ball at impact, SO being the common normal. If $ASO=\pi-\theta$, θ and α are connected by the relation $\sin\theta/\sin\alpha = AO/OS = AO/2$ if we denote OS, the diameter of a ball, by 2; and in the special case considered of $AO=PO=30$, or 15 diameters, we might to a very near approximation use α instead of $\sin\alpha$. Further, the angle OPS is denoted by P_1, and the angle of deviation, $\pi-ASP$, by δ. It is then shown that as the equation connecting δ and θ,

$$\tan(\theta+\delta)=p\tan\theta,$$

where, for reasons given in the former edition, $p=3\cdot5$. From this last equation δ may be obtained in terms of θ or α. In fact,

$$\tan\delta=(p-1)\sin\theta\cos\theta/(\cos^2\theta+p\sin^2\theta)$$

is easily found.

The complete method, were it practicable, would be to find an equation in θ or α having two roots, one of which, say θ_1, should correspond to the fine, the other, θ_2, to the through, stroke, and thence the margin of error might be found for each stroke. This analysis being difficult, a practical solution is obtained by means of a diagram in which the ordinate y represents $\sin\Delta$, given by the conditions, and the abscissa x represents $\sin\theta$ in an actual stroke in which, for given Δ, the ball A passes over or very near to P. A series of values of $\sin\theta$ being found corresponding to a series of values of $\sin\Delta$, we draw a freehand curve through them. In general, a line parallel to x for given y cuts this curve in two points, namely, P_y, in which θ has the smaller value (the through stroke), and Q_y, in which it has the greater value (the fine stroke). It comes next in order to find for any y the margin of error for P_y and for Q_y. This is done by using the formula of appendix ii., first edition. The linear error on the object ball is (AO being 30) $30\delta\alpha$. The consequent linear error at P ($PO=30$) is denoted by E. Then $30\delta\alpha/E$ gives the margin of error. A new curve, called the blue curve, is then drawn, having for abscissa $x=\sin\theta$, and for ordinate $y=30\delta\alpha/E$, in the same way, by a series of trials, as the first curve. The blue curve has two branches. Then the margin of error for any of the points P_y or Q_y of the first curve is that ordinate of the blue curve which has the same abscissa. As the result of this method it is found that the margin of error is the same for the through as for the fine stroke, when $\sin\Delta=0\cdot320$, and $\sin\theta=0\cdot132$ for the through, and $\sin\theta=0\cdot960$ for the fine stroke. For smaller values of Δ the through stroke has the advantage; for larger values of Δ the fine stroke, until a certain maximum is reached.

In appendix iv., f, the coefficient of friction between two balls at impact, formerly taken as zero, is assumed to have the values 0·01 or 0·02, and it is found that, instead of $p=3\cdot5$, as above assumed, we should have

$$\text{for } f=0\cdot01\quad p'=3\cdot445+0\cdot0625\cos\theta$$
$$\text{for } f=0\cdot02\quad p'=3\cdot391+0\cdot125\cos\theta.$$

It will be observed that both these values of p' give very approximately $p'=3\cdot5$ when $\theta=30^\circ$, that is, for the half-ball stroke.

Before this notice was in type Mr. Hemming was taken from us by death, to the sincere regret of his many friends, including the present writer.

S. H. BURBURY.

A MORPHOLOGY OF THE ALGÆ.

Morphologie und Biologie der Algen. By Dr. Friedrich Oltmanns. Vol. i. Special part. Pp. vi+733; illustrated. (Jena: Gustav Fischer, 1904.)

THE charming little university town of Freiburg has been the birthplace of important ideas in an obscure department of natural history. De Bary began there his researches into the life-history of the lower fungi, and afterwards continued them at Halle and Strassburg. Owing to his great work and inspiration we botanists owe a germ-theory of disease—a theory which was in time to bear fruit in practical, medical and surgical form in the mighty hands of Lord Lister. To Freiburg, then, we come again for a morphology of the kindred group of the Algæ.

There is a difficulty in understanding how even an assiduous German professor, living so remote from the sea as Freiburg is, can have obtained the inspiration which has guided his research for years past. The study of organisms, which in a living state are for the most part many hundreds of miles from his door, must have presented a task in conquering which his zeal and power of work can find no better example than the volume before us. To a great extent this work must have been book work, and excellent book work it is, the purely bibliographical work especially; and with the aid of herbarium specimens Dr. Oltmanns has succeeded in giving us a general morphology of the Algæ—a treatise to have been expected only from one with abundant leisure and a microscope near the sea. To approach, then, in a spirit of criticism an encyclopædic book of this kind, to try to gauge its worth, seems in the circumstances scarcely "sportsmanlike," if I may use such a term, on the part of one who has had so many greater opportunities of observation.

The De Bary of the subject is, of course, Dr. Bornet, and no student can for a moment question his pre-eminent claims to instruct us. Schmitz, of Greifswald, whose loss we can never cease to deplore, seemed destined to employ his indomitable industry in a work of this kind. Happily we have Dr. Oltmanns, and happily he has had the courage to undertake a task so full of use and pleasure to all students of this fascinating group of plants.

I do not wish for a moment even to seem to detract from the great performance of Dr. Oltmanns. One irresistibly comes back to the Freiburg and De Bary standard. One hoped for a general morphology of the Algæ as De Bary gave us one of the fungi. Dr. Oltmanns has given us an encyclopædic book—an admirable one—but not the reasoned work of genius botanists have dreamt of.

According to personal prejudice, very possibly, I mean prejudice in the right sense of the word, I turned first to the obscure groups of primitive Algæ, groups that I have had so many opportunities of studying on the sea, and of which Dr. Oltmanns can have had few chances of seeing living specimens. It so happened that while writing this review the present writer was engaged in describing a new generic form of pelagic Alga obtained on the outward voyage of the *Discovery*. The point was put to the test by consulting Dr. Oltmanns's descriptions and bibliography. From that, of course, the original sources were taken and verified, not so much for the immediate purpose, as was natural in any case, as for the aim of doing justice in reviewing Dr. Oltmanns's book. The result was triumphant for Dr. Oltmanns—every reference and every description having been pursued to its original source. It is difficult to establish a negative, but no reference was found wanting.

Naturally one turned next to the group Dr. Oltmanns has made his own—the Fucaceæ. It may seem presumption, but it was dutiful, and here, again, the book stood every test. The other groups of Algæ were not made the subject of such rigorous treatment, but they were examined with scrutiny enough to warrant the expression of a very warm and hearty recommendation of this great book to the consideration of botanists and cultivated readers.

George Murray.

OUR BOOK SHELF.

Game, Shore and Water Birds of India: with Additional References to their Allied Species in Other Parts of the World. By Colonel A. Le Messurier, C.I.E., F.Z.S., F.G.S. Fourth edition. Pp. xvi+323. (London: Thacker and Co., 1904.)

The first edition of this work was a modest little volume, printed for private circulation only, on the birds of Sind. This appeared so far back as 1874. Four years later, with some additions, it was issued to the public. Hume and Marshall's epoch-making work on the game birds of India appearing at the same time made a third edition imperative. This in due time appeared, and large additions were made thereto, taken, with acknowledgments, from this formidable rival. Meeting with a well merited success, a fourth edition has now been issued, which differs from the earlier volumes in that it "includes references to all species in other parts of the world that are allied to the Game, Shore, and Water Birds of India."

This addition is made on the curious plea that "owing to the facilities of travel, Anglo-Indians are now engaged in most countries either on business or pleasure." It is to be supposed that Anglo-Indian sportsmen are here specially referred to, and further, that, save for this volume, no information concerning the avifauna of the countries they propose to visit is obtainable. That this is not the case it is needless to say, and the traveller-sportsman would be ill advised who started on his journey with this volume for his only guide and counsellor.

In so far as it concerns the birds of India likely to interest the sportsman, this book will do very well; but it would have been vastly improved if the space now devoted to extra-Indian birds had been utilised for fuller descriptions of the native species, and for the description of the geographical and climatic conditions of the several regions of this vast hunting ground.

The introduction to this book contains, we venture to think, not a little that is out of place in a work of this kind. Much of it is admittedly compiled from abstruse scientific treatises, or from the labels of the Natural History Museum at South Kensington.

There can be no doubt but that the author, during his long residence in India and his wide experience in the field, must have accumulated a vast store of facts concerning Indian birds which would be well worth recording. For this reason, therefore, we regret that he decided on including in this edition matter really foreign to the scope of his book. His first-hand observations would have been of infinitely more interest and value than the compilation now presented.

The illustrations are numerous, and mostly very crude. W. P. P.

The Species of Dalbergia of South-Eastern Asia. By Dr. D. Prain. (Annals of the Royal Botanic Gardens, Calcutta, vol. x., part i.) Pp. iv+114; and plates. (Calcutta, 1904.) Price 1*l.* 13*s.*

The stages in the evolution of the genus Dalbergia are sketched in the early pages of this memoir. After removal of the extraneous species, the genus was delimited by Bentham in 1851, and four subdivisions, Selenolobium, Dalbergaria, Sissoa, and Triptolomea, were mapped out. Although Bentham himself pointed out that there was overlapping in these subdivisions, the grouping has been maintained by later systematists down to and including Taubert, who undertook the Leguminosæ for the "Pflanzenfamilien" in 1894. Dr. Prain, who had previously reviewed the genus when collating the Leguminosæ in connection with "Materials for a Flora of the

Malayan Peninsula," has, after a study of several years, introduced a new arrangement with two main sections, Sissoa, which includes the greater part of Bentham's Triptolomea and Sissoa, and Amerimnon, called after an American type. Dr. Prain's classification differs from Bentham's, since he adopts the shape and orientation of the corolla and the form of the style as the criteria of his subdivisions instead of the characters of the inflorescence, stamens, and fruit.

The genus is distributed through the tropics of Africa and America as well as Asia, and it seems a pity that the author did not see his way to extend his monograph to all the known species. The distribution in Asia is considered for five provinces, East China, Indo-China, Indo-Himalaya, Malaya, and Papuasia; the number of endemic species in each is large, and amounts to 72 per cent. for East China. Very few species are found in more than two of these provinces; *Dalbergia tamarindifolia* occurs in four, and *Dalbergia torta* (= *D. monosperma*), which has pods well suited for dispersal by ocean currents, is the only species found in all five provinces. Owing to the inclusion of recent specimens from Malay and China, the total number of authenticated species amounts to eighty-six; a few, including the *Dalbergia laccifera* of Lanessan, still remain unidentified. The memoir is illustrated with diagrams of groupings and maps of distribution, as well as with figures of each species, and issued as the first part of the tenth volume it forms a valuable addition to the *Annals* of the Royal Botanic Gardens, Calcutta.

The Process Year Book. Penrose's Pictorial Annual, 1904–5. Edited by William Gamble. Pp. xvi + 160. (London: Penrose and Co.)

EVERY year we receive this annual, and each time it is our pleasure to point out the very high standard which the volume attains. The current issue bids us to repeat the opinions expressed in our previous notices, and to supplement them with the statement that the standard has again been changed to one of a higher order.

To gain some idea of the possibilities of process work of to-day, when the best work and materials are employed, the reader has only to take up this book and examine the contents, which will at once indicate the high state of efficiency and the variety of methods that are available. In the first place we have a series of instructive articles, covering 160 pages, most of which are from the pens of well-known workers. These deal with manifold portions of a far-reaching subject, and give the advice, results of experience, and views of these workers on numerous points of interest. Of the illustrations, which form such a conspicuous feature of this annual, much could be written, for it is in them that we see the practical results of the processes in use to-day. If we sum up the plates, colour prints, supplement illustrations, and illustrations in the text, we have a collection which for variety of subjects and excellence of reproduction is unique. The photogravure, as a frontispiece by J. J. Waddington, Ltd., the "Turner" reproduced by the three-colour process of André and Sleigh, and the interlayed half-tone by the Arthur Cox Illustrating Co., Ltd., are three amongst a host of other good samples that are met with.

Apart from the large number of process workers who await annually the appearance of this year book, this handsome volume will appeal to a wide circle of readers who are in any way connected with the artistic or utilitarian side of the art of reproducing pictures. The editor and his contributors, together with the publishers and printers, all deserve great credit for such an admirable result of their combined efforts.

LETTERS TO THE EDITOR.

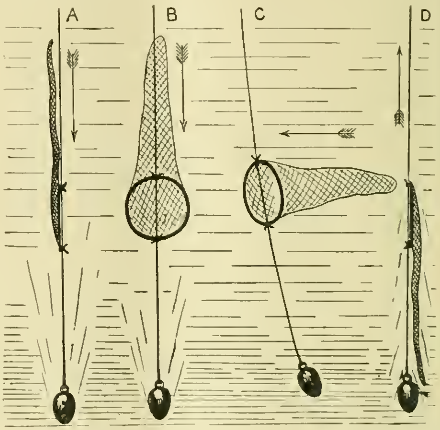
[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

On a Method of Using the Tow-net as an Opening and Closing Tow-net.

EVERY naturalist who has engaged in marine research is aware of the great difficulties which attend upon research in the intermediate depths.

Great ingenuity has been displayed in the invention of very elaborate instruments—many of them hopeful, some of them successful. It had appeared to me, as the result of observations, and after conversation with Mr. J. Y. Buchanan, who had made similar observations, that a solution of this problem might be found easily in experiments with the ordinary tow-net.

Our joint experience was this. If an ordinary tow-net were lashed at two opposite points of the rim to a rigid sounding-wire, and so plunged at speed into the depths, the net would fold over and close. It might then be towed at the required depth and afterwards reeled in by the sounding engine at express speed—again closing in its upward course.



Through the great kindness and sympathy of Mr. M. H. Gray, of the Silvertown Submarine Telegraph Company, I was afforded an opportunity of putting this theory to the test on board the *Dacia*.

The conditions of the experiment appeared to me at the time adverse, since my tow-nets and other apparatus were missing at Gibraltar; but this was a blessing in disguise. I set to work and made a tow-net out of old bunting and the rim out of a barrel hoop. This tow-net was so flimsy that in towing it alongside at little more than mere steerage-way it frequently burst. To plunge it into the depths would be a supreme test, since not even No. 20 Miller's Silk in an open net could stand the strain I proposed. Off the north-west coast of Africa I had three days' opportunity of experiments, the absurd tow-net being in ludicrous inverse proportion to the magnificent sounding crew and sounding engine. A reference to the diagram will show A, the descent of the net folded over; B, the net opening at the required depth; C, the net being towed at the required depth; and D, the net being reeled in closed as in its descent.

I confess that when the first experiment was made I had faint hope of seeing that flimsy tow-net again, but it emerged with many organisms we had not captured on the surface. To cut matters short, these experiments were repeated for three days without a hitch at from 200 to 300 fathoms, the flimsy net emerging from its trials on every occasion with success.

There are two practical points. The first is the art of plunging the net at the surface, the next that of whipping it out on reeling in, so that there may be no contamination of surface organisms during the critical moments. With a highly expert sounding crew such as I had at my service this was easily done.

My repeated experiments were also addressed to this point, viz. to ascertain the best rate of descent and ascent of the net, and my experience was 100 fathoms a minute. The flimsy net stood all tests.

To the modern marine naturalist, whose complicated (and expensive) opening and closing tow-net is an object of worship, this simple advice may seem like telling him to "bathe seven times in Jordan"; he wishes to do a great thing. GEORGE MURRAY.

February 5.

The Sixth Satellite of Jupiter.

THE author of the article on the sixth satellite of Jupiter in NATURE of January 19 has obviously made a slip in assuming that the "retrograde" motion ascribed to the satellite means retrograde in the sky, and not in the orbit. According to the ephemeris, Jupiter on January 4 was moving direct, *i.e. eastward,* about 225″ daily. The satellite was *west* of the planet (position angle 269°), approaching Jupiter at the rate of 45″ a day, and, therefore, moving eastward (direct) about 270″ daily.

The position angle on January 17, according to the latest bulletin from Mount Hamilton, was 266°, having decreased 3°; the distance of the satellite had decreased from 45′ to 36′. If the object is really a satellite this necessarily indicates a retrograde orbital motion, unless the plane of its orbit is so much inclined to that of the other satellite-orbits as to make the new one pass north of the planet at inferior conjunction instead of south as the others now do.

The observations thus far published would, however, apply equally well to an asteroid a little within or beyond the orbit of Jupiter, and near perihelion in an orbit of some eccentricity and with a mean distance from the sun somewhat greater than that of Jupiter. We must wait for further observations to determine the truth. C. A. YOUNG.

Princeton, N.J., U.S.A., February 3.

The Circulation of the Atmosphere.

I HAVE read with great interest your review of Prof. H. H. Hildebrandsson's report on "The General Motion of Clouds" (NATURE, February 2, p. 320).

All his observations appear to support the theory of my father, the late Prof. James Thomson, as set forth in the Bakerian lecture on "The Grand Currents of Atmospheric Circulation" (*Phil. Trans.*, vol. clxxxiii. p. 653, 1892) and in his earlier paper read before the British Association in 1857.

Is it possible that Prof. Hildebrandsson has not seen these papers, and has accepted theories put forward as Prof. James Thomson's instead of referring to the originals? Anyone who takes the trouble to read these papers carefully must see that it is distinctly stated that the main direction of the upper current of the atmosphere is from west to east while moving steadily and gradually towards the Poles, and that the air keeps this west to east motion as it sinks to a lower level, and becomes the great return current towards the equator. This motion can hardly be termed "vertical circulation." As for Prof. Hildebrandsson's assumption concerning Hadley's theory, I should like to quote the following passage from my father's paper:—

"In 1735 George Hadley submitted to the Royal Society the paper of which I have made mention already as supplying for the first time a substantially true theory of the primarily dominant conditions of atmospheric circulation. The paper is entitled 'Concerning the Cause of the General Trade Winds,' and it is right here to notice that Hadley applied the name 'General Trade Winds' not merely to those winds of equatorial regions to which the name Trade Winds is ordinarily restricted, but uses it as including also the west to east winds known to be prevalent in higher latitudes, and used in trade by mariners for ocean passages from west to east. Thus the scope of his theory must be understood as being much wider than what would be conveyed in ordinary nomenclature by the name Theory of the Trade Winds."

So far then from opposing Hadley's theory, my father's amplifies and completes it. JAMES THOMSON.

22 Wentworth Place, Newcastle-on-Tyne, February 6.

Remarkable Temperature Inversion and the Recent High Barometer.

DURING Friday and Saturday, January 27 and 28, the barometric pressure over the south of England was exceptionally high, readings of 31.00 inches being observed at 6 p.m. on Saturday in the extreme south-west of the country. In the neighbourhood of London the barometer rose to 30.90 during the night of January 26, and remained at about that height until the morning of January 29, a well marked anti-cyclone with readings over this value being shown on the morning and evening weather charts of January 27 and 28.

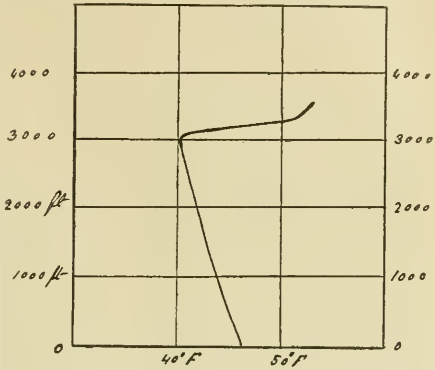


FIG. 1—Temperature inversion on January 28 at Oxshott, Surrey.

During such conditions it is in general impossible to raise a kite, owing to the want or lightness of wind; but on January 28, during the afternoon, there was sufficient breeze from the west to start a kite carrying recording instruments, and to take them to a height of 3600 feet. A very remarkable temperature inversion was found to exist, the details of which are shown in the accompanying chart. At 3.40 p.m. the surface temperature was 47°.0 F.; at 4.45 p.m. it had fallen to 45°.0 F. The temperature decreased steadily to 40° F. at 3000 feet; a little higher a rise of 12° took place, the temperature at 3300 feet being 52° F. At 4.28 p.m., at 3600 feet, the temperature was 53° F. Unfortunately, the humidity trace on the meteorograph partially failed, but it suffices to show that the temperature inversion was, as such inversions in my experience always are, accompanied by extreme dryness of the air.

The wind was west at the surface, and shifted gradually to north-west at the highest point reached, but there was no sudden change of direction at the height where the temperature inversion occurred.

I do not wish to imply that the high barometer and the temperature inversion are necessarily correlated phenomena, but the coincidence is interesting. W. H. DINES.

Dates of Publication of Scientific Books.

WITH reference to the complaint of Mr. R. P. Paraiypye (p. 320) that a big sum is still asked for Price's "Treatise on Infinitesimal Calculus," I should be obliged if you would allow me to point out that the price of this work is, and has been for some time, 5s. a volume.

HENRY FROWDE.

Oxford University Press Warehouse, Amen Corner, London, E.C., February 8.

A National University Library.

It must be the experience of any graduate of Oxford or Cambridge who is residing at a distance from those university towns that a serious obstacle to the prosecution of research arises from the impossibility of consulting the university libraries, and the absence of any provision for borrowing volumes, or obtaining references under arrangements similar to those pertaining at the libraries of the Royal and other scientific societies. Moreover, while Oxford and Cambridge possess the special privilege of acquiring free copies of books copyrighted in England, there are now many universities in this country which are far too poor to keep up even a decently respectable library in any branch of science.

The conditions of modern times have created a need for a National University Library, enjoying the same privileges as the Oxford and Cambridge libraries, and which should be available for graduates of any British university; persons engaged in any specified branch of research to have the opportunity of borrowing books through the post as in the case of the Royal Society. G. H. BRYAN.

Mutation.

THE term mutation is applied in biology to that sort of variation in which the equilibrium of the organism seems to be disturbed, and a new position of equilibrium is found, which is markedly different from the original one. This may apply to a whole organism or merely to some one organ, so far as external appearances show.

In all the discussions regarding mutation which have lately taken place, the difficulty has been felt that it is impossible by any methods yet known to perceive and measure the internal changes and influences leading to mutability. It is certainly not supposed that mutability is without cause, but it is obviously difficult to detect the causes which bring it about.

It occurs to me that some help may be obtained from analogies derived from psychology and sociology. What mutation is in biology, conversion is in psychology, and revolution in sociology. It may be said that to assume such parallels is merely to beg the question, but I think that the apparent parallelism cannot be without significance. Now the phenomena leading towards conversion have been studied subjectively (*cf.* James, "Varieties of Religious Experience"), and those leading towards revolution have been studied objectively, with certain well-defined results. If the supposed analogy is a valid one, it appears to follow that mutability is due to the same general causes as ordinary variability (just as change of opinion and reform are due to the same general causes as conversion and revolution), but that there is this difference—mutability represents an explosion of energy, as it were, in a given direction, and therefore differs from ordinary variation somewhat as the firing of a gun differs from the explosion of a loose heap of powder. It also follows that the cause of the explosion is not plasticity in the organism, but in some measure the reverse; that is, the power of being influenced, and at the same time of withstanding the expression of the influence until it had acquired considerable force. This implies a certain rigidity of type, quite comparable with a type of mind familiar to all. It further appears to follow that the chance of mutations succeeding from the first is comparatively remote, though such a thing is quite possible; but since they are the result of general causes, the sort of changes the mutations exhibit are likely to come about in due course, just as the sort of changes represented by a revolution are likely to prevail ultimately, though the revolution itself may appear to fail.

University of Colorado, Boulder, Colorado, January 25.

Fact in Sociology.

MR. WELLS is a dangerous man to criticise. Such thunderbolts as "crude," "dull," "balderdash," come hurtling at one's head even from his modified letters (NATURE, February 2). But I prefer to regard it all as meant only for sheet lightning. Indeed, when I consider the courtesy that characterised my article (NATURE, December 29), plain-spoken though it was on some points, I cannot take any other view.

Now to Mr. Wells's points in order.

(1) "'The Food of the Gods' does not claim to forecast the future." My mistake was natural. It only shows the risk Mr. Wells runs in appearing before the world in two entirely different characters. Still, I hit upon a weak point. He pictures an ideal State, but cannot show us how it is to be realised. Archimedes had no fulcrum for the lever with which he would have moved the world. Mr. Wells has no power to apply to his.

(2) "*I have mixed up 'Anticipations' and 'Mankind in the Making.'*" Why keep them separate? "Anticipations" also deals largely with ideals.

(3) *Re* the question—Which of the great national "syntheses" will attain predominance, see "Anticipations," chap. viii. *passim*, and especially pp. 100, 101 (6d. ed., 1904). This chapter seemed to me an interesting speculation, but Mr. Wells describes what I thought, and, on re-reading, think is to be found in it as "balderdash." True, through inadvertence I wrote "Anglo-Saxon" instead of "English-speaking," for which I am sorry.

(4) *Re* the recruiting of the upper strata of society from the lower, nothing, he says, is known about this. Still, those who have studied human evolution think they know something. Prof. Karl Pearson even says that there are "class statistics" for the population of Copenhagen, and writes, "the population would accordingly appear to be ultimately, and in the long run, reproducing itself from the artisan classes" (*Natural Science*, May, 1896). Dr. Mercier (see the Sociological Society's papers, 1904, p. 55) regards "a civilised community in the light of a lamp, which burns away at the top and is replenished at the bottom." As to "stagnant" classes, I find in "Anticipations," p. 121, "It (the new Republic) will tolerate no dark corners where the people of the Abyss may fester, no vast diffused slums of peasant proprietors, no stagnant plague preserves." See especially p. 117 for Mr. Wells's plan for getting rid of undesirable types. As to careful parentage, see "Mankind in the Making," p. 99:—"The first step to ensuring them (the ends aimed at) is certainly to do all we can to discourage reckless parentage."

In conclusion, let me describe myself as a much-battered but not unfriendly critic of the New Republic.

F. W. H.

The Melting of Floating Ice.

MAY I suggest that Dr. Deventer, of Amsterdam, whose letter to you is referred to in your issue of January 26 (p. 303), has discovered a "mare's nest"?

His observant pupil, who noticed that in a glass filled to the brim with water and floating ice the melting of the latter did not cause overflow, was apparently totally ignorant of the laws of flotation, or he would not have expected otherwise. Why should the level of the water change? The ice in melting must of necessity just fill with water the space that it displaced when floating, and so the level remains unaltered. So Dr. Deventer's statement that "when a vessel contains a solid floating in its own liquid, the level of the latter does not change by the melting of the solid" appears quite superfluous.

As to making this a "general" law applying to *solids floating in their own liquids*, surely the rule is that solids do *not* do so, but sink. Why make a general law which only applies in the case of a very few exceptional substances, such as ice, cast iron, and bismuth? HEAT.

February 8th.

A Lunar Rainbow.

LAST night, after 10 p.m., a thunderstorm passed over this town, travelling from west to east. When the storm had passed and the rain had almost ceased, a bright quarter-moon shone brilliantly almost overhead. To the east the clouds were still very heavy and dark, and in that direction there appeared a perfect rainbow. The arc of the bow was low; it appeared as a grey band with a certain suggestion of colour, against the dark leaden sky.

I should be glad to know from any of your readers if such moon rainbows are of common occurrence, as the one of last night is the first which I have seen.

Pretoria, Transvaal, January 15. J. MCCRAE.

NOTES ON STONEHENGE.[1]

III.—THE EARLIEST CIRCLES.

WHEN we come to examine Stonehenge carefully in relation to the orientation theory, it soon becomes clear that its outer circle of upright stones with lintels and the inner naos, built of trilithons, oriented in the line of the "avenue" and the summer solstice sunrise, are not the only things to be considered. These stones, all composed of sarsen, which, be it remarked, have been trimmed and tooled, are not alone in question. We have:—

(1) An interior circle broken in many places, and other stones near the naos, composed of stones,

FIG. 8.—Map of the Stones made by the Ordnance Survey. A, N.W. stone; B, S.E. stone; C, Friar's Heel; D, Slaughter stone.

"blue stones," which, as we have seen, are of an entirely different origin and composition.

(2) Two smaller *untrimmed* sarsen stones lying near the vallum, *not* at the same distance from it, the line joining them passing nearly, but not quite, through the centre of the sarsen circle. The amplitude of the line joining them is approximately 26° S. of E. and 26° N. of W. Of these the stump of the N.W. stone is situated 22 feet from the top of the vallum according to the Ordnance plan. The S.E. stone has fallen, but according to careful observations and measurements by Mr. Penrose, when erect its centre was 14 feet from the top of the vallum. The centre of the line joining the stones is therefore 4 feet to the S.E. of the axis of the present circles, which, it may be stated, passes 3 feet to the N.W. of the N.W. edge of the Friar's Heel (see Fig. 8).

There are besides these two large *untrimmed* sarsen stones, one standing some distance outside the vallum, one recumbent, lying on the vallum, both nearly, but not quite, in the sunrise line as viewed from the centre of the sarsen circle. These are termed the "Friar's Heel" and "Slaughter Stone" respectively.

I will deal with (1) first, and begin by another quotation from Mr. Cunnington, who displayed great acumen in dealing with the smaller stones not sarsens.

"The most important consideration connected with the smaller stones, and one which in its archæological bearing has been too much overlooked, is the fact of their having been brought from a great distance. I expressed an opinion on this subject in a lecture delivered at Devizes more than eighteen years ago, and I have been increasingly impressed with it since. I believe that these stones would not have been brought from such a distance to a spot where an abundance of building stones equally suitable in every respect already existed, unless some special or religious value had been attached to them. This goes far to prove that Stonehenge was *originally a temple,* and neither a monument raised to the memory of the dead, nor an astronomical calendar or almanac.

"It has been suggested that they were Danams, or the offerings of successive votaries. Would there in such case have been such uniformity of design or would they have been all alike of foreign materials? I would make one remark about the small impost of a trilithon of syenite, now lying prostrate within the circle. One writer has followed another in taking it for granted that there must have been a second, corresponding with it, on the opposite side. Of this there is neither proof nor record, not a trace of one having been seen by any person who has written on the subject. This small impost, not being of sarsen, but syenite, must have belonged to the original old circle; *it may even have suggested to the builders of the present Stonehenge the idea of the large imposts and trilithons, with their tenons and mortices.*"

In Prof. Gowland's examination of the contents of the holes necessarily dug in his operations, it was found that the quantity of blue stone chippings was much greater than that from the sarsen stones. While the sarsen stones had only been worked or tooled on their surface, the blue stones had been hewed and trimmed in extraordinary fashion; indeed, it is stated by Prof. Judd that some of them had been reduced to half their original dimensions in this process, though evidence of this statement is not given.

It seems, then, that when the sarsen stones were set up, the sarsen and blue stones were treated very differently. This being so, the following quotation from Prof. Judd's "Note" is interesting (*Archaeologia*, lviii., p. 81):—

[1] Continued from p. 342.

"I may repeat my conviction that if the prevalent beliefs and traditions concerning Stonehenge were true, and the 'bluestone' circles were transported from some distant locality, either as trophies of war, or as the sacred treasures of a wandering tribe, it is quite inconceivable that they should have been hewed and chipped, as we now know them to have been, and reduced in some cases to half their dimensions, *after having been carried with enormous difficulty over land and water, and over hills and valleys.* On the other hand, in the glacial drift, which once probably thinly covered the district, the glacial deposits dying out very gradually as we proceed southwards, we have a source from which such stones might probably have been derived. It is quite a well-known peculiarity of the glacial drift to exhibit considerable assemblages of stones of a particular character at certain spots, each of these assemblages having probably been derived from the same source.

"I would therefore suggest as probable that when the early inhabitants of this island commenced the erection of Stonehenge, Salisbury Plain was sprinkled over thickly with the great white masses of the sarsen-stones ('grey wethers'), and much more sparingly with darker coloured boulders (the so-called 'blue-stones'), the last relics of the glacial drift, which have been nearly denuded away. From these two kinds of materials the stones suitable for the contemplated temple were selected. It is even possible that the abundance and association of these two kinds of materials, so strikingly contrasted in colour and appearance, at a particular spot, may not only have decided the site, but to some extent, have suggested the architectural features of the noble structure of Stonehenge."

If we grant everything that Prof. Judd states, the question remains why did the same men at the same time treat the sarsen and blue stones so differently in the same place?

I shall show subsequently that there is a definite answer to the question on one assumption.

I next come to (2). The important point about these stones is that with the amplitude 26°, at Stonehenge, a line from the centre of the circle over the N.W. stone would mark the sunset place in the first week in May, and a line over the S.E. stone would similarly deal with the November sunrise. We are thus brought in presence of the May-November year.

Another point about these stones is that they are not at the same distance from the centre of the sarsen stone circle, which itself is concentric with the temenos mound; this is why they lie at different distances from the mound. Further, a line drawn from the point of the Friar's Heel and the now recumbent Slaughter Stone with the amplitude determined by Mr. Penrose and myself for the summer solstice sunrise in 1680 B.C. cuts the line joining the stones at the middle point, suggesting that the four untrimmed sarsen stones provided alignments both for the May and June years at about that date.

Nor is this all; the so-called tumuli within the vallum may merely have been observation mounds, for the lines passing from the northern tumulus over the N.W. stone and from the southern tumulus over the S.E. one are parallel to the avenue, and therefore represent the solstitial orientation.

So much, then, for the stones. We see that, dealing only with the untrimmed sarsens that remain, the places of the May sunset and June and November sunrises were marked from the same central point.

Statements have been made that there was the stump of another stone near the vallum to the S.W., in the line of the Friar's Heel and Slaughter Stone, produced backwards, at the same distance from the old centre as the N.W. and S.E. stones. This stone was not found in an exploration by Sir Edmund Antrobus, Mr. Penrose, and Mr. Howard Payn by means of a sword and an auger. But the question will not be settled until surface digging is permitted, as a "road" about which there is a present contention passes near the spot.

But even this is not the only evidence we have for

FIG. 9.—The rod on the recumbent stone is placed in and along the common axis of the present circle and avenue. It is seen that the Friar's Heel, the top of which is shown in the distance, would hide the sunrise place if the axis were a little further to the S.E.

the May worship in early times. There is an old tradition of the slaughter of Britons by the Saxons at Stonehenge, known as "The Treachery of the Long Knives"; according to some accounts, 460 British chieftains were killed while attending a banquet and conference. Now at what time of the year did this take place? Was it at the summer solstice on June 21? I have gathered from Guest's "Mabinogion," vol. ii. p. 433, and Davies's "Mythology of the British Druids," p. 333, that *the banquet took place on May eve "Meinvethydd."* Is it likely that this date would have been chosen in a solar temple dedicated exclusively to the solstice?

Now the theory to which my work and thought have led me is that the megalithic structures at Stonehenge—the worked sarsens with their mortices and lintels, and above all the trilithons of the magnificent naos—represent a re-dedication and a re-construction, on a much more imposing plan and scale, of a much older temple.

NORMAN LOCKYER.

ANIMAL LIFE.[1]

WITH the appearance of this half-volume we have to congratulate the author and his publishers on the completion of a work which must have involved an enormous amount of labour, and which, in this country at any rate, is unique. The great impulse which has of late years been given to "nature-teaching" rendered a work of this class almost essential (for the mode of treatment could not have been adopted in a systematic natural history), and Prof. Davis has realised the want, and done his best to supply what was required.

In spite of certain errors and blemishes, to some of which we have directed attention on previous occasions, and bearing in mind the magnitude of the task for a single individual, it may be safely said that, on the whole, the author has been successful in his efforts, and that when a second edition is called for, and the necessary emendations and corrections have been made the work will take its place as an important popular text-book of bionomics.

The half-volume now before us includes some of the most interesting sections of the whole subject, discussing as it does the economic aspect of zoology, the natural history of sport, animals as pets, geographical distribution, the palæontological record, and the doctrine of evolution and heredity. Unfortunately, the author has not allowed sufficient space for some of these subjects. Fur-bearing animals are, for instance, very imperfectly described, no mention being made of such important furs as Arctic and silver fox, otter and nutria; and if only the author had left out the "old wives' tales" about the shrew on pp. 319 and 320 he would have had ample room for proper treatment.

Neither is the volume altogether free from downright errors. For instance, the statement on p. 313 that Lake Baikal was recently connected with the sea is totally opposed to modern views; and it is equally untrue that the great Indian rhinoceros "bites" (p. 373), while the statement (p. 421) that there are no wild oxen in Africa at least requires qualification. On p. 469 we find the usual exaggerated statement of the size of dinosaurs (115 instead of 60 or 70 feet!). Among misspelt names it must suffice to mention (p. 430) *Pudus* for *Pudua*, and (p. 432) *Euneces* for *Eunectes* (we can guess whence the author copied the latter); but it may be added that Saccomyidæ is not the proper title for the pocket-gophers, or Euspongia for the typical sponges. An expression on p. 375 leads one to believe that the author is unaware of the existence of the Devon and Somerset staghounds; while (p. 379) the term "hunting," as applied to fishes, seems somewhat misplaced.

FIG 1.—Mexican Poisonous Lizard (*Heloderma horridum*). From "The Natural History of Animals."

The section on geographical distribution may perhaps be best described as feeble, the author "wobbling" on the subject of "Wallace's line," and being apparently unacquainted either with the works of Max Weber or with a certain text-book published by the Cambridge University Press. In fairness to his readers the author should have told them that there are distributional divisions of the globe other than those adopted by Dr. Wallace; and also that such divisions are based on the range of mammals and birds, and do not accord with that of several other groups.

The coloured plates render this and its fellow volumes attractive to the general reader, and most of the other illustrations (one of which is here reproduced) are well chosen and well executed.

[1] "The Natural History of Animals; the Animal Life of the World in its various Aspects and Relations." By J. R. A. Davis. Half vol. viii. Pp. xviii+261–555. (London: The Gresham Publishing Co., 1904.) Price 7s. net.

THE CONDITION OF CHEMICAL INDUSTRIES IN FRANCE.

THE results of an inquiry into the present condition of French chemical industries are described in the *Revue scientifique* of January 28. The upshot of this inquiry is the recommendation that a society should be founded for France, having its headquarters in Paris, with branches in all large towns in France, with a council consisting of the heads of industrial enterprises, the professors in universities and "lycées," of independent persons, and of all interested in industrial chemistry. The duties of this society should be (1) to suggest and press on the Government solutions of the great economic problems of importance to chemical industry; (2) to collect statistics abroad and to endeavour to gain markets for French products by aid of the consular service; and to devise means to prevent competition between French manufacturers, and to promote combination among them against their foreign rivals; and (3) to act as an advisory body to industrial chemists, and to take steps to direct the education of young chemists into channels helpful to the progress of chemical industry. It is suggested that the work of the society should be aided by congresses in certain towns, which should be attended by the local manufacturers, as well as by those who carry on the same or similar processes elsewhere. In conclusion, the future president, it is suggested, should be Prof. Haller, who has done so much for the industrial progress of the town and University of Nancy, and who is now professor at the Sorbonne, the University of Paris.

Such are the recommendations of the report. The reasons annexed to these recommendations, which form the earlier part of the report, are derived from numerous letters from and interviews with members of some eighty-two representative firms. The opinions of some of these form amusing reading. Thus we learn from the manufacturers of "eau de Javel," the precursor of bleaching-powder, that Monsieur B., "suffit à l'exploitation." In another case "The brewery has no chemist at all, and gets all its analyses made at the brewing-school." Another firm which produces "some rare bodies" (one would like to know what they are) dismisses the question in almost the historical words which preceded the decapitation of Lavoisier—"Aucun besoin de la collaboration des savants"! Another intelligent manufacturer, designated as X, (1) ventures the daring statement that "the candle industry and chemistry have nothing in common." Oh, shade of Dumas! X (10) does not think that the collaboration of "savants" would be useful in the extraction of dyeing stuffs from wood; and a soap-maker, X (16), who confesses himself ignorant of chemistry, thinks that "chemistry can contribute nothing of use to the soap industry, seeing that soap is always made in the same way"!

These examples show that some educative action is necessary in France. The necessity is also apparent when recent statistics are considered. For while the raw materials exported from Germany have remained practically stationary for the last twenty years, those imported have doubled in value; and while the imports of manufactured products have barely increased in value during the same interval of time, the value of the exported manufactured chemical substances has risen from 200 million marks in 1880 to 352 million marks in 1900. The progress in France, accordingly, is much behind that of Germany. To add insult to injury, the red trousers, so conspicuous in the French Army, were designed originally to encourage the cultivation of the madder plant; the plant is commercially as extinct as the dodo, and the trousers are now dyed with artificial alizarin supplied from Germany! Sacre nom de tonnerre!

As this article is written in the hope of reaching the ignorant, the author, M. Jean Jaubert, has taken some pains to show how many-sided the industrial chemist should be if he is to direct his enterprise intelligently, and he sketches the steps taken by the Germans to secure such general knowledge. The collaboration of manufactories and university professors, the give and take, the university training of the scientific heads of departments in chemical works, account for an increase between 1887 and 1900 in the number of works in Germany from 4235 to 7169; in the number of workmen from 82,000 to 153,000; and for *an increase in the average wage of these workmen from 38l. to 50l. a year;* and the average percentage dividend of 121 joint-stock companies, obliged by law to publish their accounts, has risen from $9\frac{3}{4}$ per cent. in 1888 to $13\frac{1}{2}$ per cent. in 1899. Evidently German chemical industry is prosperous, and profitable to all classes concerned. Indeed, the dividend of artificial colouring companies shows a still better figure; the increase in dividend is from 15 per cent. in 1888 to $20\frac{1}{2}$ per cent. in 1900.

Unfortunately, similar statistics are not furnished for France, either because they do not exist or because they are better concealed.

How can this distressing state of affairs be remedied? To what is industrial France to turn? The opinions of many manufacturers are quoted, and some shall be adduced here. First, secondary education is at fault; all initiative is crushed in the secondary schools, and all pupils are turned out of one uniform mould. But, it is acknowledged, an attempt is being made to remedy this. Second, it is said nearly unanimously, by all those asked for their opinions, that the training of young chemists is not sufficiently practical. There is in the universities too much tendency to train teachers rather than industrial men; and the professors often look down on the commercial side of their science. The union of science and industry is recommended. Like ourselves, the French manufacturers, ignorant themselves, often engage a young chemist, and expect him at once to know all about their work and to be able to devise improvements; when they find out that he is of little value they contemn chemistry, as we have seen in what precedes. Others complain that they have to pay their chemists for a year or a year and a half while he is learning their needs; and yet it is acknowledged that no education in a technical school can be of any value; for the teacher cannot teach anything worth knowing about the really important dodges employed by the manufacturer, nor is he welcomed in the work if he lectures on any special process. In a minority of works the German system is followed; young men are engaged as juniors, and work under the supervision of seniors; according to the ability and tastes which they show for routine work, for management, or for invention, they are kept as analysts, made managers, or left in the research laboratory. But it is justly remarked that this excellent plan is impossible for small manufacturers.

In many (most?) cases the difficulty lies in the smallness of the remuneration. It appears common for a chemist to receive 48l. to 72l. a year, rare for the pay to exceed 100l. Now that is little more than workmen's wages; and it is the reward of an expensive education. Yet the manufacturer often grumbles at having to teach such young men their business, and says that they should pay for his tuition; and on the other hand, the chemist who has survived the kicks, cuffs and insults from the foreman, and hard work of the first year, and has acquired some practical knowledge, does not see why he should not better himself if he can.

Again, German firms employ chemists in many walks of life. A man who is a chemist makes a much better traveller for a chemical firm than an ignoramus who can only tout his goods; and their chemists, if they show commercial ability, often take to the business side of the concern, and they know chemistry is a recommendation, not a drawback.

In spite of the low pay, France, according to all reports, is overcrowded with chemists. Some pity them; others think that this plethora will lead to the survival of the fittest. The old-fashioned foreman is as undying in France as here, however, and as opposed to any attempt at innovation. Yet he is being displaced by chemists in some works; and this, common in Germany, is one of the chief causes of her industrial prosperity. The foreman, knowing some tips of importance, looks askance at anyone who attacks experimentally the problems of his manufactures; for he knows if they are once discovered his use is past. On the other hand, if foreman work is done by a chemist, trained in experimental methods and anxious to improve his product (and his position), reforms can be made, and are willingly undertaken. We in England are in a similar plight; one of the greatest preventives to progress is the foreman. Why, many chemists would be glad of his $3l.$ a week, and would be infinitely more useful.

A closer intimacy between professor and manufacturer is strongly urged. But in France there is apparently mutual distrust. The standing of the professors is low, for one thing, the best paid post (at Paris) bringing in only 800*l.* a year; in the provinces the salaries run from 240*l.* to 400*l.* This contrasts unpleasantly with German salaries, which seldom fall below 600*l.*, and may amount to 3600*l.* In France, many men have a taste for the career of professor, and will work cheap for glory; "that is the French character." Most French professors, according to one of them (rashly named in this article), do nothing and care nothing for industry. In short, collaboration between manufacturer and chemist is wanting owing to jealousy of the latter towards colleagues who meddle with industrial problems, to ignorance and shyness of both parties, and to the want of any intermediary who can bring them into contact.

Besides the recommendations stated in the outset, it is advised that special schools be created, *e.g.* for perfumes, for colours, for soaps, where young chemists shall receive special training.

Now what can we in England learn from this exhaustive discussion? We have many of the same defects; we suffer from the supremacy of the foreman; from the want of interest in industry of the professors (although this is lessening); from the want of intelligence and scientific training of many manufacturers; and from the lack of special schools. In the old days of the Le Blanc soda process the works served as schools for young chemists; now things are too specialised. In prosperous times, the manufacturer does not see the need of a chemist; when bad times come, the luxury of a chemist cannot be afforded. What we want, what the Germans have got, and what the Americans are rapidly getting, is a race of scientifically trained manufacturers; combinations of those engaged in the same industry, so that common laboratories of research may be kept running; the replacement of rule-of-thumb foremen by chemically trained submanagers of a better class, who have had something in the nature of a scientific education, and who are imbued with the spirit of research, leading them to keep their eyes open to every possible improvement; this they would gain first in actual educational establishments, under the guidance of capable professors, and later in the special laboratories mentioned above; and lastly, thorough cooperation between teachers and manufacturers, so that problems capable of being solved in a university laboratory, and of scientific interest, should be transferred there, with the prospect of an ultimate reward should they prove commercially useful; and a liberal attitude of mind on the part of manufacturers, so that they would take a little trouble to become acquainted with the progress of scientific chemistry, with the view of its utilisation for money-making purposes, and a readiness to consider any problems suggested in the university laboratory, with the view of their being worked out industrially. We are moving slowly towards attaining this ideal. Is it any comfort that France appears on her own showing to be more backward? Until the people concerned learn to view such problems from a scientific standpoint, little more can be done. The only thing is for those who can to preach, and above all to practise.

W. R.

NOTES.

The new session of Parliament was opened on Tuesday by the King, who was accompanied by the Queen, with the customary ceremonial. The King's speech to the House of Commons announced that provisions for amending the laws relating to education in Scotland will again be brought forward, and that a proposal for establishing a Minister of Commerce and Industry will be introduced.

At the annual meeting of the Royal Astronomical Society on Friday last, the gold medal of the society, awarded by the council to Prof. Boss, director of the Dudley Observatory, Albany, New York State, was received by Mr. Choate, the United States Ambassador, for transmission to Prof. Boss. The president afterwards handed to the secretary the Jackson-Gwilt bronze medal for transmission to Mr. Tebbutt, who for many years has carried on astronomical research in his observatory in New South Wales.

At a meeting of the trustees of the Percy Sladen fund, held at the Linnean Society, Burlington House, on February 3, grants varying in amount were made to Mr. W. R. Ogilvie Grant, toward the expenses of a collector for the British Museum in Central Africa; to Miss Alice L. Embleton, to enable her to continue her investigations in insect cytology; and to Mr. J. Stanley Gardiner, toward the expenses of an expedition to the Indian Ocean.

M. Radau has been appointed president, Vice-Admiral Fournier vice-president, and M. Bigourdan secretary of the Bureau des Longitudes, Paris.

M. F. J. P. Folie, honorary director of the Royal Observatory at Brussels, died at Liège on January 29 in his seventy-second year.

We regret to see the announcement of the death of Mr. Robert Tucker, who was for thirty-five years (November, 1867–November, 1902) honorary secretary of the London Mathematical Society.

Reuter states that the Argentine sloop of war *Uruguay*, last reported at Punta Arenas, has returned to Buenos Ayres after her voyage in the Antarctic seas, having failed to obtain any news of the French Antarctic Expedition under Dr. Charcot.

It is proposed to establish an International Association of Anatomists at a meeting to be held at Geneva on August 7–10. The initiative has been taken by the anatomists of the Swiss universities and has the support of the anatomical societies of Germany, Great Britain, France, Italy, and America.

The *Athenaeum* announces the death, on January 29, of Prof. H. Landois, professor of zoology and director of the Zoological Garden at Munster, in his seventieth year. Prof. Landois was the author of "Der Mensch und das Tierreich," "Das Pflanzenreich," "Das Mineralreich," and other works.

Captain John Donnell Smith, of Baltimore, has given, says *Science*, to the Smithsonian Institution his private herbarium consisting of more than 100,000 mounted sheets and his botanical library of nearly 1600 bound volumes. Captain Smith's collection is probably the largest private herbarium in America, being very rich in tropical plants.

A TELEGRAM has been received at the office of the Scottish National Antarctic Expedition in Edinburgh announcing the safe arrival at Buenos Ayres of Mr. R. C. Mossman, who was left in charge of the meteorological station at Scotia Bay, South Orkneys, last February. Mr. Mossman has spent two continuous years in the Antarctic regions.

THE Treasury has agreed to make a contribution from public funds toward the cost of establishing and maintaining a national museum and a national library in Wales, on the condition that sufficient local support is forthcoming. The Lord President of the Council has appointed a committee of the Privy Council to consider and determine the place at which each of the two institutions should be established and other matters relating to their foundation and future maintenance.

M. JACQUES FAURE accomplished a successful voyage in a balloon from London to Paris on February 12. He left the Crystal Palace at 6.45 p.m. on February 11 with M. Hubert Latham, and they at once rose to a height of 500 metres, which they kept until within sight of the sea, near Hastings. They then descended until the guide-rope touched the water, when they travelled at the rate of 110 kilometres an hour. At 10 p.m., seeing a lighthouse, they rose to 2000 metres, and soon passed over Dieppe. The balloon descended at St. Denis, outside Paris, six hours after starting.

WE regret to see the announcement of the death of Mr. William Sellers, the eminent mechanical engineer of Philadelphia. When president of the Franklin Institute in 1864, he read a paper on screw-threads and nuts, and his form of thread subsequently became the standard for the United States. He had many friends in this country. He was a member of the Institution of Civil Engineers, and as chairman of the Philadelphia committee took an active part in the reception of the Iron and Steel Institute in its recent visit to America.

THE new Premier diamond-mine, situated about twenty miles W.N.W. of Pretoria, in the Transvaal, produced in January of this year an enormous diamond far surpassing in size the largest previously known. It measures $4\frac{1}{2} \times 2\frac{1}{4}$ inches, is said to be of excellent quality, and weighs 3032 carats ($=676\frac{1}{2}$ grams, or nearly $1\frac{1}{2}$ lb. avoirdupois). The largest diamond previously discovered is the "Excelsior," which was found in 1893 in the Jagersfontein mine, Orange River Colony, and was valued at 1,000,000*l*. It was as large as a hen's egg, weighed $971\frac{3}{4}$ carats, and has been cut into nine brilliants. The world-famous Indian diamonds, the "Koh-i-noor" and "Great Mogul," are considerably smaller than the "Excelsior," and compared with this huge latest-found diamond their size sinks into insignificance. An account of the Premier mine was recently published in the report for 1903 of the Geological Survey of the Transvaal (NATURE, 1904, lxxi., p. 55). The mine was opened up in 1902, since when it has produced a rich yield. It is of the same type as the Kimberley mines, but considerably larger in size. The pipe containing the "blue-ground" has an oval-shaped cross-section; its longer diameter measures just over half a mile, and its area is estimated at 350,000 square yards. The pipe breaks through felsitic rocks, which were earlier intruded in the quartzites of the Pretoria series.

"NOTES on Phosphorescence in Plants and Animals" is the title of a paper by Miss Bage in the *Victorian Naturalist* for November last, of which the author has been good enough to send us a copy. Special attention is directed to the occurrence of phosphorescence in butchers' meat, since a remarkable prevalence of this has been recently noticed in Melbourne. So far as the author could ascertain, no cultures have been taken from phosphorescent meat, so that the bacteria by which the phenomenon is produced are still unknown.

The Times of February 9 devotes nearly a whole column to the collection of giraffes in the Natural History Museum, which has recently been enriched by examples of the Kilimanjaro and Nigerian races. The article mentions the names of the various donors of the series in the national collection, which is altogether unrivalled. Brief reference is made to the earlier specimens of giraffes brought to this country, and to the history of the evolution of our knowledge of the local variations of the species. In conclusion, special attention is directed to the importance of ascertaining the reason for these and analogous colour-variations in animals.

WE have received copies of Nos. 1 to 3 of the fourth volume of the Goeldi Museum at Para, the first of which is dated February, while the other two were published in December, 1904. The catalogue of Para mammals in No. 1, by Messrs. Goeldi and Hagmann, has been already noticed in our columns. Among the contents of Nos. 2 and 3, mention may be made of a list of the mosquitoes of Para by Dr. Goeldi, with an account of the measures taken to exterminate *Stegomyia fasciata* and *Culex fatigans*, and also of Dr. Hagmann's synopsis of the birds described by Spix, Wied, Burmeister, and Pelzeln. Considerable interest attaches to a paper on a disease which has recently affected domesticated animals in the Island of Marajo.

THE *Scientific American* of January 21 contains an illustrated account of the setting-up in the American Museum of Natural History, New York, of a skeleton of the dinosaur Brontosaurus, obtained from the deposits near the famous Bone Cabin Quarry in 1898. The skeleton, which is the largest and at the same time the least incomplete specimen of its kind, is being set up under the immediate direction of Prof. Osborn, and will be the only mounted example of the bony framework of the brontosaur. Its estimated length is sixty-two feet. Contrasted with that of Diplodocus, the skeleton of Brontosaurus is characterised by its relatively shorter body and limbs, and its more massive general structure, the arrangements for lightening its weight being more specialised than in any other member of the group. From the rough terminal surfaces of the limb-bones it is inferred that the creature was largely aquatic in its habits; and when sitting down it is supposed that the weight of the body was partly supported by the extremities of the ischia and pubes, which may have been furnished with elastic pads of cartilage or connective tissue.

THE "One and All" Annual, 1905, contains a number of articles connected with gardening, among which are some practical notes on growing mushrooms, celery and herbs.

THE Japanese have a malted preparation, known as ame, which is a kind of candy or barley-sugar, made by the action of barley malt on glutinous rice. Midzu-ame, or liquefied ame, a syrup, forms the subject of an article by Prof. F. H. Storer and Mr. G. W. Rolfe in vol. iii. part iv. of the *Bulletin* of the Bussey Institution, Harvard University. The preparation of ame dates back many centuries, and it is interesting to compare it with *must*, or the more modern wort. Prof. Storey also describes some experiments made with pop-corn which bear out the opinions of previous investigators that popping is caused by bursting of the starch grains.

THE experiments described by Dr. M. Koernicke in the October (1904) number of the monthly journal *Himmel und Erde* prove that both Röntgen and radium rays can produce a very marked action on plants. The general result of exposure of seedlings was to cause retardation and eventually cessation of growth of stem and root; in some cases growth was resumed after an interval, in others the plants never recovered. The first effect of the rays on dry bean and turnip seeds was to accelerate germination, but while the beans ceased to develop after a time, the turnips did not even show signs of retardation; had the exposure been longer, then undoubtedly the turnips would also have reacted.

THE latest number of the *Izvestia* of the Russian Geographical Society (1904, i. and ii.) contains a further report by Colonel Novitsky on his explorations of the range of Peter I., and an interesting and detailed geographical sketch by A. Dunin-Gorkavitch of the northern portions of the government of Tobolsk and its inhabitants. The latter paper is accompanied by a new map of the province, on a scale of 27 miles to the inch, which gives with special detail the inhabitable portions of this immense region. M. Dubyago gives the results of new pendulum observations in the Urals.

A "CONFERENCE NUMBER" of the *West Indian Bulletin* has just been published (46 pp.). It relates to the agricultural conference held at Trinidad on January 4–13, and contains the list of the representatives from the several West Indian colonies who attended; an account of the reception by Sir Henry Jackson, the Governor of Trinidad; a verbatim report of the presidential address by Sir Daniel Morris; and an abstract of the proceedings at the conference and social gatherings. A full account of the papers and discussions will form No. 4 of vol. v. and No. 1 of vol. vi. of the *Bulletin*, and afford valuable information on the great progress made in scientific agriculture in the colonies since the Imperial Department was called into existence by Mr. Chamberlain a few years ago.

WE have received a copy of the meteorological observations made at the Adelaide Observatory and other places in South Australia during the years 1900–1901, under the direction of Sir Charles Todd, Government astronomer. Although the rainfall of some districts is still unrepresented, the monthly and yearly results are published for 463 stations in 1900, and for 474 in 1901, and these are compared with the averages for previous years. This represents a very large amount of valuable work, in addition to that entailed by the usual tables of meteorological results for a large number of stations distributed over the colony. A table is given showing the approximate mean monthly rainfall over the whole of the agricultural districts from the year 1861, and the average yield of wheat per acre. It is pointed out that wheat-growing can only be successfully prosecuted where the percentage of winter rains is largely in excess of that for the summer months, which is only usually the case in the southern districts.

WE are glad to be able to announce the issue of part i. of the new edition of Dr. Hann's excellent "Lehrbuch der Meteorologie." Although so short a period has elapsed since the publication of the first edition, the science has made such important advances, owing to the results obtained from international balloon and kite observations, and from the study of the movements of the upper air by means of cloud observations, that some of the older theories have to be modified, and a new edition has been rendered necessary. We learn from the notice accompanying the part in question that while many details not considered essential to ordinary readers will be omitted, the principles of the theories adopted in recent investigations by men of science, *e.g.* Prof. Bigelow, in the United States, Dr. Shaw, in this country, and Dr. Hildebrandsson, in Sweden, will be included. The work will consist of about six parts; the first deals with air-temperature generally, and with the amount of heat received by and radiated from the solid and fluid surface of the earth. From a communication from Dr. Hann which we lately published we learn that his elaborate meteorological charts will, so far as possible, be extended and include the important additions to our knowledge made by recent expeditions to the Antarctic regions.

FROM Dr. Carmelo Scrivanich we have received a short pamphlet, printed by the Tipographia sociale of Spalato (Italy), dealing with the question of the origin of matter, a subject on which the author invites discussion.

AT the present time investigations of the law of force between two elements carrying currents (Ampere's and allied laws) are commonly regarded as chiefly of academic interest. Several papers on this subject have been written at various times by Dr. Franz Kerntler, of Budapest, and a further paper dealing with the "correct law" as claimed by the same author has just been issued by him. It is published by the Budapester Lloyd Press, and bears the date 1905.

THE internationalisation of scientific literature is well illustrated by the publication in the *Proceedings* of the Academy of Amsterdam of a paper in English by Prof. Sommerfeld, of Aachen, on a simplified deduction of the field and the forces of an electron moving in any given way. The paper is supplementary to one published in the *Göttinger Nachrichten*, and leads to the conclusion that the motion of an electron with velocity exceeding that of light is impossible, as it would require an infinite expenditure of force and energy to maintain it, if the electron be regarded as a sphere with a uniform surface-charge. On the contrary, in the case of a sphere with a bodily-charge the force remains finite. In this problem the electron moves faster than the field of force which it propagates outwards, and a "shadow of motion" is produced. A simple illustration might be afforded by comparison with the effects produced on a sheet of still water by a disturbance moving with a velocity greater than that with which the ripples which it produces radiate outwards.

IN the "Publicationen des astrophysikalischen Observatorium zu Potsdam," No. 41, Dr. Lohse gives the results of a detailed study of the photographic spark spectra of the metals titanium, vanadium, chromium, manganese, iron, nickel, cobalt, molybdenum, palladium, tungsten, iridium, bismuth, lead, uranium, zirconium, lanthanum, cerium, thorium, and didymium. In the majority of cases the region investigated is from λ 340 to λ 400, but for a few metals the record is extended towards the red. Thus, the record for iron goes to λ 446, uranium to λ 431, zirconium to λ 471, lanthanum to λ 567, cerium to λ 467, and didymium to λ 569. The wave-lengths are given to the nearest hundredth of a tenth-metre, and a comparison of these with Rowland's wave-lengths for corresponding solar lines indicates that they are probably correct to within 0·03 tenth-metre in the mean. Lohse has adopted the awkward intensity scale of 0·1 to 10, thus allowing for a hundred gradations. Such a large range is neither necessary nor practicable, and it would have served a better purpose to have kept to the scale 1 to 10 which he used in a previous publication on the same subject. A thorough and detailed knowledge of the spark spectra of the chemical elements is of primary importance in the proper study of celestial spectra, and Dr. Lohse's record will be very useful in that connection. It seems to us, however, that his work would have been greatly enhanced in value if he had confined his attention to the same region of spectrum for each metal, and had included the portion from λ 400 to λ 486 (F), say, especially as that is the region of stellar spectra most ordinarily investigated.

INDEXES to the literature of gallium (1874–1903) and germanium (1886–1903), prepared by Dr. P. E. Browning, have been issued as parts of vol. xlvi. of the Smithsonian *Collections*.

THE general occurrence of radium in association with uranium has formed an important argument in connection with current views relative to the formation of radium. In a recent note M. Danne states that certain plumbiferous earths in the neighbourhood of Issy-l'Évêque contain radium, but are completely free from uranium. Certain facts seem, however, to indicate that the radium has made its appearance in the pyromorphite at a comparatively recent date through the medium of radio-active water from springs in the neighbourhood.

THE International Committee on Atomic Weights has issued its annual report and a table of numbers for use during 1905. On the basis of new determinations, changes are recommended in the atomic weights of indium, iodine, rubidium, and samarium. As the result of several independent investigations on the atomic weight of iodine, there can now be no reasonable doubt that the value 126·85 given by Stas is too low, and 126·97 is adopted in the new table. The atomic weight of nitrogen would also appear to be much closer to the round number than is represented by the value 14·04 at present in use, and further investigations of this element are needed.

AN interesting paper on the production of calcium cyanamide and its employment in agriculture as fertiliser was recently read by Prof. Frank before the "Klub der Landwirte" in Berlin. As manufactured at present, 250 kilograms of atmospheric nitrogen can be obtained per year in the form of calcium cyanamide for each electric horse-power. The efficiency of the substance as fertiliser has been established by experiments at a large number of agricultural stations, and the combined nitrogen is stated to be as effective as an equal quantity in the form of ammonium sulphate or Chili saltpetre.

THE much discussed question as to the nature of the hydrosulphites has been subjected to further experimental investigation by Messrs. Baumann, Thesmar, and Frossard, and an account of these experiments is given in the *Revue générale des Matières colorantes*, vol. viii., p. 353. The view of Schützenberger that hydrosulphurous acid is to be represented by the formula H_2SO_2 receives strong confirmation. As is pointed out, the crystalline sodium salt $Na_2S_2O_4.2H_2O$ obtained by Bernthsen may be written $NaHSO_2.NaHSO_3.H_2O$, and the behaviour of the mother liquors, from which this salt separates, corresponds with this view. In fact, two formaldehyde compounds corresponding to $NaHSO_2.CH_2O.2H_2O$ and $NaHSO_3.CH_2O.H_2O$ have been separated and analysed.

A NEW booklet has been added by Messrs. Dawbarn and Ward, Ltd., to their "Country House" series of practical handbooks. It is by Mr. D. Grant McIver, and is entitled "Pruning, Training, and Trimming Trees and Shrubs."

MR. JOHN MURRAY has published an attractive English edition of Prof. W. H. Pickering's work on "The Moon," the American edition of which was reviewed in NATURE of May 5, 1904. The work contains a summary of the existing knowledge of our satellite, and the statement of Prof. Pickering's observations and arguments in favour of lunar activities, illustrated with a complete photographic atlas of the moon. The price is two guineas net.

THE second volume of "Papers of the British School at Rome" has been published by Messrs. Macmillan and Co., Ltd. The volume is by Mr. T. Ashby, jun., and is concerned with sixteenth-century drawings of Roman buildings attributed to Andreas Coner. The drawings are preserved in Sir John Soane's Museum at Lincoln's Inn Fields, London. The contents of the sketch-book in which the original drawings are preserved include ground plans, plans and elevations of tombs, elevations, architectural details, Doric entablatures, Ionic and Corinthian entablatures, plain mouldings (cornices and plinths), Doric capitals, and plain and ornate bases. The reproductions of these sixteenth-century drawings which are now available will be of great service for the purposes of study and criticism.

OUR ASTRONOMICAL COLUMN.

EPHEMERIS FOR BROOKS'S COMET, 1904 I.—On a photograph obtained at Greenwich in January the image of Brooks's comet (1904 I.) was quite strong, and indicated that the object was, probably, not fainter than the eleventh magnitude. The following is an ephemeris for this object as given in No. 354 of the *Observatory*.

Ephemeris 12h. M.T. Greenwich.

1905	R.A. h. m. s.	Dec.
Feb. 17	9 55 56	+64 37
,, 23	9 34 55	+64 25
Mar. 1	9 15 34	+63 55
,, 7	8 58 27	+63 11

This ephemeris required corrections of −5s. and −0′.8 on December 7, and shows that the comet is travelling in a westerly direction through the constellation Ursa Major. On March 7 it will be very near to, but S.W. of, τ Ursæ Majoris.

OBSERVATIONS OF COMETS.—A number of photographic and visual observations of Encke's comet were made by M. Quenisset at Nanterre during December. The photographs obtained show that the comet gradually became brighter during the period covered by the observations, and that the coma was extensive and fan-shaped, its extension being in a W.S.W. direction, *i.e.* turned away from the sun. On the photographs this coma was about 4′ in diameter and contained a nucleus which was not at the centre. Visual observations made on December 7 showed the fan-shaped coma to be 5′ or 6′ in diameter with the nucleus situated near to its E.N.E. edge and having a position angle of about 70°, reckoned from the centre of the coma. On this date the comet was at the limit of naked-eye visibility, its estimated stellar magnitude being about 6.5.

Borrelly's comet (1904 *e*) was also observed, photographically and visually, on January 1 and 2 by M. Quenisset, and was seen as a faint nebulosity of 1′.5 to 2′ diameter with ill-defined boundaries. A very faint nucleus of magnitude 11.5 occupied the centre of the coma, and the photograph obtained on January 2 showed a faint tail extending in an E.S.E. direction (*Bulletin de la Société astronomique de France*, February).

ADDITIONAL PERIODICAL COMETS DUE THIS YEAR.—In addition to those periodical comets previously mentioned by Mr. W. T. Lynn as being due at perihelion this year, Mr. Denning, writing to the *Observatory*, mentions Tempel's 1867 comet, which should pass through its perihelion point in April. This object has suffered considerable perturbations from Jupiter, which have lengthened its period from 5.982 to 6.530 years, and have changed its perihelion distance from

1.56 to 2.07. The comet was re-observed on its return in 1873 and in 1879, but has not been seen since.

Wolf's 1884 comet is also due at perihelion in April, but the conditions for its observation will be very unfavourable.

Another comet which may return towards the end of this year is the faint one discovered by Prof. Barnard in 1892. It was not seen, however, in 1899, and, as its exact period is doubtful, although probably about 6½ years, it may again escape detection.

CASTOR A QUADRUPLE STAR.—In a communication to the Astronomical Society of the Pacific (*Publication* No. 99) Prof. Campbell discusses the multiple character of Castor, and states that Dr. Curtis, using the Mills spectrograph attached to the 36-inch refractor of the Lick Observatory, recently discovered that the brighter component of the system is attended by a faint companion. The fainter component was shown by M. Belopolsky, in 1896, to be similarly double, so that in Castor we have a quadruple system in which each component of a visual double is attended by a faint companion. The period of the fainter system is about three days, but further observations of the brighter double will have to be made before its period can be determined.—(*Popular Astronomy*, No. 2, vol. xiii.)

BLOOD PRESSURES IN MAN.[1]

THE lecturer began by contrasting Galen's conception of the oscillation of the blood, about the liver as a centre, with the cardiac circulation of Harvey. The pulmonary circulation—for the purposes of this lecture—was omitted, and attention directed exclusively to that in the systemic arteries.

The physical characters of the flow of fluids were briefly described by the example of water in an open stream. A stream might well up from a spring in a flat country, and swim with very low pressure to its mouth; or, falling from a mountain, might have pressure enough to carry men and horses off their legs. If the volume were also great, as in the sea, it might exercise a pressure of many tons to the square yard, and smash great bulwarks to pieces. But in the higher animals the blood flows in closed channels, so that in such a scheme as theirs the dimensions of the channels assume a very important value. Moreover, in mammalia the circulating fluid is not water, but a thicker fluid—the blood—which (in man) has at least four times the viscosity of water. The enormous value of friction in the circulation was then considered, and it was shown that in this factor the kind of vessel wall does not signify much, as the wall is lined by a practically stationary layer of the fluid; friction, therefore, which uses up 99/100ths of the heart's power, depends on the factor of viscosity together with that of the dimension of the channels, or closed bed. It may be said that the blood pressures—that is, the arterial pressures—in man depend on viscosity and dimension of stream bed.

Now so far the closed tubes had been regarded as rigid. But if in animals the tubes were rigid the circulation would be carried on under great difficulties. For instance, there would be no accommodation; only so much blood could be driven into the system as issued at the periphery; the stream, too, would be quite intermittent, with very high maximum and very low minimum pressures, which would not serve for continuous nutrition, and by its extremes of pressures would soon wear down the arteries. For instance, in the bagpipes, were it not for the air reservoir the sound would issue in spasmodic screams; whereas the air-bag turns the intermittent blowing into a continuous feed of air. In the arterial system of man the same provision is made; its tubing is highly elastic, and a chief part of it—namely, the aorta—being relatively wider than other branches of the tree, contains, like the bagpipe reservoir, accommodation for very variable supplies of output from the heart pump. Thus a very large part of the heart power is used in dilatation of the vessels, and by these is given back to the blood. The valves of the heart serve a like purpose of regulating the pressure of the supply to the vascular system.

The lecturer in the next place dealt with the pulse, contrasting the travel of the wave with the travel of the blood itself. The wave due to the shock of the heart beat travels, ordinarily, about twenty times as fast as a given particle of the blood itself. The tenser the walls of the arteries the faster the wave travels along the taut vessels, but the slower the passage of the blood itself. Herein lies one of the chief evils of a morbid rise of arterial pressure; more stress on the vessels, less distribution of their contents. Many of these processes were illustrated by lantern slides and demonstrations by Dr. Dixon, demonstrator of pharmacology in Cambridge.

After these principles Dr. Dixon exhibited the various instruments in use for measuring blood pressures in man, and the means by which their curves may be recorded on a revolving drum (kymograph).

The lecturer then entered upon the vital properties of the arteries—that they are not only elastic, and so accommodate themselves to the varying pressures, but are endowed also with nervous governance, whereby they effect a large economy in work and material. Several functions of the human body cannot, save within small limits, work together. If we are digesting we are not apt for thought; the Alpine climber is mercifully unable to worry over affairs—his mind is put into abeyance; and so on. Thus the arterial system, by the means of its nervous connections, contracting in some areas and dilating in others, automatically diverts its fertilising streams hither or thither as needs arise. Moreover, it can enlarge or diminish its bed according to the total quantities of blood temporarily in circulation—a quantity which is very variable. By contracting the arteries in considerable areas and correspondingly dilating them in others, the fields of the various functions of the body can be used alternately, as we see in the irrigation of Alpine meadows. By the same means the very various pressures of the blood can be counteracted. When under muscular effort, for instance, the pressure is raised, a corresponding area outside the muscles is dilated, and pressure more or less equalised; thus the heart is enabled to do the most work with the least disturbance of stresses. So in a bath, cold or very hot, the crimping up of the large cutaneous areas is compensated by large dilatations in internal areas, and pressures return to the normal in two or three minutes. The chief area in which blood can be accommodated, and thus for a time put out of circulation, is a large abdominal area.

By these considerations the lecturer was led to explain why the blood in the body does not drop down into our feet and legs, and leave the brain and other vital parts. Indeed, the blood has a strong disposition thus to obey the action of gravitation, and one of the events of approaching death is the falling of the blood into lower parts of the body, deserting the heart and brain. Obviously this is especially the case in upright animals, as in man chiefly, and in apes in some measure. It is by the vigilance of the nervous governance that the blood is held up, by the contraction of the abdominal vascular fields; and it is the failure of these mechanisms which appears as shock, syncope, or collapse. The lecturer, assisted by demonstrations by Dr. Dixon, illustrated these dispositions, citing especially the researches of Prof. Leonard Hill on the distribution of the blood in various positions of the body. He also referred to the bearing of these principles on the researches of Prof. Waller and others on the dangers of anæsthetics. By some most interesting experiments by Dr. Cushing he showed how enormously the arterial pressures may be raised in case of danger of failure of supply of blood against gravity when, as in apoplexy or a depressed fracture of the skull, the blood-vessels, in the parts of the brain where all these mechanisms find their centres, are compressed and thus more or less liable to be emptied.

In the last part of the lecture the lecturer apologised for occupying time with so much physiology, in which subject he is not an investigator. But it was necessary to make manifest to his audience how great is the importance of the integrity of the arteries themselves, and of their nervous governance in function, an integrity which is a matter of life and death; for if the circulation fails in the nervous centres or heart, life must cease. Now the arteries are subject to many injurious conditions, as of certain poisons and infec-

[1] Abstract of a lecture delivered by Prof. T. Clifford Allbutt, F.R.S., at the Royal Institution on February 3.

tions, or of hard muscular labour; there are also the unexplained deteriorations of age. His personal investigations had been into the effects on the arteries of gradual increases of blood pressure. Normally, arterial pressures, as taken in the arm, rise somewhat from childhood to age—say from 80–90 mm. Hg. to 140° or perhaps 150°. These upper limits are not inconsistent with health at the age of three score, though no doubt they signify some loss of mechanical efficiency. A demonstration was given by Dr. Dixon of the difference in vascular efficiency under muscular effort between a young and an elderly man. Into the effect of certain poisons and infections on the arteries he could not enter. Senile degenerations of the arteries are not essentially allied to rise of blood pressure, though in such subjects, as in others, high pressures may arise, and must be, of course, the more dangerous. Still, senile arterial degeneration is compatible with very long life, even if with diminution of function, as the vessels silt up rather than burst.

The lecturer's own observations, now extended over many years, had been upon rise of pressure in middle life beyond, often very far beyond, that which he had regarded as normal for elderly persons. The reasons of this morbid tendency cannot yet be given, but fortunately, by medicinal and dietetic means, it can be abated, and in early stages abolished. If permitted to persist, and it is not rarely consistent with fair general health or but vague indisposition, it slowly ruins the vascular system by overstretching it. It is in such persons that the arteries may break, as in apoplexy, a catastrophe which, by timely precautions, can be prevented. The lecturer strongly urged upon all persons of middle and advancing years to have their arterial pressures tested by their physicians every four or five years, so that any disposition to excessive pressures may be averted and the integrity of the arterial tree preserved.

RADIATION PRESSURE.[1]

A HUNDRED years ago, when the corpuscular theory held almost universal sway, it would have been easier to explain the pressure of light than it is to-day, when it is certain that light is a form of wave-motion. The means at the disposal of early experimenters were inadequate to detect so small a quantity; but if the eighteenth century philosophers had been able to carry out the experiments of Lebedeff and of Nichols and Hull, and had they further known of the emission of corpuscles revealed to us by the kathode stream and by radio-active bodies, there can be little doubt that Young and Fresnel would have had much greater difficulty in dethroning the corpuscular theory and setting up the wave theory in its place. The existence of pressure due to waves, though held by Euler, seems to have dropped out of sight until Maxwell, in 1872, predicted its existence as a consequence of his electromagnetic theory of light. The first suggestion that it is a general property of waves is probably due to Mr. S. T. Preston, who in 1876 pointed out the analogy of the energy-carrying power of a beam of light with the mechanical carriage by belting, and calculated the pressure exerted on the surface of the sun by the issuing radiation. It seems possible that in all cases of energy transfer, momentum, in the direction of transfer, is also passed on and that there is, therefore, a back pressure on the source. Though there is as yet no general and direct dynamical theorem accounting for radiation pressure, Prof. Larmor has given a simple indirect mode of proving the existence of the pressure which applies to all waves in which the average energy density for a given amplitude is inversely as the square of the wave-length. He has shown that when a train of waves is incident normally on a perfectly reflecting surface, the pressure on the surface is equal to $E(1+2u/U)$, where $E/2$ is the energy density just outside the reflector in the incident train, U is the wave-velocity, and u the velocity of the reflector, supposed small in comparison with U. In a similar manner it can be shown that there is a pressure on the source, increased when the source is moving forward, decreased when it is receding. It is essential, however, that we should be able to move the reflecting surface without disturbing the medium except by reflecting the waves.

[1] A lecture delivered before the Physical Society on February 1[illegible] by Prof. J. H. Poynting, F.R.S., president of the society.

Though Larmor's proof is quite convincing, it is interesting to realise the way in which the pressure is produced in the different types of wave-motion. In the case of electromagnetic waves, Maxwell's original mode of treatment is the simplest. A train of waves is regarded as a system of electric and magnetic tubes transverse to the direction of propagation, each kind pressing out sideways, that is, in the direction of propagation. They press against the source from which they issue, against each other as they travel, and against any surface on which they fall. In sound-waves there is a node at the reflecting surface. If the variation of pressure from the undisturbed value were exactly proportional to the displacement of a parallel layer near the surface, and if the displacement were exactly harmonic, then the average pressure would be equal to the normal undisturbed value. But consider a layer of air quite close to the surface. If it moves up a distance, y, towards the surface, the pressure is increased. If it moves an equal distance, y, away from the surface, the pressure is decreased, but to a slightly smaller extent. The excess of pressure during the compression half is greater than its defect during the extension half, and the net result is an average excess of pressure on the reflecting surface. Lord Rayleigh, using Boyle's law, has shown that this average excess should be equal to the average density of the energy just outside the reflecting surface. In the case of transverse waves in an elastic solid, it can be shown that there is a small pressure perpendicular to the planes of shear, that is, in the direction of propagation, and that this small pressure is just equal to the energy density of the waves. The experimental verification of the pressure of elastic solid waves has not yet been accomplished, but the pressure due to sound-waves has been demonstrated by Altberg, working in Lebedeff's laboratory at Moscow, the pressure obtained sometimes rising to as much as 0.24 dyne per sq. cm. By means of a telephone manometer it was found that through a large range the pressure exerted on a surface was proportional to the intensity of the sound.

Both theory and experiment justify the conclusion that when a source is pouring out waves, it is pouring out with them forward momentum which is manifested in the back pressure against the source and in the forward pressure when the waves reach an opposing surface, and which, in the meanwhile, must be regarded as travelling with the train. It was shown that this idea of momentum in a wave-train enables us to see the nature of the action of a beam of light on a surface where it is reflected, absorbed, or refracted without any further appeal to the theory of the wave-motion of which we suppose the light to consist. In the case of total reflection there is a normal force upon the surface, in the case of total absorption there is a force normal to the surface and a tangential force parallel to the surface; while in the case of total refraction there is a normal force which may be regarded as a pull upon the surface or a pressure from within. In any real refraction there will be reflection as well, but with unpolarised light, in the case of glass, a calculation shows that the refraction-pull is always greater than the reflection-push, even at grazing incidence. An experiment, made by the president in conjunction with Dr. Barlow, was described to serve as an illustration of the idea of a beam of light being regarded as a stream of momentum. A rectangular block of glass was suspended by a quartz fibre so that the long axis of the block was horizontal. It was hung in an exhausted case with glass windows, and a horizontal beam of light was directed on to one end of the block so that it entered centrally and emerged centrally from the other end after two internal reflections. Thus a stream of momentum was shifted parallel to itself, or in this particular case a counter-clockwise couple acted on the beam. By suitable means the clockwise couple on the block, due to the pressures at the two internal reflections, was distinctly observed and approximately measured. The result obtained was of the same order as that deduced from the measurement of the energy of the beam by means of a blackened silver disc.

The extreme minuteness of these light forces appears to put them beyond consideration in terrestrial affairs, but in the solar system, where they have freer play, and vast times to work in, their effects may mount up into importance. On the larger bodies the force of the light of the sun is small compared with the gravitational attraction, but as the ratio of the radiation pressure to the gravitation pull varies inversely as the radius if the density is constant, the pressure will balance the pull on a spherical absorbing particle of the density of the earth if its diameter is about a hundred-thousandth of an inch. The possible effects of radiation-pressure may be illustrated without going to such fineness as this. In the case of a particle of the density of the earth, and a thousandth of an inch in diameter, going round the sun at the earth's distance, there are two effects due to the sun's radiation. In the first place, the radiation-push is 1/100 of the gravitation-pull, and the result is equivalent to a diminution in the sun's mass. In the second place, the radiation absorbed by the particle and given out again on all sides is crushed up in front as the particle moves forward and is opened out behind. There is thus a slightly greater pressure on the advancing hemisphere than on the receding one, and this appears as a small resisting force in the direction of motion. Through this the particle tends to move in a decreasing orbit, spiralling in towards the sun. As there is good reason to believe that some comets, at least, are composed of clouds of dust, there is hope that some of their eccentricities may be explained by the existence of radiation pressure. If the particles of a dust cloud circling round the sun are of different sizes or densities, the radiation accelerations on them will differ. The larger particles will be less affected than the smaller, will travel faster round a given orbit, and will draw more slowly in towards the sun. Thus a comet of particles of mixed sizes will gradually be degraded into a diffused trail lengthening and broadening, the finer dust on the inner and the coarser on the outer edge. If a planet, while still radiating much energy on its own account, captures and attaches to itself, as a satellite, a cometary cloud of dust in which there are several different grades, with gaps in the scale of size, it may be possible that in course of time the radiation-pressure effects will form the different grades into different rings surrounding the planet. Such may possibly be the origin of the rings of Saturn.

GEOGRAPHICAL RESULTS OF THE TIBET MISSION.

The paper read by Sir Frank Younghusband at the Royal Geographical Society on Monday, February 13, was one of the most interesting and instructive that the fellows of that society have been privileged to listen to for many years. It afforded a striking exemplification of the advantages of a due coordination of geographical facts and their combination, by a master-hand, into a well-arranged whole. The country traversed by the Tibet mission was by no means a *terra incognita* to the geographer, for its main features had long been known through the labours of the zealous native explorers of the Survey of India. But it is none the less true that Sir Frank Younghusband's admirable descriptions of the conditions of nature and man in that romantic region enabled his audience to realise those conditions in a way that was never before possible, and brushed away many false ideas which had been previously entertained. The speaker was also able to touch briefly upon some of the results obtained by the scientific experts who accompanied the mission, as well as by the survey party under Captains Rawling and Ryder, which in the late autumn did excellent work along the whole course of the Upper Brahmaputra, proving definitely that no peaks higher than Everest exist on this flank of the Himalayas.

In regard to the general nature of the country traversed, Sir F. Younghusband was able to correct the current idea that the whole of Tibet is more or less barren and worthless. This may be true for northern Tibet, the part traversed by recent European explorers, but not for the southern third, which is dotted over with thriving villages and well-built residences. The valleys in which Lhasa, Gyantse, and Shigatse are situated, as well as that of the Brahmaputra, are neither barren plateaux nor narrow, V-shaped gorges, but flat valleys covered with good soil, well irrigated, and richly cultivated. The passage to Tibet, as made by the Kongra-lama Pass, involves, however, a sudden change from the deep-cut valleys and luxuriant vegetation of Sikkim to wide plains on which not a tree is to be seen, while if, in some secluded nook, a plant a foot high is met with it is a curiosity. The summer climate of Khambajong was described as charming, while the unrivalled panorama of the Himalayas, at the very culminating point of their grandeur, is a full compensation for anything that may be otherwise lacking. Sir Frank Younghusband's eloquent descriptions of the snowy range as seen from the north, with the ever-varying atmospheric effects, are of special interest as the first ever given by a European capable of appreciating adequately the glories of the prospect.

The discovery by Mr. Hayden, of the Indian Geological Survey, of a bed of fossil oysters, permitted an accurate determination of the age of the hills in this part of Tibet, showing them to be geologically quite recent, though somewhat older than the main axis of the Himalayan range. The Chumbi Valley, through which the final advance was made, is less wide and open than the valleys in Tibet proper, of which, in fact, it is not considered a part. The passage hence into Tibet, made during the height of winter by the Tang-la Pass, 15,200 feet high, involved much suffering from the effects of the great cold (18° below zero Fahr.) combined with the rarity of the air. The subsequent march over the elevated plateau was made in the teeth of bitter winds and blinding blizzards, which continued through January, February, and March. But on arrival at Gyantse (April 11) the piercing cold was left behind. Willow and poplar trees were bursting into foliage, and the banks of the river were covered with masses of iris-plants, which later on became sheets of purple. On July 14, the day of the start for Lhasa, heavy rain destroyed the delusion that Tibet is a rainless country. Frequent rain was experienced until September, and the size of the rivers showed that this part of Tibet receives—probably up the Brahmaputra Valley—a quite considerable rainfall. Finally, in a lovely valley covered with trees, rich with cultivation, and watered by a river as broad as the Thames at Westminster, the mysterious city which no living European had seen before was at last reached, hidden away by range after range of snowy mountains. It proved anything but a dreamland city, and its streets were horribly muddy, but the grand lama's palace was an imposing, massive structure. Even the leading men were of low mental calibre, having much of the nature of children. The Ti Rimpochi—the leading lama—though benevolent and genial, had few intellectual attainments, and was firmly convinced that the earth was triangular; while the religion of the Tibetans was described as the most degraded form of Buddhism in existence.

THE LONDON CONFERENCE ON SCHOOL HYGIENE.

The conference on school hygiene, organised by the Royal Sanitary Institute, met on February 8, 9, and 10 at the University of London. Sir Arthur Rücker, who was installed as president of the conference, delivered an address in which he insisted that the elements of education should include some knowledge of the dangers by which mankind is surrounded and of the means to keep them at bay, and that those to whom young lives are entrusted should learn the main outlines of hygiene.

The ignorance of household management and of the principles of hygiene among the poor is responsible in no small measure for their high preventable mortality, their inferior physique, their intemperance and their poverty. How possible it is to better the conditions of modern life, and thus to improve the health, happiness, and physical powers of the people, and thereby their mental vigour and industrial efficiency, is generally recognised, and to this end a suitable hygienic education, moral and material, of the future parents seems essential. Not only have 15,000 medical men and the Commissions on Physical Degeneration recommended that such teaching should be made compulsory, but the English Board of Education and the Scotch Education Department have accepted that recommendation. It is important that from the earliest years of school life children should be taught by example as well as precept the elements of healthy living. The knowledge that may be procured subsequent to that age is often gained at the price of a needlessly costly personal experience. The object then, of school hygiene is to secure for the physical life its maximum possibility of sound health, and to develop the mental life side by side with this. The need of bodily health as the foundation of sound mental work is largely recognised at the present day, and we must not rest content until in the homes as well as in the schools there is sound knowledge of what may be done to give the proper environment for healthy life and work.

At the conference considerable prominence was given to the subject of the physical development and physical inspection of the scholar. Fresh air, good light, wholesome food, and abundant sleep are essentials of development. These should form, as it were, the compulsory subjects in childhood. The co-relation between the healthy mind and the healthy body is disputed by no one, and yet it is necessary still to plead against the unimportant position which is given to physical education in the curriculum of a large majority of schools, particularly in those for girls. The responsibility of the education authority may be said to be of a dual nature, viz. the responsibility not to injure the child's health during school life either by bad building or furniture, by the discipline or curriculum of the school, or by preventable risks of infection, and the responsibility to take the consequence of its own defective training of the future parent. The relative merits of systems and methods of physical training were not discussed, but free play was held to be preferable to gymnastics for physical training. The methods in the former are more spontaneous and thorough, and the most enthusiastic disciple of gymnastics does not wish the gymnasium to take the place of our great games. Discipline, prompt and unquestioning obedience to command, is perhaps the greatest gain derived from class drilling. But the lesson in physical exercise is not the only opportunity for paying attention to the needs of the growing child. If the best results are to be produced, the necessary standing and sitting positions of the pupils throughout the rest of the school routine must not be treated with indifference.

The early age at which children commence education and the length of the school day were both objects of adverse comment. It was pointed out that in primary schools children at three years of age pass the same number of hours in school as those of fourteen years of age; and in secondary schools a child of fourteen has allotted to him the same number of hours of work as the youth of nineteen. Longer intervals of rest and recreation and the abolition of home-work for young children were advocated, and it was pointed out that, in the experience of many authorities, the beginning of the day after a night's rest, the commencement of the week after the Saturday and Sunday rest, and the beginning of a term after the rest of the vacation, are the times when the best work is accomplished.

It is at present by no means unusual in many first-grade girls' schools to make the first test which a pupil undergoes a physical one based on a medical inspection. Before a scholarship can be held, physical as well as mental fitness should be required to be shown. It is a waste of public money to allot scholarships to those who are physically unfit to make use of them. But while we may discuss the physical inspection of children as specially referable to the school period of life at which, for convenience, it is conducted, we should keep in mind the bearing of the facts thereby disclosed on the periods of life which precede and follow it. Much educational energy is at present misspent in endeavouring to educate children who are physically unfit, as evidenced in Glasgow by the small proportion of underfed children who reach a reasonable standard of proficiency according to the master's estimate. In this important work of physical inspection the school teacher should be able to co-operate intelligently with the medical man.

Owing to various causes, artificial and economic, thousands of children three years of age are found in English elementary schools. It is a question whether taking the child out of the mother's hands for the greater part of the day, at so tender an age, may not have weakened the maternal instinct. It is certain, on the other hand, that, owing to the high susceptibility to certain infectious diseases amongst such young children, the practice is dangerous; and the conference passed a resolution to the effect that no child should be permitted to begin formal instruction in school classes under the age of six.

The subject of school buildings and equipment is one of great importance. The school premises often need to be improved if they are to illustrate the sanitary precepts which it is necessary to inculcate and if they are to enable the child to pursue its education under the best hygienic environment. The requirements of the Board of Education with reference to the floor space and air space given to each child were subject to some adverse criticism. Surely it may be claimed that as 15 feet is generally recognised as the healthy minimum floor space per child, 10 feet should no longer be officially recognised as sufficient. The school furniture, moreover, generally leaves much to be desired. Observation has shown that the difference in height of the children of the same age may vary from 6 to 11 inches, and this difference in height and growth ought to be provided for in the seats and desks of every class-room if physical deformities are to be prevented. That is to say, the desks and seats should be adjusted to the pupils' bodies, and not the bodies to the desks and seats. Teachers, moreover, must be taught to realise that, though their effective administration may be aided by efficient inspectors, actual daily care in providing fresh air, including cleanliness and teaching the children to use all sanitary appliances with cleanly decency, is a responsibility which cannot be shifted to other people's shoulders. Unfortunately, however, the local authorities themselves need stimulating and educating. Nor is this to be wondered at when one recalls the fact that the English Board of Education, though responsible for the compulsory attendance at school of some 6,000,000 children, is absolutely without expert assistance where problems of health and sanitation are concerned.

The last day of the conference was devoted to discussions upon the training of teachers and scholars in hygiene. Not only must the teacher have a knowledge of hygiene, but he must also be made responsible for the supervision of the hygienic environment of the pupil while at school, and he must ever bear in mind the circumstance that he will probably do most to create a sanitary conscience among the rising generation by example and personal influence. The training in the observation of sanitary precepts is a form of moral training, and if the home influences are antagonistic to those of the school the home influences will often prevail. The dirty and neglected child indicates the necessity of attempting to do something to improve the parent. The teaching of hygiene to the scholars must be suitably graduated to the age and capacities of the scholars; whereas from the very commencement of school life the object lessons of a sanitary environment should always be presented to the child, it is not before he at least reaches the age of seven—and several authorities prefer a later age—that he should commence to receive definite instruction in domestic and personal hygiene.

Subsequent to the age of ten or eleven, the scholar may be taught some of the more elementary scientific principles involved in hygiene precept and practice, but in the whole scheme of teaching hygiene it is only from the broadest point of view the simple and essential laws of health that require to be taught. It is almost sufficient to give to the scholar rules regarding health and reasons for them. If the teacher is to have an intelligent appreciation of the significance of hygienic principles, he must be taught the elements of physiology. The two subjects naturally go hand-in-hand and must be taught together. Their interests mutually reinforce. Physiology gives the basis and hygiene the application.

Reference was made at the conference to the circumstance that it had been repeatedly urged that there is no room for extra subjects such as "hygiene" to be taught at our schools; but surely hygiene, if properly taught, need not contribute to further over-pressure. The subject of hygiene has a great educative value in itself, and there is no subject which can be so easily co-related to many other branches of knowledge. Hygiene could be introduced as the practical outcome of the whole of the science teaching in the school, and, if the subject is properly taught to the teachers, an enthusiastic and intelligent teacher could prepare his or her own scheme of work and obtain the necessary results without the displacement of a single subject at present being taught. The great requirement for success in whatever may be attempted is an enthusiasm which will stimulate both the teacher and scholar to convert knowledge into conviction and conviction into conduct.

In connection with the conference there was a trade exhibition of school building and furnishing appliances, which consisted chiefly of school furniture; and the Board of Education, the Scotch Education Department, the Technical Instruction Department for Ireland, the London County Council, Home Office, &c., contributed loan exhibits.

A conference upon school hygiene, international in character, is to be held in London in 1907.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Cambridge.—The subject selected for the Adams Prize in 1906 is "The inequalities in the moon's motion due to the direct action of the planets." The successful candidate will receive about 225*l*.

The syndicate appointed to draw up a scheme of instruction and examination in mining engineering has issued a second and amended report to the Senate. It is proposed that a diploma in mining engineering be granted to students who have passed the previous examination and have kept nine terms, and who have attained an honours standard in geology and chemistry in part i. of the natural sciences tripos and a second class standard in certain of the papers in the special examination in mechanism. The candidates have also to produce a certificate in mechanical drawing. This amended scheme meets the objections which had at one time been raised to the recommendations of the syndicate, and it was warmly welcomed at the discussion in the Senate house a week or two ago.

Mr. William Loring, formerly fellow of King's College, Cambridge, and late director of education under the County Council of the West Riding of Yorkshire, has been appointed warden of the Goldsmiths' College, New Cross.

Science states that the Emperor of Germany has directed the German Ambassador to the United States to lay before President Roosevelt in official form the suggestion for an exchange of professors between German and American universities which he made to the American Ambassador on New Year's Day.

The administration of the Board of Education in respect of secondary schools under the board's regulations for secondary schools, as also of charitable trusts and endowments connected therewith, will be conducted in future in the board's offices at Whitehall, and not at South Kensington. All correspondence on these matters should therefore be addressed to the Secretary, Board of Education, Whitehall, London, S.W. This change does not apply to the board's administration under the regulations for evening schools, technical institutions, and schools of art and art classes, which will remain for the present at South Kensington.

In the *Journal* of the Royal Statistical Society for December 31, Mr. L. L. Price contributes a paper on the accounts of the colleges of Oxford, 1893–1903, with special reference to their agricultural revenues. An interesting feature of the discussions was the reference to the disastrous results arising from the new statutes drawn up by the last commission, consequent on the fact that the work of the commission was done at a time when agriculture was prosperous, and no sooner had the sittings ceased than agricultural depression came on the country, and the resources of the colleges were seriously hampered.

The trustees of the Peabody Education Fund have, we learn from *Science*, voted to dissolve their trust. An appropriation of 200,000*l*. for the George Peabody School for Teachers in Nashville, Tenn., was made by a unanimous vote, the State and city having together voted an equal sum for the school. This appropriation leaves a fund of approximately 240,000*l*., which will be distributed later among other educational institutions. From the same source we learn that the trustees of Syracuse University are about to construct, with the bequest made to the university by the late Mr. John Lyman, which is said to amount to 40,000*l*., a building to be known as the John Lyman Laboratory of Natural History. Mr. Adolph Lewisohn, of New York, has given 1000*l*. for the reconstruction of the chemical laboratories at Dartmouth College.

The following recent appointments are announced:—Dr. Ernst Neumann, associate professor of physics at Marburg; Dr. Emil Wiechert, professor of geophysics at Bonn; Dr. Holleman, of Gröningen, professor of inorganic chemistry at Amsterdam; Dr. Bernhard Dessau, of Bologna, professor of physics at Perugia; Dr. C. Russjan, of Cracow, professor of mechanics at Lemberg; Dr. L. Courvoisier, of Heidelberg, observer at the Berlin Observatory; Dr. Ferdinand Henrich, associate professor of chemistry at Erlangen; Dr. Boehm, associate professor of mathematics at Heidelberg; Dr. Kueser, professor of mathematics at Breslau; Dr. Th. Vahlen, of Königsberg, associate professor of mathematics at Greifswald; Dr. M. Weber, professor of mechanics at the Hanover Technical College; Mr. B. H. Camp and Dr. G. D. Richardson, instructors in mathematics at Wesleyan and Yale Universities respectively.

SOCIETIES AND ACADEMIES.

London.

Royal Society, June 16, 1904.—"On the Influence of the Time Factor on the Correlation between the Barometric Heights at Stations more than 1000 Miles apart." By F. E. **Cave-Browne-Cave**, Girton College, Cambridge. Communicated by Prof. Karl Pearson, F.R.S.

The conclusions drawn from the results given in this paper are as follows:—

(1) The correlation between the barometric readings at two stations upwards of 1000 miles apart depends upon the interval between the readings. In the case of Halifax and Wilmington, the correlation is sensible for at least nine days, and it reaches a maximum for an interval of about sixteen hours in summer and twenty-three in winter. For these stations, and also for St. Helena and Cape Town, the observation at the more easterly station should be taken later for maximum correlation.

(2) There is a considerable correlation between the daily rise at Halifax and Wilmington, and this correlation changes with the interval in a manner somewhat analogous to that in which the correlation between simultaneous heights at two stations approximately on the same meridian depends upon the distance between them.

(3) There are considerable differences between the summer and winter correlations, and these differences are of the same general nature for both pairs of stations considered.

(4) It is possible to predict the barometric height at one station from an earlier height at a second station more than 1000 miles away, with a fair degree of accuracy, the mean observed error for forty dates, taken at random, for Halifax and Wilmington, being $0''{\cdot}15$.

January 19.—"On the Comparative Effects of the Trypanosomata of Gambia Fever and Sleeping Sickness upon Rats." By H. G. **Plimmer**. Communicated by C. J. Martin, F.R.S.

The organisms used in these experiments were given to the author by Col. Bruce, F.R.S., and they were taken from monkeys which had been inoculated in Africa from cases of the respective diseases; so that when the author's experiments were commenced each organism had been through one monkey, and they were therefore similar as regards conditions.

Rats inoculated with the Trypanosomata from Gambia fever lived about two and a half months; the Trypanosomata were present in the blood from about four weeks after inoculation until death. *Post mortem* the organisms were present in the blood and in all the organs; the spleen was very much enlarged, and the liver and kidneys were congested. The lymphatic glands were enlarged.

Rats inoculated with the Trypanosomata from sleeping sickness lived without any symptoms for a period of from six to nine months, when they became paralysed, first in one hind leg and then in the other, and they died in from two to eight weeks after the paraplegia was complete, living altogether up to eleven or twelve months. At no time were any Trypanosomata found in the blood, nor *post mortem* in the viscera or glands. But in the spinal cord they were present in small numbers, and inoculation of the cord into other rats has produced similar symptoms, whilst inoculation of the organs has been negative. In sections of the spinal cord amoeboid and adult forms of the Trypanosoma have been found, and also those lesions which Dr. Mott found in the nervous system of man in cases of sleeping sickness, viz., a considerable cellular exudation around the vessels. This is not found in monkeys, in which the organisms become generalised, and do not get localised in the nervous system as is the case in rats.

These experiments go to show that the organisms associated with the diseases of Gambia fever and sleeping sickness, which are thought by some to be the same disease in different stages, are quite distinct in their effects, and they are also distinct morphologically; that the Trypanosoma of sleeping sickness can be inoculated into rats, which has been denied; and that there is a great similarity in the lesions produced in the nervous systems of man and of rats, and in the localisation of the disease to the nervous system.

From experiments made, a double infection would seem to be quite possible, and to be a likely event in these diseases.

January 26.—"On the Modulus of Torsional Rigidity of Quartz Fibres and its Temperature Coefficient." By Dr. Frank **Horton,** St. John's College, Cambridge, late Mackinnon Student. Communicated by Prof. J. J. Thomson, F.R.S.

In this research the dynamical method of experimenting was employed, and the investigaton was divided into three parts:—

(1) The determination of the absolute value of the torsion modulus.

(2) The variation of the modulus between 15° C. and 100° C.

(3) The variation of the modulus between 20° C. and 1000° C.

The radii of the fibres used were determined by measuring their circumferences, the fibres being rolled between two fine glass capillary tubes and the number of revolutions made in travelling a distance of 5 mm. counted. By this method fibres of diameter 0.001 cm. were measured to 0.01 per cent.

In the second part of the research the jacket enclosing the fibre was heated by using the vapours of various liquids boiling under atmospheric pressure. The modulus of rigidity was found to increase as a linear function of the temperature, but the values of the temperature coefficient of the modulus obtained from different fibres were considerably different. In the experiments between 20° C. and 1000° C. the fibres were suspended inside a platinum tube, which was heated electrically. It was found that the modulus of rigidity increased with the temperature, at first as a linear function of it, but as the temperature rose the rate of increase gradually diminished and a maximum rigidity was attained at about 880° C. After passing this point the rigidity decreased very rapidly with increase of temperature.

"Note on the Cause of the Period of Chemical Induction in the Union of Hydrogen and Chlorine." By D. L. **Chapman** and C. H. **Burgess.** Communicated by Prof. H. B. Dixon.

The induction period in the union of hydrogen and chlorine exposed to light, which has been ascribed by various authors either to a change in the physical condition of the chlorine or of the mixture of hydrogen and chlorine, or to the primary formation of an unstable intermediate compound, has been shown by the authors to be due to impurities. The impurities are those which react with chlorine, such as ammonia and sulphur dioxide. At the ordinary temperature in the dark the reaction between these substances and chlorine is not completed. In the light or by raising the temperature these impurities can be entirely removed by the chlorine. The time required for their removal is the induction period during which the chlorine is rendered incapable of combining with the hydrogen.

It has been hitherto supposed that an induced mixture of hydrogen and chlorine if left to stand for some time in the dark must be again induced before combination will proceed at its normal rate. This is not the case if a quartz actinometer is substituted for a glass one.

"The Theory of Symmetrical Optical Objectives.—Part II." By S. D. **Chalmers.** Communicated by Prof. Larmor, Sec.R.S.

In photographic objectives, consisting of two similar lenses symmetrical to a central stop, the back member is generally corrected for spherical and chromatic aberrations, astigmatism, and curvature of field for distant objects, and thus the whole system is perfectly corrected for unit magnification. The present paper discusses the aberrations for distant objects. In part i. it was proved that, to the first approximation, the above defects are corrected in the whole system when they are corrected in the single member. By geometrical constructions, using the symmetry with respect to the axis and to the stop, these results are extended to practical systems. The paths of parallel rays, incident on the combined system, are obtained from those of two sets of parallel rays incident on the single system; the aberrations of the combined system are expressed in terms of the single system with small errors—negligible in practical systems—due to the image of the stop being imperfect.

"Exterior Ballistics. Error of the Day and other Corrections to Naval Range Tables." By Prof. Geo. **Forbes,** F.R.S.

Gun-sights are always marked for standard conditions of muzzle velocity (m.v.) and air density (a.d.). When either of these change the sights must be corrected. The author finds from theory that if a.d. is increased *m* fold, and the range is diminished *m* fold, then the elevation and time-of-flight must be diminished *m* fold; and, empirically, that up to 10° of elevation (10,000 yards for a 12" gun) elevation varies very closely as $1 \,[\text{m.v.}]^2$, as *in vacuo*. On these laws he calculated from the naval range table of a 12" gun, 850lbs. shot, 2463 m.v., at 2, 4, 6, 8, and 10 thousand yards, the table for a 6" gun, 100lb. shot, 1960ft. secs. The elevations only differed from the Naval 6" table by −1, −4, −2, +2, and +4 min. of arc.

The laws, therefore, may be applied with perfect confidence for the comparatively small variations that occur in any one gun.

Linnean Society, January 19.—Prof. W. A. Herdman, F.R.S., president, in the chair.—The Rev T. R. R. **Stebbing** exhibited and explained specimens of Crustacea, in various ways remarkable for structure, habits, habitat, or colouring.—Botanical collecting: Dr. A. **Henry.** The actual methods were briefly alluded to, stress being laid on truthful labelling of the specimens at the moment of collection, instead of months afterwards, when identical numbers were often given to plants of different *provenance*. Dr. Henry described observations made by him in China. He alluded to mimicry in plants, in the case of two species of Lysimachia (a protomorphic genus in China), one of which mimicked *Paris quadrifolia*, with 4 leaves, while the other recalled another species of Paris with 10–12 leaves. He referred also to the extraordinary richness of species on calcareous soils as compared with other soils, a fact constantly seen in China, and well marked also in France, and asked for some explanation. In China, as elsewhere, pure woods were rare, being only formed by a few conifers, like *Abies Fargesii* at high altitudes in Hupeh, *Cupressus funebris* in the same province at lower levels (the home of the Reeves's pheasant), *Pinus Massoniana* (almost everywhere in the central and southern provinces), other species of Pinus more local; also certain species of oak widely distributed; and *Alnus nepalensis* in Yunnan. The explanation of the occurrence of pure forests was also a subject not completely understood: *e.g.* in this country ash seeded freely, and in some places for a time looked as if it would grow into a pure wood; but apparently pure forests of ash only occurred on extremely rich soil in some districts in Russia. With regard to botanical collecting, three stages had occurred. At an early period plants were collected to be merely named and classified; in fact, they were treated like postage stamps. The second period began with Sir Joseph Hooker, who inaugurated the study of the geographical distribution of plants. The third period, that of the present day, was a step forward, in that attention should be paid to the plants themselves as social organisms, living in harmony and yet in competition together; and Dr. Henry urged that the time had come when the hunt for new species should cease to be the sole aim of the collector, and the study of the known species be taken in hand in their living conditions. He advocated map-making of small areas, census-taking, measurements, records of natural seedlings, soil, shade, &c., and to illustrate this plan showed a series of slides taken in France, the idea of which was to explain how the commoner species of trees behaved at different altitudes and on different soils.—Cranial osteology of the fishes of the families Osteoglossidæ, Pantodontidæ, and Phractolæmidæ: Dr. W. G. **Ridewood.** This paper is a fourth instalment of the results of an extensive investigation upon the skull of the lower teleostean fishes begun in 1896. Descriptions are given of the skulls of Osteoglossum, Heterotis, Arapaima, Pantodon, and Phractolæmus; and in a summary Dr. Ridewood points out that the evidence of the skull goes to show that the three genera Osteoglossum, Heterotis, and Arapaima, first brought together into the family Osteoglossidæ by Dr. Günther, constitute a perfectly natural group; that the Pantodontidæ are more closely related to the Osteoglossidæ than to any other family of fishes, as has been suspected since the first discovery of the genus Pantodon in 1876; and that the Phractolæmidæ do not in their cranial osteology offer any evidence of close alliance with either of these families.

February 2.—Prof. W. A. Herdman, F.R.S., president, in the chair.—Descriptions of some new species and notes on other Chinese plants: W. J. **Tutcher.** The species in question had been found on the island of Hong Kong, with one from Kowloon and one from Wei-hai-wei. Bentham's "Flora Hongkongensis" in 1861 enumerated 1053 species from the island, 159 of which had not at that time been found elsewhere, but at the present time only about 50 of these remain peculiar to the island. The flora as now known amounts to about 1400 species, of which 100 are regarded as endemic, though probably many will be found natives of the mainland Ferns amount to 100; grasses about as many; Leguminosæ nearly as many; between 70 and 80 Cyperaceæ; Compositæ more than 60, and orchids 60. *Quercus Eyrei*, first found by Capt. Champion, was not collected by any recent collector until the author re-found it in quantity; even Hance had declared that Champion must have been mistaken in his locality. The luxuriance usually associated with tropical vegetation is here wanting, due to the poverty of the soil, which is almost exclusively disintegrated granite. The new territory leased to Great Britain in 1898 has an area of about 300 square miles, that is, ten times the area of Hong Kong. Lantao is an island resembling Hong Kong, but its highest peak is 3050 feet, with many well-wooded ravines, and when explored will doubtless prove rich in plants.—Revision of the European marine forms of the Cirolaninæ, a subfamily of Crustacea Isopoda: Dr. H. J. **Hansen.** Three new species are described—*Cirolana gallica, C. Schmidtii*, and *Eurydice affinis*. Comparative tables of the genera and species are supplied, distinguishing eight European species of Cirolana, one of Conilera, and six of Eurydice.

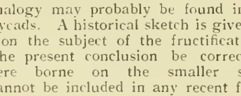
Challenger Society, January 25.—Sir J hn Murray in the chair.—Mr. E. W. L. **Holt** exhibited and made remarks on some rare and interesting deep-water fish and Crustacea from West Ireland.—Dr. R. N. **Wolfenden** exhibited and made remarks upon some Copepoda from the *Gauss* (German Antarctic) expedition; their large size, up to 10mm., was remarkable, as also the fact that, of the 42 species from the *Gauss* and *Belgica*, five were common to the subpolar seas and continuous by way of the mesoplankton.—Sir John **Murray** spoke on the relation of oceanography to other sciences. He pointed out that recent expeditions had made only inconsiderable alterations in the contour lines of the sea-bottom published in the *Challenger* reports, and was of the opinion that no great changes were likely to be made by the soundings of future expeditions. He expressed his belief that the great ocean basins had been practically unaltered through geological time, but that the continents, including a zone of not more than 200 miles seaward of their present outline, had frequently altered their levels, supporting this belief by the fact that all known sedimentary rocks are of "terrigenous" character, to the exclusion of deep-sea materials. The meteorology of mid-ocean, where the diurnal temperature range of the water is about 2° F., was contrasted with the meteorology over land-masses, where absorption and radiation are high, and the diurnal atmospheric range may amount to 80° F. As an example of the far-reaching effects of temperature, Sir John Murray cited the range of annual variation where hot and cold currents are at war, amounting in some cases to 40° F.; in such regions the animal death-rate is very high, and the dead organisms decomposing on the bottom start the formation of glauconite, a well-known constituent of sedimentary rocks. As another result of temperature, it has been estimated that a tropical Copepod lives twenty-four times as fast as an Arctic Copepod in the same period of time; this may explain the predominance of specimens and paucity of species in the Arctic as compared with the Tropical fauna. In connection with chemistry, he pointed out the gradual transference of lime from the poles to the tropics by organic agency; and, in connection with physiology, the possible relation between the serous and similar fluids of existing organisms, and the constitution of the primæval sea in which life first began on our earth.

Faraday Society, January 30.—Prof. A. K. Huntington in the chair.—Mass analysis of Muntz's metal by electrolysis, and some notes on the electrolytic properties of this alloy: J. G. A. **Rhodin.** The first portion of the paper describes an apparatus which was specially designed by the author for the purpose of the accurate and rapid determination of the copper content (which should lie between 60·5 and 61·5 per cent.) of Muntz's metal. The author also discusses the electrochemical properties of Muntz's metal. The metal is largely used as a sheathing to protect ships' bottoms from certain mollusca and algæ, and to be successful it should dissolve in sea-water just to a sufficient extent as to render the surface poisonous, the best conditions being the equal dissolution of the copper and zinc. The author shows how these may be calculated approximately by supposing that the electrolytic dissolution rate is proportional to the heat of formation of the ultimate compounds (zinc and cuprous chlorides), and to the conductivities of the metals which dissolve.—The equilibrium between sodium sulphate and magnesium sulphate: R. B. **Denison.** Experiments conducted from the standpoint of the phase rule are described, the object of which was to determine whether the double salt of sodium and magnesium sulphates, $2MgSO_4.Na_2SO_4$, which has been described as a naturally occurring mineral, is capable of existence in contact with solution, that is, whether it has been formed in nature by the evaporation of saline waters. The corresponding potassium compound is known to occur in Stassfurt as langbeinit, and it was thought that a detailed investigation might result in the isolation of the sodium langbeinit from solution. Dilatometer and tensimeter experiments pointed fairly conclusively to the assumption that the compound sodium-langbeinit cannot exist in contact with solution, at least below 100° C., and hence this substance, if found as a mineral, must be a product of a higher temperature.—Refractory materials for furnace linings: E. K. **Scott.**

Mineralogical Society, January 31.—Prof. H. A. Miers, F.R.S., president, in the chair.—Danalite from Wheal Maudlin, Cornwall; crystallographic characters of barium-radium bromide: Prof. H. A. **Miers.**—Epidote from Inverness-shire: H. H. **Thomas.** The crystallographic and optical characters were described. A chemical analysis made by Dr. Pollard showed that the mineral contained a very low percentage of ferric oxide (6.81). In this respect it was similar to epidotes from Huntington, Mass., and the Zillerthal, and like them showed correspondingly low refractive and double refractive power and large optic axial angle, as compared with epidotes containing higher percentages of iron.—Preliminary note on the regular growth of crystals of one substance upon those of another: T. V. **Barker.** The observations of previous investigators were in general confirmed with regard to the growths of KI, KBr, KCl and $NaNO_3$ upon mica, and of $NaNO_3$ upon calcite. In all cases a clean surface is necessary. Attempts to get a regular deposition of $NaNO_3$ upon other rhombohedral carbonates of the calcite group and upon dolomite were without any positive result, although the rhombohedral angle of some of them is much nearer to that of $NaNO_3$ than is that of calcite. The topic axes, however, are in order of magnitude as follows:—$NaNO_3$, calcite, rhodochrosite, dolomite, chalybite, so that if the regular growth depend on the fitting together of similar structures, the experiments point to the usefulness of the conception of topic axes. The author is continuing his observations.—Apparatus for determining the density of small grains: K. A. K. **Hallowes.** The method is by hydrostatic weighing, and the grain is held under water (or preferably alcohol) in a spring-clamp, made of brass wire and two cover-glasses, which is suspended from the beam of the balance by a fine hair.—*Exhibits*: Specimen of phenacite and one of aurichalcite from Cornish localities: A. **Russell.**—Specimens of sulphide of lead and oxide of zinc artificially produced in furnaces at Laurium: H. F. **Collins.**

Geological Society, February 1.—Dr. J. E. Marr, F.R.S., president, in the chair.—On the sporangium-like organs of *Glossopteris Browniana*, Brongn.: E. A. Newell **Arber.** Some specimens from New South Wales, on which scale-fronds of Glossopteris occur, also exhibit impressions of minute bodies, not unlike the sporangia of certain recent and extinct ferns and cycads. They have never been found, except in the closest association with the scale-leaves of Glossopteris, and this is regarded as an indication that they may be attributed to that genus, a conclusion supported by the evidence of the scale-fronds, which show scars of attachment and fragments of the sac-like bodies still apparently in continuity. It is impossible to be quite certain that these bodies are sporangia, but there is much to be said for this view. The closest analogy may probably be found in the microsporangia of cycads. A historical sketch is given of the present evidence on the subject of the fructification of Glossopteris. If the present conclusion be correct (that the sporangia were borne on the smaller scale-fronds), Glossopteris cannot be included in any recent family of the true ferns.

Chemical Society, February 2.—Prof. W. A. Tilden, F.R.S., president, in the chair.—The following papers were read:—Camphorylcarbimide: M. O. **Forster** and H. E. **Fierz.** The authors described this substance and some of its derivatives and reactions.—Configuration of *iso*nitrosocamphor and its unstable modification: M. O. **Forster.** It is proposed to represent *iso*nitrosocamphor and its unstable isomeride by the configurations



Syn-form and *Anti*-form

respectively. The evidence for this view is principally based upon the behaviour of the two isomerides towards magnesium methyl iodide.—The determination of molecular weight by lowering of vapour pressure: E. P. **Perman.** The author has worked out the details of a simple method by which molecular weights can be determined with moderate accuracy from measurements of the lowering of vapour pressure of the solvent in which the substance under investigation is dissolved.—Note on β-NH-ethenyldiaminonaphthalene: R. **Meldola** and J. H. **Lane.** The ethenyldiaminonaphthalene, obtained by Prager in 1885 by debrominating the bromo-anhydro-base prepared by the reduction of 4-bromo : 2 : nitroaceto-α-naphthalide, is now shown to be identical with the anhydro-base obtained from Markfeldt's ethenyltriaminonaphthalene by the diazo-method.

Mathematical Society, February 9.—Prof. A. R. Forsyth, president, in the chair.—The president referred to the loss sustained by the society by the death of Mr. R. Tucker, who was honorary secretary of the society from 1867 to 1902. A resolution of condolence with Mr. Tucker's surviving relatives was passed.—The following papers were communicated:—General theory of transfinite numbers and order types: Dr. E. W. **Hobson.** The paper deals with the well-known contradiction which arises in the theory of aggregates, and is expressed in the statements:—The aggregate of all ordinal numbers has an ordinal number which must be the greatest of all ordinal numbers, that is, the last of the series; but the series cannot have a last element. The source of the contradiction is traced to the assumption that an ordered aggregate necessarily possesses a definite order-type which can be regarded as an object, viz. the ordinal number coming immediately after all those which are the elements of the aggregate of which it is the order-type. The author proposes to deny this principle, and points out that those parts of the theory of aggregates which are of importance for the general purposes of mathematical analysis would not be affected by this denial.—The Maclaurin sum-formula: Rev. E. W. **Barnes.** The paper contains a new form for the remainder, and a fresh demonstration of the conditions in which certain generalisations of the formula are valid.—The asymptotic expansion of integral functions of finite non-zero order: Rev. E. W. **Barnes.** The object of the paper is to investigate the asymptotic expansions of functions of the class in question without making any appeal to the theory of divergent series. It is shown that the most general type of integral function of finite non-zero order with a single sequence of non-repeated zeroes admits, when the argument is large, an asymptotic expansion valid everywhere save in the neighbourhood of the zeroes of the function, and all the coefficients of this expansion can be built up from the simple Riemann Zeta function. Expansions are also found in the case of integral functions of multiple linear sequence.—On the function $\sum_{n=1}^{\infty} x^n/n^s$: G. H. **Hardy.**—On the reducibility of covariants of binary quantics of infinite order, part ii.: P. W. **Wood.**

EDINBURGH.

Royal Society, January 23.—Dr. Traquair in the chair.—On deep water ship waves: Lord **Kelvin.** The waves were supposed to be produced by a floating or submerged body of proper form moving forward with a given speed in a canal of rectangular section. A solution of the approximate equations was first obtained for a particular form of surface wave associated with a definite distribution of pressure over part of the surface and moving forward with a given speed of propagation. The vanishing of the pressure distribution or "forcive" occurred for a given speed which coincided with the speed of propagation of the free sinusoidal wave. When the forcive did not vanish it acted with or against the displacement according as the speed of propagation was less or greater than this critical velocity. By a suitable synthesis of a series of distributed forcives with their associated surface displacements, the solution was put in a form which lent itself towards the elucidation of several important problems. Thus in certain cases it was possible to imagine a cover fitting part of the water surface and moving forward with the proper speed associating this form of surface with a definite forcive, and in this way a solution was obtained of the train of waves accompanying the passage of a suitably shaped pontoon over the fluid surface. Again, by superposition of two exactly equal forcives half a wave-length apart, the surface outside the region over which the forcive acted was reduced to rest. The disturbed surface within the region of the acting forcive and moving forward with it could then be imagined as fitted with a cover; and thus was solved the problem of finding the form of pontoon which, advancing through the fluid at a given speed, would be unaccompanied by any displacement of fluid surface either before or behind.—A comparison of the lakes of Denmark and Scotland: Dr. **Wesenberg-Lund.** Dr. Lund had visited Scotland on the invitation of Sir John Murray with the view of making this comparative study. The greatest possible contrasts existed between the lakes of Denmark and the typical Highland lakes of Scotland, the Danish lakes being, for example, comparatively small and shallow, with great variations of temperature from season to season, the water being rich in lime, and the littoral region being characterised in most cases by luxurious vegetation forming the home of numerous animals. Scottish lakes like Loch Leven, however, approximated more closely in character to the lakes of Denmark. The paper contained an important discussion of the fauna of the two types of lakes, and of its influence on the lakes themselves and their surroundings. The Danish lakes are gradually being silted up, and will before long disappear, while the lochs of Highland Scotland will remain practically unaltered through long ages.—On a new family and twelve new species of Rotifera of the order Bdelloida: J. **Murray.** The great uniformity of structure hitherto observed throughout the order Bdelloida gives much interest to the discovery in the Scottish lochs of an animal showing great divergence from the general type. The new family, which is called Microdinadæ, is peculiar in the structure of head and jaws. The discs and wreaths are quite absent, so that there is no corona, unless the terminal cilia of the throat are regarded as such. The rostrum and toes are as in the genus Philodina. The jaws of all other Bdelloida are *ramate*; those of Microdina are between *ramate* and *malleo-ramate* or *malleate*. The large teeth are all towards the anterior end of the jaws, and there are usually from one to two loops on the manubrium. A remarkable feature of the animal by which alone it could be distinguished from all other Bdelloida is a large crimson gland attached to the œsophagus.—Variations in the crystallisation of potassium hydrogen succinate due to the presence of other metallic compounds in the solution: A. T. **Cameron.** The crystals were obtained from solutions containing small quantities of ferric and chromic compounds, and may be described as oblique elliptic double cones showing curved surfaces only. The crystals belong to the same system as those of the acid succinate, and are evidently modifications due to the presence in small variable quantities of the other metallic compounds possibly in a state of solid solution.—(1) Continuants whose main diagonal is univarial; (2) the eliminant of a set of general ternary quadrics: Dr. Thomas **Muir.**

MANCHESTER.

Literary and Philosophical Society, January 24.—Rigidity of gelatin: H. **Morris-Airey.** After describing some of the properties of aqueous solutions of gelatin, the results of a series of measurements of the rigidity of these media were given.—The cause of the period of chemical induction: C. H. **Burgess** and D. L. **Chapman** (see p. 380).

PARIS.

Academy of Sciences, February 6.—M. H. Poincaré in the chair.—On the stability of ships: E. **Bertin.**—On the action of hail cannons: J. **Violle.** There are in the Beaujolais twenty-eight societies for breaking up the hail-storms common in that region by means of the hail cannon. A comparison of the damage done during the period 1891–1900 with the losses through hail subsequent to the introduction of the cannon (1900–1904) shows marked evidence in favour of the use of this means of dispersing the hail clouds. It has been frequently noticed that both lightning and thunder are suppressed within the protected zone, although they may be raging just outside this area.—Syntheses in the anthracene series. Symmetrical diamido-tetra-alkyl derivatives of the dihydride of γ-tetraphenyl-anthracene: A. **Haller** and A. **Guyot.** As a result of the condensation of γ-diphenyl-γ-dihydroxy-anthracene dihydride with dimethylaniline two stereoisomeric compounds are produced, which, on account of the wide differences in their properties, are very readily separated. A similar reaction takes place with diethylaniline, but the stereoisomers are more difficult to separate.—The substances producing softness in wine: A. **Muntz.** A discussion of the effect of the gummy matters present in wine on its taste.—On the extension of the Cretaceous seas in Africa: A. **de Lapparent.** Traces left by the seas of the Upper Cretaceous have been recognised for some time in the Sahara and the Soudan, but up to the present there has been no direct proof of a communication between this and the Atlantic. Fossils recently collected by Lieut. Desplagnes and Capt. Théveniaud make the existence of this communication highly probable.—On the three methylcyclohexanones and the corresponding methyl-cyclohexanols: Paul **Sabatier** and A. **Mailhe.** The three cresols are readily reduced to the corresponding cyclohexanols by hydrogen in presence of reduced nickel at 200°–220° C. These were converted by heating with zinc chloride into methylcyclohexenes, and by oxidation into methylcyclohexanones. The latter substances are more conveniently obtained from the alcohol by the reaction discovered by Sabatier and Senderens, passing the vapours of the alcohol over copper heated to 300° C., the yield by this method being nearly theoretical.—On a measurement of the height of the reversing layer obtained with the aid of the large telescope of the Observatory of Mont Blanc: M. **Millochau.** Measurements of two calcium lines under good conditions gave a thickness of $0''.15$.—Observations of the zodiacal light made at the summit of Mont Blanc: A. **Hansky.** A detailed account of observations taken under very favourable conditions on September 21–22.—On solutions of systems of linear differential equations with monodrome coefficients: Ed. **Maillet.**—On Poisson's integral and singular lines of analytical functions: P. **Fatou.**—On the whole of the curves traced on an algebraic surface, and on the Picard integrals of this surface: Francesco **Severi.**—On the deviation of freely falling bodies: M. **de Sparre.** Reply to a paper of M. Maurice Fouché on the same subject.—On a new mechanical clutch: M. **Hérisson.**—An integrating thermometer: Ch. **Féry.**—A synchronising electromagnetic brake: Henri **Abraham.** The axis of the motor carries a toothed wheel of copper, the teeth of which pass between the poles of an electromagnet, actuated by the same current as the motor. If synchronism is established, each tooth passes this space at the instant when the electromagnetic field is nil, and there is no braking action. If the synchronism is imperfect, the brake absorbs the whole of the extra energy of the motor.—Magnetic hysteresis at high frequencies in nickel and nickel steels: Ch. Eug. **Guye** and A. **Schidlof.**—On the direct fixation of ethero-organomagnesium derivatives on the ethylene linkage of unsaturated esters: E. E. **Blaise** and A. **Courtot.** Ethyl methacrylate reacts with magnesium-methyl-iodide giving the tertiary alcohol dimethylpropenylcarbinol, the ketone methyl-ethyl-acetone, and diisopropenyl. The conditions giving a maximum yield of either of these have been worked out.—On the cryoscopy of the sulphates: Albert **Colson.**—A new method of testing for ammonia: application to the examination of water for sanitary purposes: MM. **Trillat** and **Turchet.** In presence of potassium iodide and sodium hypochlorite, ammonium salts develop a black coloration, due to iodide of nitrogen, which can be estimated colorimetrically. The coloration appears to be less liable to be interfered with by certain substances commonly present in natural waters than is the case with Nessler's reagent.—On the evolution of carbon in combustibles: Isidore **Bay** and Just **Alix.**—Some hereditary anomalies provoked by traumatisms: M. **Blaringhem.**—On the use of leucine and tyrosine as sources of nitrogen for plants: L. **Lutz.** These two nitrogenous substances can be assimilated both by phanerogams and fungi. The difference noted in a previous paper between these two classes of plants was due to the use of sand as a medium for the growth of the former.—On the cause of the impoverishment of springs in plains: M. **Houllier.** The author draws the conclusion that the progressive impoverishment of the springs in the basin of the Somme during recent years is the result of the increased use of the land for agricultural purposes, leading to a very considerable increase in the amount of water evaporated by plant transpiration.—The proportions of the gases in arterial blood during the course of anæsthesia due to chloroform, remaining invariable so long as the pulmonary respiration remains very nearly normal: J. **Tissot.**—The mechanism of accommodation: H. **Bertin-Sans** and J. **Gagnière.** The experiments described, which were carried out with rabbits' eyes, support

Tscherning's theory, as opposed to that of Helmholtz.—Observations on the absorption bands of blood and oxyhæmoglobin: MM. **Piettre** and **Vila**.—Myelitis produced by tuberculous toxins: E. **Clément**.—On the constitution of Djebel Hadid: Paul **Lemoine**.—On the Eocene strata in Western Morocco: A. **Brives**.—On the mode of formation of high glacial valleys: Paul **Girardin**.

NEW SOUTH WALES.

Royal Society, November 16, 1904.—Mr. C. O. Burge, president, in the chair.—On the occurrence of isolated crystals of augite in the tufaceous mudstones near the top of the upper marine series at Gerringong: H. G. **Foxall**. The author gives the results of crystallographical and chemical examinations of isolated crystals of augite, together with a note on their occurrence.

December 7, 1904.—Mr. C. O. Burge, president, in the chair.—Mr. C. O. Burge delivered his presidential address on the connection between engineering and science. Among the future triumphs of engineering helped by science were mentioned the application of electricity to main line railways. Then there are promises as regards convevance of power by electricity without wires. Increased economy in the utilisation of heat units in the ordinary steam engine will be a work of the future, thus saving our rapidly diminishing fuel supply. Other subjects mentioned as fit ones for the future were the direct utilisation of the sun's rays for power, and of the rise and fall of the tide for the same purpose; the diminution of skin friction in ships; and of the resistance to air in ships and trains; the dispersion of fog by electricity; the further investigation of fatigue in metals used for construction; and the application of single phase electricity to traction.—The approximate colorimetric estimation of nickel and cobalt in presence of one another: R. W. **Challinor**. Use is made of the complementary colours of Ni and Co solutions. The method is to be applied to the solution of the weighed Ni and Co deposited by electrolysis. The mixed metals are dissolved in HNO_3, the solution evaporated and diluted to a definite volume and a fraction taken. Standard Ni $(NO_3)_2$ or Co $(NO_3)_2$ solution is added until the colour matches a neutral tinted solution of known strength; both solutions are brought finally to the same dilution, the colours being compared by looking vertically down the tubes.—Note on a combined wash-bottle and pipette: J. W. **Hogarth**.

DIARY OF SOCIETIES.

THURSDAY, FEBRUARY 16.

ROYAL SOCIETY, at 4.30.—Pularised Röntgen Radiation: Dr. C. G. Barkla.—The Effects of Momentary Stresses in Metals. Prof. B. Hopkinson.—The Halogen Hydrides as Conducting Solvents. Parts I.—IV.: B. D. Steele, D. McIntosh, and E. H. Archibald.—Further Observations on Slip-bands. Preliminary Note: W. Rosenhain.
ROYAL INSTITUTION, at 5.—Recent Work of the Geological Survey: Prof. J. J. H. Teall, F.R.S.

RECENT ENGLISH HISTORY.

Social England. Edited by H. D. Traill and J. S. Mann. Vol v., pp. lii+864; vol. vi., pp. lvi+948. (London: Cassell and Co., Ltd., 1904.) Price 14*s*. net each volume.

An Introductory History of England. By C. R. L. Fletcher. Pp. xvii+397. (London: John Murray.) Price 7*s*. 6*d*.

Studies on Anglo-Saxon Institutions. By H. M. Chadwick. Pp. xiii+420. (Cambridge University Press, 1905.) Price 8*s*. net.

IN the fifth and sixth volumes of "Social England," lately re-issued in an illustrated edition (1904), considerable prominence is given to subjects of scientific as well as of historical interest. Thus Mr. T. Whittaker (rather more adequately than in earlier stages) writes on philosophy and natural science in the eighteenth century and the Napoleonic age, and for the same period Mr. D'Arcy Power discusses medicine and public health, Mr. Raymond Beazley exploration and the advance of geographical knowledge, and Mr. G. T. Warner manufacturing progress, machinery, and the transformation of industry (v., 31–47, 56–73, 145–55, 292–307, 321–33, 408–35, 543–6, 560–84, 625–45, 756–60, 805–22).

In the final or nineteenth century volume, geology, chemistry, astronomy, physics, biology, anthropology, engineering, mining and metallurgy, applications of electricity, and the railway system of the United Kingdom are also treated, in addition to our old friends philosophy, medicine, and exploration. The list of scientific writers is much enlarged, and comprises Prof. T. G. Bonney, Mr. Robert Steele, Mr. H. C. Jenkins, Lord Farrer, Miss A. M. Clerke, Mr. W. G. Rhodes, Mr. O. G. Jones, and Dr. J. Scott Keltie (vi., 76–95, 239–90, 413–48, 675–793, 892–927).

Among these contributions we may especially notice, for the sake of illustration, that of Dr. Keltie on British exploration, 1815–85. Here we have a good, clear, business-like summary (very well illustrated, especially by contemporary maps) of a great and significant chapter in the life-history of the English people. But the amount of matter to be treated is so vast, and Dr. Keltie is so conscientious in his determination not to omit a reference, however brief, to every important personage and event within the limits of his subject, that the narrative becomes at times a chronicle of the nature of "materials for history." Thus, in tracing the course of British explorations in Central Asia and the Far East alone, the work of Moorcroft, Wood, Shaw, Forsyth, Hayward, Trotter, Carey, Bell, James, Younghusband, Basil Hall, Collinson, Fortune, Blakiston, Ney Elias, Sladen, Margary, Gill, Baber, Colquhoun, McCarthy, Williamson, Gilmore, Alcock, and Mrs. Bishop is summarised in two pages. It is no doubt difficult to avoid such treatment, and the secretary of our Geographical Society is an excellent chronicler; but it is perhaps open to question whether a more selective and less annalistic method might not have been followed in this as in certain other articles, such as the "Engineering" of Mr. O. G. Jones, where a more philosophic style is adopted with marked success.

The British history of the nineteenth, or even of the eighteenth, century in one volume, even though that volume run to 930 pages, is an undertaking of no small difficulty; as the assistant editor—and true chief pilot—of the venture, Mr. J. S. Mann, himself admits. Intellectual and industrial achievements are now so multifarious that they can hardly be dealt with in the same book as the political and social history. Science has become more than ever cosmopolitan; processes in the great staple trades have undergone developments far too specialised for the ordinary reader; to a vast number of secondary and miscellaneous industries and interests it is impossible to assign any adequate recognition; a bare enumeration, the recognition of an allusion, is all that can be spared for whole chapters of national progress during the last age. To such themes as railways, merchant shipping, the machinery of commerce, the new developments in social organisation, art, and literature, it seems almost useless to devote a few pages; while the subject of colonial history has only to be mentioned for the most casual reader to recognise the increased complication which the nineteenth century has brought to the national story.

Even since 1885, where the editors originally drew their line (evidently with some later regrets that this boundary could not be shifted down to the close of the Victorian reign), the local government of the United Kingdom has been profoundly modified; new methods have been introduced into industry; shipbuilding has taken a fresh start; legal reform has made notable progress; labour questions have been attended by many fresh developments; and an Imperial and Conservative movement (or reaction) of the most far-reaching character has influenced every side of national life and consciousness.

All the more heartily, then, we can congratulate the editors, contributors, and publishers of "Social England" on the measure of success they have realised, on the immense body of valuable information (sometimes a trifle unsifted, sometimes marred by error, but on the whole highly creditable) which is presented in these volumes, on the impartiality and truly scientific spirit which pervade almost the whole of the work, and by no means least, on the suggestive and representative illustrations by which the best of all possible commentaries is afforded to the text.

Mr. Fletcher's "Introductory History of England" down to the accession of the Tudors, where the author fixes, for his purpose, the close of the Middle Ages, is a brave and vigorous attempt to get away from dulness without losing touch of truth, to invest the story of mediæval England with an interest which is lacking in such arid text-books as have become only too plentiful of late. As we might expect from

Mr. Fletcher, the book he has now given us is eminently characteristic, full of his own energetic, practical activity, his love of health, fresh air, and good exercise.

"When I began," he tells us, "I had foolish hopes that it might be a book some boys would take up for amusement, but I soon discovered that twenty-three years of teaching had made it impossible for me to do more than smear the powder with a thin layer of jam. We cannot render our dreams of the past (however convinced we may be of their truth) into an intelligible consecutive story."

Here, it seems to us, there is both truth and untruth. Mr. Fletcher's story is, in the main, highly intelligible and adequately consecutive (though one may make an exception of the Anglo-Saxon period, where the author seems at times almost to sink to Milton's notions of "kites and crows"); but how can any true student regard English history as if it were a nauseous drug, to be made palatable by some device? Should one not rather look at it as a storehouse from which a good judgment is needed to draw forth those treasures best suited to the audience one addresses—to the specialist this, to the general reader that, to the working man one thing, to the merchant, the professional man, or the politician another?

Yet though Mr. Fletcher anxiously disclaims the idea of pouring information into anyone, and still more anxiously repudiates the ambition of helping anybody to pass any examination, he has certainly given us here a sketch of living men by a living man, and everyone who is not a pedant, everyone who desires to remember that history is the life-record of humanity, will be grateful to him for this book. Peculiarly interesting is the picture attempted of an imaginary village in pre-Norman, Norman, and post-Norman times, with its three fields, for wheat, barley, and pasture, its arable strips, its green common or waste, its water-meadows, its pig-grazing woods, its no-man's land, and its bull-croft—as successful an attempt to realise the township-manor as any popular treatise has supplied in English of recent years; while a word must also be said in praise of the capital little chapter of geological history, illustrated by a serviceable map of N.W. Europe in the Old Stone age, with which Mr. Fletcher commences.

Mr. Chadwick's "Studies on Anglo-Saxon Institutions" supplies a useful corrective to the studied vagueness with which Mr. Fletcher treats our English history. Here a careful re-examination of the evidence bearing on some of the most interesting problems of early English history and sociology is attempted with distinct success. The writer's object has especially been to call attention to those branches of the subject which have hitherto suffered from comparative neglect. Thus he has dealt very lightly with Mercian and Northumbrian history because he had nothing of importance to add to previous work; but evidence relating to Kent, Sussex, Essex, and the Hwiccas has been reviewed and re-stated with great care, and with the belief that some fresh results have been attained. The most valuable portion of the volume seems to be that dealing with the old English monetary system (accompanied by a useful excursus on Frankish coinage, pp. 1–75). And next to this the reader may be recommended to the chapters dealing with the history of the older counties (Kent, &c., pp. 269–307) and with the origin of the nobility (pp. 378–411). Great caution marks all Mr. Chadwick's work, and this quality is never more useful than in such a difficult period as the Anglo-Saxon. But his treatment of our early charters is also noticeable for its courage; when, even in obviously spurious documents, names and titles otherwise unknown are met with, the author, with a daring that will perhaps greatly shock some dogmatists, ventures to think that such names and titles are not necessarily products of imagination. To find one who will say this, and who will appeal moreover for a fairer hearing in the examination of tradition, popular as well as ecclesiastical, is certainly refreshing at the present moment.

STEREOCHEMISTRY.

Materialien der Stereochemie. (In Form von Jahresberichten.) Band i., 1894–1898; Band ii., 1899–1902. By C. A. Bischoff. Pp. cxxxvi+1977. (Brunswick: Vieweg and Son, 1904.) Price 90 marks.

IN the course of his reply to a letter from the Chemical Society of London congratulating him on the completion of the twenty-fifth year of his doctorate, Prof. Emil Fischer writes as follows:—

"The time when the fundamental principles of our science were laid down, and when it was possible for the individual investigator to stamp the impress of his own mind upon it, is long since past, and in the gigantic structure, which it now represents, each fellow-worker can only finish some small fragment, or it may be, if he is fortunate, a pretty balcony or a striking turret."

The two ponderous tomes, in which Prof. Bischoff records the advances made in stereochemistry from 1894 to 1902, illustrate in a very striking manner this ever-increasing tendency to specialism in chemical research, which Fischer emphasises in the sentence just quoted.

Although Pasteur, in 1861, by his classical experiments with the isomeric tartaric acids, may be said to have laid the foundation of stereochemistry, the growth of this branch of chemical science was at first slow, since it was not till 1873 that Wislicenus pointed out as a consequence of his work with lactic acid that differences between compounds of identical structure must be ascribed to differences in the spacial arrangement of their atoms within the molecule. The publication in the following year by van't Hoff and Le Bel of their theory of the asymmetric carbon atom gave an immense impulse to experimental work, so that optically active compounds, which in those earlier days were numbered by tens, may now be counted by thousands.

The rapid development of stereochemistry is not, however, restricted to the field of optically active compounds. The researches of Victor Meyer and of Bischoff are fundamental in that branch where the normal and abnormal courses of many reactions are interpreted from a stereochemical standpoint. Then again, the study of geometrical isomerides, such as substances of the ethylene type with the so-called double linkage between carbon atoms, of polymethylene and heterocyclic compounds, of compounds with a double linkage between a carbon atom and a nitrogen atom, and finally of compounds with a double linkage between two nitrogen atoms, has engaged the attention of many prominent contemporary workers.

The well-known "Handbuch der Stereochemie," by Walden and Bischoff, gives a comprehensive survey of stereochemical literature up to the year 1894. Owing to the rapid developments of the last ten years, however, this work has lately lost much of its initial value as a source of reference. This defect is now remedied. In the "Materialien der Stereochemie" we have an addendum to the "Handbuch," the literature of each successive year from 1894 to 1902 being classified in a manner which cannot fail to prove of the utmost service. The subject matter for each year is treated under four sections, namely, general stereochemistry, optical isomerism, geometrical isomerism of optically inactive compounds, and interdependence of spacial relationships and chemical reactions. A brief description of each paper quoted is usually given. The first section on general stereochemistry, in addition to the bibliography of special monographs published during the particular year, embraces references to chemical dynamics, crystallography, spectroscopy, &c., in so far as those subjects have any stereochemical bearing. In the three other sections the papers of more general interest are first quoted; then follow references to the more special papers which are not quoted chronologically, but are conveniently classified according to their subject matter.

The field reviewed in the first subdivision of the fourth section deals with ring systems, and is so vast that, as a rule, only references are given to the innumerable papers quoted. On the other hand, the papers on polymerisation, substitution, addition reactions, hydrolysis, &c., included in the same section are dealt with in more detail.

The general student will find this work unreadable. The author contents himself with the abstract he gives, and hardly ever ventures on any criticism. Little or no attempt is made to differentiate between the important and the unimportant, and in this respect it seems to the present reviewer that more prominence might with advantage have been given to such research as is acknowledged by all to be outstanding. From the point of view of the specialist, however, the work is admirable. Its value lies not so much in the information actually afforded by the abstracts themselves as in the remarkably complete bibliography which it presents. The ardent stereochemist, who in his own particular sphere may be tempted to exclaim, "Zwar weiss ich viel, doch möcht' ich alles wissen," will assuredly find in this work an aid to the realisation of his desire.

A. McK.

A TRAVELLER'S GUIDE TO INDIA.

The Imperial Guide to India, including Kashmir, Burma and Ceylon. Pp. xi+244; with illustrations, maps, and plans. (London: John Murray, 1904.) Price 6s. net.

THE large and constantly increasing number of tourists and sportsmen who visit our Indian Empire during the winter, together with the smaller section who extend their trip so as to include a summer sojourn in Kashmir or some other Himalayan district, must create an extensive demand for a work like the one before us, and the wonder is that an attempt has not been made long ago to supply such a manifest want. In the present volume, which is got up in convenient size and shape for the pocket, and printed in small although clear type, with the chief items in caps. or block type, the anonymous author seems, on the whole, to have discharged a by no means easy task in a thoroughly satisfactory and painstaking manner. Indeed, so far as a somewhat extensive personal experience of the country permits of our forming a judgment, we may say that, as a viaticum and itinerary, which is, of course, its main purpose, the work is well-nigh all that can be desired so far as its somewhat limited space permits. Although necessarily brief, the descriptions of the towns, cities, and stations, and of the railway or other routes by which they are reached, are in the main excellent, and convey a very large amount of useful and necessary information. The various routes are also carefully planned and thought out, and will enable the tourist to find his way about and to visit much of what is most worth seeing with the least amount of discomfort and difficulty. Whether, however, the "selected Hindustani phrases" at the end of the volume will enable the tourist to make himself understood by the natives of even the Hindustani-speaking provinces may be more than doubtful.

But the author has not been content to make his work a mere itinerary. On the contrary, he treats his readers to brief dissertations on the ethnology, natural history, and geology of the Indian Empire, with scrappy pieces of information with regard to the sport to be obtained. With respect to this aspect of the volume, we are compelled to say, in the first place, that the author has not allowed himself sufficient space to make the information he attempts to convey of any real value, and secondly, that it would have been well had he taken expert advice and assistance.

One fault about the introductory chapter is that it is too "parochial." The volume professes to treat of India, Ceylon, Burma, and Kashmir, but this chapter, although the reader is not told so, seems to refer only to India proper. For instance, we are told that shooting licences are not required (p. 10), and yet we find (p. 186) that these are necessary in Kashmir. Again, in the ethnological paragraphs we find no reference under the heading of non-Aryan races to either the Veddas of Ceylon, the Burmese, or the Mongoloid tribes of the north-east frontier, while the classification of the natives of the peninsula merely by religion leaves much to be desired. The general description of Indian scenery—inclusive of natural history and geology—is, moreover, little short of ludicrous. What, for instance, are we to say of a writer who describes the rocks of the Himalaya as Archæan, although he does qualify this by stating later on that a band of Cretaceous (which is incorrect) and Tertiary rocks skirts the foot of the range? The reference to the Mesozoic rocks of the peninsula is also misleading, and we should like to know what "similar scenery in Europe" is recalled by the traps of the Ghats. A few colourêd plates of more or less characteristic Indian mammals and birds relieve the necessarily dry details of the work, but it would have been better if the author had made up his mind what name to employ for the Indian antelope, instead of calling it *Antelope* (in error, by the way, for *Antilope*) *bezoartica* on p. 12 and *A. cervicapra* on the plate. When a future edition of this otherwise excellent little work is called for it may be hoped that the introductory chapter will be re-written with the aid of some one who has at least a smattering of elementary information with regard to the geology and zoological products of the country. R. L.

OUR BOOK SHELF.

Bacteriology and the Public Health. By Dr. George Newman. Third edition. Pp. xx+497. (London: John Murray, 1904.) Price 21s. net.

DR. GEORGE NEWMAN is well known as a public health expert and bacteriologist, and his contributions to the literature of preventive medicine have attracted considerable attention both in this country and abroad. The present volume may be regarded as an elaboration of his previous writings, and is, in most respects, thoroughly up to date.

There are thirteen chapters, dealing with subjects as follows:—the biology of bacteria, bacteria in water, bacteria in the air, bacteria and fermentation, bacteria in the soil, the bacteriology of sewage and the bacterial treatment of sewage, bacteria in milk and milk products, bacteria in other foods, bacteria in disease, tuberculosis as a type of bacterial disease, the etiology of tropical diseases, the question of immunity and antitoxins, and disinfection. There is also an appendix on technique and a welcome index.

The chapters dealing with some of the pressing administrative problems of the day are specially worthy of commendation.

The chapter on bacteria in milk is an admirable dissertation, and the author deserves much credit for his judicious handling of a mass of conflicting opinion and apparently irreconcilable facts. For the benefit of those who regard the bacterial diseases of animals, some of which are preventable, as of little economic importance, the following quotations (p. 324, p. 319, p. 203, p. 204) may be given:—

"In 1903 there were in Great Britain as many as 1463 outbreaks of glanders in which 2490 horses were attacked. This is the highest number of outbreaks since 1892, when they numbered 1657. The prevalence of this disease is localised often to certain counties and districts. In 1903, 855 of the 1463 outbreaks occurred in the county of London."

"In 1903 there were 761 outbreaks of anthrax in Great Britain, in which 1127 animals were attacked. This is the largest return recorded since the passing of the Anthrax Order in 1886."

"It is a well known fact that tuberculosis is a common disease of cattle. Probably not less than 20 to 30 per cent. of milch cows in this country are affected with it."

"In the United Kingdom in 1901 there were 4,102,000 milch cows. If we take 2 per cent. of these as having tuberculous udders, it gives us 80,000. The average annual yield of milk per cow may be taken as, at least, 400 gallons, which means that from these 80,000 tuberculous udders 32,000,000 gallons of milk are obtained."

It is perhaps unnecessary to add that glanders, anthrax, and tuberculosis afflict man as well as the lower animals.

The book, judged as a whole, is a most valuable contribution to the literature of preventive medicine. It will prove most useful to medical officers of health, medical men, bacteriologists, veterinary surgeons, trade experts, and many others. The lay reader will find it replete with information, and written in a lucid and agreeable style.

In a sense, the present volume is a later edition of "Bacteria," which was noticed by the present writer in these columns in 1899; but the new publication is amplified and improved to such an extent as fully to merit this second notice. A. C. HOUSTON.

Die bisherige Tätigkeit der Physikalisch-technischen Reichsanstalt. (Brunswick: Vieweg and Son, 1904.)

Die Tätigkeit der Physikalisch-technischen Reichsanstalt im Jahre 1903. (Berlin: Springer, 1904.)

IN these publications is given an interesting account of the progress of the Reichsanstalt from its foundation in 1887 to the present time. From the first pamphlet by the president, Dr. Kohlrausch, we find that the total number of instruments tested up to the end of 1903 was 290,000, an average of nearly 20,000 a year. If, however, we deduct from this the number of clinical thermometers and of safety fusible plugs for boilers, the aggregate is reduced to 50,000, or an average total of about 2800 a year for all other instruments. Against this figure we may compare the totals taken from the report of the National Physical Laboratory for 1903, from which it appears that the aggregate for the year for instruments and tests of all kinds was 30,817, or, excluding clinical thermometers, 11,424.

An interesting recent development of the Reichsanstalt is the opening at various towns throughout Germany of five branch stations, where electrotechnical instruments can be verified. The report concludes with a long list of the recent original papers published by the members of the staff.

It is not possible to give in the space here available anything like an insight into the manifold contents of the second publication—the report of the Reichsanstalt for the year 1903. The researches mentioned include the expansion of water between 0° C. and 100° C., and of numerous materials from liquid air temperatures upwards, the laws of radiation, light units, and magnetic permeability. Full details are given as to the numerous instruments tested.

J. A. H.

The Principles of Inorganic Chemistry. By Wilhelm Ostwald. Translated by Dr. Alexander Findlay. Second edition. Pp. xxxi+799. (Macmillan and Co., Ltd., 1904.) 18s. net.

THE best proof of the excellence of this work and its appreciation by English-speaking students is that a new edition has been found necessary after such a comparatively short time as two and a half years. The work, unlike many text-books on chemistry, forms interesting reading, and this is greatly caused by the excellence of Dr. Findlay's translation. The present edition is practically a reprint of the first, except in so far as a few pages have been added on radio-active phenomena, in connection with the metals thorium and uranium; a necessarily short description is given of compounds of radium, and a sketch of the transformations undergone by that curious element in arriving at a stable condition. W. R.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* Nature. *No notice is taken of anonymous communications.*]

A Contemplated Magnetic Survey of the North Pacific Ocean by the Carnegie Institution.

A project for a magnetic survey of the North Pacific Ocean by the Department of International Research in Terrestrial Magnetism has been favourably acted upon by the executive committee of the Carnegie Institution of Washington, and authorisation has been given to begin the work this year. An initial allotment of 20,000 dollars has been made to cover the expenses for the current year.

As is well known, the state of our knowledge of the distribution of the magnetic forces over the greater portion of the earth—the oceanic areas—owing to the paucity of precise data, is exceedingly unsatisfactory. This fact is especially true for that great body of water the Pacific Ocean, rapidly developing in great commercial importance.

Captain Creak, for many years superintendent of the Compass Department of the British Admiralty, now retired, says:—"The North Pacific Ocean is, with the exception of the voyage of the *Challenger*, nearly a blank as regards magnetic observations, and I therefore think the Magnetic Survey proposed will be of great value."

Hence, except for data from occasional expeditions and such as were acquired in wooden vessels a long time ago, the present magnetic charts used by the navigator over this region depend largely upon the observations on islands and along the coasts. Such land observations, however, are rarely representative of the true values because of prevalent local disturbances. It is, therefore, impossible to make any statement as to the correctness of the present charts. The demands of science, as well as those of commerce and navigation, require a systematic magnetic survey of this region under the most favourable conditions possible, and that the work be done under the auspices of some recognised research institution in order to ensure that the scientific aspects of the work receive their adequate recognition.

The eminent physicist and magnetician Prof. Arthur Schuster states as his opinion:—"I believe that no material progress of terrestrial magnetism is possible until the magnetic constants of the great ocean basins, especially the Pacific, have been determined more accurately than they are at present. There is reason to believe that these constants may be affected by considerable systematic errors. It is possible that these errors have crept in by paying too much attention to measurements made on islands and along the sea coast. What is wanted is more numerous and more accurate observations on the sea itself." Furthermore, the superintendent of the United States Coast and Geodetic Survey, Mr. O. H. Tittmann, says:—"There is no doubt in my mind that a survey for that purpose would result in obtaining data of great and permanent value, and that it should be undertaken."

Additional quotations could be given; the above, however, are representative, and show sufficiently the great importance of the proposed work and the fruitful results that may confidently be expected. It is hoped that upon the completion of the magnetic survey of the North Pacific the means will be forthcoming for extending the survey so as to include other oceanic areas. An effort will furthermore be made to secure the interest and cooperation of all civilised countries, so that we may look forward to the completion of a general magnetic survey of the accessible portions of the globe within about fifteen years. Thanks to the awakening and renewed interest in magnetic work shown on all sides, I fully believe that this hope will be realised.

The matter of prime consideration in magnetic work at sea is the elimination of the effects resulting from the ship's own magnetism as due to her construction and equipment. Such effects are especially troublesome to eliminate when it is proposed to obtain not only the magnetic declination at sea, but also the other magnetic elements (the dip and the intensity of the magnetic force). The plan therefore to be attempted this year, as worked out by Mr. G. W. Littlehales, Hydrographic Engineer of the United States Hydrographic Office, and Consulting Hydrographer of the Department of Terrestrial Magnetism of the Carnegie Institution, is, in brief, as follows:—"To charter a wood-built, non-magnetic, sailing vessel of about six hundred tons displacement, which starting out in summer from San Francisco, shall pursue a clockwise spiral course embracing the entire North Pacific Ocean. The object of planning such a course is to gain continuous advantage throughout the survey of the dynamical agencies of the atmosphere and the ocean, in passing in succession into each of the five degree quadrangles into which the chart[1] is divided, and in which observed values of the three magnetic elements need to be obtained.

"The seasonal shifting of the permanent centres of barometric pressure will cause a variation from month to month of the conditions of wind and current that are represented on this particular chart, but if the departure from San Francisco be taken in the summer, the chain of meteorological events will contribute toward the maximum progress over the course passing thence along the west coast of America to the vicinity of the Galapagos Islands, thence across the Pacific in latitude between two and three degrees north, thence along the eastern side of the Philippine Archipelago and the Empire of Japan, thence eastward in about latitude fifty-two degrees north, thence to the latitude of San Francisco, and thence continuing through the series of areas, bounded by parallels of latitude and meridians of longitude each five degrees apart, lying next on the mid-ocean side of the circuit last made, and proceeding gradually and by successive circuits into the central region of the North Pacific."

The total length of the course marked out is about 70,000 knots; however, each of the first circuits practically closes at San Francisco, so that, if it is found that the method pursued is not the best, the work can readily be terminated or modified. From inquiries made, it would appear that the entire work of observation and reduction can be accomplished in three years. The cost per month of the field work, inclusive of all expenses and services, will be approximately fifteen hundred dollars. Counting eight months of continuous service per annum, the total annual outlay is estimated at about twelve thousand dollars.

This project, as a result of careful consideration and solicitation of expert opinion, is believed to be thoroughly feasible. It permits of useful comprehensive results being immediately obtained, and is one which can be interrupted without any important waste of antecedent expense whenever circumstances may render a discontinuance or a modification of the original plan advisable.

The region it is proposed at present to survey fortunately contains magnetic observatories in requisite number and proper distribution for furnishing the necessary corrections to be applied to the observed magnetic elements in order to reduce them to a common epoch. Thus continuous records of the magnetic variations required for this purpose will be available from the following stations:—Sitka, Mexico, Honolulu, Manila, Shanghai, Tokio. In addition, it is hoped that there may be soon a magnetic observatory in California or vicinity for lending effective cooperation, and that the German Government will continue its magnetic observatory at Apia throughout the period of the survey. Also excellent opportunities for controlling instrumental constants and obtaining required additional data will be afforded by stations on the coasts and on islands.

It should also be pointed out that the plan of the courses

[1] The course to be followed was shown in red ink on a U.S. Hydrographic Office Pilot Chart of the North Pacific.

as mapped permits ready adjustment of the observed quantities for closed areas, in accordance with the potential hypothesis, and it may even permit, to a certain degree, the testing of the accuracy of this assumption, though as regards the latter more can be said at the end of a year's work.

While it is not anticipated that any marked irregularities in the distribution of the earth's magnetism will manifest themselves over the deep waters of the Pacific, it may confidently be expected that in the neighbourhood of the islands and along the coasts distortions and irregularities will be revealed. With the aid of the results of the detailed magnetic survey of the United States and Alaska, opportunity will therefore be afforded of studying the effect of the configuration of land and water upon the distribution of the magnetic forces. The first circuit, passing as it does along the American and Asiatic coasts, will yield especially interesting results in this respect. Thus, for example, along the Aleutian Islands marked local disturbances will be disclosed. Reports are received frequently from mariners in this region regarding the unsatisfactory behaviour of the compass; it is therefore greatly to be desired that a systematic magnetic survey of the waters in this region be made.

Recently Observed Satellites.

IN reply to Sir Oliver Lodge's letter in NATURE of January 26 (p. 295), it may be said that while it is perfectly possible that the newly discovered satellites are captured comets (see *Harvard Annals*, liii., p. 60), yet the chances against the actual occurrence of the required conditions at exactly the right times, even in one case, are exceedingly large; in two cases they are practically prohibitive.

With regard to a possible meteoric constitution, it is known that the density of the four larger satellites of Jupiter is extremely small—but little above that of water. That their discs are frequently found to be elliptical when seen under favourable conditions has now been noted by more than a dozen different astronomers. The regularly recurring changes in their ellipticity, noted by several observers, taken in connection with the small density of these bodies, can hardly be explained in any other manner than by a meteoric constitution. Such being the case, it is highly probable, as Sir Oliver Lodge suggests, that the newly discovered satellites are similarly constituted.

A reply to his further suggestion that they are now in process of dissolution is impossible in the present state of our knowledge. If formed according to the nebular hypothesis, however, as seems most probable, and if they have accordingly existed through the æons during which their primaries have been contracting to their present dimensions, it seems highly unlikely that they should not yet have reached a permanent condition.

WILLIAM H. PICKERING.

Cambridge, Mass., U.S.A., February 9.

Compulsory Greek at Cambridge.

THE proposals of the Studies and Examinations Syndicate in regard to certain changes in the Previous Examination are to be submitted to the Senate on March 3 and 4. Members of the Senate may record their votes on either of these days between 1 and 3, or between 5 and 7 p.m. The controversy has chiefly turned on the proposal to abolish compulsory Greek, and it is mainly on this question that the issue will be decided.

All the five Graces are important, but Grace II., which raises the main issue, is the most important of all.

The secretaries of the committee in support of the recommendations of the syndicate will be glad to hear from non-resident members of the Senate who have not already intimated their intention of supporting the proposed reform. It is believed that amongst resident members of the Senate a majority will vote in favour of the new scheme, but the decision is largely in the hands of non-resident voters. As it is proposed to issue a final list of supporters shortly before March 3, it will be a convenience if additional names are sent to Mr. A. C. Seward, Emmanuel College, Cambridge, at once.

R. VERE LAURENCE,
H. RACKHAM,
A. C. SEWARD.

Cambridge, February 21.

THE experiences of Mr. Willis and others suggest that mine may be in point. Mr. Willis was behind in classics. He wasted $105\frac{1}{2}$ hours on Greek and passed. His present knowledge of Greek, he adds, is *nil*.

Mathematics were my difficulty. Being destined for Cambridge, I was specially coached in mathematics at school. Arrived here I was again coached, but failed. Coached once more I passed, having wasted, not one, but several hundred hours on that study. Needless to say, my knowledge of mathematics is *nil*.

My case is that of hundreds. Why, then, are not compulsory mathematics to be reformed away? Because they can be used in trades and professions for the making of money. But the things that put one touch of art in the life of a dull boy, that open his eyes for once to another world, where "utility" does not count—they, forsooth, must be dispensed with because in the market they have no value. And, verily, they are without price.

Away from Cambridge, an intelligent lady was lately speaking to me of her nephew at the University of Birmingham. Knowing nothing of our pending "reform," she said: "He is going to be an engineer. But he has got to waste his time passing in French, and German, and English. He will never want them again in his whole course. It is absurd." W. BATESON.

Cambridge, February 17.

Secondary Radiation.

IN a paper recently published (*Transactions* Royal Dublin Society and *Phil. Mag.*, February) I described some work on secondary β radiation given off by substances when exposed to β (and γ) rays from radium. The paper gave the relative intensity of this secondary radiation for only a few elements, but the results from these few indicated that the greater the atomic weight the greater was the secondary radiation.

I have since tested a large number of elements, and found this rule to hold without a single exception. The list of substances tested was a very varied one, including carbon, magnesium, aluminium, chromium, iron, nickel, copper, zinc, arsenic, selenium, molybdenum, silver, tin, antimony, tungsten, platinum, mercury, lead, and bismuth.

The secondary radiation is not proportional to the atomic weight; it increases less rapidly than the atomic weight.

This very general result appears to be of interest as bearing on the subject of radio-activity and atomic structure in general, but cannot be further discussed here.

Tenacity to Life of a Grass-snake.

A GRASS-SNAKE which the writer had in his possession for eighteen months has just died.

A fact which seems worthy of note is the length of time during which this snake fasted. The last time the snake fed was June 11, 1904, the meal consisting of a small frog. From that time until the date of its death, February 2, it took no food, although constantly offered it. The animal thus existed for close on eight months without food. During the whole of this time it appeared in good health, and was, at times, most animated. No approach to hibernation was observed, and only for a little more than a week before its death did the snake seem out of health. The body was not unduly thin. E. V. WINDSOR.

Barnet, February 7.

NOTES ON STONEHENGE.[1]

IV.—THE EARLIEST CIRCLES (*continued*).

THE conclusion at which I have arrived is that the older temple dealt primarily, but not exclusively, with the May year; the newer temple represented a change of cult, and was dedicated primarily to the solstitial year. In both, however, the sunrises and sunsets of the June-December and May-November years could be, and doubtless were, observed. I direct attention to the following considerations in support of this theory.

(1) The blocks of unworked sarsen, perhaps dating from a time when the use of stone tools for working stone in Britain was unknown, are precisely those which give us the alignments, both for the May and June years.

FIG. 10—The vertical rod is placed in the axis, and marks the common direction of the present temple and avenue, which passes about 3 feet to the N.W. of the Friar's Heel.

(2) The blue stones, unworked for the same reason, may have originally composed two circles and a central stone as a start point for these alignments. The central stone, marking the centre of the two concentric circles, would naturally stand half-way between the N.W. and S.E. exterior sarsen stones.

In this first simplest form we should have the equivalent of the ancient temple described by Virgil, with the uncovered altar at the centre after the Etruscan fashion.

> "Ædibus in mediis, nudoque sub ætheris axe,
> Ingens ara fuit."

It is sad to think that at Avebury not so very many years ago there were two such double circles as those I postulate. They have now almost entirely disappeared. The central observing place, a cove, in the northern circle still remains with some of the stones of the outermost circle; all the rest have been taken up, broken, and used for building. Truly the English are a "practical" people.

(3) At the reconstruction, about 1680 B.C., the solstitial cult was made predominant, and for some reason or other it was determined to change the centre of the circles in the new structure, and throw the N.E. alignment nearer the north, still remaining parallel to its old direction.

There may possibly have been two reasons for the reconstruction of the temple about the time I have named. At the date mentioned the place of sunrise from the old centre, which I have indicated, was hidden by the Friar's Heel, unless the observer, the high priest, were raised some few feet above the ground at its present level. It may have happened, then, that the difference of the sunrise place, brought about, as we now know, by the gradual reduction of the obliquity of the ecliptic, had shown itself in a very unmistakable way to the priests; in 2680 B.C. it was certainly well to the north of the Friar's Heel, and occupied an uninterrupted horizon, so that they might well wish to secure a clear horizon for the future; this they found by moving the centre of the circles, and therefore the solstitial line, a few (about 4) feet further to the N.W., still preserving their ancient pointer.

But this is not all. Colonel Johnston, the director of the Ordnance Survey, has obligingly pointed out to me that the present centre of Stonehenge, Sidbury Hill to the N.E., and the earthworks at Grovely Castle and Castle Ditches to the S.W., all lie exactly on the solstitial line in 1680 B.C. The top of Sidbury Hill may, then, have been taken for the new pointer, in which case the earthwork camp some 30 feet high on the top had not been built, for it lies a little to the north-west of the line.

(4) While it was determined to erect a temple on a much larger scale by the addition of a larger exterior circle of sarsens and a naos also of trilithons, it was also determined to utilise the unworked blue stones composing the two circles. But while the new sarsens were shaped where they were found (for the very good reason stated by Prof. Judd), the blue stones were taken up and trimmed *sur place* as the new more northerly line and the new centre, to say nothing of the new naos, necessitated their re-arrangement. In this way the excess of blue stone chippings found by Prof. Gowland is simply and sufficiently explained.

(5) It is quite possible that the rebuilding of the temple in 1680 B.C. was part of a very large general plan which could only have been undertaken by a large, powerful and comparatively civilised tribe or people under strict government, commanding the services of skilled mathematicians, for Colonel Johnstone's revelations do not stop at the continuation of the Stonehenge solstitial line to Sidbury and Grovely Castle.

The absolute straightness of this line might have been secured by fires at night, but there is more in

[1] Continued from p. 368.

it than this. Stonehenge, Old Sarum, and Grovely Castle occupy the points of an equilateral triangle of *exactly* six miles in the side, and the three sides are continuations of the entrances at Stonehenge and Old Sarum and of a ditch running through the centre at Grovely Castle. Further, the centre of the triangle

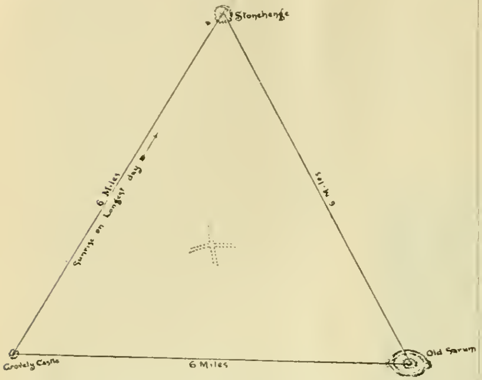

FIG. 11.—The equilateral triangle formed by Stonehenge, Old Sarum, and Grovely Castle.

is on the oldest cross roads in that part of Salisbury Plain.

The figures will show this, and also the curious position of other earthworks, as well as the fact that the line Stonehenge—Old Sarum passes *exactly*

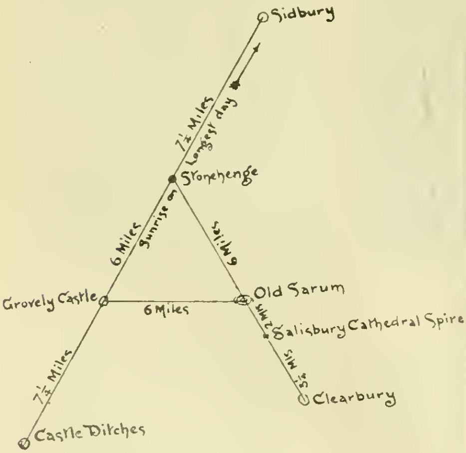

FIG. 12.—Showing the prolongations of the sides of the equilateral triangle.

through Salisbury spire, which again is exactly two miles from Sarum. We ought to restore the old name, Solisbury.

(6) It is probable that the avenue and vallum were added when the line of orientation was moved to the N., placing the new centre to the N.W. of its original position. In this way we can explain how it is that the Friar's Heel lies to the S. of the central line of the avenue, and that the N.W. and S.E. stones are situated at different distances from the vallum.

(7) The number and spacing of the sarsen stones in the new great circle were so chosen that the use of the N.W. and S.E. stones to mark the May new year's day originally could be replaced by observations through one of the trilithons. This was necessary if the May year was to be considered at all, as the use of the N.W. and S.E. stones was blocked by the new outer circle.

Now, on the hypothesis of an earlier temple, it becomes quite clear, from the method of erecting the sarsens revealed by Prof. Gowland's excavations, that the stones comprising the two concentric circles must have been removed, even if there were no other reason.

In the case of the leaning stone, we have evidence that it was erected from the inside of the circle, as the perpendicular wall of chalk is on its S.W. side. If all the other naos sarsens were erected in the same way, there could have been no upright blue stones in the naos. They must have been set in the places they occupy afterwards, because the upright members of the naos trilithons are well over 20 feet long, and this about represents the distance to the central portion of the naos.

The relation between the naos and outer circle trilithons also shows that the naos must have been built first, and further that the outer circle sarsens must have been raised from the inside. Those fallen are about 18 feet long; the average distance between the two systems of naos and outer circle trilithons is about 23 feet. Supposing the outer sarsens are 4 feet in the ground, and that there was a slope for them to slide down some 6 feet long, there would just be room, but none to spare, between the naos and the outer circle. There certainly would not be room enough to pull the stones upright unless the intervals between the naos sarsens were used, and the positions of the stones show that they could not have been conveniently so used, in some cases at all events; we may assume that to pull the stones finally into their perpendicular positions ropes at least as long as those employed by Mr. Carruthers would be needed.

In any case the blue stone circles must have been away, whether removed from their old positions or not, when the naos and sarsen circle were put up.

On this point Prof. Gowland is quite clear.

He writes: "That the stones of the central trilithon were erected from the inside of the circle has been conclusively demonstrated by the excavations, hence the 'blue stones' in front cannot have been erected before them. Moreover, the 'blue stone,' No. 68, the base of which was laid bare in Excavation V., was found to be set in the rubble which had been used to fill up the foundation of No. 56, and further, in a lower layer than its base, there were two small blocks of sarsen with tooled surfaces.

"Whether the outer sarsens were set up from the inside of the circle like the trilithons, or from the outside, is a point which can only be settled by future excavations. If from the inside their erection must have preceded that of the trilithons, and hence of the 'blue stones.'

"On the other hand, should the outer sarsens have been raised from the outside, it would not be possible for the 'blue stones' to have been placed in position before them, as they would then have seriously interfered with if not altogether prevented the erecting operations."

We may take it, I think, that the ring was erected from inwards, sufficient ground only being available outside for "a long pull and a strong pull."

In former notes I have referred to Mr. Cunnington's remarks on the remains of the syenite trilithon, and his suggestion that it formed part of an older temple. He expressed the view that the structure of Stonehenge as we know it with its trilithons was, in fact, suggested by it.

Now if we attempt to find the place it occupied before it fell by seeing where it would be most symmetrically placed in relation to the adjacent stones of the blue stone circles still standing, we are led to an interesting result. Using the old centre as determined from the N.W. and S.E. stones we find that the May sunrise would be seen through the small syenite trilithon. In this way also we can account for the fact that so far as is known this is the only trilithon which existed in the old blue stone circle; it may well have been that the centre and diameter of the new blue stone circle were so regulated as to retain it in position; I have already remarked that this was done in the case of the older unhewn sarsens, as a memorial of the past.

NORMAN LOCKYER.

THE APPROACHING TOTAL SOLAR ECLIPSE OF AUGUST 30.

THERE are many special features about the total solar eclipse of August of the present year. In the first place, perhaps the chief of these is that it will occur about the time when the solar atmosphere is greatly disturbed, or in other words, at a time when the number of sun-spots is about a maximum. Second, the localities from which it may be observed are well distributed over land surfaces, and some are easily accessible from the British Isles. Thirdly, observers will have to wait many years before another favourable eclipse occurs. That in 1907 will be visible in Central Asia, but its occurrence in January will deter many from seeing it. The two eclipses in 1908 will be visible only from the Pacific and South Atlantic. The eclipse of 1909 will occur in June in Greenland, while that in 1910 will be visible only from the Antarctic regions. In 1911 only a short portion of the end of the eclipse track will pass through a part of South Australia. It is therefore the eclipse of 1912, that will take place in April in Spain, which will be the next easily accessible one to observe; but as totality will only last 60 seconds, its duration will be brief compared with that of this year, which will last for more than $3\frac{1}{2}$ minutes.

Further, the fact that the approaching eclipse occurs in a month, such as August, when a great number of people are taking their summer holiday, and therefore can more easily leave these shores, should ensure the presence of many volunteer observers at the more easily reached stations. In the present instance the zone of totality commences in Canada towards the south of Lake Winnipeg, skirts the extreme south of Hudson's Bay, passes a little to the north of Nova Scotia, and then crosses the Atlantic. In Europe it strikes Spain (Fig. 1) on its north-west coast line, and leaves the eastern coast, enveloping the islands of Majorca and Iviza. Reaching Africa in the neighbourhood of eastern Algeria (Fig. 2), it passes through Tunis, Tripoli, Egypt, and the Red Sea, and finally terminates in Arabia.

In Spain an opportunity is afforded of making observations at some stations of high altitude, for the eclipse track includes several lofty mountains. For instance, Penas de Europa, south-west of Santander, and 8000 feet high, is one of numerous possible observing peaks, and advantage should be taken of this or some other elevated region.

It will thus be seen that there is plenty of scope for observers to scatter themselves along the line of totality, and this should be done as much as possible. The low altitude of the sun during totality at Labrador (27°) and Egypt (24°) renders both these regions somewhat unfavourable for the best observations, but there parties should at any rate be present. The former region can undoubtedly be left to Canadian and American observers, for it does not seem necessary that European observers should journey so far when more favourable stations are nearer at hand. The close proximity of Egypt to many European countries renders this part of the zone of totality easily accessible. Here the central line of totality passes just a little north of Assuan, the outer limits enclosing Edfu on the north and Darmut on the south.

The probable weather conditions at the different stations form an important item in eclipse matters, for clouds can easily mar the work of even the best

FIG. 1.—The path of totality across Spain. The duration of totality and the altitude of the sun at that time are given for four different stations along the line.

organised expedition. Omitting Labrador, a station that will not be occupied by observers from this country, the north-western portion of Spain does not seem to be particularly favoured with the required weather conditions. According to Señor F. Iñiguez, the director of the Astronomical and Meteorological Observatory of Madrid, this locality during August is not only cloudy and damp, but storms are of frequent occurrence. Such a report, however, should not prevent one party at least from taking up a position there, but it should suggest to many who had up to the present made up their minds to observe in that locality to seek stations further along the line, and not congregate at a very probably unfavourable station such as this appears to be. At stations towards the east the conditions seem to be more suitable the closer the Mediterranean side is approached, and, according to the authority mentioned above, the probability of fine weather on this coast is very high. Inland stations will probably have the disadvantages of dust and heat combined.

Perhaps one advantage of the north-west over the east coast is that the former will be very much the cooler, but in eclipse matters sky conditions precede temperature considerations.

With regard to such matters as suitable sites for instruments, their safety, guards for camps, building materials, &c., the Spanish Government can be depended upon to render every assistance to those who apply through the proper channels, and the valuable aid they gave to parties during the eclipse of 1900 is still in the memory of many observers.

Those who wish to know something about the routes to Spain, the methods of travel and approximate cost, will find some interesting and useful information in an article recently writen by Mr. G. F. Chambers, and published in the *Journal* of the British Astronomical Asociation (vol. xv., No. 2, p. 93). Another source of information specially useful to those visiting Spain is a publication just received from the Astronomical Observatory of Madrid, entitled "Memoria sobre el Eclipse Total de Sol del dia 30 de Agosto de 1905." This has been prepared by the director, Señor Francisco Iñiguez, and contains details about climate and many useful maps, in addition to data about the eclipse itself.

The weather conditions for the stations situated in Algeria, Tunis, and Tripoli seem to be very favourable, and should be made the most of. For Algeria, and more especially for the neighbourhood of Philippeville, we have some useful facts which have been communicated through M. Mascart by M. A. Angot, of the Bureau Central Météorologique, Paris. Dealing first with cloud and rain, we learn that during the months of July and August Philippeville is the clearest and driest of all the coast stations in Algeria, the mean rainfall for these months amounting to 4 and 10 millimetres respectively out of a total of 807 millimetres for the whole year. The average number of rainy days for each month totals two or three. Storms are rare, but increase towards the interior. If we represent clear sky by 0 and sky covered by 10, then 2 or 3 would represent the condition of cloudiness at Philippeville.

As regards temperature, the diurnal variation has an amplitude of 9° C. or 10° C., the mean temperature being 24° C. (75° F.). By night the temperature would thus be about 18° C. or 19° C. (64° F. or 66° F.), and at two hours after noon the maximum day temperature would reach 29° C. or 30° C. (84° F. or 86° F.). For stations situated some tens of miles inland there is a very rapid increase of day temperature.

The prevailing winds in August vary from N.E. to N.W., *i.e.* are sea winds; they are not strong, and are not much augmented by the sea breeze.

In Egypt the prospect of fine weather in August is also very great, so that observers who go to that region need not be very anxious, at any rate about clouds.

It is impossible at present to give a full or even final statement regarding the distribution of parties along the line of totality, but the following preliminary, but incomplete, list may be of interest, and indicates not only the regions that will be occupied by most of the British expeditions, but the chief types of observations that are proposed during the brief interval of totality. For the greater part of this information I am indebted to Major E. H. Hills, C.M.G., secretary of the Joint Permanent Eclipse Committee of the Royal Society and Royal Astronomical Society:—

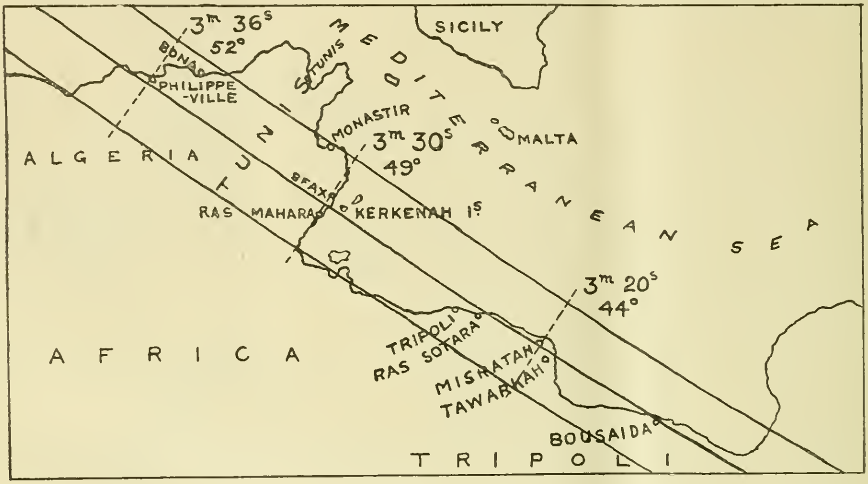

Fig. 2.—The path of the totality track in northern Africa. For three stations the duration of totality and the altitude of the sun during the eclipse are marked on the map.

Labrador.

Lick Observers ... ... — Search for intra-mercurial planets. Large scale corona photographs.

(Canadian parties probably.)

Spain.

Lick Observers		Search for intra-mercurial planets. Large scale corona photographs. Integrating spectroscopic photographs.

One of the novelties that will be attempted during this eclipse will be the photography of the eclipsed sun by means of the three-colour process. The camera that will be employed will probably be one having three lenses, so that the exposures through the three coloured screens can be made simultaneously, the correct ratio of the exposures being obtained by adjusting the apertures of the lenses.

When it is considered that in addition to these parties there will most probably be expeditions from several other countries, such as Spain, Portugal, Holland, France, Germany, Italy, Russia, Egypt, &c., and probably one or two more United States expeditions, there is a great opportunity not only for occupying a large number of different stations along the line, but of gaining a quantity of valuable material to enlarge our knowledge of solar physics.

WILLIAM J. S. LOCKYER.

THE CEYLON PEARL FISHERIES.[1]

LITTLE enough is done by the State in this country in the matter of aiding scientific research, and this is especially true of biological science. To this attitude of indifference, or aloofness, we have grown accustomed; abroad it is a subject for uncomplimentary comment. This attitude cannot be due to the conviction on the part of our ministers that "science is bankrupt," since when some great industry is threatened by injuries which legislation is powerless to check, or some pest is threatening the welfare of the community, the aid of the man of science is at once invoked.

The Pearl Fishery Commission is a striking example of the intervention of the State to aid a crippled industry by calling in the aid of the biologist.

The series of barren years alternating in some mysterious way with years of plenty puzzled those engaged in this fishery for more than two centuries, and, moreover, seriously reduced the profits of the fishing. To fathom this strange uncertainty, and if possible to find means whereby more uniform harvests could be ensured, the Government submitted the matter to a commission of inquiry, which has been held under the auspices of the Ceylon Government. The results of this inquiry have abundantly justified those responsible for its inception, and should do much to establish the advisability of instituting inquiries into other problems to which we could point that can only be dealt with by trained and experienced biologists.

The second part of Prof. Herdman's report to this commission in no wise suffers by comparison with the first volume. It is a very mine of information, yielding rich lodes of fact without the trouble of any preliminary crushing or sifting.

This report opens with a luminous review of the history of the principal fisheries from 1801 to the present time, and should prove of the highest value to those engaged in pearl fishing in future, for the causes of the rise, zenith, and decline of the different fisheries between these dates have been analysed and tabulated.

It is now established beyond doubt that the normal life of the pearl oyster does not average more than five years, and that these, especially to an animal so peacefully disposed as an oyster, are full of catastrophes and rumours of catastrophes!

By way of illustration as to the truth of this, we may well select an instance or so from this report. On the "Kondatchi Paar" in March, 1902, there were about 5,750,000 oysters. By March, 1903, these had been almost entirely wiped out of existence—eaten by starfish! File-fishes and enormous rays also show an insatiable appetite for oysters, and in the course of a few months will devour millions! Not seldom these oysters are smothered or killed by the invasion of hordes of young of their own species. But this is not all. Shifting sands may overwhelm incredible hosts, and millions are swept away by currents.

Man, says Prof. Herdman, "can do comparatively little to mitigate the severity of such influences as tell against the life and prosperity of the Pearl Oyster."

But it is just because he can do so little that there is so great a need of a vigilant and intelligent watch being constantly kept on the different fishing grounds. To a very considerable extent, Prof. Herdman has shown that man can make good these ravages, or snatch the remnant at least of a disappearing host from destruction. His plan is to transplant young oysters from beds known to be dangerous into more sheltered areas. This rescue work is to be further turned to account by using the waifs and strays, which are to be garnered by the inspection vessel, for restocking old beds, where they may grow and thrive—and become infected by the chosen parasite to keep up the growth of pearls of great price!

To ensure this infection is one of the problems which Mr. Hornell, the inspector of fisheries, is to solve.

The life of the pearl oyster is, as we have remarked, about five years, and it is from those of this age that the finest pearls are obtained. Herein lies a danger, since there is always a strong temptation to delay fishing as long as possible to ensure big pearls. Unless, as Prof. Herdman points out, these beds be carefully watched, one of the many catastrophes which attend pearl oysters may carry off this precious crop before

[1] "Report to the Government of Ceylon on the Pearl Oyster Fisheries of the Gulf of Manaar." By W. A. Herdman, D.Sc., F.R.S., &c. Part ii. Pp. viii+300. (London: The Royal Society, 1904.)

it can be gathered. A case in point is given by Prof. Herdman. The Mutuvaratu Paar, which lies to the south-west of Karativo Island, yielded during 1889, 1890, and 1891 some 117,000,000 oysters, which realised very nearly 1,000,000 rupees—the only fishery since 1814 that has returned so large a sum. The oysters raised during these three years steadily increased in value, those lifted in 1891—the oldest—being by far the most valuable. "But the record," he remarks, "shows the risk there is in trying for the enhanced value by delaying the fishery once the oysters are over 5 years of age. In 1891 this bed must have been 6 years old, and they are described as rapidly dying off, many being dead and putrid."

There are prospects of a good fishing for next year and 1906, but the results of 1907 and the succeeding years depend largely, it is pointed out, on extensive measures of transplantation being undertaken without delay. This Mr. Hornell will doubtless accomplish.

Prof. Herdman's memoir on the anatomy of the pearl oyster adds much to our knowledge of the subject, and contains some valuable observations on the living animal. As an instance of the latter we may cite his remarks on the functions of the foot. These, he points out, "are three-fold: the distal ventral surface subserves locomotion; the median and posterior parts effect attachment by means of the byssal fibres; and lastly, on account of the general mobility of the organ, and probably of its sensory nature, the tip is of great use in clearing the gills and mantle from the intrusive particles that cannot otherwise be got rid of."

FIG. 1.—Pearl-fishing Fleet at work on the Cheval Paar.

It is concerning the latter function that we would direct special attention here. In the living animal Prof. Herdman has observed the foot "pushed between the gill-plate, and over the inner surface of the mantle gently stroking the surface and insinuating itself into the crevices, thus freeing the parts from any foreign bodies . . . that might cause inconvenience."

Mr. Hornell observed one oyster, which had sustained an injury to the mantle, pass the foot-tip gently around the edges of the wound so as to work off the particles of dirt collected there. The tip was even passed *through* the wound to make the cleansing the more thorough.

Concerning the byssus, it is interesting to notice that the operation of dredging for oysters for transplantation in no wise injures the animal when anchored by the threads of which this is composed. Under a great strain these break, and are renewed again within an hour or so, the root of the old byssus being sloughed off.

Some interesting points concerning gill structure are given, especially with regard to the passage from interfilamentar junctions by ciliated discs to junctions by organic union.

With regard to sense organs, the pearl oyster is not very well provided. But a distinct response is shown to the stimulus of light and shadow—"a sensibility which may be termed dermatoptic," and appears to be located in the edges of the mantle and the surface of the foot, where patches of more or less deeply pigmented epithelial cells are met with.

All kinds of creatures seem to find the pearl oyster a particularly "toothsome" morsel, man alone excepted, who prefers to make manure of their bodies for the sake of possible pearls contained therein.

No less than seven different kinds of parasitic worms are now known from the pearl oyster, six of which are new species described in this volume. Of these, only one, a cestode larva (*Tetrarhynchus unionifactor*), appears to be concerned in the formation of cyst pearls. This fact is interesting, inasmuch as the formation of similar pearls in European mussels is due to the cercaria of trematodes.

As to the sequence of hosts called upon to nurse this precious cestode of the pearl oyster to maturity much uncertainty prevails. It was thought that file-fishes and elasmobranchs were the intermediate vertebrate hosts, and this will probably prove to be the case.

Certain novel features seem to be foreshadowed in the life-history of this parasite when the chain of evidence is complete.

To begin with, it would appear that it enters its first host—the pearl oyster—as a free-swimming planaria-like larva, inasmuch as certain larvæ of this type, but containing calcareous corpuscles recalling those of cestodes, were taken in plankton, and these bear, in many features, a close resemblance to the earliest encysted larvæ found in the pearl oyster.

It is assumed that these free-swimming forms are tetrarhynchids, though hitherto it has been believed that tetrarhynchid larvæ make their way into their first hosts while still encased within the egg-shell. The bothriocephalids have free-swimming larvæ, but these are ciliated. That the larvæ in question must be tetrarhynchids seems certain, since older larvæ, showing several stages of development, belonged unquestionably to the genus Tetrarhynchus.

It was believed that these larvæ were next ingested by file-fishes (Balistes), but it now appears that the tetrarhynchid larvæ of Balistes, of which three species are described in this report, are quite distinct forms, distinguished by the presence of a vesicle, which is wanting in the pearl oyster larvæ. Further, the more advanced larvæ of the pearl oyster have arrived at a later stage of development than the larvæ found in Balistes.

The final stage of the pearl oyster cestode was supposed to be undergone within the body of an elasmobranch which fed upon Balistes. But, so far, the only elasmobranch tetrarhynchid which the authors have examined was obtained from the spiral valve of a sting ray (*Taeniura melanospilos*), and this larva was of a species quite distinct from either the Balistes or oyster larvæ. It is to be noted, however, that from this ray two perfect specimens of Balistes were taken.

Thus, though we may yet find that the sequence of hosts is as was indicated in the first volume of this report, we are at present left somewhat in doubt. In due time, doubtless, Messrs. Shipley and Hornell, the authors of this really fascinating section, will solve the riddle.

We have dealt at some length on this matter because, apart from its interest as a sequence of stirring events in the life-history of a very humble organism, it has considerable importance from an economic point of view: since, when the chain of evidence is complete, it may be possible, as was first suggested by Keelart in 1857, to raise the percentage of pearls by infecting oysters in other beds with their parasites.

Prof. Jeffrey Bell contributes some notes on the echinoderms, appended to a description of the species collected, by Prof. Herdman. Although these notes barely fill three pages, Prof. Bell has crowded into this space some trenchant criticisms and some really valuable facts.

The reports on the arthropods are full of interesting matter, and deal with a large number of new species; but we venture to think that a longer summary of the principal results arrived at would have added to the usefulness of these chapters. Dr. Calman's work on the Cumacea will be welcomed, inasmuch as no species of this group have hitherto been described from any part of the Indian Ocean.

The collection of cephalopods has been worked out by Dr. W. E. Hoyle. Though small, it contained one new species of unusual interest. This was a small octopus, which has been named *Polypus arborescens* on account of the presence of curious branched processes scattered all over the body, some of which are surmounted by a tuft of fibrils. After a most careful study Dr. Hoyle is still uncertain as to their purpose. He dwells at considerable length upon their microscopical structure. He is satisfied that they are not parasitic organisms, nor are they, he considers, glandular or phosphorescent organs. The fact that no nerves have been traced to them would seem to show that they are not tactile bodies, yet on the whole he considers that it is this function which they perform. Prof. Herdman, who has studied the living animal in a small tank, describes these mysterious processes as being contractile, and "kept frequently moving—uncoiling to a considerable length and then curling up again suddenly." This seems to suggest that they may be alluring organs comparable to the waving flag of the angler-fish or the long, worm-like tongue of the "mata-mata" tortoise.

The fishes collected during this investigation have been described by Mr. J. Johnstone. Twelve species in all are dealt with.

The most interesting feature of this report is that concerning the supposed naso-pharyngeal passage in Cynoglossus. Kyle, in 1900, described in this genus a curious nasal sac, which, he believed, communicated with the mouth by means of a pore in the floor of the sac, a feature which he regarded as of considerable morphological importance.

Mr. Johnstone examined several species belonging to this genus, and in no case did he find this naso-pharyngeal passage. But what is really interesting is the fact that he found this cavity, on more than one occasion, inhabited by a copepod. Since this creature anchors itself by hooks, the presence of an occasional hole in the floor of this chamber is not to be wondered at!

There is a wealth of plates in this volume, all of which are as good of their kind as one could wish. The same cannot be said of one or two of the text figures, however, which leave much to be desired—notably the figure of the dissection of a pearl oyster on p. 43.

Yet another volume is required to complete this report; this is promised early next year. Judging by the standard set by the two volumes now issued, the complete work will form one of the most valuable commentaries on a great industry yet issued.

W. P. P.

NOTES.

AT the invitation of the British Association, the local committee in Johannesburg has nominated the following as vice-presidents and secretaries respectively of the different sections for the meeting in South Africa, the general arrangements of which were described in NATURE of February 2 (p. 323):—*Mathematics and Physical Science*—vice-president, Dr. Breyer; secretary, Mr. R. T. A. Innes. *Chemistry*—Mr. J. R. Williams, Mr. W. A. Caldecott. *Geology*—Dr. Corstorphine, Dr. Molengraaff. *Zoology*—Dr. Gunning, Dr. Pakes. *Geography*, Mr. E. H. V. Melvill, Mr. F. Flowers. *Economic Science and Statistics*—Mr. S. Evans, Mr. Robert A. Ababrelton. *Engineering*—Mr. S. Jennings, Mr. E. Williams. *Anthropology*—Dr. Schonland, Mr. A. von Dessauer. *Physiology*—Sir Kendal Franks, Dr. A. Mackenzie. *Botany*—Mr. Burtt Davy, Prof. Pearson. *Educational Science*—Mr. E. B. Sargant, Prof. Hele-Shaw.

THE Hunterian oration delivered by Mr. John Tweedy at the Royal College of Surgeons on February 14, and abridged elsewhere in this issue, contains several interesting references to the growth of natural knowledge by the use of the experimental method, with illustrations from John Hunter's work. It has been said that though Hunter had never read Bacon, his method was as strictly Baconian as if he had. Mr. Tweedy pointed out that this view is based upon a complete misinterpretation of the Baconian system. Francis Bacon himself neither knew nor understood the physical sciences, and his spirit was much less modern than that of his illustrious namesake, Roger Bacon, who lived three hundred years before him. John Hunter did not follow the mechanical methods of the Baconian system, but he possessed every moral and intellectual qualification for useful scientific research—a fertile imagination ready to suggest possible relations of facts, openness of mind, and a conscientious scientific spirit that submitted every hypothesis to the test of observation and experiment, taking nothing on trust. Mr. Tweedy occupied the chair at the festival dinner held at the college in the evening of February 14, when there were present, among others:—Prof. C. Allbutt, Sir W. Broadbent, Sir Lauder Brunton, Sir D. Duckworth, Sir Harry Johnston, Sir Norman Lockyer, Sir W. Ramsay, Prof. C. Stewart, Sir W. T. Thiselton-Dyer, Prof. W. A. Tilden, and Sir F. Treves.

THE death on February 9, at the age of forty-four, of Mr. F. O. Pickard-Cambridge makes a break it will be impossible to fill in the ranks of British arachnologists. From boyhood he had devoted himself to the study of English spiders, and was rightly regarded as the leading authority upon this subject. He completed, moreover, in 1904, his monograph of the Central American spiders for

Godman and Salvin's "Biologia," and this work, supplemented by the determination of specimens in the British Museum and of the collections made by himself on the Amazons, gave him a quite special knowledge of the Neotropical species. He unfortunately left unfinished his revision of the generic nomenclature of spiders, and also the county records of Arachnida he was compiling for the "Victoria History." Mr. Cambridge was an admirable draughtsman, as is testified by the plates illustrating the many papers he contributed to scientific societies and periodicals.

MATHEMATICIANS will have heard with regret that Mr. Robert Tucker died on January 29. He received his university education at St. John's College, Cambridge, of which he was a scholar, and was placed among the wranglers in 1855. He became a schoolmaster, and was for many years head mathematical master at University College School. His original contributions to mathematics deal chiefly with configurations of points, lines and circles related in special ways to a fixed triangle, and one system of circles, which he discovered, is called after his name. He was also the editor of Clifford's "Mathematical Papers." In 1867 he became one of the secretaries of the London Mathematical Society, founded in 1865. From that time forward he made the society his peculiar care, and the success which it has attained is almost entirely due to him. He retained the office of secretary for thirty-five years, editing the *Proceedings*, and conducting the correspondence with authors and referees—a delicate duty in respect of which he established an admirable tradition. He also wrote an account of the early history of the society. In all his work he was business-like and thorough, and at the same time modest and unselfish.

THE new wing which is to complete the Armstrong College of Science in Newcastle-on-Tyne will be opened by the King next year.

THE Société nationale d'Agriculture de France has awarded to Prof. Wm. B. Alwood, of Charlottesville, Va., a diploma and silver medal for his recent work in pomology, especially as relates to the fermentation of by-products from apples.

THE anniversary meeting of the Geological Society was held at Burlington House on Friday, February 17. Dr. J. E. Marr, F.R.S., was elected president. After the presentation of the medals and prizes already announced (p. 253) the president delivered his anniversary address, which dealt with the classification of the sedimentary rocks.

ARRANGEMENTS have been made whereby messages may be sent to Cunard mail steamers at any stage in their voyage across the Atlantic. During the first three or four days after the vessels leave Liverpool the messages will be sent from Poldhu, Cornwall, direct to the steamer. During the next three or four days the messages will be forwarded by cable to the North American Continent, and repeated thence to the approaching ship.

WE learn from the *Times* that the Treasury has agreed to place at the disposal of the Board of Trade 500*l*. per annum for four years for the purpose of taking practical steps to encourage and investigate the development of the cotton-growing area of the Empire. This sum will be used (1) for the payment of scientific assistants, who would themselves do part of the proposed work and would also set free members of the existing staff of the Imperial Institute for the purpose; and (2) for defraying the cost of equipment. It has also been notified, in connection with the mineral survey which the Government of Northern Nigeria has in contemplation, that a sum of 300*l*. per annum will be paid to the Imperial Institute in order to defray the expenses of examining specimens of minerals, &c., sent to the scientific and technical department so long as the survey is in progress, probably a period of three years.

ON Saturday next, February 25, Mr. D. G. Hogarth will begin a course of two lectures at the Royal Institution on "Archæology." On Tuesday, February 28, Prof. Karl Pearson will deliver the first of three lectures on "Some Recent Biometric Studies." On Thursday, March 2, Prof. H. H. Turner will commence a course of three lectures on "Recent Astronomical Progress," and on Saturday, March 11, Prof. J. J. Thomson will begin a course of three lectures on "Electrical Properties of Radio-active Substances." The Friday evening discourse on March 3 will be delivered by Chevalier G. Marconi, on "Recent Advances in Wireless Telegraphy," and on March 10 by Prof. J. J. Thomson, on the "Structure of the Atom." Mr. Perceval Landon will give two lectures, on April 4 and 11, on "Tibet," Mr. A. Henry Savage Landor's lectures on "Exploration in the Philippines" having been deferred until after Easter.

THE annual report of the council of the Institution of Mechanical Engineers was read at the annual general meeting of the institution on February 17. The first report, by Prof. David S. Capper, to the steam-engine research committee, has now been completed, and, together with a preliminary report on progressive speed and pressure trials carried out previous to March, 1896, will be presented at the March meeting. Since the presentation, in January, 1904, of the late Sir William Roberts-Austen's last report, the alloys research committee has continued its work at the National Physical Laboratory. Dr. Glazebrook, director of the laboratory, has arranged a series of investigations on specimens of nickel steel presented by Mr. R. A. Hadfield. It is anticipated that a further report will be presented this year by the committee, communicating the results of these researches. Further investigations having great practical importance are now being considered. Prof. F. W. Burstall reports that the two specially constructed large gas-engines and a gas-holder erected in the new power house of the Birmingham University are now available for the gas-engine research committee's experiments. A scheme of experiments, indicating the methods of working, is under consideration, and it is hoped that the next report will be ready for presentation at the opening of next session. A gift of 100*l*. towards the expenses of carrying on the research has been received from Dr. Ludwig Mond, F.R.S. The series of experiments on initial condensation in steam cylinders, which Prof. T. Hudson Beare is carrying out with special apparatus for the purpose, are in active progress, but are still incomplete. The results obtained so far, however, justify the hope that the committee will be able to present, during the year 1905, an interim report dealing with the results obtained in the experiments on non-jacketed cylinders. It is intended to hold the next summer meeting in Belgium, in view of the International Exhibition to be held at Liège this year.

WE have received from Messrs. John Wheldon and Co., of Great Queen Street, a copy of a catalogue of zoological and sporting books and papers arranged geographically. To those who are working on faunas and distribution the list will be distinctly useful.

In vol. v., No. 5, of the *Records* of the Australian Museum, Mr. R. Etheridge describes the remains of a plesiosaurian reptile of the genus Cimoliosaurus from the Upper Cretaceous of White Cliffs, New South Wales, which have been completely opalised. This is the second skeleton of the genus which has been obtained from these deposits in an opalised condition. Precious opal occurred only here and there—more especially in the transverse processes of the neck—in the second specimen, the richness of the colour of which bore no comparison to that in the example first obtained.

Mr. W. E. Clarke, of the Edinburgh Museums, sends us a paper from the *Annals of Scottish Natural History* for January on the vole and the shrew of Orkney. The vole, which it will be remembered was recently discovered and named by Mr. Millais, turns out to be remarkably interesting, for it appears to come nearest to the water-vole, although its dentition is of the type of the common field-vole. The shrew, Mr. Clarke believes, will probably turn out to be the pigmy species. Mr. Clarke has been assisted in his investigation into the structure of the vole by Prof. O. C. Bradley.

Dr. Gilchrist's presidential address to the South African Philosophical Society at the meeting in August last, which is reported in the latest issue of the *Transactions* of that body, deals with certain features of the marine fauna of South Africa. It is shown that as the Cape seas receive currents from different parts of the ocean, so the fauna is of a particularly varied type, containing North Atlantic, Antarctic, and Indian types, and even an element from the Far East.

The subject of the affinity of the endothiodont reptiles is resumed by Dr. R. Broom in part iv. of vol. xv. of the *Transactions* of the South African Philosophical Society. The author emphasises their relationship to the dicynodonts, and shows that, while in the endothiodonts the tendency has been to increase the development of the molars, in the dicynodonts the latter teeth have been completely eliminated. In our own opinion, Dr. Broom's work tends to show that both groups should be included in a single family.

The report of the director of the botanic gardens and domains, Sydney, for 1903 refers to the changes in the gardens consequent upon the extension into the inner domain. Tree-planting in the Centennial Park has been continued, the additions during the year being principally *Acacia binervata*, *Eucalyptus botryoides*, woolly-butt, *Tristania conferta*, brush-box, and species of Casuarina. Many of the various species of Eucalyptus have suffered from the attacks of a coccid identified as *Eriococcus coriaceus*.

The Philippine Islands are yielding a number of interesting plants. A second list by Mr. E. D. Merrill has been issued as a publication, No. 17 of the Bureau of Government Laboratories, Manila. The author distinguishes twelve species of Terminalia in his synopsis of the genus, three being new. Among other new plants are four species of Pandanus, three of Illipe (= Bassia), and a climbing Dischidia belonging to the section Conchopyllum in which the leaves flattened against the supporting tree trunk serve as a shelter for ants.

A progress report on the strength of structural timber by Dr. W. K. Hatt forms *Circular* No. 32 of the forestry series published by the United States Department of Agriculture. Tests were made with long-leaf pine, *Pinus palustris*, loblolly, *Pinus taeda*, and a red fir, known also as Oregon pine, *Pseudotsuga taxifolia*. Long-leaf pine is the standard timber of construction, but is not always obtainable in long pieces, when red fir takes its place; red fir produces long, straight timber, but shows considerable variation in quality; loblolly being principally sap-wood has to be treated with preservatives if it is required for external work. Experiments were also made with sweet gum, *Liquidambar styraciflua*, to ascertain whether the timber could be bent and put to the same uses as hickory, but the results were not favourable.

When we consider the enormous mass of material which has been accumulated regarding the quantity of rain which falls, it is remarkable how little attention appears to have been given to the number and size of the drops. A very simple and ingenious method of studying raindrops is described in a paper in the *Monthly Weather Review* for October, 1904, by Mr. W. A. Bentley. The raindrops are allowed to fall into a layer of dry flour one inch deep, which is exposed to the rain for a few seconds. The flour is allowed to stand for some time, and the pellets of dough, each representing a raindrop, are then picked out and may be preserved. The method was tested by allowing measured

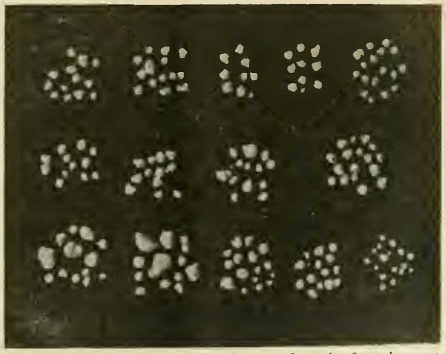

Fig. 1.—Forms of raindrops. Complete set of samples from the great general storm of August 20, 1904. Duration of storm, fifteen hours. One raindrop sample per hour was taken throughout the storm.

drops of water to fall from a height into the flour; it was found that the dough pellet differed but little in size from the drop which produced it. In the paper a series of interesting photographs of such dough-pellets is given, illustrating the variation in the size of the raindrops during the course of showers of different types. The largest drops met with somewhat exceeded a fifth of an inch in diameter; this is in agreement with the observations of Wiesner (quoted by Hann in his "Lehrbuch"), which gave 7 mm. as an upper limit. Mr. Bentley gives tables showing the relative frequency of occurrence of drops of various sizes in rain from various kinds of clouds.

We have received from the secretary of the English Ceramic Society a copy of its *Transactions* for the session 1903–4. The society, which has its headquarters at Tunstall, Staffordshire, is still in its infancy, but it would appear that its existence is likely to exert considerable influence for good on the future development of the English potteries. The *Transactions* contain papers describing attempts to solve special problems in the industry, and the keen discussion which followed their delivery is indicative of the interest with which they were received. There can be little doubt that such a society must tend to the spread of knowledge and the improvement of method in pottery manufacture.

An interesting paper by R. Kremann on the melting point of dissociating substances and the degree of dissociation during melting is contained in the *Sitzungsberichte* (1904, vol. ciii., part vii.) of the Imperial Academy of Sciences of Vienna. From theoretical considerations involving the law of mass action, melting-point curves are deduced for substances, such as the compounds of phenol with aromatic bases and with picric acid, at different degrees of dissociation. By comparing the shape of these curves with those obtained, for instance, on adding aniline to the compound of aniline and phenol, the actual degree of dissociation of these substances during melting may be very approximately ascertained. Incidentally, the important result is established that the addition of one of the products of dissociation of the compound may in many cases cause a rise in the melting point without there being question of the formation of an isomorphous mixture. The results obtained are applied to an investigation of the additive compounds of nitrosodimethylaniline with various aromatic bases.

In an inaugural dissertation for a doctorate at Bonn University, Herr Jacob Steinhausen presents the results he has obtained during a research on "enhanced lines." Adopting the English name originally proposed by Sir Norman Lockyer, the author gives a detailed description of the enhanced lines and their different appearances in various spectra, and then describes the apparatus and methods employed by him in his own research. Using a small grating of 1 metre radius, which produced a dispersion such that 10 Ångström units extended over 0.595 mm. on the plate, he photographed and compared the arc and spark spectra of the elements Al, Sb, Pb, Cd, Mg, Hg, Bi, Sn, Zn, Ba, Ca, Sr, and Tl, using in most cases metallic poles for the spark, and powdered metal, or salt, on carbon poles for the arc. The wave-lengths are only given to the nearest unit, and will, therefore, need re-determining, with a larger dispersion, before they become of any great use for stellar identifications. In discussing the nature of the lines the author adopts an error made by Prof. Kayser ("Handbuch der Spectroscopie"), viz. that in accounting for spectral variations Sir Norman Lockyer has always considered only the temperature of the spark as the cause; yet it is now more than thirty years since the discoverer of enhanced lines explicitly stated that the possible effects of electrical variations must be included in the general term "temperature."

Some ten years ago Prof. H. Moissan, in the course of his work on the production of carbides in the electric furnace, prepared aluminium carbide and showed that in contact with water pure methane was evolved, thus giving a new and direct synthesis of this important hydrocarbon. In the current number of the *Comptes rendus* (February 13) Prof. Moissan and M. Chavanne give an account of their determinations of the physical constants of pure marsh gas prepared in this way. The methane, after being freed from traces of moisture and less volatile impurities by passing through a tube cooled to -85° C., is solidified by cooling with liquid air, and any more volatile gases present pumped away. The gas allowed to boil off from the crystals was proved to be pure by a combustion analysis, and possessed at 0° C. and 760 mm. pressure a density of 0.5547, the theoretical density being 0.555. The melting and boiling points were measured by means of an iron-Constantin thermocouple, previously standardised against a petroleum ether thermometer, the crystals melting sharply at -184° C. and boiling at -164° at atmospheric pressure. The authors add that the methane, purified in this way, always possessed a sweet, faint garlic odour, which cannot be attributed to impurities, and must be regarded as due to the gas itself. The reaction between solid methane and liquid fluorine was studied at the same time; the two substances instantly combined, the reaction being accompanied by a bright flash and a violent explosion, completely pulverising the glass tubes.

A twelfth edition of Mr. W. T. Lynn's booklet on "Remarkable Comets" has been published by Messrs. Sampson Low, Marston and Co., Ltd.

The Cambridge University Press has published the first number of a new scientific periodical entitled the *Journal of Agricultural Science*. The magazine is edited by Messrs. R. H. Biffen, A. D. Hall, T. H. Middleton, and T. B. Wood, in consultation with Messrs. W. Bateson, F.R.S., J. R. Campbell, and W. Sommerville. It is intended to circulate among agricultural teachers and experts, and will be issued, as material accumulates, in parts of about one hundred pages. Each volume will consist of four parts. The first number appeals to workers in many departments of agricultural research, and among the articles it contains may be mentioned those on Mendel's laws of inheritance and wheat breeding, by Mr. R. H. Biffen; the influence of pollination on the development of the hop, by Mr. A. Howard; the importance of the removal of the products of growth in the assimilation of nitrogen by the organisms of the root nodules of leguminous plants, by Mr. J. Golding; the analysis of the soil by means of the plant, by Mr. A. D. Hall; variation in the chemical composition of the swede, by Mr. S. H. Collins; soil analysis as a guide to the manurial treatment of poor pastures, by Messrs. T. B. Wood and R. A. Berry; and the improvement of poor pastures, by Prof. T. H. Middleton. The magazine should prove of interest and help to all teachers of agricultural science as well as to those engaged in research in this field of knowledge.

The third part of Herr C. K. Schneider's "Illustriertes Handbuch der Laubholzkunde" has just been published by the firm of Gustav Fischer, Jena. The first two parts were reviewed in Nature of November 24, 1904 (vol. lxxi., p. 76), and a further notice will appear after the work, consisting of about nine parts, has been completed.

OUR ASTRONOMICAL COLUMN.

Ephemeris for Comet 1904 *e*.—The following is an extract from a continued ephemeris for comet 1904 *e*, as calculated from M. Fayet's elliptical elements by Dr. E. Strömgren, and published in No. 3994 of the *Astronomische Nachrichten*:—

Ephemeris 12h. (M.T. Berlin).

1905	α (true) h. m. s.	δ (true) ° ′	log *r*	log Δ	Brightness
Feb. 25	3 10 47	+30 7	0·1669	0·1233	0·46
Mar. 1	3 22 3	+32 0	0·1711	0·1359	0·43
,, 5	3 33 44	+33 47	0·1757	0·1486	0·39
,, 9	3 45 49	+35 25	0·1805	0·1611	0·36
,, 13	3 58 16	+36 56	0·1855	0·1736	0·33

The comet is now becoming very faint, and is travelling in a north-easterly direction through the southern part of the constellation Perseus. On March 11 it will pass near to ξ Persei.

Revised Elements for Borrelly's Comet (1904 *e*).—When publishing the previous set of elements for comet 1904 *e*, M. Fayet explained that, as his computations were based upon the results of only a few observations, they could only be regarded as approximate. Now, however, the observations extend over nearly a month, and M. Fayet has made another research regarding this comet's orbit, obtaining the following set of elements as his result:—

$$T = 1905 \text{ Jan. } 16{\cdot}65370 \text{ (M.T. Paris)}$$

$$\left.\begin{aligned} \Omega &= 76^\circ\ 41'\ 34''{\cdot}49 \\ i &= 30^\circ\ 31'\ 58''{\cdot}75 \\ \omega &= 352^\circ\ 13'\ 58''{\cdot}98 \end{aligned}\right\} 1905{\cdot}0$$

$$\log q = 0{\cdot}145175$$

$$\log e = 9{\cdot}792206$$

$$\mu = 503''{\cdot}932$$

These elements give a close agreement with the places determined by independent observations, and indicate that Borrelly's 1904 comet is, really, of the short-period type, completing its orbital revolution in about seven years, instead of six years as given by the previous elements (*Comptes rendus*, No. 5, 1905).

The Sun's Rotation.—During the years 1899, 1900, and 1901 Prof. N. C. Dunér made a further series of observations of the rotation velocity of the sun at different heliocentric latitudes. Combining the results with those obtained by him during a similar research prosecuted in the years 1887–1889, and now corrected, he found the values given in the following table:—

ϕ	v km.	n	$\xi \cos\phi$ °	ξ °
0·4	+2·08	183	14·770	14·77
15·0	+1·97	180	13·989	14·48
30·1	+1·70	184	12·072	13·95
45·0	+1·27	181	9·018	12·75
60·0	+0·81	183	5·752	11·50
75·0	+0·39	184	2·769	10·70

wherein ϕ = the heliocentric latitude, v = the rotational velocity of the sun's edge, n = the number of observations, and ξ = the daily rotation angle (*Astronomische Nachrichten*, No. 3994).

Secondary Shadow on Saturn's Rings.—During a series of observations of Saturn made at Aosta (Italy) in October, November, and December, 1904, Signors M. Amann and Cl. Rozet observed a secondary shadow, other than that of the planet, projected on to the illuminated surface of the rings. First seen on October 20, this shadow was thinner and much less accentuated than that of the planet, whilst its curvature was in the opposite sense to that of the latter body. From October 20 to November 15, despite the fact that numerous opportunities of observing it occurred, the shadow was not seen, but from the latter date until the end of December it was shown on twenty-six drawings of the system. On seven drawings made between December 22 and 27, the shadow appeared bifurcated where it traversed the inner ring, and on November 28 and 29 a third line of shadow, narrower and feebler than the preceding and much further from the planet, was seen (*Comptes rendus*, No. 5, 1905).

Observations of the Zodiacal Light.—During a sojourn on the summit of Mont Blanc on September 21 and 22, 1904, M. A. Hansky made a number of observations of the Zodiacal Light, and found that its form was that of a spherical triangle having its apex near to the ecliptic. At 3h. 40m. (M.T. Paris) the altitude of the apex was 52°, the length of the triangle, reckoned from the centre of the sun, was 80°, and its breadth was, at the horizon, 25°, and in the plane of the sun's axis 30°. The latitude of the apex was +2°, and three zones were distinguishable in the light. The first of these had the form of a spherical triangle and was very feeble, the second was more parabolic, whilst the form of the third was a parabola.

In his paper, published in the *Comptes rendus* (No. 6, 1905), M. Hansky indicates the points of resemblance between this phenomenon and the corona, and makes a number of speculations as to the true nature of the light. He concludes by saying that he believes it to be an electrical phenomenon of the same type as the corona, and that it is, probably, simply a prolongation of the coronal streamers.

Permanent Numbers for the Minor Planets discovered during 1904.—In No. 3994 of the *Astronomische Nachrichten*, the permanent numbers allotted to the minor planets discovered during 1904 are given. The list contains the numbers 522 to 548, inclusive, thereby showing the number discovered during last year to be twenty-seven. The provisional designation, the name of the discoverer, the date of discovery, and the authority for the orbit are also given for each planet. A number of notes explain the absence, for various reasons, of several bodies, to which provisional designations were allotted, from the final list.

STUDIES IN EUGENICS.

At a meeting of the Sociological Society on February 14 Mr. Francis Galton communicated two papers:—(1) restrictions in marriage, and (2) studies in national eugenics.

In the first paper he remarked that marriage, as one of the social agencies that influenced the racial qualities of future generations, came within the purview of eugenics. It belonged to the practical policy arising out of eugenic science, to promote such choice in marriage as should tend to the reproduction of the higher types of individual. Anthropological investigation had shown marriage to be one of the most modifiable of social institutions. Hence the assumption was warrantable that with the gradual incorporation of eugenic conceptions in the social ideal, there would proceed a concomitant change in the customs and conventions affecting marriage. The paper then proceeded to illustrate by actual examples the modifiability of marriage customs. In one or other of its many forms polygamy was now permitted—by religion, customs and law—to at least one-half of the population of the world, though its practice might be restricted, on account of cost, domestic peace, and the insufficiency of females. In Christian nations the prohibition of polygamy, under severe penalties, by civil and ecclesiastical law had been due, not to any natural instinct against the practice, but to consideration of social well-being. Hence it might be inferred that equally strict limitations of freedom of marriage might, under the pressure of worthy motives, be hereafter enacted for eugenic and other purposes. Endogamy, or the custom of marrying exclusively within one's own tribe or caste, had been sanctioned by religion and enforced by law in all parts of the world, but chiefly in long-settled nations, where there was wealth to bequeath and where neighbouring communities professed different creeds. Endogamous systems of marriage rested on customs determined by a certain religious view of family property and family descent. Eugenics dealt with what was more valuable than money or lands, namely, with natural inheritance of high character, capable brains, fine physique and vigour, in short, with all that was most desirable for a family to possess. It aimed at the evolution and preservation of high races, and it well deserved to be strictly enforced. In every society there existed conventional restrictions of the nature of "taboo," though not necessarily called by that name. If non-eugenic unions were prohibited by such taboos, none would take place. Marriage selection was very largely conditioned by motives based on religious and social convention. Persons who were born under the various marriage systems lived under such rules without any objection. They were unconscious of their restriction.

Under the heading "Studies in National Eugenics," Mr. Galton communicated what he described as "an unauthorised programme" of what he conceived to be the duties of the Francis Galton research fellowship in national eugenics. The topics to be considered he classified under the following headings:—(1) Estimation of the average quality of the offspring of married couples from their personal and ancestral data. This included questions of fertility, and the determination of the probable error of the estimate according to the data employed. (2) Effects of action by the State and by public institutions. (3) Other influences that further or restrain particular classes of marriage. (4) Heredity. The facts, after being collected, should be discussed, for improving our knowledge of the laws both of actuarial and of physiological heredity, the recent methods of advanced statistics being of course used. (5) Bibliographical compilations. (6) Extension of eugenic studies by wider cooperation. (7) Certificates. With regard to the last named, he said that in some future time, dependent on circumstances, he looked forward to a suitable authority issuing eugenic certificates to candidates for them. They would imply more than an average share of the several qualities of at least goodness of constitution, of physique, and of mental capacity.

The discussion on the papers was opened by Dr. Haddon, who said Mr. Galton sought to establish a science of eugenics, he took it, because the postulates of eugenics were an inevitable corollary from the general doctrine of organic evolution—in the building up of which Mr. Galton had played a notable part. The evolution of the species having reached a self-conscious stage in man, it followed of necessity that increasingly rational and coordinated attempts should be made to guide and direct the evolutionary process towards definable and verifiable ideals. It was, as he understood it, the aim of eugenic studies to ascertain the means available for this rational guidance of human evolution, and the defining of the ideals towards which it should be directed. There was ample warrant in anthropological data for the assumption that in the development of marriage customs there was a tendency towards adaptation to higher social purposes.

Dr. F. W. Mott said there were two general ways towards the rational improvement of the stock:—(1) by checking the reproduction of the unfit, and (2) by encouraging the reproduction of the fit. For the former purpose the readiest means would be the segregation of defective children while quite young, and the curtailment of their social privileges as they grew to maturity. As regards means towards the encouragement of fertility in the higher types, he suggested as an initial tentative in practical measures a further development of the present system of marriage registration. Why, for instance, should not medical as well as legal certificates of marriage be procurable at registry offices? The former would be of the nature of a bill of health, certifying that the contracting parties reached a certain standard of hygienic requirement. Such certificates would of course be voluntary, but since they would be valuable not only to their possessors but also to their children, they would tend to come into general usage. In any case he considered it a matter of national importance that Mr. Galton's conception of eugenics should be most seriously considered. The first desideratum was to get it accepted as a legitimate and hopeful study.

Mr. Ernest Crawley said Mr. Galton's paper showed how anthropological studies could be made fruitful in practical politics. Sociology should be founding its science of eugenics upon anthropology, psychology, and physiology. He hoped that while chiefly considering the normal individual it would not forget the special claims of those abnormal persons whom we call geniuses. In a well ordered State they should be considered before the degenerate and the diseased. As regards marriage customs, he took it as an assured generalisation of anthropological science that there are two permanent polar tendencies in human nature, first against unions in the same home, and secondly against too promiscuous marriage. Many customs assumed by early anthropologists as normal types were, he believed, mere sports—such as group-marriage, and marriage of brother and sister. Polygamy he believed to be an example of a certain tendency in man to confuse sexual (*i.e.* organic), with matrimonial (*i.e.* social) concerns. They must beware of this confusion, and therefore be on their guard against its possible effects in studying eugenics. Mr. Galton's suggestion that religion was called upon to play a part in the development of eugenics he considered to be a sound deduction from history and anthropology. In the sanctification of marriage, religion had one of its earliest and greatest functions; and as primitive religion, in this as in other respects, was based upon the best knowledge of primitive times (*i.e.* upon primitive science), so the most developed form of religion should be illuminated by the most advanced form of knowledge (*i.e.* by contemporary science).

Dr. E. Westermarck said he entirely agreed with Mr. Galton's contention that restrictions in marriage as they existed in the simpler social formations, so they might be further modified and developed for eugenic purposes amongst the most highly civilised peoples. The germ of eugenic intentions was well seen amongst savage and barbarian peoples in those customs which imposed a test of fitness on the husband before marriage. In Kaffir tribes, for instance, a man may not marry until he has demonstrated his strength and courage and competence in the chase by killing a rhinoceros. In the Malay Archipelago there are peoples where the marriage test consists in the collection of a number of skulls from hostile tribes. Among the Arabs of Upper Egypt, the young aspirant to marriage must evidence his courage and self-control by suffering—with smiling countenance—a severe ordeal of whipping by the relatives of the bride. He considered that on this question of marriage, whereby the individual was brought into both organic and social relation with the species, moral teachers had before them one of the greatest of tasks, in inculcating a keener sense of foresight in the individual. There was perhaps hardly any other point in which the moral consciousness of civilised men stood in greater need of intellectual training.

As contributions to the discussion, a considerable number of written communications were received, from the following amongst others:—Dr. Havelock Ellis, Mr. A. H. Huth, Dr. Max Nordau, and Profs. Yves Delage, J. G. McKendrick, Posada, Sergi, Steinmetz, Tonnies, and Weismann. The last named raised the question whether, when a hereditary disease like tuberculosis has made its appearance in a family, it is afterwards possible for it to be banished entirely from this or that branch of the family, or whether, on the contrary, the progeny of those members who appear healthy must not sooner or later produce a tuberculous progeny. He himself considered that a tainted stock might produce a branch entirely free from that specific disease.

Mr. Galton, in the course of his reply, said it gave him satisfaction to find that no one amongst his critics had impugned the conclusion which his memoir on "Restrictions in Marriage" was written to justify.

THE ABSORPTION OF LIGHT BY THE ATMOSPHERE.[1]

THE great attention that has been paid during the last few years to the subject of photometry has brought into prominence the problem of the amount of light absorbed by the atmosphere. At the same time, the improvement that has taken place in the instrumental means, which renders possible the detection of minute changes in lustre, has required the use of accurate corrections by which the effect of the earth's atmosphere can be eliminated from the observations. The corrections which have been applied to photometric measures have been based generally on empirical or interpolation methods rather than on a strictly physical basis. There are several reasons which have contributed to this unsatisfactory condition of the problem. The difficulty of computing the length of the path of the ray of light in its passage through our atmosphere, the want of homogeneity in the constitution of the atmosphere itself, our ignorance of the law of the temperature gradient at considerable heights above the surface, and of the distribution of water and dust particles near the surface, have all complicated a subject the theory of which under ideal limiting conditions may not be very difficult. Bouguer left a very satisfactory theory, based, however, on the assumption that the path of the ray was rectilinear. Laplace attacked the subject from the side of the theory of refraction, but practically did not much advance it. From that time onward, the question has rather been left in the hands of observers, who have been content to make their observations homogeneous by the employment of an interpolation formula, based on the results of their actual practice.

Dr. A. Bemporod thinks that the time has come for the discussion of a physical theory of the extinction of light in the atmosphere, and certainly his pamphlet bearing this title is a most welcome contribution to this subject. It may be that in some sense it is a premature effort. That is to say, that the data for a complete solution of the problem do not exist. The series of observations which are now being conducted by means of kites and balloons, and which have for their object the examination of the different

[1] "Zur Theorie der Extinktion des Lichtes in der Erdatmosphäre." By Dr. A. Bemporod. Pp. 78. (Mitteilungen der Grossh. Sternwarte zu Heidelberg.)

strata of the atmosphere at various distances remote from the surface, may be expected to throw some additional light upon the constitution of the gaseous envelope through which the light passes, and, moreover, there is the troublesome and disturbing question of selective absorption, the importance of which the author fully admits, but does not consider numerically in his work, which may play a very important part in the future theory of atmospheric extinction. But any improvement which may hereafter be made will not invalidate the calculations, so far as they refer to the mass of the air through which the light beam penetrates.

Dr. Bemporod divides his work into five sections. In the first he presents the problem in its most general form, and defines the function F(z), the so-called path of the ray in the atmosphere. Chapter ii. exhibits a critical examination of the theories of Bouguer, Lambert, Laplace, and of some others less well known. In the next the author discusses the hypotheses of Ivory and Schmidt on the constitution of the atmosphere. Of the two, Schmidt's hypothesis of a uniform decrease of the temperature with the height above the surface gives the best agreement with the observed temperatures derived by Assmann and Berson from balloon ascents. The latter hypothesis is the one therefore selected for development, but both Ivory and Schmidt give practically the same values for extinction, while Laplace's theory at the zenith distance of 87° appears to be a tenth of a magnitude in error. Chapter iv. explains the formation of the extensive numerical tables that accompany the work, and in the last the author has some remarks on the influence of geographical position on the absorption, as well as of the effects of oscillations in temperature and pressure. The whole forms a valuable addition to a subject of great interest and importance.

JOHN HUNTER AND HIS INFLUENCE ON SCIENTIFIC PROGRESS.[1]

As the history of philosophy, considered from one point of view, is the record of the development and growth of ideas and of the formation of beliefs and doctrines respecting man and the universe accomplished through the thinking of a few great *minds*, so the history of medicine is a record of the observations, thoughts, and achievements of a few great *personalities*—Hippocrates, Celsus, Galen, Paré, Harvey, and John Hunter, to name only the greatest. John Hunter is the theme which has been assigned to me.

Throughout the ages of civilisation the growth of knowledge has been slow and often irregular, but it has been continuous and it has been sure. How slow and yet how sure we may realise by comparing the dialectic notions of Aristotle respecting weight and motion with the direct appeals to the evidences of the senses afforded by the demonstrations of Galilei, whereby it was shown that, so far from there being in nature bodies possessing positive levity, all matter is equally affected by gravity, irrespective of its form, magnitude, or texture. By the simple experiment of dropping objects from the Tower of Pisa, Galilei, who began life as a medical student, laid the foundation of modern physical science, and especially of dynamics. This expedient was one of the first appeals, at least in modern times, to the use of direct experiment in physical science, and the truth thereby established became a determining factor in Newton's great discovery of the law of gravitation. From Aristotle to Galilei an interval of more than eighteen centuries had elapsed. Galilei and Harvey were contemporaries.

John Hunter was born exactly a century after the publication of Harvey's "Exercitatio De Motu Cordis." It is one hundred and eleven years since John Hunter died. Yet how modern Hunter is! Inventions and discoveries now crowd upon us so thick and fast that we are apt to forget how recently modern physical science began, and especially modern medicine. In the order of time medicine, in its rudest and simplest forms, must have been one of the first of the empirical arts, but in the order of ideas it was one of the last to enter into the hierarchy of the sciences. As a system of organised knowledge medicine presupposes and requires not only centuries of clinical observation and a complete logical apparatus, but it also requires an advanced state of all the other natural sciences. It concerns itself with the recondite problems of life in the most complex and the most highly differentiated of its manifestations, whether under the conditions of health or under those of disease. Until physics and chemistry had advanced from the conjectural and the aprioristic to the scientific stage, medicine could only be conjectural and aprioristic too, however useful it may have been as a practical art. The thoughts and labours, the experiments and discoveries of the great pioneers of modern knowledge in the physical sciences were the necessary prelude to a scientific progress in biology, which, in its turn, was a condition precedent to any real advance in the science of medicine, surgery, and pathology. Harvey, in the order of time and of thought, was the necessary antecedent of Hunter.

The starting-point of John Hunter's career as anatomist, biologist, and surgeon was in the year 1748, when he came to London with a receptive and intelligent mind, a quick and observant eye, and a well-trained hand, to collaborate with his brother William in the anatomical school which had been started two or three years before.

Considering the important part that human anatomy now plays in medical education, it is difficult to conceive that there was no systematic teaching of anatomy in England before the middle of the eighteenth century. During the many centuries which elapsed between, say, the time of Hippocrates and the middle of the sixteenth century, the dissection of the human cadaver was almost unknown. Forbidden alike by the laws and customs and religion of the ancient Greeks, and by the creed of Mohammed, the study of human anatomy was placed under a civil and religious ban until the end of the thirteenth century. In ancient Greece the laws relating to immediate burial were very stringent. Even victorious generals had been condemned to death because they neglected to bury the slain. The pathos of Sophocles' tragedy of "Antigone" turns, it will be remembered, upon the sacredness of the dead, and of the necessity, higher than imperial commands, of immediate burial.

When the tradition of Greek medicine passed—in the seventh and eighth centuries—into the hands of the Mohammedans, human anatomy was equally neglected, the practice of dissection being implicitly forbidden by the Qurân. Even after the dissection of the human cadaver received the sanction of the civil authorities in southern Europe, the teaching of anatomy was cursory and occasional, and merely descriptive. Mundino of Bologna, in the fourteenth century, who was the first in modern times to dissect the human cadaver, seems to have dissected only two bodies. So little was known of human anatomy, and so strong was the tyranny of tradition, that when Vesalius, in the middle of the sixteenth century, alleged that the anatomical descriptions of Galen could not be adapted to man, there were not a few who, in their zeal to repel the accusation that Galen had used animals in dissection, did not hesitate to maintain that the human organisation had changed since Galen's time.

In England, notwithstanding Harvey lectures on anatomy in the first quarter of the seventeenth century, there was no organised teaching of anatomy before William Hunter's time. In this matter William Hunter has not received all the credit he deserves. Had his ambition been realised, he would, nearly a century and a half ago, have solved a problem in early medical education in London which is still perplexing the minds of many thoughtful persons. He desired to establish an anatomical school in London upon an extensive scale. With this object in view, he offered to erect a building at the cost of 7000*l.* for the study and teaching of anatomy provided the Government would grant him a piece of ground to build upon. It was also his intention to give to this institution all his preparations and his books. With a lamentable lack of sympathy which British Governments have too often manifested in their dealings with science and education, William Hunter's offer was declined. Smarting under a keen sense of disappointment and full of resentment, he determined to transfer his favours to Glasgow, which now enjoys the possession of his priceless museum and his library. *Beati possidentes.*

[1] Abridged from the Hunterian oration, delivered before the Royal College of Surgeons, February 14, by Mr. John Tweedy, president of the college.

After John Hunter had worked at human anatomy for ten years, he manifested his intellectual growth by directing his thoughts to the higher and more scientific discipline of comparative anatomy and physiology. He realised that human anatomy alone was an insufficient guide to pathology and surgery. He collected all manner of animals at his house and grounds at Earl's Court in order to study their ways and habits, and from every available source he acquired animals, living or dead, for the purposes of observation, experimentation, or dissection. In his use of the lower animals for the elucidation of physiological problems he followed while amplifying the practice of Harvey, who in his turn adduced the authority of Aristotle. There was, however, a striking and characteristic difference between the use which Aristotle made of the dissection of animals with reference to human anatomy and that of Hunter. There is no trustworthy evidence that Aristotle or Hippocrates or even Galen dissected the human body, certainly not in the sense we understand by the term "dissection." They dissected the bodies of animals *instead of* those of man, and transferred their observations of animals to the corporeal organisation of man. Hunter, on the other hand, practised the dissection of lower animals *in addition to* that of man, and transferred his observations to the embryology and morphology of man and to the elucidation of the problems of human and comparative physiology and pathology.

John Hunter was a philosopher in the strict and primary sense of the word. He had a passion for knowledge. "Let no man presume to call himself wise," says Pythagoras; "God alone is wise. Man can never get beyond the passion for wisdom." John Hunter had this passion. He devoted himself to the pursuit of knowledge, searching for it in every department of the organic world, animal and vegetable. In one of his letters to Jenner he says: "I have but one order to send you, which is, to send everything you can get, either animal, vegetable, or mineral, and the compound of the two, either animal or vegetable mineralized." And, again: "Have you any large trees of different kinds that you can make free with? If you have, I will put you upon a set of experiments with regard to the heat of vegetables." With respect to the observations and experiments which he directs Jenner to make, he says, "Be as particular as you possibly can." These sentences express briefly and in epitome, as it were, Hunter's habits of mind and his attitude towards the problems of organic life.

John Hunter may have lacked the power of clear exposition, and he may have disliked routine teaching. He was, however, full and overflowing with ideas, new and original, to which he often found it difficult to give distinct shape and utterance. In contrast with William Hunter's didactic powers, John had the suggestive, the constructive, the creative faculty, the faculty of discovery, of coordinating knowledge, and he had the art of stimulating thought and calling forth effort from others. He taught by example rather than by precept.

Ottley, the first and one of the best of Hunter's biographers, remarks that in pursuing his researches Hunter strove, not like many of his more learned and less philosophical predecessors, to unravel the mysteries of nature by taking up principles *a priori* and seeking for facts to support his theory, but that, on the contrary, he followed in the strictest manner the inductive method laid down by Bacon as the only sure though arduous road to knowledge; and Babington, in his Hunterian oration, remarks of him: "He had never read Bacon, but his mode of studying nature was as strictly Baconian as if he had." Other critics and historians of Hunter's work, and not a few Hunterian orators, have written or spoken in a similar strain. In my judgment this view is entirely erroneous with respect to Hunter's method, and it is a complete misinterpretation of the Baconian system. Bacon's eloquence and influence undoubtedly did much to attract men to the observation and study of natural phenomena. He directed attention to the necessity of studying the powers and forces of the world as a means of subjecting the world to the human mind, and so far his message was appropriate and opportune. The significance of that message is probably greater now than at the time he delivered it. The future belongs to the nation which understands best the forces of nature, and which can most skilfully and economically employ them. But Bacon himself neither knew nor understood the physical sciences. His spirit was essentially mediæval, and much less modern than that of his illustrious namesake Roger Bacon, who lived three hundred years before him. Francis Bacon's aim was purely utilitarian. He had no idea of knowledge for its own sake, and he cherished the hope that by increasing our knowledge of nature the secret of the transmutation of substances would be learnt, and probably the knowledge of the making of gold. He not only had no practical acquaintance with natural science, but he lacked insight into the true methods of its investigation. He understood very imperfectly the value of experiment, and he assigned quite a subordinate position to quantitative determination, the precise quality which is the most striking characteristic of modern science, and which constituted the most original and perhaps most brilliant of the reasonings which Harvey employed in his famous induction. So far from being the founder of the modern scientific method, Bacon's writings were themselves one of the products of the intellectual awakening which began at the end of the sixteenth century. Notwithstanding his affectation of scientific knowledge and scientific methods, Bacon had an unscientific weakness for superstitions. He believed in natural and judicial astrology, though not without some hesitation and discrimination. He believed in the transmutability of elements and of the metals, in charms and signatures as remedies, and so completely did he ignore Harvey's discovery of the circulation of the blood that in one of the latest of his writings he ascribes the pulsation of the heart and arteries to the dilatation and contraction of the spirits. Well might Harvey say, in disparagement of Bacon's scientific writings: "He writes philosophy like a Lord Chancellor."

Bacon's ruling idea was the collection of masses of facts and then the employment of processes of arrangement, and separation, and exclusion, so artificially contrived that a man of common intelligence should be able to announce the truth sought for. This method has been slightingly described as a kind of scientific bookkeeping. "It is difficult," says Stanley Jevons, "to imagine a less likely way of arriving at great discoveries. The greater the array of facts the less is the probability that they will by any routine system of classification disclose the laws of nature." The answer to the claim that Bacon was the philosophic father of modern methods of scientific investigation is that none of the scientific truths established by the great masters of science can be made even to *appear* in correspondence with Bacon's methods. Whether we look to Copernicus, who preceded him, or to Kepler, Galilei, Torricelli, Pascal, Gilbert, and Harvey, or to Newton, Descartes, or Huygens, or to Thomas Young, or to the chemists Black, Priestley, Scheele, and Lavoisier, we find that discovery was achieved by a method quite different from that advocated by Bacon. So dispassionate a critic of philosophy as John Grote remarks: "I have not the smallest belief in Bacon's having reformed the method of discovery, believing rather that if he had *had* any success in that way, in the manner he wished, it would have been most calamitous for science." And even with regard to the claim of Bacon to be the founder of inductive philosophy, Ellis, one of the ablest of his editors, asserts that the nature of the act of induction is as clearly stated by Aristotle as by any later writer, while Aristotle himself ascribes the credit to Socrates. Perhaps the Baconian claim has never been more convincingly refuted than by Augustus De Morgan, at once one of the profoundest and subtlest thinkers of the nineteenth century. "Modern discoveries," he says, "have not been made by large collections of facts, with subsequent discussion, separation, and resulting deduction of a truth thus rendered perceptible. A few facts have suggested an *hypothesis* which means a *supposition* proper to explain them. The necessary results of this supposition are worked out, and then, and not till then, other facts are examined to see if these ulterior results are found in nature. . . . Wrong hypotheses rightly worked from have produced more useful results than unguided observation. But this is not the Baconian plan. . . . What are large collections of facts for? 'To make theories *from*,' says Bacon; 'To try ready-made theories *by*,' says the history of discovery."

Bacon's plan was purely mechanical. He ignored the work of the mind in the constitution of knowledge. He imagined that he had discovered a method by which scientific truth might be determined with absolute certainty, and by a mechanical mode of procedure such that all men were capable of employing it. "Our method of discovering the sciences is," he says, "one which leaves not much to sharpness and strength of wit, but nearly levels all wits and intellects." And this opinion is endorsed by most writers of the empiricist school in complete disregard of the teaching of history. Those who imagine that science requires nothing but the registering and classification of facts forget that the facts observed can only be connected and related by the mind, and that the laws of nature are after all mental products from given data.

Not only did John Hunter not follow the mechanical methods of Francis Bacon, but it is the work of the mind which is the peculiar characteristic of his method and its chief glory. Others could do as well as he the more mechanical part of his task—indeed, much of it was done by others; but the suggesting, controlling, coordinating mind was Hunter's, which, amidst the multiplicity of phenomena and of data apparently conflicting, discovered unity amidst multiformity, which is the special function of science.

John Hunter's constant aim was to arrive at principles, and he was distrustful of so-called facts. "The principles of our art," he said, "are not less necessary to be understood than the principles of other sciences; unless, indeed, the surgeon should wish to resemble the Chinese philosopher whose knowledge consisted only in facts. In that case the science must remain unimproved until new facts arise. In Europe philosophers reason from principles, and thus account for facts before they arise."

Hunter possessed every moral and intellectual qualification necessary for useful scientific research. He had a large knowledge of facts based on an intimate acquaintance with the phenomena of organic nature. He had a fertile imagination ready to suggest possible relations of those facts. He had openness of mind, and a conscientious scientific spirit which submitted every hypothesis to the test of observation and experiment. Scepticism is the first condition of reasoned knowledge. Hunter was not only observant, but he was rationally sceptical and critical, and he himself ascribed his success as a scientific investigator to the sceptical qualities of his mind. He took nothing on trust. He was always careful to distinguish between mere conjecture and reality, and drew a sharp distinction between the actual results of an experiment physically performed and what might have been mentally anticipated. "In pursuing any subject," he says, "most things come to light as it were by accident, that is, many things arise out of investigation that were not at first conceived, and even misfortunes in experiments have brought things to our knowledge that were not, and probably could not have been, previously conceived; on the other hand, I have often devised experiments by the fireside or in my carriage, and have also conceived the result; but when I tried the experiment, the result was different, or I found that the experiment could not be attended with all the circumstances that were suggested." Here, in a sentence, we note the wide difference between the modern and the mediæval spirit in science. The alchemists performed experiments innumerable, but with them theory ranked above experiment, and if experiment gave an unexpected result, this was forced into an artificial conformity with the aprioristic theory. It was therefore, says Lange in his "History of Materialism," "essentially directed to the production of this previously anticipated result rather than to free investigation."

While Hunter was intolerant of a state of doubt in small things as in great, if by any means decision was possible, he ever held his judgment in suspense if certainty was not attainable. Like all strong characters, he cared little for systems or consistencies of opinion. He followed wherever Truth should lead, and by his very nature was always open to new and higher knowledge. To a pupil who asked with surprise whether he had not the year before stated an opinion on some point directly at variance with one he had just put forth, he boldly replied: "Very likely I did; I hope I grow wiser every year." And again: "Never ask me what I have said, or what I have written; but if you will ask me what my present opinions are I will tell you."

In attempting an appreciation of John Hunter's method I have suggested rather than explained the development and growth of the modern knowledge of physics, chemistry, and biology under the influence of the experimental method; but it has not been my purpose or intention to offer any defence of this method. To defend the use of experiment in physics and in chemistry would be manifestly absurd, and I assume that in this place and before this audience it is equally unnecessary to offer an apology for its use in physiology and pathology. I opine, however, that it is within my province as Hunterian orator to anticipate the possible censure of some who would not hesitate in the sacred name of religion to traduce the memory of Hunter because he practised experiments in physiology. John Hunter did employ the method of experiment. He employed it no less with zeal than with intelligence. He employed it not from idle curiosity, not from the promptings of vainglory, or for the purposes of worldly advancement; all that he had he gave to science. He employed it in the service of humanity and in the study of the nature and laws of life; and the knowledge which he thereby acquired he transferred to the domain of medicine and surgery, and applied to the alleviation of sickness and suffering among animals no less than among men.

I pretend not either impiously to affirm or not less impiously to deny all the purposes of infinite wisdom in giving man dominion over the fish of the sea, and over the fowl of the air, and over every living thing that moveth upon the earth; but we do know that throughout historic time man has not hesitated to capture, to subjugate, and to slay, beast and bird and fish, for his pleasure, his sustenance, and his service. Was the lordship over the animals given to man only for the satisfying of his physical and sensuous needs? Is not the life more than food? Was it only with reference to man's bodily well-being that the question was asked: Are ye not of much more value than the birds of the heaven? Does the mind need no aliment? And is the veto to be applied only when animals are to be used for the purposes of elucidating the kindly functions of physiology, or of disclosing the baneful secrets of disease?

The vicarious suffering and sacrifice of animals for the service and the salvation of man have obtained throughout the ages, and constituted the basis of the elaborate ceremonial system of the ancient Israelites. In anticipation of the great Passover, Moses directed the Israelites each to kill a lamb according to their families, and to sprinkle its blood upon the lintel and the two side posts. "For the Lord will pass through to smite the Egyptians; and when He seeth the blood upon the lintel, and on the two side posts, the Lord will pass over the door, and will not suffer the destroyer to come into your houses to smite you." The complete purification of *one* leper and his reception back into society involved not only the slaughter of three lambs, but the convalescent had to appear with two living clean birds, one of which was slain, while the other, still living, was baptised in the dead bird's blood, and then allowed to fly away free. The principle of substitution was actualised in the ceremony of the scapegoat. At the annual Feast of Expiation, a young bullock, two kids, and one ram were slain; and two goats were taken upon which lots were cast, one lot for Yahwè, the other for Azazel. The goat on which the lot fell for Yahwè was sacrificed for a sin offering; but the goat upon which the lot fell for Azazel was presented alive, and when the high priest had symbolically placed upon its head the sins and transgressions of all the people, the goat was led into the desert, there to become the victim of hunger and thirst, and the prey of ravenous bird and beast.

Are these hecatombs to be regarded as of Divine origin and sanction, while the inoculation of a cat or dog, or it may be a rat, is to be denounced as a desecration and a violation of the purposes and will of God? Who will say but that in our day, as the Angel of Death passes through the land, seeing upon us the sprinkling of the immunising blood, takes that for a token, and is not suffered to come into our houses to smite us? "Dipt in his fellow's blood the living bird went free"; and so we, dipped in blood, aye, the blood of our fellow-man, as the annals of medical martyrology bear witness, we enjoy a growing freedom from plague and pestilence and noisome disease, and in the fulness of knowledge the measure of our freedom will be full.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—The sum of 1600*l.* has been recently contributed to the University Benefaction Fund for the endowment of a lectureship in special pathology. The collection of this fund is largely due to the activity of Prof. G. Sims Woodhead, and the lectureship will be known as the Huddersfield lectureship, in recognition of the town which has largely supplied the capital sum. The general board will proceed shortly to elect the lecturer. Applications should be sent in to the Vice-Chancellor, on or before Tuesday, March 7.

The general board has approved Mr. J. J. H. Teall, of St. John's College, Director of the Geological Survey, for the degree of Sc.D.

The Smith's prizes have been awarded to Mr. H. Bateman for his essay on "The solution of linear differential equations by means of definite integrals," and to Mr. P. E. Marrack for his essay on "Absorption by matter of Röntgen and γ rays." Both the students belong to Trinity College.

Mr. F. J. M. Stratton, of Caius College, has been elected to an Isaac Newton studentship.

LONDON.—At the South-Western Polytechnic Miss Gladys Martyn has been elected to the free studentship in the physical training department. She will devote part of her time to the scientific study of anthropometric measurements and eugenics. Mr. L. D. Coueslant, lecturer in the engineering department of the polytechnic, has been elected to be head of the mechanical and civil engineering department of the Technical Institute of Sunderland. Mr. A. J. Makower has been elected head of the electrical engineering department in succession to Mr. C. F. Smith.

The Fishmongers' Company has granted a sum of 1000*l.* toward the funds necessary for the incorporation of University College in the University of London. By this grant the amount still required to complete the funds necessary for incorporation is reduced to 17,000*l.*, a total of 183,000*l.* having now been raised for the purpose. Dr. A. R. Cushny, of the University of Michigan, U.S.A., has been appointed to the chair of pharmacology and materia medica in the college. Prof. L. F. Vernon-Harcourt has resigned the chair of civil engineering and surveying.

WE learn from *Science* that Mrs. Goldwin Smith has given 4000*l.* to Cornell University; and that by the will of the late Mr. E. A. Goodnough, of Worcester, gifts are made as follows:—5000*l.* to Mount Holyoke College, 3000*l.* to Iowa College, 5000*l.* to the Huguenot Seminary in South Africa, 1000*l.* to Washburn College in Kansas, 2000*l.* to Drury College in Missouri.

THE *Engineering and Mining Journal* of New York publishes the views of Prof. H. M. Howe, the eminent American metallurgist, on the vexed question whether technical schools serve the interests of the community better if they are parts of great universities or if they are isolated institutions. Wisely guided association, while it need not deprive the technical school of character and individuality, should, he thinks, benefit the community through the broadening interaction of the teachers of pure science and the technical teachers, with their closer contact with active life. The grand scale should effect great economy, not so much in saving salaries and in widening the use of the more expensive instruments, as in fitting work to worker, and in supplying more fully the eminent with work on their own plane.

IN a paper on "Architectural Education" read before a meeting of the Royal Institute of British Architects on Monday, Mr. R. Blomfield described the report and syllabus prepared by the Board of Architectural Education appointed by the institute. The following is the syllabus proposed by the board:—(1) Building materials; (2) construction, including (*a*) applied mechanics, strictly in practical relation to construction, and (*b*) the practical methods of the building trades; (3) architectural drawing, including working and freehand drawings, solid geometry, and measured drawings of historical examples of architecture; (4) geometrical projection and rudimentary perspective, this latter to be studied as an aid to the shaping and modelling of buildings, not as a means of elaborating architectural drawings; (5) design and the history of architecture as supplemental to and elucidatory of the study of construction. It is pointed out that these subjects should be taught by class work in the schools and by demonstration in the laboratory or lecture theatre of practical work. The laboratory or workshop for training in practical work is an essential feature of the scheme. The demonstrations given in the laboratory should be in intimate relations with the lectures given in the class-rooms of the schools, and the course must be arranged so that the training in the class-rooms and in the workshops proceed together. In moving a vote of thanks to Mr Blomfield, Sir Arthur Rücker said that, if the great movement which is taking place in technical education is to have a sound foundation, it is absolutely necessary that it should be carried out by those who are themselves the professional members of the great professions and trades which they wish to carry to a point of higher education.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, January 26.—"On the Drift produced in Ions by Electromagnetic Disturbances, and a Theory of Radio-activity." By George W. **Walker**. Communicated by Prof. A. Gray, F.R.S.

Electromagnetic waves produce certain mechanical forces on an electrically charged particle, and the equations of motion of such a particle can be formed. When the particle is regarded as exceedingly small and endowed with a charge e and inertia m, which includes electrical inertia, the equations take a comparatively simple form. When the small viscous term due to radiation from the particle is neglected the equations can be integrated in certain cases, and it is found that the continued propagation of waves involves an alteration of the position of the particle in space.

The case which suggested the general result was that in which the waves form an infinite simple harmonic train, and the solution showed that while the passage of a complete wave restored the initial velocities of the particle, its position in space was altered.

This alteration of position is not completely accounted for by the change due to the initial velocities had there been no waves. In particular, if the particle is initially at rest, the passage of a complete wave restores the state of rest, but the particle now occupies a new position in space. This curious result has an analogue in the case of a simple pendulum making complete revolutions, where the elapse of a complete period restores the velocity while the angle described has increased by 2π.

The continued propagation of the waves thus involves the result that the particle appears to drift through space in a manner which can be completely determined when the initial circumstances are given and the constants of the train of waves are known.

Similar results are found to hold for any kind of plane disturbances propagated in a straight line. Several cases are worked out where the disturbance is of a simple character. The disturbance is that in which the electric force is X_0, with the appropriate magnetic force X_0/V at right angles to X_0, for a time d/V succeeded by zero force for a time d/V, and this again succeeded by electric force $-X_0$ for a time d/V, and zero force for a time d/V, after which the disturbance recurs. In one case where the particle is initially at rest it appears to drift with the waves, while in another case where the particle has a certain initial velocity at right angles to the direction of propagation it drifts against the waves. If radiation from the particle is neglected, the passage of a complete pulse in which the integrated effect of electric force is zero involves a restoration of the original energy of the particle, and thus the transference of the particle is accomplished without abstraction of energy from the pulse. The expressions for the apparent velocity of drifting in the direction of propagation of the waves are found to depend on the squares of the charge, so that it is probable that an electrically neutral system will also be made to drift.

It is pointed out that if the equations held up to velocities of the charged particle equal to that of radiation, a particle originally moving in the direction of propagation with a velocity slightly less than that of radiation may be picked up by the waves and carried forward with the velocity of radiation.

The conclusion is that the propagation of disturbances of any form in a straight line involves a sorting of free ions and molecules according to their initial circumstances, and streaming of these both with and against the waves must take place.

These results are general, and are limited only by the limits of the electrodynamic equations. They suggest, however, a possible explanation of the action of all kinds of ionising agents.

In particular, it is suggested that if a radio-active substance is an origin from which electromagnetic disturbances are radiated, these disturbances probably ionise the gas in the immediate vicinity and produce streaming of ions and molecules with their associated properties both outwards from and inwards to the substance. This view does not necessarily involve the supposition that there is a continual diminution of the substance.

The results may also throw some light on the question of the energy sent out. For, suppose that there exist a positive and a negative ion which, in the absence of the pulses, would recombine at some point A, thereby radiating a certain amount of energy, then the directive action of the pulses may make them recombine at some other point B. Thus the radiated energy will proceed from the point B instead of from the point A. The transference of a single free ion can be accomplished without the expenditure of energy, and it is possible that the transference of the positive and negative ions may take place without any abstraction of energy from the pulses. Since, however, in general the transference may involve a relative displacement of the two ions, abstraction of energy from the pulses may be involved, so that the question is one about which the greatest caution must be exercised. It cannot be decided without further investigation.

These considerations are in general agreement with the views that have been expressed by Lord Kelvin and Prof. and Madame Curie.

The question whether the apparent velocity of drifting may be of the order indicated by experiment is considered; and it is shown that in order to give velocities comparable with that of radiation, the theory leads us to expect that the frequency of vibration of the waves radiated by the particles should be of the order for visible or ultra-violet light.

The differences between ionising agents would turn to a considerable extent on the character of the disturbances radiated.

Since the propagation of waves through a region of space containing matter involves streaming of the matter, the continued propagation cannot be quite independent of any statical, electric or magnetic field present.

February 2.—"Note on the Determination of the Volume Elasticity of Elastic Solids." By Dr. C. **Chree**, F.R.S.

PARIS.

Academy of Sciences, February 13.—M. Troost in the chair.—On the existence of an ellipsoid of absorption in all translucid crystals, even when without a plane of symmetry or a principal axis: J. **Boussinesq**.—Study of the silicide of carbon from the Cañon Diablo meteorite: Henri **Moissan**. In the residue left after dissolving a block of this meteorite weighing 53 kilograms in hydrochloric acid, a hexagonal crystal of silicon carbide was noticed. It was completely identified by its appearance, density (3·2), and indifference to most chemical reagents. Fused caustic potash gave potassium silicate, and fused lead chromate, carbon dioxide. The origin of this block of iron may be terrestrial or sidereal, but the existence of silicon carbide in the midst of the metal shows that the products prepared with the electric furnace are met with in nature.—On some constants of pure methane, and on the action of solid methane on liquid fluorine: H. **Moissan** and **Chavanne** (see p. 400).—The eruptive basic rocks of French Guinea: A. **Lacroix**. Besides biotite granite, numerous basic eruptive rocks have been found in French Guinea, especially gabbros, peridotites, and diabases, a detailed account of which is given. Attention is directed to the difference in the mode of weathering in tropical and in temperate climates, as exemplified in these samples.—On the use of photography as an aid to topography: A. **Laussedat**. An account of an application of the photographic method to the survey of the region round Mount Argée, in Cappadocia, on a scale of 1/80,000. The use of photography has the advantage of reducing very considerably the time required as compared with the ordinary methods of surveying, and is especially advantageous in mountainous regions.—Observations of the Borrelly comet (1904 *e*) made with the Brunner equatorial at the Observatory of Lyons: J. **Guillaume**. The apparent position of the comet was measured on January 3, together with the positions of two comparison stars. The comet appeared as an object of the tenth magnitude, and possessed a small nucleus.—Observations of the sun made at the Observatory of Lyons with the 16-centimetre Brunner equatorial during the fourth quarter of 1904: J. **Guillaume**. The results are summarised in three tables giving the number of spots, their distribution in latitude, and the distribution of the faculæ in latitude.—Actinometric observations made at the summit of Mont Blanc: A. **Hansky**. The observations were made in the observatory at the summit of Mont Blanc with the instruments of M. Crova. The conditions in 1900 were more favourable than in 1897 and 1898, and the results for this year are given in detail, the most probable result for the constant being between 3·0 and 3·5.—On linear partial differential equations: M. **Hadamard**.—On the deviation of falling bodies: Maurice **Fouché**. A reply to a criticism of M. de Sparre on a former paper by the author.—The thickness of transparent sheets of iron: L. **Houllevigue**. After trying unsuccessfully various methods for estimating the thickness of thin films of iron, a colorimetric estimation with sulphocyanide was found to give trustworthy results. The transparency (T) of these films was determined before dissolving in acid for the colorimetric test, and for films varying in thickness from 0·024 to 0·056 milligram per square centimetre the thickness was found to be a linear function of log T. This curve being established, the thickness of any given film could be quickly determined by the photometer.—The automatic registration of atmospheric ionisation: Charles **Nordmann**. The charge introduced by the ions is removed from the condenser plate by falling drops of water, the constancy of flow being secured by a Marriotte's bottle. The deviations of the electrometer in the arrangement described, a diagram of which is given, are proportional to the number of ions per unit volume of the gas.—On the heat given off by paraffin submitted to the action of a rotating electrostatic field of high frequency: Ch. Eug. **Guye** and P. **Denso**.—On a new reaction of aldehydes and the isomerism of their oxides: A. **Conduché**. The aldehyde is added to a dilute aqueous solution containing equimolecular proportions of hydroxylamine hydrochloride and potassium cyanate. Well crystallised compounds separate out, the melting points of which characterise the aldehyde. The discussion of the composition of these compounds throws light on the constitution of the isomeric aldoximes. No corresponding compounds are obtained when a ketone is substituted for the aldehyde in the reaction.—The action of hydrocyanic acid on epiethyline: M. **Lespieau**. The nitrile $C_2H_5.O.CH_2—CH(OH)—CH_2.CN$ is obtained in this reaction, and the preparation and properties of several substances derived from this are described.—On the non-existence of two stereoisomeric ethyl dioximidobutyrates: L. **Bouveault** and A. **Wahl**. The supposed existence of two stereoisomers indicated by Hantzsch and by Nussberger is shown to be erroneous.—On the transformation of amylocellulose into starch: Eugène **Roux**.—On the electrolysis of organic acids by means of the alternating current: André **Brochet** and Joseph **Petit**. The electrolysis of formic and oxalic acids can be easily effected with the alternating current; the results are the same as with the direct current, but the yields are much higher.—On the phosphorescence of phosphorus: E. **Jungfleisch**. It is shown that an inert gas, saturated with the vapour of phosphorus, contains an extremely small weight of phosphorus, the oxidation of which gives rise to scarcely appreciable light effects. The author regards his experiments as proving that a lower volatile oxide is first produced, and that it is the oxidation of this which gives rise to the luminous phenomena.—On isodimorphism: Frédéric **Wallerant**.—On the extension of the alkaline rocks in the basin of Aouache: H. **Arsandaux**.—Two species of Dalbergia in Madagascar producing a variety of ebony wood: Henri **Jumelle**.—On the biology of the Saprolegnia: Paul **Dop**.—The utilisation of the essential oils in the etiolated plant: Eug. **Charabot** and Alex. **Hébert**. It is shown that in the absence of light the plant is capable of consuming the essential oil which it contains, especially the terpenic compounds.—The relations between *Bougainvillia fruticosa* and *Bougainvillia ramosa*: Paul **Hallez**. The author regards these as one and the same species, the one belonging to calm water, the other to rough water, the slight difference between the two being due to this difference in the surroundings.—Experimental researches on the relations between arterial pressure and the amounts of chloroform absorbed: J. **Tissot**. In the case of subjects under chloroform the examination of the arterial pressure gives indications of approaching trouble earlier than the respiratory modifications, the latter only appearing when the dangerous condition is already set up.—A comparative study of the auto-conducting cage and the condensing couch in the treatment of arterial hypertension by d'Arsonvalisation: A. **Moutier** and A. **Challamel**. The results obtained with the solenoid are better than with the couch, the commonly accepted view that the two are equivalent being erroneous.—The action of radium on the torpedo fish: Maurice **Mendelssohn**.—On the tectonic of the region north of the Montagne Noire: Jules **Bergeron**.—The daily variation of temperature in the upper regions of the atmosphere: L. Teisserenc de **Bort**.

DIARY OF SOCIETIES.

THURSDAY, February 23.

Royal Society, at 4.30.—On some New Species of Lagenostoma: a Type of Pteridospermous Seed from the Coal-measures: E. A. Newell Arber.—On a New Rhabdosphere: G. Murray, F.R.S.—Two Cases of Trichromic Vision: Dr. F. W. Edridge-Green.—On Changes observable in the Liver Cells during Digestion, and their Relation to Hepatic Secretion: Prof. E. Wace Carlier.—The Colour-Physiology of the Higher Crustacea. Part III.: F. Keeble and Dr. F. W. Gamble.—Phosphorescence caused by the Beta and Gamma Rays of Radium. Part II.—G. T. Beilby.

A TEXT-BOOK OF ELECTROMAGNETISM.

Elements of Electromagnetic Theory. By S. J. Barnett, Ph.D. Pp. 480. (New York: The Macmillan Company; London: Macmillan and Co., Ltd., 1903.) Price 12*s.* 6*d.* net.

MODERN electromagnetic theory is so full of interest, and yet at the same time so full of difficulties, that every fresh attempt to present an elementary account of it in a systematic and connected form is sure to attract the attention of students who are endeavouring to gain a grasp of the fundamental principles of the subject. Such students are always looking out for a "good text-book," hoping that this book, when found, will be better adapted to their needs than those they already possess. Their desire for something better probably arises, in part, from the difficulty of the subject, and the large number of new ideas which it presents to their minds. It is perhaps too much to expect that a student should be able to gain from any single book really vivid physical conceptions of electric and magnetic phenomena and principles, for perhaps, after all, these can only gradually grow in the mind. The author of the treatise under review has, it is clear, made a serious attempt to supply the student's want, so far, at least, as the more formal theory is concerned.

The book is meant to give an introduction to the subject, and thus the author does well to keep the analytical processes within the limits which are suitable for students whose mathematical attainments do not go beyond some knowledge of the differential and integral calculus and of simple differential equations.

In the first part of the book, general electrostatic theory is treated in a fairly complete way, many problems being solved. The chapters on the conduction current, on electrolysis and on thermal and voltaic E.M.F.'s, which then follow, will be found useful. The author next introduces magnetism, the magnetic action of currents, electromagnetic induction and the magnetic effects of moving charges, and concludes with a chapter on the transference of electromagnetic energy and on electromagnetic waves.

Throughout the book the system of rational units originated by Mr. Oliver Heaviside is employed. On this system, if two unit charges are placed at unit distance apart in a vacuum, each exerts a force of $1/4\pi$ dynes upon the other. The adoption of this system banishes the great 4π from many important formulæ; for instance, on the rational system, the magnetomotive force in any circuit is numerically equal to the total current linked with the circuit, and the energy per unit volume in an electrostatic field is $\frac{1}{2}c\mathrm{E}^2$, where E is the electric force and c the specific inductive capacity. But though the 4π is driven from some formulæ it finds a refuge in others, with the result that every one of the rational units corresponding to the practical units, *i.e.* to the Coulomb, Volt, Farad, Ampere, Ohm, Gauss, Maxwell and Henry, differs from the practical unit by some power of 4π. Yet the rational system is doubtless an advantage from the point of view of pure theory, and would probably have been adopted in practice if only there had been someone to suggest it in the early days of the science. The student must remember that he is using the rational system when he compares the formulæ in this treatise with those in most other text-books.

The magnetic properties of currents are deduced from Ampère's result that the mechanical action experienced by a circuit carrying a current I is the same as it would experience if each element of length $d\mathrm{L}$ were acted on by a force $\mathrm{IB}\sin\theta.d\mathrm{L}$, where B is the magnetic induction and θ is the angle between $d\mathrm{L}$ and B; the direction of the force is at right angles to both $d\mathrm{L}$ and B. In this way the idea of the equivalent magnetic shell is avoided, and, in fact, we have found no mention of a magnetic shell in the book. Yet the ideas which group themselves round a magnetic shell and the solid angle subtended by it are of real assistance, and are not easily replaced.

The book, for the most part, goes over well worn ground, and thus the reviewer's attention is naturally directed more to the treatment of the various propositions than to the propositions themselves. The treatment is generally fresh and vigorous, but in a few instances is hardly satisfactory. Taking the electrostatic field due to a point-charge, the author considers the equilibrium of a portion of the field bounded by an elementary circular cone and two concentric spheres, and shows that the tension along the lines of force requires a pressure of equal amount at right angles to them. The result is extended to the general case by the remark that "since the field within the element of volume is uniform when the element is made indefinitely small, and since this is true of any electric field, the result just obtained for a radial field holds universally."

The attempt to establish a general result by the consideration of a single special case is seldom satisfactory. In the present instance the student would not fail to notice that the method which succeeds for the non-uniform field within the conical element will not apply if the tube of force is a circular cylinder so that the field within the element is really uniform.

In chapter xiii. "the coefficient of self induction (L) of a coil or circuit is defined to be the quotient of the coil flux, N, due to the coil's own magnetic field divided by the current I in the coil." This is the way in which the coefficient is usually defined, but it is an exceedingly unsatisfactory way, for unless the conductivity of the wire be infinite, lines of magnetic induction penetrate the wire, and then it becomes difficult to understand what is meant by the "coil flux." It is impossible to escape from the difficulty by supposing the wire to become infinitely thin, for the only result of this is to make L become infinite.

Later in the chapter the coefficient of self induction is defined by means of the expression ($\frac{1}{2}\mathrm{LI}^2$) for the energy of the system. It would be preferable to follow

T

Maxwell and to adopt this definition at the outset, for it is from the value of the energy that the coefficient is always calculated.

The methods of vector analysis are so useful in electromagnetic theory and present so little difficulty that the reader naturally expects to find them used in a book which is intended to present a "thoroughly modern introduction" to that theory. The author makes a slight use of this analysis in his later chapters, but in the case of vector products adopts a hybrid notation. In the true vector analysis, as used by Heaviside, if the vector product of the two vectors **A** and **B**, which make an angle θ with each other, be the vector **C**, the result is denoted by

$$\mathbf{C}=\mathrm{V}\mathbf{AB},$$

while the magnitude (C) of the product is given by

$$C=AB \sin \theta.$$

In the author's notation the relation between **C**, **A** and **B** is expressed by

$$C=\mathbf{v}AB \sin \theta,$$

the letter **V** serving to indicate that **C** is at right angles to the plane of **A** and **B**. It is difficult to see that this hybrid notation has any advantage over Heaviside's.

A few misprints have been noticed in a list sent out by the author; only a few others have been detected.

The reader has probably already gathered from this review that the treatise can hardly be described as that "good text-book" for which the student searches. Yet it is undoubtedly a useful book, and with a little modification and revision would be one of the best books of its class. The student who is fortunate enough to have it at hand will often turn to it with profit.

G. F. C. SEARLE.

ASTRONOMICAL LECTURES AT CHICAGO.

Astronomical Discovery. By Herbert Hall Turner, D.Sc., F.R.S., Savilian Professor of Astronomy in the University of Oxford. Pp. xi+225. With plates. (London: Edward Arnold, 1904.) Price 10s. 6d. net.

THE object of this book and the reason for its appearance are explained in a short preface. The purpose is "to illustrate by the study of a few examples, chosen almost at random, the variety in character of astronomical discoveries." The words "almost at random" seem a little out of place, for we learn that the book comprises the matter that was originally delivered in a series of lectures to the University students of Chicago, at the hospitable invitation of President Harper. The expression is probably not to be taken too seriously. It is not likely that a distinguished astronomer, enjoying what may be regarded as a cathedral position, would be careless in the preparation of his material. He would be anxious to give his best, both for the credit of English astronomy and for his own reputation. There is ample internal evidence, not only that the lectures were carefully prepared, but also of judicious selection.

The subjects chosen are about equally distributed between those that are made at the telescope and those that have resulted from the discussion of the observations so made. This will be seen from a list of the several chapters or lectures—(1) Uranus and Eros, (2) discovery of Neptune, (3) Bradley's discoveries of aberration and nutation, (4) accidental discoveries, (5) the sun-spot period, and (6) the variation of latitude. Some subjects which might have been expected to find a place, such as the discoveries resulting from the application of the spectroscope, have been omitted, but the list is sufficiently varied, and we gratefully acknowledge having received a considerable amount of pleasure from reading the well-known and familiar tales, treated, as they are, with the brightness and acuteness characteristic of the author.

The choice of the discovery of Uranus permits a well-deserved tribute to be paid to the memory of the elder Herschel for the keenness, assiduity and patience which mark the work of that astronomer; while the mention of Eros allows something to be said of the problem of the sun's distance and of the history of those times when the discovery of a small planet added something to the reputation of the lucky discoverer. The Savilian professor has some amusing remarks on the subject of naming the host of small planets that diligence has added to our catalogues. He quotes the case of Victoria as giving rise to an outcry by foreign astronomers, who objected to the name of a reigning sovereign being found in the list. But the real struggle of the purists was, we believe, over the christening of Fortuna, which Airy happily settled in favour of the discoverer's choice, by aptly quoting the well known lines of Juvenal:—

"Nullum numen habes si sit prudentia
Sed nos te facimus fortuna deam, cæloque locamus."

The second chapter or lecture is probably the least satisfactory in the book. The tale might have been told without parading the old scandal of sixty years ago to such wearisome length. Controversy seems out of place in lectures of this character. Prof. Turner in reopening the old sore has apparently two objects, the one, the whitewashing of Airy, and the other, the besmirching of Challis' reputation. Very hard things are said of the latter to which we do not wish to give further currency by repeating, but on the subject of Challis' lectures we doubt whether the words given in Airy's "Life" will bear the construction put upon them by Prof. Turner. There is no evidence to show, or at least the author has not produced it, that Airy's opinion was different in 1844 from what it was in 1834, when he wrote to the Rev. T. J. Hussey: "I am sure it could not be done (predict the place of the disturbing planet) till the nature of the irregularity was well determined from several successive revolutions" (of Uranus), p. 43. Airy, it may be suggested, did not believe the problem soluble until he received Le Verrier's memoir in 1846.

The account of Bradley's discoveries is excellent, and the feature in it which will be especially valued is the brief history given of the Rev. James Pound, Bradley's maternal uncle. The reputation of Pound has been overshadowed by that of his more brilliant, but perhaps less versatile, nephew, and it is most desirable to give the uncle his proper position. The whole chapter constitutes a most delightful piece of biography.

The accidental discovery of a "new star" does not differ materially from that of a planet, and the author admits that this fourth chapter might very well have been the first of the series, but we agree with him that it is not a matter upon which to lay any particular stress. The particular discovery is only a peg on which to hang the remarks that the author wishes to make on certain subjects. In this case the discovery of the "new star" in Gemini, at Oxford, by means of photography, serves to introduce an account of the International Chart of the Heavens, and some remarks connected with the behaviour of Nova Persei. This chapter presents a careful examination of the facts and suggestions that have been brought to light by observation. The history of Schwabe and his work on sun-spots do not call for any particular remark. The chapter is not long, and it covers the ground very satisfactorily. In the last lecture, Prof. Turner gives an account of the variation of latitude, wherein he is seen quite at his best. The subject is not so hackneyed as some of the other selections, but to speak to Americans of the work accomplished by Mr. Chandler was, no doubt, inspiring, and the successive steps by which Mr. Chandler established his case are described with clear, logical sequence. Usually the author ends his lecture by pointing out what particular lessons are to be drawn from the discovery under examination, and they generally amount to this, that there is no line of research, however apparently unimportant or monotonous, which can be safely neglected. Some inquiries seem to offer a more immediate prospect of success, such as the establishment of observatories in the Southern Hemisphere, to make accurate observations on the motion of the Pole; but at the same time unexpected discoveries may lie in a direction precisely opposite to that indicated by the most educated opinion at present available. The conclusion may be obvious, but the remark is not unnecessary. To be led too strictly by authority is unwise, to neglect the teachings of experience is a crime.

W. E. P.

ZOOLOGICAL RESULTS.

Zoological Results based on Material from New Britain, New Guinea, Loyalty Islands and Elsewhere, collected during the Years 1895, 1896, *and* 1897, *by Arthur Willey, D.Sc.Lond.* Parts i.–vi. Pp. vi+830; illustrated. (Cambridge: University Press.)

THIS splendid series of "zoological results" should have been recognised at an earlier date in our columns, but the six volumes have appeared through a lustrum of five years, and the fine series of memoirs has mounted up to a total which baffles reviewing. As Balfour student of the University of Cambridge, Arthur Willey went in 1894 to the Pacific in search of the eggs of the pearly nautilus. He found these, but so much more of great interest, *e.g.* as to Peripatus, Amphioxus, Balanoglossus, Ctenoplana, that his tenure of the Balfour scholarship was on two successive occasions judiciously extended for a year beyond the allotted triennium. In his arduous but well rewarded explorations, Dr. Willey was aided by the Government Grant Committee of the Royal Society, who may congratulate themselves on the fact that the money at their disposal was never better spent than on this enterprise. It has seldom been the happy fortune of a single zoologist to bring together in a short span such rich material, including some of the most interesting zoological types.

In part i. Dr. Willey describes the structure and development of *Peripatus novae-britanniae*, n.sp., and in so doing throws some fresh light on the heterogeneity of the class Onychophora, which this "delightful creature" represents. Dr. Paul Mayer describes a new caprellid; Mr. G. A. Boulenger discusses a very rare sea-snake (*Aipysurus annalatus*) from the South Pacific; Mr. R. I. Pocock reports on the centipedes, millipedes, scorpions, Pedipalpi, and spiders; and Dr. Sharp gives an account of the phasmids, with notes on their remarkable eggs.

In part ii. Prof. Hickson reports on Millepora, showing that the single species (*M. alcicornis*) illustrates that great variability in the form of growth which is a characteristic feature of the genus. Prof. Jeffrey Bell discusses the echinoderms (other than holothurians, which are dealt with separately by Mr. F. P. Bedford). Mr. Arthur E. Shipley reports on the sipunculoids, Mr. J. Stanley Gardiner on the solitary corals and on the post-embryonic development of Cycloseris, Mr. Beddard on the earthworms, and Miss Isa L. Hiles on the Gorgonacea, which includes some interesting new species.

In part iii. Dr. Gadow has an interesting essay on orthogenetic variation in the shells of Chelonia, that is to say, cases in which the variations from the normal type seem to lie in the direct line of descent; Dr. Willey describes three new species of Enteropneusta, and develops several theories, *e.g.* that the gill-slits arose originally as perforations in the inter-annular grooves for the aëration of the gonads which occupied the dividing ranges; and Mr. A. E. Shipley reports on the echiurids, making a welcome attempt to revise the group and to determine its geographical range.

In part iv. Mr. Stanley Gardiner describes the structure of a supposed new species of Cœnopsammia from Lifu, and comes *inter alia* to the striking conclusion that the so-called endoderm in Anthozoa, giving rise to the muscular bands and generative organs, and performing also the excretory functions, is homologous with the mesoderm of Triploblastica. In terms of the layer theory, of whatever value it may be, the actinozoon polyp must be regarded as a triploblastic form. Dr. Sharp reports on insects from New Britain, Mr. L. A. Borradaile on Stomatopoda and Macrura from the South Seas, Mr. Walter E. Collinge on the slugs, Mr. E. G. Philipps on the Polyzoa, Miss Laura Roscoe Thornely on the hydroid zoophytes, and Mr. J. J. Lister describes a remarkable type of a new family of sponges (*Astroclera willeyana*), a very interesting novelty. Mr. W. P. Pycraft discusses the pterylography of the Megapodii, Prof. Hickson and Miss Isa L. Hiles the Stolonifera and Alcyonacea, and Dr. Ashworth the Xeniidæ.

In part v. Mr. Arthur E. Shipley gives a description of the Entozoa which Dr. Willey collected during his sojourn in the western Pacific, including *Porocephalus tortus*, Shipley, a member of the interesting family Linguatulidæ. Mr. R. C. Punnett discusses some South Pacific nemertines, Mr. L. A. Borradaile has an interesting note on the young of the robber crab, Miss Edith M. Pratt describes the structure of *Neohelia porcellana*, Mr. Boulenger reports on a new blind snake from Lifu, and the Rev. T. R. R. Stebbing deals with the Crustacea.

Part vi. contains Dr. Willey's contributions to the natural history of the pearly nautilus—a fine piece of work—and his personal narrative, which is not less creditable. In his narrative, amid interesting details of how he went about his collecting business, he discusses, as a zoologist, his new Peripatus, the Ascidian *Styeloides eviscerans*, which readily throws out its entrails in holothurian fashion, the interesting intermediate type Ctenoplana, "which no zoologist could encounter without experiencing a momentary thrill of satisfaction," the lancelets and enteropneusts which he observed, some of the remarkable new forms which he discovered, such as Astroclera, and the egg-laying of nautilus—his main quest. The whole story reflects great credit on the indefatigable explorer himself and on those who have assisted him in working up the descriptions which form this imposing six-volume series of zoological results.

OUR BOOK SHELF.

Flora of the County Dublin. By Nathaniel Colgan. Pp. lxx+324. (Dublin: Hodges, Figgis and Co., Ltd., 1904.)

IN many respects this district is an interesting one, and the floral distribution not quite what might have been expected from a consideration of the adjacent counties. The flora resembles that of southern rather than northern Britain, but the somewhat unexpected result is arrived at that the western Irish flora has a considerably larger proportion of northern plants than has the corresponding eastern flora. The book opens with a summary of previous work in the district from the fifteenth century to the present day. The physical features are then described, and a section headed "Relations of Plants and Soils" lays particular emphasis on the distinction between "calcifuges" and "calcicoles."

Some plants curiously absent from the county are mentioned, one of which, *Nymphaea alba*, L., occurs in Meath, Kildare, and Wicklow. Both *Trifolium repens*, L., and *T. dubium*, Sibth., are stated to do duty as the shamrock or shamrogue. Probably *Oxalis acetosella*, L., has never served as the Irish national badge, this erroneous impression apparently dating from a paper by J. E. Bicheno published in 1830. Mr. Colgan cannot add *Epilobium tetragonum*, L., to the Irish list, although *E. obscurum*, Schreber, is common in the upland districts. A description of that interesting hybrid *Senecio Cineraria*, D.C., × *S. Jacobaea*, L., is given. The belief that one of its forms is identical with the Italian *S. Calvescens* must be abandoned if Sig. Sommier's conclusion that this last plant is *S. Cineraria* × *S. erraticus*, Bertolini, be accepted. It is decidedly suggestive to find that our common *S. Jacobaea* hybridises so much more readily with an alien species than with its fellow Senecios of the British Isles. Another curious fact concerning hybrids deserves mention. The common cross *Primula veris* × *vulgaris*, as found in Kenmure Park and in several other localities, approaches very nearly to the primrose, while the Ballinoscorney plant closely resembles the cowslip. This curious state of affairs demands experimental investigation. Space limitations forbid mention of any more of the numerous points of general botanical interest contained in the volume.

The author is to be congratulated on having produced something far more useful than the mere catalogue of names and places sometimes dignified by the title "County Flora." Particularly pleasing is the attention paid to local names, given in the Irish-Gaelic characters. It is rather surprising that philologists do not devote more study to local and often rapidly disappearing dialects. The botanist working a country district is exceptionally well placed for collecting information on such subjects, and might with advantage make use of his opportunities.

Exercises in Practical Physiological Chemistry. By Sydney W. Cole, M.A. Pp. vii+152. (Cambridge: W. Heffer and Sons; London: Simpkin, Marshall and Co., Ltd., 1904.) Price 5*s*. net.

Practical Exercises in Chemical Physiology and Histology. By H. B. Lacey and C. A. Pannett, B.Sc. Pp. 112. (Cambridge: W. Heffer and Sons; London: Simpkin, Marshall and Co., Ltd., 1904.) Price 2*s*. net.

NOTHING more forcibly illustrates the growing importance attached to the chemical side of physiology than the institution of practical courses dealing with this branch of the subject in centres of physiological teaching. Accompanying this is a multiplication of practical guides. Every teacher has his idiosyncrasies in the exercises he selects for his classes, but one is inclined to doubt whether these are always sufficiently pronounced or important to justify him in issuing a fresh handbook. Competition, however, is not to be despised, and will in the end lead to the survival of the fittest. In the struggle, Mr. Cole's little book, which represents the Cambridge course, will doubtless maintain its own. Though short it is admirably clear, and the practical exercises are judiciously selected. The author is well known for his researches in physiological chemistry, and possesses that preliminary knowledge of pure chemistry which is so necessary nowadays for a successful pursuit of its physiological application.

The book is free from illustrations; the student is required to make his own drawings of crystals, absorption spectra, and so forth in the blanks left for the purpose. This is an admirable idea, and one hopes that the zealous and interested care that Mr. Cole asks from the students in his preface will be responded to in the manner he desires.

The book does not pretend to be complete, but as an elementary introduction to more advanced work it is excellent. I do not propose to direct attention to faults of omission, for these are obviously intentional; the only fault of commission I have discovered is on p. 78, where the statement made implies that potassium ferricyanide contains oxygen.

The second book, that by Messrs. Lacey and

Pannett, demonstrates that practical classes in physiology are not confined to universities and colleges of university standard. The book itself is not a serious contribution to scientific literature, and its authors have neither the requisite training nor knowledge to make it such. It is a mere compilation or *rechauffé* from other well known text-books. One notes that one of the authors blazons upon the title-page that he has obtained a scholarship at the inter. M.B. examination at the University of London, and this is a fair index of what the reader may expect in the interior of the volume. A note-book carefully kept by any moderately good medical student would be equally worthy of publication.

W. D. H.

Laboratory Notes on Practical Metallurgy: being a Graduated Series of Exercises. Arranged by Walter Macfarlane, F.I.C. Pp. x+140. (London: Longmans, Green and Co., 1905.) Price 2s. 6d.

THIS little book is apparently intended as a first course for beginners in practical work in a metallurgical laboratory, and especially for those who are preparing for the examination of the Board of Education in stages 1 and 2 of practical metallurgy. For these classes of students it will be useful and deserves commendation.

It consists of a series of practical exercises, all well within the grasp of the average boy, graduated and arranged with the view of developing the habit of observation, and the instructions given for doing them show a much more intimate acquaintance with the simpler operations of a metallurgical laboratory than is generally found in works of this class. In the first eighteen pages the student is introduced to furnace work by simple experiments on the melting of metals under various conditions, to prepare him for the subsequent more difficult operations.

The preparation of the ordinary common alloys follows, and then a series of well-chosen exercises illustrates the oxidation of metals and the reduction of metallic oxides and sulphides. Later, the more complex subject of the principles on which the processes for the extraction of copper, lead, gold, and silver from their ores depend is dealt with.

The book concludes with a few elementary exercises in assaying gold and silver ores, and the analysis of coal and coke. In the appendix are several tables, the most important being one giving the percentage composition of some of the common alloys.

There are a few slips and blemishes in the text, but they are for the most part trivial, one of the chief being in the table just mentioned, in which the composition of the British gold coinage is given as gold 91.66, silver 8.33; the latter should of course be "copper." The book contains much useful information for junior students, and can be recommended for their use.

Le Liège. Ses produits et ses sous-produits. By M. Martignat. Pp. 158. (Paris: Gauthier-Villars and Masson et Cie.) Price 2.50 francs.

THE latest addition to the "Encyclopédie Scientifique des Aide-Mémoire" is divided into two parts. The first part is concerned with the formation of cork in *Quercus suber*, the distribution of the tree, its treatment, its maladies and enemies, &c., and concludes with an account of prices and other commercial considerations. The second part describes how the natural product is treated in the manufacture of corks of all kinds, and how it is utilised in the production of linoleum and other materials.

LETTERS TO THE EDITOR.

Charge carried by the α Rays from Radium.

No special difficulty has been experienced in showing that the β particles (electrons), expelled from radium, carry with them a negative charge of electricity. The positive charge left behind on the vessel containing the radio-active material is simply and strikingly illustrated in the arrangement devised by Strutt, which is now popularly known as the "radium clock."

Since the α particles are deflected by a magnet as if they carried a positive charge, it is to be expected that this charge should be easily detected; but all the initial experiments made for this purpose resulted in failure. Since there are four products in radium which give out α particles, and only one which gives out β particles, it is theoretically to be expected that four α particles should be expelled from radium for each β particle.

In the Bakerian lecture (*Phil. Trans.*, series A, vol. cciv., p. 212, 1904) I described some experiments that were made to determine the charge carried by the α particles. About half a milligram of radium bromide was dissolved in water, and spread uniformly over a metal plate and evaporated to dryness. With a plate of 20 sq. cm. in area, the absorption of the α rays in the thin film of radium bromide is negligible. The solution of the radium released the emanation, and, several hours after removal, the activity of the radium fell to about one-quarter of its maximum value, and the β and γ rays from it practically disappeared. The experiments were made with the radium film at this minimum activity, in order to avoid the complication which would ensue if the β particles were present. An insulated plate was placed parallel to the radium plate and about 3mm. away from it. The apparatus was enclosed in an air-tight vessel, which was exhausted to a very low vacuum. The current between the plates was measured by an electrometer. The saturation current between the plates rapidly fell with decrease of pressure, but soon reached a limiting value—about 1/1000 of the initial—which could not be reduced further, however good a vacuum was obtained. No certain evidence that the α particles carried a positive charge could be obtained. It was thought possible that the inability to reduce the current below this value might be due to a strong secondary radiation, consisting of slow-moving electrons, which were liberated by the impact of the α particles on matter. Strutt (*Phil. Mag.*, August, 1904) has also observed a very similar effect, using a plate of radio-tellurium, which is well suited for this purpose, as it gives out only α rays.

J. J. Thomson (*Proc.* Camb. Phil. Soc., November 14, 1904; see NATURE, December 15) has recently shown in a striking manner that a large number of slow-moving electrons are liberated from a plate of radio-tellurium, although this substance is supposed to emit only α particles. These electrons could be readily bent back to the plate from which they came by the action of a magnetic field. No indication, however, that the α particles carried a charge was obtained.

I have recently attacked this problem again, using the methods and apparatus previously described, but, in addition, employing a strong magnetic field to remove the slow-moving electrons present with the α particles. The apparatus was placed between the pole-pieces of an electromagnet, so that the field was parallel to the plane of the plates. In such a case, most of the escaping electrons describe curved paths and return to the plate from which they set out. On application of the magnetic field, a very striking alteration was observed in the magnitude of the current. The positive and negative currents for a given voltage were greatly reduced. The upper plate, into which the α particles were fired, rapidly gained a positive charge. In a good vacuum, this was the case whether the lower plate was charged positively, or negatively, or connected to earth. The magnitude of the charge, deduced from these experiments, was found to be practically independent of the voltage between 0 and 8 volts. When once a magnetic field had been applied, of sufficient strength to stop all the slow-moving electrons, a large increase in its value had no effect on the magnitude of the positive charge. I think these experiments undoubtedly show that the α particles do carry a positive charge, and that the previous failures to detect this charge were due to the masking action of the large number of slow-moving electrons emitted from the plates.

Observations were made under different experimental conditions, and with very concordant results. In one set of experiments a weight of 0·19 mg. of radium bromide was used, spread on a glass plate, which was covered with a thin sheet of aluminium foil; in the other 0.48 mg., spread on an aluminium plate. The saturation current due to the latter plate, measured between parallel plates 3·5 cm. apart by means of a galvanometer, was found to be $7{\cdot}8 \times 10^{-8}$ amperes. It is possible that the failure of Prof. Thomson to detect the positive charge carried by the α rays from radio-tellurium was due to the smallness of the effect to be measured; for with the plate of radio-tellurium in my possession, the current was only about 1/40 of the above value.

Since the film of radium bromide is so thin that all the α particles escape from its surface, it is easy to deduce from the observed charge from a known weight of radium the total number of α particles expelled per second from one gram of radium bromide. Taking into consideration that half of the α particles were projected into the radium plate, and assuming that the α particle carries the same charge as a gaseous ion, it was deduced that one gram of radium bromide emits $3{\cdot}5 \times 10^{10}$ particles per second. Now the activity of radium bromide in radio-active equilibrium is four times this minimum, and contains four products which emit α particles at the same rate. It is thus probable that one gram of radium bromide in radio-active equilibrium emits $1{\cdot}4 \times 10^{11}$ particles per second. I had previously deduced (*loc. cit.*), from indirect data, the value about $1{\cdot}1 \times 10^{11}$, so that the theoretical and experimental numbers are in very good agreement.

I have also made experiments, by a special method, to determine the total number of β particles emitted from one gram of radium bromide in radio-active equilibrium, and have found a value about the same as the number of α particles emitted at its minimum activity. It is thus seen that four α particles are expelled from radium for each β particle. The number of β particles obtained by Wien was much smaller than this, but, in his experiments, a large proportion of the more slowly moving β particles was absorbed in the radium itself and in the envelope enclosing it.

The number of α particles expelled per second from one gram of radium is a most important constant, for on it depends all calculations to determine the volume of the emanation, and of helium, the heat emission of radium, and also the probable life of radium and the other radio-elements.

E. RUTHERFORD.

McGill University, Montreal, February 10.

Compulsory Greek at Cambridge.

THE conclusion to be drawn from Mr. Bateson's letter seems to be that it is useless to compel candidates to get up subjects for which they have no aptitude, or in which they take no interest. The glories of "another world," whether in science or art, are reserved for those that can see them, and a bright boy, not to say a dull one, is unlikely to discover the beauties of compulsory Greek, if he happens to have a distaste for dead languages. But is it not rather a narrow view which recognises only one new world and the entrance to it through compulsory Greek? It is said of a great creative mathematician that surveying his subject from a high pinnacle of abstract thought, he exclaimed, "And we too are poets"; but the most enthusiastic would scarcely expect this feeling to be aroused by compulsory mathematics in a dull boy; it does not seem to have occurred even to an exceptionally bright one.

Sullied, as Mr. Bateson seems to consider mathematics, by a degrading usefulness to "trade and professions," it nevertheless remains of essential importance to nine-tenths of our scientific work, and most of those of us who have but little of it sigh that we have not more. Mr. Bateson himself has not disdained its assistance in his work on breeding and heredity.

The point of previous letters is not that the writers had no aptitude for Greek, but that they found it useless to them in the studies to which they devoted their life. German is indispensable; soon we shall have to read Russian too, and if a man is to keep abreast of his subject he must not only read German, but read it with ease, so great is the bulk of literature to be got through. Arbitrarily to compel a boy to learn Greek, which, if he does not appreciate it, will be perfectly useless to him, when he might be learning German, which, whether he likes it or not, is indispensable for the full pursuit of his scientific studies, seems to be one of the cruellest conceivable tyrannies of pedantic folly. Could there be greater intellectual waste, and could any means be designed more likely to defeat the end for which it is designed? Compulsion and education are terms as opposed philosophically as they are etymologically; let the student be encouraged to work at the subjects he has really at heart and he will proceed from one success to another, and may even find his training in natural science leading him to the higher things in Greek literature.

But since the most natural classification of candidates would seem to be into those having a tendency to exact thought—who will naturally gravitate towards mathematics, and those with a love of art—who will naturally aspire to literature, and those with a little of both—who will be given over to natural science, why not allow a first class in any two of the three to count as a pass? such a measure would prove a great relief both to congenital non-mathematicians and non-linguists.

Finally, why should a want of sympathy with Greek, the noblest language of the noblest literature the world has known, be imputed to those who think that it is too good a thing to be wrested to injurious purposes?

X.

IF Mr. Bateson's case is that of hundreds, I make bold to say the case of the boy who wastes hundreds of hours on Greek grammar is that of thousands.

We do not want to abolish compulsory Greek because it has no value in the market, but because, stopped where the boy who takes it no further than the Little-Go stops it, the study of Greek has no value, ninety-nine times out of a hundred, in the forming of an active, living intelligence.

Mathematics may have contributed nothing to the formation of Mr. Bateson's mind; it is not unlikely, though it is deplorable. But if Mr. Bateson seriously thinks that elementary mathematics contributes no more than elementary Greek to the sound training of an average mind, surely he is curiously destitute in experience of the run of faculties in a young human being. This explanation of Mr. Bateson's astonishing argument suggests itself the more readily, because his idea that Greek is one of the things that put "one touch of art in the life of a dull boy, and open his eyes to another world," appears absolutely grotesque.

The narrow (and conspicuously *unintelligent*) utilitarian idea of education represented by Mr. Bateson's "intelligent lady" must be fought with all our strength, but it cannot be fought successfully with the rusty sword of Mr. Bateson's reactionary classicism. That is a weapon which will break in our hands and leave us defenceless to the spoiler.

A. G. TANSLEY.

New University Club, London, S.W., February 23.

MAY I be permitted to suggest, with all deference, that Mr. Bateson's statement that his knowledge of mathematics is "*nil*" must be taken *cum grano*! He is now, I believe, largely engaged in the business of counting chickens before they are hatched. How could he do this without some mathematics? As a matter of fact, the research in which he is engaged involves mathematical conceptions of no mean order, yet I presume he knows something about his subject.

Mr. Bateson's letter might be a good argument in favour of lowering the mathematical standard in the previous examination. But, as he uses it, it is merely an unusually frank example of the reasoning which is the real support of compulsory Greek, *viz.*, "When I was a little boy the big boys bullied me; now that I am a big boy myself I mean to take it out of the little ones!"

EDWARD T. DIXON.

Racketts, Hythe, Hants, February 24.

A Large Indian Sea-Perch.

THE dimensions and weight of a sea-perch caught in December last by some native fishermen near Diamond Harbour in the River Hooghly seem to me to be worth recording.

Its length is nearly seven and a half feet, its girth just behind the shoulder is a little more than five feet nine inches, and its weight, the day after its capture, was four hundred and sixty pounds.

The fish is so old and worn that its specific identity must remain in doubt, but it agrees fairly well with Day's description, in the "Fauna of British India," of *Epinephelus lanceolatus*, Bloch.

The largest Indian sea-perch of which I can find any record is the one mentioned by Russell (quoted by Day under *Epinephelus pantherinus* and *malabaricus*), which was taken at Vizagapatam in January, 1786, and measured seven feet in length, five feet in girth, and weighed upwards of three hundred pounds.

The scales of the Diamond Harbour monster are so altered by deposit that their accretion lines are very difficult to follow; but in a large scale from the shoulder I can count between 500 and 600 such lines, which are sometimes grouped in series of about eight, but oftener show no grouping at all. A. ALCOCK.

Indian Museum, Calcutta, February 2.

Attractions of Teneriffe.

THOSE members of the British Association who visit South Africa this year will probably desire to spend as much time as they can near their journey's end. But it is just worth mentioning that some of the oceanic islands en route have very special attractions. For instance, I write from Teneriffe, which has igneous rocks, cinder cones, and lava streams for the geologist; and for the botanist all zones of vegetation from the subtropics to the snows. The scientific literature of the island is at present more in German than in English. A single day's excursion, 2000ft. up into the hills by electric tram, is possible whilst the steamer waits to coal. A week would allow of a short tour to Orotava and across the mountains to Guimar, through some of the most interesting parts of the island.

HUGH RICHARDSON.

SAMUEL PEPYS AND THE ROYAL SOCIETY.

MAGDALENE COLLEGE, Cambridge, with which the name of Samuel Pepys is indissolubly associated, held in his memory at the college on Thursday last, his birthday, a reunion which may become an annual event. Some of the institutions with which he was more especially connected were invited to send delegates to this gathering. Thus the Royal Society was represented by one of its secretaries and its foreign secretary. From the immortal Diary it appears that the first proposal that Pepys should join that Society was made to him in the spring of the year 1662 by his friend Dr. Timothy Clerke, who offered to bring him "into the College of Virtuosos and my Lord Brouncker's [P.R.S.] acquaintance, and to show me some anatomy; which makes me very glad, and I shall endeavour it when I come to London." Two years, however, elapsed before his election. From the minute-books of the Society it appears that he was unanimously elected and admitted on the same day (February 15, 1664)—a rapidity of procedure which contrasts with the much more leisurely action of the present day. He records that he "was this day admitted by signing a book and being taken by the hand by the President, my Lord Brunkard, and some words of admittance said to me. But it is a most acceptable thing to hear their discourse and see their experiments. . . . After this being done they to the Crowne Taverne, behind the 'Change', and there my Lord and most of the company to a club-supper."

The meetings of the Royal Society in those days must have been a good deal more lively than they are at present. Robert Hooke, the most fertile and inventive genius of his time, was then "Curator of Experiments," and brought forward at each meeting either some ingenious contrivance of his own or some device provided by one of the members. This constant and exciting variety of practical demonstration would be entirely after Pepys' heart, gratifying his spirit of curiosity and his keen desire to increase his knowledge in every direction. Another feature of the meetings could not but gratify one of his most characteristic proclivities—his sociability and love of congenial company. The evening adjournments to the "club-supper" at the Crowne Taverne behind the 'Change or to the Devil Taverne in Fleet Street would end off his day as he always delighted that it should end. These meetings for supper contained the germ of the Royal Society Club, the oldest extant records of which do not go back further than 1743. This club consists of a limited selection of fellows of the Society who still dine together at some restaurant on the evenings of the Society's meetings.

At the time of Pepys' election the Society met at Gresham College, but a few years afterwards moved to Arundel House. An effort was then being made to raise money for the purpose of building a house in which the "virtuosos" might hold their meetings and place their library and apparatus. Among the other fellows, Pepys was applied to for a subscription. Under date April 2, 1668, he writes, "with Lord Brouncker to the Royall Society, where they were just done; but there I was forced to subscribe to the building of a College and did give 40*l*."—certainly a generous donation at that time. He evidently had some reluctance to join in the scheme, for he thought that this canvassing for money "may spoil the Society for it breeds faction and ill will, and becomes burdensome to some that cannot or would not do it."

The Royal Society held its annual meeting for the election of the council and officers on St. Andrew's Day, November 30—a date which is still kept sacred for the same purpose. But some of the usages that were formerly in vogue have disappeared. Thus Pepys writes on November 30, 1668, "To Arundel House and there I did see them choosing their Council, it being St. Andrew's Day; and I had his cross in my hat, as the rest had, and cost me 2*s*." The diarist himself had already been nearly selected to serve on the council, so well did he stand in the esteem of his fellow members. Only three years and a half after his admission into the Society he records that "I was near being chosen of the Council, but am glad I was not, for I could not have attended, though, above all things, I could wish it; and do take it as a mighty respect to have been named there."

At last, at the end of twenty years from the time of his entry into the Royal Society, his associates showed the estimation in which they held him by electing him President on December 1, 1684. He was the sixth who filled that office in the history of the society. The council minute-book shows that he obtained twenty-nine votes out of thirty-nine, and that he was sworn in upon December 10. The council included at that time Sir Christopher Wren, Dr. Martin Lister, Robert Hooke, E. Halley, John Flamsteed (Astronomer Royal), John Evelyn, and Sir John Hoskyns. The difficulty which Pepys would have had in attending the meetings of council appears to have still continued after his election to the presidency, for he was only occasionally able to be present. Unfortunately, the Diary, which gives such a full and faithful record of his daily life, stops short long before the date of his election to the chair of the Royal Society, so that we are without any memoranda of his own regarding what took place during his tenure of the office. The minute-books of the Society, however, furnish some interesting particulars.

One of the undertakings of the Royal Society during the time that Pepys presided over its business was the publication of the elaborately illustrated work of Francis Willughby, the "Historia Piscium." It was a somewhat costly production, so that several members of the Society agreed to subscribe for one or more plates, which were to be supplied at the cost of one guinea each. Pepys far surpassed all other subscribers in his generosity, seeing that he paid for no fewer than sixty plates. The book is appropriately dedicated to him, and when it was ready for issue the council, to mark its appreciation of his assistance (June 30, 1686), "ordered that a Book of Fishes, of the best paper, curiously bound in Turkey leather, with an inscription of dedication therein, likewise five others bound also, be presented to the President." On the same occasion the following amusing entry was made on the minutes:—"Ordered that the Society to encourage the measuring a Degree of the Earth do give E. Halley 50*l.*, or fifty Books of Fishes (!) when he shall have measured a degree to the satisfaction of Sir Christopher Wren, the President and Sir John Hoskyns." There is no record to show which alternative the future Astronomer Royal accepted.

Undoubtedly the most important event which occurred at the Royal Society during Pepys' term of office was the acceptance and publication of Newton's immortal "Principia." In the MS. journal-book of the Society under date April 28, 1686, it is recorded that Dr. Vincent "presented the Society with a manuscript Treatise intituled *Philosophiae Naturalis Principia mathematica,* and dedicated to the Society by Mr. Isaac Newton wherein he gives a mathematical demonstration of the Copernican hypothesis, as proposed by Kepler, and makes out all the phenomena of the celestial motions by the only supposition of a gravitation towards the centre of the sun, decreasing as the square of the distances therefrom reciprocally. It was ordered that a letter of thanks be wrote to Mr. Newton and that the printing of the book be refer'd to the consideration of the Councell; in the mean time the book to be put into the hands of E. Halley, who is to make a report thereof to the Councell." On May 19 it was "ordered that Mr. Newton's book be printed forthwith in a quarto of a fair letter, and that a letter be written to him to signifie the Societye's resolution, and to desire his opinion as to the print, volume, cutts and so forth." On June 30 the council ordered "that the President be desired to licence Mr. Newton's book, dedicated to the Society." Accordingly the title-page of the famous quarto bears the licence in conspicuous print—"Imprimatur, S. Pepys, Reg. Soc. Praeses, Julii 5, 1686."

Pepys held the office of president for two years, and was succeeded on St. Andrew's Day, 1686, by the Earl of Carbery, by whom he was named one of the vice-presidents. Though not in any sense a man of science, he was distinguished among his contemporaries for his keen interest in scientific progress and his eager desire to acquire as much as he could of "natural knowledge." Though careful of his money, he could be generous where the interests of science appealed to him. The absorbing character of his work at the Admiralty and the enthusiastic devotion with which he applied himself to it no doubt prevented him from taking as active a share in the business of the Royal Society as he would have wished to do. But among the distinguished men who during two centuries and a half have occupied the presidential chair there have been few more entitled to kindly remembrance than Samuel Pepys.

Arch. Geikie.

COMPULSORY GREEK AT CAMBRIDGE.

It is earnestly to be desired that every member of the Senate who is on the side of the Studies and Examinations Syndicate will record his vote in favour of their proposals on either Friday or Saturday, March 3 and 4, between the hours of 1–3 p.m. or 5–7 p.m.

The proposals of the syndicate have been in many places misrepresented. The committee which is opposing them heads its manifestoes "Defence of Classical Studies at Cambridge," but no one has yet attacked these studies. It is true that the proposals allow a modern language instead of either Greek or Latin, but every candidate must take one ancient language, and whichever he elects to offer for the Previous Examination he will have in the future to show a really respectable knowledge of that tongue. At present, as is demonstrated by the students of Newnham and Girton, and many others, and as letters in Nature have shown, a mere smattering of Greek which can be "got up" in a couple of months is all that can be demanded in view of the existing state of education in our public schools.

Those who think no man can be cultivated without Greek (they do not say the same about women) often forget that the Greeks, who are held to have been incomparable educators, dispensed entirely with the study of dead or foreign languages. They did not educate their sons on a basis of ancient languages, they educated them on their own language and their own literature. The Romans, again, got on very well without studying dead languages. It is true that the educated men in ancient Rome studied the Greek authors, but Greek was to them a living language, and the intercourse between the thinkers and the doers of classical times was at least as close as between the French and British of our own day.

The supporters of the present proposals are often charged with encouraging undue specialisation. But what do we mean by specialisation? The term is usually used to denote the study of one subject to the exclusion of others. If this definition be sound it is the advocates of what is called compulsory Greek who are the culprits. A boy begins Latin, say, at eight or nine, and shortly afterwards takes up Greek, and for the next nine or ten years, at many of our public schools, does comparatively little else. He has specialised to such an extent, and his intellect is so cramped and dulled by the process, that he not unfrequently fails to reach the low standard of the Previous Examination when he leaves school. Even if he has a real gift for classics he is often but a narrow specialist. Fifty-five years ago a Mr. John Smith published in his "Sketches of Cantabs" an appreciation of the classical man of the middle of the last century. "He seldom reads an English work, and of the history of his native country is strangely, almost supernaturally, ignorant. Passing occurrences do not affect him. He doesn't care how many men are slaughtered on the banks of the Jhelum. His heart is at Marathon, his sympathies with the great Hannibal at Cannae." We have improved since then, but the type is not extinct.

It is to be regretted that the proposals do little to encourage science. It must distinctly be understood that the alternative to Greek or Latin is not science, but French or German. The papers on experimental mechanics and other parts of elementary physics, and the paper on elementary inorganic chemistry are, with three other papers, alternatives of which two must be taken.

The case for additional recognition of science has been put so well by a distinguished naturalist who was a member of the syndicate, and one of the three who did not sign the report, that we cannot do better than quote his words. "The real substitute for Greek, and the only worthy substitute as it seemed to him, was science. If they are not to meet art let them at least meet truth. Let the boys know the place man had in nature. It seemed to him shocking that they should turn out hundreds of men every year who had not the faintest idea of what was going on in nature, in combustion or chemical decomposition, and who knew nothing of the relation of man to the animal world."

The present issue does not lie between the friends of science and the friends of letters. Nearly one-third of the classical staff at Cambridge are on the side of reform, and amongst them are many of the men who have built up the present classical tripos until it is amongst the biggest of the Cambridge schools. A majority of the university professors and readers *other than those in mathematics and natural science* are on the side of the syndicate. The head masters are half-heartedly with the syndicate, a majority of the Head Masters' Conference and the Head Masters' Association desiring the exemption from Greek of candidates for honours in mathematics and science. A very large majority of the assistant masters in secondary schools are in favour of the change, and it must not be forgotten that the assistant masters have a far more intimate experience of the actual teaching of the boys than have the head masters.

A certain number of the resident members of the Senate have declared their intention of not voting. Some of these are tutors and coaches, who, while agreeing with the general principles of the report, fear that the proposed examination will be so difficult that their pupils will fail to pass. Amongst the residents who intend to vote there is now a majority in favour of the report. If the matter rested upon the Cambridge vote there is little doubt which way it would go. The result, however, rests on the vote of a large electorate of which the resident members form roughly one-tenth. From the fact that the committee for supporting the proposals has issued a very long list of supporters, and from the fact that the committee opposed to the proposals has thought it more politic to publish but a short, select list, there is a strong feeling of confidence that reform may this time win. But the duty of voting cannot be too strongly urged. A single vote may decide the issue.

FOLK-TALES OF PLAINS INDIANS.

A NOTICEABLE addition to the literature of American folk-tales has been made by two recent publications of the anthropological series of the Field Columbian Museum *Publications*. Vol. v. of this valuable series is devoted to the traditions of the Arapaho by Drs. G. A. Dorsey and A. L. Kroeber, collected under the auspices respectively of the Field Columbian Museum and of the American Museum of Natural History. The authors worked independently, and in many instances collected variants of the same tale; but they have published all as they were collected rather than amalgamate the two versions of the one legend. Certain incidents in the tales are translated into Latin, and even some whole tales are similarly translated. A synopsis is given at the end of the volume of each of the hundred and forty-six tales, a feature that will prove of great use to the student. There are one origin-myth and three or four culture-myths; a large number of the stories refer to an individual called Nihançan, whose doings were frequently of a reprehensible nature. No. 1 of vol. vii. of the same series contains a collection of forty folk-tales of the Osage by Dr. Dorsey, who admits that this collection does not adequately represent the traditions of the tribe. The Osage are of Siouan stock, and are now degenerating rapidly, as they are very lazy and much addicted to drink; further, the use of the peyote, or mescal, among them is rapidly increasing, and for these reasons there was great difficulty in engaging the attention of the old men for any length of time. In No. 20, "The Rabbit and the Picture," we have a tar-baby episode. An abstract is given of each tale.

A third collection of folk-tales by Dr. Dorsey is entitled "Traditions of the Arikara"; these were collected under the auspices of the Carnegie Institution at Washington, and the eighty-two tales constitute *Publication* 17 of that institution. The Arikara belong to the Caddoan linguistic stock, and were formerly closely allied with the Skidi band of Pawnee. Like the Skidi, they constructed the earth-lodge, and their social organisation and religious ceremonies in general were also similar. An examination of the tales shows, as might be expected, many points of resemblance with those of the Skidi (*cf.* "Traditions of the Skidi Pawnee," by G. A. Dorsey, *Memoirs* of the Am. Folk-Lore Soc., vol. viii., 1904), but it is apparent that the mythology of the Arikara contains many elements not found among the Skidi; possibly it will be found that there are Mandan affinities, but material for this comparison is not yet available. Two tales narrate the creation of the earth by the Wolf and Lucky-Man, and the creation of people by Spiders through the assistance of the Wolf. The variant tales of the emergence of the Arikara from the earth are undoubtedly original. In several tales a poor boy is a culture hero; in one case he was the son of a woman who climbed to heaven and married a star; his greatest work was freeing the land of four destructive monsters. The Sun-Boy made long life possible after a series of contests with his powerful father. Another boy, Burnt-Hands, saved his tribe from despotism and famine, and furnished by his life a perpetual example to the poor of the Arikara of the value of honest and long-continued effort. Some tales are rite-myths, as they refer to the origin of a ceremony or rite, or to incidents connected with a ceremony. In one tale is found an interesting account of the origin of the well known ring and javelin game of the plains, which is really part of the ceremonial calling of the buffalo (bison); the tale also relates the origin of the buffalo dance. Eleven tales relate to animals; in all of them the coyote plays a prominent part, always as a mean trickster, and committing deeds that generally result disastrously to himself. Several are ordinary traditions, in some of which the supernatural crops up. Abstracts are given of all the tales.

Another memoir on folk-tales, entitled "The Mythology of the Wichita," by Dr. Dorsey, forms *Publication* No. 21 of the Carnegie Institution. The Wichita are a small and dwindling tribe of Caddoan stock who differ somewhat from the surrounding plains tribes; both men and women tattoo, they are very moral and good natured, and their home life is extremely well regulated. The pursuit of the bison was secondary to that of agriculture, and, as among the Pawnee, many of their most important ceremonies were concerned with the cultivation of their fields. All the details of the grass-lodges were symbolic. The social organisation was by villages, at the head of each of which was a chief and a subchief. Election to the chieftainship was never through heredity alone; it was possible for the youngest and meanest-born boy of the village to rise to this position through bravery, generosity, and kindness. In general, the gods of the Wichita are spoken of as "dreams." The sixty tales refer to the first period or Creation, the second period or transformation, and the third period or the present. A few tunes are given by F. R. Burton. Three long Wichita tales by the same indefatigable observer will be found in the *Journal of American Folk-lore* (vol. xv. p. 215, xvi. p. 160, xvii. p. 153). Legends of ancient time were related that the listeners might realise that evil creatures and monsters and evil spirits no longer exist; they were removed from the earth and their destructive powers taken from them by Wonderful Man, who knew that the world was changing, so that human beings might be human beings, and animals exist as animals to serve as food for man. But, above all, the value of many stories for the young lay in the lesson taught by example

FIG. 1.—Hupa woman soaking acorn meal on the river shore. The meal is placed in a crater of sand, water is heated in the basket to the right by dropping hot stones into it, and the hot water is ladled out by means of a basket-cup and poured over the meal until it loses its bitter taste.

that bravery and greatness depended solely upon individual effort, and that there might befall him the same longevity and good fortune as was possessed by the hero of the tale.

In the handsome volume which contains the ninety traditions of the Skidi Pawnee collected by Dr. Dorsey, there are fifteen plates and some interesting ethnological and explanatory notes. The village was the basis of the organisation of the Skidi, no trace of the clan having been found. Each village possessed a sacred bundle, and marriage was endogamous in each village. The religion of the Pawnee reached a higher development than that of any other of the plains tribes, and its ceremonial side was especially developed among the Skidi. Each bundle ceremony and each dance was accompanied, not only by its ritual, but by its tale of origin, and all of these are regarded as personal property. Dr. Dorsey makes some interesting remarks upon the ownership and telling of the tales. Of these some are cosmogonic; a number tell of boy heroes in which the path to renown is due to fixity of purpose and a humble spirit. Numerous tales relate to the tricky coyote; these are told whenever the men assemble during the winter months, but never during the summer, or rather during those months when snakes are visible, for at such times the Coyote-Star directs the Snake-Star to tell the snakes to bite those who talk about the coyote. In one group of tales there is a marriage between humans and animals, or the transformation of a man into an animal.

The first volume of the University of California *Publications*, American archæology and ethnology, contains a study of the Hupa by Mr. P. E. Goddard. The Hupa Indians occupy the beautiful lower valley of the Trinity River; so secluded was it that sixty years ago the news of the coming of the white man had not reached the inhabitants. The people seem to have lived a simple, peaceable life; their social organisation was very simple, but more information is required. A family consisted of a man, his wife or wives, his sons and their wives, the unmarried and half-married daughters and unmarried or widowed brothers and sisters of the man and of his wife. There appears to have been a classificatory system of relationship. The next social unit was the village; a man lived and died where he was born; the women married into other villages. Each village was ruled by the richest man. There seem to have been no formalities in the government of a village or tribe. There was a deep undercurrent of religious feeling, and a great reverence for the spoken word.

The texts are word for word translations and anglicised versions of fourteen myths and tales, and thirty-seven texts relating to the dances and feasts, the majority of which are formulæ. The latter are of especial value, as it is usually so difficult to get the exact words of a magical formula. Thirty excellent heliotype plates embellish the volume.

Mr. Goddard and the university authorities are alike to be congratulated on this excellent piece of work, which augurs well for the success of the new department of the University of California.

A. C. H.

A NATURALIST'S JOURNAL.[1]

THIS daily journal of an observant field-naturalist may be heartily welcomed by every lover of country life and country scenes. It is true the style is somewhat scrappy and *staccato*, but this is to a great extent unavoidable in a work of this nature, and is, after all, no great drawback, although we think it might have been somewhat modified during the revision for press. Mr. Robinson, who is already no stranger to the reading public, has the good fortune to be a resident in Norfolk, the county *par excellence* of redundant bird-life and of enthusiastic bird-lovers; and he is therefore practically assured of a number of sympathetic readers, for every dweller in Norfolk likes to be acquainted with all that is written about his own district.

To the general reader the most attractive feature of the book will almost certainly be the large series of exquisite reproductions from photographs of animal and plant life, taken, we infer, by the author himself. Where all are of such high excellence, it is difficult to make a selection; and the illustration we present to our readers as a sample must not be regarded as either better or worse than its fellows. It has been chosen on account of its depicting an interesting phase of bird-life.

As a rule, the author has nothing specially new to

[1] "The Country Day by Day." By E. K. Robinson. Pp. xix+371 illustrated. (London: W. Heinemann, 1905.) Price 6s.

tell, and his book may be regarded as a guide to what the observant country resident ought to see and notice, rather than as an exponent of fresh facts. In places, indeed, he forsakes his usual style for what we suppose must be called "word-painting," but we can scarcely congratulate him on the result of the change. Neither, we think, is he altogether happy in his theory that bird-song is largely due to rivalry and jealousy; although his eagerness to trace out the reason of every phenomenon in natural life is a trait deserving of the highest commendation.

The reader who follows in Mr. Robinson's footsteps and takes him as guide will not have much to learn about the animals and plants of his native district after a year's diligent apprenticeship.

R. L.

FIG. 1.—Young Peewit hiding. From "The Country Day by Day."

PROF. G. B. HOWES, F.R.S.

GEORGE BOND HOWES, whose state of health for the past two years had been the cause of grave anxiety, passed away on February 4. Born in London on September 7, 1853, his active and useful life was cut short at the age of fifty-one.

Howes was of Huguenot extraction; his father, the late T. J. Howes, married the daughter of the late Captain G. H. Bond—a member of a talented family. While attending a private school he spent his spare time in making microscopical slides, and a prize of one of J. G. Wood's books helped to arouse further his interest in natural history. His parents at first intended that he should prepare for entering the Church, but this plan was given up, and on leaving school he was for a short time in business, which proved very distasteful to him. Having worked out the anatomy of the house-fly, made careful drawings of his preparations, and given a lecture on the subject, his talent was recognised by a friend of the family—a clergyman—who introduced him to Mr. Walter White, then secretary to the Royal Society. Through Mr. White's instrumentality an introduction was obtained to Prof. Huxley, and this resulted in an appointment under the Science and Art Department.

A short time previously, Huxley, assisted by T. J. Parker, had begun to organise his pioneer practical classes in biology at South Kensington, and Howes's first scientific work consisted in making a series of enlarged coloured drawings illustrating the anatomy of various animals, and thus further developing his powers as a draughtsman. These drawings now form the well known series hanging on the walls of the laboratory at the Royal College of Science, copies of which were subsequently made by Howes for use in various universities and colleges in this country and abroad. Although he had no previous scientific training, he rapidly became an expert anatomist, and many of his exquisite dissections are still to be seen on the shelves of the laboratory.

All this time, Howes was taking every advantage of his opportunities for studying under our greatest biological teacher in a school of high tradition, where students are able to devote themselves to one subject at a time, and are fortunate in being unhampered by syllabuses. He was soon appointed assistant demonstrator, and on Parker's election to the chair of biology in the University of Otago, Howes succeeded him as chief demonstrator, so that his originality, zeal, and enthusiasm had full scope for development. The wide knowledge he gradually obtained of his subject, his valuable contributions to zoological literature, and more especially his power and influence as a teacher, soon made it apparent that he was to take an important place in the scientific world. On Huxley's partial retirement in 1885, Howes was appointed assistant professor, and in 1895—when the chair of biology was subdivided—professor of zoology. During his career as demonstrator, he had also for two years held the post of lecturer on comparative anatomy to the St. George's Hospital Medical School.

In 1897, Howes was elected to the fellowship of the Royal Society. He was a vice-president of the Zoological Society, honorary zoological secretary to the Linnean Society, honorary treasurer of the Anatomical Society, ex-president of the Malacological Society, president of Section D of the British Association at the Belfast meeting, corresponding member of the New York Academy of Science, and an honorary member of the New Zealand Institute. He also took an active interest in the work of several local natural history societies, of which he was a member. In 1902 he acted on the committee for the reorganisation of the Zoological Gardens, and in the same year received the degree of D.Sc., *honoris causa*, in the Victoria University, having previously—in 1898—received that of LL.D. at St. Andrews. He had held examinerships in several universities, *e.g.* London, Oxford, Victoria, and New Zealand.

The veneration and affection which Howes felt for his great chief were unbounded, and apparent in all his work, to carry on which on the lines laid down by Huxley was the summit of his ambition.

His publications are too numerous to be mentioned in detail; they consist of some fifty papers and addresses, as well as numerous reviews and articles, all written in a characteristic style; apart from the two editions of his well known "Atlas," and the revised and extended editions of Huxley and Martin's "Elementary Biology" (in collaboration with Prof. D. H. Scott). He also edited the translation by Bernard of Wiedersheim's "Bau des Menschen," and had undertaken to prepare a new edition of Huxley's "Anatomy of Vertebrated Animals," which he had mapped out in his mind, but never actually began. His original work deals mainly with vertebrate comparative anatomy, and all shows the same thoroughness and accurate knowledge.

Considerable and important as his direct contributions to science have been, they only represent a part of his life's work in this direction, for he considered it his duty to devote much time to the business of scientific societies and in helping any serious workers who applied to him; he spared no trouble in assisting others.

Never a robust man, Howes's power of work was extraordinary. He never seemed to be in a hurry, and did not give one the impression that he spent an excessive amount of time in reading the current literature of his subject, although his knowledge and memory in this direction were quite unique. His mind was of a remarkable type, and was, one may say, almost overburdened with details, though he never lost sight of the main issue, and was always clear and stimulating. He absorbed everything which had the remotest bearing on his science, and would talk by the hour on almost every branch of zoology; one had only to ask him some question and he would either have the point at issue at his finger-ends, or would at once give references to the most recent papers on the subject. When giving a lecture or an address, he would put so much into an hour's discourse as to make his hearers marvel at his memory and grasp of the subject. His presidential address to the zoological section of the British Association in 1902 contains no less than 186 references to original authorities, and its preparation must have cost him an enormous amount of labour at a time when he was already over-fatigued.

Howes was a man of high moral standard and ingenuous nature, generous and unselfish in all he did, and his death is mourned by a wide circle of scientific friends, who will long cherish the memory of his friendship and hospitality. He carried out his own belief that "higher ambition than that of adding to the sum of knowledge no man can have; wealth, influence, position, all fade before it; but we must die for it if our work is to live after us."

W. N. P.

NOTES.

THE following fifteen candidates have been selected by the council of the Royal Society to be recommended for election into the society:—Mr. J. G. Adami, Mr. W. A. Bone, Mr. J. E. Campbell, Mr. W. H. Dines, Capt. A. Mostyn Field, R.N., Mr. M. O. Forster, Mr. E. S. Goodrich, Mr. F. G. Hopkins, Mr. G. W. Lamplugh, Mr. E. W. MacBride, Prof. F. W. Oliver, Lieut.-Col. D. Prain, I.M.S., Mr. G. F. C. Searle, Hon. R. J. Strutt, and Mr. E. T. Whittaker.

THE piercing of the Simplon Tunnel was completed at 7.20 a.m. on February 24. At the time of piercing, the north gallery was inaccessible on account of the accumulation of water. The south gallery is on a lower level than the north, and the final connection was made by the explosion of charges placed in holes driven into the roof of the south gallery, which left a large hole on a level with the floor of the north gallery. No sooner was the piercing effected than the accumulated water flowed rapidly away down the southern side, and was discharged into Italy without doing damage. It is unnecessary again to direct attention to the particulars of this triumph of engineering skill, for a detailed account of the difficulties with which the engineers have had to contend, and the expedients utilised to surmount these obstacles, will be found in an article by Mr. Francis Fox in NATURE for October 27, 1904 (p. 628, vol. lxx.). The work that now remains to be done is to put in place the masonry arching, to cover over the water channel beneath the floor of the tunnel, and to lay the permanent way. It is expected that within three months trains will be running, and the railway will prove a vital link in the line of communication between the Italian cities and mid-Europe.

ON Friday, March 17, Senor Manuel Garcia, the inventor of the laryngoscope, will complete his hundredth year, and the anniversary will be celebrated by a meeting of laryngologists at the rooms of the Royal Medico-Chirurgical Society, Hanover Square. We learn from the *British Medical Journal* that the Spanish Ambassador will attend to congratulate the illustrious centenarian in the name of the Government of his native country, and among the addresses will be one from the Royal Society, before which Senor Garcia read his paper entitled "Physiological Observations on the Human Voice" just fifty years ago. The Berlin, Vienna, French, Dutch, Belgian, and South and West German Laryngological Societies will send special deputations. Most of the addresses will be taken as read, and the proceedings will conclude with the presentation of a portrait of Senor Garcia, painted by Mr. John Sargent, R.A., together with an album containing the names of all the subscribers. In the evening a banquet will take place at the Hotel Cecil, at which it is hoped that Senor Garcia himself will be present.

THE death is announced, on February 6, of Father Timoteo Bertelli. Father Bertelli was born in Bologna in 1826, and was the son of the professor of astronomy at the University of Bologna. At eighteen he joined the Order of the Barnabites, and taught physics in various colleges of the Order. In 1871 he joined the Collège de la Querce in Florence, with which institution he appears to have been associated continuously until the time of his death, except for the three years 1895–7, when he was called to Rome by Leo XIII. to succeed Father Denza at the Vatican Observatory. But his state of health did not permit him permanently to accept this position, and in 1897 he returned to Florence. Father Bertelli first devoted himself to meteorology, and later was attracted by the study of seismic phenomena, inventing the tromometer to assist in his observations. He gave much attention to researches into the history of the sciences and especially to that of the mariner's compass. The results of his life's work are contained in some sixty memoirs, the first of which is dated 1859.

DR. A. S. PACKARD, professor of zoology and geology at Brown University, died on February 14, at the age of sixty-six years. The death occurred, on February 22, of Dr. Ernst F. Dürre, formerly professor of metallurgy at Aix-la-Chapelle, and author of several important treatises on the metallurgy of iron and steel. Dr. Guido Hauck, professor of mathematics at the Berlin Technical College, died on January 14. The deaths are also announced of J. C. V. Hoffmann, founder and editor of the *Zeitschrift fur mathematischen und naturwissenschaftlichen Unterricht*, Dr. T. H. Behrens, professor of microchemistry at Delfdt, Prof. Ludwig von Tetmeyer, principal of the Vienna Technical College, and Prof. Ditscheiner, of Vienna.

We learn from the *Times* that Prof. Adolf Bastian, director of the Berlin Ethnographical Museum, has died at Port of Spain, Trinidad, in his seventy-ninth year, while on a scientific expedition. Prof. Bastian, who was a distinguished traveller for many years, enjoyed a wide reputation as the author of numerous ethnological and anthropological works, of which the best known is "The Peoples of Eastern Asia."

The council of the University of Birmingham recently assigned a plot of land on the new university site at Bournbrook in order to enable Mr. Walter E. Collinge, the lecturer in zoology, to continue his experiments and observations upon the life-histories of the black-currant gall-mite and the plum aphis, with the view of obtaining remedies for exterminating or holding in check these pests to fruit-growers.

The annual dinner of the Institution of Civil Engineers will be held on Wednesday, March 22, at Merchant Taylors' Hall, Threadneedle-street, E.C. Sir Guilford Molesworth, president of the institution, will occupy the chair.

An interesting excursion has been arranged by the American Institute of Mining Engineers. In the first week in July a meeting will be held at Victoria, British Columbia, and this will be followed by a three weeks' trip to the mining districts of Alaska.

A valuable contribution to economic geology is afforded by an article on the Hauraki goldfields of New Zealand published by Mr. W. Lindgren in the *Engineering and Mining Journal* of New York. The occurrence of gold is very similar to that in Transylvania. The gold is met with in quartz veins traversing andesite altered into propylite. The minerals accompanying the gold are dolomite, pyrites, blende, galena, and ruby silver ore. Near the surface the sulphide ores are oxidised; and the greatest yield of gold has been obtained at points where the veins cross.

In the *Transactions* of the Faculty of Actuaries, No. 18 (1905), Dr. James Buchanan discusses the use of various modifications of Simpson's rule in the performance of the integrations involved in the calculation of survivorship benefits.

In the *Physikalische Zeitschrift* for February 1, Profs. Elster and Geitel discuss the radio-activity of certain sediments from the German mineral springs, and Messrs. A. Herrmann and F. Pesendorfer describe experiments indicating traces of radio-activity in the gases from the Sprudel spring at Carlsbad.

An interesting feature of the Johns Hopkins University *Circular* is the series of "Notes in Mathematics," edited by Prof. Frank Morley, appearing in the January number. These notes deal with "A system of parastroids" and "A curve of the fifth class" (Mr. R. P. Stephens), "Applications of quaternions to four dimensions" and "Some invariant relations of linear correspondences" (Mr. H. B. Phillips), "A closed system of conics" (Mr. Charles C. Grove), and "The normal form of a collimation and the reduction of two conics to normal form" (Mr. A. B. Coble).

Prof. Hans Landolt, of Berlin, has received the Prussian Imperial Gold Medal for Science.

The city of Lincoln is now suffering from a serious outbreak of typhoid fever. The epidemic started at the beginning of January, and up to date nearly 800 cases have been notified. The epidemic is plainly a water-borne one, milk and other articles of diet being excluded as channels of diffusion by the extent of the outbreak and its regular distribution over the whole area. The water supply of Lincoln is derived from the River Witham, the water being passed through sand filters before distribution. Attention has been directed from time to time to the unsatisfactory quality of the water, and in 1901 the boring of a deep well into the sandstone was commenced, but after the bore had reached a depth of 880 feet in 1903 the boring tool was lost, and has not been recovered, thus entailing serious delay. The epidemic, it is surmised, has been caused by pollution of the Witham or its tributaries above the intake. It is unfortunate that works were in progress in the autumn to improve the filter beds by deepening the layer of fine sand, but were put a stop to by the early frost, and the same event caused many of the consumers to leave their taps running, and thus to necessitate an increase in the rate of filtration to meet the increased demand.

The Fishmongers' Company has published a preliminary report by Dr. Klein, F.R.S., on experiments undertaken for the company to ascertain the duration of vitality of the typhoid bacillus when introduced into shell-fish. The main conclusions arrived at are:—(1) Oysters readily take up into their interior the *Bacillus typhosus* which has been introduced into their shell or into the surrounding sea-water. (2) Oysters, clean at starting, rapidly clear themselves of the ingested typhoid bacilli if they are kept in clean water which is frequently changed. (3) Oysters, clean at starting, clear themselves of the ingested bacilli to a less extent and slower if they are kept in a "dry" state—*i.e.* out of the sea-water. (4) Oysters, from a polluted locality, clear themselves of the ingested bacilli to a less extent, and at a slower rate, even if kept in clean sea-water, than oysters clean at starting. (5) Oysters from a polluted locality, containing a large number of the *Bacillus coli*, very rapidly clear themselves of this microbe, whether kept in or out of the water. This shows that *Bacillus coli* is foreign to the oyster and is rapidly destroyed by it. When, therefore, it is present in the oyster, it must have been derived from the surroundings. (6) However largely infected with typhoid bacilli, the oysters at no time present to the eye any sign of such infection; they remain in all parts of normal aspect. (7) Cockles and muscles similarly take up the typhoid bacillus, but clear themselves much more slowly, particularly in the case of cockles, than do oysters.

The geographical results of the National Antarctic Expedition, in so far as they relate to the distribution of land, water, and ice within the area allotted to the expedition for exploration, were described by Captain R.F. Scott before the Royal Geographical Society on Monday. He remarked that the main geographical interest of the expedition was the practical observation of a coast-line from Mount Melbourne, in lat. $74\frac{1}{2}°$, to Mount Longstaff, in lat. 83°, and of the conditions which lie to the east and west of this line. The coastal mountains are comparatively low between Mount Melbourne and the Ferrar glacier, and it was the tabular structure of these that first indicated the horizontal stratification of the mainland. But low as the mountains are, in one place only does the internal ice-sheet seem to pour any volume of ice into the sea. It is certain that the ice-cap is of very great extent, and there is evidence that it maintains a great and approximately uniform level over the whole continent. The greater portion of this great ice-sheet is believed to be afloat. The soundings made by the expedition show that some hundreds of fathoms of water still intervene between the bottom of the ice at the barrier edge and the floor of the sea; but the barrier edge sixty years ago was in advance of its present position, in places as much as 20 or 30 miles, and therefore the soundings lie directly beneath Sir James Ross's barrier, and a considerable distance from its edge. The ice-sheet, and the curious and often vast ice-formations met with in the Ross sea, are therefore regarded, not as the result of present-day conditions, but the rapidly wasting remnants of a former age.

Senor A. Arcimis informs us that Mr. Valderrama, director of the Municipal Meteorological Observatory at Santa Cruz (Canaries), observed a fall of dust on January 29 and January 30. During all the former day a very fine dust fell continuously, but not in great amount. On January 30 a rain of a yellow and very fine dust began at 15h. The wind-vane pointed to the S.S.W., and the atmosphere was charged with the very fine dust, the horizon being invisible through a kind of dry fog that introduced itself into the mouth and throat, producing the same effect as when marching on a dusty highway in a hot summer day. All the instruments exposed freely out of doors were covered with the nearly impalpable dust.

At the recent annual meeting of the Glastonbury Antiquarian Society, Prebendary Grant gave an account of the exploration at the ancient British Lake Village at Glastonbury during the summer of 1904. Three new mounds were examined, and the exploration of four others was completed. The "finds" included amber and glass beads, spiral finger-rings of bronze wire, a massive bronze buckle (taken to have been connected with horse-harness), a bronze object which is supposed to have been some part of horse-trapping, a variety of bone objects, wool combs, hammers, portion of horses' bits, and a roedeer antler, pointed and used as a modelling tool for decorating pottery. Several pieces of pottery were dug up. Flint flakes and knives were found, proving that flint implements were made at the village. With respect to wooden articles, two wheel-spokes, finely turned and finished, were found, and a fragment of an axle-box belonging to the same wheel. Iron bars were found also at the Lake Village, and after minute investigation the conclusion has been arrived at that these bars are iron currency bars used by the ancient Britons at the time of Cæsar's invasion.

A large number of new types of Japanese land-shells of the Clausilia group are described by Mr. Pilsbry in the December issue of the *Proceedings* of the Philadelphia Academy.

The shore fishes of the Galapagos and other Pacific islands are described by Messrs. Snodgrass and Heller in part xvii. of the publications of the Hopkins-Stanford Expedition (*Proc.* Ac. Washington, vi., pp. 333–427). Two species are described as new.

The *Emu* for January contains Captain Hutton's presidential address to the Australasian Ornithologists' Union, which deals with the geographical origin and subsequent development of the land birds of New Zealand. An interesting feature of the issue is the reproduction of a photograph of a red gum-tree containing the nests of seven species of birds.

Naturen for January and February contains two illustrated articles on whales and whaling. In the former issue Prof. G. Guldberg describes the method of hunting the Greenland right whale, illustrating his article with reproductions from two old prints. In the February number Mr. E. Koefoed records the capture of a Biscay right whale, or "nordkaper," at Mjofjord, on the west coast of Iceland, and also of a cachalot in northern waters. Two photographs of the former cetacean are reproduced.

Stepney has published a handbook to the vivaria and aquaria in the Borough Museum, the text of which is reproduced, with certain alterations and additions, from the handbook to the Horniman Museum. It is to be hoped that the descriptive portion, when read in the museum, may aid visitors to a right appreciation of the exhibits, but as it stands the guide is admirably calculated to puzzle beginners in systematic zoology. For instance, from the headings on pp. 24 and 25, the reader would be led to infer that while *Argyroneta* is the scientific designation of the water-spider, and *Podura aquatica* that of the water-springtails, *Blattidae* is the name for the cockroach, and from p. 50 that *Lacertilia* is the generic title for the typical lizards. Again, from p. 17 he would be led to suppose that *Gastropoda* is the generic term for snails, and that these rank in classificatory value with the viviparous pond-snail (*Paludina vivipara*). Careful study of the text may in some cases put matters right, but the muddle is as bad as bad can be for beginners.

The address on morphology generally, its modern tendencies and progress, and its relation to other sciences, delivered by Prof. A. Giard before the Congress of Sciences and Art at the St. Louis Exhibition in September last, is published in the *Revue Scientifique* of February 4 and 11. After referring to the revolution in biology effected, first by Lamarck and subsequently by Darwin, the author proceeds to sketch the gradual evolution of modern biological conceptions and theories, dwelling especially on Wolff's hypothesis of epigenesis. Reference is then made to the importance of the study of variation, both among living and extinct types, after which the author passes on to review the influence that palæontology has exerted on biology and the doctrine of evolution. Abiogenesis next claims attention, while the author concludes his discourse by reference to some of the evils attendant on the extreme specialisation of scientific work at the present day. It is time, he urges, that a general organisation to direct scientific work should replace the present state of anarchy, whereby much energy that is now practically wasted would be diverted towards the attainment of a common end and object.

The fifth part of Mr. J. H. Maiden's "Critical Review of the Genus Eucalyptus" includes three species. *Eucalyptus stellulata* receives its name from the disposition of the buds, and is known as black Sally, or muzzlewood; the leaves show longitudinal lateral veins similar to those of the next species, *Eucalyptus coriacea*, which is distinguished by its clean white stem. The third species, *Eucalyptus coccifera*, confined to Tasmania, is sufficiently hardy to have been planted in parts of the United Kingdom.

The alien problem is not unknown to botanists, and the genus Sisymbrium has added two foreign species to the flora of Lancashire. *Sisymbrium pannonicum* is definitely naturalised along the coast from St. Anne's to Crosby, and according to a recent account by Mr. C. Bailey in vol. xlix. part i. of the *Memoirs and Proceedings* of the Manchester Literary and Philosophical Society, *Sisymbrium strictissimum*, a native of continental Europe, has obtained a foothold near Heaton Mersey, where it has been observed for fifteen years.

In a paper only recently published in vol. ii., No. 3, of the *Contributions* from the botanical laboratory of the University of Pennsylvania, but which represents work done two years earlier, Dr. O. P. Phillips maintains that the central body in the cells of the Cyanophyceæ represents a true nucleus, but he failed to obtain complete stages in its mitotic division. Dr. Phillips is of opinion that the movement of the filaments of Oscillaria and Cylindrospermum is due to protoplasmic processes or cilia which, he says, are to be observed around all the cells. The chromatophore, containing cyanophycin granules, was identified as a peripheral zone.

AN interesting address on the present problems of meteorology was given by Mr. A. L. Rotch to the section of cosmical physics of the International Congress of Arts and Sciences at St. Louis, and was printed in *Science* on December 23 last. The author pointed out that although it is nearly fifty years since the first commencement of weather telegraphy, and much has been done to complete and extend the area under observation, the methods employed in the preparation of weather forecasts are still essentially empirical, and practically little or no progress has been made. This is mostly due to the fact that until recently observations have been carried on solely at the bottom of the atmosphere. Even the observations made at mountain stations still pertain to the earth and do not represent the conditions prevailing in free air. The still more recent use of unmanned balloons and kites has led to the acquirement of a knowledge of the vertical gradients of meteorological elements which contradicts previous conceptions, *e.g.* that the temperature diminished with increasing altitude more and more slowly, whereas the results show that it decreases more and more quickly with increasing altitude. The international cloud observations at various altitudes discussed by Dr. Hildebrandsson also show that theories held heretofore are untenable, and that there is no exchange of air between poles and equator. With regard to cosmical relations to meteorology, the author points out that neither the effects of the periods of solar or lunar rotation upon the earth's meteorology can be claimed to have been proved. But coincidences—if nothing more—have been shown by Sir Norman and Dr. Lockyer to exist between sun-spot frequency and atmospheric changes, especially as manifested by barometric pressure, rainfall, and temperature. It does not seem impossible, therefore, that the discussion of meteorological observations from the point of view of their relation to solar phenomena may eventually lead to seasonal predictions of weather possessing at least the success of those now made daily.

THE Survey Department of the Egyptian Public Works Ministry has sent us the meteorological report for the year 1902. This volume indicates that the Director-General of the Survey Department, Captain H. G. Lyons, is making rapid strides, not only in increasing the number of stations which send in records, but in publishing a considerable amount of valuable information which should prove of great value. We are told that arrangements are in progress for commencing a systematic measurement of rainfall in the Delta and western part of the Mediterranean coast; that a monthly *résumé* of the weather has been started; and that forecasts during the early and late months of the year have been issued. All these show the activity that is being displayed in the collection and dissemination of meteorological data. The present report includes magnetic as well as meteorological observations, and also Nile gauge readings. At the end are given numerous curves representing the variations of the meteorological elements as registered at the Abbassia Observatory.

THE *Journal* of the Röntgen Society (vol. i., No. 2) contains a note by Mr. J. H. Gardiner on the new ultraviolet glass manufactured by Messrs. Schott and Genossen, of Jena; it is illustrated by photographs of spectra showing the transparency of the glass in the ultra-violet region.

FLUORESCENT substances are usually regarded as exceptions to Kirchhoff's law of absorption on account of their being able to emit light which in ordinary circumstances they do not absorb, but hitherto no investigation has been made of the absorptive power of such substances during active fluorescence. In the *Physical Review* for December 1904, Messrs. E. L. Nichols and Ernest Merritt show that substances such as fluorescein, when caused to fluoresce strongly in solution, produce a decidedly different absorption from that of the feebly illuminated material, and that the absorption curve obtained in this way is intimately connected with the curve of fluorescence. In the case of five different substances, moreover, there is conclusive evidence of a slight increase in electrical conductivity accompanying the phenomenon, and on this account a dissociation hypothesis is brought forward to explain the nature of fluorescence.

AN address delivered by Prof. Edward B. Rosa at the opening of the John Bell Scott Memorial Laboratory of Physical Science at Wesleyan University, Connecticut, is printed in *Science* for February 3. It deals with the National Bureau of Standards, which commenced work in the United States in 1901, and defines its functions and ideals. It is to be noted that research plays a prominent part in the programme of the bureau. We have already had occasion to refer to Dr. Guthe's critical investigation of the various forms of silver voltameter (NATURE, vol. lxx., p. 583), and to the determinations by Drs. Waidner and Burgess of the temperature of the electric arc (NATURE, vol. lxxi., p. 132). Both these researches were carried out under the auspices of the bureau, and in addition to these, the *Physical Review* for December, 1904, contains a valuable communication by Drs. Waidner and Burgess on "Radiation Pyrometry," in which the degree of accuracy of several radiation pyrometers is discussed. The bureau does not confine itself entirely to physical and mechanical measurements, but contains a department devoted to chemistry, one of the purposes of which is to attempt to secure uniformity in technical analyses. A characteristic of the bureau which deserves particular notice is its aim not only to conduct investigations through its own staff, but also to afford facilities for research to others who may come to work for a limited period as scientific guests. In this way it is hoped that "the output of original research in America will be materially increased."

THE remarkable catalytic power of reduced nickel, discovered some years ago by MM. Paul Sabatier and J. B. Senderens, has been applied by them in many directions, and has been especially fruitful in the addition of hydrogen to cyclic compounds. Applying this reaction in another direction, the authors in the current number (February 20) of the *Comptes rendus* describe the reduction of nitriles to amines. The nitrile, with an excess of hydrogen, is passed over reduced nickel at temperatures between 250° and 300° C. Hydrocyanic acid might be expected to yield methylamine, but, as a matter of fact, the nickel was found to exert a further action, both dimethylamine and trimethylamine being produced, together with ammonia and the primary amine. With acetonitrile all three amines are likewise produced, the diethylamine, which forms about three-fifths of the mixture, predominating. Dipropylamine was similarly the chief product of the reaction with propionitrile; with capronitrile, derived from ordinary amyl alcohol, besides the three amines, two of which were new, an appreciable proportion of the hydrocarbon α-methyl-pentane was obtained. The yields were in all cases good with fatty compounds, but the reaction was less satisfactory when applied to the aromatic series, there being a tendency for the hydrocarbon and ammonia to be the chief products.

Globus for February 23 is a special number containing contributions by friends and admirers of Prof. R. Andree, who reached his seventieth birthday on February 26.

The third part of the *British Journal of Psychology*, published by the Cambridge University Press, has been received. The number contains five papers in addition to a report of the proceedings of the Psychological Society. Mr. Norman Smith discusses Malebranche's theory of the perception of distance and magnitude; Mr. F. N. Hales considers the materials for the psychogenetic theory of comparison; Mr. W. G. Smith makes a comparison of some mental and physical tests in their application to epileptic and to normal subjects; Prof. Mary W. Calkins defines the limits of genetic and of comparative psychology, and Mr. C. Spearman makes an analysis of "localisation," illustrated by a Brown-Séquard case.

OUR ASTRONOMICAL COLUMN.

Astronomical Occurrences in March:—

March 5. 17h. Sun eclipsed; invisible at Greenwich.
7. 13h. Juno in conjunction with Moon. Juno 1° 27′ S.
9. Jupiter in conjunction with Venus. Venus 5° 30′ S.
,, 11h. Jupiter in conjunction with Moon. Jupiter 3° 15′ N.
12. 10h. 11m. to 11h. 6m. Moon occults γ Tauri (mag. 3·9).
17. 12h. 34m. Minimum of Algol (β Persei).
20. 9h. 2m. to 9h. 49m. Moon occults β Virginis (mag. 3·8).
,, 9h. 23m. Minimum of Algol (β Persei).
21. 12h. Venus at maximum brilliancy.

Reported Discovery of a Seventh Satellite to Jupiter.—A telegram received from the Kiel Centralstelle announces the discovery of a seventh satellite in the Jovian system. The description reads:—16 magnitude, position on February 25 62 degrees, distance 21 minutes, daily motion 60 seconds south-easterly.

Planetary Tides in the Solar Atmosphere.—In a communication published in the *Bulletin de la Société astronomique de France* (February, 1905), M. Émile Anceaux discusses the question as to whether the undecennial periodicity of sun-spots may not result from the fluctuations of tides set up in the solar atmosphere by the concerted action of Jupiter, the earth, Venus, and Mercury. He classifies the tides as binary, ternary, and quaternary, according to the number of planets acting in their production by being in, or near, opposition or conjunction. The ternary tide due to the combined action of Jupiter, Venus, and the earth is supposed to be the most important factor in regulating the appearance of spots, and a curve showing the fluctuations in the strength of this tide, as calculated from the knowledge of the planetary positions, agrees fairly well with the sun-spot curve for the years 1891 to 1905.

Finally, the author arrives at a number of conclusions of which the more important are:— (*a*) That sun-spots are the indirect consequences of such tides; (*b*) that the combined action of the three planets especially mentioned governs the fluctuations of the spot period; (*c*) that this ternary tide obeys an eleven-year period; (*d*) that the variation of the sun-spot period is due to the eccentricities of the planets, chiefly Jupiter.

The Bruce Photographic Telescope.—The Bruce photographic telescope, with which a number of beautiful photographs of nebulæ, Milky Way regions, &c., have already been obtained at the Yerkes Observatory, is described in detail in an illustrated article by Prof. Barnard published in No. 1., vol. xxi., of the *Astrophysical Journal*.

The telescope was erected, at the cost of Miss Catharine Bruce, at Yerkes in April, 1904, but has now been dismounted and shipped to Mount Wilson, Pasadena, where it is to be used for photographing those regions of the Milky Way not attainable at the former observatory.

It consists of a 5-inch guiding telescope firmly bolted to two other tubes, which carry photographic doublets of 10-inches and 6¼-inches aperture respectively. The focal length of the 10-inch is only 50 inches, and the polar axis of the instrument has been formed by bending the upper part of the iron pier to the required inclination so that the camera may make a complete revolution about the axis without having to be "reversed." For use in different latitudes an iron wedge-shaped section may be introduced between the upper and lower parts of the pier in order to produce the required change of inclination, whilst a special arrangement, whereby the clock motion may be reversed in two minutes, has been introduced into the driving gear so that the same mounting may be used in the southern hemisphere.

The 10-inch doublet, by Brashear, gives excellent definition over a field 7° wide, and the scale is such that 1 inch = 1°·14, or 1° = 0.88 inch. The ratio aperture/focal length = 1/5.03 is that which Prof. Barnard believes to be the best for the purpose for which this instrument was designed. The 6¼-inch Voigtländer doublet has a focal length of 31 inches, and is used in conjunction with the 10-inch for the purpose of verification. Specimen photographs accompany the description, and these testify eloquently to the satisfactory performance of each of the doublets.

Physical Conditions of the Planets.—In a communication to No. 3992 of the *Astronomische Nachrichten* Prof. T. J. J. See deals exhaustively with the methods that he has employed and the results he has obtained in a research on the internal densities, pressures and moments of inertia of the principal bodies in the planetary system. Some of the results obtained in the preliminary discussion of the available fundamental data are of great interest. For example, he arrives at the conclusion that the most probable values for the rotation period and for the oblateness of Uranus are 10h. 6m. 40.32s. and 1 : 25 respectively, whilst for Neptune the similar values are probably 12h. 50m. 53s. and 1 : 45.

In the case of the earth, Laplace's law of densities appears to be a natural law, for the value obtained for the oblateness of the outer stratum, or surface, of the globe agrees very well with that obtained as a mean of the most trustworthy of the determinations by more direct methods. The probable value obtained for the pressure acting at the earth's centre is 2383·152km. of mercury, a quantity so enormous that Prof. See attempts to render it more comprehensible by suggesting that it is 7838 times as great as a column of mercury equal in height to the Eiffel Tower.

The probable pressure at the sun's centre is nearly 212 billion atmospheres. A column of mercury acting solely under terrestrial gravitational acceleration would have to be high enough to extend beyond the sun in order that it might exert such a pressure.

Similar results for the density and pressure at different levels in the planets and satellites are given in two of the tables accompanying Prof. See's paper, and are also shown diagrammatically, whilst a third table shows the ratios of the actual moments of inertia to those of corresponding homogeneous spheres.

Discussion of Central European Longitudes.—In a series of tables published in Nos. 3993–4 of the *Astronomische Nachrichten*, Prof. Th. Albrecht brings together, weighs and tabulates all the longitude results, affecting central European observatories, hitherto obtained. In the first table the longitude differences between 176 pairs of observing stations, as determined since 1863, are thus dealt with, whilst in the second the longitude differences between Greenwich transit circle and numerous other important circles or observatories are brought together. In the third table the corrections to be applied to the differences given in table i., as determined from the discussion of the whole set, are shown.

THE SCOTTISH NATIONAL ANTARCTIC EXPEDITION.[1]

AFTER getting free from the winter quarters in the South Orkneys on November 23, 1903, the *Scotia* left for the Falkland Islands and Buenos Aires to get into communication with home and obtain a fresh stock of coals and provisions. During the ship's absence a party of six men was left at Scotia Bay under the charge of Mr. R. C. Mossman to carry on the systematic meteorological, magnetic, and biological work.

FIG. 1.—Gough Island, showing hanging valley truncated by shore cliff.

Perhaps the most interesting discovery made by the summer party was the egg of the Cape pigeon (*Daption capensis*). Although known to breed on South Georgia and Kerguelen, its eggs had never hitherto been obtained. As is the case with the majority of petrels, only a single egg is laid—a pure white egg, deposited in a nest which consists of a few angular fragments of stone raked together on a bare ledge of the cliff.

While at Buenos Aires Mr. Bruce arranged for the Argentine Government to take over and continue the meteorological and magnetic observatory at Scotia Bay, South Orkneys. On January 21, 1904, the *Scotia* left Buenos Aires with three Argentine men of science on board in addition to her own staff, and on February 22 they were left on the South Orkneys under the leadership of Mr. Mossman, who had consented to remain for a further period of twelve months.

This season the distribution of the pack ice was very different from that of the previous year. Almost no ice was met with near the Orkneys, and very little until reaching the Antarctic circle in about 32° W. long. In the beginning of March the previous year's southern record, and also that of Ross in 1843, was passed, but in 72° 18′ S. 17° 59′ W. a sudden change of conditions was met with. The water suddenly shallowed from about 2500 fathoms to 1131, and at the same time land was reported ahead. Steaming towards this we found a lofty ice-barrier stretching in a north-easterly and south-westerly direction, effectually barring further progress to the south. Close, heavy pack ice prevented a nearer approach than two miles. This barrier was traced for a distance of 150 miles to the south-west. In 73° 30′ S. 21° 30′ W., a depth of 159 fathoms was met with, the barrier being then two and a half miles off. In 74° 1′ S. 22° 0′ W., the *Scotia* was nipped by the ice in a heavy N.E. gale, and was preparing to spend the winter there; but on March 13 the floe broke up and the ship was released. During the six days' imprisonment collections of the marine fauna were got from a depth of 161 fathoms, and a splendid view was obtained of the inland ice. Although no actual bare rock was seen, there can be no doubt we were really on the edge of the Antarctic continent—off "Coats Land," as it has been named after Mr. James Coats, jun., and Major Andrew Coats, the two chief subscribers to the expedition. In this connection we quote the words of Mr. Bruce:—"I have been asked by several if I am sure that this great ice-

FIG. 2.—Glacier at head of bay, north coast of Laurie Island, South Orkneys.

[1] Abstract of a paper on the "Second Antarctic Voyage of the *Scotia*," by Mr. J. H. Harvey Pirie and Mr. R. N. Rudmose Brown in the *Scottish Geographical Magazine*.

barrier was really part of the Antarctic continent. I have no hesitation in saying 'yes,' and my reasons are these: All our soundings between 60° and 70° S. were 2500 to 2700 fathoms. In 72° S. they shoaled to about 2300, fifty miles from the barrier. Thirty-five miles from the barrier they shoaled to 1400 and 1200 fathoms, and two miles from the barrier to 160 fathoms. This alone should answer the question in the way which I have done. Secondly, from the vertical cliff of ice 100 to 150 feet in height which bordered the ocean, the ice rose high inland in undulating slopes and faded away in height and distance into the sky. It was impossible to estimate the height of this field of ice—the true inland ice of Antarctica—but probably it was many thousands of feet. Thirdly, seals and birds, which up till now had become few in numbers, were seen in myriads—penguins, especially emperors, many petrels, and terns swarming in every direction—the inhabitants of the beaches and rocky cliffs of some actual land not very far distant."

After the escape from the ice the *Scotia* turned north-eastwards to continue the oceanographical survey of the Weddell Sea, and had some very successful deep-sea trawling in high southern latitudes—one haul in 71° 22′ S. 16° 34′ W. (1410 fathoms) yielding more than sixty species of animals. Ross's reported *deep* of 4000 fathoms no bottom was shown conclusively not to exist, the whole Weddell Sea being apparently an almost level plain submerged between 2400 and 2700 fathoms.

FIG. 3.—Weddell Seal—off Coats Land.

Pursuing a track northwards along the meridian of 10° W., although encountering very heavy weather between 45° and 55° S. lat., some very interesting soundings were obtained demonstrating the extension of the mid-Atlantic ridge southwards as far as 52° S. lat. The diatom ooze band extends between 48° and 58° S.; to the south of this is blue-mud, the detritus of the Antarctic ice-sheets, to the north, globigerina ooze.

On April 22 a landing was effected with considerable difficulty on Gough Island, a previously unexplored outlier of the Tristan da Cunha group. This apparently entirely volcanic island is richly clad with vegetation, but the extremely precipitous nature of the ground prevented any extensive survey being made, though two new species of plants were obtained—a Cotula and an Asplenium; and amongst the birds two entirely distinct and new species of finches. Shallow water collections were got off the shore by means of the dredge and trap. Between Gough Island and Cape Town several soundings were taken between the parallels of 39° and 40°.

On February 8 of the present year, the Argentine sloop *Uruguay* returned to Buenos Aires from the South Orkneys, having brought back safely Mr. Mossman and his party, and landed a fresh staff there. The station is being continued for meteorological and magnetic work, and a complete outfit of self-recording magnetic instruments has been installed. This work is in connection with the systematic magnetic survey of Argentina which is at present being undertaken.

THE EARLY HISTORY OF SEED-BEARING PLANTS, AS RECORDED IN THE CARBONIFEROUS FLORA.[1]

A LARGE number of the fern-like fronds of Carboniferous age, including many whole genera, as Neuropteris, Alethopteris, Callipteris, Linopteris, &c., have never been found to offer any satisfactory indications of a fern-like fructification. Some suspicion was thus awakened that such fronds may have belonged to plants other than true ferns.

Positive evidence first came from the anatomical side. The vegetative structure of *Lyginodendron Oldhamium* was completely worked out, chiefly by Williamson, and proved to present a combination of filicinean characters with those of cycadaceous gymnosperms. Similar results were attained in other genera, as Heterangium, Medullosa, Calamopitys and Protopitys, and hence the class Cycadofilices was founded to embrace these apparently intermediate forms. Decisive evidence as to the fructification was first obtained in 1903, when it was shown by Prof. F. W. Oliver, in collaboration with the lecturer, that the seed *Lagenostoma Lomaxi* agreed so closely in certain structural features with the associated *Lyginodendron Oldhamium* as to leave no doubt that the one belonged to the other. Observations on other Lagenostomas support this conclusion and show that the seeds were borne on modified fronds. It thus appears that the family Lyginodendræ consisted of seed-bearing plants, allied to the cycads, but retaining filicinean characters; their foliage was of a sphenopteroid type.

In another extensive family, that of the Neuropterideæ, precisely analogous conclusions have been reached. Here, too, the anatomical evidences indicated a position intermediate between ferns and cycads. In the case of *Neuropteris heterophylla* it has been proved by Mr. Kidston that large seeds, referred by him to the genus Rhabdocarpus of Goeppert and Berger, were borne on the frond. There are reasons for believing that Trigonocarpon was the seed of Alethopteris, and M. Grand-'Eury, on the ground of extensive observations on the distribution of fronds and seeds, is led to conclude that the Neuropterideæ generally were seed-bearing plants, of cycadean affinity.

It has been proposed to group these fern-like seed-plants, which in Carboniferous times probably exceeded the ferns themselves in number, under the name Pteridospermeæ. Their relation to the fern-phylum is evident from many points in their structure, apart from the relatively unimportant external characters.

Other seed-bearing plants of the Carboniferous flora have long been known, notably the Cordaiteæ, great trees with large simple leaves, totally different from the Pteridospermeæ in habit, and with little indication of fern-like structure. The fructifications also are of a more advanced character than those of the pteridosperms. In the structure of the seeds, however, and in some anatomical points, a certain affinity, though a distant one, with that family is suggested. It is probable that the Cordaiteæ ultimately sprang from the same stock as the Pteridospermeæ, though at a very remote period. On the other hand, there is reason to believe that the Coniferæ, appearing at the close of the Palæozoic period, were related to the Cordaiteæ. It is thus indicated as probable that the gymnosperms generally were, in a wide sense, of monophyletic origin, as having been ultimately derived from a common stock allied to the ferns; in a narrower sense they may be termed polyphyletic, as having sprung from this common stock at different points.

Although, as we now know, certain of the Palæozoic lycopods had likewise attained to the production of a seed-like fructification, there is at present no satisfactory evidence for connecting the members of this phylum with any of the groups of seed-bearing plants which have come down to our own day.

[1] Abstract of the Wilde Lecture delivered before the Manchester Literary and Philosophical Society on February 28 by Dr. D. H. Scott, F.R.S.

FORESTRY IN THE UNITED STATES.

WE have lately received five publications from the United States Bureau of Forestry, viz. *Bulletins* Nos. 46, 52 and 53, together with *Circulars* Nos. 30 and 31. *Bulletin* No. 46 is entitled "The Basket Willow," by Mr. William F. Hubbard. The author has evidently made a special

FIG. 1.—Twisted Furrows in Bark of Chestnut from Seed.

study of willow cultivation from every conceivable point of view. At the outset, he gives the general history of willow culture, together with the distribution and characteristics of the willow. This is followed by a most interesting account of willow-growing in the United States from its commencement down to the present time. The present practice is fully described, and much valuable advice is given, showing where improvements can be made on the existing methods of planting and tending the willow holts, choice of species, harvesting, cutting, sorting and packing the rods. The paragraphs which deal with expenditure and returns in American willow culture should go a long way to encourage and increase the development of what is at the present time a somewhat neglected industry in the United States.

The Bureau of Forestry is actively engaged in carrying out field experiments which are yielding, and will yield in the future, information of the utmost importance to willow-growers. The bulletin is not entirely confined to willow-growing in the United States, as the author gives a most interesting account of the development of scientific willow-culture in Europe, which he adds as an object lesson for the guidance of the American cultivator. The manufacture of willow ware in the United States is an important feature of the bulletin, which is replete with suggestions for both grower and basket-maker. A chapter on insects injurious to the basket-willow has been added, by Mr. F. H. Chittenden. A useful appendix at the end of the bulletin gives the production and consumption of willow in the United States.

Forest planting in western Kansas, by Mr. Royal R. Kellogg, constitutes *Bulletin* No. 52. The object of the paper is to show the species of tree best adapted for western Kansas, and the methods of treatment which have proved most successful. It seems, from the nature of the climate, that forestry on large areas is impracticable, but nevertheless, with an intelligent selection of species and a proper method of treatment, it may be possible to raise sufficient timber to exercise a marked effect upon the landscape, and to supply wood for domestic purposes. Among other things, the bulletin shows the enormous importance and influence tree-growth has on agriculture, not only in breaking and tempering the effect of cold, dry winds, but also in increasing the available supply of moisture in the soil. The bulletin is practically a condensed volume on sylviculture. It shows the most suitable species for western Kansas, and the site, soil, method of planting and subsequent treatment, together with the rate of growth and possible returns, are all gone into in a most thorough and workmanlike fashion. Plate iv. in the bulletin shows a row of Russian mulberry, and illustrates how the proper treatment of this species might be turned to the greatest use by the farmer. The above row extends more than 20 rods, and contains 200 trees 3 inches in diameter and 20 feet in height. Its total value, if converted into posts and stakes, would amount to 36.40 dollars, and, as the author remarks, a well-cared-for plantation at this place would evidently be a profitable investment.

Bulletin No. 53, entitled "The Chestnut in Southern Maryland," is by Mr. Raphael Zon. This species is evidently of great commercial importance in Maryland. It is apparently used principally for railway ties and telephone poles. As the result of his investigations, the author has arrived at the conclusion that pure coppice is the sylvicultural system to which the chestnut is best suited. Among other things, the report brings out clearly the difference between trees grown from seed and those from the stool. It is interesting to note that coppiced trees have thicker bark than trees from seed. The author further finds, from careful measurements and observations, that coppiced trees grow faster than seed trees during the first twenty years, and finally yield better and earlier returns than trees from seed. The illustrations reproduced show the interesting fact observed by the author that the furrows in the bark of coppice chestnut are straight, while those in the bark of chestnut from seed show the characteristic spiral twist. The report also contains many tables, showing the rate of growth and dimensions of trees from seed and coppice at various ages.

Circular No. 30, by Mr. Gifford Pinchot, is a description of an exhibit of forest planting in woodlots at the Louisiana Purchase Exposition. The exhibit is intended to illustrate the different methods of planting with different species and mixtures suitable for the different parts of the United

FIG. 2.—Straight Furrows in Bark of Coppice Chestnut.

States. There are in all forty-eight plots, representing different regions to which the various mixtures and density of planting are best adapted. This should form a valuable guide to sylviculturists all over the United States.

Circular No. 31, by the same author, is a description of a forest nursery exhibit at the above exposition. The most suitable form of bed, different methods of sowing, and various kinds of shelter screens are described. The coniferous and deciduous nurseries are for obvious reasons treated separately.

This batch of literature gives some idea of the value of the work which the United States Bureau of Forestry is doing, and, on the whole, its value to the country cannot be over-estimated.

PROGRESSIVE BUDDHISM.[1]

THE handsomely got-up and well-printed review, *Buddhism*, is an interesting sign of the times. The Buddhist community is apparently realising that it is advisable, so far as possible, to bring itself into line with modern developments, and to the monthly periodicals appearing in Ceylon, Japan, and (strange to say) San Francisco, has now added this quarterly journal appearing in Burma.

The present venture is edited by Ananda Maitreya, the name, in religion, of a Scotchman who has entered the Buddhist Order; and he has secured the cooperation for this number not only of Indian, Burmese, and Sinhalese, but also of American and English writers.

In the editor's article on "The New Civilisation," he maintains that the new civilisation which is beginning, in a way that no ancient civilisation did, to permeate mankind should be heartily welcomed by Buddhists as being based on that conception of the inviolable sequence of cause and effect, of the reign of law, which was, indeed, the main tenet in the teaching of the Buddha. And he ventures on a glowing prophesy of what the future of humanity will be when this conception of law, claimed by him as a special mark of Buddhist teaching, shall have worked out its effect in the daily lives of men by an increased deference to knowledge, and to the men of knowledge, by the growth of a spirit of wide toleration and humanity. The courageous optimism of this article is in striking contrast with ideas usually held about Buddhist teaching; but it is interesting to see how thoroughly the party represented by this newest Buddhist journal is in sympathy with the teachings and the spirit of science.

Dr. Paul Carus, of Chicago, follows with an article on "The Philosophy of Buddhism," in which he claims that the latest, as well as the earliest, Buddhism, rests upon the belief in a universal reign of law, and on the idea that nothing is but everything becomes. Mr. Chandra Das has an interesting historical paper on the foundation of Lhassa, and Mr. Tau Seng Ko another on the introduction of Buddhism into Burma, each of them writing with special expert knowledge of his subject. There are shorter articles by other writers, paragraphs of notes and news, and some scholarly reviews. The journal would be useful to those who desire to follow the tendencies in the forward movement among the Buddhist communities; whether it is entitled to speak for all Buddhists is another matter.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Cambridge.—Mr. A. W. Hill, of King's College, has been appointed University lecturer in botany until Michaelmas, 1909.

The degree of Sc.D. *honoris causa* is to be conferred on Prof. E. B. Tylor, of Oxford, at a congregation held to-day. At the same congregation Mr. J. W. Willis, director of the Botanical Gardens, Peradeniya, Ceylon, will proceed by proxy to the same degree.

Mr. C. Shearer, advanced student of Trinity College, has been re-nominated to the university table at the zoological station at Naples.

The Board of Geographical Studies has published the following schedule for the special examination in geography and for part i. of the examination for the diploma in geography:—(1) *Physical Geography*.—Form and motions of the earth. Elementary climatology and oceanography. Typical forms of land configuration, their distribution and modes of formation. (2) *Historical and Political Geography*. The historical development and political partition of the different regions of the world, with a consideration of the influence of their physical features. A more detailed knowledge of the geography of a selected region (for 1905 and 1906, *Europe*). (3) *Economic and Commercial Geography*.—The economic growth of the different regions of the world, and the main lines of commerce and communication by land and sea in past and present times. A more detailed knowledge of a selected region (for 1905 and 1906, *Europe*). (4) *Cartography*.—The construction and use of maps. A general knowledge of the methods of exploratory surveying: plane tabling, latitudes and azimuths by the sun, latitude and azimuth traverses, route traverses and compass sketching. Heights by barometer and boiling-point thermometer. The candidate will be examined orally and practically on maps and on the ordinary surveying instruments. Any candidate who can produce a sketch made by himself of a route traversed by compass, and checked by observations for latitude and azimuth with the necessary computations, will be examined thereon and will receive special credit for good work. (5) *History of Geographical Discovery*.—The outlines of the history of geographical discovery, with special questions on a selected region or period (for 1905 and 1906, *The Fifteenth Century*). (6) *Elements of Ethnology*.—The principal races of mankind, their migrations and present distribution.

London.—At the annual meeting of University College on February 22, the following resolution, moved by Lord Reay, on behalf of the council, was unanimously adopted:—That the Bill now submitted, entitled "A Bill for Transferring University College, London, to the University of London and for other matters connected therewith and for Amending the University of London Act, 1898," be and the same is hereby approved subject to such additions, alterations, and variations as Parliament may think fit to make therein.

Dr. Michele Cantone, of Pavia, is to succeed Prof. E. Villari as professor of physics and director of the physical laboratory at Naples. At Göttingen, Prof. F. Dolezalek has been appointed head of the department of physical and electrical chemistry. Dr. H. Kneser has been appointed professor of mathematics at Breslau. Dr. Ludwig Claisen late professor of chemistry at Kiel, has been appointed honorary professor at Berlin, and Dr. Karl Stöckl professor of mathematics and physics at Passau.

In his last report President Eliot recommends, says *Science*, the collection of 500,000*l*. as an endowment for the college of Harvard University, and it is said that the alumni are making efforts to collect this sum before the next commencement day. The class of 1880 expects to contribute 20,000*l*. on the occasion of its twenty-fifth anniversary. From the same source we learn that Mr. Andrew Carnegie has given to the Rensselaer Polytechnic Institute at Troy 25,000*l*. toward rebuilding the main building which was burned last June. He has also given 20,000*l*. to Tufts College for the erection of a library building.

The committee appointed by the Prince of Wales, as president of King Edward's Hospital Fund, to inquire into the financial relations between the hospitals and medical schools has now issued its report. The committee has formed, it is to be noted with satisfaction, the opinion that a broad line of distinction ought to be drawn between the preliminary and intermediate studies of a medical student on one hand, and the final studies on the other; and that whilst the final studies can be pursued with advantage only within the walls of a hospital, the earlier scientific studies have no real relation with a hospital, and are pursued more properly in an institution of university character. The committee expresses satisfaction that the statutes of the University of London direct the Senate to "use its best endeavours whenever practicable to secure such common courses of instruction for internal medical students in the preliminary and intermediate portion of their studies under appointed or recognised teachers at one or more centres." To do this effectively will mean a great expenditure, and the Senate of the university is appealing for funds to assist it in carrying out the work. The conclusions arrived at by the committee appointed by the Prince of Wales should prove of advantage both to the hospitals and to the

[1] "Buddhism." An Illustrated Quarterly Review. Vol. i., No. 4. Pp. xxii+170. (Rangoon: Hauthbrawaddy Press, 1904.)

university. The hospital should be a school only in the sense of being a school of applied science where general principles of science are applied to a specific technical purpose. But if the medical student is to be no longer provided with instruction in scientific fundamentals at the hospitals, there must be forthcoming—if London is to remain a great medical and surgical centre—funds enough to provide other institutions where this teaching may be given. University College and King's College have long done work of this kind, but the accommodation which they are able to provide is quite inadequate for the instruction of the students of all the hospitals, and other colleges are required where general education of a university standard may be obtained.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, January 26.—"On the Comparison of the Platinum Scale of Temperature with the Normal Scale at Temperatures between 444° and −190° C., with Notes on Constant Temperatures below the Melting-point of Ice." By Prof. Morris W. **Travers**, F.R.S., and A. G. C. **Gwyer.**

The authors conclude that, as might be expected, it is possible to apply the parabolic formula of Callendar and Griffiths to the re-calculation of the differences between the platinum scale of temperature and the scale of the gas thermometer, though the range through which it is applicable, and value of the constant ∂, precludes the possibility of employing it except for interpolation. A standard scale of temperature, based on Callendar's three fixed points, using standard wire, and taking 1.5 for the value of ∂, would lead to absurd results at low temperatures; and the converse may be said of the authors' own observations. The results referred to in this paper may be summed up as follows:—

Nature of gas thermometer.	Observer.	∂
Constant pressure air (0° to 444°) ...	Callendar and Griffiths	1·50
Constant volume nitrogen (−23° to 445°)	Chappuis and Harker	1·54
Constant volume nitrogen standardised by constant pressure air at 444° (500° to 1000°)	Harker	1·51—1·49
Constant volume hydrogen (−190° to 34)	Travers and Gwyer ...	1·90

February 2.—"On the 'Blaze-currents' of the Gall Bladder of the Frog." By Alice M. **Waller.** Communicated by Dr. Augustus D. Waller, F.R.S. (From the Physiological Research Laboratory of the University of London.)

This investigation was made in continuation of Dr. Waller's work on blaze-currents. A blaze-current, as defined by Dr. Waller in previous communications to the Royal Society and in his lectures on the signs of life, is a current of action, an electric current aroused in living tissues by stimulus; the term "blaze" has reference to the vitality of the tissue, to a chemical exchange going on within it; a muscle at rest is smouldering, a muscle in action is blazing. Dr. Waller's apparatus and method of work were employed; the apparatus consists essentially of a keyboard containing four keys, opening respectively to an induction coil, a compensator, the object to be studied, and a galvanometer or electrometer. Any accidental current in the object is compensated so that the galvanometer key can be opened without altering the zero, then the object is stimulated by a single break induction shock, the galvanometer key is opened, and the after-effect observed.

As seen in previous work by this method, the direction of blaze-current varies in different living objects or tissues, *e.g.* in a plant the blaze-current is either post-anodic or homodrome or it runs from younger to older tissue, in the crystalline lens from anterior to posterior surface, in skin from within outwards. The tissues and organs of the frog were systematically examined, and it was found that the liver gave responses either antidrome or from surface to hilum, and the gall bladder gave surprisingly large electrical variations, as much as 1/10 volt, always antidrome, in a way that one is accustomed to regard as due to polarisation currents in non-living matter. These polarisation currents were proved to be physiological by their abolition on submitting the organ to strong chloroform, boiling or electrocution by tetanisation. The effect is local, it can be destroyed by tetanus at two spots, and was found to persist at other parts of the round bladder.

Employing Waller's A. B. C. method, in which a three-way switch is employed so that the anode and kathode of the exciting current can be separately interrogated, it is found that the blaze at each pole is post-kathodic or antidrome. The blaze lasts about two minutes; it is often diphasic or triphasic; a single break shock with coil at 5000− (Berne scale) gave +0.0125 volt, then −0.0110, then +0.0010.

The bladder was washed out and filled with salt solution, and the same effect obtained; a piece was snipped off and electrodes applied to mucous and serous surfaces, and still antidrome blaze obtained, though there was a tendency to exhibit the usual mucous to serous blaze.

The simplicity of structure of the gall bladder—a sphere having a single row of columnar epithelium on the mucous interior surounded by layers of smooth muscle fibre cells—may account for the large and definite blaze-currents obtained, but why the cells should exhibit negative polarisation, antidrome rather than homodrome or positive polarisation, is not yet apparent.

Entomological Society, February 1.—Mr. F. Merrifield, president, in the chair.—*Exhibitions*:—Specimens of *Oligota granaria* found in a granary at Holborn, the only other localities reported hitherto being Shoe Lane, London, and Scarborough: H. St. J. **Donisthorpe.**—An Erycinid butterfly *Mesosemia eumene* pinned in its natural position of rest to show its resemblance to the head of a small mammal, such as a mouse: W. J. **Kaye.**—A variety of the female of *Lycaena melanops* named by him var. *wheeleri*: Dr. T. A. **Chapman.** As a mere aberration it was interesting, but it was of value as showing that the position in the genus for long accorded to the species, whether by accident or design, close to the Arion-Euphemus group, was correct. The considerable extension of the blue in this specimen showed up certain black spots on the upper surface of both upper and lower wings, strictly similar to these characteristics of the Arion-Euphemus group.—A living ♀ *H. defoliaria*, taken as late as February 1, at rest on north side of oak-tree, and another ♀ taken January 28 in the same wood at Bexley. A ♂ *Notodonta ziczac* × ♀ *N. dromedarius*, with two hybrids, the colour of the hybrids being that of *dromedarius*, while the markings were those of *ziczac*: F. **Enock.**—A living specimen of *Acridium aegyptium*, L., found in a cauliflower in Bloomsbury, and probably imported from Italy: O. E. **Janson.**—Two specimens of *Malachius barnvillei*, Puton, captured by Mr. Thouless at Hunstanton, Norfolk, in June, 1899, a recent addition to the British list: G. C. **Champion.**—♂ and ♀ specimens of *Machimus rusticus*, Mg., a rare Asilid, taken *in cop.* at Freshwater, Isle of Wight, on August 13, 1903: H. W. **Andrews.**—A ♀ example of *Panorpa cognata* taken at Byfleet Canal on August 23, 1904: W. J. **Lucas.** The insect occurs at Folkestone, and is said to be found in the New Forest. It is a little difficult at times to identify the ♀ alone, but Mr. K. J. Morton also had identified the specimen exhibited as *P. cognata*. For comparison he also exhibited ♀♀ of *P. communis* and *P. germanica*.—*Papers*:—A revision of the genus Criocephalus, with notes on the habits of *Asemum striatum* and *Criocephalus ferus*: Dr. D. **Sharp**, F.R.S., and T. G. **Smith.**—Another entomological excursion to Spain (with descriptions of two new species of Hemiptera by Dr. O. M. **Reuter**): Dr. T. A. **Chapman** and G. C. **Champion.**—On the matrivorous habit of the species of Heterogynis, Ramb., and on the pupal suspension of Thais: Dr. T. A. **Chapman.**—Notes on New Zealand Lepidoptera: E. **Meyrick**, F.R.S.

Zoological Society, February 7.—Mr. Howard Saunders, vice-president, in the chair.—A second collection of fishes made by Mr. S. L. Hinde in the Kenya District of East Africa: G. A. **Boulenger**, F.R.S. Examples of five species were contained in the collection, three of which were new to science.—On some points in the anatomy of a theriodont reptile: Dr. R. **Broom.**—Field-notes on the mammals of Southern Cameroons and the Benito: G. L. **Bates.**—A collection of Heterocera from the Fiji Islands: G. T. **Bethune-Baker.** Of the species enumerated eleven were new to science.—A contribution to the knowledge of the arteries of the brain in the class Aves: F. E. **Beddard**, F.R.S.—The function of the antennæ in insects: M. **Yearsley**. After reviewing the literature on the subject the author pointed out that Lowne, in his work on the blowfly, suggested that the antennæ were probably balancing rather than auditory organs. Lord Avebury and Latreille were cited in favour of this view, and the work of Yves Delage on Crustacea and of Clemens upon a moth (*Samia cecropia*) as confirmatory experiments. The author then gave details of experiments upon thirty wasps (*Vespa vulgaris*) in which the antennæ had been removed. The results of this mutilation were:—(1) Loss of power of flight; (2) loss of sense of direction; (3) noticeable slowness in all movements. The conclusion arrived at was that in wasps, the antennæ were equilibrating in function. This supported Lowne's surmise and corroborated the experiments of Clemens on *Samia cecropia*.

Anthropological Institute, February 14.—Prof. W. Gowland, president, in the chair.—Exhibition of native dances and ceremonies from the Torres Straits: Dr. A. C. **Haddon**, F.R.S. The exhibition was illustrated by lantern slides and kinematograph films, and dealt with the "Malu" ceremony, secular dances, and fire-making by a rotary method. Dr. C. S. Myers sang several of the native songs, which are sung at the dances, and accompanied himself on a native drum.—Dog-motive in Bornean design: E. B. **Haddon**. The methods of tattooing are constant among the tribes of Borneo, and most of the patterns are derived from the Kenyah and Kayan tribes. The different patterns are all derived from the dog-motive. The rosette pattern, for instance, which is tattooed on the shoulders of the men, is directly derived from the eye of a dog, although the Iban tribe, who have adopted the pattern, call it by the name of various fruits and flowers. The conventional tattoo pattern found on the firearms of Kenyah and Kayan men in Sarawak, although modified out of all recognition, is also clearly derived from the same source, as it is named *asu*, which means dog; from this same pattern a series can be traced to the Iban pattern, which is said to represent a scorpion, *Kala*, but was clearly originally a dog. Similarly the so-called prawn pattern, *Udang*, was shown to be derived from the dog-motive.

Royal Meteorological Society, February 15.—Mr. R. Bentley, president, in the chair.—Report on the phenological observations for the year 1904: E. **Mawley**. The weather of the phenological year ending with November, 1904, was chiefly remarkable for the persistent rains in January and February, the absence of keen frosts in May, the long continuance of hot and dry weather in July, and the small rainfall during the autumn. Throughout the year wild plants came into flower behind their usual dates, but at no period were the departures from the average exceptional. Such spring migrants as the swallow, cuckoo, and nightingale made their appearance in this country at as nearly as possible their usual time. The yield of wheat per acre was the smallest since 1895, while those of barley, beans, and peas were also deficient. On the other hand, there were good crops of oats, potatoes, and mangles. The best farm crops of the year were, however, those of hay, swedes, and turnips. Both corn and hay were harvested in excellent condition. Apples were everywhere abundant, and all the small fruits yielded well, especially strawberries, but there was only a moderate supply of pears and plums.—Observations of meteorological elements made during a balloon ascent at Berlin on September 1, 1904: Dr. H. **Elias** and J. H. **Field**.—The winds of East London, Cape Colony: J. R. **Sutton**.

Linnean Society, February 16.—Prof. S. H. Vines, F.R.S., vice-president, in the chair.—A revised classification of roses: J. G. **Baker**, F.R.S. The author dealt with the genus by dividing it into three groups. In the first group primary species were enumerated; in the second, sub-species and varieties; in the third, the principal hybrids. The primary species as estimated by the author are sixty-nine in number, and they are classified under eleven groups. The geographical distribution can be very briefly stated as follows:—Five species are found south of the Tropic of Cancer in elevated situations, two in Abyssinia, one in the Neilgherries, and two in Mexico. There are six geographical regions in the North Temperate Zone, each with a considerable proportion of endemic species. (1) Europe, with twenty-nine species; (2) Northern Asia with China and Japan, twenty-six species; (3) Western Asia, with eighteen species; (4) India, with nine species; (5) Western North America with the Rocky Mountains, with ten species; (6) Eastern North America, six species.—The botany of the Anglo-German Uganda Boundary Commission—Polypetalæ, E. G. **Baker**; Gamopetalæ excl. Convolvulaceæ, S. **Moore**; Convolvulaceæ, Apetalæ, and Monocotyledons, Dr. A. B. **Rendle**. The Commission commenced demarcating the boundary in the Uganda Protectorate in December, 1902, H.M. Commissioner on the British side being Lieut.-Col. Delmé-Radcliffe. The collections which are the subject of this paper were made by Dr. A. G. Bagshawe, the medical officer. They contain a considerable number (some fifty) of novelties, as also of known plants not hitherto recorded from the Uganda Protectorate. For the Angolan plant previously known as *Asystasia africana*, C. B. Clarke, which also is in the collection, a new genus, Styasasia, is proposed. A considerable percentage of West African coast-plants is a feature of the Protectorate flora as now made known, and worthy of mention is the presence of a small South African element.

Cambridge.

Philosophical Society, January 30.—Prof. Marshall Ward, F.R.S., president, in the chair.—On the non-electrification of γ rays; Prof. **Thomson**, F.R.S. Experiments were described in which the electrifications imparted to two equal cylinders made of thin brass, one of them hollow and the other filled with lead, were measured. The cylinders were in electrical connection and were symmetrically placed in a large vessel from which the air was exhausted. The cylinders were exposed alternately to the γ rays of radium, and from the measurement of the charges received by them it was concluded that the electrifications observed when γ rays fall on a body are not due to a charge on the γ rays, but to the charge carried by secondary β rays excited by the γ rays when they fall on the body or on the walls of the vessel containing it.—Are metals made radio-active by the influence of radium radiation? Prof. **Thomson**, F.R.S. From experiments made on lead, brass, and tin it was shown that these bodies, after exposure to radium radiation, exhibit no trace of radio-activity four minutes after the radiation has ceased to fall upon them; there was no evidence of induced activity of any kind, but the method used was not adapted for testing the existence of a very short-lived radio-activity; this has been done by Prof. Bumstead by a method described in the next paper.—Are metals made radio-active by the influence of radium radiation? Prof. **Bumstead**. The experiments described formed a continuation of those reported by Prof. Thomson, and were designed to ascertain whether the secondary rays given out by a surface exposed to the β and γ rays of radium persisted for a very short time after the exposure to the exciting rays had ceased. A rotating disc was used and four substances were tested, viz. copper, lead, tin, and blotting-paper which had been soaked in a solution of uranium nitrate and then dried. The interval between exposure to the rays from 30 mg. of pure radium bromide and the subsequent test for residual activity was less than 0·009 second; and no rays capable of penetrating 7 mm. of air and 0.00005 cm. of aluminium were detected. If any were present they must have been considerably less intense than those given out by a layer of potassium uranium sulphate with a surface-density of one milligram per square centimetre.—Note on the positive leak from hot platinum in air: O. W. **Richardson**. Experiments showing that the rate of discharge of positive electricity by a platinum wire, which had been heated in air long enough for the current to become steady, consists of two parts, one proportional to, and the other independent of, the pressure.—Some methods of increasing the spark length of the Wimshurst machine: B. J. **Palmer**.

February 13.—Prof. Marshall Ward, president, in the chair.—Orthogonal and other special systems of invariants, part i.: Major P. A. **MacMahon**, F.R.S. In this paper orthogonal concomitants are discussed by means of a symbolic calculus with imaginary umbræ. For a binary quantic of any given order, the author finds an inferior limit to the maximum degree of an irreducible covariant of given order belonging to it: a superior limit is also found in certain cases. For the first three degrees of the concomitants, for a quantic of any order, the actual number of irreducible concomitants is found; and hence the number of fundamental syzygies is inferred. Tables of ground-forms are given for quantics of order 2, 3, 4, 5, 6 respectively.—Reduction of generating functions by means of complex integration: G. B. **Mathews**, F.R.S. It is shown in this note how a class of generating functions which occur in the theory of invariants, and in that of the partition of numbers, may be reduced by means of Cauchy's calculus of residues.

DUBLIN.

Royal Irish Academy, February 13.—Prof. R. Atkinson, president, in the chair.—Verb functions or explicit operations, with notes on the solution of equations by operative division: Major Ronald **Ross**, C.B., F.R.S. If any expression is being considered as the result of an operation performed on one of its elements, the actual operation can be separately and explicitly represented in the following manner. The place occupied by the subject-element is called the base of the operation and is always denoted by β. Thus, $\beta \cos^{-1}\beta$ is the operation performed on x in order to produce the function $x \cos^{-1}x$. As β has no quantitative value, such an expression as $\beta \cos^{-1}\beta$ denotes, not a quantity, but an *action*, and may be called a *verb function*. Before applying such an expression to a subject it must be placed in special (square) brackets in order to distinguish operation from multiplication. The method may be applied to the solution of a complete equation of the nth degree in $2n$ ways, and applies equally to the solution of linear differential equations.

EDINBURGH.

Royal Society, February 6.—Dr. Traquair in the chair.—On Penella, a Crustacean parasitic on the Finner Whale (*Balaenoptera musculus*): Sir William **Turner**. This copepod was originally recognised by Koven and Danielssen as parasitic on *Balaenoptera rostrata*. The author's specimens were obtained in 1903 from *B. musculus*. The memoir comprised an account of the external characters and internal anatomy of the female, which, being from 10 to 12 inches long, varying in different specimens, is a giant amongst copepods. A comparison of the species with other species of Penella was made, and the great length of the thoracic in comparison with the genito-abdominal segment was referred to. The male of this species has not yet been recognised.—The ontogeny of the neuron in vertebrates; a cytological study of the embryonic nucleus: Dr. John **Cameron**. The results of the investigation tend to show that the so-called neuroblasts of the central nervous system in the early vertebrate embryo are really nuclei, from which the rudiments of the axis cylinder are formed as delicate protrusions. The neuroblast nuclei are found to exhibit remarkable structural changes, as evidence of the formation of these processes. The results attained in this research support the central theory of nerve-genesis as formulated by, among others, His and von Kölliker. They also tend to throw fresh light on the properties and functions of the cell-nucleus.

MANCHESTER.

Literary and Philosophical Society, February 7.—Prof. H. B. Dixon, F.R.S., vice-president, in the chair.—A new direct-vision spectroscope: T. **Thorp**. In Mr. Thorp's instrument the dispersion is effected by means of a transparent grating of about 14,500 lines to the inch, mounted on the long face of a light crown prism having a refracting angle of about 37° to secure direct vision. This prism-grating is mounted in a hinged frame and adjusted so that the grating face is at an angle of 45° with the axis of the instrument when the frame is at the centre of its range of motion. A spring holds the frame tightly against the end of a micrometer screw having a graduated head, this head being in the focus of a lens placed near the ocular of the spectroscope so that it can be read off without taking the instrument away from the eye. The D lines can just be separated in the pocket instrument, and readings can be made by taking the mean of several to about one Ångstrom unit.—Leaden weights found at Melandra Castle, an old Roman edifice near Glossop, among them being the uncia, or ounce, and other weights related thereto: F. A. **Bruton**.—A direct determination of the atomic weight of chlorine by burning a known weight of hydrogen in a known weight of chlorine: Prof. H. B. **Dixon**, F.R.S., and E. C. **Edgar**. The hydrogen was occluded in palladium and so weighed; the chlorine was prepared by the electrolysis of silver chloride, and was weighed in the liquid state. The atomic weight comes out about 35·192, higher than the accepted number by 0.012. This higher value is of interest in view of the recent (unpublished) work of Prof. Theodore Richards, of Harvard, who obtains a value 0.019 higher than the accepted atomic weight.—On the occurrence in Britain of the Pacific eider (*Somateria v-nigrum*, Gray), a species new to the European avifauna: C. **Oldham**.—Some habits of bats, with special reference to the lesser horse-shoe bat (*Rhinolophus hipposiderus*): C. **Oldham**. Proofs were given that the hibernation of these animals is not continuous, but interrupted by transient periods of activity.

PARIS.

Academy of Sciences, February 20.—M. Troost in the chair.—Observation of the partial eclipse of the moon on February 19: G. **Bigourdan**. Owing to the cloudy condition of the sky no observations were possible before 7.50 p.m.—On a new method of synthesis of alkyl derivatives of certain cyclic saturated alcohols: A. **Haller** and F. **March**. The sodium derivatives of propyl, isobutyl, and isoamyl alcohols, heated to 200° to 225° C. in an autoclave with β-methylcyclohexanone, act partly as reducing and partly as alkyl substituting agents. Homologues and isomers of menthol result from the reaction.—On the examples of Palinuridæ and Eryonidæ collected in the eastern Atlantic by the French and Monaco expeditions: E. L. **Bouvier**. The study of the collections brought home by the two expeditions has resulted in the discovery of some new interesting species, among others two types belonging to the genera Puer and Eryonicus, examples of which are extremely rare. These two forms show their distinctive morphological characters very early.—The application to the nitriles of the method of direct hydrogenation by catalysis; the synthesis of primary, secondary, and tertiary amines: Paul **Sabatier** and J. B. **Senderens** (see p. 423).—The large solar spot of February, 1905: Th. **Moureux**. On February 2 this spot, which was clearly visible to the naked eye, had a length of 180,200 kilometres. Its area was 1/20th of the solar disc, and hence it is greater than any sun-spot previously observed.—On Taylor's series on the circle of convergence: Paul **Dienes**.—On differential equations of the second order containing a single parameter: G. **Tzitzeica**.—On the approximate integration of differential equations: Emile **Cotton**.—On the mode of working of the differential gear of automobiles: A. **Petot**.—On the coefficient of magnetisation of bismuth and on some fixed points in the diamagnetic scale: Georges **Meslin**. The coefficient found for mercury was $-0{\cdot}185.10^{-6}$, taking water as $-0.79.10^{-6}$. For crystallised bismuth the value, with the additive correction for the air, was $-1{\cdot}39{\cdot}10^{-6}$, whilst a slightly higher result, $-1.42.10^{-6}$, was obtained for the fused metal.—On the perborates: P. **Melikoff**. A claim for priority as against M. Jaubert.—On lactyllactyllactic acid and the dilactide of the inactive acid: E. **Jungfleisch** and M. **Godchot**.—On the carbimide of natural leucine: MM. **Hugounenq** and **Morel**. The leucine ethyl ester was heated to 130° C. with carbonyl chloride in toluene solution, and the mixture submitted to fractional distillation *in vacuo*. The carbimide sought for was readily separated in this way from the substituted urea formed at the same time.—On the perborates: J. **Bruhat** and H. **Dubois**. A description of the preparation and properties of the perborates of potassium, sodium, and ammonium.—Assimilation outside the organism: Ch. **Bernard**. It has been stated by Friedel and confirmed by Macchiati that the enzyme extracted from leaves by glycerine in the presence of chlorophyll and light was capable of decomposing carbonic acid and setting free oxygen. The author has not been able to obtain any trace of oxygen under these conditions, and on repeating an experiment exactly in accordance with Macchiati's instructions found that the gas evolved consisted of methane and other inflammable gases, arising from the anaërobic decomposition of the plant tissue, this change not taking place in the presence of antiseptics, such as camphor. The author therefore regards the decomposition of carbonic acid outside the plant as unproven.—On the composition of brandy from wine: X. **Rocques**. A table is given showing the results of analysis of twenty-two samples of brandy arising from the distillation of wine, and it is pointed out that a brandy containing a relatively small amount of esters contains an increased amount of higher alcohols.—The prediction of a chemical reaction forming a monovariant system: Camille **Matignon**.—On two plants producing rubber: E. de **Wildeman**. A description of two plants, *Bassea gracillima* and *Periploca nigrescens*, the rubber producing properties of which have not hitherto been recognised.—On a new coffee plant in Central Africa: Aug. **Chevalier**. A detailed account of *Coffea excelsa*, with analyses of the soil in which it flourishes and of the coffee-bean produced from it. The amount of caffeine and the taste and aroma of the coffee are good, and would be worth cultivating in the French Congo.—On the secreting apparatus of Dipterocarpus: P. **Guérin**.—On the effect of low temperatures on the zoospores of the Algæ: E. C. **Teodoresco**. The spores of *Dunaliella salina* were found to retain their activity in a salt solution even after exposure to a temperature of $-30°$ C.—On a new cellular type with metamerised cytoplasm, *Taenicystis mira*: Louis **Léger**.—Geographical variations of the Pleuronectidæ: A. **Cligny**.—The extension of the functional states of the auricle to the ventricle: H. **Kronecker**. The author's experiments lead him to regard this effect as being entirely due to nervous elements.—Variations in morbid processes according to the composition of the organs: MM. **Charrin** and **Le Play**. Hydrolysis of the hepatic glycogen produced by the injection of amylase into the portal vein: M. **Pariset**.—On the stimulation of the nerves by very short electric waves: Louis **Lapicque**.—The experimental reproduction of leprosy in the ape: Charles **Nicolle**.—The geology of the Pyrenees of Haute-Garonne and Ariège: Léon **Bertrand**.—On the Amana meteorites: G. D. **Hinrichs**.—The cave lions: Marcellin **Boule**.

DIARY OF SOCIETIES.

THURSDAY, March 2.

Royal Society, at 4.30.—Further Researches on the Temperature Classification of Stars. No. 2: Sir Norman Lockyer, K.C.B., F.R.S.—On the Radio-active Minerals: Hon. R. J. Strutt.—Atmospheric Electricity in High Latitudes: G. C. Simpson.—On the Spectrum of Silicon, with a Note on the Spectrum of Fluorine: J. Lunt.—On the Electric Resistance to the Motion of a Charged Sphere in Free Space or in a Field of Force: G. W. Walker.

Royal Institution, at 5.—Recent Astronomical Progress: Prof. H. H. Turner, F.R.S.

Chemical Society, at 8.—The Latent Heat of Evaporation of Benzene and some other Compounds: J. Campbell Brown.—The Relation between Natural and Synthetic Glycerylphosphoric Acids: F. B Power and F. Tutin.—The Reduction of Isophthalic Acid: W. H. Perkin. jun., and S. S. Pickles.—The Transmutation of Geometrical Isomers: A. W. Stewart.

Röntgen Society, at 8.15.—A discussion on "The Necessity of Accurate Measurement in X-ray and High Frequency Work," opened by Dr. W. D. Butcher.

Civil and Mechanical Engineers' Society, at 8.—Engineering Expert Evidence: J. F. Reade.

Linnean Society, at 8.—Zoological Nomenclature; International Rules and Others (to be followed by a discussion): Rev. T. R. R. Stebbing, F.R.S.—Biscayan Plankton. Part IV. The Thaliacea: Dr. G. Herbert Fowler.

Institution of Electrical Engineers, at 8.—Type-setting by Telegraph: D. Murray.

FRIDAY, March 3.

Royal Institution, at 9.—Recent Advances in Wireless Telegraphy: Chev. G. Marconi.

Geologists' Association, at 8.—The Diamond Mines of South Africa: Prof. H. A. Miers, F.R.S.

SATURDAY, March 4.

Royal Institution, at 3.—Archæology: D. G. Hogarth.

MONDAY, March 6.

Society of Arts, at 8.—Internal Combustion Engines: Dugald Clerk.

Society of Chemical Industry, at 8.—Mechanics of Fire: Prof. H. E. Armstrong, F.R.S.—On the Estimation of Arsenic in Fuels—A Shortened Method: Dr. G. McGowan and R. B. Floris.

Victoria Institute, at 4.30.—Geological Exterminations: Dr. C. B. Warring.

Faraday Society, at 7.50.—Annual general meeting.—At 8.15.—Recent Developments in Electric Smelting in Connection with Iron and Steel: F. W. Harbord.

TUESDAY, March 7.

Royal Institution, at 5.—Some Recent Biometric Studies: Prof. K. Pearson, F.R.S.

Zoological Society, at 8.30.

Institution of Civil Engineers, at 8.—Surface-Condensing Plants, and the Value of the Vacuum produced: R. W. Allen. (*Continuation of Discussion.*)

WEDNESDAY, March 8.

Geological Society, at 8.—(1) Observations on some of the Loxonematidæ, with Descriptions of two New Species: (2) On some Gasteropoda from the Silurian Rocks of Llangadock: Miss Jane Donald.

Society of Arts, at 8.—Ethics of Japanese Society: Baron Suyematsu.

THURSDAY, March 9.

Royal Society, at 4.30.—*Probable Papers*: The Rate of Transmission of the Guatemala Earthquake of April 19, 1902: R. D. Oldham.—Ionic Sizes in Relation to the Conductivity of Electrolytes: W. R. Bousfield.—Explosions of Mixtures of Coal Gas and Air in a Closed Vessel: L. Bairstow and A. D. Alexander.

Royal Institution, at 5.—Recent Astronomical Progress: Prof. H. H. Turner, F.R.S.

Institution of Electrical Engineers, at 8.—Report on Experiments carried out at the National Physical Laboratory: On the Effect of Heat on the Electrical and Mechanical Properties of Dielectrics, and on the Temperature Distribution in the Interior of Field Coils: Dr. R. T. Glazebrook, F.R.S.—On Temperature Curves and the Rating of Electrical Machinery: R. Goldschmidt.

FRIDAY, March 10.

Royal Institution, at 9.—The Structure of the Atom: Prof. J. J. Thomson, F.R.S.

Royal Astronomical Society, at 5.

Malacological Society, at 8.—On a Dibranchiate Cephalopod from the Eocene of Arabia: G. C. Crick.—Note on the Horizon and Locality of the Type Specimen of *Pleuronautilus pulcher*: G. C. Crick.—New Marine Mollusca from the Collection of the late Admiral Keppel: G. B. Sowerby.—On the Occurrence of Internal Septa in *Glyptostoma newberryanum*: G. K. Gude.—Note on a Dart found in the Body Cavity of *Helix aspersa*: R. G. Barnes.

Institution of Civil Engineers, at 8.—The Purification of Sewage: F. G. Helsby.—The Purification of Sewage by Hydrolysis and Oxidation: F. O. Kirby.

Physical Society, at 8.—On the Stresses in the Earth's Crust before and after the Sinking of a Bore-hole: Dr. C. Chree, F.R.S.—On the Lateral Vibration of Bars of Uniform and Varying Sectional Area: J. Morrow.—On Direct Reading Resistance-Thermometers, with an Appendix on Composite Thermocouples: A. Campbell.

SATURDAY, March 11.

Royal Institution, at 3.—Electrical Properties of Radio-active Substances: Prof. J. J. Thomson, F.R.S.

CONTENTS.

THURSDAY, MARCH 9, 1905.

THE ORIGIN OF MAN.

Morphology and Anthropology. A Handbook for Students. By W. L. H. Duckworth, M.A. Pp. xxvii+546. (Cambridge: University Press, 1904.) Price 15*s.* net.

Studies from the Anthropological Laboratory, the Anatomy School, Cambridge. By W. L. H. Duckworth, M.A. Pp. x+291. (Cambridge: University Press, 1904.) Price 10*s.* net.

THE publication of Mr. Duckworth's text-book for students, bearing on its title page the rather vague terms, "Morphology and Anthropology," marks the culmination of the remarkable movement initiated by the publication of Huxley's "Man's Place in Nature" in 1863, and quickened in 1871 by the appearance of Darwin's "Descent of Man." At the commencement of this movement the subject of man's origin had its abode in the divinity schools; it was taught by theologians; the opening chapters of Genesis constituted the accepted text-book; now, in 1905, the subject is assigned to the anthropological laboratory; the lecturer on physical anthropology is its custodian, and the text-book is the work now under review.

In a clearly written introductory chapter Mr. Duckworth defines the subject-matter of his book as an inquiry into (1) man's zoological position; (2) the nature of his ancestry. That such a work is needed there can be no doubt. Ever since Darwin and Huxley gave this subject a legitimate place in the hands of biologists, experts have been busy as ants, seeking, collecting, and storing facts in the tome upon tome that annually come to crowd our bookshelves. The embryological history of man, anthropoid and ape have become known; important additions have been made to the geological record; our knowledge of the structure of the Primates has increased twenty-fold; all the additional evidence of thirty years thus lay at Mr. Duckworth's disposal awaiting systematisation. He has every qualification for the task; he has devoted many years to examining and extending the evidence on which our conception of man's origin rests. "Studies from the Anthropological Laboratory," the second work included in this review, containing thirty-six papers dealing with various aspects of primatology, guarantee his industry and first-hand knowledge. He has the advantage, too, of having at his disposal the great anthropological collections accumulated by Prof. Macalister, and free access to one of the best libraries of the world.

It is natural to expect that Mr. Duckworth, having so much additional evidence at his command, is able to define man's position in the animal kingdom with a greater degree of precision than was possible at the time when Huxley and Darwin wrote. Huxley, it will be remembered, restored man to the position originally assigned to him by Linnæus, namely, that of a family in the order of Primates, because, on the evidence he was able to adduce, man differed less in point of structure from the family of anthropoids than the anthropoids from the family of the Old World monkeys. Further, Huxley regarded the chimpanzee and gorilla as the animal forms most nearly related to man. In these two respects Darwin agreed with Huxley. In the classification adopted by Mr. Duckworth, man retains the position assigned to him by Huxley. Mr. Duckworth's style in producing evidence and conflicting theories is open, frank, and impartial, but in setting forth his conclusions he is so eminently non-committal that it is difficult to cite a passage which concisely expresses his conception of the exact position which man holds with regard to other families of Primates. On p. 226 the following passage occurs:—

"But no single example among the larger Simiidæ can be pointed out with confidence, as embodying the characters of the human ancestor at the simian stage of evolution more completely than any other, though there is a slight margin of evidence in favour of the Chimpanzee, rather than the Gorilla or the Orang-utan."

Thus it will be seen that the matter of man's zoological position remains where Huxley left it. Huxley had an incomparable faculty of drawing just conclusions from limited data, but few men who are experts on this matter will agree that Mr. Duckworth has utilised the evidence at his disposal to the fullest extent possible.

Nor has the evidence which has accumulated in the last thirty-three years permitted Mr. Duckworth to make a more definite statement as to the ancestral chain or phylogenetic path of man than was made by Darwin in his first edition of the "Descent of Man" in 1871.

"The Simiadæ," wrote Darwin, "then branched into two great stems, the New World and Old World Monkeys; from the latter, at a remote period, Man the Wonder and Glory of the Universe proceeded" (vol. i., p. 213, 1st ed.).

Mr. Duckworth's conclusions in this matter are summed up at p. 542 as follows:—

"But while it is shown that the Hominidæ have in their evolution passed through a stage which is better reproduced by the Simiidæ (anthropoids) than by any other of the Primates, it is practically certain that the modern Simiidæ did not themselves figure in the ancestry of man and that they are themselves specialised in a high degree, more specialised in many ways than the Hominidæ and more specialised than their own ancestors. As Klaatsch puts it, the ancestors of the modern Simiidæ were more anthropoid than the actual Simiidæ, just as the ancestor of the Hominidæ was more pithecoid than modern Man. And the balance of evidence indicates that the line of human ancestry would, were the material still available, be traceable down to the lowest Primates (Lemuroidea) and even to the lowest Mammals. Moreover, it is undeniable that the Hominidæ have retained in hand and foot some features of an early ancestor, from which they have departed less in type than have the (modern) Cercopithecidæ and Simiidæ. But detailed information on these points is still lacking."

U

Leaving out of account the oracular statement quoted from Klaatsch, there can be no question that Mr. Duckworth's inference as to man's line of ancestors is much less definite than that of Darwin, and certainly, in the opinion of many well qualified to judge, less in keeping with the evidence at our disposal. What the peculiar primitive characters of the human hand and foot may be the writer cannot guess, but it is certain that there are numerous characters in the human hand and foot which can be accounted for only on the supposition that at one time they were used functionally as are now the hands and feet of anthropoids. Mr. Duckworth states his opinion guardedly, but it is evident from the statement just quoted that he believes the line of ancestors that connect modern man with a primitive lemuroid (Eocene) stock is extinct and unknown, and that this line of ancestry runs an independent and parallel course to the ancestral stock of the anthropoids. Now man shares with the chimpanzee and gorilla some three hundred structural features which are not possessed by any lemuroid form of which we have any knowledge, nor can the common possession of these characters be accounted for except on the supposition that man and these two anthropoids are derived from a common stock. A full investigation of the evidence will show that Darwin was not far from the truth when he supposed that the gorilla, the chimpanzee, and man have their origin from a common stock. Modern man differs from the Miocene anthropoid Dryopithecus in structure no more than does the modern horse from its Miocene ancestor. In Dryopithecus, characters are recognisable which link it with the gibbon on the one hand and the chimpanzee on the other. Palæopithecus, a Pliocene anthropoid, in the characters of its teeth and jaw, which are the only parts yet found, links the chimpanzee to the orang. The modern gibbon differs in an incredibly small degree from its Miocene ancestor, and shares many characters in common with the great anthropoids, man, the Old World monkeys, and New World monkeys, and is by far the most generalised form of higher Primate now extant, in spite of many adaptive features. In short, the evidence points to the common origin of man and the great anthropoids from a gibbon (Hylobatian) stock; this in turn, with monkeys, must be traced to a lemuroid origin.

Mr. Duckworth deals very justly with the evidence yielded by embryological investigation. Thirty years ago, when it was believed that the embryo recapitulated its ancestral stages *in utero*, it was thought that the history of man could be written when his development became known. "Palæontology is good but Embryology is better," wrote Kitchen Parker, but now we know, and Mr. Duckworth states the case fully, that the embryological phases are so obscure that they can only be construed by the help of comparative anatomy and palæontology. It has come to be recognised that every mammal is adapted to two separate lives—an intra-uterine life and an independent life; the features of the one existence mask those of the other. Yet Mr. Duckworth makes the important fact stand out that the intra-uterine life of man is exactly similar, so far as we yet know, to that of the anthropoids, and in that, while it resembles in most points the lower Primates, yet differs from all other mammals.

It must be admitted that Mr. Duckworth's task was not an easy one; yet no essential or important contribution has been passed unnoticed by him. His statements are clear and impartial; he has even a kindly word to say for some notions, such as the temporary fissures of the brain, which most anatomists, in common with himself, now regard as *post-mortem* artefacts. In another edition, which this work is certain to attain, the statements made in the following sentence (p. 201) will require some amendment:—

"Selenka thus regards the syncytium (a peculiar tissue) as derived neither from the chorion-entoderm (Kollmann), nor from the submucous uterine decidual connective tissue cells (Minot, 'Human Embryology,' pp. 13 and 375) nor from the fœtal ectoderm (Robinson, 'Hunterian Lectures,' *Journal of Anatomy and Physiology*, vol. xxxviii. p. 493), but from the epithelial lining of the uterus."

Mr. Duckworth unwittingly does the late Prof. Selenka a double injustice; in the first place he reproduces an acknowledged modification (Fig. 148, p. 203) of a figure by Selenka, in which the syncytium is made to appear as a continuation of the lining epithelium of the uterus, whereas in Selenka's figure it is clearly shown not to be continuous; secondly, Selenka ("Studien ueber Entwickelungsgeschichte," Heft viii., pp. 190, 193) expressly states that he is uncertain of the origin of the syncytium, but that the evidence is rather in favour of its origin from the cells of the uterine glands. Expert opinion regards it as settled that the syncytium does not so arise, but springs from the ectoderm of the embryo, a conclusion which seemed to Selenka not improbable. He does Kollmann also an injustice, for in his text-book (p. 201) that author expressly states that it arises from the lining epithelium of the uterus—the opinion ascribed by Mr. Duckworth to Selenka. Nor will Minot acknowledge the opinion ascribed to him, for on p. 322 of a text-book on human embryology he states that he is convinced that the syncytium is derived from the embryonic (chorionic) ectoderm, the opinion here ascribed to Prof. Robinson. Nor will Prof. Robinson be willing to accept priority for the theory of the ectodermal origin of the syncytium; probably Hubrecht has the greatest claim to be accounted the pioneer in this matter.

It would not be just to close this review without acknowledging the number of original facts and fresh opinions that mark the pages of this work. The opening chapters are perhaps too condensed; the long lists of characters enumerated are rather apt to lead to mental dyspepsia even in the pages of a text-book, and one misses a statement of their functional meaning, which would greatly assist the memory in ranking them together. The chapters on the cerebral organisation are specially well done, and contain the best exposition yet published of our knowledge of that part of the Primate organisation. Special prominence is deservedly given to the brilliant work of Prof. Elliot Smith. There can be no doubt, too, that this work will lead to a renewed vigour in the search for evidence bearing on the origin and relationships of the higher Primates.

A. K.

CHEMISTRY FOR YOUTHS: MRS. MARCET REDEVIVA.

Die Schule der Chemie. By W. Ostwald. Zweiter Teil—Die Chemie der Wichtigsten Elemente und Verbindungen. Pp. viii + 292. (Brunswick: Vieweg and Son.) Price 7·20 marks.

ABOUT a year ago, the first volume of Prof. Ostwald's dialogues on chemistry was noticed in these columns. We have now the second volume, written in as lively a strain as the first, and conveying the author's views, which bid fair to become in the main everybody else's views, as regards the presentation of the elementary facts of chemistry. It would be wrong to say that in this volume, consisting of 292 pages, there is more system; but in it we come to a discussion of chemical facts and theories which are generally treated in school text-books. The pupil is introduced to chlorine, its preparation and properties; its behaviour with water; acids and bases, and elements; combining weights, and multiple proportions; the atomic hypothesis, and the laws of volume combination; electrolysis and salts. Chlorine is again considered as regards its compounds with oxygen, and then follow bromine and iodine; sulphur and its compounds; nitrogen, ammonia, phosphorus, and so on through the commoner elements and their compounds.

Throughout the volume we find neat remarks which sustain interest, at least, when it is glanced through, for I do not think that anyone who is already a chemist will read the volume as carefully as he may have read the first volume. For example, on the first page is an aphorism, too often neglected, but none the less true:—"When much has been learnt, time must be given for digestion." In English "cramming doesn't pay in the long run."

Everyone knows that Prof. Ostwald does not hold by the atomic theory. Yet he does not escape from it. His presentation of it is, however, ingenious, as indeed are all his methods. Discussing the facts of multiple proportion he gives the following illustration:—

"Think of a collection of coins, where German marks, English shillings, French francs, Russian roubles, and other coins are to be found. You can combine these coins in twos and threes; each combination, however, has the value of the sum of the individual value of the coins, and you cannot obtain any other values, combine them as you will. Similarly, no other compounds can be formed but those obtained by bringing the elements together according to their combining weights."

The pupil then draws the required conclusion:—

"That is as if each element consisted only of equal pieces, just as all francs or marks are equal among themselves." "Yes," answers the teacher; "that is the picture which has represented the state of affairs to men's minds for long. It is supposed that each element consists of minute particles, named atoms," and so on. When the boy asks, "Is all this true?" the teacher replies, "No one has seen an atom, nor weighed one. This is therefore a hypothesis, but a very convenient one, because the various applications of the laws of combining proportions can be better realised (merken) when the picture of atoms is simple and clear." "But we can do without it!" says the pupil. "Certainly," says the teacher. "But just as you found it easier to count on your fingers than in your head, so it is easier to think of atoms, than of the abstract and general laws of combination." So we have to teach by means of atoms. Indeed, few of us would go further, especially in these later days, when even atoms are failing us. The hypothesis is, however, ignored a little later, when it is stated that "the rule has been made never to write fractional parts of combining weights." The doctrine of the indivisibility of atoms would appeal more readily to a young mind. Yet in fairness, it must be acknowledged that the writer makes the pupil suggest that each chemical symbol stands for an atom, and acknowledges, in the mouth of the teacher, that "the atomic theory can be easily grasped" ("etwas sehr eingängliches hat").

When electrolysis is discussed, the author's ingenuity in devising analogies is at its best. The pupil has difficulty in picturing a positive and a negative current going in opposite directions through the same wire. He is reminded of waves crossing each other in a pond, and of the upper and under parts of a driving-belt travelling in opposite directions.

Heats of combustion, discussed under the heading "carbon," are measured in kilojoules, instead of calories. This is perhaps logical, but it appears to the reviewer that the older unit might have been retained until a later stage. It is easy to make the reduction when required; and it is easier to realise heat as heat than as work, at first, at least.

While acknowledging that the subject of chemistry is here well treated, and that the author has maintained his lively style and faculty of lucid presentment, it may be questioned whether this method of discussing chemistry should have precedence over the ordinary text-book. A youth who advances so far as to grasp the contents of volume I., will, I think, tire of the plan of question and answer. Yet perhaps there are some who prefer to take their food, as they do medicine, in spoonfuls, and to whom the form of dialogue has its attractions. In old days "Pleasant Pages" was widely read, and no doubt conveyed valuable lessons. And at any rate, teachers of chemistry may learn much from this volume in hints as to how best to present the very numerous facts of the science to their students, whose digestive powers are as a rule limited.

W. R.

FLORAL MORPHOLOGY.

Praktikum für morphologische und systematische Botanik. By Dr. Karl Schumann. Pp. viii+610. (Jena: Gustav Fischer, 1904.) Price 13 marks.

THE morphology of the flower, although an important item in the curriculum of the advanced student of botany, is not infrequently compressed into a period quite insufficient for obtaining a knowledge of more than a few cohorts or families. But the relegation of this branch of botany to an uncertain stage is easily explained, since, as a course for training students, and this is the first object of a scientific curriculum, floral morphology does not offer the same scope as vegetative anatomy or physiology. Nevertheless, the art of discovering all the essential points of a flower is by no means easily acquired, while the ability to distinguish between critical genera and orders requires intuition, based upon experience and practice.

Dr. Schumann has prepared his book, in the first instance, for botanists who are dependent upon their own unaided efforts, thereby providing for that large class of enthusiasts who can only devote their leisure time to botany; but he had also in view the much higher object of leading those who use his book on to the plane, if not to the work, of systematists, and the final chapters deal with determination of species and the essentials of floral monographs.

The book contains two courses, of which the first is the easier, but it includes certain types, such as Phaseolus and Iris, which require some experience to explain thoroughly; the arrangement is according to the order of flowering. There are approximately 130 types of flowers, most of them common varieties, or easily obtainable, and these represent about 80 orders, which are, for the greater part, indigenous to Europe. There is a natural tendency to form a misleading conception of the importance of those orders which preponderate in the flora of one's own country, and for this reason it would have been advantageous to include representatives of more exotic orders, but since the aim of the author has been to present specific instances of floral variation and not systematic types, the choice seems to be very suitable. The keynote to the book lies in the author's inspiring enthusiasm for the study of foliar and floral morphology, and those who use the book will regret that Dr. Schumann did not live to see it completed. To Dr. Max Gürke was entrusted the responsibility of completing the book and of seeing it through the press. The discussion of each type includes general foliar arrangement, branching, inflorescence, floral parts, and methods of pollination, and each chapter has been made self-complete; in addition the author has contrived in a number of cases to derive from the specimen an illustration of some special theoretical point; thus the examination of the pine and fir cones introduces phyllotaxis, the balsam flower leads to the consideration of empirical diagrams, and the origin of double flowers is discussed in the case of the chrysanthemum. In dealing with questions for which different explanations have been offered, Dr. Schumann has carefully avoided dogmatic statements, and, as a rule, gives the arguments, but leaves it to the student to form his own conclusions. There are several allusions to the rules of botanical nomenclature adopted in various countries, and the author inclines towards English practice in the matter; but the instances which he quotes, *e.g. Succisa pratensis* and *Ampelopsis hederacea*, are not the names adopted in the Kew lists for the plants in question. Mention is made of the botanical congress which will be held in Vienna this year, when the subject will be again under discussion.

It has hitherto been a difficulty to obtain a thoroughly trustworthy and full presentation on the subject of floral morphology except in Eichler's "Blutendiagramme"—copies of which are few and expensive—so that teachers and students will do well to note this book, since it contains a number of careful analyses of every-day types with a particularly clear account of inflorescences and bracts, and it may therefore be used for reference to confirm or correct the deductions based upon personal examination. The illustrations were drawn by Dr. Schumann's daughter, and these, like the descriptions, may well be taken as models which the student should emulate.

SCIENTIFIC ASPECTS OF LAWN TENNIS.

Lawn Tennis. By J. Parmly Paret. Edited by Caspar Whitney. American Sportsman's Library. Pp. xiv+419. (London: Macmillan and Co., Ltd., 1904.) Price 8s. 6d. net.

Great Lawn Tennis Players: their Methods illustrated. By George W. Beldam and P. A. Vaile. Pp. xxix+403. (London: Macmillan and Co., Ltd., 1905.) Price 12s. 6d. net.

IN the first of the above books we have an excellently illustrated and interesting volume dealing with the early history, development, and present condition of lawn tennis, the author having produced a treatise which will be heartily welcomed by all lovers of this healthy game.

The author quite rightly deals only with the play of those who have attained a very high order of execution, and are past masters as regards the manipulation of a rapidly moving ball. A plan of campaign, quick decision, and still quicker action on the part of the player are necessary for success, and when these are accompanied by accuracy of execution, steadiness, easiness of style, and good condition, greater achievement is attained. Modern lawn tennis is undoubtedly a combination of skill and science of a high order, and the reader will find described in these pages the different ways in which well-known players employ these fundamental desiderata. By an ingenious application of photography it has been possible to record the start, stroke, and finish of individual strokes on one plate, to illustrate the positions of the body, hand, wrist, and racket during the movement. Many illustrations of this kind are given, serving as valuable guides to correct action. Numerous other snapshots of positions of play taken singly or on three plates with brief intervals form a special feature of this volume.

The physiological side of the game is not lost sight of, and is dealt with by the author in three short chapters, while Part iv. is devoted to "lawn tennis encyclopædia," containing much miscellaneous information useful to players, including a bibliography of the literature on the subject, which, by the way, is very considerable.

The volume concludes with an account of the history and growth of the game of lacrosse, by William Harvey Maddren.

The very complete index adds considerably to the utility of this publication, which should form a welcome addition to any sportsman's library.

In the second of these volumes, which is the combined work of Messrs. G. Beldam and P. A. Vaile, we have another valuable contribution to the literature of lawn tennis. Mr. Beldam presents us with 229 of his action photographs, all of which are here beautifully reproduced. In his book on "Great Golfers" he showed how much could be learnt by closely studying action-photographs, and in the present volume on great lawn tennis players a similar attempt is rewarded with equal success in spite of the greater difficulties involved, since both player and ball are in rapid motion. The photographs here given are not casual snapshots, but taken specially to illustrate the positions occupied by players for particular strokes. Mr. Vaile, writes, so to speak, round these pictures, and in his breezy and straightforward style points out which in his estimation are the good or bad points. This author is of the opinion that the true science of the game is but dimly appreciated in this country, and it is his main endeavour throughout these pages to indicate in which direction progress can be made. The lawn tennis reader will find, therefore, much to think over in these pages, and particular attention is drawn to the first chapter, in which the racket, *per se*, and the methods of holding it are discussed. Mr. E. G. Meers contributes an interesting chapter on "Advanced Tactics of the Single Game," while "The Half-Volley" is treated by Mr. G. A. Caridia.

OUR BOOK SHELF.

New Streets: Laying Out and Making Up. By A. Tayler Allen. Pp. 175. (London: The Sanitary Publishing Company, Ltd.) 3*s*. net.

THIS is not the sort of book that anyone but a proof-reader could read straight through, not even a reviewer or a surveyor or architect, for whom especially it is written. This statement is not made by way of disparagement, quite the reverse, and the author would be the first to agree to it.

In these days, with a multiplicity of petty and of local bye-laws and regulations, all put together primarily and ostensibly to prevent scamping of different kinds, but often, and the more so the more petty the authority, used as weapons to compel public spirited parties to go to unnecessary and extravagant expense so that the members of the petty body or their friends may be the more prosperous, it is above all essential that the surveyor or architect or engineer or even private individual, who has occasion to make a new street or a cottage or a side-walk or a retrospective drain should act warily, and have before him the several acts and bye-laws that regulate or hamper, as the case may be, the particular work he has in hand. The author, judging by this, and by the titles of his previous works, seems to be a good Samaritan and to take pleasure in pointing out the numerous pitfalls that must be avoided by the man who would, if possible, live at peace. The present book is largely filled with a recitation of laws and of district council requirements which no one would wish to read unless under compulsion. The latter part contains examples of work in very full detail and with illustrations.

However, the author has not, as might have been expected, lost all interest in the progress of his subject in wrestling with these dismal details. For instance, on p. 2 he says:—

"The author is one of a few surveyors who believe that all wide carriageways (where traffic is considerable), should have the channel in the centre instead of at the sides, thus obviating the tendency of vehicles to slide down the haunches of the road towards the kerb. The gradient to the centre channel from the kerb need not exceed 1 in 40."

Whatever advantages or the reverse there may be in this plan, spectators on the pavement would no doubt prefer to see this sliding in the direction desired by the author, especially if the vehicles happened to be quick motor-cars going in opposite directions.

The author is to be complimented on performing a tedious and uninteresting task for the general good.

C. V. B.

A Popular Guide to the Heavens. By Sir Robert S. Ball, LL.D., F.R.S. Pp. xii+96; 83 plates (London: George Philip and Son, Ltd., 1905.) Price 15*s*. net.

THIS is a new edition of the "Atlas of Astronomy," by the same author, which appeared in 1892, the revision having extended even to the title of the book. As before, star maps and pictures of the heavenly bodies are the chief feature, but in many cases drawings have been replaced by admirable reproductions of some of the finest celestial photographs at present available. The star charts, comprising twelve maps indicating the aspect of the heavens in the different months, and twenty others showing much greater detail, are excellent in every respect, and will meet the needs of those making a first acquaintance with the stars as well as of those who may wish to observe interesting objects with telescopes of moderate aperture. A valuable feature in connection with the maps is an index to the planets, whereby the positions of these bodies in each month during the next fifty years may be approximately ascertained. A very complete guide to observations of the moon is also provided by the maps and catalogues of lunar formations. So far, the book justifies its title, but the remaining parts give the impression of a scrap-book with pages still remaining to be filled, and pages which would have been filled differently by different owners. The sun, for example, is inadequately represented; the only photograph of a sun-spot which is given conveys no indication of the dimensions of the spot, and there are no illustrations of faculæ or photographs in monochromatic light. A more serious omission, in a book which is styled a "guide," is the absence of all reference to the modes of observing the sun, although careful drawings of the paths of spots at different times of the year are included. Again, there is an elaborate chart of the planet Mars, but nothing to show what the planet looks like in an ordinary telescope.

The text amounts to little more than a description of the plates and is too scrappy to give a connected view of the subject. The book, however, is well produced, and will be valued for its excellent star maps and examples of celestial portraiture.

Denkmäler mittelalterlicher Meteorologie. No. 15 (Schlussheft). Neudrucke von Schriften und Karten über Meteorologie und Erdmagnetismus herausgegeben von Prof. Dr. G. Hellmann. Pp. lviii + 200. (Berlin: Asher and Co., 1904.)

This is the final volume of a valuable series of publications which we owe to the energy of Prof. Hellmann. In them we have had brought before us the more interesting abstracts and reprints of early works dealing with meteorology and terrestrial magnetism. Prof. Hellmann has thus made available to those interested in these subjects, the records of ancient times, which to many would have remained unread and possibly unknown.

In the present volume, which deals more especially with meteorology, we have presented to us a set of twenty-six separate parts ranging from the seventh to the fourteenth century. Many others have been taken from printed works, but some of them, as we are told in the preface, are here published for the first time.

Further, many of these old texts have here been translated into German so that those who are not familiar with old Saxon, old English, old Norwegian, or Arabic will still be able to gain a good insight into the ideas of the Middle Ages.

In the introduction to this volume Prof. Hellmann gives a brief sketch of the character of meteorology at these periods, and adds a short and interesting summary of biographical facts relating to the writers of the texts to which reference is here made. An appendix contains additions and corrections to the earlier numbers.

For the labour involved in bringing together and preparing this collection of old texts a large debt of gratitude is due to Prof. Hellmann, and it is hoped that from time to time, when further ancient writings are brought to light, he will render them in like manner so conveniently available.

The Birds of Calcutta. By F. Finn. Second edition. Pp. vi + 136. (Calcutta: Thacker, Spink, and Co; London: Thacker and Co., 1904.)

The fact of a work reaching a second edition may generally be taken as an indication that it has received the seal of public approval, and that it accordingly needs no commendation from us. In the present instance, a ready reception would seem to be assured to the new edition, since many additions and improvements have been made. The most important addition is undoubtedly the series of life-like cuts of Indian birds, which adds very largely to the interest of the little volume; but it is also satisfactory to find that the arrangement and nomenclature have been revised so as to bring the work into harmony with the volumes on birds in the "Fauna of British India," to which it may serve in some degree as an introduction. Mr. Finn has a vivacious, if sometimes flippant, style, which removes his works from the "dry-as-dust" category; but in some cases, as in the application of the term "disreputable" to the babbler, we venture to think some of his epithets might be better selected. To a former resident the omission of the adjutant stork from the list of Calcutta birds seems strange, but it appears that for many years these weird birds have ceased to visit the city of palaces. R. L.

Toning Bromide Prints. "Photography" Bookshelf Series, No. 10. By R. E. Blake Smith. Pp. xv + 104. (London: Iliffe and Sons, Ltd., 1904.) Price 1s. net.

Instead of producing a black and white bromide print it is often desirable to change the normal tone to suit the subject photographed. There are many methods by which this change of tints can be obtained, and these pages are devoted to describing the various processes that are available. The material on which this book is based first appeared in a series of articles in *Photography*, but in the present handy form it will be found more convenient for workers. The author gives a good detailed account of each case, and discusses the probable effect of the different processes on the permanence of the finished picture. Workers with bromide papers will find this book of considerable service.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Charge on the α Particles of Polonium and Radium.

With reference to the interesting letter on this subject by Prof. Rutherford in last week's Nature, I should like to point out that in my paper "On the positive electrification of α rays and the emission of slowly moving kathode rays by radio-active substances" (*Proc.* Camb. Phil. Soc., xiii., p. 49) I have described experiments which demonstrate the communication of a positive charge of electricity to bodies struck by α rays from polonium or radium. I had considerable difficulty in disentangling this positive charge from the copious streams of slowly moving negatively electrified corpuscles which I found were given out by these substances, and the experiments in which I finally succeeded in doing this were not completed until a few days after the reading of the paper on November 14, and are not referred to in the abstract quoted by Prof. Rutherford. A description of them will be found in the paper which has lately been published. I may take this opportunity of saying that I have recently found that uranium also gives out slowly moving corpuscles, so that this effect seems a general property of radio-active substances. The velocity of these corpuscles is very small compared with that of the β rays, and is more nearly of the order of the velocity of the corpuscles emitted by metals when exposed to light. J. J. Thomson.

Cavendish Laboratory, Cambridge, March 4.

A conversation I had with Prof. Bragg, of the Adelaide University, in passing through Adelaide last summer suggested some thoughts in regard to the nature of the α rays which may be of interest in view of Prof. Rutherford's letter in last week's Nature. Prof. Rutherford announces that he has at last succeeded in detecting the positive charge carried by the α rays of radium by using a magnetic field to deflect and remove the slow-moving electrons present with the α particles. He says, "I think these experiments undoubtedly show that the α particles do carry a positive charge, and that the previous failures to detect this charge were due to the masking action of the large number of slow-moving electrons emitted from the plates." These results, while they afford a welcome confirmation of the conclusions drawn from the evidence of the magnetic and electric deviation suffered by the α rays, do not, to my mind, finally settle the question.

It must be admitted that the α particles in ordinary circumstances do carry a positive charge. Certain evidence, however, seems to point to the conclusion that the α particle at the moment of its expulsion from the parent atom is uncharged, and that it derives its positive charge from secondary causes, independently of, and subsequent to, the expulsion process. To devise a crucial experiment which would decide between the two views would be far from easy, but as I interpret Prof. Rutherford's letter, the results there given do not definitely disprove the view that the α particle is initially uncharged.

I recently directed attention ("Radio-activity," p. 181) to the importance of the fact that in certain well-established cases there appeared to be a simultaneous production of two positive charges in the disintegration of an electrically neutral atom. Thus in the disintegration of the emanation atom a positively charged α particle is expelled, and the residue of the atom—the matter causing the excited activity—is also positively charged, and is concentrated on the negative electrode in an electric field. In a recent paper by Bragg (*Phil. Mag.*, December, 1904, p. 721), the following sentence occurs: "It is easy to see that even if the α particle is uncharged when it leaves the parent body, it must immediately become positive, since in traversing an atom it is just as likely to lose one of its own electrons as to take one away from the atom traversed." As I am unaware that this consequence has received the attention it deserves, perhaps I may be allowed to direct attention to its bearing on the present question. There is a fundamental distinction between the ionisation of the atom of a gas molecule by radiant *electrons* or β particles, and radiant *atoms* or α particles. For in the latter case, if the atom struck suffers ionisation, the radiant atom is just as likely to be ionised in the process also. The ionisation of a neutral atom consists in the detachment from it of an electron which forms the negative ion, the atom thereby becoming positively charged and forming the negative ion. Hence the radiant α particle, if uncharged initially, will become positively charged on collision with the atoms of the gas or other obstacle in its path, and at the same time will lose an electron. The "slow-moving electrons present with the α particles," which Rutherford describes as "emitted from the plates," may therefore in reality be derived from the α particles themselves in the act of becoming positively charged. The fact that they, unless deflected by a magnetic field, exactly neutralise the charge carried by the α particles seems to point in the same direction.

In further support of the view that the positive charges on both the radiant particle and the residue of the atom after disintegration are derived by collision with the gas molecules, Prof. Rutherford's results on the distribution of the excited activity in an electric field at low pressure may be cited (Rutherford, "Radio-activity," p. 282). If the excited-activity-matter particle gains its positive charge in its recoil by collision with the gas molecules, it is to be expected that at low pressures it will not become charged, and will not, therefore, be concentrated on the negative electrode, as is, in fact, the case. FREDERICK SODDY.

The Pressure of Radiation.

THE success of Lebedeff and Nichols and Hull in recognising and measuring the pressure of radiation has aroused much interest in radiation pressure generally, real or apparent. It has some interesting and sometimes somewhat difficult theoretical aspects. In the first place, if the ether is really absolutely at rest (this rigidity is a very difficult idea), the moving force on it has no activity, and its time integral $\nabla\mathbf{DB}$ can only be called momentum out of compliment. The force becomes active in a moving ether, with interesting consequences not now under examination. The present question is rather how to interpret the pressure of radiation on the assumption of a fixed ether, in the measure of its effects on matter which is either fixed or moving through the ether.

The following is striking in what it proves. Let plane radiation fall flush upon a perfect reflector moving in the same direction at speed u, a case considered by Larmor. Let the energy density $p = p_1 + p_2$, the incident being p_1, the reflected p_2. Assume, which seems reasonable at first, that p_3, the pressure in the reflector, is zero, then the moving force $p_1 + p_2 - p_3$ reduces to $p_1 + p_2$. Therefore

$$p_1(v-u) - p_2(v+u) = (p_1+p_2)u, \tag{1}$$

because the left side is the rate of loss of energy from the waves, and the right side the activity of the force on the reflector. So

$$\frac{p_2}{p_1} = \frac{1-2u/v}{1+2u/v} = s^2, \text{ say,} \tag{2}$$

and $s = \mathrm{H}_2/\mathrm{H}_1$ is the ratio of magnetic forces in the electromagnetic case. Now (2) asserts that the reflected wave gets smaller as the mirror goes faster, and vanishes when $u = \frac{1}{2}v$. Or if the mirror be pushed against the radiation, the reflected wave gets stronger, and the resisting force stronger until $u = -\frac{1}{2}v$, when it is infinite. The mirror could not be pushed against the radiation faster than $\frac{1}{2}v$.

An immediate objection is that when u has risen to $\frac{1}{2}v$, if it be maintained at that speed it acts like a perfect absorber to the incident energy. Moreover, since there is the pressure p_1 left, why should it not accelerate the mirror? But, if it does, p_2 becomes negative, and s becomes imaginary. Considered mechanically only, say by $\mathrm{F} = m\dot{u}$, the motion of m is quite determinate when $u = \frac{1}{2}v$, up to v, in fact. But electromagnetically it means that the energy in the reflected wave is negative. Now although there is nothing to object to quantitatively in a continuous transition from a Maxwellian stress consisting of a tension along an axis combined with equal lateral pressure, to its negative, a pressure along the axis with equal lateral tension, still the negativity of the energy in the reflected wave causes difficulty. The stress for both the electric and magnetic energy becomes of the gravitational type. That is, like imaginary electrifications attract, and unlike repel, or matter is imaginary electrification in this comparison. The moving forces and energies are real. But let a real charge and an unreal one co-exist, the energy density becomes imaginary. That is out of all reason in a real universe.

We should, I think, regard (2) as a demonstration that (1) is untrue, in that $(p_1+p_2)u$ is not the activity of the force on the mirror, although p_1+p_2 may be actually the pressure of the radiation. In fact, in the electromagnetic case, the variation of p constitutes a force on the ether itself. We must find the force on the mirror in another way. Let radiation fall flush upon the plane surface of a dielectric, which call glass, moving the same way at constant speed u, and let the circuital equations in the glass be

$$d\mathrm{H}/dx = c\dot{\mathrm{E}} + \partial\mathrm{I}/\partial t, \quad -d\mathrm{E}/dx = \dot{\mathrm{B}} = \mu\dot{\mathrm{H}}; \tag{3}$$

that is, the same as for the ether, with the addition of the electric current of polarisation $\partial\mathrm{I}/\partial t$. The reference space is the fixed ether, and $\partial/\partial t$ is the moving time differentiator. Now if the relation between I and E is such as to permit of an undistorted plane wave, we shall have

$$\underset{\text{(incident)}}{\mathrm{E}_1 = \mu v\mathrm{H}_1}, \quad \underset{\text{(reflected)}}{\mathrm{E}_2 = -\mu v\mathrm{H}_2}, \quad \underset{\text{(transmitted)}}{\mathrm{E}_3 = \mu w\mathrm{H}_3}, \tag{4}$$

if v is the speed in the ether, and w the wave speed referred to the ether in the glass. This w is a function of u. Also, the boundary conditions,

$$\mathrm{E}_1 + \mathrm{E}_2 = \mathrm{E}_3, \quad \mathrm{H}_1 + \mathrm{H}_2 = \mathrm{H}_3, \tag{5}$$

combined with (4), give

$$\mathrm{H}_2/\mathrm{H}_1 = (v-w)/(v+w), \quad \mathrm{H}_3/\mathrm{H}_1 = 2v/(v+w). \tag{6}$$

An incident pulse of unit depth is stretched to depth $(1-u/v)^{-1}$ in the act of reflection; the reflected pulse is of depth $(v+u)(v-u)^{-1}$, and the transmitted pulse of depth $(w-u)(v-u)^{-1}$.

The rate of loss of energy from the waves in the process of reflection is

$$p_1(v-u) - p_2(v+u) - p_3(w-u), \tag{7}$$

where the p's are the energy densities. But, by the above,

$$p_1 v = p_2 v + p_3 w; \tag{8}$$

therefore the rate of loss of energy is

$$(p_3 - p_1 - p_2)u, \tag{9}$$

and the moving force on the mirror is

$$\mathrm{F} = p_3 - p_1 - p_2. \tag{10}$$

This is, in its expression, exactly the *negative* of the previous pressure difference. It is in the direction of the rise of energy density. Its amount is

$$\mathrm{F} = 2\mu\mathrm{H}_1\mathrm{H}_2 = 2p_1(v-w)/(v+w) = \tfrac{1}{2}\mu\mathrm{H}_3^2 - \tfrac{1}{2}c\mathrm{E}_3^2 = \mathrm{U}_0. \tag{11}$$

The first form in terms of $\mathrm{H}_1, \mathrm{H}_2$ is useful. The second is in terms of the wave speeds. The third is in terms of the ethereal energy inside the glass. All these come out of the ratios $\mathrm{H}_2/\mathrm{H}_1$, &c. Now the electric energy equals the magnetic energy in the transmitted wave. Consequently U_0 means the energy of the polarisation I. And the activity is $\mathrm{U}_0 u$, the convective flux of energy.

These properties are true for various relations between I and E. The first approximation is $f = c_1 E$. The second, introduced by Lorentz, is $f = c_1(E - uB)$, that is, the polarisation is proportional to the moving force on a moving ion. Other forms allowing of undistorted pulse propagation may be proposed. All give special relations between w and u. In Lorentz's case,

$$U_0 = \tfrac{1}{2} c_1 E_3^2 (1 - u/w)^2. \quad (12)$$

To pass to perfect reflection, reduce w to u, its least value. U_0 does not vanish, but has the value given by (10), (11) still, with $w = u$. But the transmitted wave is reduced to a surface film, moving with the glass. The moving force on the glass is now

$$F = 2p_1 (w - u)/(v + u), \quad (13)$$

and finally, if $u = 0$, $F = 2p_1$.

Here we come right back to the pressure of radiation. It does measure the force on the glass when at rest, when it reflects perfectly, and it looks as if (13) were merely the form $p_1 + p_2$ a little modified by the motion. But appearances are very deceitful here, for (10) above is the proper formula.

As regards the distribution of F. With an actual transmitted wave consisting of a pulse of uniform intensity all through, F is entirely at the wave front. So, with total reflection, it is just under the surface of the glass. Again, if E_3 varies continuously in the transmitted wave, F is distributed continuously, to the amount $B(\partial f/\partial t)$ per unit volume. What F means in (11) now is the total of this volume force, *i.e.* the integral from the surface up to the wave front, expressed in terms of the momentary surface state.

After a pulse has left the surface there is an equal opposite force at its back, so there is no further loss of energy or moving force on the glass. The obscurities and apparent contradictions arise from the assumption that the ether is quite motionless. If we treat the matter more comprehensively, and seek the forces in a moving ether, with moving polarisable matter in it as well, if this is a complication one way it is a simplification in another, viz. in the ideas concerned. There is harmony produced with the stress theory. To illustrate, $(\partial/\partial t)V\mathbf{DB}$ is the moving force per unit volume when the ether and polarised matter have a common motion, $\mathbf{D}$ and $\mathbf{B}$ being the complete displacement and induction. (The variation of $\mathbf{u}$ is ignored here.) But if we stop the ether, a part of this force becomes inactive. If the matter is unmagnetisable, the only active part is that containing the polarisation current, for that is carried along.

Besides this electromagnetic force, there is also a force due to a pressure of amount U_0. But it does not alter the reckoning of the moving force on the glass, because the pressure acts equally and oppositely at the front and back of a pulse.

Some other illustrations of the curious action between electromagnetic radiation and matter can be given. For example, two oppositely moving plane pulses inside moving glass. Say $E_1 = \mu w_1 H_1$ one way with the glass, and $E_2 = -\mu w_2 H_2$ against the glass. If $H_1 = -H_2$, work is done upon the glass when they cross, ceasing the moment they coincide, so that the energy of the momentary electric field is less than the wave-energy. On separating, the loss is restored. If, on the other hand, $E_1 = -E_2$, work is done by the glass on the waves when uniting, so that the momentary magnetic energy, together with the polarisation energy, is greater than the wave energy. In this second case, too, it is noteworthy that the solitary waves are of unequal energy, whereas they are equal in the first case. But details must be omitted, as this communication is perhaps already too long.

Oliver Heaviside.

February 21.

Secondary Röntgen Radiation.

In a paper read before the Royal Society on February 16, I described experiments demonstrating the partial polarisation of Röntgen radiation proceeding from an X-ray bulb, and at the same time verifying the theory previously given of the emission of secondary X-rays from gases and light solids subject to Röntgen radiation.

Later experiments have shown that beams of X-radiation may be produced exhibiting a greater amount of polarisation than there was evidence of in the original experiments. This discovery has proved useful in the investigation of secondary radiation proceeding from solids.

It has been found that while the intensity of secondary radiation from light substances varies considerably in different directions owing to the partial polarisation of the primary radiation, the amount of this variation diminishes with an increase in the atomic weight of the radiator, and ultimately is inappreciable. The radiations from air, carbon, paper, aluminium, and sulphur vary in intensity in different directions by a considerable amount. From calcium the variation is much less, while from iron, copper, zinc, and lead it is inappreciable. This must be connected with the fact that the radiation from light substances differs in character only very slightly from the primary, while the heavier substances emit radiations differing more from the primary producing them. The radiation from the heavier metals was found not to consist of an easily absorbed radiation superposed on a radiation such as proceeds from light substances, and of intensity given by the law found for that from light substances, but is as a completely transformed radiation. This is strong evidence that the freedom of motion of the electrons which permits what may be called a simple scattering in substances of lower atomic weight is interfered with in the heavier atoms, for we find from them a more absorbable radiation *in place of, not simply superposed on,* a more purely scattered radiation.

With this change in character, the polarisation effect disappears. No special absorption of the radiation proceeding from a substance by plates of the same substance has been observed.

A considerable variation in the penetrating power of the primary radiation incident on heavy substances is accompanied by a smaller change in that of the secondary (measured by change of absorbability).

Radiation from compounds appears to be merely a mixture of the radiations which proceed from the separate elements in the compound, both the absorbability and polarisation effects being what would be given by such mixtures. Atomic weight, not molecular weight or density, thus seems to govern the character of the radiation produced by a given primary.

These results may be accounted for by considering the electrons constituting the atoms as the radiators. In light atoms the electrons are far enough apart, and have sufficient freedom to move almost entirely independently of one another, under the influence of the primary pulses, consequently to emit a secondary radiation similar to the primary, but the intensity of which depends on the direction of propagation with regard to that of electric displacement in the primary beam. In heavier atoms considerable inter-electronic forces are probably brought into play by small displacements, and the resultant acceleration of motion of an electron is then not in the direction of electric displacement of the primary beam, and evidence of polarisation of that beam vanishes. Also there ceases to be a simple connection between the time for which the electron is accelerated and that of passage of the primary pulse.

In atoms of greater weight we would expect appreciable inter-electronic forces to be called into play sooner, and to attain a much greater intensity than in lighter atoms.

The precise connection between the atomic weight of the radiator and the absorbability of the radiation is being investigated.

Dates of Publication of Scientific Books.

I have just bought a copy of "A Treatise on Slate and Slate Quarrying, Scientific, Practical, and Commercial," by D. C. Davies, F.G.S., fourth edition, dated 1899 (Crosby Lockwood and Son).

To my astonishment, I find no statistics of later date in it than 1876, *e.g.* p. 33, statistics of 1872 and 1873, p. 58, list of quarries in 1873, p. 59, production in 1876, p. 64, production last year (1876), p. 170, prices of slates in London last year (1876).

As the Home Office publishes annually a general report and statistics of mines and quarries, and also a list of mines and quarries, there is no excuse for the book being so out of date in its statistics.

B. Hobson.

The Owens College, Manchester, February 21.

SOME SCIENTIFIC CENTRES.

VII.—The Physiological Research Laboratory of the University of London.

THE seat of the University of London was transferred to the Imperial Institute in 1900, and in the same year the University received a new constitution, and commenced its career as a teaching university. In May, 1902, a laboratory devoted to research physiology was housed within the same Imperial building, and the secretariat of the University of London was for the first time brought into contact with one of the sources of knowledge, which it had been newly arranged not only to control but also to foster.

The laboratory occupies the upper floor of the eastern wing of the Imperial Institute, and has already been described in the pages of this Journal (Nature, vol. lxvii., pp. 441, 442). It covers a space of about 3000 square feet.

There are special rooms for experimental psychology, experimental physiology, electrical and chemical work, a lecture theatre fitted up for the delivery of the special courses of lectures in advanced physiology, and a departmental library. The work carried on has been of the double character indicated in the scheme originally adopted by the University Senate. In the first place courses of lectures have been given by a large number of the physiologists who form the professorial staff of the University in this subject. It should not be forgotten that this cooperation has been obtained without an offer of the most trifling award. The professorial staff, by this free gift of its labour, has once more shown its loyalty to interests which are really wider than the interests of any local scheme, but which, nevertheless, are well expressed as the interests of the University of London.

All these lectures, as was originally intended, have been of a peculiarly living type—lectures delivered upon subjects on which each lecturer was actually engaged in research at the time. After submission to referees, they are published for the University by Messrs. Murray; a volume entitled "Signs of Life," by Dr. Waller, and another on the "Biochemistry of Muscle and Nerve," by Prof. Halliburton, have already appeared, and a volume on the Blood, by Dr. Buckmaster, is in the press.

In the second place, room and facilities are afforded to workers in the prosecution of research whether for their doctoral theses or for other purposes. The researches carried on since May, 1902, have resulted in thirty published papers; among them, and specially noteworthy as regards their immediate practical bearing, are the contributions of Captain Leonard Rogers, I.M.S., to our knowledge of the physiological action of the poison of the Hydrophidæ and the physiological action and antidotes of colubrine and viperine snake poisons; of Waller and Plimmer on the physiological action of a ptomaine extracted from commercial beet sugar; and of Waller on the quantitative estimation and graduated administration of chloroform. In physiological psychology, work is continuously carried on by Miss Edgell, who has published a paper on time judgment, and whose work on memory and grasp of the meaning of words is opening out a most important subject.

The output of work from most laboratories bears the stamp of the Director, for in his hands mainly lies the attraction of workers, and their useful employment in the earlier stages of their career. It is his constant patient interest in the problems under investigation in the laboratory which largely determines their direction, and serves to weld them into a solid phalanx of advancing facts. An examination of the list of papers shows the presence of such an influence here, an influence which has already started several workers upon paths of independent inquiry. Acknowledgments of this fact may, for instance, be found in the papers of Drs. Alcock, Collingwood, Legge Symes, Wells, from all of whom valuable contributions have come. Dr. Alcock has carried out several excellent researches upon the electrical response of mammalian medullated and non-medullated nerve. Boldly selecting material offering, as it was thought, almost insuperable difficulties, he has been able to make many observations of value, and in doing so has also extended

Fig. 1.—Dr. Augustus D. Waller, F.R.S., Director of the Laboratory.

the general field of inquiry. Dr. Collingwood has designed an apparatus for the exact dosage of chloroform, and elaborated a method for the estimation of percentage of chloroform vapour in expired air. Mr. Legge Symes has published work on the respiratory quotient, estimation of chlorides in blood, and is carrying on work on the physiological action of chloroform and betaine. Mrs. Waller has continued the work upon the distribution and meaning of "blaze currents."

That the many-sided industries of this laboratory are by no means completely stated in the last paragraph is at once seen from the fact that its walls have also looked out upon the work of several investigators who have obviously been attracted by its conveniences and equipment alone. It is sufficient to mention the names of Drs. Brodie, Buckmaster, Goodall, Locke, Macdonald, Mummery, Seemann. Dr. Pavy is engaged in work on the metabolism of the carbohydrates, and will give a course of three lectures in the summer on the results of his investigations. Dr. George Oliver is now working in the laboratory on the effects of various organic products on the blood-pressure of animals and man, and on the improvement of blood-pressure apparatus for physiological and clinical observation on man. He will shortly also be engaged with Dr. Samuel Rideal in investigating the influence of various gases on the blood-pressure in man. Some of this work has already found expression in this term's course of lectures by Sir Lauder Brunton. Mr. G. P. Mudge is engaged in work which will bear on the theory of transmission of acquired characters. The laboratory is, in fact, not only a consistent school making its influence rapidly felt in work of a particular character, but also a laboratory offering highly appreciated advantages to independent workers.

The laboratory owes no small share of the fact of its existence and present energetic life to the director, Dr. Augustus Waller. His prescience and alertness, and the confidence felt by the authorities and by his colleagues and friends in a scheme which had obviously enchained the full measure of his personal interest, must in this connection remain accountable for many things. The value of his services is best assessed after a consideration of the indefatigable years which he has spent in fruitful furtherance of the science of physiology. His first paper, a contribution to the study of cardiac and vascular innervation, was published from Ludwig's laboratory in 1878. His remaining contributions, many and all well known, have been published as a consequence of work carried out within London itself; and with the scientific life of this city Dr. Waller has been identified since 1879. "The graphic record of the propagation rate of the pulse wave," "The recurrent pulse," "Measurements of the length of systole and diastole with different pulse frequencies," are titles of some of these earlier papers, reminding us of our indebtedness to Dr. Waller for valuable contributions to our knowledge of the circulation. In 1881 he secured the thanks of all workers upon the phenomena of the central nervous system by his contributions to the study of tendon-reflex. In 1881 he devised and first made use of the method, now generally adopted, for the photographic record of electrical currents. His work upon electrotonic currents in the nerves of the human body, carried out with the assistance of Dr. De Watteville, 1882, forms one of the foundation-stones of the art of electro-therapeutics. This and his subsequent record of the electrical changes accompanying the beat of the human heart, 1887, serve to render the first decade of Dr. Waller's experimental work ever memorable in the annals of "Animal Electricity," and were made the basis of two ceremonies of mutual honour. Dr. Waller was invited to Berlin by Du Bois-Reymond to demonstrate the electrical changes due to the heart-beat, and the Academy of Science at Bologna—the birthplace of animal electricity—presented him with the award of the Premio Aldini sul Galvanismo. The Academy of Science of Paris also showed its recognition of the interest of these observations by its award of the Prix Montyon.

In 1885, Dr. Waller laid a basis for the study of "fatigue," by recording his discovery of the site of peripheral fatigue. He again facilitated the study of this phenomenon by the invention and use of the "dynamograph," and contributed important papers upon the "Sense of Effort." In these papers Dr. Waller dealt with matters on the border-line between physiology and psychology, and here also is placed other work of his of admitted importance upon colour contrast, hearing, weight discrimination, the functional attributes of the cerebral cortex. In 1891, Dr. Waller published his "Text-book of Human Physiology." This book marked an era in the methods of physiology classes throughout the country, and served as a standard for the increased extent of scientific training rendered possible by the changes then taking place in physiological staffs and laboratories. In writing this book Dr. Waller rendered an important service not only to physiology but also to medical education.

In 1895 began a series of researches based on the Weber-Fechner law, the electrical response of the retina to the stimulus of light, the mechanical response of muscle to electrical stimulation, the electrical response of medullated nerve to electrical stimulation, leading to the general conclusion that where we can plot physical cause along an abscissa, and physiological effect along ordinates, an S-shaped curve is the result.

The foregoing experiments involved an examination of the electrical response of nerve under the influence of anæsthetics, and led to the systematic employment of nerve to gauge the activity of a large number of reagents, a method having been devised for exciting the nerve at regular intervals and recording its negative variation by photography.

Three mainly important conclusions resulted from this method of work—that CO_2 is evolved in nerve during tetanisation, that the inexhaustibility of nerve and retina is due to an extremely rapid disintegration and reintegration in their tissues, that the effect of anæsthetics on nerve may be taken as a measure of their effect on the human subject, and the method may therefore be employed for studying the limits of safety of chloroform dosage. The important fact was educed that safe anæsthesia requires the continuous administration of a mixture of chloroform and air at an average percentage of 1·5—not below 1 per 100 and not above 2 per 100. Many of the facts of physiological interest made known by these researches are to be found in a course of lectures delivered by Dr. Waller at the Royal Institution, and published in 1897 under the title of "Animal Electricity." Short, and freed from technicalities as it is, this book is unique and permanent, and, as a classic, needs no commendation. The "Characteristic of Nerve," "Veratrine and Protoveratrine," are titles of other papers of physical and physiological interest.

From a study of the electrical response of the eyeball (retina) to the admission and exclusion of light Dr. Waller passed to a consideration of its response to electrical stimulation. This very marked and vigorous response he named the retinal blaze, and this led to a general study of the "blaze-currents" of the eyeball and of other living plant and animal tissues; the importance of this phenomenon as an exact and critical measure of the processes occurring in living tissues can scarcely be overestimated. As a sign of life, its observation (*e.g.* for vitality of seeds) may be of practical advantage.

Within recent years Dr. Waller's energies have also been largely directed towards the problems connected with chloroform anæsthesia, and the apparatus designed and inspired by him promises to lead not only to a further knowledge of the subject, but also to check the lamentable waste of human life so often caused by faulty and inaccurate methods of chloroform administration.

The little that has been said may serve to show that in this Institution and its officers the University has already much upon which it may be congratulated. It is surprising to examine the financial basis upon which this scheme has already been carried to such a pitch of usefulness. When the scheme was first mooted, in March, 1901, no funds were available for its support. The only asset was the promise made by the foremost physiologists in London to deliver courses of lectures, without emolument, upon the branches of physiology with which they were most conversant. The Senate favoured the scheme, and Sir Walter Palmer, by a timely gift of 2000*l.*, rendered available the space which the Senate had assigned for the laboratory. The University supported the scheme with a grant of 500*l.*, and has since provided an annual grant of 400*l.* for five years, conditional upon the acquisition of 600*l.* per annum from other sources. Upon this annual subsidy of 1000*l.*, it is estimated that the present activity of the laboratory can be sustained. So far the support obtained from outside sources, the 3000*l.* required for the five years, 1904–1909, is represented by 2000*l.* subscribed by Mr. G. W. Palmer and Mr. A. Palmer. The sum asked for has therefore not yet been collected; when collected, it should be noted, it will not serve to maintain the laboratory upon a scale commensurate with its activity and promise. Thus the estimated expenditure of 1000*l.* per annum includes no provision for the honoraria of lecturers, or for additional assistants, or for research scholarships. The sum of 50,000*l.*, it is estimated, would suffice for the accomplishment of this greater object.

THE MONTE ROSA AND COL D'OLEN INTERNATIONAL LABORATORIES.

SOME time ago (Nature, April 17, 1902, vol. lxv. p. 568) I directed the attention of the readers of Nature to the international laboratory, the Capanna Regina Margherita, which had been established on the Gnifetti peak of Monte Rosa by Prof. Mosso, of Turin, through the generous aid of the Regina Madre of Italy. Already much valuable work has been done in that laboratory, and if this has been chiefly of a physiological kind, though provision is made in the laboratory for physical and meteorological as well as other investigations, the reason is to be sought partly in the fact that Prof. Mosso is a physiologist, partly in the special interest attaching to the physiological problems presented by living beings at high altitudes.

In August and September, 1903, two physiological expeditions were carried out at the Capanna Regina Margherita, one under the direction of Prof. Zuntz, of Berlin, the other by Prof. Mosso, several observers taking part in each. The records of some of (not of all) the results obtained in these two expeditions are now brought together by Prof. Mosso in a volume [1] of some 300 pages, elegantly bound in such a way as to be easily itself carried to high altitudes, and appropriately dedicated to that Mæcenas of science M. Ernest Solvay, who has so freely given back to science of the good things which science has given to him.

I do not propose, in this notice, to deal in detail with the twenty-one memoirs which make up the volume. One, that by Durig and Zuntz, is given in German; all the others, though written by Italian observers, with that generous abnegation of their own tongue which it is to be hoped will not be considered necessary for them in the coming years, appear in French. I may here perhaps be allowed to express my regret that no memoir by any English observer, either in his own or any other language, is to be found among them. All of them treat, more or less directly, with one or other of the many problems of metabolism which are presented by life at such a high altitude as 4560 metres. At that height the responses which internal chemical, metabolic, processes and the expenditure of energy make to changes in the environment are so different from those which take place at lower levels as to raise great hopes that persistent researches in such Alpine laboratories may carry us far towards solving the intricate problems of the relation of chemical and physical changes of living substance to the energies of life. It may be added that such researches may be expected to explain, and so to afford practical guidance as to, the beneficial sanitary effects of life at high altitudes on many diseases.

Most of the memoirs, as might be expected, record studies on the respiratory exchange and on the condition of the blood at the high altitude as compared with what is found at an ordinary low level; and in some of them the effects of artificially lowering barometric pressure at Turin are compared with the effects of the natural low pressure on Monte Rosa, accompanied as the latter is with other conditions. All these are of great interest to the physiologist, and to him chiefly; but one memoir may perhaps attract the attention of the general reader, and that is the one by Mosso and Galeotti on the physiological effects of alcohol at high altitudes. These observers found that a dose of alcohol, 40 c.c. of absolute alcohol adequately diluted, which at Turin brought about a condition bordering on drunkenness produced, on Monte Rosa, so far as subjective sensations were concerned, hardly any effect at all. I may add that the present volume does not record all the observations made in the expeditions of 1903, a second volume being about to appear shortly. Nor are physiological researches the only ones which have been carried out; important meteorological and physical inquiries have also been conducted.

In spite of every effort to make the accommodation at the Gnifetti laboratory as complete as possible in the circumstances, those circumstances offer many obstacles to continued successful observations. The period during which study is possible is short, and the hardships of living and working at such a high altitude are such as cannot easily be borne by many persons otherwise capable of carrying out fruitful investigations. Hence Prof. Mosso conceived the idea of establishing in connection with the Gnifetti laboratory a supplementary laboratory at a lower but still high level, where work could be carried on in connection with the higher laboratory, but under easier conditions, and for a longer period of the year.

Visitors to the southern slopes of the Monte Rosa group probably know well the little wooden inn at the Col d'Olen at the height of about 3000 metres, reached by a long but easy walk or mule ride from Alagna, and most admirably kept by the well known enterprising hotel proprietors Guglielmina. From it one may, when the air is clear, see afar off the Duomo of Milan, while at one's feet alongside the path to Gressonay lies an Alpine garden which Kew may envy, brilliant in late summer with sheets of gentian and other lovely flowers. Close by the inn, Prof. Mosso has secured a plot of ground on which he is building the new laboratory; this he hopes to have finished next autumn, but it will not be ready for actual use until the summer of 1906.

It is to be a laboratory fully equipped for researches in physiology, meteorology, physics, and botany; but in addition to this it will have sixteen comfortable bedrooms, so that sixteen workers carrying on investigations will have each a bedroom to himself; and if the number of observers should happen at any time to exceed sixteen, accommodation can be obtained at the inn close by. At such altitudes success in investigation is largely dependent on personal comfort, including suitable food; and probably there are not a

[1] Laboratoire Scientifique International du Monte Rosa. Travaux de l'année 1903. Publiés par A. Mosso. (Turin: Loescher, 1904.)

few to whom research at the high Gnifetti laboratory would be impossible, but who could do solid work at a somewhat lower level provided that the life was not too rough, and especially if they had no fear of being hampered by indigestion caused by too rude or monotonous a diet. For these especially is the Col d'Olen Laboratory intended; and unless things have altered sadly in the last few years, such need have no fear for their stomachs. I still have a vivid recollection of a stay at the inn at Col d'Olen during which the efforts of a talented cook produced results which would have satisfied tastes of a far higher epicurean level than my own.

The new laboratory, like the old, is to be carried out as an international institution. It received warm support from the International Physiological Congress at Turin in 1901, and again at Brussels this year. After the plan of the Stazione Zoologica at Naples, its maintenance is to be provided by subsidies which will give the right to occupy working places. Already the Italian Ministry of Instruction has secured accommodation for two investigators, the Italian Alpine Club for one, and the German Government for two. M. Solvay, who has otherwise been a lavish benefactor to the whole enterprise, has taken two places for Belgium, and, through the generosity of Dr. Ludwig Mond, our own Royal Society has the right of nominating two investigators. The undertaking, therefore, is well on the way to success; but much remains yet to be done. Prof. Mosso informs me that though he has obtained 70,000 lire, he still needs some 50,000 lire in order that everything should be on a safe basis, and especially that an annual income should be provided sufficient to ensure at the laboratory adequate service and assistance, which, as might be expected from the circumstances, have to be well paid. The existence of such a laboratory offers unusual opportunities for investigation, not only to those who are interested in the general problems of physiology, of meteorology, and of the physics of the earth, but also to the perhaps larger class who desire a wider and more exact knowledge of the manifold fascinating phenomena of the High Alps. Is it too much to hope that Prof. Mosso will find no great difficulty in obtaining the further funds which he needs?

M. FOSTER.

NEOLITHIC DEPOSITS IN THE NORTH-EAST OF IRELAND.

THE recent changes of level in the north-east of Ireland attracted a considerable amount of public interest during the year 1903, in consequence of the lawsuit, known as the "Gold Ornaments Case" (Attorney-General *v.* the Trustees of the British Museum). A golden boat, collar, and other objects were found in ploughing at Broighter, on the extensive flat that stretches around Limavady Junction in county Londonderry. They were buried eighteen inches deep in stiff clay soil, at a spot which is four feet above ordinary high-water mark. The British Museum authorities rested their claim to the retention of the objects in part on the theory that the ornaments in question constituted a votive offering, which was

FIG. 1.—Wind excavated Pit in Portstewart Sand-dunes, showing "black-layers." From *Proceedings* of the Royal Irish Academy, December, 1904.

deposited in Lough Foyle about the beginning of the Christian era, the spot where the objects were sunk having since become dry land, owing to upheaval of the coast-line. The claim of the British Museum was, however, not sustained.

In connection with this contention, Messrs. George Coffey and R. Lloyd Praeger made special investigations into the evidence of recent geological changes, and these they have brought forward in an essay on "The Larne Raised Beach: a Contribution to the Neolithic History of the North of Ireland" (*Proc.* R. Irish Acad., vol. xxv., December, 1904). To this essay we are indebted for the preceding statement. After dealing generally with the phenomena indicative of changes of level in Glacial and post-Glacial times, the authors treat particularly of the post-Glacial history, which began with a long period of emergence, and a land-level at least 30 feet higher than at present. The evidence obtained near Larne and Belfast tells of subsequent submergence, re-elevation (the amount of which increased northward), and of a final slight movement of submergence in recent times that has left the surface as we now find it. The raised beach of the Curran at Larne was accumulated over estuarine muds during the period of submergence, and it is of peculiar interest owing to the occurrence in it from top to base of worked flints of Neolithic type. A detailed account, with figures of the flints, is given. The evidence is taken to indicate that man was on the ground during the submergence that allowed of the continued laying down of 20 feet of gravels in shallow water or between tides. Moreover, the abundance of flint flakes in the surface-layers renders it probable that Neolithic man persisted after that movement of elevation had set in which made the top of the gravels a land-surface. Attention is directed to further evidence at Whitepark Bay, east of the Giant's Causeway, and again in the neighbourhood of Portstewart, which lies only 13 miles E.N.E. of Broighter. At Whitepark Bay, Neolithic "black layers" or land-surfaces occur at various levels among the sand-dunes, while near Portstewart old surfaces with Neolithic remains are found in deep wind-excavated hollows in the dunes. (see Fig. 1). This evidence proves conclusively that the ground on which the gold ornaments were found has been a land-surface, with an elevation at least as great as at present, since Neolithic times, the whole of the movement of elevation, which formed the post-Glacial raised beach of the north-east of Ireland, having been accomplished during Neolithic times.

NOTES.

THE president of the Royal Society, and Lord Rayleigh, chairman of the general board of the National Physical Laboratory, have issued invitations to a visitation of the laboratory on Friday, March 17, when the various departments will be on view and apparatus will be exhibited.

THE thirteenth "James Forrest" lecture of the Institution of Civil Engineers will be delivered by Colonel R. E. B. Crompton on Monday, April 10, upon the subject of "Unsolved Problems in Electrical Engineering."

PROF. W. J. SOLLAS, F.R.S., has been elected a member of the Athenæum Club under the rule which empowers the annual election by the committee of nine persons "of distinguished eminence in science, literature, the arts, or for public services."

MR. J. E. S. MOORE has been appointed director of the Cancer Research, which is carried out in connection with the Royal Infirmary.

IT is stated that the Madras Government has sanctioned the establishment of an experimental garden in Malabar for the investigation of pepper vine disease.

THE second annual dinner of old students of the Royal College of Science, Ireland, will be held on St. Patrick's Day, Friday, March 17, at the Holborn Restaurant, London.

PROF. K. MÖBIUS has retired from the directorship of the Berlin Museum of Natural History. The position has been offered to Prof. H. H. Schauinsland, director of the museum at Bremen.

SIR WILLIAM BROADBENT will preside at a medical conference on the teaching of hygiene and temperance, to be held at the Examination Hall, Victoria Embankment, on Friday, March 24.

THE *British Medical Journal* states that Prof. E. A. Minchin, F.R.S., has undertaken to conduct—on the spot—further investigations, under the auspices of the Royal Society's Committee, into the causation of sleeping sickness in the Uganda Protectorate.

THE fifteenth German Geographentag will be held at Danzig on June 13–15. The chief subjects of papers and discussions will be south polar exploration, vulcanology, coast morphology and formation of dunes, and school geography.

AFTER a pause of many years France has again entered the list of gold-producing countries. In December, 1904, the first gold mill in France was started at the La Lucette antimony mine, near Laval. A 10-stamp mill is running steadily, the daily production amounting to about 1 kilogram of gold in the form of a rich concentrate.

WE learn from the *Chemist and Druggist* that two prizes, one of 5000 francs (200*l*.) and the other of 3000 francs (120*l*.), have been offered by Dr. Henri de Rothschild to the Scientific Society of Alimentary Hygiene, Paris, for the best treatises written in French on the rational food for man. The prizes will be awarded in 1906, and the papers must be sent in by December 31, 1905.

THE experiments with wireless telegraphy between Diamond Island and the Andamans are, says the *Pioneer Mail*, giving most satisfactory results. A recent message transmitted from Port Blair reached Calcutta in nineteen minutes, though it had to come over the land-lines after being received at Diamond Island.

THE Paris correspondent of the *Times* reports that a telegram has been received from M. Jean Charcot, the explorer in command of the French Antarctic expedition, dated Puerto Madryn, March 4. It is stated that scientific work was carried on under good conditions while wintering on Wandel Island. Several parts of Graham Land hitherto unknown have been explored, and by following the coast continuously its outline has been determined.

THE *Times* states that the French Ministry of Public Works has commissioned M. Jacquier to project plans for a railway between Chamonix and Aosta. It is considered that the difficulty would not be so great as with the Simplon tunnel; the tunnel would be $4\frac{1}{2}$ miles shorter, and the rock gives no indication of subterranean reservoirs of water. The tunnel would commence at Chamonix, 3415 feet above sea level, and end at Entrèves (4550 feet), a distance of $8\frac{1}{2}$ miles. The Dora Baltea would give ample water power for the boring work, and afterwards for locomotion.

The preliminary programme has been issued for the International Congress of Botany to be held at Vienna in Whitsun week, June 11–18. The formal opening of the congress will take place on Monday, June 12, in the large hall of the University of Vienna. A conference on the nomenclature question will be opened on the same day, and will be continued on other days. The chief subject of papers on June 13 will be the development of the European flora since the Tertiary period. On June 14 a general meeting of the botanical societies assembled for the conference will be held, as well as a conference of agricultural botanists. The subjects of discussion for the scientific meetings on June 14 will be (1) the present condition of the theory of the assimilation of carbonic acid, and (2) regeneration. Among the papers to be read on Friday, June 16, may be mentioned one by Dr. D. H. Scott, F.R.S., on the fern-like seed-plants of the Carboniferous flora. The organising committee has arranged for excursions before, during, and after the congress, and these will afford visitors an opportunity of learning to know botanically interesting regions under the guidance of specialists. In connection with the conference, too, an international botanical exhibition has been arranged, and will take place in the orangery of the Imperial Chateau at Schönbrunn. Full particulars of the conference can be obtained by intending visitors on application to the general secretary, Dr. A. Zahlbruckner, I., Burgring, Vienna.

A short time ago we chronicled the death of Prof. Emilio Villari, of Naples. Some interesting biographical details relating to this well-known physicist have now been published by Prof. A. Ròiti in the *Memorie* of the Italian Spectroscopists' Society (Catania, December, 1904) and the *Atti* of the Lincei Academy, xiv. (i), 1. As in the case of the late Prof. G. F. Fitzgerald, there can be no doubt that Villari's death was largely due to overwork, a result in both instances brought about by the great amount of teaching work which these physicists were required to undertake in their professorial duties, and which, when combined with research work, left them no time for rest. From his birth, in 1836, Villari suffered from epilepsy, and, partly in consequence of this, his early education was obtained at private schools. He graduated in medicine at Pisa. In 1860 he taught in the medical school of Naples; the next year he returned to Pisa as professor of physics and chemistry; in 1864 he studied in the laboratory of Magnus at Berlin. From 1865 to 1871 he occupied chairs at Florence; he was then, by competition, appointed to the chair at Bologna, which he held until 1889, when he went to Naples. His duties at the latter place involved the conducting of three separate University courses of lectures, and it is not surprising that in the session 1902–3 he broke down under the stress of work, and after a long and painful illness died on August 20 of last year. In the forty years from 1865 to 1904, Villari produced a long series of papers, which might advantageously be collected and published in a volume. His most recent work refers to the properties of air and gases which have been rendered radio-active by Röntgen rays, and to which he gave the name "aria ixata," or, literally, "X'd air." He was an honorary member of our Royal Institution and the Physical Society of London, and for some time previous to his death was president of the Lincei Academy.

The usual prize announcements of the Royal Lombardy Institution are given in the *Rendiconti*, xxxviii., 1. The triennial gold medal for industry is awarded to Messrs. Vermot and Rejna for carriage springs and axles. The Cagnola prizes for velocity of kathode rays, steering of balloons and prevention of forgery, as well as several other prizes, remain unawarded, while for cure of pellagra a premium is awarded to Dr. Carlo Ceni, of Reggio (Emilia), and for miasma and contagion the full prize and a gold medal are conferred on Dr. Adelchi Negri, of Pavia. As usual, there is keen competition for the Brambilla industrial prize, and the institution has awarded three first prizes with gold medals and four second prizes with gold medals to Lombardy manufacturers. Under the Fossati foundation an award is made to Dr. Giuseppe Pagano for a thesis on cerebral localisation. The Kramer prize for an essay on electric traction is awarded to Giovanni Giorgi, engineer, of Rome, and three awards under the Ciani prize are given for books on modern Italy.

The following list of prize subjects now issued by the Lombardy Institution for 1905 and following years includes the announcements made last year. Institution prizes, for 1905, on the ophiolitic formations of the Apennines; for 1906, on modern psychiatry. Cagnola prizes, for 1905, on phenomena of catalysis; for 1906, on pathology of suprarenal capsules. Fossati prizes (open to Italian subjects), for 1905, on our present knowledge of neurology; for 1906, on visual centres of higher vertebrates; for 1907, on nuclei of cranial nerves; for 1908, on the central nervous system. Kramer prize, for 1905, on the resistance of cement structures. Secco Comneno prize for a discovery on the virus of rabies. In addition, the triennial medals, Cagnola, Brambilla, Pizzamiglio, Tommasoni, Zanetti, and Ciani prizes are offered under the usual conditions, which have been referred to in previous years in the columns of Nature.

In the West India Committee *Circular*, Mr. Kenrick Gibbons suggests that mosquitoes are largely destroyed in Barbadoes by swarms of small fish, locally known as "millions," which prey on the larvæ.

In the February number of the *Zoologist* Mr. E. Bergroth, of Tammerfors, Finland, gives a list of generic zoological names not included in the supplement to the "Index Zoologicus" compiled by Mr. C. O. Waterhouse and published in 1902. While the number of names in the latter is about 250, no less than about 300 are recorded by Mr. Bergroth, all dating before 1901.

Some months ago Schaudinn published some interesting observations on the development of trypanosome forms from Halteridium, a protozoan blood parasite of birds. Novy and MacNeal now criticise Schaudinn's work, and ascribe his results to a double infection with Trypanosoma and Halteridium, and not to the development of the former from the latter.

We have received the *Transactions* of the Epidemiological Society for the session 1903–4 (vol. xxiii.). It contains a paper by Prof. Simpson on the epidemiology of plague, in which he shows that the domestic animals and birds may contract plague by feeding on plague-infected offal, and important discussions on sleeping sickness, the etiology of scurvy, industrial anthrax, and enteric fever and cholera in Hamburg, together with an obituary notice of the late Sir John Simon.

Some interesting notes on the habits of Natterer's bat (*Myotis nattereri*) are contributed by Mr. T. A. Coward to the *Zoologist* for February. From these it appears that in certain habits this bat is to some extent intermediate between other members of the Vespertilionidæ and the horse-shoe bats (Rhinolophidæ). It has, for instance, the habit of turning in the air, characteristic of the latter. Again, whereas in the horseshoe-bats the short tail is carried bent over the back, while in most British Vespertilionidæ this appendage is usually carried beneath the body, in Natterer's bat, despite the fact of its being used as a pouch to contain the insect-food, it is borne extended in the line of the body.

To the complex subject of nuclear changes is devoted the greater portion of the February issue of the *Quarterly Journal of Microscopical Science*, Messrs. Farmer and Moore discussing the "maiotic" phase (reduction divisions) in animals and plants in the first article, while in the second Prof. Farmer and Miss Shove describe the structure and development of the somatic and heterotype chromosomes of Tradescantia. The term "maiotic" phase is a new one, proposed to cover the whole series of changes formerly known as heterotype and homotype; as being derived from μείωσις (reduction) its orthography should apparently be "miotic." Of the other two articles, one, by Messrs. Moore and Robinson, describes the behaviour of the nucleolus in the spermatogenesis of Periplaneta, while the other, by Mr. G. Wagner, is devoted to certain movements and reactions of Hydra.

From a letter which Mr. P. Olsson-Seffer has written to *Science*, we learn that a Danish botanist, Mr. M. P. Porsild, has sought the help of his Government in founding an Arctic laboratory, which it is proposed to establish near Godhavn (lat. 69° 15′ N.), on Disko Island, North Greenland. Such a laboratory would be the first institution of its kind for investigating Arctic problems, and would form a counterpart in the cold regions to the tropical stations at Buitenzorg and Ceylon. The power of plants to withstand intense cold, and their nutrition under the peculiar conditions of light, will probably be among the earliest researches.

Mr. J. H. Maiden has contributed to the *Proceedings* of the Linnean Society of New South Wales (August, 1904) an account of the plants collected by Mrs. David on Funafuti, one of the Ellice group of coral islands. The list agrees very closely with those of collections made on similar islands, notably Samoa, Fiji and Keeling Islands, and consists of fifty flowering plants representing thirty-three orders. The native names are very similar to the Samoan. Although the plants include various edible products, such as the almonds of *Terminalia Catappa*, the sword-bean, and fruits of Pandanus, the islanders subsist chiefly on taro and bananas.

The second part of Prof. E. C. Jeffery's treatise on the comparative anatomy and phylogeny of the Coniferales claims attention not only for the facts which he has observed in examining various genera of the Abietineæ, but more especially on account of the deductions which, evolved from the consideration of certain formulated canons of comparative anatomy, by their evident consistency go far to establish the validity of these canons. It is possible to trace in the Abietineæ a sequence from forms such as Tsuga and Cedrus, in which resin-canals are absent from the wood of all normal stem parts, through certain species of Abies, in which the resin-canals occur only in the wood of the reproductive axis, to Picea, Larix, and Pinus, where they are formed normally in the wood of the vegetative axis. Among the former, resin-canals are freely produced in the vegetative shoots as a result of injury. From these and other facts Prof. Jeffery concludes that the Abietineæ are a very ancient order, older than the Cupressineæ, and by the possession of a double leaf-trace are allied to the Cordaitales. The treatise forms the first number of vol. vi. of the *Memoirs* of the Boston Society of Natural History.

We have received the report of the Meteorological Commission of Cape Colony for the year 1903. A comparison of the number of ordinary stations shows a fair increase over that for 1902, except in the case of purely rainfall stations, where there is a decrease of 31. This is partly due to the fact that owing to severe drought many farmers have had to trek with the remains of their cattle to adjoining territories, leaving their homesteads entirely unoccupied. The report contains useful monthly and yearly average rainfall data, for districts, over Cape Colony for the ten-year period 1894–1903.

Prof. H. Hergesell, president of the International Aeronautical Committee, has favoured us with a summary of the monthly ascents made during the last six months of the year 1904 for the exploration of the upper air by means of manned and unmanned balloons and kites. The average number of ascents per month was eighteen, and some remarkable altitudes were attained by the unmanned balloons, seven of them exceeding 15,000 metres, and eighteen exceeding 10,000 metres, the extremes being 24,070 metres, at Strassburg, and 19,750 metres, at Pavlovsk, both in the month of September. Special mention may be made of some important kite ascents from the yacht of the Prince of Monaco last autumn, during which a height of 4510 metres was attained to the north-west of the Canary Islands, and 4360 metres south of the Azores. We hope shortly to refer to some valuable results obtained from the discussion of these observations in the region of the trade winds.

We have received a copy of the fifth edition of Jelinek's excellent "Instructions for taking Meteorological Observations," issued under the superintendence of Dr. J. M. Pernter, the present able director of the Austrian Meteorological Service. The first two editions (1869 and 1876) were written by Dr. Jelinek, the third and fourth (1884 and 1893) were revised by Dr. J. Hann, who is justly recognised as the foremost of living meteorologists. Not forgetting the excellent meteorological instructions issued in Russia by the late Dr. H. Wild, in France by M. Angot, and in Germany by Dr. van Bebber, nor the useful handbooks of smaller pretensions by Dr. Scott (late of the Meteorological Office) and Mr. Marriott (Royal Meteorological Society), we can have no hesitation in asserting that the work now under notice is second to none among works of a similar kind. It is thoroughly up-to-date, and contains all that is necessary to be known in connection with the recent considerable advances made by the introduction and more general use of various self-recording instruments, and with the more systematic observations of clouds. It contains good representations of eight of the principal forms of clouds, reproduced from the International Cloud Atlas, and 37 other illustrations, with sound advice in the choice of necessary instruments and the establishment of stations of all classes, whether first-order observatories or stations intended to record merely rainfall and temperature. Any observers in our own country who may be conversant with the German language would, we think, be much interested by a careful perusal of this very instructive work.

The current number of the *Fortnightly Review* contains an article by M. A. Santos-Dumont on "The Future of Air-Ships." The difficulties against which the nagivator of the air has to contend are explained, and the means adopted by various aëronauts to overcome these obstacles are described. The two great obstacles to ballooning, M. Santos-Dumont points out, are contraction and expansion. To counteract contraction ballast must be thrown out, to compensate for expansion, gas must be allowed to escape. The skill of the aëronaut of a spherical balloon consists in maintaining his desired altitude with the greatest economy of gas and ballast. But in any case repeated contractions must mean the loss of the last lot of ballast, and repeated expansions must result in the loss of so much gas that the balloon sinks eventually to earth. The latest plan proposed to overcome this weakness is described at length in the article. Steam circulating in a long aluminium worm will be used to heat the gas of the balloon, and contraction will mean merely the condensation of so much steam into water, while expansion will be brought about by its reconversion into steam. The difficulty consists in preventing any loss of water, and M. Santos-Dumont explains how he proposes to effect this. The successful use, at an early date, of air-ships in Arctic exploration is predicted, and the part that air-ships will take in the warfare of the future is outlined.

We have received from Messrs. A. Gallenkamp and Co. specimens of some new spectrum tubes which we have tested with very satisfactory results. The tubes, three in number, contained argon, helium, and a mixture of argon and helium, and the trial showed that they are a great advance on any other forms that have previously been examined. For spectroscopic work they should be of the greatest service, for the exceeding brilliancy of the gases, when only a small coil, with or without a jar in circuit, is used, will render them particularly useful in research work. The tubes themselves are of rather novel construction, the main point being the insertion of a short capillary tube in a tube of larger dimensions, the latter being connected with two other tubes fixed at right angles, and containing the electrodes. The current passing from one electrode to the other has to pass through the capillary, and the gas in this space is rendered very brilliant. When placed end on to the slit of a spectroscope, the bulb end of the tube containing the capillary being on the slit side, a method first adopted by Monkhoven to obtain the maximum of brilliancy of the illuminated gas on the slit, the result is a brilliant concentration of light which can be examined with large dispersion. The tubes are strong, compact, and well made, and can be strongly recommended both for student and research use.

Prof. A. H. R. Buller, writing from the University of Manitoba, describes some striking electrical effects due to the dryness of the atmosphere at Winnipeg. The air during the winter months contains so little water-vapour that bodies charged with electricity lose their charges relatively slowly. When the thermometer is low, ranging as it often does for a week or more at a time from 0° to −40° F., very little friction, such, for instance, as may be produced by walking along a carpet, causes a person to become charged with sufficient electricity to produce a visible and audible spark on touching an iron bedpost, the radiator, the gas-tap, or any other conductor. It is a favourite amusement of some children to take sparks from each other's noses after running about a carpeted room. In the Manitoba Hotel, now burnt down, there was a ballroom with some iron pillars in it. Prof. Buller was told by a trustworthy eye-witness that after a dance dancers on several occasions have been "severely stung" by accidentally coming into contact with one of the pillars. Many ladies have considerable difficulty in combing their hair; for during the process it becomes so charged with electricity that it stands out in the most astonishing manner. Even the short hair of a man, when being combed, often "crackles," "stands on end," and in the dark produces a display of sparks. It is quite easy to light the gas with a spark from the finger when matches are not handy by merely shuffling a few paces over the carpet and then holding a finger to the burner. On February 6, at 1 p.m., when a thermometer in the shade out of doors registered −5° F. and indoors 62° F., Prof. Buller found that a spark half an inch long could be obtained between his finger and an earth-connected iron pipe after sliding his feet smartly for twenty paces along the maple-wood floor of his laboratory. In the chemical laboratory calcium chloride may be exposed to the air for some weeks without showing the least apparent signs of deliquescence. In order to demonstrate the deliquescence of this substance to the students, the professor of chemistry is obliged to use a damp-chamber.

No. 2 of vol. ii. of *Le Radium* contains an account by M. J. Danne of the deposits of pyromorphite containing radium which have recently been discovered at Issy-l'Evéque (Saone et Loire), and the first part of a study of phosphorescence by M. L. Matout. A description is also given by Dr. Robert Abbe, of St. Luke's Hospital, New York, of several cures of external tumours and cancerous growths which were effected by means of radium.

An investigation of the effect of temperature on the magnetisation of steel, nickel and cobalt by Prof. H. Nagaoka and S. Kusakabe constitutes article 9 of vol. xix. of the *Journal of Science of the University of Tokio*. The most interesting results were obtained with cobalt and with tungsten-steel. The former is characterised by undergoing several remarkable changes of magnetisation as the temperature is raised, whilst with tungsten-steel, between the temperature of disappearance of magnetism on heating and that of its reappearance on cooling, there exist at least five corrugations in the curve of magnetisation in a constant field. When once the magnetisation has disappeared it cannot be recovered until the temperature has been lowered by about 240° C., and the cooling curve again exhibits peculiar sinuosities. In addition to these peculiarities, tungsten-steel shows a very pronounced recalescence at 660° C., this temperature practically coinciding with that at which magnetism reappears in the cooling metal.

In No. 3 of vol. vi. of the *Physikalische Zeitschrift* Messrs. Elster and Geitel describe further investigations of the highly radio-active muds from the thermal springs of Nauheim and Baden. These sediments are completely soluble in hydrochloric acid, and on adding dilute sulphuric acid to the solution, a precipitate of radio-barium sulphate is obtained having an activity many times as great as that of an equal quantity of the original mud. The oxides precipitated by ammonia from the filtrate of the barium sulphate are also radio-active, the character of the emanation indicating the presence of thorium, although this substance could not be separated by chemical methods. Prof. G. Vicentini and M. Levi de Zara, in the *Atti* of the Royal Venetian Institute (vol. lxiv., ii., 95), also deal with the question of radio-active sediments. The radio-activity of the mud and of the incrustation formed by the thermal springs of Battaglia, Abano, Montegrotto and the Lake of Lispida has been measured. The Cittadella spring at Montegrotto is particularly noteworthy on account of the high value of its radio-activity and of the fact that this appears to be due to radium only. The air in the vicinity of the springs was in all cases found to contain notable quantities of a radio-active emanation.

The latest addition to the Philosophische Bibliothek published by the Dürr'schen Buchhandlung, Leipzig, is a translation of Spinoza's "Ethics," with an introduction and notes, by Dr. Otto Baensch. The volume is No. 92 of the series of philosophical manuals in which it is published, and its price is three marks.

WE have received from Mr. A. C. Cossor, of Farringdon-road, E.C., an illustrated catalogue of Röntgen ray tubes, electrical instruments and fittings, and small electric lamps for all purposes. The catalogue should be of interest to physicists, medical men and others interested in high vacuum work.

THE fourth part of the second volume of "The Fauna and Geography of the Maldive and Laccadive Archipelagoes: being the Account of the Work carried on and of the Collections made by an Expedition during the years 1899 and 1900," edited by Mr. J. Stanley Gardiner, has been published by the Cambridge University Press. This part contains reports on the Alcyonaria of the Maldives by Prof. S. J. Hickson, F.R.S.; on marine crustaceans by Major Alcock, F.R.S., and Prof. H. Coutière; on hydroids by Mr. L. A. Borradaile; on Rhynchota by Mr. W. L. Distant; and notes on parasites by Mr. A. E. Shipley, F.R.S.

MESSRS. TEUBNER, of Leipzig, have just issued a fifth edition of Schlömilch's "Uebungsbuch zum Studium der höheren Analysis," part i., of which the first edition appeared in 1868, and a second edition of Dr. A. Föppl's "Einführung in die Maxwell'sche Theorie der Elektrizität," the first edition of which appeared in 1894. Of these, the former, which in England would be called a "treatise on the calculus," has been revised by Prof. E. Naetsch, of Dresden, and several new paragraphs on transformation of coordinates have been added. The work of editing Dr. Föppl's treatise has been undertaken by Dr. M. Abraham, who is preparing a second volume dealing with "theory of electromagnetic radiations."

OUR ASTRONOMICAL COLUMN.

JUPITER'S SEVENTH SATELLITE.—*Circular* 74 from the Kiel Centralstelle confirms the telegram received last week concerning the discovery of a seventh satellite to Jupiter.

It contains a message from Prof. Campbell in which he states that the object was discovered by Prof. Perrine, using the Crossley reflector. The position previously given, viz. position angle = 62°, distance from Jupiter 21′, was that occupied by the satellite on February 25.6 (G.M.T.). The apparent motion was direct, and the orbit is considerably inclined to the ecliptic. This latest satellite has been under observation, with the Crossley reflector, since January 2, but no particulars of the observations, other than those for January 25, are given in the circular.

LONGITUDE OBSERVATIONS OF POINTS ON MARS.—*Bulletin* No. 14 from the Lowell Observatory contains the results of the longitude determinations of nearly sixty features on the surface of Mars made at Flagstaff during 1903. For each point the times of the several observations and the resulting longitudes are given, and these are followed by the mean value for the longitude and its probable error; the mean value for the latitude of each point is also given.

The longitudes were determined by noting the time of transit of each marking across the micrometer thread when the latter was placed parallel to the position angle of the polar axis, as given in Mr. Crommelin's ephemeris, and passing through the polar cap. As the thread obliterated the markings it became easier in practice to record the time at which the marking and the cap were equidistant from the thread.

Mr. Lowell has allotted a number to the result of each determination showing the relative weight to be attached to the value obtained.

OBSERVATIONS OF COMETS.—The comets 1904 *e* (Borrelly), 1904 *d* (Giacobini), and 1904 *a* (Brooks) have been regularly observed, at Lick, by Dr. R. G. Aitken, and the results are published in No. 69 of the Lick Observatory *Bulletins*.

Observations of comet 1904 *e* were made during the end of December and the beginning of January, and two sets of parabolic elements were computed from the results. Subsequent observations did not confirm these, and consequently Dr. Aitken computed elliptic elements from his observations of December 31, 1904, January 17 and 27, 1905. When the observational values were compared with the places calculated from these elements, the agreement was found to be satisfactory, and it seems probable that the comet is moving in an elliptical orbit with a period of about 7.3 years. An ephemeris based upon these elements and extending to March 31 is given, and shows that on March 11 the comet will be only 0.27 as bright as at the time of discovery, when it was variously estimated as being of the tenth or eleventh magnitude.

Comet 1904 *d* was observed on January 28, and the observation showed that the orbit published in *Bulletin* No. 67 needs very little correction. From the comet's appearance on that date it is evident that this object will soon be beyond the reach of all but the most powerful telescopes. An ephemeris extending to April 3 is given.

Observations of comet 1904 *a* were made with the 12-inch refractor by Messrs. Maddrill and Aitken during the period June 21–September 4, 1904, and the results are given in the same circular. A footnote by Dr. Aitken states that the comet was still visible in the 12-inch telescope on January 26, and an observation made on that date showed that Prof. Nijland's ephemeris is very nearly exact.

THE GOVERNMENT OBSERVATORY AT VICTORIA.—We have received the annual reports of the board of visitors and the director of the Victoria (Australia) Observatory for the years ending March 31, 1903, and 1904.

The reports show that the routine work connected with the meridian observations, the time service, the meteorological, magnetic, and seismological observations, and instrument testing was carried out as usual.

On the later date the taking of the catalogue plates for the astrographic chart, to the number of 1149, had been completed, whilst satisfactory progress had also been made with the other sections of the work. The measurement of both the Sydney and the Melbourne plates is being carried out at Melbourne, and on March 31, 1904, 239 Sydney plates containing 137,812 stars, and 522 Melbourne plates containing 151,343 stars, had been completely measured. A new measuring machine designed by Mr. H. C. Russell was finished, and its fitness was being investigated when the report was issued.

The director, Mr. P. Baracchi, states that the work of measuring the magnetograph curves and reducing all the magnetic observations made since 1868 is progressing satisfactorily, and that he hopes the results will be published within the next two or three years.

OBSERVATIONS OF SATURN'S SATELLITES.—The results of a series of observations of the relative positions of the seven inner satellites of Saturn are published in *Bulletin* No. 68 of the Lick Observatory. The observations were made by Prof. Hussey with the 36-inch refractor between August 3 and December 2, 1904, and in each case the position angle and distance of the satellite in regard to one of the other satellites are given.

BRIGHT METEORS.—Mr. R. L. Jones, writing from 3 King's Bench Walk, Temple, E.C., refers to three bright meteors observed on the nights of February 27 and 28. All the three appear to have started from the constellation Monoceros, and to have tracked thence in a north-westerly direction. A brilliant meteor was also seen at 12.10 a.m. on March 1, its brightness far exceeding that of Venus.

THE MAGNETIC SURVEY OF THE UNITED STATES.

THE report for the year ending June 30, 1904, on the magnetic survey of the United States and its outlying territories has lately been issued by the authorities of the Coast and Geodetic Survey, and contains a long list of field observations of the magnetic elements made with the usual completeness, supported by results obtained in five fixed observatories. Two of the latter are at Porto Rico and Honolulu respectively.

The new feature in the present report is that the survey has been extended to the neighbouring seas both on the Atlantic and Pacific sides of North America, and it records the successful observation at sea of thirty-four values of the Dip, and thirty-two of the Intensity, with fifty-two of the Declination.

The observations of the Declination were made with the ship's standard compass in the process of "swinging." Those for Dip and Intensity at the same time with the Lloyd-Creak (shortly L.-C.) dip circle, an instrument originally designed for sea observations of those elements, but which in field work on land has also been found to give results hardly inferior to those of the specially designed land instruments. The degree of accuracy hitherto obtained at sea as compared with land observations with the same instrument is also given.

The accompanying illustration shows the L.-C. circle mounted for observations on land and fitted on top with an arrangement proposed by the U.S. C. Survey for observing the Declination, but which also serves the purpose of placing the circle in the magnetic meridian. At sea the circle is mounted on a gimbal stand with the declination fitting removed, as the angle between the direction of the ship's head and the magnetic meridian is then obtained from the ship's standard compass.

A detailed description of the L.-C. circle is given in the

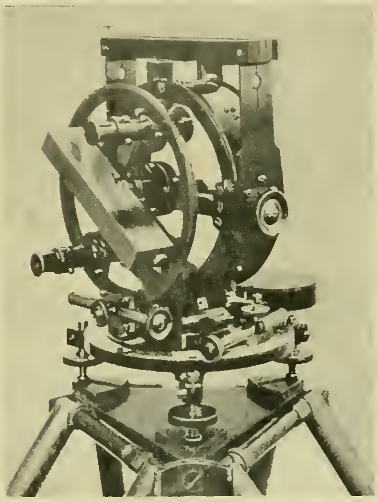

FIG. 1.—Lloyd-Creak Dip Circle, mounted for Observations on Land.

report with the methods adopted for observing therewith at sea in the U.S. surveying vessels, which are, however, not specially adapted to the work. A wood-built vessel, specially designed and devoted to magnetic work as a primary object, is required to obtain the full value from this instrument, and it is therefore pleasant to record that the magnetic survey of the North Pacific Ocean in such a vessel will be commenced this year by the United States.

THE NEST OF THE FIGHTING FISH.

IN most, if not in all, the members of the group of Oriental fishes typified by the so-called climbing perch (*Anabas scandens*), the males take charge of the eggs as they are extracted from the females and place them in a "nest" of mucus-covered bubbles, which they have previously prepared. A well-known representative of the family is the "fighting fish" (*Betta pugnax*), which takes its name from the circumstance that a semi-domesticated breed is kept by the Siamese for the sake of the sport offered by the combats of the males. Of this fish living specimens from Pinang have recently been in the possession of Mr. E. H. Waite, of the Sydney Museum, who has published an illustrated account of their nesting habits in the *Records* of the Australian Museum for December last (vol. v. No. 5). Mr. Waite has obligingly sent us a copy of his original photograph of the nest, which is herewith reproduced.

Mr. Waite states that he received these fish early in April last year, and that the male almost immediately proceeded to blow bubbles, which it produced by rising periodically to the surface and taking in gulps of air. A circular mass of mucus-clad bubbles, about 3 inches in diameter, was soon produced; and in course of time several other layers were formed, which resulted in the final production of a large dome-shaped structure, as shown in the photograph. The structure was completed on the third day, when the female commenced to lay her eggs, which were received between the pectoral and ventral fins as they were extruded, and were then suffered to sink slowly in the water. Here they were collected by the expectant male, decked in his resplendent breeding colours, and placed, after being coated with mucus, below the mass of bubbles, to which they adhered. From three to seven eggs are extracted at a time, and the process is continued until there are from one hundred and fifty to two hundred. When the laying is over, the female is kept away from the nest to prevent her devouring the eggs, which are carefully tended by the male, being constantly moved and from time to time re-coated with slime.

On the third day the eggs hatched, the larvæ remaining beneath the shelter of the bubbles. From time to time some fell off, when they were immediately replaced by the watchful male, but in a day or two the numbers which became de-

FIG. 1.—Nest of the Fighting Fish. About two-thirds natural size. From a photograph by Mr. Waite.

tached were too many for him to secure, although he frequently had seven or eight in his mouth at once. Some were, however, recovered from the bottom of the tank and returned to the shelter of the nest, but many were devoured by the female. Eventually all the larvæ died, and, although the fishes bred on two other occasions, none of the offspring were reared.

SOME RECENT WORK OF THE U.S. GEOLOGICAL SURVEY IN THE WESTERN STATES.[1]

IF it be possible for envy to lurk in the breast of the scientific worker, then surely might we look for it in the geologist of these islands when he regards the lot of his fellow-worker across the Atlantic. In the breadth of field open to research, in the freshness of the land, and in the public support accorded to his labours, the geologist of the present day in the United States may justly claim preeminence. In the four memoirs before us, a mere random selection from the recent publications of the U.S.

[1] "Zinc and Lead Deposits of Northern Arkansas." By G. I. Adams and others. Pp. 118; with 17 plates and 6 figures.
"The Copper Deposits of the Encampment District, Wyoming." By A. C. Spencer. Pp. 107; with 2 plates (maps) and 49 figures.
"Economic Resources of the Northern Black Hills." By J. D. Irving and others. Pp. 222; with 20 plates and 16 figures.
"A Geological Reconnaissance across the Bitterroot Range and Clearwater Mountains in Montana and Idaho." By W. Lindgren. Pp. 123; with 15 plates and 8 figures.
Being "Professional Papers" Nos. 24, 25, 26 and 27 of the U.S. Geological Survey. (Washington, 1904.)

Geological Survey, all these stimulants are conspicuous. The memoir on the Bitterroot Range alone deals with an area of about 12,000 square miles, respecting which our scientific knowledge has been hitherto of the scantiest; while the other three, though professedly more limited in scope, treat in detail of areas ranging from about 450 to 560 square miles which may be taken as selected illustrations of parts of the vast region west of the Mississippi.

Of course, it is not area only that counts in geology; and in considering the magnificent distances of the Great West, we may take heart in that our own shreds of land have not been carved out of some wide monotonous tract covered by a single formation within which it might be the fate of an ardent geologist of limited means to find himself hopelessly tethered! It is, indeed, fortunate that in the geological map of the world the British Isles lie, as it were, athwart the index.

It is less easy to find consolation when we compare even the most presentable of our British geological publications with these beautifully printed and liberally illustrated memoirs, wherein the native asperities of the technical treatise are so smoothed and adorned that they are hardly perceptible. Take, for example . . . . but comparisons are proverbially odious, and, moreover, the one in mind has been frequently made, with no good result, so let it pass!

It is noteworthy that all four treatises give the results of investigations which, although essentially scientific in scope, have centred around the economic resources of the specified districts. In all cases, also, the prospector and miner, working more or less at haphazard, had made considerable progress in developing the metalliferous deposits before the advent of the geologist, whose function has been to explain the general principles deducible from the discoveries already made, and to indicate the lines along which further exploration may proceed with the best chance of success. This is the proper course, for it is not until the average "practical man" begins to feel the need for professional advice that he is likely to pay much heed to such advice if it be proffered him. All the memoirs, and more especially that on the northern Black Hills, give full descriptions and many illustrations of the principal mine-workings, to which we need not further refer.

First on our list stands the description of the zinc and lead deposits of northern Arkansas, by G. I. Adams, assisted by A. H. Purdue and E. F. Burchard, with a palæontological appendix on the correlation of the formations by E. O. Ulrich. Though occurring mainly at a lower stratigraphical position, these metalliferous deposits appear to be very similar in mode of occurrence and in character of vein-stuff to the lead-ores of the Carboniferous Limestone of the north of England.

The principal locus of the deposits is in "the Yellville formation," a dolomitic limestone of Ordovician age; but they also range upward, less abundantly, into Lower Carboniferous Limestones. The Silurian system appears to be absent from the district described, and the Devonian is represented only by impersistent sandstone and shale, of which the maximum thickness does not exceed 40 feet. The region has been little disturbed; igneous rocks are absent; and the Ordovician rocks still maintain their nearly horizontal position. Nevertheless, there has been in some places much differential movement among the strata, probably as the result of compressive forces, whereby the thinner and more brittle beds have been brecciated and the fragments made to rotate or to shear past each other, producing the structure that in this country has been termed "crush-conglomerate." These breccias have permitted the percolation of the ore-bearing solutions, and are sometimes enriched by metalliferous deposits, though usually only in the vicinity of the nearly vertical fissures which appear to have formed the principal channels of the mineralised waters. It is suggested that the ores represent the concentration of minerals originally disseminated in the country rock, and more especially in the Mississippian (Carboniferous) limestones, this concentration having been effected by waters which, after circulating through the upper belt of weathered rock, have passed downward to the "belt of cementation."

The next memoir carries us some 700 miles north-westward, to the southern border of Wyoming, and to a geological province of utterly different character. "The Copper Deposits of the Encampment District," by A. C. Spencer, describes a hilly region on the Continental Divide, ranging in altitude from about 6650 feet to 11,007 feet, occupied for the most part by a complex mass of pre-Cambrian rocks, broken into and altered by igneous intrusions, with Mesozoic formations lying upon the flanks of the ancient massif as foot hills and dipping away beneath the surrounding prairie. The pre-Cambrian group

Fig. 1.—Trapper Peak, showing gradual slope of Gneiss Zone to the left and Glacial Amphitheatre in Granite at centre.

includes hornblende-schists derived from bedded volcanic rocks, limestones and shales, quartzite and slate, and a thick conglomerate, with intrusions of quartz-diorites, granites, and gabbros in great variety. The structure of the sedimentary rocks of this group is interpreted as a synclinorium, striking east and west, with its component strata dipping invariably to the south. With respect to the conglomerate, it is noted that though locally almost unchanged from its original condition, it is more frequently metamorphosed, and that this metamorphism, both mechanical and chemical, has often been carried so far that the contained boulders and pebbles have been mashed into disc-like plates, and the rocks, by re-crystallisation, converted into a gneiss the origin of which would be entirely indeterminate except through the study of its gradual passage from the unaltered condition. Certain mineral transformations described in the gabbros are assigned to dynamic pressures insufficient to inaugurate actual crushing, and also unaccompanied by a notable degree of hydration. The copper-ores which constitute the chief mineral wealth of the district occur under diverse conditions, which are carefully described and classified. It is believed that a large part, though not all, of the metalliferous deposits had their original source in the gabbros, of which eighteen samples, representing various phases of the rock, were tested in the laboratory of the survey, and in each case yielded traces of copper.

In the richest lodes the ores appear to have been concentrated by ascending solutions.

In the third memoir we are transported some 500 miles north-eastward to consider the economic resources of the northern Black Hills of South Dakota. A brief sketch of the general geology of the district is given in part i. (28 pages) by T. A. Jaggar, jun., and the rest of the volume, forming part ii., by J. D. Irving and S. F. Emmons, deals fully with the economic resources. The dome-like structure of the Black Hills, with their laccolitic intrusions of igneous rock, is already well known. "They rise like an island in the midst of the Great Plains, with culminating peaks of pre-Cambrian granite intrusive in Algonkian schists, and these same schists and granite may be followed outward from the centre of the Hills to an encircling escarpment of Palæozoic rocks dipping away on the northern, southern, and eastern sides, and mantling over the schists to form an extensive forested limestone plateau on the west." The limestones have been crushed in places into "pseudo-conglomerates," and Dr. Jaggar suggests a similar origin for many supposed conglomerates or "intraformational breccias" that have been described in other parts of the continent.

The picture of the region presented in the first few pages of part i. is remarkably clear and impressive. The Cambrian series of shales, quartzite, sandstone, and thin limestones, 200–400 feet thick, which rest in bold unconformity upon the upturned edges of the Algonkian schists, include at their base an irregular conglomerate, evidently an ancient beach-deposit. This basal Cambrian conglomerate contains detrital gold, derived from the erosion of auriferous lodes in the Algonkian rocks, and, according to the present authors, has been further enriched by later infiltration. It thus constitutes in favoured localities a gold-producing ore second only in importance to the lodes in the underlying Algonkians. The last-mentioned lodes are usually fissured belts of rock along which the precious metal, accompanied by other minerals, has been more or less irregularly deposited by permeating solutions. Another important source of gold is described under the heading of "Refractory Siliceous Ores." These ores represent the replacement of portions of the Cambrian dolomitised limestones by silica and other minerals, including gold, that appear to have been carried upward in solution by waters ascending along vertical joints. These waters, when checked by a comparatively impervious bed, tended to spread out laterally along the dolomites, which were partially dissolved and replaced by other substances. This part of the memoir is illustrated with some beautiful plates of microscopic slides. Besides gold, the district has yielded ores of silver-lead, wolframite, and a little copper, with some traces of tin.

FIG. 2.—Upper Valley of Mill Creek, Bitterroot Range, looking East from Main Divide. Notice pronounced U-shape of Valley narrowing toward the lower part. The prevailing rock is granite.

The last memoir of our series, which takes us again 900 miles to the westward, is the description of a geological reconnaissance across the Bitterroot Range and Clearwater Mountains in Montana and Idaho, by Waldemar Lindgren, and is in some respects the most instructive of the series; but unfortunately we have no space in which to do it justice. It deals with a vast tract of mountainous country, for the most part exceedingly difficult to traverse, and as yet very imperfectly explored. A huge "batholith" of granite or quartz-monzonite 300 miles in length from north to south, and 50 to 100 miles in width, occupies the central part of this region, and has been locally pressed and deformed, especially along its eastern margin, into gneiss. Sedimentary rocks are comparatively restricted in their range, and the age of most of those which are exposed is doubtful, as no well defined fossils have been found; but it is believed that, along with complexes of pre-Cambrian age, the Triassic, Carboniferous, and possibly older Palæozoic systems are represented. In the west the country is overspread by the great Columbia River lavas of Tertiary age. The physiographic features of the region are of extreme interest, and are carefully discussed. It is shown that the Clearwater Mountains had already acquired a sharply accentuated topography before the outpouring of the Columbia River basalts, and that the lower portions of the principal valleys were flooded and dammed by the lava-flows. The most important structural feature of the region, however, is the great fault by which the Bitterroot Mountains have been elevated on the west and the Bitterroot valley carried down on the east. This fault-plane is described as being remarkably flat, though apparently normal. It is supposed to represent a twofold movement, by which the foot-wall has been raised and the hanging wall depressed. It indicates a vertical movement of from 4000 to 6000 feet, and the horizontal component is estimated to be at least two miles. The schistose belt of the granite underlies this plane, and the structure is considered to be an outcome of the disturbance. Movement appears to have continued along the fault up to recent times.

G. W. L.

ANTHROPOLOGICAL NOTES.

AN interesting paper by A. L. Kroeber on the types of Indian culture in California is to be found in vol. ii. of the *Publications* of the University of California—"American Archæology and Ethnology, 1904." Ethnologically, California is characterised by the absence of agriculture and pottery, by the total absence of totemism or gentile organisation, by an unusually simple and loose social organisation in which wealth plays a rather important part, by the very rude development of all arts except basketry, by the lack of realism in art, by a slight development of fetishism and by the conspicuous lack of symbolism and ritualism, by the predominance among ceremonials of mourning and initiation rites, and by a considerable development of true conceptions of creation in mythology. The natives are of an unwarlike nature, and lack intensity and pride. It will therefore be seen that in almost every instance the Californian Indians are among the least characteristic of the Indians of North America, being lacking in the typical qualities of that race, and thus they are the most generalised of the peoples of that continent. In the same volume Dr. Kroeber gives an account of the languages of the coast of California south of San Francisco.

Drs. A. Bloch and P. Vigier have re-examined the hair follicles of negroes (*Bull. et Mém.* Soc. d'Anth., Paris, 1904, p. 124), and have obtained interesting results. The follicle forms at least half a spiral and is not flattened; the distribution of hair on the scalp is uniform, but all the hairs of the same spiral tuft have the intradermic portion of their curves orientated in nearly the same direction, and it is apparently this uniformity of the neighbouring follicles that determines the formation of spiral tufts; a semicircular oblique crest ridge of fibrous tissue constricts the upper portion of the hair bulb, and thus causes the flattening of the hair and its spiral twist.

Mr. E. H. C. Walsh, in an illustrated note on stone implements found in the Darjeeling district (*Journ.* As. Soc. Bengal, lxxiii. p. 21), states that all the implements he found were polished "celts," with the exception of a dumb-bell shaped hammer head. The general belief of the people is that these axe-heads are thunderbolts which have fallen from heaven; they are chiefly found with the medicine men, who use them as charms in their incantations to drive out or cure disease, and also on account of their reputed medicinal properties when mixed with water; on several specimens the scraping or rubbing on stones to obtain medicine is very noticeable. Numerous references to other papers dealing with the subject are given. On p. 27 of the same *Journal* P. O. Bodding describes some shoulder-headed and other forms of stone implements in the Santal Pargans; it is not yet clear who were the makers of these distinctive implements—possibly they were Mon-Kmer and Munda peoples. The *Journal* also contains some interesting folklore.

Some time ago M. Verneau directed attention to some skulls from Palæolithic interments at Mentone with a remarkable negroid aspect, and M. Hervé has noted two somewhat similar Neolithic skulls from Brittany. Prof. Manouvrier points out in the *Bull. et Mém.* Soc. d'Anth., Paris (1904, p. 119), that all these "negroid" characters occur in European or other non-African skulls, but they are very rarely found in conjunction. All the skulls of this type are female; in following out this hint Dr. Manouvrier discusses the "negroid" characters, and comes to the conclusion that in a dolichocephalic population in which the prognathism of the men is so marked, a corresponding degree of prognathism in the women, combined with other characters that are characteristic of female skulls, would give a negroid appearance without any need to conclude that there was a negro element in the population. The same author describes (p. 67) a remarkable trepanned Neolithic skull, and (p. 101) some senile Neolithic skulls.

As the result of a long and careful comparative study of the skeletal variations of the foot in primates and in the races of man, Th. Volkov (*Bull. et Mém.* Soc. d'Anth., Paris, 1903, 1904) arrives at the following conclusions:—The skeleton of the foot of the prosimians bears many traces of the primitive type of foot of the ancient mammals, and presents many intermediate forms between this type and that of the foot of monkeys. The skeleton of the foot of the lower primates appears to be the result of adaptation to arboreal life of ancestors whose foot resembled that of existing rodents. The skeleton of the foot of anthropoids represents the extreme of this adaptation, but at the same time (among the hylobates and partly in the gorilla) the beginning of adaptation to standing and to bipedal progression. The skeleton of the foot in the lower races of man presents as a whole, and for each bone in particular, evident and numerous traces of adaptations characteristic of climbers antecedent to the assumption of the erect attitude and bipedal progression. The ethnical characters range from the oblique and flat foot to the straight and arched foot. Consequently the arch of the foot represents the most essential character from an anthropological point of view. The index of curvature, that is to say, the relation between the height and length of the foot, or especially the tarso-metatarsian length, should be considered as a very important anthropometric datum. The skeleton of the foot of the new-born infant reproduces primitive and transitory forms in the development of the human foot in general, and thus its study possesses a very great anthropological importance.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—The following is the speech delivered by the Public Orator, Dr. Sandys, on Thursday last, in presenting Dr. E. B. Tylor, F.R.S., professor of anthropology in the University of Oxford, for the degree of Doctor in Science *honoris causa*:—

Adest vir et propter aetatis dignitatem et propter studia in rerum originibus primis exquirendis praeclare posita inter primos merito numerandus, quem iamdudum admirati, nunc demum honore diu debito decoramus. Abhinc annos quinque et quadraginta consuetudines Mexicanas antiquas diligenter exploravit. Deinde de prisco hominum cultu, opere in maximo et doctrinae variae plenissimo, plus quam semel disputavit. Illo vero in opere, animarum praesertim in regno perlustrando aliorum antecursor constitutus, successoribus omnibus facem splendidam praetulit. Denique de anthropologia universa egregie disseruit, hominum ipsorum studium hominibus imprimis proprium esse iure optimo arbitratus. Nemo fortasse magis merito liberalitatem illam Terentianam prae se ferre potest:—

"homo sum, humani nil a me alienum puto."

The proposals forwarded by the Studies Syndicate have been rejected by the Senate by, roughly speaking, three to two. The poll taken was the largest on record, and on the Grace affecting Greek the "non-placets" were 1559 and the "placets" 1052. The result is extremely disappointing to all those who wish to see Cambridge take its rank as a leading university in the Empire. There is, however, a strong consensus of opinion that the matter should not be allowed to rest where it is. Perhaps a consultation between the two opposing bodies might lead to some plan acceptable to the more moderate members of both parties.

The Vice-Chancellor announces that he has appointed Colonel Sir Frank Younghusband, K.C.I.E., to the office of reader on Sir Thomas Rede's foundation for the present year.

Mr. E. H. Hankin, Fellow of St. John's College, and analyst and bacteriologist to the North-West Provinces and Oudh, has been approved by the general board of studies for the degree of Doctor in Science.

MR. H. O. ARNOLD-FORSTER, M.P., Secretary of State for War, has consented to give away the prizes to the students at the Woolwich Polytechnic on April 1.

THE Huxley lecture of the University of Birmingham will be delivered by Prof. E. B. Poulton, F.R.S., in the large lecture theatre of the Midland Institute, on Thursday, March 23.

IN the *Engineering and Mining Journal*, Mr. G. S. Raymer gives an illustrated description of the Simpkins laboratory at Harvard. It is designed for the study of continuous ore-dressing operations on a considerable scale, the plant consisting of a 5-stamp battery and additional apparatus of the most recent type.

THE formal opening of the new building of the École polytechnique of Montreal, in affiliation with Laval University, took place on January 28. This school was founded in 1874 to give French-Canadian youths an opportunity of obtaining a training in practical science. Its sphere has been limited, but with the new building and improved equipment better results are anticipated.

MR. CHARLES H. HACKLEY, of Muskegon, Mich., has made, we learn from *Science*, a bequest of 50,000*l.* to the Hackley Manual Training School of Muskegon, which, added to 72,000*l.* already given by Mr. Hackley, makes the school's total endowment 122,000*l.* Mount Holyoke College will receive, we learn from the same source, 34,400*l.* as the residuary legatee of the late Mr. Edmund K. Turner.

IN an article entitled "The Lesson of Coopers Hill," the *Indian Daily Telegraph* of February 1 institutes a comparison between the methods of government in the cases of Coopers Hill and the City and Guilds of London technical colleges. The success of the latter is traced to adaptation in them of the methods followed in the great German polytechnics which is shown by their senates or college boards responsible for their educational systems. The article proceeds to direct attention to the Thomason Civil Engineering College at Rurki in connection with a proposal at a recent meeting of the Allahabad University to abolish the faculty of engineering, and favours the introduction in the college at Rurki of the method of government which has assured the success of the colleges of the City and Guilds.

THE Berlin correspondent of the *Times* states that in the course of a debate on the estimates for the Ministry of Education in the Prussian Chamber on March 2, an official of that Ministry, Geheimrath Reinhardt, gave some interesting information with regard to the success of the so-called "reform schools," in which the study of the classics is begun at the age of twelve, and Greek not until the age of fourteen. One great advantage of this system is that the decision to assign a pupil to the modern (Realschule) or to the classical school (Gymnasium) can be postponed to a stage when his abilities and tastes can be better estimated. Geheimrath Reinhardt stated that the system of this "reform school" had hitherto been adopted at three classical Gymnasia, and the result was that of 123 pupils in the highest form who presented themselves for the leaving examination only four failed to pass, and of these four three succeeded six months later. Experience had shown that as a result of beginning Latin and Greek at a later age than was customary, the interest of the pupils in their work was rendered keener, and their diligence was certainly in no wise inferior to that of the pupils of the ordinary Gymnasia.

THE fourth annual report of the executive committee of the Carnegie Trust states that sums amounting to 38,114*l.* have been claimed and handed over to the four Scottish universities during the year. The grants for library purposes and for provisional assistance in teaching, amounting in all to 6400*l.*, have been fully paid. The grants for buildings and permanent equipment available for 1904, including a balance of 12,635*l.* unexpended in 1903, amount to 33,035*l.* Of these, the sum of 20,146*l.* has been claimed. Claims for grants towards teaching endowments amount for the year to 11,568*l.* These include contributions to the foundation of two chairs—that of history in the University of Aberdeen, and that of geology in the University of Glasgow. The scheme of endowment of post-graduate study and research has now entered upon its second year. The total expenditure for 1903–4 under the scheme was 3386*l.* The estimated outlay for the current academic year is 5177*l.* Applications for fellowships, scholarships, and grants for 1905–6 must be lodged on or before May 1 with the secretary to the trust, from whom application forms and regulations can be obtained. In the research laboratory of the Royal College of Physicians, the purchase of which was announced in the previous annual report, the superintendent reports that the past year has been one of steady and satisfactory work in all departments. Thirty-five workers have held places in the laboratory, and have been engaged in forty-seven investigations.

THE twenty-seventh annual general meeting of the Institute of Chemistry was held on March 1. In the course of an address Mr. David Howard, the president, referred to the steady growth of the institute, saying that he thought there was still a wide field for those possessing the highest chemical knowledge and skill, and that those who had to call in the aid of such knowledge and skill were becoming more and more alive to the importance of employing only the properly trained and competent. He emphasised the importance of requiring all candidates to produce evidence of a high standard of general education. The professional chemist should be a professional man as well as a chemist, and must, therefore, possess that general culture which is essential if he is to deal with his work in a professional spirit. Referring to the position of the institute in connection with the Sale of Food and Drugs Acts, he mentioned that 94 per cent. of the public analytical appointments were held by fellows of the institute. The president alluded to the action of the Board of Agriculture in encouraging provincial technical and agricultural colleges to undertake professional chemical work gratuitously, or at purely nominal fees. In the endeavour to help dairy farmers, the board has induced the colleges, which are maintained by grants for technical education, for the benefit of a particular class, to compete with professional chemists, particularly those maintained by the agricultural associations, at the expense of the general public. The president held that the colleges need the grants for the promotion of the education of farmers in the science and practice of agriculture, without diverting them to other purposes. It is for them to instruct the farmers in agricultural chemistry.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, February 2.—"The Theory of Photographic Processes: on the Chemical Dynamics of Development." By S. E. **Sheppard** and C. E. K. **Mees**.

If a photographic plate be exposed to light and developed, the transparency to light of the silver deposited is related to the mass thereof by the equation $D = -\log_{10} T$, where D (termed the density) is proportional to the mass of silver per unit area. This relation has been confirmed with great care for densities varying from 0.5 to 3.5, and for the plates and developer used a density of 1.00 corresponded to 0.01031 gram of silver per 100 sq. cm. This quantity is termed P, the "photometric constant" of the deposit.

A study of the relation of the density to the time of development resulted as follows:—

(*a*) The silver deposited increases rapidly at first, then more slowly, and finally tends to a limit.

(*b*) This limit depends only on the exposure.

(*c*) The velocity depends on the concentration of the reducer.

(*d*) A soluble bromide reduces the velocity, but the "slowing off" with time is not so rapid.

A theoretical investigation of development based on the theory of reaction-velocities in heterogeneous systems led under certain conditions to the equation $dD/dt = \kappa(D_\infty - D)$, w D_∞ is the limiting density, D that at the time t. On integration this leads to the expression

$$1/t \log D_\infty / D_\infty - D = \kappa ;$$

$(D_\infty - D)$ is then the reacting surface.

κ was experimentally shown to be constant.

Further, as κ is theoretically $\Delta/\delta\ a$, where Δ is a diffusion-constant, δ the diffusion path, and a the concentration of the reducer, the velocity should be proportional to this, which was experimentally found.

The addition of alkaline bromides gradually alters the course of the reaction, introducing an induction period, but for the "maximum" velocity $\kappa \times \log Br =$ a constant.

The value of κ depends greatly on the physical condition of the plate, diminishing with keeping, probably from lowered diffusivity.

An important deduction from the development formula is that the ratio of the densities due to two exposures is constant and independent of the time of development, which was confirmed.

For a series of increasing exposures for a certain range Hurter and Driffield showed that $D = \gamma(\log E/i)$, where γ is development-constant.

Hence as γ is proportional to D, and as

$$1/t \log D_\infty / D_\infty - D = \kappa,$$

therefore $1/t \log \gamma_\infty / \gamma_\infty - \gamma = \kappa$, an expression which may be used to compare the velocities of different developers. For ferrous oxalate, citrate and fluoride the following table was obtained:—

Developer	Relative efficiency
Ferrous citrate	1.00
Ferrous fluoride	2.95
Ferrous oxalate	48.7

Further communications are to be made on the influence of temperature, of soluble bromides, on the reversibility of the reaction, on the microscopy of, and on the exposure and development, nature and destruction of the "latent image."

The object of the investigation is to make the study of development quantitative and to bring it in line with general physicochemical theory.

Chemical Society, February 15.—Prof. W. A. Tilden, F.R.S., president, in the chair.—Nitrogen halogen derivatives of the aliphatic diamines: F. D. **Chattaway**. The compounds ethylenetetrachlorodiamine, ethylenetetrabromodiamine, and other similar bodies derived from diamines or their diacyl derivatives were described.—The nitration of substituted azophenols: J. T. **Hewitt** and V. H. **Mitchell**. The authors have systematically studied the action of dilute nitric acid and of a mixture of concentrated nitric and sulphuric acids on the three nitrobenzeneazophenols.—The estimation of saccharin: C. **Proctor**. The process described by E. Emmet Reid for the estimation of saccharin has been tested and found to be convenient and trustworthy. The paper also described a simple volumetric process by means of which the combined percentage of *o*-benzoicsulphinide and *p*-sulphamidobenzoic acid in commercial saccharin can be determined.—The analysis of samples of milk referred to the Government Laboratory in connection with the Sale of Food and Drugs Acts: T. E. **Thorpe**. This paper contained the results of an inquiry into the changes which occur in the "souring" of milk, and especially as to the effects of these on the usual analytical constants of milk.—The condensation of anilinodiacetic esters in presence of sodium ethoxide: A. T. **de Mouilpied**.—The basic properties of oxygen at low temperatures; additive compounds of the halogens with organic substances containing oxygen: D. **McIntosh**. A continuation of previous work on the combination of organic compounds containing oxygen with the halogen hydrides to form definite compounds.—Organic derivatives of silicon: F. S. **Kipping**. The preparation and reactions of a number of these compounds were described. For the purpose of systematic nomenclature these compounds are regarded as derivatives of *silicane*, SiH_4, or of *silicol*, $SiH_3.OH$.—Photographic radiation of some mercury compounds: R. de J. F. **Struthers** and J. E. **Marsh**. The mercury compound $HgC_2N_2,2(NH_2.NH.C_6H_5)$ was found to act on a photographic plate through paper and aluminium foil, and slightly through sheet zinc. Phenylhydrazine and a number of mercury salts were also found to exert a similar action.

Royal Microscopical Society, February 15.—Dr. Dukinfield H. Scott, F.R.S., president, in the chair.—The Finlayson "comparascope": Mr. **Finlayson**. The arrangement exhibited provides a means of examining two slides simultaneously.—An optical bench for microscope illumination, microphotography, micro-projection, lantern projection, &c., and a large photomicrographic and enlarging camera, both bench and camera being on rigid iron tables provided with castors and fixing pedestals: C. **Beck**.—Practical micrometallography: J. E. **Stead**, F.R.S. Mr. Stead described the machinery by means of which metals may be cut and polished rapidly, and explained the various operations of cutting, grinding, and polishing. Many specimens shown by means of the epidiascope exhibited clearly the details of the surface, and especially the coloration. The beautiful colours produced by the heating process, by which some portions became oxidized more quickly than others, were very striking, especially in the case of a specimen of a polished section of a meteorite, which almost equalled in brilliancy and colour that well-known microscopic object the wing of *Morpho menelaus*.

Physical Society, February 24.—Prof. J. H. Poynting, F.R.S., president, in the chair.—On the curvature method of teaching geometrical optics: Dr. C. V. **Drysdale**. The paper has been undertaken with the two-fold object of giving a systematic exposition of the method of teaching elementary optics which the author has found most suitable, and of giving an introduction to a subsequent paper on the treatment of aberrations by curvature methods.—Dr. Meisling's colour-patch apparatus: R. J. **Sowter**. The apparatus is simple in its principle and construction, and is specially adapted for testing colour-blindness.—A method of illustrating the laws of the simple pendulum: J. **Schofield**. A pendulum is fitted at its lower end with a narrow horizontal framework carrying vertical transverse wires. During the oscillations of the pendulum these wires are caused to cut a jet of mercury, and time signals are sent to the recording mechanism of a chronograph. The distances between the wires are known, and together with the time-measures they yield a displacement-time curve of the motion. From this the kinematical curves and equations of the moving system may be deduced by the usual methods. In the actual apparatus a tuning-fork arrangement with an accuracy of about 1/200 of a second is used as the chronograph, and the results obtained from the pendulum are accurate to about three per cent. The principle has also been applied to torsion pendulums.—String models of optical systems: J. **Schofield**. In these models the lenses and prisms are made of celluloid, so that the paths of rays through them can be shown.

PARIS.

Academy of Sciences, February 27.—M. Troost in the chair.—The precautions necessary in the mode of execution of certain researches requiring high precision: M. **Lœwy**. A lengthened study as to the cause of some systematic errors in the circle of a meridian instrument, wrongly attributed to flexure of the circles, showed that these effects were due to bad definition of the images of the lines, and could be remedied by increasing the definition of the reading microscopes and improving the lighting. In the determination of the constant of aberration, and of refraction, by means of a double mirror cut out of one block of glass, a deformation of the image was observed which rendered accurate readings difficult. The form to be given to the two reflecting surfaces to get regular stellar images has been worked out.—On the observation of the partial eclipse of the moon of February 19: M. **Puiseux**. The twelve photographs taken are discussed in detail, and in some respects are not in agreement with descriptions given before 1866. Recent observations render improbable any new changes in the moon's crust.—On an application of the iris diaphragm in astronomy: M. **Salet**. An iris diaphragm, introduced into the plane of the micrometer wires of an eyepiece, has the effect of suppressing diffused light, and thus facilitating observations on faint objects.—Families of Lamy with plane orthogonal trajectories: G. **Carrus**.—On algebraic surfaces: Federigo **Enriques**.—On functions with an infinity of variables: Maurice **Fréchet**.—On some theorems of Riemann: P. **Fatou**.—The theory of the limiting trajectory of an aëroplane: Marcel **Brillouin**.—On the intensity of photographic impressions produced by feeble illuminations: C. **Gutton**. It is shown experimentally that in a photographic negative the contrasts are exaggerated in the faintly illuminated regions and attenuated in the more strongly lighted parts. On a positive, on the contrary, the differences of lighting are faithfully reproduced.—On the kathode rays emitted by the anode: E. **Rogovsky**.—The surface tension of a dielectric in the electric field: Ch. **Fortin**. In an electric field of 20,000 volts per centimetre, normal to the surface, the relative variation of the surface tension of the petroleum, if it exists, is less than 1/450th. If the variation of the surface tension with the strength of the field be regarded as negligible, the arrangement of apparatus described serves as a new method of measuring the specific inductive capacity of the liquid.—On the spectra of the fluorides of the alkaline earths in the electric arc: Ch. **Fabry**.—On the ionisation due to the radium emanation: William **Duane**.—On the purification of gadolina and on the atomic weight of gadolinium: G. **Urbain**. The method of purification adopted was the fractional crystallisation of the double nitrate of gadolinium and nickel from nitric acid of density 1.3. The purity of the product was established by the constancy of the ratio between the crystallised sulphate and the oxide, and the mean atomic weight is given as 157.23 (O = 16). The spark spectrum of this product is being specially studied by Sir William Crookes, and the arc spectrum by Dr. Eberhard, who will publish their results shortly.—On some osmionitrites and on a nitrite of osmium: L. **Wintrebert**.—A special constituent obtained in the tempering of an aluminium bronze: Pierre **Breuil**.—On β-decahydronaphthol and the octahydride of naphthalene: Henri **Leroux**. β-naphthol, reduced by means of the Sabatier and Senderens reaction, gives rise to several substances, from which the decahydride was separated in the pure state. That it is an alcohol was clearly shown by the preparation of the acetate and the phenylurethane, and also by its dehydration to naphthalene octahydride by potassium bisulphate.—On the glycol of anethol: E. **Varenne** and L. **Godefroy**.—The characters of the polygastric muscles: J. **Chaine**.—On the salivary, cephalic and metathoracic glands of some Hemiptera: L. **Bordas**.—The phagocytic resorption of the reproductive elements in the seminal vesicles of *Lumbricus herculeus*: Louis **Brasil**.—On the practical importance of the determination of the arterial pressure to avoid accidents in anæsthesia: L. **Hallion**. Remarks on a recent note of M. Tissot, and directing attention to a paper published by the author and M. Duplay in 1900 on the same subject.—The influence of the radium emanation on the toxic power of snake poison: C. **Phisalix**. Cobra poison, which is distinguished by resistance to destruction by heat, is readily destroyed by the radium radiations. On the other hand, the poisons from the salamander and toad are unaffected by the emanation.—The application of the vowel siren to the study of deafness: M. **Marage**. Each kind of deafness gives a special curve with this instrument, the form of which is characteristic of the seat of the lesion.—The glandular atrophic action of the X-rays: Foveau de **Courmelles**. The ovaries, the breasts, and the lymphatic ganglions can be atrophied under the action of the X-rays.—On the application of thermometry to water supply: E. A. **Martel**.—The coal formation in the Balkans: L. **De Launay**. On the uniformity of composition of the Amana meteorites: G. D. **Hinrichs**.

DIARY OF SOCIETIES.

THURSDAY, MARCH 9.

ROYAL SOCIETY, at 4.30.—The Rate of Transmission of the Guatemala Earthquake of April 19, 1902: R. D. Oldham.—Ionic Sizes in Relation to the Conductivity of Electrolytes: W. R. Bousfield.—Explosions of Mixtures of Coal Gas and Air in a Closed Vessel: L. Bairstow and A. D. Alexander.—On some Continuous Observations on the Rate of Dissipation of Electric Charges in the Open Air: C. Coleridge Farr.

ROYAL INSTITUTION, at 5.—Recent Astronomical Progress: Prof. H. H. Turner, F.R.S.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Report on Experiments carried out at the National Physical Laboratory: On the Effect of Heat on the Electrical and Mechanical Properties of Dielectrics, and on the Temperature Distribution in the Interior of Field Coils: Dr. R. T. Glazebrook, F.R.S.—On Temperature Curves and the Rating of Electrical Machinery: R. Goldschmidt.

MATHEMATICAL SOCIETY, at 5.30.—On the Weddle Quartic Surface: Mr. H. Bateman.—On the Projective Relations between Two Planes: Prof. M. J. M. Hill, Dr. L. N. G. Filon and Mr. H. W. Chapman.—On the Theory of Perpetuants: Mr. P. W. Wood.

FRIDAY, MARCH 10.

ROYAL INSTITUTION, at 9.—The Structure of the Atom: Prof. J. J. Thomson, F.R.S.

ROYAL ASTRONOMICAL SOCIETY, at 5.—Theory of the Motion of the Moon. Part IV.: Prof. E. W. Brown.—The Great Nebula of ψ Eridani: Dr. Max Wolf.—Observations of Uranus and Saturn: C. J. Merfield.—Observations of Uranus at Windsor, New South Wales: John Tebbutt.—The Spectroheliograph of the Solar Physics Observatory: W. J. S. Lockyer.—Nebular Photography; a Suggestion: W. S. Franks.—The Late Leonids of November, 1904: Rev. S. J. Johnson.—Magnetic Disturbances and their Association with Sun-spots; a Reply: E. W. Maunder.—*Promised Papers:* On the Large Sun-spot of 1905, January 29–February 11, and the Contemporaneous Magnetic Disturbances, observed at the Royal Observatory, Greenwich (communicated by the Astronomer-Royal).—Notes on the Siderostat and Cœlostat: H. C. Plummer.

MALACOLOGICAL SOCIETY, at 8.—On a Dibranchiate Cephalopod from the Eocene of Arabia: G. C. Crick.—Note on the Horizon and Locality of the Type Specimen of *Pleuronautilus pulcher*: G. C. Crick.—New Marine Mollusca from the Collection of the late Admiral Keppel: G. B. Sowerby.—On the Occurrence of Internal Septa in *Glyptostoma newberryanum*: G. K. Gude.—Note on a Dart found in the Body Cavity of *Helix aspersa*: R. G. Barnes.

INSTITUTION OF CIVIL ENGINEERS, at 8.—The Purification of Sewage: F. G. Helsby.—The Purification of Sewage by Hydrolysis and Oxidation: F. O. Kirby.

PHYSICAL SOCIETY, at 8.—On the Stresses in the Earth's Crust before and after the Sinking of a Bore-hole: Dr. C. Chree, F.R.S.—On the Lateral Vibration of Bars of Uniform and Varying Sectional Area: J. Morrow.—On Direct Reading Resistance-Thermometers, with an Appendix on Composite Thermocouples: A. Campbell.

SATURDAY, MARCH 11.

ROYAL INSTITUTION, at 3.—Electrical Properties of Radio-active Substances: Prof. J. J. Thomson, F.R.S.

MONDAY, MARCH 13.

SOCIETY OF ARTS, at 8.—Telephony: H. L. Webb.

ROYAL GEOGRAPHICAL SOCIETY, at 8.30.—The Anglo-German Boundary Expedition in Nigeria: Colonel Louis Jackson, R.E.

TUESDAY, MARCH 14.

ROYAL INSTITUTION, at 5.—Some Recent Biometric Studies: Prof. K. Pearson, F.R.S.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Shipbuilding for the Navy: Lord Brassey, K.C.B.

AËRONAUTICAL SOCIETY, at 8. Some Recent Experiments in Aërodynamics: P. Y. Alexander.—The Shape of Navigable Balloons: Eric Stuart Bruce.—Automatic Stability: E. C. Hawkins.—Note on an Aluminium Kite: Alan H. Burgoyne.

ANTHROPOLOGICAL INSTITUTE, at 8.15.—Manners and Customs of the Melanesians: Lantern Illustrations: Rev. W. H. Edgell.

WEDNESDAY, MARCH 15.

CHEMICAL SOCIETY, at 5.30.—The Velocity of Oxime Formation in Certain Ketones: A. W. Stewart.—Catechin and Acacatechin; Supplementary Note: A. G. Perkin.—The Action of Ethyl Dibromopropanetetracarboxylate on the Disodium Compound of Ethyl Propanetetracarboxylate; a Correction: W. H. Perkin, jun.—On Glutaconic Acid and the Conversion of Glutaric Acid into Trimethylenedicarboxylic Acid: G. Tattersall.—The Ultra-violet Absorption Spectra of Certain Enol-keto Tautomerides: E. C. C. Baly and C. H. Desch.—Esterification Constants of Substituted Acrylic Acids: J. J. Sudborough and D. J. Roberts.—α-Chlorocinnamic Acids: J. J. Sudborough and T. C. James.—Di-orthosubstituted Benzoic Acids. Part VI. Conversion of Methyl into Ethyl Esters: J. J. Sudborough and T. H. Davies.—Simple Method for the Estimation of Acetyl Groups: J. J. Sudborough and W. Thomas.—Gynocardin, a New Cyanogenetic Glucoside: F. B. Power and F. H. Lees.

ENTOMOLOGICAL SOCIETY, at 8.

ROYAL MICROSCOPICAL SOCIETY, at 8.—A Review of Work done by Metallographers: J. E. Stead, F.R.S.

ROYAL METEOROLOGICAL SOCIETY, at 7.30.—On the Growth of Instrumental Meteorology: R. Bentley.

MINERALOGICAL SOCIETY, at 8.—On Some New Mineral Localities in Cornwall and Devon: A. E. I. M. Russell.—On a Crystal of Phenakite from East Africa: L. J. Spencer.—(1) Notes on Various Minerals from the Binnenthal, Switzerland.—(2) A New Oxychloride of Copper from Sierra Gorda, Chili: G. T. Prior and G. F. Herbert Smith.

THURSDAY, MARCH 16.

ROYAL SOCIETY, at 4.30.—*Probable Papers:* A Preliminary Note upon the Question of the Nutrition of the Early Embryo: E. Emrys-Roberts.—On Reciprocal Innervation of Antagonistic Muscles. Seventh Note: Prof. C. S. Sherrington, F.R.S.—On the Absence or Marked Diminution of Free Hydrochloric Acid in the Gastric Contents, in Malignant Disease of Organs other than the Stomach: Prof. B. Moore, with W. Alexander, R. E. Kelly, and H. E. Roaf.—On the Heterogenetic Origin of certain Ciliated Infusoria from the Eggs of a Rotifer: Dr. H. C. Bastian, F.R.S.

ROYAL INSTITUTION, at 5.—Recent Astronomical Progress: Prof. H. H. Turner, F.R.S.

SOCIETY OF ARTS, at 4.30.—Manipur and its Tribes: T. C. Hodson.

LINNEAN SOCIETY, at 8.—Contributions to the Flora of Liberia: Dr. Otto Stapf.—*Exhibitions:* Penguins and other Birds from the Falkland Islands, and Scratched Rocks from a Rockhopper's Rookery: R. Vallentin.

CONTENTS.

THURSDAY, MARCH 16, 1905.

MODERN OPTICAL THEORY.

An Introduction to the Theory of Optics. By Prof. A. Schuster, F.R.S. Pp. xv+340. (London: Edward Arnold, 1904.) Price 15*s.* net.

PROF. SCHUSTER has done excellent service to teachers and students alike by publishing this book, which fills a very obvious gap. It is an introduction to the theory, and purposely does not deal with details of methods of measurement or instrumental appliances; these are properly left to courses of laboratory instruction. At the same time the necessity for experiments and observations is everywhere present to the author's mind. The book is not a mere mathematical treatise on simple harmonic motion; indeed, the analysis is generally easy, and purely mathematical difficulties are avoided. Prof. Schuster writes as a physicist. The physical meaning of the steps and processes employed is everywhere insisted on, and the student is made to think throughout.

The standpoint of the author is best explained by two short extracts from his preface. After stating that the elastic solid theory of optics as developed in England by Green and Stokes has proved insufficient, he continues,

"Those who believe in the possibility of a mechanical conception of the universe, and are not willing to abandon the methods which from the time of Galileo and Needham have led uniformly and exclusively to success, must look with the gravest concern on a growing school of scientific thought which rests content with equations correctly representing numerical relationships between different phenomena, even though no precise meaning can be attached to the symbols used."

And again,

"The equations which at present represent the electromagnetic theory of light have rendered excellent service, and we must look upon them as a framework into which a more complete theory must necessarily fit, but they cannot be accepted as constituting in themselves a final theory of light.

"The study of physics must be based on a knowledge of mechanics, and the problem of light will only be solved when we have discovered the mechanical properties of the ether. While we are in ignorance on fundamental matters concerning the origin of electric and magnetic strains and stresses, it is necessary to introduce the theoretical study of light by a careful treatment of wave propagation through media the elastic properties of which are known. A study of the theory of sound and of the old elastic solid theory of light must precede therefore the introduction of the electromagnetic equations."

The book proceeds on these lines; the first part is almost entirely kinematical; the second part deals with theories of light, starting first from an analysis of the equations of motion of an elastic medium; then passing to those of the electromagnetic field, and developing the two theories side by side as far as possible.

To turn now to some details. In the earlier chapters, in accordance with the views expressed in the preface, the author deals with the properties of vibrating mechanical systems, *e.g.*, the air in a closed space, or a stretched string. After some discussion as to periodic motion in general, the equation of motion for an elastic body, propagating plane waves of distortion, is found in an elementary manner, and certain fundamental results are shown to follow from its similarity to the equation for a stretched string. Huyghens' principle of the superposition of small motions is explained, and then the reader, after a chapter on the nature of light, is introduced to the principle of interference.

The problems of diffraction are treated very fully, making use of the method of Fresnel's zones; the method is modified by the author in a manner which permits numerical results of a high order of accuracy to be obtained without the introduction of Fresnel's integrals.

After an interesting chapter on diffraction gratings we come to one on the theory of optical instruments, in which the resolving power of telescopes and spectroscopes is carefully discussed. The theory of the microscope does not find a place in Prof. Schuster's book; perhaps it belongs rather to the domain of geometrical optics.

Fresnel's theory of double refraction is given very fully, and it is based not on any unsound dynamical reasoning, but on the observed experimental fact that the velocities of wave propagation of a plane wave moving through a crystal are given by the axes of the section of a certain ellipsoid by the plane of the wave; this is clearly the right way to deal with this problem. When the laws of the propagation of light in a crystal are once determined the discussion of the rays and brushes due to the interference of polarised light follows easily, and thus we are led to Part II., which, as has been already said, deals with theories of light.

The equations of motion are found both on the elastic solid and electromagnetic theory, and the simpler phenomena are considered from both standpoints.

The weak points of the elastic solid theory, however, soon manifest themselves, and for the rest of the book the equations of the electromagnetic theory are mostly used; in dealing with dispersion Sellmeyers' hypothesis of sympathetic vibrations is applied to the electrons of a molecule, following Drude, and the usual expression connecting the refractive index and the frequency obtained; the same method is applied to explain the rotatory effects of sugar and other active substances, and in a most interesting series of sections the Zeeman and other allied effects are dealt with. In the last chapter we have a discussion on the nature of light as the resultant disturbance arising from the individual vibrations of the molecules of the source. Enough has probably been said to show the nature of the book, but one characteristic should not be omitted. Prof. Schuster has included short historical accounts of the men who have made the science of physical optics. Among them we find the names of Young, Fresnel, Cauchy, Stokes, and Maxwell; the interest of the book is increased by this course, and the subject made more human.

In conclusion, it is perhaps sufficient to say that the treatment is marked throughout by the author's well-known and admirable lucidity of style. Take, for example, the last paragraph in the book discussing the result which follows from the fact that as an extreme case for the green thallium light the periods of 88 per cent. of the vibrating molecules are identical within about one part in two millions.

"If you had a great many clocks, and found that taking their average rate to be correct, not more than one in eight would be wrong by a second in twenty-three days, that would represent the maximum amount of variation which one interpretation of the experiment allows us to admit in the case of molecular vibrations. But would any maker undertake to supply you with a number of clocks satisfying that test? If, further, it is considered that the limits we have chosen for the possible variations of molecular vibrations are far too great, we see that though Sir John Herschel's saying that atoms possess the essential character of manufactured articles is still correct, yet no manufactured article approaches in accuracy of execution the exactitude of atomic construction. We may conclude with Maxwell that 'Each molecule therefore throughout the universe bears impressed on it the stamp of a metric system as distinctly as does the metre of the archives at Paris or the double royal cubit of the Temple at Karnac.'"

TECHNICAL ANALYSIS.

Manual of Chemical Analysis. By E. Prost, D.Sc. Translated by J. C. Smith, B.Sc. Pp. iv+300. (London: Maclaren and Sons, 1904.) Price 12*s*. 6*d*. net.

Techno-Chemical Analysis. By Dr. G. Lunge. Translated by A. I. Cohn. Pp. vi+136. (New York: Wiley and Sons; London: Chapman and Hall, Ltd., 1905.) Price 4*s*. 6*d*. net.

DR. PROST'S manual contains a number of selected methods dealing more particularly with mineral and metal analysis which have been compiled, so the preface states, for the use of the "industrial chemist," and which the author assures us are the result of his own experience or that of specialists with whom he is in touch.

The analysis of mineral products—silicates, phosphates, clays, cements, iron and iron ores, and the assaying of lead, silver, gold, &c., have been so fully elaborated that no analyst deserving the name would be satisfied without knowing the latest improvements in the methods connected with his own industry. A chemist in an iron works, for example, wants all the information he can obtain from the specialist who has made a minute study of iron and steel analysis, including the character of etched surfaces, and through whose hands a large variety of specimens have passed The same, of course, applies to raw materials and finished products of other manufactures. The works analyst is not a student, and though he may wish to be informed on analysis in general, it is not essential to his business.

Does Dr. Prost's book as a whole fulfil its promise? Whilst there is no doubt that many of the methods answer to the description given in the preface, and will be found serviceable to the works analyst, it must be confessed there are also many others which fall short of it. In too many instances there is a lack of descriptive detail, an absence of reference to recent improvements, and the omission of recognised and standard methods. The common fault of this class of book is to be too discursive; to cover too much ground. The small treatise on one subject by an expert like Blair or Ledebur on iron and steel analysis, Brown on gold and silver assaying, Lunge on the alkali manufacture, is the sort of thing one would like to see multiplied.

The writer has no wish to deal unfairly with the manual under review. It is not uniform in character, and if the above criticism applies to certain sections, it is also abundantly evident that other portions have been carefully and conscientiously put together by one who possesses a thorough knowledge of his subject. Moreover, the introduction of mechanical tests, which are too frequently overlooked, is a feature deserving mention. The translator's attention should be directed to the mis-spelling of Stanfurt for Stassfurth, p. 41, Vollard for Volhard, p. 106, and Spiegal for Spiegel, p. 206. The illustrations suffer very much from the rough surface of the paper.

The name of Dr. G. Lunge on the title page of any book, and especially one connected with technical analysis, would command a careful perusal and a thoughtful judgment. It must be confessed that in the present case the author has not done himself justice. Anyone who purchased the volume in the hope of obtaining practical information on techno-chemical analysis (the translator's rendering of chemisch-technische Untersuchungsmethoden) would, to say the least, be disappointed.

When it is stated that in 128 small octavo pages, in addition to "general operations," and gas, water, and fuel analysis, the analysis of about eighty technical inorganic and organic products is described, further comment seems superfluous. The subject of glycerine, which comes under the section of *soap*, may be taken as a specimen of the method of analytical treatment.

"Glycerine is found in large quantity only in toilet soaps. The method of determining it is given here, because it must be examined by itself as an individual commercial article, and the glycerine yield of raw fats in the manufacture of stearin must also be determined. The determination is effected either by oxidation with potassium-permanganate solution in alkaline solution, precipitating the oxalic acid formed as a lime salt, and titrating the latter, or by oxidation with normal potassium-dichromate solution, with the addition of an excess of ferrous sulphate solution of known effective value, and then titrating the dichromate solution."

This occupies half a page, sugar is elaborately treated in four pages, tanning in two and a half, dyeing in as many as seven, mineral oils, vegetable oils, and fats in seven, and so on. The most useful page in the volume is the bibliography of important works of reference at the beginning, though it is scarcely worth the price of the book. J. B. C.

THE ZOOLOGICAL RECORD.

The Zoological Record, Volume the Fortieth; Relating Chiefly to the Year 1903. Edited by D. Sharp. (London: The Zoological Society, 1904.) Price 30s.

YEAR by year this invaluable publication appears with commendable regularity, and year by year its bulk steadily increases, the bulk of the present issue being nearly double that of its predecessor of forty years ago. Hitherto the subscribers have yearly obtained more for their money, but there are limits beyond which even the generosity of a great scientific society cannot go, and it has consequently been decided, although with reluctance, that in future the price of the annual volume must be increased. The bulk of the present volume has been somewhat diminished by printing it on thinner paper than its predecessors; and, although this innovation may have been unavoidable in order to bring the weight within the limits laid down by the Post Office for transmission abroad, it cannot be said to be altogether an improvement, as in places the type shows through in a decidedly obtrusive manner.

Whether such a radical alteration was really inevitable may perhaps be doubtful, for it is quite evident that a large amount of space might be saved if a uniform plan were adopted throughout the work. For instance, in the section on mammals 385 titles are recorded and their subjects epitomised in a space of forty-two pages, whereas in the section on echinoderms no less than 105 pages are taken up in dealing with 339 papers.

If such prolixity is necessary in the one case, it is equally essential in the other; and, conversely, if the brief mode of treatment will suffice in one instance, it should be adopted in the other. Much space might also be gained, without any loss, in the sections on reptiles and fishes, as well as in certain others.

This lack of uniformity in treatment is, in our opinion, the one point in which this "Record" compares unfavourably with the one issued by the committee of the "International Scientific Record"; and it is high time that it was amended. Surely the editor is strong enough to keep his contributors in hand, and to make them do the work his way and not their own. As an instance of this slackness of the guiding hand we may refer to the fact that in one of the sections the recorder has been allowed to adopt the spelling Meiocene and Pleiocene, which is both wrong (on the supposition that we form our scientific names through the Latin) and pedantic. If any alteration in orthography of this nature were permitted, it should be the substitution of Plistocene for Pleistocene; but if such a change were made it should run through the entire volume.

The comparatively early date at which many of the sections are now sent to press renders it impossible to include so many of the papers for the year to which they specially refer as was formerly the case, but this is a matter of no great moment, so long as such papers make their appearance in the volume for the following year.

Mistakes and omissions there must of course be; but these seem to be few and far between. We notice, however, in the mammal part that Condylarthra has been put in place of Amblypoda, while in the concluding paragraph of the first page of his introduction to the insects the editor is guilty of a blunder which should cause him to be lenient to the shortcomings of his contributors. Whether he can escape blame for errors like the omission of a reference number in the penultimate line of p. 21 of the mammal part may, however, be open to question.

Taken all in all, the volume is a marvellous production, both as regards accuracy, fulness, and the comparatively early date of its appearance; and the editor and his staff are entitled to the best thanks of the zoological world. When we have said that the "Zoological Record" still stands without a rival, we have said sufficient.

R. L.

OUR BOOK SHELF.

A Synonymic Catalogue of Orthoptera. By W. F. Kirby. Vol. i. Orthoptera Euplexoptera, Cursoria, et Gressoria. (Forficulidæ, Hemimeridæ, Blattidæ, Mantidæ, Phasmidæ.) Pp. x + 501. (London: the Trustees of the British Museum, 1904.)

THE value of such a general synonymic catalogue as this work is obvious, but the increased interest which has been taken in Orthoptera in recent years, and the rapidly accumulating mass of literature, has made a complete and systematic catalogue of this order an urgent necessity. The work is upon the same model as the author's previous catalogue of dragon-flies. The species are numbered, though no particular order appears to have been followed; the distribution is given in the margin, and synonymy is attached, although a complete list of references is not given in every case. One of the most prominent features of the list is the conscientious manner in which the author refuses to admit as synonymous such names as to the absolute identity of which he is not personally convinced, resulting in an apparent multiplication of species. Thus, on pp. 30 and 31, we find *Spongiphora parallela*, *S. lherminieri*, *S. dysoni*, and *S. croceipennis* all entered as separate species, though nowadays there are few who doubt their identity, and fewer still who can discriminate between them. Again, on p. 2, *Diplatys gerstaeckeri* and *D. longisetosa* are regarded as separate, although it is impossible to distinguish them. To such an extent does the author carry this principle, that he admits names published with figures only, such as *Pygidicrana huegeli*, Sharp, and even *Ancistrogaster petropolis*, Wood, based upon a reference and an illustration in a popular work. But yet he relegates *Psalis indica*, Hagenb., var. *minor*, Borm., as a synonym of *P. guttata*, Borm., although the describer insisted upon the extreme variability of the older known species. But questions of nomenclature and classification are of necessity controversial; many may disagree with the author's arrangement of the genus Labidura, in which a number of insufficiently described so-called species are regarded as valid, only on account of the difficulty of proving their identity with the excessively variable and universally distributed *Labidura riparia*, Pallas.

Otherwise, changes of well-known names are few. We are glad to see *Blatta* retained, at the expense of *Stylopyga* for *orientalis* and not for *germanica*.

Hololampra, Saussure, 1864, replaces the more familiar Aphlebia, Brunner, 1865.

But this catalogue should be received less with criticism than with gratitude to the painstaking author, and we hope the second volume will appear at an early date; it will doubtless include such omissions as have been unavoidable in the first volume, owing to the time necessary for publication.

M. B.

Percentage Tables for Elementary Analysis. By Leo F. Guttmann, Ph.D. Pp. 43. (London: Whittaker and Co., 1904.) Price 3*s.* net.

THIS book is only intended to facilitate the calculation of the results of an ordinary organic analysis, and its title, therefore, is somewhat misleading. It is stated that "the tables have been carefully calculated and checked, they are therefore absolutely accurate." After this statement, nothing is left to us but to see if they are likely to be useful. After careful consideration of this question we are compelled to give an unfavourable reply. If we have the analytical result that 0·1173 gr. of a substance gave 0·2869 gr. carbon dioxide, we can, in the ordinary course of things, by looking out the logarithm of 0·2869, adding the easily remembered logs. of 12/44 and of 100, and subtracting the log. of 0·1173, get the log. of the percentage. But according to the tables before us, we look out a number corresponding to 0·117 and 0.28. We then look again for a number corresponding to 0.118 and 0·28. We subtract the two numbers, multiply by 0.3 by means of another table, and subtract this result from the first number looked out. We next find a number corresponding to 0·117 and 0·69, divide by 100 and add this result, and thus, after four references to tables, two arithmetical operations in the head, one subtraction and one addition on paper, we get our percentage. Appeal to a chemist constantly engaged in organic analysis has only confirmed the view that these tables are unlikely to save time or to promote exactitude in the calculation of organic analyses.

A. S.

How to Photograph with Roll and Cut Films. "The Amateur Photographer" Library, No. 30. By John A. Hodges. Pp. xviii+120. (London: Hazell, Watson, and Viney, Ltd., 1904.) Price 1*s.* net.

THE ever increasing number of photographers and more especially amateurs, who work with either roll or cut films, will find in these pages all the necessary information for the production of pictures. The author does not pretend to have written a treatise on the whole art and science of photography, but he has given a straightforward account of the various operations that have to be completed to ensure good results. The treatment is well suited for amateurs, and the numerous well reproduced illustrations serve admirably to render many points clear.

The Telescope. By Thomas Nolan. (New York: D. Van Nostrand Company, 1904.) Price 50 cents.

THE first edition of this small treatise on the elementary principles of optics as applied to telescopes appeared in 1881. In the present issue the author has left this matter practically as it first appeared, with only one or two minor corrections, but has added a chapter describing in a brief manner the advances that have since been made. At the end is also given a bibliography relating to the telescope, which will be of service to those who wish to study more in detail different branches of the subject to which slight references only have been given. The book is published in the Van Nostrand Science Series, and should prove a useful addition.

LETTERS TO THE EDITOR.

The Infection of Laboratories by Radium.

IN a recent attempt in the physics building of McGill University to make electroscopes with a very small natural leak, repeated failures were encountered. The rate of discharge of several instruments, carefully made, was found to be about sixty to one hundred times as large as that obtained by Mr. H. L. Cooke two years earlier in the same building. At first it was supposed that the insulation of the sulphur bead was defective. But the natural leak was large and unaffected when the upper support of the sulphur bead was raised to a higher potential than the gold leaf system, so that the insulation was not at fault. Nor was the rate of discharge altered when the electroscope was entirely surrounded by lead one inch thick. Removal to another building produced no effect on the leak of the electroscope. It appeared probable that the trouble was due to the radio-activity of the materials from which the electroscope was made. A rude instrument, made in a private house with a tobacco tin, the amber mouthpiece of a pipe, and a cork, was found to give better results than the most carefully constructed instrument in the physics building. Some electroscopes were next made in the chemistry building, using materials which had never been into the physics building. Instruments with a very slow rate of discharge were now easily manufactured. These were used to test materials from various parts of the physics building, and it was found that all were infected with excited activity. Sheets of mica, lead foil, iron, zinc and tin were all active, even when taken from drawers or cupboards.

Of the substances tested, the only one which showed no activity was some thin Dutch metal leaf kept between tissue paper in a closed drawer. About 90 per cent. of the excited activity could be removed from the metal sheets by strong hydrochloric acid, but the activity was transferred to the solution. It was also possible to volatilise a portion of the deposit by raising the metal sheet to a red-heat in a Bunsen flame. Both α and β rays were detected, but it was difficult to measure their exact proportion. The natural leak of an electroscope was increased to a measurable extent when a mica window was replaced by one cut from a sheet of mica kept in the physics building.

The difficulty of conducting radio-active experiments in rooms where strong preparations of radium were present was early observed by Madame Curie, and later by Elster and Geitel, but the present experiments seem to show that the effect may be widely spread. The emanation from radium used in the large physics building has passed by convection and diffusion into various rooms. In a few days each fresh supply of emanation is transformed into the rapidly changing substances radium A, B, and C. The further changes of the products of radium have been investigated by Prof. Rutherford, and described by him in his Bakerian lecture (*Phil. Trans.*, vol. cciv., pp. 169–219), and in a recent letter to NATURE (February 12). In the former he has pointed out that bodies exposed to the air in the open will be covered with an invisible film of radio-active matter of very slow rate of change, and that the strong radio-activity observed in a room in which radium preparations have once been used is probably due to the deposit on the walls of the room of this slowly decaying matter from the emanation. In his letter to NATURE, he has shown that radium C gives rise to radium D, and that the further change to E is rayless in character and attains half value in forty years. The further change to F emits β rays, and reaches half value in six days, whilst the change from F to the final product is accompanied with α rays, reaching half value in 150 days.

The α and β rays emitted by the coating on the materials in the physics building are doubtless due to the changes above mentioned. If the supply of emanation were arrested at the present date, the activity already deposited would rise to a maximum in two or three years, and then gradually decay, following an exponential law, and reaching half value in forty years. But should the supply of emanation in the future equal that in the past, the activity would continue to increase in magnitude for the next hundred years or so, until the supply and decay of radium D attained a steady value. By that time radio-active experiments of a delicate nature would become difficult or impossible, as the excited activity would rapidly discharge a gold-leaf electroscope.

As the excited activity can be largely removed by acid, the infection will at present cause no serious difficulty in the majority of experiments on radio-activity, particularly as the leak arising from it remains almost constant for weeks or months. But when an electroscope with a very small natural leak is required, it will be necessary to employ fresh materials which have not been exposed to emanation.

It appears desirable, in the case of laboratories not yet infected, to keep radium in sealed vessels, and to blow the emanation into the open air, and not into the rooms of the laboratories.

McGill University, Montreal, February 25.

International Atomic Weights.

The committees engaged in revising the tables of atomic weights have now sent in their reports for 1905. The one which appeared in the *Berichte* is, of course, printed in German, and that which has just been circulated by the Chemical Society is in English.

Unfortunately, there is a want of uniformity in the naming of the elements. Thus, in the English table we find Glucinum, Gl, and Columbium, Cb, whereas in the German table these elements are called Berylium, Be, and Niobium, Nb, respectively. Historically, no doubt, the names adopted in the English table are more accurate. But in all text-books the names and symbols employed in the German tables are used, and have been for many years.

It is difficult to see where the advantage in making the change comes in, but, on the other hand, the disadvantages of having two forms of nomenclature are obvious.

The Planet Fortuna.

Perhaps Airy quoted his Juvenal correctly, which "W. E. P." (p. 410) has failed to do. The poet was so well satisfied with the lines that he gives them twice, in his tenth and fourteenth satires. And they run thus:—

> Nullum numen habes, si sit prudentia; nos te
> Nos facimus, Fortuna, deam cæloque locamus.

W. T.

The lines are variously quoted, and I cannot say what version Airy favoured. I believe he spoke from memory.

W. E. P.

COSTA RICA.[1]

Up to 1540, Spain had reserved for the crown that part of the territory of Veragua lying west of the portion which had been granted to the heirs of Columbus; but, in that year, it was erected into a province and called Costa Rica. It lies between Nicaragua and the newly hatched, but featherless, republic of Panamá, and is the smallest State of the New World except Salvador. But it is one of the most interesting, for, with Panamá, it forms the connecting link between North and South America, not only physically but ethnologically. If more were known of its ancient inhabitants, their type, character, modes of life, habits and customs, inter-tribal relations and forms of worship, and of the ruins of ancient towns and burial places which are silently dotted over the country, one might go far towards a solution of many vexed problems as to the relation betwen early Mexican culture and that of the Andean peoples—Chibchas of ancient Cundinamarca, the Quitos and Cañaris of Ecuador, the Quichuas and Aymarás of the Inga empire. Much of the data necessary to the formation of a just conclusion are buried on the slopes of the volcanoes of Turrialba, Irazú, Barba and Poás, and, in that richest of fields for archæological research, the district lying between Lake Nicaragua and the Gulf of Nicoya on the Pacific coast of Costa Rica, while the lowlands lying between Nicaragua and the Atrato River of Colombia probably hide, under their densely matted and almost impenetrable vegetation, whatever evidences may exist of their occupation by man, not only in the far-remote past, but even at the date of the Spanish conquest.

Hence we may welcome a scientific examination of any section of the region outlined above, but especially when the results are so carefully and clearly set forth as they are in the work under review—a large quarto volume richly illustrated. Its publication, as well as the explorations of which it treats, have been made at the expense of Mr. Åke Sjogren, who has presented to the Royal Ethnological Museum of Stockholm the valuable archæological collection with which Mr. Hartman returned home. This gentleman, whose studies had well equipped him for his task, proceeded to Costa Rica in 1897, where he remained more than a year in the territory once occupied by the Guëtare race. He commenced his researches in May (the beginning of the rainy season) near the *hacienda* of Mercedes, which is situated on the Guapiles branch of the Costa Rica Railway, about fifty miles from Port Limon.

"On the Atlantic side, the moisture-laden atmosphere and tropical heat have clothed the mountain chains and the low swamp lands with eternal verdure, with forests which are almost impenetrable, woven together as they are by lianas passing from tree to tree. Neither aboriginal nor Spanish culture ever made great inroads on the primeval forests of the Atlantic coast."

Near Mercedes is a mound about 100 feet in diameter at the base, 65 feet at the top, and 20 feet high. It is in a partially walled enclosure, and probably served as a platform on which to erect statues facing the rising sun. The mound may have been covered with a wooden structure with a thatched roof. Among the many human figures found there, all mutilated, were two of life size, one of which is notable as having ear plugs. The chest and back are crossed by two thick ropes, which pass over the shoulders and reach to the hips. The right wrist supports a human head. The other large statue has its hands resting on the hips. The heads of both figures are covered with conical hats. Rudely sculptured representations of alligators, pumas, and other animals were found, but in fragments. All of these, including the statues, were cut from hard, basaltic lava.

Mr. Hartman also examined the extensive burial places of the ancient inhabitants of this district, and opened a great number of cists. These varied in dimensions, but it is apparent that they were rarely intended for the interment of more than one person. They had side and end walls of cobble stones, but the bottom and top were of slabs of limestone. The horizontal section of the cists was very irregular. Only in one did he find traces of bone, but the "dark soil near the bottom seemed to prove that the body or bodies had been placed there."

Many vessels of burnt clay, sometimes roughly

[1] "Archæological Researches in Costa Rica." By C. V. Hartman. The Royal Ethnological Museum in Stockholm. Pp. 195; map+87 plates. (Stockholm: C. E. Fritzes, 1901.)

decorated, were lying in the cists, but a great part of them, covered with soot, appear to have served as cooking utensils. Several contained charred maize and fragments of corn cobs. In one was found some Millefiori beads, the manufacture of which was an important industry in Venice during the latter part of the fifteenth century, and the author says that, "Later on, I discovered a number of this kind in a grave at Osori in the highlands."

Thus it appears that these Indian towns were still in existence at the time of the Spanish invasion.

Mr. Hartman also opened a *cache*, similar to a cist, but there was no proof that it had ever been used as a grave; in fact, it was too small. It contained sixteen clay vessels, some of them ornamented, and much broken pottery. There were several globular bowls and vases. "The practice of secreting household articles as well as food in pits or in caves has from early days been observed among widely disseminated tribes of North America."

The work-yard of the ancient stone-cutters was happily discovered, and many unfinished idols were lying about.

In June, 1895, I roughly examined the mounds and some of the graves near the *hacienda* of Mercedes, and especially remember the two great statues described by Mr. Hartman. People resident in the vicinity, who know much of the region, said that the whole Santa Clara district, occupying the slopes of Turrialba, Irazú and Barba, and the heavily forested lowlands to the north and east, are dotted with ancient burial grounds.

Fig. 1. Shallow, tripod bowl found in Field II., Chircot Height, 12·8 cm.; Diameter, 22 cm. From "Archæological Researches in Costa Rica."

From the coast lands, Mr. Hartman ascended to the highland plains near Cartago, one and a half miles west of which town is the water divide, 5100 feet elevation, between the Atlantic and Pacific Oceans. Cartago is about 4800 feet above sea-level, and lies upon the southern slope of the volcano of Irazú, the only one of Costa Rica which has ejected compact lavas. In its eruptions of 1841 and 1851 it almost completely destroyed Cartago, which was the former capital of Costa Rica. In its vicinity Mr. Hartman uncovered numerous cists similar to those of Mercedes, but they contained a greater variety of potsherds and ornamental pottery. He made especially rich collections at a spot called Chircot, where he observed that a favourite figure of the ancient artists was a flute-playing god. In the stone-bordered necropolis at this place he found 205 cists, many of them in three layers. In about thirty there were skeletons, or fragments of skeletons, which averaged five feet in length. The skulls were dolichocephalic, but most of the remains were too decayed for removal. Summarising his year's work, he says of the culture of the Guëtares "that it proves to be that of a stone-age people of high standing, possessed of ornaments of gold and copper, but with no tools or weapons of metal at all. We have no data whatever to enable us to determine how far back into the past this culture reaches, but the presence of beads of glass in the graves goes to show that it continued to exist after the arrival of the Spaniards. No traces of a more primitive culture were met with."

Similar cists are to be found on the slopes of Popocatapetl in Mexico, Zaculen in Guatemala, Chiriqui in Panama, and at Arayo in the Cauca valley of Colombia. In outline and elegance, the clay vessels of the Guëtares are inferior to those found in Chiriqui, but the objects in stone from the two sources closely resemble each other.

It is to be regretted that Mr. Hartman has not given us his views as to the ethnological relations of the Guëtares to the other aboriginal tribes of Central America. No doubt, in his travels subsequent to the researches so elaborately detailed in his valuable volume, he must have formed opinions of much importance to the student of aboriginal America. Costa Rica was a debatable ground between the Mexican race and the warlike Carib of the northern shore of South America. It may, perhaps, be conceded that an offshoot of the highland people of Mexico pressed south and east from Chiapas into and through the long strip of the Pacific coast occupied by the Chorotegas or Mangues, followed the Pacific slope of the Cordillera and the narrow belt of land between Lake Nicaragua and the ocean, penetrated into north-western Costa Rica, settled and helped the Mangues to develop a considerable civilisation in the Guanacaste and Nicoya districts, and in part subdued all the mountainous area lying north and west of the river Reventazon. The culture which was characteristic of the region indicated was infinitely superior to anything attained by the Guëtares, for the Mangue-Náhua people carried some of the arts, such as pottery, sculpture, weaving, and tilling the ground, to greater perfection than any of the tribes occupying the territory between theirs and that of the Chibchas of the plateau of Bogotá. In their graves are found examples of the ceramic art and gold ornaments showing taste in design superior to any that the present civilised Indian of Costa Rica can equal. Their graves produce beautiful specimens of obsidian, greenstone, and finely wrought nephrite

Fig. 2.—Seat of Stone. Found in the forest in the neighbourhood of the large mound, Mercedes. From "Archæological Researches in Costa Rica."

tools and jade ornaments, knives, hatchets, arrowheads, armlets, rings, and a multitude of stone seats and idols.

Let us hope that Mr. Hartman may follow up his good and useful work by an exploration of the northwestern slope of the country which has been the scene of his labours. GEORGE EARL CHURCH.

PROGRESS IN AËRIAL NAVIGATION.

THE problem of aërial navigation has been attacked by direct methods for so many centuries that the results of the recent aëronautical competition at St. Louis can scarcely be regarded as a matter of surprise. It is doubtful whether the offering of large prizes for the achievement of a result which has been attempted for years without success is the best means of promoting progress. As will have been learnt from the daily Press the great prize of 20,000*l.* was not even competed for, and a much more useful purpose would have been served by a systematic and organised attempt to encourage, by means of prizes, investigations calculated to throw an indirect light on the general question of aërial navigation, such, for example, as improvements in the efficiency of propellers, diminution of the angle of gliding of gravity-propelled machines, reduction of air-resistance of motor-propelled balloons, solution of the difficulties connected with longitudinal stability, especially in gliding machines travelling at low speeds, and what is still more important, the discovery of new results in any direction whatever calculated to open up fresh methods of approaching the whole question.

If we chronicle merely the attempts that have successfully been made in striking out on new lines, leaving out of account improvements subsequently made on the same lines, and also omitting early attempts such as those of Dante of Perugia and Le Bris, a history of aërial navigation will be summed up in the following short list :—(1) Montgolfier's discovery of the balloon; (2) application of mechanical power to the propulsion of balloons by Renard and Krebs; (3) introduction of gliding experiments under gravity by Lilienthal; (4) the introduction of explosion engines and other light motors theoretically capable of maintaining a flying machine in the air. Each of these innovations has brought the goal more distinctly in view, and yet experiments so far have left a wide gap between the results of actual performance and what is necessary to render aërial navigation practically useful. The special difficulty connected with aërial navigation is that it is not easy to see how to approach the problem except by direct methods of attack, while the great majority of scientific discoveries have been made indirectly as the result of observations originally undertaken for some entirely different object that has been known from the very outset to be possible of attainment.

By analogy with fishes and birds, respectively, the two forms of machine experimented on, involving as they do the use of gas bags and aëroplanes or aërocurves, might not inappropriately be described as the aërial swimming machine and the flying machine proper. It is somewhat remarkable in the face of natural evidence that the swimming machine has up to the present proved by far the most tractable of the two, and has undoubtedly led to the best results. It is the safest to experiment with. That accidents have frequently occurred is perfectly true, but they have all been attributable to causes not beyond the ken of an ordinary practical but intelligent mechanic.

Of aërial swimmers constructed within the last few years the most notable ones are undoubtedly the Santos Dumont series, the ill-fated De Bradski airship, the Lebaudy, Barton, Spencer, Baldwin, Benbow, Beedle, and Deutsch forms. A few details of these, collected for comparison, may be of interest.

M. Santos Dumont's No. 7 is 160 feet long and 23 feet in diameter, and is provided with a four-cylinder motor capable of developing 60 horse-power and making 1200 revolutions per minute. Its predecessor, No. 6, was 108 feet long and 20 feet in diameter, with a motor of 16-20 horse-power. This was the machine which won the Deutsch prize, and its speed relative to the air was probably about 19 miles an hour. No. 7 was originally intended to compete at St. Louis, but M. Santos Dumont did not enter.

The De Bradski airship is now a thing of the past. It was 111 feet long and weighed about 1923lb., and a special feature was that the machine was not *quite* light enough to raise itself, the ascent being effected by a screw revolving in a horizontal plane. The experiment ended in October, 1902, with a fatal accident, the airship becoming unmanageable, and the car breaking away owing to the weakness of its supporting wires.

The experiments of MM. Lebaudy have been remarkably successful in spite of an accident which destroyed their first machine in November, 1903. This did not deter these indefatigable aëronauts from constructing, partly out of the wreckage of the old one, a new machine of the following dimensions :— Length 58 metres, greatest diameter 9·8 metres, volume of gas 2600 cubic metres, or about 94,000 cubic feet; motor, a four-cylinder Daimler of 40 horse-power running at 250 to 1200 revolutions per minute; propellers, two screws 2·44 metres in diameter running at 800 to 1000 revolutions per minute. Of the thirty voyages made with this "aërial cruiser" in 1904, the following appear to have been the most successful :— August 16, a distance of 16 miles in 41 minutes; November 22, a run of 1 hour 33 minutes. An accident occurred on August 28 owing to the "swimmer" breaking loose, but it floated away to a distance and finally got caught in a wood 70 kilometres distant, whence it was brought back with slight damage. The present model is remarkably like a fish in shape, and the resemblance is further accentuated by the tail-like double horizontal rudder in the stern. The balloon has a flat base with a long vertical keel, and all these arrangements are well calculated to make it travel steadily.

Beyond the mere rumour of an accident last spring the Barton airship seems to have lapsed into oblivion of late, but it must not be forgotten that a year is small interval of time in the construction of aëronautical machines. The dimensions given are as follows :—Length of balloon 170 feet, diameter 40 feet, total estimated weight 15,700lb.; number of propellers, six, each consisting of six blades arranged tandem fashion, placed in pairs, one on each side of each motor; motors, three in number, developing 50 horse-power each, and running at 1600 revolutions. A peculiarity of Dr. Barton's design is the series of aëroplanes, thirty in number, employed to raise the machine. The shape of the balloon and the structure of the underlying framework and car suggest the possibility of considerable head resistance.

Of the performances of Messrs. Spencer's airship satisfactory records were given in the Press at the time. The dimensions are :—Length 93 feet, diameter 24 feet; propeller, a single screw 12 feet in diameter, placed in front; engine of 24 horse-power running at 1050 revolutions.

Mr. Baldwin's and Mr. Benbow's airships, exhibited at St. Louis, appear not to have made any noteworthy performances, the former having failed to stem a wind of six to eight miles an hour, and the latter having made progress at the rate of three miles an hour. We have before us a brief description of the machine with which Mr. Beedle made a successful preliminary trial in November, 1903, and further trials were promised for last spring. Mr. Beedle proposed to dispense with rudders and steer by means of a screw fan in front which could be turned in any desired direction, an arrangement calculated to leave much to be desired in the matter of steadiness. The particulars are:—Length 90 feet, diameter 24 feet, horse-power 12. Of the Deutsch "swimmer" only a model was exhibited at St. Louis.

A comparison of the figures of several of these airships gives the impression that the Lebaudy balloon is far ahead of most of its rivals in its well designed proportions. The only questionable feature is the presence of horizontal rudders at the back of the car, in a place where they might prevent the stream lines of air from closing round the balloon, and thus increase the resistance. About this point MM. Lebaudy are best able to judge.

The limits of speed of the aërial swimmer attainable by existing methods are now pretty well known, and fall far short of the amount necessary to travel in the teeth of a high wind. Still, the navigable balloon offers the most promising field of experiment for those who are not prepared to devote themselves to a long course of purely mathematical and experimental researches, or to run blindfold into the dangers which such a course of study would enable them to predict.

For the successful realisation of mechanical flight proper, what is most wanted is a complete and exhaustive investigation, both by mathematical and experimental methods, of the longitudinal stability of various forms of machine gliding at various angles either under gravity alone or when mechanically propelled.

The small fluctuations of a gliding machine about steady motion are determined by exponential functions of the time the coefficients of which are the roots of an equation of the fourth degree. If these roots determine oscillatory motions there will be, not one, but two different oscillations of the machine in a vertical plane. Either of these oscillations may increase or decrease with the time, and unless they both tend to decrease the pitching will become dangerous and the machine will overturn. Photographs of the paths of gliders taken by Mr. Williams some time ago with magnesium light distinctly showed the two oscillations, and in several cases the final overturning in a manner perfectly consistent with theory.

Now it is possible to determine experimentally for any given machine the coefficients of stability when gliding at every different angle. To do this it would be necessary to measure, by means of dynamometers, the force and couple components acting on either a full-sized machine or a model when moved through the air in different directions in its plane of symmetry. It is necessary also to take account of the small changes in these forces and couples when the machine has a small rotational motion, such as occurs when it is turning upwards or downwards in the course of its oscillations. These small changes may, and in all probability do, play an important part in affecting the stability. A whirling table gives exactly the kind of small rotation required in addition to the necessary translatory motion. By reversing the model experimented on, the direction of this rotation may be reversed, and the differences of the two sets of dynamometer readings will give three of the coefficients of stability.

If observations of this kind were made it would be possible to work out on paper the oscillations, and to ascertain the lowest velocity at which a machine would glide safely.

But experimenters have hitherto confined their attention to measurements of the air resistance, and very few have up to the present given much attention even to the variations in the position of the centre of pressure except for a few cases such as a square lamina. The object in most cases has been merely to find out the speed at which a flying machine would travel under favourable conditions, and not its powers of extricating itself from the most unfavourable positions which it might assume on a gusty day. "Stability of motion" is a phenomenon which rarely enters into practical problems. In the flying machine it is of paramount importance.

A similar mathematical investigation has been made by Signor G. A. Crocco in Italy, in connection with stability of airships, but the author obtains an equation of the third instead of the fourth degree. He, however, takes no account of the fluctuations in the horizontal motion, which are certainly of importance in the case of gliders.

Meanwhile the artificial balancing of gliders under gravity has been the subject of a considerable number of experiments in America, and more recently in France, and the initial success of Mr. Orville Wright in rising from the ground on a motor-driven machine in the face of a wind, and landing safely constitutes the first achievement of an actual flight. It is a matter of congratulation that Mr. Wright was not so emboldened by his success that he became reckless, and pushed the experiments on to a premature end.

The large curved surfaces of the disastrous Lilienthal and Pilcher experiments have now given place to a pair of narrow superposed rectangles, first introduced by Chanute and Herring. The tail has since, in the hands of Messrs. Wilbur and Orville Wright, been replaced by a front rudder, and the adoption of a horizontal position "à plat ventre" shows that the maintenance of balance has been reduced to a matter of steering.

These types of gliders have been taken up in France by Captain Ferber, of the Artillery, and subsequently by Mr. Ernest Archdeacon, both of whom have become enthusiastic "aviators," and have in their turn brought gliding experiments into considerable popularity in that country. As Captain Ferber remarks, a sloping hillside with a wind blowing straight up it are necessary, and a convenient experimenting ground has been found at Meudon. With the object of experimenting on larger motor-driven models Captain Ferber constructed an aërodrome consisting of a column eighteen metres high, supporting a rotating beam thirty metres across. This apparatus would be very useful for determining the stability coefficients of an actual machine firmly attached to its beam, but it must not be forgotten that any kind of suspension may seriously modify the longitudinal oscillations. So, too, may the rotation about the vertical axis; it is much easier to make a glider describe a corkscrew path than glide in a straight line. A kite illustrates the same properties. Its oscillations also depend on a biquadratic equation, but the supporting string modifies their character, and Mr. Cody claims that a man has been lifted 1600 feet by kites, though how the *photograph* of "the Cody man-lifting kite 800 feet high" was taken, which appears in the *Aëronautical Journal*, is not explained. The use of kites for saving life at sea might well receive more attention than has been bestowed on this question up to the present. The clumsy plan of sending up rockets in the teeth of a gale such as would just blow a kite line from ship to shore needs reconsideration.

Little has been published about Prof. Langley's experiments beyond a reference to the accident which gave Prof. Manley a premature bath in the Potomac.

The idea of combining a glider and boat was tried initially with success and ultimately with failure by Herr Kress on a reservoir a few miles out of Vienna, near the main railway line from Germany. Major Baden-Powell has adopted the same plan at the Crystal Palace. The machine descends a kind of chute from a height of about thirty feet, and is shot off into the air about six feet above the water. With this small height it is not unlikely that successful glides might be made even if the steady motion were longitudinally unstable, for by careful projection several wave-lengths might safely be described in the air before the pitching became dangerous.

It is probable that a motor driven machine travelling at high speed would be much more stable than a gravity machine, but to understand the management of the machine is a necessary condition of success, and the more this can be made the subject of mathematical study the easier will the task be for an aëronaut who is perfectly familiar with the equations of motion. In regard to the effect of speed on stability, the pretty butterfly-like "helicoptera" driven by elastic must not be quoted as instances. They raise themselves nearly vertically; we are concerned with machines moving nearly horizontally.

From all that has been said above it will be seen that there is plenty of work to be done in connection with aërial navigation. At the present time, careful quantitative measurements of the coefficients of stability of actual machines by attaching them to whirling tables are even more needed than further balancing experiments in mid-air.

G. H. BRYAN.

PHAISTOS AND HAGIA TRIADA, CRETE.

IN the south of Central Crete, a day's journey from Candia on a good horse, lies the scene of discoveries no less important than those of Dr. A. J. Evans at Knossos. They consist of the ruins of two palaces, one large and one small, but both built on the same general plan and with the same materials (stone and concrete) as that which has made Dr. Evans famous. There can be no doubt that all three belong to one age and one social system; that they were under one Government is clear from the fact that none of the three were fortresses. Crete was, in fact, as Thucydides told us long ago, a sea-power which had no fear of assault by land. With the architectural or historical interest of these remains we need not concern ourselves at present, nor with the general character of the articles found in them. In all three we meet with vessels of use and ornament, painted frescoes, inscribed blocks or tablets, seals, human and animal figures, and articles of domestic or religious character. But in or near Hagia Triada there came to light a number of objects of special interest which distinguish that palace, smallest of the three, above the others.

First there is a sarcophagus of stone, painted upon all four sides. Each of the two ends bears a chariot in which are two female figures; a pair of horses draws one, a pair of griffins the other. The two sides bear a representation of sacrifice to the dead. Men leading animals—bull, goat, or sheep—women with baskets of fruit, others with bowls apparently full of wine or some other liquid, which is being poured into a large jar; a flutist and a harper, playing upon a lyre of seven strings (which are therefore older than Terpander by a thousand years); men carrying animals in their arms; and lastly the dead man himself, standing beside a tree before his own tomb and receiving the pious offerings. A most noteworthy fact in this representation is that the men wear women's skirts.

Next come three vases of steatite, each bearing a scene carved in relief. The workmanship of these carvings is astonishing for its finish, and the designs are full of life, reminding us not distantly of good Attic work. On one vase a couple of youths stand face to face, one leaning upon a spear or staff, the other bearing over his shoulders a staff and a whisk of some sort. Both are naked, save for the familiar loincloth of the Mycenæans (which the Greeks never wore, except in the very earliest times at the Olympian games), and high boots of the same kind which are still worn in Crete and always have been. The second vase represents several pairs of men, some wrestling and some boxing, and a bull-hunt or bull-baiting. The boxers have their hands bound about with straps of leather, or something like a fingerless glove. Some of these men wear helmets, which in part at least seem to be made of metal; and helmets hitherto have been undreamt of at this period.

But the last vase is the most striking of all. It bears a procession of men marching two and two, led by a personage clad in a stiff bell-shaped tunic covered with scales. He is bareheaded and carries a long staff or sceptre resting upon his shoulder. The men behind him wear flat caps something like to a turban, and loincloths, and each carries over his left shoulder a long pole branching out into three long flexible wands at the end. In the middle of the procession are four men singing, one bearing the *sistrum* of Isis; these have no wands. Some see in this a triumphal procession of soldiers after war. The lack of arms or shields makes this unlikely; the three-pronged objects can hardly be weapons, for they seem to be flexible, but what they are it is impossible to say. Those are more likely to be right who believe it to be a harvest festival of some kind, and the three-pronged implement an implement used in some harvesting process. If we may assume that these objects have no use at all, but are ornamental (which is not likely), the whole might be a religious procession without regard either to war or husbandry.

NOTES.

THE Bakerian lecture of the Royal Society will be delivered by Dr. Horace T. Brown, F.R.S., on March 23, upon the subject of "The Reception and Utilisation of Energy by the Green Leaf."

IT is proposed to erect in Jena a memorial to Prof. Ernst Abbe, so that all who see it may be reminded of his great services to optical science and industry, and his sterling qualities as a man. Abbe's work and influence are appreciated wherever physical science and sociology are studied, and there should be no difficulty in obtaining sufficient funds to raise a noble monument to his memory. The committee organised for this purpose includes the names of Dr. Czapski, Dr. Eggeling, Dr. G. Fischer, Prof. Rosenthal, and Prof. Winkelmann. Subscriptions for the memorial should be sent to the treasurer, Dr. Gustav Fischer, Jena.

Science states that the Prussian Academy of Science has awarded its Helmholtz medal to Prof. Ramón y Cajal, professor of neurology at Madrid.

It is announced that Prof. Albert B. Prescott, professor of organic and applied chemistry, dean of the school of pharmacy and director of the chemical laboratory of the University of Michigan, died on February 26 in his seventy-third year.

We learn from the *Times* that negotiations are in active progress for the amalgamation of the Society of Arts and the London Institution. A scheme has been prepared by a joint committee, and it only remains to be submitted to the general body of the members, whose assent in all likelihood will be given.

A committee of the French Physical Society has arranged to have a medal struck in commemoration of M. Alfred Cornu.

The Royal Society of Naples (mathematical and physical section) has awarded its prize of 40*l.* to Prof. E. Pascal, the subject being the theory of the invariants of the ternary quartic with special reference to the conditions for splitting into inferior forms. A prize of 20*l.* is now offered for the best essay in Italian, Latin or French on "The theory of electrons and the dispersion of light." The last day for sending in is June 30, 1906, and the essays are to be submitted under a pseudonym.

Since our note on the late Prof. Emilio Villari appeared in last week's Nature, we have received a copy of the *Rendiconto* of the physical and mathematical section of the Neapolitan Royal Society (x., 8–11) containing another notice of Prof. Villari by Prof. L. Pinto. It differs from the previous notices in containing a general summary of the scope of Villari's works, classified under the various headings of acoustics, molecular mechanics, heat, light, electricity, and Röntgen rays, and it will be found a very useful notice for purposes of reference, especially for physicists, whose time is limited, interested in Villari's researches.

The *Lancet* states that the King has acceded to a suggestion that the skeleton of Ambush II., the famous steeplechaser from the Royal Stables which died some weeks ago, should find a place in the Museum of Veterinary Anatomy at the University of Liverpool. The skeleton will be mounted and placed in a prominent position at the University museum, and a plate will be affixed giving a short history of the well-known horse.

It is announced in the *Electrician* that Lord Kelvin will be the recipient of the first John Fritz gold medal awarded by the joint committee of the four national American engineering societies, under the deed of gift, to the man most representative of, and eminent in, scientific advance in the engineering field. This medal was founded three years ago on the occasion of the eightieth birthday of John Fritz, the famous inventor and engineer in the iron and steel industry, who is still enjoying excellent health.

On Tuesday next, March 21, Prof. W. E. Dalby will deliver the first of a course of two lectures at the Royal Institution on "Vibration Problems in Engineering," and on Thursday, March 23, Mr. Thomas G. Jackson will begin a course of two lectures on "The Reasonableness of Architecture." The Friday evening discourse on March 24 will be delivered by Sir Oliver Lodge, his subject being "A Pertinacious Current," and on March 31 by Prof. J. Wright on "The Scientific Study of Dialects." Prof. Meldola will give the first of his two lectures on "Synthetic Chemistry" (experimental) on Thursday, April 6.

The Liverpool correspondent of the *Lancet* states that Mr. J. E. S. Moore, who has become director of cancer research in succession to Prof. A. S. F. Grünbaum, has also been appointed a member of the staff of the Royal Infirmary, Liverpool, in accordance with the terms of the donation that the research work in cancer should be carried on at that infirmary. From the same source we learn that, in response to an appeal made for funds to initiate a permanent memorial to the late Sir W. M. Banks, the sum of 5523*l.* has been subscribed. Of this amount, the sum of 1500*l.* is to be devoted to founding a lectureship, to be attached to the University of Liverpool, and to be called the "Mitchell Banks lectureship." The University authorities will be enabled to invite yearly a distinguished surgeon, pathologist, or anatomist to treat of the latest investigations and discoveries in medical science.

At the Optical Convention to be held in May next at the Northampton Institute, Clerkenwell, to which attention has already been directed in these columns, the following amongst other papers will be read. Dr. R. T. Glazebrook, F.R.S., will deliver the presidential address. Mr. H. Dennis Taylor will read a paper on some properties of lens systems; Mr. Walter Rosenhain will deal with two subjects—the mechanical design of instruments, and some problems relating to optical glass; Dr. C. V. Drysdale will discuss binoculars, and, in collaboration with Mr. S. D. Chalmers, will introduce a discussion on aberration; Mr. J. Gordon will take up the question of diffraction in optical instruments; Mr. J. Blakesley, some optical measurements; Mr. J. H. Sutcliffe, ophthalmometers; Dr. R. M. Walmsley, education in optics; Prof. Forbes, spectroscopic vision; Prof. Poynting, F.R.S., a parallel plate micrometer; and Dr. W. Watson, F.R.S., fused quartz for optical purposes. Full particulars of the convention can be obtained from the secretary, Mr. C. L. Redding, at the Northampton Institute, Clerkenwell, E.C.

The March number of the *American Journal of Science* contains a short account of the work of Prof. A. S. Packard, who died in Providence, R.I., on February 14, at the age of nearly sixty-six years. Prof. Packard was graduated from the Maine Medical School and the Lawrence Scientific School in 1864. At Cambridge, Mass., he was one of that remarkable group of students—Hyatt, Morse, Packard, Putnam, Scudder, Shaler and Verrill—associated with the elder Agassiz in the early 'sixties. He served for a time in 1864–5 as assistant surgeon in the U.S. Army, but never became a regular practitioner of medicine, his life being devoted to his chosen work in zoology and geology. He was specially distinguished as an entomologist, and he was an enthusiastic field naturalist, collector, and explorer, and a voluminous author who wrote on a remarkably wide range of subjects. He will probably be longest remembered for his original work on insects and his several text-books on entomology and zoology. Early in his career he accepted the theory of evolution and later became an ardent neo-Lamarckian. One of his last works was "Lamarck, the Founder of Evolution, his Life and Work." He was one of the founders of the *American Naturalist*, for twenty years its chief editor, and a constant contributor to its pages. Prof. Packard was a member of the National Academy of Sciences and of many other scientific societies.

The ceremony of transferring the museum of the Hastings and St. Leonards Museum Association to the Corporation of Hastings took place on March 1. The museum is a representative one, and is divided into several sections. The anthropological section includes a cosmopolitan ethnological collection, geographically arranged. In it are some good local bronze and bone objects, a series of

Neolithic stone implements from many parts of the world, an ethnological collection from New Guinea and the South Sea Islands, the relics recovered from the Hastings kitchen middens—numbering many thousands of specimens—and many worked flints of the Palæolithic period. The geological section is remarkable for its collection of animal remains of the Pleistocene period from the Lewis Abbott collection, and a collection of Wealden fossils from the neighbourhood. The biological section has a representative collection of the local fauna. After the museum had been accepted by the Mayor on behalf of the Corporation of Hastings, Sir Arthur Rücker, F.R.S., delivered a short address, in which he emphasised the value of museums in the study of natural science, and commended the active part municipal authorities are now taking in educational work. Dr. J. J. H. Teall, F.R.S., expressed the opinion that local museums should illustrate local natural history, and outlined a plan which would secure this end. Sir Harry Johnston, G.C.M.G., K.C.B., also spoke on the value of museums.

A BOTTLE thrown overboard in latitude 29° 30′ N., longitude 68° 10′ W., by Colonel Swalm, U.S. Consul at Southampton, in May, 1903, has just been found on the Donegal coast, Ireland, near Arranmore. The bottle had apparently been carried by the Gulf Stream along the North American coast, then across the Atlantic to the Irish coast. To travel this distance it had taken 662 days at an approximate speed of five miles a day.

ACCORDING to a Reuter despatch from St. Petersburg, dated March 9, the North Pole Commission has officially declared that the expedition under Baron Toll to the new Siberian Islands, in the Arctic Ocean, has ended with the death of all the members of the party. The party sent in search of the expedition found in Benett Island a letter written by Baron Toll saying that the members of the expedition had continued on their journey though having only eighteen or twenty days' provisions left. It is therefore believed that Baron Toll and his companions perished of hunger.

THE *Weekly Weather Report* of March 11 issued by the Meteorological Office showed that the rainfall from the beginning of the year was still deficient in all districts except the north of Scotland and the north of Ireland; the deficiency amounted to 2 inches and upwards in several parts of England and in the south of Ireland. During the recent severe gales, however, falls of about an inch in twenty-four hours have been recorded in several localities. In the neighbourhood of London the rainfall during the part of the present month already elapsed has exceeded the mean for March, which is 1·5 inch.

AN exhibition of meteorological instruments with photographs and records of meteorological phenomena, under the auspices of the Royal Meteorological Society, was opened on Tuesday at the Institution of Civil Engineers, Great George Street, Westminster, and the exhibition will remain open until 5 p.m. to-morrow, Friday. The instruments exhibited represent all branches of meteorology, and show clearly the great advance which the science has made in recent years. Continuous records can now be secured in nearly all branches, and in many of these ample choice is provided. There are several forms of self-recording rain-gauges, notably the Beckley and the Richard patterns, while Halliwell's improved float pattern pluviograph is of more recent invention, and of exceptional scientific value. The thermometer exhibits are fairly numerous, and of various designs, from Callendar's electrically recording thermometer to instruments of an ordinary character. There are to be seen the thermometers in use in Sir J. C. Ross's Antarctic Expedition, 1839–43, and in the Arctic expeditions 1850–59, as well as thermometers used by the National Antarctic Expedition 1901–4. These instruments show the greater degree of accuracy obtainable in manufacture now than was the case, say, half a century ago. Barometers and barographs exhibit considerable advance. An instrument of considerable value is Dines's self-recording mercurial barometer; and a microbarograph, for the study of minor variations of atmospheric pressure, under the joint names of Mr. W. H. Dines and Dr. W. N. Shaw, is likely to prove of much value. A typical climatological station is shown, its enclosure containing all the necessary instruments in position for observation. A prominent position is given to aëronautics, and there are specimen kites with meteorograph in position. There are anemometers of very varied description, many of these being self-recording. Sunshine recorders, past and present, are to be seen, from the wooden bowl, by Campbell, used as early as 1853, to the almost perfect instrument known as the Campbell-Stokes. Among the many drawings and photographs may be mentioned the water-colour drawings made during the recent National Antarctic Expedition, exhibiting sky and cloud effects. The Royal Meteorological Society is to be congratulated on the thoroughly interesting character of the exhibition.

PROF. H. HERGESELL has communicated to the *Comptes rendus* of the Paris Academy of Sciences, January 30, some of the preliminary results of the kite ascents made on the yacht of the Prince of Monaco in the Mediterranean and North Atlantic Ocean in the summer of 1904. Altogether, twenty-five ascents were made, eight in the Mediterranean, one in the Baltic, and sixteen in the Atlantic. The principal object of the latter was the exploration of the meteorological conditions in the region of the trade winds. The results show that in the lowest strata of the air there is a considerable decrease of temperature with increase of altitude; the adiabatic gradient (1° C. per 100 metres) is always attained, and even exceeded in the lowest stratum. The depth of this adiabatic stratum varies from 100 to 600 metres; the relative humidity at the sea-level is 70 or 80 per cent., and rises gradually to 95 or 100 per cent. At the upper limit of this stratum a sudden change occurs: the temperature rises quickly by several degrees, and the humidity suddenly diminishes to below 50 per cent. The temperature continues to rise, through a stratum sometimes extending to a depth of 1000 metres, and the humidity decreases to 10 or 20 per cent.; at a height of 1000 metres, temperatures of 30° C. are experienced, while at the sea-level only 22° or 23° are recorded. Above this stratum the adiabatic gradient again holds, but the humidity is low, compared with that of the first adiabatic stratum. In the lower stratum the N.E. trade is experienced, the velocity being about sixteen miles an hour; with increasing elevation the wind gradually shifted through N. to N.W., and in two instances it shifted through E. to S.E. and S. A south-westerly current, which would correspond to the theory of anti-trades, was never exhibited by the kites, although they several times exceeded the height of the Peak of Teneriffe. The velocity of the N.W. or S.E. winds experienced in the highest strata did not exceed seven or nine miles an hour, and was generally still less in the intermediate strata.

THE latest issues of the *Proceedings* of the U.S. National Museum include a description, by Dr. Stejneger, of a gecko and three frogs from the Philippines, and an article by Mr.

Gill on the gurnard commonly known as *Prionotus stearnsi*, which is made the type of a new genus.

The structure of the squamoso-parietal crest in the skulls of the horned dinosaurs of the Cretaceous of Alberta is deemed by Mr. L. M. Lambe of sufficient interest to merit a paper by itself, and he has accordingly described this part of the skeleton in a recent issue of the *Transactions* of the Royal Society of Canada (vol. x., sect. iv.).

Our weekly budget includes copies of Nos. 3 and 4 of the *Sitzungsberichte* of the Vienna Academy for the current year. Among the notes is one by Prof. Molisch on phosphorescence in eggs and potatoes after cooking, and a second by Dr. F. Werner on the Orthoptera of the Egyptian Sudan.

In the January number of the *American Naturalist*, Mr. J. Stafford discusses the larva and spat of the Canadian oyster, the latter of which is extremely minute and very difficult to discover. Unlike the later stages, the very young spat presents a dark metallic lustre. When once recognised, the young spat is, however, by no means difficult to discover, and the sailors soon became adepts in the search. Although found on many kinds of shells, and sometimes on stones, the spat displays a preference for the young of *Crepidula fornicata* and colonies of *Ralfsia verrucosa*.

To the *Biologisches Centralblatt* of February 15, Mr. J. P. Lotsy contributes an article on "X-generation and 2X-generation," in which he proposes a theory to explain certain features connected with cell-development and heredity. In the second article in the same issue Mr. E. Wasmann seeks to explain the origin and development of slavery among ants, showing the manner in which a colony of *Formica truncicola* may have been gradually modified from a type in which a certain number of stranger ants were received as guests, to one in which a host of captives are maintained.

The *Otago Daily Times* of January 6 contains an article on the marine fish-hatchery at Portobello and the progress recently made there. The institution was nominally opened a year ago last January, but it was by no means in good working order, having to contend with such difficulties as leaky tanks. Work during the past year has been to a great extent confined to observing the behaviour of a few kinds of food-fishes in captivity. Many of these died off quickly when introduced into the tanks, some, apparently, on account of having been injured in their capture, and others owing to a difference in the temperature of the water. Blue cod, however, thrive well, although the endeavours to rear the fry were unsuccessful. The introduction of the European lobster is contemplated.

Mr. L. Frederico, director of the class of science in the Belgian Royal Academy, sends us a copy of an essay (from the *Bulletin* of the Academy for December last) on the Glacial fauna and flora of the plateau of Baraque-Michel, the culminating point of the Ardennes. The boreal conditions of climate have, it appears, preserved on this exposed plateau a small colony of animals and plants of an essentially arctic type, the nearest relatives of which are to be met with only in the extreme north, and on certain much higher mountains in central Europe. This assemblage seems to be at the critical stage as regards temperature, a very slight elevation of which would lead to its disappearance. We thus have a definite refutation of the prevailing idea that the temperature of this part of Europe has been higher at some date since the Glacial epoch than it is at the present day.

The February number of the Johns Hopkins Hospital *Bulletin* (vol. xvi., No. 167) is mainly devoted to anatomy. The teaching of anatomy is discussed by Mr. Mall, who also writes on the working of the Anatomy Act (U.S.A.) and preservation of material, and the anatomical department of the University of California is described by Dr. Flint. Three papers dealing with points in the development of the kidney, a review of Flechsig's researches on the brain, and an article on body-snatching in England complete the contents of an excellent number.

On the subject of the mandrake or mandragora, Mr. C. B. Randolph has collated, in the *Proceedings* of the American Academy of Arts and Sciences (vol. xl., No. 12), a number of references from the classics, from which he concludes that, on account of its narcotic qualities, it was employed as an anæsthetic about the first century of the Christian era.

Experiments by Mr. E. S. Salmon showing that "biologic forms" of *Erysiphe graminis* can be identified according to their power of infecting different species of cereals have been previously referred to. Pursuing his investigations on the subject, Mr. Salmon states, in the *Annals of Botany* (January, 1905), that portions of a host plant which is normally immune, become susceptible to infection by the fungal conidia if they are injured or subjected to heat or the action of anæsthetics, but the conidia produced as a result of such infection cannot attack a healthy plant of the same species. The practical application of this fact is far reaching, as a wheat-rust can in this way spread to barley leaves which have been injured by animals or storms.

With the object of arousing interest in the subject of the giant trees of Victoria—all species of Eucalyptus—Mr. N. J. Caire has collected data as to size, height, and localities of specimens known to him in a paper published in the *Victorian Naturalist* (January, 1905). Big Ben, a specimen of *Eucalyptus amygdalinus*, possessing a trunk of 57 feet girth, was destroyed by a bush fire in 1902, and Billy Barlow, a blackbutt of the same circumference, was sacrificed for the Paris Exhibition; both these veterans were probably more than a thousand years old. Most of these trees of enormous girth present signs of senile decay, as shown by broken tops or later by hollow stems.

The results of recent experiments have proved conclusively, says the *Pioneer Mail*, that silk of excellent quality can be raised in Ceylon, and samples of cocoons raised at Peradeniya from European seed have been classed by a European expert as second only to the best Italian silk. Hitherto all experiments have been on a small scale, limited partly by the comparative scarcity of mulberry trees. The time seems now to have arrived when more extensive operations might be undertaken with advantage; and, with this object, it is proposed that an experimental silkworm rearing establishment be created. A scheme is under consideration by the Ceylon Board of Agriculture.

Some interesting observations of the spark discharge from a Holtz machine are described in a paper by Dr. L. Amaduzzi in the *Atti* of the Italian Electrotechnical Association for 1904. Marked variations in the character of the discharge were observed with varying atmospheric conditions.

The peculiar photographic activity of hydrogen peroxide has recently been considered by Graetz to be due to a special radiation, in virtue of the fact that its influence is capable of penetrating solid bodies, particularly thin sheets of metals. It is, however, shown by J. Precht and C. Otsuki, in the *Verhandlungen* of the German Physical Society (vol. vii. p. 53), that hydrogen peroxide itself is capable of penetrating thin films of gelatin, celluloid, india-rubber and black paper, the peroxide being subsequently capable of detection by titanic acid. Metals in the form of the thinnest sheet are, nevertheless, impervious to hydrogen peroxide, if small holes be not present; the same is true of thin films of paraffin, glass, and ebonite.

Two papers dealing with the accurate measurement of coefficients of expansion are contained in the January number of the *Physical Review*. Mr. H. McAllister Randall describes the determination of the coefficient of expansion of quartz between the temperatures of 36° and 500° C. by means of Pulfrich's optical method, and shows that up to about 250° C. the expansion of quartz follows a straight-line law; between 250° and 470° C. it is necessary to include a term involving the square of the temperature, whilst at 500° C. a sudden large increase in the expansibility becomes visible. At this temperature it is probable, as suggested by Le Chatelier, that quartz undergoes a change into a second modification having very different physical properties from those of the ordinary form. The second paper, by Mr. H. D. Ayres, deals with the measurement by Pulfrich's method of the coefficients of linear expansion of the metals aluminium and silver at temperatures between 100° and −184° C.

THE firm of Leybolt Nachfolger in Cologne has recently issued a very complete and interesting catalogue of physical apparatus and fittings sold by them. The book starts with a history of the instrument trade in Cologne during the last century. In its second section we find an account of the construction and fittings of various chemical and physical institutions. It is noteworthy, perhaps, that while the students' laboratory, with its work tables and appliances for experiments, figures prominently in the chemical institutions, the arrangements for practical work by the students in the physical laboratories are distinctly less complete. After this follows the catalogue proper, filling some 800 large pages, profusely illustrated and admirably arranged. The book will be most useful to the teacher, and is a striking illustration of German enterprise and go. At the same time it is observable throughout that the apparatus is intended chiefly for demonstrations and the lecture-room. The list of electrical measuring instruments, for example, is comparatively meagre, while there are not many examples of the simpler forms of apparatus supplied to an English school laboratory for use by the students. It is probably the case that such apparatus is less used in Germany than here, but though this is absent the book is full of apparatus of the greatest value and utility.

A SECOND edition of Prof. Luigi de Marchi's "Meteorologia generale" has been published by the house of Hoepli, of Milan. The book has been revised and enlarged.

A SECOND edition of the "Rural Calendar," fully revised and enlarged, has been prepared by Dr. A. J. Ewart and published by Messrs. Davis and Moughton, Ltd., Birmingham. The book is a helpful index to observations of animate nature throughout the year, and a guide to gardening and farming operations. It includes an artificial key to the commoner wild British herbs, giving description, common name, scientific name, and natural order. By using this key as plants become available, a good knowledge of common flowers may be obtained. The price of the book is one shilling net.

OUR ASTRONOMICAL COLUMN.

STRUCTURE OF THE CORONA.—In an interesting paper published in No. 3 (1905) of the *Revue générale des Sciences*, Dr. Ch. Nordmann discusses the structural details of the solar corona and their causes. In the first place, he shows that the incurvation of the coronal rays cannot be due solely to the action of gravitation, for the angles which they make with the normals to the limb at the points of their projection are far too small for this theory.

He then shows that the "minimum" corona, which obtains at the time when the solar surface is least disturbed simply assumes the form natural for it to assume under the action of centrifugal force, if it be granted that the particles forming the coronal streams are exactly balanced in the solar atmosphere—that is to say, if their weight is counterbalanced by the force of the light-repulsion. At times of "maximum," when the solar surface in the sun-spot (*i.e.* equatorial) region is most disturbed, the local disturbances, and their consequent convection currents, modify the action of the normal centrifugal forces, and thus produce the *abnormal* coronas observed at eclipses occurring during periods of maximum solar activity, which, although of the same general form, vary greatly in their detailed features.

RADIANT POINT OF THE BIELID METEORS.—From a number of observations of the Bielids made on November 21, 1904, Herr K. Bohlin, of Stockholm, has calculated the radiant point of the shower.

The resulting position is only about 3° from γ Andromedæ, and has the following coordinates:—

1904 November 21·33 (Mid-European time).

$$\left.\begin{aligned}\alpha &= 26^\circ\ \ 2' \\ \delta &= +43^\circ\ 10'\end{aligned}\right\}1900.$$

(*Astronomische Nachrichten*, No. 3997.)

BRIGHTNESS OF ENCKE'S COMET.—The results of a number of magnitude observations of Encke's comet, made by Herr J. Holetschek, at Vienna, during the present apparition, are published in No. 3997 of the *Astronomische Nachrichten*. The observations covered the period November 25–December 27, and, in the table wherein the results are shown, the vertical diameter, the magnitudes of the nucleus, and the magnitudes of the whole comet are given. From the last-named values we learn that on November 25 the magnitude of the comet was 9·0, on December 10, 6, and on December 23, 5·3. The value obtained on December 27 was mag. = 5·0, but this is queried.

JANUARY FIREBALLS.—A note from Mr. Denning to the *Observatory* (No. 355) shows that the appearance of fireballs during the predicted dates in January was well sustained. On January 14 a bright object was seen by several observers, and on combining the records a radiant point situated in Monoceros at 119°+3° was obtained. The height of this fireball ranged from 60 miles over Brecon to 29 miles over Aberystwith. Two fireballs were seen on January 27 and one on January 29, thus corroborating the January 28 epoch. One of those on the former date was very bright, and was apparently stationary at 118°−18°.

In February, bright fireballs were seen on February 11, 13 and 18, the time of the apparition on the last-named date being 7h. 15m. a.m., *i.e.* in daylight.

ROTATION OF JUPITER'S SATELLITES I. AND II.—During the period January 13–20, Dr. P. Guthnick, of Bothkamp Observatory, made a series of magnitude observations of Jupiter's first and second satellites, the period of observation covering about four revolutions of the former and two revolutions of the latter round the planet.

The measurements were made with a Zollner photometer attached to the 11-inch refractor. Plotting the values obtained on curves having the "anomaly" of each satellite as abscissa and the corresponding apparent magnitude as ordinate, it was seen that the period of the light-variations coincided with that of the revolution about Jupiter, and as a consequence it seems probable that the periods of revolution and rotation are coincident in each case (*Astronomische Nachrichten*, No. 4000).

ORBITS OF MINOR PLANETS.—In No. 4000 of the *Astronomische Nachrichten*, Prof. J. Bauschinger publishes the elements of the orbits of those minor planets discovered during 1904 of which the paths have been computed at the Berlin Astronomischen Recheninstitut. The list contains the orbits of 28 minor planets, 24 (523–549) of which are referred to the epoch 1904.0, and 4 (550–553) to 1905.0, and is followed by a series of remarks which name the observations on which the computations were based, and the corrections to some of the orbits as obtained from subsequent observations. A note concerning (526) NQ says that that object is probably identical with 1901 HA.

An additional list of five asteroids discovered during November and December, 1904, and to which the permanent numbers 549–553 are now allotted, brings the total number discovered during last year up to thirty-two.

EFFECT OF AUTUMNAL RAINFALL UPON WHEAT CROPS.[1]

BY autumn, in this note, is to be understood the period from the thirty-sixth to the forty-eighth week, both inclusive, of the year, as represented in the *Weekly Weather Report* of the Meteorological Office; it covers the months of September, October, and November, approximately. The rainfall to be referred to is the average amount in inches, for the general consonance, with exceptions, more or less striking, in a few of the years. In other words, the yield of wheat in any year seems to depend mainly on the absence of rainfall in the previous autumn, and but little on any other factor.

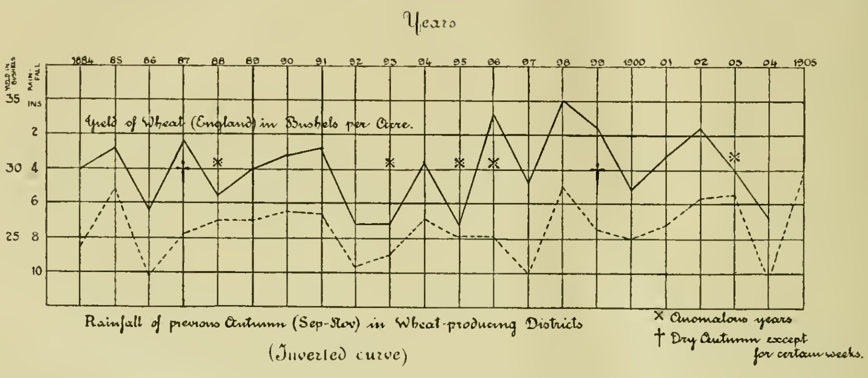
The obvious algebraical expression for such a condition as the curves represent is a linear equation, and the equation which represents the relation between yield of wheat for England and the previous autumn rainfall is:—

Yield = 39.5 bushels per acre − 5/4 (previous autumn rainfall in inches).

If we call the yield obtained from the rainfall by this equation the "computed yield," a comparison with the actual yield for the twenty-one years shows that the computed yield agrees with the actual yield within half a bushel in seven years out of the twenty-one. In fourteen years the agreement is within 2 bushels; in the remaining seven years the difference between computed and actual yield exceeds 2 bushels. The extreme variation of yield in the twenty-one years is 9 bushels, from 26 bushels per acre in 1892 and two other years to 35 bushels per acre in 1898.

Of the seven years for which the formula gives yields differing from the actual by upwards of 2 bushels, 1896 is the most conspicuous; its actual yield exceeds the computed yield by 4.5 bushels.

These seven years all show anomalous seasons. Taken



"Principal Wheat Producing Districts," for the period mentioned, in successive years. The amounts are taken from the summaries of the *Weekly Weather Report*.

The yield of wheat is that given for successive years in the annual summaries of the Board of Agriculture and Fisheries as the average yield in bushels per acre for England, since 1884, or more strictly since 1885, as that is the first year for which the figures for England are given separately. In 1884 the figure for Great Britain, which generally differs but little from that for England, is used.

These are the only figures in the official publications which are immediately available for the purposes of comparison. The totals of rainfall for the thirteen weeks have been compiled from the weekly amounts, otherwise the figures are taken as they stand in published returns. The areas referred to are not exactly coterminous, but they are more nearly so than if the rainfall values had been taken for the whole of England, or the wheat yield for Great Britain.

When the autumn rainfall and the yields of wheat for successive years from 1884 to 1904, as thus defined, are plotted, the rainfall curve being inverted, *i.e.* rainfall being measured downward on the paper while yield is measured upward, there is a very striking similarity between the curves, so much so as to suggest that if the scales were suitably chosen the two curves would superpose and show

[1] "On a Relation between Autumnal Rainfall and the Yield of Wheat of the following Year.—Preliminary Note." By Dr. W. N. Shaw, F.R.S., Secretary of the Meteorological Council. Read before the Royal Society on February 2.

seriatim, they are 1887, 1888, 1893, 1895, 1896, 1899, and 1903.

In 1888 and 1903 the crops were washed away by 10 inches of rain in the summer; 1893 is the year of phenomenal drought, and the crop was below the computed figure by 2.5 bushels. The years 1892 and 1899 are interesting, because though the amounts of rain were up to the average, the former had eight dry weeks and the latter ten dry weeks out of the thirteen included in the conventional autumn. They were thus dry autumns, the average amount of rainfall being made up by a few exceptionally wet weeks. The yields correspond with dry autumn values. They are above the average and above the computed figures by some 2 or 3 bushels per acre.

There remain 1895 and 1896. 1895 was the year of remarkably cold weather, and in that year the yield fell short, but in the following year the deficiency was made up by a yield as much above the computed value as the previous one fell short. It would appear that in this instance the productive power not utilised in the year of the great cold was not lost, but stored. On the other hand, it must be remarked that 1896 had the advantage of a specially dry winter.

It appears from these considerations that the dryness of autumn is the dominant element in the determination of the yield of wheat of the following year. The averages of yield and of rainfall are taken over very large areas, and it may be taken for granted that the investigation of the question for more restricted areas would introduce some modification in the numerical coefficients, if not in the form of the relation.

The data for making such an investigation are not yet in an available form. A comparison has been made between autumnal rainfall for "England, East," and the average yield for the counties of Cambridge, Essex, Norfolk, and Suffolk, which shows a similar relation but a magnified effect of autumnal rainfall upon the crop, and also two exceptional years which have not yet been investigated.

GEOLOGICAL NOTES.

FROM the Geological Survey we have received a memoir on the water supply of Lincolnshire from underground sources, with records of sinkings and borings, edited by Mr. H. B. Woodward, with contributions by Mr. W. Whitaker, Dr. H. F. Parsons, Dr. H. R. Mill, and Mr. H. Preston. In the introduction a description is given of the various geological formations with especial reference to the water-bearing strata. The bulk of the work is taken up with records of borings, among which we note particulars of a new boring in progress at Boultham for the supply of Lincoln; many records from the prolific locality of Bourn, where from one bore-hole five million gallons of water a day have been obtained; and other records from Scunthorpe, Skegness, Woodhall Spa, &c. Many analyses of water are given, and Dr. Mill contributes a useful section on rainfall, with a colour-printed map.

The Geological Survey has issued a memoir on the geology of West-Central Skye, with Soay, in explanation of sheet 70 of the geological map of Scotland. The memoir is written by Mr. C. T. Clough and Mr. Alfred Harker. The area is mainly occupied by the Tertiary igneous rocks of the Cuillin Hills, but it includes also some Torridonian rocks, and small tracts of Trias, Lower Lias, and Cretaceous. The occurrence of Cretaceous strata, probably cf Upper Greensand age, is of especial interest. The Glacial and post-Glacial accumulations, the physical features and scenery are duly described. The memoir, in short, is in a handy form (pp. 59, and price 1s.), well suited as a guide on the ground, and as an introduction, as regards the volcanic rocks, to the larger work by Mr. Harker (lately noticed in NATURE) on the Tertiary igneous rocks of Skye.

Another memoir issued by the Geological Survey is on the geology of the country around Bridgend, being part vi. of the "Geology of the South Wales Coal-field," by Mr. A. Strahan and Mr. T. C. Cantrill, with parts by Mr. H. B. Woodward and Mr. R. H. Tiddeman. The district here described includes the Vale of Glamorgan, for the most part an area of Lias with irregular scatterings of Drift; an agricultural district, famed also for its Blue Lias lime, so well known in old times at Aberthaw, and now largely manufactured at Bridgend. The basement portions of the Lias at Sutton and Southerndown, conglomeratic in character, are duly described, as well as the littoral portions of the Keuper and Rhætic Beds. A small tract of the main coalfield enters the area, bounded by Millstone Grit and Lower Carboniferous Rocks, and the Old Red Sandstone appears in inliers. The bulk of the work is taken up with a description of the Keuper, Rhætic Beds and Lias, which furnish many points of interest.

The fifteenth report by Prof. W. W. Watts on photographs of geological interest in the United Kingdom (Brit. Assoc., Cambridge, 1904) is of a most satisfactory character. A clear profit of 130*l*. has been made. This shows that the work of collecting and storing typical photographs of geological features and phenomena, and of supplying copies to teachers and others in various parts of the world, has proved a great success, and a distinct service to geological and perhaps also to geographical science. This success is due to the indefatigable energy of Prof. Watts.

In his address to the Liverpool Geological Society, Mr. T. H. Cope took as his subject types of rock-flow in the Ceiriog valley and their analogies with river structure (*Proc.* Liverpool Geol. Soc., vol. ix., part iv.). The author points out the evidence of flow structures and other terrestrial movements in igneous and metamorphic rocks, and compares them with the known movements of water.

We have received No. 37 of vol. v. of "Spelunca" (*Bulletin* and *Mémoires* de la Société de Spéléologie). This contains a number of articles on caves and on underground waters, on prehistoric remains from caves, on the present subterranean flora, on contamination of waters, and on the use of fluorescence in detecting the flow of underground streams. A report on the sources of the water of Arcier, with special reference to the water-supply for the town of Besançon, is contributed by Prof. E. Fournier to the same periodical (No. 38), and he concludes that the supply from Arcier must at all costs be abandoned. The subject has excited much controversy owing to the fact that the probable sources of contamination through porous and fissured limestones are at a distance from the outlet of the stream at Arcier.

In the ninth report of the periodic variations of glaciers by Dr. H. F. Reid and M. E. Muret (*Arch. des Sc. phys. et nat. Genève*, xviii., 1904), the general record is one of decrease.

The records of the Geological Survey of India (vol. xxxi. part iii.) contain an article by Mr. R. D. Oldham on the glaciation and history of the Sind Valley, Kashmir, a subject illustrated by six excellent photographic views, which exhibit features produced respectively by glaciers and by rivers, and afford support to the view of the author of a diversion of the drainage since the glaciers attained their greatest dimensions.

A report on the Jammu coal-fields has been written by Mr. R. R. Simpson, mining specialist to the Geological Survey of India (*Mem.* Geol. Surv. India, vol. xxxii. part iv.). The coal-fields lie in a mountainous country, varying from three thousand to nine thousand feet above sea-level, and the strike of the coal-bearing rocks does not conform to any of the main natural features. The prospects of working the coal with profit are not considered good, in present circumstances, as the expenses would be great on account of the inclined and broken character of the rocks, the possibility of landslips, and of trouble from water. Otherwise a fairly good steam-coal may be obtained.

A geological map of Cyprus, by Mr. C. V. Bellamy, has been issued by Mr. Stanford (price 6s.). It is accompanied by a key or short explanation, in which the author describes the physical features and the various geological formations which range from Cretaceous to Pliocene and Pleistocene. Between the Oligocene and Pliocene there is a break, marked by the occurrence of basic igneous rocks, which have baked and altered the Oligocene (Idalian) limestones. These igneous rocks, which comprise serpentine, variolite, gabbro, &c., form a broad belt of mountainous ground in the south-central portion of the island. The map, which is produced on a scale of 5½ English miles to one inch, is printed in colours, and clearly shows the extent of the main geological divisions. It will be a useful guide to those interested in the geology, whether from a scientific or practical point of view. The economic products include building stones, marble, pottery clay, gypsum, &c.

Our knowledge of the geology of South Africa proceeds apace. We have received vol. vii., part iii., of the *Transactions* of the Geological Society of South Africa, which contains among other articles an essay by Dr. F. H. Hatch and Dr. G. S. Corstorphine on the petrography of the Witwatersrand conglomerates, with special reference to the origin of the gold. The original explanation was that the Rand conglomerates were ancient placer deposits, in which the gold was as much a product of denudation as the pebbles which accompany it. The authors show that the theory of the subsequent infiltration of the gold is most in accordance with the facts. The gold is practically confined to the matrix of the conglomerate, and occurs there in crystalline particles in association with other minerals of secondary origin.

Mr. E. Jorissen, in the same *Transactions*, deals with some intrusive granites in the Transvaal, the Orange River Colony and in Swaziland. These old granites, mostly grey in colour, penetrate the crystalline schists which are regarded as of Archæan age, but they do not intrude into the Witwatersrand series. Mr. J. P. Johnson contributes further notes on some pigmy stone implements from Elandsfontein No. 1. They are regarded as scrapers belonging to the Neolithic stage of culture.

In his address to the South African Association for the Advancement of Science (Johannesburg meeting, 1904), Dr. Corstorphine took for his subject the history of stratigraphical investigation in South Africa, and in a table he gives the groupings successively introduced by A. G. Bain, A. Wyley and others up to those of G. A. F. Molengraaff and F. H. Hatch.

We have received from the Minister of Mines, Victoria, a diagram, compiled and drawn up by the director of the Geological Survey, Mr. E. J. Dunn, showing the yield of gold and other statistics from 1851 to 1903. The gross value of the gold is stated to be 266,945,344*l*. The greatest yield was in 1856.

We have received the annual progress report of the Geological Survey of Western Australia for 1903, by Mr. A. Gibb Maitland, Government Geologist. This includes observations on the Pibara and Murchison gold-fields, on the Arrino copper deposits, the Irwin River coal-field, &c., miscellaneous notes on minerals, including gypsum and diatomite, and notes on water supply. The report is accompanied by several maps.

The progress of vertebrate palæontology in Canada forms the subject of an essay by Mr. Lawrence M. Lambe (*Trans. Roy. Soc. Canada*, series 2, vol. x.). As he remarks, our knowledge of this life-history began when Sir William Logan, in 1841, discovered amphibian footprints in the Lower Coal-measures at Horton bluff in Nova Scotia. Since then remains of vertebrates have been found in rocks from the Silurian to the Pleistocene, and a full list is given, together with a bibliography of the subject.

In the *American Journal of Science* (December, 1904) two new species of reptiles from the Titanothere Beds (Oligocene) of Dakota, are described by Mr. F. B. Loomis. These are *Crocodilus prenasalis* and *Chrysemys inornata*. Some derived Cretaceous fossils are recorded also from the same strata, which form a part of the White River formation, and the author is led to regard the beds as of fluviatile origin.

The *American Journal of Science* for January contains an article on the submarine great canyon of the Hudson River, by Dr. J. W. Spencer. The early work of the Coast Survey brought to light a depression extending from near New York to the border of the continental shelf, and J. D. Dana was the first to recognise this feature as the submerged channel of the Hudson River, formed when the continent stood at a greater altitude above the sea than it does now. Later on, Prof. A. Linden Kohl discovered that the channel became suddenly transformed into a canyon near the continental border, reaching to a depth of 2400 feet below the surface of the submerged plain, which was then about 400 feet beneath sea-level. Following on to these observations, Dr. Spencer has pointed out that the channel was traceable to much greater depths—the canyon section having sunk from 6000 to 7000 feet, and the valley beyond to 9000 feet. He maintains that the period of great elevation coincided with the early Pleistocene. Since then there has been a subsidence to somewhat below the present level, followed by a re-elevation of 250 feet, as seen in the shallow channels of the shelf.

The *American Journal of Science* for February contains an important essay on the isomorphism and thermal properties of the feldspars, by Mr. Arthur L. Day and Mr. E. T. Allen. To the same journal Dr. Albrecht Penck contributes an interesting article on climatic features in the land surface, and indicates how the features of past as well as present climates may be discerned. Instances are seen in areas that were formerly covered by ice and are now exposed to river action. They are seen in desert regions, as in those of the Great Salt Lake and of the Sahara, where ancient shore lines and old river valleys have been traced. In some mountain areas evidence of river action, preceding glacial action, has been noticed. Dr. Penck points out that a study of the oscillations in the situation of the climatic belts of the earth is fraught with interest, and that observations on the erosional forms of rocks and on the corresponding deposits derived from them assist in the interpretation of climatic conditions.

In the *Bulletin* from the Laboratories of Natural History of the State University of Iowa (vol. v., No. 4) there is a series of papers on the loess by Prof. B. Shimek. The loess of Natchez and of the lower Mississippi valley is of special interest, inasmuch as in that region loess was first recognised in America by Lyell in 1846. The researches of the author afford arguments against both the aqueous and glacial theories of its origin. The characteristic fossils are terrestrial upland species of land snails. Even the extremely delicate shells of snails' eggs are preserved in the loess. Natchez lies far south of the limits of glaciation, and the molluscan fauna does not support the notion of a glacial climate. The æolian theory offers the best explanation. The discovery of human remains in a deposit regarded as loess near Lansing, in Kansas, is discussed, and Prof. Shimek concludes that the deposit is not loess, but a talus. Considering, again, the relations of loess to the Iowan drift, the author points out that there were several periods of loess formation, inter-Glacial and post-Glacial. Far beyond the border of the newer drift sheets, however, the sharp lines of distinction between the successive accumulations disappear, and there the deposits of loess probably represent the combined accumulation of several inter-Glacial and later drift periods. The essays are illustrated by pictorial views and figures of the mollusca. In another article Mr. F. J. Seaver describes and illustrates the Discomycetes of eastern Iowa.

The "Materials and Manufacture of Portland Cement," by Mr. E. C. Eckel, with an essay on the cement resources of Alabama, by Mr. E. A. Smith, form the contents of *Bulletin* No. 8, Geological Survey of Alabama. In that State there is found an extensive series of limestones capable of furnishing material for the manufacture of Portland cement, while clays and shales necessary to complete the mixture are abundant.

In an article on the genesis of the magnetite deposits in Sussex Co., New Jersey (*Mining Magazine*, December, 1904), Mr. Arthur C. Spencer concludes that they are connected in origin with intrusive dioritic pegmatites. To the same magazine Mr. W. H. Heydrick contributes a paper on the physical and commercial conditions of the Kansas oil-fields. The area extends over more than ten thousand square miles. In 1889 the yield was 500 barrels of oil, while in ten months during 1904 the yield was more than four million barrels.

A reconnaissance in Trans-Pecos Texas, by Mr. G. B. Richardson (Univ. of Texas, Mineral Survey, *Bulletin* No. 9), was undertaken mainly to determine the conditions of occurrence of underground water. The author was enabled, however, to make general observations on the successive formations from the pre-Cambrian to the Cretaceous and Quaternary, and on the occurrence of coal, salt, petroleum, and sulphur. The presence of underground water was found to be widespread, but in a number of places the wells contain much gypsum and other salts. The report is accompanied by a geological map and pictorial views.

Some account of the exploration of the Potter Creek Cave in California, is given by Mr. W. J. Sinclair (Univ. of California Publications, *Amer. Archaeol. and Ethnol.*, vol. ii., No. 1). The cave is about one mile south-east of the United States fishery station at Baird, on the McCloud River, and it lies in a belt of carboniferous limestone at an elevation of 1500 feet above sea-level, and about 800 feet above the river-level at the mouth of Potter Creek. Remains of various vertebrate animals were obtained from fan-like deposits of earth and stalagmite-cemented breccia, which formed the floor in a large chamber, above which there were vertical chimney-like openings. With the exception of the stalagmitic growths and fallen blocks, the entire cave deposit was brought in through the vertical chutes. Apart from fragments, more than 4600 determinable specimens were collected of dissociated limb bones, jaws, and teeth. Complete skeletons were not common. Associated parts of the skeletons of squirrels and wood-rats, of a snake (Crotalus), and a bat were found; also several complete limbs of *Arctotherium simum*, remains of Megalonyx, Mastodon, *Elephas primigenius*, and a new genus named Euceratherium, a member of the cavicorn division of Artiodactyla, which combines characters of several groups. Of the fifty-two species listed, twenty-one belong to extinct forms. No human remains were found, but some very doubtful "implement-like bone fragments" are described and figured. The cave-fauna is older than the Glacial period in California, and it is remarked that the 1500 foot contour marks approximately the present elevation of an earlier valley stage beneath which the existing cañons are trenched.

FORTHCOMING BOOKS OF SCIENCE.

MESSRS. BAILLIÈRE, TINDALL AND COX announce:—"Mucous Membranes," by W. Stuart-Low; "Conjunctivitis," by N. Bishop Harman; "Surface Anatomy," by T. Gillman Moorhead; "Elementary Microscopy," by F. Shillington Scales; "Lectures on Appendicitis, Hernia, and Perforating Ulcers," by G. R. Turner; "Surgical Diagnosis," by H. W. Carson; "Medical Diagnosis," by Dr. A. J. Whiting; "Manual of Anatomy," by Prof. A. M. Buchanan; "Manual of Midwifery," by Dr. H. Jellett; "Psychiatry," by Prof. Bianchi, translated by Dr. J. MacDonald; "Manual of Practical Sanitary Science and Laboratory Work," by Dr. D. Somerville; "Asepsis," by Dr. A. S. Vallack; "Dictionary of New Medical Terms," by Dr. A. M. Gould; "Military Hygiene," by Major R. Caldwell; "Veterinary Toxicology," by Lieut.-Col. J. A. Nunn; "Lectures on Clinical Surgery," by Dr. H. C. Hinder; "Diseases of the Foot of the Horse," by H. Caulton Reeks; "Artistic Anatomy of Animals," by E. Cuyer, translated by G. Haywood; "Coroners' Duties," by Dr. R. H. Wellington; "Pathology," by Dr. W. D'Este Emery; and new editions of "Röntgen Rays in Medical Work," by Dr. D. Walsh; "Manual of Veterinary Hygiene," by Lieut.-Col. F. Smith; and "Animal Parasites," by Prof. G. Neumann, translated by Dr. G. Fleming, and edited by Prof. J. Macqueen.

In Messrs. A. and C. Black's list we notice:—"The Metaphysics of Nature," by Carveth Read, and a "Treatise on Zoology," edited by Dr. E. Ray Lankester, F.R.S., part v., "Mollusca."

The announcements of the Cambridge University Press include:—"The Lands of the Eastern Caliphate," by G. Le Strange; "Trees, vol. iii., Inflorescences and Flowers," by Prof. H. Marshall Ward, F.R.S.; "The Origin and Influence of the Thorough-bred Horse," by Prof. W. Ridgeway; "The Plague," by Dr. W. J. Simpson; and "Immunity in Infectious Diseases," by Prof. E. Metchnikoff, authorised English translation by F. G. Binnie, illustrated.

The list of Messrs. Cassell and Co., Ltd., contains:—"The Book of Photography, Practical, Theoretic, and Applied," edited by P. N. Hasluck, illustrated; "Cassell's Popular Gardening," edited by W. P. Wright, illustrated; "Nature's Riddles, or the Battle of the Beasts," by W. H. Shepheard-Walwyn, illustrated; "Cassell's Physical Educator," by E. Miles, illustrated; and "Pictorial Practical Tree and Shrub Culture, by W. P. Wright and W. Dallimore, illustrated; "Certificate Geometry," by W. P. Workman and A. G. Cracknell; and "General Elementary Science, part ii., Plant and Animal Life," by W. S. Furneaux.

Messrs. Chapman and Hall, Ltd., promise:—"The Principles of Heredity," by Archdall Reid.

The Clarendon Press list contains:—Schiaparelli's "Astronomy in the Old Testament," authorised English translation, with additions by the author; "The Faroes and Iceland," by N. Annandale; "The Farther East," by A. Little; "Index Kewensis Plantarum Phanerogamarum, supplementum secundum, nomina et synonyma omnium generum et specierum ab initio anni 1896 ad finem anni 1900 complectens," pars. i., fasc. ii; Goebel's "Organography of Plants," authorised English translation, by Prof. I. Bayley Balfour, F.R.S., vol. ii., "Special Organography"; Knuth's "Flower Pollination," authorised English translation, by Prof. J. R. Ainsworth Davis; Solereder's "Anatomical Characters of the Dicotyledonous Orders," authorised English translation, by L. A. Boodle; and "The Masai: their Language and Folklore," by A. C. Hollis.

Messrs. Archibald Constable and Co. will publish:—"Leprosy and Fish Eating," by Dr. J. Hutchinson, F.R.S.; "Principles of Practical Microscopy," by Dr. A. E. Wright; "Physiology of the Nervous System," by J. P. Morat, translated and edited by Dr. H. W. Syers; "The Lymphatics," by G. Delamere, P. Poirier, and B. Cunéo, translated and edited by C. H. Leaf; "Surgical Anatomy of the Lymphatic Glands," by C. H. Leaf; "The Prevention of Disease," translated from the German by Dr. W. Evans; "Steam Boilers," by H. H. Powles, illustrated; "Steam Pipes," by W. H. Booth, illustrated; "The Economic and Commercial Theory of Heat Power Plants," by Prof. R. H. Smith; "Motor Vehicles and Motors," by W. W. Beaumont, vol. ii., illustrated; "Compressed Air: its Production, Uses and Applications," by G. D. Hiscox, illustrated; "Reinforced Concrete Construction," by A. W. Buel and C. S. Hill, illustrated; "Cotton Seed Products: a Manual of the Treatment of Cotton Seed for its Products and their Utilisation in the Arts," by L. L. Lamborn, illustrated; "Plat and Profile Book for Civil Engineers and Contractors," by H. F. Dunham; "Engineering Contracts and Specifications," by Prof. J. B. Johnson; "Earthwork and its Cost," by H. P. Gillette, illustrated; "The Elements of Water Supply Engineering," by E. S. Gould; "Tables of Squares," by J. L. Hall; "Mechanics—Problems for Engineering Students," by Prof. F. B. Sanborn, illustrated; "The Railway Transition Spiral," by Prof. A. N. Talbot; "Tables for Obtaining Horizontal Distances and Differences of Level from Stadia Readings," by Noble and Casgrain; "Technic of Mechanical Drafting," by G. W. Reinhardt, illustrated; "Surveying Manual," by W. D. Penee and M. S. Ketchum; "Earth Dams," by B. Bassell, illustrated; "The Design of Steel Mill Buildings, and the Calculation of Stresses in Framed Structures," by M. S. Ketchum, illustrated; "Topographical Record and Sketch Book for use with Transit and Stadia," by D. L. Turner; "Cleaning and Sewerage of Cities," by Prof. R. Baumeister, illustrated; "Field Practice of Railway Location," by W. Beahan, illustrated; "Tables of Logarithms of Lengths up to 50 Feet, varying by 1/16 of an Inch," by T. W. Marshall; "Economics of Road Construction," by H. P. Gillette; "Maxwell's Theory and Wireless Telegraphy," part i., "Maxwell's Theory and Hertzian Oscillations," by H. Poincaré, translated by K. Vreeland; part ii., "The Principles of Wireless Telegraphy," by K. Vreeland; and new editions of "Gas Engine Construction," by H. V. A. Parsell, jun., and A. J. Weed, illustrated; "Gas, Gasoline and Oil Engines," by G. D. Hiscox, illustrated; "Liquid Air and the Liquefaction of Gases," by Dr. T. O'Conor Sloane, illustrated; "Shop Kinks," by R. Grimshaw, illustrated; "Railway Track and Track Work," by E. E. R. Tratman; "City Roads and Pavements Suited to Cities of Moderate Size," by W. P. Judson, illustrated.

Messrs. J. M. Dent and Co. announce:—"Physiological Psychology," by Dr. W. McDougall.

Messrs. Duckworth and Co. promise:—"Metapsychical Phenomena," by Dr. J. Maxwell, with prefaces by Sir Oliver Lodge and Prof. Ch. Richet, translated by Mrs. Finch.

Messrs. R. Friedländer and Son (Berlin) announce:—"Annales Mycologici," vol. iii.; "Die Vögel der paläarktischen Fauna," by Dr. E. Hartert, Heft iii.; "Die Vögel Islands," by P. Hantzsch; "Analytische Übersicht der paläarktischen Lepidopterenfamilien," by C. v. Hormuzaki; "Wissenschaftl. Ergebnisse einer zoologischen Expedition nach dem Baikal-See 1900–2," by A. Korotneff, i. Lief., by W. Michaelsen, "Die Oligochaeten"; "Mitteilungen aus dem zoologischen Museum in Berlin," ii. Band, iv. Heft, by J. Thiele, "Beitrage z. Morphologiss. Arzuliden"; "Abbildungen der in Deutschland und den angrenzenden Gebieten vorkommenden Grundformen der Orchideen," by W. Müller and F. Kranzlin, illustrated; "Das Tierreich," edited by F. E. Schulze, Lief. 21, T. R. Stebbing, "Aphipoda," i.; Lief. 22, H. Stichel and H. Riffarth, "Heliconiidæ"; Lief. 23, L. v. Graff, "Turbellaria, i. Accœla"; "Catalogus Mammalium tam viventium quam fossilium," by E. L. Trouessart, Quinquennale Supplementum, Anno 1904, Fasc. iii.; "Die neue Lösungs- und elektrochemische Theorie," by L. Zeschko.

Messrs. Gauthier-Villars (Paris) promise:—"Précis de Photographie générale," by E. Belin, tome ii., "Applications scientifiques et industrielles"; "Traité d'Analyse," by Prof. E. Picard, tome iv., "Équations aux Dérivées partielles"; and "Leçons de Mécanique céleste," by Prof. H. Poincaré, tomes ii. and iii.

Mr. Henry J. Glaisher announces:—"Mucomembranous Entercolitis," by Dr. Froussard, edited by Dr. E. Blake; "The Westminster Hospital Reports, 1903–4," vol. xiv., edited by Drs. E. P. Paton and P. Stewart; "The Intestinal Catarrhs," by Dr. E. Blake; "X-Ray Charts," by Dr. R. J. Cowen; "A Short Essay on Insanity," by C. Williams; and "Ethyl Chloride in Surgical and Dental Practice," by A. de Prenderville.

The announcements of Messrs. Charles Griffin and Co., Ltd., are:—"An Introduction to the Design of Beams, Girders, and Columns, in Machines and Structures, with Examples in Graphic Statics," by W. H. Atherton, illustrated; "Smoke Abatement," by W. Nicholson, illustrated; and new editions of "Electrical Practice in Collieries," by D. Burns, illustrated; "The Principles and Construction of Pumping Machinery (Steam and Water Pressure)," by H. Davey, illustrated; "The Metallurgy of Steel," by F. W. Harbord, illustrated; "Gas, Oil, and Air Engines," by B. Donkin, illustrated; and "Properties of Matter" (vol. i. of "A Text-Book of Physics"), by Profs. J. H. Poynting, F.R.S., and J. J. Thomson, F.R.S., illustrated.

Mr. Heinemann directs attention to:—"Publications of an American Archaeological Expedition to Syria in 1899–1900, part iv., Semitic Inscriptions," by Dr. E. Littmann, illustrated.

Messrs. Hodder and Stoughton's list includes:—"Nerves in Order, or the Maintenance of Health," by Dr. A. T. Schofield; "Modern Electricity," by J. H. and K. J. Hora; "Woodmyth and Fable," by E. Thompson Seton; "The Lure of the Labrador Wild, a Story of the Exploring Expedition conducted by Leonidas Hubbard, jun.," by D. Wallace; and "The New Knowledge, a Simple Explanation of the New Physics and the New Chemistry in their Relation to the New Theory of Matter," by Prof. R. K. Duncan.

Mr. U. Hoepli (Milan) announces:—"Contribuzioni alla Storia della Botanica," by O. Penzig; and "La Flora Legnosa del Sottoceneri," by A. Bettelini.

In Messrs. Longmans and Co.'s list we notice:—"A Systematic Course of Practical Organic Chemistry," by L. G. Radcliffe; "Elementary Steam Engineering," by H. W. Metcalfe, illustrated; and "An Atlas of Dermatology," by Dr. M. Dockrell; "A Common Humoral Factor of Disease, and its Bearing on the Practice of Medicine," by Dr. F. Hare, 2 vols.; "Ice or Water, another Appeal to Induction from the Scholastic Methods of Modern Geology," by Sir H. H. Howorth, K.C.I.E., F.R.S.

Messrs. Macmillan and Co., Ltd., direct attention to:—"The Life History of British Flowering Plants," by Lord Avebury, F.R.S.; "The Historical Relations of Medicine and Surgery," being the address delivered at the St. Louis Exhibition by Prof. T. Clifford Allbutt, F.R.S.; "Tribes of the Malay Peninsula," by W. W. Skeat, illustrated; "A Treatise on Chemistry," by Sir H. E. Roscoe, F.R.S., and Prof. C. Schorlemmer, F.R.S., i., "The Non-Metallic Elements," revised by Drs. H. G. Colman and A. Harden; "Stonehenge Astronomically Considered," by Sir Norman Lockyer, K.C.B., F.R.S., illustrated; "The Theory of Light," by Dr. C. E. Curry; "Magnetism and Electricity for Students," by H. E. Hadley; "Lectures on the Philosophy of Kant, and other Lectures and Essays," by the late Prof. H. Sidgwick; "Philosophical Studies," by D. G. Ritchie, edited by Prof. R. Latta; and a new edition of "A Handbook of Metallurgy," by C. Schnabel, translated and edited by Prof. H. Louis.

Messrs. Masson and Co. (Paris) promise:—"Traité de Chimie minérale," edited by H. Moissan, tome ii., fasc. i.; tome iv., fasc. i.; "Le Chauffage des Habitations, par Circulation d'Air chaud, de Vapeur ou d'Eau chaude," by R. Périssé; "Le Chauffage électrique," by Lévylier; "Les Moulins à Vent," by Prof. Hérisson; "Le Vinaigre," by Astruc; "Procédés de Commande mécanique par l'Électricité," by Capt. Frilley; and "L'Industrie de l'Or," by L. M. Granderye.

Messrs. Methuen and Co. announce:—"Archæology and False Antiquities," by Dr. R. Munro.

Mr. John Murray's list includes:—"Lhasa and its Mysteries," by Lieut.-Col. L. A. Waddell, C.B., illustrated; "Our Sudan, its Pyramids and Progress," by J. Ward; "An Expedition into the Central Tian Shan, carried out in the Years 1902–1903," by Dr. G. Merzbacher, illustrated; "An Account of the Rothamsted Experiments," by A. D. Hall; "Recent Development in Biological Science," by W. B. Hardy, F.R.S.; "Descartes: his Life and Times," by E. S. Haldane, illustrated; "Artillery and Explosives," essays and lectures written and delivered at various times, by Sir A. Noble, K.C.B., F.R.S., illustrated; "Growth and Spread of Culture," by Prof. E. B. Tylor, F.R.S., illustrated; and new editions of "Marine Boilers, their Construction and Working," dealing more especially with tubulous boilers, based on the first edition of the work by M. L. E. Bertin, edited by L. S. Robertson, illustrated; "The Vegetable Garden, or the Edible Vegetables, Salads and Herbs Cultivated in Europe and America," by W. Robinson.

Messrs. George Newnes, Ltd., promise:—"Reptile Life," by W. P. Pycraft.

Messrs. Oliver and Boyd (Edinburgh) direct attention to:—"Structural and Field Geology for Beginners in Geology and Students of Mining, Civil Engineering, Agriculture, Public Health, &c.," by Prof. J. Geikie, F.R.S., illustrated.

Messrs. G. P. Putnam's Sons give notice of:—"The Case for Physical Culture," by H. I. Hancock, illustrated; "The Jordan Valley and Petra," by Prof W. Libbey and Rev. F. E. Hoskins, illustrated; "Physical Regeneration," by J. Cantlie, illustrated; "The Trees of North-Eastern America," with introduction by N. L. Britton; and new editions of "The Shrubs of North-Eastern America," by C. S. Newhall, illustrated; "An Introduction to Vertebrate Embryology based on the Study of the Frog and the Chick," by Dr. A. M. Reese, illustrated; "Materia Medica for Nurses," by L. L. Dock; and "Thinking, Feeling, Doing," by Dr. E. W. Scripture, illustrated.

The list of the Walter Scott Publishing Co. includes:—"Diet and Hygiene for Infants," by Dr. F. H. Alderson.

Messrs. Swan Sonnenschein and Co., Ltd., announce:—"The History of Philosophy," by Dr. J. E. Erdmann, fifth German edition, revised by W. B. Erdmann, an English abridgment, translated and edited by W. S. Hough; "Student's Text Book of Zoology," by A. Sedgwick, F.R.S., vol. ii., illustrated; "The Races of South Africa: their Migrations and Invasions, showing the Intrusion of the Stronger Races into Hunting Grounds of the Ancient Abatura or Bushmen, the Aboriginal Cave Dwellers of the Country," by G. W. Stow, illustrated; "Physiological Psychology," a translation of the fifth and wholly re-written (1902–3) German edition, by Prof. E. B. Titchener, vol. ii., illustrated; and new editions of "Introduction to the Study of Organic Chemistry," by J. Wade; "Sanatoria for Consumptives in Various Parts of the World," by F. R. Walters, illustrated; and "Handbook of Systematic Botany," by Dr. E. Warming, edited by Prof. M. C. Potter, illustrated.

The list of the University Tutorial Press, Ltd., comprises:—"Chemistry, First Stage, Theoretical Organic," by Dr. R. A. Lyster; "Chemistry, Junior," by R. H. Adie; "Technical Electricity," by Prof. H. T. Davidge and R. W. Hutchinson; "Magnetism and Electricity, School," by Dr. R. H. Jude; "Practical Physics," by W. R. Bower; "Properties of Matter," by C. J. L. Wagstaff; "Elementary Science of Common Life (Chemistry)," by W. T. Boone; "Physiography, Section One"; "Geometry, Junior," by W. P. Workman and A. G. Cracknell; "Geometry, Preliminary (Part i., Junior Geometry)," by the same authors; "Geometry, Theoretical and Practical," by the same authors; "Scholarship Geometry," by W. P. Workman and A. G. Cracknell; "Scholarship Elementary Science, Section i."; "Scholarship Elementary Science, Section ii., (a) Chemistry, (b) Astronomy, (c) Biology"; and new editions of "Chemical Analysis," by Drs. W. Briggs and R. W. Stewart; "Light, Text-Book of," by Dr. R. W. Stewart; "Inorganic Chemistry, Second Stage (Theoretical)," by Dr. G. H. Bailey; and "The New Matriculation Physics: Heat, Light, and Sound," by Dr. R. W. Stewart.

Mr. T. Fisher Unwin announces:—"Travels of a Naturalist in Northern Europe," by J. A. Harvie-Brown; "Siberia, a Record of Travel, Exploration, and Climbing," by S. Turner; "The Age of the Earth, and other Geological Studies," by Prof. W. J. Sollas, F.R.S.; and "Gardening for the Million," by A. Pink.

Messrs. W. Wesley and Son promise:—An authorised English edition of the "Atlas of Emission Spectra of most of the Elements," by Prof. A. Hagenbach and H. Konen, translated by Dr. A. S. King.

The following are Messrs. Whittaker and Co.'s announcements:—"Steam Turbines," by H. M. Hobart and T. Stevens; "Armature Construction," by H. M. Hobart; "Concrete-Steel, a Treatise on the Theory and Practice of Reinforced Concrete Construction," by W. Noble Twelvetrees; "Practical Wireless Telegraphy and Telephony," by Prof. Mazzotto, translated by S. R. Bottone; and new editions of :—"Electricity in its Application to Telegraphy," by T. E. Herbert; "Central Station Electricity Supply," by A. Gay and C. H. Yeaman: "The Alternating-Current Circuit and Motor," by W. P. Maycock; and "Radium," by S. R. Bottone.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Cambridge.—An Arnold Gerstenberg studentship will be offered for competition in the Michaelmas term of 1906. The studentship will be awarded by means of essays. Every candidate must send on or before October 1, 1906, an essay on one of the subjects printed below addressed to Dr. James Ward, Trinity College. The studentship, which will be of the annual value of nearly 90*l.*, will be tenable for two years, upon the condition that at the end of the first year the student's progress in philosophical study is deemed satisfactory by the board of managers. The subjects for essays are :—(1) a philosophical discussion of the doctrine of energy and particularly of the new theory of energetics; (2) a critical examination of Descartes' philosophy of nature; (3) the relation of mathematics and the theory of probability to physics; (4) the theory of psychophysical parallelism; (5) the scope and methods of comparative psychology; (6) the philosophical import of post-Darwinian theories of natural selection.

The principal and the professors at McGill University, Montreal, have nominated Mr. L. V. King, a student in the faculty of arts, to the Canadian scholarship lately established at Christ's College.

An exhibition of 50*l.* a year tenable for two years is offered by the governing body of Emmanuel College to an advanced student commencing residence at the college in October, 1905. Applications should be sent to the master of Emmanuel (from whom further particulars may be obtained) not later than October 1.

The local examinations and lectures syndicate is about to elect an assistant secretary for the department of the local lectures. The appointment will be in the first instance for one year. The stipend will be 150*l.* in an ordinary year, and 200*l.* in those years in which summer meetings are held. Graduates of the university who desire to offer themselves as candidates are requested to send their names before May 8 to the Rev. D. H. S. Cranage.

The London School of Tropical Medicine has been admitted as a school of the University of London in the faculty of medicine in tropical medicine only.

The committee of the Liverpool School of Tropical Medicine has appointed Mr. R. T. Newstead lecturer in economic entomology and parasitology.

The fourth annual students' soirée of the Sir John Cass Technical Institute will be held in the institute, Jewry Street, Aldgate, E.C., on Saturday, March 18. Exhibits and demonstrations referring to the work of the various departments form part of the programme.

It is reported, says *Science*, that Mr. Andrew Carnegie has offered to give 100,000*l.* to the University of Virginia on the condition that the authorities of the institution raise a similar amount from other sources, and that the late James C. Carter, the eminent New York lawyer, has bequeathed 40,000*l.* to Harvard University. *Science* also states that at the first of the winter convocations of the George Washington University a gift of property, estimated to be worth 20,000*l.*, was announced for the establishment of a chair and course of graduate study on the history of civilisation. Various sums of money raised by the trustees and alumni association, aggregating 55,000*l.*, were also announced.

A Commission was appointed a few years ago to inquire into the condition of manual and practical instruction in Irish primary schools, and, as the result of the recommendations made by this Commission, instruction in elementary experimental science was introduced into the primary schools of Ireland. The results of this teaching have, in the opinion of competent authorities, been in every way satisfactory. Not only has the educational value of experimental science again been demonstrated, but its beneficial effects on the progress of Ireland's industries and agriculture have been made clear. Notwithstanding the success which naturally has followed the introduction of practical instruction in scientific principles into Irish elementary schools, the Treasury has refused to renew the small grant required to meet the necessary expenditure, and the work of organising science instruction in the schools—after four years—is being stopped. It is difficult indeed to understand so retrograde a policy. The incompleteness of all schemes of education which ignore the claims of practical instruction in the fundamental facts of science has been demonstrated repeatedly; the connection between American and German industrial success and the scientific systems of education established in these countries has become familiar to all interested in their country's welfare, so that no excuse—not even the urgent need of economy in national expenditure—can justify this action of the Treasury. It is to be hoped earnestly that steps may yet be taken to avert what would be nothing short of a calamity to Ireland, and that the work, which has begun so auspiciously under the present organisers of science instruction, instead of being stopped may be broadened and extended.

It is stated in the *Times* that the committee, presided over by Mr. Haldane, M.P., appointed to consider the allocation of the increased grant-in-aid of education of a university standard in arts and science has now finished its inquiry. Excluding 9000*l.* to be allotted later in the financial year, the committee proposes that the sum of 45,000*l.* (making a total grant of 54,000*l.*) be allotted as follows:—Manchester, 6000*l.*; University College, London, 5000*l.*; Liverpool, 5000*l.*; Birmingham, 4500*l.*; Leeds, 4000*l.*; King's College, London, 3900*l.*; Newcastle-on-Tyne, 3000*l.*; Nottingham, 2900*l.*; Sheffield, 2300*l.*; Bedford College, London, 2000*l.*; Bristol, 2000*l.*; Reading, 1700*l.*; Southampton, 1700*l.*; Dundee, 1000*l.* The committee expresses the view that the time has come for making a new departure in the principle on which State assistance is to be given to the highest education. It is recommended that a moderate sum should be set aside for distribution by way of payment to post-graduate students from the university colleges who devote themselves for one, two, or three years to special problems; and that to ensure the money being applied most efficiently to the stimulation of individual study, as distinguished from the general purposes of the college to the development of which other sums out of the grant are directed, the distribution should assume the form of a grant made directly to the student on the advice of some impartial authority. It is also suggested that the grant-in-aid should in future be made to a committee, instead of to the colleges direct, and that this committee should make an annual report to the Treasury, to be laid before Parliament. In conclusion the committee urges the necessity of leaving to the advisory committee discretion to deal with particular circumstances as they arise.

SOCIETIES AND ACADEMIES.

London.

Royal Society, February 9.—"On the Stellar Line near λ 4686." By Sir Norman **Lockyer**, K.C.B., F.R.S., and F. E. **Baxandall**, A.R.C.Sc.

In this paper the authors direct attention to a well-marked line of unknown origin which appears in one of the Kensington photographs of the helium spectrum near λ 4686.

It is shown that a conspicuous line near the same wave-length occurs in the spectra of the chromosphere, nebulæ, bright-line stars, certain Orion stars, and in ζ Puppis, the star the spectrum of which was found by Prof. Pickering to contain a new series of lines which he considered to belong to hydrogen.

The mean wave-length of the stellar line, as derived from the available published records, is shown to agree very closely with the wave-length of the line in the laboratory spectrum, and the authors conclude that the identity of the two lines is probably a real one.

Rydberg has shown that the line near λ 4686 is the first line in the principal series of hydrogen, and the authors of the present paper consider that the "strange" line in the helium spectrum is probably none other than the same line. They can, however, assign no reason for its appearance in only one of the numerous photographs of the helium spectrum taken at Kensington.

"Note on the Spectrum of μ Centauri." By Sir Norman **Lockyer,** K.C.B., F.R.S., and F. E. **Baxandall,** A.R.C.Sc.

In this note the authors give an analysis of some of the bright lines in the spectrum of μ Centauri. This star not being available at Kensington, an excellent reproduction by Prof. Pickering was used as a basis for the analysis.

The chief bright lines belong to hydrogen, as Pickering and other observers have pointed out. The minor bright lines, however, have hitherto had no origin suggested for them. In this note it is shown that the most marked of the minor bright lines agree very closely in position with the strongest enhanced lines of iron, and the authors conclude that the stellar and terrestrial lines are probably identical in origin. It is pointed out that the same lines are conspicuous in the spectra of Novæ in their earlier stages.

"The Arc Spectrum of Scandium and its Relation to Celestial Spectra." By Sir Norman **Lockyer,** K.C.B., F.R.S., and F. E. **Baxandall,** A.R.C.Sc.

In this paper a record is given of the lines in the arc spectrum of the rare element scandium between λ 3900 and λ 5720. The photograph used for reduction was taken with a large Rowland concave grating, having a ruled surface of $5\frac{3}{4}\times 2$ inches ($14\frac{1}{2}\times 5$ cm.) and a radius of 21 feet 6 inches. The scale of the photograph is such that the distance between K and D is $30\frac{1}{4}$ inches, or 77 cm. This is equivalent to 2·6 tenth-metres per millimetre.

An analysis of the lines is given with regard to their appearance in the Fraunhoferic spectrum. It is shown that nearly all the stronger lines occur as solar lines, but the great majority of the lines weaker than intensity 6 (maximum intensity 10) are missing from the solar spectrum.

Short analyses are also given of the relation of the scandium arc lines to the lines in the spectra of the chromosphere, sun-spots, and stars. The strongest scandium lines are shown to be specially prominent in the chromospheric spectrum, the same lines being conspicuous in stellar spectra of the Polarian type (*e.g.* γ Cygni). In the higher stellar type Cygnian (α Cygni), the strongest scandium lines are present, but only weak. At the still higher stages of stellar spectra the scandium lines are lacking.

With regard to sun-spot spectra, the only solar-scandium line (λ 5672·047) given by Rowland in the region F to D, is found to be nearly always well affected, and it often occurs amongst the twelve most widened lines recorded at Kensington in spot spectra.

"On Europium and its Ultra-violet Spectrum": Sir William **Crookes,** F.R.S.

Exner and Haschek have measured the wave-lengths of the europium lines[1] from material supplied by Demarçay. A comparison of their lines with the present author's shows that the material was by no means pure. Urbain's europia is not quite so free from impurities as his gadolinia. The author has been able to detect in his photographs the following lines:—Gadolinium is represented by very faint lines at 3450·55, 3481·99, 3585·10, 3646·36, 3654·79, 3656·32, 3664·76, 3697·90, 3699·89, 3743·62, 3768·52, 3796·58, 3805·70, 3850·83, 3851·16, 4050·08, 4225·33. Yttrium is represented by the line at 3774·51, lanthanum by the line at 3988·66, and calcium by the two lines at 3933·825 and 3968·625.

February 9 and February 23.—"Phosphorescence caused by the Beta and Gamma Rays of Radium." By G. T. **Beilby.** Communicated by Prof. Larmor, Sec. R.S. Part i. read February 9, part ii. read February 23.

The conclusions arrived at in these papers may be summarised as follows:—

(1) Certain types of phosphorescence are due to the molecular movement or displacement which is produced by heat, by mechanical stresses, or by radiant energy.

(2) Certain other types are distinguished by their appearance in three stages, called here primary, secondary, and revived phosphorescence. These can be explained as due to atomic changes in which chemical affinity is the controlling factor.

(3) The phenomena of this type appear to support the view that a species of electrolysis occurs in solids exposed to the β or kathode rays; that the products of electrolysis are insulated from each other, as in a viscous electrolyte; and that it is the breaking down of this insulation with the re-combination of the ions which causes revived phosphorescence.

When the canary-yellow crystals of barium platinocyanide are exposed to the β and γ rays for some hours, they turn red, and their phosphorescence in the rays falls to 8 per cent. of its original value. Neither the colour nor the phosphorescence is restored by exposure to sunlight or to diffused daylight. The only way completely to restore these qualities is to dissolve the salt in water and re-crystallise it. In this way the reddened salt is completely re-converted into the yellow form, and there are no signs that the reddening has been associated with any permanent chemical change. The possible physical changes were, therefore, investigated. When the crystalline structure of the yellow salt is impaired, either by mechanical flowing or by dehydration by heat, there is a very conspicuous colour change, the canary-yellow giving place to an intense brick-red colour, while the phosphorescence in the radium rays falls to 2 per cent. of its original value. By solution and crystallisation these amorphous forms are restored to the yellow crystalline state with its full phosphorescent value. The effects produced by the β rays are, therefore, closely analogous to those produced by the change from the crystalline to the amorphous state. In the light of the author's earlier observations on the phase changes $A \rightleftarrows C$ in metals and salts, it was to be expected that the change $C \rightarrow A$, produced by mechanical flow, would be reversed by raising the temperature of the substance to the stability point of the A phase. Making due allowance for the difficulty caused by the presence of water of crystallisation and its partial loss on heating the salt, it was found that the change $A \rightarrow C$ could be brought about in the mechanically-flowed salt at a temperature of about 90°, the colour being thereby changed from red to yellow, and the phosphorescence raised from 2 per cent. to 33 per cent. of its original value. It was found that the crystals reddened by the rays could also be partially restored to their former condition of colour and phosphorescence by quickly heating them in a sealed capillary tube to about 120°. By this treatment the phosphorescence was raised from 8 per cent. to 33 per cent. of its original value in the yellow crystals. The analogy between the phase changes caused by mechanical flow and the change which results from exposure to the β rays is thus complete, and it is concluded that the over-stimulation to which the vibrating molecules of the platinocyanide crystals are subjected under the action of the β rays during the preliminary stage of bright phosphorescence results in a state analogous to that of elastic fatigue in vibrating metal wires or glass fibres. Up to a certain point, this fatigue may be recovered from, that is to say, if the relative displacement of the molecules from their proper crystalline relations has not passed beyond a certain stage; but beyond this stage there is no power of self-recovery, and heat is necessary to endow the molecules with freedom of movement sufficient to enable them to return to their crystalline positions. The final stage of permanent fatigue or over-strain in the salt corresponds with the amorphous condition which results from mechanically-produced flow. The comparative instability of the crystalline structure in this salt has thus been the means of directing attention to the part which may be played by physical structure in phosphorescence. But the persistence of phosphorescence, even in the amorphous state, gives an equally clear indication that a more general explanation of these phenomena is still needed.

This further explanation was reached by a study of the action of the β and γ rays on quartz, glass, calcspar, and the haloid salts of potassium. In these substances, in addition to a primary phosphorescence, the rays produce certain well-marked coloration effects; quartz is turned brown, calcspar faint yellow, glass purple or brown, potassium chloride reddish-violet, and bromide and iodide blue to green. Further, whether the coloration lasts for months or only for a few moments, it is found that phosphor-

[1] "Wellenlängen-Tabellen für Spektralanalytische Untersuchungen," F. Deuticke. (Leipzig and Vienna, 1902.)

escence is revived when the substance is heated, while the colour fades or disappears. In quartz, glass, and calcspar it is easy to locate the seat of phosphorescence within the layers which have been penetrated and coloured by the rays. This penetration may take place to the depth of several millimetres, and in materials like quartz, glass, or calcspar it is certain that whatever changes occur in these layers must be chemically self-contained and quite removed from atmospheric influences. The view, therefore, that coloration is due to the reduction of one of the elements of the substance, *e.g.* potassium in glass, affords only a partial explanation of the phenomena. It is necessary to suppose that the separation and retention of the metal ions must equally involve the separation and retention of the ions of the acid radicle with which the metal had been combined. Further, in order that the different ions may be kept apart, the unaltered molecules must act as barriers or insulators to prevent their re-combination. But the molecules are not always immovable barriers, for, as the temperature is raised, their mobility is increased, and their insulating power is correspondingly diminished. Experiments were made on the storage of latent phosphorescing power at all temperatures between -100° and $+300^\circ$. While for each substance there is a range of temperature over which its storage capacity is at a maximum, yet the range over which storage can take place is sometimes very wide. In calcspar, storage occurs over the whole range investigated, while in crystallised platinocyanide of barium it was only observed between -100° and -50°.

February 16.—"Polarised Röntgen Radiation." By Dr. Charles G. **Barkla**. Communicated by Prof. J. J. Thomson, F.R.S.

Experiments on secondary radiation from gases and light solids subject to X-rays led to the theory that during the passage of Röntgen radiation through such substances each electron has its motion accelerated by the intense electric fields in the primary pulses, and consequently is the origin of a secondary radiation which is most intense in the direction perpendicular to that of acceleration of the electron, and vanishes in the direction of that acceleration. The direction of electric intensity at a point in a secondary pulse is perpendicular to the line joining that point and the origin of the pulse, and is in the plane passing through the direction of acceleration of the electron.

A secondary beam the direction of propagation of which is perpendicular to that of the primary will, according to this theory, be plane polarised, the direction of electric intensity being parallel to the pulse front in the primary beam. If the primary beam be plane polarised, the secondary radiation from the electrons has a maximum intensity in a direction perpendicular to that of electric displacement in the primary beam, and zero intensity in the direction of electric displacement.

In these experiments the secondary radiation from light substances was too feeble to allow accurate measurement of the intensity of the tertiary radiation.

A consideration of the method of production of primary Röntgen rays in an X-ray tube, however, leads one to expect partial polarisation of the primary beam proceeding from the antikathode in a direction perpendicular to that of propagation of the impinging kathode rays, for there is probably at the antikathode a greater acceleration along the line of propagation of the kathode rays than in a direction at right angles; consequently, in a beam of X-rays proceeding in a direction perpendicular to that of the kathode stream, there should be greater electric intensity parallel to the stream than in a direction at right angles.

Using such a beam as the primary radiation, and a light substance, as air, paper, or aluminium, as the radiator, the intensity of a secondary beam as indicated by an electroscope was found to reach a maximum when the direction of the kathode stream was perpendicular to that of propagation of the secondary beam, and a minimum when these two were parallel.

A number of experiments made this evidence of partial polarisation of the primary radiation conclusive.

When heavier metals, such as copper, tin, and lead, which emit a secondary radiation differing considerably in character from the primary producing it, were used as the radiators, no variation in intensity of secondary radiation was observed as the bulb was rotated, though experiments were made with primary radiations varying considerably in penetrating power.

Geological Society, February 17.—Dr. J. E. Marr, F.R.S., president, in the chair.—Annual general meeting.—In his anniversary address, the president directed attention to the classification of the sedimentary rocks, pointing out that the arrangement of the events which, taken together, constitute earth-history, according to their proper sequence in time must ever remain the territory of the geologist in which he will pursue his labours by exclusively-geological methods. He pointed out that, since the time of William Smith, and mainly by the adoption of his principles, the classification of the strata had progressed towards perfection by the method of successive approximations. He directed attention to the many similarities between the records of the geological column and the records preserved in the "meteorograms" of meteorologists. In each case the records were impressed as zigzag and broken lines, though an additional difficulty occurred in the case of the geological records owing to their frequently-blurred nature. Further, the meteorologist had his chronometer, whereas the geologist must construct his time-scale from the records on what might, for purposes of comparison, be referred to as the "geograms," or strips of the geological sediments. In some cases the lines of the geograms closely coincided with time-lines, in other cases they departed therefrom more or less widely, and it was one of the tasks of the geologists, from study of the geograms, to attempt to draw in the time-lines. It was to be remembered, however, that however closely the time-lines and lines of the records coincided, they were not the same lines. The principal variations in the records of the geograms are due to alternate formation and cessation of deposit; to the differences in character of the deposits owing to various local conditions; to accumulation of contemporaneous volcanic material; to variations in the nature of the earth-movements; to changes in the nature of the included organisms; and lastly to climatic changes, and proceeded to consider the significance of these records as bearing upon the classification of the sediments. The president advocated the adoption of a triple classification, such as had been already tacitly adopted in the case of some of the sediments, as, for instance, those of Jurassic age, where divisions were made according to (1) lithological change, (2) organic change, and (3) time; and pointed out how such a classification could be adopted without any violent changes in an existing nomenclature or in the rules of priority. He illustrated the suggested changes by a more detailed discussion of the classification of the Ordovician strata, and pointed out that we had names which might be used with chronological significance in the case of the divisions of the rocks of most of the great systems; and maintained that, as our knowledge increased, we could refer beds of new areas to their places among the different series, marking periods of time with a confidence similar to that with which we have long assigned strata of remote regions to one or other of the great systems.

February 22.—Dr. J. E. Marr, F.R.S., president, in the chair.—Exhibition of a series of Danish rocks illustrating (1) the share that Echinoderms may take in rock-building; (2) the transition from the Secondary to the Tertiary Era in the Baltic basin near Denmark; (3) the special conditions at the close of the Glacial Period, in the limited area where alone these rocks are now found as erratic blocks: Dr. F. A. **Bather**.—On the order of succession of the Manx slates in their northern half, and its bearing on the origin of the schistose breccia associated therewith: Rev. J. F. **Blake**.—On the wash-outs in the Middle Coal-measures of south Yorkshire: F. E. **Middleton**. The opinion of the author is that the wash-outs occupy the sites of winding streams, meandering through the alluvial tracts in which the coal-seams were being formed.

Zoological Society, February 21.—Mr. Howard Saunders, vice-president, in the chair.—A contribution to our knowledge of the varieties of *Lacerta muralis* in western Europe and North Africa: G. A. **Boulenger**.—The Nigerian giraffe (*Giraffa camelopardalis peralta*) and the Kilimanjaro Giraffe (*G. camelopardalis tippelskirchi*): R. **Lydekker**.—Dolphins from Travancore: R. **Lydekker**. In this paper the author made special reference to two specimens of the genus

Tursiops, drawings and particulars of which had been supplied to him from the Trevandrum Museum.—A second collection of mammals made by Mr. C. H. B. Grant for Mr. C. D. Rudd's exploration of South Africa: Oldfield **Thomas** and Harold **Schwann.** The collection, which has been presented to the National Museum by Mr. Rudd, was made in the Wakkerstroom district of the South-eastern Transvaal, and includes examples of twenty-six species. Several local subspecies were described, besides a new shrew from Zululand.—The greater kudu of Somaliland: R. I. **Pocock.** The author pointed out that the northern form of *Strepsiceros strepsiceros* differed from the southern in having only about five white stripes instead of nine or ten on each side of the body. The northern form should thus rank as a distinct subspecies, for which the name *chora* was available. The difference in coloration seemed to be correlated with a difference of habitat, the northern form frequenting more mountainous and less thickly-wooded country than the southern, which was frequently found in the thick jungle along river-banks as well as in the hills.

Anthropological Institute, February 28.—Prof. W. Gowland, president, in the chair.—Group marriage, with especial reference to Australia: N. W. **Thomas.** In the course of his remarks the author pointed out that the theories of Lewis Morgan were without sufficient basis. In the place of Lewis Morgan's fifteen stages, later theorists had postulated first a period of promiscuity, and following on that group marriage, so-called, which in Australia is only now being transformed into individual marriage. But here too no sufficient account had been given of the causes which led to the abolition of promiscuity. The grounds on which it was assumed that promiscuity and group marriage were stages in human development were first philological and secondly sociological. The philological grounds were shown in the paper to be wholly insufficient, and the facts of present-day Australian life to be susceptible of other explanations.

Chemical Society, March 2.—Prof. W. A. Tilden, F.R.S., president, in the chair.—The following papers were read:—The relation between natural and synthetical glycerylphosphoric acids: F. B. **Power** and F. **Tutin.** The authors have shown that the discrepancies of statement respecting the properties of the glycerylphosphates are due to contamination with salts of the di-ester. They have prepared and analysed a number of these salts in pure condition. Proof is also adduced that the conclusions of Willstätter and Lüdecke that the differences between the salts of natural (derived from lecithin) and artificial glycerylphosphoric acids are not those existing between mere optical isomerides are not justified.—The transmutation of geometrical isomerides: A. W. **Stewart.** The author assumes as a phase of the reaction the formation and disruption of a tetramethylene compound, which in the case of fumaric and maleic acids would be tetramethylene-1:2:3:4-tetracarboxylic acid, and this by disruption in two different directions would give rise to either fumaric or maleic derivatives. Illustrations of the applicability of this explanation to other cases are also given.—Linin: J. S. **Hills** and W. P. **Wynne.** Linin, $C_{23}H_{24}O_9$, a crystalline substance obtained by hydrolysis of a glucoside present in *Linum catharticum*, melts at 203°, contains four methoxyl groups, and is physiologically inactive.—The constitution of phenylmethylacridol: J. J. **Dobbie.** Hantzsch's view that the substance formed when phenylacridine methiodide is treated with an alkali is a carbinol is confirmed by the fact that the absorption spectra are different from those of the parent methiodide, and similar to those of dihydrophenylacridine.—The ultra-violet absorption spectra of certain diazo-compounds in relation to their constitution: J. J. **Dobbie** and C. K. **Tinkler.**—The latent heat of evaporation of benzene and some other compounds: J. C. **Brown.**—The reduction of *iso*phthalic acid: W. H. **Perkin,** jun., and S. S. **Pickles.** When *iso*phthalic acid is reduced with sodium amalgam at 45° it yields two tetrahydro-acids, Δ^2 and *cis*-Δ^5, and from these two others may be obtained, so that the four possible tetrahydro*iso*phthalic acids have now been prepared. The properties and reactions of these are described.—The influence of temperature on the interaction between acetylthiocyanate and certain bases. Thiocarbamides, including carboxy-aromatic groups: the late R. E. **Doran** (compiled by A. E. Dixon).—The influence of solvents on the rotation of optically active compounds. Part viii. Ethyl tartrate in chloroform: T. S. **Patterson.**—A further note on the addition of sodium hydrogen sulphite to ketonic compounds: A. W. **Stewart.**—Action of hydrogen peroxide on carbohydrates in presence of ferrous sulphate: R. S. **Morrell** and A. E. **Bellars.** In this work attempts have been made to trace the disappearance of different sugars by optical measurements during oxidation, and from the initial and final reducing powers of the solutions. The simpler acids, formic and oxalic, resulting from the oxidation, were detected, but the more important keto-acids could not be isolated, though evidence of their presence was obtained.—Studies in chlorination. The chlorination of the isomeric chloronitrobenzenes: J. B. **Cohen** and H. G. **Bennett.** It is shown that when the first two hydrogen atoms of benzene or toluene have been substituted either by two chlorine atoms or by one chlorine atom and one nitro-group the positions occupied by subsequent chlorine atoms or nitro-groups are the same.

Linnean Society, March 2.—Prof. W. A. Herdman, F.R.S., president, in the chair.—The Ashe-Finlayson "Comparascope": D. **Finlayson.** The instrument displays two objects in the same magnified field, this being attained by a secondary stage and objective at right-angles to the primary instrument, the rays being transmitted up the body of the microscope through a right-angled prism, and clearness of the two images preserved by means of a diaphragm placed longitudinally in the microscope-tube.—Zoological nomenclature: international rules and others: Rev. T. R. R. **Stebbing.** The author's paper, introductory to a discussion, insisted on the paramount importance of obtaining agreement among zoologists on this subject. Incidentally, Mr. Stebbing ventured to ask whether there were not many rules of nomenclature on which it would be satisfactory and advisable for zoologists not only to agree among themselves, but also to come to terms with their botanical colleagues. In this regard he offered some remarks in favour of adopting the year 1751 and the "Philosophia Botanica" as starting-point and basis for what might be called the Linnean era. A section of the paper was devoted to the "Nomenclator Entomologicus" of F. Weber, published in 1795, with the object of showing that the generic names in that catalogue are without value in questions of priority. While consigning various smaller details to an appendix, the body of the paper concluded with a proposal to get rid of tautonymy (as in *Trutta trutta, Apus* (*Apus*) *apus,* or other comical arrangements) by a plan distinguishing what was legal in the past from what is to be legal in the future.—Biscayan plankton collected by H.M.S. *Research* in 1901, part ii., Thaliacea: Dr. G. Herbert **Fowler.**

Mathematical Society, March 9.—Prof. Forsyth, president, and temporarily Dr. Hobson, in the chair.—The following papers were communicated:—On the projection of two triangles on to the same triangle: Prof. M. J. M. **Hill,** Dr. L. N. G. **Filon,** and Mr. H. W. **Chapman.** A construction is given for projecting two given triangles on to the same third triangle when the plane of the latter is given, and this construction makes it possible to determine the projective relation between two planes when four points in the one and the four corresponding points in the other are given. The lines joining corresponding vertices of the two given triangles are generators of one system of a regulus, and the possible points of projection when both are projected on to the same triangle lie on a generator of the other system. As this line describes the regulus, the locus of the point in the plane of the second triangle which corresponds to a given point in the plane of the first triangle is a cubic curve with a double point. A construction for the points of the cubic is obtained.—The Weddle quartic surface: H. **Bateman.** The surface is the locus of pairs of points which are conjugate with regard to all quadrics passing through six given points. Any chord of the twisted cubic which passes through the six given points is cut harmonically by the surface. This result leads to a parametric representation of the points of the surface. The reciprocal of the surface belongs to a family of surfaces, described by Darboux, which possess conjugate systems of plane curves.—On the complete reduction of any transitive permutation group, and on the arithmetical nature of the coefficients in its irreducible components: Prof. W. **Burnside**. The first part of the paper contains a determination of the number of times that any given irreducible component occurs, when any representation of a group of finite order as a transitive permutation group is completely reduced. The second part of the paper is occupied with the actual reduction of the permutation group. The reduction takes two forms according as the domain of rationality is defined by the characteristics, or by the roots of unity of which the characteristics are functions.—On the theory of the logarithmic potential: Prof. T. J. I'A. **Bromwich**. The paper is occupied with the conditions for the existence of the second differential coefficients of the potential within an area carrying surface-density, and of the first differential coefficients of the potential on a curve carrying line-density. At a corner of the area in the first case, or of the curve in the second, the differential coefficients in question do not exist unless the axes of coordinates have certain special directions.—Alternative expressions for perpetuant types: P. W. **Wood**.—An informal communication on the theory of geodesics was made by Prof. **Forsyth**.

Cambridge.

Philosophical Society, February 27.—Mr. F. H. Neville in the chair.—Soluble forms of metallic dihydroxytartrates: H. J. H. **Fenton**, F.R.S. Sodium dihydroxytartrate is remarkable for its very sparing solubility in water, and it has previously been shown by the author that this property may be made use of for the qualitative and quantitative estimation of sodium. When equivalent quantities of dihydroxytartaric acid and sodium ethylate are mixed in alcoholic solution a semi-transparent gelatinous precipitate is obtained which is altogether unlike the salt above mentioned and is extremely easily soluble in water. Its aqueous solution after standing for a few minutes deposits a white, crystalline precipitate of the sodium salt in its ordinary hydrated form. The calcium salt shows a similar behaviour, and it would appear that the ordinary metallic dihydroxytartrates must be regarded as derivatives of a hydrated form of the acid $C_4H_6O_8$.—Studies on unsaturated ketonic compounds: S. **Ruhemann**. The author has continued his researches on the combination of mercaptans with unsaturated ketones (see *Trans.* Chem Soc., 1905, lxxxvii., 17). In the light of previous researches, an explanation is given of the catalytic action of organic bases in the formation of additive products of mercaptans with unsaturated ketonic compounds.—Some compounds of guanidine with sugars: R. S. **Morrell** and A. E. **Bellars**. The addition of guanidine to a solution of any sugar in absolute alcohol causes a precipitate of an addition product of the sugar and the base. The compounds are only slightly hydrolysed in aqueous solution, but they are easily decomposed by acids. Their optical properties are peculiar; in some cases the rotation angle is opposite in sign to that of the parent sugar, in others there is a marked multi-rotation.—The influence of strong electromagnetic fields on the spark spectra of some metals: J. E. **Purvis**. The electromagnet is an exceptionally strong one. The pole pieces are conical, and the strength of the field between the two poles with a current of 25 amperes is 40,000 C.G.S. units. It was placed in such a position that a line joining the poles was perpendicular to a line drawn from the slit to the grating. The metals of which an account is given are gold, bismuth, antimony, lead, and tin. The results so far show that amongst the various lines a considerable number aré divided into triplets; whilst, of those which do not show any division, some seem to be widened when the spark is in the field. By analysing the divided lines by means of a calcite crystal, the components do not seem to be polarised in the same way; *i.e.* the outside components of one triplet are vibrating perpendicular to the lines of force, whilst those of another are parallel to the lines of force, and the same applies to the inner component. Some lines appear as doublets; but in many cases most probably the doublets are reversals, and these phenomena are particularly marked amongst the lines of antimony and bismuth. It will be necessary to study these with the magnet placed "end on." Two lines may be very close together, one stronger than the other, and the stronger line will be divided into three, whilst the weaker one is slightly widened only. The work is still in progress, and with other metals.

Paris.

Academy of Sciences, March 6.—M. Troost in the chair.—The president read a telegram from Dr. Jean Charcot concerning the work of the Antarctic Expedition.—On the orthogonal trajectories of a family of surfaces: Gaston **Darboux**.—A rational formula for the coefficient of absorption of light by a translucent body: J. **Boussinesq**.—The study of 1-methyl-4-benzylcyclohexanol and 1-methyl-4-dibenzylcyclohexanol: A. **Haller** and F. **March**. Methylcyclohexanone reacts with sodium derivatives of alcohols in a manner resembling camphor, the sodium derivative of benzyl alcohol giving a mixture of methyl-benzyl- and methyl-dibenzyl-hexanol, separable by fractional distillation in a vacuum.—*Eumedon convictor*, a crustacean accompanying a sea-urchin: E. L. **Bouvier** and G. **Seurat**. The Eumedon occupies a pouch near the anal region of the sea-urchin, and is well protected by the long spines of the latter. The crustacean is not parasitic on its host, the relations between the two closely resembling those holding between *Pionodesmotes phormosoae* and the sea-urchin *Phormosoma uranus*.—On the constitution of sun-spots: Th. **Moreux**. A discussion of the penumbra of the large sun-spot of January, 1904, of which a drawing is given. The second penumbra, attributed by some observers to irregularities in the nucleus of the spot, is clearly shown, and the author regards this as an additional proof of the theory advanced by him in June, 1900.—On sliding friction: L. **Lecornu**. The author considers that the law of Coulomb cannot be regarded as rigorously true, but is rather an empirical rule only roughly approximate.—The oscillations of railway carriages on their springs: Georges **Marié**. The author has deduced a relation between the periodic variations in level of the permanent way, the friction of the spring, and the deflection of the spring, and has applied this experimentally to various classes of rolling stock. As a rule, the condition of convergence was realised, but there were a few faulty vehicles in which this was not the case.—On the determination by the chronometer of differences of latitude at Madagascar and Réunion: M. **Driencourt**. The data given have a probable accuracy of 0·1 sec. This precision is rarely attained in such measurements, and details of the working methods are given.—On the determination of gaseous densities and the accuracy possible in such measurements: A. **Leduc**. For the more permanent gases the author regards the possible accuracy in the density as about 1 in 10,000; for the more easily condensable gases the probable accuracy is lower. The results recently published by MM. Moissan and Chavanne, Moissan and Binet du Jassoneix, Guye and Pintza, and Jacquerod and Pintza are criticised.—The action of radium bromide on the electrical resistance of metals: Bronislas **Sabat**. Bromide of radium, placed near wires of bismuth, iron, steel, copper, platinum, brass and German silver, increases their electrical resistance. This effect cannot be wholly attributed to the rise of temperature caused by the radium salt.—Contribution to the study of ionisation in flames: Pierre **Massoulier**. Previous experimenters have employed electrodes placed one above the other in the flame, and the dissymmetry thus necessarily introduced partially masks the results. The author employs vertical electrodes placed symmetrically in the flame, and the reversal of the field is then without effect on the course of the phenomena. Curves are given showing the relation between the distances from the electrodes and the fall of potential.—The variations of the equivalent spark of an X-ray tube: S. **Turchini**.—On the time that appears before precipitation appears in solutions of hyposulphites: Gaston **Gaillard**.—On the electrolytic solution of platinum in sulphuric acid: André **Brochet** and Joseph **Petit**. Platinum is dissolved in sulphuric acid under the action of a variable current, and the action of the alternating current is not specially due to the change in the sense of the current. In the presence of an oxidising agent the solution of the platinum is impeded.—A comparison of the physical properties of pure nickel and cobalt: H. **Copaux**. Nickel and cobalt have been obtained practically free from other metals, and containing only one or two thousandths of non-metallic impurities. They are magnetic, very crystalline metals, not malleable in the cold. They differ in appearance, cobalt being bright, resembling silver, whilst nickel is dull. Determinations of the density, hardness, melting point, electrical resistance, and breaking load are given.—The action of potassium permanganate on salts of hydroxylamine: L. J. **Simon.** A study of the oxidation of the nitrate, phosphate, and arsenate of hydroxylamine.—On quadrivalent oxygen: E. E. **Blaise.** The author has succeeded in obtaining a zinc compound,

$$(C_2H_5)_2.O.(I).Zn.(I).O.(C_2H_5)_2,$$

crystallising in fine prisms, and corresponding in composition to the magnesium compound previously described. The bearing of this compound on the theory of quadrivalent oxygen is discussed.—On the decomposition of orthonitrobenzyl alcohol under the influence of aqueous and alcoholic soda: P. **Carré.**—On the comparative assimilability of ammonia salts, amines, amides, and nitriles: L. **Lutz.** Experiments with Aspergillus and Penicillium show that of all nitrogenous compounds amides are the most easily assimilated; ammonia salts come next, then amines and nitriles.—The distribution of estragol and terpene compounds between the various parts of an annual plant: Eug. **Charabot** and G. **Laloue.**—On the so-called physicochemical analysis of arable earth: H. **Lagatu.** A description of a graphical mode of representing the analysis into three proximate constituents of an arable earth.—On some facts relating to the development of the kidney in Elasmobranchs: I. **Borcea.** A detailed study, illustrated with four diagrams, of the development of the renal system of *Acanthias vulgaris.*—On a form of scales peculiar to the Pandalidæ: H. **Coutière.**—On some anomalous forms of amitosis in the epithelium of mammals: M. **Pacaut.**—On some diseases of the tobacco plant: Georges **Delacroix.**—An experimental study of the conditions which determine the penetration of the vapours of chloroform into the blood during chloroformic anæsthesia, and on the influence of the variations of the pulmonary ventilation on this penetration: J. **Tissot.** It is shown that, contrary to the view generally accepted, during anæsthesia with mixtures containing between 7 and 12 per cent. of chloroform there is no possibility of establishing an equilibrium between the blood and the mixture, since this equilibrium would correspond to a fatal dose of chloroform. The variable equilibrium which is actually produced depends largely on the pulmonary ventilation.—On the secreting power of the kidney: Henri **Lamy** and André **Mayer.**—The spectroscopic study of oxyhæmoglobin: M. **Piettre** and A. **Vila.**—The action of ammoniacal salts on the nitrification of sodium nitrite by the nitric ferment: E. **Boullanger** and L. **Massol.**—On the distemper of dogs: H. **Carré.**—On a geological section of the High Atlas in the region of Glaoui, Morocco: Paul **Lemoine.**—Examination of the fossils brought from the Yunnan by the Lantenois expedition: H. **Mansuy.** The study of these fossils confirms the analogies previously recognised between the primary and secondary fauna of the Indo-Chinese region and the synchronic fauna of India and Central Asia.—The Bishop's circle of Mt. Pelée, Martinique: F. A. **Forel.**

DIARY OF SOCIETIES.

THURSDAY, MARCH 16.

ROYAL SOCIETY, at 4.30.—A New Radio-active Element, which evolves Thorium Emanation. Preliminary Communication: Dr. O. Hahn.—A Determination of the Amounts of Neon and Helium in Atmospheric Air: Sir William Ramsay, K.C.B., F.R.S.—A Preliminary Note upon the Question of the Nutrition of the Early Embryo: E. Emrys-Roberts.—On the Absence or Marked Diminution of Free Hydrochloric Acid in the Gastric Contents, in Malignant Disease of Organs other than the Stomach: Prof. B. Moore (with W. Alexander, R. E. Kelly, and H. E. Roaf).—On the Occurrence of certain Ciliated Infusoria within the Eggs of a Rotifer, considered from the Point of View of Heterogenesis: Dr. H. C. Bastian, F.R.S.—On the Dimorphism of the English Species of Nummulites, and the Size of the Megalosphere in Relation to that of the Microspheric and Megalospheric Tests in this Genus: J. J. Lister, F.R.S.—Observations on the Brains of Man and Animals with Trypanosome Infection. Preliminary Note: Dr. F. W. Mott, F.R.S.

ROYAL INSTITUTION, at 5.—Recent Astronomical Progress: Prof. H. H. Turner, F.R.S.

SOCIETY OF ARTS, at 4.30.—Manipur and its Tribes: T. C. Hodson.

LINNEAN SOCIETY, at 8.—Contributions to the Flora of Liberia: Dr. Otto Stapf.—*Exhibitions:* Penguins and other Birds from the Falkland Islands, and Scratched Rocks from a Rockhopper's Rookery: R. Vallentin.

FRIDAY, MARCH 17.

EPIDEMIOLOGICAL SOCIETY, at 8.30.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—First Report to the Steam-Engine Research Committee: Prof. David S. Capper.

SATURDAY, MARCH 18.

ROYAL INSTITUTION, at 3.—Electrical Properties of Radio-active Substances: Prof. J. J. Thomson, F.R.S.

MONDAY, MARCH 20.

SOCIETY OF ARTS, at 8.—Telephony: H. L. Webb.

VICTORIA INSTITUTE, at 4.30.—The Nebular and Planetesimal Theories of the Earth's Origin: Warren Upham.

TUESDAY, MARCH 21.

ROYAL INSTITUTION, at 5.—Engineering Problems: Prof. W. E. Dalby.

ROYAL STATISTICAL SOCIETY, at 5.

ZOOLOGICAL SOCIETY, at 8.30.

INSTITUTION OF CIVIL ENGINEERS, at 8.—*Discussion:* Shipbuilding for the Navy: Lord Brassey, K.C.B.—*Paper:* Coolgardie Water-Supply: C. S. R. Palmer.

WEDNESDAY, MARCH 22.

GEOLOGICAL SOCIETY, at 8.—An Experiment in Mountain-Building Part II.: Lord Avebury, P.C., F.R.S.—The Rhætic Rocks of Monmouthshire: L. Richardson.

SOCIETY OF DYERS AND COLOURISTS, at 7.30.—The Dyeing and Finishing of Leather for Bookbinding; with remarks on Preparatory Manufacturing Processes: F. W. Colin Robinson.—A Dyeing Drum Door, removable and replaceable without stopping the Drum: H. W. Ley.

THURSDAY, MARCH 23.

ROYAL SOCIETY, at 4.30.—Bakerian Lecture: The Reception and Utilisation of Energy by the Green Leaf: Dr. Horace T. Brown, F.R.S.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Report of Experiments carried out at the National Physical Laboratory: On the Effect of Heat on the Electrical and Mechanical Properties of Dielectrics, and on the Temperature Distribution in the Interior of Field Coils: E. H. Rayner.—*Discussion:* On Temperature Curves and the Rating of Electrical Machinery: R. Goldschmidt.

ROYAL INSTITUTION, at 5.—The Reasonableness of Architecture: Thomas G. Jackson.

FRIDAY, MARCH 24.

ROYAL INSTITUTION, at 9.—A Pertinacious Current: Sir Oliver Lodge, F.R.S.

PHYSICAL SOCIETY, at 5.—Note on the Voltage Ratios of an Inverted Rotary Converter: W. C. Clinton.—On the Flux of Light from the Electric Arc with varying Power Supply: G. B. Dyke.—The Application of the Cymometer and the Determination of the Coefficient of Coupling of Oscillation Transformers: Prof. J. A. Fleming, F.R.S.—Exhibition of Cymometers and other Instruments.

INSTITUTION OF CIVIL ENGINEERS, at 8.—The Wanki to Victoria Falls Section; Victoria Falls Railway: C. T. Gardner.—Design of a Double-Line Plate-Girder Railway-Bridge: H. S. Coppock.

SATURDAY, MARCH 25.

ROYAL INSTITUTION, at 3.—Electrical Properties of Radio-active Substances: Prof. J. J. Thomson, F.R.S.

CONTENTS.

THURSDAY, MARCH 23, 1905.

THE KALAHARI DESERT.

Die Kalahari. Versuch einer physisch-geographischen Darstellung der Sandfelder des südafrikanischen Beckens. By Dr. Siegfried Passarge. Pp. xvi+822; illustrated; and with a "Kartenband" containing 11 maps and 10 sheets of sections, sketches, &c. (Berlin: Dietrich Reimer [Ernst Vohsen], 1904.) Herausgegeben mit Unterstützung der königlich-preussischen Akademie der Wissenschaften. Price 80 marks (unbound).

NOW if we could imagine that Mr. Shandy the elder were alive, this is a book that, like many another of its class, would have delighted him. Hereby he could have proved triumphantly to Yorick the potency of that great scheme of education—that "north-west passage to the intellectual world"—which he propounded so enthusiastically upon a memorable occasion. His scheme, it will be remembered, was that upon every substantive in the dictionary the Auxiliaries (so gravely misunderstood by the Corporal and Uncle Toby) should be brought to bear exhaustively:—"Every word, Yorick, by this means, you see, is converted into a thesis or an hypothesis:—every thesis and hypothesis have an offspring of propositions;—and each proposition has its own consequences and conclusions; every one of which leads the mind on again, into fresh tracts of enquiries and doubtings.—'The force of this engine,' added my father, 'is incredible. . . .'"

Even up to the numberless "tracts of enquiries and doubtings," it is in this spirit that Dr. Passarge has attacked "Die Kalahari"; and the book before us, with its mass of spacious solidly printed pages, is the result. It is a work which compels our admiration, not only for the thorough and painstaking manner in which its author has carried out his personal investigations, often in circumstances of great difficulty; but also for the acumen with which he has grasped the bearing of his observations upon problems of world-wide range; and for the astounding industry with which he has pushed his researches into all the ramifications of his subject. In giving us, for the first time, an adequate knowledge of a large part of that hitherto little known region of South Africa, the Kalahari Desert, he has also contributed most significantly to our earth-knowledge in general. Hence his book, besides forming the basis for all future work in the Kalahari, must have a weighty influence in many questions pertaining to the geological history of the continent of Africa and to the changes of climate that are recorded in the rocks of many other parts of the globe.

We feel that it is a forlorn hope to attempt within the limits of our space to present in true proportion even an outline of the contents of this great mass of information with its leaven of speculative deduction. But let us to the attack!

Dr. Passarge was attached, as mining expert, to an expedition of the British West Charterland, Ltd., organised to explore the Kalahari, under the leadership of Sir Frederick Lugard, during the years 1896–9. Of the main expedition and its personnel we hear very little throughout the book. It had left Palapye some time before Dr. Passarge reached that place, at the beginning of October, 1896. He followed with a small party, and a few days after starting he was stricken with fever. A woful month ensued, during which, with a dying prospector as his companion in misfortune, he lay in or under the wagon as it trekked slowly north-westward across the eastern part of the desert.

Not until the middle of November did he regain his feet; but his recovery thereafter was rapid, and his field-work in various parts of the Middle Kalahari was carried on subsequently without serious interruption until its termination in October, 1898. During the two years thus spent, his traverses extended east and west over a breadth of about 700 km., and north and south for about 500 km., the site of the desiccated Lake Ngami lying roughly central to these journeys. His official investigations were directed chiefly to the islands of ancient rocks with which the region is sparingly studded, mainly in the form of subdued hill-chains but occasionally in comparatively low-lying tracts that have remained uncovered by the superficial formations of the desert. To reach these islands it was necessary to cross the level sandy veldt for longer or shorter distances—traverses that were often very difficult and full of hardship—and Dr. Passarge had thus the opportunity to carry out that careful study of desert conditions in the Kalahari which forms what we must regard as the main subject of his book. The ancient rocks were found to consist of two great series of unfossiliferous greywackes, schists, and limestones, often much altered by dynamic and thermal agencies, and probably in the main pre-Cambrian, though possibly ranging down into Cambrian times. Among these ancient sediments there are many intrusions of acid and basic igneous rocks. The thin superficial deposits, though incomparably more recent, are believed by Dr. Passarge to include beds that may date back to Eocene times. By their composition and structural alteration through weathering, these desert-formations are held to indicate the successive conditions that have ruled in the region since Mesozoic times; and it is in his discussion of these deposits that the author gives the fullest play to his powers.

To take the contents of the book in their given order:—After a modest preface, the author deals, in chapter i., with the explorations of his predecessors in the Kalahari. The list of references added at the end of the chapter constitute his bibliography of the subject—a convenient arrangement that is followed throughout the book. In the second chapter Dr. Passarge gives a consecutive account and itinerary of his travels and experiences. This account is to a large extent repeated and amplified in the topographical descriptions of later chapters. The third chapter is occupied with a short description and categorical formulation of the topographical and hydrographical conditions of South Africa generally, through all its divisions and subdivisions. In chapter iv. the author deals in the same manner with South African geology, with the literature of which he appears to be well acquainted. Respecting this literature, he remarks (p. 39):—

"So ist denn die Geschichte der geologischen Forschung in Südafrika eine wahre Komödie der Irrungen. So viel Forscher, so viel Ansichten! Ja, ein und derselbe Forscher . . . haben ihre Auffassung wiederholt gewechselt. . . ."

He debates anew the many doubtful points in the correlation of the rocks, and expresses his views thereon. This chapter with its bibliographical appendix might be used as a general introduction to the study of South African geology. It is illustrated by a geological map of Africa south of 10° S. lat. (Blatt ii. in the "Kartenband"), which, though rough in execution and crude in colouring, serves to give at a glance the main lines on which the rocks of this part of the continent are arranged. The climate of South Africa and of the Kalahari afford material for chapter v., which includes a summary of the author's personal observations on the weather, and concludes with some very acceptable notes on the rapidly progressive desiccation of the country, based on a comparison of the experiences of the earlier and later explorers.

Then follows a solid block of chapters—vi. to xxiv., pp. 105-530—devoted, except for an interlude in chapters xvi. and xvii., to the detailed account of the author's investigations in the several districts visited—the Kwebe and neighbouring hill ranges; the region bordering on Ngami and the Botletle River; the Haina Veldt; the Chanse Veldt and the adjacent German frontier; the western part of the Okavango basin with its rapidly perishing river-system, of which the description is of extreme interest; the Kaukau Veldt; the Kung Veldt; and the Mahura Veldt. With many an "Überblick" and "Rückblick," "Übersicht" and "Folgerung," the author pursues his way through masses of detailed observations, all carefully classified, subdivided, and marked with sign-posts in the form of head-lines; and many a pertinent interrogative sentence, spaced out in the text, is conscientiously answered or as conscientiously evaded by further questions. It is in these chapters that the operation of the Auxiliaries is most forcefully felt. To the general reader the greater part of these details must be arid, as befits the description of a desert, yet not without refreshing oases here and there. Nor can it be denied that in a region undergoing such rapid changes in respect to rainfall and drainage-systems, the full particulars as to the exact condition of all the water-pans at the time that they were examined are certain to prove of value in the future for purposes of comparison; while to the geological traveller who may hereafter visit the Middle Kalahari the whole of these chapters are likely to prove of service. Indeed, when we remember how much more might have been written from the impressions of a trained observer at work in a new country during two whole years, we feel, on the whole, inclined to be grateful to Dr. Passarge for his moderation.

The two chapters already mentioned as forming an interlude to the topographical details are comparatively amusing. The first (xvi.) describes the geological effect of the burrowing animals of the desert, both mammals and insects, upon the superficial formations, with numerical calculations as to its efficacy in producing large results. The second gives a summarised description of the structure of the deposits found on the sites of the desiccated lakelets or "Kalkpfannen" of a certain district, with a particular inquiry into the origin of the water-holes ("Pfannenkrater") that in many cases still persist within them. After stating the problem in his favourite manner, under various headings in interrogative form, the author proceeds to show that all the peculiar features of the water-holes may be assigned to the agency of the wild animals that have used them as drinking places and bath-tubs. He enumerates these animals; shows from the records of the first white travellers how multitudinous they once were; gathers data from the Berlin Zoological Gardens as to the drinking capacity of most of the larger herbivores; supplements this with observations on the drinking of his draught animals when trekking in the desert; calculates the amount of dissolved and suspended matter in the water of the "pans," and how much would be carried away in the interiors of the beasts that drank it; and also how much they removed on their exteriors after their occasional mud-baths. Then, the cubic space of the water-hole being known, and the number of its former visitants estimated, a simple calculation brings out the number of years in which, by this agency, the hole could have been produced.

Is there not the germ of a glorious question for some future examination paper in the following sentences?—

"Nehmen wir die Oberfläche eines Nashorns auf 6 qm an und die Kruste nach jedem Schlammbad auf 1 mm, so trägt jedes Tier 6 l Schlamm fort. Wenn also 10 dieser Tiere während der Trockenzeit (180 Tage) täglich baden, tragen sie im Jahr 10.8 cbm Schlamm fort, im Laufe von weniger als 2000 Jahren also den Inhalt einer Pfanne von 20,000 cbm. Das würden 10 Nashörner allein fertig bringen!" (p. 321).

Let us acknowledge, however, that from this singular line of research a very important deduction is drawn, and is in keeping with all the other evidence:—

"Denn diese Zahl besagt, dass vor dieser Zeit—sagen wir rund 6000–7000 Jahren—das Chansefeld ein wesentlich anderes Klima gehabt haben muss" (p. 322).

After giving, in chapter xxx., a summary of our scanty knowledge of the vast area of the Kalahari beyond the regions which he visited, the author proceeds to epitomise his own observations and to deal with the broader aspects of his subject. The orographic and hydrographic conditions of the Kalahari as a whole are briefly stated in chapter xxxi., with a summary of the evidence for the rapidly progressive desiccation of the land in a definite direction. Then follow chapters on the basement-rocks (das Grundgestein) of the region; on the development and antiquity of the South African land-mass; and on the superficial formations (die Deckschichten). In chapter xxxv., entitled "Die Mesozoische Wüsten-periode," the author discusses the different stages of alteration shown both by the older rocks and by the superficial formations, through "einkieselung" or cementation by infiltrated silica, and "verkieselung" or replacement of carbonates by silica; and he gives his reasons for recognising successive periods of alteration and deposition consequent upon changes in the physical conditions of the land. He goes far afield in his argument, touching upon the various effects of rock-weathering under almost every climate of the globe, but with especial reference to desert-conditions. He brings this information to bear upon the South African geology generally, where he recognises evidence for desert-conditions of great antiquity and long duration, but with occasional intermission. Whether these speculations are well founded it will remain for the keen investigators now working in South Africa to decide.

In the same strain of more or less hypothetical deduction following upon an epitomised re-statement of the main facts, are the next two chapters—xxvi. "Die Periode der Brackwasserkalke und der Laterite," and xxvii. "Die Pluvialzeit und ihr Abklingen bis zur Gegenwart"—in which the probable condition of the interior of South Africa is traced through Tertiary and post-Tertiary times. It seems somewhat hazardous to correlate the isolated and widely scattered patches of thin sandstone and limestone by their lithological characters alone, and to assign them to successive periods. One line of argument by which the author reaches his conclusions with respect to the age of the desert-beds of the Kalahari is by comparing them with the more readily determinable Tertiary succession of Egypt. On questionable grounds he suggests that his "Pfannensandstein" may be assigned to the Eocene, his "Kalaharikalk" to a somewhat moist episode in Miocene and Lower Pliocene times; after which he recognises a period of dry conditions in the Middle Pliocene, and then a Pluvial period of late Pliocene and early post-Pliocene times. This Pluvial period may be accepted with some confidence as being in close relation to the occurrence of the Glacial period in northern Europe. Evidence from many other parts of the world tends to show that the progressive desiccation that has gone on since that period has not by any means been confined to the African continent.

Among the interesting side-issues raised or recapitulated in these later chapters of the book are questions as to the antiquity of the Kalahari fauna; the geological effect of wind-action; the obliteration of dry river-beds; "zoogene erosion"; the change of climate in North Africa during historic times; and others that we have no space even to catalogue.

The next—and last—chapter gives a review of the plant-life of the Kalahari, with especial reference to the evidence which it bears as to the changing conditions of the land. Then follow various appendices, occupying one hundred pages. These contain a few astronomical observations; a petrographical description of 447 rock-specimens and slides by Prof. Kalkowsky; twelve chemical analyses of rocks; an account of the land and freshwater shells from the newer superficial deposits by Prof. E. v. Martens; a full account of the diatoms by H. Reichelt; and a list of plants. The last twenty-seven pages of the book are occupied by the classified indices.

There is no attempt at artistic embellishment in the text-illustrations; and the same may be said of the numerous sheets of maps, plans, and sections contained in the "Kartenband," some of which, indeed, appear scarcely to justify their reproduction, while in many the scale seems to be unnecessarily large.

And now that we have growled our way through the book, and have earned the concluding pipe of peace, let us add that when a capable and earnest worker is willing, in publishing his results, to undergo the severe labour that a production of this kind must have entailed, our sense of gratitude toward him should be paramount, and should stifle all minor complaints and especially the impatient grumbling that arises in the main from our own unrealised indolence.

G. W. L.

ANIMAL PHOTOGRAPHY.

Photography for the Sportsman Naturalist. By L. W. Brownell. American Sportsman's Library. Pp. xviii+311; illustrated. (New York: The Macmillan Company; London: Macmillan and Co., Ltd., 1904.) Price 8s. 6d. net.

On several previous occasions we have had the pleasure of noticing some of the admirable volumes belonging to that series of the "Sportsman's Library" which deals exclusively with the various animals constituting the sportsman's quarry. In the volume now before us we have, on the other hand, one of a second series devoted to different aspects of sports and matters connected therewith. In regarding practical photography as an essential element in the education and outfit of every modern sportsman who desires to be something more than a mere slayer of game, the editor has undoubtedly been well advised; and he also has been exceptionally fortunate in securing the services of an expert with the experience and reputation of Mr. Brownell to make known to the beginner the mysteries of the camera and the technique of outdoor animal photography. If the reader is careful to bear in mind that when the author refers to "our animals" he means the members of the North American and not of the British fauna, the book will, we venture to think, prove as acceptable to sportsmen and field-naturalists on this side of the Atlantic as to the countrymen of the author; and if this turn out to be the case, a wide circulation would seem to be assured.

In his introduction Mr. Brownell gives a concise and yet comprehensive sketch of the history of photography, dwelling especially on the enormous strides it has made during the last half-dozen years. The loss of time that he himself experienced in having to learn everything for himself when first taking up animal photography is alluded to as a kind of justification (if one be needed) for the appearance of his volume, while the value of accurate photographs of animals as a means of instruction in natural history is noticed in the concluding paragraphs of the introduction.

Possibly, and if so pardonably, the author is inclined to over-rate the importance of photographic illustrations in zoological work. In many respects, such as representing birds in their natural surroundings, its importance cannot, indeed, be over-estimated. But when the author goes on to deride the work of the pencil of the artist as a means of illustrating books on natural history, and to declare that the wood-cut and the "process-block" are things of the past in this connection, we take leave to differ from such a sweeping assertion. Nor are we alone in so doing, for Mr. W. T. Hornaday, in his recently issued "American Natural History," takes occasion to point out that photography has its limitations in the portrayal of animals, and that some illustrations demand the artist's pencil in order to become satisfactory zoological portraits. It is quite true, as Mr. Brownell urges, that the sketch, as compared with the photograph, may be crude and unfaithful to nature, yet it will nevertheless often accentuate or display essential features which are scarcely perceptible or absolutely hidden in the sun-portrait.

With this reservation, we are absolutely at one with the author in regard to the extreme importance and value of photography in natural history work, and, like him, we look forward to the time when real colour-photography will have been discovered and made available for everyday use. After describing in full detail the general technique of the photographic art and the kinds of camera and other apparatus best suited to the outdoor photographer of animal life, the author proceeds to discuss the mode of procedure in the case of different subjects, devoting one chapter to the larger mammals, another to the small mammals, a third to birds, and so on. So far as we can judge, all his advice is to the point, and the illustrations given as samples are in most cases admirable animal portraits. Not that attention is confined to animated nature, for we have a chapter on plant-photography, and another on the use of the camera in depicting sporting scenes and incidents, each as charmingly illustrated as their predecessors. Above all, the book is by no means dry reading, the technical details being enlivened with numerous and appropriate anecdotes. Mr. Brownell has, in fact, succeeded in producing a treatise on practical field-photography which it will be very hard to beat.

R. L.

A POPULAR STAR ATLAS.

Popular Star Maps. A Rapid and Easy Method of Finding the Principal Stars. By Comte de Miremont, F.R.A.S. (London: George Philip and Son, Ltd., 1904.) Price 10s. 6d. net.

IT is by no means an easy task to construct a series of charts of the principal stars in the sky that will at once be of service to those wishing to make themselves familiar with the chief constellations or star groupings. Many, if not the majority, of star atlases printed for beginners are so belaboured with lines indicating right ascensions and declinations, names of constellations, Greek letters or numbers against each star, different notations for variable stars, &c., that when the beginner turns his eyes from the starry heavens towards a chart in order to find out the particular grouping in question he is unable to recognise it among the innumerable markings. For this reason many who have made valiant attempts to learn the stars have given up trying, and it is the atlases that are to blame and not the seekers after knowledge.

The ideal set of charts for a beginner should in the first place represent the appearance of the starry heavens as near as possible, and consist of maps showing small white discs or stars on a dark background, the discs or stars varying in size according to the magnitude of the star; secondly, a fairly large region should be included in each map; thirdly, only stars to the third or fourth magnitude should be inserted; and lastly, each map should have an accompanying duplicate chart or key-map on the same scale, but with dark discs or stars on a white background, on which as much information as may be useful should be given.

In this way the beginner can at once find his particular stars on the first map, and learn their names, &c., on the accompanying key-map. This seems to be the logical method of aiding those who are not accustomed to deal with star charts, and it is a pleasure to find that such a series of maps is now available for those who wish to take advantage of them.

The charts is question, ten in numb-r, and each accompanied by a key-map, have been prepared by Comte de Miremont, one who is thoroughly acquainted with the stars from the navigating point of view, and is familiar with the desire of sailors and others for a simple star atlas. Stars to the fourth magnitude only are inserted, and these are represented, on charts 10 inches square, as white stars on a dark blue background; in the accompanying but separate key-maps, of the same size, the stars are black on a white background. Great care has been taken to ensure accuracy in the star positions.

The method of projection, namely, the gnomonic, is also one which lends itself well to this type of atlas, for the whole of the celestial sphere can be projected on six plates, each plate thus representing one side of a cube enveloping the sphere. The upper and lower sides of the cube enclose the north and south polar regions respectively, and the other four sides the equatorial regions. To render more clearly the relations to each other of star groups near the edges of each of these equatorial sides in contact, four additional overlapping maps are added. Thus there are ten charts in all, and there is this advantage, that each one with its corresponding key-map can be taken out of the portfolio and used in the observatory, in the field, or on board ship by itself. On each chart and its key is a scale of right ascensions with the seasons of the year when each of the constellations is visible in these longitudes; the declinations are omitted from the maps, but this information, and the right ascensions of every star marked, are given in the table showing the mean places (and annual change) for January, 1904. Other lists include the names of the constellations and the principal stars in each, and a complete alphabetical list of stars in the maps.

With regard to the general get-up of the maps, letterpress, and portfolio which encloses them, more could not be desired, and great credit is due to both compiler and publisher for producing such a serviceable and handsome set of star charts for the use of beginners, and at such a low price. W. J. S. L.

A CONTRIBUTION TO MUSEUM HISTORY.

The History of the Collections contained in the Natural History Departments of the British Museum. Vol. i. Pp. xvii+442. (London: Printed by Order of the Trustees of the British Museum, 1904.)

EVERY museum of the first rank has two histories, one of which is usually written but rarely published—the history of the gradual accumulation of the museum material, by purchase, exchange, or donation, and another, which can hardly ever be written—the history of the internal metabolism, the arrangement and re-arrangement, the differentiation and integration, the "Kampf der Theile im Organismus." It may not be difficult to indicate how various museums have adapted themselves to the advance of science and to their growing constituency under the influence of effective directors, how nature has crept in between the teeth of the abstractive scientific fork, how evolutionary series have replaced static taxonomic displays, how problems of practical human interest have been recognised, how a mere chamber of horrors has become an introduction to a rational study of pathological variation, and so on; but who can ever tell the detailed physiological story of the metamorphoses? For the great museum is an organism of many parts, each with its *spiritus rector,* each developing independently, and yet in cooperation with the rest. It may not be difficult to show how a museum has changed or is changing as the various objectives—for instruction, for investigation, for inspiration—have become more clear to the organisers; when, for instance, the simple step is taken of discriminating between what can be usefully exhibited and what should be as usefully concealed; but who can ever tell how much even this simple step costs? Is the priceless connecting link to be shown with blinds up or with blinds down, or not at all? But we must not intrude further into the real history of a great museum; it is an intricate story of thrust and parry between keepers and their environment, both animate and inanimate. The history before us is a history, not of the British Museum (Natural History Departments) as a growing organism; it is the history of the collections—a story of accretion.

The first volume of the history of the collections preserved in the four natural history departments of the British Museum deals with the botanical, geological, and mineralogical material, and also with the libraries. It has been produced at the suggestion of the director, Prof. E. Ray Lankester, by the officers in charge of the collections. Mr. B. B. Woodward has written the history of the libraries; Mr. George Murray, assisted by Mr. Britten, that of the department of botany; Dr. Arthur Smith Woodward, with valuable help from the late keeper, Dr. Henry Woodward, and from Dr. Bather, assistant keeper, that of the department of geology; and Mr. Fletcher that of the department of minerals. The second volume will deal with the department of zoology.

It need hardly be said that the various histories of the collections are scholarly productions; they tell of the foundation-stones and of the additions made from year to year, and they give an annotated alphabetical list of the numerous benefactors and vendors. The result is not adapted for fireside perusal, but it is very impressive, giving us a correct idea of the variety, extent, and importance of the immense series of collected specimens which are carefully guarded and ordered, "not only" (according to the terms of Sir Hans Sloane's will) "for the inspection and entertainment of the learned and curious, but for the general use and benefit of the public to all posterity." And it is also interesting to turn over the leaves and observe how many famous names occur on the honourable lists. Many of the short biographical notes in the geological and mineralogical sections supply valuable historical material. A useful addendum, we think, would have been a series of references to the catalogues and memoirs in which the collected material has been described.

The book will be of great value to investigators who wish to trace collections and specimens, or who wish to know beforehand what to expect in the British Museum; and everyone will agree that it furnishes abundant documentary proof of the carefulness and business-like methods of the great museum, which is one of the national assets that we have most reason to be proud of.

SCIENCE AND METAPHYSICS.

Scientific Fact and Metaphysical Reality. By Robert Brandon Arnold. Pp. xxiii+360. (London: Macmillan and Co., Ltd., 1904.) Price 10s. net.

IF this book does not conform to the adage "*Nonum prematur in annum*"—for Mr. Arnold's undergraduate career is no distant memory—that is no ground for complaint. The work is not only one of great promise, but a notable performance. In originality of conception, vigour and clearness of statement, width of outlook and fairness to all the aspects of experience, it would be with difficulty surpassed. At the same time it is quite unpretentious; there is no parade of learning; there is not a single foot-note. The one digression of any length—or modern militarism—is as interesting as it is pardonable.

The following are some of the main characteristics of the author's point of view:—(1) While defending metaphysics from the charge of being "built upon air or quicksands," he readily admits that it has not always taken full advantage of the science which it knows, and that greater accuracy of scientific detail ought to be displayed if it is to appeal to the "plain man" with some knowledge of physics, chemistry, and biology. In the same spirit the chapters on God and the Absolute and Human Immortality attempt to do something like justice to the religious aspirations of the "plain man," which are so severely neglected in such a work as "Appearance and Reality." (2) Mr. Arnold prefers *activity* to *existence* as a basis for investigation. The lower animals, in his view, display only "teleological activities"; the entity "mind" (self-conscious and introspective) belongs only to men. And perhaps not even to all men: "a human being might theoretically pass through life and never be actual mind; possibly with some savages this is almost the truth." (3) Again, Mr. Arnold is fond of the contrast between the individuation (real and objective in every sense) by means of the atom or the electron—"the true physical entities"—and the individuation by means of colour, sound, and the like which depends on our "particular sensuous evolution." The latter form of individuation, which finds expression particularly in the "material totalised image," seems therefore to show that in mind (including "teleological activity") there is something new in principle. "But by asking whether it is a new entity we merely confuse matters. For we should thus assume that the physical world is once and for all limited to atomic activities, whereas all observations tend to show that the various entities are continually changing and re-organising themselves, and developing new relations and qualities." In one sense Mr. Arnold claims that his view of mind in the non-introspective animal is as materialistic as it could be, since mind under such conditions "is matter totalised in a special manner in relation to an external crisis." But he hastens to add that "premental matter was not merely the matter of physics and chemistry." And mind in man he certainly regards as something very different.

It is impossible to do justice to this suggestive work in a short notice, and we are well aware that the above is only a hasty and somewhat arbitrary selection of a few of the topics treated. The views of matter and ether, in particular, might well have a notice of their own; so might the chapter on psychophysical interaction, which is almost a model of philosophical discussion. In this last the theory is stated that the initial impulse required to liberate the energy of the muscular system comes ultimately from "external sources," *e.g.* when the sight of some object moves us to pursue it, from the ethereal vibrations which we apprehend as light. But for the author's defence (in many ways successful) against the obvious objections to this view, we must refer to the book itself.

OUR BOOK SHELF.

Index of Spectra. (Appendix O.) By W. Marshall Watts, D.Sc. (Lond). Pp. 40. (Manchester: Abel Heywood and Son, 1904.) Price 3*s*.

THIS is the latest addition to the very useful series of appendices which Dr. Marshall Watts has given to his well-known "Index of Spectra." In it he has brought together the arc spectrum of molybdenum by Hasselberg, the spark spectra of calcium, scandium, indium, beryllium, lithium, thallium, antimony, and arsenic, by Exner and Haschek; of calcium, lithium, thallium, and antimony, by Eder and Valenta; of radium, by Runge and Precht; and the oxy-hydrogen flame spectra of lithium, potassium, rubidium, and cæsium, by Ramage. Hasselberg's comprehensive record of the arc lines of molybdenum takes up about half the pages of the appendix. In the cases of metals investigated both by Exner and Haschek, and Eder and Valenta, the records are compared in parallel columns. The oscillation frequencies corresponding to the wave-lengths of all the lines given have been reduced by the compiler.

La Matière, l'Éther et les Forces physiques. By Lucien Mottez. Pp. 236. (Paris: Gauthier Villars, 1904.) Price 4 francs.

THE time is fast coming when the qualification which will play the most important part in determining a man's reputation as a physicist will be that he shall abstain from writing books on the philosophy of ether, matter, and the universe. The present book discourses pleasantly about gravitation, heat, electricity and magnetism, polarisation of light, chemical action, and such like matters. It is hardly the kind of book to which a beginner would turn to get his first lessons on physics, as the style is too discursive, and it contains little but what an average physicist either knows or has probably thought of already; and yet we can only say about books of this kind, "still they come." Who reads them?

The Uses and Wonders of Plant-hairs. By Kate E. Styan. Pp. iv+65; with plates. (London: Bemrose and Sons, Ltd.) Price 1*s*.

THE nature and purpose of plant-hairs will have occurred to many teachers as a favourable subject for a course of nature-study. The presence or absence of hairs in allied plants, even in the same plant when growing under different conditions, their position and form, their mechanism and use, afford plenty of opportunity for consideration and deduction. The book offers a fair *résumé* of facts, but it is not obvious that the writer is recording personal observations, and the appendix of illustrations loses some of its value as no allusion is made to it in the text.

LETTER TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Planet Fortuna.

ALTHOUGH NATURE is scarcely the proper place for a disquisition on a Latin quotation, perhaps you will admit of a further correction of "W. T.'s" correction (p. 461) of the lines quoted by "W. E. P." Numen is, I believe, never used except in the sense of *good* luck, being derived from nuo, and signifying the nodding approval of the gods; hence "Nullum numen habes, si sit prudentia," would mean just the opposite to the obvious sense of the passage. The best editions give, in both the satires where the line occurs, "Nullum numen abest," and this makes sense. Except for this word, "W. T.'s" version is correct.

SPENCER PICKERING.

STATE AID FOR HIGHER EDUCATION.

THE announcement that the committee, presided over by Mr. Haldane, M.P., appointed to consider the allocation of the Treasury grant to the university colleges has finished its inquiry, was made in our issue of last week. In the note dealing with the subject on that occasion the part of the grant to be received by each college was specified, and the fact remains to be recorded that 9000*l.* has been allotted to the purchase of books, apparatus, specimens, instruments, &c., to form equipment for teaching of a university character. As will be known already to most readers of NATURE, the Treasury this year has doubled its contribution to the university colleges, and in this way has acknowledged the national services which these institutions are rendering. The total Treasury grant to the fourteen university colleges is now 54,000*l.*

That the grant has been increased in this substantial manner is certainly a matter for congratulation, and men of science will view with satisfaction the evidence this additional State aid for higher education affords that the Government is beginning to realise the important part played by higher education in securing national efficiency—especially by higher education in science, using that term in its most catholic sense. But, even at the risk of appearing to be ungracious, it must be pointed out at once that the amount is even now ludicrously small and altogether inadequate when regarded as the contribution of the State to the pressing work of placing our system of higher education upon a satisfactory basis. As has been consistently and persistently urged in these columns, there is an enormous amount of leeway to be made up before the facilities for education of university standard in Great Britain can be compared with those in several European countries and with those in the United States, compared, that is, with any chance of a satisfactory result. The reason is a simple one. Great Britain alone among the first-class nations of the world has not learnt that the reign of muscle is over, that success, whether in commerce or war, will be always with the most highly trained and scientifically educated people. Other nations have taken this truth to heart, and believe enthusiastically that what is worth having is worth paying for, and paying for well. Surely, in view of the object-lesson that events in Manchuria afford, it will not be long before our own country will be prepared to make great sacrifices to secure as efficient a system of higher education as that of any other nation on the face of the earth.

The total grant to the fourteen university colleges is, as has been said, 54,000*l.*, and this is a large sum compared with what the colleges have received in previous years. But the State endowment of the University of Berlin in 1891–2 amounted to very nearly 169,000*l.*; that is to say, one university in Germany receives from the State in a year more than three times as much as our fourteen university colleges receive together from the Treasury. A single fact of this kind is enough to convince the student of educational problems that while Germany takes higher scientific education seriously, and reaps the advantages of her sacrifices, Great Britain has still to understand that commercial success and educational efficiency stand in the relation of effect and cause. If at the present day there still exist sceptics as to our educational inefficiency and our national parsimony towards universities and colleges, the presidential address of Sir Norman Lockyer to the British Association at Southport in 1903 may be commended to them. Though men of science who have at heart the true welfare of their country are at present rather like "voices crying in the wilderness," it is clearly their duty to continue to urge the paramount importance of higher scientific education and of scientific research, and to petition the Government to act more generously on their behalf.

But it is not enough to provide large and adequate State grants for education in order to secure efficiency in the face of modern needs. It is just as important so to choose the subjects of study and to arrange the curricula of schools and colleges that our boys and young men may begin life as well and as suitably trained as the youths of other countries. The kind of education suited to the conditions of the days of the Renaissance is not in harmony with the needs of the twentieth century. The work of men of science in the last century has revolutionised life, and our system of education must be adapted to existing circumstances. The custodians of English education are still too much actuated by mediæval ideals. The entrance of the student of science to the older universities is still obstructed by an obsolete and ludicrous test in Greek. There is a tendency even yet among those in charge of our Department of Education to discourage and hamper the instruction in science in our elementary and secondary schools. The Prime Minister is reported once to have said that the only knowledge our boys have of natural phenomena is that obtained on the cricket and football fields, and on the river. The man of science has still much to teach his fellow citizens. The work to which Huxley gave so much of his energy is not yet done, and it is the duty of his successors to continue his efforts, and to take every opportunity of advocating the application of the principles of science to educational administration.

It must be recognised that there are many ways of obtaining culture. The idea of the Middle Ages that culture was obtainable only by studying Latin and Greek, though true enough then, is to-day hopelessly narrow and indicative rather of the state of mind of the Philistine. The scholar steeped in classical lore, yet ignorant of nature's laws and of modern literature, is but an uneducated pedant. The scientific specialist with a complete knowledge of some restricted subdivision of science, yet knowing nothing of the ideas of ancient and modern poets and philosophers, is but a narrow technical registrar. Culture is something broader and higher than anything with which the pedant or cataloguer is acquainted. The man of science desirous of producing cultured men and women will strive so to arrange school and college time-tables that they contain in due measure subjects designed to cultivate and develop all the faculties of the healthy human mind; and in this work the heritage which has been left us by the nineteenth century will not be ignored. The teachings of science, the love of truth wherever it may lead, will be inculcated consistently, so that a race may be produced able to deal with modern problems in a modern way.

Though the Government moves but slowly, and perceives so incompletely the unsatisfactoriness of our supply of higher education, there is cause for satisfaction in another direction. There are growing evidences that the broad-minded policy of wealthy men in the United States, which leads them to give of their millions to colleges and universities, is being emulated in a measure by our merchant princes. We have on several occasions lately been able to record noble instances of private munificence on behalf of higher education, and it may be that before long the Government will recognise its imperative duty.

CAVE HUNTING.[1]

SINCE the memorable researches of Dr. Buckland in the early part of last century, the exploration of British caves has had a great fascination for many investigators. This is no matter for surprise, for there are many points of interest which await elucidation regarding prehistoric man and the animals by which he was surrounded in very early times, and there is a great probability that some of these problems will be solved by cavern researches. When we remember, also, how much has already been revealed by cave hunting, we are led to hope for more in the future, and consequently investigations in this direction raise our expectations.

The current number of the *Quarterly Journal* of the Geological Society contains an interesting account of a cave discovered about two years ago near Brassington, Derbyshire. Shortly after its discovery the cave was visited by a number of "ardent collectors," and many bones and teeth were carried away; but very soon permission was given by Major Nicholson, the owner, for the deposits to be carefully investigated on behalf of the Derbyshire Archæological and Natural History Society, the work falling almost wholly on the authors of this paper.

The cave is in a quarry situated on the south-eastern edge of the Mountain Limestone plateau, and its floor is about 1090 feet above Ordnance Datum, the top of the quarry being some 30 feet higher. The highest part of the plateau in the neighbourhood is formed by the Harbro Rocks, which at some little distance, and with a depression between, rise to a height of 1244 feet, that is, about 120 feet higher than the entrance to the swallow hole which opened into the top of the cavern.

The cavern itself was a master joint in the limestone, enlarged by the action of water, and when found (it is now entirely destroyed) extended about 120 feet from the S.S.E. to the N.N.W., and in this direction it deepened considerably. Much care seems to have been taken to keep separate the bones from each layer, and fifteen spots are marked on the section given to indicate distinct layers or places where bones were discovered. Eventually, however, these were grouped into three series:—(1) The upper inclined layers which had accumulated to the S.S.E. of the swallow hole, and from which they were evidently derived. By far the greater number of the specimens were found in this part of the cave. To the N.N.W. of the swallow hole very few bones were met with, and the deposit was of a more irregular character, seeming to indicate a different mode of origin.

(2) The second division included all that was obtained in a stratum about three feet in depth excavated below the level of the quarry floor, and extending throughout the length of the cave. Very few bones were found, but these included remains of hyæna and of a small deer which it was important to know were present at this early stage of the cave's history.

FIG. 1.—Hoe Grange Quarry, showing entrance to Cave. From photograph by H. Arnold-Bemrose.

(3) The third, and oldest series of deposits, were some highly inclined beds at the N.N.W. end of the cave, which were explored to a considerable depth in the hope of meeting with Pliocene mammals, such as were recognised by Prof. W. Boyd Dawkins in the cave at Doveholes in 1903, but unfortunately without finding any such remains. We wish the explorers had had more success in this deeper exploration; however, it is satisfactory to know that the search was made, even though the results were negative.

The number of bones yielded by this cave could scarcely have been less than 10,000, for the authors have accounted for 8000, and many were carried away before they began work. Nearly half these remains belonged to bovine and cervine animals, while between six and seven hundred of them are referable to hyænas. It seems pretty certain that this cave was a hyæna-den, and although no entrance was found except the swallow hole, yet it is possible that this was the means of access.

Some twenty-seven species of mammals, birds, and amphibia have been identified from Hoe Grange cave, but about half of these belong to the smaller forms of vertebrates, which as a rule have not been recorded in cave researches. The rich harvest of these small creatures which rewarded the patient labour of Mr. Lewis Abbott some ten years ago in the rock fissure at Ightham, Kent, has caused more careful search to be made for them in recent researches, and with good results, such as those of Mr. R. S. Ussher in his cave hunting in Ireland during the last two or three years, only a part of which have yet been published. Search was made for these smaller animals at Hoe Grange, but with only partial success. Among the larger animals represented in the cave, the lion will perhaps attract most attention, and one of the few specimens obtained is part of the lower jaw of a cub with some of the milk teeth still in place. The hyæna, wild cat, wolf, fox, grisly bear, and badger are the other carnivores which have been identified.

Rhinoceros remains occurred in some abundance, and the teeth show that they belong to the *Rhinoceros leptorhinus*, not to the woolly rhinoceros, the form hitherto found in Derbyshire. The elephant is re-

[1] "On an Ossiferous Cave of Pleistocene Age at Hoe Grange Quarry, Longcliffe, near Brassington (Derbyshire)." By H. H. Arnold Bemrose, J.P., M.A., and E. T. Newton, F.R.S. (*Quart. Journ.* Geol. Soc. vol. lxi. p. 43, 1904.)

presented by a single specimen, part of a milk molar of *Elephas antiquus;* this again is peculiar, the elephant previously met with in Derbyshire being the mammoth (*E. primigenius*). The presence of *Elephas antiquus* and *Rhinoceros leptorhinus,* as we learn from the discussion following the paper, led Prof. Dawkins to regard the deposits at Hoe Grange as belonging to the older Pleistocene group of caves.

Among the numerous bovine remains there are no horn-cores and frontal bones to indicate the species to which these remains belong, and the measurements of several metacarpals given in the paper show that limb-bones alone are not sufficient to indicate whether the remains are those of Bos or of Bison.

The Cervidæ are represented by four species, the

FIG. 2.—Mammalian Bones from Hoe Grange Cavern. 1, Lion-cub, lower jaw; 2 Wild Cat, femur; 3, Wild Cat, humerus; 4, Bear, molar tooth; 5, 5A, *Elephas antiquus*, milk tooth; 6, Fallow deer, three molar teeth.

great Irish deer (*Cervus giganteus*), the red deer (*C. elaphus*), the roebuck (*Capreolus caprea*), and another form, intermediate in size between the last two, which is regarded by the authors as fallow deer (*Cervus dama*). Bones and teeth of the last-named form were very numerous, nearly 1600 specimens having been found. If these remains are indeed parts of Pleistocene fallow deer, and we see no way to any other conclusion, they are of the greatest interest. The fallow deer has not hitherto been accepted, at least by modern writers, as a member of the British Pleistocene fauna, but is thought to have been introduced to this country probably by the Romans.

There are two points, however, which have to be settled before we can accept this addition to our Pleistocene mammals:—(1) Are these remains certainly those of fallow deer? and if so (2) Is the deposit in which they were found really of Pleistocene age?

It is to be regretted that there are no sufficiently well preserved antlers to define the species clearly, but the limb-bones and teeth are of such a size that if there had been no question of age there would have been little or no doubt in referring them to fallow deer. In the circumstances the authors have carefully measured the teeth and made comparisons with both fallow and red deer, and feel compelled to regard these remains as parts of fallow deer or of a closely allied species. The only Pleistocene species of a size which might compare with these bones and teeth is the *Cervus Browni* described by Prof. Boyd Dawkins from Pleistocene beds at Clacton, and this is only known by its antler, which is distinguished from that of the fallow deer by the presence of an additional tine. It has been shown, however, that modern fallow deer sometimes have this additional tine (see NATURE, vol. xi., p. 210), and it thus becomes very doubtful whether *C. Browni* is really a distinct species. Although there are no antlers from Hoe Grange cave that can be compared with *C. Browni,* yet it seems almost certain that the authors are correct, and that these Hoe Grange remains are representatives of the fallow deer.

We have now to consider the age of the Hoe Grange deposits. There can be no question as to the Pleistocene age of the elephant, rhinoceros, hyæna, and lion, and there is no doubt as to the fallow deer bones being found with the remains of those animals; but it is just possible that the fallow deer was living in the neighbourhood at a time when a previously existing Pleistocene deposit was washed into this cave, and so the more modern animal got mixed with the older forms. In order that such a re-deposition of large bones might take place there must have been a considerable supply of water, and seeing that the cave at the present time is near the top of the plateau there is no collecting ground for water; and it becomes necessary to suppose that, at the time of the re-deposition of the bones, the land was much higher than it is now, and that it has since been denuded. But it must be remembered that this would mean a very large amount of denudation, and, if we are to accept the fallow deer as a Roman importation, this denudation must have taken place since Roman times, which seems extremely improbable. We think, therefore, that the authors are justified in regarding these particular cervine remains as those of fallow deer, and as good evidence that the species lived in this country in Pleistocene times.

A fallow deer's antler has been recorded recently by Dr. Herlaf Winge from an interglacial deposit in Denmark; and this early extension of the species so far north on the Continent makes its occurrence in England in Pleistocene times still more probable. It is remarkable that *Cervus dama,* or rather its equivalent, *C. Browni,* should have been so rarely found, hitherto, in Pleistocene deposits, seeing that it is so abundant in the Hoe Grange cave.

A word regarding the illustrations accompanying this paper, two of which, by the courtesy of the council of the Geological Society, we are able to reproduce. The views of the cave are very creditable reproductions, but we have nowadays become accustomed to good things of this kind. It is rarely, however, that we have seen such satisfactory reproductions of photographs taken directly from the fossils as we have in the two plates. Most of the good collotype reproductions of fossils that have recently appeared are from photographs of water-colour drawings, and some of them are certainly very effective; but there is the artist's equation to allow for. In the present case, no such allowance has to be made, and the figures of the lion's jaw as well as of the teeth of the fallow deer and elephant are admirable. These plates do credit to all concerned in their production.

FIJIAN FOLK-TALES.[1]

ETHNOLOGISTS have all along suspected that Mr. Fison has plenty of unpublished information concerning Fiji. They are grateful to him for what he has already published in the *Journal* of the Anthropological Institute, but they clamoured for more, and even now they will not remain satisfied with the handsome book that has just been issued by the De La More Press. This new book contains a dozen folk-tales capitally told; "each contains a genuine legend as its skeleton, for the flesh with which that skeleton has been covered, the most that can be claimed is that it is of the native pattern." The tales are interesting as stories, and have increased value when compared with other tales from Oceania, but their greatest importance rests in their value as evidence of the ideas and actions of the natives before the white man came. In the introduction Mr. Fison gives a long discussion concerning cannibalism, and he sums it up thus:—

"It is impossible to establish a certainty as to the origin of cannibalism, and the question resolves itself into a comparison of probabilities, the balance being in favour of the strongest motive. This is undoubtedly Hunger. It is stronger than Superstition; it is stronger than Revenge. Man is a carnivorous animal, whatever the vegetarians may say; and in a savage state of society, if he cannot get the food for which his stomach craves, he will '*kusima*' (crave, or hunger after flesh) until he eats his brother."

For, as Mr. Fison argues, the Fijians were formerly scantily supplied with animal food. The serious student is occasionally tantalised by hints of further information, and by allusions to possible discussions of social and other questions, all of which are passed by as not being suitable for a popular book; doubtless Mr. Fison was wise in restraining himself, but, for the sake of science, it is sincerely to be hoped that he will give all his information to the world in some form or another. In the meantime we thank Mr. Fison for this publication, which can be recommended to those who like interesting information about real savages told in a pleasing manner.

NOTES.

On Friday last, March 17, the worlds of science and art combined to do honour to a man who has rendered to both services of the utmost value and of a nature that time cannot diminish for so long as the human throat is capable of emitting musical sounds, and so long as throats are liable to disease, the great invention of Manuel Garcia will hold its place among vocalists and laryngologists. The celebration of Señor Garcia's centenary was held in the hall of the Royal Medical and Chirurgical Society, Hanover Square, under the direction of Sir Felix Semon, chairman of the Garcia committee. Señor Garcia sat alone on a daïs, while in front of him were ranked the representatives of kings, governments, universities, scientific societies, and his old pupils who had gathered to do him honour. Sir Felix Semon announced that that morning the King had invited Señor Garcia to Buckingham Palace, and with his own hands invested him with the insignia of Commander of the Royal Victorian Order, and had expressed a desire to be represented at the banquet in the evening by his Lord-in-Waiting, Lord Suffield. The Marquis de Villalobar then delivered a congratulatory message from the King of Spain, and added, "In the name of His Majesty and your motherland, I invest you with the Royal Order of Alfonso XII. as a reward of your merits and the services you have rendered to mankind. I desire also to make public the sentiments of my beloved Sovereign and of his Government to King Edward VII. for the distinction he has conferred upon our compatriot, and the hearty gratefulness of Spain to all who have come here to-day to honour Don Manuel Garcia." Other tributes followed thick and fast during a crowded hour. Prof. Frankel presented on behalf of the German Emperor the great gold medal of science. Sir Archibald Geikie, Mr. Francis Darwin, and Prof. Halliburton, representing the Royal Society, presented an address, recalling the fact that their *Proceedings* for March 22, 1855, contained the epoch-making paper in which Señor Garcia laid the foundations of the experimental study of the voice. The Royal Prussian Academy of Sciences, the University of Königsberg, the Victoria University, the Medical Faculty of Heidelberg, the Royal Academy of Music, and the Royal College of Music sent distinguished representatives, who in rapid succession laid before the maestro illuminated addresses in rich profusion, until the table in front of him was heaped. We have not space to give the long list of public institutions and societies, laryngological and other, which brought tribute; but every quarter of the globe was represented, and during the proceedings a constant stream of telegrams poured in. After the addresses a portrait of Señor Garcia, painted by Mr. Sargent, R.A., and subscribed for by friends and admirers in all parts of the world, was unveiled and presented to him by Sir Felix Semon. The proceedings were concluded by a remarkably eloquent speech by Señor Garcia. In the evening Señor (now Don) Garcia was entertained at a banquet held in his honour at the Hotel Cecil.

We learn from the *Times* that further papers have been published by the Government of India in respect to the late Mr. J. N. Tata's offer of an endowment in the shape of properties valued at 200,000*l.* for the creation of an institute of Indian research at Bangalore. Certain conditions in respect to Government assistance were attached to the offer, which was first made six years ago, and these have been the subject of prolonged discussion and correspondence between the Government, Mr. Tata during his lifetime, and his representatives. The papers now published show that the difficulties in the way of a settlement have been removed. Guarantees have been offered by the representatives of the donor to secure the full income estimated from the endowment properties, and the management of the latter is vested in a board the chairman of which is to be an officer selected by the Bombay Government. In addition to making a grant of 2½ lakhs of rupees (16,666*l.*) towards the construction of the necessary buildings and provision of scientific apparatus, the Government will make an annual grant to the institute of half the local assets up to a limit of 1½ lakhs of rupees, provided that the institute is conducted on lines approved generally by the Government. The scheme will provide for the reference of certain questions to the advisory committee of the Royal Society, or to such other scientific authority as may be appointed for the purpose. The Governor-General in Council disavows any desire to be intimately associated with the actual administration of the institute, or to claim a determining voice in the settlement of the lines of research to be followed or the methods of instruction to be employed. The Government will exercise no more than that degree of influence and control which is justified by the grant in aid that has been promised.

Prof. Emil Warburg, of Berlin, has been appointed president of the National Physical Laboratory at Charlottenburg, and his place in the university is to be taken by Prof. Paul Drude, of Giessen.

The magnificent collection of birds' eggs possessed by the British (Natural History) Museum has been largely augmented by the gift of the splendid series brought together by Mr. W. Radcliffe Saunders, of High Bank, Tonbridge. This collection comprises close on ten thousand specimens of the eggs of Palaearctic species, together with one hundred and sixty-five nests.

We regret to record the death at the age of seventy-six of Mr. Jeremiah Slade, one of the founders of the Geologists' Association. Mr. Slade had for many years been a teacher of geology, mineralogy, zoology, and botany at the Working Men's College, the Birkbeck Institution, and the City of London College. He was an ardent microscopist and member of the Quekett Microscopical Club.

The anniversary dinner of the Chemical Society will be held on Wednesday, March 29.

The sixth International Congress of Applied Chemistry will be held at Rome next year, probably during the week following Easter.

The French Société d'Encouragement pour l'Industrie nationale has awarded the Lavoisier medal to M. Héroult in recognition of his electrometallurgical researches. In recommending the award the committee refers to his work in connection with the manufacture of aluminium, and the preparation of steel in the electric furnace.

Official statistics show that the production of natural gas in the United States in 1903 was greater than in any previous year. The production had a value of 7,143,000*l.*, or 16 per cent. more than that of 1902. Four States, Pennsylvania, West Virginia, Indiana, and Ohio, furnished together 94 per cent. of the supply of gas. The total volume of the gas at atmospheric pressure was 6757 million cubic metres, representing in heating value 12,129,468 tons of bituminous coal.

Reuter's Agency has received some details of an expedition which went to British New Guinea in September, 1903, and has lately returned to England. The expedition was organised by Major W. Cooke-Daniels, an American traveller, and it also included Dr. C. G. Seligmann, Dr. W. M. Strong, and Mr. A. H. Dunning. The objects were primarily ethnographical, but studies were also made in other branches of science, and a number of general pathological observations were made. A collection of photographs was secured by Mr. Dunning, and the travellers have brought back kinematograph pictures and a selection of phonographic records.

A CORRESPONDENT writing to the *Times* from Florence directs attention to the fact that the famous Tower of Galileo, on the hill of Arcetri above Florence, is now practically destroyed. This historic thirteenth century building—known locally as the Torre del Gallo—has for some months past been concealed in scaffolding set up for the purpose of raising its castellated tower by a third of its former height, of placing in its walls new windows, of adding a loggia, and, in fine, of converting the world famous "Star Tower" into a pretentious modern erection. To the Anglo-Saxon race Galileo's Tower possessed a special interest, in that it was the scene of the classic meeting between Milton and Galileo.

IN No. 1395 of the *Proceedings* of the U.S. National Museum, Mr. C. D. Walcott continues his account of American Cambrian brachiopods, describing several new genera and species. It is explained that these notes and their forerunners are published in the hope that they may be of service to students prior to the appearance of the full monograph promised on the subject.

WE have received the reports of the Wellington College and of the Felsted School science societies for 1904. The former, which is illustrated, contains summaries of a number of lectures delivered before the society, among which one by Mr. H. W. Monckton on the geology of the London district deserves special mention. In the Felsted report attention is directed to the lack of keenness displayed by the members of the zoological section, who failed to take nature-study seriously. Although one prize was offered for an account of the birds of the district, and a second for the best collection of butterflies and moths, there were no competitors.

IN addition to the *Bulletin* on the fauna and flora of the plateau of Baraque-Michel, already noticed (from an author's copy) in NATURE of March 16 (p. 468), No. 12 of the *Bulletin* of the Belgian Royal Academy contains two biological articles of considerable interest. In the first of these, Miss J. Wery discusses the attractions offered to bees by flowers, and, as the result of direct experiments, arrives at the following conclusions. Brilliantly coloured flowers offer much greater attraction when entire than when the petals, &c., have been cut away; honey has no attractive power; artificial flowers are just as attractive as natural ones if both are under glass shades; flower perfume by itself offers but little attraction; while colour and form, apart from scent, are powerfully attractive; the mingling of the three factors, form, colour, and scent, constitutes the most powerful attraction of all. Finally, if the latter item be reckoned as 100, the attractive power exerted by form and colour will be 80 per cent., while the other factors (pollen, nectar, and scent) will only rank as 20 per cent.

IN the second of the two articles from the *Bulletin* of the Belgian Academy referred to above, Prof. A. Lameere discusses Darwin's theory of female sexual selection as the primary factor in the production of secondary sexual characters in the male, and comes to the conclusion that such an hypothesis offers an inadequate and untenable explanation of the phenomenon. In place of this, the author suggests that such features in the male are the equivalents of maternity in the female, that is to say, the products which in the female are required for generative purposes are superfluous in the male, and are accordingly employed for sexual ornament. If we mistake not, the same theory has been already promulgated by Captain Barrett-Hamilton.

WE have received copies of four articles from the third volume of "Marine Investigations in South Africa." In describing, in two of these, the polychætous annelids collected by Dr. Gilchrist, Prof. McIntosh directs attention to the community of type between South African and European marine annelids generally, many of the types from the two areas being specifically identical, while others, in a more or less modified form, extend eastwards into the Indian and Pacific Oceans, and westward to America. A nearly similar feature has been recorded in the case of crustaceans, and it thus seems that the distribution of invertebrates in these seas is governed by very different laws from those which obtain, for instance, in the case of the commoner food-fishes. The anatomy and variation of the Flabellum-like corals form the subject of the third article, in which Mr. J. S. Gardiner has found himself compelled to dissent from the classification of corals proposed by the late Prof. P. M. Duncan. In the fourth fasciculus Dr. Gilchrist continues his investigation into the development and life-history of South African fishes, describing and figuring a number of larvæ, some of which cannot at present be specifically identified.

IN the *Monthly Review* for March, Mr. W. E. Hodgson discourses very pleasantly on certain problems connected with salmon-fishing. After pointing out the inaccuracy of the common opinion that the north of Scotland in spring is necessarily colder than the south of England, the author proceeds to discuss the reason why loch-fishing for salmon is carried on with a minnow instead of with a fly. One reason seems to be that salmon lie deeper in the water than trout, and will consequently, owing to the set of their eyes, see the approach of a boat at a greater distance. A minnow trolled behind a boat is probably, therefore, the best lure for *Salmo salar*; but whether the boatmen are right in giving a sinuous course to the boat is very questionable. In the first place a boat may be rowed right over a deep-lying salmon without being seen by the fish; secondly, there is considerable reason to believe that disturbed water is conducive to the salmon biting; and thirdly, it is not unlikely that the fish which takes the trailing lure has not been lying in the wake of the boat, but may have made a dash from the side. Mr. Hodgson, who is by no means convinced that salmon fast during their sojourn in fresh water, thinks they take the minnow for a wounded fish, and dash at it owing to the impulse which makes most animals attack a cripple.

PART IV. of the third volume of *Biometrika* contains several memoirs of interest. Mr. Punnett contributes a careful study of variation in *Spinax niger*, showing, from an analysis of the characters of 263 adults and 304 embryos, that a well-marked sexual dimorphism exists in this shark, and that the variability of male embryos considerably exceeds that of male adults, this pointing to a more stringent selection in the case of the male. Homœosis rather than intercalation or excalation is held by the author to be the more feasible explanation of the various relative positions occupied by the structures examined—this supporting Gegenbaur's theory of the origin of limbs. The same material is thought by Mr. Punnett to favour the hypothesis of gametic purity—a view from which Prof. Pearson dissents for reasons given. Dr. Beddoe's craniometric formula, lately published in *L'Anthropologie*, is vigorously impugned by M. A. Lewenz and Prof. Karl Pearson, who produce in evidence the "auto-icon" of Jeremy Bentham preserved at University College. In another paper, Prof. Edmond Gain deals with variation in the flower and heterostylism in *Pulmonaria officinalis*. Local races are shown to present significant differences in the former respect. The miscellanea include interesting applications of a new method of determining correlation.

The Bureau of Forestry of the United States Department of Agriculture has erected an extensive plant on the grounds of the St. Louis Exposition for carrying out a series of experiments under the direction of Drs. von Schrenk and Hatt on the value and methods of preserving timber. According to the general programme, which is outlined in the *Press Bulletin*, No. 62, the timber will be subjected both to static and impact tests. Preliminary results indicate that steaming reduces the strength of the timber in proportion to the pressure and duration of the process.

Under the title "Place-constants for *Aster prenanthoides*," Mr. G. H. Shull has contributed to the *Botanical Gazette* (November, 1904) a biometric article based upon the number of bracts and florets which were counted on the inflorescences of this plant as collected in a specified area during the autumn of 1903. In general, the first head to bloom on any stem had the highest number of parts, and the last to bloom the lowest, but precocious flowering on the part of the weakest individuals produced a low mean at the beginning of the season, and the belated flowering of a few vigorous specimens caused a rise towards the end.

A practical and detailed comparison of the cost of production of sugar on a muscovado estate and in a central factory using the vacuum pan with triple effect, such as that given by the Hon. R. Bromley, administrator of St. Kitts, in vol. v., No. 3, of the *West Indian Bulletin*, should carry conviction to the planters of Barbados and other islands, who, trusting to the high saccharose yield of their canes, and the profit on molasses, have preferred to retain their simple process of manufacture. Apart from the advisability of manufacturing a product of the best quality, the figures show that the profit per ton of sugar prepared in a central factory is four times that obtained on a muscovado estate.

The Société Helvétique des Sciences naturelles celebrated, at its eighty-seventh congress at Winterthur, the fiftieth jubilee of the discovery of ancient pile dwellings, described by Dr. Ferdinand Keller. The report and appreciation of the work of Keller and others is written by M. F. A. Forel. The same authority lately directed attention (*Gazette de Lausanne*, January 19) to the discovery at Boiron, near Morges, by the Lake of Geneva, of a tomb or place of burial of the Bronze Age—the age of the old lake-city of Morges. Human bones, cinders and burnt earth, bronze trinkets, vases and other pottery were found, but of special interest was the discovery alongside the calcined human bones in the burial chamber, of leg-bones of a goat uninjured by fire, and evidently deposited with the flesh as an offering to the shades of the departed. M. Forel concludes from the evidence that a belief in the resurrection of the dead was held in the Bronze Age.

We have received a copy of the results of the meteorological observations made at the stations in connection with the Deutsche Seewarte (Hamburg) for the year 1903. The stations number sixty-nine, and include hourly readings at four first-order observatories. The tables are arranged as in previous years, and leave nothing to be desired either in thoroughness of discussion or in detailed explanation of the methods employed. Mid-European time was adopted in Germany in April, 1893, but the observations are recorded according to local time as before, with the exception of the occurrences in the remarks column, which are stated in Mid-European time. A table is given showing the difference of these times for each of the stations.

The last published *Bulletin* of the Philippine Weather Bureau (for August, 1904) contains, in addition to the usual useful summaries of meteorological and seismological observations at various stations, a valuable discussion of the cyclones which affected the archipelago, with a map showing their tracks. The director of the central observatory at Manila, the Rev. J. Algué, S.J., author of the valuable work, "The Cyclones of the Far East," makes a special study of these interesting phenomena, and his discussion of their behaviour is most instructive. During the month in question five typical cyclones are dealt with. One of them (August 17–21) moved at the rate of thirty miles an hour; this storm was experienced by the U.S. Army transport *Sherman*, near Formosa, and an interesting account of it is given by the second officer of that vessel.

A summary of the present state of knowledge in regard to long range weather forecasts, by Prof. E. B. Garriott, has been published by the Weather Bureau of Washington. It is accompanied by a paper by Prof. C. M. Woodward on the planetary equinoxes. Prof. Garriott finds that at the present time practically no value is to be attached to weather predictions based on astronomical phenomena or observations of birds, animals or plants. At the same time, every attention is being given to the advancement of meteorology on such a basis as may lead to substantial improvements in weather forecasting. In his prefatory report Mr. Willis L. Moore remarks:—"It is to be regretted that so many newspapers not only give space to these harmful predictions, but actually pay for them. Forecasts of this description may properly be classed with advertisements of quack medicines—they are both harmful in the extreme."

In the February number of the *Bulletin de la Société astronomique de France*, M. J. Loisel presents his annual summary of the climatology of the past year. On one chart he shows the rainfall, the daily temperatures, the humidity, the barometric pressure, the insolation, the amount of cloud, and the declination and phase of the moon. Each of the atmospheric elements is then discussed in detail month by month. Among other outstanding features, one sees that the temperature during July, 1904, was abnormally elevated, whilst that of December was higher than that obtaining during November. The figures and the curve indicating the number of hours of sunshine are especially interesting, and show that in each of the months May, June, July and August there only occurred one day when the sun was completely obscured at Juvisy, whilst in July the number of hours of effective sunshine amounted to 72 per cent. of the theoretical number. A comparison of the solar radiation during 1903 and 1904 shows an increase of about 23,134 calories, or rather more than 16 per cent., in the latter year.

More than ten years ago Prof. Landolt described a series of experiments which were considered to throw doubt on the law of the conservation of mass in chemical action, and in 1901 Heydweiller concluded that a change in the total mass had been experimentally established in a number of cases. In a paper published by Antonino Lo Surdo in the *Nuovo Cimento* (1904, series 5, vol. viii.), the question is re-investigated. By excluding all possible sources of error, such, for instance, as a difference of temperature in the two arms of the balance, differences of volume of the vessels used, it is established that the change of mass due to the interaction between iron and basic copper sulphate, which by Heydweiller was considered to be about 0·2 milligram, in reality falls within the limits of the error of weighing, being certainly less than 0.02 milligram. In the experiments described, the sealed tubes in which the interaction took place were not removed from the balance during the whole of the series of weighings, and an ingenious mechanism was designed by which the tubes and weights were manipulated within the case.

The operations of the Smithsonian Institution during the year ending on June 30, 1904, and the work of the U.S. National Museum, the Bureau of American Ethnology, the International Exchanges, National Zoological Park, and the Astrophysical Observatory, are described in Dr. S. P. Langley's report which has just reached us. Among the matters mentioned is the removal of the remains of James Smithson, founder of the Smithsonian Institution, from the British cemetery at Genoa to America, at the beginning of last year. The report states that the remains rest temporarily in a room at the Smithsonian Institution containing a few personal relics of Smithson, awaiting their final disposal by the Regents. Dr. E. W. Scripture, of Yale University, has been awarded a grant from the Hodgkins fund for the construction of a "vowel organ." Dr. Scripture expects to be able to construct an organ which can sing the vowels, or a vowel register which, attached to a pipe organ, may be used effectively in church music. An exploration of some of the glaciers of British Columbia has been undertaken by Dr. W. H. Sherzer, under the auspices of the Smithsonian Institution, for the purpose of gathering definite information regarding glacial phenomena, such as the nature and cause of the ice flow, the temperature of the ice at various depths, and its relation to air temperatures, the amount of surface melting, and the possible transference of material from the surface to lower portions. Reference is made in the report to the new building of the National Museum in course of erection in the Smithsonian Park. The floor area in the four stories of the new building will be about 9½ acres. The accessions to the museum in the year covered by the report amount to 241,547 specimens, which bring the total number of objects in the collections up to nearly six millions. The work of the astrophysical observatory has been chiefly concerned with solar radiation, and its possible variability. The investigations point to the conclusion that the radiation supplied by the sun may perhaps fluctuate within intervals of a few months through ranges of nearly or quite 10 per cent., and that these fluctuations of solar radiation may cause changes of temperature of several degrees centigrade nearly simultaneously over the great continental areas of the world.

The latest report issued by the Engineering Standards Committee deals with British standard specification for structural steel for marine boilers. Copies may be obtained from Messrs. Crosby Lockwood and Son at 2*s*. 6*d*. net.

Messrs. Henry Sotheran and Co. have issued a new catalogue of second-hand books, containing works on mathematical, astronomical, physical, and chemical subjects. The works catalogued include the library of the late Prof. A. W. Williamson, F.R.S., and many important foreign works on the exact sciences published within the past twenty years.

OUR ASTRONOMICAL COLUMN.

The Alternating Variability of Martian Canals.—During 1903 Mr. Lowell observed an apparent alternation in the visibility of the Martian canals Thoth and Amenthes, which he suggested might be due to the artificial regulation of a deficient water supply for irrigation purposes (Nature, vol. lxix. p. 496).

In a telegram, dated March 10, communicated to Prof. E. C. Pickering and published in No. 4003 of the *Astronomische Nachrichten*, Mr. Lowell announces that he has again observed "a functional alternative visibility" of these two canals, both of which are double.

Discovery of Jupiter's Sixth Satellite.—In No. 100 of the *Publications* of the Astronomical Society of the Pacific, Profs. Perrine and Aitken describe the first observations of Jupiter's sixth satellite, and abstracts of their communications are published in No. 4002 of the *Astronomische Nachrichten*.

Prof. Perrine states that several years ago it was proposed that the Crossley reflector, when reconstructed, should be employed in a search for additional satellites to the outer planets. In accordance with this programme, photographs of Jupiter were taken on December 3, 8, 9 and 10, 1904, and a comparison of them showed that the planet, which was slowly retrograding at the time, was apparently accompanied by an object of the fourteenth magnitude. Photographs taken on January 2, 3 and 4 showed that the newly discovered object was following Jupiter in such a manner as to suggest its dependence on that body. The greatest elongation (west) of the new satellite, about 50′, seems to have been passed on December 25, and the inclination of its orbit to the ecliptic appears to be greater than those of the inner satellites. The direction of the satellite's motion, although apparently retrograde, cannot be determined until further observations have been made.

On January 28, Prof. Aitken, using the 36-inch refractor under unfavourable atmospheric conditions, found the satellite quite easily, using the position predicted from the Crossley photographs, and, after a few minutes' observation, the identification was confirmed by the motion in right ascension. Following the object for nearly an hour, he found it to have an hourly motion in R.A. of about +20″, and this agrees with the photographic result. A comparison with neighbouring faint stars showed that the satellite was about as bright as a star of the fourteenth magnitude.

Forthcoming Oppositions of Mars.—As during the oppositions of Mars in 1905, 1907, and 1909 the planet will become successively more favourable for observation, Mr. R. Buchanan has communicated to *Popular Astronomy* (No. 3, vol. xiii.) the following figures, showing the respective conditions for each opposition:—

Year	Mars passes perihelion	Opposition	Distance from Earth	Brilliancy
1905	Nov. 7	May 8	0·543	36·8
1907	Sept. 22	July 5	0·411	75·4
1909	Aug. 13	Sept. 25	0·390	86·6

The sun's distance from the earth is taken as the unit of the mean "distance from earth." In the oppositions of 1901 and 1903 the respective apparent brilliancies of the planet were 20·0 and 23·4.

Variable Radial Velocity of Sirius.—In No. 70 of the Lick Observatory *Bulletins*, Prof. Campbell discusses the spectrographic observations of the bright component of Sirius made at Lick since 1896, thirty-one plates in all.

Before treating the main subject, however, he discusses the difficulty experienced in binary star work through the employment of numerous different systems of nomenclature to define the orbital elements, and then propounds a new system which would be readily adaptable to all requirements, visual or spectroscopic.

The observations of Sirius have been made under varying conditions, instrumental and otherwise, and a better accordance in the individual results might be obtained by making the observations under uniform conditions. The resulting value, obtained from all the plates, gave the velocity of the system of Sirius as $-7\cdot36$ km. per second. There is a marked progression among the individual values obtained for the velocity of the primary which is attributed to the effect of orbital motion. The sense of this progression indicates that the positive value of i (the inclination of the plane of the orbit) should be used. The above value, whilst disagreeing with others, agrees very well with the value obtained by Profs. Frost and Adams in 1901–2.

The values of the radial velocities of the centre of the system and of the primary and secondary components are given in a table, with yearly intervals, for a whole revolution, *i.e.* from 1870·09 to 1918·09, the time of the apastron passage being 1918·5110.

CONSTANT ERRORS IN MERIDIAN OBSERVATIONS.—In an address delivered to the astronomy section of the St. Louis International Congress of Sciences and Arts, Mr. J. G. Porter discussed the various sources of error to which meridian observations are peculiarly subject, and proposed various methods whereby the constant errors might be eliminated.

Among other methods for eliminating the magnitude error which affects right ascension determinations, he recommends the one proposed by Prof. Turner wherein the transits would be registered on a regularly moving photographic plate, the reticule wires being replaced by spots of light projected on to the plate at regular intervals from a fixed source.

Regarding declination observations, the error due to varying refraction is the most important, and Mr. Porter suggests that this might be eliminated by having a perfected system of fundamental stars well distributed over the sphere, from observations of which, on any evening, the deviation of the actual refraction from the assumed law might be determined and used to correct the observations. Another, more costly, method would be to have a number of observatories widely distributed in latitude, so that zenith observations, where refraction is non-effective, of more stars might be made. Mr. Porter considers the solution of this constant error difficulty in meridian observations to be one which is eminently suitable for international cooperation (*Popular Astronomy*, No. 3, vol. xiii.).

THE NATIONAL PHYSICAL LABORATORY.

ON Friday last the annual general meeting of the governing body of the National Physical Laboratory was held at that institution, when the report of work done in 1904 was received and the programme of work proposed for the forthcoming year approved. A number of guests were invited to meet the members of the general board and inspect the laboratory. Among those present were about thirty Members of Parliament, several colonial agents-general, and a representative gathering of leading physicists and engineers.

In the 45-page report submitted by the director, Dr. Glazebrook, are found particulars regarding the various researches and tests carried out during the past year, with special reference to the newer developments. The test work at Bushy for the year shows a marked growth, the total number of separate tests made having increased from 1330 in 1903 to 1906 in 1904, the increase being spread over almost all the different departments of the laboratory. These figures are distinct from the work of Kew Observatory, where in all more than 26,000 instruments were verified during the year.

In the engineering department, Dr. Stanton has made considerable progress with the research on the distribution of wind pressure over large areas, which forms a continuation of the important work embodied in his paper read at the Institution of Civil Engineers last session. A steel tower fifty feet high has been erected in the grounds, carrying large and small pressure plates with the necessary gauges. From the general results of the observations made it would appear that the distribution of pressure on the windward side of a large plate in the open air falls off more rapidly from the centre to the sides than in the case of a small plate, but that the ratio of the pressures on the windward and leeward sides appears to be practically the same in both cases.

The research on the specific heat of superheated steam by the continuous flow method has been continued by Mr. Jakeman, who has been mainly occupied in contending with certain experimental difficulties, such as the attainment of sufficiently high insulation between the various parts of the electrical superheater, especially at low superheats. Some preliminary figures have been obtained which do not appear to confirm the rapid rise in specific heat shown by the results of some recent observers.

A testing machine for studying the effect of alternating stresses of varying periodicity on engineering materials has been constructed and was described in last month's *Engineering* by Dr. Stanton. It has already been used on a set of nickel-steel specimens, which are the basis of a research in the metallurgical department.

A new building has been erected to house the new standard leading-screw machine, which is now at work. Several standard screws have been cut and measured for use in Government arsenals.

Dr. Chree, at the observatory department, has been occupied with some important investigations on terrestrial magnetism, and the measurement and tabulation of some of the old Kew magnetic records. The men of science of the British Antarctic Expedition have, since their return in September last, had the opportunity of again comparing with recognised standards many of their instruments, and arrangements have been made for cooperation with them in the reduction of the mass of magnetic and meteorological data they brought home with them.

In the physics department numerous researches have been in progress. We have only space for mention here of some of the more important. Dr. Harker, in the thermometry division, has been occupied with preliminary work on which it is hoped may ultimately be based some new direct electrical method of very high temperature measurement. With this object he has undertaken a study of the resistance and thermoelectric properties of solid electrolytic conductors such as are used in Nernst lamps. The existence at high temperatures of large thermoelectromotive forces between rods of the various earths made up as ordinary thermojunctions has been securely established by direct electrometric methods, and a new form of electric furnace has been designed capable of continued use at temperatures above 2000° C. By means of these furnaces and a number of thermojunctions of widely different properties, a careful re-determination of the melting point of platinum was made. More than sixty determinations concorded in giving a value which differs considerably from that now accepted. The results of this work are embodied in a paper just sent in to the Royal Society.

The research on the specific heat of iron, which has been extended to temperatures above 1100° C., is complete, and will shortly be published.

In the electrical standards department, Mr. Smith has been mainly occupied with work on the standard ampere balance designed by the late Prof. Viriamu Jones and Prof. Ayrton for the British Association committee on electrical standards. The weighing mechanism was constructed by Mr. Oertling, and the four marble cylinders carrying the coils have been successfully wound and insulated at the laboratory. On each cylinder are two double helices of bare copper wire. Though the air space between the consecutive turns is less than 0·006 inch, an insulation resistance over 30,000 megohms was finally secured for each of the coils. Many accessories have been constructed, and the outlook for a speedy determination of the absolute unit of current to at least one decimal place further than hitherto attained is very hopeful.

In electrotechnics, Mr. Paterson has installed large cells for ammeter verification, and for alternate current measurements a specially constructed set of Mr. Addenbrooke's instruments, and a Kelvin voltmeter with circular scale of $2\frac{1}{2}$ metres radius. In photometry have been included investigations on several Harcourt 10-candle pentane lamps and a number of Fleming large bulb standard electric glow lamps, which now form the working standards of candle-power. Intercomparisons have been made by means of glow lamps with the National Standards Bureau of Washington, the Electrical Standardising Laboratories of New York, and the Berlin Reichsanstalt.

In the general electrical department, Mr. Campbell has devised a method for obtaining for inductance measurements alternating currents having very high frequencies and a wave form almost a pure sine-curve. A large amount of new apparatus has been set up for testing purposes, much of it of a novel character.

The standard current balances and electrostatic voltmeters have been studied, and it has been found that the allegation that the Kelvin balance, when used with alternating current, is affected by eddy currents in the metal parts near the coils is without foundation for all ordinary frequencies.

Researches on the distribution of temperature in field coils of dynamos and motors, and on the behaviour of insulating materials under heat treatment, have been made by Mr. Rayner, and form the subject of a report to the engineering standards committee communicated to the Institution of Electrical Engineers at their last meeting.

In the department of metallurgy, Dr. Carpenter and Mr. Keeling, during the early part of the year, completed their work on the range of solidification and critical ranges of iron-carbon alloys, and an account of the work was read at the meeting of the Iron and Steel Institute in May last. The value of Dr. Carpenter's work was recognised by his election as Carnegie scholar. On Mr. Keeling's leaving the laboratory, Mr. Longmuir, also a Carnegie scholar, was appointed on the staff, and Dr. Carpenter and he have since been carrying on, in cooperation with Mr. Hadfield of Sheffield, an elaborate systematic research on the properties of the nickel-steels. In all, seventeen different kinds of physical, mechanical, and chemical tests have been performed on the different samples used, which contained varying amounts of nickel up to 16 per cent. The results obtained will shortly be submitted to the alloys research committee of the Institution of Mechanical Engineers.

An investigation on modern high-speed tool steels, such as those shown in use in the engineering department on Friday last, has also been completed by Dr. Carpenter, cooling curves and photomicrographs having been obtained showing clearly the various modifications in structure after different heat treatment.

The optical department is rapidly being organised, and, in addition to lens testing, the work has included the accurate measurement of the angles of prisms and determination of the optical constants of numerous samples of glass.

In the weights and measures department, the chief work has been the study of the master screw of the new leading-screw lathe, which has been carefully calibrated throughout its entire length.

The foregoing serves to indicate the substantial progress made by the laboratory, and to prove that though it has only been at work a little more than three years, it has already begun to make its mark on the science and industry of the country, and to justify in a large measure the expectations of its promoters.

FUNGI.[1]

HAVING pointed out that the attempts to derive the word fungus from *funere*, or *funus* and *ago*, *fungor*, &c., have been shown to be failures—that it comes from the Greek σπογγος, and is the same word as sponge, the lecturer proceeded to give illustrations of the fungi known to the ancients. These were, of course, all of the larger kinds, since no knowledge of micro-fungi was possible. Nevertheless, references in the Old Testament show that certain diseases—mildew, smuts, &c.—were known to the Hebrews, but of course their connection with fungi was not suspected.

[1] Abstract of a discourse delivered at the Royal Institution on February 24 by Prof. H. Marshall Ward, F.R.S

The Greeks and Romans not only knew several forms of Amanita, Agaricus, Boletus, Polyporus, and of Truffles, Morels, &c., but they discriminated clearly between the poisonous and wholesome species.

Their ideas as to the nature and origin of such fungi seem childish to us, but they were consistent with the naif attitude of the Greeks towards natural objects. Theophrastus, about 320 B.C., Dioscorides, about 60 B.C., and Pliny, for example, argued that since truffles and other fungi had no roots, leaves, stems, &c., they are objects apart. They arise spontaneously from earth, or by fermentation from the sap of trees, or from water.

It is interesting to note that *Polyporus officinalis* was imported and used as an article of medicine not only during classical times, but also for centuries afterwards.

In mediæval times the herbalists chiefly copied from Galen, Theophrastus, &c., and as they had no figures the early herbals give us little information. In 1576, however, Clusius gave a series of wood-cuts which are well worth looking at, and in 1601 he made a series of water-colour sketches of eighty-two of the fungi of Austria—the first drawings of the kind known. Figures in Dalechamps, 1536, Dodoens, 1583, and Parkinson, 1640, may also be compared.

The next step forward was only possible after the microscope had come into use as a scientific instrument.

It is a curious point that abundant and conspicuous as the powdery spores of the fungi are, no one seems to have observed their importance until Micheli, in 1729, collected and sowed a series of them, and with results, for he obtained mycelia, and in a few cases even sporophores; but it was not until a century later, 1820, that Ehrenberg, in his classical "De Mycetogenesi," traced the larger fungi to their mycelial filaments, collected and sowed spores, and grew several species of Moulds, and especially discovered the sexual act in Zyzygites. For although Micheli's ideas had been confirmed by Gleditsch in 1753 and by Schaeffer in 1762, Rudolphi and Persoon had more or less denied the germination of spores, and insisted on the spontaneous generation of the moulds.

However, before 1840 Nees von Esenbeck had cultivated a Mucor from spore to spore, and Dutrochet, 1834, and Trog, 1837, had seen the "puffing" of asci and practically established the doctrine of wind-distribution of spores.

By these and similar successes the era of the Mould-fungi was initiated, and the labours of Corda, Tulasne, Pringsheim, Cohn, and De Bary soon introduced system into their study, and especially the exact study of life-histories showed what important results for morphology lay in the biological investigations of these micro-fungi.

The lecturer here gave illustrations of the commoner types of mould fungi, with notes on their botanical importance, and some remarks on the points he wished to emphasise later.

An early outcome of the investigations of the moulds and their allies was the discovery of what curious substrata some of them grow upon. A rapid survey of all saprophytic fungi shows that while the majority grow on the soil, on plant remains, or on dung of various kinds, peculiar forms or species occur on such bodies as resin, cork, bees' and wasps' nests, bones, limestone, insect-remains, horn, hair, feathers and hoofs, fats, and in chemical solutions such as picric acid, copper sulphate, arsenic, and poisons such as atropin, muscarin, and so forth.

Here, also, the lecturer gave some notes on details, of which the most striking was, perhaps, his own proof that the horn-destroying fungus will not act until its spores have been passed through the alimentary tract of an animal, or subjected to the influence of gastric juice.

In 1866, the year of publication of De Bary's book on mycology, a revolution in the study of fungi was brought about by the first morphological proof of parasitism and infection, and the clear distinction drawn between the saprophytic micro-fungi or "moulds" and the parasitic fungi which induce "diseases." The matter was of especial importance as explaining away prevalent erroneous ideas according to which these disease-fungi were outgrowths (*exanthemata*) from the moribund tissues of the host-plant itself.

De Bary's great service was to prove that a spore of a fungus arrived from outside, and after germinating on the leaf or other organ of a plant, bored its way in, or through a stoma, and entered the tissues. Here it lived, as does a plant in any other medium, at the expense of the substances in the tissues, which it eventually kills. It then emerges and develops its spore on the outside.

Thus was founded the "germ theory" of disease.

The lecturer here gave illustrations of the kinds of parasites referred to, and showed how the spotting of leaves is brought about by various epiphytic and endophytic forms, such as Oidium and Erysiphe, Phytophthora, Ustilagineæ and Uredineæ, &c., and directed attention to certain special genera, such as Botrytis, Aspergillus, &c.

That the ancients were acquainted with the phenomena of rot in timber is attested by remarks of Theophrastus on hollow trees and the decay of oak; but it was not until about 1830 that any idea of connecting the phenomena with fungi can be traced, and even then Theod. Hartig, who discovered hyphæ in the rotten wood, thought they originated from the wood-fibres themselves. Schacht, in 1850 and 1863, figured many instances of hyphæ in wood, and showed that the fungus fed on the starch, pierced the cell-walls, and in some way induced their putrefaction; and to these and Willkomm's researches, in 1864, we may trace the origin of our knowledge of fungi as the causes of decay in timber.

Meanwhile the palæontologists also were bringing forward examples of fungus-hyphæ in fossil woods.

But the real founder of this important subject was R. Hartig, who in his works, 1874 and 1878, proved that not only are there several kinds of wood-rots in different species of trees, each induced by different forms of fungi, but that the different woods show special markings, and break up in peculiar manner for each case, so that particular kinds of rot can be recognised by particular symptoms. Hartig, moreover, showed how the fungi got into the tree, and that these wound-fungi have special peculiarities. He traced their hyphæ into the vessels and wood-elements, showed how they pierce the cell-walls, and, most important of all, proved that they dissolve out from the wood-elements the lignified constituents to which their fundamental physical properties—as wood—are due, and either leave the delignified walls soft and cellulose in character or dissolve them to a jelly.

Here the lecturer showed illustrations of the mode of action of dry rot, of *Polyporus igniarius*, and of other wood-destroying fungi, and referred to Czapek's recent discovery of Hadromal, the probable uniform constituent of wood hitherto vaguely known as Lignin.

In another direction activity was turned to the fungi which attack insects, and which are now known often to become epidemic, to the great advantage of areas devastated by locusts, cockchafers and other grubs, caterpillars, &c.

It is a remarkable fact that whereas the diseases of plants due to fungi are numbered by their thousands, only some two hundred or so of animal maladies due to fungi proper are known. Whether this is due to the more acid nature of vegetable sap, to the high temperature of animal tissues, or to the greater abundance of the anti-bodies in animals cannot be decided.

The lecturer gave illustrations of caterpillars with their destroyers, Cordyceps, Isaria, &c., growing from their mummified bodies, and referred to Torrubia's "Vegetable Wasp" legend of 1749. He also showed photographs of the "plant-worms" used in Chinese medicine, and rapidly surveyed the work of Cesati, Pasteur, De Bary, Cohn, &c., on Muscardine, Entomophthora, Empusa, Saprolegnia, and other insect-killing fungi.

But these entomophagous fungi are merely particular cases of mycoses. Every group of animals from the Protozoa and Infusoria upwards have their fungus parasites; hyphæ penetrate the ceratin of sponges and the calcareous walls of corals, and fishes and amphibia are by no means immune.

Birds and mammals suffer particularly from certain mycoses due to fungi which we have been in the habit of regarding as harmless moulds, *e.g.* Aspergillus, and even man is sometimes in danger from such fungi.

When, in 1869–70, Grohe and Block showed that small doses of the spores of Penicillium and Aspergillus are fatal to kittens, their statements were emphatically disbelieved; but Grawitz confirmed them, and the body of evidence showing that Aspergillus contains poisons toxic to birds and higher animals can no longer be overlooked. Some of these forms of aspergillosis are very serious diseases indeed.

While the new era of mycology was stimulating observers to new investigations into the life-histories of moulds, and of the parasites of animals and plants, and into the ætiology of the timber-destroying fungi, and so forth, on the one hand, it was, on the other, gradually attracting to its domain areas of investigation which had grown up independently out of the past, and which the older thinkers could never have dreamed of associating with fungi.

A conspicuous example was the study of fermentation, which, since Janssen in 1590 had brought forward a microscope of several lenses, and Leeuwenhoek had applied an improved form of it to the animalculæ in putrefying liquids, had undergone the initial stage of passage into the hands of the naturalists.

The lecturer then sketched in rapid outline the history of the theory of fermentation, from the early days when the lees or sediment (yeast) were known as the "*Faeces Vini*"—apparently owing to the shrewd suggestion of a Venetian doctor, who, in 1762, said putrefactive and fermentation processes are due to the vital activity of minute worms, the excreta (*faeces*) of which induce the turbidity and mal-odour of the liquid—to the days when the living plant-nature of these "*faeces*" was gradually established by the work of Astier, 1813, Desmazières, 1826, Quevenne, 1838, and Persoon, and especially by Erxleben, 1818, Kützing, 1834, Cagniard Latour and Schwann, 1837.

At the same time, the sketch included an outline of the first great controversies regarding abiogenesis or spontaneous generation, brought forward from its ancient strongholds in the ignorance of the classical and mediæval writers—*e.g.* Pliny, Bock, Van Helmont—by Needham in 1745, and confuted by Spallanzani, 1765–76, Schultze, 1836, Schröder and Dusch, 1854; and to which the *coup de grâce* was given by the work of Pasteur, 1862, Cohn, 1870–75, and Tyndall.

Information derived from the brewing of quass, saki, pulque, kava, toddy, koumiss, mead, metheglin, spruce and other beers and wines by peoples all over the world has only confirmed the ideas, of Pasteur especially, that all such fermentations are due to the presence of fungi; and although the discussions as to the process itself being due to catalytic actions and the communication of internal movements to the molecules of sugar broken up, initiated by Stahl in 1697, and revived in various forms by Liebig, 1839, and Naegeli, 1879, culminating in Buchner's views on the discovery of zymase in 1896–97, have modified the older forms of the vitalistic theory of Cagniard Latour and Pasteur, they have not dissociated fermentation from the life of the cell.

The lecturer then passed to a survey of the enzymes, those remarkable bodies which, though not themselves living, are capable of breaking up organic substances apart from the protoplasm of the cells which secrete them, and showed that since the discovery of diastase in malt by Payen and Persoz in 1833, of pepsin in gastric juice by Schwann in 1836, and of invertase in yeast by Berthelot in 1860, numerous other special enzymes have been isolated, and all the principal forms of sugar-inverting, starch-saccharifying, cellulose-dissolving, fat-splitting, proteid-converting, and oxidising enzymes occur in the fungi. Bourquelot has shown the presence of nine such enzymes in *Polyporus sulphureus* and of seven in Aspergillus alone.

The presence of certain deadly poisons in putrefying fish, flesh, &c., and the researches consequent on the increasing knowledge of septic poisoning of wounds—with which Lister dealt so practically at the time—led to researches which, in the hands of Brieger, Sonnenschein, Armand Gautier, Selmi, and others resulted in the isolation of more or less specific bodies, such as sepsin, cadaverine, ptomaines, leucomaines, &c. In 1876 Neucki obtained an unusually pure form, and the doctrine of ptomaine poisons may be regarded as thereby established.

For us, the point of interest here is that these poisons proved to be analogous, if not identical as a class, with a number of vegetable poisons, such as atropine, brucine, nicotine, strychnine, or at any rate presented striking resemblances to them in their physiological actions.

As close, or even closer, resemblances were found in the poisons extracted from the fungi; amanitin, bulbosin, cornutin, sphacelotoxin, &c., all came under the same general category. In 1880 Pasteur showed that fowl cholera could be produced by means of the poison excreted by the bacilli, from which the bacilli themselves had been removed; and

Brieger, in 1885, then showed the same to be true for tetanus and typhoid. Löffler, 1887, and Hankin, 1890, then showed the same to be true for diphtheria and for anthrax, and the toxins of tetanus, cholera, &c., were obtained shortly afterwards.

Thus was founded the doctrine of toxins. The bacilli of disease do not merely induce the formation of ptomaine poisons in the decomposing tissues; they form the toxins in their own cells, and then excrete them.

The lecturer then referred to the similarities of the venenenes of snakes, scorpions, and spiders; of the toxins in eels' blood; and of the vegetable toxins ricin, robin, &c., emphasising the fact that all these bacterial, animal, vegetable, and fungal poisons belong to one and the same great family of toxic bodies.

The horribly intoxicating and poisonous drink made by certain Siberian and Kamschatkan peoples from the fly Agaric, the dry gangrene and paralysis due to ergotism, now a rare disease in western Europe, and the effects of the toxins of tetanus, diphtheria, and other bacilli, all have points in common with the poisons of snakes, of certain seeds, and so on—certain Australian species of Swainsonia impel horses which have eaten it to behave as if trying to climb trees, or to refuse to cross a twig as if it were a large log, reminding one of the effects of *Amanita muscaria* on man.

In great part, if not entirely, owing to an experiment of Nuttall's in 1888, in which he found that normal blood has bactericidal properties, researches were undertaken which resulted in the discovery that the sera of animals, either normally or if rendered immune by minimal doses of toxins, contain antidotal substances to the toxins. Behring and Kitasato, in 1890, who demonstrated the antitoxic power of blood immunised with diphtheria or tetanus to the toxins of these bacilli, were followed in rapid succession by Brieger, Ehrlich, Pick, and others, and the doctrine of the anti-enzymes and antitoxins was established.

The lecturer then gave two illustrative cases. Dunbar, in 1903, showed that hay-fever, as already maintained by others, was not only due to the pollen of grasses, but he isolated from the pollen-grains a toxin which itself induces all the symptoms of the malady.

Not only so. He showed that the serum of horses, &c., to which the hay-fever is communicated becomes antitoxic to the malady. This antitoxin has been distributed, and the statistics uphold the accuracy of Dunbar's views.

That pollen-grains contain enzymes has long been known, and the experiments of Darwin and others have shown that some pollens are poisonous to the stigmas of the wrong plant. Another suggestive illustration is that given by Woron, in which, bees having conveyed pollen, together with the spores of a Sclerotinia, to the stigmas of certain species of Vaccinium, the pollen-tubes and the fungus-hyphæ race each other down the style, and the latter usually win, and destroy the ovules. Moreover, everyone knows how corrosive and destructive the pollen-tubes of pines, &c., are in the tissues, and we must not forget that pollen-grains are spores.

The second case dwelt on by the lecturer is that of pellagra, a disease to which the ill-nourished peasantry of maize-growing countries are liable in bad seasons, when the crops are poor and mouldy.

Cene and Beste, in 1902, referred the malady to the presence of an Aspergillus in the bad grain. They also extracted from this mould a highly toxic body. Mariani, in 1903, then showed that the blood of patients cured of pellagra is antitoxic to the poison of the disease.

The lecturer pointed out that, without committing ourselves to any premature opinion as to the absolute accuracy of these views, there are two increasing classes of evidence which support his suspicion that numerous as yet insufficiently examined cases of this kind will turn out to be due to what he calls "lurking parasites" in bad grain and fodders.

The first is the large class of mycoses now referred to the poisonous action of such a "mould" as Aspergillus, a fungus shown to abound in enzymes and toxic bodies. The second is the increasing number of cases of poisoning by fodder and grain-plants, normally wholesome, but found to be deleterious in certain circumstances or years.

Cases of poisonous wheat, oats, &c.—the "Taumel-Getreide," "Taumel-Roggen" of the Germans—have long been known, and the lecturer quoted cases where similar noxious effects are traced to the presence of Ustilagineæ, Helminthosporium, Cladosporium, and other fungi.

A notable case is that of the Darnel, a tiresome weed in some countries. The ancients—*e.g.* Galen—knew that darnel in bread causes dizziness, headache and sickness, and thought that neglected wheat, &c., was transformed into darnel. Hofmeister, in 1892, examined and extracted the toxic bodies, and confirmed the repeated statements as to their deleterious and even fatal action on animals.

Yet it was not until 1898 that Vogl discovered the existence of a mycelium in the seed-coats of the poisonous darnel, and in the same year this was confirmed by Hanausek and Nestler, though they did little beyond recording the presence of a fungus.

In 1903, Freeman, in the lecturer's laboratory at Cambridge, worked out the details, and left no doubt that the poisonous property is due to the fungus.

The lecturer then pointed out that a whole series of questions concerning these and similar diseases now being investigated in his laboratory lie under suspicion of connection with grain-poisoning, or at any rate with poisoning of fungi introduced as food.

To say the least, we want further and extensive researches from this point of view into the ætiology of Acrodymia in Mexico, Algeria, &c., and of the Colombian Pelade, of the "trembles" of cattle and sheep, and of the "milk sickness" of the North American prairies, and even diseases like beri-beri, &c.

The conclusions, the lecturer pointed out, to which we are driven may be thus summarised:—

(1) Fungi, like animals and other plants, including bacteria, excrete enzymes, and utilise them in the same way and for the same purposes.

(2) The poisons of the fungi are toxins, not only similar in character to the poisonous alkaloids, toxalbumens, &c., of the bacteria, and of the higher plants, the venenenes of the snakes, &c., but their poisonous actions in the paralysis of nerve-ends, &c., are essentially the same.

(3) These poisons, &c., introduced into the blood of animals, call forth the activities of antitoxins and anti-enzymes, as do the toxins of animals, bacteria, &c., in similar circumstances.

(4) The presumption is, therefore, justified that the action of the enzymes and toxins of parasitic fungi on the proteid cell-contents of their plant-hosts is similar in principle to that on animal proteids, and that the host reacts by means of anti-enzymes and antitoxins.

The lecturer then adverted to the difficulties of obtaining the toxins and antitoxins from sap, and concluded by showing in specific cases—the rusts of wheat and grasses—how probable it is that, since no anatomical features explain the facts of predisposition and immunity, and the latter cannot be referred to climatic conditions or to peculiarities of soil, &c., the above considerations will be found to apply, a matter dealt with elsewhere by the lecturer.

TRYPANOSOMIASIS AND EXPERIMENTAL MEDICINE.[1]

THE greater portion of the first Report deals with the subject of human trypanosomiasis, particularly in the Congo district. The trypanosomata are flagellated protozoa, which have been found to be parasitic in many animals, sometimes causing no symptoms, as in the rat, but sometimes associated with serious effects, as in the tsetse-fly disease of the horse. During the last few years trypanosomata have been found to be parasitic in man in various districts of West and Central Africa. If the infected person shows irregular fever without other marked symptoms the condition has been termed trypanosomiasis; if in addition there is somnolence and stupor, and later wasting, convulsions, and fatal coma, the condition is the

[1] "Reports of the Trypanosomiasis Expedition to the Congo, 1903–1904." Liverpool School of Tropical Medicine. Memoir xiii. Pp. 111. (1904.) Price 15*s*.
"The Thompson-Yates and Johnston Laboratories Report." Vol. vi. (New Series), Part i., January, 1905. Pp. 205. (University Press of Liverpool; London: Williams and Norgate.) Price 12*s*. 6*d*.

dreaded sleeping sickness which has destroyed tens of thousands of lives in Central Africa. Much of the matter in the volume under review deals with the relationship between these two diseases.

The first article is a report by Messrs. Dutton, Todd, and Christy on an expedition into the Congo Free State, undertaken at the request of the King of the Belgians. At the hospital at Boma, and during a journey into the cataract region, a number of patients were seen who were regarded by the district medical officers as cases of sleeping sickness, but in whom the somnolence, so characteristic of the disease in Uganda, was completely absent. Nevertheless, trypanosomes were found in the blood both of those cases in which the diagnosis of sleeping sickness was certain and of those which were atypical. But in addition trypanosomes were frequently seen in the peripheral blood of apparently healthy individuals.

In the next article, the relationship of human trypanosomiasis to Congo sleeping sickness is discussed by the same observers. The conclusion is arrived at that the *Tr. gambiense* of the first-named condition is the probable cause of Congo sleeping sickness; but it must be admitted, in spite of the positive statements which have been made on the subject, that something remains to be cleared up. This view is confirmed by Dr. Christy's researches on the cerebro-spinal fluid in sleeping sickness. He considers that all that can definitely be stated is that (1) on the whole the presence of the trypanosome parasites in the cerebro-spinal fluid tends to increase the gravity of the case, (2) in many cases trypanosomes never find their way into the cerebro-spinal fluid, and (3) in the vast majority of cases death is the result of complications, mainly bacterial infections.

Fig. 1.—Flies, pupa and larvæ (nat. size) of the Congo Floor Maggot.

The identity or non-identity of the various trypanosomes of man has been investigated by Dr. Thomas and Mr. Linton, who conclude that the parasites found (*a*) in the cerebro-spinal fluid of Uganda sleeping sickness, (*b*) in that of Congo Free State sleeping sickness, (*c*) in the blood of Uganda trypanosomiasis cases, and (*d*) in the blood of Congo Free State trypanosomiasis cases, are all identical in morphology and animal reactions with the *Tr. gambiense.*

In an interesting paper, Messrs. Dutton, Todd, and Christy describe the Congo floor maggot, a blood-sucking dipterous larva extensively found in various parts of the Congo Free State, and identified by Mr. Austen as the *Auchmeromyia luteola*, Fabr. These larvæ seem to lurk in the cracks and crevices of the mud floors of the native huts, from whence they emerge at night and attack the persons sleeping there. The volume concludes with a note by Mr. Austen on tsetse-flies. Since his monograph on the tsetse-flies was issued, further observation has convinced Mr. Austen that the *Glossina tachinoides*, regarded by him as a variety of *G. palpalis*, must be reckoned as a distinct species.

The volume of the Thompson-Yates and Johnston Laboratories Report contains the reports on trypanosomiasis, &c., described above, and several additional papers of interest. Dr. Stephens describes a new hæmogregarine from an African toad, two cases of intestinal myiasis (fly larvæ) observed in children in Liverpool, a note on swellings of uncertain ætiology in a tropical patient, and a note on non-flagellate typhoid bacilli. The last named were from an old laboratory strain which had been subcultured for some years, and seemed completely to have lost their flagella and motility. Mr. Shipley describes a new human trematode parasite from German West Africa, and Mr. Dutton defines the intermediate host of a lymph worm (filaria) of an African swift; this is found to be the louse which infests these birds. Prof. Moore and Mr. Roaf contribute an important experimental study of the physical chemistry of anæsthesia, from which they conclude that chloroform forms an unstable chemical compound or physical aggregation with proteid and hæmoglobin, and is carried in the blood in such a state of combination, the compounds so formed limiting the chemical activities of protoplasm and inducing anæsthesia. Mr. Edie describes the action of chloroform on serum proteids and hæmoglobin, and, lastly, Mr. Roaf and Mr. Edie describe a simple method for the preparation and determination of lecithin which seems to be a great improvement on the methods hitherto in use. Both volumes are beautifully printed and illustrated, and appear in a new cover, which, artistically, is a great improvement on the old one.

R. T. Hewlett.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Cambridge.—The General Board of Studies has appointed Mr. T. S. P. Strangeways, St. John's College, Huddersfield lecturer in special pathology, from Lady Day, 1905, until Michaelmas, 1909, and the appointment has been confirmed by the Special Board for Medicine. Mr. R. P. Gregory, of St. John's College, has been appointed senior demonstrator in botany for four years, until June 24, 1909.

The list of successful candidates for open scholarships at Downing College is so far unusual that all the winners are natural science students. It is as follows:—A. W. Bourne, Rydal Mount School, Colwyn Bay, 50*l.*; A. C. Johnson, Merchant Taylors' School, 40*l.*; W. G. Stevens, The Leys School, Cambridge, 40*l.*; I. K. Matthews, Merchant Taylors' School, Crosby, Liverpool, 40*l.*

Oxford.—The university has resolved to contribute a sum not exceeding 1000*l.* towards the printing of that portion of the British section of the International Astrographic Catalogue which has been executed at the university observatory.

By a statute passed in 1904, the university established a "diploma in scientific engineering and mining subjects," and the committee appointed to arrange the details of the scheme has now issued the regulations concerning the diploma. Members of the university will be eligible for the diploma who have passed at the examinations required for the degree of B.A., and have satisfied the examiners in certain special subjects mentioned in the following list, after an approved course of study in those subjects extending over two years, and have also gone through an approved course of practical training lasting four months, either at a mine or in engineering works. The subjects that may be offered are :—(*a*) mathematics for applied science ; (*b*) physics and chemistry ; (*c*) French and German translation ; (*d*) engineering principles and machine drawing ; (*e*) surveying ; (*f*) geology ; (*g*) mineralogy ; (*h*) mining and engineering, hygiene and mine-ventilation ; (*i*) electricity ; (*j*) assaying. For the ordinary diploma candidates will be required to pass in (*a*), (*b*), and (*c*), and in not less than three of the remaining subjects, provided that (*f*), (*g*), and (*i*) are not taken together without one or more of the others. Candidates who propose to become colliery managers and desire to obtain exemption from two of the five years' underground work required by the Home Office as a qualification for a certificate as colliery manager, must obtain a special diploma by passing in the subjects (*a*), (*b*), (*c*), (*h*), and three (not being *f*, *g*, *i*) of the remainder, and by taking their four months' course of practical training at a mine.

PROF. W. JAMES, of Harvard University, has accepted, *Science* reports, the acting professorship of philosophy at Stanford University. He will lecture at Stanford during the second half of the next academic year, and will organise a department of philosophy for the university.

A GENERAL meeting of the Association of Teachers in Technical Institutes will be held on Saturday, March 25, at the Regent Street Polytechnic, London, when an address, to be followed by a discussion, will be delivered by Mr. W. J. Lineham, head of the engineering department, Goldsmiths' Institute, entitled "Technical Training—a Teacher's Views."

IN connection with the International Exposition to be held at Liége, Belgium, from April to November during the present year, it is proposed to hold an International Congress of Childhood on September 17–20. The congress will be organised in four sections, as follows :—(1) education of children ; (2) study of children ; (3) care and training of abnormal children ; (4) parents' associations, mothers' clubs, and other supplementary agencies for the improvement of youth.

THE council of Liverpool University has accepted an offer from the president, Mr. E. K. Muspratt, to provide for an extension and equipment of the chemical laboratories at an estimated cost of 10,500*l*. The following contributions for the extension and maintenance of the chemical department have also been acknowledged by the council :—100*l*. per annum for five years from the United Alkali Company, Ltd., 100*l*. each from Mr. George Wall, West Kirby, and Mr. T. Threllfall, London.

A NEW technical college and secondary school at East Ham was opened by the Prince and Princess of Wales on Saturday. The building has been erected and equipped at a cost of about 24,000*l*., towards which the Essex County Council has contributed 6000*l*., and the remainder has been made up by the East Ham Corporation. The accommodation includes a botanical room, chemical class-room and laboratory, physics laboratory, carpenter's shop, and provision for the pursuit of various crafts—plumbing, metal-work, brickwork, &c. In replying to the address presented by the Mayor of East Ham, the Prince of Wales said :—It is difficult to realise that only ten years ago these crowded streets were green lanes, that your population has multiplied nearly twentyfold in the last thirty years, and that within your borough one industry alone employs more than 10,000 men. You have very rightly recognised that this remarkable growth carries with it serious responsibilities. The vast and rapidly increasing population of the borough necessitates the provision of suitable secondary and technical education, and in this institution you are furnishing that educational equipment for the rising generation which is indispensable if we intend to maintain our place in the great struggle for commercial supremacy. My heart is with you in all such undertakings as that which we are about to inaugurate, and I trust that every success may attend your useful and patriotic efforts.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, February 16.—"Further Observations on Slip-Bands.—Preliminary Note." By Walter **Rosenhain**. Communicated by Prof. Ewing, F.R.S.

The paper describes what the author believes to be a novel method of investigating the micro-structure of metals, and some preliminary results obtained by its aid. The method was devised in order to throw further light on the true nature of slip-bands, and the preliminary results relate mainly to this question.

A direct means of examining the surface configuration of a piece of metal upon which slip-bands have been produced would be presented by a transverse section of such a specimen, provided that the section could be produced with an absolutely sharp edge, but no useful result can be obtained by cutting the specimen through and simply polishing the exposed section. The edges of specimens prepared by the usual methods of polishing are always rounded off, so that it becomes impossible to focus upon any definite edge with high-power lenses ; and even apart from this defect, there would be no guarantee that the edge represented a true section of the pre-existing surface.

FIG. 1.—Transverse Section of Slip-bands. Vertical illumination × 1000 diameters.

The author has adopted the principle sometimes used in optical work of supporting the surface, which in section becomes the edge, by means of an adherent layer of hard material ; but the conditions which such a layer must satisfy for the purposes of metallography are very stringent. In order to satisfy them, the author uses a deposit of another metal obtained by electrolytic means, and this method has proved satisfactory.

The specimens used consisted of strips of the mildest steel, and after preparation an electro-deposit of copper was applied to them. By first bending the strips into a flat **U** shape, short portions of their length could be polished in the usual manner for microscopic examination ; subsequently the strips could be readily strained in tension. The slip-bands and other features of the specimens having been satisfactorily observed, electro-deposition was proceeded with, care being taken to avoid chemical action on the prepared surface by the preliminary use of a bath of copper cyanide.

The specimens were then cut across. In order to obtain a satisfactory polish, the ordinary method of polishing had to be modified ; it was found that polishing with rouge rapidly eroded a deep groove between the copper and iron, thus defeating the object of the method. A satisfactory polishing medium for this and other purposes where surface erosion is undesirable was found in calcined oxide of magnesium, the magnesia powder being used in the same way as rouge.

The section, when polished by means of magnesia, is not yet ready for examination, as it is found that a considerable amount of metal is smeared or dragged over the surface, more or less obliterating the true boundary line which it is desired to examine. To overcome this obstacle, it is arranged that the last rubbing on emery paper shall be done in a direction approximately parallel to the boundary of the two metals; the direction of rubbing during the final polishing should then be at right-angles to the boundary, the unavoidable tendency to drag or smear then being such as to draw the iron over the copper on the side where the boundary is to be examined.

The film of metal smeared over the boundary in these circumstances is extremely thin, and can be removed by slight etching with picric acid. This treatment leaves a clearly defined boundary line appearing under a certain incidence of "vertical" illumination as a narrow black line, and under other illumination being visible merely by the colour-contrast between the iron and copper.

When a previously polished and etched specimen of iron which has had slip-bands developed upon its surface by strain is treated and examined in this way, the boundary line shows well-marked steps or serrations, readily visible under a magnification of 1000 diameters. To show that these steps were not due to any of the processes gone through by the specimen, such as the initial etching of the prepared surface or the electro-deposition itself, a series of test specimens was prepared and treated in a similar manner, except that either the preliminary etching, or the deformation, or both, were omitted. The stepped boundary was always found in specimens where slip-bands had been produced, but not otherwise.

The author therefore feels justified in concluding that the steps seen in transverse sections of strained specimens are the sectional views of slip-bands. It will be seen that the steps, although very minute, are perfectly distinctive, and that they could not be mistaken for generally rounded foldings of the surface; they possess, in fact, a general geometrical character, which the author regards as conclusive evidence that they are caused by slip on cleavage or gliding planes of the crystals, and not by any folding or crumpling of the metal.

"The Effects of Momentary Stresses in Metals." By Prof. Bertram **Hopkinson.** Communicated by Prof. Ewing, F.R.S.

If a wire be hung from a firm and massive support, and if a falling weight strike a stop at the lower end of the wire, with a velocity V, it is easy to calculate the strain at any point in the wire at any subsequent time, if it be assumed to be perfectly elastic. When the weight strikes, a wave of extension starts up the wire and travels with a velocity $a = \sqrt{E/\rho}$, where E is Young's modulus, and ρ is the density. For steel a is about 17,000 foot-seconds. When the wave reaches the top end, it is reflected down the wire. The history of the strain at any point of the wire is as follows:—When the wave reaches it, the strain, which was zero, suddenly becomes V/a; it then diminishes as the wave passes over it, according to an exponential law, until the reflected wave reaches it, when it again increases by V/a. Each bit of the wire is, therefore, subjected to strain which rises suddenly, and then very rapidly diminishes. The maximum strain at any time or place occurs at the top of the wire, where it is $2V/a$ at the moment when the wave arrives there. For a height of fall of 10 feet, and an iron wire, $2V/a$ is 0·003, and the corresponding stress is about 42 tons per square inch, so that momentary strains greatly exceeding the elastic limit may be produced in this way.

In the experiments described in the paper, the momentary extension in the top 20 inches of the wire, produced by a blow, was measured by electrical means, and compared with that given by the elastic theory. Where the two agree, and not much permanent extension is left, it follows that the theory is correctly applied, and that the material is substantially elastic up to the maximum stress, so calculated, if applied for the time given by the theory. In this way it is proved that a metal wire will stand a load, momentarily exceeding that which (steadily applied) would break it, with but very small permanent extension. In the case of the iron wire, the elastic limit was 17.8 tons per square inch, and the breaking stress 28.5 tons; and it was found that a load reaching $33\frac{1}{2}$ tons, and exceeding the elastic limit for 1/1000 sec., produced very little permanent extension. Similar results were found for copper wire.

February 23.—"On a New Rhabdosphere." By George **Murray,** F.R.S.

The author refers to the interest which the rhabdospheres and coccospheres possess, not only to naturalists, but to geologists and students of deep-sea deposits. He names it *R. Blackmaniana,* after Mr. V. H. Blackman, his fellow author in an exhaustive study of such organisms (*Phil. Trans.*, B., vol. cxc., 1898). It was obtained by Mr. Murray on the outward voyage to the Cape of the *Discovery,* in lat. 28° 25′ S., long. 23° 56′ W., and differs from the only other forms, two in number, known to science in possessing tapering, acute, spinous processes in contrast to the trumpet-shaped and club-shaped processes of the two known species. No sign of the new form has yet been detected in the deep-sea deposits or geological formations, Mr. Murray accounting for this by the minuteness and extreme tenuity of the spines.

March 2.—"Further Researches on the Temperature Classification of Stars, No. 2." By Sir Norman **Lockyer,** K.C.B., F.R.S.

The paper contains a discussion of the more recent photographs obtained with a calcite-quartz prismatic camera. Each negative contained the spectra of two stars, obtained under identical conditions of altitude, exposure and development, the relative temperatures of which were estimated by comparing the relative intensities of their ultra-violet and their red radiations. The term "temperature" is understood to include the possible effects of electrical variations. In a previous paper, communicated to the society in February, 1904, the author showed that by thus comparing the relative temperatures of those stellar genera which were placed on different levels of the chemical classification temperature curve, their arrangement on that curve was vindicated. In the recent research the relative temperatures of the genera placed on the *same* horizons, but on the opposite sides, of the curve were similarly compared, with the result that their equality of temperature, as suggested by the chemical classification, was confirmed. The results also indicate that *specific* differences exist which will necessitate the subdivision of the previously proposed "genera" into "species."

Entomological Society, March 1.—Mr. F. Merrifield, president, in the chair.—*Exhibitions.*—(1) An example of *Oxypoda sericea,* Heer, taken in Dulwich Wood, June 17, 1904, a species new to Britain; (2) *O. nigrina,* Wat., with a type lent by Mr. E. A. Waterhouse, to demonstrate that it is not synonymous with *sericea* as stated on the Continent; (3) *O. exigua,* which is also regarded there as synonymous with *nigrina*: H. St. J. **Donisthorpe.**—Series of *Colias edusa,* with var. *helice,* bred from one ♀ *helice,* sent by Dr. T. A. Chapman from the South of France, to show the proportion of type and variety obtained: H. **Main** and A. **Harrison.** The results of similar experiments with *Amphidasys betularia,* bred from a ♂ var. *doubledayaria,* and a type ♀ taken in cop. at Woodford, Essex, in 1903, were also shown.—Specimen of *Helops striata,* showing an abnormal formation of the right antenna, which was divided into two branches from the fifth joint: R. **Priske.**—(1) Examples of *Hydrotaea pilipes,* Stein, ♂ and ♀, the latter sex being previously unknown; (2) several specimens of *Hydrotaea tuberculata,* Rond., not hitherto recorded as British, captured in various localities; P. H. **Grimshaw.**—Cocoons, and perfect imagines of hybrid Saturniids, including ♀ and ♂ of *S. pavonia,* L., × *S. pyri,* Scheff., with added specimens of both sexes of the parent forms for comparison, the cross product resembling a large *S. pavonia* rather than a small *S. pyri.* The exhibit further included three ♂ ♂ and three ♀ ♀, of which the ♀ parent was *S. pavonia,* and the ♂ parent a hybrid between *S. pavonia*, ♂, and *S. spini*, ♀, viz. the cross product to which Prof. Standfuss has given the name *S. bornemanni*: Dr. F. A. **Dixey**.—(1) Groups of synaposematic Hymenoptera and Diptera captured by Mr. A. H. Hamm, of the Hope Department, Oxford University Museum; (2) three much worn specimens of *Papilio hesperus*, taken at Entebbe in 1903, by Mr. C. A. Wiggins, to show that the tails of a Papilio, if untouched by enemies, can endure a great deal of wear; (3) Nymphaline butterflies from northern China, apparently mimetic of the male *Hypolimnas misippus*, which is not known to occur in this region: Prof. E. B. **Poulton**, F.R.S.—Examples of *Pyrameis atalanta* and *Aglais urticae*, illustrating the effects of cold season breeding by Mr. Harwood, of Colchester, some of them lent by Mr. R. S. Mitford: the **President**.—*Papers*:—Butterfly hunting in British Columbia and Canada: Mrs. De la B. **Nicholl**.—On three remarkable new genera of Microlepidoptera: Sir George **Hampson**.—Descriptions of some new species of diurnal Lepidoptera, collected by Mr. Harold Cookson in northern Rhodesia in 1903–4. The Lycænidæ and Hesperiidæ described by Hamilton H. Druce: H. **Druce**.—Descriptions of some new species of Satyridæ from South America: F. Du Cane **Godman**.—Additions to a knowledge of the homopterous family of Cicadidæ: W. L. **Distant**.

Faraday Society, March 6.—Recent developments in electric smelting in connection with iron and steel: F. W. **Harbord**. The paper embodies the principal results of the investigations made by the commission sent to Europe last year by the Canadian Government for the purpose of reporting upon the different thermoelectric processes for the smelting of iron ores and the manufacture of steel at work in Europe, together with some additional information bringing the subject up-to-date. The author acted as metallurgist to that commission. The following general conclusions are stated in the paper:—(*a*) Steel, equal in all respects to the best Sheffield crucible steel, can be produced even in this country, either by the Kjellin, Héroult, or Keller proceses, at a cost considerably less than the cost of producing a high-class crucible steel, assuming electric energy to cost 10*l*. per E.H.P.-year. (*b*) At present, structural steel, to compete with Siemens or Bessemer steel, cannot be economically produced in the electric furnaces, and such furnaces can be used commercially for the production of only very high-class steel for special purposes. (*c*) Speaking generally, the reactions in the electric smelting furnace are similar to those taking place in the blast furnace. By altering the burden and regulating the temperature by varying the electric current, any grade of iron, grey or white, can be obtained, and the change from one grade to another is effected more rapidly than in the blast furnace. (*d*) Pig iron can be produced on a commercial scale at a price to compete with the blast furnace, only when electric energy is very cheap and fuel very dear. Under ordinary conditions, where blast furnaces are an established industry, electric smelting cannot compete; but in special cases, where ample water-power is available, and blast furnace coke is not readily obtainable, electric smelting may be commercially successful.

Zoological Society, March 7.—Dr. W. T. Blanford, F.R.S., vice-president, in the chair.—Pictures of the zebra in "Aldrovandus" (1640) and the "Commentarius" of Ludolphus (1691): H. **Scherren**. In the course of his remarks Mr. Scherren said that in the seventeenth century zebras (now known as *Equus grevyi*) had been sent by the ruler of Abyssinia to the governor of the Dutch East India Company at Batavia, and to the Sultan of Turkey, so that the species was seen in Europe two centuries before the type of *Equus grevyi* reached France in 1882. In proof, passages were cited from Philostorgius Ludolphus, Jean de Thévenot, and other writers.—A series of spirit-specimens of fishes from Lake Chad and the Chari River, collected and presented to the British Museum by Captain G. B. Gosling: G. A. **Boulenger**.—Exhibition of hybrid ducks bred at Cambridge: J. L. **Bonhote**. The crosses exhibited dealt chiefly with four species, of which the following were shown:—*Anas boschas* × *A. poecilorhyncha*, *Anas boschas* × *A. poecilorhyncha* × *Dafila acuta*, *Anas boschas* × *A. poecilorhyncha* × *A. superciliosa*, *Anas boschas* × *A. poecilorhyncha* × *A. superciliosa* × *D. acuta*.—Ecology and deposits of the Cape Verde marine fauna: C. **Crossland**. The author pointed out that so far as the Cape Verde group was concerned there was no evidence of any common tropical marine fauna, though certain species were found in both the Atlantic and Indian Oceans. Reef animals were remarkably few in number, the fauna in their place having a considerable subtropical constituent. Rock simulating coral-rag was formed at the low-tide level by serpulid tubes fused together by Lithothamnion, and by the latter and Foraminifera between 5 and 20 fathoms. The absence of reefs might be due in some degree to the remarkably steep coasts of the islands, but it was more especially owing to the extraordinary dominance of boring sponges, worms, and molluscs. Beach sandstone was formed by the deposition of calcareous cement where the fresh water met the salt; it was only found in certain situations, and was everywhere being slowly eroded away by the sea.—A revision of the South-American cichlid genera, Crenacara, Batrachops, and Crenicichla: C. Tate **Regan**. Twenty-three species were described, four of them new to science.—A new antelope from British East Africa: Captain R. **Meinertzhagen**.

Royal Astronomical Society, March 10.—Mr. W. H. Maw, president, in the chair.—Description of the spectroheliograph of the Solar Physics Observatory: Dr. W. J. S. **Lockyer**. The complete instrument consists of a siderostat to throw the solar beam in a horizontal and southerly direction, a lens placed in this beam to form the solar image, and the spectroheliograph itself to photograph in monochromatic light the image thus formed. The apparatus was fully explained and illustrated by photographs on the screen. Specimens of results obtained were also exhibited, the photographs of the sun showing the fine network covering its surface, becoming thicker and more agglomerated in middle and low latitudes to form the calcium flocculi. The sun-spots appear to be closely related to these flocculi, but the prominences bear no relation to them, though they give brilliant images in the "K" or calcium light.—The large sun-spot of January 29 to February 11, and the contemporaneous magnetic disturbances: **Astronomer Royal**. A series of photographs, taken at the Royal Observatory, Greenwich, was shown on the screen.—Spectroscopic observations of the recent great sun-spot and associated prominences: A. **Fowler**. The paper dealt with the reversed lines, the widened lines, &c., and the spectra of the chromosphere and prominences overlying the spot on the western limb.—Observations of the great sun-spot made at Stonyhurst, and photographs of the spectra: Father **Cortie**.—Reply to criticisms of a paper on sun-spots and the associated magnetic disturbances: E. W. **Maunder**.

Physical Society, March 10.—Dr. R. T. Glazebrook, past-president, in the chair.—On direct reading resistance-thermometers, with a note on composite thermocouples: A. **Campbell**. The paper describes two methods by which the reading of a resistance-box in connection with a platinum resistance-thermometer gives directly the actual temperature without the use of any formula or table.—On the stresses in the earth's crust before and after the sinking of a bore-hole: Dr. **Chree**. In NATURE, October 20, 1904, there appeared letters by Mr. G. Martin and the Hon. C. A. Parsons dealing with the size of the stresses in the earth's crust and speculating as to what would happen if a hole were bored to a depth of 12 miles. The present paper discusses the subject, treating the earth as an elastic solid, and points out the various uncertainties that exist. Solutions are presented of a number of mathematical problems having a bearing on one or other of the possibilities discussed. The principal novel case considered is that of a composite earth, consisting of a core of incompressible material and of a crust which may be compressible or incompressible.—On the lateral vibration of bars of uniform and varying sectional-area: J. **Morrow**. Lord Rayleigh has given a method by which the approximate period of vibration of a rod can be calculated without the use of transcendental equations. The question has recently been further discussed by Mr. Garrett and Dr. Chree. The object of the paper is to show that, by assuming a type of vibration consistent with the conditions obtaining at the ends of the bar, the period can be obtained approximately in a simple manner, and that by a process of continuous approximation the period and the type of the vibration may be determined, in a large number of cases, with great accuracy.

Royal Meteorological Society, March 15.—Mr. Richard Bentley, president, in the chair.—The growth of instrumental meteorology: **President.** After briefly touching on the historic and non-instrumental era of meteorology, reference was made to the seven great weapons of meteorology—the thermometer, and of later years the heliograph, for temperature, the hygrometer and rain-gauge for moisture, the barometer for pressure, and the anemometer and kite for the study of the upper air—and of the great foundation of instrumental meteorology laid by Galileo, Torricelli, Wren and Hooke. The president, in dwelling upon our indebtedness to Italy in science (as well as in art) from Galileo to Marconi, pointed out that the theory of rainfall was correctly enunciated as early as the beginning of th fourteenth century by Dante. He also dwelt on the great services rendered to the community by meteorologists, largely by volunteers at their own expense, and referred to the close observation kept by rain-gauges on the steadily diminishing water supply of the country, by anemometers protecting the traffic over some of our lofty and more exposed railway viaducts, by the use of the barometer for storm warnings and for the safety of miners in our pits, by the heliograph with relation to the ripening of fruits and crops, and regretted how much of the immense mass of information daily accumulating had still to be analysed and put to use. It was disappointing to find in so wealthy a country as this, and where the results could not fail to be of the greatest practical utility to the nation, that the means of digestion of this vast data are so meagre, and the aid given by the Government is so slender as to be a constant source of reproach when compared with the large provision made for the same purpose in other countries for their own benefit.

DUBLIN.

Royal Dublin Society, February 21.—Dr. W. E. Adeney in the chair.—(1) On the transmissibility of tuberculosis of the monkey to the ox and goat; (2) on the use of tuberculin in the detection of tuberculosis: Prof. A. E. **Mettam.** (1) The tuberculous material was obtained from a drill monkey. After passage through guinea-pigs, emulsions of the organs of the latter were inoculated into a bull and into a goat. Both animals have been infected with tuberculosis, though free from the disease prior to injection, local lesions having been established and reaction to tuberculin being pronounced. (2) Experiments were carried out with the object of determining if an increased dose of tuberculin would reveal tuberculosis in an animal which had already a short time previously received a dose of tuberculin, and if any immunity to tuberculin was established as to how long it lasted. It was shown, as Vallée maintains, that a double dose of tuberculin would reveal tuberculosis even if the animal had received a prior dose a few days before, and that the immunity to an ordinary dose was evident for ten days to a fortnight after injection.—Secondary radiation and atomic structure: Prof. J. A. **McClelland.** Every substance gives off a secondary radiation of β particles when acted upon by the β rays of radium. The intensity of this secondary radiation, in the case of elementary substances, depends on the atomic weight; the greater the atomic weight the greater is the secondary radiation. This very general law has been found to hold true for all the elements tested, which were twenty-one in number. The paper further discusses this result from the point of view that all atoms are groups of similar electrons.

Royal Irish Academy, February 27.—Prof. R. Atkinson, president, in the chair.—A list of the Irish jelly-fishes, corals, and sea-anemones: being a report from the R.I.A. fauna and flora committee: Jane **Stephens.** This is a catalogue of all the species of Cœlenterata hitherto recorded for the coast of Ireland. The list, containing about 250 species, includes the fresh-water hydroids. In a prefatory note a short account of the Irish Cœlenterates is given; there is also a bibliography of the papers (which date back to the year 1755) dealing with the subject.—Notes on the homotaxial equivalents of the beds which immediately succeed the Carboniferous Limestone in the west of Ireland: Dr. Wheelton **Hind.** The counties of Clare and Limerick contain the Carboniferous sequence of the west of Ireland in the form of a basin, the western side of which has been cut off by the sea, and consequently the geological structure is well seen in the line of cliffs from Black Head, co. Clare, to Ballybunion, co. Kerry. In the north of Clare the beds dip gradually at 5°, and there are few or no faults. In the south of the county and in co. Limerick there have been stronger earth movements, and faulting is more frequent. The sequence shows Coal-measures (Foynes coalfield), olive grits, flags and sandy shales, black shales with bullions, Carboniferous Limestone without shales or detrital beds. The whole series is conformable and fossiliferous. The Carboniferous Limestone is characterised by the same fossils as occur in the Carboniferous Limestone and Yoredale rocks of England, and at the top of this series is a great faunal change. The black shales with bullions, which overlie the Carboniferous Limestone, contain *Posidoniella laevis, P. minor, Posidonomya membranacea, Pterinopecten papyraceus, Glyphioceras diadema, G. spirale, G. davisi, G. reticulatum, Dimorphoceras gilbertsoni, G. descrepans, Nomismoceras spirorbis,* and many others which characterise the Pendleside series and the Lower Culm of England. The marine bands intercalated in the olive grit and flag series, and the shales, recall the marine bands in the Millstone Grits. Hence it is interesting to find the same faunal sequence in the west of Ireland as exists in the midlands of England, and it is erroneous to classify the beds which succeed the Carboniferous Limestone in the west of Ireland as either Yoredales or Coal-measures, but they are the homotaxial equivalents of the Pendleside series and Millstone Grits.

PARIS.

Academy of Sciences, March 13.—M. Troost in the chair.—On surfaces applicable to the paraboloid of revolution: Gaston **Darboux.**—On the laws of sliding friction. Paul **Painlevé.** A discussion and extension of a paper on the same subject by M. Lecornu.—On the pressures developed at each instant in a closed vessel by colloidal powders of different forms: R. **Liouville.** The work of M. Vieille on the explosion of gun-cotton powders in a closed vessel led him to conclude that the speed of combustion is proportional to a power of the pressure, about 2/3. On account of the difficulty introduced into ballistic calculations, it is usual to consider the speed of combustion as proportional to the pressure. An investigation is given showing the accuracy of Vieille's exponent, and indicating where further experimental work is required.—On the explosive wave: E. **Jouguet.** The numerical data given in a previous note were calculated on the assumption that the combustion was total in the explosive wave, and that the dissociation could be neglected. In the present paper the dissociation is taken into account, the formula of Gibbs being adopted. Figures are given for mixtures of oxygen with acetylene, cyanogen, and methane, and it is shown that the dissociation may be considerable without seriously affecting the velocity of the explosive wave.—On the emptying of systems of reservoirs: Ed. **Maillet.**—On the dangers of atmospheric electricity for balloons and the means of remedying them: A. **Breydel.**—On halation in photographs: Adrien **Guébhard.**—On the atomic weights of hydrogen and nitrogen, and on the precision attained in their determination: A. **Leduc.** The value obtained by the author for the atomic weight of nitrogen from his density measurements was 14·005, but the figure still adopted by the International Committee on Atomic Weights is 14·04. It is pointed out that the lower number is confirmed by the recent experiments of Guye and Bogdan, and Jaquerod and Bogdan.—On dextrorotatory lactic acid: E. **Jungfleisch** and M. **Godchot.** The preparation of *d*-lactic acid in a pure state from its salts is complicated by the tendency to pass over into the inactive acid and by the formation of lactyl-lactic acid. The precautions necessary to avoid both these changes are given in detail, and the properties of the pure acid described.—The action of magnesium amalgam upon dimethylketone: F. **Couturier** and L. **Meunier.** The chief product of the reaction is pinacone. By the dry distillation of the magnesium compound there is produced acetone, isopropyl alcohol, pinacoline (the principal product), and mesityl oxide. The yield of pinacoline is 21 per cent., and this forms the most rapid and advantageous method of preparing this substance.—On oxyethylcrotonic acid and ethylerythric acid: M. **Lespieau.**—On a method for the volumetric estimation of hydroxylamine: L. J. **Simon.** The method is based upon the conversion of the hydroxylamine salt into the oxalate by the addition of sodium oxalate, and titration in neutral solution by potassium permanganate. The influence of dilution and of excess of the sodium oxalate has been studied.—The glycerophosphates of piperazine: A. **Astruc.** A description of the preparation of the acid glycerophosphate of piperazine, and a method for its estimation based on the use of two indicators, phenol-phthalein and methyl orange.—On the experimental bases of the reticular hypothesis: G. **Friedel.**—The requirements of the tobacco plant in fertilising materials: A. Ch. **Girard** and E. **Rousseaux.** The average amounts of lime, potassium, phosphoric acid and nitrogen required per 1000 kilograms of dried leaves are given.—The genesis of the gametes and anisogamy in Monocystis: Louis **Brasil.**—On the Alpheidæ of the Laccadive and Maldive Islands: H. **Coutière.**—Sterility and alopecy in guinea-pigs previously submitted to the influence of ovarian extracts of the frog: Gustave **Loisel.** The ovarian extracts of the frog contain a poison which acts by causing the atrophy of a certain number of ovules. Other effects of the poison are noted.—On the antidote to nicotine: C. **Zalackas.** Experiments on rabbits and guinea-pigs show that strychnine has not the effects as an antidote to nicotine usually attributed to it. The effects of eserine are more favourable, and an extract of *Nasturtium officinale* led to still better results, the effects of a mortal dose of nicotine being entirely removed by the injection of the latter substance.—On the lowering of the arterial pressure below the normal by d'Arsonvalisation: A. **Moutier** and A. **Challamel.** In certain cases the use of high frequency, high tension currents leads to a lowering of the blood pressure under the normal. It is therefore necessary to measure this pressure with great care when d'Arsonvalisation is being used therapeutically.—A modification of the spectrum of methæmoglobin under the action of sodium fluoride: J. **Ville** and E. **Derrien.**—On the Middle Eocene deposits in Senegal: J. **Chautard.**—On the phenomena of the deviation of water courses dating from the seventeenth, eighteenth, and the commencement of the nineteenth centuries, proved my maps: E. **Fournier.** In a series of five maps of a valley near Lons-le-Saunier, dated 1658, 1748, 1790, 1841, and the present day, the various changes undergone by the water courses can be traced.—The results of a year's study of the electrical conductivity of the water of the Rhone at Lyons: M. **Chanoz.** The water supply of Lyons, obtained from the Rhone, contains mineral matter in relatively constant amounts throughout the year, as indicated by the freezing point and electrical conductivity.

DIARY OF SOCIETIES.

THURSDAY, MARCH 23.

ROYAL SOCIETY, at 4.30.—Bakerian Lecture: The Reception and Utilisation of Energy by the Green Leaf: Dr. Horace T. Brown, F.R.S.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Report of Experiments carried out at the National Physical Laboratory: On the Effect of Heat on the Electrical and Mechanical Properties of Dielectrics, and on the Temperature Distribution in the Interior of Field Coils: E. H. Rayner.—*Discussion:* On Temperature Curves and the Rating of Electrical Machinery: R. Goldschmidt.

ROYAL INSTITUTION, at 5.—The Reasonableness of Architecture: Thomas G. Jackson.

FRIDAY, MARCH 24.

ROYAL INSTITUTION, at 9.—A Pertinacious Current: Sir Oliver Lodge, F.R.S.

PHYSICAL SOCIETY, at 5.—Note on the Voltage Ratios of an Inverted Rotary Converter: W. C. Clinton.—On the Flux of Light from the Electric Arc with varying Power Supply: G. B. Dyke.—The Application of the Cymometer and the Determination of the Coefficient of Coupling of Oscillation Transformers: Prof. J. A. Fleming, F.R.S.—Exhibition of Cymometers and other Instruments.

INSTITUTION OF CIVIL ENGINEERS, at 8.—The Wanki to Victoria Falls Section; Victoria Falls Railway: C. T. Gardner.—Design of a Double-Line Plate-Girder Railway-Bridge: H. S. Coppock.

SATURDAY, MARCH 25.

ROYAL INSTITUTION, at 3.—Electrical Properties of Radio-active Substances: Prof. J. J. Thomson, F.R.S.

MONDAY, MARCH 27.

SOCIETY OF ARTS, at 8.—Telephone Exchanges: H. L. Webb.

ROYAL GEOGRAPHICAL SOCIETY, at 8.30.—Liberia: Sir Harry Johnston, G.C.M.G., K.C.B.

INSTITUTE OF ACTUARIES, at 5.—Bonuses in Model Office Valuations and their Relations to Reserves: Dr. James Buchanan.

TUESDAY, MARCH 28.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Coolgardie Water-Supply, C. S. R. Palmer.

ROYAL INSTITUTION, at 5.—Vibration Problems in Engineering: Prof. W. E. Dalby.

SOCIETY OF ARTS, at 4.30.—The Manufactures of Greater Britain—Australasia: The Hon. W. H. James.

WEDNESDAY, MARCH 29.

SOCIETY OF ARTS, at 8.—British Woodlands: Sir Herbert Maxwell, Bart., M.P.

THURSDAY, MARCH 30.

ROYAL SOCIETY, at 4.30.—*Probable Papers:* On the Observations of Stars made in some British Stone Circles (Preliminary Note): Sir Norman Lockyer, K.C.B., F.R.S.—On the Distribution of Velocity in a Viscous Fluid over the Cross-section of a Pipe, and on the Action at the Critical Velocity: J. Morrow.—The Direct Synthesis of Ammonia: Dr. E. P. Perman.—The Determination of Vapour Pressure by Air Bubbling: Dr. E. P. Perman and J. H. Davies.—Note on Fluorescence and Absorption: J. B. Burke.—The Determination of the Specific Heat of Superheated Steam by Throttling and other Experiments: A. H. Peake.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.

FRIDAY, MARCH 31.

ROYAL INSTITUTION, at 9.—The Scientific Study of Dialects: Prof. J. Wright.

SATURDAY, APRIL 1.

ROYAL INSTITUTION, at 3.—Some Controverted Questions of Optics: Lord Rayleigh.

CONTENTS.

THURSDAY, MARCH 30, 1905.

THE CLASSIFICATION OF THE SCIENCES.

Philosophy as Scientia Scientiarum and a History of Classifications of the Sciences. By Robert Flint, D.D., LL.D., F.R.S.E. Pp. x+340. (Edinburgh and London: William Blackwood and Sons, 1904.) Price 10s. 6d. net.

THE relation of science to philosophy is, in theory, filial. It is, perhaps, no contradiction of the filial relationship that in practice it has an unfortunate tendency to run to mutual recrimination. The man of science too often ignores the philosopher, or despises him as an obscurantist who habitually confounds abstraction with generalisation. To the metaphysical philosopher, on the other hand, the typical specialist in science is a variety of daylabourer, dulled by the drudgery of occupational routine. Amidst such conjugal plain-speaking on both sides, it is no wonder that we hear much of what is called the divorce of philosophy and science; and yet there are many problems which for their adequate treatment surely require the combined resources of both science and philosophy. Is not the problem of the classification of the sciences one of these? Yet the comparative isolation of the scientific and philosophic approaches to this subject is a conspicuous fact, well attested by some recent instances. One of the most eminent of European men of science quite recently brought forward, as an original contribution, a scheme of classification which the philosophical critics at once detected as almost identical with that of Auguste Comte. Another very eminent man of science not long ago published a critical survey of some of the best known schemes of classification. His criticsm of Comte's scheme was apparently based upon an allusion in the practical treatise (the "Positive Polity"), the critic himself being presumably in ignorance that Comte's treatment of the subject can only be adequately studied in the "Positive Philosophy," where indeed the general theory of science is so elaborately worked out as to extend over several volumes.

Then again, there is that stupendous work, the "International Catalogue of Scientific Literature," itself a classification of the (natural) sciences in being. For the taxonomic preparations antecedent to this, the Royal Society was mainly responsible. It would be interesting to know if the Royal Society, in preparing its scheme, consulted either the Aristotelian Society (as the leading corporate representative of philosophy in England), or any individual philosopher, known, like Herbert Spencer, to have made a special study of the classification of the sciences. Had a precedent been wanting for the explicit and formal cooperation of science and philosophy, a not unworthy one might have been cited in the collaboration of Whewell, sought and obtained by Lyell, for the classification and nomenclature of Tertiary geological strata.

Prof. Flint's new book should serve as a mediating influence between philosophical and scientific interests. It brings together into one convenient source the leading attempts made, from Plato to Karl Pearson, towards a classification of the sciences. This, it seems, is the first time in the history of the subject that an exhaustive endeavour has been made to collect these data. How invaluable a service Prof. Flint has thus rendered to future investigators, can be appreciated only by those who have tediously toiled at the scattered literature of this subject. Its bibliography appears hitherto to have been left unorganised —having escaped even the ubiquitous zeal of German scholarship. As a special study, the classification of the sciences has been singularly little cultivated in Germany, though Wundt went too far when, first taking up the subject himself, about a generation ago, he declared that German sources were nil.

In point of purely taxonomic requirement, the first questions evoked by the problem of classification of the sciences are:—(1) What order of phenomena is it that falls to be classified? (2) Which (if any) amongst existing sciences deal with this particular order of phenomena? Can we, without leaving the assured ground of scientific method, adequately determine the first of these two questions? Does science itself yield criteria for determining its own order of phenomena? Science, to be sure, when self-contemplative, is more often in a postprandial mood than in a critical one. But when the man of science, in a metaphysical moment, does critically turn his eye inwards, and surveys the whole scientific domain, does he not see a manifold complexity of very partially analysed phenomena? Truth to tell, the evolution of science itself—*i.e.* its rationalised history and its methodology—considered as a department of scientific research, is one that has scarcely begun to be cultivated. It would be interesting, incidentally, to inquire whether the establishment of a chair of the "History of Science" in the Collège de France (due to positivist advocacy) has been followed by any similar initiative elsewhere; while as to methodology, what chance would even the most eminent amongst men of science have as a candidate for a chair of logic?

The few great men of science who have contributed to these departments of study have done so as philosophers rather than as men of science. Personal and individual views on the history and the methods of science—views of the first value and significance —have time and again been emitted, but there has scarcely yet been initiated in this field, that system of cooperative, impersonal, detached research which ensures continuity and consensus—the essential criteria of science. Not far short of a hundred systems of classification come within Prof. Flint's survey. The great majority of these have been put forward explicitly in the name of philosophy. Perhaps less than a dozen may be counted as having issued from professed men of science; and of these, each is, like the philosophical schemes, a personal and individual production, generated in comparative isolation from other similar endeavours. Hence it is, that while there is no generally recognised system of arranging the sciences in any rational order, there is a whole series of competing pseudo-classifications, each characterised by the particular qualities and defects of its individual originator. One of the unfortunate results, is that the problem itself has fallen into some disrepute. Prof. Flint's book will help substantially to rescue the problem both from neglect and obloquy.

With existing resources, what tentative lines of orderly development may be discerned in the evolution of science which may help towards this preliminary problem of classification? Looking at the sciences collectively, and their field of investigation as a whole, we may without transcending scientific limits take several standpoints in turn. These may be held to include the following:—

(1) Science, collectively considered as a body of knowledge, differentiated from other bodies of knowledge (*e.g.* common knowledge on the one side and philosophy on the other) by its more systematic character, its greater quantitative precision, its more fully and explicitly known sources of origin and methods of growth, the more certain verifiability of its generalisations, the greater exactitude of its forecasts. Here, from this standpoint, science appears as a system of symbolism, a methodised scheme of notation, an organisation of interdependent formulæ —in short, a well-made language, as Condillac said.

(2) Science considered as a psychological process—*i.e.* as a power or faculty which, under certain definable conditions of heredity, training, and environment, the individual mind may acquire and utilise in the course of its normal growth. Here, from this standpoint, science appears as an artificial Psychic Organ, a portable illuminant like the miner's lamp, a racial eye adjustable to the individual brain—an eye that discerns the obscurities of the present, penetrates the past, and reveals the future. In short, science is here a rational development of instinct, by means of which the individual may be educated to possess himself more fully of the accumulated social heritage; and, in turn, more fully contribute to it, from his personal experience—the individual being here postulated as unique.

(3) Science considered as a social process, *i.e.* as a growth of racial experience, accumulated by an infinitude of contributions from cooperating individuals and generations in endless succession. It is a social process differing in its development from parallel growths of racial experience, chiefly in being more capable of consciously directed control and guidance, and therefore able to yield more verifiable ideals. Here, from this third point of view, science appears as a Social Institution, aiming at the organisation of communitary experience by a collective process in which the intervention of any given individual is a negligible quantity. The personality of the individual man of science is here to be observed as a social fact of a definitive order, and interpreted as itself the product of past and contemporary social evolution. The individual is here postulated, not as unique, but as a type. The existing body of men of science make up, at any given moment, the temporary and evanescent personnel of one amongst abiding social institutions. They constitute one of a number of competing and cooperating social groups, composed of types of personality which are material for observation and study, like any other commensurable objects of natural history. And in this observational study of types of scientific personality would, of course, be included the corresponding study of their mental products—*i.e.* their contributions to science.

Here, then, are three aspects of science, under which it may approach the problem of its own structures and functions, its own history and ideals. The first approach is that of the nascent science of methodology (inheriting the philosophical traditions of logic and epistemology); the second is that of the well-established science of psychology; and the third, that of the nascent science of sociology (inheriting the traditions of philosophy of history and social philosophy). As each of these three sciences develops, it must, in pursuit of the first of scientific ideals—that of an over-evolving order—work out an increasingly natural classification of the phenomena with which it deals. The whole field of science would be surveyed from each of these points of view, and it would follow that in course of time there must emerge several classificatory schemes, each with a scientific status and validity of its own. But, given these several taxonomic systems—logical, psychological, sociological, and perhaps also æsthetic and ethical—there would, of course, remain the problem of their unification. Here surely would be scope for the activities of the philosopher; and yet the man of science would presumably decline to delegate that supreme taxonomic survey of his own domain. As sociologist, he may even propose a scientific survey of the philosophical field! For are not systems of philosophy themselves to be observed and classified as sociological facts, and interpreted as products and factors in social evolution?

What, then, is the right division of labour between science and philosophy? Is it not expressed in the simple and homely ideal—every man of science his own philosopher? Does not the existing fashion of exclusive devotion, either to speculation or to observation, tend to a multiplication of individuals who are neither philosophers nor men of science, but degenerate variants known to American psychologists as respectively "lumpers" and "splitters"? Is it not an alternation of speculation and observation, of the philosophical and the scientific mood, that most prolongs and intensifies each of these two complementary phases of mental activity? That surely is the lesson to be learned from the lives of the great initiators in science—of Faraday and Darwin, of Virchow and Helmholtz, of Bichat and Claude Bernard. The ordinary working man of science is ready enough, like Claude Bernard, to put off his imagination with his coat when he enters the laboratory. Only let him remember, like Claude Bernard, to put it on again when he leaves, for without it he cannot cultivate philosophy.

ELEMENTARY MATHEMATICS.

(1) *Elementary Pure Geometry, with Mensuration.* By E. Buddon, M.A., B.Sc. Pp. viii+284. (London and Edinburgh: W. and R. Chambers, Ltd., 1904.) Price 3*s.*

(2) *Lessons in Experimental and Practical Geometry.* By H. S. Hall, M.A., and F. H. Stevens, M.A. Pp. viii+94+iii. (London: Macmillan and Co., Ltd., 1905.) Price 1*s.* 6*d.*

(3) *The Elements of Geometry, Theoretical and Practical.* By B. Arnett, M.A. Books i., ii., and iii. Pp. viii+195, viii+238, and viii+242. (London: Simpkin, Marshall, Hamilton, Kent and Co., Ltd., 1904.) Price 2*s.* each volume.

(4) *The Elements of Trigonometry.* By S. L. Loney, M.A. Pp. xii+339+xiv. (Cambridge: The University Press, 1904; London: Macmillan and Co., Ltd., 1904.) Price 3*s.* 6*d.*

(5) *Elementary Algebra, Part II.* By W. M. Baker, M.A., and A. A. Bourne, M.A. Pp. viii+277 to 468+lxxvi. (London: George Bell and Sons, 1904.)

(6) *Clive's Shilling Arithmetic.* Edited by W. Briggs, LL.D., M.A., &c. Pp. viii+154. (London: W. B. Clive, 1905.) Price 1*s.*

(7) *Graphic Statics.* By T. Alexander, C.E., and A. W. Thompson, D.Sc. Pp. viii+50. (London: Macmillan and Co., Ltd., 1904.) Price 2*s.*

(1) THE geometry of Mr. Buddon is a notable addition to the elementary text-books which owe their appearance to the freedom of the last few years. The subject is introduced by experimental work, very suggestive in character, and leading by induction to fundamental definitions and theorems. Thus from the sliding and folding of flat cards and the like the author arrives at his definition of a plane as "a surface, infinite in extent, which can be folded about any two points of the surface so that one part lies entirely on the other." The definition of a straight line naturally follows as the infinitely extended fold of a plane. A plane angle is clearly and rationally defined. Parallel lines are those having the same direction in a plane, direction being measured by the angle made with any reference line. It is pointed out that a plane, a plane angle, and a straight line can in each case be reversed on itself, and thus symmetrical properties are satisfactorily established in which the two halves are alike but of opposite aspect. Then follow general cases of congruence. In dealing with ratio and proportion the idea of a continually subdivided decimal scale is introduced; this enables all numbers which can be expressed as continuous decimal fractions, *e.g.* 1·4142. . . ., to be included, and to any degree of approximation. In later chapters the subject-matter comprises a very full treatment of the properties of circles; elementary trigonometry; an introduction to projective geometry; conic sections treated by modern methods; and solid geometry with the mensuration of the simple geometrical solids. The book contains in profusion sets of graphical and deductive exercises. The figures are drawn with thick, thin, and dotted lines on a systematic plan to distinguish more readily between the data, the construction lines, and the result. The use of variable type serves to differentiate parts of greater or less importance. In fact, the book on every page bears witness to the great care and thought bestowed on its production. There is a stimulating freshness in the matter and its method of presentation. Some will doubt the wisdom of carrying on at school the study of pure geometry to the extent covered in the book; others may wish that the geometry of vectors had been included; but all will agree that the author has produced one of the most important of the new elementary text-books, and one that should be known to every teacher interested in the subject.

(2) The "Lessons in Experimental and Practical Geometry" by Messrs. Hall and Stevens might very fittingly be incorporated in the authors' "School Geometry," to which it forms an excellent introduction as well as supplement. The subject is treated in the masterly way that is found in the mathematical text-books of these writers. Young pupils are fortunate who obtain their first notions of geometry from a course such as the one outlined in its pages. They will become accustomed to the use of compasses, squares, scales, and the protractor by interesting quantitative and experimental work, fundamental propositions being at the same time inductively established. They will have practice in the application of geometrical problems; will learn how to measure areas; and will be introduced to the simpler geometrical solids. The authors make good use of tracing paper. The list of instruments and apparatus which they give might with advantage have included the drawing and compass pencils, with a caution added against the employment of soft blunt leads.

(3) In the preface of his elementary geometry Mr. Arnett states that the work "has been written for the use of candidates who are being prepared by a master for the different examinations conducted by the universities and the Civil Service Commission." The subject-matter is confined to plane geometry, and is almost wholly deductive. The first book gives definitions and axioms, and investigates some of the properties of lines, angles, parallels, triangles, and quadrilaterals. The second book deals mainly with the circle and with ratio and proportion, and the last book treats of areas and of similar figures. The principal feature of the work is the very large number of exercises provided, a few of which are numerical or graphical, the great bulk, however, being of the nature of geometrical riders. The text-book is not at all suitable for beginners, for general school work, or for private study except under the direction of a tutor who could direct the student as to which parts should be read and which omitted, and who would probably re-arrange the order in which the theorems and problems should be taken.

(4) Mr. Loney's "Elements of Trigonometry" is mainly taken from part i. of the author's "Plane Trigonometry," and is designed as an easier text-book. The subject is treated in the usual way, and there is nothing to call for special mention. The first chapters relate to acute angles and right-angled

triangles. The definitions are then extended to angles of any magnitude, and formulæ are established for the sum and difference of angles, and for multiple and submultiple angles, &c. There is a chapter on logarithms, and a number of four-figure tables are given. This work leads up to the properties and solution of triangles with applications. Inverse functions are introduced, and general expressions established for angles having given trigonometrical ratios. There are a large number of examples, any necessary answers to which are given at the end of the book.

(5) Part ii. of Messrs. Baker and Bourne's excellent algebra begins by formally establishing the laws of operation of algebraical symbols. It contains chapters on surds and indices, proportion, logarithms, progressions, series, scales of notation, permutations and combinations, the binomial theorem, interest and annuities, exponential and logarithmic series and partial fractions. There are numerous groups of examples, and special sets of revision papers at intervals, the answers being all given in an appendix. A special feature of the book is the frequent use of graphs and of geometrical illustrations. This text-book must give satisfaction wherever used.

(6) Clive's shilling arithmetic is intended for the use of teachers who adopt almost entirely the oral method of instruction, and who only require a class-book containing concise statements of rules, with graduated sets of exercises, and with the formal proofs of theorems omitted. Thus a small volume is sufficient to cover the range of subjects usually taught in schools, and which this manual contains. The book can be obtained with answers included at an extra cost of threepence.

(7) In the graphical statics of Messrs. Alexander and Thompson the authors first give a set of sixteen graduated problems on coplanar forces, solved by means of force and link polygons; these include couples, centres of area and moments of inertia of beam sections. Then follows a set of seventeen examples showing applications to roof trusses, girders, walls, and masonry arches. The treatment is somewhat fragmentary and arbitrary, but, if supplemented by the teacher, the course would prepare a student for a systematic study of graphic statics, and the book is intended more particularly as an introduction to the author's "Elementary Applied Mechanics."

SALT-BEDS AND OCEANS.

Zur Bildung der ozeanischen Salzablagerungen. By J. H. van 't Hoff. Pp. vi+85. (Brunswick: Vieweg and Son.) Price 4 marks.

THIS work will be welcomed alike by chemists, geologists, and oceanographers. It forms the first instalment of the collection into one publication of the results of some forty memoirs of the author and his collaborators on the formation of double salts.

The principal object of the work was the study of the problem of the natural salt beds. As these beds have in all probability been formed by the evaporation of a body of water comparable with the existing oceans, which certainly contain some of everything, it was necessary to set limits to the investigation. This was effected by confining attention to the principal constituents of the salt-beds. These are chloride of sodium, in great preponderance, and the chlorides and sulphates of magnesium and potassium with their water of crystallisation. The latter form a series of more complex bodies which appear and disappear with the changing equilibrium of the solution. After these come the calcium salts, such as anhydrite and polyhalite; but they are held over for treatment in the next fascicule.

The work is a gigantic exercise in physical chemistry, which the author carries through on strictly scientific lines, while at the same time touch is kept with the important applications of his results in the economy of nature, and chemistry is thus vindicated as a branch of natural history.

The experimental part of the work is of especial interest to physical chemists, and the publication of it in a connected and condensed form will be welcomed by them. It is proposed here to notice only the application of it to the occurrence of salts in nature in beds and in solution.

The experimental basis of the work is the determination of the solubility, at certain temperatures, of the common salts of the sea, in water and in solutions of each other. With the information so obtained, it is possible to follow exactly the crystallisation of a solution containing all these salts, as it gradually loses water by evaporation at the temperature of the experiment. The temperature most used is 25° C., which is fairly representative of the temperature of sea water evaporating in salt gardens, such as those of Hyères or Cadiz in summer.

When average sea-water has been evaporated down to the point at which chloride of sodium begins to crystallise, the liquor contains (in molecular proportions) 100 $NaCl$, 2·2 KCl, 7·8 $MgCl_2$, 3·8 $MgSO_4$; and this mixture of salts is associated with, roughly, 1000 mol. H_2O (exactly 1064). On allowing this liquor to evaporate at 25° C., the crystallisation follows a definite route, which can be traced exactly, and without difficulty, on one of those marvellous charts representing the march of physical and chemical phenomena with which the resourceful inventiveness of van 't Hoff has familiarised us.

The crystallisation takes place in four acts corresponding to the regions in the chart.

(1) Rock-salt: separation of chloride of sodium in great abundance. Of the 100 NaCl present when crystallisation began, only 4·6 NaCl remains dissolved; the remainder, 95 NaCl, has been deposited.

(2) Kieserite region: separation of chloride of sodium, sulphate of magnesium, and kainite

$$(MgSO_4KCl3H_2O).$$

The salt separated in this act consists of 4·42 NaCl, 2·02 KCl, and 3·07 $MgSO_4$; or, 4·42 NaCl, 1·05 $MgSO_4$, and 2·02 kainite.

(3) Carnallite region: separation of chloride of sodium, carnallite ($KMgCl_3,6H_2O$), and kieserite ($MgSO_4.H_2O$), and the amounts separated are 0·03 NaCl, 0·1 carnallite, and 0·35 kieserite.

(4) Final liquor: what remains solidifies to 0·15

NaCl, 7·62 $MgCl_2$ (bischofite), 0·08 carnallite, and 0·38 kieserite.

	Rock salt	Kieserite	Kainite	Carnallite	Bischofite
(1)	95·4	—	—	—	—
(2)	4·42	1 05	2·02	—	—
(3)	0·03	0·35	—	0 1	—
(4)	0·15	0·38	—	0·08	7·62
	100·00	1·78	2·02	0·18	7·62
		3 8	2·2	7·8	
	NaCl	$MgSO_4$	KCl	$MgCl_2$	

Within the limits of a notice of this kind it is impossible to give an adequate account of so important a work. It is hoped, however, that the above extract will show that it has an interest for others as well as for chemists. J. Y. B.

EVOLUTION FOR BEGINNERS.

An Outline of the Theory of Organic Evolution; with a Description of some of the Phenomena which it Explains. By Dr. Maynard M. Metcalf, Professor of Biology in the Woman's College of Baltimore. Pp. xxii+204. (New York: The Macmillan Company; London: Macmillan and Co., Ltd., 1904.) Price 10s. 6d. net.

THIS is one of the best popular accounts of the theory of evolution that have come under our notice. The author makes little or no claim to originality, but he has on the whole succeeded in his aim of providing a clear and intelligible statement of evolutionary doctrine in most of its recent developments. Technicalities have been largely avoided; but, as the author truly says, "the subject is somewhat intricate, and cannot be presented in so simple a manner as to require no thought on the reader's part." With regard to controverted points, the position taken is generally sound; Dr. Metcalf has no difficulty in recognising the supreme importance of natural selection, or in rating at their true value the speculations of the Lamarckian school, whether new or old. He rightly lays stress on the great fact of adaptation as affording the most conclusive evidence of the controlling power of selection; "adaptation," as he remarks, "is the key-note of organic nature." To some readers his faith in the beneficial character of certain modifications will seem a trifle too robust; but for the most part he treats this branch of the subject with sound judgment and the force born of reasoned conviction.

An excellent feature of the book is its wealth of pictorial illustration. Many of the figures are already well known, but it is of great advantage to the ordinary reader to have them grouped together in such a way as to throw fresh light on each other, and thus materially to assist his comprehension of the subject. Many of the reproductions of original photographs are particularly good; to "find the woodcock" in plate l. makes an interesting puzzle. The representation of the snow grouse in plate lvii., and of the sargassum fish in plate lxv. are also admirable, while the copies in colour of Tegetmeier's figures of fancy poultry, though a little rough in execution, are amply sufficient for their purpose.

A few points call for criticism. The author is occasionally betrayed into a slipshod or unmeaning expression, as when he speaks of the sun "moving along its appointed daily course under the control of gravitation." A sentence on p. 31 is entirely misleading, unless the word "artificial" be substituted for "natural." The factors to which special attention has been directed by Osborn, Baldwin and Lloyd Morgan, though not ignored, are rather inadequately treated; the author, moreover, falls into some confusion between individual and specific plasticity. On p. 134 Fritz Müller's interpretation of "synaposematic" resemblances is erroneously attributed to Bates. Indeed, the whole subject of common warning colours, which is one of the most interesting and complicated in the entire range of evolution, deserves more extended and more accurate treatment than it receives at Dr. Metcalf's hands. On plate lxxvi. *Papilio merope* (*caeneae*) is somewhat uncritically assumed to be edible, and on plate lxxvii. we meet with the astonishing statement that the male of *Perrhybris* (*Mylothris*) *pyrrha* is edible, and "imitates the inedible Heliconidæ," while the female of the same species "is not a mimic"; the fact being that it is one of the best mimics known, probably of the Müllerian kind. The lettering of many of the plates stands in need of revision. F. A. D.

OUR BOOK SHELF.

Précis de Chimie physiologique. By Prof. Allyre Chassevant. Pp. iv + 424; illustrated. (Paris: Félix Alcan, 1905.) Price 10 francs.

THIS is a very excellent text-book of physiological chemistry, and it presents the subject in an attractive way. It treats first of the chemical substances found in the body, then of the various liquids and tissues of the organism, and finally of function.

The work contains all the essential facts of this branch of science, without going exhaustively into details; references are given throughout to the names of investigators, but not, as a rule, to their writings. The subjects treated most fully are the urine, the milk, and diet, for the work aims at being not only academic, but also of practical use to the clinical investigator.

The author is well known for his original work in chemical physiology, and he will be personally known also to many in London, as he was one of those who joined in the recent visit of French medical men to London. He possesses what is rarely absent in French writers, a power of clear and lucid exposition. He is fully conversant with recent progress in science, as evidenced by the way he deals with questions in which physical chemistry is involved.

The line between physiology and pathology is never a well defined one, and thus we find in the book subjects like immunity, serum diagnosis, and serum therapy to the fore. It is inevitable that this should be so, for a proper understanding of ferments and anti-ferments, the prime factors in animal chemistry, cannot be attained except through the knowledge and new ideas which were in the first instance the outcome of study in pathological fields.

M. Chassevant is to be congratulated on his interesting work. He has furnished the student, the investigator, and the teacher with what will be useful to all of them. W. D. H.

Unsere Pflanzen. By F. Söhns. Dritte Auflage. Pp. iv+178. (Leipzig: Teubner, 1904.) Price 2·60 marks.

Children's Wild Flowers. By Mrs. J. M. Maxwell. Pp. viii+171. (Edinburgh: David Douglas, 1904.) Price 7*s.* 6*d.* net.

The derivation of many botanical names being very uncertain, it is probable that the subject appeals more to the philologist than the botanist. Who shall say, for instance, whether the speedwell takes its name from a saint Veronica, or should be derived from "vera icon" or "vera unica"? Vernacular names are perhaps more easily explained, but vary greatly in different districts. Similar difficulties occur with German popular names, so that Mr. Söhns has a number of problems of an indeterminate nature to solve in his book, which deals with the nomenclature of plants and their place in mythology and folklore. Generally the author's arguments are carefully deduced and convincing, and, as might be expected, the correct derivation is not always obvious. Tausendgueldenkraut, the popular name of *Erythraea centaurea*, suggests a connection with "centum aurum," but the specific name is undoubtedly given in honour of the Centaur Chiron, who was skilled in medicine, and the German name, which was at first hundert guelden Kraut, has apparently given place to Tausendgueldenkraut, where thousand is used in a hyperbolic sense, and thus the Centaur's plant has become associated with a fanciful expression. In addition to etymology, the book contains many references to popular superstitions. On account of the dissimilarity between German and English popular names it cannot be expected that the book will appeal strongly to English readers, but a third edition points to its success in Germany.

The book by Mrs. Maxwell is intended to interest children in wild flowers by narrating the legends and stories connected with them. Scientific description is practically limited to habitat and comparative characters for distinguishing between the species of a genus, and coloured illustrations are provided as a means of identification of the plants. Obviously the purpose of the writer is not to train the powers of observation or inculcate accuracy, but rather to stimulate the faculties of imagination.

Superstitions about Animals. By Frank Gibson. Pp. 208. (London and Newcastle-on-Tyne: Walter Scott Publishing Co., 1904.) Price 3*s.* 6*d.*

This is an unpretentious little book which will interest many people. It brings together some of the most common superstitions about animals, "dealing with them in a light and popular way," with copious quotations from the poets. One of its aims is to sweep away those superstitions that are foolish and degrading, to clear the air for a free appreciation of the real wonders of nature. For "there is no subject under heaven which will give more pleasure or lasting and real profit than that of Natural History." Mr. Gibson deals first with omens, such as the ticking of the death-watch and the baying of a dog; he goes on to distortions of facts of natural history, such as "salamanders in the fire," "crocodile's tears," "the hibernation of swallows"; he ends up with creatures of the imagination, like the "basilisk," the "phœnix," and the "griffin." The author is a devout admirer of the real things of nature with an unusual knowledge of the poets both great and small. He has not seriously tackled the difficult side of his subject—the attempt to account historically and psychologically for the origin and persistence of the more important superstitions. He has forgotten the salt.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* Nature. *No notice is taken of anonymous communications.*]

A Great Oxford Discovery.

In a recent study of some eighteenth century naturalists' writings I was a good deal struck by the amount of attention devoted to the problem of whether the white man was a sport from negroid stock or the negro a sport from a white race. The matter was discussed from every standpoint, physiological, geographical, and theological, but the consensus of opinion, based chiefly on the existence of albinotic and pied negroes, and on the misunderstood effects of leucoderma, was that the white might be a negro sport, but that there was no evidence of a black sport in the case of the white races. If such an opinion were correct, and the white man only a negro sport, we should certainly expect to find the negroid cranial type common among the white races. Two distinguished Oxford men of science have just thrown remarkable light on this problem. They have given a very simple series of conditions by which crania can be classed into skulls of negroid, non-negroid, and intermediate types. These conditions depend entirely on a classification of nasal and facial indices, and by their processes our authors are able to distinguish between the negroid, non-negroid, and intermediate types among prehistoric Egyptian crania. Not being an anatomist, I am quite unable to judge of the processes by which they have reached their criteria, and the photographs which accompany their volume are of so obscure a character—indeed, in the present state of cranial photography somewhat unworthy of a university press—that they hardly allow the uninitiated even with a lens to appreciate the justification which the authors find for their classification in the outward appearances of their cranial groups. I think, however, we may safely give the greatest weight possible to a judgment formed by the Oxford professor of human anatomy and the Oxford reader in Egyptology in a folio volume just issued by the syndics of the University Press.

Taking their classification as beyond discussion, I have applied it:—

First, to a fairly long series of admittedly negro crania, all males. I find 7·3 per cent. are non-negroid, 39·0 per cent. are truly negroid, and 53·7 per cent. are intermediate. It is clear that we only need to let the negroes change their skins, and a sensible percentage will be non-negroid.

Secondly, to a fairly long series of English skulls, male and female. I find of Englishmen 20 per cent. are negroid, 46 per cent. non-negroid, and 34 per cent. are intermediate in type. Among Englishwomen 11 per cent. are negroid, 48 per cent. non-negroid, and 41 per cent. are of intermediate type. Thus of the whole English population slightly more than 50 per cent. are either pure negroid or partially negroid; while in an outwardly pure negroid group, upwards of 60 per cent. are non-negroid or mixed with non-negroid elements.

I have not yet had time to apply Prof. Thomson and Mr. Randall-Maciver's test to Asiatic races, but I have not the least doubt that I shall find there also pure negroid and intermediate negroid elements. But that the Englishman should have as large a negroid element in his constitution as the prehistoric Egyptian, and only half as little pure negroid element as admitted negroes, is to my mind an epoch-making discovery, which will at once attract attention to Oxford as a centre for a novel school of craniometry and anthropology. Karl Pearson.

University College, London.

Inversions of Temperature and Humidity in Anti-cyclones.

In Nature of February 16 Mr. W. H. Dines cited an example of a large temperature inversion, observed with kites during the prevalence of very high barometric pressure in England, and remarked on the possible connection between the two phenomena.

Observations with kites at Blue Hill during the past ten years, and with balloons elsewhere, show that inversions of temperature occur at some height in the free air under almost all weather conditions. In a discussion of the kite observations at Blue Hill, published in 1897 in part i., vol. xlii., *Annals of the Astronomical Observatory of Harvard College*, Mr. H. H. Clayton probably first pointed out that marked inversions of temperature at heights of from a quarter to half a mile in the free air occur in the rear of anti-cyclones. He gives one example of a rise of 26° F. between 2180 feet and 2530 feet, accompanied by a corresponding fall of 50 per cent. in the relative humidity, this rise of temperature being more than twice that mentioned by Mr. Dines.

Prof. Hergesell's soundings with kites on board the Prince of Monaco's yacht last July, in the permanent high barometric pressure south of the Azores, showed a decrease of temperature of 6° F. up to about 1800 feet, when the temperature suddenly rose 14° F., and so remained throughout a stratum 3000 feet thick, above which it fell at the adiabatic rate, the relative humidity decreasing 50 per cent. with the rise in temperature. It would appear, therefore, that such inversions of temperature and relative humidity at a moderate height are characteristic of areas of high barometric pressure, both over the land and water.

A. LAWRENCE ROTCH.

Blue Hill Meteorological Observatory, Hyde Park, Mass, U.S.A., March 13.

The Planet Fortuna.

ONE point of interest to Airy's brother men of science has not been noticed—that he either misunderstood or wilfully misapplied the lines of Juvenal. The "Purists" urged that planets had always been named after deities, and that Fortuna was not a deity. Airy said that she was, and quoted "nos te, nos facimus, Fortuna, deam." What did Juvenal really say? He said, "the wise see *no* divinity in Fortune; it is only human folly that calls her goddess, and assumes for her a place in heaven." As Gifford renders it:—

"We should see
If wise, O Fortune, nought divine in thee;
But we have deified a name alone,
And fixed in heaven thy visionary throne."

"Nullum numen *abest*" belongs to a numerous class of misquotations, and spoils the whole tenor of the passage. The supreme authority on Juvenal, J. E. B. Mayor, does not even condescend to cite it.

W. T.

CITY DEVELOPMENT.[1]

THE elegant volume under notice was written by Prof. Patrick Geddes in response to an invitation by the Carnegie Dunfermline Trust. The report is copiously illustrated, and embodies a very great amount of valuable and important information, plans, and suggestions as to the laying out of the public park, and as to the buildings, in or around it, needed or desirable for carrying on the work of the trust.

The author set to work by having a complete photographic survey made of the park and its environments. All those photographs, however, could not be incorporated in the report, but they will be preserved as a permanent record of the appearance of the park and its surroundings before any changes were inaugurated by the trust. Not content with mere photographs and maps, the author strongly recommends the construction of a relief model of the park, bearing on its surface pasteboard models of the new buildings proposed, in order that the general effect of these buildings on their surroundings may be clearly anticipated, and thus the erection of structures out of harmony with their surroundings may be avoided.

[1] "City Development, a Study of Parks, Gardens, and Culture Institutes." A Report to the Carnegie Dunfermline Trust. By P. Geddes. Pp. 232. (Westminster: Geddes and Co., 5, Old Queen Street.) Price 21*s*. net.

At the beginning of the report a general plan of the park is given, showing the proposed improvements. At first sight the plan appears very elaborate and overcrowded with detail, but this is due

FIG. 1.—View down House Dene, showing back of old Mansion-house to left (south), and on opposite bank, a little nearer than the large tree, Wallace's Well, fallen in. Old paths effaced. From "City Development"

to the fact that its designer has endeavoured to show all the essential details in the plan, in order to reduce the number of blocks in the text, and a little study is all that is required to show that the proposed improvements are not of such a radical nature as a first impression might convey. The proposed treatment is essentially a conservative one, and the suggested changes and improvements have been designed to interfere as little as possible with the existing features, views, and even details of the park and glen.

About one-half of the report is devoted to a detailed consideration of the park, its environs, gardens, and nature museums. The possible approaches and entrances are carefully considered and selected. These must render easy access to, and be in keeping with, the important centre to which they lead. The park must not end abruptly where the town begins, but its environs or setting should be such that a harmonious blending—one with the other—is secured, and in this connection the author seems to have made the most of the material at his disposal.

FIG. 2.—The same view, with Wallace's Well simply re built, and roughly rustic foot-bridge, uniting old paths now renewed. The Mansion-house shows also one of the proposed new turrets. From "City Development."

As regards the laying out of the park, the proposed lakes, gardens, tennis courts, cricket pitches, bowling greens, and other recreation grounds, its pavilions, band-stands, museums, walks, and groves, are too numerous to be noticed individually here. Shortly stated, the author has given the benefit of his extensive knowledge and wide experience in the planning, equipment, and arrangement of parks and all their accessories. Every practical expedient that ingenuity can suggest to encourage that open-air life and physical exercise so necessary and beneficial for young and old has been adopted in the schemes and plans submitted by the author of the report.

A word or two about the nature palace may not be out of place. This very important building has been designed to serve several different purposes, such as a winter garden adapted to receptions and conversaziones, and it also could be used as a promenade and popular assembly room, and as a centre for bazaars, periodic industrial exhibitions, flower shows, &c. The author further proposes to give this building the additional and educational interest of a great museum—a museum which, however, should not aim at having a large general collection of geological, botanical, zoological, and anthropological material, such as those which already exist in larger cities. Indeed, the author points out that it would be cheaper for the trust to send whole schools to the museums of Edinburgh than to attempt to possess an independent institution containing, say, the sixth best collection of skeletons in Scotland or the like. This museum in the nature palace is to be something apart from any existing type of museum; in the words of the author, "A museum not primarily of geology, botany, natural history, anthropology, and so on, yet the whole of these within the living unity of nature, scene by scene—in short, a museum of geography." So far as the special requirements of the various natural sciences are concerned, the author recommends as a model the Perth Museum, with its well chosen collection of types.

The latter half of the report, forming book ii., deals with the culture uses of museums and institutes. In this part of the volume, art, music, history, and science are all provided for and suitably housed, with a view not merely to their immediate wants, but ample allowance and provision are made for the future development and expansion of each and every phase of human activity bearing on culture and industry.

In this handsome volume, the author has included a vast amount of detailed information and convincing arguments to show the value of parks, gardens, museums, and culture institutes in the social advancement, education, and well-being of communities.

NATURE'S WAYS.[1]

UNLIKE the great majority of works of the same class, this little volume takes no notice of birds, but, as its title implies, is entirely devoted to the lower forms of life which may be met with during rambles in different parts of the country, including both animals and plants. As in the case of his earlier book, all the articles have previously been published in various periodicals and journals; and the opportunity for revision given by their re-publication ought to have enabled the author to correct certain deficiencies in style and expression by which the present issue is disfigured.

For example, on p. 29, Mr. Ward manages to introduce the word "which" three times in the course of a single sentence without the use of any higher stop than a comma. On p. 2 we find an obtrusive instance of the *ego et rex meus* class; and on p. 172 we are told that *occasionally* examples of a certain organism are not *uncommonly* met with. Again, on p. 204 the reader, owing to the misuse of the pronoun "they," is informed that the jaws of a snail possess neither jaws nor teeth; while in the

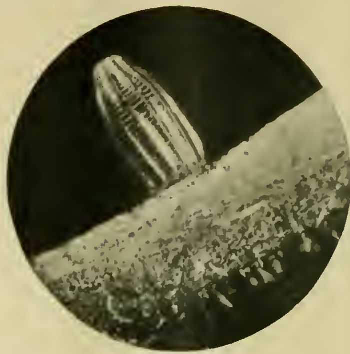

FIG. 1.—Magnified egg of the orange-tip butterfly, on a flower-stalk. From "Peeps into Nature's Ways."

second paragraph on p. 91 we observe a plural pronoun used in connection with a substantive in the singular. The misprint in the first sentence on p. 181 is perhaps excusable; but the statement (p. 186) that

FIG. 2.—A sprig of broom, showing fertilised and unfertilised flowers. From "Peeps into Nature's Ways."

carbon chemically combines with the water sucked up by plants is scarcely an exact definition of what takes place.

Apart from blemishes like the above, the author may

[1] "Peeps into Nature's Ways; being Chapters on Insect, Plant, and Minute Life." By J. J. Ward. Pp. xviii + 302; illustrated. (London: Lister and Co., 1905.)

be heartily congratulated on his work, which is interesting and readable from start to finish; while the illustrations, reproduced from his own photographs, are in most cases exquisite, as our readers may see for themselves from the two examples furnished herewith. Although he appears to have little or nothing new to record, Mr. Ward is evidently a careful and accurate observer, with the faculty of recording his facts in language that "can be understanded of the people."

With the exception of one chapter on the hydra and a second on the "tongues" of molluscs, Mr. Ward's work is restricted to insects and plants. In his opening chapter he details the fascinating life-history of the orange-tip butterfly, showing how its coloration harmonises with the plants it frequents, and how the beautiful green mottling on the hind wings is produced by the blending of dots of black and yellow. As an example of the author's skill in microscopic photography, we reproduce from this chapter his enlarged figure of the egg of the butterfly in question.

Another chapter we have read with special interest is the one on the gorse, in which the author points out how this plant retains evidence of its relationship to the clovers in the form of its seed-leaves; while he also suggests that the broom may be regarded as in some degree representing a plant in course of evolution to the gorse type, but that its career to this goal has been checked by the fact of its having a bitter taste, which renders its leaves, unlike those of the gorse, uneatable by cattle, so that a protective panoply of spines is superfluous. As a specimen of the author's exquisite photographs of plants, we reproduce the one showing the broom in blossom. Of the other chapters dealing with plants, one is devoted to their hairs and scales, in the course of which the author expresses his belief that he has brought to notice a hitherto undescribed type (in the Auricula); a second chapter is accorded to the sensitive plant, a third to the flowers of woodland trees, a fourth to plant-battles, and a fifth to plants that catch flies.

Reverting to the zoological series, it may be mentioned that the devotion of two chapters to the biographies of a couple of nearly allied species of hawk-moth is perhaps an ill-judged arrangement, as giving too much importance to one group. Be this as it may, the chapter entitled "Living Files and Rasps," in which are described and figured the lingual ribbons of a number of species of gastropods, can scarcely fail to be generally interesting, although it would have been better had the author in every case particularised the genus and species to which his specimens pertain, instead of merely labelling them "snails." In the chapter on mosquitoes and gnats the author does his best to clear up the popular misconception with regard to these insects, and shows how the female, so far as mankind is concerned, is the source of all harm and evil.

While, as already stated, it is somewhat marred by errors and inelegances of style, the book as a whole may be pronounced decidedly interesting and attractive, and free from all cant and faddism.

R. L.

GERMAN EDUCATIONAL EXHIBITS AT ST. LOUIS.

THE German educational exhibit at St. Louis was, as is usual with German exhibits, remarkably complete, and to enhance its value a series of descriptive catalogues was issued. Among the science catalogues were three on scientific instruments, chemistry, and medicine respectively which have special interest for readers of Nature. They are all on the same plan, and include a general introduction explanatory of the scope of the work, and a detailed account of the apparatus, &c., exhibited. They served a twofold purpose, that of informing visitors to the exhibition as to what there was to see, and also that of bringing together an account of the best products of German workmanship in the respective subjects of the catalogue.

In the catalogue of scientific instruments the introductory description is very full and of real use; special reference is made to novel instruments. Dr. Lindeck, of the Reichsanstalt, who edited the catalogue of the German exhibit in Paris in 1900, is responsible for this, while Dr. Krüss had charge of the section.

The description of the instruments which follows is arranged alphabetically according to the names of the exhibitors. The system of classification with cross references is somewhat less complete than that adopted in the 1900 catalogue, but by aid of the introduction it is easily possible to find any given kind of apparatus. A glance through the catalogue is sufficient to show its utility, and it is to be hoped that the support given to the proposed optical convention and exhibition in May next will be sufficient to justify the committee in issuing a catalogue of English optical goods which will serve the same purpose.

The chemical section at the exhibition contained a reading-room and library, and in this an interesting collection of alchemistic work was shown. Besides these most of the important modern German works on chemistry were to be found on the shelves. Two very interesting exhibits were the alchemistic laboratory, containing partly original apparatus, partly copies of old examples from the museum in Nuremberg, and the Liebig laboratory, a faithful copy of the well-known laboratory at Giessen. The rest of the exhibition illustrated modern chemical apparatus, methods and preparations.

The object of the medical exhibit is said to have been "to show how the German universities deal with the subject of medical instruction," and this was attained by judiciously grouping the articles shown, and by carefully selecting the apparatus. Naturally, various methods are adopted in the different branches; thus, in the department of internal medicine a complete clinical lecture on the diagnosis and therapeutics of tuberculosis is included, the objects required for demonstrating it being exhibited.

Among the apparatus, the microscopes and projection apparatus of Karl Zeiss occupy a prominent place.

It is noteworthy that among the infectious diseases and disease germs tuberculosis comes first.

The catalogue contains a full list of the exhibits with some account of the principal among them, and it is clear that great pains have been taken to secure that the primary object of the exhibition should be carried out.

The three catalogues, in their completeness and orderly arrangement, are examples of the German plan of carrying the teaching and method of science into everyday life.

NOTES.

The council of the Linnean Society has appointed a committee to consider the question of zoological nomenclature.

Prof. Lancereaux has been elected president for 1905 of the Société internationale de la Tuberculose.

The Canadian Government has decided to place a Marconi wireless telegraph station on Sable Island. The station will come into operation by August 1 next.

M. Paul Labbé has been appointed general secretary of the Paris Society of Commercial Geography in succession to the late Ch. Gauthiot.

MR. ALFRED BEIT has informed the honorary treasurers of the Institute of Medical Sciences Fund, University of London, that he has decided to increase the amount of his donation to the institute from 5000*l*. to 25,000*l*.

SENOR DON IGNACIO BOLIVAR, of Madrid, has been elected an honorary fellow of the Entomological Society. Profs. W. G. Farlow, H. S. Jennings, E. B. Wilson, and R. B. Wood have been elected honorary fellows of the Royal Microscopical Society.

THE King's Institute of Preventive Medicine was opened at Madras on March 11. The institute supplies animal vaccine to the whole of the Presidency, besides preparing curative and prophylactic sera. On the opening day there was an exhibition of bacteriological and sanitary engineering appliances.

A MOUNTED specimen of the great auk, formerly in the Hawkstone collection, has been sold by Rowland Ward, Ltd., of Piccadilly, to one of the American museums for 450*l*. This is the "record" price, the next highest being 350*l*. obtained some years ago by the same firm for a specimen now in a private museum.

DR. A. R. WALLACE recently presented to the British Museum a number of pencil drawings of fishes from the Rio Negro which were saved some fifty years ago at the time the veteran explorer's collections were burnt at sea on his return from the Amazonian journey. These drawings, some fifty in number, were exhibited at one of the meetings of the Zoological Society, when it was stated that while some of the species depicted had been identified, others appeared to be still unknown to science. This should stimulate investigation of the fish fauna of the Amazonian system.

M. JULES VERNE, whose works are better known in this country than those of any other French writer, died on March 24 at seventy-seven years of age. Jules Verne was one of the first novelists to recognise and utilise the store of scientific knowledge as a source of material from which attractive romances could be constructed. The charm of his style and the realism of his pictures have done much to encourage the study of science among boys and girls. Few writers, indeed, have produced healthier and more stimulating stories, or weaved fancy and fact together so successfully.

ON Saturday next, April 1, Lord Rayleigh will deliver the first of a course of three lectures at the Royal Institution on some controverted questions of optics. On Tuesday, April 4, Mr. Perceval Landon will give the first of two lectures on Tibet, and on Thursday, April 6, Prof. Meldola will commence his course of two lectures on synthetic chemistry, experimental. The Friday evening discourse on April 7 will be delivered by Mr. Alfred Mosely on American industry, and on April 14 by Lord Rayleigh on the law of pressure of gases.

THE Estimates for Civil Services for the year ending March 31, 1906, provide for education, science, and art, the total sum of 16,328,947*l*., being an increase of 533,409*l*. over the grants for 1904–5. There is an increase of 46,100*l*. for university colleges, the grant being raised from 54,000*l*. to 100,000*l*. Of the increase 416,790*l*. under Board of Education, the greater proportion must be described as automatic in character, due to the anticipated growth in the number of scholars in average attendance, and to the larger number of teachers for whose training provision is made by the State. The principal increase, 262,704*l*., is in respect of the elementary education grants. With a view to the further development of the National Physical Laboratory, Parliament is being asked to sanction an increase of 1500*l*. on the grant in aid of salaries and other expenses of the laboratory, and also an additional grant of 5000*l*. in aid of new buildings and equipment for the same institution. Further provision is also included for investigations in connection with the North Sea fisheries.

THE fourth International Ornithological Congress will be held in London in Whitsun week, June 12–17. The organising committee has been able to obtain from the University of London accommodation for the meeting at the Imperial Institute, and from the trustees of the British Museum the use of the Natural History Museum for the purpose of a conversazione on one evening of the week of the congress. The Prince of Wales has consented to become the patron; and the two honorary presidents are Prince Ferdinand of Bulgaria and Dr. A. R. Wallace, F.R.S. The president-elect of the congress is Dr. Bowdler Sharpe. The congress will be divided into general meetings and meetings of sections, of which there will be five, as follows:—(1) systematic ornithology; general distribution, anatomy and palæontology; (2) migration; (3) biology, nidification, oology; (4) economic ornithology and bird protection; and (5) aviculture. It is proposed to devote one day to an excursion to Tring to inspect the collection of birds belonging to Mr. Walter Rothschild. On June 16 the congress will be received by the Lord Mayor of London at the Mansion House. At the close of the proceedings in London, on the invitation of the Duke of Bedford, an excursion will be made to Woburn to view the collection of live animals in Woburn Park, and the following day will be spent at Cambridge, where Prof. Newton will welcome the members at Magdalene College. Finally, a journey has been planned to Flamborough Head, in Yorkshire, of special interest to ornithologists.

THE programme of arrangements for the Optical Convention shortly to be held in London is now beginning to assume a definite shape. The convention will be formally opened with an address from the president, Dr. R. T. Glazebrook, F.R.S., on the evening of Tuesday, May 30, and the gathering will extend over the four following days up to and including Saturday, June 3. The mornings will be devoted to papers and discussions, and in view of the interesting series of papers already announced, there is no doubt that this most important section of the proceedings will result in valuable contributions to optical science, and will fulfil the aims which those who have been active in promoting the convention have set before them. In addition to the papers, demonstrations of apparatus of special interest will be given in the afternoons in the laboratories of the department of technical optics of the Northampton Institute. An exhibition of optical and scientific instruments will be held at the Northampton Institute, and will be open from May 31 to June 3, both dates inclusive. The catalogue is now in active preparation. The arrangement made by the "exhibition and catalogue" subcommittee that each section should be dealt with by an expert in the construction of the instruments represented in the section, together with an independent scientific member of the committee, will ensure that all classes of instruments shall be adequately dealt with and described. In addition to the presidential address to be given on the evening of May 30, there will be an evening lecture by Prof. S. P. Thompson, F.R.S., on the polarisation of light by Nicol prisms and their modern varieties. On a third evening it is proposed to hold a conversazione, and for Saturday afternoon, June 3, a visit to the National Physical Laboratory is proposed. Further particulars will be announced later, when the programme is more definitely settled. The hon. secretary, Mr. F. J. Selby, Elm Lodge, Teddington, Middlesex, will be glad to hear from those wishing to join the convention.

IN an account of a journey to Lake San Martin, Patagonia, published in the *Geographical Journal* for March, Captain H. L. Crosthwait directs attention to the magnetic and meteorological observatory established by the Argentine Government on New Year Island—a small island situated in lat. 54° 59′ S., and about five miles off the north coast of Staten Island. The observatory, which is complete in every respect, is superintended by four Argentine naval officers, and is here illustrated from Captain Crosthwait's paper. The observatory was opened in February, 1902, and during the time which has since elapsed, the temperature conditions recorded there by the officers are:—highest temperature recorded, 55°·4 F.; lowest temperature, 16°·4 F.; annual mean temperature, 41° F. The magnetic observatory is kept at an almost constant temperature of 64° F. Many interesting facts about Tierra del Fuego are given by Captain Crosthwait in his paper. He directs attention to the astonishing number and variety of the glaciers, and to the fact that most of the larger ones show signs of shrinkage. Of San Martin Lake he says it undoubtedly occupies what was once a strait joining the Atlantic and Pacific Oceans. The level of the water of the lake rises and falls in a peculiar manner. Exact measurements of these "seiches" show that the movements are irregular, but on an average they amount to about five inches, having a period of about four minutes between two successive high waters. The surface of the water to the eye is perfectly smooth.

FIG. 1.—Magnetic and Meteorological Observatory, New Year Island.

THE "Fauna of New England," in course of publication by the Boston Society of Natural History, has reached its fourth part, which is devoted to the echinoderms, the author being Mr. H. L. Clark.

BEAVER-DAMS on the Slate River, Colorado, form the subject of a paper by Mr. E. R. Warren in the *Proceedings* of the Washington Academy (vol. vi. p. 429), in the course of which the author shows how largely these rodents have altered the features of the valley.

IN the *Biologisches Centralblatt* of March 1, Mr. S. J. Wasmann continues the account of his theory of the origin of slavery among ants, Mr. H. Prandt discusses reduction processes and "karyogamy" among infusorians, while Prof. von Hansemann reviews the so-called heterotype cell-formation in malignant tumours, more especially in connection with the recent cancer investigations of Messrs. Farmer, Moore, and Walker.

To the *Proceedings* of the Boston Society of Natural History (vol. xxxii., No. 3) Miss Emerson contributes an account of the anatomy of *Typhlomolge rathbuni*, the blind salamander first made known by specimens thrown up by an artesian well in Texas in 1894. Despite its external resemblance to the olm (Proteus) of the Carniola caves, the author is of opinion that the creature is a member of the family Salamandridæ, and most nearly related to the American Spelerpes.

THREE American publications on fishes have reached us this week. In the first Messrs. Jordan and Starks (*Proceedings* U.S. Nat. Mus., No. 1391) describe a collection from Corea, containing several new generic and specific types, while in the second (*loc. cit.*, No. 1394) Mr. T. Gill discusses the generic characters of Synanccia and its allies. Of more general interest is the much larger memoir by Dr. S. E. Meek on the fresh-water fishes of Mexico north of the Isthmus of Tehuantepec, issued in the zoological series of the publications of the Field Columbian Museum (vol. v.). In this memoir, which is very fully illustrated, the author discusses the physiography of Mexico in connection with its fish fauna in considerable detail.

IN July, 1902, Dr. Merkel, of Wiesloch, was fortunate enough to discover in an overflow of the Leimbach a large number of the generally rare phyllopod crustacean *Limnadia lenticularis*. The specimens then collected form the basis of a paper on the anatomy of this species by Mr. M. Nowikoff, which appears, with numerous illustrations, in vol. lxxviii., part iv., of the *Zeitschrift fur wissenschaftliche Zoologie*. In the same issue Mr. L. Cohn describes the subocular tentacle of the remarkable frog *Dactylethra calcarata*, the function of which, in the absence of living specimens, cannot yet be definitely determined. The third article in this part forms the completion of the account by Mr. F. Voss of the anatomy of the thorax of the house-cricket, with special reference to the comparative anatomy and mechanism of the organs of flight in insects generally.

IN the second part of an essay on the structure and relationships of the opisthocœlian, or sauropod, dinosaurs, issued in the geological series of the Field Columbian Museum publications (vol. ii., No. 6), Mr. E. S. Riggs dissents from the view that these gigantic creatures were semi-aquatic, or at least marsh-haunting in their habits. Although the massiveness of their vertebræ recalls cetaceans, yet there is no trace in the latter group of the lightening of this part of the skeleton by means of hollowing and fluting which is so characteristic of these reptiles. More important evidence is afforded by the structure of the limbs, which appears to conform strictly to the terrestrial type. The species described in this paper, *Brachiosaurus altithorax*, is regarded as the type of a family characterised by the great relative length of the fore-limb, the humerus in this genus being as long as the femur.

From Dr. Florentino Ameghino we have received a copy of a paper published at Buenos Aires entitled "Nuevas Especies de Mamíferos, Cretáceos y Terçiarios, de la República Argentina," and purporting to be a reprint from vols. lvi.–lviii. of the *Anales* of the Scientific Society of Argentina. It contains a large number of new generic and specific names, which in the absence of illustrations can scarcely be regarded as of much scientific value; and it may be suggested that, despite their admitted richness, the Argentine extinct faunas can scarcely include such a number of forms as the author would have us believe. Moreover, we feel sure that naturalists will display great reluctance in admitting the occurrence of ancestral forms of Tragulus and Galeopithecus in the Argentine Tertiaries, while they will most certainly refuse to follow the author in regarding the latter genus as a member of the Typotherium group of ungulates.

We have been favoured with a copy of the *Schriften* of the Philosophical Society of Danzig for 1904 (new series, vol. xi., parts i. and ii.). To the naturalist the most interesting of its contents is perhaps the long article by Dr. W. Wolterstoff, director of the Magdeburg Museum, assisted by several specialists, on the fauna of the districts of Tuchel and Schwetz, in west Prussia ("Beiträge zur Fauna der Tucheler Heide"). A systematic zoological survey of this well-wooded area appears to have been undertaken in 1900, and the general results of this are summarised in the introductory chapter. Specialists are responsible for the determination of the specimens collected, Captain Barrett-Hamilton having undertaken this duty in the case of the mammals, represented only by three mice and one vole. The amphibians receive special attention, a coloured plate indicating the distinctive features of *Rana esculenta* and *R. arvalis*.

The nuclear divisions in the embryo sac of *Fritillaria imperialis* have been studied by Dr. B. Sijpkens, who has published his results in the *Recueil des Travaux botaniques neerlandaises*, No. 2.

The scope of plant morphology, and the nature of the fundamental problems in this subject which await investigation at the present day, could have no better exponent than Prof. Goebel, who has expressed his views in the *Biologisches Centralblatt* (February). Distinction is drawn between structural morphology, originally based upon systematic study, but later concerned with comparison and phylogeny, and causal morphology, which, inquiring into circumstances and conditions, can only be determined by experiment. The question whether a sporophyll is a modified leaf, or a vegetative leaf a sterilised sporophyte, is not without interest to botanists, but whether it is possible to control development and produce at will a vegetative life or a sporophyll is a problem of much greater significance.

Amongst American horticulturists engaged in plant breeding with the object of improving certain definite characters of flowers and fruit, Mr. L. Burbank, of California, holds a high position. The improvement of plums by hybridisation and selection is a subject which has received much attention, and by crossing the Japan plum with American species he has produced such fine varieties as the Golden, Climax, and the Wickson. More remarkable are the raspberry-blackberry hybrids, of which the Primus, a cross between the western dewberry and the Siberian raspberry, ripens its fruit several weeks before either of its parents, and is superior in productiveness and size of fruit. The first part of an appreciative article by Mr. W. S. Harwood appears in the *Century Magazine* for March.

We have received a copy of the observations made at the Hong Kong Observatory in the year 1903. In addition to the usual tables for the year in question, the report contains a valuable summary of hourly and monthly results of the various elements for the ten-yearly period 1894–1903. During this period the maximum shade temperature recorded was 77°, in August, and the minimum 37°·5, in January, and the highest solar radiation was 160°·1, in September. The greatest daily rainfall was 10·19 inches, and the maximum hourly fall was 2·86 inches. A comparison of the daily weather forecasts with the weather subsequently experienced gave a total and partial success of 92 per cent. The extraction of observations from the logs of ships for the construction of trustworthy pilot charts has been continued; the number of days' observations collected during the year was 9428. This useful work is undertaken by Miss Doberck.

The rainfall of the six months September, 1904, to February, 1905, is summarised in *Symons's Meteorological Magazine* for March, and forms an interesting supplement to the account we published last week from the official reports of the Meteorological Office. The results obtained from fifty-five representative stations are tabulated, and referred to the average rainfall of the thirty years 1870–1899, and although, as Dr. Mill points out, the circumstance is not unprecedented, it very rarely happens that the general rainfall of the country remains below the average for each of six consecutive months. The great advantage of graphical representation in dealing with such data is clearly shown by the map which accompanies the discussion; from that it is seen at a glance that while the rainfall for the six months reached, and even slightly exceeded, the average over a narrow strip in the west of Scotland, and amounted to 75 per cent. in the north of that country, in the north-west of Ireland, in the English Lake district, and a small part of the Welsh coast, all the rest of the British Isles had less than three-quarters of the usual fall. In two large areas it fell short of 50 per cent. of the average, viz. in the south-east of Scotland and in the midland counties of England. Taking each country separately, the rainfall of the six months was:—for England and Wales 60 per cent., Scotland 78 per cent., and Ireland 75 per cent. of the average for the thirty years referred to. The necessity of economising the water supply had already made itself felt in several large towns within the dry area before the end of February.

Prof. G. Torelli, of Palermo, contributes to the Naples *Rendiconto* (physical and mathematical section), x., 12, some new formulæ for calculating the totality of prime numbers below a given limit. The formulæ are non-asymptotical, and they are applicable to an arithmetical progression as well as to natural numbers.

In the *Annals of Mathematics* for January, recently received, Prof. G. A. Bliss discusses the proofs of the existence of solutions of the differential equation of the first order in terms of initial values, and Prof. L. Wayland Dowling discusses the conformal representation of triangles, with special reference to cases in which the solution can be represented by hyperelliptic integrals of given deficiency.

In a contribution to the Berlin *Sitzungsberichte* (1904, lii.), read December 8, Prof. Leo Koenigsberger discusses the extension of the principle of energy to a system having a kinetic potential of any order, and any number of variables dependent and independent. The paper forms a continuation of Prof. Koenigsberger's researches on the dynamics of systems in which *time*, instead of being one dimensional, may be of two or more dimensions.

Prof. Garbasso has published a short note (Genoa, Angelo Ciminago, 1904) in which he proposes a new theory to account for the duplication of lines in the spectra of variable stars. According to this theory, it is assumed that the phenomena are due to the presence of an element the atoms of which are formed of two separate conductors, and that these atoms are mostly in a state of dissociation. The paper consists of a mathematical investigation of the periods of a system of electric oscillators forming a model of the supposed atoms.

In 1890 a paper was presented to the Lincei Academy by Prof. Filippo Keller entitled "An itinerary guide to the principal magnetic rocks of Latium," of which only an abstract was printed. Since Prof. Keller's death in 1903 the complete paper has been brought out by Dr. G. Folgheraiter as No. 11 of his series of *Frammenti* dealing with the geophysics of the environs of Rome. It is accompanied by a map of the district and a portrait and biographical notice of Keller, the latter by Prof. S. Günther. It is printed by Panetto and Petrelli, of Spoleto.

The *Revue générale des Sciences* for February 28 contains a reprint of the paper read at Breslau by Dr. A. Kohler (Jena) on photomicrography by ultra-violet-light. It is illustrated by figures showing the arrangement of the microscope and camera, and the illuminating apparatus. It is pointed out that, independently of the increase of resolving power, ultra-violet light often affords a method of differentiating between organic tissues in virtue of their different degrees of transparency to the rays, and, further, it in some cases can be used to excite interesting phenomena of fluorescence in microscopic objects.

The *Atti dei Lincei*, xiv. (1) 3, contains a short account of some experiments by Mr. Alessandro Artom on wireless telegraphy with the use of circular or elliptically polarised waves. The experiments were divided into four groups, and in every case established the predicted property that it would be possible to send methods in definite directions by the use of these waves. Thus, in the last series of experiments, signals were sent from Monte Mario (Rome) to the island of Maddalena without any effects being noticed at the island of Ponza, which is situated some way off the line joining the first two stations. Further, it appears that with the use of circular waves the height of the aërial conductors can be reduced.

The ninth supplement to the present series of *Communications* from the Physical Laboratory of the University of Leyden contains an address delivered in commemoration of the 329th anniversary of the University of Leyden by Dr. H. Kamerlingh Onnes, Rector Magnificus of the university. It deals with the importance of accurate measurements at very low temperatures, a need which, it is pointed out, was first appreciated by Boyle. An important application of such observations has arisen in connection with van der Waals's theory of corresponding states, and Dr. Onnes points out that further researches at low temperatures are required for the problems of the mechanism of the atom that have been forced upon us by recent discoveries. Dr. Onnes emphasises the very important work done by Dewar in rendering such low temperature observations possible.

"Mathematical Progress in America" forms the subject of Prof. Thomas B. Fiske's address to the American Mathematical Society published in the *Bulletin* of the society for February. Prof. Fiske divides the history of pure mathematics in America into three periods, the first extending up to the foundation of the Johns Hopkins University in 1876, the second extending from 1876 to 1891, when the New York Mathematical Society was converted into the present American Mathematical Society and began to issue the *Bulletin*, and the third covering recent times. The *Bulletin* contains, further, the continuation of the report on last summer's congress at Heidelberg by Dr. E. B. Wilson, and a report of the meeting of the Deutsche Mathematiker Vereinigung by Mr. R. E. Wilson. The *Bulletin* thus furnishes a summary of mathematical progress of a cosmopolitan character such as does not exist in this country.

Of the increasing attention which is being devoted on the Continent to the history of the sciences, and in particular to that of mathematics, abundant proof is afforded by vol. xii. of the *Atti* of the International Congress of Historical Sciences, which met in Rome in April, 1903. This volume is devoted entirely to the proceedings of the section which dealt with the history of mathematical, physical, natural, and medical sciences, and it occupies 330 pages. It includes general discussions by Prof. Elia Millosevich on the iconography of solar eclipses, by M. Paul Tannery dealing with proposals for advancing the history of science, some remarks by Messrs. D. Barduzzi, P. Giacosa, and Gino Loria on the introduction of university courses on history of sciences, and proposals by Prof. Gino Loria for the publication of Torricelli's works, and by Prof. Pietro Giacosa for a catalogue of the scientific manuscripts in Italian libraries and archives. Among the papers read, the two mathematicians associated with the solution of the cubic, Tartaglia and Cardan, receive mention at the hands of Mr. Tonni-Bazza and Prof. Moritz Cantor; Prof. M. Darvai deals with the life of Bolyai; Prof. A. von Braunmühl contributes an interesting paper on the history of the integral calculus; Prof. R. Amalgià writes on early theories of the tides; Prof. Icilio Guareschi on the alleged plagiarisms of Lavoisier. Altogether the volume contains no less than thirty-four papers.

Attention has already been directed to the important series of papers on applied mathematics now being issued by Prof. Karl Pearson, F.R.S., under the title "Drapers' Company Research Memoirs." Two further numbers have now reached us. One of them is the fourteenth of Prof. Pearson's mathematical contributions to the theory of evolution, and deals with skew correlation and non-linear regression. The highly specialised character of the work may be inferred by quoting one of four conclusions on p. 53:—"The correlation between auricular height of head and age in girls is cubical, of nomic heteroscedasticity and of anomic heteroclisy. It is probably really a case of isocurtosis." The other paper is by Mr. L. W. Atcherley and Prof. Pearson, and deals with the graphics of metal arches. In it the authors point out the impossibility of applying purely graphical constructions with any degree of accuracy to the very flat metal arches used in modern bridges, and they propose a kind of "semi-graphical" method, depending partly on analysis and partly on graphics. Some interesting conclusions are drawn as to the relative merits of doubly pivoted, three pivoted, and doubly built in arches. These memoirs are rendered more accessible by being issued with their pages cut. They show what a lot of good work may be done by the expenditure by a public body of a very moderate sum on the endowment of mathematical research. We have another example of the same fact in the Cambridge Smith's prizes and the large number of former winners of these prizes who are now Fellows of the Royal Society.

THE widely extended use of the freezing point and boiling point methods of molecular weight determination has been to a large extent rendered possible by the manufacture of sensitive thermometers of the now familiar Beckmann type. In the current number of the *Zeitschrift für physikalische Chemie* is a very interesting paper by Mr. Ernst Beckmann giving a complete history of the differential mercury thermometer, with especial reference to the modifications it has undergone since its first use in freezing point work. He mentions the fact that the original Beckmann thermometer was due to an accident. A costly instrument, divided into 1/100ths of a degree, was being carried in the hand down a corridor when it was broken in half by the sudden opening of a door. In order still to be able to use the thermometer, a small bulb was blown on above the capillary, and from this the present type was evolved through a series of instruments illustrated in the present paper. Some of the thermometers figured are masterpieces of glass-blowing, notably one combining a Beckmann and ordinary thermometer on one instrument.

MESSRS. JOHN WHELDON AND CO. have sent us their latest catalogue of scientific books they have for sale. The catalogue includes many scarce sets of *Journals* and *Transactions*, as well as selections from the libraries of the late Prof. Everett, Dr. C. W. Siemens, and others.

THE most recent addition to the report being issued by the Engineering Standards Committee is the "British Standard Specification and Sections of Flat-bottomed Railway Rails." Copies of the publication may be obtained from Messrs. Crosby Lockwood and Son. The price is 10s. 6d. net.

WE have received from Mr. Nasarvanji J. Readymoney, of Bombay, a copy of a publication he has prepared entitled "An Outline of Descriptive, Defining Nature-History Tables, Illustrated; or Nature-History Research Thinking Tables; or Work of Genesis Minutely Tabulated." The object of the tables is to enable the student to summarise and classify "all events in nature or creation" in a philosophical manner.

THE February number of the *Journal* of the Straits Branch of the Royal Asiatic Society has reached us from Singapore. Among other important papers we notice contributions by Dr. Charles Hose on various methods of computing the time for planting among the races of Borneo, by Mr. P. Cameron on descriptions of new species of Iphiaulax and Chaolta (Braconidæ) from Sarawak, Borneo, and by Mr. H. W. Firmstone on Chinese names of streets and places in Singapore and the Malay Peninsula.

A NEW and revised edition of the volume of Prof. W. Schlich's "Manual of Forestry" dealing with forest management has been published by Messrs. Bradbury, Agnew and Co., Ltd. The mathematical problems have been simplified, and some of the calculations have been shortened. The appendices have been considerably altered. In the preface to the new edition Prof. Schlich directs attention to the fact that the most urgent need of British forestry is the collection of statistics, which will enable the proprietor and his forester to gauge the economic value of forest operations. He insists that the fully equipped forester must have a good knowledge of mathematics if he is to secure the best results.

A NEW encyclopædia, prepared and printed by Messrs. T. Nelson and Sons, is to be published in forty fortnightly parts under the title of the "Harmsworth Encyclopædia." Three of these parts, each of 160 pages, have been received, and judging from these we do not hesitate to say that the complete work should be a useful aid to students and a responsive friend to general readers. So far as we have tested the parts received, we have found the information accurate and confined to essential points. Of course, it must be understood that within the limited space allotted to any subject only bare outlines can be described; but as references are in many cases given to authoritative works, inquiring readers may be led to pursue their search for information, inspired by what they find in this encyclopædia. The work is liberally illustrated, and as a convenient guide to information which men and women often seek to know it will be of service.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN APRIL:—

April 4. 2h. Mercury at greatest elongation (19° 11′ E.).
5. 23h. Mercury in conjunction with the Moon. (Mercury 7° 28′ N.).
6. 6h. Jupiter in conjunction with Moon. (Jupiter 3° 35′ N.).
9. 11h. 4m. Minimum of Algol (β Persei).
12. 7h. 53m. Minimum of Algol (β Persei)
15. Venus. Illuminated portion of disc = 0·049; of Mars = 0·975.
17. 8h. 18m. to 9h. 12m. Moon occults η Virginis (mag. 4·c).
20–22. Epoch of Lyrid meteors (Radiant 271° + 33°).

DISCOVERY OF A NEW COMET, 1905 *a*.—A telegram from the Kiel Centralstelle announces the discovery of another new comet by M. Giacobini at Nice on March 26.

The position of the comet at 8h. 11·8m. (M.T. Nice) was R.A. = 5h. 44m. 14s., dec. = +10° 56′ 56″, and its daily movement in R.A. = +3m., in dec. −1° 15′.

This shows the object to be in the constellation Orion, about 6m. W. and 3° 34′ N. of Betelgeuse, or a little more than one-fourth the distance from Betelgeuse to ζ Geminorum, along a straight line joining the two. Apparently the comet passed very near to Betelgeuse on March 29.

COMET 1904 *c* (BORRELLY).—A continuation of the daily ephemeris for comet 1904 *c* is given by Dr. E. Strömgren in No. 4004 of the *Astronomische Nachrichten*.

The ephemeris extends from March 29 to May 4, and from it we see that on the first named date the comet will apparently be situated very near to ζ Aurigæ, and will have a brightness of 0·24. Travelling thence in an E.N.E. direction it will enter the constellation Lynx, its computed position on May 4 being R.A. = 7h. om., dec. = +45° 17′, whilst its brightness on that date will be 0·12. The brightness at time of discovery (about mag. 10) is taken as unity.

OBSERVATIONS OF THE RECENT ECLIPSE OF THE MOON.—In No. 9 (1905) of the *Comptes rendus* is published a paper by M. Puiseux wherein he discusses a series of twelve photographs taken between 7h. 32m. and 8h. 12m. on the occasion of the partial lunar eclipse which occurred on February 19.

Amongst other conclusions he states that the apparent changes in the aspects of the circles Messier and Messier A are simply due to differences of illumination and not to actual variations, and that, whilst the recent observations of these two circles and of Linné are not in accordance with the records obtained prior to 1866, there is no substantial evidence for recent changes in these features such as have been announced by several selenographers. M. Puiseux believes that many of the circles are undoubtedly of later origin than certain systems of divergent streaks seen on the lunar surface.

NEW VARIABLE STARS IN THE REGION ABOUT δ AQUILÆ.—In No. 4005 of the *Astronomische Nachrichten* Prof. Wolf publishes a list of thirty-six newly discovered variable stars in the region about δ Aquilæ. Their variability was detected by the comparison of two plates taken with the Bruce telescope on July 12, 1902, and July 6, 1904, respectively. The positions (1875·0) of the new variables are given in the catalogue, and, together with the positions of four others which are also probably variable, are shown on thirty-two circular charts accompanying the paper, each chart including a field twenty-one minutes of arc in diameter. In a second table the magnitudes of the stars on the two plates mentioned above are compared with the magnitudes as shown on a third plate taken on August 11, 1898.

ORBIT OF THE BINARY STAR CETI 82.—The orbit of the binary star Ceti 82 (designated 395 in Prof. Burnham's catalogue) is discussed by Prof. Aitken in *Bulletin* No. 71 of the Lick Observatory.

The Lick observations confirmed the rapid orbital motion, but have also indicated a very different orbit from that previously published by Prof. See (*Astronomische Nachrichten*, vol. cxliv., p. 359, 1897).

The elements obtained by Prof. Aitken show a period of 24·0 years, and give the G.M.T. of periastron passage (T) as 1899·7. The elliptical orbit is graphically presented, and shows the differences between the observed and computed places. The eccentricity of the ellipse is 0·15, and the apparent length of its semi-major axis 0″·06 of arc. Prof. Aitken also gives an ephemeris extending from 1905·7 to 1910·7.

RADIAL VELOCITIES OF CERTAIN STARS.—In No. 70 of the Lick Observatory *Bulletins* Prof. Campbell and Dr. H. D. Curtis discuss the radial velocities of Polaris, η Piscium, ε Aurigæ, and Rigel from the spectrograms obtained at Lick during the last eight years.

In the case of Polaris, the measurement of groups of plates taken during the last four years indicated that the velocity of the centre of mass of the rapid pair in this triple system is changing very regularly with a period of at least eleven or twelve years, but the period may be found to be much longer when further observations are completed.

The radial velocity of η Piscium was suspected by Prof. Lord to be variable with a long period, but as no spectrograms of this star were secured at Lick during the period covered by him, the Lick observations do not settle the question, although the values obtained only range from +16·6 to 13·3 km. per second, whilst Prof. Lord's range was from +9·5 to 25·4 km.

The spectrograms obtained of ε Aurigæ fully confirm Prof. Vogel's conclusion that this star is a spectroscopic binary with a period of several years.

Prof. Vogel's view that Rigel has a variable radial velocity is not confirmed by the Lick observers, who rather favour the conclusion arrived at by Profs. Frost and Adams that the apparent variation is only a function of the difficulty experienced in measuring the wide lines.

STAR PLACES IN THE VULPECULA CLUSTER.—In No. 4004 of the *Astronomische Nachrichten* Dr. H. Meyer gives a catalogue of the positions of thirty-five stars in the Vulpecula cluster. The catalogue contains the B.D. number, the magnitude, and the positions, the latter referred to the equinox of 1900·0 for the epoch of observation 1901·6. The precession and the secular variation in each coordinate are also given for each star, and in the case of fourteen of the brighter ones the proper motion, as determined from the discussion of previous catalogues, is likewise given.

THE U.S. COAST AND GEODETIC SURVEY.

THE report of the Coast and Geodetic Survey for 1904 is a record of manifold labours and results which have for their theatre of action an area practically coterminous with that of the United States and all its island possessions. The main body of the report contains a detailed account of the wide range of duties devolving upon this bureau, and in the appendices we have a presentation of discussions and results which must prove of great economic value and interest to surveyors, engineers, navigators, and physicists.

The re-surveys and developments imperatively required to show the changes in harbours and approaches due to works of improvement or the ceaseless action of natural causes along the Atlantic, Pacific, and Gulf coasts of the United States, and to meet the ever-increasing demands of commerce and the Navy for up-to-date charts, particularly of the waters of Alaska, Porto Rico, Hawaii, and the Philippines, gave constant employment to the eleven vessels available for these duties.

In Alaska the work included the continuation of the survey of Prince William Sound, the survey of Controller Bay, and a deep-sea examination from the Strait of Juan de Fuca to Prince William Sound, preliminary to the laying of a deep-sea cable from Seattle to Valdez. The Porto Rico work was continued in certain bays and harbours as well as in the development of the conditions in the off-shore waters. In the Philippine Archipelago the Survey has secured the cooperation of the Insular Government, and a detailed *résumé* shows a most satisfactory progress of the triangulation, hydrographic, topographic, magnetic, and astronomical operations.

The reconnaissance for the primary triangulation along the 98th meridian was completed to the Canadian border, and a scheme was extended eastward connecting this work with the triangulation of the Mississippi River Commission. The execution of the primary triangulation in the Dakotas and Texas was prosecuted at a rate which surpassed even the notable record which had already secured an enviable reputation for the geodetic operations along the 98th meridian, the total extension amounting to 300 miles (500 kilometres). An equal distinction must be accredited to similar work in California and Oregon, whereon remarkable progress has been made in connecting the Transcontinental Arc work with Puget Sound.

The progress of the magnetic work is shown in detail in Appendix No. 3, which includes a table of results of the magnetic declinations, dip and intensity of force observed on land and sea during the year, this being supplemented with full descriptions of the magnetic stations occupied and meridian lines observed. (This report has been noticed separately, NATURE, March 9, p. 449.)

The determination of the longitude of Manila from San Francisco, thus completing the first longitude circuit of the earth, was one of the astronomical events of the year, and in Appendix No. 4 is a comprehensive illustrated report on the various instruments and operations used in the undertaking, with a comparative *résumé* of the various links and results from which the longitude of Manila had been determined from the westward. The generous cooperation of the Commercial Cable Company, through the patriotic enterprise of which the work was made feasible, is gratefully acknowledged. The results of the determinations from the eastward and westward differ only by 0·006s., or about 8·8 feet. The other results of this expedition are the determinations by the telegraph method of the longitudes of Honolulu and Midway and Guam Islands.

The third attempt at representing the tide for the world at large, the first having been made by Whewell and Airy and the second by Berghaus, is described in Appendix No. 5. The advancement in recent years of the general use of the harmonic analysis, and the greatly improved tidal data that are now obtainable for such a great part of the globe, coordinate to make a new presentation of this subject very opportune. The theoretical discussion of the problems involved, the wide range of data and authorities consulted and referred to, the graphic presentation of the cotidal lines, the results presented, and the conclusions deduced, make a most suggestive paper, and one which will be highly interesting to all students of the subject.

The results of the precise levelling operations for the year are published in Appendices Nos. 6 and 7, which submit them in a detail that makes them immediately available for the requirements of surveyors and engineers. These extend the precise level net, as previously published, six hundred miles to the westward, from Red Desert, Wyoming, to Owyhee, in eastern Idaho, and from Holland, Texas, two hundred miles south-west, to Seguin, Texas. An interesting feature is an account of the change in the manner of support for the levelling rods, with the comparative discussion of the old and the new methods, and the consequent confirmation of the importance of the new system.

The account of operations submitted by the assistant in charge gives the story of the work of the various computing, drawing, engraving, and chart divisions of the office in which the results of the field work are discussed or prepared for the publications and charts wherein they are placed at the service of the public.

A full account of the first recording transit micrometer devised for use in the telegraphic longitude determinations of the Coast and Geodetic Survey is submitted in Appendix No. 8, with an account of the exhaustive tests it was subjected to, and a recapitulation of the results of experience with this form of instrument, mainly in Europe, during the last thirteen years. The results of these experiments indicate that with the transit micrometer the accuracy of telegraphic longitudes may be considerably increased if desirable, or the present standard of accuracy may be maintained at much less cost than formerly.

The results of all triangulation in California south of the latitude of Menterey Bay are printed in the concluding appendix in full, including descriptions of stations as well as their latitudes and longitudes and the lengths and azimuths of the lines joining them. In compact and convenient form there is given all the information in regard to this triangulation that is needed by an engineer or surveyor who wishes to utilise the results in controlling and checking surveys or in constructing maps or charts. The locations of more than 1300 points are accurately fixed by this triangulation.

The report, in addition to the details of the foregoing operations and results, contains a record of a wide range of important work for which the aid of the Survey was sought because of the special training of its officers.

PROTECTIVE RESEMBLANCE.

AN interesting paper on "Protective Resemblance in the Insecta," by Mr. Mark L. Sykes, is published in the *Proceedings* of the Manchester Field Club (vol. i., part ii). After briefly describing the law of natural selection, as propounded by Darwin, the evolution of new species through variations, and the elimination of the least fit during long periods of time, reference is made to the colours of insects, to the advantage of conspicuous adornment, and the consequent easy identification of those of them which possess some feature repellent to the insect-eating animals. The absence in young animals of an intuitive faculty of discrimination between edible and inedible material in the selection of food is emphasised, and reference is made to authors who have experimented on the subject.

Müller's theory of mutual protection, through similarity of colours and patterns, amongst inedible Lepidoptera, and Bates's explanation of the "mimicry" or simulation of distasteful species by edible species, are described, and the superficial resemblances between entirely different species and genera are attributed to the influence of natural selection and elimination, and the transmission and accumulation of variations. The method by which many of these likenesses are produced is shown by a number of camera lucida drawings of the wing scales of many of the butterflies and moths referred to and illustrated in the article; and the scale variations, in colour, size, pattern and arrangement, which produce a common resemblance in the insects, are described. Another branch of the subject, treated in some detail, is protective resemblance of environment, as seen in the striking similarity of many insects, especially amongst the Lepidoptera and Orthoptera, to leaves, twigs, moss, &c.; and a number of illustrations are given of resemblance to natural surroundings, three of which we select as examples.

FIG. 1.—*Embusa gongylodes* (Ceylon) at rest on twi

Among the many curious and interesting insects which are found in Ceylon, *Empusa gongylodes* is one of the most singular. It is a brown insect. The thorax is like a long

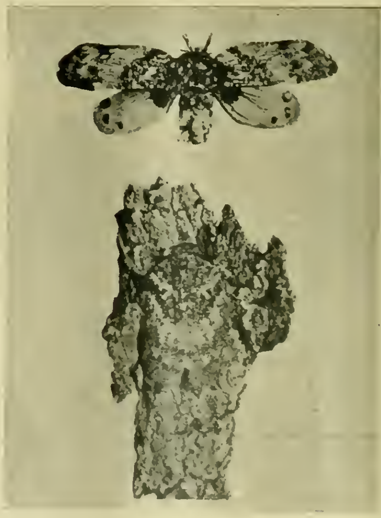

FIG. 2.—*Eurybrachis Westwoodii* (Ceylon) with the wings expanded, and at rest upon a piece of bark.

thin twig, with a wide leaf-like expansion immediately behind the head. The wings are broad, veined and crumpled, like dried leaves, and the long legs, which are spread out in any direction as the animal is at rest, harmonise so closely with the twigs to which they cling that it is difficult to see where one begins and the other ends. Fig. 1 illustrates this insect in the attitude in which it was resting before being captured.

Another interesting insect from Ceylon is one of the moths, *Eurybrachis westwoodii*. The fore wings of this insect are marked in a mottled pattern of green, grey and brown, the hind wings being white, with deep claret-coloured marks near their base, and when it is on the wing the moth is an attractive-looking creature. But its appearance alters when it is at rest, with the mottled wings folded over the back. In Fig. 2 it is shown with the wings expanded as it appears when flying, and below is a piece of bark with the same insect resting upon it, where it was discovered by the keen sight of the collector—a clever capture, as will be admitted when it is noticed how excellently the wings and bark harmonise, and how they seem almost to merge one into the other.

There is found in Madagascar a small beetle which, looked at apart from its natural surroundings, has nothing specially interesting about it except that it is a conspicuous, rugged-looking, pure white and black insect, about three-quarters of an inch long. It feeds upon a species of fungus, which grows upon the bark of trees in mixed cream and black coloured patches. The beetle is shown at the

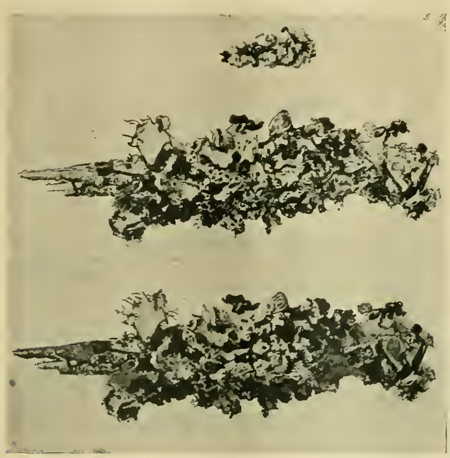

FIG. 3.—*Lithinus nigrocristatus* (Madagascar). The upper figures show beetle and bark separately, and in the lower figure *the beetle is on the bark*.

top of Fig. 3, and beneath it a piece of twig with the fungus growing upon it. At the bottom of the same illustration the same piece of fungus-covered twig is shown, but here the beetle is resting right in the middle of the fungus, effectually concealed amongst the vegetation upon which it feeds.

The paper is very fully illustrated by more than two hundred figures of the insects described, with the localities in which they were taken, covering the whole subject treated by Mr. Sykes.

Exception is taken to the use of the words "imago" and "imagine," introduced by Linnæus, as representing the final stage of insect metamorphosis, and "matura" (maturo = to ripen) is suggested and employed as a substitute, conforming conveniently with the accepted terms for the earlier stages—larva and pupa. The word "mimicry" is also adversely criticised, as implying conscious resemblance, which is not known to exist, and "simulism," "simulation," "simulating," are substituted "as being at once expressive, explanatory and euphonious, and free from the inference of designed and cognitive resemblance."

REPORT OF THE CARNEGIE INSTITUTION, 1904.[1]

IN NATURE for January 7, 1904, a list was given of the awards made by the Carnegie trustees for the prosecution of inquiries in various scientific directions. The third year book, just published by the board of trustees, contains reports upon most of these researches, but the time is far too short to gather in the full harvest, which may hereafter be expected, from so lavish and, presumably, judicious expenditure. There is abundant evidence that many well-known men, engaged in every department of science, have been enabled to attack problems which must otherwise have been neglected, or pursued with inadequate material and less energy. Beyond this general fact, the present volume does not, in most instances, enable us to estimate the results. The balance sheet attached shows that the trust is in a very flourishing condition, and that 267,000 dollars have been provided for inquiries, which the management discuss under the three heads of large, special, and minor grants.

Under the division of large grants, we have a description of the station erected, or adapted, for the study of experimental evolution at Cold Spring Harbour, some twelve miles from New York. Plans of the building are given, and a full account of the opening ceremony, at which Dr. Hugo de Vries gave a scientific address. The objects sought to be gained by such an institution are typical of the uses of the trust, and legitimately appeal to a liberal consideration. The investigations must be long continued, the results may be doubtful or negative, and it is a research which no individual or institution is likely to undertake on a scale sufficiently broad to produce decisive results.

Another far-reaching scheme, the Marine Biological Laboratory at Dry Tortugas, Florida, under the care of Dr. H. G. Mayer, is quite in its first stages of development, but one whose usefulness may be confidently predicted in due time. The buildings that have been erected consist of a main laboratory, 100 feet long, one story high, and with special arrangements for keeping the building cool in the hot weather of those latitudes. A feature in the construction of the laboratory and of the smaller buildings connected with it, is that all are made portable, so that they can easily be removed from their present site and erected elsewhere if thought desirable. Attached to the station is a sea-going vessel of light draft, fifty-seven feet over all, and sixteen feet beam, with a 20 h.p. naphtha engine. There is sufficient accommodation for seven men on board, and the vessel is specially designed to dredge in depths of 500 fathoms or less. Among other projects for which large grants have been made is the subject of economics, whose many subdivisions include, among others, population and immigration, mining and manufactures, banking and finance, social legislation and the labour movement, &c. Reports on all these subjects have been added, showing the scope of the respective inquiries and the progress that has been made. Historical research and terrestrial magnetism are the remaining two subjects which come under the division now being considered. On the latter subject we have some of the results of the discussion of the magnetic disturbance observed during the eruption of Mont Pelée, which are of special interest, since the inquiry discloses the fact that in certain respects the disturbance resembled those storms which are believed to be of cosmic origin.

The Transcaspian archæological expedition and geophysical research are the subjects of special grants. The former is under the charge of Prof. Pumpelly, who left America in December, 1903, and began excavations in the following March, first attacking Anau, in Turkestan. By means of excavations in tumuli and by shafts sunk in the city of Anau, the exploring party has traversed some 170 feet of the accumulations of successive generations of peoples, extending from recent times, through the iron and bronze civilisations, and some 45 feet deep into the stone age. Among the objects of this investigation is the hope of throwing some light on the source of our domestic animals.

The reports on the subjects of the so-called smaller grants cannot be particularly referred to here. The inquiries cover

[1] Carnegie Institution of Washington. Year Book, No. 3, 1904. (Washington: Published by the Institution, 1905.)

the whole ground of physical science, and are in many instances of the greatest importance, but generally have reference to definite researches undertaken by individuals not calling for wide cooperation. A list of papers, prepared possibly to pave the way for future applications, is added, in which are discussed the conditions of solar research at Mount Wilson, by Prof. Hale; the southern observatory project, by Prof. Boss; fundamental problems of geology, by T. C. Chamberlin; plans for obtaining subterranean temperatures, by G. K. Gilbert; magnetic survey of the Pacific Ocean, by L. A. Bauer; and geological research in Eastern Asia, by B. Willis.

THE RECEPTION AND UTILISATION OF ENERGY BY A GREEN LEAF.[1]

THE subject of my lecture is derived from the series of papers laid before the society to-day by my colleagues and myself, dealing with some of the physiological processes of green leaves. In giving an account of some of these investigations I shall dwell mainly on their relation to the *energetics* of the leaf, and shall endeavour to show how the leaf behaves under various conditions when regarded from the point of view of the exchange of energy between itself and its surroundings.

One of the problems which we attempted to solve was to draw up a "revenue and expenditure account" of energy for a green leaf, showing the proportion of the incident energy absorbed, the amount of this absorbed energy which is used up for the internal work of the leaf, and the proportion which is dissipated by re-radiation and the losses due to the convective and conductive properties of the surrounding air under varying wind-velocities.

Of these various factors, the one I have last mentioned, which presupposes a knowledge of the *thermal emissivity* of the leaf-surface, presented by far the greatest difficulty; but during the past year Dr. W. E. Wilson and I have been able to devise a suitable method for determining the thermal emissivity of a leaf-surface in absolute units, so that our story is now fairly complete.

The discussion of the thermal relations of a leaf to its surroundings will be simplified if we first consider the case of a leaf when it is shielded from solar radiation. We will assume that a detached leaf, freely supplied with water, is placed in an enclosure the walls of which are non-reflective and are maintained, along with the enclosed air, at a perfectly uniform temperature t. We will further assume that the air is saturated with water-vapour.

Under these conditions the system would remain in thermal equilibrium if it were not for the respiratory processes going on within the leaf-cells. These are exothermic in their final result, so that the state of complete thermal equilibrium can only be attained when the temperature of the leaf has risen to a point t', somewhat higher than t. The magnitude of the difference $t'-t$, representing the maximal thermometric disturbance between the leaf and its surroundings, will depend on three main factors:

(1) On the rate of evolution of the heat of respiration.

(2) On the rate at which this heat is dissipated by the thermal emissivity of the leaf-surface, and,

(3) On the magnitude of the slight rise of partial pressure of the water-vapour in the interspaces of the leaf, which gives rise to a certain amount of diffusion of water-vapour through the stomata.

The rate of evolution of the heat of respiration can be deduced with sufficient exactness from the amount of carbon dioxide liberated per unit area of the leaf-lamina in unit of time, since there is evidence that the carbon dioxide proceeds from the oxidation of a carbohydrate with a heat of combustion which cannot be far removed from 3760 calories per gram. Taking the concrete example of a leaf of the sunflower respiring at the rate of 0·70 c.c. of carbon dioxide per square decimetre per hour, it can be shown that the heat of respiration in this case amounts to about 0·00582 calorie per square centimetre of leaf-lamina per minute. From the known weight of a square centimetre of the leaf-lamina, and its specific heat, this spontaneous liberation of energy within the leaf might conceivably raise its temperature through $0°{\cdot}033$ C. per minute, provided there were no simultaneous losses due to radiation, conduction and convection of the surrounding air, and internal vaporisation of water. All these sources of loss, of course, become operative immediately the temperature of the leaf exceeds that of its surroundings. We shall see presently that the thermal emissivity of this leaf in still air is 0·015 calorie per square centimetre of leaf-surface per minute, for a difference of temperature of 1° C. between the leaf and its surroundings, so that the temperature of the leaf, under the conditions postulated, cannot exceed that of its surroundings by more than

$$0{\cdot}00582/2\times0{\cdot}015=0°{\cdot}019 \text{ C.}$$

But this is assuming that transpiration has been in abeyance, which is certainly not the case, so that this small temperature difference of $0°{\cdot}019$ C. will be still further reduced.

The main point which I wish to bring out here is that the thermometric disturbances due to the processes of respiration are very small, so small, in fact, that they may be neglected in considering the large disturbances induced by other causes.

Let us now suppose our leaf to be placed under the same conditions as before, but in air which is not fully saturated with aqueous vapour for the temperature t.

The conditions are manifestly unstable owing to the excess of the partial pressure of the water-vapour in the saturated air of the interspaces of the leaf over that of the vapour in the unsaturated air outside.

The diffusion-potential thus set up will result in water-vapour passing outwards through the stomata, and the temperature of the leaf will fall. This fall will continue until the gradient of temperature between the surroundings and the leaf is sufficiently steep to allow energy to flow into the leaf from without at a rate just sufficient to produce the work of vaporisation, at which point a steady thermal state will be established which will remain constant so long as other conditions are unaltered. The leaf will then have assumed a temperature t', which in this case will be *lower* than that of its surroundings.

Now it is manifest that when this steady thermal condition has been attained, the amount of water vaporised per unit of area of the leaf in unit of time must be a measure of the energy flowing into the leaf for the gradient of temperature represented by $t-t'$, and provided we determine the amount of water lost by the leaf, and the temperature difference between the leaf and its surroundings under the steady conditions, we have all the data necessary for finding the *coefficient of thermal emissivity* of the leaf-surface in absolute units, that is to say, the rate at which a leaf-surface will emit or absorb energy from its surroundings in still air for a difference of temperature of 1° C.

Following out this idea, Dr. Wilson and I have successfully determined the constants of thermal emissivity for leaves of different kinds, both under "still-air" conditions and in air-currents of determinate velocity. The results are interesting from several points of view, since amongst other things they enable us to estimate the rate at which the excess of solar radiant energy falling on a leaf is dissipated by mere contact with the air moving at any ordinary wind-velocity, and they also give us, under certain conditions, a means of deducing the actual rate of transpiration from mere observations of temperature-differences.

Before proceeding to show more in detail the manner in which the thermal emissivity of a leaf is determined, we will turn for a moment to the magnitude of the difference of temperature between a leaf and its surroundings which may be expected from a given rate of transpiration. We will assume that the leaf of a sunflower, transpiring into the unsaturated air of the enclosure, when the steady thermal condition is attained, is losing water at the rate of 0·5 gram per square decimetre per hour, or 0·0000833 gram per square centimetre per minute.

The heat required to vaporise this amount of water at 20° C. is $0{\cdot}0000833\times592{\cdot}6=0{\cdot}04938$ calorie, which, on the theory of exchanges, must represent the amount of energy entering and leaving a square centimetre of the leaf-lamina per minute. The thermal emissivity of this leaf

[1] The Bakerian lecture, delivered at the Royal Society, March 23, by Dr. Horace T. Brown, F.R.S.

is 0·015 calorie per square centimetre of leaf-*surface* per minute, for a temperature gradient of 1° C., so that the temperature difference $t-t'$ will be represented by

$$0{\cdot}04938/2\times 0{\cdot}015 = 1^{\circ}{\cdot}64 \text{ C.}$$

For the simultaneous determination of the temperature difference $t-t'$ and the amount of water transpired, we employed two differential platinum-resistance thermometers each consisting of about 2·4 metres of fine wire arranged in a mica and ebonite plate so as to form a flat grid, against the two sides of which two similar leaves were lightly pressed and held in position by ebonite frames furnished with cross-threads of silk. The two leaf-laminæ were thus in close apposition to the resistance-coils, which were favourably placed for rapidly acquiring the mean temperature of the leaves, which were supplied with water from two small tubes attached to the frames. A definite area of leaf-surface was exposed, amounting in each case to 139·4 square centimetres. The loss of the water of transpiration was determined by weighing the apparatus at suitable intervals.

The difference in temperature between the two coils was determined by means of a Callendar's recorder. Instead of determining the difference of temperature between the leaf and the surrounding air, it was found more convenient to clothe both coils with leaves, but to arrange them in such a manner as to produce differential transpiration between the two pairs, a result which can in most cases be brought about by arranging one pair of leaves with their dorsal sides turned to the platinum coils, and the other pair with their dorsal sides facing outwards. Owing to the comparatively rapid thermal adjustment which takes place, the results are not affected by the gradual closing of the leaf stomata during an experiment, provided the record is correctly integrated so as to give the mean difference of temperature. From this mean difference of temperature between the two pairs of leaves, and the differential transpiration corresponding to this, the thermal emissivity of the leaves is readily calculable.

As an example, we may take an experiment with the leaves of *Liriodendron tulipifera*, in which the experiment lasted 129 minutes. The difference in the amount of water transpired by the two pairs of leaves was 0·510 gram, and the mean temperature difference was 1°·41 C. Taking the latent heat of water at 593·6 calories, it follows that $0{\cdot}510\times 593{\cdot}6 = 302{\cdot}7$ represents in calories the excess of energy which must have entered the cooler pair of leaves from their surroundings, an excess which is conditioned solely by the temperature gradient of 1°·41 representing the difference of temperature between the two sets of leaves. The surface area of the leaves exposed was 139·4 square centimetres, so that the *thermal emissivity* of a square centimetre of leaf-surface per minute for a 1° C. temperature gradient will be

$$302{\cdot}7/129\times 139{\cdot}4\times 1{\cdot}41 = 0{\cdot}01194 \text{ calorie.}$$

As examples of the extent to which the thermal emissivities of leaves of various plants differ, the following may be given. They represent the emissivity under conditions of still air:—

Thermal Emissivity of Leaves of Various Species of Plants, under Still-air Conditions.

Species of Plant	Therma emissivity in calories per sq. cm. of leaf-surface for a 1° C. excess of temperature	
	Per minute	Per second
Liriodendron tulipifera (*a*)	0·0119	0·000199
„ „ (*b*)	0·0127	0·000212
Helianthus multiflorus	0·0150	0·000249
Tropoeolum majus	0·0142	0·000237
Tilia europoea	0·0159	0·000266

Under ordinary outdoor conditions we never have to deal with perfectly still air, and the inquiry had therefore to be extended to the influence of *moving* air currents on the thermal emissivity of leaves.

This was investigated by observing the differential temperature and differential transpiration when the two pairs of leaves were placed in a shaft through which a current of air was passed having a definite and steady velocity. The results of two such experiments with leaves of *Liriodendron tulipifera* and *Helianthus multiflorus* are given in the figure. It will be seen that the effect of the cooling or heating due to the air is a linear function of the velocity, the coefficient of thermal emissivity of the leaf-surface increasing at the rate of 0·017 calorie per square centimetre per minute for an increased velocity of the air current of 100 metres per minute. This effect of moving air in dissipating the excess of radiant energy falling on a leaf is a very important fact in the economy of some plants in which transpiration is reduced to a minimum, and it is one of nature's means for preventing the rise of temperature in strongly insolated plants from reaching a dangerous point.

We must now turn our attention to the thermal relations of a leaf to its surroundings when it is receiving direct solar radiation, and here again, for the purpose of simplifying my argument, I must ask you to imagine an ideal set of conditions under which a healthy leaf, well supplied with water, is exposed to sunlight of constant intensity, and that there is no variation in the temperature, humidity, or degree of movement of the surrounding air, or in the dimensions of the leaf stomata.

As in the previous case, a state of thermal equilibrium will be speedily established between the leaf and its environment, when the simultaneous loss and gain of energy will just balance.

When this condition is attained, let R represent the total radiation falling on 1 square centimetre of the leaf

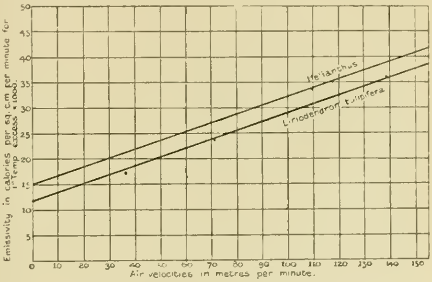

FIG. 1.—Influence of moving air on the thermal emissivity of leaves.

in one minute, and, further, let the "coefficient of absorption" of the leaf for this radiation be represented by a; then Ra will represent the radiant energy absorbed per square centimetre of leaf-lamina per minute.

At this stage it is of some interest to give absolute values to R and a in order to see what would be the thermometric effect produced on a leaf by ordinary sunshine in default of there being some ready means of dissipating the absorbed energy.

If we denote the mass of a square centimetre of the leaf-lamina by m, and its specific heat by s, then on the above assumption the rise of temperature of the lamina per minute will be represented by Ra ms.

Let R=0·8 calorie per square centimetre per minute, which represents the intensity of ordinary summer sunshine in these latitudes.

Let a, the coefficient of absorption, be 0·78, a value which is determinable by a method presently to be described; further, let the mass, m, of a square centimetre of leaf be 0·020 gram, and its specific heat $s = 0{\cdot}879$, then the rise of temperature of the leaf under the conditions postulated will be at the rate of

$$0{\cdot}8\times 0{\cdot}78/0{\cdot}02\times 0{\cdot}879 = 35^{\circ}{\cdot}4 \text{ C. per minute,}$$

a result which would be speedily fatal to the leaf.

The dissipation of the absorbed energy necessary to keep the temperature of the leaf within working limits is provided for, on the one hand, by the internal work of the leaf, consisting mainly of the vaporisation of water, and to a less extent of the endothermic process of photosynthesis, and on the other hand by the losses due to thermal emissivity, which even in still air are considerable, and may assume large dimensions if the air is in movement.

First, as regards the energy used in internal work, that portion which produces the vaporisation of water, and which I will denote by W, is determinable from the weight of water lost by a given area of the leaf in a given time, and from the known latent heat of water-vapour. On the other hand, the amount of the absorbed energy which is used up in the photosynthetic process, and which I will denote by w, is deducible from the actual amount of carbon dioxide which enters the leaf, on the legitimate assumption that the synthesised product is a carbohydrate, the heat of formation of which is approximately known.

The generalised form of the thermal equation of a leaf which is receiving solar radiation, and has acquired a state of thermal equilibrium, may therefore be represented by $Ra = (W + w) \mp r$.

When Ra is greater than $W + w$, that is to say, when the energy absorbed by the leaf in a given time is more than sufficient to perform the whole of the internal work, r is a positive quantity, and represents in absolute units the sum of the losses due to radiation and convective cooling, and it is the only portion of R which can produce a rise of temperature in the leaf.

Provided we know the thermal emissivity of the particular leaf which we are using, the actual rise of temperature of the leaf-lamina above its surroundings can be determined from r; for if e is taken to represent the emissivity, then the temperature difference between the leaf and its environment, that is to say, $t' - t$, will be $r/2e$.

On the other hand, when Ra is less than $W + w$, that is to say, when the absorbed radiant energy is insufficient to perform the whole of the internal work, r is a negative quantity, and the excess amount of energy requisite to perform the internal work must be drawn from the surroundings of the leaf; in other words, when thermal equilibrium is established the temperature of the leaf under these conditions must be *below* that of its surroundings. Here again, however, the thermometric difference expressed by $t - t'$ will be $r/2e$.

The true measure of the photosynthetic work effected by suitable radiation is, strictly speaking, not given exactly by the amount of atmospheric carbon dioxide absorbed by the leaf, but by this amount *plus* the small amount of carbon dioxide which would have been evolved by respiration if photosynthesis had been in abeyance. This is a correction which has to be taken into account in certain special cases, but it does not affect the generalised thermal equation I have given, since the heat of respiration is opposite in sign to that of the heat of re-formation of the carbohydrate, and these values, representing a concurrent gain and loss of energy by the leaf, must exactly balance each other if the carbohydrates standing at the two ends of the reversed process are identical, and if they are not identical the difference in their thermal relations must be so small as to be inappreciable.

Before proceeding to show how these general views can be applied to the construction of a revenue and expenditure account of energy for a leaf, I must briefly refer to the mode in which the various factors have been determined. We have already considered the manner in which the thermal emissivity of the leaf e is determined, a value which is all-important in considering the temperature of the leaf, and I have also sufficiently indicated how we can determine the work of transpiration, and consequently the value of W.

R, the intensity of the solar radiation falling on the leaf-surface, was measured by means of a specially constructed Callendar's radiometer, the coils of which were enclosed in a flat rectangular case mounted on an adjustable stand so that the orientation of the receiving surfaces could be made to correspond with that of the leaf under experiment. The radiometer was connected with a Callendar's recorder furnished with a planimeter which automatically integrated the curve recorded on the drum.

The constants for the instrument were determined for us by Prof. Callendar, and the planimeter readings were readily convertible into water-gram-units of energy incident on unit area of surface in unit of time, thus giving a mean value of R.

The proportions of the radiant energy of sunlight respectively absorbed and transmitted by the leaf-lamina were determined with the same instrument by observing in steady sunlight the amount of radiation which reaches the radiometer with and without the interposition of the leaf. This gives a measure of the coefficient of absorption of the leaf a with a close approach to accuracy, if we neglect the amount of reflected radiation, which is very small in cases of perpendicular incidence.

The coefficient of absorption, as might be expected, varies considerably with leaves of different species of plants, as shown in the following table, and there are also small individual differences in leaves of the same plant.

Coefficients of Absorption (a) and Transmission (1 − a) of the Radiant Energy of Sunlight for Leaves.

Plant	Coefficient of absorption (a)	Coefficient of transmission ($1 - a$)
Helianthus annuus	0·686	0·314
Polygonum Weyrichii	0·647	0·353
Polygonum Sachalinense	0·691	0·309
Petasites officinalis	0·728	0·272
Silphium terebrinthaceum	0·699	0·391
Arctium majus	0·728	0·272
Verbascum olympicum	0·758	0·242
Senecio grandifolius	0·774	0·226

In the generalised thermal equation the value w, representing the amount of energy expended in photosynthesis, measures the effective internal work of a useful and constructive kind, for the due performance of which the leaf may be said to exist, and the relation which this bears to the total energy flowing into the leaf gives an estimate of the true *economic coefficient* when the leaf is regarded as a thermodynamic engine.

In the five or six years during which these researches occupied Mr. Escombe and myself at the Jodrell Laboratory, a large share of our attention was given to determining the best means of estimating the rate of photosynthesis in green leaves exposed to sunlight in air containing the normal amount of carbon dioxide.

At the time we commenced our experiments the only practical method was a gravimetric one introduced by Sachs, by which the amount of material assimilated by a leaf in a given time is deduced from variations in the dry weight of known areas of the leaf-lamina. Unfortunately, we found that the errors to which this method is liable tend on the whole too much in one direction, and their sum, which frequently exceeds the value we are trying to estimate, is swept into the final result.

The method which we finally adopted was one based on the measurement of the intake of carbon dioxide at a partial pressure somewhere near that at which it exists in normal air, *i.e.* 3/10,000 of an atmosphere.

It is evident that such experiments must be conducted on a relatively large scale, both as regards the area of leaf-surface exposed and the volume of air passed over it.

(The nature and disposition of the apparatus were shown in a diagram on the screen.)

The leaf, which, if desired, may still remain attached to its plant, is enclosed in a glazed case through which a stream of air is drawn by a water-pump, the volume of the air being measured by a suitable meter. Between the leaf-case and the meter there is a Reiset's absorption-tube filled with a solution of caustic soda, which ensures the complete absorption of the carbon dioxide remaining after the air has passed through the case.

A duplication of the meter and absorption apparatus allows of a simultaneous determination of the carbon dioxide in the air before it passes over the leaf, and the difference between these values measures the carbon dioxide taken up by the leaf. This is referred to unit area of the leaf by measuring, by means of a planimeter, the area of the photographic impression of the lamina on sensitised paper.

A very delicate method was used for titrating the absorbed carbon dioxide in the alkali, and when all proper precautions are taken the errors of experiment are small.

and with certain modifications there is practically no limit to the scale on which the experiments can be conducted.

It is evident that with this apparatus the mean carbon-dioxide content of the air in contact with the leaf must be somewhat less than that of the entering air, so that a correction of some kind is necessary in order to obtain an estimate of the rate of assimilation under free-air conditions. This is afforded by the fact, established early in our work, that when all other conditions are the same, the rate of assimilation by the leaf is *directly proportional to the partial pressure of the carbon dioxide*, provided this does not exceed five or six times that of the carbon dioxide of normal air.

In deducing the amount of energy used up in the photosynthetic work from the amount of carbon dioxide absorbed by the leaf, we have assumed, as we are entitled to do, that the product of assimilation is a carbohydrate. If the particular form of carbohydrate is known, the amount which corresponds to a definite mass of carbon dioxide absorbed by the leaf is of course determinable; and, further, the energy used up in synthesising this amount of carbohydrate will be represented by its heat of combustion.

No sensible error will be introduced into this calculation by selecting one of the carbohydrates existing in a leaf in preference to another. We have based our calculations on the assumption that we have to deal with a *hexose* having a heat of combustion of 3760 calories per gram. On this basis the assimilation of 1 c.c. of carbon dioxide corresponds to the absorption of 5·02 water-gram-units of energy; hence by multiplying this value by the number of c.c. of carbon dioxide assimilated per unit area of leaf in unit of time we obtain the value of w for the generalised thermal equation.

In using the apparatus I have just described we found, amongst other things, that the actual rate of photosynthesis induced in a leaf which is bathed by ordinary air remains practically constant within very wide limits of insolation. This is due to the fact that the special rays which produce photosynthesis are present in solar radiation of even moderate intensity far in excess of the demands of the assimilatory centres for dealing with the atmospheric carbon dioxide which reaches them by the process of diffusion. The proof of this is afforded in the first place by the enhanced assimilatory effect which is produced by increasing the partial pressure of the carbon dioxide in the air surrounding the leaf, and, secondly, by the fact that we can reduce the intensity of ordinary summer sunlight to a very considerable extent by using revolving radial-sectors placed in front of the leaf, without sensibly affecting the rate of photosynthesis.

It follows from this that the *economic coefficient* of the leaf, which is the ratio of the energy utilised for photosynthesis to the total radiation falling on the leaf, must necessarily increase with diminished insolation, until a point is reached at which practically the whole of the special rays which are active in producing assimilation are utilised. At this point the economic coefficient of the leaf must be at a maximum with respect to a given partial pressure of carbon dioxide; in other words, the leaf regarded as a thermodynamic engine is then working with the least possible waste of energy.

In order to illustrate this I will take the case of a leaf under the influence of moderate sunlight of an intensity of 0·50 calorie per square centimetre per minute, and assimilating at the rate of 2·07 c.c. of carbon dioxide per square decimetre per hour. This corresponds to an economic coefficient of 0·34 per cent. On gradually diminishing by suitable means the radiation falling on the leaf, it was found possible to reduce it to 1/12 of the original amount before any appreciable difference in the rate of assimilation was observed. The economic coefficient was thereby raised to the maximum of a little more than 4·0 per cent. This 4 per cent. will also approximately measure the proportion of the special grade of energy in the original radiation which is capable of inducing photosynthesis.

It is, however, only under very exceptional conditions that we can obtain anything like this maximal "duty" from the leaf.

The following table, showing the results with leaves of *Polygonum Weyrichii* under varying degrees of insolation, will give some idea of the values of the economic coefficient ordinarily met with:—

The Economic Coefficient of Leaves of Polygonum Weyrichii under Various Degrees of Insolation.

Radiant energy falling on 1 sq. cm. of leaf per minute, in calories R	Economic coefficient $w/R \times 100$
0·612	0·42
0·194	1·59
0·150	1·66
0·143	1·32

Turning once more to the generalised thermal equation

$$Ra = (W + w) \mp r,$$

we must not lose sight of the fact that this represents a set of conditions in which all the determining factors, both internal and external, remain constant for a sufficient time to allow of the attainment of steady *thermal equilibrium* between the leaf and its surroundings.

In practice this ideal state is never attainable. In the first place the incidence of solar radiation is subject to rapid oscillations of considerable magnitude, even under the most fair-weather conditions, and every variation of this kind necessarily alters the value of Ra, the energy absorbed by the leaf, and will produce its effect on r, on which the temperature of the leaf depends. This, again, will influence the amount of water-vaporisation, and so affect the value of W. In addition to this, complex disturbances may be introduced by the automatic opening or closing of the stomata, by variations in the hygrometric state of the air, and, perhaps more important than all, by changes in the velocity of the air blowing over the leaf, which will alter its rate of emission.

With all these varying factors acting and reacting on each other in endless complexity, it will be readily understood that under natural open-air conditions the thermal relation of a leaf to its surroundings must be undergoing constant re-adjustment, and that the point of thermal equilibrium must change from moment to moment with every passing cloud, with every gust of wind, and with each change of inclination of the leaf-lamina to the incident radiation.

In the absence of means for instantaneously recording all these variations, it is manifestly impossible to determine the thermal conditions for any particular moment of time, and perhaps there would be no special advantage in doing this even if it were possible. It is, however, quite practicable to determine the *mean* values of the varying factors and the average effects which they produce during a period of time, say of several hours' duration, and we can then introduce these mean values into our equation, which will thus give us all the information we require.

I will now proceed to illustrate the application of these general principles by the consideration of a few concrete examples.

The first is that of a leaf of the sunflower, in which the experiment lasted for about four hours. The results are expressed in water-gram-units (calories), and the units of area and of time are the square centimetre and the minute respectively.

The conditions were such that the total solar radiation absorbed by the leaf was in excess of that required to perform the internal work of transpiration and photosynthesis; in other words, Ra was greater than $W+w$. Hence r was a positive quantity, and the temperature of the leaf was consequently somewhat higher than that of its environment.

CASE A.—*Leaf of Helianthus annuus.*

Total solar radiation	R 0·2569	calorie.
Coefficient of absorption, $a = 0·686$, ∴ solar energy intercepted, ...	$Ra = 0·1762$	,,
Water vaporised = 0·000209 gram, ∴ W, the internal work of vaporisation = 0·000209 × 592 6	0·1243	,,
Rate of photosynthesis = 0·000355 c.c. CO_2, hence w, absorption of energy due to assimilation = 0·000355 × 5 02 ...	0·0017	,,

$$Ra = W + w + r$$
$$0·1762 = 0·1243 + 0·0017 + 0·0502$$

Velocity of wind = 25·7 kilometres per hour = 428 m. per minute.
Thermal emissivity of leaf-surface in still air = 0·0150 cal.
Thermal emissivity (e) in air of velocity of 428 m. per minute = $0·0150 + 0·00017 \times 428 = 0·0577$ calorie.
Hence mean temperature of leaf *above* that of surroundings = $r/2e = 0·0502/2 \times 0·0577 = 0°·43$ C.

The disposal of the incident radiant energy deduced from these data is given in the next table, the total incident energy R being taken at 100.

Case A.—*Disposal of Incident Solar Energy by leaf of Helianthus annuus.*

w	Energy used for photosynthesis	0·66
W	,, ,, transpiration	48·39
$W + w$	Total energy expended in internal work ...	·05
$R - Ra$	Solar energy transmitted by leaf	31·40
r	Energy lost by thermal emission	19·55
		100 00

We will not consider another case in which the facilities for the performance of the internal work of vaporisation of water were more than sufficient to use up the whole of the direct solar radiation absorbed by the leaf, *i.e.* Ra was less than $W + w$.

Such conditions are afforded by fully opened stomata, high temperature, and a low degree of humidity of the air. The leaves used were again those of the sunflower, but in this case one-half of the solar radiation was intercepted by the revolving sectors.

Case B.—*Helianthus annuus.*

Solar radiation incident on leaf R ... ... = 0·2746 calorie
Coefficient of absorption, $a = 0·686$, ∴ solar energy intercepted, Ra ... ... = 0·1884 ,,
Water vaporised = 0·000618 gram, ∴ W, the internal work of vaporisation = 0·000618 × 592 6 ... ... = 0·3668 ,,
Rate of photosynthesis = 0 000657 c.c. CO_2, hence w, absorption of energy due to assimilation ... . = 0·0033 ,,

$$Ra = (W + w) - r$$
$$0·1884 = 0·3668 + 0·0033 - 0·1817$$

Velocity of wind = 12 kilometres per hour = 200 m. per minute.
Thermal emissivity of leaf-surface in air of this velocity = $0·015 + 200 \times 0·00017 = 0·0490$ calorie.
Hence mean temperature of leaf *below* that of surroundings = $r/2e = 0·1817/0·0490 = 1°·84$ C.

Case B.—*Disposal of Energy Received by Leaf from Solar Radiation and from Heat Conveyed from Surroundings.*

$R + r = 100.$

w	Energy used for photosynthesis	0·72
W	,, ,, transpiration	80·38
$W + w$	Total energy expended in internal work ...	81·10
$R - Ra$	Solar energy transmitted by leaf	18 90
		100·00

During the time at my disposal I have only been able to give a brief outline of the general principles underlying an attempt to deal with the main functions of a foliage leaf from the point of view of its energetics, and I must refer those of my hearers who are specially interested in the subject to the papers themselves for the further elaboration of the argument and for the facts on which it is based. I trust, however, that this short account of the work may be sufficient to indicate that we have experimental means of studying quantitatively the reception of various grades of energy by a leaf, the proportion of this which is utilised for the two main kinds of internal work, and also the thermal relations of a leaf to its surroundings under given conditions.

In conclusion, I wish to anticipate a possible objection which may be raised on theoretical grounds to some of the views I have expressed. I have assumed throughout that the second law of thermodynamics is applicable to the phenomena we have been discussing. The statement of that law by Lord Kelvin limits its application to "inanimate objects," and doubtless if the living elements of the leaf-cells possess any power of dealing with the individual molecules of the surrounding medium so as to select and utilise the kinetic energy of those which are moving faster than the "mean square speed," it may well happen that a leaf may be able to perform some kind of internal work without there being any difference of mean temperature between it and its surroundings. In this event the views I have put forward would doubtless require some slight revision, but I think we may well wait until this restriction of the second fundamental principle of thermodynamics has received some experimental support.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Mr. H. O. Arnold-Forster, M.P., will distribute the medals, prizes, and certificates at Woolwich Polytechnic on Saturday, April 1.

Dr. E. O. Lovett, professor of mathematics of Princeton University, has been elected professor of astronomy in succession to Prof. C. A. Young.

The Prince of Wales is to visit Cardiff toward the end of June, when he will lay the foundation stone of the Welsh University College in Cathays Park.

Dr. Peter Thompson has been appointed professor of anatomy, and Prof. Arthur Dendy, of the South African College, Cape Town, professor of zoology, at King's College, London.

The celebration of the jubilee of the Cheltenham Ladies' College and the opening by Sir Henry Roscoe of the new science laboratories and lecture rooms will take place on Friday and Saturday, May 12 and 13. The Marquis of Londonderry, President of the Board of Education, has promised to be present.

Private munificence has provided further sums for the promotion of higher education in the United States. We learn from *Science* that by the death of Mrs. George L. Littlefield, Brown University becomes the recipient of the bulk of the Littlefield estate, estimated at 100,000*l*. The will provides that the corporation shall apply the money as it sees fit, except that 20,000*l*. shall be used for the establishment of the George L. Littlefield professorship of American history. By the will of the late Mr. William F. Milton, of New York, his estate will go to Harvard University on the death of Mrs. Milton. The daily papers state that it is worth between 200,000*l*. and 400,000*l*. Columbia University has received 20,000*l*. from Mr. Jacob H. Schiff to endow a chair of social work, and the new professorship has been filled by the appointment of Dr. Edward T. Devine.

In the House of Commons on Monday Mr. Clancy asked the First Lord of the Treasury whether there are any requirements, statutory or otherwise, in the case of grants in aid of university colleges in England, that four times the amount is required from local subscriptions before anything is derived from the public funds. In reply, the Chancellor of the Exchequer said that there has been such a requirement in regard to the grant in past times. But proposals in regard to the future allocation of the grant are now under the consideration of the Government. Mr. Clancy asked whether it was not proposed that there should be a grant of 100,000*l*. a year to the university colleges mentioned in the report; and whether there was any requirement, statutory or otherwise, in regard to this grant. The Chancellor of the Exchequer answered: There is a proposal by the committee that the distribution should be governed by the amount of voluntary subscriptions obtained by these colleges. The Government has not yet come to a decision on the subject.

At a meeting of the Association of Teachers in Technical Institutes on March 25, Mr. W. J. Lineham, chairman of the association, delivered an address on technical training in

England. He insisted that in considering the future education of a boy who has completed his primary education—say, at thirteen—the subject must be regarded from the point of view of his future livelihood. Mr. Lineham sketched what he called an ideal scheme of technical education. After the child has followed a good primary education from the ages of six to thirteen, his education must be continued with some idea of his future occupation. If he is to be educated for a commercial pursuit he should now attend a purely secondary school; but if he is to enter a trade or technical profession he should attend what is known as a day technical school until the age of sixteen, having spent three years therein, the first part of which should be mainly literary, the middle scientific, and the last technical. His apprenticeship should then begin. But the apprentice must not now lose the lessons learnt in the technical day school. On the contrary, he must continue his studies to an even higher level by attendance at an evening technical school simultaneously with his apprenticeship. As to the apprenticeship itself, its character should entirely depend upon the trade or profession to be followed.

SOCIETIES AND ACADEMIES.

LONDON.

Anthropological Institute, March 14.—Sir T. H. Holdich, K.C.M.G., K.C.I.E., in the chair.—Manners and customs of the Melanesians: Rev. W. H. **Edgell**. The ethnographical objects and lantern slides shown included views of the different types of people, and illustrated the development of canoes and houses. One of the finest of the slides illustrated a Melanesian waiting to shoot a fish. He was poised on one leg, and the lecturer stated that he had seen natives waiting motionless for hours by the side of the rivers waiting for an opportunity to shoot. Of particular interest was the lecturer's statement that some of the natives have entirely lost the art of canoe making, although they still make paddles, which they use to propel rafts made of bamboos.

Entomological Society, March 15.—Mr. F. Merrifield, president, in the chair.—*Exhibits*.—Butterflies from Natal presented by Mr. G. A. K. Marshall to the Hope Department at Oxford: Dr. F. A. **Dixey**. Dr. Dixey read a note upon his experiments conducted with a view to ascertaining whether the assumption of the wet or dry season form of various African butterflies could be controlled by exposure in the pupal state to artificial conditions of temperature and moisture.—Drawings of the genitalia of noctuid moths, and also a number of slides showing the respective peculiarities of many members of the genus: F. W. **Pierce**. Among other things, attention was directed to the fact that in the case of the Tæniocampidæ the genitalia were widely dissimilar, while the author's investigations had led him to conclude that Ashworthii, at present ranked as an Agrotis, should more properly be included in the Noctua group.—A specimen of the North American longicorn, *Neoclytus erythrocephalus*, discovered in a sound ash tree in the neighbourhood of St. Helens, Lancashire: W. E. **Sharp**. Some palings of American ash in the vicinity suggested the origin of the progenitors of the colony, but it was not known how long they had been erected. The beetles were taken in their galleries in the summer dead, which seemed to indicate a weakening of the species under the conditions in which they found themselves. Mr. Sharp also showed examples of *Amara anthobia*, Valle, new to the British list (with a series of *A. familiaris*, Duf., and *A. lucida* for comparison) from Leighton-Buzzard, where they occurred not infrequently at the roots of grass in sandy places.—Mutilated Stenobothrus from the Picos de Europa, Spain: M. **Burr**. These grasshoppers were taken at a height of about 1300 metres, on turfy ground exposed to north wind from the Atlantic, and covered with tufts of a short, dense, tough, and spiky shrub, together with heather. Of the grasshoppers occurring on this spot, almost every specimen had the wings and elytra more or less mutilated, sometimes actually torn to shreds, entirely altering their appearance. A notable exception was *St. bicolor*, of which no single specimen was found mutilated.

PARIS.

Academy of Sciences, March 20.—M. H. Poincaré in the chair.—Thermochemical researches on brucine and strychnine: MM. **Berthelot** and **Gaudechon**.—A determination of the heats of combustion and formation of the two alkaloids, together with measurements of the heats of neutralisation with various acids. The equilibrium between strychnine and ammonium salts was also studied thermochemically.—On the variations of brightness and the total eclipses of primary images formed on the retina by very feeble luminous sources of constant value: A. **Chauveau**. A discussion of a recent paper by M. Lullin, in which the latter describes an experiment with phosphorescent screens, the visibility of which depends on the visual angle, and on the duration of the observation.—On the valency of the atom of hydrogen: M. **de Forcrand**. A discussion of the assumptions upon which the monovalency of hydrogen is based. The author brings forward the cases of Ag_2F, Ag_4O, ICl_3, and others, and suggests that the difficulty of explaining these can best be met by adopting the convention that the hydrogen atom is divalent.—On the photography of the solar corona at the summit of Mont Blanc: A. **Hansky**. Hitherto, attempts to photograph the solar corona at other times than during a total eclipse have not met with much success. By the use of a disc of blackened brass, the diameter of which is a little larger than that of the image of the sun at the focus of the telescope used, combined with coloured screens capable of absorbing the spectrum about up to $\lambda = 660\ \mu\mu$, photographs of the solar corona have been obtained.—Remarks on the preceding note: J. **Janssen**. Reproductions of two of the photographs mentioned in the preceding paper are given.—The notion of distance in the functional calculus: Maurice **Fréchet**.—On the calculation of closed arcs: M. **Pigeaud**.—The distribution and control of actions produced at a distance by electric waves: Édouard **Branly**. The three effects chosen for control at a distance by means of electric waves are the starting of an electric motor, lighting incandescent lamps, and producing an explosion. Details are given of the apparatus by which this has been done in the laboratory. The succession of the effects can be varied at will.—On the variation of the specific inductive power of glass with the frequency: André **Broca** and M. **Turchini**. Glass Leyden jars may be used in the production of currents of high frequency, between the limits 10^5 and 3×10^6 per second, on condition that the capacity introduced into the formulæ is about one-half that measured with charges of 0·1 sec., or 0·7 of the capacity measured with the frequency of an ordinary rotating sector.—On the coefficient of specific magnetisation and magnetic susceptibility of salts: Georges **Meslin**. The results of measurements for a considerable number of paramagnetic and diamagnetic salts are given.—On photographic halation. Reply to a note of M. A. Guébhard: P. **Villard**. The author regards the explanation of his experiments given by M. A. Guébhard as inapplicable. Particulars of an experiment are given for which an explanation is at present wanting.—On the ionisation produced between parallel plates by the radium emanation: William **Duane**.—The diazoamines of diphenylamine, derivatives of the homologues of aniline and naphthylamines: Léo **Vignon** and A. **Simonet**.—The characterisation of lactones by means of hydrazine: M. **Blaise** and A. **Luttringer**. The lactone is heated on the water bath with a slight excess of hydrazine hydrate. The crystalline mass which separates on cooling is re-crystallised from boiling ethyl acetate, and its melting point, which is usually well defined, serves to characterise the lactone. The melting points of six of these compounds are given.—On menthone derived from the hexahydrothymols: Léon **Brunel**. In a preceding note the preparation of two thymomenthols has been described; the present paper describes the thymomenthone obtained by the oxidation of these products.—On monobromoacetal: P. **Freundler** and M. **Ledru**. By attention to some details the yield of bromoacetal by Fischer's method has been raised from 50 per cent. to 115 per cent. of the acetal employed. Magnesium reacts violently on this bromine compound at 110°, giving rise to vinyl ethyl ether.—Remarks on the diphenylamine reaction with nitric acid: Isidore **Bay**. The blue coloration is produced by a large number of oxidising agents, and is not characteristic of nitric acid.—On the antiseptic properties of certain kinds of smoke and on their utilisation: A. **Trillat.** In previous papers the author has shown that formaldehyde is a constant constituent of chimney smoke. He now finds that a polymerised formaldehyde is always present in soot, in proportions varying from 0·28 per cent. to 0·34 per cent.—The effects of phosphorus on the coagulation of the blood. The origin of fibrinogen: M. **Doyon,** A. **Morel,** and N. **Kareff.**—The duration of the process of stimulation for different muscles: M. and Madame L. **Lapicque.**—On the anatomical and functional independence of the lobes of the liver: H. **Sérégé.** The arguments from the anatomical and physiological points of view are summarised and shown to be all in favour of the independence of the lobes.—An experimental study of the relations between the arterial pressure and the pulmonary circulation in anæsthesia by chloroform. The determining cause of chloroform accidents: J. **Tissot.**—On the measurement of disposable energy by a self-registering integrating dynamometer: Charles **Henry.** The apparatus consists essentially of a rubber ball filled with mercury. The pressure of the hand on this raises a mass of iron up and down a graduated tube, this iron being connected with the registering apparatus. The area registered measures the statical work done by the pressure of the fingers.—The cardiac area in cured consumptive cases: H. **Guilleminot.**

PSYCHOLOGY AND PHYSIOLOGY.

Grundzüge der physiologischen Psychologie. Von Wilhelm Wundt. 5th edition. Vols. ii. and iii. Pp. viii+865, ix+796 and 133; and Gesamtregister. (Leipzig: Engelmann, 1902-3.) Prices 13s., 14s., and 3s.

Principles of Physiological Psychology. By Wilhelm Wundt. Translated from the fifth German edition by E. B. Titchener. Pp. xvi+347. (London: Swan Sonnenschein and Co., Ltd., 1904.) Price 12s.

WITH these two volumes Prof. Wundt concludes what in all probability is the last edition of this great work prepared by his own hand. The single volume of the first edition of 1874 is now expanded to three large volumes comprising 2168 pages. Founded, as it is, chiefly upon the author's own researches and those of his pupils, the treatise forms a splendid monument to his life-long labours in a field in which he has been for long a pioneer and the most prominent figure.

The main part is an expansion and development of the views expounded in earlier editions in accordance with the data that have accumulated so rapidly in recent years. For, as Wundt points out, psychology has now happily achieved methods of research by which any intelligent and industrious worker may add something, however small, to the mass of empirical data on which the future science is to be built up, and in so doing has assured its place among the progressive sciences. To this edition a final section is added, in which the veteran thinker sets forth his matured conclusions on the general principles of psychology and on its relations to other sciences. To the exposition of one of the most important of these principles this article may profitably be devoted. Not many years ago most writers who discussed the functions of the brain postulated what they called a *sensorium commune*, a central nervous organ or "centre" in which the afferent nerves of all the sense-organs were supposed to come together, and to the substance of which each such nerve was supposed to communicate its specific mode of activity, generally assumed by those writers to be some peculiar form of molecular vibration. It was supposed, therefore, that when two or more sensory nerves of different functions are simultaneously stimulated, this "centre" becomes the seat of a complex resultant physical process, embodying the specific characters of the two or more kinds of neural process. And this hypothetical physical resultant was held to be the immediate correlate or excitant of the complex affection of consciousness. In this way it was sought to explain the unitary character of the state of consciousness resulting from the simultaneous stimulation of different sensory nerves. To every part of the brain that is median and therefore has no symmetrically disposed duplicate, this position of honour has been assigned by one or other writer—to the pineal gland by Descartes, to the pons by Spencer, to the basal ganglia in general by Maudsley and Carpenter, to the *septum lucidum* and to the third ventricle by others, to some undefined region by Herbart and Lotze. Under the powerful impulse of this supposed necessity others, notably G. H. Lewes, E. v. Hartmann and Ed. Montgomery, have made the whole brain the *sensorium commune*, assuming that the specific mode of vibration initiated in each kind of sensory nerve thrills throughout the whole or the greater part of the mass of the brain.

In the *Psycho-physik* (1860) Fechner clearly exposed the untenable character of all such assumptions and showed that "the psychically unitary and simple are resultants from physical manifolds, the physically manifold gives rise to a unitary or simple (psychical) resultant." This principle was accepted by Helmholtz, and by Lotze in his later writings; and the progress of our knowledge of the brain achieved since that time has made patent to all the impossibility of assigning the psycho-physical processes, the processes immediately correlated with psychical processes, to any one part or "centre" of the brain.

Nevertheless, in dealing with concrete instances of unitary psychical resultants from multiple sensory stimulations, as in the case of the compound colour sensations or of the fusion of the effects of stimuli applied simultaneously to corresponding areas of the two retinæ, many, perhaps most, physiologists and psychologists still postulate a fusion of the underlying neural processes to a unitary physical resultant. It is more difficult to refute this view in such special cases than to prove the erroneousness in principle of the conception of a *sensorium commune*, but fortunately Prof. Sherrington's recent research on the functional relations of corresponding retinal points[1] demonstrates in the clearest manner the separateness of the physiological effects in the brain-cortex of stimuli simultaneously applied to corresponding retinal areas, the instance of fusion of effects to which the doctrine of physiological fusion has been most confidently and plausibly applied; and many pathological and experimental observations bear out this view, both in this case and in other similar cases of fusion of effects of sensory stimuli. The principle laid down by Fechner in the words quoted above may therefore be regarded as well established. This principle Wundt adopts, and he extends its application in a thorough-going manner to the relations of neural and psychical processes in general. Assuming that every "psychical element" is related in a constant manner to an accompanying neural process, he asks (vol. iii., p. 775), Is there any corresponding constant relation between the connections (*Verbindungen*) of those elements and the connections of these processes? "It goes without saying that this question must be answered affirmatively in the sense that to all the psychical elements that are comprised in a complex affection of consciousness, the corresponding physical processes must also be given in simultaneous connection." But that is by no means to say that these physical correlates will constitute a unitary resultant, which would correspond to the psychical resultant. "The complex psychical

[1] See *British Journal of Psychology*, part i. 1904.

formations are further removed from their physiological correlates (than the psychical elements), and this removal is greater the more complex the psychical compounds become. And it is just at this point that psychology as an independent science in the proper sense of the word takes up its task." That is to say, it is the task of psycho-physics to discriminate the elements of our psychical processes and to discover their physiological correlates, but it is the task of psychology proper to discover the purely psychical laws of the synthesis of these elements—a task which would remain to be carried out, though the workings of the brain "stood as clearly exposed to our eyes as the mechanism of a watch."

Wundt then formulates four such fundamental psychical laws or principles, of which the first and most important is the "principle of creative resultants," the principle "that the product arising from any number of psychical elements is more than the sum of those elements . . . . it is a new formation incomparable in all its essential attributes with the factors that contribute towards it." So "a clang is more than the sum of its partial tones." "In the same way every spatial percept is a product in which certain elements (the local signs) have yielded up their independence to impart to the product an entirely new property, namely, the spatial ordering of the sensations. In binocular vision the separate images of the two organs of vision disappear, to give rise in the common resultant image to the immediate perception of solidity and depth." On the other hand, the neural correlates of these elements remain a spatially ordered manifold, exhibiting no corresponding fusion or synthesis. The acceptance of this principle is of the first importance for the progress of physiological psychology, but whether it is compatible with adhesion to the doctrine of psycho-physical parallelism, as Wundt maintains, may be seriously questioned, as also whether it can properly be called a principle of psychical causation. It seems clear that if with Wundt we recognise this and the other psychical laws that he formulates, whether or not we admit them as principles of psychical causation, we cannot maintain the principle of psycho-physical parallelism in the rigid form in which it is so widely current at the present time.

It is a pleasure to welcome the appearance of the first part of an English translation of this great work. Prof. Titchener has accomplished this part of his difficult task with all the care and skill which his previous labours in this line have prepared us to expect.

In spite of the title of this work, it is as much a treatise on experimental as on physiological psychology, and in view of the common misconceptions of the relations of experimental to other methods in psychology the following quotation may fitly conclude this brief notice:—"We now understand by 'experimental psychology' not simply those portions of psychology which are directly accessible to experiment, but the whole of individual psychology. For all such psychology employs the experimental method: directly, where its direct use is possible; but in all other cases indirectly, by availing itself of the general results which the direct employment of the method has yielded, and of the refinement of psychological observation which their employment induces."

W. McD.

RADIUM AND RADIO-ACTIVITY.

Radium Explained. By Dr. W. Hampson, M.A. (Jack's Scientific Series.) Pp. x+122. (Edinburgh and London: T. C. and E. C. Jack, 1905.) Price 1s. net.

THIS little book, which is sold for the modest price of one shilling, will, we think, serve a useful purpose in giving an elementary acquaintance with the subject of radio-activity, so far as that is accessible to those with little scientific knowledge. The explanations given of the experimental properties of radium are, so far as we have observed, clear and accurate, and the get-up of the book, though not superb, is respectable. Probably one of the most valuable chapters in the book is that on the medical aspects of radium, and its possible uses in the cure of disease, for few writers on radio-activity generally are competent to discuss this part of the subject. Dr. Hampson is of opinion that the medicinal value of mineral waters is connected with their radio-activity. This question, we think, should easily be susceptible of a definite and conclusive answer. There would not be the slightest difficulty in giving baths of weak radium solution more potent by far than the richest mineral waters. Why not test the medicinal value of these? It is really urgent that this experiment should be tried by competent hands.

It is, we think, to be regretted that Dr. Hampson has plunged into an attack on modern views of the constitution of matter, as expounded by Prof. J. J. Thomson, Sir Oliver Lodge, and others. We have read these criticisms with the attention due to a worker like Dr. Hampson, who has done good service in the cause of science, but cannot admit that they possess any validity. To go fully into the questions which he raises would take us beyond the limits of this notice, but we may briefly discuss one or two of the points. At the outset, Dr. Hampson objects to the definition of mass by means of inertia. Mass, he says, is quantity of matter; inertia is dependent on velocity as well as on mass.

It is true, no doubt, that the definition of mass as quantity of matter may be found in some old-fashioned text-books of repute. But such a definition has no value, for how is the quantity of matter to be ascertained? The choice practically lies between defining mass by inertia at a given speed or by gravity. So far as is known, exactly the same ratio between two masses of ordinary matter will result, whichever method of comparison is adopted. As, however, gravity depends on local circumstances, while inertia (at given velocity) does not, the latter property is preferred for the definition of mass, as being more fundamental.

No doubt, before it can be granted that the electron theory fully accounts for the observed properties of matter, it will be necessary to show that it will explain the phenomena of gravitation. This, at present, it makes no pretence of doing, as, of course, its distinguished authors would at once admit. But mass, as we have seen, is not conventionally defined with reference to gravity, but by means of inertia, or momentum at unit velocity. As a moving electric charge can be shown to possess this momentum, it is a strictly correct use of words to say that the electron theory explains the property of mass.

Dr. Hampson argues, in the second place, that electricity is a form of energy, and that it cannot therefore be identified with matter.

> "When an electrical machine . . . is used to charge a Leyden jar . . . there is no change in the quantity of material substance with which operations were started; it is the mechanical energy driving the machinery that has been converted into electricity" (p. 87).

The misconception here lies in confusing the separation of positive and negative electricity with the creation of either. Take the case of a Leyden jar. The coatings of the jar, according to modern views, initially both contain a number of chemical atoms, all with their normal complement of constituent electrons. The operation of charging consists in the removal of some of these electrons from the outer coating, say, and their transference to the inner one. This leaves the outer coat with a defect of electrons, and therefore positively charged, while the inner one acquires an excess of them, and consequently becomes negatively charged. The transference involves the expenditure of energy on the electrons, but no alteration in their number, and therefore no change in the amount of matter concerned.

We are sorry to have had to dwell principally on the parts of the book with which we disagree, as these are but a small portion of the whole, and do not detract from the usefulness of the rest.

R. J. S.

OIL FUEL.

Oil Fuel: Its Supply, Composition and Application. By S. H. North. Pp. viii+152. (London: Chas. Griffin and Co., Ltd., 1905.) Price 5s. net.

MR. SYDNEY H. NORTH has utilised the store of data collected whilst he was editor of the *Petroleum Review* to supply a most valuable addition to Griffin's scientific text-books in his work on "Oil Fuel" and to give his readers a concise and valuable record of the developments in the use of liquid fuel for the generation of power.

In the first chapter of the book he deals with the distribution and sources of supply of petroleum, and points out that the chief sources are now so geographically situated as to place the United Kingdom at a disadvantage in case of war, should the use of liquid fuel be largely adopted in the Naval Service, a fact which accentuates the importance of developing such fields as those of Canada and Burmah, and also of opening up new areas where possible in British Possessions.

In concluding this portion of the work, the author expresses his opinion that recent developments and extensions of oil-bearing areas are now progressing so rapidly that it is quite within the bounds of possibility that the liquid-fuel question may in the near future be placed above the control of price and geographical position.

In dealing with the economic aspect of liquid fuel it is pointed out that although the enormous advantages accruing from its use were early recognised, the prohibitive price prevented any great advance in its use, but that with the increase in output its utilisation now comes within the range of practical possibility, and that the advantages in winning, transporting, and storing and using the oil, especially for marine purposes, are so great that the supply of the liquid fuel is now the only factor checking its universal introduction.

In considering the absolute economy as a fuel, the author very properly leaves out the extravagant claims made by some of the early experimentalists, and only gives the best authenticated values, which vary from 12·5 to 16 lb. of water evaporated per lb. of liquid fuel. Variations in the use of oil as a fuel are of course largely dependent upon the method by which the oil is burnt, and too little stress is put upon the importance of the space factor, which is a most essential one, as, given plenty of combustion space in the boiler, the smokeless burning of liquid fuel is a perfectly simple problem, which, however, increases enormously in difficulty as the available space becomes more and more cramped.

The chapter on the chemical composition of fuel oils gives an excellent summary of analytical results, and this ends with a table showing the composition, calorific value and evaporative power of different descriptions of British coal. This, however, is liable to lead to misconception, as the value expressed in lb. of water evaporated per lb. of fuel is calculated, and not that obtained in practice, so that the reader who finds that by this table 1 lb. of Welsh coal will evaporate 14·98 lb. of water will be a little puzzled to see where the large economy comes in, when 1 lb. of oil only evaporates from 12·5 to 16 lb. of water. As a matter of fact, all recent work points to the relative evaporative results under the best conditions being 9 lb. of water per lb. of coal, or 15 lb. of water per lb. of oil, whilst the theoretical results give 14·98 lb. of water for coal, and 20 to 21 lb. for oil.

The section dealing with the conditions of combustion in oil furnaces is a useful reproduction of the views expressed by Messrs. Ord, Paul, and Lewes, and the author does not venture on any generalisation of his own.

Turning from consideration of the oil itself to the methods of burning it, the author gives a very useful historical summary of the early experiments down to the year 1883, when Mr. James Holden, whose name will always be inseparably connected with the subject of liquid fuel, introduced his method of consuming the oil on the Great Eastern Railway.

A chapter is then devoted to modern burners and methods, and steam, air, and mechanical injectors are discussed. The author very properly concludes that

> "for the successful use of liquid fuel it appears to be a *sine qua non* that auxiliary apparatus

and extraneous sources of heat must be avoided, and the furnaces made practically self-contained, if anything approaching perfection is to be attained. It must be upon simplicity, ease of working, and freedom from complicated parts that the progress of liquid fuel must chiefly depend.

"The direct pulverisation of the oil is now coming to be recognised as the proper method; it is the most efficient and the most economical."

The next two chapters are devoted to discussing the use of oil fuel for marine and naval purposes, but the division into two chapters is hardly needed, as the naval side of the question is scarcely touched upon, the bulk of the matter in that chapter being taken up with the trials of liquid fuel on the s.s. *Mariposa*, and the tests made on land by the American Liquid Fuel Navy Board.

The chapter on oil fuel in locomotives is an excellent summary of the work of Urquhart and Holden, whilst the use of oil fuel for metallurgical and domestic purposes also receives some attention.

The whole work compares very favourably indeed with the far more pretentious treatise on the subject which until now has been the only book of reference, and everyone interested in this important question will welcome Mr. North's excellent text-book.

THE DYNAMICS OF CHEMICAL CHANGE.

Chemical Statics and Dynamics. By J. W. Mellor, D.Sc. (N.Z.), B.Sc. (Vict.). Pp. xiii+538. (London: Longmans, Green, and Co.) Price 7s. 6d.

FOR some years past a marked increase of attention on the part of English chemists towards the rapidly developing physical chemistry has been observable. Until recently, however, the available English literature on the subject was confined to German translations, a state of things which is now being in a large measure remedied.

The present work forms one of the series of text-books of physical chemistry edited by Sir William Ramsay. According to the table of contents, four chapters are devoted to the consideration of homogeneous reactions, and in succeeding sections the initial periods in chemical change, heterogeneous reactions, equilibrium and dissociation, electrolytic dissociation, catalysis and the theory of chemical change, fermentation, the influence of temperature and pressure in chemical reactions, and finally explosions, are dealt with.

Since the appearance of van 't Hoff's "Etudes de Dynamique Chimique" a vast amount of work has been done in connection with the problems involved here, and the necessity for a summary of newly discovered facts, a criticism of recent theories, and an unbiased statement of our present position in regard to the dynamics of chemical change and allied problems must have been felt by many. Dr. Mellor's work will, therefore, receive an undoubted welcome.

The accumulated evidence on the nature of chemical change resulting from kinetic studies leads the author to favour the view that the "association" or "intermediate compound" theories describe in the most rational manner the mechanism of the majority of reactions. Simple consecutive changes determine the character of many apparently complex reactions.

In connection with the determination of the number of molecules taking part in reactions in gaseous systems the author sounds a very necessary warning note. The rate of decomposition of phosphine or arsine is a frequent text-book illustration of one of the methods employed, and the experimental data fit in with the assumption that the reaction is unimolecular and non-reversible. But there is another side to this and similar problems. It is not improbable that the reaction takes place on the surface of the walls of the containing vessel, and that its rate is conditioned solely by the rate of absorption of the gas by this surface. The course of the reaction will in this case also be that of a unimolecular change.

In the section on the measurement of chemical affinity we meet old and familiar friends in the illustrations of the thermal and density methods of comparing the affinities of two acids. The very moderate accuracy attainable in these methods, which involve the small difference between two experimental quantities, and in which corrections have frequently to be introduced in consequence of secondary changes, is scarcely ever sufficiently emphasised, and attention might have been directed to this point. A method depending upon the measurement of a property possessed by only one component of a system has obvious advantages, even if such methods are of limited application. Whether Thomsen's relative avidities and the relative ionic affinity coefficients are always identical conceptions is left for the reader to infer.

Chapter x., dealing with catalysis and the theory of chemical change, is most attractive reading. Here the processes of slow combustion or autoxidation are discussed in the light of the theories of Brodie, Schönbein, Clausius, van 't Hoff, Traube, Bach, Engler and Wild, and the interesting phenomena included under induced or sympathetic reactions are treated. In the chapter on explosions the account of older work is supplemented by many new and interesting facts.

In the reviewer's opinion Dr. Mellor's work is to be warmly recommended. The fact that it contains three thousand or so references to original papers is in itself evidence of its utility to the teacher, to the advanced student, and to the physical chemist engaged in research.

H. M. DAWSON.

RECENT EARTHQUAKES.

A Study of Recent Earthquakes. By Charles Davison, Sc.D., F.G.S. Pp. xii + 355; 80 illustrations. (London: Walter Scott Publishing Co., Ltd.) Price 6s.

IN this copiously illustrated volume Dr. Charles Davison, whose seismological investigations, especially those relating to British earthquakes, are so well known, gives a popular account of the results which have been arrived at by modern seismology. The method in which he treats his subject is one that appeals to the general reader. Rather than grouping seismic phenomena, as we should expect to find them in a text-book, the author has given a concise history of eight disturbances, each of which has a special interest. The Neapolitan earthquake is of interest from an historical point of view, the Ischian earthquakes illustrate the relationship between volcanic and seismic activities, a Japanese earthquake is described on account of the fault line which was produced at the time of its occurrence and the numerous after shocks by which it was followed, whilst a British earthquake illustrates the growth of a fault. From the work of Robert Mallet upon the first of these earthquakes, which in 1857 devastated a district to the south-east of Naples, and when upwards of 9000 people lost their lives, the scientific world learned that out of ruins much might be learned respecting the direction and intensity of the movements which had caused them. Although his methods of investigation, as, for example, those relating to the determination of the depths of seismic foci, may have been modified by new observations, Mallet directed attention to new problems for the solution of which he employed scientific methods.

The Andalusian earthquake in 1884, we are told, is chiefly remarkable from the fact that it was recorded at very distant stations, as, for example, by magnetographs near Paris, at which city the movements of the ground could not be felt. For this disturbance the depth of its origin is determined by means of angles of emergence calculated from the directions of fractures in masonry walls. That the direction of these fractures might be due to the varying steepness of the earth waves which produced the shattering is not considered

The peculiarity of the Charleston earthquake is that it occurred in a region where such disturbances are almost unknown, that it had two foci about thirteen miles apart, and that it illustrated the behaviour of different races when confronted by a terrible disaster. With the negroes there was wild fear, panic, and a "selfish rush for safety." With Europeans in similar circumstances similar conditions prevail, but we are told that with Japanese there is calmness. Our own idea is that Japanese like to save their necks as well as other people. They will bolt at the time of an earthquake, to return, not with hysterical and shattered nerves, but chattering and laughing as if earthquakes were very fine jokes.

A subject attractive to the general reader which is referred to in several chapters is an account of signs which have given warning of a coming earthquake. Underground sounds have been heard, springs have varied in their flow, horses, birds, dogs, and even human beings have been restless for some time before great earthquakes. In his reference to the Riviera earthquake in 1887, Mr. Davison remarks that as premonitions were noted at 130 different places within the central area, "there can be little doubt that they were caused by microseismic movements for the most part insensible to man." In these days of psychical research we think that the author has lost an opportunity for romantic speculation.

Although the book is intended more for the person of ordinary intelligence than for the specialist, here and there we come upon information of an uncommon kind. For example, it is pointed out that the areas over which earthquake sounds are heard is variable in different countries. One reason for this is that the limits of audibility vary with different races. From illustrations given it would appear that for certain sounds the Anglo-Saxon ear is more acute than the Neapolitan, and very much more than that of the Japanese. This relationship between the physiological structure of the human ear and earthquake music is, to say the least, extremely interesting, but while discussing the same the fact must not be overlooked that in the same country districts may be found where seismic sounds are frequent, whilst there are other districts where Pluto shakes the ground but mutterings are never heard.

Dr. Davison's book is well worth reading, whilst the manner in which its contents have been arranged should obtain for it a circulation amongst those who seek for general information.

OUR BOOK SHELF.

A German-English Dictionary of Terms used in Medicine and the Allied Sciences. By Hugo Lang and B. Abrahams. Pp. vi + 598. (London: J. and A. Churchill, 1905.) Price 15*s*. net.

There is undoubtedly a vacant place which would be filled by a well-compiled work bearing the above title. The book now under review has a certain claim on our regard in this connection, and in some respects is a useful work. It purports to be, in the first place, a medical dictionary, and, so far as we can judge, fulfils this promise in a satisfactory manner. With a few minor blemishes there is a complete vocabulary of medical terms, and as a rule these are very fairly rendered by their English equivalents. But in the allied sciences, which are also supposed to be included, there are curious lacunæ. Chemistry is pretty well represented—for example, we found most of the technical terms in Biedermann's "Chemiker Kalendar" duly set down—but the pathological vocabulary leaves much to be desired, and apparently physiology is not considered an allied science at all—at any rate, physiological terms are very seldom to be met with.

The authors have generally avoided the pitfalls set for the unwary in works of this kind, and there are few actual mistakes; occasionally it is difficult to ascertain the real meaning of a word without extraneous assistance. For example, the word "typhus" by itself is not correctly translated by "typhus"; it invariably means "enteric" (typhoid), and the English typhus fever is "fleck-typhus," the latter being, however, correctly entered in its place. The medical meaning of "Belastung" is given; the completely different signification when the word is applied to muscle is omitted. But the cardinal fault of the dictionary is the treatment of compound words. These are separately set forth at length instead of being collected under their first components, and this increases the bulk and cost of the work (already too great) without conferring any real ease of reference. The courteous way in which the authors in the preface invite suggestions disarms too caustic comments, and we merely hint gently that in the next edition the space that could be saved by the course indicated could be profitably employed by the insertion of a few additional pathological and physiological terms, and that it would be unwise to translate these in the fashion adopted at present in such words as "luftweg."

Règles internationales de la Nomenclature zoologique. Pp. 63. (Paris: F. R. de Rudeval, 1905.)

It has frequently been remarked that it is not of much use making laws and regulations unless you have the power to enforce their observation; and this trite saying applies, in our opinion, very forcibly to this code of regulations for zoological literature, drawn up by an international committee the deliberations of which have extended over some years. The code, which is published in three languages, is admirably drawn up, and for the most part free from ambiguity; but the question is, will naturalists agree to abide by it? In our opinion, a large number will refuse to accept it, since a rigid and slavish adherence to the law of priority is enjoined, and to many this is anathema. The rule that when a genus-name is changed this entails the change of the family title will be generally regarded as satisfactory. As regards emendation in names, this is held to be justifiable only when an error in transcription, a *lapsus calami*, or a misprint is apparent; but in the interpretation of this difficulties may arise, as in the well-known case of Neurogymnurus, which is *believed* to be an error for Necrogymnurus. Differences of opinion, again, are likely to arise with regard to the rejection of names on account of unsuitableness or similarity to others already in use. The retention of such names as Polyodon and Apus when applied to animals which do not properly come under such designation will, no doubt, be generally accepted; but what is to be said when, for instance, an essentially African species is named asiaticus? Such names as Polyodus, Polyodon, Polyodonta, Polyodontus, &c., are held not to come under the category of synonyms, although the converse rule is followed in many systematic works and catalogues, such as Dr. Trouessart's "Catalogus Mammalium."

As a "pious" expression of opinion on the part of the International Committee the "Règles" are, no doubt, valuable; but they would have been much more so had a *plebiscite* of zoologists and palæontologists agreed to accept and abide by the ruling of the committee.

A New Thallium Mineral.

The element thallium, discovered by Sir W. Crookes in 1861, has up to the present been known as an essential constituent of only two minerals, viz. crookesite, a selenide of copper and thallium, and lorandite, a sulpharsenite of the latter element. To these minerals a third must now be added in hutchinsonite, a new sulpharsenite from the Binnenthal, which also contains thallium as an important constituent. The crystallographic characters of hutchinsonite were described about a year ago by Mr. R. H. Solly, who, of late years, has been particularly successful in discovering new mineral species in the Binnenthal. At the time of its discovery very little in the way of chemical investigation was possible owing to the extreme scarcity of the mineral, but during the past year additional crystals have been acquired for the British Museum, and from these about eighty milligrams of fairly pure material have been obtained for chemical analysis. Thallium is present (up to nearly 20 per cent.), together with lead, silver, and copper, in combination with arsenic and sulphur. A full description of the mineral will appear shortly in the *Mineralogical Magazine*.

G. T. PRIOR.

The Legendary Suicide of the Scorpion.

I HAVE recently come across the following passage in the Rev. John Campbell's "Travels in South Africa" (London, 1815), p. 38:—"Having caught a scorpion near our tent, we tried whether naturalists were accurate in relating, that if that animal be surrounded with fire, and sees he cannot escape, he will sting himself to death. However, it died as quietly as any other animal, only darting its sting from it, as if to oppose any ordinary assailant." The experiment was made near Zwellendam, Cape Colony, on February 20, 1813.

Propagation of Earthquake Waves.

A FEW days ago I read Major C. E. Dutton's book on "Earthquakes in the Light of the New Seismology." While acknowledging the high merits of this book, I take the liberty of pointing out some statements which seem misleading.

I refer to chapter xiii., where the author, quoting the results of the experimental investigations of Mr. Nagaoka, gives the speeds V_1 and V_2 of the normal and transverse waves. Now a glance at the table on pp. 230 and 231 shows that for many rocks the two moduluses E_1 and E_2 perpendicular and parallel to the bedding planes are far from being equal; on the contrary, the quotient E_1/E_2 varies so much as from 1·43/2·49 for rhyolite tuff to 32·1/17·5 for rhyolite. Hence the physical properties of the rocks in question are different in different directions, and the speeds of propagation of waves are also different in different directions, so that the speeds V_1 and V_2 of the table being the same for all directions have no real meaning for many rocks.

Again, in chapter xiii. and in other chapters of the book, the author refers to normal and transverse waves in rocks. It would be better, perhaps, to speak of dilatational and torsional waves; but leaving the question of terminology out of consideration, I observe that it is only for perfectly elastic homogeneous and isotropic bodies that the separation of the dilatational (normal) from the torsional (transverse) wave takes place with certainty. We have no right to extend this property to æolotropic bodies. When the body is æolotropic the deformation of an element on the passage of a wave need not be of a purely dilatational (normal) or of a purely torsional (transverse) character; it is rather of a mixed nature.

I will not say that æolotropic bodies able to propagate purely dilatational and purely torsional waves cannot exist, but I observe that such bodies are to be considered rather as possible exceptions, inasmuch as certain special conditions must be fulfilled in order that the generation of purely dilatational and purely torsional waves should be rendered possible. So, for example, the elastic potential of a perfectly elastic homogeneous uniaxial body implies five independent constants. When we introduce the condition that purely dilatational waves may be propagated apart from torsional ones, we find that two definite relations between the constants must be satisfied so that the number of independent constants is reduced to three. But we have no reason to maintain *a priori* that the conditions in question must be always satisfied.

Of course it is to be understood that a perfectly elastic homogeneous uniaxial body cannot be considered as an exact "model" of stratified rocks; it is only very similar to them; but it is more than highly improbable that the effect of internal friction would neutralise the effect of æolotropism.

K. K. Sternwarte, Krakau (Austria), March 24.

NOTES ON STONEHENGE.[1]

V.—On the Star Observations made in British Stone Circles.[2]

THE work I have tried to do so far on our British stone circles has dealt with the observations of the sun made in connection with them, and the attempt to determine a date has been based upon the slow change in the obliquity of the ecliptic which is continually taking place.

In continuation of my work in Egypt in 1891, and Mr. Penrose's in Greece in 1892, I have recently endeavoured to see whether there are any traces in Britain of the star observations which I found connected with the worship of the sun at certain times of the year. We both discovered that stars, far out of the sun's course, especially in Egypt, were observed in the dawn as heralds of sunrise—"warning-stars"—so that the priests might have time to prepare the sunrise sacrifice. To do this properly the star should rise while the sun is still about 10° below the horizon.

I stated ("Dawn of Astronomy," p. 319) that Spica was the star the heliacal rising of which heralded the sun on May-day 3200 B.C. in the temple of Min at Thebes. Sirius was associated with the summer solstice at about the same time. The equinoxes were provided for in the same way in Lower Egypt, but they do not concern us now.

Mr. Penrose found this May-day worship continued at Athens on foundations built in 1495 B.C. and 2020 B.C., on which the Hecatompedon and older Erechtheum respectively were subsequently built, the warning star being now no longer Spica, but the cluster of the Pleiades.

It is generally known that Stonehenge is associated with the solstitial year, and I have recently suggested that it was originally connected with the May year; but the probable date of its re-dedication, 1680 B.C., was determined by Mr. Penrose and myself by the change of obliquity.

Now if Stonehenge or any other British stone circle could be proved to have used observations of warning stars, the determination of the date when such observations were made would be enormously facilitated. Mr. Penrose and myself were content to think that our date might be within 200 years of the truth, whereas if we could use the rapid movement of stars in declination brought about by the precession of the equinoxes, instead of the slow change of the sun's declination brought about by the change of the value of the obliquity, a possible error of 200 years would be reduced to one of 10 years.

In spite of this enormous advantage, so far as I know no one has yet made any inquiry to connect star observations with any of the British circles.

I have recently obtained clear evidence that some circles in different parts of Britain were related to the May year, a vegetation year, which we know was general over the whole of Europe in early times, and which still determines the quarter-days in Scotland.

If the Egyptian and Greek practice were continued here, we should expect to find some indications of the star observations utilised at the temple of Min and at the Hecatompedon for the beginning or the other chief months of the May year.

Following the clue given me in the case of the Egyptian temples, such as Luxor, by successive small changes of the axis necessitated by the change in a star's place due to precession, I have looked out for this peculiarity in an examination of many maps and plans of circles.

I have already come across two examples in which the sight line has been changed in the Egyptian manner. The first is the three circles of the Hurlers, near Liskeard, a plan of which is given in "Prehistoric Stone Monuments of the British Isles: Cornwall," by H. C. Lukis, published by the Society of Antiquaries, who were so good as to furnish me with a copy, and also some *unfolded* plans on which sight lines could be accurately drawn and their azimuths determined. I am anxious to express my obligations to the council and officers of the society for the help thus afforded me.

The second is at Stanton Drew, in Somerset, consisting of three circles, two avenues, and at least one outstanding stone. These were most carefully surveyed by Mr. C. E. Dymond some years ago, and he was good enough to send me copies of his plans and levelling sections.

How can such plans help us? The easiest way for the astronomer-priests to conduct such observations in a stone circle would be to erect a stone or barrow indicating the direction of the place on the horizon at which the star would rise. If the dawn the star was to herald occurred in the summer, the stone or barrow itself might be visible if not too far away, but there was a reason why the stone or barrow should not be too close; in a solemn ceremonial the less seen of the machinery the better.

Doubtless such outstanding stones and barrows would be rendered obvious by a light placed on or near them. Cups which could hold oil or grease are known in connection with such stones, and a light thus fed would suffice in the open if there were no wind; but in windy weather a cromlech or some similar shelter must have been provided for it.

Now if these standing stones or barrows were ever erected and still remain, accurate plans—not the slovenly plans with which Ferguson and too many others have provided us, giving us either no indication of the north or any other point, or else a rough compass bearing without taking the trouble to state the variation at the time and place—will help us in this way.

The work of Stockwell in America, Danckworth in Germany, and Dr. W. J. S. Lockyer in England has provided us with tables of the changing declinations of stars throughout past time, or enough of it for our purpose.

An accurate determination of either the *azimuth* (angular distance from the N. or S. points) or *amplitude* (angular distance from the E. or W. points) of the stone or barrow as seen from the centre of the stone circle will enable us to determine this declination.

This, of course, only gives us a first approximation. The angular height of the point on the horizon to which the alignment or sight-line is directed by the stone or barrow from the centre of the circle must be most accurately determined, otherwise the declinations may be one or two degrees out.

To come back to the two cases to which I have referred, the Hurlers and Stanton Drew. I will begin with a reference to the available descriptions of the circles.

The three circles of the Hurlers, some five miles to the north of Liskeard, are thus referred to by Lukis in the valuable monograph which I have already mentioned.

"On the moor, about a mile to the south of the singular pile of granite slabs, which rest upon and overlap each other, and is vulgarly called the Cheesewring, there are three large circles of granite stones placed in a nearly straight line in a north-north-east, and south-south-west direction, of which the middle one is the largest, being 135 feet in diameter, the north 110 feet, and the south 105 feet.

"The north Circle is 98 feet, and the south 82 feet

[1] Continued from p. 393.

[2] This article is generally based upon a note communicated to the Royal Society on March 15.

from the central one. If a line be drawn uniting the centres of the extreme Circles, the centre of the middle ring is found to be 12 feet 6 inches to the west of it.

"These Circles have been greatly injured. The largest consists of 9 erect and 5 prostrate stones; the north Circle has 6 erect and 6 prostrate, and a fragment of a seventh; and the south has 3 erect and 8 prostrate. In Dr. Borlase's time they were in a slightly better condition. A pen-and-ink sketch made by him, which is extant in one of Dr. Stukeley's volumes of original drawings, represents the middle Circle as consisting of 7 erect and 10 prostrate stones; the north of 10 erect and 6 prostrate; and the south of 3 erect and 9 prostrate. The stone to the east of that marked C in the plan of the middle Circle is the highest, and is 5 feet 8 inches out of the ground, and appears to have been wantonly mutilated recently. Two of the prostrate stones of the north Circle are 6 feet 6 inches in length.

"About 17 feet south from the centre of the middle Circle there is a prostrate stone 4 feet long and 15 inches wide at one end. It may possibly have been of larger dimensions formerly, and been erected on the spot where it now lies, but as Dr. Borlase has omitted it in his sketch it is probably a displaced stone of the ring.

"If we allow, as before, an average interval of 12 feet between the stones, there will have been about 28 pillars in the north, 26 in the south, and 33 in the middle Circle.

"At a distance of 409 feet westwards from K in the middle Circle there are 2 stones, 7 feet apart, both inclined northwards. One is 4 feet 11 inches in height out of the ground, and overhangs its base 2 feet 7 inches; the other is 5 feet 4 inches high, and overhangs 18 inches."[1]

I next come to Stanton Drew.

I will begin by giving a short account of the stones which remain, abridged from the convenient pamphlet prepared for the British Association meeting at Bristol in 1898 by Prof. Lloyd Morgan.

The circles at Stanton Drew, though far less imposing than those of Avebury and Stonehenge, are thought to be more ancient than are the latter, for the rough-hewn uprights and plinths of Stonehenge bear the marks of a higher and presumably later stage of mechanical development. Taken as a group, the Somersetshire circles are in some respects more complex than their better known rivals in Wiltshire. There are three circles, from two of which "avenues" proceed for a short distance in a more or less easterly direction; there is a shattered but large dolmen—if we may so regard the set of stones called "the cove"; and there are outlying stones—the "quoit," and those in Middle Ham—which bear such relations to the circles as to suggest that they too formed parts of some general scheme of construction.

The "quoit," lying in an orchard by the roadside, has nothing very impressive about its appearance—a recumbent mass of greyish sandstone; but it seems to be a brick in the Stanton Drew building. By some regarded as a sarsen block from Wiltshire, it is more probably derived from the Old Red Sandstone of Mendip. In any case it is not, geologically speaking, *in situ*; nor has it reached its present position by natural agency.

With regard to two of the megalithic circles, at first sight the constituent stones seem irregularly dotted

FIG. 13.—The Circles and Avenues at Stanton Drew. Photograph of 25-inch Ordnance Map, giving approximate azimuths of sight-lines.

[1] "The Prehistoric Stone Monuments of the British Isles: Cornwall." By William Collings Lukis, M.A., F.S.A., Rector of Wath, Yorkshire. P. 4.

about the field; but as we approach them the unevenly spaced stones group themselves.

The material of which the greater number of the rude blocks is composed is peculiar and worthy of careful examination. It is a much altered rock consisting, in most of the stones, of an extremely hard silicious breccia with angular fragments embedded in a red or deep brown matrix, and with numerous cavities which give it a rough slaggy appearance. Many of these hollows are coated internally with a jasper-like material, the central cavity being lined with gleaming quartz-crystals.

The majority of the stones were probably brought from Harptree Ridge on Mendip, distant some six miles. Weathered blocks of Triassic breccia, showing various stages of silicification, there lie on the surface; and there probably lay the weathered monoliths which have been transported to Stanton Drew. It is important to note that they were erected unhewn and untouched by the tool. A few stones are of other material—sandstone, like the "quoit," or oolite from Dundry.

In the great circle, of the visible stones some retain their erect position, others are recumbent, several are partially covered by accumulation of grass-grown soil. Others are completely buried, their position being revealed in dry seasons by the withering of the grass above them.

To the east of this circle a short avenue leads out, there being three visible stones and one buried block on the one hand, and two visible stones on the other. But one's attention is apt to be diverted from these to the very large and massive megaliths of the small N.E. circle. This is composed of eight weathered masses, one of which (if indeed it do not represent more than one), Prof. Lloyd Morgan tells us, is recumbent and shattered. From this circle, all the stones of which are of the silicious breccia, a short avenue of small stones also opens out eastwards.

The third or S.W. circle lies at some little distance from the others. The average size of the stones is smaller than in either of the other circles, and not all are composed of the same material.

"The Cove," which has been variously regarded as a dolmen, a druidical chair of state, and a shelter for sacrificial fire, is close to the church.

The dimensions and number of stones are as follow:—

Great Circle,	diameter 368 feet,	30 stones.
N.E. ,,	,, 97 ,,	8 ,,
S.W. ,,	,, 145 ,,	12 ,,

We now pass from general descriptions of the circles to the azimuths of the sight lines already referred to, so far as they can be determined from the published Ordnance maps.

To investigate them as completely as possible without local observations in the first instance, I begged Colonel Johnston, R.E., C.B., the Director-General of the Ordnance Survey, to send me the 25-inch maps of the sites giving the exact azimuth of the side lines. This he obligingly did, and I have to express my great indebtedness to him.

Of the various sight lines found, those to which I wish to direct attention in the first instance, and which led me to the others, are approximately, reading the azimuths to the nearest degree,

Hurlers Lat. 50° 31′ N.	Az.	Stanton Drew Lat. 51° 10′ N.	Az.
S. circle to central circle	N. 12° E.	Great circle to Quoit	N. 17° E.
Central to N. circle	N. 15° E.	S.W. circle to great circle	N. 20° E.
N. circle to tumulus	N. 19° E.		

For the purposes of a preliminary inquiry in anticipation of the necessary local observations with a theodolite, for which I am making arrangements; assuming hills half a degree high, which roughly compensate the refraction correction so that we may use sea-horizon values, we have the following declinations approximately:—

The Hurlers. Lat. 50° 31′	Stanton Drew. Lat. 51° 10′
Dec. N. $38\frac{1}{2}°$	Dec. N. 37°
,, 38°	,, $36\frac{1}{2}°$
,, 37°	

Here, then, we have declinations to work on, but declinations of what star? To endeavour to answer this question I prepared a diagram showing the declination of the three brightest stars in the northern heavens, having approximately the declinations in question for the period 0 to 2500 B.C. The calculations for 0 to 2000 B.C. are taken from the tables published by the Astronomisches Gesellschaft,[1] and have been completed from 2000 to 2500 B.C. by Dr. Lockyer.

Vega is ruled out as its declination is too high. The remaining stars Capella and Arcturus may have been observed so far as the declinations go. For time limits we have:—

Dec. N.	Capella.	Arcturus.
$38\frac{1}{2}$	500 B.C.	1550 B.C.
36°	1050 ,,	1150 ,,

The interesting fact must be pointed out that about 1000 B.C. the declination of the two stars was very nearly the same.

Now there is no question as to which of these two stars we have to deal with, for I find by the use of a precessional globe that for about 1400 B.C. and 800 B.C. the warning stars were as follows for the critical times of the year, *i.e.* May, August, November, February.

	1400 B.C.	Az.	800 B.C.	Az.
May	Pleiades rising		Pleiades rising	
Aug.	Arcturus rising	N. 14° E.	Sirius rising	
Nov.	Capella setting		Betelgeuse rising	
Feb.	Capella rising	N. 29° E.	Capella rising	N. 21° E.
		Dec. 34° N.		Dec. 37 N.

It is quite clear, then, that we have to deal with Arcturus, and this being so, the approximate dates of the use of the three circles at the Hurlers can be derived. They are:—

		B.C.
Southern circle aligning Arcturus over centre of	central circle	1600
Central ,, ,, ,,	N. circle	1500
Northern ,, ,, ,,	tumulus	1300

I have already pointed out that Mr. Penrose found the warning star for May morning at the date of foundation of the Hecatompedon, 1495 B.C., to be the group of the Pleiades. As the foundations of the Hecatompedon were only built some few years before the stones of the central circle of the Hurlers were used, we ought to find traces of the observations of the same May morning stars. We do; there is a stone with amplitude E. 15° N., which, when aligned from the S. circle, would have pointed out the rising place of the Pleiades in 1300 B.C., that is, the date we have already found from the observations of Arcturus. I regard this as an important confirmation of the time of the use of the temple, all the more as the high situation of the circles, not generally dominated by higher levels for some miles, renders it probable that large corrections for hills will not be required to be made.

There are alignments in connection with the N. circle which indicate the introduction of the solstitial year, but these and some others may wait until local observations have been made before more is said about them.

With regard to Stanton Drew, it is clear that we are there also dealing with Arcturus. Mr. Dymond's

[1] Dr. O. Danckworth, *Vierteljahrschrift der Astronomischen Gesellschaft*, 16 Jahrgang 1881, p. 9.

levels give an idea of the height of the hills, so with the Ordnance map azimuths, read to 1°, the dates of the use of the great and S.W. circles are approximately as under:—

	B.C.
Great Circle	1260
S.W. Circle	1075

We seem, then, to have made a step in advance. More accurate readings of the Ordnance maps and accurate determination of the heights of hills may vary the above values slightly. But that is an unimportant detail if it can be shown that we have a new method of dating what went on in prehistoric Britain at the time when the Athenians were building the Hecatompedon.

A great amount of local theodolite work has to be done, for while Mr. Lukis only referred to two outstanding stones at the Hurlers, there are many more marked on the Ordnance map; there are also others besides the "quoit" at Stanton Drew.

I am more rejoiced than I can say to know that this local work has already been begun under the best possible conditions. As it was impossible for me to leave London when the significance of the alignments was made out, I appealed to the authorities of University College, Bristol, and of the Royal Cornwall Polytechnic Society for aid. The principal of the college, Prof. Lloyd Morgan, together with Prof. Morrow and his engineering class, have already made observations at Stanton Drew, and Captain J. S. Henderson, of Falmouth, an accomplished surveyor, sent me last week from the Hurlers the angular heights along some of the alignments, the means of eight readings obtained with a 6-inch theodolite, both verniers and reversed telescopes being employed. Other students of science besides myself will, I am sure, feel their indebtedness for such opportune help.

Norman Lockyer.

BRITISH ASSOCIATION GEOLOGICAL PHOTOGRAPHS.

The geological photographs committee of the British Association and its indefatigable secretary, Prof. W. W. Watts, are to be congratulated on the third issue, which completes the first series, of their admirable photographs. There are twenty-four photographs in this issue, all of great interest, showing much skill in technique, and considerable artistic power in the choice of the point of view from which the objects were taken. They treat of a variety of subjects, chiefly the action of wind and rain, frost and ice, and sea-waves, igneous intrusion, the character of sedimentary rocks, and structures due to faulting and folding.

There are two good pictures of the remarkable rain-eroded pillars of Old Red Conglomerate which occur at Allt Dearg, on the Spey, Morayshire, and remind us of the similar forms which may be seen in much younger deposits on the right side of the Brenner as we travel towards Italy. They were first figured by Sir Archibald Geikie, who provides a description to the photographs, in which he directs attention to the comparative rapidity of their formation, as shown by the fact that "some of these isolated stacks of conglomerate are capped by boulder clay, and their capitals may here and there be seen to have retained their covering of thick peaty soil."

The photograph of the tower of Eccles Church, an object made so familiar by Lyell's "Principles," is the last that was taken (in 1886), and the last that will be taken, for the tower itself was destroyed in 1895. Prof. Reynolds's photograph of the great Axmouth landslip gives a good view of the "mighty chasm which separated the foundering mass from the land." The original describers of this were Buckland and Conybeare, and a water-colour copy by Ruskin of Mrs. Buckland's drawing still hangs in the University Museum at Oxford. Of queer forms the "Rock and Spindle," St. Andrews, Fifeshire, photographed by Mr. G. Bingley and described by Prof. Bonney, and "Lot's Wife," Marsden, Durham, a "breccia gash" transformed into a sea-stack, described by Prof. Lebour, are among the quaintest; they would be good puzzles to set a student in examination. The most novel subject is the wind-worn surface of granite disclosed beneath the Keuper marl in the Mountsorrel quarry, one of the several proofs discovered by Prof. Watts of the desert conditions which prevailed in these islands and elsewhere during a part of the Trias period. We have selected this for reproduction.

Fig. 1.—Keuper marl resting on terraced granite surface; Mountsorrel Quarry, Leicestershire. Photographed by Prof. H. E. Armstrong, F.R.S.

As this is the last issue of the first series it is usefully accompanied by some introductory letterpress, which includes the names of the committee, a preface, table of contents, and other information. We learn from the preface that the idea of forming a systematic collection of geological photographs originated with Mr. Osmond W. Jeffs in 1889; to carry it out a committee of the British Association was appointed in 1890, and Mr. Jeffs acted as secretary until 1896, by which time 1412 photographs had been contributed. In 1895 Prof. W. W. Watts became secretary, and by 1903 the collection had grown to the magnificent total of 3754. It is housed in the Museum of Practical Geology, 28 Jermyn-street, S.W. The series issued to subscribers and just completed consists of a selected number (72) of these photographs, taken from negatives generously lent by their owners, and furnished with descriptions by many of the leading geologists of the day.

The success of the scheme is shown by the fact that it has resulted in a considerable profit; of this one half has been returned to the subscribers in the form of additional whole-plate photographs, and the other half will provide funds for carrying on the work of the committee for at least four years. In a strictly business undertaking it is to be presumed that a good slice of the profits would disappear in "wages of superintendence," and subscribers may therefore regard their additional photographs as a gift from Prof. Watts.

THE SOCIETY OF ARTS AND THE LONDON INSTITUTION.

On Wednesday next a special meeting of proprietors of the London Institution will be held to consider a scheme for its amalgamation with the Society of Arts. Founded in 1805 by merchants and bankers of the City of London, given a charter two years later, and housed in its present imposing, if rather sombre, premises in 1819, the London Institution has done good work in its day. The object of its founders was to maintain, in what was then a central position, an extensive general library of reference, comprising works of intrinsic value and utility in all languages; to provide reading rooms for periodical publications and interesting contemporaneous pamphlets; and to promote the diffusion of knowledge by lectures and *conversazioni*. But since the foundation of the institution circumstances have greatly changed, and not to the advantage of the institution. In 1817, and for many years afterwards, the City contained a large residential population, which for a long time past has been gradually disappearing, until now the number of proprietors who use the institution as a centre of intellectual culture is comparatively small, and is more likely to grow smaller than to increase. In these circumstances the board of management has recognised that if the institution is to live and thrive some scheme must be devised for increasing its usefulness, and the proposal to amalgamate with the Society of Arts is the outcome of prolonged consideration of a difficult problem.

The Society of Arts carries on to a large extent work of the same nature as that for which the London Institution was founded, but whereas the institution has suffered from residential changes, the society was never more prosperous. But it, too, has had its ups and downs. In the early 'forties of the last century it began to show signs of decrepitude, and in 1841 a committee was appointed to examine its position and make recommendations. But little seems to have been done until measures were taken for obtaining a Royal Charter of Incorporation, which was granted in 1847. Then it was proposed to hold an exhibition of English industry. Prizes for modern industrial art were offered, and eagerly competed for, and by 1850 the membership had risen again to 1500. An exhibition of ancient and mediæval art was held which was very successful, and a proposal to hold an international exhibition culminated in the Great Exhibition of 1851. Since then the Society of Arts has done much good work in promoting industrial art and encouraging inventive genius. The prosperity of the 'fifties was followed by some lean years, but for a generation past it has been highly prosperous, largely owing to the sagacious guidance of its present secretary. Sir Henry Wood has always attached great importance to the constitution of the council of the society. He has not only sought for and found eminent men, he has got those who were willing to give time and attention to the affairs of the society, men like Sir Frederick Bramwell, Sir F. Abel, Sir W. Siemens, Sir Douglas Galton, Lord Alverstone, Sir J. W. Barry, Sir W. Preece, the Duke of Abercorn, and Sir W. Abney. All these gentlemen have served as chairmen of the council, and the society owes them much.

Both institutions are financially strong. The London Institution possesses a site which is worth at least 150,000*l.*, besides a fund invested in consols of the present value of 31,000*l.* Its income in 1903 was 3583*l.*, and its expenditure was 3616*l.* The Society of Arts has an annual income which last year exceeded 11,000*l.*, a capital fund of about 20,000*l.*, which has accumulated from surplus income during the last twenty years, and trust funds amounting to nearly 15,000*l.* What, then, are the inducements to the one institution and the other to consent to an amalgamation? It is not proposed that either should absorb the other. The suggestion is amalgamation into a single body for the promotion of science, art, and literature, and their practical applications, the members of each corporation preserving all their present rights, and sharing in the government of the new institution and in the direction of its future action.

The determining consideration with the Society of Arts is that the amalgamation would give it a permanent local building. The society does not own its premises. They were built for it by the Brothers Adam in 1774, but the lease has run out, and it is now practically a tenancy at will. Moreover, the building is inadequate for the growing needs of the society, and the funds at its disposal are not sufficient to enable it to build for itself, whereas by amalgamation with the London Institution, which would sell its Finsbury premises, ample funds would be available. It is believed that the accommodation required could be got for a sum of 100,000*l.*, and a suitable site found "east of Charing Cross and west of Chancery Lane." If it were decided to erect a building of sufficient size there are several other societies who would probably be prepared to join in the scheme, separate and distinct accommodation being provided for each, much as Burlington House now accommodates a number of independent institutions.

The amalgamation would give the London Institution a large accession of annual income, and the revenues of the new institution would justify the extinction in perpetuity of the annual payment of two guineas now required from the proprietors of the London Institution, while leaving them a permanent property in their shares disposable by will, or otherwise, as heretofore, the Society of Arts having approved of this as one of the terms of amalgamation. It would be part of the arrangement that any proprietor preferring to withdraw from the scheme and to surrender his share would be enabled to do so, and be paid 25*l.* in discharge of his rights and interests in such share. Those who remained would be members of an institution of very great importance and influence, well endowed, and in a position to carry into effect many objects of the highest public, scientific, and economic importance.

It is not to be supposed that the proposed amalgamation will be carried through without encountering opposition, but it will probably be found that a very large majority of both institutions is prepared to accept it. In the opinion of eminent counsel, the effect of its charter is to constitute the London Institution in a legal sense a charity, with the result that its property and funds are impressed with a charitable trust, and cannot be divided or applied to any other purpose than that prescribed by the charter. Consequently, the property could not be divided up without serious risk. If the amalgamation is to be carried through, the most convenient and least costly way of carrying it into effect would be to promote an Act of Parliament for the purpose, and, granted the authorisation of general meetings, this will be done. But an Act cannot be got until next year, and a site for the new building can hardly be secured before the Act is got, so that if all goes smoothly, a year or two must elapse before the united societies, to be known as "The Society of Arts and the London Institute," can receive their friends under the altered conditions, and in their new premises.

The idea of thus combining into a single body two scientific institutions, each of considerable importance, is a bold and novel one, and it is to be hoped that it may not fail of success. It would be a pity if any narrow views or selfish considerations hindered the carrying out of a very interesting experiment. Each of the two corporations can supply much of what the other lacks. The constitution of the London Institution is unfortunate. It consists of a body of shareholders, the descendants or heirs of the original founders, many of whom are naturally out of sympathy with the objects of the institution, and no means exist of introducing fresh blood or attracting to its membership the men who would most fitly carry on its proper work. Very early in its career the kindred Royal Institution altered its constitution, disendowed its proprietors, and adopted a more popular and democratic organisation. Its unfailing success ever since has proved the wisdom of the change. But the Finsbury institution possesses considerable property. It has a magnificent library. Its list of members is still a showy one. It only requires the infusion of fresh blood; it wants new life and vigour. The Society of Arts is a very popular and vigorous body, full of life and energy. It does much really useful public work. Its examinations, for instance, attract more candidates than that of any other private body in the kingdom. Its Cantor lectures (which are always freely open to London students) are a valuable educational agency. But it is hampered by want of larger offices, its library is far from being a credit to it, and it might well devote more attention and more funds to purposes of research and investigation.

A new institution such as should be formed ought to possess the good points of both its parents, while avoiding the weaknesses of either. It might also form a nucleus round which might gather many of the smaller societies, now often inadequately housed. In a suitable building accommodation might well be provided for many other societies, scientific, literary, and artistic, which are now scattered about in various quarters of London.

Even a larger scheme is conceivable. Burlington House can find room for but a small proportion of the scientific bodies of London. Why should not this proposed amalgamation lead to the erection of a second Burlington House, of which those of our larger and richer societies who are not satisfied with their premises should erect each their own part, independent certainly of one another, and yet combined under a common roof?

NOTES.

Lord Kelvin, who has been out of health for some time, underwent a serious operation on March 29. He passed a restless night on March 30, but has much improved since then, and appears to be making satisfactory progress toward recovery. The King and the Prince and Princess of Wales have made special inquiries as to his condition; and there have been numerous callers.

Sir William Ramsay, K.C.B., F.R.S., has been elected a member of the Athenæum Club under the provisions of the rule which empowers the annual election of nine persons "of distinguished eminence in science, literature, the arts, or for public services."

It is reported by the Exchange Telegraph Company that a violent earthquake occurred at Lahore on Tuesday, April 4, causing serious loss of life and great damage to public buildings and other property.

A grant of 30,000*l.* has been authorised by the Carnegie Institution, *Science* states, for the solar observatory on Mt. Wilson. It is expected that the first equipment will cost about twice this sum.

We learn with sincere regret that Prof. Pietro Tacchini, formerly director for many years of the astronomical observatory of the Collegio Romano, and of the Central Office for Meteorology and Geodynamics at Rome, died on March 24 at sixty-seven years of age.

The *Times* states that the Chartley herd of white cattle has just been purchased by Mr. J. R. B. Masefield, of Cheadle, Staffordshire, on behalf of the Duke of Bedford, who has come forward and saved the herd from leaving the country or falling into the hands of the taxidermist.

An agricultural education and forestry exhibition will be held in connection with the show of the Royal Agricultural Society at Park Royal on June 27–30. Any offers of exhibits, or inquiries, should be addressed to the secretary of the society, at 13 Hanover Square, London, W.

The Easter excursion of the Geologists' Association will be to mid-Lincolnshire. The party will leave London for Grantham on Thursday, April 20, and after visiting several places of geological interest will leave Lincoln for London on Wednesday, April 26. The excursion secretary is Mr. W. P. D. Stebbing, 8 Playfair Mansions, Queen's Club Gardens, London, W.

A great historical pageant is in active preparation at Sherborne, Dorsetshire, to commemorate the 1200th anniversary of the founding of the town, bishopric, and school by St. Ealdhelm, A.D. 705. The pageant, which will be presented in the ruins of Sherborne Castle on June 12–15, will take the form of a folk-play written by Mr. Louis N. Parker and dealing with the chief historical events of the town.

The death of Dr. L. Bleekrode, of the Hague, is announced in the *Chemical News*. Dr. Bleekrode's work was principally connected with electrical matters, his first paper, in 1867, being on the influence of heat on electromotive force. In 1870 he wrote a paper on a curious property of gun-cotton; other papers dealt with electrical conductivity and electrolysis in chemical compounds, observations on the microphone, &c.

We regret to see the announcement of the death, on March 25, of the eminent German metallurgist, Prof. Bruno Kerl, at the age of eighty-one. He was professor of metallurgy at the Clausthal School of Mines, and subsequently at the Berlin School of Mines, and was the author of a number of metallurgical works. His first book, on the smelting processes of the Upper Hartz, was published in 1852. His important treatise on metallurgy was translated into English by Sir W. Crookes and E. Röhrig in 1868. His books on assaying were also translated.

The importance of the application of mathematics to engineering problems has frequently been insisted upon in these columns. Another instance of the close connection between pure and applied science is afforded by an investigation of some disregarded points in the stability of masonry dams, by Prof. Karl Pearson and Mr. L. W. Atcherley, referred to by Sir William Garstin in connection with the scheme for raising the Nile dam, in a recent report to the Egyptian Council of Ministers. It appears that the theory of stresses upon masonry dams requires important modifications, which will have to be taken into consideration in all future designs for such works. We understand that much experimental work on the subject is at present in progress, and that results of great interest to hydraulic engineers may be expected.

The anniversary dinner of the Chemical Society was held at the Whitehall Rooms, Hôtel Métropole, on March 20, when the president, Prof. W. A. Tilden, was in the chair, and many leading representatives of the physical sciences were present. Sir William Church, in giving the toast of "Prosperity to the Chemical Society," spoke of the advances which chemical science has made, and declared that the advantages which have accrued to the United Kingdom, as a result of the work of chemists, cannot be over-estimated. Prof. Meldola submitted the toast of "Scientific Institutions," which was responded to by Prof. J. Larmor and Dr. R. T. Glazebrook. Sir William Ramsay proposed the toast of "The Guests," and in replying Mr. Haldane said that as science never stood still, but progressed continually, so the Government of this country must, if the nation is to hold its own, make an increasing use of science in all departments of the State service. He expressed the belief that in the course of the next few years the position of science in the Government of the country will be much more prominent, and that scientific methods will become much more general. Prof. Perry also spoke.

A meeting of the Institution of Naval Architects will be held at the Society of Arts, John Street, Adelphi, on April 12–14. Lord Glasgow, president of the institution, who will occupy the chair, will deliver his address on April 12; and Mr. W. E. Smith, C.B., Colonel N. Soliani, and Mr. Herbert Rowell will submit papers for discussion. On April 13 Prof. J. H. Biles will read a paper on the strength of ships, with special reference to experiments and calculations made upon His Majesty's ship *Wolf*, and other papers will be submitted by Mr. F. H. Alexander, Mr. J. Bruhn, Mr. R. E. Froude, Mr. C. E. Stromeyer, Mr. A. W. Johns, and Herr S. Popper. Among the papers to be read on April 14 is one on the Admiralty course of study for the training of naval architects by Mr. E. L. Attwood, and another on submarine signalling by means of sound by Mr. J. B. Millet, of Boston, U.S.A.

The Royal medals of the Royal Geographical Society for this year have been awarded to Sir Martin Conway (founder's medal) for his explorations of various mountain regions of the world, and his work among the islands of Spitsbergen; and to Captain C. H. D. Ryder, R.E. (patron's medal), for the important and extensive work which he accomplished while acting as principal survey officer on the recent Tibet Mission. The Victoria research medal, for distinguished service to the cause of geographical research, as distinguished from exploration, has been awarded to Mr. J. G. Bartholomew. The Murchison grant goes to Mr. William Wallace, C.M.G., Deputy High Commissioner of the Northern Nigerian Protectorate. Colonel F. R. Maunsell, R.A., has been awarded the Gill memorial for his explorations during many years' residence in Asia Minor; Mr. F. J. Lewis the Cuthbert Peek grant for contributions to the knowledge of botanical distribution by his researches into the geographical distribution of vegetation in the north of England; and Captain Philip Maud, R.E., the Back grant for survey work in 1903 along the southern border of Abyssinia.

The concluding issue of the *Proceedings* of the Philadelphia Academy for 1904 contains the reports of the secretaries and curators for that year, from which it appears that the society continues to be in a flourishing condition, both as regards its publications and its museum.

In an article published in *Naturen* for March, Mr. J. Rekstad shows the value of photography to illustrate the secular variation in glacier terminations, the respective differences between two glaciers in August, 1899, and September, 1903, being admirably exhibited. In both instances, it may be remarked, there has been very decided shrinkage in the length of the glacier. The value of photographs of this nature as a basis of comparison in the years to come will be very great.

We have been favoured with a copy of No. 17 of the *Boletin* of the Institute of Mining Engineers of Peru, which contains an account of certain annelid remains and ammonites in the Salto del Fraile and Morro Solar districts by Mr. C. I. Lisson. Both formations appear to be of Neocomian age, the higher beds of Salto del Fraile being remarkable for the number of borings of annelids of the genus Tigillites they contain, while the lower Morro Solar stratum is noteworthy for its ammonites of the group Sonneratia.

In the *Report and Transactions* of the East Kent Scientific and Natural History Society for the past year, the secretary takes occasion to direct attention to the general apathy towards matters scientific prevailing in that portion of the county he represents. Owing to this cause, the season's excursions were practically a failure, and there may be some connection between this apathy and the fact that it has hitherto been found impracticable properly to arrange and display the natural history collections in the Royal Museum.

The *Zoologist* for March opens with an article by Mr. Lydekker on the small Asiatic mountain antelopes known as gorals. The main object of the article was to describe the Burmese species; but in the course of his investigation the author was led to believe in the existence of two Himalayan representatives of this group, one of which he names *Urotragus bedfordi*, on account of the type specimen having lived in the park at Woburn. In the penultimate line on p. 84 we notice that the word "eastern" should be "western." The second article, by Mr. John Gurney, is devoted to Norfolk bird-life in 1904, and it is interesting to note that in the spring of that year the author had the good fortune to see two avocets and seven spoonbills on Breydon Broad.

From the fisheries branch of the Department of Agriculture and Technical Instruction for Ireland we have received a copy of No. 4 of *Scientific Investigations*, containing an account by Messrs. Holt and Tattersall of schizopod crustaceans from the north-east Atlantic slope, and a note on one genus of the same group by Dr. Calman. In proposing several new generic types, the authors of the first paper suggest that these may prove of only temporary value, and add the remark that these, if not forgotten, "will, at least, cease to be harmful whenever the fashion of reviving deservedly forgotten names has run its due course." Dr. Calman proposes the name Nematobrachion to replace his Nematodactylus of 1896, which he regards as preoccupied by Richardson's Nemadactylus. Evidently neither of the three authors are in sympathy with the rules for nomenclature in zoology drawn up by the Paris committee.

Dr. T. H. Montgomery, in the *Proceedings* of the American Philosophical Society for the last quarter of 1904, runs a tilt at the generally accepted view as to the morphological superiority of the male sex in animals. Among invertebrates, he urges, it is always the male which is of inferior size and development, while as regards vertebrates, although the males have in many cases secured superiority in the matter of bodily size and secondary sexual characters, yet, as regards the generative organs (notably the suppression in certain instances of one ovary), the advantage, from the point of view of specialisation and development, is largely on the side of the female. While admitting that different morphologists might estimate the value of these characters differently, the author is inclined to give the greatest morphological value to the higher development of the reproductive organs.

In discussing in the same issue the origin of the markings of organisms, the late Prof. Packard arrived at the conclusion that these are dependent on the physical rather than on the biological environment. The alleged instances of "Müllerian" mimicry he explained, for example, by convergence due to the action of similar physical and climatic causes, since he regarded the attacks of birds as a negligible factor. Again, the frequent instances of colour and pattern resemblance between different animals he attributed to pigmentation caused by exposure to sunlight and shade, due to the repetition of fundamental colours. "To claim that Müllerian mimicry," he added, "is due to the attacks of birds, is to overlook the fact of the existence of stripes, bars, and spots on the wings of palæozoic insects which flourished before the appearance of birds, and even of modern types of lizards."

The *Report* on the third outbreak of plague at Sydney in 1903 by Dr. Ashburton Thompson is interesting as showing how an epizootic of plague among the rats preceded the two cases of human plague. From July 15, 1902, to April 30, 1903, 31,075 rats were caught, of which 17,160 were examined and found to be free from plague. On May 12 a rat was found on certain premises which on examination proved to be infected with plague, and up to August 15 14,671 rats and mice were caught, of which 111 rats and 50 mice were ascertained to be infected with plague. From then until December, 1903, 13,389 rats and mice were captured of which none was infected. The two human cases occurred on June 20 and July 4, *i.e.* during the period when the epizootic existed among the rodents.

The February number of *Indian Public Health* (i., No. 7) contains several papers of interest, notably one criticising the plague policy of the Indian Government, in which it is concluded that the only way to grapple with the plague problem is the formation of a properly organised and equipped *permanent* public health service for the country.

In the course of a report on the characters and analyses of sweet potatoes cultivated in Jamaica, Mr. H. H. Cousins, writing in the *West Indian Bulletin* (vol. v., No. 3), records the fact that the process of cooking increases the sugar content of sweet potatoes very considerably. Further experiments are being undertaken to ascertain the exact chemical nature of the change. A comparison of tubers freshly dug with others that had been stored for some weeks indicated that during storage there is also a development of sugars at the expense of other substances in the tubers.

Various kinds of citrus fruits, including oranges, pomeloes, grapefruit, and more particularly lemons and limes, are liable to suffer from the ravages of a parasitic fungus, *Colletotrichum gloeosporioides*, which attacks the leaves, causes spot or canker on the fruit, or brings about abscission of the inflorescence. The fungus has been reported from various orange-growing countries, and on account of its partiality for limes, planters in the West Indies will do well to consult the account by Mr. P. H. Rolfs which is published in the *Bulletin*, vol. iii., part ii., of the Department of Agriculture, Jamaica.

The publication of pamphlets dealing with the cultivation, varieties, and market requirements of well known commercial plant products, as instituted by the director of the Royal Botanic Gardens, Ceylon, is a practical and important phase in the development of economic botany. In vol. ii., Nos. 23 and 25, of the *Circulars* of the gardens, Mr. H. Wright takes up the subjects of ground nuts and castor oil plants. The best quality of ground nuts, and these can be grown in Ceylon, are bought for eating, but the demand is limited; on the other hand, the requirement of the nuts for oil-crushing, although the price is less remunerative, is practically unlimited, and the cake furnishes an excellent cattle food. In the castor seed trade it does not appear that Ceylon will become a formidable rival to India.

The Cerro de Pasco silver mines are the most remarkable in Peru, having been worked since the year 1630. At the present day operations are chiefly confined to the reworking of old slags and waste heaps. On March 21, 1902, a Government Commission was appointed to make a survey of these mines, and the report of the commission has now been published in the form of a *Boletin* issued by the Peruvian Corps of Mining Engineers. Illustrations and descriptions of the smelting works are given, and it is noted that the output in 1903 amounted to 7213 tons of matte containing 4071 tons of copper. It is curious that these ancient silver mines should develop as copper mines in depth.

A note in Nature for January 26 (p. 305) referred to Adelaide, in South Australia, and Coolgardie, Western Australia, as the places having the highest maximum temperatures recorded in the British Empire. Mr. W. E. Cooke, Government astronomer of Western Australia, writes to say that Marble Bar, in the north-west division of that State, is very much hotter than Coolgardie. The *mean* of the daily maximum temperatures for January, 1905, was 109°·8, and the highest reading 120°·5. He adds that at Jacobabad, in India, the *average* daily maximum temperature is 111°·6 in May, 112°·7 in June, and 107°·8 in July, and at Duem, in the Egyptian Soudan, the mean maximum for March, 1902, was 114°·4, and the absolute maximum 127°·4.

We have received from Mr. J. van Breda de Haan a copy of a valuable series of meteorological observations made during the year 1901 at the State Botanical Gardens at Buitenzorg, Java. The observations are made with the view of explaining certain problems connected with vegetable physiology, and consequently special attention is given to air and underground temperature, humidity and sunshine, and more particularly to the intensity of rainfall showers. Observations and monthly means are given for several hours of each day, in addition to daily means.

The *Quarterly Journal* of the Royal Meteorological Society for January last contains an interesting paper on the decrease of fog in London during recent years. The results are given for months and for seasons for each of the thirty-three years 1871 to 1903, based upon the observations for London (Brixton) published in the daily weather report of the Meteorological Office. The mean annual number of foggy days is 55, of which 45 occurred in the winter half of the year. Dividing the thirty-three years into three equal periods, the result is, for the first period, a mean of 55, for the second 69, for the third only 41. Since the year 1888 a steady and uninterrupted decrease is shown in the mean annual number of fogs. Among the principal agencies which may have conduced to this desirable result must be mentioned the efforts of the Coal Smoke Abatement Society and the London County Council, also the use of incandescent gas light and electricity; but, as pointed out by Captain A. Carpenter and Mr. C. Harding, the increase of wind in recent winters is probably chiefly responsible for the decrease of fog. As we have remarked before, the geographical situation of London is, from a purely meteorological point of view, eminently favourable to the development of fog, and the only permanent improvement we can hope for is an abatement of its more injurious effects caused by the imperfect consumption of coal and gas.

We have received a copy of part i. of the "Katalog der Bibliothek der Naturforschenden Gesellschaft in Danzig," published at Danzig in 1904. Although the list of books included is not completely representative, this publication, containing the sections mathematics and astronomy, may be found useful to those desiring to refer to the works of certain authors on these two subjects. The range of subjects is a wide one, and the books are entered under the names of the authors.

Having occasion recently to devise a short-focus spectrograph, Prof. Wood, of the Johns Hopkins University, found it necessary to make a study of the distribution of light (monochromatic) in the different orders of a typical grating. His method, a beautifully simple one, is described and illustrated in No. 2, vol. xxi., of the *Astrophysical Journal*. The result showed that, in the typical grating experimented with, half the reflected light was concentrated in one spectrum, and as the grating reflected about 76 per cent. of the total incident light, this means that about one-third of this total was found in the one spectrum, which was one of the two first orders. It was also found that the ruling makes little or no difference to the total reflecting power of the speculum. Two flint prisms of 60° would give about the same average dispersion as that produced, and, according to Pickering's table in Kayser's "Handbuch," they would transmit a little more than twice the light reflected, in the first order of the grating used.

The *Psychological Bulletin*, ii., 2, contains reports of the proceedings of the thirteenth annual meeting of the American Psychological Association and of the fourth annual meeting of the American Philosophical Association, which were both held at Philadelphia on December 28–30. Abstracts of the papers are given. Invitations on behalf of Harvard University to hold the next annual meeting in Cambridge, Mass., to signalise the opening of the Emerson Hall of Philosophy were accepted by both associations, and it is proposed that the Western Philosophical Association and the Southern Society for Philosophy and Psychology shall also meet at the same time and place.

A coloured plate of a new species belonging to a new genus of Hydrachnidæ is given in the *Rendiconti* of the Lombardy Institution, xxxviii., 3, in illustration of a note by Mr. R. Monti on the new "find." This water mite was obtained in cold springs on the right bank of the Anza, near Ceppomorelli, and has been named *Polyxo placophora*. The same writer in another number of the same journal discusses the horizontal migrations of lacustrine plankton, and finds in mountain lakes that, in addition to the known vertical movements, there are well-marked diurnal migrations of the small crustacea to different parts of the lake depending on sunshine and shade.

In the March number of the *American Journal of Science* Mr. Charles S. Hastings utilises some observations of the power of accommodation of the eye for light of different wave-lengths to make a complete determination of the optical constants of the eye for all conditions of accommodation and for all colours. The results are given in two tables, by the use of which all problems connected with the purely optical properties of the schematic eye may be solved.

In the course of an investigation of radio-active muds which is published by Prof. G. Vicentini in the *Atti* of the Royal Venetian Institute (vol. lxiv., ii., 535), the connection existing between the ionisation produced by the mud and the quantity of material used is experimentally ascertained. When the mud is spread uniformly over a definite area, the intensity of the radiation increases as the thickness of the layer is increased, but a direct proportionality does not exist between them. After a certain point, moreover, the radio-activity is not increased by adding fresh material. Mr. H. S. Allen, in a paper read before the Royal Philosophical Society of Glasgow on January 25, also deals with radio-active water and mud, the material in this case being derived from the springs of Bath and Buxton. An interesting point which is established incidentally is that the fluorescence excited in a sensitive plate by the radium rays plays only a very minor part in the production by these rays of a photographic effect.

An interesting investigation of the secondary radiation produced when the β and γ rays of radium impinge on metallic plates is published by Prof. J. A. McClelland in the *Transactions* of the Royal Dublin Society (vol. viii., No. 14). It is shown that the secondary rays are not produced merely at the surface of the plate struck by the primary rays, but that they come from all parts of a layer of considerable depth. Apparently the less penetrating β rays are more efficient in producing a secondary radiation than the γ or highly penetrating rays. The nature of the secondary radiation depends largely on the character of the metal employed; the greater the atomic weight of the latter the greater is the amount of the secondary radiation produced by it. Of all the substances experimented with, lead gives rise to the greatest effect, both as regards the quantity of the secondary radiation and its penetrating power. The secondary radiation consists, apparently entirely, of a species of β rays, that is, of negatively charged particles capable of deflection in a magnetic field. Perhaps the most important feature of the paper lies in its directing attention to the necessity of considering secondary radiations in all measurements of the absorptive power of substances with regard to the rays produced by radio-active bodies.

We have received a copy of a memorandum on the construction and verification of a new copy of the imperial standard yard, by Mr. H. J. Chaney, superintendent of the Standards Department of the Board of Trade. Since the original standard yard of bronze was made some sixty years ago, it has been found that bars which are constructed of copper alloys do not retain their original length with that degree of accuracy now demanded for scientific purposes. The new copy (f.P.) is made of an alloy containing 89·81 per cent. of platinum and 10·10 per cent. of iridium, such an alloy being little affected by changes of temperature and not at all by oxidation; as the alloy admits of a high specular polish, the fine lines marking the extremities of the yard can be traced directly on the bar without the intervention of gold plugs or pins as in the older type. Instead of using the old solid 1-inch section, for the purpose of lightness the so-called "Tresca" section has been adopted. The memorandum gives full details of the verification of the length and a description of the apparatus used, including the thermometers by which temperature was measured and a new microscopic "comparator" similar to that used at Paris by the Comité international des Poids et Mesures. This instrument has been purchased by the Board of Trade and mounted in a special chamber at Old Palace Yard, Westminster.

Vessels of fused quartz can now be obtained commercially, and on account of the remarkable properties of this substance, a wide field of research at high temperatures would appear to be opened up by their use. In high temperature gas thermometry, for example, where glass is excluded on account of its comparatively low melting point, and platinum on account of its permeability to hydrogen, fused quartz promised to be an ideal envelope. Unfortunately, Villard has found that fused quartz is also permeable to hydrogen at high temperatures, well below its melting point, and Jacquerod and Perrot have proved that helium resembles hydrogen in this respect. In the current number of the *Comptes rendus* (March 27) M. Berthelot shows that the use of quartz vessels is still further limited, as both oxygen and nitrogen can penetrate into hermetically sealed quartz bulbs at 1300° C. Thus carbon, heated in sealed vacuous quartz tubes for half an hour at 1300° C., gave a mixture of nitrogen and carbon monoxide on cooling the tube and extracting the gases. Experiments were made on other substances, and all the facts pointed to the conclusion that at a high temperature fused silica behaves towards gases like an animal membrane, susceptible of endosmosis and exosmosis, the phenomenon depending partly on the thickness of the wall. It is clear, therefore, that before this substance can be used with confidence in high temperature work, a further study will have to be made of its defects in this direction.

The *Comptes rendus* for March 27 contain an interesting paper on the cryoscopic behaviour of hydrocyanic acid, by M. Lespieau. According to the views of Nernst and Thomson on the relation between the dielectric capacity and the power of electrolytic dissociation, the fact that the dielectric constant of prussic acid is higher than that of water should give the acid a higher dissociating power. M. Lespieau has accordingly carried out a series of experiments on the lowering of the freezing point of this substance by the addition of alcohol, chloroform, benzene, water, trichloracetic acid, sulphuric acid, potassium iodide and nitrate, and has found that for the first six substances the cryoscopic constant is between 19 and 20, whilst for the two latter it is approximately double. Hence the two acids, which are strongly dissociated in water, are not sensibly dissociated in prussic acid solutions of the same strength, and this is in accord with the experiments of Kahlenberg, who found that these solutions were bad conductors, these facts being in contradiction with Nernst's theory. On the other hand, the solutions of potassium salts in hydrocyanic acid were found by Kahlenberg to be better conductors than aqueous solutions of the same concentration, and this agrees with the cryoscopic results, according to which the two salts are nearly completely dissociated into their ions in prussic acid.

Mr. W. Woods Smyth will give a lecture on "The Bible in the Light of Modern Science" at Stafford Rooms, Tichborne Street, Edgware Road, to-morrow, April 7, at 5 p.m.

Messrs. Watts and Co. will shortly publish, for the Rationalist Press Association, Prof. Haeckel's "Evolution of Man," being a translation of the recently issued fifth edition of "Anthropogenie."

OUR ASTRONOMICAL COLUMN.

Comet 1905 *a* (Giacobini).—A second telegram from the Kiel Centralstelle announces that comet 1905 *a* was observed by Prof. Aitken at Lick on March 27. The position at March 27d. 7h. 57·1m. (Lick M.T.) was R.A. = 5h. 48m. 55s., dec. = + 12° 35′ 43″.

Apparently, then, the northern declination is increasing, and not decreasing as previously stated. An error in the key by which the code telegrams are translated substituted declination for N.P.D., so that the daily movement in declination should be read as *plus* 1° 15′.

The following elements have been computed by Dr. E. Strömgren from observations made on March 26, 28, and 30, and are given in *Circular* No. 76 of the Kiel Centralstelle, together with a bi-daily ephemeris extending from March 30 to April 23:—

Elements.

T = 1905 April 3·2098 (M.T. Berlin).

$$\left.\begin{aligned} \omega &= 357^\circ\ 9'\cdot49 \\ \Omega &= 156^\circ\ 7'\cdot94 \\ i &= 41^\circ\ 37'\cdot48 \end{aligned}\right\} 1905\cdot0$$

$\log q = 0\cdot05232$

Ephemeris 12h. (M.T. Berlin).

1905	α h. m. s.	δ	log Δ	Brightness
April 7	6 31 16	+25 26·9	9·8661	0·98
9	6 40 5	+27 39·9		
11	6 49 13	+29 48·1	9·8745	0·93
13	6 58 39	+31 50·9		
15	7 8 22	+33 47·9	9·8855	0·87

Brightness on March 26 = 1·0.

Photography of the Corona without a Total Eclipse.—According to a note communicated to the French Academy of Sciences, and in the opinion of M. J. Janssen, M. A. Hansky has succeeded in photographing the corona of the uneclipsed sun. The photographs were taken with a 12-inch telescope in the exceptionally transparent atmosphere which obtains at the observatory situated on the summit of Mont Blanc.

After a number of preliminary experiments on the selective absorption of screens dyed with various aniline colours, M. Hansky obtained a combination which absorbed all radiations more refrangible than 660 $\mu\mu$, and, as the red radiations of the corona are very intense and do not suffer absorption or dispersion in passing through the terrestrial atmosphere, he used this screen in obtaining twelve negatives. The individual screens were prepared by soaking a fixed undeveloped Lumière film in each of the suitable dyes, and, between each exposure, they were re-arranged *inter se* so that no false effect due to any particular disposition of the "grain" might affect the resulting picture. The direct photospheric and chromospheric rays were prevented from reaching the plate by the interposition of a blackened brass disc slightly larger than the solar disc.

The resulting negatives showed distinct halos around the disc, and, notwithstanding the fact that some time elapsed between the successive exposures, these halos exhibited the same form, thus testifying to their solar origin. Some of the negatives were photographically intensified by repeated copying, and reproductions of them were submitted to the academy. In presenting the communication M. Janssen—to whom M. Hansky acknowledges his obligations for assistance and advice—stated that "the photographs actually show the solar corona with an intensity and a perfection only known on the photographs obtained during total eclipses" (*Comptes rendus*, No. 12).

Search-ephemeris for Tempel's First Periodic Comet (1867 II).—Although Tempel's first comet has not been seen during its last three perihelion passages, *i.e.* since 1879, M. A. Gautier, of the Geneva Observatory, thinks that the probability of its re-discovery this year is great enough to justify a careful search. For this reason he re-publishes, in No. 4008 of the *Astronomische Nachrichten*, the elements he prepared for the 1898 apparition, reduced to the mean equinox of 1905·0. As the probable time of perihelion is somewhat uncertain, he gives three ephemerides, extending from March 31 to July 13, in which this time is reckoned as May 2·5, April 20·5, and April 8·5 respectively, the mean date being the most probable. The declination varies from $-16°$ to $-31°$, so that the more southerly observatories are more likely to be successful in the research.

Right Ascensions of 2120 Southern Stars.—In an appendix to "Observations made at the Hong Kong Observatory during 1903," Prof. W. Doberck, the director, publishes the right ascensions of 2120 southern stars for the epoch 1900, as determined from observations made by Mr. J. I. Plummer and himself during the years 1898 to 1904.

The observations were made with a 3-inch Simms semi-portable transit instrument, which, together with the method of reduction and the comparisons with other catalogues, is briefly discussed in the director's preface.

In the catalogue itself, the number of the star as given in Lacaille, or Stone, or both, the R.A., epoch and magnitude, the variation of the R.A. from Stone's corresponding value, the proper motion, and several other particulars are given for each star.

The Iris Diaphragm in Astronomy.—In a communication to the French Academy of Sciences, M. Salet states that he has recently and usefully adapted the iris diaphragm to a telescope in which the magnification employed is 500. The diaphragm is placed very near to the plane of the micrometer wires in front of the field lens, and its *raison d'être* is to prevent the light from the sky, and from the illumination of the wires, from reaching the eye when feeble objects are being observed, the diaphragm being closed by an external cylinder when the object has been brought to the centre of the field. By reducing the extent of the micrometer wires, the diaphragm also reduces, or eliminates, the effect of astigmatism when observations of double stars are being made (*Comptes rendus*, No. 9).

Constancy of "Spark" Wave-lengths.—A question which is of first importance to those observers engaged in stellar line-of-sight work, viz. that of the constancy of wave-lengths in spark spectra taken under various conditions of discharge, has recently been re-investigated by Mr. G. W. Middlekauff at the Johns Hopkins University. A detailed description of the apparatus and methods employed, together with the results obtained, appear in No. 2, vol. xxi., of the *Astrophysical Journal*.

Mr. Middlekauff used a concave Rowland grating of 20,000 lines to the inch and a focal length of 21·5 feet. The self-induction in the spark circuit could be varied from 0·00007 to 0·0012 of a henry, and the capacity from 0·0085 to 0·0739 of a microfarad, and the results obtained afford strong evidence that in the case of a spark discharge in air, at atmospheric pressure, no "shift" in wave-length is produced by variations of self-induction or capacity within the above limits. A further result obtained was that the analogous wave-lengths in the arc and the spark spectra of the same elements are not measurably different.

STATISTICS OF VARIATION.[1]

A PAPER consisting mainly of a large number of elaborate records bearing on the important subject of variation has recently been issued by the Washington Academy of Sciences. The data, which have been collected with much care and industry, cannot fail to be of high interest to all students of evolution. They afford an excellent example of the peculiar value of insect studies in reference to many difficult problems in biology—a point which has lately received fresh emphasis from Prof. Poulton's valedictory address as President of the Entomological Society of London.

The authors start with an "Introduction," in which they declare their "belief in the marked betterment and effectiveness of practically all variation study when pursued from the point of view of the biometrician"; adding, however, that "from the writers' point of view the study of variation is a phase of biology, and not of mathematics." Dealing with the special advantages presented by insect data in this inquiry, they assert that the phenomena of complete metamorphosis afford a ready means of distinguishing "variations which are strictly blastogenic from others which may be in large part acquired." This, it may be remarked, is only true under certain limitations. It is not the case, for instance, as the authors appear to think, that the imaginal colour-patterns of lepidoptera are uninfluenced by the conditions obtaining during individual development.

Coming now to the main substance of the paper, we find a series of short articles or sections giving statistics of variation in some two dozen species of insects. Among the structures thus dealt with are the venation and costal wing hooks in bees and ants, the venation in gnats, the colour-patterns of sundry beetles, wasps and bugs, the eye-spots of certain butterflies, the tibial spines, tarsal and antennal segments, tactile hairs and elytral striæ of other insects of various orders. In the case of the hive bee it is incidentally shown that the parthenogenetically produced drones are as subject to variation in their wings as are the workers of biparental ancestry. The results are in many cases graphically summarised in the form of the frequency polygon; and the "mode," "standard deviation," "index of variability," and "coefficient of variation" are duly reckoned and recorded in accordance with approved biometrical methods. It is interesting but not surprising to observe that the frequency curve is usually in fair correspondence with the law of error.

The paper ends with a section devoted to "general results." Here we think that too much is made of the difficulty of distinguishing between congenital variation and acquired modification. For practical purposes the distinction is usually obvious enough. A little later the authors observe, "The most satisfactory answer to the question of the hereditary transmission of acquired characters will come as the result of a quantitative (statistical) study of variations known to be blastogenic compared with a similar study of variations known to be acquired, both studies to be made on complete series of individuals bred under quantitatively determined life conditions." This seems to us somewhat like using a steam-hammer to crack an egg. It is not astonishing to find that there is little or no evidence of differing selection-value in the variable number of spots on the elytra of a ladybird; but it hardly seems clear that the authors are justified in claiming this fact, together with an apparent change of "mode" between the years 1895 and 1901, as evidence in favour of "determinate variation." Before any such inference can properly be drawn, the question of possible correlation ought at least to be considered. The authors, however, arrive on the whole subject at the satisfactory conclusion that natural selection "is after all a logical necessity and undoubtedly an actual actively-regulative factor" in the formation of species.

INTERRUPTERS FOR INDUCTION COILS.

It has been thought that an account of the more important forms of interrupter would not be unwelcome to readers of Nature.

A rotating air-break interrupter is shown in Fig. 1. An accurately balanced brass fly-wheel, F W, driven by a small motor, is fitted with two insulating segments, I S, let into its periphery. Bearing on the fly-wheel are two copper gauze brushes, B_1 and B_2; the circuit is interrupted as each brush slips over from the brass to the insulating

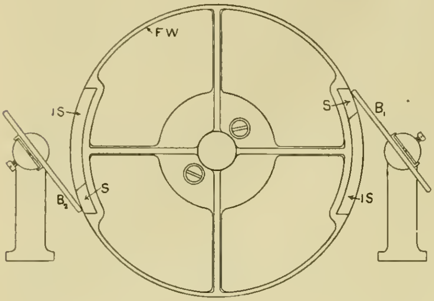

Fig. 1.

portion of the rim. It is evident that the arcing which occurs at the break necessitates the use of a fire-proof insulator. A small piece of slate (s in Fig. 1) is fitted immediately behind each brass segment, and this takes the spark; it is easily renewed, the remainder of each insulating segment consisting of vulcanised fibre.

So far as the writer is aware, this type of interrupter was first described by Wadsworth in 1894, and was used by Prof. Michelson in some Geissler-tube experiments (*American Journal of Science*, pp. 496–501, December, 1894).

As might be expected, the suddenness of the break depends

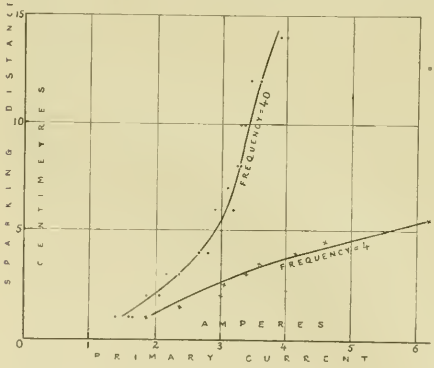

Fig. 2.

on the speed of the motor (or frequency of interruption). In Fig. 2 are plotted the results of some experiments bearing on this point. It will be seen that for a given value (root-mean-square) of the primary current, an enormously greater spark-length—especially with the larger currents—is obtained at the higher speed.

This form of interrupter is not very expensive, and works very satisfactorily so long as the primary current does not exceed about 5 amperes. It shares with the platinum interrupter the advantage of cleanliness. Renewals and repairs cost very little, as the only parts which are subjected to any considerable wear are the slate distance-pieces; the rim of the fly-wheel may occasionally require truing-up. It is important to keep the edges of the brass contact-segments and the surfaces of the slate distance-pieces clean by the occasional application of fine sand-paper.

In Fig. 3 are shown the essential parts of the mechanism of a "double-dipper" interrupter. The double motor-driven crank, C, carries two connecting-rods, C R, each of which is attached to a cross-head, C H. Each cross-head is fixed to the top of a stiff rod, R, which passes between the guide-springs, G S, and through the guide-block, G B. The latter is supported by a strong bracket, B, screwed to the stand supporting the motor. Each reciprocating rod ends in an amalgamated copper wire, C W, which dips into the mercury. It will be readily seen that by the adoption of the two-crank arrangement the frequency is doubled for a given speed as compared with the single-crank interrupter; for while with the latter there is only a single break per revolution, the former gives two breaks per revolution, one of the contact-rods or "dippers" entering the mercury shortly after the other has left it. The mercury cup itself is made adjustable in a vertical direction, and is, as usual, immersed in alcohol.

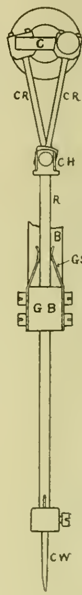

Fig. 3.

The curve marked "double dipper" in Fig. 4 gives the results of a test with this form of interrupter. The frequency of interruption was 22. The results correspond fairly well with those plotted in Fig. 2 for the rotary air-break interrupter at a frequency of 40.

This type of interrupter is comparatively cheap and simple, and works very steadily. There is no complicated mechanism to get out of order, and only a small quantity of mercury is required (about 2lb.).

One of the most successful types of rotary interrupter is the mercury jet interrupter. Several varieties of this have been used. One of the best known is shown in Fig. 5. The vertical motor-driven shaft, S, carries a cylinder, C, the lower portion of which is cut up into a number of teeth, T. The shaft S is continued downwards, and passes through the mercury pump casing. The mercury pump is of very simple construction, and is shown in Fig. 5 (*b*). Inside a flat oval box, which forms the pump casing, are arranged two thick toothed wheels. One of these is mounted on the lower end of the shaft S, which carries the toothed cylinder, Fig. 5 (*a*), and drives the other. The wheels fit the inside of the casing very closely, and are arranged to rotate as indicated by the arrows in Fig. 5 (*b*). The mercury imprisoned between the teeth of the wheels and the casing is consequently carried round and forced through the nozzle. The issuing fine jet of mercury, M J—Fig. 5 (*a*)—is directed against the rotating teeth, the break taking place at the vertical edge of a tooth. The height of the nozzle N is adjustable, and by this means the magnitude of the current may be regulated, as by raising the nozzle the jet will be directed against a tooth for a longer period, and the current will attain a larger value before the break takes place. The entire mechanism of this interrupter is contained in a strong cylindrical glass vessel, the lower portion of which contains mercury, in which the pump is immersed, and with which the pump chamber freely communicates by means of a suction orifice, while above the mercury is the usual alcohol filling the bulk of the vessel.

If in good working order, the mercury jet interrupter gives excellent results, as may be seen by referring to the curve marked "mercury jet" in Fig. 4, which corresponds to a frequency of interruption = 40. A comparison of this curve with that given in Fig. 2 for the rotating air-break interrupter at once shows the superiority of the jet interrupter. The mercury jet interrupter is much more expensive and complicated than the "double-dipper" type, and requires a larger amount of mercury; but it yields somewhat better results.

In Fig. 6 is shown the Wehnelt interrupter. A large rectangular glass vessel containing dilute sulphuric acid is fitted with an ebonite cover, E C, which supports the electrodes. The terminal T_2 is in connection with the lead plate, L P, which forms the kathode. The bridge-piece, B,

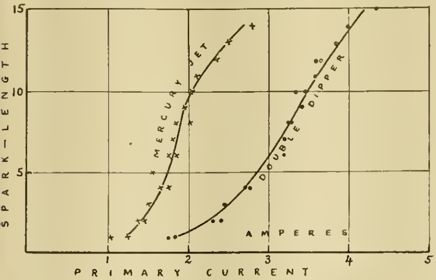

FIG. 4.

supports two rack rods, R, and the anode terminal T_1. Each rack rod is geared with a pinion by means of which it may be raised or lowered as required, M H being the milled heads for turning the pinions. The rack rods are continued downwards in the form of thinner rods encircled by glass

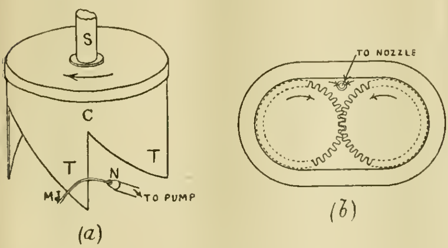

FIG. 5.

tubes, G T, and finally end in stiff platinum points, P P, around which the tapered ends of the tubes fit very closely. By raising or lowering either anode, a smaller or greater surface of it may be exposed to the surrounding electrolyte. The density of the acid depends on the voltage at which the

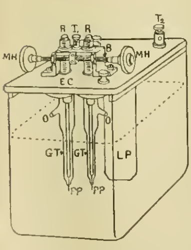

FIG. 6.

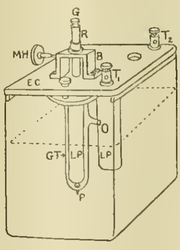

FIG. 7

interrupter is to be supplied. The interrupter is connected in series with the primary of the induction coil, and, if necessary, with an additional self-inductance. As soon as the circuit is closed, and provided the area of anode surface exposed to the electrolyte is not excessive, and the self-inductance not too small, the interrupter begins to act. A pink glow appears around the extremities of the anodes, the interrupter emits a loud note of definite pitch, and a shower of sparks is produced across the space between the secondary terminals of the coil. Bubbles of gas rush up each glass tube, G T, the electrolyte rises in each tube, and may overflow through the side openings, O.

Another form of electrolytic interrupter, originally due to Caldwell, but subsequently improved and modified in various ways by others, is shown in Fig. 7. The terminal T_2 is, as in the Wehnelt interrupter, connected to a lead plate. But instead of a platinum anode, a lead plate is also used for the other electrode. This second lead plate is surrounded by a glass tube, G T, which completely separates it from the remainder of the electrolyte except for a small perforation at the bottom of the tube, through which passes the pointed end, P, of a long glass rod, G, supported in a tubular rack rod, R, which may be raised or lowered by means of a pinion fitted with the milled head, M H. The area of communication between the electrolyte in the tube and that outside is controlled by raising or lowering the conical glass plug. Either electrode may be used indifferently as anode or kathode. The break takes place at the perforation of the glass tube.

In conclusion, thanks must be expressed to Mr. A. C. Cossor, of 54 Farringdon Road, E.C., who very kindly provided an induction coil and a number of interrupters required to carry out the tests recorded in this article.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

IT is stated that Sir William MacDonald, of Montreal, has decided to give 800,000*l.* toward the erection of a normal school at St. Anne de Bellevue, a few miles distant from Montreal, and the erection and endowment of an agricultural college at the same place.

THERE is no sign of diminution in the interest shown by public authorities and by private benefactors for higher education in the United States. We learn from *Science* that by the will of Mrs. Stanford about 400,000*l.* is bequeathed to Leland Stanford Junior University. The university also comes into possession of the house built by Senator Stanford at San Francisco and its contents, which are valued at more than 400,000*l.* The legislature of North Carolina has appropriated 10,000*l.* for the erection of a chemical laboratory at the University of North Carolina.

WE have received a copy of the prospectus of courses of instruction in poultry-keeping held at University College, Reading, and the college poultry farm at Theale. The farm, which is of about 40 acres, largely meadow land, is used also as an experimental station. The courses are of varying lengths and different degrees of difficulty to meet the requirements of all grades of students. The practical work is exhaustive, and due attention is given to kindred technical subjects such as carpentry. It appears that this branch of the work of the college has had an important influence on the development of scientific poultry-keeping in Berkshire and neighbouring counties.

A STRONG committee has been formed for the purpose of securing suitable conditions of work, and providing opportunities for development, of Bedford College for Women in London. An appeal to the public on behalf of the college has just been issued. The college, which is a school of the University of London, must before long come to an end unless it can obtain a large amount of public support. A freehold site and a new building are essential, and it is estimated that their cost may amount to 150,000*l.* Experience has shown that the fees of the students and the allotted share of the Treasury grant to university colleges are not sufficient without considerable additional support to carry on the higher education supplied by the college, the cost of which is constantly increasing. To make the work of the college fully effective, it is therefore desirable to obtain further endowment to the extent of 100,000*l.*, or the equivalent income. The Senate of the University of London has shown approbation of the scheme for re-housing and endowing the college by passing the following resolution:—"That the authorities of Bedford College in issuing an appeal for funds in accordance with the scheme submitted to the Senate be permitted to state that the appeal is made with the knowledge and full approval of the Senate." The Princess of Wales has promised a donation to the funds, and Lady Tate has promised 10,000*l.* for a library to be called after the late Sir Henry Tate. Donations to the fund may be sent to Major Darwin, hon. treasurer of the college, or to Miss Henrietta Busk, hon secretary of the appeal fund, at Bedford College, Baker Street, W. Friends of higher education for women are urged to help in placing the college on an adequate and permanent basis.

Mr. Arnold-Forster, M.P., Secretary of State for War, distributed the prizes to successful students of the Woolwich Polytechnic on Saturday last. In his speech which followed the presentation of the prizes Mr. Arnold-Forster emphasised the importance of sound scientific and technical education. He said that the great lesson this country has to learn is the importance of scientific organisation. There was a time, not so long ago, when we were in the habit of laughing at the methods and ways in vogue on the Continent, and of considering ourselves immeasurably superior to Germany and other nations. But a change has taken place, and these other nations—not by following our example, but by organising on scientific lines—have become immeasurably more advanced and fit to succeed than those who preceded them one or two generations ago; and we have to exert ourselves to protect ourselves from defeat in the industrial contest. Referring to the importance of scientific organisation, Mr. Arnold-Forster spoke of an instance in which he discovered that the electric carbons in use by the Admiralty were largely manufactured in France. Realising the importance of this in case of war, he made inquiries, and, as the result of these and of experiment, it has been found possible to produce electric carbons in this country of the same perfection and accuracy as those formerly brought in from abroad. He expressed his pleasure that a great step forward has been made in the matter of standardising and testing, and that in both these departments this country is abreast of the times. A good deal could be done by scientific organisation, and he looked to such institutions as the polytechnics to accomplish much in that direction.

The address delivered by Prof. Henry T. Bovey, F.R.S., at the Universal Exposition, St. Louis, 1904, on the fundamental conceptions which enter into technology, has been reprinted as a pamphlet from the *McGill University Magazine*. After defining the "technologue" as an intermediary between the savant and the mechanic, translating the discoveries of the former into the uses of the latter, Prof. Bovey tries to ascertain the controlling ideas common to all technical experts. These, he says, have all observed that nature works in no arbitrary manner, but by fixed laws; that if these laws could be brought into right relation with us, we might be able to gear our small machines to the vast wheel of nature; that in the study of the laws of nature there is certainly revealed more of the infinite possibilities of our environment. In order to study to advantage, workers in pure and applied science must get into line with psychological laws, when it will be found that the apprehension of a fact by the mind requires the exercise of the power of observation, and the observations must be of a special character, minute, accurate, and selective. Observation, he says, means to see with attention, and as soon as concentration takes place, a process of analysis begins and the worker passes to classification and generalisation. Throughout this process the training of the hand stimulates the brain centres. Technology has a two-fold nature; first, learning by specialised study how to understand and apply the principles of mechanics to the construction of works of utility, and, secondly, training the mind to work easily along lines of scientific thought. The idea of utility, he maintains, seems to be the key to the distinction between pure science and technology; indeed, technology may be called the child of science on one hand, and of industrial progress on the other.

SOCIETIES AND ACADEMIES.

London.

Royal Society, March 16.—"On the Occurrence of Certain Ciliated Infusoria within the Eggs of a Rotifer, considered from the Point of View of Heterogenesis." By H. Charlton **Bastian,** M.A., M.D., F.R.S.

The weight of preconceptions against the possibility of the occurrence of heterogenesis has hitherto been so strong as to have made it almost impossible to obtain any adequate consideration for the actual evidence adduced in favour of this or that alleged instance. But of late, preconceptions in the domain of physics and chemistry have received severe shocks, and when we are told that a so-called "element" is daily being transformed and another is actually originating therefrom, there appears more chance of attention being paid to the alleged existence of phenomena in the organic world which would seem to be but the carrying on into a higher platform of the familiar but important phenomena known as allotropism and isomerism.

Hitherto, alleged instances of heterogenesis have, without adequate consideration of evidence, been almost always assumed to be results of "infection," but the writer claims that in the cases with which the present memoir is concerned, any such explanation is quite impossible in regard to one of the cases, at least, in which we have masses of living matter so large that they average $\frac{1}{8}$ mm. in diameter, being converted in the course of three days into great ciliated Infusoria of equal bulk.

The communication (which is illustrated by a large number of photomicrographs) deals with two sets of heterogenetic transformations occurring in the great eggs or "gemmæ" of one of the largest of the rotifers, namely, (1) the transformation of the entire contents of a Hydatina egg into a single great Otostoma; and (2) the segmentation of the Hydatina egg into twelve to twenty spherical masses, and the development of these sometimes into embryo Vorticellæ and sometimes into embryo Oxytrichæ.

(1) *The Transformation of the Entire Contents of a Hydatina Egg into a Great Otostoma.*—Having witnessed on very many occasions the stages of this remarkable transformation of the contents of a rotifer's egg into a ciliated infusorium, the author is desirous of acquainting the Royal Society with the simple procedure needful to enable zoologists to study for themselves the series of changes leading to a result which many of them may be disposed to deem incredible.

All that is necessary is to procure a good stock of these large rotifers by placing some surface mud, having a coating of Euglenæ, from a ditch in which Hydatinæ are known to exist, into a glass bowl, and to pour thereon water to a depth of about 4 inches. In the course of two or three days (with a temperature of 16° C. or 17° C.), if the Hydatinæ are abundant, a good crop of their large eggs will be seen at the surface of the fluid, where it is in contact with the glass.

By the aid of a scalpel passed along their track for a short distance, groups of twenty or thirty eggs may be taken up at one time, and gently pressed off the edge of the blade into a small, white stone pot full of water. Some of such small masses of eggs (mixed, perhaps, with a few Euglenæ) will float, and others will sink. After seven or eight of these masses have been gathered and deposited, the cover should be placed upon the pot so as to cut off from the eggs all light rays, both visible and invisible. Two other pots should be similarly charged.

When the pots have remained covered for thirty-six hours, one of them may be opened, and some of the small masses of eggs from the bottom of the pot should be taken up with a tiny pipette and placed in a drop of water on a microscope slip.

On examination by a low power it will be seen that there are many empty egg-cases, that within some eggs there are embryo Hydatinæ in different stages of development, while within the remaining eggs the contents will be wholly different, consisting of an aggregate of minute pellucid vesicles, each containing a few granules, together with a variable amount of granules interspersed among the vesicles.

When a second pot is opened two and a half or three days after the eggs have been placed therein, and portions of its contents are examined in the same way, a larger proportion of empty egg-cases will be seen. There may be very few or even no developing rotifers still within the eggs, and in other egg-cases, instead of the motionless vesicular contents previously seen, great ciliates may be found slowly revolving, or, under the influence of the light, rupturing the egg-case, struggling out, and swimming away with rapid movements, partly of rotation. Some of the Infusoria before they emerge undergo segmentation into two, four, or rarely, even into eight smaller ciliates.

The large undivided Infusoria have their bodies densely packed with large corpuscles (modified representatives of the vesicles of an earlier stage), and a large elongated nucleus which can be readily seen in some of them. They possess the characteristic ear-shaped mouth indicated by the name Otostoma, and cilia are distributed all over the body in longitudinal lines, so as to give the appearance of a delicate longitudinal striation.

As a control experiment it will be well at the time that the pots are charged to place two or three batches of the eggs with some of the same water into a watch glass, which is left exposed to light; and at the expiration of three or four days, as well as at later periods, to search among its contents for any of the same large ciliates, and also for any eggs in the intermediate vesicular stage above referred to. The author has invariably found that such a search yielded only negative results.

In taking batches of eggs, in the manner indicated, to be placed in the pots, individual eggs will necessarily be of different ages. It is only eggs that have not begun to develop which, under the cutting off not only of ordinary light, but probably of some invisible light rays, become speedily transformed into great ciliated Infusoria. Cutting off ordinary light rays alone from the eggs, by placing them in a small covered glass dish shut up in a cupboard or box and maintained at the same temperature as before, seemed at first not to lead to similar results, but it was subsequently ascertained that the transformation will occur under such conditions, though only after the lapse of about nine days. It looks, therefore, as if the stoppage of some invisible rays, capable of passing through wood but not through stone, notably hastens the process.

During the time that these observations were being made, and previously, no Otostomata had ever been seen in association with Hydatinæ, except those that had been taken from the experimental vessels. On two occasions since, though from wholly different localities, Otostomata had been found in association with Hydatinæ. The adult forms have been found to be much larger, having from two to three times the length of the great embryos which issue from the egg-cases, and also to be more highly organised.

Many of these adult specimens the author has been able to keep for two months, and he has seen them pass into an encysted condition, when they constitute masses the bulk of which is several times greater than that of Hydatina eggs. They are, likewise, enclosed in thick cyst walls, wholly unlike the thin egg-cases of the Hydatina.

A Hydatina egg could not possibly be confounded with an adult encysted Otostoma, and the embryo Otostoma which emerges from the egg-case embodies the whole of the transformed substance of the egg. *No minute Otostoma is ever to be seen within an egg, devouring its contents.* No ciliate is seen until the total contents of the egg having been transformed, the whole mass begins to revolve within the egg-case as a great embryo Otostoma.

(2) *The Origin of Twelve to Twenty Vorticellae or Oxytrichae from the Substance of a Single Hydatina Egg.*—These are most remarkable variations, which at different times have been occasionally met with in Hydatina eggs taken from the experimental vessels.

If the egg-substance is found to have segmented into twelve to twenty more or less equal spherical masses, there is at first no means of knowing whether such masses are to be developed into embryo Vorticellæ or into embryo Oxytrichæ. But if either of the masses is seen to be revolving within its own delicate cyst, we may be sure that this particular egg will not yield Vorticellæ, as these embryos do not revolve before rupturing their cysts, and the Hydatina egg produces either the one or the other form—never a mixture of the two.

It cannot be supposed that twelve to twenty of either of these ciliates in an embryo condition could penetrate the egg-case, could devour its contents without being seen, and would then, as embryos, encyst themselves (all in two days, or less)—only, almost immediately after, again to pass out of their encysted condition, and to appear as the active young Vorticellæ or Oxytrichæ the development of which the author has traced.

In its normal development the Hydatina egg never goes through changes in which it is converted into an aggregate of minute vesicles, or into a smaller number of separate and larger spheres, such as occurs as a prelude to the transformation of the egg-contents into ciliated Infusoria of this or that kind.

Geological Society, March 8.—Dr. J. E. Marr F.R.S., president, in the chair.—*Exhibits.*—A series of photographic views illustrating the geological structure and physical features of the mountains of Skye: A. **Harker.** The "Cullinan" diamond: Dr. F. H. **Hatch.** By means of lantern slides from photographs the diamond was shown from four points of view. The stone was a portion (probably less than half) of a distorted octahedral crystal. As it now existed, the stone was bounded by portions of four original octahedral surfaces and by four cleavage-planes. The former showed in places a slight curvature, a mammillary structure, striations, and triangular pittings, while the cleavage-surfaces were distinguished by greater regularity and smoothness. The stone weighed 3024¾ carats. Its greatest linear dimension was 4 inches. It was of remarkable purity for so large a stone, approaching "blue-white" in colour. It was found at the beginning of the present year, in the "yellow ground" of the Premier Mine, at a depth of 18 feet below the surface. The Premier Mine was a true "pipe," situated on the farm of Elandsfontein, twenty miles north-east of Pretoria (Transvaal).—*Papers.*—Observations on some of the Loxonematidæ, with descriptions of two new species: Miss J. **Donald.** Shells having more convex whorls, or less sigmoidal lines of growth than *L. sinuosum*, cannot be left within the genus Loxonema. The two new species described resemble the type in form and in the sinuosity of the lines of growth; but the whorls are ornamented with spiral striæ, two of which frequently stand out and give the shell a banded appearance.—On some Gasteropoda from the Silurian rocks of Llangadock (Caermarthenshire): Miss J. **Donald.** These fossils occur almost entirely in the state of casts and moulds. Eleven distinct forms have been made out, referable to seven genera; but only seven are sufficiently well preserved for specific determination. Five of these are new, including one described in the previous communication; a new genus is described, for the reception of *Euomphalus funatus.*

Chemical Society, March 15.—Prof. W. A. Tilden, F.R.S., president, in the chair.—It was announced that Prof. Percy Frankland had presented to the society the eudiometer made and used by the late Sir Edward Frankland for the analysis of ethyl in 1849; that Prof. Retzius, of Stockholm, had presented an engraving of Berzelius; and that Mr. Oscar Guttmann had presented a bronze medal struck in honour of Roger Bacon in Paris in 1818. The council, on behalf of the society, had expressed its thanks for these gifts.—The following papers were read:—The velocity of oxime formation in certain ketones: A. W. **Stewart.** The results of measurements of these velocities are generally in agreement with those already found for the addition of sodium hydrogen sulphite to ketonic compounds, and since the two reactions belong to different types, it seems probable that the hindrance to the reactions in the case of ketones containing many methyl groups near the carbonyl is due to stereochemical and not to purely chemical causes.—The ultra-violet absorption spectra of certain enol-keto-tautomerides, part ii.: E. C. C. **Baly** and C. H. **Desch.** The results indicate that the absorption band in these compounds is due to change of linking taking place when one tautomeric form passes into the other. It is possible to account for the formation of the absorption bands by adopting the physical conception of the atoms as a system of electrons, and in this way the formation of the bands is placed in the same category as other spectral phenomena.—Esterification constants of substituted acrylic acids: J. J. **Sudborough** and D. J. **Roberts.** The esterification constants of some twenty-two substituted acrylic and allied acids with methyl alcohol have been determined. The results indicate that a substituted acrylic acid is esterified less readily than the corresponding saturated acid, and more readily than the corresponding acetylenic acid, and that the effect of introducing substituents into acrylic acid is to lower the rate of esterification.—α-Chlorocinnamic acids: J. J. **Sudborough** and T. C. **James.**—Di*ortho*-substituted benzoic acid, part vi., conversion of methyl into ethyl esters: J. J. **Sudborough** and T. H. **Davies.**—Simple method for the estimation of acetyl groups: J. J. **Sudborough** and W. **Thomas.** The acetyl derivative is hydrolysed with benzenesulphonic acid and the mixture subjected to steam distillation.—Gynocardin, a new cyanogenetic glucoside: F. B. **Power** and F. H. **Lees.** This substance, obtained from the seeds of *Gynocardia odorata*, has the formula $C_{13}H_{19}O_9N$, and is readily hydrolysed by *gynocardase*, the enzyme present in the seeds, and with difficulty by boiling 5 per cent. hydrochloric or sulphuric acid yielding *d*-glucose, hydrogen cyanide, and an undetermined aldehyde or ketone. With alkalis it yields *gynocardinic acid*, $C_{12}H_{19}O_9.CO_2H$.—Catechin and acacatechin. Supplementary note: A. G. **Perkin.**—The action of ethyl dibromopropanetetracarboxylate on the disodium derivative of ethyl propanetetracarboxylate. A correction: W. H. **Perkin,** jun.—Glutaconic acid and the conversion of glutaric acid into trimethylenedicarboxylic acid: W. H. **Perkin,** jun., and G. **Tattersall.**—The transformations of highly substituted nitroaminobenzenes: K. J. P. **Orton** and A. E. **Smith.**—An asymmetric synthesis of quadrivalent sulphur: S. **Smiles.** It is shown that the two isomeric *d*- and *l*-methylethylthetine *l*-menthyl ester bromides are produced in equal amount from the interaction of methylethyl sulphide and *l*-menthyl bromoacetate.—The action of α-halogen ketones on alkyl sulphides: S. **Smiles.** It has been found that certain α-halogen-substituted ketones interact with alkyl sulphides, forming the halides of sulphine bases. Descriptions of the products formed in several cases are given.—Pinene *iso*nitrosocyanide and its derivatives: W. A. **Tilden** and H. **Burrows.** Pinene *iso*nitrosocyanide is shown to be a nitrile, and from it has been obtained the corresponding pinene *iso*nitrosocarboxylamide,

$$C_{10}H_{15}(:NOH).CO.NH_2,$$

which on hydrolysis with hydrochloric acid yields an oily substance which is probably the ketonic acid

$$O:C_{10}H_{15}.CO_2H.$$

—Some interactions of metallic cyanides with organic bases: R. de J. **Fleming-Struthers.** Descriptions of a number of compounds produced by the interaction of phenylhydrazine with various metallic cyanides are given.

Royal Microscopical Society, March 15.—Mr. A. D. Michael in the chair.—A review of the work done by metallographers: J. E. **Stead,** F.R.S. Illustrations were shown of the changes produced in metals by strains, a diagram of the apparatus by which rapid reversals of strains were effected being exhibited in illustration of this portion of the subject. The effect of the continued heating of an alloy of copper and tin in boiling mercury, and also that produced by immersion in liquid air, were demonstrated. Slides were also shown to illustrate "surface flow" in antimony, and the microscopic structure of the new silver standard.

Linnean Society, March 16.—Prof. W. A. Herdman, F.R.S., president, in the chair.—*Exhibits.*—Animated photographs of plants taken by the kammatograph, showing the natural movements of the plants accelerated so as to be followed readily by the eye: Mrs. D. H. **Scott.**

A series of thirty lantern-slides, from photographs, of bird-life in the Falkland Islands: R. **Vallentin.**—*Paper.*—Contributions to the flora of Liberia: Dr. Otto **Stapf.** Descriptions of 3 new genera and 56 new species, in a collection of about 260 species, collected by Mr. Alexander Whyte in the neighbourhood of Monrovia, in three different localities. The flora shows a specific likeness to that of Sierra Leone, and the new genera are not endemic.

Physical Society, March 24.—Prof. J. H. Poynting, F.R.S., president, in the chair.—Note on the voltage ratios of an inverted rotary converter: W. C. **Clinton.** The values of the voltage ratios usually given for an inverted rotary converter make no allowance for the resistance of the armature. In this note terms due to the effect of armature resistance are introduced into the ordinary theoretical equations. The resultant voltage on the alternate current side is found to be less than that given by the usual rule. The calculation is only made for open circuit conditions on the alternate current side.—On the flux of light from the electric arc with varying power supply: G. B. **Dyke.** The paper records the results of experiments made on the electric arc with the following objects:—(1) To obtain a series of curves for alternating and continuous arcs of different lengths showing the relation between the mean spherical candle-power and the power supplied to the arc; (2) to compare the efficiencies of the alternating and continuous arcs under different conditions of arc-length and power-supply.—On the application of the cymometer to the measurement of coefficiencies of coupling of oscillation transformers: Dr. J. A. **Fleming.** This paper deals first with the latest pattern of instrument called by the author a cymometer, designed for the measurement of the frequency of electric oscillations, and also the length of long electric waves.

CAMBRIDGE.

Philosophical Society, March 13.—Prof. Marshall Ward, president, in the chair.—On the relation in size between the megalosphere and the microspheric and megalospheric tests in the Nummulites: J. J. **Lister.** At the meeting of the society on October 31, 1904, the author directed attention to the fact that in the three English species of Nummulites, viz. *N. laevigatus, variolarius* and "*elegans*," both megalospheric and microspheric forms were represented and associated in the Bracklesham and Barton beds of the Hampshire basin. A comparison of the sizes of the megalospheres in these species suggested that a definite relation might exist between them and the sizes of the whole microspheric tests. To examine this question several species have been studied. Arranging these species in order of the sizes of the megalospheres, this is found to coincide with the order of the volumes of the microspheric tests (with the exception of the variety *obesus* of *N. perforatus*, the microspheric test of which falls one place out in the series).—The penguins of the Antarctic: E. A. **Wilson.**—The old moraines of South Victoria Land: H. T. **Ferrar.** The paper first dealt with the topography of South Victoria Land, a land consisting of a range of mountains some 800 miles long in a north and south direction, with a steep eastward face on an average 10,000 feet high, facing the sea and buttressing a vast interior ice-field. Details were given of the stranded moraines on Cape Adare, on the Possession Islands and on Franklin Island, as well as those high on the slopes of Mount Erebus and Terror. The latter could only have been landed there by the Ross ice-sheet being thicker than it is at present. Reversed glaciers, glaciers not reaching the sea, and beheaded glaciers were mentioned, all pointing to the same conclusion, a retreat of the ice. This retreat is now going on, so that increase of cold could not produce a greater glaciation. If this former greater extension was due to a warmer climate, why have the New Zealand glaciers decreased of late, and what is the connection of the "Ice-age" of Europe with the "Great Glacier Epoch" of New Zealand and Patagonia?—Notes on a collection of parasites from the museum of University College, Dundee: A. E. **Shipley.** The collection consisted of fifteen species of Nematoda and ten Cestoda, and came mainly from marine animals of the northern seas, as might have been expected from the importance of Dundee as a whaling centre.—On the maturation of the egg and early development in certain sawflies (Tenthredinidæ): L. **Doncaster.** In the eggs of sawflies which produce males when unfertilised (*Nematus ribesii, N. lacteus, N. pavidus*), the second polar nucleus conjugates with the inner daughter nucleus of the first polar body. The conjugating nuclei then break up into a group of chromosomes which contain twice the number that is found in the maturation mitoses. These chromosomes persist for some hours, but finally disappear. In the species which produce females from unfertilised eggs (*Poecilosoma luteolum*, *Hemichroa rufa*, *Croesus varus*) no conjugation between polar nuclei takes place. In all cases the egg-nucleus sinks into the yolk and gives rise to the cells of the embryo, and the chromosome number remains the same as that observed in the maturation divisions. Centrosomes were never seen in the maturation mitoses, but are present in the division-spindles of the yolk-nuclei and blastoderm of both fertilised and virgin eggs.—Densities of the earth's crust beneath continents and oceans compared: Rev. O. **Fisher**.

PARIS.

Academy of Sciences, March 27.—M. Troost in the chair.—On vessels of fused silica, their employment in chemistry, and their permeability: M. **Berthelot** (see p. 544).—The construction in an opaque homogeneous medium of luminous rays which penetrate by a plane face: J. **Boussinesq**.—On surra and the differentiation of trypanosomes: A. **Laveran** and F. **Mesnil**. An experimental comparison of the trypanosomes of surra arising in the island of Mauritius and in India shows that they are morphologicaly the same, but the pathogenic action upon animals in the laboratory showed some differences between the two trypanosomes. It seems clear that the trypanosomes of surra of Mauritius and of India are the same species. There are three species which differ in their virulence, the order of activity being India, Mauritius, and Mbori.—On the plants from the Coal-measures found in the borings at Éply, Lesménils, and Pont-à-Mousson: R. **Zeiler**. The impressions of plants found at Éply correspond to a well marked Westphalian flora. Of the specimens from the Lesménils boring two, *Lonchopteris Defrancei* and *Cingularia typica*, have hitherto been observed in the Sarre coal basin, and hence would appear to point to the beds now being explored being a prolongation of this field. The specimens from Pont-à-Mousson also point to the Sarrebrück stage of the Westphalian Coal-measures.—On the monochloro-derivatives of methylcyclohexane: Paul **Sabatier** and Alp. **Mailhe**. Chlorine acts readily upon methylcyclohexanone at the ordinary temperature, giving rise to numerous chlorinated derivatives. Of these a special study has been made of the monochlor-derivatives, the main product being shown to consist of two of the five possible isomers.—Prof. van 't Hoff was elected a correspondant for the section of mechanics in the place of the late Prof. Willard Gibbs.—The search for Tempel's periodic comet (1867, 2) in 1905: R. **Gautier**. This comet, first seen in 1867, and again in 1873 and 1879, did not make its reappearance as predicted in 1885, 1892, and 1898. The date of its possible appearance in 1905 is discussed, and its elements calculated. The author expresses the hope that a special search will be made over the regions indicated by observatories possessing instruments of sufficient power or equipped with photographic apparatus.—On Coulomb's law: L. **Lecornu**. A reply to some remarks of M. Painlevé on the same subject.—On a new arrangement for the use of the methods of interferential spectroscopy: Ch. **Fabry**. The method is specially adapted for the study of a spectrum formed of numerous brilliant lines, such as that of iron, in the electric arc. The apparatus is a modification of one previously described by the author. Instead of the interference bands being observed directly, they are viewed through a spectroscope, the slit of which may be left fairly large, unless rays very close together are under observation. The arrangement possesses several advantages over the earlier form, the chief being that there is no possibility of mistaking the radiation under examination.—An electrometer with sextants and a neutral needle: M. **Guinchant**. The theory of the instrument is given, together with its experimental verification. The instrument gave a deflection of 310 mm. for a potential difference of one volt, and the delicacy can be increased three times by a slight modification of the arrangements.—The oxidation of metals in the cold in presence of ammonia: C. **Matignon** and G. **Desplantes**. In the presence of ammonia the slow oxidation by oxygen at the ordinary temperature of a large number of metals takes place, including mercury, silver, nickel, cobalt, molybdenum, tungsten, and copper.—Cryoscopic studies made in hydrocyanic acid: M. **Lespieau** (see p. 544).—Ferric ethylate: Paul **Nicolardot**. The author has repeated the experiments of Grimaux, and concludes that the soluble ferric ethylate described by the latter does not exist. The compound always contains sodium.—On substituted ureas from natural leucine: MM. **Hugounenq** and **Morel**. From the carbimide of the ethyl ester of leucine the authors have prepared leucine-hydantoic acid, the mixed urea of leucine and aniline, and symmetrical leucine urea.—On some iodomercurates of pyridine: Maurice **François**.—On the heat of formation of calcium hydride and nitride: A. **Guntz** and Henry **Basset**. By distilling commercial calcium in a vacuum, with rapid cooling of the vapour, the authors succeeded in obtaining the metal in a pure state, and in a finely divided condition suitable for its conversion into the hydride and nitride. The calorimetric results show that all the heats of formation of calcium compounds, based on Thomsen's data, ought to be increased by 20·4 calories. This gives a positive instead of a negative heat of formation for calcium carbide.—Some applications of Watt's principle to the dissociation of the carbonates of lead and silver: Albert **Colson**.—The heat of formation of oximes: Ph. **Landrieu**. The amount of heat given off by the reaction between aldehydes and ketones has been studied in two ways: firstly, by the interaction of the two substances in aqueous solution in presence of soda, and secondly, indirectly, by the bomb calorimeter. Figures are given for oximes derived from acetone, acetaldehyde, methyl-ethyl-ketone, benzaldehyde, acetophenone, camphor, and diphenyl-ketone, good agreement being obtained between the two methods.—On the origin and composition of the essence of herb-bennet root: Em. **Bourquelot** and H. **Hérissey**. It is found that the essential oil does not exist preformed in the plant, but is the result of the interaction of a new enzyme upon a glucoside. The smell is due to the presence of eugenol, the latter being identified by conversion into its benzoyl ester.—On the experimental bases of the reticular hypothesis: G. **Friedel**.—On a case of commensalism between a species of Balanoglossus and *Lepidasthenia Digueti*: Ch. **Gravier**.—On the cause of the variations in the length of the intestine in the larvæ of *Rana esculenta*: Émile **Yung**. It is shown that the shortening is retarded by the presence of undigested substances, the shortening taking place when the intestine is empty.—On the growth in weight of the guinea-pig: Mlle. M. **Stefanowska**. The relation found between weight and age is shown in the form of two curves, algebraic expressions for which are also given.—On the heats of combustion of the nervous and muscular tissue of the guinea-pig, expressed as a function of the age: J. **Tribot**.—Contribution to the study of acid dyscrasia: M. A. **Desgrez** and Mlle. Bl. **Guende**.—The action of calcium permanganate upon the toxins of tetanus, diphtheria, and tuberculosis: J. **Baudran**.—On a case of osteomalacia causing extreme deformation of the skeleton, and terminated by a spontaneous retrocession of the lesions: P. **Berger**.—On the favourable action of the X-rays in some cases of non-suppurating tuberculous adenopathy: J. **Bergonié**.—The palæontological discoveries of M. de Morgan in Persia: H. **Douvillé**.—On the discovery of coal at Meurthe-et-Moselle: C. **Cavallier**.—On the boring for coal at Meurthe-et-Moselle: R. **Nicklès**.—The discovery of a workable seam of coal in French Lorraine: Francis **Laur**.—On the course of the solidification of the earth: A. **Leduc**. A discussion of the views on this question recently put forward by MM. Lœwy and Puiseux.—On the influence of eclipses on the movement of the atmosphere: W. **de Fonvielle** and Paul **Borde**.—The relation between the density and salinity of sea-water: A. **Chevallier**.

INDIA.

Asiatic Society of Bengal, March 1.—Earwigs of the Indian Museum: M. **Burr**. A list of the specimens in the Indian Museum, with descriptions of four new species.—On the fresh-water polype of the Calcutta tanks, with exhibition of living specimens: N. **Annandale**. The polype of the Calcutta tanks is identical with *Hydra viridis*, Linn. It varies considerably in colour. What is probably the same species has been seen in the botanic gardens at Penang.—The composition of the oil from Bir

Bahoti or the "rains insect" (*Bucella carniola*): E. G. **Hill.** An oil extracted from this mite is used medicinally by the Mohammedans of Allahabad. Analysis shows that its chief constituent is myristodiolein, with small quantities of stearin, cholesterol and colouring matter.—Contributions to Oriental herpetology, ii., notes on the lizards in the Indian Museum, with descriptions of new forms and lists of species recorded from British India and Ceylon, and of specimens collected on Sinkip Island (East Sumatra) by the late Prof. Wood-Mason's collector (part i.): N. **Annandale.** The present contribution deals with the collection of Oriental geckos, eublepharids, agamids, slowworms and monitors in the Indian Museum. Three new forms and a doubtful fourth are described, while notes on the distribution and systematic position of a number of others are given. Customs in the trans-border territories of the North-West Frontier Province: H. A. **Rose.** A contribution to the customary law of the trans-border tribes on the North-West Frontier of India.—The Agraharis of Sasaram: L. S. S. **O'Malley.**

DIARY OF SOCIETIES.

THURSDAY, April 6.

Royal Society, at 4.30.—On Reciprocal Innervation of Antagonistic Muscles, Seventh Note: Prof. C. S. Sherrington, F.R.S.—The Influence of Cobra-Venom on the Proteid Metabolism: Dr. James Scott.—Further Experiments and Histological Investigations on Intumescences, with some Observations on Nuclear Division in Pathological Tissues: Miss E. Dale.—On the Toxin-Antitoxin Reaction, with Special Reference to the Neutralisation of Lysin by Antilysin: J. A. Craw.—On the Nature of the Silver Reaction in Animal and Vegetable Tissues: Prof. A. B. Macallum.—On Endophytic Adaptation shown by *Erysiphe Graminis* DC. under Cultural Conditions: E. S. Salmon.—Ovulation and Degeneration of Ova in the Rabbit: Walter Heape.

Chemical Society, at 8.—The Basic Properties of Oxygen at Low Temperatures. Additive Compounds of the Halogens with Organic Substances containing Oxygen: D. McIntosh.—Note on the Interaction of Metallic Cyanides and Organic Halides: N. V. Sidgwick.—The Chemical Dynamics of the Reactions between Sodium Thio-sulphate and Organic Halogen Compounds. Part II. Halogen-substituted Acetates: A. Slator.—The Chemical Kinetics of Reactions with inverse Reactions. The Decomposition of Dimethylcarbamide: C. E. Fawsitt.—The Tautomerism of Acetyl Thiocyanate: A. E. Dixon and J. Hawthorne.—A Method of Determining the Specific Gravity of Soluble Salts by Displacement in their own Mother Liquor, and its Application in the Case of the Alkaline Halides: J. Y. Buchanan.—The Combination of Mercaptans with Unsaturated Ketonic Compounds: S. Ruhemann.—A new Formation of Acetylcamphor: M. O. Forster and Miss H. M. Judd.—Preparation and Properties of 1:4:5-Trimethylglyoxaline: H. A. D. Jowett.—Bromomethylheptylketone: H. A. D. Jowett.—On the Existence of a Carbide of Magnesium: J. T. Nance.—The Action of Carbon Monoxide on Ammonia: H. Jackson and D. N. Laurie.—Isomeric Salts of the Type $NR_1R_2H_3$. A Correction. Isomeric Forms of *d*-Bromo- and *d*-Chloro-camphorsulphonic Acids: F. S. Kipping.—Isomerism of α-Bromo- and α-Chloro-camphor: F. S. Kipping.—*l*-Phenylethylamine: F. S. Kipping and A. E. Hunter.

Institution of Electrical Engineers, at 8.—Discussion of the Report to Council on the International Electrical Congress at St. Louis, by W. Duddell, and of Papers on Systems of Electric Units Published in Part clxx. (last issue) of the *Journal*.

Royal Institution, at 5.—Synthetic Chemistry: Prof. R. Meldola, F.R.S.

Röntgen Society, at 8.15.—Exhibition Evening.

Linnean Society, at 8.—Intra-axillary Scales of Aquatic Monocotyledons: Prof. R. J. Harvey Gibson.—A further Communication on the Study of *Pelomyxa palustris*: Mrs. Veley.

Society of Arts, at 4.30.—The Prospects of the Shan States: Sir J. George Scott.

Civil and Mechanical Engineers' Society, at 8.—The Design of Concrete-Steel Beams: W. Noble Twelvetrees.

FRIDAY, April 7.

Royal Institution, at 9.—American Industry: Alfred Mosely.

Institution of Civil Engineers, at 8.—Cofferdams for Dock Use: R. G. Clark.—Bath Corporation Waterworks Extension: J. R. Fox.

Geologists' Association, at 8.—The Relative Ages of the Stone Implements of the Lower Thames Valley: M. A. C. Hinton and A. S. Kennard.

SATURDAY April 8.

Royal Institution, at 3.—Some Controverted Questions of Optics: Lord Rayleigh.

The Essex Field Club, at 6.30. (At Essex Museum of Natural History, Stratford).—Twenty-fifth Annual Meeting.—Natural History Museums: F. W. Rudler.

MONDAY, April 10.

Institution of Civil Engineers, at 8.—"James Forrest" Lecture: Unsolved Problems in Electrical Engineering: Colonel R. E. B. Crompton, C.B.

Royal Geographical Society, at 8.30.—The Problem of the Upper Yangtse Provinces and their Communications: Colonel C. C. Manifold.

TUESDAY, April 11.

Royal Institution, at 5.—Tibet: P. Landon.

Institution of Civil Engineers, at 8.—The Maintenance and Strengthening of Early Iron Bridges: W. Marriott.

WEDNESDAY, April 12.

Society of Arts, at 8.—The Industrial Resources of the State of Matto Grosso, Brazil: G. T. Milne.

THURSDAY, April 13.

Royal Society, at 4.30.—*Probable Papers*: A Quantitative Study of Carbon Dioxide Assimilation and Leaf-temperature in Natural Illumination: F. F. Blackman and Miss G. Matthaei.—On Colour Vision by Very Weak Light: Dr. G. J. Burch, F.R.S.—On a New Type of Electric Furnace, with a Redetermination of the Melting Point of Platinum: Dr. J. A. Harker.—The Refractive Indices of Sulphuric Acid: Dr. V. H. Veley, F.R.S., and J. J. Manley.—(1) The Improved Electric Micrometer: (2) The Amplitude of the Minimum Audible Impulsive Sound: Dr. P. E. Shaw.—On the Intensity and Direction of the Force of Gravity in India: Lieut.-Colonel S. G. Burrard, R.E., F.R.S.

Royal Institution, at 5.—Synthetic Chemistry: Prof. R. Meldola, F.R.S.

Institution of Electrical Engineers, at 8.—The Alternating Current Series Motor: F. Creedy.—Discussion of Mr. Bion J. Arnold's address to the joint meeting at St. Louis.

Institution of Mining and Metallurgy, at 8.—The Kedabeg Copper Mines: Gustav Köller.—Refining Gold Bullion and Cyanide Precipitates with Oxygen Gas: T. Kirke Rose.—Wood Gas for Power Purposes and Gas Generator: G. M. Douglas.—Notes on the Prestea District, Gold Coast Colony: P. Poore.—Notes on the New Dharwar Gold Field of India: R. O. Ahlers.—The Cause of Border Segregation in some Igneous Magmas: J. Park.

Mathematical Society, at 5.30.—On Irreducible Jacobians of Degree Six: P. W. Wood.—On Fermat's Numbers and the Converse of Fermat's Theorem: A. E. Western.—On the Strains that accompany Bending: Prof. A. E. H. Love.

FRIDAY, April 14.

Royal Institution, at 9.—The Law of Pressure of Gases below Atmosphere: Lord Rayleigh.

Physical Society, at 8.—On Ellipsoidal Lenses: R. J. Sowter.—(1) The Determination of the Moment of Inertia of the Magnets used in the Measurement of the Horizontal Component of the Earth's Field: (2) Exhibition of a Series of Lecture Experiments illustrating the Properties of the Gaseous Ions produced by Radium and other Sources: Dr. W. Watson, F.R.S.

Royal Astronomical Society, at 5.

Malacological Society, at 8.—Anatomical and Systematic Notes on Dorcasia, Trigonephrus, Corilla, Thersites, and Chloritis: Henry A. Pilsbry.—Some Account of the Anatomy of *Cassidaria rugosa*, L.: Alexander Reynell.—Notes on a small Collection of Shells from the Victoria Falls, Zambesi River: H. B. Preston.—Descriptions of Six New Species of Land Shells from South Africa: H. Burnup.

SATURDAY, April 15.

Royal Institution, at 3.—Some Controverted Questions of Optics: Lord Rayleigh.

CONTENTS.

A DOCTOR'S VIEW OF THE EAST.

The Other Side of the Lantern. By Sir Frederick Treves, Bart. Pp. xvi+424. (London: Cassell and Co., Ltd., 1905.) Price 12s. net.

AN admirable book; a book written in terse and epigrammatic style, as full of cleverness as anything written by Kipling, and intensely interesting as illustrative of the first impressions conveyed to a highly trained and observant mind by the familiar and superficial details of eastern life. But there is nothing deeper in the book than first impressions, and it was perhaps inevitable that to the student of human nature under those aspects of sorrow and suffering which shadow the sick bed and the hospital, those first impressions should be tinged with the pathos and sadness rather than with the brightness and fulness of the east, and that the general tone of the book should be almost pessimistic. It is as if the lantern had proved to be no better than a common "bull's eye," with nothing on the far side but deep shadow and the policeman. Not that the book is wanting in humour by any means. On the contrary, some of the quaint outlines of men and things sketched in by the artist's hand are as full of humour as anything drawn by Phil May; but it is the grim humour of the man who complained in South Africa of the "plague of women and flies" rather than that of the ordinary holiday tourist infected with the light and sunshine of the eastern world.

The fascination of the book lies in the strength of it, and its appeal to ordinary experience. What Sir Frederick Treves describes with a few powerful and graphic touches of the pen is what we all know and have seen thousands of times for ourselves, and it is the reproduction of our own unwritten (and perhaps unrecognised) sensations that gives such pleasure to the understanding. The keen power of observation possessed by men who are trained by medical experience to judge character by the small superficial details of every-day action is sometimes almost uncanny to those who have eyes to see but see not, passing from country to country well wrapped up in a layer of self-satisfied insularity, regarding the changeful world of human existence as a sort of variety show with no reality at the back of it. Occasionally, no doubt, Sir Frederick permits an artistic fancy to introduce embellishments into the arena of actual observation; but where this occurs one cannot but recognise that he shares with Turner the great faculty of rendering his picture all the more truthful in realising the impression which he seeks to convey.

From the very start at Tilbury the author displays a powerful conception of all those minor features of the voyage eastward which are the framework and making of the voyager's daily experience. He begins with his fellow passengers:—"As an arena for the display of the resources of selfishness a departing ship has great advantages," and follows this up with a record of the mean little stratagems in which travellers will permit themselves to indulge on such occasions, and (it should be fairly admitted) on such occasions only. If there was anything of the usual good fellowship and interchange of little kindnesses which usually distinguishes the fellow voyagers of a P. and O. ship (many of whom are necessarily well acquainted with each other), Sir Frederick does not seem to have remarked them. He is impressed with the aspect of selfishness only. He is deeply interested in Gibraltar (the Rock of the past rather than of the present); charmed with the vision of Crete; inclined to relieve Port Said from the weight of universal anathema with which it is invested; and disappointed with India. At least, so one gathers from his book. He is profoundly impressed with the multitudes of India, and with the melancholy which tinges their whole existence. The truth is that the multitudes would not so much signify if they were equally distributed over the whole continent; and a comparison with France in the matter of population is ineffective for the reason that France much wants more people than she possesses. It is, however, the growing of the multitudes (checked even though it be by periodic famines over vast areas) that affords most serious consideration to Indian administrators.

The general prevalence of an atmosphere of melancholy pervading native life in India is real enough, and it is this which tends greatly to discount the chequered pleasures of European existence in that country. For it is an undoubted fact that in spite of isolation and exile in this "land of regrets" (the land of "grim extremes" Sir Frederick calls it), and the absence of so much that makes life worth living under European skies, life in India has more in it of pleasure than of pain. There are few who leave India quite of their own free will, and many who would gladly end their days there were it not for the disjointing of all ties of friendship by the departure to England of those whom they know best and love best in their own social circle.

Sir Frederick (perhaps naturally) appears to associate melancholy with misery. The association is by no means true of India whatever it may be in other lands; nor does he, with all his profound knowledge of human nature and the effect of environment and occupation thereon, quite appreciate the point of view from which the native looks at the conditions of his own existence. For instance, he finds in the Pahári (the hill men of the Himalayas) a class of people condemned to work as beasts of burden all their lives. Visiting Simla in the "off" season, he finds these men of the hills pervading the Tibet road, toiling painfully towards the Simla market loaded with planks of sawn wood. "They move slowly and they walk in single file, and when the path is narrow they must move sideways. In one day I met no less than fifty creeping wretches in this inhuman procession . . . if there were but a transverse beam to the plank, each one of these bent men might be carrying his own cross to a far-off place of crucifixion." If the author had waited until the "wretches" had stacked their planks for the evening, lit their fires for cooking, and gathered round for the day's ending, he would have found no cheerier, happier hearted folk on the face of the earth than they. There is nothing melancholy about the Pahári. It is perhaps extraordinary that any people who are content (for there is no necessity in this case) to take the place of beasts of burden should be so absolutely unaware of the depth of their own miserable degradation. But so it is, and they would no more thank Sir Frederick for drawing them as central figures in a picture of a "circle in Purgatory" than would the bare-backed inhabitants of the bazaar thank the good missionary for calling them indecent. If he tried to turn a Pahári into a hospital orderly, and to wean him from his mountains and his planks, the contract would not last for a week!

But it is necessarily only with the outward aspect of things Indian that the casual traveller can possibly deal, and it is the freshness and vigour of Sir Frederick's descriptions of native life, his love of colour and nature, that make the charm of his book. Can anything be better than his description of the small shopkeeper of the bazaar? He "lives in the street *coram populo*, and his inner life is generously laid open to the public gaze. In the morning he may think well to wash himself in front of his shop, and to clean his teeth with a stick while he crouches amongst his goods and spits into the lane. He sits on the ground in the open to have his head shaved and watches the flight of the barber's razor by means of a hand glass. The barber squats in front of him and from time to time whets his blade upon his naked leg. The shopkeeper will change his clothes before the eyes of the world when so moved. He also eats in the open, and after the meal he washes his mouth with ostentatious publicity and empties his bowl into the road."

In moving amongst the historical cities of India and in describing them in detail there is, of course, a danger of treading on the skirts of the guide book. Sir Frederick only escapes the peril by the strength and beauty of his descriptions of these relics of the past and his keen appreciation of the stories that these stones can tell; his power of investing palaces and forts with all the movement and glitter, the coming and going, of past races of kings, making these old walls live once more under the light of an India which shall never be again. It is all delightful reading, and the stirring India of Sir Frederick's imaginings owns an enchantment which is wanting in the shadowed India of his latter day observation. There is not much said about Calcutta. The flavour of the place, that "essence of corruption which has rotted for a second time" (Kipling), seems to have been too much for the author; and yet we know that Calcutta is reckoned (statistically, at least) to be one of the wholesomest cities of the world, even when judged by the European standard.

Passing from India to Burma one is not surprised at the air of relief which pervades his book when dealing with that bright and laughter-loving land. Not even the stern critic of woman's mission in camp and hospital can resist the fascination of the Burmese coquette; and his description of Burma and Ceylon (where, *en passant*, the eminent surgeon was introduced to the devil of appendicitis and found him "unreasonably noisy") includes the best and brightest chapter in the book.

China falls again within the shadows cast by the far side of the lantern. The "nightmare city of Canton," where "such peace as is to be found in the city lies only on the green hill side without the walls, where the dead are sleeping," gives the key note of the almost morbid view of Chinese social existence which is taken by the author; and yet throughout his story of China and Japan (which country he also finds somewhat disappointing) there is the same brilliancy of description, the same fertile power of supplying precisely the right touch that is required to complete the sketch, that marks the work as original from beginning to end. It is almost Kiplingesque (to coin a word) in its epigrammatic summary of the usually complicated view of eastern humanity and its environment. It is the best book of travel that has been written for years; and yet when one lays it down regretfully (regretfully because it has come to an end), a feeling of thankfulness steals over one that the endless procession of human life and all the sweet variety of nature in the east is usually ranged for view before our eyes untinted by the medium of medical spectacles. A BOOK ON MUSEUMS.

Museums, their History and their Use; with a Bibliography and List of Museums in the United Kingdom. By D. Murray. 3 Vols. Vol. i., pp. xv+339; vol. ii., pp. xiii+339; vol. iii., pp. 363. (Glasgow: MacLehose and Sons, 1904.) Price 32s. net.

WE have read the text of the first volume of this work (the second and third are devoted to bibliography, &c.) from title-page to index with the greatest pleasure and satisfaction, and can therefore recommend it to the best attention of those interested in the history and progress of museums. The book itself offers an illustration of an evolution somewhat similar to that of many of those institutions, for it is based on an address delivered by the author, in his capacity as president, to the Glasgow Archæological Society so long ago as the winter of 1897, and from this slender foundation it has gradually grown to its present dimensions. Much of the original address appears to remain in the final chapter of the text, where we find the author comparing the state of museums in 1897 to what it was half a century earlier, and what he presumes it will be in the future.

The work, which claims to be the first really full and approximately complete account of museum history in general, is confessedly written from the standpoint of an archæologist rather than of a naturalist; and it is none the worse for this, although, as we shall point out, there are a few instances where it would have been well had the author taken counsel with his zoological colleagues. Before proceeding to a brief notice of some of the leading features of the text, it may be well to mention that the list of museums in the British Islands is based on the one prepared by the Museums Association in 1887, and that in the bibliographical and "museographical" lists forming the subject of the second and third volumes, reference is made only to museums of which there are printed catalogues or descriptions, or to which reference is made in other works. Consequently, many museums, including a few of some importance, are not referred to at all. In the case of large institutions like the British Museum, only such publications as refer directly to the building and its contents are quoted, so that the strictly scientific "catalogues" find no place in Dr. Murray's lists. That these lists, which must have involved an immense amount of labour in their preparation, will prove of great interest to "museographists" in the future can scarcely be doubted. We are unable, however, to find any reference to Dr. A. B. Meyer's well known survey of European and American museums.

In his first chapter the author discusses what we may call rudiments of museums, directing special attention to curiosities and rarities preserved in churches and cathedrals. Among these we miss a reference to the horn of the aurochs, or extinct wild ox, preserved in the cathedral at Strassburg up to the time of the French revolution. "Some Old Exhibits" forms the title of the sixth chapter, in which reference is made to our ancestors' extraordinary belief in the medicinal value of mummy, "unicorn's horn," and such like. In discussing the so-called giants' bones, the author makes a strange mistake (pp. 46 and 47) in regard to the bones which were assigned early in the seventeenth century to Teutobochus Rex, stating that they turned out to be those of a giant salamander, whereas they were really those of a mammoth. Dr. Murray has evidently confused these remains with Scheuchzer's *Homo diluvii testis*, based on the fossil salamander of the Œningen Pliocene.

Here we may take the opportunity of alluding to certain other errors in connection with zoological matters. On p. 58, for instance, we find the name of the red deer given as *Cervus elephas*, which might well be attributed to the "printer's devil" were it not that a few lines later the author deliberately states that this animal was the ἔλεφας of the Greeks! Again, in discussing the barnacle-goose myth, the author makes the following statement (p. 76):—

"Sir Robert Sibbald, about the same time, examined the whole subject personally, and showed that the Barnacle goose (*Bernicla leucopsis*) was a bird produced from an egg, and that the Barnacle shell (*Concha anatifera*) instead of being that egg was a *pholas*; the Scots piddocks."

If Sibbald made this misidentification, the mistake should have been pointed out—we scarcely dare think the author believes it to be true. As a minor error, it may be pointed out that the skeletons referred to on p. 187 as those of the mammoth are really referable to the mastodon. Finally, the statement on p. 136 that the Sloane herbarium "has recently been transferred from *Montague House* to the Natural History Museum" is scarcely exact or up to date.

Reverting to our survey of the contents of the first volume, we find in chapter vii. an account of some of the earliest museums, while in the eighth chapter those in existence at or about the date of the foundation of the Royal Society (1660) are discussed in considerable detail. A whole chapter is devoted to the history of the collections which formed the basis of the British Museum, and the gradual development of that institution. Museums for the exhibition of special subjects and the museums of Scotland next claim attention. From these the author passes on to museums which were "run" for profit, such as the well known museums of Lever and Bullock in London. Incidentally, it is mentioned how the former of these was disposed of *en bloc* by means of a guinea lottery; and from this there is an easy transition to the breaking-up of museums, with, in certain cases, the total loss of some of the most valuable of their contents.

In the fifteenth chapter Dr. Murray describes the arrangement—or rather want of arrangement—of the old style of museum, and takes occasion to express regret that a sample of one of these has not been preserved to our own day, as an illustration of museum evolution. Thence we pass on to modern museum arrangement, local museums, and the use of museums in general. In connection with museum buildings, it is interesting to note that Haltman, a pupil of Linnæus, advocated the importance of having a north light to the main galleries—advice which has been strangely neglected in the planning of many of our modern institutions. Of the importance of local museums, if run on right lines, and not made into mere curiosity shops, the author is fully convinced; but he is also equally convinced that they should not be left to the administration of local bodies, the members of which, as a rule, have but little conception of their true needs and purpose.

With regard to public museums in general, and especially those of the metropolis and our larger cities, Dr. Murray insists that modern methods of conservation and exhibition, and especially the labour of writing descriptive labels (which have to be from time to time renewed to keep pace with scientific progress), must entail constantly increasing expenditure, both in respect to the staff and to the upkeep of the whole establishment. In one passage (p. 280) he incidentally mentions that specimens shown in a museum do not grow out of date, apparently oblivious of the terrible effects of light in destroying so many zoological exhibits. His arguments for the increase of expenditure in the upkeep of museums are therefore, to a certain extent, understated rather than overestimated.

In regard to the general awakening of the country to the necessity of adequate training in every branch of culture and every department of industry, Dr. Murray writes as follows:—

"One of the most potent engines by which this is to be secured is the museum. Some of our museums are among the finest in the world; many are lending valuable assistance to the advancement and appreciation of art and science. A large number, however, are still content to be mere holiday resorts. All, even the best, must advance, and for this end enlightened and sympathetic administration and a liberal income are required. The museum of 1897 is far in advance of the museum of 1847; but it in turn will be old-fashioned by the end of twenty years, and when the coming (= present) century is half-way through, its methods and arrangements will probably be wholly superseded by something better."

With these words we take leave of a very instructive and fascinating book, which it may be hoped will in some measure serve to awaken greater public interest in museums, and thereby enable them to receive adequate financial support from those responsible for their management. R. L.

ELEMENTARY PHYSIOLOGY.

(1) *A Primer of Physiology.* By Prof. E. H. Starling, F.R.S. Pp. viii+128. (London: John Murray, 1904.) Price 1s.

(2) *Elementary Practical Physiology.* By John Thornton, M.A. Pp. viii+324. (London: Longmans, Green and Co., 1904.) Price 3s. 6d.

(1) ASSUMING an elementary knowledge of the main facts of chemistry and physics on the part of the readers, Prof. Starling has endeavoured to present with as few technical terms as possible the leading ideas which make up present-day physiology.

It is clear that within the limited space of about 120 short pages the accomplishment of such a task is well-nigh impossible, and except in the accuracy of the stated facts due to the author's mastership of his subject, we do not think that the present attempt is more successful than those of others which have preceded it.

The great difficulty in writing such diminutive primers does not lie in the direction of finding matter to insert, but in a superabundance of material which must be left out if the reader is not to be stifled by a congested mass of facts crammed together into the shortest possible space, and as a consequence expressed in the tersest and baldest of language.

It is the difficulty of freeing the mind from the bondage of detail and dealing only with broad outlines which makes such primers dry and uninteresting reading, and causes one to sympathise with the children who are forced to read and to attempt to digest them mentally.

The primer at present under consideration is no worse, and perhaps somewhat better, in this respect than many similar productions; still, it would have served its purpose better if much of the detail had been left out, and room so provided for more ample treatment of the prominent and important aspects of the subject.

In the small amount of space at his disposal the author deals not only with the anatomy and physiology of the mammal, but finds room for some instruction regarding toxins and antitoxins, and a short chapter upon the defence of the body against micro-organisms. The introductory chapter takes up the consideration of the animal as a thermodynamic machine, includes the famous candle-burning experiment and the use of the calorimeter, and then passes rapidly to adaptive reactions, adaptation to poisons, and finally to antitoxins, thus showing that the whole of life is a series of adapted reactions.

In this chapter even the junior chemist who may read the primer will object to the illustration which shows him soda-lime as a fluid in bottles 1 and 4 of the illustration on p. 5, and it is to be feared that the junior physicist will be inclined to regard the calorimeter shown in section on p. 8 as a somewhat impossible piece of apparatus.

The remaining chapters furnish accounts of structure, food, digestion, circulation of the blood, breathing, exertion, the skin and its uses, the history of the food in the body, the chemical factories of the body, the defence of the body against micro-organisms, the physiology of movement and the muscles, the central nervous system, feelings—the whole contained in 112 brief pages, and forming a veritable *multum in parvo*.

(2) It is somewhat difficult on first glancing through Mr. Thornton's book to understand why the word *practical* appears on its title-page, for by far the greater part of the text is purely descriptive, although at intervals directions for simple dissections and experiments are interspersed in an unobtrusive manner.

On looking at the page opposite to the descriptive title page, however, one discovers that it is a member of the "Practical Elementary Science Series" issued by the publishers, and intended, as the author states in his preface, to meet all the requirements of stage 1 (the elementary stage) as set forth in the syllabus issued by the Board of Education, and in similar syllabuses of other examining bodies. Hence both the "elementary" and the "practical" of the title form, so to speak, the "class name" of the series, and are suggested by the syllabus and examination which have evidently given rise to their existence.

It is, in the opinion of the reviewer, a pity that even elementary text-books of science should have to be written to suit the requirements of syllabuses and examinations, but it appears to be inevitable in view of the artificial manner in which a love of science is propagated in this country that the majority of our text-books must be so written.

It accordingly becomes a problem whether such books can best be written by experts engaged upon the particular subject treated, or by the schoolmasters engaged in teaching that subject along with others.

The schoolmaster can claim the advantage in that he is a teacher of children, and knows best how to put the subject so that they will understand it; also, being engaged year after year in preparing pupils for the examination, he knows the requirements of the situation so far as success in the examination is concerned; but his knowledge of the subject and his presentation of it must be chiefly second-hand, since the prosecution of the study is not his daily occupation. On the other hand, the specialist, while he can give a review of the subject from a living acquaintance with it, may fail signally in writing to suit the requirements of the syllabus and the examination, disappoint both teacher and scholars in this respect, and leave his publisher without a market.

The book before us will lead to no disaster in examination results, as a comparison of the sets of examination papers included at the end of the volume with the text of the book amply demonstrates, and it must be added that if an observant student carries out the simple experiments so clearly described at various places in the volume, he will have acquired a very desirable knowledge of the more important features of physiology. But so much cannot be said of the remainder of the text, which aims at far too much statement of detail for the space available, a matter in which the syllabus may be much more to blame than the author.

For example, the student who has learnt no chemistry previously will not be able to digest much from the description of the chemical elements given in a single page, and the same is true of the description of the chief inorganic compounds and the organic compounds of the body, each dismissed in less than a page.

The valuable habit of coordinating knowledge in the form of tables is visible at places in the book, but summaries have a way of becoming either too sweeping or too inexact, and we fear that the pupil, especially after such a concise training in chemistry as we have just indicated, may be in danger of concluding from a perusal of the table on p. 13 that the body contains "mineral salts" formed from a very strange combination of elements, or, from the table on p. 162, that these same "mineral matters" share only "in forming bone and assist in digestion," and not that they are found in every cell and tissue in the body, and form as essential a constituent there as the all-important proteids, which are in the same table represented as the only tissue formers.

B. Moore.

TERRESTRIAL MAGNETISM.

Terrestrial Magnetism and its Causes. By F. A. Black. Pp. xii+226. (London and Edinburgh: Gall and Inglis, 1905.) Price 6*s.* net.

With regard to the earth's magnetism, the general conclusions from observations made on its surface are that it is partly permanent, partly induced, and subject to the effects of electric currents in the earth's crust and the surrounding atmosphere. Moreover, that the direct action of the sun plays a comparatively subordinate part in producing the observed phenomena.

In this book, however, various reasons are submitted for the belief that the general magnetism of the earth, and the constant changes thereof as shown by the hourly variations of the needle, are due to causes external to the earth. In short, that the earth is to be considered as an electromagnet excited by electric currents proceeding from the sun and impelled towards the earth with inconceivable rapidity, the orbital and axial movements of the earth through these currents producing magnetic effects in a manner similar to the winding of an electromagnet through which a current passes.

In order that we may believe this to be the case, we must agree that the sun gives out electric waves continuously in every direction equal to the work of maintaining the earth as an electromagnet. For example, that during the forty-five years of the last century, when, according to computation from observed facts, the earth's magnetic moment hardly changed, these emanations were continuous. At present there does not appear to be any ground for such a belief.

In an endeavour to explain the hourly angular variations of the needle, it is submitted that the earth's magnetic poles probably occupy a considerable area round the centre of which certain centres of primary attraction in them make a daily circuit, due to the action of the sun as the earth rotates on its axis. In addition to the "primary" magnetic pole in North America, it is suggested that a "secondary" pole of a similar nature must exist in northern Siberia. The daily variations of the needle, both in declination and dip, in the northern hemisphere are then attributed to a battle for the mastery between the revolving centres of attraction in the two poles mentioned, modified as the magnetic equator is approached by the attraction of the south magnetic poles.

As one reads through several of the first chapters the fully expressed acceptance of the idea that the attraction of the needle by the magnetic poles is the immediate cause of its variations seems unaccountable, until a fundamental error is reached. This is when the author takes it as generally agreed that, in the same way as steel is attracted by the poles of an ordinary artificial magnet, the magnetic needle is attracted by the poles of that great natural magnet, the earth. Such a statement vitiates whole pages of the arguments adduced.

On the question of the position of the magnetic equator with regard to the terrestrial equator, the results of observation have also been too much ignored. There have not been four crossings of the two equators during the last sixty years, neither are the two known points of crossing regulated by the position of the magnetic poles as suggested. In the Atlantic region, the point of crossing seems to be chiefly regulated by local causes below the earth's surface.

It may be finally remarked that the chapter on magnetic storms is the most acceptable in the book.

OUR BOOK SHELF.

Mechanical Appliances, Mechanical Movements and Novelties of Construction. By Gardner D. Hiscox. Pp. 396. (London: Constable and Co., Ltd., 1905.) Price 12*s.* 6*d.* net.

This book is luxuriously printed, with clear figures, but it is difficult to say more in its praise. It consists of a series of short paragraphs, each with its illustration, describing some mechanical or constructional device. It is similar in plan to those "Centuries of Invention" of which the Marquis of Worcester's was the earliest (1746). The devices described are of the most heterogeneous character, old and new, important and unimportant, useful and useless. They are arranged in the roughest way in sections which have no relation to any natural order of classification. It is difficult to see to whom such a work appeals, but in fairness to the author it should be stated that a previous work of which this is a continuation appears to have reached a tenth edition.

Section ii. is on the transmission of power. The first example is a screw-driver, and the second a sewer rod coupling. Another example is a cash conveyor, which, as money is power, is no doubt an example of transmission of power. On the next page is a viscosimeter, though what power is transmitted in this case is less obvious. Nor would one naturally expect four examples of acoustic telephones to be found under this heading.

Section vii., on hydraulic power and appliances, commences with some very sketchy ideas for wave motors, and then describes a fog-horn buoy. There is no reasonably good account of any one of the important class of water turbines, but there is a quite impossible design for a "multinozzle turbine," and next to this a duplex steam feed pump. There is a figure of a Venturi meter, but the description does not explain its action, and the curiously inaccurate statement is made that the differential velocity produces a differential pressure in two tubes with mouths turned in "opposite" directions, and ends with the very misleading statement that "the measurement is made by a meter." The reader would not realise that the Venturi tube is the meter, and that what the author probably mistakes for a meter is a recorder.

Section viii., on air power, motors and appliances, contains the "pneumatic ball puzzle," an "aërial top," "grain elevators," "a magic ball," a "megascope," a "sailing wagon," a "tail-less kite," and a "sail-rigged merry-go-round"; but nothing about the air-compressors, air-motors, and pneumatic tools which are now so important.

Enough has been said to indicate the general character of the work. Many useful and important devices are described amongst many others which are mere inventors' schemes. There may be readers who like an olla podrida of this kind.

Perhaps the most curious section, and we think the longest, is that on perpetual motions. About these the author does not seem to have quite made up his own mind. He does warn the reader in the preface that the problem is "unsolvable." But later, p. 363, he remarks that "attempts to solve this problem would seem, so far, only to have proved it to be thoroughly paradoxical," a statement which would hardly get many marks in a science examination. Further, we are told on the next page that, although admitting difficulties in the way of its discovery, "many eminent mathematicians have favoured the belief in the possibility of perpetual motion"; also that "it is evident, therefore, that even mathematicians are not agreed."

Modern Theory of Physical Phenomena, Radio-activity, Ions, Electrons. By Augusto Righi. Authorised translation by A. Trowbridge. Pp. xiii + 165. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1904.) Price 5s. net.

IT is an interesting sign of the times that so many books have appeared during the last few months with the object of explaining in non-technical words the recent development of physical science. Part of the interest shown in these subjects by the general reading public is, no doubt, of the unintelligent and wonder-seeking order, which classes the more striking discoveries of natural science with the latest sensation of the law courts, or the cost of the flowers at a Transatlantic ball. But it is fair to hope that some, at all events, of those who read of the advance of knowledge do so with a desire to comprehend the method, as well as to admire the results, of scientific research. A more widely spread application of the open-minded and truth-seeking methods of science to the problems of individual and collective life is, for the sake of the community, greatly to be desired.

The little book before us deals in a light and interesting manner with the conceptions of the physical world which have been used of late in investigating the phenomena of light, electricity, and radio-activity. It states the results of recent inquiries in a clear and intelligible manner, and, if the account of the methods used in reaching the results sometimes seems inadequate, the difficulty of explaining those methods to non-scientific readers may be urged as an excuse.

After an introduction, the book contains chapters on electrolytic ions and electrons; electrons and the phenomena of light; the nature of the kathode rays; the ions in gases and solids; radio-activity; mass, velocity, and electric charge of the ions and of the electrons; and the electrons and the constitution of matter. The volume ends with a useful bibliography of the subjects considered.

The translation, on the whole, is well done, though a certain want of crispness in the literary style is felt in places.

In a future edition one or two corrections would be advisable. The period of vibration of light cannot be "expressed by a fraction whose numerator is unity and whose denominator is a number of fifteen places" unless it is understood that "a fraction" is a fraction of a second. The usual figure given to illustrate the opposite deflection by a magnetic field of the α and β rays from radium exaggerates greatly the deflection of the α rays compared with that of the β rays. This exaggeration is legitimate, in fact, necessary, in a diagrammatic representation; but it should be pointed out in the text, or misconception of the relative magnitudes of the two effects is sure to follow. In Thomson's method of determining the properties of the ions produced by the incidence of ultra-violet light on a metallic surface, the exactness is limited not only by the differing velocities of the ions, as stated in the book. Probably the ions are produced, not solely at the metallic surface, but also in a layer of the gas of finite thickness in its neighbourhood. Thus the distance from the surface reached against the influence of a magnetic field may be different for different ions even if their velocities be the same.

The Journal of the Royal Agricultural Society. Vol. lxv. Pp. clxvi + 392. (London: Murray, 1904.)

THE *Journal* of the Royal Agricultural Society makes its appearance this year in a rather slimmer form than usual, due, however, more to the use of a thinner paper than to a curtailment of the printed matter. The affairs of the society bulk largely as usual, taking up more than half the present volume, while the miscellaneous articles, to which the ordinary reader turns, only occupy about 150 pages. The volume is, in fact, burdened far too much with reports of council meetings and committees, which have lost all interest for the members by the time the annual volume reaches them, and which would be much more to the point if circulated as "proceedings" immediately after the meetings and not reprinted here.

The volume opens with a vivacious and readable account of Sir Humphry Davy by Mr. H. B. Wheatley, who well brings out the charm and fascination of Davy's personality. But we cannot help thinking Mr. Wheatley rates Davy's agricultural work altogether too highly; if any man is to be called "father of the science" it is De Saussure, and not Davy, who can be identified with no new discovery or novel point of view in agricultural science. In this respect Davy was somewhat like Liebig; both were great men who had the power of getting the world to listen to them, and when they turned their attention to agriculture the influence they wielded, each in their generation, and the stimulus they gave to the progress of agriculture were out of all proportion to the value of the knowledge or even of the ideas they contributed to the subject. Davy gave dignity to the study of agricultural science; where Davy had laboured no man in future need be ashamed to work. Two articles follow on fruit farming, by Mr. Charles Whitehead, and on vegetable farming, by Mr. James Udale. Both are sound enough, but they are rather jejune performances for the *Journal* of the Royal Agricultural Society, since from the inevitable limitations of space they are too lacking in detail to be of service to anyone but the amateur. When it comes to reproducing pictures of the wireworm from the Society's text-book of agriculture, instructions for making Bordeaux mixture, and similar elementary matters, the farmer reader may well wonder where the editor's blue pencil has been lying. Mr. Dudley Clarke writes on a burning question of the day, the cost of labourers' cottages, and gives a number of sensible plans, bringing out the cost of a brick and tile cottage with three bedrooms at about 150*l*., including the land and the cost of a well.

Mr. A. D. Hall writes on the agricultural experiments of Mr. James Mason, the well-known founder of the firm of Mason and Barry, who spent his later leisure in attempting to apply science to agriculture with some success, while the rest of the volume is occupied with the last Park Royal show, with reports of the experiments in progress at the Woburn Farm, and with other society matters.

Mediaeval Lore from Bartholomew Anglicus. By Robert Steele; with preface by William Morris. Pp. xv+195. (London: Alexander Moring, Ltd., 1905.) Price 1*s.* 6*d.* net.

THIS beautiful addition to the "King's Classics," of which Prof. Gollancz is the general editor, is likely to prove of interest to students of science. Written by an English Franciscan, probably before 1260, to explain the allusions to natural objects met with in the Scriptures and elsewhere, it is really an account of the properties of things in general so far as they were understood by an educated writer of the Middle Ages. After studying the quaint and pleasant accounts of mediæval science, medicine, geography, and natural history which the book contains, the student will begin to realise that during the Middle Ages science was not stagnant, but, by gradual development, was making possible the rapid growth of scientific knowledge characteristic of the nineteenth century. The reprint deserves to be read widely.

Ergebnisse und Probleme der Zeugungs- und Vererbungs-lehre. By Prof. Oscar Hertwig. Pp. 31. (Jena: G. Fischer, 1905.) Price 1 mark.

PROF. OSCAR HERTWIG is well known as a pioneer in the researches on fertilisation. In 1875 he made the important discovery that the essential fact in the process lay in the fusion of a single male with a female cell, and he also saw and recognised the fusion of the nuclei. It was fitting that at the congress held at St. Louis last year he should choose this subject as the text of his lecture. The reprint forms a clear statement of the chief details of fertilisation, and also indicates some of the theoretical conclusions towards which modern cytology is tending. The sketch of the so-called "reduction divisions" is specially good, and the author shows how clear a light they throw on the modern experimental results obtained from the study of heredity. The lecture will be welcomed by all who are interested in these and kindred questions, and those who know Prof. Hertwig's writings will not be surprised to find that if the treatment is of necessity brief, it is masterly of its kind.

LETTERS TO THE EDITOR.

The Dynamical Theory of Gases.

IN Mr. Jean's valuable work upon this subject he attacks the celebrated difficulty of reconciling the "law of equipartition of energy" with what is known respecting the specific heats of gases. Considering a gas the molecules of which radiate into empty space, he shows that in an approximately steady state the energy of vibrational modes may bear a negligible ratio to that of translational and rotational modes.

I have myself speculated in this direction; but it seems that the difficulty revives when we consider a gas, not radiating into empty space, but bounded by a perfectly reflecting enclosure. There is then nothing of the nature of dissipation; and, indeed, the only effect of the appeal to the æther is to bring in an infinitude of new modes of vibration, each of which, according to the law, should have its full share of the total energy. I cannot give the reference, but I believe that this view of the matter was somewhere expressed, or hinted, by Maxwell.

We know that the energy of ætherial vibrations, corresponding to a given volume and temperature, is not infinite or even proportional to the temperature. For some reason the higher modes fail to assert themselves.[1] A full comprehension here would probably carry with it a solution of the specific heat difficulty. RAYLEIGH.

The Physical Cause of the Earth's Rigidity.

SINCE publishing the paper in the *Astronomische Nachrichten* (No. 3992), the investigations there outlined have been considerably extended, and lead to some remarkable results. My only purpose in this letter is to direct attention more particularly to the physical cause of the earth's rigidity. This seems to have remained rather obscure, and I am not aware that any definite theory has been adopted to account for the remarkable fact established by the researches of Lord Kelvin and Prof. G. H. Darwin.

It was pointed out in the *Astronomische Nachrichten* (3992) that the physical cause of the earth's high effective rigidity is to be found in the great pressure existing throughout the interior of our globe. This may be made somewhat more obvious by remembering that in any concentric spherical surface the resistance of the enclosed nucleus must be just equal to the pressure of the surrounding shells resting upon it, and thus the strain upon the matter of the globe increases towards the centre according to the same law as the curve of pressure given in the *Astronomische Nachrichten* (3992). This pressure is sustained by the increasing density and rising temperature of the matter in the earth's interior, which is thus under an inconceivable strain, far surpassing the strength of any known substance. As the matter is above the critical temperature of every element, it is essentially a gas reduced by pressure to a hardness greater than that of steel, and with an elasticity and rigidity infinitely near to perfection. The result is that the explosive strain upon the matter of our globe from within, which is everywhere just equal to the pressure sustained by the enclosed nucleus, renders the interior matter more rigid than any known substance; and even the outer layers, which are but slightly compressed, yield so little under the action of external forces that the globe as a whole is more rigid than steel, as Lord Kelvin and Prof. G. H. Darwin found from their profound researches on the long-period tides of the ocean.

It was these considerations which led to the conclusion that all the heavenly bodies of considerable mass when condensed to moderate bulk have nuclei of great effective rigidity, and experience no sensible circulation at great depths. T. J. J. SEE.

U.S. Naval Observatory, Mare Island, Cal., March 20.

The Lyrid Meteors.

THOUGH in the present year the light of the full moon will impede observations of these meteors, yet it is not improbable that the shower will be sufficiently strong to manifest its presence, provided that the atmospheric conditions prove favourable for the occasion. In 1905 the calculated maximum will fall on the night of April 19, as was the case last year, when Lyrids were found to be somewhat more numerous at Utrecht on the night of April 19 than on the succeeding night, both nights having been clear; observations at Dublin, made, however, under less favourable conditions, tended also to confirm this result.

On the present occasion the shower will extend throughout the night of April 19, and of its three constituent maxima two at least will be visible to Cisatlantic observers. The calculated time of the first of these maxima is April 19, 11h. 15m. G.M.T., while the second occurs at 15h.; the third may occur shortly after 14h., but owing to an uncertainty respecting some of the data requisite for its calculation, it is liable to arrive two or three hours later, and consequently elude the vigilance of observers of the first two maxima.

The conditions under which the anticipated display will take place indicate that it will be much above the average in brightness, and probably, notwithstanding the presence of the full moon, several brilliant meteors will be observed on April 19, owing to the meteoric concentration that characterises this night. JOHN R. HENRY.

ANTARCTICA.[1]

WE have entered upon a new era of South Polar literature, since each of the recent expeditions bears the promise and the potency of several books. Of these the recent publication of Dr. Otto Nordenskjöld's "Antarctica" is an addition to our knowledge of southern regions.

[1] "Antarctica, or Two Years amongst the Ice of the South Pole." By Dr. N. Otto G. Nordenskjöld and Dr. Joh. Gunnar Andersson. Pp. xviii+608. (London: Hurst and Blackett, Ltd., 1905.) Price 18s. net.

Dr. Nordenskjöld sailed from Buenos Aires on Christmas Eve, 1901, with the Swedish expedition. The object of the expedition was not to make a dash for the Pole, but, in conjunction with the English, Scottish, and German expeditions, to pursue certain scientific studies in the unknown Antarctic, the special sphere of operations being that section known as the Weddell Quadrant. Dr. Nordenskjöld appears to have succeeded in carrying out much of his programme, although he was unable to push far south, indeed, not so far as the Antarctic Circle, and notwithstanding disasters and hardships without a parallel in the history of Antarctic exploration.

The narrative is divided into two parts. The first, by Dr. Nordenskjöld himself, deals with the cruise of the *Antarctic* in the summer of 1901–1902, and with the two consecutive winters spent on shore near Seymour Island. The second part is by Dr. Andersson and Capt. Larsen, and describes the attempt of the *Antarctic* to reach Nordenskjöld's winter quarters in the summer of 1902–1903, and the loss of the ship in the ice-pack off Louis Philipp Land near the entrance of Erebus and Terror Gulf.

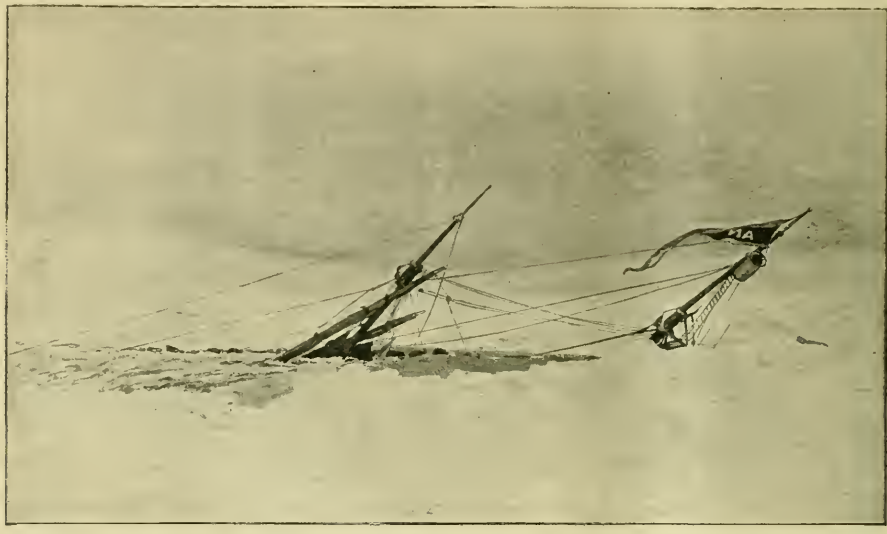

FIG. 1.—The loss of the *Antarctic*. From Nordenskjöld and Andersson's "Antarctica." The original illustration is slightly larger than the above.

Geographically, the summer of 1901–1902 was perhaps the most prolific in discoveries. Louis Philipp Land was found to be continuous with Danco Land, and Gerlache Channel nothing but a continuation of D'Urville's Orleans Channel. Indeed, D'Urville is the real discoverer of the whole island. It appears that the *Belgica* maps of this locality present many difficulties and differences. The illustrations of this land from about lat. 63° S. to 65° S. bear a strong resemblance to Victoria Land, and seem as desolate and as heavily glaciated as land in lat. 75° S. in the Ross Quadrant.

Continuing southwards down the east coast of King Oscar II. Land, the *Antarctic* was at last stopped by a perpendicular wall of ice about 130ft. high. This was in about the 66th degree of latitude south, and it grew clear to Dr. Nordenskjöld "that the chief aim of the expedition to penetrate to unknown regions along the coast of King Oscar's Land was utterly annihilated by powers of nature against which it would be fruitless to combat."

Sailing eastwards along the barrier some trawl hawls were made in deep water, a fairly constant depth of 2000 fathoms found, and indications of a layer of warm water at about 300 fathoms. This layer of warm water at a certain depth is characteristic of a great part of the polar sea.

On February 1, 1902, in lat. $63\frac{1}{2}^\circ$ S. and long. 45° 7′ W., it was decided to return westwards and seek a suitable place for winter quarters. The spot selected was Snow Hill, a little to the south of Seymour Island, where Capt. Larsen first discovered fossils in 1892. A party of six, including Nordenskjöld, was landed, with a strong, comfortable log hut, a few dogs, and provisions and equipment for two years. Before finally leaving the party an attempt was made by Capt. Larsen to establish a depôt farther south, but it was unsuccessful on account of the close conditions of the ice.

The two winters seem to have been passed cheerfully and harmoniously. The party was too far north to feel the terrors of a real polar night, for even at midwinter the sun remained four hours above the horizon, but the weather, common to all parts of Antarctica, was most boisterous; storm followed storm, and made outdoor work only too frequently impossible and the carrying out of scientific observations most arduous. Perhaps we do not thoroughly realise what physical hardships attend the taking of scientific observations in the Antarctic regions.

The magnetic work was undertaken by Dr. J. Bodman. There were no self-recording variometers like those of the *Discovery*, and there is therefore no continuous magnetic record, but the conditions of the International Term Days were fulfilled by means of the ordinary method of eye readings.

Bacteriological investigations were undertaken by Dr. Ekelöf, and chiefly concerned the bacterial flora of the surface soil. The result seems to show that "in these regions the surface soil must almost be considered as the place of origin of bacteria, and the results which were pursued during different seasons and with regard to different kinds of earth have given rise to wholly new ideas concerning the conditions of bacterial life within the polar regions."

The taking of the meteorological observations was shared by all alike. At first readings were taken only at 7 and 8 a.m. and 2 and 9 p.m., but towards the middle of April night observations were also taken.

August 6 was the coldest day, when the thermometer registered $-42^\circ.3$ F. ($-41^\circ.3$ C.). At Cape Adare (lat. 71° S.) the lowest temperature observed was $-43^\circ.5$ F., also in August, and with the *Discovery* in lat. 78° S., $-67^\circ.8$ F.

Dr. Nordenskjöld expresses the opinion that the summer of 1902–3 was exceptionally cold, and points out that the German ship *Gauss* alone succeeded in extricating itself from the ice, but no figures are given to prove the statement. Fewer heavy storms in the summer of 1902–3 were more likely the direct cause of the ice not breaking up.

On October 1, Dr. Nordenskjöld set out with Lieut. Sobral and a sailor on a sledge expedition southwards along the coast of King Oscar II. Land. The one sledge drawn by Nordenskjöld and Sobral weighed in all 200 lb., and the other, drawn by five dogs, 485 lb. The total length of route traversed in thirty-four days was 400 miles. As a result of this journey the chart of this coast has become completely changed.

During the summer of 1902–3, while waiting for the return of the *Antarctic*, important fossil finds were made on Seymour Island. The first were bones belonging to a species of penguin considerably larger than the largest now living—the Emperor penguin. This demonstrates that even at such a distant epoch—probably the beginning of the Tertiary period—the penguin was an inhabitant of the Antarctic regions. The other was that of numerous large and quite distinct leaves in a brown, coarse, hard, tuff-like rock, belonging to different forms of exogenous trees, firs, and ferns. The leaves are small and narrow, and call to mind similar fossils from the Tertiary form-

FIG. 2.—Tertiary plant fossils from Seymour Island (drawings by Prof. A. G. Nathorst). From Nordenskjöld and Andersson's "Antarctica."

ations of Central and Southern Europe, but also certain South American types of leaves.

Dr. Nordenskjöld writes: "If there was one hope whose fulfilment or non-fulfilment was, in my thoughts, almost synonymous with the success or failure of this expedition, it was just that of being able to discover in these regions determinable Tertiary vegetable fossils."

Dr. Andersson also discovered a fossil flora from the Jurassic system in Hope Bay, about a degree farther north, and some very fine illustrations of the

Cladophlebis, Pterophyllum, and Otozamites are given.

Some form of fossil plant was found by the geologist of the *Discovery* as far south as lat. 78°, but it has been found quite impossible to identify it on account of the imperfect nature of the specimen.

The second part of the book makes some thrilling reading, but adds very little to our knowledge. The attempt of Dr. Andersson, Lieut. Duse and seaman Grunden to reach Nordenskjöld across the ice from the *Antarctic* in the summer of 1902–3, their failure either to reach the winter quarters or to regain the ship, and subsequent lonely winter in Hope Bay, is given in detail. The *Antarctic* foundered on February 12, 1903, as the result of a severe ice "nip," and the crew succeeded in reaching Paulet Island across the ice, where they spent the winter under extremely trying conditions. Fortunately, both Dr. Andersson and Captain Larsen and their parties succeeded in reaching Nordenskjöld's winter quarters in the following summer, and, with the exception of a sailor who died on Paulet Island, all were rescued by the Argentine ship *Uruguay* in November, 1903.

The book consists of about 600 pages, and there are a large number of illustrations, some of which are from crude drawings and are indifferently reproduced. The coloured plates might have been advantageously omitted, as they give no idea of the extreme delicacy and beauty of Antarctic colour. Here and there are slight slips, such, for instance, as appears on p. 119, where the velocity of the wind is given as forty-five miles per second! However, there are no serious blemishes. The field of operations was, geographically, a limited one, and well outside the Antarctic Circle. Scientifically we may look forward to more interesting results. No attempt has been made to give an account of the scientific work, and Dr. Nordenskjöld hints that several years must elapse before the results of the voyage of the *Antarctic* can be published in full.

L. C. B.

A NEW BRITISH MARINE EXPEDITION.

THE hydrographical and biological investigation of the central and western parts of the Indian Ocean will this year be the object of a special cruise of H.M.S. *Sealark*, which is fixed to leave Colombo for the purpose about April 20. This yacht, which is the latest addition to the survey vessels of the Navy, is under the command of Captain Boyle Somerville, who will be accompanied by two scientific civilians, Mr. J. Stanley Gardiner and Mr. C. Forster Cooper.

It will be remembered that the Indian Ocean was not visited by the *Challenger* Expedition in the famous cruise around the world, the course then taken lying further to the south, almost within the Antarctic circle. Meantime, however, knowledge of the region has been steadily increased by the exertions of individual explorers and by special Admiralty surveys. To the east there has been continuous progress, culminating in the Dutch *Siboga* Expedition of 1899–1900 through the East Indies, while other explorers have investigated Keeling Atoll, Christmas Island, and parts of Torres Straits and Western Australia. To the north, the Indian survey vessel *Investigator* has been active from the Persian Gulf almost to the Straits of Malacca, while individual explorers have borne their full share. Prof. Ortmann examined the reefs of Ceylon, and Prof. Herdman is now publishing a full account of the marine fauna and flora of that region. In addition, Mr. Stanley Gardiner, with Messrs. Borradaile and Forster Cooper, devoted sixteen months in 1899–1900 to the examination of the Laccadives and Maldives, being followed through the same region in 1901 by Prof. Alexander Agassiz, who devoted himself mainly to the coral reefs, with the surface and the deeper pelagic fauna.

The Red Sea and the coast of East Africa is largely a German zone, but to the south a regular systematic investigation of the hydrography and biology is being undertaken by Cape Colony in connection with its sea fisheries. The French have accumulated much knowledge of Madagascar (mainly of the land), while Rodriguez and Mauritius have become fairly well known, to a large extent owing to the Royal Society Expedition of 1874. Of greater importance, however, were the Admiralty surveys of the numerous islands and banks to the north of and around Madagascar, carried out for the most part by Captain (now Admiral Sir Wm.) Wharton. Lastly, the German *Valdivia* Expedition in 1898–9 ran a rapid traverse from St. Paul to Nicobar, Ceylon, Chagos, Seychelles, and up the East African coast. Its work showed the existence of a pelagic fauna at all depths, and of practically the same deep-sea fauna as exists in other oceans. A relatively shallow bank was found between Chagos and the Seychelles, an important discovery which ought to have been followed up by an extended investigation of the region.

The present expedition, organised by Mr. Stanley Gardiner, is an attempt to correlate in some degree the work of all these different expeditions and explorers by a thorough investigation of the oceanography and biology of the region between India and Madagascar, and is the direct outcome of the Maldive and Laccadive expedition of 1899–1900. As at present proposed, H.M.S. *Sealark*, after leaving Ceylon, will proceed to the Chagos Archipelago, situated to the south of the Maldives in lat. 7° S. This group, for the topography of which we are at present depending almost entirely on a survey made by Captain Moresby in 1837, consists of a series of atolls and submerged banks, of which Great Chagos, an irregular circle upwards of seventy miles in diameter, is the most conspicuous, being the largest existing circular coral reef with a basin in the centre. It is, however, perhaps better known through the atoll of Diego Garcia to the south-east, at one time used as a coaling station by the Orient Line between Aden and Australia. That there will be plenty of hydrographical work in the group is quite clear, for there are at present no bottom soundings between any of the banks, and considerable changes may reasonably be expected to have taken place in the last seventy years owing to the growth of the reefs. The expedition will endeavour to fill in these omissions, and while this work is proceeding a close biological and geological survey of the reefs will be undertaken.

From Chagos the *Sealark* will proceed to Mauritius, which should be reached about August 1. Here fresh stores will be taken in, and the collections so far obtained sent home. No extensive work around the island will be possible, but it is hoped to visit some of the reefs. The *Sealark* will then proceed to Cargados, a surface reef to the south of the submerged Nazareth Bank, and the line will be continued along to the Seychelles group over the likewise submerged Saya da Malha Bank. Both these banks may well lie on a crescent of relatively shallow water (less than 1500 fathoms) connecting the Seychelles with Mauritius, but the actual depths should be settled by the expedition. In any case, the examination of these two great submerged banks should throw much-needed light on the formation of coral reefs. The Agalegas group may also be surveyed, and the nature of its land ascertained. From the Seychelles the *Sealark* will return to Colombo, while the civilian members of the expedition will spend some months in that group and its vicinity, returning home in January, 1906.

The scientific work of the expedition will be of a varied nature. In the first place, the soundings and temperature observations taken by H.M.S. *Sealark* should settle such questions as the existence or non-existence of any relatively shallow banks connecting India and South Africa, and also of any bank from Mauritius to the Seychelles. They should also give an accurate knowledge of the rise and relationships of the various Chagos atolls and banks to one another, and show whether they are really isolated by deep sea or arise on some shallow plateau as do the greater number of the Maldive atolls. Incidentally, also, the soundings may reasonably be expected to indicate what changes, if any, have taken place in the reefs and banks since the last surveys. At the same time it is hoped to examine the currents at various depths, so as to see as far as possible the actual influences at work. In the same connection an investigation has already been commenced on the waters of the Indian Ocean. By the kind assistance of the Meteorological Council, cases of bottles have been sent out to many captains of the British India, P. and O., Orient, Bibby, Clan, and other lines for daily samples of the surface waters, while the expedition itself will obtain samples both from the surface and from various depths during the whole of its sojourn in the Indian Ocean. Mr. D. Matthews, English hydrographer to the North Sea investigation, has undertaken the analyses of these samples, and it is hoped that by continuing the collection for twelve months a more accurate knowledge may be obtained of the movements of the waters of the Indian Ocean. In meteorology a careful log and graphic records will be kept, which, coming from such a little known region, should be useful for comparison with the more regular steamer routes.

In biology, the expedition will everywhere take samples of the bottom and of the pelagic fauna at various depths. The coral reefs will be examined, both surfaces and slopes, while the currents and other factors, possibly influencing the same, will be carefully investigated. The dredges and trawls will be let down as frequently as possible, both to ascertain the general characters of the bottom off the islands and banks, and also to sample the flora and fauna. The deep-sea fauna will not be collected, work being for the most part devoted to intermediate depths (50 to 500 fathoms), within which light tails off into absolute darkness. At the same time, the fauna at lesser depths, both in the Chagos and Seychelles, will be investigated as completely as possible. By these means some clear idea should be obtained of the vertical distributions of both animals and plants, and the comparisons of the marine fauna and flora of the Seychelles and Chagos, together and with those of the surrounding slopes of the Indian Ocean, should at least illuminate the question as to how far the horizontal distribution of such is of value in tracing the former connections of continents and lands. The land flora and fauna can scarcely be expected to be of great interest—it will not at present be attempted in the Seychelles—but it will nevertheless be collected in view of the gradual peopling of oceanic islands.

On the whole, this most recent British exploring expedition may be said to be conceived in the interests, not of one, but of many sciences, and all who sympathise with the advancement of knowledge may be grateful to the Admiralty for detailing a vessel for such work. The hydrographic results alone should more than justify the dispatch of H.M.S. *Sealark*, while any discovery which may be made of the laws which govern the formation and growth of coral and other reefs—and to which we seem to be tending—would make navigation in tropical waters appreciably safer. The scientific members of the expedition have been required to find all the extra gear and instruments necessary for their work. In this they have been materially assisted by grants from the British Association and from the Balfour memorial fund at Cambridge; but the bulk of the expense has been undertaken by the Trust recently founded by Mrs. Percy Sladen in memory of her late husband—to whom, it is felt, the objects of this expedition would have very closely appealed, and whose name will appropriately appear upon the publications issued as a result of the investigation.

THE INDIAN EARTHQUAKE OF APRIL 4.

A LARGE part of north-western India was severely shaken by an earthquake which occurred on April 4, shortly after six o'clock in the morning, causing the destruction of numerous buildings and the loss of many lives—the number being estimated at twenty thousand. The last great earthquake in India, in June, 1897, was one of the most violent of which there is any historical record, but the casualties and damage due to that disturbance were comparatively small, because the earthquake occurred at five o'clock in the afternoon, when many people were out of doors, and there were no large cities within the area of maximum violence. In the case of the earthquake on April 4, most people were indoors at the time of the shock, and the area of greatest disturbance included, unfortunately, several centres where fairly large towns have grown up, chiefly round the official settlements, cantonments, and sanatoria of the British Government. Dharmsala, Dalhousie, Simla with several neighbouring cantonments, Mussoorie, Dehra Dun, Almora, Ranikhet, and Naini Tal are the chief of these; and the many substantial stone buildings in them have naturally suffered much damage from the earthquake shocks.

The reports so far available show that the earthquake, like that of other great disturbances of the same kind, was of Himalayan origin, the centre being about Dharmsala. Its intensity decreased through the Punjab and the United Provinces, while from Rajputana to the north it decreased rapidly. There appears to have been no wide extension of the disturbance towards Assam or Afghanistan, but information from the west is very imperfect.

The whole area where serious damage is known to have been done is included within a line drawn from Shahpur through Kangra to Jawalamukhi, thence east to Sujanpur, and then to Baijnath; but what occurred eastwards of this area is not known.

It is clear from the Viceroy's telegrams that the towns of Dharmsala, Kangra, and Palampur are virtually destroyed, that the loss of life has been very great, and that the full measure of catastrophe, owing to difficulty of communication, cannot be ascertained for some time.

The King has sent to the Viceroy a telegram expressing his "profound concern at the news of the calamity which has befallen Lahore and surrounding district," and a message of sympathy with all who have suffered from the earthquake has been sent by the Prince and Princess of Wales.

No news about the earthquake has been received from the regions north of Kashmir, but two days before the first shock was felt in India the Punjab stations reported the arrival of storms bearing large quantities of dust and ash. Natives arriving at Simla from the interior declare that a volcanic eruption has occurred in the hills in Bashahr State.

The earthquake was clearly registered by the seismograph in the observatory at Göttingen, and a record was also obtained at the Royal Observatory, Edinburgh. The record began with some very minute tremors about 1 a.m., while the larger waves began about eight minutes later. The *maximum* disturbance was recorded about 1.30, and was followed by one of almost equal severity a minute and a half later. From that point the tremors were gradually reduced until 4.43 a.m. The difference of time between Edinburgh and Dharmsala is about five hours. Seismograms recording the earthquake were also obtained by Prof. Milne at Shide, Isle of Wight, and at the hydrographic station at Pola.

A severe earthquake shock, lasting six seconds, was felt at Benevento, Italy, at 8.20 p.m. on April 9, and fresh shocks were experienced at Simla on April 10 and 11.

The following particulars of the effects produced by the earthquake in various parts of India have been extracted from the extensive reports which have appeared in the daily papers.

Dharmsala.—All houses and buildings throughout the entire station, including cantonment and bazaars, totally destroyed, with loss of many lives. About 80 per cent. of the population killed or injured, and from 20 per cent. to 30 per cent. in the neighbouring villages.

Kangra Valley.—Kangra and Jowala Mukhi and other villages in Kangra Valley reported totally destroyed, and many hundred lives lost. Every building, without exception, in Kangra and Bhawan in ruins. Of a total population of nearly 5000 in Kangra town it is believed that only about 500 remain alive. Similar state of affairs in most other villages in the neighbourhood. At Palampur, in the Kangra district, all the houses, including the Government buildings, reported totally destroyed, and many hundred lives lost.

Lahore.—A succession of violent shocks caused a panic. The inhabitants rushed from their houses to seek safety in the open. Almost every house suffered by the earthquake, and much serious damage was done to public and private property, and twenty-five people were killed. The shock created an extraordinary uproar at the zoological gardens. The shrieks of the pea-fowls were heard all over the station, while crows and other birds flew in alarm from the swaying trees.

Mussooree suffered severely. Two slight shocks were felt during the night of April 3. A succession of shocks began at 6.10 a.m. on April 4, the first, which lasted three minutes, being the severest. In all eleven shocks were felt. Every house in the city more or less injured. Several small landslips occurred, and many casualties reported. This is the fourth severe earthquake that has happened at Mussooree, and the second worst as regards its effects. Four or five slight shocks were felt during the night of April 4–5.

Simla.—Much damage done to buildings. The Viceregal Lodge is so badly damaged that the re-building will occupy several months. Other estate houses have been seriously damaged. *Delhi.*—The shock was severely felt, and damage was done to buildings, but no reports of injury to monuments. A further shock occurred at midnight on April 4–5. *Agra.*—A violent shock lasting several minutes, and travelling from west to east, was experienced at 6.10 a.m. No reports of injury to architectural monuments.

Jalandhar.—Much damage done. *Amritsar.*—Extensive damage, and several lives lost. *Ambala.*—A large number of houses thrown down. *Srinager.*—Much damage, and several lives lost. *Mudki.* Serious damage. *Sialkot.*—Not a house escaped damage of some sort, but no lives lost. *Dalhousie.*—Property damaged, but no deaths.

Kashmir.—Communication interrupted by landslips and accidents to telegraph lines.

Slight tremors appear to have been recorded at Calcutta and Bombay, but no decided disturbance was felt.

PROF. PIETRO TACCHINI.

THE death of Prof. P. Tacchini on March 24, at the age of sixty-seven years, has caused much regret among men of science interested in celestial and terrestrial physics. Italy has thus lost a representative man of science who especially devoted himself to the cause of astronomy with zeal and patience. For many years, as director of the Observatory of the Collegio Romano, he proved himself an indefatigable observer of planets and comets; but recently this position has been filled by Prof. Millosevich, and Prof. Tacchini had been known as the director of the Central Office of Meteorology and Geodynamics. But the especial work with which his name will ever be connected has been upon lines that have long commended themselves to Italian observers. Secchi made his reputation in the domain of spectroscopy and solar observation, and the example he set has been followed with no less eagerness and success by the distinguished astronomer whose death we have now to regret. All that related to sun-spots, faculæ, or protuberances had a fascination for Tacchini, and for years past our columns have borne witness to his continuous devotion to this subject. He was particularly interested in the heliographical distribution of solar phenomena, and every three months, in the pages of the *Mem. degli Spettroscopisti Italiani* or the *Comptes rendus*, he recorded the variations and gave comparative tables showing the growth or decline of solar activity as testified by these outbursts. Researches carried on so long and so industriously cannot but prove of eminent service, and we may well hope that the work he inaugurated will be carried on with equal zeal by his successors. Prof. Tacchini's work in this direction well deserved the Janssen prize which was awarded him by the Paris Academy of Sciences in 1892.

To a solar observer of such ardour, eclipses of the sun especially appealed, and he took part in several expeditions to observe these phenomena. He was present on the Caroline Island reef, where he associated himself with the French party organised by Janssen. Again in Egypt, and later on in 1886, he visited the American continent for the purpose of observing the great eclipse in that year. On this occasion he showed, by comparing the forms and appearances of the prominences seen during the eclipse with the images ordinarily seen in the spectroscope, that it is only the vaporous cores of these objects which are rendered visible by the usual methods of observation. In many other ways he showed not only his skill as a spectroscopist, but his anxiety to promote astronomical knowledge. He laboured long and diligently in the cause of science, and left a reputation that his countrymen will cherish; while his memory will be held in esteem by the astronomers of many nations. He was elected a foreign member of the Royal Society in 1891, and was awarded the Rumford medal of the society. He was also a foreign associate of the Royal Astronomical Society in 1883, and many other societies have been proud to enrol his name among those of their honoured fellows.

The progress of solar physics is largely due to Prof. Tacchini's unremitting labours; and the numerous papers published by him on solar phenomena stand as an enduring monument of work done by a pioneer in a fruitful field of scientific inquiry.

NOTES.

WE are glad to see the report that Lord Kelvin's condition continues to improve. It was stated on Monday that he now takes nourishment fairly well, and that his medical advisers are well satisfied with the progress he is making. It is expected that he will be able to leave his bed in about a fortnight's time.

THE Irish branch of the Geological Survey has been transferred from the Board of Education to the Department of Agriculture and Technical Instruction for Ireland. The work will be carried on under the immediate direction of Prof. G. A. J. Cole.

WE regret to learn that Mr. H. B. Medlicott, F.R.S., formerly director of the Geological Survey of India, 1876–1887, died on April 6, at seventy-six years of age.

AMONG the portraits recently added to the National Portrait Gallery are those of Sir Charles Lyell, painted by Lowes Dickinson, Charles Darwin, and Prof. W. Whewell.

REUTER'S Agency is informed that the Duc d'Orléans has organised a North Polar expedition, which will leave for the Arctic under the Duc's personal leadership next month. For the purposes of the expedition the *Belgica*, the vessel of the recent Belgian Antarctic Expedition, has been secured, together with the services of Lieut. Gerlache, who will again command the ship on the present occasion. The object of the expedition is not to reach the North Pole, and, according to present arrangements, the Duc will not winter in the Arctic, although the *Belgica* will be provisioned for the event of her being closed in by the ice. The expedition will leave Norway probably on May 1 and proceed direct to Franz Josef Land, where it is believed that an attempt will be made to push northwards by way of a new channel. The Duc's staff will include some French men of science and a number of Norwegian sailors.

AT the annual meeting of the Australasian Ornithologists' Union, held at the end of last year, Captain F. W. Hutton, F.R.S., submitted a presidential address dealing with some interesting problems in connection with New Zealand's avifauna. The evidence he has obtained during his years of research leads him to think that the ancestors of many New Zealand birds went south along a land ridge which connected New Zealand with New Caledonia and New Guinea, probably in the early Eocene period. New Zealand ornithologists, Captain Hutton pointed out, have special advantages for studying the effects of the absence of enemies on development, and New Zealand itself offers more examples of degeneration in the wings of birds than does any other country in the world.

PROF. J. MACMILLAN BROWN, of Christchurch, New Zealand, recently paid a visit to the Maoris who live in the fastnesses of the great King country and Urewera country, in the heart of the North Island of New Zealand. He went specially to visit the "Uru-kehu," or red-headed Maoris, who are often seen in those districts. He had previously come to the conclusion that the Maoris' ancestors, in their migrations, crossed with a white race, and he informed a representative of the *Lyttelton Times* that his visit has strengthened his opinion. He states that in one assembly at which he was present at least 25 per cent. of the children had brown, or even flaxen, hair, a complexion which resembled that of the Italians, and fine European features.

DR. W. J. HOLLAND, director of the Carnegie Museum, Pittsburg, has arrived in London for the purpose of superintending the setting-up of the plaster model of the skeleton of the gigantic herbivorous dinosaur *Diplodocus carnegii*, presented by Mr. Andrew Carnegie to the British (Natural History) Museum. The restoration, which is described by the late Mr. J. B. Hatcher in No. 1 of the *Memoirs* of the Carnegie Museum, is mainly based upon two incomplete skeletons discovered respectively in 1899 and 1900 in the Upper Jurassic beds of Sheep Creek, Albany County, Wyoming. As restored, the skeleton is nearly 80 feet in length. Whether this dinosaur is really specifically distinct from the typical *Diplodocus longus* may be a question.

DURING a violent thunderstorm on March 31 the second pyramid of Ghizeh was struck by lightning slightly below the apex of the monument. Several of the immense stones of which the pyramid is built were dislodged and rolled down the sides to the sands below. The storm was the most violent experienced in Egypt for the past fifteen years. This is the first recorded instance of any of the pyramids having been struck by lightning.

IT is announced in *Science* that the first John Fritz gold medal will be conferred upon Lord Kelvin. This medal is awarded by a joint committee of the American Institute of Electrical Engineers, the American Society of Mechanical Engineers, the American Society of Civil Engineers, and the American Institute of Mining Engineers to the man most representative of, and eminent in, scientific advance in the engineering field.

THE following are the lecture arrangements at the Royal Institution after Easter:—Prof. L. C. Miall, three lectures on the study of extinct animals; Sir James Dewar, three lectures on flame; Prof. J. A. Fleming, three lectures on electromagnetic waves (the Tyndall lectures); Prof. H. Marshall Ward, two lectures on moulds and mouldiness; Dr. J. G. Frazer, two lectures on the evolution of the kingship in early society; and Mr. A. H. Savage Landor, two lectures on exploration in the Philippines. The Friday evening meetings will be resumed on May 5, when a discourse will be delivered by Prof. H. E. Armstrong on problems underlying nutrition.

A BRANCH of L'Alliance Française, an association for the spread of the French language, is to be established in London and Paris under the title of "Alliance littéraire, scientifique et artistique Franco-Anglaise." Information as to membership of the new association can be obtained from 186 Boulevard Saint-Germain, Paris. The first *soirée* will take place in London in the course of the present month. The presidents of the association are M. Paul Delombre, previously Minister for Commerce, and M. Pierre Foucin, Inspecteur-Général de l'Instruction publique. Among those who have promised their support to the new society are Lord Avebury, Sir William Crookes, Sir Archibald Geikie, Sir Oliver Lodge, Prof. Meldola, Sir William Ramsay, Sir Henry Roscoe, and Sir William White.

THE *Times* correspondent at Athens reports that the proceedings in connection with the Archaeological Congress began on April 7 with a reception at the university, at which the King and the Crown Prince were present. The opening ceremony took place at the Parthenon under the presidency of the Crown Prince, the King and Queen being also present. On April 8 Prof. Lambros delivered an address of welcome, recapitulating the achievements of foreign and Greek research in recent years. The ceremony of inauguration of the Penrose Memorial Library took place on April 8 in the British School. The King and Queen and all the members of the Royal family were present. After Mr. George Macmillan had given an account of the past history of the school, a marble tablet to the memory of Penrose was unveiled by the Crown Prince, who delivered an address in English. Speeches were then delivered by Mr. Cecil Smith, a former director of the school, M. Homolle, secretary to the congress, who paid an eloquent tribute to the amiable and noble character of Penrose, as well as to his great scientific attainments, and by Profs. Conze, Wheeler, Waldstein, and Bosanquet (director of the school). The various sections of the congress met for the reception and discussion of papers on April 9 and 10.

A meeting of the Association of Economic Entomologists will be held at Birmingham on April 19 and 20, in the large medical theatre of the university. The president of the association is Mr. F. V. Theobald, and the secretary Mr. W. E. Collinge, University of Birmingham.

The London Geological Field Class, conducted by Prof. H. G. Seeley, F.R.S., will begin its twentieth year's season on Saturday, April 29, with a visit to the north downs at Betchworth. The field class, which is carried on continuously on the Saturday afternoons in May, June and July, affords practical teaching in geology by studying direct from nature the structure and modes of occurrence of the rocks in the basin of the Thames and adjacent country. Further particulars may be obtained from the secretary, Mr. J. W. Jarvis, St. Mark's College, Chelsea, S.W.

At the annual meeting of the Iron and Steel Institute, to be held on May 11 and 12, the Bessemer gold medal for 1905 will be presented to Prof. J. O. Arnold. The awards of the Andrew Carnegie gold medal and research scholarships will be announced; and the president, Mr. R. A. Hadfield, will deliver his inaugural address. The following is a list of papers that are expected to be submitted:—experiments on the fusibility of blast furnace slags, Dr. O. Boudouard; recent developments of the Bertrand-Thiel process, Mr. J. H. Darby and Mr. G. Hatton; the application of dry-air blast to the manufacture of iron, Mr. James Gayley; the effect produced by liquid air temperature on the mechanical and other properties of iron, Mr. R. A. Hadfield; the cleaning of blast furnace gas, Mr. Axel Sahlin; the failure of an iron plate through fatigue, Mr. S. A. Houghton; the continuous steel-making process in fixed open-hearth furnaces, Mr. S. Surzycki; accidents due to the asphyxiation of blast furnace workmen, Mr. B. H. Thwaite; and the behaviour of the sulphur in coke in the blast furnace, Prof. F. Wüst and Mr. P. Wolff.

Reuter's correspondent at Rome reports that the draft scheme for the organisation of the International Agricultural Institute, which will be considered by the conference to be held in May, is as follows:—(1) The constitution and organisation of the institute. (2) Functions of the institute: (a) To report periodically information concerning agricultural production, the conditions of labour in rural districts, and the diseases of plants and live stock. (b) To facilitate the organisation and working of cooperation between the rural communities of different countries, and to provide insurance and banking facilities for the benefit of agriculture. (c) To propose on its own initiative or at the invitation of Governments interested, international measures and institutions for the protection of the common interests of the agriculturists of all countries, and at the same time to consider the resolutions passed by international congresses on agriculture. (d) To exercise other functions which are already exercised by the great agricultural associations, which the institute could discharge independently of the action of the different Governments. (3) The financial resources of the institute.

In the House of Commons on April 5 Sir W. Palmer asked the President of the Board of Agriculture whether his attention has been directed to experiments which have been carried on in America with a view to the propagation and use upon the land of nitrogen-producing bacteria, whether he is aware that certain rights relating to the method of preparation of these bacteria are the property of the United States Government, and that that Government is distributing packets of these bacteria free of charge to any farmers who apply for them, and that the result of such distribution has been beneficial for farming; and, if so, could he say whether any rights relating to the preparation of these nitrogen-producing bacteria prevent His Majesty's Government from adopting a similar course; and, if not, whether he is prepared to recommend that a similar free distribution be adopted in this country. In reply, Mr. Fellowes remarked that some articles on the subject have appeared in the Board's monthly journal. Experiments as to the value of nitrogen-producing bacteria are now being carried out under the auspices of the Board by several of the agricultural colleges in this country, and so soon as the results are known the Board will consider what further action in the matter can be taken in the interest of British agriculturists. The process of producing and cultivating the bacteria has been patented by the United States Department of Agriculture, but it appears that the department does not propose indefinitely to continue its gratuitous distribution. There appears to be nothing to prevent the manufacture and sale of the material in this country.

According to the report of the Australian Museum, Sydney, for 1903-4, remarkable fluctuations occur in the annual number of visitors. In 1900, for instance, the total was 85,474, in 1901 123,326, in 1902 106,704, and in 1903 118,372. The general condition and progress of the museum appear to be satisfactory

No. 3 of the Johns Hopkins University *Circular* for the current year contains an account of observations and experiments with regard to the abnormally elongated form assumed by a considerable percentage of American oysters during the early stages of growth. The author, Mr. O. C. Glaser, concludes that this is due to crowding, and that it is a premature assumption of the normal adult condition. The crowded condition of these prematurely old oysters makes it impossible for them to expand and grow to the normal width, but if removed to a more favourable situation they quickly assume the ordinary shape.

The second portion of the article by Mr. F. Voss in part iii. of vol. lxxviii. of the *Zeitschrift fur wissenschaftliche Zoologie*, on the thorax of the house-cricket, with especial reference to the articulation of the wings and their movements, and thus to the mechanics of insect flight in general, is devoted to the musculature, and is illustrated with several diagrams and text figures. The other article in the same issue, by Mr. F. Fuhrmann, of Gratz, is devoted to the history of the adrenal bodies of the guinea-pig. The internal tissue of these organs is subject to very rapid *post-mortem* degeneration, so that the investigation is one of considerable difficulty.

According to its report for the past year, the Rugby School Natural History Society continues to do steady work, and its permanent collections are making satisfactory progress. During the year two important additions have been made by gifts to the museum, namely, a collection of British butterflies and one of birds' eggs, the latter including many rare specimens. The conservatory, containing the greater part of the vivarium, has been rebuilt, and a new case is in course of construction for the geological collection. On the other hand, the secretary deplores the lack of interest in microscopy, and also the few competitors for prizes.

In the report of the Northumberland Sea Fisheries on the scientific investigations conducted in 1904, it is stated that there has been a decided decrease in the number of flat fish, especially plaice, in Cambois Bay, although in this respect the other stations do not depart materially from the satisfactory results of the last few years. A number of flat fish, chiefly dabs, were marked and returned to the sea. Those re-captured apparently indicate that plaice do not usually leave the inshore waters until they are approaching maturity (four or five years old), but that dabs show a separation of the sexes, the females remaining near the shore while the males migrate to deeper water twenty or thirty miles to the south. Legislation for the protection of lobsters does not work well, as the fishermen are in the habit of stripping and selling the "berried" females instead of returning them to the sea.

In the first part of vol. xxxiii. of Gegenbaur's *Morphologisches Jahrbuch* is continued Dr. A. Fleischmann's article on the skull of the Amniota, Dr. O. Hofmann contributing a section on the structure of the roof of the mouth-cavity in lizards. The second article, by Dr. H. Adolphe, is devoted to a discussion of the variation in the human sternum and vertebral column, more especially as regards the number of vertebræ which may bear ribs and which may enter into the composition of the sacrum. After referring to analogous variations in apes and monkeys, the author considers that there is no evidence that any of the earlier mammals had eight cervical vertebræ. In the third article Mr. W. M. Smallwood records some observations on the chromosome vesicles developed in the earlier stages of nudibranch molluscs.

The two original articles in *Biologisches Centralblatt* of March 15 are devoted to the subject of ants, Mr. E. Wasmann continuing his account of the origin of slavery among these insects, while Prof. D. H. Forel figures and describes the nests and "fungus-gardens" of certain South American ants. The photographs and notes on which the latter account is based were communicated to the author by Dr. E. Goeldi, director of the museum at Pará. In the case of *Atta sexdens*, it appears that the female has a fungus-garden to herself, in which the eggs are laid; and while this and other large species of the same genus, together with certain kinds of Acromyrmex, make their fungus-gardens in holes in the ground, the smaller *Atta moelleri* constructs them in hollow trees, under leaves, and in such-like situations.

A further instalment of the account by Mr. B. Fedtschenko of his journey in Central Asia is given in vol. iv., parts vi. and vii., of the *Bulletin du Jardin Impérial Botanique*, St. Petersburg. These letters relate to his wanderings across the Pamir plateau, and he describes the vertical sequence of plant formations observed in the unexplored valley of the Mouskol River.

The present time, when changes are pending in India in connection with the formation of a department of commerce and industry, is opportune for considering the possibility of changes in allied departments. A pertinent article advocating the establishment of a bureau of forestry as a complement to the Indian Forest Department appears in the *Indian Forester* (January). The duties of the staff would include the preparation of working plans, the institution and supervision of experimental investigations, and the responsibility of regulating the cultivation and supply of forest products.

A *Circular* (vol. ii., No. 24) of the Royal Botanic Gardens, Ceylon, by Mr. R. H. Lock, deals with the varieties of cacao trees existing in the gardens and the experiment station, Peradeniya, and incidentally supplies some interesting information on the colour of the seeds. As a primary division, Criollo varieties having seeds with a thin shell are distinguished from the Forastero varieties with a hard shell. Fruits of the old red type of Criollo were found to contain about 14 per cent. of purple and 80 per cent. of white seeds. Forastero varieties pass from forms of good quality, having well rounded beans of a light colour, to those of a poor quality, in which the beans are flat, purple, and bitter. The proportion of white to purple seeds in a number of pods of one of the best Forastero varieties was 35 per cent. to 63 per cent.

Nos. 1 and 2 of the *Zeitschrift* of the Berlin Gesellschaft für Erdkunde contain a valuable paper by Dr. S. Passarge on the Kalahari region and its significance as a factor in the ethnography of South Africa. The paper discusses the physical and biological conditions of the region, and the distribution of the races of mankind. It is illustrated by a number of excellent maps.

The most recent addition to the *Abhandlungen* of the Vienna Geographical Society is a paper by Dr. Artur Gavazzi, forming the first or "morphological" part of a monograph on the lakes of the Karst region. The work includes measurements of permanent lakes, fresh-water, brackish, and salt, "periodic lakes," and periodically inundated "poljen." Observations of the micro-plankton and diatoms have been made by Drs. L. Car, A. Forti, and V. Lurgaiolli. Dr. Gavazzi's paper forms an important contribution to our knowledge of an extremely interesting region.

We have received the report of the Danish Meteorological Institute on the state of the ice in the Arctic seas during 1904. The statistics go to show that the winter of 1903–4 was comparatively mild in that part of the Arctic regions which lies north of the Atlantic Ocean, that during 1904 the East Greenland current supplied the temperate seas with a smaller quantity of polar ice than in a normal year, and that the Labrador current carried more than the average number of icebergs past Newfoundland. It is expected that during 1905 there will be more ice along the coast of East Greenland and in Davis Strait than in 1904, and less off Labrador and Newfoundland.

The Meteorological Institute of the Netherlands has issued a paper, by M. J. P. van der Stok, continuing and extending M. Phaff's discussion of tidal observations made on board the light-ships on the Netherland coasts. The periodic movements in horizontal and vertical planes, and the progressive movements of the waters, are dealt with separately, and the general result is to support the view set forth by Lord Kelvin in 1878, that the tides of the North Sea would not be materially affected if the Straits of Dover were closed. Further observations, especially off the English coasts and in the centre of the North Sea, are necessary for the complete investigation of the complex conditions which occur.

AN interesting address was recently delivered to the Royal Meteorological Society (published in its *Journal* for January last) by Mr. C. W. R. Royds, first lieutenant of the National Antarctic vessel *Discovery*. As the observations are now under discussion, he was only able to give a general account of the meteorological conditions of the Antarctic, but entered fully into the arduous labours which were zealously carried out by the whole of the observing staff. The meteorological instruments were set up on the ice on April 17, 1902, in lat. 77° 50′ S., and eye observations were continued until February 15, 1904, at intervals of two hours; between 8h. a.m. and 10h. p.m. they were taken under the superintendence of Mr. Royds, and the night observations were divided between the eleven officers, each taking one night. In addition there were the self-recording instruments; these were managed under great difficulties, and their continuous registration was entirely due to the mechanical skill of Mr. Skelton, as they were frequently choked by blizzards. On these occasions the rain gauge would be buried under three or four feet of snow. The lowest screen temperature recorded in the winter quarters was $-59°.5$; on the same day at Cape Armitage ($1\frac{1}{2}$ miles distant) it was $-64°.6$; the coldest day at the latter station was $-67°.7$ (or nearly 100° of frost) on May 16, 1903. The highest black-bulb reading in the sun was 154°, on December 21, 1902. The heaviest gale recorded was 85 miles per hour, by the Robinson anemometer. Throughout the stay in the Antarctic Circle no *rain* was recorded, and fogs were not nearly so prevalent as is generally supposed; day after day clear skies and continuous 24 hours' sunshine were recorded. Speaking of the barometer as an instrument of warning of gales, Mr. Royds states that all faith was lost in it, as they came on without any appreciable sudden change in the motion of the mercury.

THE final report of the Royal Commission on Coal Supplies was recently reviewed at some length in NATURE (February 2, p. 324). The minutes of evidence, the reports on the various districts, and the appendices, on which the commissioners' conclusions were based have now been issued. The district reports contain much information of great value, and it is satisfactory to find that, in order to render them generally accessible, they are issued separately at moderate prices. The contents of the various parts are as follows:—part ii., report of Sir W. T. Lewis on the available coal resources of South Wales and the south of England; part iii., report of Prof. Lapworth and Mr. A. Sopwith on the coal resources of the midlands; part iv., report of Prof. E. Hull, Sir G. J. Armytage, and Mr. A. Strahan on the coal resources of North Wales, Lancashire, and Cheshire; part v., report of Mr. A. Currer Briggs on the coal resources of Yorkshire, Derbyshire, and Nottinghamshire; part vi., report of Sir Lindsay Wood on the coal resources of Northumberland, Durham, and Cumberland; part vii., report of Mr. J. S. Dixon on the coal resources of Scotland; part viii., report of Prof. E. Hull on the coal resources of Ireland; and part ix., report of the geological committee, consisting of Prof. E. Hull, Prof. C. Lapworth, Mr. J. J. H. Teall, and Mr. A. Strahan, on the resources of the concealed and unproved coalfields of the United Kingdom. Part x., which covers 400 pages, contains the minutes of evidence, and part xi. includes a series of appendices of great interest. Among these are an estimate of the future coal output of the United Kingdom, calculated at its average decreasing rate of increase during the last thirty years, by Mr. R. Price-Williams, a report on the colonial and foreign coal resources by Mr. Bennett H. Brough, and a report on deep borings through Secondary rocks by Mr. W. Whitaker. Lastly, part xii. is a supplement containing the plans and diagrams referred to in the evidence. The report on the coal available in concealed unproved areas at depths less than 4000 feet is certainly the most important of this valuable series of documents. Without being over-sanguine, the committee has added 40,000 million tons to the probable coal resources of the kingdom. The coloured geological map of the United Kingdom, on the scale of 25 miles to the inch, accompanying this report, is of particular interest.

THE well known firm of Bausch and Lomb (London agents, Messrs. A. E. Staley and Co.) has brought out an admirable instrument in their "B.B.P. portable microscope." The workmanship is excellent, and in spite of the fact that the stand and accessories are packed away into a case measuring $11.4 \times 7.8 \times 4.6$ inches, the instrument is thoroughly serviceable and convenient for use. The base of the stand is made of two diverging bars, which move on the upright column so as to assume a parallel position when ready for packing; but they are well and heavily constructed, and are perfectly rigid when open. The stage is large, and is ingeniously contrived to turn into the plane of the stand when in the case, and when open it is firmly held in its place. The objectives are of the quality which would be expected from a firm with so high a reputation, and the cedar oil for the immersion lens is contained in a metal box, so that there is no danger of breakage or leakage. We think the instrument quite justifies the description given of it as a microscope "capable of being taken out and set up in a few seconds ready for use, giving all the desirable features of the highest grade bacteriological laboratory instrument."

IN the classical researches of Sainte-Claire Deville on dissociation much use was made of the "hot and cold tube" in proving the existence of chemical reactions at high temperatures, the idea being that by suddenly cooling a gaseous system there would not be time for the recombination of the gases, and hence that some clue could be obtained as to the actual composition of the gaseous mixture at the high temperature. The properties of fused quartz have led M. Berthelot to repeat these experiments under different conditions, and an account of the results is given in the *Comptes rendus* for April 3. The substances under examination were enclosed in hermetically sealed quartz tubes, heated for about an hour at 1300° C. to 1400° C., and then suddenly cooled by dropping the tubes into cold water. The cooling in this way was at least as sudden as in Sainte-Claire Deville's experiments, and the whole contents of the tubes could then be examined. The observations were too numerous to be given in detail here, but the whole trend of the results was to show that no dissociation could be detected in cases where from the earlier experiments a positive result would be expected. Oxygen furnished no trace of ozone, and no trace of hydrocarbon could be formed from carbon, in any of its states, with hydrogen. The dissociation of carbon monoxide was practically inappreciable, and in a case of special practical importance, the dissociation of carbon dioxide, and in which two experiments were made, one with slow and the other with instantaneous cooling, no trace of dissociation could be detected.

A booklet on "Pattern Making," by Mr. J. E. Dangerfield, has been added by Messrs. Dawbarn and Ward, Ltd., to their "Home Workers' Series of Practical Handbooks."

A new edition of Mr. W. Woods Smyth's "Divine Dual Government" has been published by Messrs. Horace Marshall and Son. The present issue has been revised and illustrated with new matter, some of which has already appeared in earlier books, now out of print, by the same author.

Messrs. Longmans, Green and Co. have published a new edition of "Telegraphy," by Sir W. H. Preece, K.C.B., F.R.S., and Sir J. Sivewright, K.C.M.G. The book has been revised and enlarged, and now includes descriptions of recent devices used in telegraphy, in relation to fast-speed recorders, to automatic and translating apparatus for submarine circuits, to Murray's improvements in the Wheatstone automatic apparatus, and to the new telegraph switching system. A chapter on wireless telegraphy considered theoretically and in its most recent application has been added.

Mr. Henry Frowde has sent us two pages of the "New English Dictionary on Historical Principles," edited by Dr. J. A. H. Murray, to show how the word refraction and its congeners are defined and traced. The number of references to uses of these words is astonishing; and a vast amount of research must have been necessary to bring so much material together. We extract a few early references of historical interest:—Refracting, causing refraction, refractive; 1704, Newton, "Optics" (1721), 4 def. iv., "the perpendicular to the reflecting or refracting surface at the point of incidence"; 1764, Hornsby, in *Phil. Trans.*, liv., 145, "an excellent refracting telescope of 12 feet focus." Refraction; 1603, Holland, "Plutarch's Mor.," 1295, "the rainbow is . . . distinguished by sundry colours, by the refraction of our eie-sight against a cloud"; 1646, Sir T. Browne, "Pseud. Ep.," 347, "the colours are made by refraction of light, and the shadows that limit that light"; *Astron.*: 1603, Heydon, "Jud. Astrol.," 137, "there lieth a deceipt or fallacie in the refraction of beams, which cheifly happeneth about the horizon, where the aire is alwaies thickest"; 1669, Sturmy, *Mariner's Mag.*, ii., 118, "the refraction of the sun, moon and stars, causeth them to appear higher above the horizon than they are." Refractive; 1673, Flamsteed, in Rigaud's "Corr. Sci. Men" (1841), ii., 168, "the refractive air reaches some height above our heads"; *a* 1691, Boyle, "Hist. Air" (1692), 190, "the air . . . was filled with vapours and exhalations, that made it much more refractive than formerly."

OUR ASTRONOMICAL COLUMN.

Comet 1905 *a* (Giacobini).—A further extract from Dr. Strömgren's daily ephemeris for comet 1905 *a*, as published in No. 4009 of the *Astronomische Nachrichten*, is given below. A set of elements and an ephemeris similar to those obtained by Dr. Strömgren have been computed at the U.S. Naval Observatory, from observations made on March 26, 27, and 28, and are published in the same journal.

Ephemeris 12h. (Berlin M.T.).

1905	α (h. m. s.)	δ (° ′)	log r	log Δ	Brightness

Brightness at time of discovery (March 26) = 1·0.

The following magnitudes have been estimated by various observers at the times named:—

	h. m.		mag.
March 28	7 59·6	(Geneva M.T.)	11·5
29	8 28·2	(Vienna ,,)	13·0
April 1	9 6·3	(Bamberg ,,)	11·0

On the last mentioned date Prof. Hartwig found that the comet was circular, about 3′ in diameter, and had a scattered nucleus.

Variability of a Minor Planet.—A telegram from Prof. Pickering, published in No. 4009 of the *Astronomische Nachrichten*, announces that Prof. Wendell has discovered a variation of 0·5 magnitude in the brightness of the minor planet (15) Eunomia.

This is one of the asteroids situated at an intermediate distance from the sun, and having a revolution period of 1570 days.

Visual Observation of Jupiter's Sixth Satellite.—A further visual observation of Jupiter's sixth satellite has been made at the U.S. Naval Observatory with the 26-inch refractor.

Observing on January 8, Mr. Hammond made a search for the recently discovered satellite in the position computed from the Lick photographs, and there found a very faint object, which, from its movement in relation to a neighbouring star, proved to be the object sought.

Real Path of a Bright Meteor.—From a large number of observations made in south-west Germany, Herr H. Rosenberg has calculated the real path of an exceptionally bright meteor which was seen at 8h. 22m. (central European time) on March 21, 1904, and emitted about one-quarter of the light given by the moon at full.

After giving the details of the times and places of the various observations, he deduces the following values for the actual path of the object. Length of path 385 km., duration of flight about 9 seconds, mean velocity 42·8 km. per second, mean velocity relative to the earth 41·4 km. per second. The average absolute height of the path above the earth's surface was about 30 km. Other deductions are made concerning the actual size, brightness, parabolic velocity in space and actual path, and the following value is obtained for the radiant point:—long. = 23° 8′, lat. = +9° 10′ (*Astronomische Nachrichten*, No. 4008).

A New 24-inch Reflector at Harvard.—In No. 93 of the Harvard College Observatory *Circulars* Prof. E. C. Pickering announces that the construction of the new 24-inch reflector—one of the chief acquisitions with the Anonymous Fund of 1902—is now so far advanced that the instrument may be used for visual observations. The mirror was made by Messrs. Alvan Clark and Sons, and the mounting has been designed and constructed in the observatory workshop.

Magnitude observations of three of the variable stars discovered by Miss Leavitt near the Orion nebula have been made with this instrument, and their variability confirmed, by Mr. L. Campbell, and the results are set out in detail in the *Circular*.

Stars with Variable Radial Velocities.—A list of nine spectroscopic binaries discovered with the Mills spectrograph, in addition to the forty-eight previously announced, is given in No. 70 of the Lick Observatory *Bulletins*. Amongst them we find α Andromedæ, which was announced as a binary by Mr. Slipher in 1904, and which the Lick spectrograms show to have a negative radial velocity varying from 2 km. (October 5, 1903) to 36 km. (November 30, 1903). ζ Ceti has a small but undoubtedly real variation, whilst γ Geminorum shows a variation from −17 km. (on October 24, 1899) to −4·7 km. (on January 27, 1904). Twenty-five spectrograms of the brighter component of Castor, α^2 Geminorum, indicate a variation of about 26 km. in the radial velocity. Applying the values determined to Prof. Doberck's orbit of Castor, a preliminary value of 0″·05 is found for the parallax of this star; but this has not very great weight, owing to the uncertainty in the elements of the visual system. η Böotis with a period of several years, ξ Serpentis with a probably short period, ζ Lyræ, τ Sagittarii, and 71 Aquilæ are the other stars for which variable radial velocities have been discovered.

NORTH AFRICAN PETROGLYPHS.

M. E. F. GAUTIER has published in *l'Anthropologie* (xv., 1904, p. 497) an illustrated account of a recent find of rock carvings in the ravine of Zenaga, between

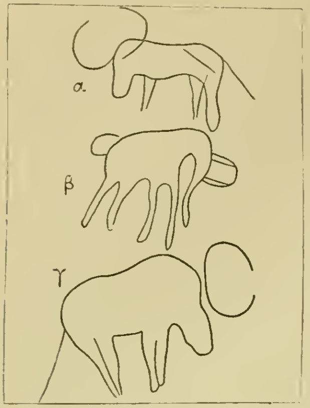

FIG. 1.—Rock carvings from Zenaga. Dimensions from the furthest point of the horns to the end of the body. α, 43 cm.; β, 39 cm.; γ, 53 cm.

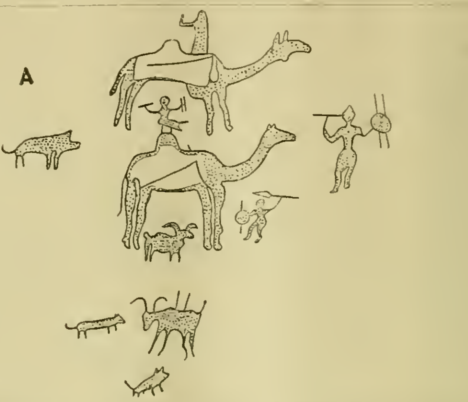

FIG. 3.—Touareg rock carving. Total height of the space occupied by the people.

Figuig and Beni-Ounif, in Sahara. The drawings are in deep outline and of large size, sometimes life-size, and their antiquity is established by the patina in the cuts being as pronounced as that on the surface, and by the fact that

FIG. 2. Rock carving from Zenaga. Dimension, 1 metre from the head to the tail. All the part of the design left white is carefully polished in the original.

some of the animals represented, such as the elephant, no longer exist there, while others, like the buffalo, are now extinct. In Fig. 1 we have two recognisable portraits of *Bubalus antiquus* and one of an elephant. Several South Oranais petroglyphs represent a ram or goat with a spheroid on its head, provided with projecting appendages (Fig. 2). It is suggested that the spheroid is a solar disc flanked on each side by a snake (*uraeus*), and this would be a representation of the great god Ammon, of Thebes. If this be so, the question arises, did the inspiration of the South Oranais engraving come from Egypt, or had the god Ammon a Libyan origin? The goat (*Ovis longipes*) of Zenaga differs in some details from those of Bou-Alem, and the "solar disc" is provided with rays. The other drawings of this problematic design were exhibited at the International Congress of Anthropology of 1900, and gave rise to a long discussion.

Rock carvings of a very different character were discovered by the author in the Touareg (Tawarek) country on the first slopes of the Hoggar (Ahaggar) massif, 200–300 kilometres south of In Salah. Some are scribblings in which animals and men are represented diagrammatically, and with these inscriptions are associated. M. Flamand some time ago described entirely similar graffiti in South Oranais which he identified as "Libyco-berbères." The greater part of the figures in this paper illustrate engravings of a very different character, and are far less ancient than those just referred to, for the animals represented are forms that still exist there. The presence of the camel is very significant, since it is generally admitted that it was only introduced, or re-introduced, into north-west Africa in the first centuries of our era, and appears to have been abundant there about the period of Justinian. Other animals represented are the horse, ass, cattle, goat, moufflon, gazelle, dog, ostrich, &c. The engraved portions differ in their colour markedly from the rest of the rock, and lack patina. From their appearance, these petroglyphs may be recent, but it has been denied that they have any relation with the Touaregs. Direct evidence is afforded by the representations of men instead of the square shield, very long spear, and sword of the present inhabitants. These men are provided (Fig. 3) with a small round shield and three javelins, thus proving that they are "Libyco-berber" productions.

A. C. H.

THE MINERAL RESOURCES OF CANADA.

THE publications of the Geological Survey of Canada have long been characterised by the want of promptness of publication. This defect is, however, to a large extent removed by the new departure made by the section of mines under the direction of Mr. E. D. Ingall. It consists in issuing a series of bulletins, giving in condensed and popular form information regarding the mineral resources of the Dominion, together with particulars of similar occurrences in other countries, which may be of use to mining engineers in Canada. We have received thirteen of these bulletins, and from the information given it is evident that the mineral resources of the Dominion are of a most varied character, and that the mineral industry is in a healthy condition. The subjects dealt with are platinum, coal, asbestos, infusorial earth, manganese, salt, zinc, mica, molybdenum and tungsten, graphite, peat, apatite, and copper.

So far the production of platinum has been obtained from placer workings on the Similkameen river in British Columbia. At Sudbury, Ontario, it is found *in situ* in combination with arsenic and associated with the nickeliferous pyrrhotite deposits. The yield of platinum in Canada has been falling off for some years past and is now insignificant.

The bulletin on coal covers sixty-four pages, and contains a collection of analyses of typical coals and a valuable bibliography of the subject. In 1902 the output of coal in Canada exceeded seven million tons. The principal areas at present worked are the Nova Scotia coalfields with rocks of Carboniferous age, and the Cretaceous coalfields of Vancouver island, and of the Crow's Nest Pass, British Columbia. Anthracite is mined in Alberta, and lignite is mined in the Souris river district, Assiniboia, and in the Yukon district.

The asbestos industry of Canada is of considerable importance, the production having increased from 380 tons in 1880 to 40,000 tons in 1902. Canada now furnishes about 88 per cent. of the world's supply. The deposits are found in serpentine. In 1896 the manufacture of asbestic was begun. This is a finely-ground serpentine in which there is a small amount of very fine fibre disseminated, and the resulting product is specially adapted for fine plaster for walls and interior decoration. Its value per ton is low, but as its preparation involves little extra expense, it is claimed that a profit results from its manufacture.

Infusorial earth was produced in Canada in 1902 to the amount of 1000 tons, valued at 3300*l*. It is mined at Bass river lake, and St. Ann's, Nova Scotia, and is sold chiefly in the United States. The uses to which it is put are varied. Formerly it was largely used in the manufacture of dynamite, but it has now been replaced by cheaper absorbents, such as wood pulp. It is now chiefly used as a polishing material and as a boiler covering. It can also be used in the manufacture of bricks when great lightness is required.

Although Canada has not yet taken a prominent place among the manganese-producing countries of the world, this is not due to lack of deposits of the ore. The extent of the production depends on the development of steel manufacture, and, as Canada is now making great strides in this direction, its deposits will probably soon assume greater importance. The ores represented comprise pyrolusite, manganite, psilomelane, and wad, and as some of the Canadian deposits contain a large proportion of the first-named mineral, the ore is specially adapted for chemical manufacture.

At present Ontario is the only province producing salt, the output in 1902 having been 64,000 tons. The country's chief resources consist of the rock salt beds underlying some 2500 square miles on the eastern shores of Lake Huron. The amount of salt imported into Canada is at present double the amount produced in the country, owing to the fact that salt is produced more cheaply in England, whence the bulk of the imports come.

In eastern Canada mica occurs in large and important deposits, the mining industry being chiefly confined to the provinces of Ontario and Quebec. The merchantable mica is always associated with intrusive masses and dykes of pegmatite-granite and pyroxene, which cut the gneiss and crystalline limestone. The mica produced is chiefly used for electrical purposes.

Apatite is widely distributed in Canada in deposits in the crystalline rocks, and in fossiliferous strata of Cambrian age. In 1889 the province of Ontario produced as much as 3547 tons, but since then, owing to the competition of the cheaply mined phosphates of Carolina, the output has rapidly decreased. Graphite is widely distributed in the gneiss and crystalline limestones of Canada, the output in 1901 having been 2210 tons. Zinc ore is produced at one mine in Olden township, Ontario. The ores of molybdenum and tungsten are of frequent occurrence in Canada. Copper ores have been known in eastern Canada for nearly a century, and large amounts of capital have been expended in developing what appeared to be promising localities, but little economic success has as yet resulted.

The Canadian peat resources are dealt with by Dr. R. Chalmers in a bulletin of forty pages. The peat bogs in the eastern provinces are attracting attention in view of the depletion of the forests and the increasing prices of coal, and attempts are being made, in many cases with poor success, to utilise them in the production of fuel, coke, and moss-litter.

In connection with this valuable series of bulletins of the Geological Survey, reference may be made to a memoir in the *Ottawa Naturalist* on the marl deposits in Ontario, Quebec, New Brunswick, and Nova Scotia, by Dr. R. W. Ells, the author of most of the bulletins mentioned. The chief value attributed to this shell-marl was supposed to be confined to its use as a fertiliser for soils deficient in calcareous matter. Recently it has been found to be specially adapted for the manufacture of the best grades of Portland cement, when mixed with a proper proportion of clay; and large manufacturing establishments have been established at several points, more especially in the province of Ontario.

The latest publication of the Geological Survey of Canada is an exhaustive report by Dr. A. E. Barlow on the origin, geological relations, and composition of the immense nickel and copper ore deposits of Sudbury, Ontario. Details of the mining, smelting, and refining methods are given, and reference is made to the character and extent of all the more important nickel ore deposits in other countries. With a production of 6253 tons of metallic nickel in 1903, valued at 5,002,204 dollars, Sudbury is the largest producer of nickel in the world; and this monograph of 236 pages, with numerous plates and maps, summarises all the previous original investigations and supplies the most detailed and accurate information regarding these important deposits yet available.

THE ROYAL HORTICULTURAL SOCIETY.[1]

THE history of the Royal Horticultural Society has been chequered to an extent probably exceeding that of any other society. At one time fashionable, it enjoyed a fictitious prosperity. We say fictitious, for horticulture, especially scientific horticulture, was neglected, and, as a consequence, the wave or waves—for there were several—of prosperity broke on the shores of adversity, with the result that the gardens were curtailed, the expenditure was reduced in all directions, the valuable collections were sold or destroyed, the herbarium and the library were dispersed.

It is, however, not our purpose now to dwell on ancient history, but rather to point out the satisfactory progress in recent years of which the journal before us affords evidence. Some foreshadowings of that progress date back to the year 1866, when an international horticultural exhibition on a very large scale was held on the ground where the Natural History Museum now stands. The exhibition itself differed from others mainly in its extent and in the larger participation of foreign exhibitors. It was organised and managed, not by the society, the financial position of which at that time precluded it from embarking on such an enterprise, but by a special committee presided over by the late Sir Wentworth Dilke, to whose organising faculty and strenuous labour the success obtained was largely due.

[1] The *Journal* of the Royal Horticultural Society, vol. xxix., parts i., ii., and iii.

If this exhibition had been merely a flower-show on a gigantic scale there would have been little or no need to advert to it in these columns. But associated with it was a botanical congress attended by many of the chief European notabilities, and presided over by the late Alphonse de Candolle. The results of their discussions were recorded in a report of proceedings which still forms a most valuable document. Copies are now rarely met with, although they were distributed widely among foreign and British botanical libraries.

We have a special reason for alluding to this nearly forgotten congress, because it may be looked on as the progenitor of two important events in the modern history of the Royal Horticultural Society. A large surplus was eventually derived from the exhibition, and this surplus was devoted to the publication of the proceedings before mentioned, to charitable purposes, and to the purchase of the valuable library of the late Dr. Lindley. This library was placed in the hands of trustees for the benefit, primarily, of the fellows of the Royal Horticultural Society, and, under certain regulations, of the general public also. In this way the society once more became possessed of an extensive library, which cannot be alienated if evil days should again arise. It is now, after various vicissitudes, fittingly installed, at the expense of Baron Sir Henry Schröder, in the new building erected for the society in Vincent Square, Westminster.

Thus has been accomplished one result of the congress of 1866. Another consequence of that meeting was the formation of a scientific committee under the presidency of Sir Joseph Hooker, which has endeavoured so far as circumstances permitted to carry out the objects formulated in M. de Candolle's presidential address. The early days of the committee, when such men as Sir Joseph Hooker, Mr. Berkeley, Prof. Westwood, Mr. Wilson Saunders, Colonel Clarke, Mr. Andrew Murray, Sir William, then Mr., Thiselton-Dyer, and other naturalists took part in the discussions, remain as a pleasant memory. The Rev. Prof. Henslow, who acted as secretary for the last quarter of a century, has only lately relinquished his office. The committee still includes a body of experts in many departments of horticulture and natural history generally.

We have alluded to the new building, to the erection of which Baron Schröder has magnificently contributed, whilst others have not been backward. Much, however, remains to be done, and until the existing debt is cancelled not much in the way of scientific experiment or research can be effected. The society has been exceptionally fortunate in its centenary year. Not only has it secured a fine hall for exhibition purposes, together with commodious offices and accommodation for the library, but through the generosity of Sir Thomas Hanbury it has come into possession of the late Mr. G. F. Wilson's interesting garden at Wisley, near Weybridge.

The old garden at Chiswick, the value of the services of which in the past is beyond compute, has been abandoned, soil and climate no longer being propitious for gardening operations. The cultural trials hitherto carried out at Chiswick will henceforth be conducted at Wisley, and there is every reason to hope that in a short time a research station under a competent director may be established, and thus a great and pressing need may be supplied.

This is rather a long preface to the notice of the *Journal*, but we hope it will not be thought irrelevant. The necessity for a journal to link together all the otherwise separate departments of the society has always been recognised, but in the evil days aforementioned the publication was often spasmodic and irregular. Since the appointment of the Rev. W. Wilks as secretary, and under the steady impulse of the president, Sir Trevor Lawrence, a great improvement all round has been manifested, and in no way more remarkably then in the contents and regularity of issue of the journal. So marked is the improvement that it has become too much for the digestion of some people, and some of the fellows are crying out, not for more, but for a more limited supply.

Our notice has extended to such a length that we can only indicate some of the contents other than those relating merely to practical cultivation; such are Dr. Cooke's article on the fungous pests of the shrubbery, with coloured illustrations; on the heredity of acquired characters, by Prof. Henslow; gooseberry mildew, by Mr. Salmon; diseases of Calanthes, by Mr. Bidgood; note on electric heating, by Mr. Rogers; diseases of the potato, by Mr. Massee; Indian primulas, by Sir George Watt; and a large number of other communications which tend to show that the scientific side of horticulture is not neglected. The abstracts from botanical and horticultural literature which have of late formed so important a feature of the *Journal* are omitted from the present part, possibly because so much space has, not unnaturally, been devoted to the proceedings in connection with the centenary celebration and the formal opening of the new hall by H.M. the King.

The interests of the commercial side of horticulture, however great their importance, can very well be left to take care of themselves. Nevertheless, the cultivators may well look to the society for light and guidance in such matters as cucumber spot, and the many diseases which so very seriously affect their business prosperity. Progressive horticulture looks to the society to investigate outstanding problems, open out new paths, and generally to acquire and diffuse useful knowledge. Even if not immediately useful, such knowledge is sure eventually to be of advantage even to the "practical man." With a research station at Wisley, a competent director, a sympathetic scientific committee to direct and advise, and an energetic secretary, the society may on entering its second centenary look forward to being able to advance scientific horticulture in a more thorough manner than it has ever done before.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

The *Pioneer Mail* states that a gentleman of Nagpur has bequeathed a sum of fifty thousand rupees to the Central Hindu College, Benares.

At the spring graduation ceremony of the University of Edinburgh on April 7 the honorary degree of LL.D. was conferred upon Prof. W. W. Cheyne, C.B., F.R.S., Dr. J. H. Jackson, F.R.S., Dr. A. D. Waller, F.R.S., Sir Frank E. Younghusband, and Prof. G. A. Gibson.

The Catholic University of America will receive, says *Science*, a bequest of 20,000*l*. from Miss Helen Tyler Gardiner. We learn from the same source that Mr. Andrew Carnegie has agreed to give a 10,000*l*. library to the Washington and Lee University on condition that the university raises an endowment of 10,000*l*. for maintaining it.

The *Glasgow Herald* announces that by the will of the late Mr. Donald the sum of 20,000*l*. is bequeathed to the Glasgow and West of Scotland Technical College, to be paid on the death of Mrs. Donald. After various other bequests have been made, the residue of the estate is to go to the governors of the Glasgow and West of Scotland Technical College for purposes specified in the trust disposition and settlement.

The committee of the Privy Council has decided to recommend the King to grant a Charter incorporating a university in Sheffield. A large sum of money has already been given or promised for the endowment of the university, and, in addition, the city council has pledged the city to the gift annually of a sum equal to the proceeds of a rate of 1*d*. in the pound (the capitalised value of which gift is 200,000*l*.). The draft Charter of the proposed university provides for the establishment of a teaching university with powers to grant degrees in the faculties of arts, science, technology, and medicine.

The articles of agreement under which it is proposed to combine the Massachusetts Institute of Technology and Harvard University have been made public. Provision is made for a joint school of industrial science, to be known under the present name of the Institute of Technology, to be governed by an executive board of nine members, of which three shall represent Harvard, and to be maintained by present institute funds, augmented by the income of all funds of the Lawrence Scientific School, by three-fifths of the net income which may accrue from the Gordon McKay bequest, amounting to several millions, and by the income of all property which Harvard may hereafter acquire for the promotion of instruction in industrial science.

THE new regulations recently issued by the War Office, under which commissions in the Army may be obtained by university candidates, provide that commissions shall be allotted each half-year to the University of London. To satisfy the requirements of the regulations, the Senate has appointed a nomination board for military commissions which will nominate qualified students for commissions, and arrangements have been made for the instruction of candidates in military subjects. To be eligible for a commission, a candidate must have graduated as an internal student, and this involves three years' study at one or more of the schools of the university. Before a student can be nominated for a commission he must, as a rule, have attended the various courses of instruction in military subjects in the university, and he must have been attached for two periods of six weeks, or for one period of twelve weeks, to a regular unit. Courses of lectures in military subjects are being given at the University of London by Colonel H. A. Sawyer, P.S.C., and Lieut.-Colonel F. N. Maude, P.S.C., late R.E.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, February 23.—"Two Cases of Trichromic Vision." By Dr. F. W. **Edridge-Green.** Communicated by Dr. F. W. Mott, F.R.S.

One case (Prof. J. J. Thomson) sees only three colours in the bright spectrum—red, green, and violet. He can distinguish nothing of the nature of pure yellow, like the sensation given him by the sodium flame, in the spectrum. There is no definite colour to him at the portion of the spectrum where the normal sighted see pure blue. Reddish-green would describe the orange and yellow regions and greenish-violet the blue. λ 5950 (orange-yellow) is the point which differs most from red and green. There was no shortening of either end of the spectrum.

Difference of Hue Perception.—The author then tested him with his apparatus for ascertaining the size of different parts of the spectrum which appear monochromatic, and found him defective in distinguishing differences of hue.

Colour Mixtures.—Tested with Rayleigh's apparatus for matching spectral yellow by a mixture of red and green, the mixed colour of his match always appeared green to the author.

Classification Test.—Only a few colours were selected in each case. On being asked to pick out all the yellows he chose those with orange in them. He had considerable difficulty in matching the colours. In common with the cases previously observed, the effects of simultaneous contrast were much more marked than in the normal sighted. Two wools changed colour to him on being contrasted, when no change was evident to the author.

Lantern Test.—He correctly named the red, green, and violet with and without the neutral glasses, and saw them at the normal distance. He had difficulty with yellow and blue. He called pure yellow "greenish yellow."

The other case is that of Mr. P. S. Barlow, a research student in the Cavendish Laboratory, and was similar in most respects to the above.

The author uses the term trichromic as a statement of the fact that persons having this vision see only three colours in the bright spectrum, whilst the normal sighted see six, and may, therefore, be designated hexachromic. It is probable that the appearance of the bright spectrum to the trichromic is very similar to that of a spectrum of feeble luminosity to the normal sighted, in which only three colours—red, green, and violet—are seen. The defective difference perception which is found in these cases accounts for most of the facts. Both these cases are bordering on the tetrachromic, as the sodium flame appears to give rise to a distinct sensation.

March 2.—"Atmospheric Electricity in High Latitudes." By George C. **Simpson,** B.Sc. Communicated by Arthur Schuster, F.R.S.

This paper is an account of a year's work on atmospheric electricity undertaken at Karasjok, Norway, from October, 1903, to October, 1904, with the results of a month's observations on atmospheric radio-activity made at Hammerfest.

Karasjok is situated well within the Arctic Circle (69° 17′ N.), and during the winter has a severe Arctic climate, so that it is well situated for finding the influence of meteorological elements and the presence or absence of direct sunlight on the electrical conditions of the atmosphere.

The observations were limited to determinations of the potential gradient, electrical dissipation, atmospheric ionisation, and atmospheric radio-activity. A continuous record of the potential gradient was obtained by means of a Benndorf self-registering electrometer, and measurements of the dissipation and ionisation were made three times each day unless the weather made it impossible to use the instruments. Measurements of the radio-activity were made between the hours of 10 to 12 a.m., 3 to 5 p.m., and 8.30 to 10.30 p.m. on 253 days, and in addition 42 measurements were made between 3 and 5 a.m. The results of the work are shortly as follows:—

YEARLY VARIATION.—*Potential Gradient.*—The yearly course was found to be in accordance with the general rule for the northern hemisphere—rising rapidly from October to February, when it reaches a maximum, then falling more rapidly until the end of May, after which it remains constant until the winter sets in again during October. *Dissipation.*—The yearly course is exactly opposite to that of the potential gradient, the curves representing the two being almost mirror images of one another. *Ionisation.*—The course of the ionisation consists of a nearly linear six months' fall from the beginning of September to the end of February, followed by a similar six months' rise from March to the end of August.

DAILY VARIATION.—*Potential Gradient.*—The daily course for the whole year consists of a single period having a minimum about 5 a.m. and a maximum about 9 p.m. *Dissipation.*—For the whole year the dissipation is slightly higher at midday than earlier in the morning, while the evening observations show the lowest dissipation of the three. *Ionisation.*—The daily period of the ionisation is not so pronounced as that of the dissipation, but the ionisation is slightly lower in the evening than in the morning or at midday during the whole year.

RELATION BETWEEN THE METEOROLOGICAL AND ELECTRICAL CONDITIONS OF THE ATMOSPHERE.—*Wind.*—As is to be expected, the dissipation increases greatly with the wind strength. *Temperature.*—Both the ionisation and dissipation become much less as the temperature goes down. With temperatures between 10° C. and 15° C. the dissipation is 4·95 per cent. and the ionisation 0·44 per cent., while with temperatures below −20° C. these become 0·83 per cent. and 0·17 per cent. respectively. The potential gradient increases as the temperature falls. *Relotive Humidity.*—With rising relative humidity the dissipation falls rapidly, and the ratio of negative to positive dissipation increases. When the whole year is taken into account, the same result is found for the ionisation; but for the winter and summer six months, taken separately, the effect of the humidity of the air on the ionisation is not apparent.

INTERRELATION OF ELECTRICAL FACTORS.—Both the dissipation and ionisation greatly influence the potential gradient. Low values of ionisation and dissipation are accompanied by high values of the potential gradient, and *vice versâ*. The dissipation increases with the ionisation.

THE AURORA AND THE ELECTRICAL CONDITION OF THE ATMOSPHERE.—No relation whatever could be detected between the aurora and the electrical conditions of the atmosphere. The most careful watching of the electrometer needle revealed no variation of the potential gradient with variations of the aurora.

RADIO-ACTIVITY.—Measurements of the radio-activity were made by Elster and Geitel's method, and their arbitrary unit was used in expressing the results. A most distinct yearly course of the radio-activity was found, the maximum, 129 (mean for month), falling in December, and the minimum, 47, in June. The radio-activity has also a very pronounced daily course, the maximum, 162 (mean for year), falling in the early hours of the morning, and the minimum, 58, about midday.

There is a distinct connection between the radio-activity and the meteorological conditions of the atmosphere; the radio-activity increases as the temperature falls, rises as the relative humidity rises, decreases with increasing wind strength, and is greater with a falling than with a rising barometer. All these facts support Elster and Geitel's theory that the source of the emanation in the atmosphere is the soil of the ground. Those meteorological conditions which prevent the air immediately above the ground from ascending tend to increase the radio-activity; on the contrary, all those conditions which cause a rapid circulation of the air greatly reduce the radio-activity when measured in the lower atmosphere.

OBSERVATIONS AT HAMMERFEST.—The mean values of the radio-activity were found to be lower at Hammerfest on the coast than at Karasjok inland. The most important result of the Hammerfest measurements was the great difference between the radio-activity of the air from the sea and that from the land. The mean radio-activity with a wind from the sea was only 6, while with a land breeze the mean was 72.

March 16.—"A New Radio-active Element, which Evolves Thorium Emanation." Preliminary Communication. By Dr. O. **Hahn.** Communicated by Sir William Ramsay, K.C.B., F.R.S.

The radio-active preparation was gained from barium radium bromide, obtained from thorianite from Ceylon, while fractionating it in order to separate the radium. It collected along with small traces of iron and other impurities in the more soluble portions, and was precipitated by ammonia. From this preparation a quantity of about 10 mg. of a strongly radio-active oxalate was obtained, giving off a strong emanation and imparting bright luminosity to sensitive screens. The emanation was found to be identical with that of thorium; different samples gave for the half-period of decay from 52 to 55 seconds. For the half-period of the induced activity somewhat more than $11\frac{1}{2}$ hours was found. The emanation given off by the 10 mg. of the oxalate, dissolved in hydrochloric acid, corresponds in intensity to more than that of a kilogram of thorium in solution; consequently it was more than 100,000 times stronger than the common thorium emanation when compared weight for weight. Further work led to the separation of about 20 mg. of a substance giving nearly 250,000 times more emanation than thorium.

Whether this active substance is the constant radio-active constituent of thorium preparations, or whether it is another new radio-active element, remains still undecided. It is hoped that an even more strongly radio-active product may be obtained, and that it may be possible to describe more in detail the properties of the substance.

Recent researches would appear to show that the amount of this substance in soil is comparable with, but still considerably smaller than, radium.

March 30.—"The *Rôle* of Diffusion in the Catalysis of Hydrogen Peroxide by Colloidal Platinum." By Dr. George **Senter.** Communicated by Sir William Ramsay, K.C.B., F.R.S.

The deviations from the simple logarithmic formula in the catalytic decomposition of hydrogen peroxide by colloidal platinum are probably due to disturbances caused by convection currents. When the velocity-constant calculated on Nernst's diffusion hypothesis is great compared with the chemical velocity-constant, increased convection can produce no appreciable effect on the observed reaction-velocity.

In the case under consideration, therefore, since increased convection modifies the observed reaction-velocity, there must be some error in the assumptions which lead to the conclusion that the diffusion velocity-constant is great in comparison with the chemical velocity-constant. This error is probably to be found in the assumption that the whole surface of the platinum is, under ordinary conditions, active towards hydrogen peroxide.

It cannot be claimed, from the above considerations, that Nernst's hypothesis is true for the platinum catalysis, but only that the diffusion-velocity is not great in comparison with the chemical velocity. Other considerations, however, such as the small value of the temperature coefficient, make it probable that the above hypothesis does apply to this particular action. Further support for this view may, perhaps, be found in the fact that the deviations from the simple logarithmic law in catalysis by platinum have their exact analogy in the hæmase catalysis. On the "chemical" velocity hypothesis it would seem rather remarkable that two catalysers of so different origin should show exactly similar behaviour, but this becomes at once intelligible on Nernst's hypothesis, according to which the chemical action plays quite a secondary part in the reaction-velocities in question.

Mineralogical Society, March 15.—Prof. H. A. Miers, F.R.S., president, in the chair.—Description of the big diamond recently found at the Premier Mine, Transvaal: Dr. F. H. **Hatch** and Dr. G. S. **Corstorphine.** The stone weighed more than $1\frac{1}{4}$ lb., and its greatest linear dimension was 4 inches. It was part (probably less than half) of a distorted octahedral crystal.—On some new mineral localities in Cornwall and Devon: A. E. I. M. **Russell.** An account was given of various new finds of the minerals anatase, scheelite, wolframite, childrenite, apatite, and connellite.—On a crystal of phenakite from Africa: L. J. **Spencer.** This crystal, which was transparent and rich in faces, was brought back together with crystals of tourmaline, corundum, and amethyst, by the Rev. A. North Wood from the Usagara country in German East Africa.—Notes on various minerals from the Binnenthal, Switzerland: G. T. **Prior** and G. F. Herbert **Smith.** Further crystallographic and chemical details were given of the three new red minerals from the Binnenthal originally described by R. H. Solly, and named by him Smithite (after G. F. Herbert Smith), Hutchinsonite (after A. Hutchinson), and Trechmannite (after C. O. Trechmann). Smithite is a sulpharsenite of silver having the composition represented by the formula $AgAsS_2$; it is monoclinic with $a:b:c=2.2205:1:1.9570$, β 78° 40′. A perfect cleavage parallel to 100 distinguishes it from the other two red minerals. Hutchinsonite is rhombic with $a:b:c=1.6356:1:0.7540$. A prominent form is 140. Trechmannite is rhombohedral with $c=0.7265$. The symmetry is the same as that of quartz.—On a new oxychloride of copper from Sierra Gorda, Chili: G. T. **Prior** and G. F. Herbert **Smith.** This new mineral, to which the name paratacamite was given, has the same chemical composition as atacamite, but begins to lose its water at a higher temperature than that mineral. It is pseudorhombohedral with $rr'=83°$ nearly. Twins about r are common. It displays optical anomalies, for minute fragments under the microscope are found to be biaxial.—On Dundasite from North Wales: G. T. **Prior.** The mineral was found by Mr. H. F. Collins in the Welsh Foxsdale Mine, Trefriw, Caernarvonshire; it occurs in white silky radiating tufts on cerussite with allophane; analysis showed it to be identical with Dundasite, hitherto known only from Dundas, Tasmania. A probable formula is $PbO.Al_2O_3.2CO_2.4H_2O$ or $PbH_2(CO_3)_2.Al_2.OH_6$.

Zoological Society, March 21. Mr G. A. Boulenger, F.R.S., vice-president, in the chair.—*Exhibits.*—Photograph of a wounded Oryx (*Oryx beisa*) hiding in undergrowth of wood in its native haunts, in order to show the protective nature of the coloration of the animal: F. **Gillett.**—A series of pencil sketches of fishes of the Rio Negro and its tributaries made by Dr. A. R. Wallace about fifty years ago: C. Tate **Regan.**—Radiograph of a living snake showing the skeletons of two frogs it had swallowed some hours previously: M. **Yearsley.**—Skulls of the fallow deer (*Dama vulgaris*) and the red deer (*Cervus elaphus*) showing arrest of the growth of the antlers due to complete or partial castration: R. E. **Holding.**—*Papers.* Effects of castration upon the horns of the prongbuck (*Antilocapra americana*): R. I. **Pocock.** The effects of the operation were curvature in growth, prevention of exuviation, and practical suppression of the anterior tyne.—The mammals and birds of Liberia: Sir Harry **Johnston,** G.C.M.G., K.C.B. Although Liberia was not marked off clearly by any natural features from either Sierra Leone on the one hand or the Ivory Coast on the other, it possessed a certain distinctness and a slight degree of peculiarity as regards its flora and fauna. As regards mammals and birds, Liberia was, to a great extent, a meeting-place for the forms of northern Guinea (Sierra Leone to the Gambia) and those of the Gold Coast, the Niger Delta, and the Cameroons. The species of mammals peculiar to it included the dwarf hippopotamus, the zebra antelope, Jentink's duiker, and Büttikofer's monkey. The author enumerated eighteen species of mammals and twenty of birds, specimens of which had been obtained by various collectors in Liberia.—Abnormal remains of the red deer (*Cervus elaphus*): M. A. C. **Hinton.** The remains consisted of three antlers which were obtained from different post-Pliocene deposits in the south of England. They agreed in having all the tynes suppressed and in being supported upon very long pedicles, thus resembling in form, though much exceeding in size, those of the pricket. Rudimentary offsets were seen on the most perfect example, which proved the antler to be the third in the series. These antlers belonged to individuals who had suffered testicular injury at an early period of life, by which the characters of youth were retained for a longer period than was usual.—On the affinities of Procolophon: Dr. R. **Broom.** The author believed that reptiles in Permian times became specialised along two distinct lines, the one represented by the pareiasaurians, anomodonts, therocephalians, and theriodonts, and terminating in the mammals, the second giving rise to all the other reptilian orders. The common ancestor was believed to have been a true reptile probably belonging to the order Cotylosauria. Procolophon was held to be an early member of the branch which led to the rhynchocephalians, and possibly fairly closely allied to the land ancestor of Mesosaurus.—Skulls of the fossil reptile Procolophon from Donnybrook and Fernrocks: Prof. H. G. **Seeley.** The author concluded that the main affinities were with the Anomodontia, chiefly with the Pareiasauria, and in the teeth with the Theriodontia; but that in a less degree there were indications of affinity with reptiles classed as labyrinthodonts. All parts of the skeleton supported the separation of the Procolophonia as an order of extinct Reptilia.

Geological Society, March 22.—Dr. J. E. Marr, F.R.S., president, in the chair.—An experiment in mountain-building, part ii.: Lord **Avebury**, P.C., F.R.S. In this paper some experiments are described, which were conducted by an apparatus by means of which pressures could be applied in two directions at right angles to one another, a space of 2 feet square being reduced to one 22 inches square. In the first series, plastic materials, such as cloth and thin oilcloth, were used, with layers of sand between them. Two main folds crossing at right angles were formed, the upper one shifted over the lower. The use of two layers of linoleum produced a different type of folding, and the lower layers of the linoleum were broken along the principal ridges. In the second series, a layer of plaster was introduced; this was found to be fractured, tilted up into a "writing-desk" form, and forced irregularly into the sandy layers. Overthrusts were thus produced, so that in some cases a boring would have passed through two or even four layers of the rigid substance. In other cases, the edges of the primary fracture broke off more or less regularly, and the detached pieces were pushed up, assuming gradually a very steep angle. The remainder of the edges of the plate of plaster, having now room, were able to approach each other. Pliable material above the plaster was thrown into one or a few extensive folds, while that beneath assumed a greater number of small folds.—The Rhætic rocks of Monmouthshire: L. **Richardson.** The Rhætic rocks occur only in the neighbourhood of Newport, and the present paper describes three new sections and four new exposures.

Manchester.

Literary and Philosophical Society, February 21.—Prof. H. B. Dixon, F.R.S., vice-president, in the chair.—Electrically-heated carbon tube furnaces: R. S. **Hutton** and W. H. **Patterson.** These furnaces are intended for experimental work, and not only enable extremely high temperatures to be attained, but with them the temperature, being under perfect control, can be kept steady at any value up to the maximum.

February 28.—Prof. W. Boyd Dawkins, F.R.S., president, in the chair.—The early history of seed-bearing plants, as recorded in the Carboniferous flora (Wilde lecture): Dr. D. H. **Scott**, F.R.S. (see p. 426).

March 7.—Prof. W. Boyd Dawkins, F.R.S., president, in the chair.—Two new aldehyde reactions: W. B. **Ramsden.**

March 21.—Prof. W. Boyd Dawkins, F.R.S., president, in the chair.—A new genus Nevillina, of the subfamily Miliolininæ, of the Foraminifera: H. **Sidebottom.**—On the temperature coefficient of electrical resistivity of carbon at low temperatures: H. **Morris-Airey** and E. D. **Spencer.** The method of taking observations at temperatures between the normal temperature and that of boiling oxygen was described, and the results plotted in the form of curves. The shape of the curves was discussed in connection with the theory that carbon conductors behave like loose powders.

Paris.

Academy of Sciences, April 3.—M. Troost in the chair.—On the use of the hot and cold tube in the study of chemical reactions: M. **Berthelot** (see p. 568).—Observations on the new Giacobini comet made at the Observatory of Paris: G. **Bigourdan.** The observations were made on March 28 and 31; the positions of the comparison stars and apparent positions of the comet are given. On March 28 the comet appeared as a nebulosity of about the thirteenth magnitude, with a nucleus sensibly brighter than the rest. On March 31 the size had diminished, and the apparent brightness increased.—On the relation between the integrals of the total differentials of the first and second species of an algebraic surface: Emile **Picard.**—The variation of the band spectra of carbon with the pressure and some new band spectra of carbon: H. **Deslandres** and M. **d'Azambuja.** The kathode spectrum in air having shown peculiar variations with the pressure, it was thought desirable to study the effect of pressure upon the carbon spectrum. The negative spectrum of carbon is a band spectrum which appears at the kathode in the oxygen and hydrogen compounds of carbon, and is especially intense in the case of carbon monoxide and dioxide. Two spectra were photographed simultaneously on the same plate, one from a Geissler tube containing the gas at a pressure of about 0·2 mm., and the other from the kathode of a tube in which the pressure was capable of being varied up to nearly atmospheric. The variations noted strongly resemble those already studied for the negative spectrum of air. Details of a new spectrum of carbon dioxide, given by the kathode at a pressure of 30 cm. of mercury, are given.—On the grains found attached to *Pecopteris Pluckeneti*: M. **Grand'Eury.** In the search for fronds giving rise to fossil seeds, the author has found fronds of the above species to which are fixed, not one or two, but many hundreds of grains, proving that the fossil ferns of the Coal-measures, other than the Neuropterideæ, are gymnosperms, and must be placed among the Cycadeæ. Two reproductions of photographs of the fossils are given.—On the new Giacobini comet: M. **Giacobini.** The elements of the comet are given, calculated from observations made at Nice on March 26, 28, and 30.—The provisional elements of the Giacobini comet (1905, March 26): E. **Maubant.** The elements are calculated from observations made at Nice on March 26, and by M. Bigourdan at Paris on March 28 and 31.—Abel's theorem on algebraic surfaces: Francesco **Severi.**—On linear differential equations of the second order with a periodic solution: Maxime **Bôcher.**—On a hyperelliptic surface: E. **Traynard.**—On the dynamics of the point and the invariable body in an energy system: Eugène and François **Cosserat.**—On the properties of tungstic anhydride as a colouring material for porcelain: Albert **Granger.** The yellow enamel was obtained by heating with tungstic anhydride at 800° C., using lead monosilicate as a flux. With the addition of bismuth oxide this colour withstood firing well. The conditions under which these colours tend to become opaque have not been fully worked out, and work is being continued by the author in this direction. On the production of the hyposulphites: M. **Billy.** The production of sodium hyposulphites by the action of sulphur dioxide on sodium in presence of a neutral solvent has been claimed by a German patent, but the author's experiments have led invariably to a negative result. In presence of alcohol the reaction would appear to take place. By the introduction of sulphur dioxide into magnesium powder in suspension in absolute alcohol, the metal dissolves, possibly as an acid hyposulphite. This solution, left in a vacuum, deposits magnesium hyposulphite.—On acetyl-lactic acid: V. **Auger.** Previous accounts of this substance being contradictory, the author has attempted to procure it in a pure state. It can be obtained either by the action of acetyl chloride on calcium lactate or on lactic acid, or by using acetic anhydride in the place of the acetyl chloride. The substance was obtained in a crystalline form in all three preparations, and its physical and chemical properties are given.—On the compounds of aluminium chloride with hydrocarbons and hydrogen chloride: G. **Gustavson.** By the interaction of benzene, isopropyl chloride, and aluminium chloride, the author has isolated a definite compound, the action of which, in the Friedel and Crafts reaction, may be compared to that of a ferment. This substance can unite both with hydrocarbons and hydrogen chloride.—On the hydrides of phenanthrene: Pierre **Breteau.** Previous work on the hydrogen addition compounds of phenanthrene has been carried out with the aid of hydriodic acid. The author has applied the Sabatier and Senderens reaction with reduced nickel, and in the present communication gives the results obtained with the hexahydride and octahydride of phenanthrene.—On the retrogradation of artificial starch: E. **Roux.**—The influence of the ethylene function in an active molecule: J. **Minguin.** With the view of throwing further light on the effect of the ethylene linkage on the rotation, the author has prepared amyl succinate, maleate, and fumarate, as well as the corresponding esters of bornyl alcohol, and has measured the rotatory power.—The constitution of the ligamentary ridge and the evolution of the ligament in existing Acephalæ analogous to the Rudistæ: R. **Anthony.**—Diagrams showing the ligament in section are given for *Unio Pictorum* and *Aetheria Caillaudi* at two ages.—Heterotypical mitosis in the Ascomycetes: René **Maire.**—On the possible *rôle* of slipping in metallogeny: L. **De Launay.** An application of the idea of *charriage* to a study of the continuity of metallic lodes.—On the existence of schists with graptoliths at Haci-El-Khenig, Central Sahara: G. B. M. **Flamand.** Specimens of schists bearing fossils, collected by Captain Cottenest, prove to be characteristically Silurian, and form the first definite proof of this system in the Central Sahara.—On the presence of the Middle and Upper Carboniferous in the Sahara: Émile **Haug.**—On an extraordinary halo observed at Paris: Louis **Besson.** This halo, which was observed at the Montsouris Observatory on March 26, besides the ordinary circle and parhelia of 22°, presented two abnormal coloured arcs, the angular measurements of which are given.

DIARY OF SOCIETIES.

THURSDAY, APRIL 13.

ROYAL SOCIETY, at 4.30.—On a New Type of Electric Furnace; with a Redetermination of the Melting Point of Platinum: Dr. J. A. Harker.—On Colour Vision by Very Weak Light: Dr. G. J. Burch, F.R.S.—(1) The Improved Electric Micrometer; (2) The Amplitude of the Minimum Audible Impulsive Sound: Dr. P. E. Shaw.—The Refractive Indices of Sulphuric Acid: Dr. V. H. Veley, F.R.S., and J. J. Manley.—On the Intensity and Direction of the Force of Gravity in India: Lieut.-Colonel S. G. Burrard, F.R.S.—A Quantitative Study of Carbon Dioxide Assimilation and Leaf-Temperature in Natural Illumination: F. F. Blackman and Miss G. Matthaei.

ROYAL INSTITUTION, at 5.—Synthetic Chemistry: Prof. R. Meldola, F.R.S.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—The Alternating Current Series Motor: F. Creedy.—Discussion of Mr. Bion J. Arnold's address to the joint meeting at St. Louis.

INSTITUTION OF MINING AND METALLURGY, at 8.—The Kedabeg Copper Mines: Gustav Köller.—Refining Gold Bullion and Cyanide Precipitates with Oxygen Gas: T. Kirke Rose.—Wood Gas for Power Purposes and Gas Generator: G. M. Douglas.—Notes on the Prestea District, Gold Coast Colony: P. Poore.—Notes on the New Dharwar Gold Field of India: R. O. Ahlers.—The Cause of Border Segregation in some Igneous Magmas: J. Park.

MATHEMATICAL SOCIETY, at 5.30.—On Irreducible Jacobians of Degree Six: P. W. Wood.—On Fermat's Numbers and the Converse of Fermat's Theorem: A. E. Western.—On the Strains that accompany Bending: Prof. A. E. H. Love.—Ordinary Inner Limiting Sets in the Plane or Higher Space: Dr. W. H. Young.

FRIDAY, APRIL 14.

ROYAL INSTITUTION, at 9.—The Law of Pressure of Gases below Atmosphere: Lord Rayleigh.

PHYSICAL SOCIETY, at 8.—On Ellipsoidal Lenses: R. J. Sowter.—(1) The Determination of the Moment of Inertia of the Magnets used in the Measurement of the Horizontal Component of the Earth's Field: (2) Exhibition of a Series of Lecture Experiments illustrating the Properties of the Gaseous Ions produced by Radium and other Sources: Dr. W. Watson, F.R.S.

ROYAL ASTRONOMICAL SOCIETY, at 5.—Value of Meteoric Radiants Based on Three Paths: W. F. Denning.—Determination of Longitude on the Planet Jupiter: G. W. Hough.—(1) Revised Elements of UY Cygni; (2) Revised Elements of Y Lyræ: A. Stanley Williams.—Further Note on Instrumental Errors affecting Observations of the Moon; in reply to Mr. Cowell's paper of June, 1904: H. H. Turner.—Reply to Prof. Turner's paper: P. H. Cowell.—Note on the Point Distributions on a Sphere; with Remarks on the Determination of the Apex of the Sun's Motion: H. C. Plummer.

MALACOLOGICAL SOCIETY, at 8.—Anatomical and Systematic Notes on Dorcasia, Trigonephrus, Corilla, Thersites, and Chloritis: Henry A. Pilsbry.—Some Account of the Anatomy of *Cassidaria rugosa*, L.: Alexander Reynell.—Notes on a small Collection of Shells from the Victoria Falls, Zambesi River: H. B. Preston.—Descriptions of Six New Species of Land Shells from South Africa: H. Burnup.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—President's Address. Conclusion of discussion on Steam-engine Research Report and Prof. Capper's reply.

SATURDAY, APRIL 15.

ROYAL INSTITUTION, at 3.—Some Controverted Questions of Optics: Lord Rayleigh.

MONDAY, APRIL 17.

INSTITUTE OF ACTUARIES, at 5.—On the Importance and Practicability of a Standard Classification of Impaired Lives: Dr. S. W. Carruthers.—Social Conditions as affecting Widows' and Orphans' Pension Funds: S. J. H. W. Allin.

TUESDAY, APRIL 18.

ROYAL STATISTICAL SOCIETY, at 5.

ZOOLOGICAL SOCIETY, at 8.30.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Annual General Meeting.

WEDNESDAY, APRIL 19.

GEOLOGICAL SOCIETY, at 8.—The Blea Wyke Rocks and the Dogger in North-East Yorkshire: R. H. Rastall.—Notes on the Geological Aspect of Some of the North-Eastern Territories of the Congo Independent State: G. F. J. Preumont; with Petrographical Notes: J. A. Howe.

ROYAL MICROSCOPICAL SOCIETY, at 8.—On the Application of the Undulatory Theory to Optical Problems: A. E. Conrady.

ROYAL METEOROLOGICAL SOCIETY, at 7.30.—An Account of the Observations at Crinan in 1904, and Description of a new Meteorograph for use with Kites: W. H. Dines.—Rate of Fall of Rain at Seathwaite: Dr. H. R. Mill.

CHEMICAL SOCIETY, at 5.30.—Complex Nitrites of Bismuth: W. C. Ball.

MAN AND SCENERY.

Landscape in History and Other Essays. By Sir Archibald Geikie, F.R.S. Pp. viii + 352. (London: Macmillan and Co., Ltd., 1905.) Price 8s. 6d. net.

IN this collection of essays Sir Archibald Geikie has given us in a connected form some of his contributions to the study of the effect of geographical environment and geological changes, not only in determining the distribution of population and of the centres of rule and of commerce, but also in influencing literature and the interpretation of history. In some of them he treats of the part man has played in controlling and directing those forces of nature which tend to produce change on the surface of the earth, and he has added a few essays dealing with subjects which arise naturally out of such inquiries. In this way he has produced a most readable book, the several parts of which hang well together.

When we have exhausted all the available documents, sought out the meaning of all the descriptive place-names and gathered the local traditions, there remains the most trustworthy evidence of all, namely, the examination of the ground to see whether the events recorded can have occurred on the area to which they have been assigned, either under present conditions or other conditions the former existence of which we can learn from what we see. Our author gives as an example the story of the Battle of Bannockburn, where the army of Edward was compelled to crowd its attack into a narrow space because Bruce had rested his left flank on what the trained eye can see must at that time have been a morass with impassable bogs and sheets of water, though it is now dry and richly cultivated.

Estuaries and the rivers which run into them provided landing places and opened up the inland regions to the vessels of primæval man, and on their banks were sites for the settlements of the first comers and the cities of later more civilised times; while, on the other hand, mountain ranges and tangled forests separated tribes and offered an insurmountable barrier to expansion and intercourse.

Man, by cutting down or burning forests, and by draining lakes and swamps, has altered the conditions of many extensive tracts of country, changing the climate, the amount of rainfall, and the rate of waste of the hill-slopes and valleys.

The south of Scotland and parts of the north of England were once covered with small shallow pans of water like Finland, "the land of a thousand lakes." Most of these have got filled up in the British Isles, and the process of reclaiming and cultivating the areas once covered with water has been hurried on by the advance of agriculture; but history tells us how the early dwellers in these broken grounds took advantage of them in their struggles against the powerful races that from age to age invaded them. The Caledonians met the Romans on such ground, and the Scotch the English in later times; and, further south, the Saxons long held their own in the flooded fenlands against William and his Norman followers.

The mythology of Greece and of northern Europe is largely influenced by the character of the scenery in which it took shape. It was recognised that the plain of Thessaly had once been covered with a sheet of water, of which the remaining portions formed two considerable lakes. The opening of the gorge by which it was drained was attributed to Poseidon, the God of the Sea, or in later times to Hercules. Here we seem to have the tradition of an old controversy as to whether the sea, the natural operation of water running out of a lake or connected with inroads of the sea, or even artificial operations, had contributed most to bring about the draining of the area.

The snowy summits of Olympus, rising serenely above the shifting clouds into the calm, clear, blue heaven, naturally came to be regarded as the fit abode of the gods who ruled the world, and soon Olympus came to be synonymous with heaven itself.

So, also, in the countries of western and northern Europe the grandeur and ruggedness of the scenery and the "mountain gloom" are faithfully reflected in the Teutonic myths and superstitions.

Our author gives three examples of typical districts to show how a knowledge of the causes which have brought about the varied scenery of each, far from checking the free play of fancy, enhances the pleasure derived from their contemplation.

He takes first the little cake of rock which caps Slieve League in Ireland, and leads the imagination to recall the time when it extended over all the surrounding area; but it has been removed over most of the district, a patch being left here and there to indicate the wide area over which it once extended.

Then our author takes us to the Isle of Wight, and showing us the "long backs of the bushless downs," explains how they come to rise as they do from the waves and run across the island from side to side. The long story that they tell is a stimulus to the imagination that greatly heightens the pleasure derived from the scene.

Again he carries us to the flanks of Slioch and the shores of Loch Maree, and makes them tell their tale.

He then goes on to describe the influence of scenery upon our literature. Here he is, of course, dealing with a later stage of mental development, and what he gives us is chiefly a sketch of the distinguishing physical features which inspired the descriptive passages in the poets of nature.

He tells us of the simple, child-like delight in nature which was so characteristic of Chaucer. He points out the placid rural quiet of the Colne Valley, where Milton dwelt, and which inspired the two finest lyrics in the English tongue. He describes the scenery of the Ouse near Olney and Weston, so thoroughly characteristic of the southern lowlands which filled Cowper with images of rural peacefulness and gentle beauty.

He points out how the poetry of Thomson ever showed the impress of his early life in the Scottish lowlands within sight of the Cheviot and Lammermuir Hills.

Our author is at his best when he comes to deal with the genius of Burns, to whom the hills and woods were not merely enjoyable scenes to be visited and described, but became part of his very being; who found in their changeful aspects the counterpart of his own variable moods, and whose feelings found vent in an exuberance of appreciation which had never before been heard in verse.

He touches lightly the descriptive passages in Scott and Wordsworth, and the ballad singers of the border, who, though mostly inspired by war-like achievements, often wove into their tales a thread of tender affection and romance. In the poems attributed to Ossian, although Highland scenery is not specially described, it forms a visible and changing background.

Our author turns from the consideration of the influence exerted by the geographical features of a country upon the development and habits of thought of its inhabitants to the discussion of the origin of those features themselves. This is a subject which has of recent years received much attention both in this country and in America. Our author describes the scenic features under several heads. Mountains and valleys may be considered as correlatives, the mountains being there because the valleys have been scooped out between them. Under lakes, we turn with interest to his views on the glacial erosion of rock basins, which he holds could be effected by land ice only. He makes, however, the qualifying remark that a terrestrial surface of crystalline rock, long exposed to the atmosphere or covered with vegetation and humus, may be so deeply corroded as for two or three hundred feet downward to be converted into loose detritus, and the ice may thus have had much of its work done for it, and would be mainly employed in clearing out the corroded débris. Whether, however, this will explain many of the rock basins of the British Isles is not very clear.

In another essay he shows what Hutton did by his theory of the earth to pave the way for the accurate scientific treatment of all those questions of the changes which the earth has undergone in attaining its present configuration. Playfair, Hall, and others helped on the work. The obvious question arising out of such speculations is, how long must it have taken to bring about such great results? and thus we are taken through the controversies as to whether uniform change, which we observe, or local and intermittent catastrophic action, of which we see proofs everywhere, have done most to bring about the results in every individual case. The physicists tell us that from a consideration of the rate at which the earth parts with its heat, of the limitation of the age of the sun, of the retardation of the earth's angular velocity by tidal friction, they are not prepared to allow such a vast age as geologists have claimed for the earth. The geologists, on the other hand, having regard to the rate at which changes on its surface are observed to be brought about by existing agents, and the time demanded for the evolution of living things, insist upon a much larger estimate of time than the physicists are prepared to allow. The confidence reposed in the accuracy of such inferences must depend upon the probability or improbability that the observer has seen enough to justify his generalisations, and that no contradictory evidence can be forthcoming.

The geologist and physicist will probably arrive at a compromise when the one admits that his calculations, based on the rate of waste, may be entirely vitiated by earth movements, which will either hurry on or retard such waste, and that life will change more rapidly with the changes of environment produced by earth movements, and when, on the other hand, the physicist has corrected his estimate of the rate at which the earth is cooling by taking more careful account of the variety of conducting material of which the earth is composed, has estimated the planetary fuel for ever being thrown into the sun from space, to say nothing of the new views of radioactivity, and has re-considered his inferences from tidal friction, which some of our highest mathematicians admit is still open to doubt.

Such speculations suggest the name of the great apostle of evolution, and an essay on the life and work of Charles Darwin follows, while a biographical sketch of Hugh Miller is fitly introduced among essays which so largely deal with the influence of a man's environment upon his imagination and writings.

In an age like this, when the relative place and value of technical and literary training are so strongly forced upon the attention of the country, an essay on science in education by one whose experience and outlook are so wide will be welcomed. Then, to bring us back to the main subject with which he commenced, he gives an interesting sketch of the building up and moulding of the Campagna and the surrounding country, fitting it for the site of many an ancient city, and at last for the eternal city so long the centre of the world.

A MAGNETIC SURVEY OF JAPAN.

A Magnetic Survey of Japan reduced to the Epoch 1895·0 *and the Sea Level.* Carried out by order of the Earthquake Investigation Committee, reported by A. Tanakadate. Pp. xii + 347 and plates. (Published by the University, Tokyo, Japan, 1904.)

THE completion of the detailed magnetic survey of a country is a task requiring great skill and industry. We congratulate Prof. A. Tanakadate and his colleagues on the successful accomplishment of a heavy piece of work, which will be welcomed by all who are interested in the science of terrestrial magnetism. The work is the result of the voluntary cooperation of sixteen observers, of whom seven are professors or assistant professors of the Imperial University, Tokyo, the others also occupying responsible positions. Prof. Tanakadate modestly only claims for himself the position of a "reporter" who has collected the work of the different parties, but we imagine that we owe to him also the detailed discussion of the results which forms an essential portion of the volume before us.

A clear account is given in the initial paragraphs of the method of observations and the instruments used, but not too much space is devoted to these details, so that the reader is soon brought to the first difficulty which occurred in the working out of the observations. It was necessary, in order to reduce them to a common epoch, to take account of secular variations. This might most easily have been done by choosing as observing stations the same places at which the magnetic elements had been determined in a previous survey, but in attempting to carry this out it was found that the changes which had taken place in their surroundings made it impracticable to observe at most of the old stations. Some other method of reduction had therefore to be adopted. Empirical expressions were found for the magnetic elements in terms of longitude and latitude similar to those deduced by Prof. Knott for the previous survey. A comparison of the two expressions gave the secular variation. The results of all the observations for each station are given in the report. The reduction of the observations to sea level is always to some extent arbitrary. The process employed in the present case, where use is made of relations given by the theory of the potential between the radial variation of the horizontal components and the horizontal variation of vertical force, is an improvement on the more empirical methods which have sometimes been adopted.

A further application of the potential theory may serve as an important check on the accuracy of the observations. If a potential exists, the rate of variation of the northerly force towards the west must be equal to the rate of variation of the westerly force towards the north. If this relation does not hold, the earth's magnetism cannot be completely represented by a potential, and this would mean that vertical electric currents traverse the earth's surface. The authors of the present survey calculate the intensities of these vertical currents, but rightly do not attach much importance to them. They are much greater than observations on atmospheric electricity allow us to contemplate as possible. We may therefore take the calculated values of these currents to be indications of the extent of uncertainty in the observations.

We must refer the reader to the original for the discussion of local disturbances, but cannot avoid directing attention to one passage, which seems to indicate some kind of misapprehension on the part of the author.

"It is often erroneously believed," he says, "that the expansibility of the earth's magnetic potential in negative powers of the radius vector is a proof that the source of action is inside the earth."

In a preceding sentence the writer connects his supposed error with the fact that "inasmuch as the surface integral of the force over the earth vanishes, the so-called seat of action may be placed either inside or outside."

In this passage the author seems to doubt a well-established theorem which is quite independent of the question whether the surface integral of normal force when taken over the whole surface of the earth has a finite value or not.

To put the matter plainly: If the magnetic forces at all points of the surface of a sphere can be represented in terms of a potential which is expressed as a series of spherical harmonics proceeding by negative powers of the radius vector, then there are no magnets or electric currents outside the sphere. If the passage quoted is intended to deny the truth of this proposition, the author is guilty of a heresy which he does not justify either by his hydrokinetic analogy or by his reference to one of Lord Kelvin's papers. It should be said, however, that in other parts of his volume the author seems to adopt Gauss's reasoning as to the discrimination between outside and inside effects by spherical harmonic analysis. It may be, therefore, that the apparent meaning of the passage is not the one which it was intended to convey. It is of some importance to avoid misunderstanding on so important a matter, and it is for this reason that I feel compelled to direct attention to the only criticism which can fairly be raised with regard to a very meritorious and heavy piece of work.

May other countries follow this example of Japanese enterprise, and may, especially in English colonies, scientific men receive such help from their Governments as will enable them to keep pace with foreign nations in the successful prosecution of similar work. It is not the enterprise or the knowledge which is wanting, but the material assistance and the official recognition that a certain duty is imposed on each country to take its share in the working out of geophysical problems. ARTHUR SCHUSTER.

THE TECHNOLOGY OF THE VEGETABLE FIBRES.

The Spinning and Twisting of Long Vegetable Fibres (Flax, Hemp, Jute, Tow, and Ramie). By Herbert R. Carter. Pp. xvi+360. (London: Chas. Griffin and Co., Ltd., 1904.) Price 10s. net.

WORKS written for the textile industries may be divided into three classes, viz. descriptive works of a more or less technical and practical character, educational works leading students up to an appreciation of the difficulties to be faced, and works which combine the descriptive and educational but which too frequently meet the requirements of neither manager nor student. The work under consideration meets the requirements of the mill manager or advanced student in a manner perhaps more than satisfactory. On the other hand, to place such a work as this in the hands of the elementary student would be anything but satisfactory, rather suppressing than developing that genuine interest without which it is impossible for the student to make true progress in his studies. In its particular line, however, we must highly commend the work as representing up-to-date practice in most of the sections of the textile industries of which it treats.

The work is really arranged in four sections, the first three chapters being devoted to general particulars respecting the fibres in question, chapters iv. to xv. dealing with the mechanical processes necessary for the formation of the said materials into satisfactory yarns, chapters xvi. and xvii. referring to miscellaneous processes, such as the manufacture of threads, twines, cords, and ropes, while chapters xviii. to xxi. treat on general mill management, arrangement, and engineering.

In the first section, very interesting and useful particulars are supplied respecting the fibres and their marketing, the only difficulty being the grasping of the multitude of details here given. Had these details been represented by maps illustrating (*a*) area of growth, (*b*) area of manufacture, (*c*) area of distribution and use of the fibres in question, with graphical illustrations of quantities, &c., the facts presented would have been vastly more interesting and useful. This method, we believe, is employed in the textile museums of certain of our northern technical colleges.

The author wisely remarks in his preface that were it not for the similarity in the processes necessary for the preparation and spinning of many of the fibres here treated, it would be impossible to bring the work within reasonable limits. The similarity in treatment is certainly marked, and practically leads the author throughout to the employment of the "comparative method." Thus, in the first preparation of ramie, the hand and the chemical or mechanical methods are naturally compared with reference to quality of result and price, this latter necessarily involving the question of native hand-labour *versus* European machine-labour. Then the difference between ramie and flax is naturally noted, and so on.

The comparative method would naturally arrange itself under some six heads:—(1) methods of dealing with the fibres in the raw state commercially; (2) methods of preparing, that is, of cleaning for the subsequent mechanical operations; (3) ultimate length, diameter, colour, &c., of the fibres; (4) the conditions for preparation of the fibres as necessarily deciding the types of machines required; (5) the types of machines for each quality of fibre; (6) value of resultant thread or fabric as revealed by scientific and "use" tests.

This is approximately the grouping employed. The greater proportion of the book is devoted to the mechanical side, and it must be recognised that this is just, as in many cases not only has the machine taken the place of the hand method, but actually does what would be impossible without mechanical aid. Perhaps one of the most interesting comparisons in the book is that afforded by chapters xii. and xiii., in which dry, semi-dry, and wet methods of spinning are successively dealt with.

The section dealing with threads, twines, ropes, &c., is chiefly interesting as introducing machines which are practically unknown in the ordinary textile industries. It very often happens that principles developed in one industry would be of great value in another were they known; in this way the present work may indirectly be of considerable use to industries other than those specially dealt with.

Chapter xviii. deals in an interesting manner with the mechanical department, including the hackle setting, wood turning, fluting, oils, and oiling; this is certainly a useful chapter for the ordinary mill manager. Chapters xix., xx., and xxi., however, in our opinion, are somewhat out of place, it being impossible satisfactorily to consider modern mill construction, boilers and engines, steam and water power, and electric power transmission in the fifty-six pages devoted to this subject. Mere statement, usually very excellent, is all that is possible. We would, however, question the advice given respecting electric lighting in factories. There is a marked tendency to revert to incandescent gas lighting, not only on account of the expense, but also on account of the light value.

The work is not only to be commended to those engaged in the particular trades in question, but also to those engaged in the allied textile industries, as such questions as the position of the nip of the rollers in relation to the spindle and with reference to length of fibre, the varieties of gills employed, Combe's expansion pulley and quick change motion in place of the cones in cone drawing frames, &c., constitute interesting mechanical arrangements which may be of marked value in these allied industries.

The work is illustrated by 161 figures, usually of a most interesting type. The general arrangement is certainly such as will commend itself to the mill manager, who will naturally wish to refer to the work under conditions requiring speed and accuracy.

ALDRED F. BARKER.

ENGLISH ESTATE FORESTRY.

English Estate Forestry. By A. C. Forbes. Pp. xi+332. (London: Edward Arnold, 1904.) Price 12*s.* 6*d.* net.

AS the title suggests, the book is intended for the instruction of English foresters. In the preface, the author states that he feels,

"probably in common with many practical foresters, that English forestry is sufficiently distinct from Continental, or even Scotch forestry to entitle it to be regarded as a separate subject."

The author further emphasises this point in his chapter on thinning and pruning, where he seems to hint that all the mistakes and failures in English sylviculture, about the middle of the nineteenth century, were due to the bad influence of Scotch forestry and Scotch foresters, who, according to Mr. Forbes, were imported into England about that time, bringing with them their mistaken ideas of thinning and pruning, to the detriment of English forestry.

The following extract from the preface gives the author's own views regarding the book:—

"This book is intended to be suggestive rather than instructive to the practical forester. There is little in its pages but what he already knows, and possibly a great deal with which he will not agree. But as a more or less faithful record of individual experience it is offered as a small contribution to forestry literature, which, if it does not enrich, it will not, it is hoped, disgrace."

The concluding paragraph of the preface states

"that this book is not, nor does it make a pretence of being, a text-book. The intelligent reader, therefore, who discovers that it does not contain a planter's guide, nor a reference to more than *one* work on German forestry, is requested not to despise it on that account, nor to conclude prematurely that the author has written on a subject he knows nothing about."

The book is a fairly bulky one, and consists of thirteen chapters and twenty-three illustrations, representing different woodland scenes. The opening chapter gives an interesting historical account of English forests and the origin of forestry. The present conditions, the future prospects and possibilities of extended afforestation are next dealt with. The sylvicultural treatment of the commoner coniferous and deciduous trees, and the financial results to be derived therefrom, is a chapter which will be read with interest by proprietor and forester alike. Planting and natural regeneration are dealt with in a satisfactory manner. A chapter on the measurement of timber and its selling value contains much information, which will be of the greatest use to the English estate forester. The home nursery and forest management receive their due share of attention. The author has not forgotten the arboricultural aspect of the forester's profession. His chapters on landscape forestry and park and avenue trees are written with much artistic feeling, and contain many valuable suggestions. The more important injurious fungi and animals, including insects, are dealt with in a chapter under the heading "Enemies of English Woodlands." It deals with only a few of the outstanding pests which are of practical importance. There is probably no pest about which more has been said or written than the larch canker disease, and we find the author is no exception to the rule. A great many pages are devoted to this disease alone. It consists essentially of a criticism of all the theories that have been advanced regarding the disease since the introduction of the larch. Much of what he says is undoubtedly true, but we must confess we find great difficulty in following the author through many of his arguments, especially those which are based upon purely suppositional grounds.

Regarding the book as a whole, we find a great deal of historical detail in its pages. Past and present methods are criticised without reserve. It will not replace any of the already existing text-books intended for the instruction of the young forester, but as an addition to our existing literature on forestry we may recommend its perusal to those interested in the subject.

OUR BOOK SHELF.

Index Kewensis Plantarum Phanerogamarum. Supplementum secundum, nomina et synonyma omnium generum et specierum ab initio anni MDCCCXCVI usque ad finem anni MDCCCC complectens. Ductu et consilio W. T. Thiselton-Dyer confecerunt herbarii horti regii botanici Kewensis curatores. Abama-Leucocoryne. Pp. 103. (Oxford: Clarendon Press, 1904.) Price 12*s*. net.

Workers at the systematic botany of seed-plants, and all who are concerned that plants should have their right names, will welcome the appearance of this latest instalment of a well-known work of reference. The original "Index Kewensis," the monumental work owed to Sir Joseph Hooker and Mr. Daydon Jackson, gives the reference for generic and specific names published up to 1885. For names published during the next ten years we have the first supplement, the work of M. Durand, of Brussels, and Mr. Jackson. This makes but slow progress, and has now reached Ph; the last number appeared at the end of November, 1903. Hence, while the present instalment carries us, for the first half of the alphabet, to the end of last century, as regards the last ten letters we are twenty years behind time!

As implied in the heading, the supplement includes not only new names, but also synonyms, that is, those names which, in works published in the interval in question, have been transferred to other genera or regarded as identical with names previously published. Thus the eight names under Eriachne represent old species, chiefly of Nees, which more recent workers have transferred to Achneria. The inclusion of synonymy, while undoubtedly of value, must add considerably to the labour of preparation. Moreover, while in some cases the citation of a name as a synonym is amply justified, it is in others merely the expression of the opinion of one school of botanists, or perhaps only of an individual worker, on a matter about which perhaps much may be said on both sides. In our opinion the great use of the "Index" is that implied in its title; the working botanist wants a list containing every published name, he wants it as soon as possible after publication, and to get an exhaustive and up-to-date index he will sacrifice much in the way of botanical comment, however valuable. Refer him to the place and date of publication, and you will earn his lasting gratitude. He should be able to draw his own conclusions as to the relative value of the names.

The omission of the date from the references is, we think, matter for regret; it would have involved but very little additional labour at the time; moreover, it is given in the first supplement, an improvement instituted by Messrs. Durand and Jackson. There are also other omissions which we shall hope to see rectified in an appendix or addendum. A. B. R.

Birds I have Known. By Arthur H. Beavan. Pp. 256. (London: T. Fisher Unwin, 1905.) Price 5*s*.

This little book records the author's "experience of birds during many years in many lands and on many seas . . . its sole purpose being to bring to its readers' notice the ways and habits of these beautiful creatures of the Almighty."

With such a preface, and after the author's assurance that he prefers the unquestioning belief of his little son in the Bible story of Creation to the Darwinian theory of evolution, we are a little taken aback at the author's treatment of the Creator's handiwork.

"I have always loved the birds," he protests. Unfortunate birds! His earliest manifestation of this love was, on his own confession, to endeavour to catch them with the proverbial pinch of salt! Age brought wisdom, however, and with the judgment of mature years a piece of pork concealing a fish-hook was found more efficacious!

In other places he naïvely describes the patience he displayed in waylaying with a gun such rare birds as he happened to discover. Descanting upon the glories of Cornwall as a happy hunting-ground, he gives a list of the rarities that may turn up here during gales, enumerating such species as the golden oriole, Bohemian waxwing, hoopoe, and spoonbill—just those, in short, which the true bird-lover is most anxious to protect. The chance of killing such prizes, he assures us, makes the ornithologist "despise common bird-life," and look only for rarities!

Concerning the toucan and hornbill, he writes:—"The Almighty—speaking reverently—seems to have made certain animals and birds (*sic*) in a spirit of fun, or at least in a sportive mood"!! And this, too, in spite of a statement on a previous page to the effect that with "an ordinary beak" the toucan would be unable to procure the fruit on which it feeds, and that, in consequence, "the Almighty, in His wisdom, has provided it with a 'beak-hand'. . . ."!

We confess we do not like this book; where it is not mischievous it is puerile. The illustrations could not possibly be worse. W. P. P.

The Elements of Chemistry. By M. M. Pattison Muir. Pp. xiv+554. (London: J. and A. Churchill, 1904.) Price 10*s.* 6*d.* net.

It is somewhat difficult to understand for what class of reader this book is intended. In style and treatment it is not well adapted to beginners, yet in its descriptive matter it is quite elementary. Probably it will prove of greatest service to mature students of other subjects who wish to gain some acquaintance with the principles of chemistry without intending to study the science practically. The author tells us in his preface that his object has been "to present some of the fundamental facts, generalisations, principles and theories of chemistry, lucidly, methodically, and suggestively." In this he has had a certain measure of success, but the general impression left by the book is that in its construction substance has been sacrificed to form. When, for example, the author tells us (p. 89) that weighed quantities of the basic oxides BaO, CaO, K_2O, Na_2O, have been combined with weighed quantities of the acidic oxides I_2O_5, N_2O_5, P_2O_5, P_2O_5 respectively, and that analysis showed the resulting products to be BaI_2O_6, CaN_2O_6, K_3PO_4, and Na_3PO_4, we are inclined to doubt the statement, and also to doubt the wisdom of adducing imaginary experiments in confirmation of a formal rule. On p. 252 we find the equation

$$\text{"}Na_2O+N_2O_5 \text{ (heated)}=2NaNO_3.\text{"}$$

We wonder if the author tried the experiment; the practical instruction to heat would almost indicate that he had.

Richard Jefferies: his Life and Ideals. By H. S. Salt. New edition. Pp. vii+119. (London: A. C. Fifield, 1905.) Price 1*s.* 6*d.* net.

The fact of a new (and cheaper) edition of this work being called for may be taken as an indication of the hold the writings of the great pioneer of the true type of nature-study have taken on the popular mind. In the preface, the author emphasises his opinion that the real claims of Jefferies to literary immortality are based on his later works of the type of "The Story of My Heart"; but there can be no doubt, as the author himself is fain to admit, that "The Gamekeeper at Home" and "Round about a Great Estate" are the volumes which have made the name of Jefferies a household word. Biographers and eulogists may make what efforts they please to alter the verdict of the public; but in such cases the old maxim that the *vox populi* is *vox dei* still holds good. To the great majority of readers Jefferies will continue to be known solely by his inimitable (if sometimes too realistic) descriptions of rural life and character. Although in small type, the new edition of his life is well printed on good paper. R. L.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* Nature. *No notice is taken of anonymous communications.*]

Historical Note on Dust, Electrification, and Heat.

Your readers may remember that in July, 1883, I penned a letter to your columns (vol. xxviii. p. 297) describing some observations which the late J. W. Clark and myself had recently made; among others, one to the effect that a small electrical discharge into a smoke-laden atmosphere rapidly dissipated the smoke by coagulating the particles. Some time afterwards we found that the observation had previously been made by a Mr. Guitard, and printed in the *Mechanic's Magazine* for 1850—a reference to this fact being actually contained in that great compendium of electrical information, Wiedemann's "*Galvanismus u.s.w.*," so that it must be regarded as fully "published."

I now write to say that during the labour of indexing, at the Royal Society, Prof. McLeod has come across a much earlier instance of the same observation, showing that the phenomenon was really discovered in 1824. An extract from Prof. McLeod's letter runs as follows:—

"In the course of our indexing we have come across a paper that may interest you, if you do not already know of it. It is by Hohlfeld, "Das Niederschlagen des Rauchs durch Elektricität," Kastner, *Archiv Naturl.*, ii., 1824, 205–206. It is very short; he refers to the increase of the fall of rain and hail after a flash of lightning, and describes how he filled a globe with smoke and led into it a pointed wire connected to an electric machine which caused the smoke to settle."

If any importance attaches to the subject, it must depend upon the successful application, in future practice, of so conspicuous a result. Hitherto the only practical application of the same sort of principle has been the "coherer" used in some systems of wireless telegraphy, of which Prof. Branly's porphyrised-copper powder-smears and iron filings-tubes may be regarded as the earliest examples.

Perhaps, however, I may direct attention to my paper to the British Association (Report for 1885, pp. 743 *et seq.*), in which this electrical action on visible particles is likened to chemical agglomeration into molecular aggregates, leading to an electrostatic theory of chemistry, a matter worthy of, and now receiving, sustained attention.

May I further take the opportunity of amending an oversight? Mr. Clark and I came across the fact of the electrical deposition of smoke while we were experimenting on Tyndall's dark plane or dust-free space seen near hot bodies in illuminated air, a matter to which attention had been directed by a notable investigation of Lord Rayleigh's (see Nature for 1882, vol. xxviii. p. 139). It turned out afterwards that we were not the only experimenters on this subject, Lord Rayleigh's letter having also roused the attention of that eminent specialist in dust researches, Mr. John Aitken, of Edinburgh; and though we published our account of dust-free spaces due to heat in the *Philosophical Magazine* for March, 1884, his corresponding investigations and explanations were published a month or so earlier in the *Transactions* of the Royal Society of Edinburgh, vol. xxxii. p. 239; and to him accordingly belongs priority in such parts of this matter as are not covered by my preliminary letter to Nature of the July previous, which doubtless includes many things that were practically anticipated by Lord Rayleigh himself.

I mention this now because I have been rather too apt to forget it, and have omitted to mention Mr. Aitken's name when, if I had had all the circumstances consciously before me, I should certainly have mentioned it. In particular, in a history of the coherer principle contained in my little book on "Wireless Signalling," third edition, p. 75, I speak of the explanation of the dust-free space round a hot body, due to a molecular bombardment, as having been first published by ourselves, instead of by Mr. Aitken, whose name, I regret to say, does not appear; this is the oversight I wish to amend.

April 12. Oliver Lodge.

The late Prof. Tacchini.

As a tribute to the memory of the late distinguished Italian astronomer, of whom an obituary notice appeared in the columns of Nature last week, may I be permitted to add a few personal reminiscences? Prof. Tacchini took part in the eclipse expedition of 1875 to the Nicobar Islands. He joined our party from India, where he had been staying from the previous year, having been commissioned by his Government to make observations on the transit of Venus of 1874. The Italian Government sanctioned his remaining in India until the following year in order that he might make use of the opportunity with the instruments in his charge for the observation of the forthcoming total solar eclipse. Of the little band of observers who assembled on the Island of Camorta in April, 1875, most are happily still with us. Vogel, the introducer of "orthochromatic" photography, has passed away, but Pedler, Waterhouse, and others will remember the pleasant *camaraderie* which existed between ourselves and our Italian colleague. The expedition failed in its object through a cloudy sky, and we were all more or less the victims of intermittent malarial fever; but we made the best of adverse circumstances, and under conditions which, to many a party of observers similarly placed, would have been extremely trying, the good understanding which the members had arrived at among themselves helped to lighten the burden of our disappointment. Not the least weighty factor in the formation of this good fellowship among the representatives of different nations was the geniality of Tacchini, with whom we parted on the P. and O. steamer *Baroda* on the homeward voyage with every regret.

April 15. R. Meldola.

Propagation of Earthquake Waves.

Mr. Rudzki, in his letter to Nature of April 6, observes that "it is only for perfectly elastic and isotropic bodies that the separation of the dilatational (normal) from the tortional (transverse) wave takes place with certainty"; and his conclusion is that "it is more than highly improbable that the effect of internal friction would neutralise the effect of æolotropism." If the term "internal friction" is intended to refer to the effect of pressure, this objection was forestalled by Major Dutton by the remark that "towards this more compact and continuous condition (of a compact mineral substance with a feeble pronounced cleavage), the pressure of great depths in the earth should, it may seem, tend to bring the material subject to it."

To me it is refreshing to learn that any objection can be raised to the view that the two speeds of earthquake waves are respectively condensational and tortional, the latter being held to prove a high degree of rigidity for the interior of the earth.

To examine the question whether the interior is to a considerable depth liquid or solid formed one subject of my "Physics of the Earth's Crust," and I came to the conclusion that it is liquid; and, so far as I am aware, my arguments have never been refuted. On this question Sir A. Geikie writes (Nature, February 9), "the geological belief rests upon a large body of evidence from the structure of the terrestrial crust, which it is difficult or impossible to explain except on the supposition of an internal mass which, at least in its outer parts, is sufficiently liquid to emerge at the surface as molten lava."

To produce arguments on the opposite side of the question is another matter, and that derived from the two speeds of earthquake propagation is perhaps the strongest. I was consequently led to inquire whether the same result could not be obtained on the hypothesis of a liquid magma holding water gas in solution, subject to Henry's law that the same volume of gas can be absorbed by a given volume of the liquid at all pressures. The result which I obtained was that two waves would be propagated with different velocities, the one a condensational wave depending on the elasticity of the liquid, and the other a wave depending upon the pressure and the volume of the gas which could be held in solution by a given volume of the liquid.

If e be the elasticity of the liquid and D its density, then $\sqrt{e/D}$ will be the velocity of the condensational wave. And if P be the pressure and rV the volume of gas which can be held in solution by the volume V of the liquid, then $\sqrt{P/rD}$ will be the velocity of the gaseous wave. If we accept Laplace's law of density, P/D will increase with the depth, and r will probably decrease, hence the velocity of the gaseous wave will increase (*Proc.* Cambridge Phil. Soc., vol. xii., part v., 1903).

Harlton, Cambridge, April 10. O. Fisher.

The Ancient Races of the Thebaid.

On my return to Oxford I saw Prof. Pearson's letter in your issue of March 30.

Since Prof. Pearson admits that he is not an anatomist, it would serve no useful purpose to discuss with him the anatomical value of the criteria which Mr. MacIver and I employed in our analysis of the skulls of the ancient inhabitants of the Theban province of Egypt.

The letter may be regarded as an interesting record of a method of interpreting percentage values adopted by a professed statistician. Arthur Thomson.

Oxford, April 8.

There is an old saying that all good science is shorthand common sense. I am sorry that Prof. Arthur Thomson does not think it worth his while in the case of his just published far-reaching negroid cranial criterion to convert the esoteric methods of the anatomist into simple language for the benefit of other readers of Nature, if not for that of the "professed statistician." I hope he will meet me later when I ask him to discuss, as I propose shortly to do, the mathematico-statistical treatment of his volume, which is of a somewhat remarkable character. Meanwhile, in order to expedite those further investigations by professed craniologists which his discovery is exciting, it would be of great value if he would tell us to what negro series he, *a priori*, applied his criteria, and what percentages of pure negroid, non-negroid, and intermediate crania he found in that series. Karl Pearson.

Inversions of Temperature on Ben Nevis.

The recent letters of Mr. Dines and Mr. Rotch (Nature, February 16 and March 30) have suggested that a note as to the occurrence of temperature inversions on Ben Nevis may be of interest.

During the thirteen years 1891–1903, occasions were not infrequent when the temperature at the top of the mountain (4406 feet) was higher than that at the base. These inversions have been grouped according as the summit temperature was the higher, (1) at one hour at least of the day; (2) at each of the twenty-four hours of the day; (3) on the mean of the twenty-four hours of the day.

The total number of cases in the thirteen years was as follows:—

	Class I.	Class II.	Class III.
January	7	—	3
February	18	1	5
March	11	—	1
April	9	—	—
May	7	—	—
June	8	—	—
July	4	—	—
August	4	—	—
September	22	—	3
October	15	—	5
November	29	3	8
December	24	5	8
Year	158	9	33

Thus inversions occurred at all seasons, but inversions continued throughout the twenty-four hours of the civil day only in February, November, and December, and those of Class III. only between September and March. The average difference of temperature between Ben Nevis and Fort William ranged from 16°·8 F. in April to 14°·4 in December, the mean for the whole year being 15°·4. Hence inversions were at all seasons large departures from the usual conditions.

The greatest inversion was recorded during the great frost of February, 1895, when at 9 a.m. on February 19 the summit was 17°·6 warmer than the base (Ben Nevis 33°·6, Fort William 16°·0). The longest continued inversion occurred during November 2–5, 1897, when the summit temperature was the higher for fifty-eight consecutive hours, the mean daily temperature on November 4 being 9°·7 higher on Ben Nevis than at Fort William.

The Ben Nevis observations, of course, afford a comparison only between the conditions at the summit and those at the base of the mountain. It is more than probable that on many occasions when the summit temperature becomes nearly, though not quite, as high as that at the base, there is an inversion of temperature in part of the air-column between the summit and sea-level.

Andrew Watt.

Scottish Meteorological Society, Edinburgh, April 12.

Stanton Drew.

The mysteries of this group of circles—the next in importance to those of Avebury and Stonehenge—are not yet fully unveiled, even by the very remarkable astronomical discoveries made in them by Sir Norman Lockyer or by his interesting description of them.

The diameter of the north-east circle is 97 English feet, or 100 of an old Mediterranean foot of 11·64 inches. This is within an inch or two of the diameter of the outer sarsen ring at Stonehenge, which is in itself a very significant fact. The diameters of the south-western and central circles are respectively 150 and 380 of this old foot, so that the diameters of the circles (within a very slight working error) are in proportion one to the other of 5, $7\frac{1}{2}$, and 19, the latter being the Metonic cycle number.

The distances between the various parts of the group, subject to a working error of from $\frac{1}{2}$ to $\frac{3}{4}$ of 1 per cent. only, are:—

Centre of cove through great circle to centre of north-east circle = 14 diameters of north-east circle.

Centre of great circle to Hauteville's Quoit = 5 diameters of the great circle, or 19 diameters of the north-east circle, the latter being the Metonic cycle number.

Centre of south-west circle through great circle to Hauteville's Quoit = 7 diameters of the great circle.

Centre of great circle to two stones too far to the west to be shown on the plan in Nature = 9 diameters of the great circle.

With the exception of the last, anyone can test these proportionate distances by the plan given in Nature, but who will tell us what was the meaning or object of them?

A. L. Lewis.

ALCOHOL IN INDUSTRY.

The committee, consisting of Sir Henry Primrose, K.C.B. (chairman), Sir W. Holland, M.P., Mr. J. Scott-Montagu, M.P., Sir William Crookes, Mr. Lothian Nicholson, Dr. Somerville, of the Board of Agriculture, Dr. Thorpe, the director of the Government Laboratories, and Mr. Thomas Tyrer, appointed last autumn by the Chancellor of the Exchequer to inquire into the use of duty-free alcohol in the arts and manufactures have got together their evidence and published their report with commendable promptitude. The report, we are glad to find, is unanimous, and this unanimity has doubtless not been without its influence in accelerating the business of the committee and the appearance of their report.

The subject, as was to be anticipated, has not been without its difficulties, for, as the committee state, a duty that yields more than twenty millions a year is a public interest that cannot be trifled with; but, as usual when men are determined to find a solution, it is remarkable how purely academic difficulties tend to disappear. Now that the suggestions of the committee are before us, the wonder is that they should not have been given effect to a quarter of a century ago. We are afraid the delay does not reflect creditably upon the enterprise, energy, or constructive ability of the numerous groups of manufacturers who are interested in obtaining the greatest possible facilities in the use of duty-free alcohol in the arts. This attitude of *laissez-faire* is seen, and commented upon by the committee, in connection with the apathy and general ignorance of manufacturers with respect to the provisions of Section 8 of the Finance Act of 1902, which gave the commissioners of Inland Revenue large discretionary powers as regards the use of spirit for industrial purposes. The committee point out that advantage has not been taken of the Act to the extent that might have been anticipated, and they have been surprised to find in examining the witnesses sent by the various Chambers of Commerce, who certainly ought to have had official knowledge of its existence, how very inadequate has been their acquaintance with its provisions.

In view of this general indifference one is tempted to inquire whether the manufacturers have had any real grievance, since they have made so little individual or collective effort to remove it. There is certainly no evidence that any collective effort has been made in the past, or, if it had been made, that the Treasury or the Revenue authorities would not have sympathised with it. The Exchequer, at all events since 1855, when the present system of denaturing spirit came into existence, may be said to have disclaimed any idea of collecting a revenue on alcohol used solely as a raw material and for purely industrial purposes. If the hitherto existing system of denaturing and control had proved so irksome that the development of chemical industry was impossible, it might have been supposed that Parliament would have been troubled with the question long ago. But as an actual fact the languid interest of the chemical manufacturers needed, apparently, to be supplemented by the quickening influence of the internal-combustion engine, and the possible applications of spirit as a motor-fuel supplied to a jaded House of Commons engaged in the discussion of a Finance Bill that stimulus which was necessary to secure from the Chancellor the promise of the departmental inquiry, which it would seem the great body of manufacturing chemists was too lukewarm to ask for.

Great cry has been made in the past that the hindrances to a free and untrammelled supply of alcohol have cost us the coal-tar dye industry, which originated in this country, and at one time flourished here; but the committee apparently have had little difficulty in ascertaining how "little wool" there is in this cry. They say they are satisfied that the assertion, as a statement of historical fact, is destitute of substantial foundation. In their opinion the main cause which led to the decadence of the industry in this country is that which we have repeatedly insisted on in these columns, viz. the failure of those responsible for the management and for the finance of the industry here during the years 1860–1880 to realise the vital importance of its scientific side, and their consequent omission to provide adequately for its development on that side.

It is true, however, that after signing the report, the two Members of Parliament named were induced to modify their assent to the unanimous finding of the committee as to the real cause of the decline of the coal-tar dye industry in this country. It will be interesting to see from the evidence, when this is published, what support Sir William Holland and Mr. John Scott-Montagu are able to find for the view they express in their letter to the Chancellor.

In reality, "alcohol" plays a very small part in that industry, and of this "alcohol" methyl alcohol is the most important variety. Large classes of the coal-tar colours—alizarin, indigo, and by far the greater number of the azo dyes—require no spirit at all in their manufacture either directly or indirectly, and these represent the larger proportion of all the colours produced. It is perfectly certain that for at least 75 per cent. of the whole output of coal-tar dyes alcohol does not enter into account even now, and therefore whatever causes may have hindered the prosecution of the industry in this country, the question of "alcohol" is not one of them.

Although it has destroyed some illusions, corrected many misstatements, and, as in this example of the coal-tar colour industry, set many matters in their true perspective, the report is eminently constructive in character. To what extent the representations of manufacturers have actually aided the committee in formulating their main suggestions remains to be seen, as the evidence has not yet been published.

These recommendations are as follows:—

(1) That an allowance be granted to all industrial spirit, whether of British or foreign origin, at the rate from time to time prevailing for the allowance to British plain spirits on exportation.

(2) That imported methylic alcohol be relieved from the obligation to pay the surtax imposed by the proviso to Section 8 of the Finance Act, 1902, and that methylic alcohol be accorded favourable treatment in the matter of denaturing.

(3) That "ordinary," *i.e.* unmineralised, methylated spirit should contain only 5 per cent. of wood-naphtha instead of 10 per cent. as now.

(4) That no charge should be made on manufacturers for the regular attendance of Excise officers to supervise denaturing operations or the use of denatured spirit, in factories taking the benefit of Section 8 of the Finance Act, 1902.

(5) That where spirit is allowed to be denatured with special agents, such agents should be subject to official test and approved, and that accounts should be kept by the user showing receipts of spirit into store, the issues thereof from store in detail, and the quantities of the goods produced.

(6) That in the manufacture of fine chemicals and pharmaceutical products, spirit specially denatured should be allowed only where the manufacture is kept entirely separate from the manufacture of tinctures and other preparations in which spirit remains as spirit in the finished product.

(7) That the regulations governing the sale by retail of "mineralised" methylated spirit should be made less stringent and more elastic.

The committee are of opinion that any special cases not touched by the above recommendations can always be met under the powers conferred by Section 8 of the Act of 1902. This Act provides adequate and entirely satisfactory machinery for securing that the spirit may be used in a condition that is suitable and appropriate to each particular purpose of manufacture. The machinery is elastic—much more so than is the corresponding machinery in Germany—and it permits of every reasonable process of denaturing, or even in the last resort of the use of spirit in a pure state. For more than this it would be impossible to ask.

The committee believe that their recommendations, if adopted, will place the manufacturers of this country in respect of the use of alcohol in industry on a footing of equality, in some respects of advantage, as compared with their competitors abroad. Amongst the witnesses who appeared before them they found a very general impression that in Germany, at any rate—and Germany is always alleged to be our most formidable competitor—spirit could be used in manufacture duty-free and pure with scarcely any restraint. This, too, is one of the illusions which the inquiry may serve to dispel. As an actual fact, in practically all cases, with the exception of that of smokeless powder, in Germany duty-paid spirit must be used unless the spirit be subjected to some authorised process of denaturing prior to use. As regards price, and that is the principal factor, the committee think that the grant of the export allowance would make the average price of industrial spirit in the United Kingdom even lower than the average price in Germany. The price here, exclusive of the cost of any denaturing, and this denaturing may be what is called *ad hoc*—that is, dependent upon the use of something which is necessary to the manufacture—would be about $7d.$ the *proof* gallon, or about $11\frac{1}{2}d.$ the bulk gallon at 64 over proof—the strength common in industrial spirit. That is as low as the minimum price paid by users in Germany in 1902, when spirit was abnormally cheap, and is much below the figures of $15\frac{1}{2}d.$ per proof gallon, or $25\frac{1}{2}d.$ per bulk gallon, prevailing in Germany at the present time. Further, it is important to remember that the price of spirit in this country, where all materials may be freely used, and where none of general use is subject to taxation, is a stable price. In Germany the conditions of production are largely artificial and of very doubtful economic soundness, and they tend to wide and rapid fluctuations in price.

The main report is supplemented by a valuable report by the chairman, Sir Henry Primrose, and Dr. Thorpe, the principal of the Government Laboratories, on the working of the spirit regulations in Germany, based upon personal inquiry and observation in that country. So much stress was laid by certain witnesses upon the system and regulations established in Germany in connection with the industrial use of alcohol that it was thought very desirable to procure information at first hand upon that subject. This report may, it is hoped, serve to correct much misapprehension which appears to exist upon the benefits of State-aided alcohol in Germany. There is ample proof that the German user of spirit is not greatly benefited by the policy which the agrarian party has succeeded in fixing upon him, and is, indeed, at times greatly injured by it.

In reply to a question asked in the House of Commons on Tuesday, the Chancellor of the Exchequer announced that he has decided to deal with the subject of the committee's report in an omnibus Bill which he will introduce to the House, and not in the Budget and Finance Bill as originally proposed.

THE CAPITAL OF TIBET.[1]

ALL who have read in the columns of the *Times* about the mission to Lhasa will welcome in a more concrete form the story as re-told by Mr. Landon in the two handsome volumes now given to the public. In an expedition carried out under such conditions as those which governed Colonel Younghusband's mission, the special correspondent becomes a distinct factor in its success. The working men of the party, even if they have eyes to see and the rare gift of recording their impressions faithfully, can but present such generalisations as may be gathered during the few intervals hastily snatched from the worries and anxieties incidental to the routine of an abnormal state of existence. Usually they see but little, and that little from the restricted standpoint of their own idiosyncrasies.

[1] "Lhasa; an Account of the Country and People of Central Tibet, &c." By Perceval Landon. Vol. i. Pp. xix+414. Vol. ii. Pp. xi+426. (London: Hurst and Blackett, 1905.) Price 42s. net.

There is no lack of literature dealing with Tibet, literature dating from the early Jesuit and Capuchin friars of the seventeenth and eighteenth centuries to the latter-day expeditions of the native explorers of the Indian Survey, to whose marvellous performances in the field Mr. Landon is about the first writer to do passing justice; but we have never yet had an intelligent and accurate representation of the social existence of the people, nor a careful exposition of the weird eccentricities of that extraordinary anachronism, the Government of Tibet, at all comparable to that which Mr. Landon now gives us. Nor is this all. The enthusiasm of the true explorer pervades the book; that nameless joy in treading new and untouched fields; that absorbing interest in the aspects of nature, in its lights and shadows, fields and flowers, outline and colour; aspects which enchain the imagination everywhere, but acquire fresher value and larger interest the farther they are removed from the area of the well trodden world. Certainly there must be many more beautiful landscapes than those of the southern valleys of Tibet, the beauty of which exists, so to speak, in scraps large scraps, perhaps, but scraps that are separated by wide intervening spaces of stony desolation and dreary outlook. Yet many of the best pages of the book are full to the brim with vivid descriptions of the beauty of Tibetan scenery as Mr. Landon saw it in the basin of the Brahmaputra River.

The illustrations are excellent, and there is an added value to them in the notes which are appended indicating the general tones and local colour of each view. If Mr. Landon has invented this method of recording the principal charm of Tibetan scenery for the benefit of those who know not Tibet, he is much to be congratulated thereon. All who know and love the Himalayas can fill up the pictures with the grace of nature's colouring from Mr. Landon's description alone, although here and there his colour notes are perhaps a little indefinite. What, for instance, are "lightning greys"? But where colour reproduction has not been left to the reader's imagination, and has been attempted by some process of block printing, the results are not so satisfactory. The distances are hard and obtrusive, and atmosphere has vanished from the view. Even in Tibetan highlands there is a certain amount of atmospheric influence, however thin it may be, which affects one's appreciation of distance.

FIG. 1.—Part of the Potala Palace from the buildings at its base. It is built of granite and whitewashed once a year. The dark central portion is crimson. From Landon's "Lhasa."

To the great majority of readers Mr. Landon's descriptions of the beauty of the Brahmaputra valley to the south of Lhasa, of the glory of Tibetan sunsets, of the splendour of the Turquoise Lake set in the midst of the flower-strewn plain, of the vast impressiveness of the isolated city of mystery itself as it bursts on the view from a mountain-ringed depression beyond the Potala—the guardian sanctuary of its western gates—all these things will be just as new and as surprising as are the kindly amiability of its half barbarous people and the friendliness of disposition which they evinced towards the foreigner. Not that Mr. Landon is unduly optimistic. The extraordinary contrasts between barbarous magnificence and indescribable filth and squalor are not missed. Where the sweet scent and brightness of English flowers is noted as a passing incident there is no lack of intimation as to the nature of the rotting filth from which they spring. The interior of temples and dwelling houses, described as often impressive in its magnificence, and always surprising in the character of its artistic decoration, involves an approach through knee-deep slush and mud, terminating in the ascent of a greasy stairway foul with the accumulation of rancid butter and poisonous forms of putrid filth.

Animate nature in Tibet is no better than inanimate. We will pass by the pigs and the dogs, and refer only to the people. It was discovered by the medical staff of the mission who attended to the wounded warriors of Guru that the natural complexion of the Tibetan was quite fair—as fair as that of any European, in spite of the fact that no soap is ever used. But to judge from the aspect of the Tibetan as he (or she) appears in the ordinary unclean garb of daily life, the general tint of the skin appears to be that of a well baked potato picked out from amongst the charred sticks of a burn-out bonfire. The children are pretty and remarkably affable, and the general unloveliness of their parents is due quite as much to dirt as to exposure to the rigorous climate.

The story of the advance of the mission through the tangled forests and over the bleak passes of Sikkim is well told. There is none of the reiteration of the guide book or of the monotony of the intelligence report in Mr. Landon's tale. He takes the reader with him through the narrow and slippery ways of Chumbi, over the Himalayan backbone (not so formidable as the Sikkim-Chumbi passes), down the gentle slope to Gyantse, with an ever-varied interest gathered from what is to be seen around him as he rides. Mountains and stone-strewn slopes, trees (where there are any), flowers, and the small things that become great in a land where vegetation barely exists, all are noted in their turn, whilst we happily miss the daily routine of military movement and the everlasting repetition of marching experiences. Only when we get to the fighting stage do we hear much about the little army which formed the escort; and then there is enough of incident to make a fascinating and lasting record of really great achievement.

Not the least interesting chapters of Mr. Landon's book are those which deal with the superficial aspects of lamaism, and the relation between the Tibetan hierarchy and our frontier politics. Tibet affords a notable example (if one were needed) of the degrading, stifling, destroying effects of a dominant priesthood on a country's developments. Between the lamaism of Tibet and the pure faith of early Buddhism there is indeed a great gulf fixed, and Mr. Landon is well within the mark when he describes modern lamaism as "sheer animistic devil worship." Yet he is quite ready to recognise the power and the strength which are gained by the lofty isolation—the stern aloofness of the head of the Tibetan Church; and he is probably correct in estimating the Dalai lama as being still the recognised head of the Tibetan Church and State wherever he may be, at Urga or at Lhasa. Nor does he fail to reckon up the impressive effect of certain ceremonials, and the really awe-inspiring aspects of the temple interiors hallowed by the ever-dominating figures of the great "Master." Here we cannot quite follow him, for if his sketch of the head of the Great "Jo" in the holy of holies at Lhasa is realistic, the original can hardly be impressive.

FIG. 2.—Nichi-kang-sang (24,000 feet). This peak guards the road to Lhasa over the Karo la. The track passes suddenly through the mountain barrier between the darker hill and the icefields of Nichi-kang-sang. From Landon's "Lhasa."

It will be news to most people that our Queen Victoria of blessed memory was, and is, a Tibetan incarnation, and is represented by a bloodthirsty blue goddess who revels in horrors such as would astonish even the gifted Kali of the Hindus. Yet she is regarded rather as a beneficent and protective goddess than a malignant one. This is encouraging, for it shows that something at least of the world-wide veneration that surrounded our ever-loved Queen had filtered through the almost impenetrable armour of lamaistic isolation. The Tsar has only recently been canonised, so to speak, on Dorjieff's recommendation.

As a recent incarnation, or "last-joined" saint, he invested the Dalai lama with a complete suit of bishop's canonicals. Perhaps this recognition of a certain analogy between the two Governments is not quite so inappropriate as it at first appears.

Mr. Landon concludes his delightful book with an expression of his opinion that the doors of Lhasa are once again closed to the European. Not again (according to our author) for many a long year will any Englishman watch for the flashing cupolas of the Potala from the banks of the Kyi Chu, or penetrate into the inner sanctuary of the everlasting Jo. With this view of the future of Tibet we can hardly agree. By his own showing there is quite enough of uncertainty, even in the present political situation, to warrant the making of a straight road over the Himalayan passes with as little delay as possible; and it should not be forgotten that the right of way to Gyantse is already secured. T. H. H.

THE TREATMENT OF CANCER WITH RADIUM.

THE discovery of radium was speedily followed by its use in the treatment of cancer, and it was hoped that at last a remedy had been found for this terrible disease. Great interest has been aroused by a recent report in a contemporary of a case of cancer which has been successfully treated by this agent. The case appears to be undoubtedly one of cancer, as the patient was carefully examined before, during, and after treatment by competent authorities; but the report of cure must be accepted with caution. We are informed that the treatment began in March, 1904, and although the disease has now disappeared, it is still possible that it may recur.

A very large number of cases of cancer have been treated by radium in this country, on the Continent, and in America. Some have improved remarkably, but in most instances there has been no apparent benefit, and in no case has sufficient time elapsed to speak with certainty of cure. No surgeon would feel justified in reporting a cure of cancer until at least two years had passed without recurrence, and there are many instances on record where a longer period of apparent immunity has been followed by a reappearance of the disease.

It must be remembered that the effect of radium upon a cancerous growth is, so far as we are at present aware, purely local. The terrible feature of cancer is the early involvement of the lymphatic glands, followed by the formation of secondary tumours in the internal organs. It is impossible to follow these internal developments by such a remedy as radium. Only too often a patient is found, on first seeking medical advice, to have already these secondary deposits, and treatment by local measures is purely palliative. That relief may be afforded in some cases which are beyond operation is recognised, but nothing has yet been reported which will warrant a surgeon using radium in a case of cancer where there is a possibility of complete removal by the knife.

Radium is applied in small tubes to the surface of a tumour, and in some cases it has been found possible to place it in the interior of a growth through a small incision. The quantities available are so minute that only a small area can be treated at one time. In the case of cancer mentioned above, the quantity which was used was ten milligrams. Fortunately the radium can be used again and again, for its energy appears practically to be inexhaustible.

NOTES.

Since the appearance in Nature of April 6 of an article on the proposed amalgamation of the Society of Arts and the London Institution, a meeting of the proprietors of the London Institution has been held to consider the managers' proposals in connection with the amalgamation. The proposals met with a determined opposition from some proprietors; and after a somewhat noisy and undignified discussion, it was resolved to defer the further consideration of the scheme of amalgamation until after the annual meeting of the London Institution on April 28. The result of this meeting is to be regretted, since it implies the loss for the present of an excellent opportunity to accomplish the establishment of an important and powerful institute designed to develop a popular interest and regard for scientific work and results. It is to be hoped that it may prove possible to arrive at some agreement which will lead to the formation of a vigorous scientific organisation, in which the privileges offered by the Society of Arts and the London Institution will be combined.

The Paris Geographical Society has awarded its gold medal to M. Paul Doumer.

It is intended, if found practicable, says the *Pioneer Mail*, to arrange for daily weather reports from the Andamans by wireless telegraphy.

The death is announced of Prof. A. Piccini, professor of chemistry at the R. Istituto di Studi superiori, Florence, and author of several works on chemistry.

The President of the Board of Agriculture and Fisheries has appointed a committee to inquire into the nature and causes of grouse disease, and to report whether any, and, if so, what, preventive or remedial measures can with advantage be taken with respect to it.

The Paris correspondent of the *Times* announces the death of Colonel Renard, the director of the National Aërostatic Park at Meudon. The investigations and experiments of the Renard brothers have done much to promote the progress of aërial navigation.

It is announced that the Liége International Exhibition will be opened on Saturday, April 22, and that, unlike most exhibitions, the buildings will be complete. The exhibition will be of a very attractive and picturesque character, and the buildings cover a greater area than at any previous exhibition, except those of Paris in 1900 and of St. Louis. During the period of the exhibition several congresses will be held in Liége, that of mining and metallurgy, from June 26 to July 1, promising to be the most largely attended.

The *Times* correspondent at Athens states that at the last meeting of the Archæological Congress, on April 13, it was decided that the present executive committee should continue to exist until the next meeting of the congress, which was fixed to take place at Cairo after a *minimum* interval of two years, the Egyptian Government having signified its willingness to accept this arrangement.

Press telegrams from Martinique report that Mont Pelée is again showing volcanic activity. On April 9–10 the escape of vapour was fairly abundant. On April 10–11 a marked recrudescence manifested itself; numerous small clouds issued from the vent, and there was a small flow of lava into the valley of the White River. On April 13–14 frequent rumblings were heard, and it was noticed that blocks of rock, accompanied by white clouds, were expelled from the south side of the crater.

Mr. C. H. Hamilton records in *Science* that the world-renowned volcano Kilauea, in the Hawaiian Islands, has again become active, after a rest of thirteen years. Fresh lava appeared the last week of February, heralded by a slight earthquake. On March 10 the Volcano House reported the existence of a large lake of lava. "Heavy rumblings and explosions indicate that another outbreak is imminent." Thus there seems to be a restoration of the old-time activity—such as will cause a large increase in the number of visitors.

Dr. Davison states in a letter to the *Times* that a detailed record of the Indian earthquake was given by a horizontal pendulum at Birmingham. The first tremors were registered at 1h. 6m. 18s. a.m., and were succeeded at 1h. 29m. 2s. by long-period undulations lasting for more than an hour and a half. The more prominent of these undulations were in two series, separated by a few minutes, and little more than two hours later the diagram showed another double group of waves. The early tremors took a direct course through the body of the earth; the first double series travelled along the surface by the shortest way to Birmingham, while the second double series followed the longest possible route, through the antipodes, and back again to Birmingham.

It is announced in *Science* that Dr. Frank Schlesinger has been elected director of the New Allegheny Observatory. The observatory has an endowment fund, and a regular income from the time service, besides owning a large and valuable property in the City of Allegheny, which will become a source of income in the near future. Work has not been suspended on account of lack of funds, and much has been accomplished toward the instrumental equipment during the past year. The Keeler memorial telescope of 30-inch aperture is now ready to be set up, and the large (Porter) spectroheliograph is almost completed. The 30-inch objective is well under way, and other instruments will be installed during the year under the directorate of Dr. Schlesinger.

At the meeting of the Royal Colonial Institute, held on April 11, Sir Frederick Pollock read a paper on Imperial Organisation. He deprecated the national faculty of compromise, and asked, could we go on trusting to compromises and accidents? It is necessary to look, he continued, for some plan which will avoid elaborate legislature and formal change in the Constitution. We must be content for the present with a council of advice which will have only "persuasive authority." A permanent secretary's office is required, independent of any existing department, but immediately under the president of the Imperial council. The best living information ought to be at the service of this Imperial council through its secretariat; and this can be most effectively done, without ostentation and with very little expense, by the constitution of a permanent Imperial commission the members of which will represent all branches of knowledge and research, outside the art of war, most likely to be profitable in Imperial affairs. Not only learned and official persons would be included in such a body, but men of widespread business, travellers, ethnologists, comparative students of politics might all find scope for excellent work. It need not be paid work. It would be as willingly done without pecuniary reward as the more formal and laborious work of Royal Commissions, as to which there has never been any difficulty. Of the need for some such advisory council to secure national efficiency there can be no doubt, and it is earnestly to be desired that hopes and schemes, like that of Sir F. Pollock, will soon fructify in accomplished fact. A select advisory council on which men of science familiar with the scientific advances of recent years took a prominent place would assist statesmen to secure national efficiency more than any other expedient.

Reports of the annual general meeting of the Chemical Society and of the anniversary dinner are given in the *Proceedings* of the society, just issued. The following extracts from the official account of remarks made at the dinner by Mr. R. B. Haldane, as to the neglect of science by the British nation in the past, and the promise of an improved position in the future, are of interest:—The problem which lay in front of the British nation was how to develop what he might call the grey matter of the executive brain. All the things spoken of that night represented something new in the nation, and not only something new, but something of which they would have to see a great deal more if the nation was to hold its own in these days. Science counted for more than ever it did. The West had had a rude awakening at the hands of the East. The controversies which agitated the minds of politicians were of less importance than the great question of how to make the permanent element in politics more powerful and better than it was. There was too little science in the present day, although one or two things had been done for which they were very grateful, in connection with the Navy and the Army and the Defence Committee. If they turned to the different departments of the Government there was hardly one which did not require science, if its policy was to be an effective policy. Wherever they turned science was needed, and yet there was not sufficient attraction to a man of high attainments to put himself at the disposition of the State. Foreign Governments held out careers far in excess of any rewards and honours which the British Government could afford. Was it impossible to see an era in which the head of the Government could have at his disposition the first intelligence and the best brains which the nation could command? If we were to hold our own we must not be behind Berlin, the United States, or the French nation. Science never stands still, and if science does not stand still, Governments cannot afford to stand still in their use of science. These were speculations which, perhaps, went beyond the moment, but he had a strong feeling that the time was very nearly, if not quite, ripe for them. They would see what was the mind of the nation on this point, and doubtless they would be subjected to the acute disappointment to which all were usually subjected when they formed great expectations. He hoped to see the position of science raised in the next few years, and he looked to the time when brute force would count for little, and knowledge for more.

We have received from Messrs. R. Friedländer and Sons, of Berlin, a priced catalogue of books and papers dealing with vertebrate anatomy and physiology.

Part xxxi. of the *Transactions* of the Yorkshire Naturalists' Union contains the reports of that body for the years 1903 and 1904, and also a reprint of the excursion circulars for the same period. A satisfactory feature in the work of the union is the care devoted to the collection of photographs of important geological sections within its sphere of influence.

Prof. J. S. Kingsley discusses in the February number of the *American Naturalist* the current nomenclature and homology of the component bones of the lower jaw of reptiles, pointing out that there is still some uncertainty with regard to the proper determination of one of these elements in crocodiles. The other articles are on natural and artificial parthenogenesis, by Dr. A. Petrunkevitch; on the angle of deviation from the vertical at which stems show the strongest geotropical response, by Miss Haynes; and on the variation in the ray-flowers of Rudbeckia, by Dr. R. Pearl.

In the April number of *Bird Notes and News* reference is made to certain common misapprehensions in regard to the authorities responsible for protective regulations, and it is pointed out that many of these emanate from county councils. To the agriculturist and the horticulturist it is, however, of little consequence whether the alleged over-protection of birds in his particular district is the work of the local or of the Imperial Parliament, for the difficulty of getting ordinances repealed appears as difficult in the one case as in the other. In the statement on p. 61 as to the sale of skins of "Argus pheasants from the Himalayas," it should have been pointed out that "Argus pheasant" is the trade name for the peacock pheasants (Euplocamus) of the Himalaya, the true Argus having a very different habitat.

The following quotation in the February issue of the *American Naturalist* from a work by Messrs. Gilbert and Starks on the fishes of the two sides of the Isthmus of Panama has a very great interest from the point of view of distribution in general:—"The ichthyological evidence is overwhelmingly in favour of the existence of a former open communication between the two oceans, which must have become closed at a period sufficiently remote from the present to have permitted the specific differentiation of a very large majority of the forms involved. . . . All evidence concurs in fixing the date of that connection at some time prior to the Pleistocene, probably in the early Miocene." This agrees precisely with the conclusions drawn from the study of the fossil mammalian faunas of North and South America, which indicate that land communication between those two continents was interrupted during a considerable portion of the Tertiary epoch, and only re-established about the close of the Miocene or early part of the Pliocene epoch.

The existence of an entirely distinct second family type of lancelets (Cephalochordata) is demonstrated by Dr. R. Goldschmidt in *Biol. Centralblatt* of April 1. It appears that in 1889 Dr. A. Günther described a lancelet obtained during the *Challenger* Expedition as a new species, under the name of *Branchiostoma pelagicum*, its special characteristic being the absence of a tentacle-apparatus. Although on this ground Gill proposed the new generic name Amphioxides in 1895, while Delage and Hérouard pointed out that if the character in question was not due to imperfection the creature indicated a distinct ordinal type, yet it has generally been allowed to remain in the type genus, as in Prof. Herdman's account of the group in the "Cambridge Natural History." The examination of twenty-six entire specimens obtained during the recent German deep-sea expedition enables Dr. Goldschmidt to state that *A. pelagicus*, together with two closely allied species, represents a distinct family of Cephalochordata, which may be distinguished from the typical family as follows:—Family Branchiostomatidæ.—A peribranchial space; the ventrally-opening mouth surrounded by tentacles; gill-canal furnished throughout its diameter with lateral gill-slits. Family Amphioxididæ.—No peribranchial space; the slit-like mouth opening on the left side; gill-slits situated in the ventral median line; gill-canal divided into a dorsal nutritive and a ventral respiratory half.

Indian Public Health for March (vol. i. No. 8) contains articles on septic tank installations in Bengal, sewage disposal in India, Hankin's views on plague epidemiology, the Finsen method, &c.

In the *Revue scientifique* (April 8) M. Calmette, the director of the Pasteur Institute, Lille, writes on the important *rôle* played by medical science in the successful colonisation of tropical countries, instancing such diseases as cholera, leprosy, plague, and malaria, which can be robbed of their terrors only by the institution of efficient sanitary control in the districts in which they occur.

Major Ronald Ross, F.R.S., in a letter to the *Times* (April 7) directs attention to the remarkable diminution in malarial disease which has accompanied the institution of anti-mosquito measures at Klang and Port Swettenham in the Federated Malay States. The former, with a population of 3576, and the latter of about 700, were both perfect hotbeds of malaria, and in 1901, for the two towns, 236 sick certificates and 1026 days of leave were granted. In 1902, after anti-mosquito measures had been energetically pursued, the figures were 40 and 198, and in 1904 these had further fallen to 14 and 71 respectively. Dr. Malcolm Watson, district surgeon, from whose report these statistics are taken, sums up by saying:—"In whatever direction one turns, it is plain that the two areas which were so malarious in 1901 are now practically, if not absolutely, free from the disease, and that the district surrounding these two areas remains much as it was." These anti-mosquito measures were initiated by the Department for Medical Research, Federated Malay States (which is affiliated with the London School of Tropical Medicine), under the direction of Dr. Hamilton Wright.

In a short paper which appeared in the *Botanical Gazette* (February) Mr. C. H. Chamberlain advances the opinion that an alternation of generations as understood by botanists for plants can be recognised in animals. The egg with the three polar bodies constitutes a generation comparable with the female gametophyte in plants; similarly, the primary spermatocyte with the four spermatozoa constitute a generation comparable with the male gametophyte in plants. All other cells of the animal constitute a generation comparable with the sporophytic generation in plants.

Two debated points connected with the problems of geotropism in plants, *i.e.* the seat of geotropic sensibility, and the statolith theory simultaneously advanced by Haberlandt and Němec, form the subject of a critical review by Dr. Linsbauer, who writes in *Naturwissenschaftliche Wochenschrift* (March, No. 11). The reviewer may be regarded as an adherent to the statolith theory, and notes that although the *rôle* of statoliths is generally attributed to starch grains, in their absence other bodies, such as crystals of calcium oxalate, or certain bright bodies found in the rhizoids of Chara, may function similarly.

The *Bulletin* of the American Geographical Society contains an article on the work of the Reclamation Service of the United States, by Mr. C. J. Blanchard. During the last three and a half years a sum of nearly twenty-five million dollars has been realised from the sale of public lands, and work has been begun on eight irrigation projects which will make an area of about one million acres productive. The *National Geographic Magazine* for March has a short article, with excellent illustrations, on the same subject.

MESSRS. W. STANFORD AND CO., of Oxford, have sent us specimens of a number of outline maps of the world, on Mollweide's equal-area projection; also a map of the Atlantic Ocean, on the same projection. The maps are well drawn and clearly printed; the larger scale maps should be extremely useful for purposes of research and teaching, while the smaller maps are well adapted for museum use. The employment of equal-area maps in representing distribution cannot be too strongly recommended, and in providing such maps at very moderate prices Messrs. Stanford have done good service.

IN ore-dressing operations and in laboratory work much confusion is caused by the practice of describing the sieve or screen employed by the number of the mesh. A sieve of 30 mesh, for example, does not possess an aperture of one-thirtieth of an inch, nor does it yield a product of which the largest particles will be one-thirtieth of an inch in diameter. With coarse sieves the error is not of great moment, but with fine sieves the wire itself occupies so much space that the size of the particle passed by the sieve may vary from a quarter to two-thirds of the size indicated by the word "mesh." Consequently, in ordering wire screens or in recording results it is desirable to specify the size of aperture rather than the number of the mesh. In order to enable this to be done, Mr. G. T. Holloway has drawn up a valuable series of tables, calculated on the British Imperial Standard wire gauge, showing the size of aperture in screen wire cloth of all the principal sizes in use down to the very finest. The tables have been duplicated, one series showing the figures in decimals of an inch, and the other, for the use of those who still prefer to employ vulgar fractions, in both decimals and vulgar fractions. The tables, which have been published in pamphlet form (*Bulletin* No. 5 of the Institution of Mining and Metallurgy), have been calculated with great care, and should do much towards effecting uniformity in the nomenclature of sieve-mesh.

THE Geological Survey of Western Australia is publishing, in handy octavo form, a valuable series of bulletins, of which we have received three. One of them, dealing with the mineral production of the colony up to the end of 1903, is written by Mr. A. Gibb Maitland and Mr. C. F. V. Jackson. It shows that the total value of the mineral products was 47,779,000*l.*, gold alone representing a value of 46,441,000*l.* Other minerals mined include copper, tin, lead, silver, iron, antimony and cobalt ores, coal, graphite, limestone, precious stone, mica, asbestos, and salt. In the other bulletins Mr. C. G. Gibson deals with the mineral resources of the Murchison goldfield and of Southern Cross, Yilgarn goldfield. The reports and the accompanying coloured maps throw much light on the geology of the districts, and indicate that the areas described deserve more attention from the mining prospector than they have hitherto received. The Murchison goldfield is of some historical interest in that in 1855, when its economic value was purely prospective, it was officially stated to have the appearance of being one of the finest goldfields in the world. Although it has not come up to these high expectations, it is one of the most important goldfields in the colony, and contains not only one of the largest quartz veins mined anywhere, but also the iron ore deposits of the Weld range, which, though practically valueless owing to their inaccessibility, are among the richest in the world.

MR. V. KOUSNETZOFF communicated to the *Bulletin* of the St. Petersburg Academy of Sciences of September last some useful formulæ for the determination of the height of aurora borealis. He also gave tabular and graphical results of its occurrence at Pavlovsk from January 1, 1878, to the end of 1903. The tables show, generally, an eleven years' period, as in the case of sun-spots, but the details of the two curves do not correspond. The maxima of the auroræ occurred in 1887 and 1896, and the minima in 1884 and 1894, but this divergence may be due to the occurrence of cloud. The annual period is well marked, the maxima being in March and October, and the minima in January and July.

IN the *Archives des Sciences physiques et naturelles* of March last M. F. A. Forel summarises his own observations and those made by others on the occurrence of Bishop's Ring, following the great volcanic eruption of Mont Pelée (Martinique) on May 8, 1902. Bishop's Ring, as most of our readers are aware, consists of a solar corona of great diameter; it appears to be formed of two parts, a limb of a dazzling silvery hue being immediately round the sun, and, beyond this, a coppery red ring of some 20°–25° exterior radius. The ring appears to have been first observed in the winter of 1902–3, but only became general towards the end of July, 1903, and was constantly seen until November of that year. After that time it became less frequent, and ceased altogether in July, 1904. The phenomenon is best seen from an elevated station, and when the sun is high above the horizon. The intensity of the colours of the ring was less than in that which followed the Krakatoa eruption in 1883.

Bulletin No. 35 of the United States Department of Agriculture, Weather Bureau, will be found of great interest to those who wish to know something about the present stage of long-range weather forecasting. The first chapter is written by Prof. Garriott, and presents a verification of the work of the most prominent of the so-called long-range weather forecasters in the United States. Prof. Garriott considers chapter and verse of the forecast with the actual facts, and shows conclusively the fallacy of these predictions. Prof. Woodward, in the second chapter, devotes his attention to the impossibility of basing weather predictions on planetary influences, and at the same time criticises the work of Mr. Tice embodied in a book on the elements of meteorology. Perhaps the most interesting portions of this *Bulletin* are the pages devoted to a discussion by Prof. Garriott of the subject of long-range forecasting by many of the leading meteorologists of the world. It may be said to be a brief review of the literature on the subject, and gives quotations of their opinions regarding the practicability of long-range work. At the end is given a summary of the remarks and opinions expressed and a series of conclusions based on them, and we refer the reader to the *Bulletin* for these conclusions. There is one which may be mentioned here, since by recent work in this country it has been brought prominently forward. "Advances in the period and accuracy of weather forecasts depend upon a more exact study and understanding of atmospheric pressure over great areas and a determination of the influences, probably solar, that are responsible for normal and abnormal distributions of atmospheric pressure over the earth's surface."

NO. 3 of vol. ii. of *Le Radium* contains useful articles on uraniferous minerals and their deposits, and on the methods used in the measurement of the quantity of heat evolved by radio-active substances.

PROF. MCCLELLAND has recently shown that the emanation of radio-active substances does not carry an electrical charge, and the same conclusion is arrived at by means of a different form of apparatus by Prof. Battelli and F. Maccarrone (*Physikalische Zeitschrift*, No. 6). It must be concluded, therefore, contrary to M. Becquerel's views, that such emanations consist neither of fragments of atoms which have lost positive ions nor of the positive ions themselves.

A new method for the preparation of paraffins from their monohalogen derivatives which is described by M. Paul Lebeau in the current number of the *Comptes rendus* (April 10), is noteworthy on account of the simplicity of the reaction and the purity of the gas obtained. Sodium is converted into sodium-ammonium by the action of liquid ammonia, and this, treated with methyl chloride, gives methane, readily obtained in a pure state by liquefaction by means of liquid air. Ethyl and propyl iodides react with the same ease, giving rise to ethane and propane, the purity of which was verified by combustion analysis. It is pointed out by M. Lebeau that as these reactions take place below the boiling point of liquid ammonia there is small probability of any secondary reactions taking place.

The current number of the *Quarterly Review* contains an article by Mr. A. E. Shipley on "Pearls and Parasites."

We have received from Messrs. Isenthal and Co. a well illustrated and conveniently arranged catalogue of technical and laboratory electric measuring instruments and rheostats.

The issue of the *Journal* of the Royal Sanitary Institute for April contains a full account of the papers read and the speeches delivered at the conference on school hygiene held at the University of London in February last, and reported in Nature for February 16 (p. 377).

Many characteristic scenes of the western coast and fjords of Norway are described and illustrated in a pamphlet just issued by the Albion Steamship Co., Ltd., Newcastle-on-Tyne, as an itinerary of cruises to be taken this year by the yachting steamer *Midnight Sun*.

Messrs. John J. Griffin and Sons, Ltd., have published a ninth edition of their illustrated and descriptive catalogue dealing with apparatus suitable for the practical study of sound, light, and heat. An examination of the contents of the catalogue shows that a great improvement is taking place in the apparatus employed in the laboratories and lecture-rooms where physics is taught. Teachers and others should find this catalogue helpful and suggestive.

OUR ASTRONOMICAL COLUMN.

Astrophysical Work at the Smithsonian Institution.—Prof. Langley's report of the work performed in the various departments of the Smithsonian Institution during the year ending June 30, 1904, contains a report by Mr. C. G. Abbot of the observations made in connection with the solar radiation at the astrophysical observatory.

Among many items of interest, the following may be briefly mentioned: The bolometer apparatus has now been improved to such a state of perfection that a duplicate set for investigating the radiation of stars has been constructed. A series of experiments with the improved pyroheliometer has shown that this instrument may now be used with confidence to measure the solar radiation.

The definition of the long focus mirror has been considerably improved by churning the air inside the tube, by protecting the tube from the direct solar rays with a covering of canvas, by employing a number of supporting plates as suggested by Prof. Ritchey in order to preserve the shapes of the mirrors, and by nullifying the vibrations due to traffic by placing indiarubber pads behind the mirrors. Prior to these alterations the solar image was ill-defined; different parts of it came in focus in different planes, whilst the variation in the focal length of the instrument often amounted to 10 feet during a single day. Now the image is much better defined; all parts of it are focused in the same plane, and the focal length never varies so much as 12 inches during a day.

Well marked variations, amounting to 10 per cent. of the total, have been recorded in the value of the solar radiation, and Mr. Abbot expresses a strong hope that, on combining the solar radiation and atmospheric transparency results, long range climate forecasting will ere long become possible.

Value of the Astronomical Refraction Constant.—The third volume of the *Publications* of the Grandueal Observatory at Heidelberg contains 234 pages devoted to the discussion of the results obtained by M. L. Courvoisier in a research undertaken by him for the determination of the refraction constant.

The instrument employed was a 6-inch Repsold meridian circle, which, together with its various constants, is described at length. Two hundred stars were observed, and the observations and their peculiar errors are discussed. The meteorological data for several periods during each observing day are next given, the observations extending from June 3, 1899, to July 9, 1901, and this table is followed by sections dealing with the stellar, latitude, and declination observations respectively.

The value obtained for the refraction constant is $60''{\cdot}161 \pm 0''{\cdot}037$.

Reality of Various Features on Mars.—In No. 4007 of the *Astronomische Nachrichten* Signor V. Cerulli, of Teramo, discusses the actual subjectivity of various Martian phenomena, as seen in the telescope, from a physiological standpoint. Having observed Mars regularly for ten years, he appears to have arrived at the conclusion that the actual existence of these features is as much a subject for physiological as for astronomical investigation. He states that the phenomena observed are so near to the limit of the range of the human eye that in observing them one really experiences effects accompanying "the birth of vision." That is to say, the eye sees more and more as it becomes accustomed, or strained, to the delicate markings, and thus the joining up of spots to form "canals" and the gemination of the latter follow as a physiological effect, and need not necessarily be subjective phenomena seen by the accustomed eye.

Stonyhurst College Observatory.—In addition to the results of the meteorological and magnetic observations made during 1904, Father Sidgreaves's annual report briefly refers to the solar and stellar spectroscopical work carried out at Stonyhurst during last year.

Two series of spectrograms of β Aurigæ and γ Cassiopeiæ were commenced, and the results already obtained are very promising. A short table showing sun-spot areas and the range of the magnetic declination appears to confirm the connection between these two values for the years 1898–1904. The spectra of sun-spots in the green and violet regions have been photographed with a Rowland grating spectroscope, and a number of experiments have been made with the view of photographing the spot spectra in the red region.

Nature of Sun-spots.—In the April number of the *Bulletin de la Société astronomique de France* Abbé Th. Moreux re-discusses his theory concerning the formation and nature of sun-spots in the light of data more recently acquired, more especially during the great spot of February last. He gives numerous drawings of this spot, and several schematic diagrams showing the possible arrangement of the photospheric clouds in and over the spot, and arrives at the conclusion that spot areas are analogous to *anti-cyclonic* areas in the terrestrial atmosphere.

Instructions to Solar Observers.—Amateur observers of solar phenomena will find the instructions to solar observers, formulated by the "commission solaire" of the Société astronomique de France, of great use and interest. Chapter v. is published in the April *Bulletin* of the society, and deals with daily spectroscopic observations of the chromosphere and prominences by the Lockyer-Janssen method.

RECENT CHANGES IN THE CRATER OF STROMBOLI.[1]

STROMBOLI is the most easterly and northerly of the Lipari Islands. It is situated north of Sicily, close to the track of steamers plying between Naples and the Straits of Messina, and is thus an object familiar to passengers to or from Egypt or the East, though comparatively few have landed on its shores. Its almost constant eruptions have gained it the name of the lighthouse of the Mediterranean. It is almost circular, as its old name Strongyle indicates, and rises as an irregular cone out of deep water. On the north-west side are the crater, and the Sciara or steep slope down which the ejecta roll into the sea.

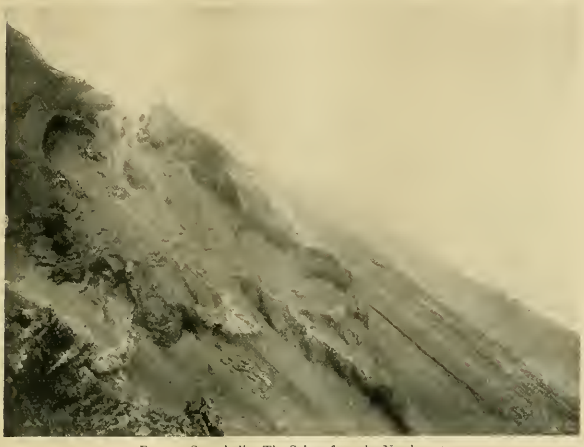

FIG. 1.—Stromboli. The Sciara from the North-east.

The summit of the mountain, which is about 3000 feet high, consists of a crescentic ridge, the Serra di Vancori, open towards the north. It forms part of an old crater ring, and thus presents points of similarity to Somma. Inside the crescentic ridge, and in places joined to it by irregular crests of rock, but mainly separated from it by a valley, "A Fossieiedda," similar to the Atrio del Cavallo of Vesuvius, is another crescentic ridge, connected with the two extremities of which, and immediately overlooking the sides of the crater, are two conspicuous pointed rocks, the Torrelle, which partly obstruct the view of the crater when viewed from the cliffs overlooking the Sciara on its north-east and south-west respectively. These Torrelle, being practically unaltered by ordinary eruptions, present good points of comparison for estimating the changes that take place, and one or other of them is included in most of the photographs. Between the two Torrelle, in the midst of a sort of amphitheatre formed by them and the crescentic ridge last mentioned, are the crater and its appurtenances, the "Apparato Eruttivo" of Italian observers. This amphitheatre is open to the north-west, and from its open side beyond the craters the steep slope of the Sciara extends down into the sea. This slope is bounded on each side by two steep cliffs, Filo di Sciara and Filo di Baraona, which are formed, like the Sciara itself, of lava-streams, agglomerates, and dykes; in fact, of almost every kind of compact volcanic material, chiefly of basic composition.

This Sciara, as is well known, is one of the most peculiar features of this volcano. It extends at an angle of about 35°, which is the "angle of repose" for the kind of material of which it is composed, down into the deep water of the Mediterranean; and though the volcano has certainly been in almost constant eruption during the whole of the historic period, and probably much longer, it has never been able to build up a talus sufficient to rise to the level of the sea, much less to that of the lip of the crater, about which, according to the analogy of other volcanoes, it might have been expected to have built up a cone on this side comparable to the portion on the south described above. Fig. 1, from a photograph[1] taken by the author in 1888 from the ridge overlooking the north-east side of the Sciara, and consequently looking south-west, shows the Sciara extending down to the right of the picture with the Filo de Barcuna behind it. The pointed rock to the left of the picture is the eastern Torrella, with a gap to the left of it through which the ejecta are thrown during the larger eruptions, and roll on to the steep slopes in front and down the Sciara into the sea. The western Torrella is just visible in the distance beyond the eastern Torrella. The crater situated between the two was in 1888 a large pit obviously formed by severe explosions. It contained two small secondary cones. One, towards its western part, and close to the edge of the Sciara, was that from which the explosive eruptions took place several times an hour; the other, towards the eastern part, emitted only smoke.

FIG. 2.—Stromboli. The Sciara from the West.

[1] Abridged from a paper by Dr. Tempest Anderson in the *Geographical Journal* for February.

[1] From "Volcanic Studies," by Tempest Anderson, plate xxi.

In 1904, when the author took comparison photographs from nearly the same spot, this large crater was almost entirely filled up, and the slope of the Sciara was continued upwards, so that the cone of ejecta overtopped and was visible behind the eastern Torrella. The activity in this eastern part of the crater still maintained the same quiet character as in 1888. The whole area constantly emitted vapour; there was more than one bocca visible, but they were quite small and only gave very feeble explosions, and these with a rhythm quite independent of those at the western part of the crater.

Fig. 2, taken by the author on April 20, 1904, from a point to the west of the crater, and consequently in almost exactly an opposite direction to Fig. 1, shows the condition of the western part of the crater sixteen years later. The conspicuous rock to the right of the plate is the western Torrella, behind which, in 1888, was the great crater above referred to. The bocca to the left, from which the explosion is taking place, is shown in some of the earlier photographs as situated on the edge of the large crater at its junction with the Sciara. The great crater is now seen to be filled up by ejecta which prolong the slope of the Sciara upwards over what was previously its site, while the bocca itself remains in all probability really in its former position, though apparently on the slope of the Sciara instead of on its edge.

It will be interesting to future visitors to see whether the volcano will continue to prolong the slope of the Sciara much further upwards, or whether a paroxysmal explosion will occur which will clear the great crater again.

The paper in the *Geographical Journal* is illustrated with twelve photographs and a map showing these and other points more in detail.

THE INSTITUTION OF NAVAL ARCHITECTS.

The annual spring meeting of the Institution of Naval Architects was held last week, commencing on Wednesday, April 12, and being continued over the two following days. The president of the institution, the Right Hon. the Earl of Glasgow, occupied the chair. A very full programme had been arranged, there being no less than fifteen papers set down for reading and discussion, and there was also the presidential address.

The first business after the usual formal proceedings was the reading by the secretary, Mr. R. W. Dana, of the report of the council. By this it appeared that the institution is in a prosperous condition, both in regard to finance and membership. Reference was made to the proposed foundation of an experimental tank for the purpose of scientific investigation of problems connected with ship design. It will be remembered that it was proposed, at the initiative of Mr. A. F. Yarrow, Dr. Elgar, Sir William White, and other prominent members of the institution, that an institution tank should be founded in connection with the National Physical Laboratory. Such a tank, devoted to research of a scientific nature, would be of great benefit to the ship-building industry, and would do much to raise naval architecture to a higher plane by the substitution of scientific principles for those empirical methods upon which ship designers too largely have to rely. It is much to be regretted, therefore, and not very creditable to an important and wealthy industry, that the appeal made by the council of the institution has met with so poor a response. Only six thousand pounds out of the fifteen thousand pounds needed has been underwritten, so that the project is shelved for the present. In spite of the enormous preponderance of the ship-building interests of this country, there are but two experimental tanks in the kingdom. One is the property of the Government, and is devoted wholly to the Royal Navy, the other being the property of a private firm of ship-builders on the Clyde. Both these tanks are devoted entirely to what is known as "practical work," that is to say, they attack subjects piecemeal, and therefore in a more or less empirical fashion. They have no time for ordered investigation of fundamental principles, upon a knowledge of which, alone, can a useful superstructure of applied science be raised. The tanks are not to blame for this. They were established for a definite purpose, which they admirably fulfil.

In the presidential address Lord Glasgow, among other subjects, referred to the spread of the steam turbine for marine propulsion, alluding more particularly to the recent trials of H.M.S. *Amethyst*. Some interesting comparisons were made between the performances of this cruiser, which is fitted with steam turbines, and the *Topaze*, a similar ship in all respects, excepting that she has ordinary crank and cylinder engines. As is well known, the steam turbine is less "flexible," to use an expression that has come into use, than the reciprocating engine; that is to say, its efficiency falls off rapidly when it is run at lower powers than that for which it was designed to give maximum efficiency. This point was well illustrated during the trials of the *Amethyst* and the *Topaze* by the coal consumption, the figures being given in Lord Glasgow's address. The steam turbines of the *Amethyst* drove her at $23\frac{1}{2}$ knots, 5·45 per cent. faster than her sister ships with reciprocating engines. At the higher speeds the turbine engines appeared decidedly more economical; at lower speeds the reciprocating engines had the advantage. At 10 knots a ton of coal would carry the *Amethyst* 7·42 miles, or the *Topaze* 9·75 miles. From this speed upwards the margin in favour of the reciprocating engines decreased, until the consumption curves would cross at a little above 14 knots, when approximately $6\frac{1}{2}$ miles would be steamed on a ton of coal. At a speed of 20 knots the *Amethyst* ran 4·22 miles, and the *Topaze* 2·9 miles, per ton of coal burnt. At 23·6 knots, a speed the *Topaze* did not reach, the *Amethyst* would steam a little more than 2 miles per ton of coal. If it may be allowed that about 14 knots is the lowest speed at which these cruisers could be advantageously run in time of war, the steam turbine has a marked advantage for warlike purposes; but it might lead to higher coal consumption in time of peace.

The first paper taken was a contribution by Mr. W. E. Smith, of the Admiralty, upon the design of the Antarctic exploration vessel *Discovery*. This was a single screw wooden steamer 175 feet long, 34 feet wide, and about 1620 tons displacement. The propeller was so arranged as to be disconnected from the shaft and lifted into a well, after the manner adopted in the old steam frigates. The rudder was also arranged to be readily unshipped. The scantling of the hull was massive, but in general plan followed the designs adopted in the days of wooden construction. The vessel was fully rigged as a barque. The fitting of a magnetic observatory was one of the special features of the design. The work done here was of great magnitude, and the observations taken are now being analysed by Captain Chetwynd, the Admiralty superintendent of compasses. No magnetic metal was allowed within a radius of 30 feet of the observatory. Main shrouds were of hemp, the lanyards being rove through wooden dead eyes. Great care was taken to lag the living part of the ship so as to economise coal. Professional details of the design were dealt with at some length. In the discussion on this paper, Sir Clements Markham gave some historical details of former Polar expeditions, and dwelt upon the advantage of having a ship expressly built for the purpose. Captain Scott, who was in charge of the expedition, Sir William White, and Admiral Fitzgerald also spoke.

The next paper was by Colonel Soliani, of the Royal Italian Navy, and gave technical details of the Japanese war vessels *Kasuga* and *Nisshin*, both built in Italy. A paper by Mr. H. Rowell giving an account of the Russian Volunteer Fleet followed.

The second day of the meeting opened with a paper by Prof. J. H. Biles, who gave details of trials made to test the strength of a torpedo-boat destroyer supplied for the purpose by the Admiralty. The vessel was placed in dry dock, being supported on cradles near the ends, so as to produce sagging stresses, and in the middle in order to induce hogging. The experiments were part of the investigation of the Admiralty Destroyer Committee. The results were set forth at considerable length in the paper and in the large number of diagrams which accompanied it. It will be sufficient to say here that the actual results observed on these practical trials established the usual methods of calculation as affording a good margin of safety, the stresses in the observed results being consistently below those calculated by the formulæ commonly used by naval architects.

A paper on a similar subject was read by Mr. F. H. Alexander.

A long and elaborate paper, illustrated by numerous diagrams, was next taken. The subject was the structural arrangements of ships, the author being Mr. J. Bruhn. Details of tests of frame girders, on the strength of flanged plates, on intercostal stringers, on the tripping of frames, and the strength of rivet attachments, were described. The paper was of considerable professional interest, and will form a valuable source of information to naval architects; but without the aid of the numerous illustrations and diagrams it would be impossible to make the descriptions clear.

At the evening meeting of the same day a paper by Mr. R. E. Froude on hollow *versus* straight lines opened the proceedings. The subject has attracted a good deal of interest of late, and has already led to some discussion. A number of naval officers, led by Admiral Fitzgerald, hold that a great mistake is made by building ships for the Royal Navy with hollow lines. Sir William White and the other naval constructors naturally defend their practice, supporting their arguments by the actual results obtained at the Haslar tank. The naval men reply that, even allowing the superiority of hollow lines in the smooth water, at which all tank experiments were made, the hollow lines gave a slower vessel amongst waves, and also a wetter ship. In order to bring the matter to a practical issue, a number of experiments were made by Mr. Froude at the Haslar tank, in which artificial waves were created by a mechanical device. The results were plotted on diagrams attached to the paper, the general conclusion arrived at by Mr. Froude being that though there was a distinct diminution in average effective horse-power due to straight lines, yet this was insufficient to annul the greater efficiency of the hollow lines in smooth water. In the discussion that followed, Admiral Fitzgerald joined issue on this point. He held that quite smooth water was comparatively rarely met with at sea, and he considered it was a question for naval officers, and not for naval architects, to decide under which condition they would prefer the higher efficiency. Moreover, the straight lines gave greater displacement forward without extra cost, and the additional buoyancy could be used for placing heavier guns forward, or in other useful ways. Prof. Biles also joined in the discussion. He gave the results of trials on this subject made at the Dumbarton tank. These results were in contradiction to those given in Mr. Froude's paper, and until this discrepancy is explained the subject must remain unsettled. The need for an independent tank devoted to experimental investigation is apparent. Mr. Froude's experiments are extremely interesting, as being the first tank trials made in other than smooth water. When it is remembered how little smooth water there is at sea, and how widely the conditions of resistance and other qualities are altered by waves, the advantage of the new departure will be apparent.

An interesting paper by Mr. A. W. Johns, of the Royal Corps of Naval Constructors, was also read at this sitting, the subject being the effect of motion ahead on the rolling of ships. The subject is one both of interest and importance, and was worked out by the author with considerable ingenuity, theoretical results being compared, with those obtained by experiment. It would appear that the effect of speed is to reduce rolling, but no doubt further tests will be made, the actual experimental data up to now being somewhat meagre.

Mr. Stromeyer also read a paper on the effect of acceleration on ship resistance.

Another paper was down for reading at this sitting, but unfortunately time did not permit of it being read. It was by Mr. S. Popper, of Pola, the subject being the results of model experiments in deep and in shallow water. The subject is one of considerable practical importance at the present time, when builders of destroyers in the south find it pays them to send their vessels to the measured mile on the Clyde, where there is deep water. They find the Clyde mile permits of a knot more being made than can be obtained on any of the comparatively shallow miles of the south.

On Friday, April 14, five papers were taken. Mr. A. E. Seaton contributed the first, the subject being margins and factors of safety and their influence on marine designs. Mr. J. H. Heck followed with some notes on the variation of angular velocity in the shafting of marine engines; and Mr. Mallock read a brief paper in which he described an ingenious device for keeping the two sets of engines of a twin screw vessel out of step, so as to prevent vibration. Mr. Attwood also read a paper on the Admiralty course of study for the training of naval architects.

Perhaps the most interesting paper of the meeting was that which came last. It was by Mr. J. B. Millet, of Boston, Massachusetts, and described a means of submarine signalling by sound, of which more will probably be heard in the future. Briefly it may be said that the sides of the ship itself are used as receivers. A tank filled with a dense liquid is attached to each side of the ship. In this a transmitter is placed, and the sound collected is taken by wires to an observer, who may be in any part of the vessel. If the source of sound is on the port side the sound will be apparent from the port transmitter; if on the starboard side the starboard transmitter will be affected; if it is directly ahead it will be heard equally through both transmitters. When the sound is astern a different effect is produced. As the result of practical trials, the positions of passing ships and of submarine bells were accurately defined. When it is remembered how untrustworthy sound signals are when passed through air, and how unchanging is the density of water, it will be seen that the new system promises to reduce the chief dangers of modern navigation, collisions, or strandings through fog. The idea of submarine sound signals, of course, is not new, but the hitherto insuperable difficulty in the way has been the confusion of sound through the overwhelming nature of the noises in the ship itself. Mr. Millet, however, appears to have overcome this difficulty, and the testimony as to the value of his invention is very strong.

The meeting was brought to a conclusion by the usual votes of thanks.

UNSOLVED PROBLEMS IN ELECTRICAL ENGINEERING.

ON April 10 Colonel R. E. Crompton delivered the annual "James Forrest" lecture of the Institution of Civil Engineers, an abstract of which is given below.

There are two groups of electrical problems, those which concern the scientific investigator and those presenting themselves to engineers. The lecturer dealt with the latter only. The phenomena of lightning discharges, especially where they affect the distribution systems of large electric power plants, require further study. Many failures are due to causes which the lecturer believes to be static discharges due to gigantic condenser effects set up in systems of well insulated overhead and underground conductors, each system acting as a plate of the condenser.

Interesting problems arise out of terrestrial magnetism; the present hypotheses are based on scant knowledge. It is known that the earth's magnetic field is not symmetrical, but the work of observing the variations of the earth's field at public observatories all over the world may eventually enable the earth's field gradually to be plotted out.

Another problem passing into the domain of engineering is the etheric transmission of power. What is now required is a better solution of the problem of producing continuous trains of Hertzian waves either by mechanical means or by electrochemical means.

The lecturer dealt rather fully with what he called the "core and coil" problem of electrical machinery, that is to say, the problems connected with the perfecting of the cores, hitherto of iron, but which in future may be made of some of the alloys invented by Dr. Huesler, which are now under test.

Dealing with the present means of using iron or steel castings of high permeability, the best methods were discussed of freeing them from blow-holes or porosity to ensure that the magnet cores should be of equal density of mass, and therefore of equal magnetic moment. In this connection the lecturer alluded to Prof. Barrett's discovery of adding silicon, thereby increasing the fluidity and reducing the tendency to form blow-holes; he also gave reasons why increased permeability might be expected from this, as the addition of silicon probably acts by reducing the combined carbon in the iron, leaving the pure iron with a sponge or network structural formation calculated to give great freedom for molecular movement.

On the subject of coil winding, he showed by diagrams that at present the space occupied by insulation may be reduced by winding the copper upon the coils in the form of thin strip on edge, and insulating the portions from one another by a paint or varnish of sufficient dielectric strength, high heat conductivity, and power of retaining its dielectric strength at temperatures of 200° C. The thinness and fragility of the copper strip, however, demand that this should be done by a machine which will roll the copper to the section and curvature just as it is ready to be wound on. The difficulty was alluded to of designing the cores and windings of high-speed turbo-generators, owing to the trouble of resisting mechanical stresses due to centrifugal forces, and at the same time of subdividing them sufficiently to prevent the formation of eddy currents.

It was pointed out that although recently the developments of electrical storage have not been much discussed, it would be better to go on improving the lead couple accumulator we now have instead of waiting for the invention of some new storage couple which we may never obtain. The combination of the internal combustion engine driving a generator and worked by suction gas plant for long hours, thereby charging a battery of accumulators, is, if combined with a small steam plant capable of taking the peak load, probably the most economical method of producing energy for the short hours of lighting. Portable storage is much required for the modern automobile, and some progress has been made, but much still remains to be done. The lecturer did not believe that much could be gained from Edison's newly invented couple.

The utilisation of single phase alternating currents for railways is already within reach, the choice of systems lying between the Finzi type of series motors and the Winter and Eichsberg compensated repulsion motors. Electric traction can supersede existing steam haulage for passenger work at the present schedule speeds with economy and advantage. It is not quite certain that electric haulage will supersede steam haulage for high-speed passenger work, as, although undoubtedly electric haulage can work trains at 100 miles an hour, the steam locomotive can be improved to work at the same speed with equal safety. Engineers will not attack the long distance haulage of goods for years to come, at least not in our present state of knowledge of the cost of generating electrical energy. The successful development by electrical means of change speed and torque gear is much needed by the mechanical engineer, not only for railway work, but for rolling mills and similar purposes.

The measuring instruments used by electrical engineers have made great strides towards perfection, but there are some problems still unsolved, notably the power measurements of alternating currents.

Although there have been recently many attempts to improve the efficiency of electric lamps, both of the arc and incandescent type, yet much remains to be done. By using a beam of violet-blue light of considerable intensity it is nearly certain that many substances hitherto considered opaque, but which owe their opacity to the diffused refraction of the red and yellow rays, will be rendered transparent.

A problem of great importance will be the discovery of a direct method of producing cold by electric means, as by such methods cold storage will be facilitated in the larders of private houses.

Electric smelting has made great advances, and although it presents many unsolved problems, much may be hoped for in this direction.

The problem which is of the greatest interest to the world in general is the satisfactory development of power schemes by which the population can be sent back to the land. The solution is more difficult in this country, where we have no power supply from natural water power, but progress may nevertheless be expected.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

At the graduation ceremony of Glasgow University on Tuesday, the degree of Doctor of Laws was conferred upon Prof. A. Crum Brown, F.R.S.

It is announced by *Science* that gifts of 20,000*l.* to Rochester University for the construction of a scientific building, and of 10,000*l.* to Norwich University, Vermont, half for a library and half for an engineering department, have been announced. A donation of 50,000*l.* has been made to Northwestern University by Mr. Milton H. Wilson, a resident of Evanston, and one of the trustees of the institution.

Replying to a discussion on university education in Ireland which was raised on the Civil Service Estimates in the House of Commons on April 13, Mr. Balfour gave it as his opinion that Ireland is not provided for adequately in respect of university education. The decline in the number of students in Trinity College he ascribes to the great revolutions in the system of land tenure, which have diminished substantially the resources and the numbers of the class that send students to that institution. There is also a diminution of attendance at the Queen's College, Belfast, which is largely due to the influence which the Royal University is exercising on education in its higher forms by substituting a mere system of examination for a university training. Another reason for the falling off at the Queen's College is that the institution is without the funds necessary for complete equipment.

SOCIETIES AND ACADEMIES.

London.

Royal Society, March 16.—"On the Absence or Marked Diminution of Free Hydrochloric Acid in the Gastric Contents in Malignant Disease of Organs other than the Stomach." By Prof. Benjamin **Moore**, in collaboration with Dr. W. **Alexander**, Mr. R. E. **Kelly**, and Mr. H. E. **Roaf.**

It has long been known that free hydrochloric acid is absent or reduced in amount in the great majority of cases of cancer of the stomach.

The absence of the acid in such cases has been attributed to local action, to continued irritation of the mucous membrane of the stomach by the presence of the growth, to retention of the food in the stomach acting as an irritant and causing gastritis when the growth has narrowed the pyloric opening, or to alkaline products thrown out at the seat of the growth and neutralising the acid.

The facts that the acid is not nearly so frequently absent in gastritis due to causes other than cancer of the stomach, and that the acid may be absent in cases of cancer and where there is no marked gastritis, and where the growth is confined to a small part of the mucous membrane, the remainder being normal, led to the surmise that the absence of free hydrochloric acid in the gastric secretion might not be due to local conditions in the stomach, but to a general condition of the blood which rendered it difficult or impossible for the oxyntic cells of the cardiac glands to secrete the acid.

To test this view, the amount of free hydrochloric acid in the gastric contents was determined in *seventeen* cases of malignant disease in which the growths were situated in regions remote from the stomach, such as tongue, cheek, floor of mouth, rectum, prostate, breast, and uterus.

As a result of the determinations it was found that free hydrochloric acid was either entirely absent (two-thirds of the cases) or greatly reduced in quantity. This shows that the absence of free hydrochloric acid in cancer of the stomach is not due to local action in that organ, but, on the other hand, that cancer, *wherever occurring*, is associated with diminution or absence of the acid from the gastric secretion.

Such a result can only arise by an alteration in the blood, which increases the difficulty of separating free hydrochloric acid by the secreting cells.

It is pointed out in the paper that the most probable alteration in the blood plasma increasing the difficulty of secretion of hydrochloric acid by the gastric glands is a decrease in the concentration of the hydrogen ions.

Blood plasma is alkaline to some indicators and acid to others, indicating the presence of both hydroxyl ions, upon which its alkalinity depends, and hydrogen ions, giving an acid reaction. Any agency which increases the effective alkalinity of the blood, that is to say, which increases the hydroxyl ions and diminishes the hydrogen ions, will increase the difficulty of separating a secretion containing free hydrochloric acid.

In cases where the gastric secretion has its acidity diminished or reduced to zero, as is found to be the case in carcinoma, it is hence highly probable that the concentration of the hydrogen ions in blood plasma is reduced. The action of the kidney cells in maintaining a definite degree of alkalinity of the plasma is hence altered, so that a greater degree of alkalinity is maintained than in the normal individual.

It has been shown by Loeb that slight increase in alkalinity of the medium leads in certain instances to a more rapid cell division and growth, and if this holds good generally, it is possible that increased alkalinity of the blood plasma may lead to increased activity in cell division, and hence be a stimulating cause leading to formation of new growths.

The acidity was determined by the following methods :—

(*a*) *Total acidity* by titration with phenolphthalein as indicator. This lay very low in the seventeen cancer cases, being normal in one case only, above 0·1 per cent. in four cases, and in the majority one or two drops of decinormal alkali sufficed to render neutral.

(*b*) *Günzberg's reagent for free hydrochloric acid* gave entire absence in eleven out of seventeen cases, a minute trace in five cases (0·0036 per cent. to 0·0109 per cent.), and 0·0365 per cent. was the highest value attained in a single case only.

(*c*) *Hydrolysis of methyl acetate by the filtered gastric contents* for the determination of the concentration of free hydrogen ions was carried out in ten cases, and it was found that the concentration in all these never exceeded one-fifteenth of the average concentration in three normal cases tested by the same method.

March 30.—"Note on Fluorescence and Absorption." By J. B. **Burke.** Communicated by Prof. Larmor, Sec.R.S.

In a paper "On the Change of Absorption produced by Fluorescence"[1] the author gave an account of the experiments by which he found the existence of a very remarkable difference in the absorption of the fluorescent light of uranium glass when in the luminous and non-luminous states. This difference he has attributed[2] to a temporary change in structure or chemical composition of the body when exposed to the influence of the exciting light, and he has been led to regard this as due to new atomic connections giving rise to new frequencies during the period of luminosity, by the formation of unstable aggregates, which radiate intensely, as they disintegrate, the energy which was stored up in their formation; the luminosity being thus the visible manifestation of a process of building up and breaking down of molecules.

Messrs. Nichols and Merritt have found recently[3] that the change of absorption depends upon the intensity of the fluorescence, and that a saturation effect takes place in the absorption as the intensity of the luminosity increases, attaining a maximum with a certain intensity of the fluorescent light. They used, not the fluorescent light from another similarly excited body, but an acetylene flame as the source of the transmitted rays.

M. Camichel has encountered some difficulty in detecting the change with the light from a flame, and this appears to have been due to the use of a screen of uranium glass, 7 cm. in thickness, to cut off the more refrangible rays from the flame, a precaution which is by no means necessary, since the effect has been observed without it. The fluorescence caused by the flame merely diminishes the apparent absorption. The screen, on the other hand, must itself fluoresce, and in so doing—if the effect sought for occurs—absorb to a considerable extent the rays the absorption of which it is proposed to measure on the assumption that they are transmitted by the screen.

[1] *Philosophical Transactions*, (A) 1898; NATURE, July 15, 1897.
[2] British Assoc. Report, Belfast, 1902, and *Phil. Mag*, 1901.
[3] *Physical Review*, December, 1904.

For fluorescence of very feeble intensity the effect may not in any circumstances be perceptible.

Furthermore, the fluorescent spectrum of uranium glass is composed of several bands, and these in turn the author regards as discontinuous, and made up of more finely divided bands or lines.

Thus the use of the screen filters the rays, and only those which are not absorbed by uranium glass are transmitted. These would not undergo any change of absorption.

The change of absorption cannot be due to the increased amplitude if the vibrations are linear, but where new free periods are produced by the exciting rays, the intensity and the absorption of the fluorescent light would both depend upon the number and duration of the periods thus produced, and it is this which the change of absorption in fluorescence most distinctly proves.

"The Direct Synthesis of Ammonia." By Dr. E. P. **Perman.** Communicated by Principal E. H. Griffiths, F.R.S.

(1) So far as can be shown by one of the most delicate tests known to chemists, ammonia cannot be synthesised by heat (except under special conditions specified below). The decomposition of ammonia by heat may, therefore, be regarded as an irreversible reaction. (2) Ammonia may be synthesised in small quantities from its constituent elements (*a*) by heating with many of the metals; (*b*) by exploding with oxygen; (*c*) by sparking. These are reversible reactions. (3) It would appear that the synthesis of ammonia is effected only when the gases are ionised; the ionisation would be brought about by sparking, or by the high temperature of an explosion of hydrogen and oxygen. The immediate decomposition of the ammonia formed would be prevented by its sudden cooling. The metals in the presence of moisture also produce "nascent" or ionised hydrogen. (4) It does not appear that nitrides of the metals form an intermediate stage in the formation of ammonia, for it was found that metals readily forming nitrides, *e.g.* magnesium, did not produce more ammonia than the others. (5) There is a close analogy between ozone and ammonia with regard to their synthesis and decomposition; both are formed by sparking, and both are completely decomposed by heat.

"Determination of Vapour-pressure by Air-bubbling." By Dr. E. P. **Perman** and J. H. **Davies.** Communicated by Principal E. H. Griffiths, F.R.S.

It was shown recently by one of the authors that the vapour-pressure of water can be determined with a considerable degree of accuracy by bubbling a current of air through water in a thermostat, and estimating the amount of water evaporated by absorbing it in strong sulphuric acid.

The accuracy of the method has since been questioned, supersaturation being specially suggested as likely to cause error. Experiments have therefore been made in order to discover what error (if any) is introduced by supersaturating the air with moisture before it enters the water in the thermostat. The effect of dust in the air and of electrification have also been investigated. In each case the arrangement of the apparatus was as described in the previous paper.

Supersaturation.—Before passing into the flasks in the thermostat, which was maintained at 70°, the air was bubbled through a large wash-bottle containing water at about 85°.

Dust in the Air.—A thick smoke was made by burning pieces of phosphorus near the inlet tube of the apparatus described in the former paper.

Electrification of the Air.—(1) The air was made to pass through a large flask in which hydrogen was being rapidly evolved from zinc and dilute sulphuric acid.

(2) One terminal of an induction-coil, capable of giving (with the battery power used) a 6-inch spark, was connected with a wire passing into the first (nearest the inlet) flask in the thermostat; the other terminal was connected with the bath, so that the silent discharge passed through the flasks and the air inside.

(3) The X-rays from an ordinary focus-tube were allowed to fall on the flasks in the thermostat, and were specially directed on to the last (nearest outlet). A wire from one of the terminals of a Wimshurst machine was passed down the gauge-tube into the last flask, the other terminal being connected with the bath.

The last mentioned experiments gave vapour-pressures 237·5 and 238·0, instead of the normal value 234·0.

The greatest deviation from the normal value obtained in the other experiments was slightly more than 0·5 per cent., which is almost exactly the same as that obtained in the original investigation.

It may safely be concluded, therefore, that no naturally occurring supersaturation, or dust, or electrification of the air would have any appreciable effect on the result.

April 6.—"On Endophytic Adaptation shown by *Erysiphe Graminis* DC. under Cultural Conditions." By E. S. **Salmon.** Communicated by Prof. H. Marshall Ward, F.R.S.

In recent papers by the author the fact has been pointed out that certain species of the Erysiphaceæ are able, under cultural conditions, to infect their host-plants vigorously when their conidia or ascospores are sown on the cells of the internal tissues exposed by means of a wound, although the fungi in question are confined normally to the external surface of the epidermal cells.

The author, reviewing the results of the present investigations, points out that they afford proof that *E. graminis* is not, as perhaps might have been expected, so highly specialised as an ectoparasite as to be necessarily restricted for its food-supply to cells of the epidermis, but shows itself capable of immediate adaptation to conditions closely resembling those obtaining in endophytism.

This fact suggests the possibility that in some circumstances the mycelial hyphæ of species of the Erysiphaceæ which are normally ectoparasites may penetrate into the internal tissues of their host-plants exposed through wounds caused in nature by the attacks of animals or by physical agency. It is pointed out, however, that the successful entry of the hyphæ might be prevented, either by the drying up of the superficial layers of cells, or by the healing processes shown by many actively growing leaves.

"On the Physical Chemistry of the Toxin-Antitoxin Reaction: with Special Reference to the Neutralisation of Lysin by Antilysin." By J. A. **Craw.** Communicated by Dr. C. J. Martin, F.R.S.

Summary of Conclusions.—(1) Megatherium lysin passed through a gelatin filter, and is diffusible through gelatin. (2) Megatherium antilysin does not pass through a gelatin filter, and is not appreciably diffusible through gelatin. (3) The filtration and diffusion of mixtures show that free lysin is present in neutral mixtures and in mixtures containing excess of antilysin. (4) Free antilysin exists in neutral mixtures, and in mixtures containing excess of lysin. (5) The reaction is at least partially reversible when excess of antilysin is present. (6) False equilibria are produced with greater facility when the lysin is in excess. (7) The neutralisation equation of Arrhenius and Madsen does not hold for multiple mixtures. (8) The removal of lysin from a solution by antilysin is not capable of interpretation as a purely chemical change, but is more analogous to certain adsorption phenomena.

Faraday Society, April 4.—Prof. A. K. Huntington in the chair.—Alloys of copper and bismuth: A. H. **Hiorns.** Results of a further research on copper alloys carried out in a similar manner to that on the copper-arsenic series published in the *Transactions* of the society, April, 1904. Prof. Arnold has investigated the effect of bismuth, from 0·1 per cent. to 0·5 per cent., on copper, and found that the investing membranes surrounding the grains of copper appeared to be split down the centre, presenting a definite plane of cleavage. Dr. Gautier obtained a freezing-point curve similar to the author's, but his temperatures are generally higher. The microscopic evidence mainly confirms the records of the freezing-point curves, of which there are four branches.—Refractory materials for furnace linings: E. Kilburn **Scott.** (Discussion.)—Electrically heated carbon tube furnaces, part i.: R. S. **Hutton** and W. H. **Patterson.** This type of furnace seems to be the most readily available for the very highest temperatures, and the authors have been able to get satisfactory results with a very simple type of construction. The important points to bear in mind are the end connections (which must be kept cool), protection of the tube from contact with air, and heat insulation. Two types of furnace are described:—(1) graphite tube furnace; (2) agglomerated carbon tube furnaces.

Anthropological Institute, April 4.—Prof. W. Gowland, president, in the chair.—The fort and stone-lined pits at Inyanga contrasted with the Great Zimbabwe: R. N. **Hall.** The walls of the fort are built upon a curved plan, and the fort itself is divided into enclosures for purposes of defence. The fort has twenty-five entrances pierced through the walls which are themselves pierced with a great number of loopholes. The fort is also peculiar for the employment of banquette walls, which are not met with except in a few ruins in southern Rhodesia. Another peculiarity of the building is the absence of buttresses. The stone-lined pits are very numerous throughout Inyanga, and are usually found in clusters of twos and threes. Mr. Hall was of opinion that they were not used as slave-pits, as had been supposed, but as shelters from the variable temperature. The pits consist of a hole lined with masonry, and a curved, paved passage used as an entrance. In almost every case the pits have a drain running through the rampart, and another peculiarity is the erection near them of a stone monolith. Mr. Hall also referred to the hill terraces found in the neighbourhood, and in conclusion contrasted the architecture of the fort and pits with the temple and acropolis at Zimbabwe.

Chemical Society, April 6.—Prof. R. Meldola, F.R.S., president, in the chair.—The kinetics of chemical changes which are reversible. The decomposition of *as*-dimethylcarbamide: C. E. **Fawsitt.** This investigation is a continuation of those already published on carbamide and methylcarbamide, and the same explanation of the decomposition holds good.—A new formation of acetylcamphor: M. O. **Forster** and Miss H. M. **Judd.** The imine

$$C_8H_{14}\begin{cases} CH.CMe{:}NH \\ CO \end{cases},$$

obtained by the action of magnesium methyl iodide on α-cyanocamphor, is resolved quantitatively by acids into acetylcamphor and ammonia.—Preparation and properties of 1:4:5-trimethylglyoxaline: H. A. D. **Jowett.** This base was prepared in the course of an attempt to obtain substances having a constitution analogous to that of pilocarpine. The base and a number of its salts are described.—Bromomethyl heptyl ketone: H. A. D. **Jowett.** This bromoketone is obtained by the action of bromine in chloroform solution on methyl heptyl ketone obtained from oil of rue.—Limonene nitrosocyanides and their derivatives: F. P. **Leach.** The α-nitrosocyanide crystallises in prisms whilst the β-compound forms fine woolly needles. These isomerides are regarded as having the *cis* and *trans* configurations, since on hydrolysis both give rise to the normal oxime of dihydrocarvone.—The action of carbon monoxide on ammonia: H. **Jackson** and D. **Northall-Laurie.** The authors find that the main reaction is the formation of ammonium cyanate, which rapidly changes to carbamide.—The action of acetylene on aqueous and hydrochloric acid solutions of mercuric chloride: J. S. S. **Brame.** The first action of acetylene on mercuric chloride is shown to be one of simple combination, the product being then decomposed by water forming aldehyde and the substance $C(HgCl)_3.CHO$.—The basic properties of oxygen at low temperatures. Additive compounds of the halogens with organic substances containing oxygen: D. **McIntosh.** Crystalline compounds of chlorine and bromine with methyl and ethyl alcohols, methyl ether, acetone, ethyl acetate, acetaldehyde, and acetic acid have been obtained.—Note on the interaction of metallic cyanides and organic halides: N. V. **Sidgwick.** A possible explanation of the formation of both nitriles and *iso*cyanides in this reaction from the same initial additive compound is given.—The chemical dynamics of the reactions between sodium thiosulphate and organic halogen compounds, part ii., halogen substituted acetates: A. **Slator.** The reactions of the thiosulphate with ethyl iodoacetate and methyl, ethyl and sodium bromo- and chloro-acetates have been investigated, and shown in all cases to be bimolecular reactions.—The tautomerism of acetyl thiocyanate: A. E. **Dixon** and J. **Hawthorne.**—A method of determining the specific gravity of soluble salts by displacement in their own mother liquor, and its application in the case of the alkali halides: J. Y. **Buchanan.**—The combination of mercaptans with unsaturated ketonic compounds: S. **Ruhemann.** —The existence of a carbide of magnesium: J. T. **Nance.** The yellow residue formed when magnesium is heated with carbon evolves hydrogen and acetylene when dissolved in acids, and may contain a carbide.—Isomeric salts of the type $NR_1R_2H_3$. A correction. Isomeric forms of *d*-bromo- and *d*-chloro-camphorsulphonic acids: F. S. **Kipping.** The further study of the isomeric α and β salts has shown that the isomerism of these compounds is not due to difference in the spatial arrangement of the groups attached to the quinquevalent nitrogen atom, but to the existence of *cis* and *trans* forms of *d*-bromo- and *d*-chloro-camphorsulphonic acids.—Isomerism of α-bromo- and α-chlorocamphor: F. S. **Kipping.**—*l*-Phenylethylamine: F. S. **Kipping** and A. E. **Hunter.**—The influence of the hydroxyl and alkoxyl groups on the velocity of saponification, part i.: A. **Findlay** and W. E. S. **Turner.** The numbers obtained show that the hydroxyl group exercises an accelerating influence on the velocity of saponification, but that on replacing the hydrogen of the hydroxyl by an alkyl group the rate diminishes, and the effect increases regularly with the mass of the alkyl group.

Linnean Society, April 6.—Mr. A. C. Seward, F.R.S., vice-president, in the chair.—Specimens and drawings of pitchers of Nepenthes, supplemented by slides, prepared by Mr. L. Farmar, to illustrate the various types of pitchers and their marvellous glandular systems: W. Botting **Hemsley,** F.R.S. Mr. Hemsley first exhibited a new species, *Nepenthes Macfarlanei,* which differs from all other known species, except *N. Lowii,* in the underside of the lip being thickly beset with stiff bristles, interspersed with honey-glands. Other species were compared with *N. Macfarlanei.* Briefly, all the complex arrangements of these plants favour the descent of insects and other creatures into the pitchers, and hinder almost all visitors from getting out again; once in, there is little hope of escape. A few hybrids were also shown, notably one named "Sir William Thiselton-Dyer," which has produced the largest pitcher known in cultivation, being a pint and three-quarters in capacity.—The axillary scales of aquatic Monocotyledons: Prof. R. J. Harvey **Gibson.** The author compared the ligule of Selaginella with the scales in question, and suggested that the latter may be looked upon as evidence that the Monocotyledons may be regarded as modern representatives of primitive Angiosperms, and in turn may have been genetically related to some ancestral form allied to Isoetes.—A further contribution to the study of *Pelomyxa palustris* (Greeff): Mrs. L. J. **Veley.** After alluding to her previous memoir in the *Quarterly Journal of Microscopical Science,* n. ser. xxxvi. (1894), pp. 295–306, the author explained that the "rods" present in *Pelomyxa palustris* (Greeff) are symbiotic bacteria (*Cladothrix pelomyxae,* Veley); they complete their development within the animal and are then ejected, breaking down into free "swarmers," which are ingested by other Pelomyxæ, and immediately re-commence the cycle. The "refringent bodies" are proteid in nature, viz. some form of albumin which is a waste product of the metabolism of Pelomyxa. They supply the bacteria with a point of attachment necessary for development, and (probably) also with nourishment.—Mansonieæ, a new tribe of the natural order Sterculiaceæ: Dr. D. **Prain.**

Paris.

Academy of Sciences, April 10.—M. Troost in the chair. —Remarks on the recognition of the solar corona at times other than during total eclipses: H. **Deslandres.** A criticism of the results recently obtained by Hansky, in which the difficulties introduced by diffused light in the apparatus do not appear to have been sufficiently taken into account. The use of a simple concave mirror, as employed by Huggins in 1883, is decidedly preferable to the system of two lenses and a mirror used by Hansky. Details are given of the method suggested by the author. —The conclusions to be drawn from the study of homogeneous enclosures in petrography: A. **Lacroix.**—The plants of the plateau of the Nilghirris: Gaston **Bonnier.** The mean temperature of Ootacamund is practically the same as that of Paris, and a detailed comparison of the flora of the two places is given. The altitude of the Nilghirris is not sufficient for the plants to acquire all the characteristics of alpine plants, but they acquire certain alpine characters. There are also special modifications induced by the large difference between the day and night temperature.—On the Peneideæ and Stenopideæ collected by the French and Monaco expeditions in the eastern Atlantic: E. L. **Bouvier.**—The conflict between the primary and accidental images, applied to the theory of inevitable variability of retinal impressions excited by objects illuminated by sources of light of constant value: A. **Chauveau.** The impression produced on the retina by a geometrical figure is complex, and is a resultant formed by the superposition of two images, the one objective, the other subjective, and an experiment is described showing how these may be separated. The effects of colour, intensity of illumination, motion of the retina, displacement of the eye or the object, and accommodation are considered systematically. The case of the *n*-rays is not actually taken by the author, but the considerations here put forward clearly suffice to explain many of the phenomena ascribed to the action of these rays.—The heat of formation of sodium hydride. The acidity of the molecule of hydrogen: M. **de Forcrand.**—On the reduction of oxyhæmoglobin: R. **Lepine** and M. **Boulud.** The oxyhæmoglobin is reduced with a titrated solution of ferrous sulphate, and the time of reduction noted, the colouring matter being considered as reduced when the two absorption bands fuse together. In normal blood from the dog the time of reduction is fixed, and is between eighteen and twenty minutes, and this time is independent of the dilution. In anæmia, with a quantity of the reducing agent proportional to the amount of hæmoglobin, the time of reduction is much increased. Prolonged inhalation of ether or chloroform also increases the time of reduction. Human blood from anæmic patients shows the same characteristics.—On Rhabdocarpus, the seeds and the evolution of the Cordaiteæ: M. **Grand'Eury.**—Report presented in the name of the committee charged with the scientific control of the geodesic operations at the equator. The operations have been much delayed by the unfavourable meteorological conditions and by the illness of several members of the expedition. A short account is given of the progress made in triangulation, levelling, and pendulum observations. An astronomical station has been installed at Cuenca, and another will be set up near the fourth parallel. On account of the limited financial resources of the expedition, it is proposed that a portion of the original scheme be dropped.—Observations of the Giacobini comet (1905 *a*) made at the Observatory of Algiers with the 31·8 cm. bent equatorial: MM. **Rambaud** and **Sy.** The observations were made on March 28, 29, and 30, and give the apparent positions of the comet with the positions of comparison stars. On March 28, when the atmospheric conditions were exceptionally favourable, a nucleus could be clearly made out of about the thirteenth magnitude.—Actinometric observations at the summit of Mont Blanc in 1904: A. **Hansky.** The weather conditions were not favourable. The most probable value of the solar constant from the 1904 observations is 3·28 calories.—On integral functions: Eugène **Fabry.**—On Monge's problem: P. **Zervos.**—On the equilibrium of arches in circular arcs: M. **Belzecki.**—On the longitudinal stability of aërostats: L. **Torres.** A discussion of a paper on the same subject by M. Renard, in which, as the result of a theoretical investigation, certain modifications of the stern are suggested. In the present paper it is shown that this investigation is not strictly correct, and that the modifications suggested will not have the desired effect.—On the diamagnetism of bismuth: A. **Leduc.** Bismuth was fused in small spherical flasks and allowed to solidify in a strong magnetic field (4000 to 5000 C.G.S. units). The sphere of solid bismuth, suspended in the same field, took up the same position as it had at the moment of solidification.—Contribution to the study of ionisation in flames: Pierre **Massoulier.** The conductivity of an ether flame is considerable. By introducing increasing proportions of carbon dioxide into this flame, although the temperature is lowered, the ionisation, as measured by the current between two electrodes in the flame, is increased. The results are interpreted by the author as being due to the dissociation of the carbon dioxide in the flame.—On the variation of the difference of contact potential for miscible solutions of electrolytes: M. **Chanoz.**—On the dichroism produced by radium in colourless quartz and on a thermoelectric phenomenon observed in striated smoky quartz: N. **Egoroff.** Colourless quartz, exposed to the action of radium for a week, exhibited dichroism identical with that ordinarily observed with smoky quartz. A plate of smoky quartz, heated to 100° C. and treated with a mixture of sulphur and red lead, gave a figure reproducing the striations.—An automatic damping arrangement applicable to pendular and oscillatory movements: V. **Crémieu.**—On a photograph of a lightning flash showing the air in incandescence: Em. **Touchet.** The persistent glow which is visible in some cases after a lightning flash is due to the incandescence of the air. This effect is not physiological, as it is clearly shown in some photographs taken by the author and by other experimenters.—The etherification of glycerin: Marcel P. S. **Guédras.**—The liquefaction of allene and allylene: MM. **Lespieau** and **Chavanne.** The two gases were prepared with great care in a pure state and solidified in liquid air. Allene melts at −146° C., boiling at −32° C., its critical point being about 121° C. Allylene melts at −110° C., boils at −23°·5 C., and has a critical point of 129°·5 C., the temperatures being all measured by an iron-constantan thermo-couple. The purity of the gases was determined by a combustion analysis.—On the hydrogenation of benzonitrile and paratoluonitrile: A. **Frébault.** Sabatier and Senderens, who have already applied their reaction to this case, found that nickel carried the reduction too far, toluene and ammonia being the only products, and were obliged to replace the nickel by copper to obtain benzylamines. Working under somewhat different conditions, the author has obtained results with nickel.—Secondary diazoamines: Léo **Vignon** and A. **Simonet.**—On the hydrates of acetol: André **Kling.**—On the use of the metal ammoniums in chemistry: the preparation of paraffins: Paul **Lebeau** (see p. 592).—On isodimorphism: Fred. **Wallerant.**—On a new indiarubber Euphorbia: Henri **Jumelle.** This tree grows in the north-west of Madagascar, and its indiarubber producing properties were discovered accidentally by the natives. It appears to be a new species, and is named *Euphorbia elastica*.—The action of ether and chloroform on dried seeds: Paul **Becquerel.** The result is due to action of these substances on the fatty material of the cell, but the effect of the chloroform is much more energetic.—On the formation and function of fatty materials in fungi: A. **Perrier.** It is shown that the fat acts as a reserve food material for the plant.—On some points of anatomy of the male organs of the Edentata, and on their means of fixation: Rémy **Perrier.** It is shown that this is not a case of retrogression, but that the condition of the male organs corresponds to a primitive form. This view confirms the palæontological results as to the age of the Edentata.—The weight of the brain as a function of the body weight in birds: L. **Lapicque** and P. **Girard.** The exponential formula given by Dubois for expressing the weight of the brain as a function of the body weight holds for the case of birds, the index having the same numerical value as in mammals (0·56).—On the alternation of eclipses and the lustre of feebly lighted objects: Th. **Lullin.**—The spectroscopy of the blood and of oxyhæmoglobin: M. **Piettre** and A. **Vila.** The reaction of sodium fluoride upon the absorption spectrum of blood is a very delicate one, and can be used to detect traces of fluorides down to 5 parts in a million. A diagram is given of the relation between the intensity of the absorption bands of oxyhæmoglobin and the dilution.—On the normal presence of alcohol and acetone in the liquids and tissues of the organism: F. **Maignon.**—Researches on hæmatogen: MM. **Hugounenq** and **Morel.**—The influence of the state of liquefaction of starch on its transformation by diastases: A. **Fernbach** and J. **Wolff.**—Experimental acid dyscrasia: M. **Charrin.**—On the age of the granite of the western Alps and the origin of the crystalline exotic blocks of Klippes: C. G. S. **Sandberg.**—On the Lahore earthquake and the variations of the magnetic needle at Paris: Th. **Moureaux.** Disturbances of the magnetic records at Paris were observed on the day of the Lahore earthquake.

GÖTTINGEN.

Royal Society of Sciences.—The *Nachrichten* (physico-mathematical section), part vi. for 1904, contains the following memoirs communicated to the society:—

October 29.—W. **Voigt**: Remarks on tensor-analysis. A. **Schœnflies**: On the geometrical invariants of the analysis of position. Eduard **Riecke**: Researches on the phenomena of discharge in Geissler tubes. F. **Bernstein**: On the theory of aggregates.

December 17.—G. **Herglotz**: On the calculation of retarded potentials.

DIARY OF SOCIETIES.

THURSDAY, APRIL 27.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—*Discussion*: Mr. B. J. Arnold's Address to the Joint Meeting at St. Louis on the Problem of the Alternate Current Motor applied to Traction.—*Paper*: The Alternate Current Series Motor: F. Creedy.

FRIDAY, APRIL 28.

EPIDEMIOLOGICAL SOCIETY, at 8.30.

CONTENTS.

THURSDAY, APRIL 27, 1905.

THREE CAMBRIDGE MATHEMATICAL WORKS.

The Algebra of Invariants. By J. H. Grace, M.A., and A. Young, M.A. Pp. vii+384. (Cambridge: The University Press, 1903.) Price 10*s.* net.

The Dynamical Theory of Gases. By J. H. Jeans, M.A. Pp. xvi+352. (Cambridge: The University Press.) Price 15*s.* net.

A Treatise on the Analytical Dynamics of Particles and Rigid Bodies. By E. T. Whittaker, M.A. Pp. xiii+414. (Cambridge: The University Press, 1904.) Price 12*s.* 6*d.* net.

WHATEVER opinions may be felt as to the desirability of University Presses competing with private firms in swelling the already too large flood of school geometries or issuing cram books for compulsory Greek examinations, there can only be one opinion as to the series of standard treatises on higher mathematics emanating at the present time from Cambridge. In a country which, in its lack of national interest in higher scientific research, particularly mathematical research, stands far behind most other important civilised countries, it necessarily devolves on a University Press to publish advanced mathematical works. We may take it as certain that the present volumes will be keenly read in Germany and America, and will be taken as proofs that England contains good mathematicians, though Englishmen as a nation may be unaware of their existence, with the exception of the senior wrangler of one year, who is forgotten the next.

For years Salmon's "Higher Algebra" has been the treatise which has done most to interest English students in invariants. At the present time a good deal more is wanted in order to bring our knowledge up to date. Messrs. Grace and Young have endeavoured to meet present requirements in a well defined direction. As they state in their preface, the book

"was started as an attempt to meet the need expressed by Elliott in the preface to 'The Algebra of Quantics'—'a whole book which shall present to the English reader in his own language a worthy exposition of the method of the great German masters remains a desideratum.'"

While no book, unless it were written in four languages, could satisfy the patriotic aspirations of every native of our country by appealing to him "in his own language," the production of an English book on a subject largely developed in Germany meets a distinct want.

The subject is practically started *ab initio*. The treatment does not strike us as very hard to follow, although it is difficult for a beginner at first to master the symbolical notation, especially in the definition of transvectants (chapter iii.). In chapter vi. the authors introduce Gordan's theorem, according to which the number of covariants of a binary form is always finite, and in the next chapter they employ his method of proof to obtain the complete irreducible set of covariants of the quintic. A short chapter on simultaneous systems brings us to Hilbert's theorem, with which the algebra of binary forms may be said to end. Chapters x. and xi. deal with geometrical interpretations, and in particular with apolarity. The sections dealing with ternary forms are less complete, as the authors have considered that "with the methods known up to the present the treatment of ternary forms is too tedious for a text-book."

Mr. Grace has previously been associated with the production of several mathematical text-books of a quite elementary character, and the present book bears many unmistakable traces of his experience as a writer in making a somewhat difficult subject appear relatively easy.

We say "somewhat" difficult, because the subject of Mr. Jeans's new book is incomparably harder than the "Algebra of Invariants." This difficulty arises largely from the fact that the kinetic theory of gases is closely associated with the representation of physical phenomena as they actually exist, and with all the difficulties connected with irreversibility and the existence of temperature. It is only by statistical methods that these phenomena are amenable to the equations of reversible dynamics, and with every method of attack some assumption must be made, since if any motion of a molecular system exists it is equally conceivable that the opposite motion should exist.

Even Willard Gibbs's appeal to experience quoted on p. 167 does not get over the difficulty. If we put red and blue ink together into a vessel and stir them up, it is true that if the inks differ in nothing more than colour the result is a uniform violet ink. But this is because the inks are viscous liquids the motions of which are irreversible. If they were perfect liquids perfect mixing would not take place, and the effect of stirring would merely be to produce vortex motions in which the vortex lines always contained the same particles and remained constant in strength. If we mix counters in a bag, the motions of the counters are retarded by friction; if the counters correctly represented perfectly reversible systems they would never come to rest.

Mr. Jeans in his preface considers that the discrepancy between theory and experiment in connection with the ratio of the specific heats of a gas "is of greater importance than all the others together," and he has endeavoured to emphasise the fact that when account is taken of the interaction between matter and the ether, theory and experiment harmonise as well as could be desired. But as soon as this ether is taken into account we have a simple means of obviating the irreversibility difficulty by saddling the ether with the whole responsibility. So long as physicists are contented, in solving the differential equations of wave motion in a medium, to omit the terms which represent waves converging from an infinite distance towards a centre of disturbance, so long will there be an easy way out of the puzzling contradictions arising out of Boltzmann's H-theorem.

But there is really no reason why the presence of a molecule in an indefinitely extended ether which undoubtedly possesses some energy should not bring about the convergence of waves coming in from an infinite distance in all directions, and gradually increasing in intensity as they approach the molecule. We do not think such cases exist, but we did not expect to discover radium a few years ago.

Let us now see how Mr. Jeans attempts to deal with the difficulties here suggested. In the first seven chapters he follows fairly closely on conventional lines, and deduces the Boltzmann-Maxwell law of distribution, the minimum theorem, the law of partition of energy, and the isothermal equations according to the Boyle-Mariotte and van der Waals's laws. In chapter viii. the author throws over the principle of conservation of energy and assumes that his gas is a dissipative system in which loss of energy occurs by radiation. On this hypothesis he finds that when the rate of dissipation has become very slow probability considerations indicate a tendency to assume a definite statistical specification different from that given by the ordinary theory. It further appears that such a gas has one principal and a number of subsidiary temperatures, a notion which we believe has been previously advanced. In chapters ix. and x. Mr. Jeans considers applications of the theory of a non-conservative gas, particularly in connection with rates of dissipation of energy, and ratios of specific heats.

We thus have a definite attempt to break away from traditional methods and boldly introduce the notion of dissipation into the kinetic theory. The idea is certainly an excellent one. Whether it is free from objection is a matter which cannot be answered as the mere result of a critical examination. Often objections to theories strike the mind of a reader quite unexpectedly.

In the remaining chapters Mr. Jeans deals with "free path phenomena" such as diffusion, conduction of heat, viscosity, and the escape of gases from planetary atmospheres. In this work he is more on the ordinary lines. We notice as an important feature the sections dealing with encounters according to the law of the inverse fifth power. This series of chapters is of considerable use in affording easy access to investigations contained in a much longer form in the original papers of Boltzmann and other writers.

Turning back to the chapter on equipartition of energy, we are led to the following inference:—Mr. Jeans leaves it an open question whether the conventional law of distribution with its attendant consequences of equipartition may represent the ultimate state of a gas, but concludes that in actual gases such as we see around us where dissipation of energy occurs a different distribution holds good.

The second conclusion seems plausible. But the assumption that equipartition of energy holds *even in a conservative system* presents difficulties in connection with Stefan's law of radiation in a black cavity. According to that law the energy of the ether should vary as the fourth power of that of the molecules. It might be said that in the "conservative system" Stefan's law would not necessarily hold good, and that there would be no objection to assuming the energy of the ether to be then directly proportional to that of the molecules, or to the temperature. But the usual thermodynamic investigation—which is more certain to be valid in the case of the conservative than in that of the dissipative system—would then give a different form for the radiation pressure—apparently $f=\psi(\log\psi+\text{constant})$—and this result would have to be admitted. On the whole it appears more likely that while distributions satisfying Maxwell's law of equipartition are always theoretically possible, other distributions may exist, and may, indeed, represent a normal and *persistent* state of affairs even in *conservative* systems.

It is remarkable that physicists strain at gnats when put down to study kinetic theory or thermodynamics, and yet they swallow camels with complacency when they read the subject of Mr. Whittaker's book, "Analytical Dynamics." Some writers even go so far as to introduce pages and pages of the most unreal dynamical problems into what they call treatises on physics.

"The soluble problems of particle dynamics" mostly represent things which have no existence. It is impossible for a particle to move on a smooth curve or surface because, in the first place, there is no such thing as a particle, and in the second place there is no such thing as a smooth curve or surface. What constitutes the chief interest of "Analytical Dynamics" is the possibility of forming clear mental pictures of its results by *imagining* bodies capable of performing the motions discussed.

Mr. Whittaker's treatment is essentially mathematical and advanced in character. He opens with sections on the displacements of rigid bodies in which Klein's parameters and Halphen's theorems on composition of screws figure near the commencement. In his chapter on equations of motion physico-philosophical discursions on force and mass are reduced to a minimum. This is as it should be, for there are plenty of people who can write about such matters, but few whose knowledge extends to the more important theorems which follow later. The Lagrangian equations are reached by § 26, which is preceded by a definition of holonomic systems. This distinction might with advantage be put into treatises in physics, for at present students of that subject are apt to assume that Lagrange's equations in their ordinary form are universally applicable, which is far from true. Passing on to chapter v., which deals, *inter alia*, with moments of inertia, our old friend the "principle of parallel axes" is treated generally for a quadratic function of coordinates, velocities and accelerations, readers being doubtless assumed to know the proof for simple cases. Chapter vii. deals with the general theory of vibrations, and the next chapter with non-holonomic and dissipative systems, the first of these two chapters consisting mainly of theory, and the second mainly of examples. The most important chapters are those which follow, dealing with the principles of Hamilton and Gauss, the integral invariants of the Hamiltonian system, and the representation of a dynamical system of equations by means of contact transformations.

Mr. Whittaker some time ago presented a valuable report to the British Association on the problem of three bodies, and he tells us that between 1750 and 1904 more than eight hundred memoirs were published on this problem. Even at the Heidelberg congress last August further additions were made to this literature. In his chapter on the subject, which is very brief, he discusses the reduction of the equations to a system of the sixth order, thus affording a useful insight into the main features of this difficult investigation. Several other interesting chapters follow.

It will thus be seen that Mr. Whittaker's treatise collects into book form the outlines of a long series of researches for which hitherto it has been necessary to consult English, French, German, and Italian transactions. In recent years Italy has played no small part in the development of dynamics, as may be seen by the number of papers by Levi Civita and other writers which have from time to time appeared in the *Atti dei Lincei*, dealing with integrals of the equations of motion of holonomic systems, particular cases of the problem of three bodies, and allied questions.

The book is thus written mainly for the advanced mathematician. But an interesting feature is the large number of examples both in the text and at the end of the chapters. Of these a good many really contain the substance of minor papers that have been published abroad. Others are followed by the reference "Coll. Exam.," and while it may be taken for granted that Mr. Whittaker has made a judicious selection, some of the questions bearing these references may give foreign mathematicians a little insight into the unpalatable nuts which Cambridge students are expected to waste time in trying to crack for examination purposes. The antics of insects crawling on epicycloids, or the vagaries of particles moving along the intersections of ellipsoids with hyperboloids of one sheet, are of no scientific interest, and the time spent in "getting out" problems of this character might better be employed in learning something useful. Moreover, Cambridge college examiners have a habit of endowing bodies with the most inconsistent properties in the matter of perfect roughness and perfect smoothness. A perfectly rough body placed on a perfectly smooth surface forms as interesting a subject for speculation as the well-known irresistible body meeting the impenetrable obstacle. What the average college don forgets is that roughness or smoothness are matters which concern *two surfaces*, not *one body*.

In our opinion a great deal of the artificiality of the more elementary parts of dynamics might be removed by the more frequent introduction of simple problems in resisted motion. There are plenty of easy ones to be found which would be more helpful to the beginner than problems about ellipsoids rolling on perfectly smooth surfaces formed by the revolution of cissoids or witches about their axes. Those who have the ability to do more difficult work should pass on to the advanced parts of a book like Mr. Whittaker's and learn what foreign mathematicians have been doing; this is much more useful.

It remains to add that the books are neatly bound; the printing and paper are somewhat unnecessarily luxurious in quality, and—most important of all—the Cambridge printers have *not* forgotten to cut the pages with their guillotine.

G. H. BRYAN.

REIN'S "JAPAN."

Japan nach Reisen und Studien. By J. J. Rein. Vol. i. Natur und Volk des Mikadoreiches. Second edition. Pp. xv+749. (Leipzig: Wilhelm Engelmann, 1905.) Price 24*s.* net, paper; 26*s.* net, cloth.

THIS is the second edition of a book first published in 1880. The author, now professor of geography in the University of Bonn, was, in 1874, commissioned by the Prussian Ministry of Commerce to go to Japan for the purpose of studying and giving an account both of the trade of Japan and the special branches of industry there carried on to so high a degree of perfection. The writer of this notice had the pleasure of making the acquaintance of Dr. Rein while in Japan, and can testify to the German thoroughness with which Dr. Rein carried out the work for which he was commissioned. The results of that work were two volumes which, from the point of view of the author, have been looked upon as the most scientific and complete of their kind. Some years after their appearance in Germany translations were published in England (Hodder and Stoughton), but both the German and English editions have for some time been out of print, and the author has done well to bring out a new edition, brought up to date in matters both of history and science. For students of Japan it is almost unnecessary to review the work of Dr. Rein, as it has long had an assured position.

The opinion of competent authorities was reflected by Prof. Chamberlain more than fifteen years ago, when, in an edition of his well known book "Things Japanese," he said:—

"At the risk of offending innumerable authors, we now venture to pick out the following works as probably the best in a general way that are accessible to English readers: (1) Dr. Rein's 'Japan,' with its sequel 'The Industries of Japan.'" No person wishing to study Japan seriously can dispense with these admirable volumes. Of the two, that on the "Industries" is the better; agriculture, cattle-raising, forestry, mines, lacquer-work, metal-work, commerce, &c., everything, in fact, has been studied with a truly German patience, and is set forth with a truly German thoroughness. The other volume is occupied with the physiography of the country, that is, its geography, fauna, flora, &c., with an account of the people, both historical and ethnographical, and with the topography of the various provinces.

It is this latter volume which is at present before us, and although it may not be so interesting, from the practical point of view, as its sequel, it is more valuable from a scientific and historical point of view. The book is essentially the same as the first edition, but the author has had the assistance of many friends in Japan in bringing it up to date, both from a scientific and a historical point of view. It is, however, unnecessary to enter into a detailed account or criticism of its contents.

The first part of the book is a very complete and interesting account of the physical geography of Japan; in fact, it is the only systematic account which has been published in a European language. When

Dr. Rein was in Japan he had, for the most part, to depend on himself for the collection of information on this part of his subject; but in the interval many ardent students of science have been trained in Japan, and they have collaborated with him in bringing the matter up to date, so we have very valuable chapters on the geological formation of the country, its physiography, hydrography, climate, flora and fauna; while very complete lists of books and papers dealing with the various departments of the subjects are given which will be useful to those who wish to study them thoroughly.

The part relating to the history of the country has had a section added to it dealing more fully with the events which have occurred during the past quarter of a century, and gives a very good outline of the developments which have taken place. It deals, however, only with what may be called the natural history or facts of the subjects involved, and does not attempt to explain the natural philosophy or dynamics. No doubt the author would say that that was beyond the scope of his work; but it is possible to make descriptions much more interesting and intelligent when the forces at work are at least indicated, and the directions and amounts of their resultants explained. The full discussion of this, however, would take us into details of historical methods about which there is still considerable difference of opinion.

Under anthropology and ethnology a considerable amount of new matter has been introduced, in which are given the results of recent investigations and speculations. An interesting sketch is given of the Japanese language and literature and of the manners and customs of the Japanese. A short account is given of the Japanese calendar and of the national festivals. The part dealing with the religious conditions of Japan is too short to allow justice to be done to it, and it does not give an adequate account of recent developments. The present war with Russia has been a revelation of the "soul of the people," a full explanation of which would require a book for itself. Still, Dr. Rein might have tried to bring this section up to date as well as the others. Its full comprehension, however, requires something more than what is usually called a scientific mind, and comparatively few men of science seem capable of entering on it with understanding. They for the most part are content to look at a people from the outside, forgetting the fact that the most powerful factors in the evolution of a nation are intellectual and spiritual.

The concluding part of the book deals with the topography of the country, and is a valuable contribution to the subject. Some useful maps are included in the book, and a very complete table of contents renders the various subjects very accessible. We venture to hope that a new edition of the second volume on the "Industries of Japan" will soon be forthcoming, for, notwithstanding all the changes which have taken place, the industrial Japan depicted by Prof. Rein still, to a very large extent, remains, and only from it can the real Japan be known.

HENRY DYER.

MAKING A PASTURE.

The Agricultural Changes required by these Times, and Laying down Land to Grass. By R. H. Elliot. Third edition. Pp. xxiii + 197. (Kelso: Rutherford, 1905.)

MR. ELLIOT and "Elliot's system" and "Elliot's mixtures" have been not a little before the agricultural public during the last ten years or so, but we have not before had the opportunity of reading at length a full account of "the system" as set out by the author.

Indeed, we doubt if we should have been very much wiser now, so formless and discursive is the book, had not the publishers been kind enough to provide a synopsis for the guidance of the reviewer.

To put the matter briefly, Mr. Elliot farms some poor high-lying land in the neighbourhood of Kelso, and has found it profitable to adopt a system of laying it down to grass for periods of four to six years, after which it will carry two crops of turnips and two of cereals, in the last of which it is laid down again to grass for another period. The essence of the system is that with the usual grass seeds, or rather with a grass mixture containing a large proportion of cocksfoot and the coarse fescues instead of rye grass, a considerable amount of chicory, burnet, sheep's parsley, kidney vetch, and other tap-rooted plants are sown, although some of these, like the burnet and the chicory, are regarded as undesirable weeds in many parts of the country. Mr. Elliot claims that the deep roots of these plants, by opening up and, on their decay, aërating the subsoil, act as the most efficient agents of cultivation and bring about a great amelioration in the texture of the soil. Further, he obtains a good turf quickly and at little cost, so that when the land comes under the plough again he can grow four crops on the accumulated fertility without the use of any manure.

It will be seen that the one point which can in any way be held to distinguish Mr. Elliot's from other systems of temporary pastures is the use of chicory, burnet, and similar plants in the grass mixtures. It is probably a sound idea to introduce these deep-rooting plants, though we should infinitely prefer the equally deep-rooting but far more valuable sainfoin and lucerne anywhere south of the Trent, yet it leaves us wondering what all the coil is about. What is there so novel or so fundamental about the scheme that the Board of Agriculture should have been expected to take up Mr. Elliot's 1250 acres and by preaching on that text revolutionise British agriculture? Mr. Elliot's system appears to have succeeded on his own somewhat special soil and climate, but there is little reason to suppose it would be equally suitable to the bulk of our farming land. Indeed, we have only Mr. Elliot's opinion that it has succeeded in his own case, for though he writes of the experiments on the Clifton on Bowmont farm, of experiments in any rigid sense we see no trace. We never read of comparative results when one part of a field was sown with Elliot's mixtures, the other with an ordinary seedsman's prescription, nor have we any balance sheet setting out the financial returns from two fields, farmed one on

Mr. Elliot's system, the other in the fashion followed by any reasonable farmer in the district. In fact, the book proves nothing more than that Mr. Elliot, by using good seed and looking carefully after his grass land, has improved his farm in his own opinion and in that of various of his visitors; otherwise the book is a farrago of irresponsible talk, of hard words for agricultural chemists and science generally, of diatribes against the Board of Agriculture and everyone else who does not see eye to eye with Mr. Elliot; it bears every mark, in fact, of the work of the man with one idea.

SOCIOLOGY.

Sociological Papers Published for the Sociological Society. Pp. xviii+292. (London: Macmillan and Co., Ltd., 1905.) Price 10*s*. 6*d*.

THESE papers, the *Transactions* of the Sociological Society, make known to the world what work the society has done during the first year of its existence, and explain the aim and scope of the work it hopes to do in the future.

The first paper recounts the history of the word sociology. After that we get to the fundamental question of eugenics, "the science which deals with all the influences that improve the inborn qualities of the race; also with those that develop them to the utmost advantage." Mr. Francis Galton, the author of this paper, would have the principles of eugenics "introduced into the national conscience, like a new religion," that so a fine race may be bred. The discussion that followed was very interesting. The view held by most medical men who have reached middle age was put without any qualification, the view that we cannot attempt to deal with "a mass of scientific questions affecting heredity," but that we must concentrate our attention on more practical questions, such as the feeding of infants. Mr. Archdall Reid, on the other hand, in a written communication, brings out with admirable lucidity the distinction between degeneracy properly so called and the defective development of the individual. These questions, both of them urgent, we must face. "In the first place we must improve the conditions under which the individual develops, and so make him a fine animal. In the second place we must endeavour to restrict as far as possible the marriage of the physically and mentally unfit." Mr. Reid might have gone on to say that the former method without the latter, the improvement of external conditions without any check upon the multiplication of the unfit, would merely hasten degeneration, as any slackening in the stringency of natural selection must inevitably do. Mr. Bateson declines to join in investigations carried on by the "actuarial" method, preferring experimental breeding with its more definite results. But is it possible to experiment with human beings?

Prof. Geddes, in his "Civics," recommends to students a geographical survey of some river basin in which is displayed the evolutionary process which, beginning with "hunting desolations" on the hill-tops, culminates in some great manufacturing city that darkens the heavens with its smoke. It is doubtful how far this method can afford definitely practical help in solving the problems of modern industrial society. Still, the historical method is capable of imparting an interest to a science which to not a few men is dismal, and certainly anything that can make our great cities interesting is to be welcomed. Dr. E. Westermarck investigates the position of woman in early civilisation, showing that she was by no means, as a rule, a slave and a nonentity, but he owns that "the condition of women or their relative independence is by no means a safe gauge of the culture of a nation." Mr. P. H. Mann follows with a paper on "Life in an Agricultural Village in England," an investigation of the economic condition of the inhabitants. He follows the method of Mr. Charles Booth and Mr. Rowntree in the study of city populations. Prof. Durkheim and Mr. Branford discuss the relation of sociology to the social sciences and to philosophy. Prof. Durkheim contends that sociology is not a mere organisation of more specialist sciences, but that it is capable of remodelling them. Historians, for instance, and political economists have already had to "reorient their studies."

In conclusion, we must congratulate the Sociological Society on its first year's work. Beyond the work which can be definitely gauged there has been the bringing together of men who hold very different views, and of men who are attacking the same great problem from different sides. F. W. H.

OUR BOOK SHELF.

First Report of the Wellcome Research Laboratories at the Gordon Memorial College, Khartoum. By the Director, Andrew Balfour, M.D., B.Sc., &c. (Khartoum: Department of Education, Sudan Government, 1904.)

The Wellcome Research Laboratories of the Gordon College, Khartoum, which were equipped by the munificence of Mr. Henry S. Wellcome, have certainly justified their existence, judging by the record of work done during the year February, 1903, to February, 1904, as detailed in the report of the director, Dr. Andrew Balfour.

The volume commences with a brief description of the laboratories, after which follows an account of the various researches that have been carried out in them.

Any medical director stationed where malaria is endemic and mosquitoes plentiful would at once direct his attention to the distribution of the latter, and institute measures to diminish their prevalence. This has been done by Dr. Balfour, and the first article is devoted to a description of his observations and administration in this respect. Of mosquitoes three species are particularly numerous, *C. fatigans*, an anophelina, *P. costalis*, and *Stegomyia fasciata*. Mosquito brigades have been organised, and anti-malarial measures conducted on the lines recommended by Ross, and there appears to be every probability that the prevalence of mosquitoes will be greatly diminished in Khartoum in the near future. Collections of mosquitoes have been received from various parts of Egypt, the Sudan, and Abyssinia, and have been examined and named by Mr. Theobald, who contributes an article descriptive of the species, many of which are new. Experiments were made on the use of an anilin dye, chrysordine, for the extermination of mossuito larvæ and pupæ. It was found to act satisfactorily in a dilution of 1 in 30,000, but for practical purposes its use in this strength would be prohibitive on account both of cost and of its yellow colour. Biting and noxious insects other than mosquitoes is the subject of the next article, the most interesting find being *G. morsitans*, the tsetse fly which carries nagana, on the Pongo River, Bahr-el-Ghazal, and a few pages are devoted to insects and vegetable parasites injurious to crops, the most important being an aphis destructive to the dura crop described by Mr. Theobald as *Aphis sorghi* (nov. sp.). Cyanogenesis, hydrocyanic production, in the dura (*Sorghum vulgare*) is another subject briefly dealt with, and of importance since considerable loss of horses and cattle has sometimes been occasioned thereby. The dura contains a glucoside which yields hydrocyanic acid on decomposition, the cause of which has been ascribed to abnormal growth, but may be due to the dura aphis as demonstrated by Dr. Balfour.

Lastly, the general routine work, pathological and chemical, of the laboratories is summarised, some interesting notes are given of the various diseases met with in the Sudan, and the occurrence of eosinophilia in Bilharzia disease and dracontiasis is discussed.

We congratulate Dr. Balfour on his first year's work contained in this report, which is copiously illustrated, some of the coloured plates of mosquitoes and other insects being beautifully executed.

R. T. HEWLETT.

Till the Sun Grows Cold. By Maurice Grindon. Pp. 113. (London: Simpkin, Marshall, Hamilton, Kent and Co., Ltd., 1904.) Price 2s. 6d. net.

THOUGH this story is, so far as its main incidents are concerned, of a familiar kind, it differs from others in that several of the persons described are interested in science. For instance, there is a Sir John Harpur, who "was making important alterations in his Observatory; he was an ardent Astronomer, and F.R.A.S."; Lady Harpur, again, "had a love of flowers beyond that of a botanist, although she was adept in the science"; and the hero, Ralph Hillary, at one time of his life had a workroom "in which he could follow up chemical and other researches to his heart's content." Moreover, after Ralph takes as a second wife his early sweetheart, they engage together in scientific research, and discover a substance of "extraordinary radio-activity" to which they give the name Helenium after Ralph's sister. We cannot say that the author has been successful in blending fact and fiction together so that one can scarcely be distinguished from the other; yet this art is essential to the writer of scientific romance or romantic science.

A Short Introduction to the Theory of Electrolytic Dissociation. By J. C. Gregory. Pp. 76. (London: Longmans and Co., 1905.) Price 1s. 6d.

THIS is a useful little book for those students who, after taking a course of systematic chemistry, wish to know something of the behaviour of electrolytic solutions. The language and mode of presentation are simple, and although one might take exception to many points of detail, the book, on the whole, should prove a trustworthy guide. The headings of the four chapters into which the book is divided afford a sufficient indication of its contents: chapter i., the condition of dissolved substances; chapter ii., ions and precipitation; chapter iii., hydrogen and hydroxyl ions; chapter iv., electrolytic and general considerations.

LETTERS TO THE EDITOR.

Electromagnetics in a Moving Dielectric.

SOME time ago, when considering the assumption that the ether inside a body is quite stationary when a body is moved, and that in the application to Maxwell's ethereal equations this involves the use of a fixed time differentiation for the ether, and a moving one for the matter, I argued that the same applied not only to the electric polarisation, as done by Lorentz and by Larmor, but also to the magnetic polarisation. I told the late Prof. FitzGerald that to make the extension seemed to be a sort of categorical imperative. For it involves no assumption as to how the magnetic polarisation is produced. At the time I made the application to plane waves only. Since then I have extended it to the general case. The principal interest at present lies in the mechanical activity, fundamentally involved in the question of the pressure of radiation, and electromagnetic moving forces in general. The results confirm the desirability of applying similar reasoning to the magnetic and to the electric polarisation, in so far as they are relatively simple, and cast light upon the subject.

Thus, let $\mathbf{M}=\mathrm{V}\mathbf{DB}$ be the complete *quasi*-momentum per unit volume, and $\mathbf{M}_0=\mathrm{V}\mathbf{D}_0\mathbf{B}_0$ the ethereal part. Then if the velocity of the matter is $\mathbf{u}$, and of the ether $\mathbf{q}$, the motional activity (in the absence of free electrification, or variation of the electrical constants in space) comes to

$$\{\mathbf{u}(d/dt)+\nabla(\mathbf{u}.\mathbf{u}\}(\mathbf{M}-\mathbf{M}_0)+\{\mathbf{q}(d/dt)+\nabla(\mathbf{q}.\mathbf{q}\}\mathbf{M}_0\,; \qquad (1)$$

or, in a more developed form,

$$\mathbf{u}\{d/dt+\mathbf{u}\nabla+\nabla\mathbf{u}+\nabla_u.\mathbf{u}\}(\mathbf{M}-\mathbf{M}_0)+\mathbf{q}\{d/dt+\mathbf{q}\nabla+\nabla\mathbf{q}+\nabla_q.\mathbf{q}\}\mathbf{M}_0. \qquad (2)$$

Here the factor of $\mathbf{u}$ is the moving force on the matter, and that of $\mathbf{q}$ the force on the ether. It will be seen that in the material part we simply deduct that part of the complete $\mathbf{M}$ which does not move with the matter. This makes a great simplification of ideas. To avoid misconception, the ∇ in (1) acts upon all that follows, whereas in (2) the first ∇ acts on the $\mathbf{M}$'s, but the second and third on the velocities only, as may be seen on comparison with (1).

It is necessary, however, to point out distinctly the data involved in the above, as the simplification comes about in a special way. Divide the displacement $\mathbf{D}$ into $\mathbf{D}_0=c_0\mathbf{E}$ in the ether, and $\mathbf{D}_1=c_1\mathbf{E}_1$ in the matter, where $\mathbf{E}_1=\mathbf{E}+\mathbf{e}$, and $\mathbf{e}=\mathrm{V}(\mathbf{u}-\mathbf{q})\mathbf{B}_0$. Similarly, divide the induction $\mathbf{B}$ into $\mathbf{B}_0=\mu_0\mathbf{H}$ and $\mathbf{B}_1=\mu_1\mathbf{H}_1$, where $\mathbf{H}_1=\mathbf{H}+\mathbf{h}$, and $\mathbf{h}=\mathrm{V}\mathbf{D}_0(\mathbf{u}-\mathbf{q})$. The electric energy is $U_0+U_1=\frac{1}{2}\mathbf{ED}_0+\frac{1}{2}\mathbf{E}_1\mathbf{D}_1$, and the magnetic energy is $T_0+T_1=\frac{1}{2}\mathbf{HB}_0+\frac{1}{2}\mathbf{H}_1\mathbf{B}_1$. Also, let there be four æolotropic pressures, of Maxwellian type, say P_0, P_1 electric, and Q_0, Q_1 magnetic. *E.g.* $P_1=U_1-\mathbf{E}_1.\mathbf{D}_1$, meaning a tension U_1 parallel to $\mathbf{E}_1$ combined with equal lateral pressure. The rest are similar. Finally, the two circuital equations are

$$\mathrm{V}\nabla(\mathbf{H}-\mathbf{h}_0-\mathbf{h}_1)=\dot{\mathbf{D}}, \qquad -\mathrm{V}\nabla(\mathbf{E}-\mathbf{e}_0-\mathbf{e}_1)=\dot{\mathbf{B}} \qquad (3)$$

where the motional electric and magnetic forces are defined by $\mathbf{h}_0=\mathrm{V}\mathbf{D}_0\mathbf{q}$, $\mathbf{h}_1=\mathrm{V}\mathbf{D}_1\mathbf{u}$, $\mathbf{e}_0=\mathrm{V}\mathbf{q}\mathbf{B}_0$, $\mathbf{e}_1=\mathrm{V}\mathbf{u}\mathbf{B}_1$. This completes the data, and from them may be derived the equation of activity

$$\nabla\{\mathrm{V}\mathbf{EH}+\mathbf{q}(U_0+T_0+P_0+Q_0)+\mathbf{u}(U_1+T_1+P_1+Q_1)\}$$
$$=\dot U+\dot T+(U_0/c_0)\dot c_0+(U_1/c_1)\dot c_1+(T_0/\mu_0)\dot\mu_0+(T_1/\mu_1)\dot\mu_1+\mathbf{F}_0\mathbf{q}+\mathbf{F}_1\mathbf{u}, \qquad (4)$$

where $\mathbf{F}_0$ and $\mathbf{F}_1$ are the forces displayed in (2). The meaning is that the left side of (4) is the convergence of the flux of energy made up of the Poynting flux, the convective flux, and the activity of the pressures, whilst the right side shows the result in increasing the stored energy *and* in work done upon the matter and ether, either, both or neither, according to the size of the two velocities.

The terms involving $\dot c$, &c., in (4) represent residual activity which may be of different sorts. The commonest is when the constants vary in space, especially at a boundary. For example, $\dot c_1=-\mathbf{u}\nabla.c_1$ if c_1 does not vary in the moving matter. This means a moving force $-(\mathrm{U}_1/c_1)\nabla c_1$. But if there is compression, c_1 probably always varies intrinsically as well.

It will be found that the omission of the auxiliary $\mathbf{h}$ has the result of complicating instead of simplifying the force formulæ. Similarly the omission of $\mathbf{e}$ complicates them. Now the use of $\mathbf{e}$ is founded upon the idea that the electric polarisation is produced by a separation of ions under the action of $\mathbf{E}$, for $\mathbf{E}_1$ is the moving force on a moving unit electric charge. Analogously $\mathbf{h}_1$ is the moving force on a moving unit magnetic charge or magneton. If there are really no such things, the interpretation must be made equivalent in other terms. But the categorical imperative is not easily to be overcome.

The application to plane waves I described in a recent letter (NATURE, March 9) will be found to harmonise with the above in the special case.

But a correction is needed. In the estimation of the moving force on "glass" receiving radiation, the assumption was made that the electric and magnetic energies in the transmitted wave were equal. So the result is strictly limited by that condition. The conditions $\mathrm{E}=w\mathrm{B}$ and $\mathrm{U}=\mathrm{T}$ are not coextensive in general, though satisfied together in Lorentz's case. When U not $=\mathrm{T}$, we have instead of (8), p. 439,

$$p_1 v - p_2 v - p_3 w = w(\mathrm{T}_3 - \mathrm{U}_3),$$

and the rate of loss of electromagnetic energy is

$$2\mu \mathrm{H}_1 \mathrm{H}_2 u + (w-u)(\mathrm{T}_3 - \mathrm{U}_3).$$

Now this is zero when $e=0$, or the polarisation is proportional to the electric force. The question is raised how to discriminate, according to the data stated above, between cases of loss of energy and no loss. To answer this question, let $\mathbf{e}$ and $\mathbf{h}$ in the above be unstated in form; else the same. Then, instead of (4), the activity equation will be

$$-\nabla \mathbf{W} = \dot{\mathrm{U}} + \dot{\mathrm{T}} + \{\tfrac{1}{2}\mathrm{E}^2(\partial c_0/\partial t) + \ldots\} + (\mathbf{f}_0\mathbf{q} + \mathbf{f}_1\mathbf{u}) - (\mathbf{e}\mathbf{J}_1 + \mathbf{h}\mathbf{G}_1), \quad (5)$$

where $\mathbf{W}$ is as in (4), whilst $\mathbf{f}_0$ and $\mathbf{f}_1$ are the forces derived from the stresses specified (not the same as $\mathbf{F}_0$ and $\mathbf{F}_1$), and $\mathbf{J}_1$, $\mathbf{G}_1$ are the electric and magnetic polarisation currents, thus, $\mathbf{J}_1 = \dot{\mathbf{D}}_1 + \mathrm{V}\nabla\mathbf{h}_1$, &c. It follows that it is upon $\mathbf{e}$ and $\mathbf{h}$ that the loss of energy depends in plane waves, when $\mathbf{u}$ and $\mathbf{q}$ are constant. For the stresses reduce to longitudinal pressures, so that by line integration along a tube of energy flux we get

$$\Sigma(e\mathrm{J}_1 + h\mathrm{G}_1) = \Sigma(\mathrm{U}+\mathrm{T}). \quad (6)$$

Thus, when a pulse enters moving glass from stationary ether, the rate of loss of energy is $\Sigma(-e\mathrm{J}_1)$. If e is zero, so is the loss, as in the special case above. There is also agreement with the calculated loss in the other case. That the moving force on the glass should be controlled by $\mathbf{e}$ is remarkable, for it is merely the small difference between the electric force on a fixed and a moving unit charge. The theory is not final, of course. If the electromagnetics of the ether and matter could be made very simple, it would be a fine thing; but it does not seem probable. OLIVER HEAVISIDE.

April 5.

The Dynamical Theory of Gases.

IN a letter to NATURE (April 13) Lord Rayleigh makes a criticism on my suggested explanation of the well known difficulty connected with the specific heats of a gas. He considers a gas bounded by a perfectly reflecting enclosure, and says "the only effect of the appeal to the æther is to bring in an infinitude of new modes of vibration, each of which, according to the law (of equipartition), should have its full share of the total energy."

The apparent difficulty was before my mind when writing my book. Indeed, as Lord Rayleigh remarks, something of the kind had already been indicated by Maxwell. (I think the passage to which Lord Rayleigh refers will be found in the "Coll. Works," ii., p. 433:—"Boltzmann has suggested that we are to look for the explanation in the mutual action between the molecules and the æthereal medium which surrounds them. I am afraid, however, that if we call in the help of this medium, we shall only increase the calculated specific heat, which is already too great.") It seemed to me, however, that the difficulty was fully met by the numerical results arrived at in chapter ix. of my book.

Suppose, to make the point at issue as definite as possible, we take a sample of air from the atmosphere, say at 15° C. Almost all the energy of this gas will be assignable to five degrees of freedom so far as we know, three of translation and two of rotation. Let us surround this gas by an imaginary perfectly reflecting boundary. The total energy of matter and æther inside this enclosure will remain unaltered through all time, but this total energy may be divided conveniently into two parts:—

(1) The energy of the five degrees of freedom, say A.

(2) The energy of the remaining degrees of freedom of the matter plus the energy of the æther, say B.

As Lord Rayleigh insists, the system is now a conservative system, so that according to the law of equipartition, the total energy A+B is, *in the final state of the gas*, divided in the ratio

$$\mathrm{A}:\mathrm{B} = 5:\infty \quad . \quad . \quad . \quad . \quad . \quad (1)$$

whereas observation seems to suggest that the ratio ought to retain its initial value

$$\mathrm{A}:\mathrm{B} = 5:0 \quad . \quad . \quad . \quad . \quad . \quad (2)$$

This I fully admit, but a further point, which I tried to bring out in the chapter already mentioned, is that the transition from the ratio (2) to the ratio (1) is very slow—if my calculations are accurate, millions of years would hardly suffice for any perceptible change—so that, although (1) may be the true final ratio, it is quite impossible to obtain experimental evidence of it.

If the sample of gas were initially at a much higher temperature than we have supposed, the transition would undoubtedly be much more rapid; but even here we could not hope for experimental verification. For the assumed boundary, impervious to all forms of energy and itself possessing none, cannot be realised in practice, and as soon as the energy of the enclosed æther becomes appreciable, the imperfections of our apparatus would become of paramount importance in determining the sequence of events. J. H. JEANS.

Growth of a Wave-group when the Group-velocity is Negative.

THE following may be of interest in connection with the recent discussion on the flow of energy in such cases.

Let the energy of an element of a linearly arranged mechanical system be

$$\{(d^2y/dxdt)^2 + y^2\}dx/2.$$

Such a system can be approximately realised by taking a bicycle chain, loading it so that the radius of gyration of each link has the same large value, and suspending it by equal threads attached to each link so that the chain is horizontal and the axes of the links vertical. By the principle of least action we immediately find the equation of motion to be $d^4y/dx^2dt^2 = y$. A simple harmonic wave is given by $y = \sin(pt - x/p)$. The group velocity is $-p^2$, and is negative. Let such a system, extending from $x=0$ to $x=\infty$, be at rest in its position of equilibrium at time $t=0$, and then let the point $x=0$ be moved so that its position at any subsequent time is given by $y = 1 - \cos t$.

By application of the usual method *viâ* Fourier's integral, the motion of the system is found to be given by either of the equivalent formulæ

$$y = \Sigma(-1)^n(t/x)^{n+1}\mathrm{J}_{2n+2}2\sqrt{(tx)},$$

or

$$y = 1 - \cos(t+x) - 1 + \Sigma(-1)^n(x/t)^n\mathrm{J}_{2n}2\sqrt{(tx)},$$

where the J's are Bessel's functions and the summations extend from $n=0$ to $n=\infty$. There are some doubtful points in the reasoning, however, and the proof consists in showing (1) that y satisfies the differential equation, (2) from the second formula that $y=1-\cos t$ when $x=0$, (3) from the first formula that y and dy/dt are both zero when $t=0$, (4) from the first formula that when t is finite y is small for all large values of x. If, now, x is finite and t great, the second formula reduces to $y=-\cos(t+x)$, so that the motion now consists entirely of waves proceeding *towards* the source of the disturbance—a most remarkable result. If in the formulæ for y we change the sign of x, the J functions are replaced by I functions. The resulting value of y does not satisfy (4), and cannot be accepted as a solution of the problem.

H. C. Pocklington.

The Transposition of Zoological Names.

Among the many radical changes in zoological nomenclature proposed of late years, none appear to me more open to objection than those where names which have long been in general use for particular species or groups are transferred to others on the ground that they were originally applied to the latter. One of the earliest of such transpositions was suggested by Prof. Newton, of Cambridge, who urged that Strix is not the proper generic designation of the barn-owl, and that while this species should be called *Aluco flammeus*, the tawny owl should take the generic title Strix, as *S. aluco*. I find, however, that this emendation is not accepted in the British Museum "Hand-list of Birds," where the barn-owl figures under its familiar title of *Strix flammea*. Uniformity is not, therefore, attained by this proposal.

Another instance occurs in the case of the walrus, which was long known as *Trichechus rosmarus*, until systematists discovered that the generic title refers properly to the manati, to which animal they transferred the name. Again, the *Simia satyrus* of Linnæus is now stated to be the chimpanzi, and not the orang-utan, and consequently Simia is made to stand for the latter instead of for the former. As a fourth example of this transference of a familiar generic name may be cited the case of the marmosets of the genus Hapale, to which it is now proposed to apply the title Chrysothrix, despite its practically immemorial use as the designation of the titi monkeys.

As an example of the transference of a species name, it will suffice to take the case of the African antelope commonly known as the white oryx (*Oryx leucoryx*). This name, it is stated, properly belongs to the Arabian Beatrix oryx, to which it is accordingly proposed that it should be transferred, after being so long used for the former animal.

Personally, I am very strongly of opinion that such transpositions should not on any account be permitted, and that when a species or genus has been known by a particular name for a period of, say, fifty years, this should, *ipso facto*, give such an indefeasible title to that name (altogether irrespective of its original application) as to bar its transference to any other group or species. It may, indeed, be deemed advisable that, as in the case of the walrus, the old name should not be retained in the generally accepted sense, but, if so, it should be altogether discarded, and not transferred. The practice of transferring names must, if persisted in, inevitably lead to much unnecessary confusion without the slightest compensating advantage. Indeed, it will render such works as Darwin's "Origin of Species" and Wallace's "Geographical Distribution of Animals," which are certain to live as biological classics, absolutely misleading to the next generation unless special explanatory glossaries are supplied.

Advanced systematists urge that those who refuse to follow their lead in this and other kindred emendations in nomenclature are not only old-fashioned and behind the times, but that they are absolutely doing their best to hinder the progress of zoological science. This, however, is but the opinion of a comparatively small (and, shall we say, somewhat prejudiced?) section. What we really want is the opinion of all those interested in zoology and natural history, namely, professional zoologists, palæontologists, geologists, physiologists, anatomists, zoogengraphers, amateur naturalists, and sportsmen. If the general consensus of opinion of all these were on the side of the proposed changes, and of others of a similar type, then, and then only, I venture to think, could they be regarded as obligatory.

It may be added that the use of combinations, which Mr. Stebbing has felicitously designated "comicalities in nomenclature," of the type of *Anser anser* and *asinus asinus* (or, still worse, *Asinus asinus asinus*, which is a possible contingency), is rapidly tending to discredit the common sense of scientific zoologists among matter-of-fact men of the world.

R. Lydekker.

A little known Property of the Gyroscope.

To my surprise I have found that the property of the gyroscope which I am about to describe, although perfectly elementary, appears to be little known to either physicists or astronomers. Neither is it mentioned in the text-books so far as I am aware. That it has a very important bearing on the mechanism of the solar system has been shown in some of my earlier papers, but the laws which govern the rotation and the simple facts themselves seem to be so little understood that I have thought it worth while to explain them more fully in this place.

If a gyroscope is mounted on gimbals so that it may shift its plane of rotation freely about an axis passing through the plane of the revolving disc, we shall find it is possessed of certain curious properties. To most persons the notable characteristic of a gyroscope is the resistance it offers to any force tending to change the plane of its rotation. This is true of it only, however, in case certain conditions are complied with. If these conditions are neglected, it will change its plane with the greatest facility.

If the wheel is properly balanced and mounted as above described, and we set it spinning, it will continue to rotate in one plane without change until it stops. Suppose that while it is spinning we set it upon a table, and cause the stand supporting it to revolve slowly about its vertical axis. Instantly the wheel will adjust itself so as to revolve in a plane parallel to the surface of the table.

Furthermore, the direction of rotation of the wheel upon its axis will be the same as the direction of rotation of the stand. If we turn the stand in the opposite direction the wheel will at once shift its plane, and turn over, so as again to rotate in the same direction as the stand.

Another way of showing the experiment is to hold the stand supporting the gyroscope at arm's length. The observer then slowly revolves upon his heels, first in one direction and then in the other. Each time the observer shifts his own direction of motion the gyroscope will shift its plane, and always in such a manner that its direction of rotation shall be parallel and in the same direction as its revolution in its orbit.

It is a well known fact that according to the nebular hypothesis all the planets should have rotated in a direction opposite to that of their revolution in their orbits, just as Neptune does at the present time. This is because by Kepler's laws the inner edge of a revolving ring must necessarily move faster than the outer edge. The fact that Neptune is the only planet that even approximately fulfils this condition has always been a source of trouble to the adherents of the nebular hypothesis. No one has ever even attempted to explain the anomalous rotation of Uranus, in a plane practically perpendicular to the plane of its orbit.

The interesting property of rotating bodies illustrated above in the case of the gyroscope, and fully explained by its theory, now at once makes the matter perfectly clear. In the case of the planetary bodies, the force rotating the stand of the gyroscope is supplied by the annual tide raised upon the planets by the sun. In former times, when the planets were large diffuse bodies, this tidal force was of considerable importance. Neptune, however, is so remote from the sun that the tidal influence upon it has always been small. The plane of its rotation, therefore, has been but slightly shifted from that of its orbit—about 35°. Uranus being nearer the sun has had its plane shifted nearly half-way over, or through 82°. The plane of rotation of Saturn has been shifted through 153°, while that of Jupiter has suffered a nearly complete reversal, and the planet now revolves approximately in the plane of its orbit. The deviation amounts to but 3°, and its plane of rotation has therefore shifted through 177°.

The explanation of the retrograde rotation of Phœbe is now also clear. Phœbe, the first-born of Saturn's numerous retinue, came into being while the planet itself still retained its original plane of rotation, that is, while it was still revolving in a retrograde direction. Before Iapetus, Saturn's second satellite, reckoning from without inwards, was created, the mighty tides acting upon the planet in its then diffuse condition had shifted its plane of rotation more than 90°. Two forces then acted on the plane of the orbit of the new satellite, one from the sun tending to bring the orbit into the plane of the orbit of Saturn, the other from Saturn tending to bring the orbit of the satellite into the plane of the equator of its primary. At first both forces tended to produce the same result, namely, to diminish the angle of inclination of the plane of the orbit of the satellite. They are now pulling in opposite directions, as is the case with our own moon, the inclination of the orbit of Iapetus, 19°, being less than that of the equatorial plane of its primary.

The inner satellites of Saturn are more powerfully affected by the equatorial expansion of the planet than by the action of the sun, the planes of their orbits, 27°, coinciding nearly with the plane of the planet's equator.

Have Chemical Compounds a Definite Critical Temperature and Pressure of Decomposition?

So far nobody seems to have considered the question whether to every chemical compound there exists a definite critical temperature and pressure of decomposition. Yet I think the following considerations show that such constants probably do exist. Suppose we place a given compound (say $CaCO_3$) in a closed cylinder and subject it to a continually increasing temperature, keeping the pressure constant by means of a weighted piston. Then at a certain definite temperature range the compound will begin to decompose. Suppose, now, we increase the pressure sufficiently; then the decomposition ceases, and the substance can now bear a higher temperature than before without decomposition.

Proceeding in this way, it is, I think, obvious from the *finite* nature of the mass of the atoms, and from the limited intensity of the forces holding them together in the molecule, that ultimately at some definite finite temperature the external forces tending to drive the atoms apart will become equal to the maximum internal forces that the atoms can exert on each other in the molecule. It therefore follows that above a certain definite temperature, depending upon the nature of the molecule, no pressure, however great, can prevent the substance from completely decomposing. This temperature and pressure, above which a compound is incapable of existing, we will call the critical temperature and pressure of decomposition of the compound. The critical temperature and pressure of decomposition would therefore be completely analogous to the critical temperature of liquefaction of a compound—only in the latter case we are dealing with the temperature whereat a certain molecular condition of existence disappears, and in the former case with the temperature whereat a certain atomic condition of existence disappears.

Since atoms are a very much more finely divided form of matter than molecules, it is clear that the critical temperature of decomposition of a compound must be a very much sharper and clear-cut constant than its critical temperature of liquefaction. The critical temperature and pressure of even very unstable compounds is usually very high, provided there exist but a few atoms in the molecule. For example, $AuCl_3$, ozone, and the oxides of nitrogen, although very unstable at ordinary temperatures, seem capable of existing at very high temperatures. In general, the greater the number of atoms contained in the molecule the lower the critical temperature of decomposition, as is evident from the general observation that the more complex a compound is the easier it is to decompose. Many of the very complex carbon compounds—for example, the proteids—have, on account of their complexity, critical temperatures of decomposition which lie very close to the normal temperature of the earth's surface.

If, now, by some means we proceed to add on atoms to such a molecule so as to make it more and more complex, we would steadily lower its critical temperature of decomposition, and by adding on a suitable kind and number of atoms we could reduce the critical temperature and pressure of the compound until they coincided with the normal temperatures and pressures which hold upon the earth's surface. Such a compound would be possessed of an extraordinary sensitiveness to external influences on account of the sharpness of the constants called above the critical temperature and pressure of the compound. The slightest increase of temperature or decrease of pressure would serve to throw it into a condition of rapid chemical decomposition, whereas a slight increase of pressure and decrease of temperature would cause it to cease to decompose. Even did we maintain the external temperature and pressure exactly at the critical temperature and pressure of the compound, nevertheless the external impulses which are continuously pervading all space in the neighbourhood of the solar system, beating intermittently upon the sensitive substance, would be sufficient to throw it into a series of rapidly alternating states of decomposition and repose.

I suggest that the temperature range of animal life is probably nothing more or less than the range of the critical temperatures of decomposition of a series of certain very complex carbon compounds which are grouped together under the name "protoplasm," the external pressure of the atmosphere coinciding roughly with their critical pressures of decomposition. In fact, I suggest that just as a tuning-fork is set into motion by vibrations of a certain definite frequency and by no others, so living matter is so constructed as to respond continuously to the incessant minute fluctuations in the external conditions which hold upon the earth, the state of response being what is known as life. The temperature of animal life keeps remarkably constant, as it should do on our supposition, a temperature too high exceeding the critical temperature of decomposition of living matter and so destroying its structure, while a temperature too low causes it to cease to decompose, and the living matter becomes inactive.

Geoffrey Martin.

[The writer of the above will see his "suggestion" discussed in Lockyer's "Inorganic Evolution," book iii.—Ed. Nature.]

Experiment on Pressure due to Waves.

I have seen both in the *Physikalische Zeitschrift* (January) and in the *Physical Review* (February) an account of an experiment by Prof. R. W. Wood to demonstrate the pressure due to waves, and which he suggests as a lecture demonstration of the effect observed by Lebedeff and by Nichols and Hull. The same experiment is quoted by Prof. Poynting in his address on this subject to the Physical Society of London (*Phil. Mag.*, April). I venture to suggest that the experiment, which consists in setting a small windmill in motion by means of Leyden jar discharges maintained by a transformer, will bear a different explanation. It was shown long ago (1793) by Kinnersley, of Philadelphia, in his "Electrical Thermometer," that a jar discharge produces in air a violent explosive effect, which we should now explain by the repulsion between constituents of the current in opposite phase to one another. The repulsive force may be very great. I think it is this explosive effect that Prof. Wood shows in the experiment, and not the pressure due to reflection of a continuous train of waves. I do not think that the suggestion is new, but it appears to me that the same cause may account for the disruption which occurs when lightning strikes a building, an instance of which is recorded in Nature of April 13 (p. 565) in the displacement of some of the blocks of the small pyramid.

Sidney Skinner.

South-Western Polytechnic, Chelsea, April 15.

TANTALUM.

THE application of electricity to chemical problems has again borne fruit in the isolation and preparation of tantalum. Dr. Werner von Bolton, of the firm of Siemens and Halske, published the results of his very interesting research upon the preparation of tantalum in the *Zeitschrift für Elektrochemie* (January 20). Although the existence of tantalum was pointed out by Hatchett in 1801, it does not appear up to the present to have been prepared in the pure condition. Moissan, indeed, in 1902 prepared the metal by reducing tantalic oxide (Ta_2O_5) in the electric furnace. But the metal was extremely hard and brittle, a property which Dr. Bolton now shows only belongs to the impure product; Moissan's metal probably contained some carbide. Dr. Bolton has succeeded in obtaining the metal by an electrical and by a chemical method.

The Electrolytic Method.

As is well known, Nernst found that when a thin rod of magnesia (MgO) is heated to whiteness it becomes able to conduct the electric current, the magnesia being split up into its components, magnesium and oxygen; the magnesium, however, immediately re-combines with oxygen, the process of electrolysis therefore becoming continuous. Other metallic oxides, such as zirconium, ytterbium, thorium, calcium, and aluminium, &c., likewise behave in a similar manner. If, now, a rod of magnesium is strongly heated in vacuum and the electric current passed through it, the oxygen given off is so dilute that re-combination does not take place, and the rod becomes powdered. Dr. Bolton, working along somewhat similar lines, found that the coloured or lower oxides of vanadium, niobium (columbium), and tantalum will conduct the electric current without the necessity of being heated to very high temperatures. Strange to say, the colourless or higher oxides have not this property.

In order to prepare tantalum in this manner a filament of the brown tantalum tetroxide (Ta_2O_4) was prepared and fixed into an evacuated globe, which was connected with a vacuum pump, so that if oxygen was given off, on heating, it could be pumped out. On passing a current through this filament, at first the two ends of the filament became white hot, and then gradually the incandescence travelled along the filament until the whole of it became incandescent. A large quantity of oxygen was given out, and the filament, which at the commencement was brown, became metallic grey. The tantalum so obtained showed on analysis a purity of 99 per cent.

The Chemical Method.

Details as to how the chemical method is carried out are not given. Dr. Bolton simply says that the metal can be obtained by fusing a mixture of potassium tantalum fluoride with potassium by means of the electric arc furnace in a vacuum. This method is a modification of that used by Berzelius in 1824.

Properties of the Metal.

One of the most remarkable properties of the metal is its extreme ductility combined with extraordinary hardness. The red-hot metal can readily be rolled into sheets and foil, and easily drawn into wire. When the sheet is again heated and hammered it becomes so extremely hard that it was found impossible, by means of a diamond drill, to bore a hole through a sheet 1 mm. thick. The drill, rotating 5000 times to the minute, was worked day and night for three days, and at the end of the time had only made a depression 0.25 mm. deep, while the diamond of the drill was very much worn. This property may very probably lead to its being used for drills in place of the diamond.

The metal melts between 2250° and 2300°. The atomic heat agrees with the law of Dulong and Petit, being 6.64. The specific gravity is 14.08. When two electrodes of tantalum are placed in a bath of dilute sulphuric acid, the tantalum becomes passive, and even with an E.M.F. of 220 volts at the terminals no current passes. When placed opposite an electrode of platinum only one phase of an alternating current passes; it may thus be used for rectifying an alternating current in the same manner that aluminium can.

In the form of wire, sheet or ingots, the metal is unacted upon by sulphuric, hydrochloric, or nitric acid, and even by aqua regia. Hydrofluoric acid reacts very slowly, unless the metal is in contact with platinum, for example, in a platinum dish, when it dissolves readily with evolution of hydrogen. Fused alkalis have no action upon it.

When made the kathode in an acid electrolyte it absorbs hydrogen, which is only partially given up, even when the metal is fused. The metal may be heated to red heat in the air without taking fire. At 400° it turns slightly yellow, at a low red heat it turns blue, and finally becomes coated with a white protective coating of the pentoxide. It absorbs nitrogen at a white heat, and unites with sulphur when melted with it under fused potassium chloride. Tantalum apparently forms no amalgam with mercury, although it produces alloys with most other metals. When united with 1 per cent. of carbon it becomes hard and brittle, and can no longer be drawn into wire.

FIG. 1.—View of Tantalum Lamp. Half-size linear.

As already stated, the original idea in working with tantalum was to find a new material to be used for incandescent electric lamps. The first experiments were tried with the oxides of vanadium and niobium (columbium); the coloured or lower oxides of these metals were found to conduct the current and to give up their oxygen when thus heated in vacuum. Vanadium so obtained was found to melt at 1680° and niobium at 1950°; but owing to these comparatively low melting points they could not satisfactorily be employed for electric lighting purposes. Tantalum, however, which melts between 2250° and 2300°, has been successfully employed for this purpose by Messrs. Siemens and Halske.

Filaments of the metallic tantalum are fused into a globe, which is then evacuated in the usual manner. The first lamp was made with the usual bow-shaped filament, and required 0.58 ampere with a pressure of 9 volts, giving 3 candle-power. It was then found that in order to produce a 22 candle-power lamp suitable to being placed on a 110-volt circuit more than 20 inches length of filament was required. The difficulty presented was to get this great length of filament conveniently into the ordinary sized globe. The illustration (taken from the *Electrical Magazine* for March) shows how the difficulty was got over. The central support is a rod of glass, having a number of wires radiating from it to act as supports. This lamp gives 22 candle-power with an energy consumption of 1.7 watt per candle-power, or about half that required by the ordinary incandescent lamp. The weight of a single filament is 0.022 gram, so that 1 kilogram of metal would be sufficient for 45,000 such lamps.

Whether it will be possible to obtain sufficient mineral to produce tantalum on a really large scale remains to be seen, because if it is possible there should be hardly an end to the usefulness of this metal, which possesses the properties ductility and hardness in such an extraordinary degree, leaving entirely out of question its employment in electric lamps. F. MOLLWO PERKIN.

PRIMITIVE WATER-SUPPLY.[1]

THE mighty earthworks that still crown so many of our hills fill the archæologist alike with wonder and despair—wonder that prehistoric man, with the most primitive tools, was equal to the task of raising them, and despair that so little can ever be known about them, despite the most laborious and costly excavation. Plenty of books, however, of the kind now under notice would do much to solve the mystery and increase our admiration for Neolithic man, for it is to the period before bronze was known in Britain that the authors assign the stupendous works of Cissbury and Chanctonbury on the South Downs.

This is an open-air book that gives life to the dry bones of archæology, and reads like the record of a well-spent holiday. A keen eye for country is one of the qualifications possessed by one or both the authors, and evidence of ramparts long since levelled is wrung from the very daisies as they grow. The construction of dew-ponds by the early inhabitants of Britain has often been glibly asserted, but few, if any, have furnished such clear and circumstantial evidence as the authors of this short treatise. The water-supply for the occupants of our huge prehistoric "camps" has always been somewhat of a mystery, and it has been suggested that they were only temporary refuges, when the country was "up," so that a permanent supply was not regarded as a necessity. But the watering of men and animals on the scale indicated by the areas enclosed would be a formidable task even for a day, and another explanation must be sought. The late General Pitt-Rivers, for example, held that the water-level of the combes was higher then than now, and streams would have been plentiful on the slopes; but, feeling the inadequacy of this view, he also had recourse to the dew-pond theory. To those familiar with the process, this might seem an obvious expedient, but the interesting account given of the formation of such reservoirs might make us chary of crediting prehistoric man with such scientific methods.

An exposed position innocent of springs was selected, and straw or some other non-conductor of heat spread over the hollowed surface. This was next covered with a thick layer of well puddled clay, which was closely strewn with stones. The pond would gradually fill, and provide a constant supply of pure water, due to condensation during the night of the warm, moist air from the ground on the surface of the cold clay. Evaporation during the day is less rapid than this condensation, and the only danger is that the straw should be sodden by leakage. It is for this reason that springs or drainage from higher ground are avoided, as running water would cut into the clay crust.

Some ponds of this kind, no doubt of very early and perhaps of Neolithic date, may still be seen in working order: others are of modern construction; but to and from the ancient dew-ponds (or their sites) can sometimes be traced the hillside tracks along which the herds were driven, one leading from the camp, or cattle-enclosure hard by, to the watering-place, another leading back, to avoid confusion on the road. These and other details as to guard-houses and posts of observation are brought to our notice in the description of selected strongholds in Sussex and Dorset; and verification, if, indeed, such is demanded, must be sought on the spot by any who have doubts or rival theories.

FIG. 1—Cattle-ways leading down to Dew-pond at the North of Cissbury Ring. From Hubbards "Neolithic Dew-ponds and Cattle-ways."

The banks, that enclosed pasture-areas sometimes of vast extent, were no doubt stockaded against man and beast, and may be compared with the base-court defences of the Norman burh; but the excavator of Wansdyke had an alternative theory that such banks were sometimes erected for driving game. Incidentally, the authors discountenance the view that the "camps," not to mention the outworks, were ever efficiently manned. Their extent would necessitate for this duty a vast number of fighting men within call.

[1] "Neolithic Dew-ponds and Cattle-ways." By A. J. Hubbard and G. Hubbard. Pp. x+69; illustrated. (London: Longmans, Green and Co., 1905.) Price 3s. 6d. net.

Possibly, in a few instances, the ridges on the hill-slopes may be due to outcropping strata, and others might suggest terrace-cultivation; but there seems ample evidence for the view taken that Neolithic cattle-tracks have survived to this day around certain of our most imposing "camps."

Failing large-scale maps, a sketch-plan of the earthworks noticed would have made the description even more illuminating; but the only matters of complaint are that the book is all too short, and that the paper selected to throw up the detail of the photographs is as chalky as the Downs they illustrate so pleasantly.

HENRY BENEDICT MEDLICOTT, F.R.S.

On April 6 there passed away one of the few survivors amongst the small body of men who laid the foundations of Indian geology. Despite much excellent work, chiefly by non-professional men, very little was really known of the geology of India, and especially of Peninsular India, before the middle of the nineteenth century, and as one instance amongst many, the Vindhyans, now believed to be Archæan, were still classed with Gondwana Permo-Carboniferous strata, and both were regarded as of Jurassic age. A comparison of Dr. Carter's "Summary of the Geology of India between the Ganges, the Indus and Cape Comorin," published in 1853, with the "Manual of the Geology of India," issued in 1879, will show the great improvement that took place in the meantime in our knowledge of the country.

In this change none had a larger share than Henry Benedict Medlicott. Born in Loughrea, county Galway, he was the second of three sons of the Rev. Samuel Medlicott, rector of Loughrea, and of Charlotte, the daughter of Colonel H. B. Dolphin, C.B. All three sons were men of great intellectual capacity and of marked originality. The eldest, J. G. Medlicott, became a member of the Geological Survey of India before his brother joined; he was subsequently in the Indian Educational Service, and died in 1866. The third brother, Samuel, was a clergyman, who has also been dead several years. The subject of the present memoir was educated at Trinity College, Dublin, and, after taking his degree, was for a short time on the staff, first of the Irish, then of the English Geological Survey. In the spring of 1853 he joined the Geological Survey of India under the late Dr. Thomas Oldham, but was almost immediately appointed professor of geology at the Roorkee College of Civil Engineering, an appointment which he held until 1862, when, on some additions being made to the staff, he re-joined the Geological Survey of India, and was made deputy superintendent for Bengal.

But during his tenure of the Roorkee post he spent part of the year surveying for the Geological Survey, and in his first season's work he and his brother made a primary step towards the elucidation of Indian geological history by separating the ancient Vindhyans north of the Son and Nerbudda Rivers from the Indian Coal-measures and their allies to the southward. In subsequent years, whilst his brother mapped the last named strata, he surveyed the older Vindhyans and their associates, and to him we owe our first recognition of the Bijawur and other ancient rocks between the old gneissic formation and the Vindhyans. In other years he explored the Himalayas, and the ranges at their base, between the Ganges and the Ravi, and he drew up the description of the older unfossiliferous beds of the mountains, and of the Tertiary and other strata fringing their base, which was published in the third volume of the Indian *Memoirs*. This contains a sketch of the history of the Himalayas which has been generally accepted ever since.

After returning to the survey in 1862 (he always protested that he really had remained a member of the staff throughout), he examined in successive years the greater part of northern India. Various tracts of the Himalayas from the Punjab to Assam, the Assam valley and the hill ranges south of it, and, in the Peninsula, Rajputana, Nimar, the Nerbudda valley and Satpura ranges, Bundelkhand, South Rewah, Chhatisgarh and Sambalpur, Chota Nagpore, Hazaribagh, and Behar were visited and reported upon in turn.

Dr. Oldham retired in 1876, and Mr. Medlicott succeeded him as superintendent, a title subsequently changed to director of the survey. The first work undertaken by him as superintendent was a general account of Indian geology. This had long been urgent, and would probably have been written by Dr. Oldham but for failing health. The "Manual of the Geology of India" was published in 1879, and a very large portion, including the account of the Azoic rocks from gneiss to Vindhyans (which between them cover the greater part of the Indian peninsula), and of the geology of the Himalayas and sub-Himalayas, in fact, nearly half the entire work, was written by Mr. Medlicott himself. In many ways a great impulse was given to survey work by the new superintendent. As regards publication alone, the volumes of the *Records* from 1877 are doubled in bulk when compared with previous issues, and these volumes, containing accounts of recent geological observations, both economical and scientific, represent the actual field work of the survey to a larger extent than the longer memoirs and palæontologia.

Throughout his career as head of the survey Mr. Medlicott adopted a most liberal policy of publication. He allowed his staff to report on their own work freely, and whilst assisting them in every way, both in the field and in the study, he never took any of the credit of their work. Not only did he welcome reports from the geologists of the survey, but he published, whenever possible, contributions from independent observers. In this manner he secured the valuable assistance of the late General McMahon, the whole of whose most important observations on the physical history of the Himalayas appeared in the *Records* of the Geological Survey of India.

Modest and retiring, he was nevertheless a man of high courage and independence. One trait of this was shown in the Indian Mutiny, when, with one companion, despite the mutiny of the guard that should have accompanied them, he saved the lives of a Christian family who had fallen into the hands of the rebels, a most gallant action, the account of which is due to Colonel Baird Smith, the head of Roorkee College and the commanding officer. After retiring from the Indian Survey in 1887, he lived very quietly at Clifton, devoting himself to philosophical problems. He published a couple of short pamphlets on "Agnosticism and Faith" in 1888, and on "The Evolution of Mind in Man," but a larger work on which he was engaged is, it must be feared, incomplete. A strain caused by bicycling led to serious heart symptoms some years ago, and although a partial recovery was made, a relapse about a year since reduced him so much that it was not surprising to hear that he passed quietly away on April 6, whilst seated in his study.

Mr. Medlicott became a Fellow of the Geological Society as long since as 1856, and in 1888, on his retirement from India, he received the Wollaston medal. He was elected a Fellow of the Royal Society in 1877. He received the military medal for his services in the Mutiny. He was also a Fellow of Calcutta University, and from 1879 to 1881 he was president of the Asiatic Society of Bengal.

W. T. B.

NOTES.

The report on the natural history collections made in the Antarctic regions by the *Discovery* Expedition, to be published by the trustees of the British Museum, and edited by Prof. E. Ray Lankester, F.R.S., promises to be of particular interest and importance. The working out of the collections has been entrusted to nearly fifty naturalists, each of whom will deal with material in which he is specially interested. Inquiries concerning the zoological and botanical collections should be addressed to Mr. F. Jeffrey Bell, British Museum (Natural History), Cromwell Road, London, S.W.

The council of the Institution of Civil Engineers has made the following awards for papers read and discussed before the institution during the past session:—Telford gold medals to Lord Brassey, K.C.B., and Mr. C. S. R. Palmer; a George Stephenson gold medal to Mr. Lyonel E. Clark; a Watt gold medal to Mr. J. F. C. Snell; Telford premiums to Messrs. L. F. Vernon-Harcourt, R. W. Allen, and Wm. Marriott; a Crampton prize to Mr. A. Wood-Hill, and the Manby premium to Mr. E. D. Pain. The presentation of these awards, together with those for papers which have not been subject to discussion and will be announced later, will take place at the inaugural meeting of next session. Sir Alexander Binnie has been elected president of the institution in succession to Sir Guilford Molesworth, K.C.I.E.

Mr. W. E. Cooke, Government astronomer for Western Australia, writes to us from the observatory at Perth to direct attention to an unusual seismic disturbance in that place. During March 5 there were three marked earthquakes in the space of a few hours, and these reached their maxima at 16h. 25·8m., 19h. 0·1m., and 13h. 42·6m. The times are given in Greenwich civil time. Each maximum was preceded by tremors from fifteen to twenty minutes earlier, and by a large wave from ten to fifteen minutes before the maximum. It is noteworthy that the transit circle was displaced considerably in both level and azimuth. Another earth tremor, the greatest yet registered on the Milne seismograph at Perth, occurred on March 19. There were no preliminary tremors; the disturbance proper commenced abruptly, and reached a maximum in 19·6m.

The workers at the Port Erin Biological Station during this spring vacation include Prof. B. Moore, Dr. H. E. Roaf, and Mr. B. Whitley (all from the biochemical department of the University of Liverpool), Mr. J. A. Dell and Mr. E. Standing (from the University of Leeds), Prof. Herdman, Mr. W. Dakin, and Mr. W. A. Gunn (from the University of Liverpool), and Mr. Chadwick, the curator. Prof. Moore and his party are investigating the changes produced in the growth of embryos by alterations in the constitution of the sea-water and other conditions of the environment. The other workers are engaged on various lines of zoological research. The fish-hatching is now going on rapidly, and more than three millions of plaice fry have already been turned into the sea this month. The parent plaice in the spawning pond were evidently about a fortnight earlier in reproducing this season than last, as the first fertilised eggs were obtained on February 14, and in large quantity, as against March 3 in 1904.

It is proposed to send out a special series of telegraphic time signals beginning at 11.55 p.m., United States Eastern Standard Time (mean time of the 75th meridian west from Greenwich), on May 3, and ending at midnight, according to the plan followed daily at noon. These special time signals will be sent out by request of the American Railway Association, with the approval of the Secretary of the Navy, in honour of the International Railway Congress, which is to meet in the capital of the United States on the following day. It is hoped that the principal observatories of the world will make efforts to receive and time these signals accurately, and reports of such observations may be made at once, without expense, through the courtesy of the various telegraph and cable companies. This was done in the case of the New Year's Eve time signals from the United States Naval Observatory, which are reported to have reached the Toronto Observatory in 0·00s.; Lick Observatory, 0·05s.; City of Mexico, 0·11s.; Manila, 0·37s.; Greenwich, 1·33s.; Sydney, Australia, 2·25s.; Wellington, N.Z., 4·00s.; and Cordoba, Argentina, 7·7s. From the rapidity and accuracy with which these time signals are transmitted over connecting land lines, as a result of long experience in transmitting the daily noon signals, it seems very probable, if the telegraph companies will take especial care in their transmission and not interpose any secondary clocks or human relays, that they may serve to give fairly accurate determinations of longitude at any telegraph station on the American continent where they can be noted exactly and compared with accurate local time.

It was decided in the Chancery Division of the High Court on April 19 that the public has not the right of free access to Stonehenge. The question of free access was raised by an action in which the Attorney-General claimed an order against Sir Edmund Antrobus to remove the fencing which now encloses Stonehenge, and an injunction to restrain him from erecting any such fencing. The claim was based on two grounds:—(1) that Stonehenge is a national monument of great interest and is subject to a trust for its free user by the public; (2) that there are public roads running up to and through Stonehenge, and that those roads have been blocked by the defendant's fencing. Mr. Justice Farwell, who heard the action, decided that both these claims were untenable; and he therefore dismissed the action, with costs. In concluding this judgment, his Lordship is reported by the *Times* to have remarked:—"I hold that the access to the circle was incident only to the permission to visit and inspect the stones, and was, therefore, permissive only, and, further, that the tracks to the circle are not thoroughfares, but lead only to the circle, where the public have no right without permission, and, therefore, are not public ways. The action accordingly fails, and ought never to have been brought. It is plain that the vicinity of the camp and the consequent increase of visitors compelled the defendant to protect the stones if they were to be preserved; and he has done nothing more than is necessary for such protection. I desire to give the relators credit for wishing only to preserve this unique relic of a former age for the benefit of the public, but I fail to appreciate their method of attaining this. The first claim to dispossess the defendant of his property is simply extravagant, so much so that, although not technically abandoned, no serious argument was addressed to me in support of it. The rest of the claim—for rights of way over the network of tracks shown on the plaintiff's plan—if successful would defeat the relators' object. If these ways were left unfenced and heavy traffic passed through the circle, there would be great risk of injury, and even without such traffic there is great risk from the increased numbers of passers-by. As Sir Norman Lockyer (whose interesting application of the orientation theory to Stonehenge has recently appeared) says in one of his articles:—'The real destructive agent has been man himself—savages could not have played more havoc with the monument than the English who have visited it at different times for different purposes.' I feel no confidence that the majority of tourists have improved, nay, rather—'Aetas parentum, pejor avis, tulit Nos nequiores.' It is only fair to the defendant to say that he is not acting capriciously, but on expert advice for the preservation of the stones. If, on the other hand, the roads are all fenced off, the general appearance would be ruined, and no human being would be in any way the better. It is not immaterial to remark that this is not the action of the district or the county council to preserve rights of way, but is brought on the relation of strangers on the score of the public interest in Stonehenge."

The death is announced of Prof. A. A. Wright, professor of geology and zoology at Oberlin College since 1874.

The Rome correspondent of the *Daily Chronicle* reports that Vesuvius is again in full eruption, and that earthquake shocks are frequent in the Vesuvian communes.

The French Government, says the *British Medical Journal*, has granted a subvention of 4000*l.* in aid of the International Congress on Tuberculosis, which is to be held in Paris next October.

Dr. L. F. Barker, professor of medicine at the Rush Medical School, Chicago, has been appointed to the chair of medicine in Johns Hopkins University, Baltimore, in succession to Prof. Osler.

A dinner will be given at the Hotel Cecil on May 10, under the presidency of Mr. Chamberlain, and with the support of the present Secretary of State for the Colonies, in aid of the funds of the London School of Tropical Medicine.

We learn from the *Times* that the twenty-fifth anniversary of the return of the *Vega* from Arctic regions after accomplishing the north-east passage under Baron Nordenskjöld was celebrated at Stockholm on April 24. The King of Sweden and the Crown Prince and the other members of the Royal Family were present at the commemorative meeting, as well as Admiral Palander, Minister of Marine, who commanded the expedition.

A distinct earthquake shock was felt shortly after 1.30 a.m. on April 23 over a large area in the north of England, including parts of Yorkshire, Derbyshire, Nottinghamshire, and Lincolnshire. The shock is reported to have been unmistakable, and to have lasted several seconds. There is a want of agreement in the reports as to whether the movement was from west to east, or *vice versâ*, and it is not clear if one or two shocks occurred. A heavy rumbling sound is said to have been heard at Sheffield, Selby, Worksop, and other places.

On Tuesday next, May 2, Prof. L. C. Miall will deliver the first of three lectures on the "Study of Extinct Animals," on Thursday, May 4, Sir James Dewar will commence a course of three lectures on "Flame," and on Saturday, May 6, Prof. Marshall Ward will begin a course of two lectures on "Moulds and Mouldiness." The Friday evening discourse on May 5 will be delivered by Prof. H. E. Armstrong, the subject being "Problems Underlying Nutrition," on May 12 by Prof. E. Fox Nicholls on "The Pressure due to Radiation," and on May 19 by Sir Charles Eliot on "The Native Races of the British East Africa Protectorate."

The annual meeting and conversazione of the Selborne Society will be held by kind permission in the theatre and halls of the Civil Service Commission, Burlington Gardens, on the evening of May 3. Lord Avebury will give the annual address, Mrs. Dukinfield Scott will show her kammatograph pictures of opening flowers, Mr. Fred Enock will describe the work of a wood-boring wasp with the help of some moving slides, Mr. Oliver G. Pike will contribute a short lecture, while Mr. Percival Westell has promised to give an account of the actions of a young cuckoo, and to show photographs in illustration of them. There will also be many exhibits, including microscopes lent by members of the Royal Microscopical Society and the Quekett Club. All particulars may be obtained from the honorary secretary, Mr. Wilfred Mark Webb, 20 Hanover Square, W.

A large portion of the second part of the first volume of the *Proceedings of the Manchester Field Club* is taken up by the beautifully illustrated article on protective resemblances in insects, by Mr. M. L. Sykes, which was summarised in Nature of March 30. In addition to a number of shorter articles, mostly the reproductions of addresses delivered at meetings of the club, the volume contains the reports for the years 1900 and 1901, together with lists of officers and council.

The first article in the *Irish Naturalist* for April is devoted to an illustrated description of the Patterson Museum in the new People's Palace at Belfast. The greater portion of this natural history exhibition is contained in a lofty chamber 75 feet in length by 25 feet in width. The work of planning the cases and obtaining specimens with which to fill them was entrusted by the managers of the palace to Mr. R. Patterson, who seems to have carried out his task with conspicuous success. Specimens were contributed by a large number of donors, and Mr. Patterson himself has consented to act as honorary curator.

From the Bergen Museum we have received copies of the *Aarsberetning* and the *Aarbog* for 1904. The former contains photographs of three exhibits added during the year to the vertebrate series. Of these, the groups of snowy owls and of sea-eagles appear unexceptionable, but we cannot congratulate the authorities on the plan of placing a red deer mounted on a quadrangular wooden stand in front of a background formed by a picture of a fir-plantation bordering a church. In the *Aarbog* the most important communication is one by Mr. R. Høye dealing with the methods of curing salt and kippered fish, and describing the mycetozoa frequently developed during or after the process.

We have received a bound copy of the second volume of "Marine Investigations in South Africa," issued at Cape Town by the Department of Agriculture of Cape Colony. Although the title-page is dated 1904, the whole of the eleven papers contained in the volume were published during 1902 and 1903. The subjects include Crustacea, by the Rev. T. R. R. Stebbing; Mollusca (two papers), by Mr. G. B. Sowerby; fishes (three papers), by Dr. Gilchrist; deep-sea fishes, by Mr. Boulenger; corals, by Mr. Gardiner; sponges (two papers), by Mr. Kirkpatrick; and ocean currents. Several of the articles have been noticed in our columns as they were issued.

To the April number of the *Journal of Anatomy and Physiology* Dr. A. Keith contributes a thoughtful article on the nature of the mammalian diaphragm and pleural cavity. The pleural cavity he considers to have been formed by a hernia-like outgrowth from the general body-cavity, the diaphragm thus being formed by a portion of the original outer wall of that cavity. Considerable interest also attaches to a paper by Dr. A. A. Gray on the membranous labyrinth of the internal ear of man and the seal, in the course of which it is shown that seals possess in this region large otoliths comparable to those of fishes. Although the precise function of these structures is at present unknown, it would appear from their occurrence in the two groups that they are correlated with an aquatic existence.

In the second of a series of articles on Canadian life, published in the April number of the *Empire Review*, Mr. A. P. Silver, of Halifax, gives a graphic description of the wild, or "feral," horses inhabiting in large droves the storm-swept Sable Island. This island, which lies about eighty miles to the eastward of Nova Scotia, consists of an accumulation of loose sand, forming a pair of ridges united at the two ends and enclosing a shallow lake; tracts of grass are to be met with in places, as well as pools of fresh water. The droves of wild horses, or ponies, and herds of seals appear to be the chief mammalian inhabitants of the island. It is generally supposed that the original stock was landed from a Spanish wreck early in the sixteenth century, although some writers make the introduction much later. Five-and-twenty years ago the number of ponies was estimated at between 500 and 600; at the present day there are less than 200, divided into five troops. Not more than two-thirds of these are pure-bred, the remainder being the offspring of mares crossed with introduced stallions. The introduction of these foreign stallions (which is to be regretted by the naturalist) has been a matter of great difficulty, as the strangers were attacked and wounded by the leaders of the droves. The author comments on the striking likeness of these wild ponies to the horses of the Parthenon frieze and to the now exterminated tarpan of Tartary. They also seem to resemble the wild horses of Mexico, although their coat is doubtless longer. These resemblances seem to point to reversion to the primitive type of the species. All colours save grey characterise the pure-bred stock; but chestnut, with a dark streak on the back and on the withers, is the most common tint, after which come bays and browns.

PROF. H. F. OSBORN has been good enough to send us a collection of papers published by himself during the past year, some of which have been already noticed in our columns. Among the latter is one on a re-classification of reptiles, from the *American Naturalist* of February, 1904, in which it is proposed to divide the class into the brigades Diapsida and Synapsida. This plan is further elaborated in part viii. of the first volume of the *Memoirs* of the American Museum, which is well illustrated, and gives the leading characteristics of a number of the chief groups. The budget also includes three papers from the *Bulletin* of the American Museum, one dealing with sauropod dinosaurs, the second with new Oligocene representatives of the horse line, and the third with armadillos from the Bridger Eocene. An interesting feature recorded in the first of these is the discovery that in some at least of the sauropod dinosaurs the first digit of the fore-foot was alone furnished with a claw, or, at all events, with a claw of large size. The discovery of what are regarded as ancestral armadillos (apparently furnished with a leathery skin) in the Bridger Eocene is of much interest from a distributional point of view. It is noteworthy that these animals were described under the name of Metacheiromys, under the impression that they were allied to the aye-aye (Chiromys).

IN a communication published in the *American Journal of Science* for April, 1904, Prof. Osborn summarises the palæontological evidence in favour of the theory that mammalian teeth are derived from a primitive tritubercular type, and comes to the conclusion that it strongly supports the theory. Reference may also be made to the preface to vol. ii. of the *Bulletins* of the American Museum (1898–1903), in which Prof. Osborn gives an interesting account of the explorations and researches carried out by the department of vertebrate palæontology during that period. Special endeavours have been devoted to collecting the dinosaurian remains from the Upper Jurassic of Wyoming and Colorado.

A CATALOGUE of second-hand books in various branches of botany, offered for sale by Mr. F. L. Dames, Berlin, has been received; the sections best represented are the diatoms and desmids, floras, and the works on anatomy and physiology.

AN abridged report on the experiments with seedling and other canes in the Leeward Isles in 1903–4, forming No. 33 of the pamphlet series of publications of the Imperial Department of Agriculture for the West Indies, shows a certain amount of divergence from the results of previous years in the list of canes arranged according to sugar production; Dr. F. Watts, the officer in charge, attributes it to the dryness of the season. In Antigua, Sealy Seedling, a cane of great vegetative vigour, appears first on the list, while B 208, which still retains its character of producing the purest juice, drops to the fourth place. A system of comparing the plants according to the number of stations in which they figure among the first seven promises to determine those most suitable for general planting.

A FLORA of the Calcutta district, where the district extends sixty miles south and forty miles in other directions, has been compiled by Dr. Prain, and is published as vol. iii., No. 2, of the *Records of the Botanical Survey of India* under the title of the "Vegetation of the Districts of Hughli-Howrah and the 24-Pergunnahs." The larger part of the district is alluvial rice-country, but a dry area occurs in the north-west, and the West Sunderbuns in the south comprise swamp forest and muddy creeks. The flora is not confined to wild plants, but includes crops and trees or shrubs of cultivation. The list of crops, with the original home of each, brings out very clearly the varied sources from which they are derived; as compared with fifty native plants, twenty-five are traced to the Mediterranean area, and about twelve each to Africa and America, besides other Asiatic species.

BEFORE vacating the post of Government mycologist in Ceylon, Mr. J. B. Carruthers placed on record in the *Circulars* (vol. ii., Nos. 28 and 29) of the Royal Botanic Gardens his observations on two cankers, caused by species of Nectria, on tea bushes and rubber trees respectively. The tea canker which has been known in India for some years was found over a large area of the tea districts, more especially at the high elevations and on some of the finest tea plantations; the fungus spreads in the soft tissues under the bark, but produces cracks where the spores are formed. The Nectria on the Para rubber trees is more insidious, as there is generally little or no evidence of the disease until the bark is peeled. The same remedy, that of cutting out and around the diseased areas, is recommended in both cases.

The *Transactions of the Leicester Literary and Philosophical Society* (vol. ix., part i.) contain useful notes on the excursions made by the several sections. The society seems to have gone far afield in its studies. Thus Mr. Fox Strangways conducted a highly interesting excursion to Whitby, and Dr. B. Stracey contributes a sketch of the igneous rocks of Morven and the Inner Hebrides.

Mr. G. K. Gilbert has submitted to the trustees of the Carnegie Institution ("Year Book" No. 3, Washington) a plan for the investigation of subterranean temperature-gradient by means of a deep boring in plutonic rock. It is proposed that the boring be carried to a depth of 6000 feet, and that a site be selected in the Lithonia district of Georgia. Here a fairly uniform and massive granite extends about three miles in one direction and ten miles in another. It is regarded as of early Palæozoic or older age.

In an article on the pre-Glacial valleys of Northumberland and Durham (*Quart. Journ. Geol. Soc.*, February), Dr. D. Woolacott points out that while borings have proved buried valleys in the lower reaches, the higher parts of the ancient valleys belong to the present drainage. The Tyne and Tees were the major rivers, and the land stood at a higher elevation than now. The greatest recorded thickness of drift is 233 feet, and the maximum depth below sea-level is 141 feet. The author discusses the character of the uplift, the distribution of the drift, and its subsequent erosion.

The Nile flood in relation to the variations of atmospheric pressure in north-east Africa has been the subject of investigation by Captain H. G. Lyons, Director-General Survey Department of Egypt, and the important results of the inquiry were recently communicated to the Royal Society. The paper itself is too lengthy to allow of even a brief abstract being made in this place, but a *résumé* of the conclusions at which Captain Lyons has arrived may be given here instead. The curve of the Nile flood on the average varies inversely as the mean barometric pressure of the summer months, high and low pressures accompanying low and high floods respectively. The pressure variations are similar over wide areas from Beirut to Mauritius, and from Cairo to Hong Kong, and are generally of the Indian type of curve of the Lockyers or Bigelow's "direct" type. Sometimes the pressure at Beirut and Cairo is in disagreement with that of the rest of the area, approaching the "Cordoba" type of pressure of the Lockyers or the "indirect" type of Bigelow. Considering monthly means of atmospheric pressure, this relation is more clearly shown, and pressure above or below the normal in months of the rainy season of Abyssinia coincides closely with deficiency or excess of rainfall. From 1869 to 1903, an accurate prediction of the flood from month to month could have been made in six years out of seven. Using the conclusions derived from the above discussion for the condition of the Nile flow during the present year, Captain Lyons writes:—"With weak summer rains and high pressure conditions in September and the first part of October, no large amount of water can have been stored up in the soil of Abyssinia, so that the springs will run off early, and a very low stage may be expected in 1905."

The next meeting of the American Institute of Mining Engineers will be held at Washington in May. Special attention will be devoted to the discussion of papers relating to the genesis of ore deposits.

The gas turbine has been regarded as the logical successor of the steam turbine, and numerous devices have been suggested to convert the energy of the confined products of combustion into mechanical power. In a paper in the current issue of the *Engineering Magazine* Dr. C. E. Lucke examines the thermodynamic principles involved in such devices, and shows, as the result of experiments conducted at Columbia University, that this conversion is not effected by free expansion in simple nozzles. In short, the pure gas turbine, provided with the simple nozzles used by steam turbines, is a failure commercially, and cannot be otherwise until some method has been found to make results by free expansion more nearly equal to those obtained in cylinders.

In the *Engineering and Mining Journal* Mr. J. B. Jaquet gives particulars of a severe explosion of rock that occurred in the New Hillgrove Mine, New South Wales, on December 15, 1904. The shock was felt throughout the country for a mile or two around, and the area affected was more than 300 feet long and 100 feet high. These sudden outbursts have long been a source of anxiety to the miners of Hillgrove, and there is evidence to show that they are increasing in violence as greater depths are reached. Explosive rocks have been described as occurring in many parts of the world. In the Derbyshire lead mines, for example, slickensided rocks were described by Mr. A. Strahan as being liable to burst on being scratched with a pick. It has been suggested that the bursts are due to molecular strain, to occluded gases, or to a compression of the slates upon their being intruded by a mass of granite. Mr. Jaquet believes that the Hillgrove bursts are due to the walls being in a condition of strain and to the fact that the slate will not bend; it only breaks and disintegrates into a number of fragments.

On account of their resistance to the action of sea-water and of their mechanical properties when heated, a number of special brasses have during the past few years been applied in naval construction. In view of this, a paper published by M. L. Guillet in the *Bulletin de la Société d'Encouragement* becomes of some general interest; it deals in detail with the changes in the mechanical properties and in the microstructure of typical brasses which are caused by the addition of lead, tin, aluminium, and manganese. The influence of aluminium is particularly noteworthy. On adding from 0·5 per cent. to 5·0 per cent. of this metal to a brass containing 60 per cent. of copper and 40 per cent. of zinc, a deep golden colour is produced, whilst after adding more than 5 per cent. of aluminium the alloy becomes superbly rose-coloured. This effect is at its maximum at 7 per cent., and with 10 per cent. of aluminium the colour has become a silvery white. Corresponding with these variations of colour, striking changes in the internal structure of the alloy may be traced. It may be added that aluminium brasses have been applied in France in the construction of submarines, but they have not as yet given complete satisfaction.

The March number of the *Gazzetta* contains an interesting paper by Nicola Pappadà on the coagulation of dilute solutions of silicic acid under the influence of various substances. Organic compounds such as glucose, saccharose, the alcohols, &c., do not produce coagulation, and the phenomenon seems to be initiated solely by the presence of the positive ion of an electrolyte. The negative ion apparently is quite without influence on the rate of coagulation; equivalent quantities, for instance, of sodium chloride, sodium nitrate, and sodium sulphate cause coagulation to occur at exactly the same rate. The nature of the positive ion, on the other hand, exercises great influence on coagulation; in the case of the alkali metals the rate depends on the atomic weight, there being a regular sequence in the order lithium, sodium, potassium, rubidium, cæsium, the metal of greatest atomic weight bringing about coagulation most rapidly. Traces of acids and of acid salts, however, inhibit coagulation, an abnormal behaviour of the hydrogen ion being thus indicated, whilst alkalis always increase the rate of formation of a coagulum.

MESSRS. BURGOYNE, BURBIDGES AND CO. have recently sent us a new edition of their price list of pure chemicals and reagents manufactured by them. Part ii. of the catalogue contains a list of chemical and physical apparatus for laboratory or lecture purposes.

WE have received the May issue of the *Stonyhurst Magazine*, an excellent example of an illustrated college magazine. The "science notes," which are entirely astronomical, are illustrated by drawings made at Stonyhurst Observatory of the great sun-spot of February. There is also a collection of notes on the bird-life of the college district.

THE Cambridge University Press has published the first supplement of the second volume of "The Fauna and Geography of the Maldive and Laccadive Archipelagoes, being the Account of the Work carried on and of the Collections made by an Expedition during the Years 1899 and 1900," which is being edited by Mr. J. Stanley Gardiner. An index is in course of preparation, and will be published shortly.

PROF. J. J. THOMSON'S work on "Electricity and Matter," containing six lectures delivered by the author at the University of Yale in 1903, has been translated into Italian by Prof. G. Faè, and published as one of the Hoepli manuals. In the opening paragraph of a short introduction to the work, Prof. Faè quotes the remark made by Sir Oliver Lodge in our columns that the volume is "Altogether a fascinating and most readable book for students of physics and chemistry."

WE have received from Messrs. Taylor, Taylor and Hobson, Ltd., of Leicester, a very neatly got up catalogue of their photographic lenses. These, as is well known, are of many varieties, and the particular features are that they are composed of three thin glasses, uncemented, and accurately adjusted to produce with full aperture sharp definition evenly throughout the plate. The principles of the action of a lens are clearly described and illustrated by Mr. William Taylor, and an interesting series of illustrations is given showing the manipulation of the glass in their works from the rough blocks to the finished lenses.

THE 1905 issue of the "Statesman's Year-book" has now been published by Messrs. Macmillan and Co., Ltd. The statistical and other information in the new issue has been brought up to the latest available date, in some cases to the end of 1904. Much alteration has been involved by the Anglo-French Convention of 1904 and by the administrative re-arrangement of French West African possessions. The space devoted to Germany as a whole, especially education, has been increased; Bulgarian statistics have been much extended; the Philippine Islands have been treated more fully; and numerous other sections have been largely re-written and thoroughly revised. Two interesting tables are included, one showing the losses sustained by the Russian and Japanese forces in the present war, and the other showing the penetrative power of the projectiles used. As usual, the maps and diagrams are numerous, well executed, and of great value—among them may be mentioned one showing the new naval distribution scheme, and one illustrating the British meat imports from abroad. The "Statesman's Year-book" is likely long to retain the high place it has held for many years among books of reference.

THE annual report of the Board of Scientific Advice for India for the year 1903–4 has been received. With the exception of that part of the report relating to the work of the Survey of India, it is based upon the departmental reports for the year under consideration. The information included is arranged under the following headings:—trigonometrical survey, topographical survey, forest survey, cadastral and traverse survey, geographical surveys and reconnaissances, total outturn, geodetic, marine survey, astronomical work, meteorology, geology, zoological survey, veterinary science, botanical survey, applied botany, and chemistry. It is worthy of note that the report contains no list of names of the men of science constituting the Board of Scientific Advice, nor are there reports of any meetings of the Board. The portion of the report relating to the work of the Survey of India is based on the report of that department for 1902–3 published in 1904, and certain other items embodying information of later date than the period covered by any of the other reports. The publication as a whole may be described as a *résumé* of individual departmental reports; it contains scarcely anything in the way of recommendations for the future guidance of departmental work, and little that is to be identified as the special function of a Board of Scientific Advice.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN MAY:—

May 1. Vesta 6° S. of β Leonis.
,, 2. 9h. 38m. Minimum of Algol (β Persei).
,, 2. 6h. Epoch of Aquarid meteoric shower (Radiant 338°–2°).
,, 3. 18h. Jupiter in conjunction with the Sun.
,, 6. 5h. 28m. to 6h. 30m. Moon occults α Tauri (Aldebaran).
,, 8. 8h. Mars in opposition to the Sun.
,, 12. 8h. 46m. to 9h. 53m. Moon occults A Leonis (mag. 4·6).
,, 15. Venus. Illuminated portion of disc = 0·100; of Mars = 0·997.
,, 17. 10h. Mars in conjunction with Moon, Mars 5° 10′ S.
,, 20. 23h. Mercury at greatest W. elongation, 25° 26′.
,, 22. 11h. 20m. Minimum of Algol (β Persei).
,, 24. Saturn. Outer major axis of outer ring = 39″·50; minor axis of outer ring = 5″·88.
,, 25. 13h. Saturn in conjunction with Moon, Saturn 1° 39′ S.

ELEMENTS AND EPHEMERIS FOR COMET 1905 *a* (GIACOBINI).—A set of elements and an ephemeris (April 6–30) for comet 1905 *a* have been communicated, by General Bassot, of the Nizza Observatory, to No. 4010 of the *Astronomische Nachrichten*. These were computed from observations made at Nice on March 26, 28, and 30, and the elements agree closely with two other sets computed at Harvard and Paris respectively, and published in the same journal. The elements and an extract from the ephemeris are here given:—

Elements.

T = 1905 April 4·141 (Paris M.T.)

$$\left.\begin{array}{l} \omega = 358^\circ\ 18'\cdot 0 \\ \Omega = 157\ \ \ 7\cdot 1 \\ i = 40\ \ 24\cdot 8 \end{array}\right\} 1905\cdot 0$$

$$\log q = 0\cdot 04836$$

Ephemeris 12h. (M.T. Paris).

1905	α h. m. s.	δ ° ′	log Δ	Brightness
April 26	8 9 33	+43 1·0	9·9079	0·70
27	8 15 24	+43 38·8		
28	8 21 17	+44 14·3		
29	8 27 13	+44 47·3		
30	8 33 11	+45 17·5	9·9247	0·61

Brightness at time of discovery = 1·0.

An observation by Dr. Palisa at Vienna on April 8 gave a correction of +2s. and +0′·2.

Changes on Mars.—A telegram from Mr. Lowell, published in No. 4010 of the *Astronomische Nachrichten,* announces that colour changes similar to those previously reported are again taking place in some of the Martian features. The Mare Erythræum, just above Syrtis, has again changed from a blue-green to a chocolate-brown colour. This change was first observed by Mr. Lampland on April 4, and the Martian season now corresponds to our February.

In a communication to No. 4, vol. xiii., of *Popular Astronomy,* Prof. W. H. Pickering observes that ice will probably begin to form at *both* poles of Mars during the present month, the north pole being turned towards the earth at an angle of 10°–13°. This opposition is particularly favourable for observations of the green colour over a greater part of the planet's surface, as Mars will be more favourably situated than during the preceding or the following opposition. Its apparent diameter will be from 13″ to 17″, and the poles should appear either of a pure white, a light yellow, or a vivid green colour, the first named being due to hoar-frost or snow, the second to clouds, and the last named, in part at least, to vegetation.

Photography of Planetary Nebulæ.—In No. 356 of the *Observatory* Mr. W. S. Franks suggests that special attention should be paid to the photography of planetary nebulæ by those observatories which possess *long-focus* cameras. Whilst using the late Dr. Roberts's 98-inch "Starfield" reflector, Mr. Franks attempted to photograph these interesting objects both with and without a secondary magnifier, but in the first case the images obtained were indistinguishable from those of the surrounding stars, whilst in the latter the definition was very unsatisfactory.

One point which is strongly in favour of anyone entering this field of research is the fact that the light emitted by these objects is of a highly actinic character necessitating only short exposures.

Radial Velocities of "Standard-velocity Stars."—No. 3, vol. i., of the *Mitteilungen* of the Nicholas Observatory, Pulkowa, contains a number of results obtained by Prof. Belopolsky for the values of the radial velocities of the "standard-velocity" stars. Each of the values was obtained from the measurement of about fifteen iron lines on a single plate, and the date, time, and hour-angle is given in each case. The stars dealt with in the present publication are α Arietis, α Persei, ε Pegasi, and β Geminorum, and taking the mean of the several values given in each case the following respective velocities are obtained:— −12·30 km., −2·14 km., +5·72 km. (one plate) and +4·21 km.

Magnitude Equation in the Right Ascensions of the Eros Stars.—In *Bulletin* No. 72 of the Lick Observatory Prof. R. H. Tucker discusses the magnitude equation which enters into the observations of the right ascensions of the Eros stars as observed at various stations engaged in the work. Comparing the equations in the first and second Eros lists, it is found that there is no marked similarity between the two sets observed at the same station; different instruments, and probably in some cases different observers, having been employed. At Lick the effect of magnitude has been measured by screen observations at three different epochs for the same observer and instrument. For clock stars the correction obtained was 0·007 second per magnitude, and, assuming it to vary with declination, this would give 0·010 second and 0·008 second per magnitude for the first and second lists respectively. Confirmation of this, in general, is found in the Königsberg results obtained with a clock-driven micrometer in which it is assumed that the magnitude equation is eliminated. Other tables given show the variation of the error with varying magnitudes.

MEMOIRS ON MARINE BIOLOGY.

The study of marine life by the sea-side is not only a delightful occupation in itself, but is now considered as an almost essential part of the training of every young biologist. It is also one of the most fruitful fields of inquiry for the elucidation of the fundamental problems of biology. Several marine stations have now been erected on our coasts, in which a naturalist may gain a practical knowledge of the rich fauna and flora of the sea, and where he may apply those modern and often expensive methods of experiment and research which can only be carried out in a well equipped laboratory.

Among the most successful of these institutions is that of the Liverpool Marine Biology Committee, established first on Puffin Island in 1887, and subsequently moved to its present quarters at Port Erin. It is chiefly due, we believe, to the efforts and enthusiasm of Prof. W. H. Herdman that this laboratory was founded. To help the student to make good use of its resources, Prof. Herdman is now editing a series of small practical monographs known as the L.M.B.C. *Memoirs.* Much valuable time may be wasted, many serious errors may be committed, and many precious opportunities may be lost in the practical study of marine biology through the want of proper guidance, or through the ignorance of the literature of the subject. Well stocked libraries are rarely to be found near at hand, and, moreover, it often happens that the commonest animals and plants are just those which have been least completely described in readily accessible works. It is with a view to remedy these defects that the memoirs are being published. As the editor tells us in his preface, the series deals with those types which have hitherto not been adequately described in English text-books and laboratory manuals.

Some thirty volumes are promised. They range over almost the whole of marine life—from the diatom to the sea-weed, from the sponge to the porpoise. Twelve volumes have already appeared. These are:—(1) Ascidia, by the editor; (2) Cardium, by J. Johnstone; (3) Echinus, by H. C. Chadwick; (4) Codium, by R. J. H. Gibson and Helen Auld; (5) Alcyonium, by S. J. Hickson; (6) Lepeophtheirus and Lernæa, by Andrew Scott; (7) Lineus, by R. C. Punnett; (8) Pleuronectes, by F. C. Cole and J. Johnstone; (9) Chondrus, by O. V. Darbishire; (10) Patella, by J. R. A. Davis and H. J. Fleure; (11) Arenicola, by J. H. Ashworth; (12) Gammarus, by M. Cussans. Not only is a detailed and accurate account given of the structure of each type, but its habits, life-history, and embryology are also dealt with, and its "economic" aspects are not forgotten.

On the whole, the various monographs seem to us most trustworthy, and reflect great credit on the work of the authors, who, indeed, are for the most part specialists thoroughly familiar with the types they describe. Yet it must be confessed that the volumes differ considerably in merit and attractiveness. Some of them contain little that is either new or original. Among the most interesting of those already published we may mention the excellent volume on the plaice, Pleuronectes, by Messrs. Cole and Johnstone, which has already been reviewed in Nature, also the memoir on Arenicola by Mr. Ashworth. Both these seem to us models of what such monographs should be—clear and practical descriptions of the anatomy and life-history of the animals concerned, with some discussion of the general problems suggested, and good illustrations. Naturally enough the embryology is in most cases very briefly described, and often the accounts provided are chiefly derived from the works of other authors. We question, indeed, whether it is really worth while reproducing in such monographs figures illustrating the development which can be found in almost any text-book.

While both a table of contents at the beginning, and an index at the end, may not always be necessary, yet it is a pity that many of the monographs should be published with neither. In some cases, also, the figures are scarcely clear enough; but considering the very moderate price at which they are issued, the L.M.B.C. *Memoirs* are excellently printed and illustrated. They will doubtless fully justify the hope of the editor, and will prove most useful to students of marine biology, who will await with eagerness the appearance of the remaining volumes.

THE PHYSICAL HISTORY OF THE VICTORIA FALLS.[1]

WHEN Dr. Livingstone discovered the Victoria Falls in 1855, he sought to explain their origin by calling in volcanic agency, and stated that they were "simply caused by a crack made in the hard basaltic rock from the right to the left bank of the Zambezi, and then prolonged from the left bank away through 30 or 40 miles of hills." All subsequent travellers support the same idea; but in his article Mr. Molyneux, in the *Geographical Journal*, claims that, as at Niagara, the combination of cañon, gorge, chasm, and falls is due to erosion and the constant reducing action of the Zambezi River (Fig. 1).

In explaining his theory, the author first refers to present-day conditions of the river, and divides it into three portions; the coastal, stretching 360 miles up as far as the Kebrabasa Range—a portion of the mountain axis of South Africa—through which it runs in a gorge 35 to 40 miles in length. The middle reach is 600 miles long, in low-lying country, and is divided from the upper regions of the river by the high Victoria Falls, 1000 miles from the coast.

The geology of the country around the falls is then sketched briefly. During what was probably the Tertiary period, South Central Africa was subject to vigorous volcanic action, the concrete forms of which can now be seen in the denuded and exposed lava-flows of the Limpopo and Zambezi valleys. In the vicinity of the falls, the Batoka country, the basalt is interbedded with the soft forest sandstones, but the Zambezi River, in draining the ancient lake regions of Central Africa, has eaten into the overlying sediments until it has reached the hard and almost level igneous sheet in which the falls occur. This sheet extends from the end of the cañon, 40 miles east of the falls, to beyond the Gonye Falls, 120 miles north-west.

On reaching the top of this sheet, the erosive action of the river was checked; but conditions were more favourable in the middle regions of the river, which had no protective covering, and where the rocks are unresisting sandstones and Coal-measures. A difference of level between the two regions came into existence—defined by the eastern edge or fringe of the basalt sheet.

It may be understood that the eastern edge would be thin, and the backward erosion of the Zambezi from its middle reaches would quickly break into it. But as the thickness of the basalt increased as the river receded westwards, the cutting action became slower, until the rate of deepening of the middle reach and Kebrabasa gorge far outstripped the slower process of forming the Grand Cañon of the Victoria Falls. The difference between the river bed where running on the basalt sheet and the altitude of the central reach became more exaggerated as time passed. Including the height of the falls (400 feet), this difference is now about 1000 feet.

Of the process by which the river cut back this Grand Cañon and shaped the falls as they are seen to-day, the author states that, as is common to all rocks of this nature, it is full of cracks and fissures due to contraction, generally assuming a columnar form. These columns can be seen at low water along the lip of the falls, more or

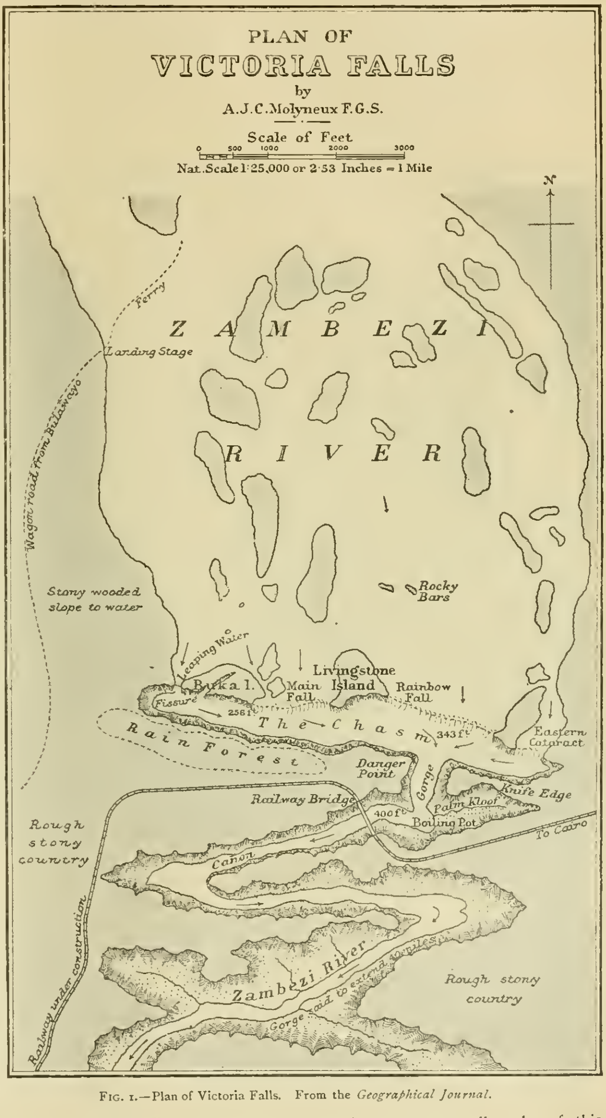

FIG. 1.—Plan of Victoria Falls. From the *Geographical Journal*.

[1] Abstract of a paper by Mr. A. J. C. Molyneux in the *Geographical Journal* for January.

less truncated as the verge is reached, and bearing little evidence of attrition (Fig. 2). Mr. Molyneux is of opinion that the cutting back of the falls is due to the perpetual hammering action of the vast bodies of water falling into, and down upon, the cracks between the basalt columns, assisted by the constant vibration of the rock from the precipitated masses of water, and that by this constantly exerted force the columns are rent asunder and fall into the chasm, taking with them huge and deep flakes of the precipice. At low water heaps of these blocks, as yet angular and unreduced, may be seen in the shallower ends of the chasm.

Such is one phase of the erosion of the falls. Another power is at work below the water line. The blocks that fall into the chasm disappear in the deeper waters at the jaws of the gorge—yet, impelled by the rush of the current in the confined walls, they must be grinding down and perpetually deepening the cañon, to emerge at the eastern end as rounded pebbles and form the shingle beds of the middle reaches.

The extraordinary zig-zags or acute angles in the cañon have always aroused comment, and the author thinks that two main causes are responsible for them—the position of islands that probably studded the river (as now) and also the existence of master joints and fissures in the basalt. On Boaruka Island this action is exemplified in a striking manner, for a stream can be seen falling down a crevice, that forms, peculiarly enough, another acute angle with the chasm.

Granted that the falls are due to the action of moving water, such parts as are protected by islands must be free from such erosion. To-day there are three important islands on the lip of the chasm, and more than fourteen large ones in 4 miles of river above the falls. In the channels between, there must be more prolonged submission to moving currents, by which the cataracts at the ends of the chasm are being deepened into sloping by-washes.

The falls have checked the deepening of the Upper Zambezi, and until they chisel the groove of the Grand Cañon back to the western edge of the basalt sheet, the upper reaches must continue to run at a high altitude and amid low-lying hills. This has prevented the Zambezi becoming a navigable river throughout, and has also had a marked influence on the geography of South Africa.

SEISMOLOGICAL NOTES.

THE attraction of the moon has always been felt by earthquake workers, whatever may be its effect on earthquakes themselves. The latest contributions to this aspect of seismology are two papers in No. 18 of the *Publications* of the Earthquake Investigation Committee in Japan. Prof. Omori deals with the lunar daily distribution, finding maxima of frequency between oh. and 5h., and again between 12h. and 13h., reckoning from the upper culmination. Dr. Imamura, dealing with the synodic monthly variation in frequency, finds that this shows an increase at the syzygies and quadratures; the former is attributed to the combined effects of the attraction of the sun and the moon, while the latter is explained by the fact that the time of high water at Tokio then coincides with that of the diurnal maximum of barometric pressure. In spite of the ingenuity of this explanation, its validity seems doubtful, for the stresses involved can at most be only a subsidiary cause of earthquakes, and consequently any effect due to them would naturally be looked for at the time when they vary most rapidly in amount rather than at that of their maximum.

The same publication contains a paper, of some importance in this connection, on daily periodic changes of level in artesian wells, by K. Honda. It is the account of a record, obtained by a self-registering instrument, of the daily changes in level of two artesian wells, 380 metres and 300 metres depth, in Tokio and Yokohama. Each of them showed a periodic change of level which is directly correlated with the tides in the neighbouring sea, and also a variation due to changes in barometric pressure, of such amount as to show that one-third of the changes in the first case, and one-fourth in the second, are absorbed by the rocks overlying the water-bearing stratum.

The catalogue of earthquakes felt in Austria during the year 1903, forming No. 26 of the *Mitteilungen* of the Austrian Earthquake Commission, is the last of the series which will be published under the auspices of the Academy of Sciences. In the introduction to the catalogue it is announced that from the beginning of 1904 the task of collecting and publishing the records of all earthquakes, whether of local or distant origin, observed in Austria, was taken over by the Zentralanstalt für Meteorologie und Geodynamik. The Earthquake Commission, having published the earthquake registers up to the end of 1903, will in future confine itself to the encouragement and publication of purely scientific investigations.

After the collapse of the campanile of St. Mark's, in 1902, there was a popular demand, inspired by the idea that the detonation was likely to precipitate the destruction of other historic buildings in Venice, for the cessation of the usual mid-day gun. The idea was, of course, unfounded, but to allay the alarm Prof. Vicentini was requested to instal one of his microseismographs, and his report has now been published. The instrument was attached to the wall of the ducal palace which faces the lagoon and is directly exposed to the sound waves of the cannon; it indicated a vertical displacement, in consequence of the report, of 0·012 mm. to 0·014 mm., and a horizontal displacement of 0·007 mm. to 0·012 mm., being about one-half of those produced by a person jumping on the floor of the room in which the instrument was installed, and one-fifteenth of the displacement caused by a high wind. From these figures it is evident that the sound waves of a cannon can have no appreciable effect on a building, though plaster may be detached where this has become loosened and separated from the wall by an air space.

SOCIETIES AND ACADEMIES.

London.

Royal Society, February 23.—"The Colour-physiology of the Higher Crustacea," Part iii. By F. **Keeble** and Dr. F. W. **Gamble**. Communicated by Prof. Sydney J. Hickson, F.R.S.

(1) The chromatophores of Hippolyte and Crangon are multicellular structures. Their branches show differentiation into a firmer ectoplasm and a more fluid mobile endoplasm in which the pigment occurs. (2) The formation of the pigments in the larval and post-larval chromatophores is described. (3) In addition to pigments, fat, in the form of colourless globules, occurs in the chromatophores of Hippolyte. This fat lies in special cells of the chromatophore, and exhibits a mobility similar to that of the pigments of the chromatophore. (4) If fed and kept in the dark, or if starved and kept in the light, Hippolyte loses little of its chromatophoric fat. Depletion of fat occurs, however, in starved, dark-kept animals. These, when exposed to sunlight for five or six hours, show fat in their chromatophores. These results show that the colourless chromatophoric fat is a reserve food material, and point to the conclusion that in the accumulation of this reserve fat light plays an important part. (5) At the time of settling on the weeds of the sea-shore, *Hippolyte varians* is a colourless or faintly brown-striped animal. At this stage it is extremely sensitive to the light conditions of its environment, assuming the colour of its surroundings within twenty-four hours. If the environment be changed, sympathetic change of colour takes place in three days. Half- and full-grown Hippolyte are less susceptible. With them sympathetic colour-change occupies a week or more.

March 30.—"On the Distribution of Velocity in a Viscous Fluid over the Cross-section of a Pipe, and on the Action at the Critical Velocity." By J. **Morrow**. Communicated by Prof. H. S. Hele-Shaw, F.R.S.

Summary and Conclusion.—(1) The experiments provide a partial confirmation of the theoretically obtained law of velocity distribution, but show that this distribution can only be obtained under very special conditions, of which absolute freedom from obstructions and end effects are important; and hence (2) When the flow is direct and stream-lines exist, the velocity distribution is not necessarily exactly that which may be described as characteristic of "normal" flow. (3) At the critical velocity the irrotational straight line motion ceases and is followed by one in which the paths of the particles of fluid are eddying and turbulent. The law of distribution of mean linear velocity parallel to the axis simultaneously changes from the parabolic (or approximately parabolic) to that typical of eddying motion. (4) The critical velocity in question (being that at which eddying motion ceases to be transformed into direct motion, and not that at which a highly unstable stream-line motion is suddenly disturbed) is not accompanied by a sudden change in the velocity parallel to the axis at any point in the cross-section. On the other hand, as the total flux increases, the experiments show a gradual transition from one state to the other, due to the change which has occurred in the law of velocity distribution. (5) The observations have little bearing on the upper limit of stream-line flow, as observed by colour bands. They indicate, however, that the unstable direct motion would follow an approximately parabolic law of velocity distribution (as represented by the equation obtained for stream-line motion), and that at the higher critical velocity this distribution would suddenly change to that represented by the equation given for eddying motion. In this case, then, instead of a gradual change of velocity, there would actually be sudden and large changes in the velocity parallel to the axis at different points in the cross-section of the pipe. (6) The "Pitot law" ($v=\sqrt{2gh}$) is at least approximately true at exceedingly low velocities.

April 6.—"The Influence of Cobra-venom on the Proteid Metabolism." By Dr. J. **Scott**. Communicated by Sir Thomas R. Fraser, F.R.S.

Conclusions.—(1) Practically no change in rate of proteid metabolism was induced by the administration of cobra-venom, in spite of well marked local reaction. (2) A slight decrease in the proportion of urea nitrogen, quite insignificant compared with that produced by diphtheria toxin and various drugs, was observed. (3) A slight rise in the proportion of ammonia nitrogen occurred. (4) There was a slight rise in the proportion of nitrogen in purin bodies. (5) The nitrogen in other compounds showed no constant change. (6) The P_2O_5 excreted showed no constant change, but in two experiments there was a slight rise. The change produced in the proteid metabolism is, therefore, small, and such as it is, being in the directions of decreased elaboration of urea and increase in the proportion of nitrogen excreted as ammonia, it seems to indicate a slight toxic action on the hepatic metabolism rather than a general action on the proteid changes, and tends to confirm the view that the poison acts chiefly upon the nervous system.

Entomological Society, April 5.—Mr. F. Merrifield, president, in the chair.—Specimens of a melanic Grammoptera, discovered by Mr. J. C. T. Poole at Enfield, and apparently quite distinct from any member of the genus taken in Britain: H. St. J. **Donisthorpe**. Mr. Gahan, to whom the species had been referred, considered it to be a form of *G. ruficornis*.—A specimen of *Megalopus melipoma*, Bates, an insect which so much resembles a bee that Bates had said they were indistinguishable in nature: M. **Jacoby**.—Specimens of *Papilio macleayana* and *Hypocysta metirius* captured in Queensland, illustrating the use of "directive" markings in the Rhopalocera in influencing their enemies to attack non-vital parts: A. **Bacot**.—An example of *Ceratopterus stahli*, Wast., a beetle from Australia possessing notable powers of crepitation: G. J. **Arrow**.—A series of *Erebia alecto* (*glacialis*), var. *nicholli*, Obth., taken at about 8000 feet at Campiglio, South Tyrol, with specimens of *Dasydia tenebraria*, var. *wockearia*, caught in the company of the Erebias in the same localities; when upon the wing the two species were not dissimilar: A. H. **Jones** and H. **Rowland-Brown**. Mr. Jones also exhibited examples of *Erebia melas* from the Parnassus Mountains, Greece, for comparison, and fine forms of butterflies found at Mendel, near Botzen.—A series of *Morpho adonis* from British Guiana, with the very rare dimorphic black and white female: W. J. **Kaye**.—The social web and pupal shells of *Eucheira socialis*, Westw., together with specimens of the perfect insect, being the actual nest from Mexico described and figured by Westwood in the *Transactions* for 1836: Dr. F. A. **Dixey**. After Dr. Dixey had read a note upon the habits of this and similar species, the Rev. W. T. Holland, of Pittsburg, Pa., U.S.A., gave his personal experiences of social silk-cocoon spinning species also from Mexico. —A note recently received from Mr. S. A. Neave giving further interesting evidence of the superstitious dread of larvæ with terrifying eye-like markings entertained by South African natives: Prof. E. B. **Poulton**.—Experiments to ascertain the vitality of pupæ subjected to submersion: F. **Merrifield**.—*Pseudacraea poggei* and *Limnas chrysippus*; the numerical proportion of mimic to model: H. A. **Byatt**.—A monograph on the genus Ogyris: G. **Bethune-Baker**.

Geological Society, April 5.—Dr. J. E. Marr. F.R.S. president, in the chair.—On the divisions and correlation of the upper portion of the Coal-measures, with special reference to their development in the midland counties of England: R. **Kidston**. The following classification of the Coal-measures is proposed by the author:—

Proposed names		Names previously used
(4) Radstockian Series	=	Upper Coal-measures.
(3) Staffordian Series	=	Transition Series.
(2) Westphalian Series	=	Middle Coal-measures.
(1) Lanarkian Series	=	Lower Coal-measures (including the Millstone Grit).

—On the age and relations of the phosphatic chalk of Taplow: H. J. O. **White** and L. **Treacher**. The rocks at the locality of Taplow are described in detail, and the following classification is adopted:—(E) Upper White Chalk (visible), 16 feet; (D) Upper Brown Chalk, or rich phosphatic band, about 8 feet; (C) Middle White Chalk, about 16 feet; (B) Lower Brown Chalk, or rich phosphatic band, about 4 feet; (A) Lower White Chalk (visible), 17 feet. Fossil-lists are given from each of the above divisions, and the authors conclude that the Lower White Chalk belongs to the zone of *Micraster cor-anguinum*, and the succeeding beds to that of *Marsupites testudinarius*; while the lower phosphate-band represents the lower part of the Uintacrinus-band, and the upper one that of the Marsupites-band of that zone.

Physical Society, April 14.—Dr. R. T. Glazebrook, F.R.S., past-president, in the chair.—Ellipsoidal lenses: R. J. **Sowter**. The paper extends the treatment of thin ellipsoidal or astigmatic lenses, and gives a simple solution for complex problems of the following types:—"To determine the astigmatic pencil, after refraction of an astigmatic pencil by an ellipsoidal lens." And "to find the ellipsoidal lens equivalent to two cylindrical lenses placed a definite distance apart, with their axes inclined at any angle." The method of treatment can be applied to crossed ellipsoidal lenses, in contact, or separated, and is applicable in general to astigmatic pencils.—Determination of the moment of inertia of the magnets used in the measurement of the horizontal component of the earth's field: Dr. W. **Watson**. One of the constants required when determining the horizontal component of the earth's magnetic field by the ordinary method is the moment of inertia of the magnet which is used in the vibration experiment. It is usual to determine the moment of inertia of the cylindrical brass bar supplied with each instrument by calculation, then by measuring the period of the magnet alone, and when loaded with this bar to calculate the moment of inertia of the magnet. This method presupposes that the density of the inertia-bar is uniform throughout. It is not easy to secure a bar of which the density is uniform throughout, and further it is difficult to test whether such uniformity has been secured. The author thinks that more trustworthy and uniform results would be obtained by determining once for all, with very great care, the moment of inertia of a standard bar and then determining the moment of inertia of the bars supplied with the different magnetometers, by comparing them with the standard bar experimentally. In the paper is described an instrument suitable for comparing the moment of inertia of bars, together with some experiments made with a view to determine the moment of inertia of a standard bar, and an investigation of the influence of the air upon the period.—Exhibition of a series of lecture experiments illustrating the properties of the gaseous ions produced by radium and other sources: Dr. W. **Watson**.

Royal Astronomical Society, April 14.—Mr. W. H. Maw, president, in the chair.—Spherical aberration of object glasses: A. E. **Conrady**. The paper dealt with the difference of phase at the focus caused by the spherical aberration. Two different rigorous solutions, by which such differences could be conveniently computed, were deduced and discussed. The paper also dealt with the relation between these differences of phase and spherical aberration in the geometrical sense.—(1) A suggested arrangement for the mounting of a cœlostat; (2) point distributions on a sphere, with remarks on the determination of the apex of the sun's motion: H. C. **Plummer**.—The four-prism spectrograph attached to the Newall telescope of the Cambridge Observatory, with remarks on the general design of spectrographs for equatorials of large aperture, considered from the point of view of "tremor-discs": H. F. **Newall**.

Royal Meteorological Society, April 19.—Mr. Richard Bentley, president, in the chair.—An account of the observations at Crinan in 1904, and description of a new meteorograph for use with kites: W. H. **Dines**. These observations, which are carried out under the direction of a joint committee of the Royal Meteorological Society and of the British Association, are made with meteorographs attached to kites with the object of ascertaining the conditions prevailing in the upper atmosphere. During last summer the kites were flown from the deck of H.M.S. *Seahorse*, which was placed at the disposal of the committee by the Admiralty. Mr. Dines designed a new and inexpensive meteorograph, which he now fully described. The weather conditions of last summer were somewhat unusual, there being a decided preponderance of east and south-east winds. Near the summit of Ben Nevis the air was often dry, and was on several occasions warmer than the air at the same level at Crinan. As a rule, however, the temperature on Ben Nevis is generally much lower than the temperature in the free air at the same level. On several occasions temperature inversions were observed at levels between 3000 feet and 7000 feet. A fact previously noticed was again observed, viz. the decrease of strength of easterly winds with elevation.—Rate of fall of rain at Seathwaite: Dr. H. R. **Mill**. This is a discussion of the records from a Negretti and Zambra self-recording rain gauge during a period of eighteen months. Seathwaite, which is in Borrowdale, Cumberland, is in almost the wettest spot of the British Isles, the average yearly rainfall being about 137 inches. Dr. Mill's results seem to show that the rainfall at Seathwaite in an average year indicates a tendency to be greater during the hours of darkness than in daylight, that rather less than half the time during which rain is falling it continues without intermission for at least six hours at a time, and that rather more than half the total amount of rain is deposited in such long showers.

DUBLIN.

Royal Dublin Society, March 21.—Sir Howard Grubb, F.R.S., in the chair.—(*a*) The temperature of healthy dairy cattle, (*b*) the temperature of tuberculous cattle, not clinically affected: Prof. G. H. **Wooldridge.** The author made 520 observations on 63 healthy dairy cattle which were subsequently submitted to the tuberculin test, and failing to react were considered free from the disease. His conclusions are that the temperature may vary between 100°·4 F. and 100°·8 F., with an average mean temperature of 101°·4 F. Feeding caused an average rise of 0°·3 F. above the temperature of the same cattle at the same time on other days, but not feeding. In the afternoon, between 4 and 5 o'clock, the average temperature was 0°·5 higher than at 8 a.m. Pregnant cows had an average temperature 0°·3 F. higher than the average of the other cattle in the same building. Tuberculous cattle numbering 74, apparently perfectly healthy, but subsequently reacting to tuberculin, were the subjects of 505 observations. These animals had a much wider range of variations. The average was 101°·7 F. The lowest observed was 100°·4 F. and the highest 104°·3 F. The widest range of an individual was from 100°·7 F. to 104°·3 F., with an average of 102°·2 F. (temperature taken 15 times). Out of 137 apparently healthy dairy cattle, 74 (54 per cent.) reacted to tuberculin, thus emphasising the advisability of using that agent in attempts to obtain a dairy free from tuberculosis.—On the petrological examination of macadam: Prof. J. **Joly,** F.R.S. Various specimens of macadam used on Scottish roads have been examined. The general results of the investigation are to elucidate the characteristics of these macadams, as well as apparent abnormalities of behaviour, and to demonstrate the value of petrological methods in such cases.—On the construction of fume-chambers with effective ventilation: Prof. W. N. **Hartley,** F.R.S. The results of a series of experiments on ventilation and of practical experience with fume-chambers have shown the conditions which are necessary for the removal of noxious fumes from a chemical laboratory with the greatest efficiency and the least possible trouble and expense. Measurements were made daily over a period of six months of the gas burnt, the air extracted, the difference between inside and outside temperatures, the barometric pressure, the direction of the wind and its strength. The direction and dimensions of the flues, and the relation of the passage of air up the flues to the cubic contents of the chambers, are stated. The average quantity of air exhausted per minute was 354 cubic feet per chamber of 51 cubic feet, and on an average the air of each chamber is completely changed every nine seconds. The small height of the flues, being 25 feet, renders such a means of ventilation as that described readily adaptable to small out-buildings, such as school laboratories. Details are given as to the construction of flues with a descending draught as fitted to a lecture table and fume-chamber in a lecture room.—On the structure of water-jets and the effect of sound upon them, part ii.: Philip E. **Belas.**

EDINBURGH.

Royal Society, February 20.—Sir John Murray in the chair.—On the graptolite-bearing rocks of the South Orkney Islands: Dr. J. Harvey **Pirie.** The presence of Silurian sedimentary rocks in these isolated islands indicates a former much greater extension of land in the area lying to the south-east of Cape Horn. The fossils Pleurograptus and Discinocaris indicate their age as corresponding to the Caradoc or Lower Llandovery, and the structure of the rocks suggests that they belong to the same series as the Silurian rocks of the Argentine.—Palæontology of the Upper Old Red Sandstone of the Moray Firth area: Dr. R. H. **Traquair.** The fossils discussed in this paper, which embodied the research of the past fourteen years, were almost entirely fish remains, other remains, in the shape of badly preserved plants and certain tracks, probably of invertebrate animals, being rare. Twenty-one species of fish were recorded, of which only seven were known from the Upper Old Red of this region when the author took up the subject. The character of the fish remains suggested the division of the strata of the Moray Firth Upper Old Red into three zones, these being, in ascending order, the Nairn, Alves, and Rosebrae beds. Reference was made to the affinity of the Rosebrae fish-fauna with that of Dura Den, the yellow sandstones of which locality constitute the highest member of the Upper Old Red of Fifeshire. Dr. Traquair specially desired to acknowledge his great indebtedness to Mr. W. Taylor, of Lhanbryde, without whose assistance in furnishing material the paper could not have been prepared.—The constitution of complex salts, i., derivatives of the sesquioxides: A. T. **Cameron.** Retger's method of investigating isomorphous mixtures was applied to the blue chromoxalates of ammonium and potassium, and showed that they had no definite composition, there being, therefore, no conclusive reason for doubling the formulæ of these and similar compounds. The striking analogy between the so-called double fluorides, chlorides, cyanides, &c., and the complex derivatives of dibasic acids was pointed out. It was shown that to almost all such compounds, whether derived from monobasic or dibasic acids, simple constitutions can be assigned by supposing the hydroxyl radicals of the metallic hydroxide to be replaced by complex groups.—Theorems relating to a generalisation of Bessel's function, ii.: Rev. F. H. **Jackson.**

March 6.—Lord M'Laren in the chair.—A study of three vegetarian diets: Drs. Noël **Paton** and J. C. **Dunlop.** Of the three diets described, one was a totally insufficient diet of bananas, a second was a fairly typical vegetarian diet showing the difficulty of avoiding an excess of sugary food, and the third was the far from economical diet of a vegetarian glutton. These were compared with the diets of the labouring classes in cities as illustrated by the author's own investigations in Edinburgh, and those of Rowntree, Alswater, and Lumsden respectively in York, New York, and Dublin, and as regards rural districts by Wilson Fox's report. It was shown that these normal diets more nearly approached the physiological standard than the vegetarian diets studied.—A further contribution to the fresh-water plankton of the Scottish lochs: W. and G. S. **West.** The thirty-six lochs studied were in the north-west Highlands. There was an abundance of Desmids, a fact attributed to the geological character of the country. The Protococcoideæ were not abundant, in marked contrast to what occurs in Continental Europe. Diatoms were very abundant, and did not disappear in May and June. Myxophyceæ, again, were relatively few. The Swedish lakes alone approached the Scottish in the richness of the plankton. The Danish plankton was relatively much poorer in Chlorophyceæ, especially Conjugates. This was to be attributed principally to the fact that the geological formations are mostly of Tertiary age.—On the Sarcodina of Loch Ness: Dr. E. **Penard.** Of a list of nearly fifty species of Rhizopods and Heliozoa obtained at depths of upwards of 250 feet, several were of interest on account of their rarity, some being found for the first time in Europe, others being previously known only from the Lake of Geneva. The majority of the Rhizopoda had probably been derived from the shallow margins of the lake or from the neighbouring peat bogs; but some half dozen species or varieties were regarded as peculiar to the abyssal portions of large lakes.—The Rhizopods and Heliozoa of Loch Ness: J. **Murray.** In this paper the list of species given in the previous paper by Penard was supplemented by a number of species observed by the Lake Survey, bringing the list of Loch Ness Sarcodina up to sixty-six species. The difficulty of accounting for the transmission of peculiar abyssal forms from one deep lake to another was met by the suggestion that the abyssal forms originate separately in each lake and are probably not good permanent species, but modified forms due to the direct action of the environment on the growing individual.

PARIS.

Academy of Sciences, April 17.—M. Troost in the chair.—Second note on the principle of cellular flotation in ships: M. **Bertin.**—Mixed treatment by arsenious acid and trypan red of infection due to Trypanosoma: A. **Laveran.** Fresh experiments on monkeys confirm the favourable results previously obtained on rats and dogs.—Observations on the new comet Giacobini (1905, March 26) made at Toulouse Observatory: F. **Rossard.**—On the differential equation $y''+\lambda A(x)y=0$: Max **Mason.**—On the relation which exists between the velocity of combustion of powders and the pressure: R. **Liouville.**—Optical properties of iono-plastic iron: L. **Houllevigue.**—On the theory and imitation of the motion of sails: A. **Bazin.**—On the use of the centrifugal method in the analysis of cocoa and chocolate: F. **Bordas** and M. **Touplain.** It is necessary, to avoid some practically impossible filtrations, to use an apparatus capable of nearly 2000 revolutions a minute.—New method for a quick analysis of milk: F. **Bordas** and M. **Touplain.** By centrifugal means one avoids much filtration as well as the protracted desiccation of the casein.—An apparatus for giving warning of the presence of luminous gas and afterdamp: MM. **Hanger** and **Pescheux.**—The crystalloluminescence of arsenious acid: M. **Guinchant.** This appears to be due to a chemical phenomenon corresponding with the reversible reaction

$$As_2O_3+6HCl \rightleftarrows 3H_2O+2AsCl_3.$$

—On the emission spectrum of the high tension electric arc: J. **de Rowalski** and P. **Joye.**—On a simple method for the study of oscillating sparks: G. A. **Hemsalech.** The method depends on the fact that a current of air directed on such a spark can separate out the oscillations.—Apparatus and methods in the medical applications of statical electricity: L. **Benoist.** An attempt to systematise the usage based on the consideration of electric density.—On the mode of formation of some monosubstituted derivatives of urethane: F. **Bodroux.** When small quantities of ethyl carbonate are dropped into an ether solution of the magnesium derivative of an aromatic primary amine, a lively reaction takes place. If aniline be used, phenylurethane is formed.—On the mineralogical analysis of arable earths: J. **Dumont.** The author describes methods for quantitatively determining the proportions of sand, mica, felspar, quartz, &c.—On some Crustacea resulting from the expedition of the *Princess Alice*: H. **Coutière.** By the use of a net with a large aperture a considerably more valuable collection was made.—On the excitation of nerves by a minimum of energy, and its application to electrodiagnosis: M. **Cluzet.** By experiments made on the nerves of human beings, it has been found through the application of a formula that the duration of minimum excitation may be 0·00020 second.—Physiology of the spleen: MM. **Charrin** and **Moussu.** The experiments made tended to elucidate the much discussed question as to the functional relationship between the liver and the spleen.—The action of intestinal fluid on enteric secretion: A. **Frouin.** Many facts seem to prove that this exciting action is not due to secretin.—Researches on animal lactase: H. **Bierry.** The experiments show that lactase is not contained in the pancreatic juice of suckling puppies.—On the production of alcohol and acetone by muscles: F. **Maignan.** The author replies in the affirmative to the question as to whether these substances, which are normally present in muscle tissue, arise by alcoholic fermentation of glucose by the agency of protoplasm. But while the acetone continues to be formed, the alcohol is sooner or later destroyed again.

DIARY OF SOCIETIES.

THURSDAY, APRIL 27.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—*Discussion*: Mr. B. J. Arnold's Address to the Joint Meeting at St. Louis on the Problem of the Alternate Current Motor applied to Traction.—*Paper*: The Alternate Current Series Motor: F. Creedy.

FRIDAY, APRIL 28.

EPIDEMIOLOGICAL SOCIETY, at 8.30.

MONDAY, MAY 1.

ROYAL INSTITUTION, at 5.—Annual Meeting.
SOCIETY OF CHEMICAL INDUSTRY, at 8.—(1) The Study of the Action of Hydrogen Peroxide on a Photographic Plate in the Dark; (2) On the Influence of the Length of the Time of Development on the Degree of Darkening of the Photographic Plate: Prof. Chiri Otsuki.
VICTORIA INSTITUTE, at 4.30.—The Influence of Physiological Discovery on Thought: Dr. E. P. Frost.

TUESDAY, MAY 2.

ZOOLOGICAL SOCIETY, at 8.30.—On *Leucosolenia contorta*, Bowerbank, *Ascandra contorta*, Haeckel, and *Ascetta spinosa*, Lendenfeld: Prof. E. A. Minchin.—Some Notes upon the Anatomy of the Ferret-Badger (*Helictis personata*): F. E. Beddard, F.R.S.—Contributions to the Osteology of Birds, Part vii., Eurylæmidæ, with Remarks on the Systematic Position of the Group: W. P. Pycraft.
ROYAL INSTITUTION, at 5.—The Study of Extinct Animals: Prof. L. C. Miall, F.R.S.
SOCIETY OF ARTS, at 4.30.—The Monumental Treatment of Bronze: J. Starkie Gardner.

WEDNESDAY, MAY 3.

ENTOMOLOGICAL SOCIETY, at 8.—The Structure and Life-history of *Psychoda sexpunctata*, Curtis: J. A. Dell.
SOCIETY OF PUBLIC ANALYSTS, at 8.
SOCIETY OF ARTS, at 8.—Recent Excavations in Rome: Mrs. Burton-Brown.

THURSDAY, MAY 4.

ROYAL INSTITUTION, at 5.—Flame: Sir James Dewar, F.R.S.
CHEMICAL SOCIETY, at 8.—The Synthesis of Substances Allied to Adrenaline: H. D. Dakin.—Methylation of p-Aminobenzoic Acid by Means of Methyl Sulphate: J. Johnston.—Some Notes on Sodium Alum: J. N. Wadmore.—Campboryl-ψ-Semicarbazide: M. O. Forster and H. E. Fierz.
RÖNTGEN SOCIETY, at 5, (1) to Medical Members only. Forty-two Cases of Ureteral Calculus Diagnosis by X-Rays proved by Operation on the Passage of the Calculi; (2) at 8.15 p.m., to the General Meeting, Measurement and Technique in Therapeutic Dosage: Dr. C. Lester Leonard, Philadelphia.
LINNEAN SOCIETY, at 8.—Œcology: its Present Position and Probable Development: A. G. Tansley.—The Flora of Gough Island: R. N. R. Brown.
CIVIL AND MECHANICAL ENGINEERS' SOCIETY, at 7.30.—Annual General Meeting.—At 8.—Card-Indexing and Filing: J. C. Osborne.

FRIDAY, MAY 5.

ROYAL INSTITUTION, at 9.—Problems underlying Nutrition: Prof. H. E. Armstrong, F.R.S.

SATURDAY, MAY 6.

ROYAL INSTITUTION, at 3.—Moulds and Mouldiness: Prof. Marsh. Ward, F.R.S.
