*" To the solid ground
Of Nature trusts the mind which builds for aye."*—WORDSWORTH.

THURSDAY, NOVEMBER 3, 1904.

APPLIED ELECTRICITY.

(1) *Wireless Telegraphy.* By C. H. Sewall. Pp. 229. (London: Crosby Lockwood and Son, 1903.) Price 10s. 6d. net.

(2) *Electricity in Agriculture and Horticulture.* By Prof. S. Lemström. Pp. iv+72. (London: The *Electrician* Printing and Publishing Co., Ltd., 1904.)

(3) *Modern Electric Practice.* Vol. iv. Edited by Magnus Maclean. Pp. viii+304. (London: The Gresham Publishing Co., 1904.)

(4) *The Theory of the Lead Accumulator.* By F. Dolezalek. Translated by C. L. von Ende. Pp. xii+241. (New York: John Wiley and Sons; London: Chapman and Hall, Ltd., 1904.) Price 10s. 6d. net.

(5) *Electric Motors.* By H. M. Hobart. Pp. x+458. (London: Whittaker and Co., 1904.) Price 12s. 6d. net.

(6) *Notices sur l'Électricité.* By A. Cornu. Pp. vii+274. (Paris: Gauthier-Villars, 1904.) Price 5 francs.

(7) *L'Année Technique* (1902–1903). By A. Da Cunha. Pp. 303. (Paris: Librairie Gauthier-Villars, 1903.) Price 3.50 francs.

(1) ALTHOUGH wireless telegraphy is of such recent development, it is apparently regarded by many as a legitimate subject for historical writing. The first volume before us is one of several which have appeared in the last three or four years in which the historical progress of wireless telegraphy is dealt with rather than its scientific principles. The book possesses to our mind the same faults which characterise all the other similar publications which we have read; there is a lack of discrimination in the selection of material which is likely to leave the untechnical reader in a state of considerable confusion. Wireless telegraphy as we know it to-day is wholly concerned with Hertzian wave telegraphy, and even if accounts of the experiments of Lindsay and others in telegraphy by earth or water conduction should be regarded as legitimate, we cannot see by what possible stretch of the imagination the achievements of, say, Marconi can be traced back to the prophecies of Galileo in 1632.

Mr. Sewall's method of compiling history appears to consist chiefly in making extracts from patents. Page after page of the book before us contains nothing more than reprints from the patents of Lodge, Marconi, Fessenden, and others, sometimes verbatim in inverted commas, at others with slightly altered context as original matter. We imagine it must be easier to write books in this way than it is interesting to read them. Mr. Sewall would have been much better advised, we think, to digest his material properly and present it to his readers in some more acceptable form. He could then have given a connected account of the remarkable developments that have followed the discoveries of Maxwell and Hertz which would have been of great practical use to students of the subject. At present we doubt if his book is intelligible to the amateur or useful to the expert.

(2) The late Prof. S. Lemström occupied himself for many years with experiments on the effect of electricity on growing plants, and this little book contains the results of his work. If the conclusions at which the author arrives are confirmed by the work of other investigators, the subject is one which merits the most careful consideration by all agriculturists. Practically only one type of experiment was tried; an influence machine was connected with one pole to earth and the other to a wire network over a field in which the crops were being grown. A discharge current could thus be passed either from the network to earth or *vice versâ* for any desired number of hours a day. The experiments were tried on a comparatively large scale in several different localities. The effect produced by this treatment was remarkable. There was an average excess of the crop of the experimental field over that of a control field of 45 per cent.; the excess varies considerably with the nature of the crop and the conditions, soil, weather, &c. Not only is this increase in quantity produced, but there is also often an improvement in quality and a diminution in the time taken for the plants to mature. This last is a factor often of great importance to the grower,

who can realise much higher prices by selling early in the season. Prof. Lemström calculated that in the case of wheat the outlay on a field of 25 acres will be repaid in two or three years, and that afterwards a net profit of 40*l*. a year or more can be realised. We cannot here enter into the details of the working, such as the best time of electrification, the effect of wet and dry weather, and so forth, but we should strongly advise those interested in the subject to study this book carefully; they will find it full of valuable suggestions, and the time spent in reading it will be amply repaid.

(3) We have already reviewed the first three volumes of this publication, so that it is only necessary here to refer briefly to the matter contained in the present volume. This is devoted to electric tramways, and is divided into seven chapters, dealing with overhead construction, feeders, surface contact systems, conduit systems, rolling stock, electric boats and motor cars, and electric traction on railways. The defects to which we alluded in our previous review are not so noticeable in this volume, which furnishes a good description of a very important branch of electrical engineering. The excellence of the illustrations is a characteristic of the whole production, and is a particularly valuable feature in the present instance, as the subjects are such that they cannot be effectually described without numerous photographs and diagrams.

(4) This exceedingly interesting monograph on the much debated theory of the chemical reactions taking place in the lead accumulator is probably already well known in the original German to those who have concerned themselves specially with this subject. Since the book first appeared the discussion has progressed a stage further, so that the English translation may be said to be out of date to a certain extent. This is, however, the penalty that the average English student has to pay for the neglect of his schoolmasters to teach him German, and he will probably therefore welcome the appearance of an English translation. Herr Dolezalek treats the subject from the standpoint of Nernst's osmotic theory, and shows that thermochemical considerations all point to the validity of the sulphate theory originally advanced by Gladstone and Tribe. Whether the author will succeed in satisfying others to the same extent as he has apparently satisfied himself may be regarded as open to question, but in any case the book is one which cannot be neglected by anyone wishing to study this complicated but fascinating problem.

(5) The design and construction of electric motors is becoming daily a matter of more importance to electrical engineers on account of the very rapid extension of the use of electricity for power purposes. When one considers the enormous number of tramcars, lifts, factories, &c., which are driven by electricity, it is easy to see not only how important the subject is, but also how very varied is the work which the electric motor is called upon to perform. If the development now is great, in a few years' time, when some of the numerous power schemes are more matured, it will be much greater still. The student of electrical engineering may find here ample scope for his abilities, and he cannot consult a better guide than the volume before us. The book is divided into two parts, the first dealing with continuous and the second with alternating current motors. The relative advantages of different types are considered in detail, and there are numerous calculations of motors of different types and capacities. In addition, there are a large number of curves, diagrams, and photographs.

(6) The essays which are comprised in M. Cornu's little book were written with a special and rather peculiar object, the author having been requested by some of his old pupils, who had been unable to keep touch with the rapid development of electrical engineering, to write for them something which would enable them to appreciate better the technical or semi-technical literature of to-day. These "Notices" are consequently of a somewhat elementary character, nor can the book be regarded in any sense as a text-book of electricity. But M. Cornu has succeeded in writing a book which should appeal to a very much larger audience than that for which it was originally intended; one cannot look through its pages without realising at every point that it is the work of a master, and such works repay study by all—the most advanced as well as the most elementary students. The beginner will find here ideas expressed clearly and concisely, and cannot fail to derive great benefit from the book as an introduction to more detailed treatises. The engineer will see well known facts expressed in new and suggestive language, and will doubtless have his own views enlarged in consequence. The subjects dealt with are the correlation of the phenomena of static and dynamic electricity, generators, transmission of power and polyphase currents, and we would strongly recommend anyone interested in any of these matters to spend a few hours reading M. Cornu's admirable booklet.

(7) We cannot help being conscious that the end of 1904 is rather late in the day to review a book which contains a *résumé* of the technical achievements of 1903. Still, as we gather that this publication is intended to appear annually, this notice may be of some service in directing readers' attention to the volume dealing with this year's progress, which we imagine will appear very soon; in addition, it may be pleaded that the lapse of time enables one to see matters more in the right perspective, and so to form a better estimate of the value of M. Da Cunha's work. The book ranges over a great variety of subjects. Thus we find at one place a mathematical calculation of the mechanical problems involved in "looping the loop," and in another a discussion of alcoholism and temperance worthy of the columns of a daily paper in the silly season. Between these extremes lie such subjects as the progress in wireless telegraphy, automobilism, aërial navigation, and the hundred and one other technical developments which are taking place in all branches of applied science. To the engineer the book can serve no other purpose than to while away an idle hour or so. The general reader who is interested in scientific and technical progress may read it with both profit and pleasure. He will find the descriptions clear, the style agreeable, and the illustrations and diagrams in many cases excellent.

M. S.

ADOLESCENCE.

Adolescence: its Psychology and its Relations to Physiology, Anthropology, Sociology, Sex, Crime, Religion. By G. Stanley Hall, Ph.D., LL.D., President of Clark University and Professor of Psychology and Pedagogy. Vol. i., pp. xx+589; vol. ii., pp. vi+784. (New York: D. Appleton and Co., 1904.) Price 31*s.* 6*d.* net.

THIS work is one of wide-reaching scope and interest. The subject of human growth has already been studied in relation to the earlier years and in its special features. The period intervening between childhood and adult life, which has been comparatively neglected, is the one to which Dr. Hall has directed his investigation. The work is thus of interest in focussing attention on an important section of human life; it is of value also in that the results of biology and anthropology are freely used in supplementing and interpreting the data which are gained from physiological and psychological investigation.

The first three chapters deal mainly with physical growth, taking up in order the increase in height and weight, the growth of parts and organs, and the growth in muscular power. The next two chapters deal with the physical and mental disorders of adolescence, and with juvenile faults and immorality. Sex is taken up in three chapters, one relating to boys and two to girls; of these two chapters one deals with the physiology of sex, the other with its bearing on education. Dr. Hall insists with great earnestness on the necessity of ceasing to mould woman's education on that of man, and of finding an education which shall be adapted to her nature, physical and mental. The volume closes with an account of adolescence in literature, biography, and history.

In the second volume, after a preliminary survey of changes in the senses and in voice, the emotional phenomena of adolescence are treated under the headings of adolescent love and adolescent feeling towards nature. Several chapters deal with social and historical relations; initiations in savage and classical times, confirmation as their correlative in modern religion, the social instincts and institutions of youth, ethnic psychology, and the treatment of uncivilised races, form the subject of successive discussions. In treating the subject of religious conversion, Dr. Hall points out that it is peculiarly a phenomenon of adolescence, and that it has close relations to the sexual life. "It is thus," he says, "no accidental synchronism of unrelated events that the age of religion and that of sexual maturity coincide." In the chapter on intellectual development and education there is a careful review of education in school and college, and a discussion of its value in the light of the results presented in preceding sections. Dr. Hall does not hesitate to condemn vigorously and comprehensively the studies and methods of schools for their aridity and want of vital relation to the developing individual, and though his criticisms are directed to American schools, they have a wider application.

It will thus be seen that we have in these volumes a text-book of adolescence in which scientific and practical interests are closely blended. Underlying the scientific treatment there may be said to be two leading principles. One principle is that of the intimate union, or rather the identity, of physiological and psychological processes.

"More summarily, then," he says, "the idea of soul we hold to is in its lower stages indistinguishable from that of life, and so far in a sense we revert to Aristotle, in holding that any truly scientific psychology must be first of all biological. . . . The first chapter of a scientific psychology, then, is metabolic and nutritive, and the first function of the soul is in food getting, assimilation, and dissimilation."

The other principle, of greater novelty and interest, is the application of the recapitulation theory to the mental as well as the bodily life of childhood and youth.

"Realising the limitations and qualifications of the recapitulation theory in the biologic field, I am now convinced that its psychogenetic applications have a method of their own, and although the time has not yet come when any formulation of these can have much value, I have done the best with each instance as it arose."

In his application of this theory Dr. Hall is undoubtedly original, but it is strange that among the many references to the literature of the subject there should be no mention of the work of Baldwin on "Mental Development in the Child and the Race," in which the same theory is applied in detail.

That the work took its origin in courses of lectures may perhaps explain in part the diffuseness and repetition which appear in these pages. There is an unnecessarily frequent use of strange words; one is at a loss to understand, for example, what is meant by the "solipsistic hopo" and by minds that are "rily." One meets with long lists of objects and with masses of facts which are not adequately correlated.

It is impossible to enter on a discussion of the many theoretical and practical questions which are raised. The treatment of the material, gathered from the most varied sources, is original and suggestive in a high degree; but among the wealth of new material and new conceptions one misses an exact discussion of the method by which the processes of psychogenesis are to be ascertained. Prominent among the data in the book are the results of the *questionnaires* which have been so much used by Dr. Hall and his pupils. We have, however, no presentation of the difficulties inherent in such a method of investigation, and of the precautions to be adopted in utilising its results. Apart from this special point there is the difficulty, which does not receive adequate attention, of distinguishing in any stage of adolescent development what is to be regarded as "palæopsychic," what is due to traditions and customs handed down from generation to generation of boys and girls, and lastly, what is conditioned primarily by the awakening mental and physical activity of the individual as he reacts on his experience. There is not sufficient treatment of the idea of individual growth in completeness and complexity, and of its relation to factors of development, the meaning of which is to be sought in past organic history; and one feels that some of the suggestions of racial influences are little more than interesting fancies. We may illustrate these points by reference to the author's interpretation of the child's attitude towards water. Human infants, we are told in one passage, have an untaught horror of water, and man must learn to swim. This is part of the evidence that there are "psychic vestiges in man which are suggestive of former arboreal life." Again, we learn that "children are phyletically older than women, and after the first shock and fright most of them take the greatest delight in water." This, among other phenomena, may be interpreted as a "pelagic vestige." Do we need arboreal or pelagic vestiges to account for the fact that, while some children dislike water at first and others delight in it, most of them in the end find it an excellent plaything? W. G. S.

A NATURALIST ON THE EAST COAST.

Notes of an East Coast Naturalist. By Arthur H. Patterson. Illustrated in colour by F. Southgate. Pp. xiv+304. (London: Methuen and Co., n.d.) Price 6*s*.

THE author of these notes, who has been in the habit of spending his spare time in a house-boat moored on Breydon Water and other East Anglian lagoons, has naturally enjoyed opportunities of making observations which are given to few people; for Breydon is a locality probably more famous than any other in the annals of British ornithology as a place where rare birds are in the habit of "dropping in." Moreover, as all field naturalists know, early morning and nightfall, ay, even night itself, are the times when the good things of their lives come to them. Hence the advantage of living on the field. In the latter part of the quarter of a century which these notes cover the author discarded the gun in favour of the field-glass, and could thus give undivided attention to observation without being distracted by the hopes and fears attendant on the wildfowler's efforts to obtain "a shot."

Breydon is a very carefully protected breeding area. A watcher has been stationed there for several years during the close season; but it will perhaps be disappointing (although we hope it may prove instructive) to ardent advocates of county council "orders" to find that Mr. Patterson writes, "I must, however, state that since stricter preservation has obtained, not nearly so many birds are to be seen on Breydon." It is impossible to deny the fact that no amount of preservation will bring back the *breeding* birds which left us with the spread of population and buildings, and the alterations in the system of agriculture. The spoonbills come and go in safety, but the late date at which they arrive shows that nesting is not the object of their visits. As a former east coast naturalist, remarkable for his common-sense views of such subjects, wrote years ago, "Unless England becomes dispeopled and uncultivated, nothing can ever bring back in numbers or variety the wealth of the ancient avifauna." But for all that the naturalist still "has his delights" on Breydon; as, for instance, on May 15, 1893, when the author, paddling up stream, saw on the "lumps" still uncovered by water "a congregation of no less than eighteen Black Terns, more than fifty Turnstones, several Common and Arctic Terns, a number of Dunlins, Grey Plovers, Whimbrel and Godwits, and not least worthy of a glance, three Spoonbills."

To one who is learned in the fishes of our seas, ready access to Yarmouth Market, and an extensive acquaintance among the fishermen have been a great advantage, and many a rare fish has the author rescued from oblivion and added to the east coast catalogue of fishes. Not the least valuable part of the book is that containing the fish notes, although the bulk of the volume deals with birds, their migrations and habits. Among the various interesting scraps of information here collected we find a record of the value of birds and the prices realised by the wildfowler and at the sales of noted collections; accounts of wildfowl brought into the market in hard winters, and incidents related by old-time wildfowlers, whose habits and customs, as well as their recollections of the hard winters and wildfowl of the "old days," are most amusing. Whales, crabs, lobsters, toads, insects, and rats all find a place in these very readable notes. Indeed, some of the most valuable paragraphs relate to the old English black rat, now extinct in most parts of the country, but so abundant in the malthouses and sail lofts of Yarmouth that Mr. Patterson can write of "a plague of Black Rats." This and many other of the records are well worth preserving as of permanent value, and the author is quite justified in thinking that some value may attach to these notes and observations "owing to their dealing with a period during which great changes have taken place in the habitat of the local fauna."

The twelve plates of bird-life reproduced in colours are among the most pleasing things of the kind we have seen, and these alone make the book one which all field naturalists will like to put on their shelves.

O. V. A.

CHEMICAL ANALYSIS FOR BEGINNERS.

Tables for Qualitative Chemical Analysis. By Prof. A. Liversidge, M.A., LL.D., F.R.S. (London: Macmillan and Co., Ltd., 1904.) Price 4*s*. 6*d*. net.

THE introductory chapter of Prof. Liversidge's book makes it clear that it is only when analytical methods are used intelligently that the time devoted to qualitative analysis is well spent, and to that end the student must have some preliminary training in other kinds of simple practical work (not described in the book), and be frequently supervised, lectured to, and examined as his work progresses.

All this is very right and proper, and quite as it should be, but leaving out the excellent counsel of perfection set forth in the introduction, the book is very much like other books on this subject. That is to say, it describes a series of qualitative tests in which inorganic and organic bases and acids, rare metals, and alkaloids are treated individually, and then collectively in tables after the old-established manner and with the old-established purpose.

It should be stated, however, that some attempt is made to introduce quantitative notions into the qualitative methods by using roughly weighed amounts of the substances; but the effect is somewhat discounted by the frequent omission of the quantity and strength of the reagents. I refer more particularly to the use of "drops," which may vary considerably in bulk, and to the omission of the strength of the acids.

Prof. Liversidge attaches great importance to the study of qualitative analysis as a means as well as an end of chemical education. It is an opinion very widely held, and is well worth discussing.

The fact is sometimes lost sight of that chemistry is a handicraft as well as a science, and that its science is as yet not exact.

Perhaps there is no branch of chemistry wherein the skill of the craftsman is in greater demand, or the inexactness of the science more clearly emphasised, than in chemical analysis.

A student may study intelligently the reactions for individual elements, and so learn their properties; but he finds that when they are mixed they behave differently, and the more observant and careful he is the more will these subtle influences, which conform to no equation, become apparent.

No substance is insoluble; mass action is a powerful factor; a precipitate will carry down a substance which should, for all he knows, remain in solution, and a substance will retain another in solution which, for equally occult reasons, should form a precipitate.

Tables for the analysis of mixtures, which are based on the behaviour of single substances by a process of simple logic, become artificial and illusory, and give a sense of false security which subsequent experience alone can dispel.

Is this a subject for extended study on the part of a beginner in chemistry? In the opinion of the writer the preparation of simple substances and a careful study of their properties, into which the general principles of qualitative and quantitative analysis are introduced, is his proper sphere of work. The host of reactions and elaborate tables of separations, and still more the countless precautions, *Kunstgriffe*, and manipulative details of practical analysis are a part of the handicraft of the specialist in chemistry. To thrust this work upon a beginner who is not to be a specialist is almost equivalent to expecting a student of mechanics, who is not to be an engineer, to work a lathe or use a planing machine.

The crux of the whole question lies in this, that qualitative analysis is a branch of practical work, calling itself chemistry, which can be easily adapted to the process of examination. Were the practical examination banished from the syllabus and replaced by notebooks supervised, signed and submitted by the responsible demonstrator or teacher of recognised standing, the mass of ill-digested analytical tests and tables would soon vanish from the curricula of schools and colleges, and its place supplied by a series of rational exercises. J. B. C.

OUR BOOK SHELF.

Les Lois naturelles. By Félix Le Dantec. Pp. xvi + 308. (Paris: Félix Alcan, 1904.) Price 6 francs.

JUST as "anyone can play the piano" with a piano-player, so anyone can write a book on the philosophy of science. The result gives satisfaction and pleasure to the performer in one case and to the writer in the other, but whether his particular interpretation is equally satisfying to an outsider is another question. The effects are, however, more lasting in the case of the author, for we are getting such an enormous accumulation of books on space, matter, force, the ether, and laws of nature that it is becoming a wonder who finds time to read them or even to cut their pages, if the publisher has failed to attend to his proper duties in this respect.

Let us examine how M. Le Dantec deals with thermodynamical considerations. In commencing he supposes bodies to have definite thermic masses, and he defines quantities of heat by the products of these masses into the changes of temperature. He also enunciates the principle of conservation of heat according to which the heat gained by one body is equal to that lost by another. But in the first place the quantities which he calls thermic masses are not constant for the same body between the same limits of temperature, but they also depend on whether the changes take place at constant pressure or constant volume; and, in the second place, his equation of conservation of heat is contrary to common experience of what happens when two rough bodies rub against each other. In the next chapter the author goes on a different tack, and speaks of the equivalence of quantities of work and quantities of heat, quite regardless (to all outside appearances) of the fact that the term "quantity of heat" is meaningless except in the case of passage of heat from one body to another. In the next chapter the author condemns the use of the term "quantity of heat" altogether. What ideas can a reader form of the nature of physical laws after perusing such a series of chapters as this?

Nature Teaching. By F. Watts and W. G. Freeman. Pp. xi + 193. (London: Murray, 1904.) Price 3*s.* 6*d.*

THIS little book forms a welcome change from the many appearing under similar titles in that it is avowedly based upon experiments, and treats of things about which the writers really know and have not merely read up. Dealing in the main with the life of the plant, it describes a simple series of experiments within the capacity of an elementary school or an evening continuation class, illustrating the function of seed, root, stem, leaf, &c., and amplifying the knowledge thus obtained with further examples drawn from the practice of the garden or the farm. A certain lack of definiteness in the description of experiments militates at times against the spirit in which the book has been conceived; in a subject where everything depends upon the cultivation of accurate observation and rigorous scientific method the authors should not allow themselves to fall into the slipshod generalised accounts of things which are the bane of so much of the current teaching of this nature. For instance, in their account of striking cuttings, the authors do not direct attention to the differences in the management of herbaceous and woody cuttings, the time of year at which they should be struck, and so forth, so that the teacher without experience would be apt to fumble over the matter at first, and would in real life be discouraged from trying any experiments in this particular direction unless he got hold of a gardener to give him some practical advice. However, with this slight drawback, the book is admirably designed for the teacher who wishes to work out an elementary course of instruction for a country school, either as an introduction to practical life or to a more special study of agriculture and horticulture.

I. *Clinical Lectures on Diseases of the Nervous System.* Pp. 279; price 7s. 6d. II. *Lectures on Diseases of the Nervous System.* Second series. Pp. 250; price 6s. net. By Sir William R. Gowers, M.D., F.R.C.P., F.R.S. (London: J. and A. Churchill, 1895 and 1904.)

IN these two volumes Sir William Gowers has collected in revised form a number of clinical lectures which have appeared in various medical journals. In the latter volume he has also printed the Bowman lecture on subjective visual sensations delivered to the Ophthalmological Society, and the Bradshaw lecture on the subjective sensations of sound. The clinical lectures deal with many subjects in neurology; some are mainly descriptive, some speculative. In reading them one not only appreciates the original and suggestive way in which the facts are presented, but also the finished literary style. In a short notice it is impossible to deal with them in detail. The two lectures on the subjective sensations of vision and hearing are perhaps of wider scientific interest than the clinical lectures. In the first the visual phenomena experienced by sufferers from migraine are described and figured, and there is an admirable *résumé* of physiological teaching with reference to vision. In the second lecture the phenomena of tinnitus, of auditory vertigo, and other labyrinthine sensations are discussed in a luminous and attractive way. Both neurologists and physiologists will find much in these volumes to assist and to stimulate them in researches into nervous phenomena.

Lectures Scientifiques. A French Reader for Science Students containing Extracts from Modern French Scientific works in Chemistry, Physics, Mathematics, Physiology and Botany, with a Glossary of Technical Terms. By W. G. Hartog, B.A. Pp. vii+371. (London: Rivingtons, 1904.) Price 5s.

THE University of London now insists that candidates for a degree in science shall be able to read and understand accounts in the original of French and German scientific work. In compiling this book Mr. Hartog has had the needs of such students in mind so far as French is concerned, and he has succeeded in bringing together a varied and representative collection of extracts from French scientific works and scientific periodicals. Among the latter the *Revue générale des Sciences* takes a very prominent position, contributing to Mr. Hartog's collection as many as fifteen extracts. The book should be of service not only to the undergraduates referred to, but also to students of science everywhere, for it is now more than ever necessary that the man of science should be able to acquaint himself at first hand with the results of fellow-workers abroad.

L'Industrie oléicole (Fabrication de l'Huile d'Olive). By J. Dugast. Pp. 176. (Paris: Gauthier-Villars and Masson et Cie., n.d.) Price 3 francs.

THIS little volume, which belongs to the Aide-Mémoire series, is a practical account of the manufacture of olive oil, and indicates several directions in which the results of scientific research have been utilised to improve technical processes. The formation and composition of olives are first explained, then the methods of extracting the oil are described and an account given of the appliances necessary for the purpose. The properties and methods of preservation of olive oil and the utilisation of the oil-cake are also considered.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

A Note on the Coloration of Spiders.

IT is well known that in a large number of animals, both vertebrate and invertebrate, the colour of the flanks and ventral side of the body differs from that of the dorsal. In the majority of cases the dorsal surface is most darkly tinted, the ventral palest, and the flanks intermediate in depth of tone between these two. This gradation of colouring has the effect of neutralising the shadows that are cast by the upper upon the lower portions of the body. Thus the animal does not stand out in prominent relief, but is, so to speak, artistically flattened, and thereby rendered less conspicuous.

To this general rule I have recently observed an interesting exception which affords strong evidence in favour of the truth of the above interpretation. The spiders belonging to the genus Linyphia are, almost without exception, darkly coloured upon the ventral surface; their flanks are variously slashed with oblique white bars and stripes, while their dorsal surface is yet more freely speckled with white or pale spots and lines. In these spiders, then, the scheme of coloration is the exact opposite to that which prevails elsewhere. Now the Linyphiidæ spin horizontal webs, in the centre of which they rest *inverted*, clinging to the lower side. Thus it is the ventral side of a Linyphia that is exposed to the strongest light, the dorsal side being in the deepest shadow. The inversion of attitude at once fully explains the inverted shading of the body.

OSWALD H. LATTER.

Charterhouse, Godalming, October 30.

Sir J. Eliot's Address at Cambridge.

AGAINST some of the main conclusions of Sir J. Eliot's opening address before Section A (subsection: cosmical physics) may be set the facts that south-east winds are rare on the south-east coast of South Africa, and that the rain of the greater part of the tableland and south-east coast comes mostly from some northerly direction.

My concern, however, is chiefly with the following remarks, reported in NATURE of August 25 last:—

"The chief features of the rainfall of the period 1895–1902, in the Indo-oceanic region were as follows:— . . . . There was a marked tendency in each year for late commencement and early withdrawal of the monsoon currents, and for deficient rainfall throughout the whole season over the greater part of India. These features were very pronounced in the years 1896, 1899, and 1901. The most remarkable feature of the period was that the region to the south of the equator, including South and East Africa, Mauritius, and Australia, was similarly affected. . . . Mr. Hutchins, Conservator of Forests, Cape Town, states that drought prevailed more or less persistently over the Karroo region in South Africa from 1896 to 1903, and that cattle and sheep perished by millions. He also states that the drought extended to British Central Africa from 1898 to 1903. The previous statements evidence the continuity, extension, and intensity of the drought. . . . The preceding statements have shown that variations of rainfall for prolonged periods similar in character have occurred, and may hence occur again, over the very large area including the Southern Asian peninsulas, East and South Africa, Australia, and perhaps the Indian Ocean. The abnormal actions or conditions giving rise to these large and prolonged variations must hence be persistent for long periods, and be effective over the whole of that extensive area."

Now the question is, what is a drought? From one point of view there is nothing but drought over a very large area of South Africa. But I gather from the table you print, showing the variation of the mean actual rainfall from the normal in India, that by drought is meant unusual and prolonged general dryness setting up marked economic results such as "large loss of cattle and great loss of capital," and so forth. If that interpretation is correct, then there has been no such drought in South Africa in the years stated.

This is proved by the accompanying table. It shows the average rainfall over each of the twenty rainfall districts of South Africa, during each year, in percentages of the means. These means have been computed for 160 stations having long records of twenty years, more or less, and are fully given and explained in my "Introduction to the Study of South African Rainfall." The information from which they are derived is open to all who take the trouble to look for it in the annual reports of the Cape Meteorological Commission.

The great mortality among cattle and stock can be explained without assuming that there has been a prolonged drought. In farming matters we live from hand to mouth. Farmers of the Karroo prefer to pray for rain rather than take the trouble to store it up when it comes. Therefore, if the rain is short in the late summer, and late in coming in the next spring, they have no reserve to fall back upon, and their cattle die. One year's drought kills off the stock almost as surely as fifty years' would. For instance, there was great loss of stock in 1897. Yet what were the facts of rainfall? At my station, where the annual mean is about 18·5 inches, the fall in December, 1896, was 8·42 inches; in the whole of 1897 it was 8·85 inches, and in January,

South Africa	124	111	114	105	94	92	77	98	93	101	104	106

It is pretty plain that the area of winter rains, including the west coast and Cape Peninsula, was short of rain in 1896; that 1897 was a dry year over the area of summer rains, which comprises the greater part of South Africa; and that the south coast and adjacent districts, where the rainfall is fairly uniform throughout the year, had a dry year in 1899, and one not very wet in 1895. The area of summer rains, being so much greater than the rest, of course sets the tone of the mean rainfall of the whole country, making 1897 a dry year on the whole, and 1891 a very wet year.

There seem to be dry areas somewhere or other in pretty well every year. For example, the rainfall was short in the western part of the area of summer rains in 1902, although the fall was good enough further east. It was short over the east-central Karroo and south-east in 1899 in sympathy with the dryness of the south in that year. Even in 1891 there was a short fall over an extensive region.

I fancy that the impression of unusual dryness over South Africa in recent years arises from the misleading mean values used by the Meteorological Commission for comparative purposes. These are taken from Buchan's rather futile "Rainfall of South Africa," and average fully two inches (equal to perhaps 10 per cent.) too great. Buchan used only the rainfall of the ten years 1885–94 in constructing his results, and therefore got inflated averages in consequence of the heavy rainfall of 1891; whence the rainfalls of recent years are made to appear *minus* as compared with what is called the mean, whereas, as compared with the better means of longer periods, they would be often *plus*.

1898, it was 8·43 inches. Thus there was a drought during 1897, many cattle died, and there was much praying for rain. The year 1903 was probably almost the same as 1897, the fall at Kimberley being only some 65 per cent. of the mean, whereas the fall during the last half of 1902 was good, and during the first half of 1904 excellent. But with the exception of these years there has been nothing that can properly be called drought, in the sense of Sir J. Eliot's address, over any extended region of South Africa within the past fifteen years at least. Thus there is nothing to justify the statement that we have been under the same influence as that which set up the prolonged drought in Australia and the dry years in India.

J. R. SUTTON.

I TRUST to your courtesy to give my reply to Mr. Sutton's criticisms on certain portions of my address at the recent British Association meeting.

My address was in part based on an investigation I have had on hand for nearly two years, and which will be shortly published as a paper in the *Indian Meteorological Memoirs.* In that will be found a statement of the chief features of the meteorology of South Africa during the period 1892–1902. It is confessedly based upon very imperfect information—partly derived from newspaper reports, partly from data in certain meteorological reports received from Cape Town by the Calcutta Meteorological Office, and partly from data obtained from Mr. Hutchins, Conservator of Forests, Cape Colony, with whom I have been in correspondence for many years on the meteorology of South Africa and its relation to that of India. Mr. Hutchins was for some years in the Madras Forest Department before he went to the Cape some fifteen or twenty years ago. He has made a special study of the rainfall of South Africa, and is a careful and enthusiastic investigator in rainfall problems. He is, from his double experience in India and South Africa and his present official work and position, eminently qualified to form a judgment on the abnormal features of rainfall distribution in either area, and on their economic effect. It is hence, as I hope to show later, very satisfactory that Mr. Sutton's figures confirm the general inferences I made about South African rainfall, based chiefly on Mr. Hutchins's information, in my address.

Before discussing Mr. Sutton's data and inferences, perhaps I may be permitted to deal with two or three important issues raised in Mr. Sutton's letter.

The first is contained in the opening paragraph, in which he says "south-east winds are rare on the south-east coast of South Africa, and the rain of the greater part of the tableland and north-east coast comes mostly from some northerly direction." If these casual remarks have any point at all, I think I am correct in assuming that they imply that Mr. Sutton considers the rainfall in the areas mentioned is not due to humid currents from the Indian Ocean, but from the dry interior to the north of the tableland. I have examined the rainfall charts of South Africa given in Bartholomew's "Meteorological Atlas," and they certainly indicate to me that the aqueous vapour, the condensation of which gives rainfall in the eastern half of South Africa, is brought up by air movement from the Indian Ocean, and occurs as a summer precipitation. Hence, so far as I can reasonably judge, that area forms a part of what I have termed the Indo-oceanic region. I might add, in further reply, that rain in certain parts of India during the south-west monsoon chiefly occurs with easterly and north-easterly, and even with northerly winds. But these facts have not yet been utilised by anyone to prove that the rainfall is not brought up from the adjacent seas and oceans by the south-west monsoon circulation.

Mr. Sutton in a later paragraph says he fancies that "the impression of unusual dryness over South Africa in recent years arises from the misleading mean values used by the Meteorological Commission for comparative purposes which are taken from Buchan's rather futile 'Rainfall of South Africa,' and average fully two inches (equal to perhaps 10 per cent.) too great." There is an air of certainty about this statement which I am unable to share without further proof. Buchan's means are based on ten years' data, Mr. Sutton's on twenty years' data. It does not necessarily follow that twenty years' means are better representatives of normal or average conditions than ten years means. It depends entirely upon whether the ten years may or may not be accepted as representing the normal conditions, and whether the additional ten years' data are for an abnormal period or not. The fact that the two sets of means differ on the average of the whole area by 10 per cent. indicates to an outsider on South African meteorology like myself that it is quite as probable the ten years' additional data erred in defect as that the ten years' data employed by Dr. Buchan erred in excess. There hence appears to be (in the absence of any proof) an element of doubt in his means, just as he asserts to be the case in the "rather futile" means of Dr. Buchan.

Again, if I read Mr. Sutton's letter rightly, he considers that the question as to whether the crops have failed over large areas being due to drought is settled by a consideration of percentage variations. It is certainly not the case in India. A percentage variation gives no certain indication unless considered in relation to the normal fall, and also to its time-distribution. A deficiency of 25 per cent. is of absolutely no economic importance in such areas as Sind (with an average rainfall of about four inches) or such as Arakan (with an average of more than 200 inches). The former area depends solely on irrigation for cultivation, and the latter is so abundantly supplied for the rice crop that it bears a loss of fifty inches lightly. On the other hand, in the regions termed the dry zones in India, where the mean rainfall ranges between fifteen inches and thirty inches, a deficiency of 20 per cent. is usually a serious matter, more especially if it accompanies more irregular distribution than usual unsuited to the staple crops. Local knowledge of the agricultural and economic conditions is hence of the greatest importance in estimating the probable effect of a given variation of rainfall in any area. Mr. Hutchins, I have every reason to suppose, possesses such knowledge for South Africa, and hence I attach the highest value to his information on such matters.

The evidence I have collected, a small portion of which was given in my address, appears to me to have established that during the period 1895–1902 there was a marked tendency to more or less continuous deficiency of rainfall over the Indo-oceanic area, most pronounced in dry inland districts, and which in India intensified into severe droughts in the years 1896, 1899, and 1901, diminishing the crop returns over large areas to such an extent that it was necessary to resort to famine relief on a large scale during the twelve months succeeding each period of crop failure.

I was unable to make as precise statements for either Australia or South Africa, but the scanty facts and information at my disposal appeared to justify the statement that these areas were similarly affected. I also pointed out that this period stood in marked contrast to a preceding period of three years, 1892–4, when the precipitation was apparently in general excess over the same large area.

I give in the following table a comparison between the rainfall variations of India, and the area of spring, summer, and autumn rains in South Africa, which, so far as I can judge, is mainly dependent on the Indian Ocean supplies of aqueous vapour. I give, in the absence of the number of stations for each area, the arithmetic means of the second and third horizontal rows of figures in Mr. Sutton's summary of his data :—

Period of general excess of rain			Period of general deficiency of rain		
	Percentage variation			Percentage variation	
Year	India	S. Africa	Year	India	S. Africa
1892 ...	+12 ...	+ 8	1895 ...	− 5 ...	− 9
1893 ...	+22 ...	+14	1896 ...	−12 ...	− 5
1894 ...	+16 ...	+ 4	1897 ...	normal ...	−21
			1898 ...	+ 1 ...	− 9
			1899 ...	−27 ...	−18
			1900 ...	− 1 ...	+ 2
			1901 ...	−10 ...	+ 7
			1902 ...	− 5 ...	+10

These figures show that the eastern half of South Africa had heavier rain than usual during the same period (1892–4) as India, that it was steadily in defect during the first five years of the period of persistent deficiency of rain in India, and was especially deficient in the years 1897 and 1899, the former being the year and rainfall season following the first severe drought year of the period in India, and the latter the same year as that of the greatest drought experienced in India during the past 100 years at least. The parallelism between the two sets of figures is, indeed, more complete than I anticipated, and hence I consider not only that Mr. Sutton's conclusion to the effect that "there is nothing to justify the statement that South Africa has been under the same influence as that which set up the prolonged drought in Australia and the dry years in India" is neither in accordance with what I hold to be the general meteorological conditions and relations of the whole Indo-oceanic area nor even with the data which Mr. Sutton furnishes. The probability, so far as I can judge, is at least twenty to one that there is some relation such as I have suggested. The chief object of my address was, I may add, to urge the necessity for the coordination and intercomparison of the meteorological observations of the whole Indo-oceanic area and their discussion as a whole by an efficient scientific staff in London. The question at issue between Mr. Sutton and myself, for example, could be authoritatively settled by such an investigating office.

In conclusion, I hope that my remarks may not be interpreted as in any way depreciating the value of Mr. Sutton's work in collecting and discussing as a whole the rainfall data of South Africa, and in utilising the data to obtain normal means for purposes of comparison. His work will, I am confident, be appreciated by all interested in African meteorology from any point of view. JOHN ELIOT.

Bon Porto, Cavalaire, Var, France.

The Origin of Life.

Although to the evolutionist it must necessarily appear more than probable that at some time or other non-living matter has by evolution acquired the properties of life, and to him the only question is as to how this has come about, yet, for all that, he has been in the habit of admitting that the complete failure of all experiment in this direction makes the negative evidence very strong indeed. My present object is to suggest that the negative evidence, so far from being strong, is so weak that perhaps it can hardly be said to exist.

In the experiments the first step has always been, and, so far as one can see, must always be, to destroy all existing life and all existing germs of life. Suppose the agent to be heat. How does the experimenter know that the very means he employs to destroy in living matter the property of life are not equally efficacious in destroying the peculiar property or properties of matter that is just on the point of transmutation? For all that we certainly know to the contrary, dead matter may be changing into living every day in every pool, especially every warm pool, on the face of the earth. If so, the difference between the last state of the non-living and the first state of the living must, by the evolutionist's hypothesis, be extremely small; and it is probable—to my mind most probable—that both would be similarly affected by an unusual degree of heat, or whatever other agent is calculated to destroy life; the precaution eliminating life and its potentiality at one stroke. But the value of the negative evidence is precisely in inverse proportion to this probability. If the probability is thought great, the negative evidence will necessarily be thought small. I submit that the probability is very great indeed, and consequently that we are pretty much in the same position as to the possible evolution of life from non-living matter as we should have been if no experiments had been made. Certainly, so far as the logic of the matter is concerned, there is no need yet to consider the hypothesis of life having been imported here from another planet.

Birmingham, October 25. George Hookham.

Thinking Cats.

I have known three cats which behaved as if they thought. The first, a large, sleek tabby, belonged to a private family living in the City. Between 1846 and 1858 the owner, Mr. I. S., was surprised by his manservant coming to his office at the back of the house in business hours and asking, "Did you ring, sir?" "No, I have not been into the house," was his answer. This occurred repeatedly. At last the man watched, and observed that, the family being in other rooms, the dining room bell rang, and when he answered it the cat ran out of the door. He then purposely shut her into the room. A leather easy chair was so placed that by getting on the seat, and then standing on the arm, she could reach the knob with her front paw; and she continued to practise this accomplishment as often as she was shut up in the room.

The second cat, also a large tabby, lived at Blackheath. Her master often sat up late writing. The cook, a "good old servant," also now and then sat late, sewing or reading, in the kitchen. One night after twelve Mr. H. F. was interrupted by the cat running into the library (the door being open), mewing and clawing him, then running towards the door, and repeating these acts. He got up and followed the cat, which now ran into the kitchen. The cook was sitting asleep close to the fender, a piece of coal had fallen on her dress, and it was burning. No harm happened, thanks to the cat.

The third was a very small, slight cat, white and tabby, a good mouser and bird catcher, and not at all afraid of a rat. On one occasion the servant, exasperated by the trouble caused by the cat's selection of a birthplace for kittens, drowned them *all*, for which she was duly rebuked. The next family arrived in a suitable corner, but, when two or three days old, disappeared, as well as their mother. As the cat was never allowed to go upstairs, it was supposed that, like another cat once before, she had made a lair in the garden, where she spent most of her time. At dusk the mistress of the house went up to dress for dinner. As soon as she entered her room she heard something fall, and it struck her that the noise was like a cat's jump from a height. Procuring light she found the cat standing by the door. She then saw that the curtains, where folded on the bed, had been a little disturbed, put in her hand, and found three soft warm kittens! They were immediately put into a basket with flannel, and set by the kitchen fire; but as soon as the lady had gone downstairs she met the cat, with a kitten in her mouth, on her way back to the bedroom. Why did she select that room? She was not petted by the lady, nor friendly to her. The housemaid was safe, busy waiting at table.

Debarred from this resource, she hid the kittens again while the family were at dinner, and apparently felt so sure that they were safe, that she went and sat by the kitchen fire, awaiting the usual scraps. Of course a search was made in all likely hiding places and corners frequented by the young people, who were very fond of this cat, and thought she was fond of them. A piteous, faint squealing betrayed the poor little creatures on the floor behind the largest folios in the library. The space above the books was so small that it is difficult to think how the cat got in with a kitten in her mouth, or even without it. This was the one room into which the housemaid seldom came, especially in the evening, as the master sat there. He did not pet the cat at any time, and she took no notice of him.

But though securely hidden, the kittens could hardly have lived in that cold place; their mother seemed to have overlooked their need of warmth. After this failure she submitted to have them kept in the basket in the kitchen.

Y. N.

Fish-passes and Fish-ponds.

In your issue of August 18, in an article dealing with fish-passes and fish-ponds, the following statement is made:—

"Much of the information as to the construction of ponds and their inlets and overflows is, of course, ancient, and can be found in such books as the 'History of Howietoun'" (by the late Sir James Ramsay Gibson Maitland, Bart.).

The above statement may easily cause the incorrect inference that the information in Sir James Ramsay Gibson Maitland's work is now obsolete. Perhaps you may care to make it known that this is, of course, not the case, although no doubt with lapse of time improvements and modifications are introduced. Howietoun Fishery Co.

Howietoun Fishery, Stirling, N.B., October 24.

Average Number of Kinsfolk in each Degree.

I thank Dr. Galton for his explanation (p. 626), which only shows how easy it is to make mistakes in things which appear perfectly trivial. The discrepancy can be accounted for, however, more simply still by the fact that families containing boys only have to be left out of account, and therefore in the families which contain *at least one girl* there are on an average more girls than boys altogether.

G. H. Bryan.

Misuse of Words and Phrases.

It is quite true, as Mr. Basset says, that "in English considerable care is often required in the arrangement of a sentence, so as to avoid ambiguity"; but he seems to go too far when he says that "brevity ought always to be aimed at." Too much brevity will often, as we are warned by Horace, lead to obscurity: "*brevis esse laboro: obscurus fio*"; and the absence of inflections and genders renders it impossible to write English in the brief, epigrammatic style that is common in Latin.

To Mr. Basset's rules the following may be advantageously added: that new words of foreign origin should not be employed when English words will suit the purpose as well or better. For instance, *autotomic* and *anautotomic*, as applied to curves, are objectionable, because *self-cutting* and *non-self-cutting* express precisely the same ideas in simpler and more familiar words. I am at a loss to know on what ground Mr. Basset objects to the phrase "non-singular cubic curve"; does he think the epithet is "uncouth" or "inelegant" or "inaccurate"?

October 31. T. B. S.

FLOODS IN THE MISSISSIPPI.

WE have on previous occasions directed attention to the reports issued by the Department of Agriculture of the United States, and to the valuable information they afford to the officers engaged in the different departments. We have now been favoured with a copy of a report issued by the Weather Bureau on the floods in the Mississippi watershed in the spring of 1903,[1] which gives an interesting and detailed account of the most disastrous floods in this district of which there is any record.

FIG. 1.—Kansas City, Missouri. Scene in the freight yard of the St. Louis and San Francisco Railway after subsidence of the flood.

These floods are described as marking a new epoch in the economic history of the country. When previous floods occurred they ran harmlessly over unbroken forests, and bottoms tenanted only by the beasts of the field, except over a limited area where there were small farms tenanted by French colonists. The floods of 1903 descended upon fertile and highly cultivated fields, and upon rich valleys filled to overflowing with vast industries devoted with never ceasing energy to the fulfilment of the insatiable demands of commerce. The resulting ruin and desolation were beyond description. Along the lower Mississippi 6820 square miles of country were inundated. In Kansas City five square miles of territory were overflowed; large portions of the manufacturing towns of Venice and Madison were flooded to a considerable depth; more than 3000 square miles of territory, one-half of which was under cultivation, were overflowed and the crops ruined.

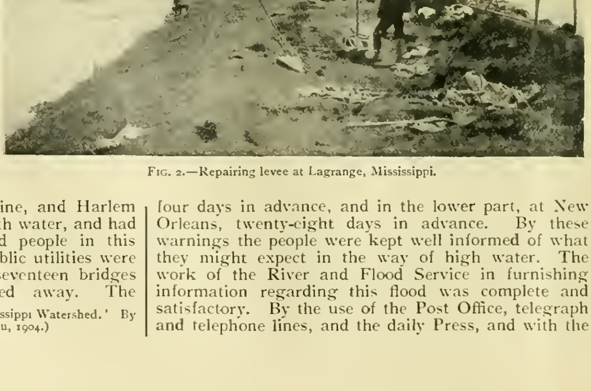

FIG. 2.—Repairing levee at Lagrange, Mississippi.

The towns of Armourdale, Argentine, and Harlem were covered from 8 feet to 12 feet with water, and had to be abandoned. Twenty thousand people in this district were made homeless. All public utilities were put out of service; sixteen out of seventeen bridges over the river Kaw were washed away. The Missouri and Kansas remained no longer rivers, but became merged into an inland sea. When the flood subsided there was revealed a condition of general ruin and desolation. Holes had been gouged in the streets some 30 feet deep; railroad tracks had been torn to pieces; an oil tank, 50 feet in diameter and 30 feet high, made of iron plates, had been torn from its foundations and tossed about like a frail shanty; freight cars had been broken up and carried away down the river; heavy locomotive engines had been rolled over and were discovered lying in mud banks; and mud from 2 feet to 4 feet deep covered everything. An approximate estimate of the loss in this district was put at $3\frac{1}{4}$ million pounds. In the vicinity of Kansas City the losses were placed at upwards of three million pounds, while the value of the bridges destroyed was more than 150,000*l*. In previous floods the losses have fallen principally on the agricultural districts, but this time the loss to the farmers was less than one-third of the total, and about the same proportion was borne by the railroads.

But great as the losses were, they would have been far greater but for the property saved owing to timely warnings issued by the Weather Bureau. Owing to the careful records kept of previous floods the department was enabled to forecast the time at which the flow would reach the various towns situated on the river, and the height to which it would probably rise, and so could send out timely warnings. In the lower district alone the value of the property saved by removal to places of safety was estimated at 5 million pounds. The forecasts as to the probable height of the flood were issued in the higher districts at least four days in advance, and in the lower part, at New Orleans, twenty-eight days in advance. By these warnings the people were kept well informed of what they might expect in the way of high water. The work of the River and Flood Service in furnishing information regarding this flood was complete and satisfactory. By the use of the Post Office, telegraph and telephone lines, and the daily Press, and with the

[1] "The Floods of the Spring of 1903 in the Mississippi Watershed." By H. C. Frankenfeld. (Washington: Weather Bureau, 1904.)

cooperation of the various railway companies, every intelligent person in the district was made aware of the impending danger in ample time to make such preparations as they were able.

The floods of 1903 owed their inception to a series of heavy rainfalls caused by a succession of storms of the south-western type, the best rain-producing quarter, coming on the top of the water derived from the melting of the snow on the mountains in the upper reaches.

In the February flood in the lower Mississippi the water rose in one long swell from Cairo to the Gulf of Mexico from 17·5 feet on the gauge on January 28, passing the danger point of 45 feet thirty-nine days later, and 50½ feet, or 5½ feet above the top of the banks, eight days afterwards. It remained above the danger line for another twelve days, and then began to fall. It will thus be seen that the water in the river during the flood rose 33 feet.

Although excessive rainfall was the original cause of these floods, the effect was greatly increased by works that had been carried out for the improvement of the river and for providing means of inland transport, necessitating the frequent crossing of the river by railway bridges. Formerly a certain amount of relief to the floods was afforded by the water flowing through the numerous crevasses or breaches of the banks that occurred, but during recent years the banks have been systematically raised and strengthened. For example, in the St. Francis system the levees have been extended and raised 2 feet over a length of 173 miles, and the area originally subject to being submerged reduced 4000 square miles. The same operations have been carried on in other districts, so that the flooded area which previous to 1897 extended over 30,000 square miles in 1903 barely reached 7000 square miles. The fight against this flood was also the most extensive and persistent ever attempted in the history of levee engineering. When a breach was likely to occur all the help and material available was concentrated at the point of greatest weakness. At one place a force of more than 1000 men was employed both day and night, in spite of which the bank gave way for more than a mile.

At another part of the river, about 36 miles below New Orleans, a crevasse occurred at a place where the river is 120 feet deep. The bank was all washed away, and where it formerly stood a hole was scoured out 60 feet deep. Owing to the precautions taken, due to the warnings of the Weather Bureau, provision had been made to meet such a catastrophe, and workmen were at once concentrated on the spot, and trainloads of material which had been provided in readiness for such an emergency were brought to the place. By this means the breach was successfully closed, and the flooding of some of the finest sugar plantations in Louisiana averted.

Other causes that contributed to the greater rise of the flood were the numerous railway bridges that had been carried across the river without leaving sufficient waterway for floods. In one place, where the natural width of the river is 900 feet, the waterway had been contracted to 400 feet by a railway bridge, the velocity of the water through which rose to twelve miles an hour.

Encroachments by reclamation have also materially interfered with the free flow of the river, the original width of the channel in some places having been reduced one-half.

The report of these floods contains numerous illustrations which give a very graphic idea of the ruin caused in the flooded areas, and also of the works carried on in repairing the levees. There is also a map of the watershed of the Mississippi and of the flooded areas, and of the rainfall in the different districts.

Two other volumes issued by the Geological Department relate to the floods of the river Passaic in 1902 and 1903, when the loss to the inhabitants of the district was estimated for the two floods at about 3 million pounds. These two volumes also contain numerous very telling illustrations of the flooded areas and of the damage done to houses and factories.[1]

WHAT IS BRANDY?

THIS question, which a few months ago greatly exercised analytical chemists in this country in consequence of the action of certain local authorities under the Sale of Food and Drugs Acts, has recently engaged the attention of the Technical Committee of Œnology, instituted by the French Minister of Commerce by decree of March 22, 1904, and the committee have adopted the conclusions of M. Rocques, the reporter of the subcommittee charged with the consideration of the matter, whose report is published *in extenso* in the *Moniteur Officiel du Commerce* of June 30. In view of the importance of the subject, it may be desirable to give a short summary of the facts and arguments which led the technical committee to adopt the conclusions of the special subcommittee.

In the first place the committee, for reasons which it is unnecessary to explain, object to the term *coefficient of impurities*, hitherto employed by French chemists, in conformity with a decree of the Minister of Commerce of May 26, 1903, to designate the aggregate proportion of the substances other than ethylic alcohol in brandy, and prefer to denote it by the term *coefficient non-alcohol*, or more simply *non-alcohol*, by which is to be understood the sum of the different volatile substances, other than ethylic alcohol, expressed in grams per hectolitre of absolute alcohol. These substances are the acids, aldehydes, ethers, the alcohols higher in the homologous series than ethyl alcohol, and the furfurol.

The causes which influence this coefficient are many, but in the main they may be said to depend upon (1) the nature of the wine, (2) the method of distillation, and (3) age.

As regards the first cause, it is found that the proportion, as well as the character, of the volatile matters vary according to the origin of the wine, the conditions under which its fermentation has been effected, the manner in which it has been kept, &c. The proportion of acids and ethers is considerably augmented if the wine becomes sour, and, speaking generally, the proportion of aldehydes is higher in white than in red wines.

But it is mainly in the method of distillation that we are to seek for the cause of the wide variations in this coefficient. This is readily understood if we examine the manner in which the various substances, which together constitute *non-alcohol*, behave during distillation. It is known that these substances pass over in very different proportion in the course of the distillation. Thus the aldehyde and the more volatile ethers are found mainly in the first runnings (*produits de tête*), whereas the taillings (*produits de queue*) contain in largest quantity the higher alcohols and the furfurol.

The separation of these various products—the *produits de tête*, the alcohol itself (*de coeur*), and the *produits de queue*—is effected in a manner more or less complete, depending upon the apparatus employed. In the larger distilleries this apparatus is of a very high order of perfection. But without further labour-

[1] The Passaic Flood of 1902, Water Supply and Irrigation Paper No. 88, and of 1903, Paper 92. (Washington: Government Printing Office.

ing this point, it is obvious that the aggregate amount and relative proportion of these products must depend very largely upon the means made use of, and hence perfectly genuine brandies must necessarily show wide differences in the *coefficient non-alcohol*.

In addition, it must be remembered that in the manufacture of brandy from wines of repute, the elimination of the substances constituting *non-alcohol* must be made with the greatest circumspection, since it is upon their bouquet that the value of these brandies depends, and this bouquet resides wholly in the *non-alcohol*.

On the other hand, if the brandy is being made from damaged wine the rectification must be most carefully conducted, and may have to be pushed to a point that the alcohol is obtained almost pure, that is to say, almost free from *non-alcohol*.

As regards the influence of age, it is observed that in those brandies which are found to improve on keeping there is an increase in *non-alcohol* due (1) to the formation of products of oxidation (acids and aldehydes), and (2) to *concentration* due to a loss of alcohol and water.

Brandies may be classified in the following manner:—

(1) The brandies of the two Charentes, which are habitually designated by the name of Cognac.

(2) The brandies of Armagnac.

(3) The brandies *de vin du Midi* and of Algeria (trois-six de Montpellier, &c.).

(4) Marc brandies.

The brandies of the Charentes are obtained by distillation of the wines of the district, and as the reputation of these brandies depends upon their bouquet they are submitted to a slight rectification only in order to preserve that bouquet.

The same may be said of the Armagnac brandies.

As to brandies made in other viticultural regions, and in particular in the middle of France, their nature is much more variable. These brandies require to be rectified in a manner, more or less complete, depending upon the nature of the wine or of the marc from which they are derived, and varying, too, with the quality of the brandy it is desired to produce. Certain wines require, in fact, to be most carefully rectified in order to produce merchantable brandy. Marc brandy is made in all viticultural regions, and that of Burgundy enjoys a special reputation.

As regards the value of the coefficient in different brandies, it is found that in those of Charente and Armagnac the coefficient is very high. Thus, as *minima*, a brandy of Clunis (1879, good, but not guaranteed) gave 259 (Girard and Cuniasse). A Cognac of 1892 gave 287 (Rocques). As *maxima* may be cited a Bois brandy of 1817, which gave 1174 (Lusson). This last number is exceptionally high. It may be said that, ordinarily, the value of the coefficient in Cognacs and *fine champagne* ranges between 275 and 450.

But little analytical evidence has been published respecting the Armagnac brandies, but, such as it is, it indicates that the coefficients in their case are less than are generally found in Cognacs.

The brandies obtained from the wines of the Midi and Algeria show much wider variations, ranging from 25 to 500.

Marc brandies have almost invariably a high coefficient. The numbers range from 555 to 1487, and it is interesting to note that the aldehydes frequently form a large proportion of the whole. Thus a Burgundy marc brandy was found to contain as much as 519 of aldehyde, and one from the Midi as high as 730 of aldehyde.

The question whether it is possible to fix minimum and maximum limits to this coefficient naturally received much consideration from the committee. The fixation of these presents a certain interest, and that from two different points of view. The fixation of a *minimum* limit has interest for the analyst, as guiding him in his inference as to the genuineness of the brandy or as to the amount of "silent" spirit with which it may have been mixed. The fixation of a *maximum* limit has an interest from the hygienic point of view, since it may become necessary if regulations are to be established in this sense.

The committee, however, are unable to recommend that any such limits should be fixed, owing mainly to the extremely variable character of brandy. Even in the case of brandies of a definite character, as, for example, Cognac, the non-alcohol coefficient is not the only element of value, and any conclusions as to character cannot be based solely upon it. Regard must be had to the proportions of the different volatile substances and their relations among themselves. Expert tasting (*dégustation*) must be considered as an indispensable complement of chemical analysis.

The hygienic point of view, involving the fixation of a maximum value for the non-alcohol coefficient, was brought to the notice of the International Congress of Chemistry in Paris in 1900, but the problem, as then stated, received no definite solution. To base conclusions on the value of the coefficient alone, with no regard to the factors which it comprises, seems illogical. For example, the acids, and in particular acetic acid, frequently make up a large proportion of this value, but it cannot be contended that these substances, at least in the proportion in which they are present in brandy, have any detrimental influence. Far more important are the aldehydes, ethers, the higher alcohols, and furfurol.

As regards the higher alcohols, the attempt has been made to establish a higher limit. Thus in Belgium, by a Royal decree of December 31, 1902, the sale is prohibited of spirituous liquors containing more than 1 gram of the higher alcohols and essences per litre of absolute alcohol when these liquors have an alcoholic content higher than 90°, and 3 grams when the alcoholic richness does not exceed 90°.

The committee remark that the effect of this regulation would be to exclude some of the most famous, and notably the oldest, brandies of the Charente, many of which exceed the maximum Belgian limit, which, expressed as a non-alcohol coefficient, is 300. Thus:—

	Higher alcohols per hectolitre of abs. alcohol
Bois Brandy, 1817 (Lusson)	... 612
Saintonge, Cazes, 1896 (Lusson) ...	... 372
Gemozac, or de Fesson, 1893 (Lusson)	... 345
Clunis, 1875 (Lusson)	... 345
Cognac, 1873 (Rocques)	... 304

From the hygienic point of view the ethers, furfurol, and especially the aldehydes, are undoubtedly of much greater importance than the higher alcohols, since admittedly the action of these substances on the organism is far more deleterious than that of the higher alcohols. From this point of view the attention of hygienists should be directed to the Marc brandies, which, as already stated, frequently contain considerable quantities of aldehydes.

Interesting and, no doubt, valuable as the report is, it is hardly calculated to facilitate the work of the unfortunate public analysts who may be called upon to express an opinion as to the genuineness of a sample of brandy. The question, What is brandy? analytically speaking, still awaits solution.

NOTES.

SPEAKING at St. George's Hospital Medical School on Friday last, Lord Kelvin remarked:—The modern medical man must be a scientific man, and, what is more, he must be a philosopher. The fundamental studies of medicine are of a strictly materialistic kind, but they belong to a different world from the world which constitutes their main subject —the world of life. Let it not be imagined that any hocus-pocus of electricity or viscous fluids will make a living cell. Splendid and interesting work has recently been done in what was formerly called organic chemistry, a great French chemist taking the lead. This is not the occasion for a lecture on the borderland between what is called organic and what is called inorganic; but it is interesting to know that materials belonging to the general class of foodstuffs, such as sugar, and what might be also called a foodstuff, alcohol, can be made out of the chemical elements. But let not youthful minds be dazzled by the imaginings of the daily newspapers that because Berthelot and others have thus made foodstuffs they can make living things, or that there is any prospect of a process being found in any laboratory for making a living thing, whether the minutest germ of bacteriology or anything smaller or greater. There is an absolute distinction between crystals and cells. Anything that crystallises may be made by the chemist. Nothing approaching to the cell of a living creature has ever yet been made. The general result of an enormous amount of exceedingly intricate and thorough-going investigation by Huxley and Hooker and others of the present age, and by some of their predecessors in both the nineteenth and eighteenth centuries, is that no artificial process whatever can make living matter out of dead. This is vastly beyond the subject of the chemical laboratory, vastly beyond my own subject of physics or of electricity—beyond it in depth of scientific significance and in human interest.

MR. H. H. JEFFCOTT has been appointed assistant in the metrological department of the National Physical Laboratory.

BY permission of His Majesty the King, the Sanitary Institute will henceforth be known as the Royal Sanitary Institute.

AN International Gas Exhibition will be held at Earl's Court from November 19 to December 17 inclusive, under the auspices of the Institution of Gas Engineers.

AN exhibition of water colours, photographs, and other articles of interest belonging to the National Antarctic Expedition will be opened at the Bruton Galleries, Bond Street, on Friday by Sir Clements Markham.

A SKETCH of some of the results of the public works policy in India during the last fifty years was given at the Institution of Civil Engineers on Tuesday, in the address of the president, Sir Guilford L. Molesworth, K.C.I.E. In the course of the address, it was pointed out that there are available in India millions of potential horse-power, in the form of water flowing from the mountain ranges, capable of being converted into electrical energy at generating stations in the hills, and conveyed, with slight loss in efficiency, to centres even at a distance, where it can be utilised for industrial purposes. A generating station has been erected at the Cauveri Falls, with a head of 380 feet. The turbines drive six generators, each of 1000 electrical horse-power, and the current is transmitted, at a pressure of 30,000 volts, for a distance of ninety-one miles, to the Kolar goldfields, with an efficiency of nearly 80 per cent. At the cordite factory, Wellington, in the Nilgiri Hills, an effective fall of 660 feet is employed to work a turbine and alternators, generating about 1000 horse-power at a pressure of 5000 volts. As to irrigation, the amount of land irrigated in British India is about 44 million acres. Of these 17 million are irrigated by canals, 8 million from tanks, and 19 million from wells and other sources. In conclusion, the president remarked that although much has been done, far more yet remains to be done—in opening up the country, in the prevention of famines, in the regulation of the water supply, in the installation of works and factories, in the transmission of power generated by the hill falls to those centres where it can be profitably utilised, and in the general development of the resources of the Empire.

THE three articles in the October number of the *Zoologist* deal exclusively with local bird-faunas, namely, those of Oxfordshire, Donegal, and Jersey. The capture of a white-beaked dolphin (*Lagenorhynchus albirostris*) off Aberdeen is recorded.

THE director (Captain S. S. Flower) of the Giza Zoological Gardens, Cairo, has sent us a copy of a list of rare animals recently received from the Sudan, among which reference may be made to a female of the Niam-niam race of the chimpanzee (*Anthropopithecus troglodytes schweinfurthi*).

"GAMMARUS," otherwise the freshwater-shrimp (a name which, by the way, appears to be omitted from the text), forms the subject of the twelfth number of the *L.M.B.C. Memoirs*. Miss M. Cussans, the author, seems to have treated her subject in the same thorough manner which has been the rule in the earlier issues of this excellent series, and the four plates, although diagrammatic, are all that can be desired from the point of view of the student.

THE greater bulk of parts i. and ii. of vol. xxv. of *Notes from the Leyden Museum* is taken up by an article on the beetles of the family Paussidæ by Mr. E. Wasmann. These beetles, which are now definitely known to live in companionship with ants, are regarded by the author as the most interesting of all living creatures, since they show better than any other group the interdependence of morphology and biology. They are remarkable for the enormous size of their antennæ, and are believed to be the descendants of pre-Tertiary Carabidæ.

THE first of three lectures on the fossil vertebrates of Egypt was delivered at University College, Gower Street, by Dr. C. W. Andrews, of the British Museum, at 4.30 on October 31. This lecture was devoted to the Proboscidea. On November 7, at the same hour, the lecturer will discourse on Arsinoitherium and the Hyracoidea, while on November 14 he will take into consideration the sirenians and reptiles. Free cards of admission to these lectures may be obtained on application to the registrar at University College.

ACCORDING to the report of the Government biologist for 1903, the Government of the Cape of Good Hope is making every effort to develop the local fisheries. During the year four large steam-trawlers arrived from Europe; two of these were unfortunately wrecked, but the others have been doing good work, as have also certain vessels belonging to private owners. A new fishing-ground, much nearer to Cape Town than any of the old ones, has been discovered, and has been the chief attraction for the new trawlers. The report contains reprints (without the plates) of various memoirs by specialists on different sections of the South African marine fauna.

"THE Animals of Africa" forms the title of an article by Mr. Lydekker in the October issue of the *Quarterly Review*. While admitting the African origin of the mastodons, the author does not consider that there are sufficient grounds for rejecting Huxley's theory that the bulk of the modern mammalian fauna of Africa came from the north. In an article on fatigue, Sir W. R. Gowers points out that the study it has received has been chiefly at the hands of Italians. The facts known relating to both muscular and brain fatigue are passed in review, and the methods of prevention are considered in turn. Mr. D. G. Hogarth describes the palace of Knossos, and his account of recent researches is accompanied by a large plan. Two other articles also are of special interest to men of science—one dealing with the Panama Canal and maritime commerce, the other summarising what has been accomplished in Wales in the provision of higher education. Referring to Sir Norman Lockyer's calculation, that to place the Welsh universities on a footing of equal efficiency with the best universities of Germany and America a capital sum of four millions is required, the writer says it is clear that Wales herself cannot raise a tithe of this large sum, and emphasises the fact that it is to the State that Wales must look for the bulk of the money needed.

IN a brief *Bulletin* issued by the Michigan State Agricultural Experiment Station (No. 218) Mr. Fred Edwards reviews in popular language our present knowledge of soil bacteria in their relation to agriculture.

THE October number of *Climate* contains articles on malaria by Dr. Harford, the climate of Uganda and of Lovaleland by Mr. Cook and Mr. Fisher respectively, and medical articles, notes, and reviews.

THE *Journal* of the Royal Statistical Society for September (vol. lxvii., part iii.) contains the second and third reports of the committee appointed to inquire into the production and consumption of meat and dairy products in the United Kingdom, with remarks thereon by Mr. Rew, from which it appears that we are well ahead of other European nations in meat consumption (122 lb. per head as against Germany's 99 lb.), but appreciably behind our American cousins (150 lb. per head), and much less carnivorous than our Australian kinsmen (262 lb. per head). Mr. Thompson contributes a paper on local expenditure and indebtedness in England and Wales, and Mr. Adam a newly calculated life-table for Scotland.

PROF. A. E. WRIGHT'S system of anti-typhoid inoculation, introduced by him in 1896, after being applied to the British Army in India was forbidden by an army order in consequence of certain objections raised against it. During the South African War the inoculation of troops proceeding there was officially sanctioned, and Prof. Wright and his assistants injected some 100,000 men without the slightest mishap. At the termination of the war the advisory board of the reorganised Army Medical Department recommended that the practice of anti-typhoid inoculation should be suspended. Prof. Wright demurred to this decision, and in consequence Mr. Brodrick referred the matter to the Royal Society, and at their suggestion a special committee of the Royal College of Physicians was appointed to examine and report. This committee was composed of Dr. Rose Bradford, Dr. Gee, Dr. Howard Tooth, Prof. Simpson, and Dr. Caiger, and reported unanimously that, "after careful scrutiny of the statistics from both official and private sources which have been made available, we are of opinion that not only is a lessened susceptibility to the disease brought about as a result of the inoculations, but the case mortality is largely reduced. We are further of opinion that with due care the process of inoculation is devoid of direct danger, but that under special circumstances there may possibly be some temporary increase of susceptibility to infection immediately following inoculation; and it is therefore desirable that the preparation of the vaccine and the inoculations should be carried out under specially skilled supervision." In spite of this favourable verdict the advisory board still maintained its opposition, and Mr. Arnold-Forster therefore appointed another committee to advise him, consisting of Colonel Bruce and Dr. James Galloway, of the advisory board, together with Dr. C. J. Martin and Dr. A. Macfadyen, Lister Institute, Dr. Bulloch, London Hospital, Dr. Bruce Low, Local Government Board, Major Leishman, R.A.M.C., and Prof. Wright. This committee has reported unanimously "that the anti-typhoid inoculation has resulted in a substantial diminution in the incidence and case mortality from typhoid fever, and recommend that the system introduced by Prof. Wright should be resumed in the Army." The Army Council has adopted this recommendation, and is proceeding to carry out inoculations and to conduct investigations, by the agency of Major Leishman, on volunteers from the 2nd Battalion of Royal Fusiliers now proceeding to India.

A LIST of fresh-water algæ, collected by Mr. A. Howard in Barbados, Dominica and Trinidad, and described by Mr. G. S. West, appears in the *Journal of Botany* (October). This contains species, some new, which are additional to those recorded in papers previously published by the same author. A species of Glœotænium, a green alga, is figured, which is distinguished by the presence of a peculiar opaque cruciform zone. Biographical notes culled from Sir M. Grant Duff's "Notes from a Diary" and other sources include references to Sir James Paget, Brodrick, and John Ball.

THE success obtained with Para rubber in Ceylon has led to the experimental plantation of the tree in other countries. In India planters are wisely hesitating before they embark upon a venture which yields no return for five years or longer. It is obviously the duty of the superintendents of experimental gardens to investigate the possibilities, and in the Tennasserim circle, Burma, the scheme instituted by Mr. Manson for developing a large Para rubber plantation at Mergui is progressing. Up to the present serious depredations have been caused by deer and pigs which attack the seedlings, but by planting out two-year-old plants it is hoped that this may be to a great extent obviated. The experiment, which was started in 1901, will be followed with considerable interest by planters.

THE annual report of the Royal Alfred Observatory, Mauritius, for the year 1903, states that the rainfall of the island for the year (mean of fifty-one stations) was 68·8 inches, the average being 77·3 inches. The greatest falls in twenty-four hours were 9 inches at Constance d'Arifat on April 23, and 8·5 inches at Britannia on January 14. The number of ships which visited the island was 274, against 686 in 1882. From the observations contained in their logs, daily synoptic weather charts were prepared and tracks of cyclones laid down. Photographs of the sun were taken daily when the weather permitted; 173 negatives were sent to the Solar Physics Committee. During the year 117 earthquakes were recorded, particulars of which will be published in the annual volume of observations. Mr. Claxton states that much damage has been done to the library by white ants, and that it has been necessary to remove the books to another position.

THE U.S. Weather Bureau has issued its meteorological chart of the Great Lakes for the winter of 1903–4. This was the coldest winter in the lake region that has been experienced since the beginning of the Weather Bureau observations in 1871. Freezing temperatures commenced about the middle of November. The climax was reached in February, when the mean monthly temperature ranged about 10° below the normal in all districts. On Lake Superior the ice-fields did not disappear from the eastern portion until the last week in May, 1904. Several interesting photographs are given of vessels and ferries forcing their way through apparently impassable masses of ice as soon as a thaw set in. When navigation is practicable storm warnings are displayed by day and night, and at almost all stations a chart is issued showing the weather conditions at 8h. a.m. daily (except Sunday); masters of vessels are invited to obtain these charts, or any other information in connection with the weather, at any of the Weather Bureau offices.

APPENDIX iii. of a report upon the basin of the Upper Nile, with proposals for the improvement of that river by Sir William Garstin, contains an interesting account of the variations of level of Lake Victoria Nyanza contributed by Captain H. G. Lyons, the director of the Survey Department of Egypt. This lake has a water surface of about 68,000 square kilometres, and is situated about 1129 metres above sea-level. It is believed to be of shallow depth, and lies for the most part of the year in the region of the equatorial rain and cloud belt, the excess water draining off at the Ripon Falls by the Victoria Nile. After reference to the geology and climate of the region, a brief historical summary is given of the early lake levels as observed by travellers and others visiting or residing by it; this is followed by a detailed study and discussion of the various gauges. Some of the results obtained are as follows:—The annual oscillation of the lake is from 0·30 metre to 0·90 metre. Between 1896 and 1902 there was a fall of 76 cm. in the average level, since followed by a rise of 56 cm. The epochs of high and low levels are given as:—1878, high level; 1880–90, falling level; 1892–95, temporary high level; 1896–1902, falling level; 1903, rising level.

WE have received from Mr. W. J. Brooks, 33 Fitzroy Street, W., some of his patent flexible curves and a parabolic curve. One of the former is a strip of celluloid with tags at intervals along its length; when placed on paper it can be bent to any desired curve, the fingers being placed on the tags to keep the strip in position; the strip does not yield under the pen. A second form (pattern B) has a steel strip and is self-clamping and reversible; this ingenious device maintains the steel strip in any position by means of stiff-hinged linkwork attached to metal tabs. The shape of any curve thus formed by this strip can be transferred from one drawing to another, a desirable advantage to many workers. A third and longer form (pattern C), also self-clamping and reversible, has been designed for such special purposes as are required by ship and boat builders, but it will have a much wider field of adaptation, such as, for instance, in the construction of interpolation curves for wave-lengths in spectroscopic work, &c. This pattern, which can be obtained from one foot up to any length, consists of light wooden cross-bars hinged to tabs fixed to a steel strip. The strips slide through brass spring-clamps, and are thus held tight against a stout wooden bar running the length of the curve. Several patterns and sizes for all the curves are obtainable, and they may be usefully employed for a great number of manipulations, such as curve drawing, transferring outlines of mouldings, &c. The parabola is of celluloid and is accurately cut, and its axis, focus and latus rectum neatly engraved on it. In addition to its use for draughtsmen, teachers of mathematics will find it serviceable for the study of that curve.

A NEW general theory of errors has been contributed to the *Proceedings* of the American Academy of Arts and Sciences, xl., 3 (August), by Mr. William Edward Story. The author's object has been to develop the theory in such a way as to avoid the usual assumptions, the legitimacy of which, as approximations, may be questioned. It is claimed that the present theory is based upon such simple principles as will be generally admitted to be necessary for the mathematical treatment of any theory. The fundamental assumptions are as follows:—Possible errors form a practically continuous sequence from a certain lower limit to a certain upper limit. The probability that the error of an observation lies between x and $x+dx$, where dx is infinitesimal, is $\phi(x)dx$, where $\phi(x)$ is an analytical function of x, developable by Taylor's theorem throughout the whole range of possible error. The probability that the error lies between given limits is independent of the unit of measurement.

ATTENTION has already been directed in these columns to the important innovation introduced into this country by the Drapers' Company in granting a sum of 1000*l.* to University College, London, for the furtherance of research in applied mathematics. No better testimony to the value of this grant could be adduced than is afforded by a reference to the pages of Nos. 1 and 2 of the technical series of the *Drapers' Company Research Memoirs*, edited by Prof. Karl Pearson. In the first of these Mr. E. S. Andrews discusses the stresses in crane and coupling hooks by means of the theory of elasticity, and describes experimental tests in verification of his theory. The present investigation shows not only that the existing theory is unsatisfactory, both theoretically and practically, but that improvements can well be made in existing types of hooks by following lines laid down in the paper. In the second paper Mr. L. W. Atcherley directs attention to certain very serious defects in the theory of masonry dams. It is shown that the stresses across vertical sections of a dam are far more important than those across horizontal sections, and that in many existing dams not only do shearing stresses exist in the vertical sections which are far in excess of any considered safe by engineers, but considerable tensile stresses also occur, which form a serious source of danger. These two papers are fitting illustrations of the many important practical problems now awaiting solution, which could be solved at a very small cost by the provision of further endowments for mathematical research.

THE third revised edition of "The Scope and Method of Political Economy," by Dr. J. N. Keynes, has been published by Messrs. Macmillan and Co., Ltd., at 7*s.* 6*d.* net.

MESSRS. ROUTLEDGE AND SONS, LTD., have added to their series of "Country Books" a profusely illustrated edition of Charles Kingsley's "Glaucus, or the Wonders of the Seashore." The volume is published at 3*s.* 6*d.*

SINCE the advent of the Nernst lamp, every physicist has recognised that it would ultimately be very serviceable for lantern purposes. Any lecturer interested in the matter may see a well designed lantern provided with Nernst filaments, in actual use, at Mr. R. W. Paul's, High Holborn.

MR. H. G. WELLS returns to the more serious side of his work in "A Modern Utopia," which is being published month by month in the *Fortnightly Review*. As in "Anticipations" and "Mankind in the Making," Mr. Wells concerns himself with sociological problems, and pictures the probable manners and customs of society in a Utopia, situated on a distant planet, which is the natural outcome of continued development on modern lines.

A REVISED edition of Mr. H. N. Chute's "Physical Laboratory Manual" has been published by Messrs. D. C. Heath and Co. In this edition sound and light have been made to follow mechanics, because, the author says, "there seems to be a consensus of opinion among teachers that . . . the grade is less steep than it is where these subjects follow electricity." A few of the problems of the first edition have been omitted, and new ones added.

THE first number of the *Journal of Agricultural Science*, edited by Messrs. T. H. Middleton, T. B. Wood, R. H. Biffen, and A. D. Hall, in consultation with other gentlemen, will be published in January next by the Cambridge University Press. The journal will publish only definitely scientific work in agricultural science, and will not include the results of the ordinary trials of manures and varieties for demonstration or commercial purposes. Papers for publication should be sent to Mr. T. B. Wood, University Department of Agriculture, Cambridge.

THE seventh edition of Dr. J. Frick's "Physikalische Technik," enlarged and completely revised by Prof. O. Lehmann, is in course of publication by Messrs. F. Vieweg and Son, Brunswick. The first half of vol. i. has been received, and the second half is promised shortly. The second volume will be published in a year or two, and will complete the work. In the part before us there are 629 pages and 2003 illustrations of lecture and laboratory apparatus for demonstrations and experiments in various branches of mechanics and physics.

A CHEAP edition (1s. net) of Mr. G. F. Chambers's "Astronomy for General Readers" has just been published by Messrs. Whittaker and Co. The book contains 268 pages and 134 illustrations, most of which represent the pictorial efforts of bygone days. As instances of the worst of these figures, reference may be made to Figs. 29, 104, 105, 106, 109, and 112. Before issuing this cheap edition an attempt should have been made to bring the text and the illustrations in line with the present position of astronomy, instead of leaving them as they were in the original volume.

THE *Journal of Anatomy and Physiology* for October (xxxix., part i.) contains a number of valuable papers, but of purely anatomical interest. The principal contribution is by Dr. Huntington on the derivation and significance of certain supernumerary muscles of the pectoral region, illustrated with fourteen excellent coloured plates.

THE new illustrated catalogue of physical apparatus just issued by Messrs. F. E. Becker and Co. (Messrs. W. and J. George, Ltd.) is likely to prove indispensable in the physical laboratories of all our schools and colleges. It runs to 628 large pages, and is strongly bound in cloth. Full particulars are provided, not only respecting the apparatus required in elementary and advanced physical teaching, but also concerning that necessary to the physicist in his research work. All branches of physics are included, and the instruments throughout are explained by excellent illustrations and concise descriptions, and, what is of prime importance, the figure and its appropriate text are close together.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN NOVEMBER :—

Nov. 5. Saturn. Outer major axis of outer ring = 39″·42.
,, ,, Outer minor axis of outer ring = 11″·01.
8. 11h. 50m. Minimum of Algol (β Persei).
9. 13h. 0m. Venus in conjunction with Moon (Venus, 6° 30′ S.).
11. 8h. 39m. Minimum of Algol (β Persei).
13. 21h. 0m. Juno in conjunction with Moon (Juno, 0° 8′ N.).
14. 0h. 0m. Saturn in conjunction with Moon (Saturn, 3° 53′ S.).
,, 5h. 28m. Minimum of Algol (β Persei).
,, 16h. Epoch of November meteors (Leonids, radiant 150° + 22°).
15. Venus. Illuminated portion of disc = 0·832, of Mars = 0·936.
16. 15h. Venus and Uranus in conjunction (Venus, 1° 28′ S.).
17. 5h. 5m. Transit of Jupiter's Sat. III. (Ganymede), egress.
19. 11h. Jupiter in conjunction with Moon (Jupiter, 1° 31′ N.).
20. 10h. 24m. to 11h. 44m. Moon occults ξ′ Ceti (mag. 4·5).
23. 5h. 20m. Near approach of Moon to α Tauri (mag. 1·1).
24. 6h. 39m. to 8h. 34m. Transit of Jupiter's Sat. III. (Ganymede).
25. Vesta in opposition to Sun (Vesta, mag. 6·5).

ENCKE'S COMET 1904 *b*.—In No. 3973 of the *Astronomische Nachrichten* M. M. Kaminsky gives a further ephemeris for Encke's comet, which he has corrected in accordance with the observation made at Heidelberg on September 11. The ephemeris gives the daily positions of the comet from October 14 to December 5, and the following is an abstract therefrom :—

Ephemeris 0h. (*M.T. Berlin*).

1904	α app. (h. m. s.)	δ app. (° ′)	log. r	log. Δ
Nov. 3	23 10 34	+24 9	0·1510	9·7380
,, 5	23 1 3	+23 21	0·1424	9·7305

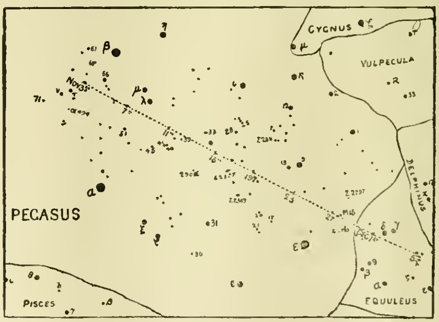
The accompanying chart shows, approximately, the apparent path of the comet through the constellation Pegasus into Equuelus from now until December 5.



SIMULTANEOUS OCCURRENCE OF SOLAR AND MAGNETIC DISTURBANCES.—Writing in No. 3, vol. xx., of the *Astrophysical Journal*, Herr A. Nippoldt, of the Potsdam Magnetic Observatory, disagrees with Father Cortie's conclusion (published in *Astrophysical Journal*, pp. 287–293, vol. xviii., 1903) regarding the absence of any allied magnetic disturbances during the appearance of a vigorous sun-spot from May 19 to June 26, 1901.

Herr Nippoldt questions the advisability of introducing statistical gradations of the magnetic disturbances, and contends that the magnetic effect at any one place or at a number of places in approximately the same latitude is, possibly, not a measure of the solar cause. That is to say, an instrument near the poles might register a "great" when the Potsdam or Stonyhurst recorders only registered a "small" disturbance. Consequently, he would urge that when the magnetograph trace shows any marked divergence from the normal one might consider that a disturbance had taken place, and he shows, by a reproduction of the "horizontal-intensity" curve obtained at Potsdam on May 30–31, 1901, that a disturbance *did* take place during the time that the spot which Father Cortie especially discussed was on the sun.

Finally, he confirms M. Deslandres's opinion that in the future the solar observations should be continuous, and thereby become more strictly comparable with the magnetic records.

THE THIRD BAND OF THE AIR SPECTRUM.—In No. 16 (1904) of the *Comptes rendus* MM. H. Deslandres and A. Kannapell publish the results of a study of the third air band, which occurs in the more refrangible part of the ultra-violet end of the spectrum (λ 3000 to λ 2000), under a large dispersion.

The apparatus used consisted of a capillary vacuum tube closed with a plate of quartz under a pressure of less than 1 mm. of mercury, and a spectrograph containing two calcite prisms of 60° and two quartz lenses of 1·3 metres focal length. The latter produced a dispersion which, in the neighbourhood of N=42,189 (λ 2370), gave a separation of 0·005 mm. for a difference of 0·06 N.

The wave-lengths of the lines were obtained by reference to a spectrum of iron, using Kayser's fundamental values for the wave-lengths of the latter, and the authors state that in the individual values obtained for N the first six figures are correct.

In the results it is seen that, although the lines of the band may be separated into four series of doublets according to Deslandres's law, so that the difference of wave-lengths in each series advances in arithmetical progression, yet the variations from the computed values are greater than may be accounted for by errors of measurement, and, what is more remarkable, the sign of these variations for series i. and ii. is opposite to that obtained for series iii. and iv.

PRE-GLACIAL TOPOGRAPHY.[1]

THE beautifully illustrated memoir by Messrs. Wright and Muff, recently issued by the Royal Dublin Society, directs attention to an ancient rock-platform on which Glacial deposits were laid down in southern Ireland. The importance of such observations is clear when we consider the possibility of the preservation of a pre-Glacial, and perhaps Pliocene, fauna in favoured localities beneath the drift. At Courtmacsherry Bay, for example, south-west of Cork Harbour, a well marked rock-shelf occurs about 5 feet above high-water mark. On this rests a raised beach, with ferruginous sand and rows of pebbles, succeeded by the blown sand that accumulated when the uplift first occurred. Blocks from the adjacent cliff slipped down over the sand, and the series was then preserved by the Boulder-clay of the Glacial epoch. The wide stretch of coast, from Carnsore Point in co. Wexford to Baltimore in the west of co. Cork, over which this raised platform has been traced, affords ample opportunities for comparing the modern with the ancient features. The authors show that the pre-Glacial sea worked against a cliff about 100 feet in height, and consequently advanced slowly, leaving a denuded surface remarkably free from stacks and irregularities. This surface commonly lies about 12 feet above the modern beach. Unfortunately, no trace of fossils has yet appeared in the old beach-deposits, and the authors believe that even pebbles of limestone have been removed by percolating water. The Boulder-clay above contains the usual molluscs, including northern species.

The pre-Glacial beach is traced into the estuaries of the rivers of southern Ireland; consequently these inlets are still older. Since they have arisen from the submergence of river-valleys, the river-system and the submergence are of pre-Glacial age. This simple but important observation seems effectually to negative the views of the late Prof. Carvill Lewis and Mr. James Porter (*Irish Naturalist*, 1902, p. 153), who argued that deposits of glacial drift might have turned the lower portions of these rivers into their present north-and-south direction. We are thrown back,

FIG. 1.—Section in Courtmacsherry Bay, co. Cork, showing beach-gravel and sand resting on shore-platform, and overlain by Boulder-clay.

then, upon the view of Jukes in accounting for the courses of the Blackwater and the Lee, and may see, as the drift is slowly washed away, further and further developments of the pre-Glacial topography of Ireland. We have been apt to assume that the western fjords and rias originated when the glaciers retreated from them and the land sank upon the Atlantic side. It now becomes possible that the tongues of ice spread into pre-existing inlets, banking out the sea, and again admitting it in warmer times. Messrs. Wright and Muff even conclude, from British as well as Irish indications, that "a considerable portion of the coast-line of Southern Britain is of pre-glacial age. The approximation over so wide an area of the sea-level in pre-glacial times to that of the present day renders it very probable that Ireland was already insulated before the Glacial Period."

This only increases the difficulty of assuming an extinction of the fauna and flora of Ireland during the maximum extension of the ice. Many points of cheerful controversy lurk behind this straightforward and descriptive paper.

THE SALMON FISHERIES OF ENGLAND AND WALES.[1]

THIS report, although the first issued by the Board of Agriculture and Fisheries, is on the same lines as the forty-three previous annual reports of the Inspectors of Fisheries of England and Wales issued by the Board of Trade. It embodies the reports of the three Inspectors of Fisheries of England and Wales, Messrs. Archer and Fryer and Dr. Masterman. Besides these reports there are twelve appendices.

It is pleasing to learn from Mr. Archer's report that the salmon and trout season of 1903 was on the whole a good one. Mr. Archer refers to the long-standing difficulty of getting accurate statistics, and has made inquiries of the various boards of conservators as to the possible methods of obtaining them. The answers from these boards are not encouraging, and it is apparent that legislation is necessary in order to compel the recording of fish caught.

As usual, the want of funds by the boards of conservators, and the impossibility of their carrying out their proper work without such funds, is discussed. The present system by which the boards derive their revenue solely from the net and rod licences granted annually is obviously inadequate, and Mr. Archer quotes a resolution adopted unanimously by the Wye Board of Conservators, which is as follows:—

"That as the present system, by which the income of Fishery Boards in England and Wales depends entirely upon the amount realised from licences paid for nets and rods, has proved inadequate for the proper protection of the Fisheries, this Board is of opinion that legislation is urgently required to enable any Fishery Board, with the consent and subject to conditions formulated by the Board of Agriculture and Fisheries, to assess the annual value of all the Fisheries in its district and to levy a rate upon each Fishery for the purpose of providing the Board with a sufficient income for the proper protection and management of the Fisheries in the district under its charge."

We quote this, not because it is new, for the suggestion that some form of assessment of fisheries was probably unavoidable was made by the Salmon Fisheries Commission in their report in 1902, but because this move on the part of the Wye Board is worthy of commendation, and seems to us to be a move in the right direction. Too often our Royal Commissions make valuable reports which are pigeon-holed, and perhaps if the various boards of conservators pass similar resolutions to that passed by the Wye Board, and thus show some common agreement in the matter, it will go some way towards making those in authority take the matter up seriously. We have heard rumours of new salmon legislation, and let us hope that the financial side of the question will have full consideration.

Mr. Archer discusses further evidence brought forward by those who believe in the advantages of artificial propagation of salmon to show the success of the experiments upon the Weser in Germany, and he shows quite clearly that "not proven" must still be the verdict on the question of their success.

We are very glad to see from Mr. Fryer's report that salmon-marking experiments, which have now been carried on for some years in Scotland and Ireland and in Norway, have been undertaken in England. The percentage of returns of marked salmon is not very high, and the more the experiment is extended the better chance there is of gathering data which will throw some light upon the migratory habits of the species.

At last steps are being taken to alter the anomalous state of the law as to the English and Scottish sides of the Solway, as recommended by the Royal Commission on Tweed and Solway Fisheries, which sent in its report eight years ago.

There is a *résumé* of the various local questions with which Mr. Fryer has had to deal, and it is in reading this that one sees the futility of our present fishery laws. While inspectors or boards of conservators are corresponding with this manufacturer or that company or corporation as to the steps to be taken to mitigate some nuisance, the seasons slip by and nothing is done, often because there is insufficient power given under existing Acts to enforce those Acts being carried out.

Dr. Masterman, who was appointed only just before the end of the period with which the reports are required to deal, submits a short but interesting paper upon fish scales and upon the method of distinguishing the species of Salmonidæ. He refers to the work so far done upon fish scales as a means of recording the age of fishes, and in this connection we are glad to learn that the salmon scale is being studied at the present time by Mr. H. W. Johnston. The salmon scale is particularly interesting, as a number of rings—roughly about thirty—immediately surrounding the nucleus of the scale, and occupying roughly about 0·5 mm. or 0·6 mm., are much finer, and are situated much closer together, than the rings outside this area, perhaps representing the fresh-water life period of the individual.

We notice that the gross revenue returned during 1903 was 7504*l*., as against 6606*l*. in 1902. There were more rod licences issued than in any previous years since the commencement of the statistics, although the revenue therefrom, amounting to 3294*l*., was not equal to that realised in 1892, when it was 3386*l*. Revenue from nets was also slightly better than in 1902, being 3994*l*. as against 3905*l*., but in 1902 these licences realised less than in any year since 1867, the first year of the statistics, when only 3851*l*. was obtained.

Trout licences produced more in 1903 than in any previous year.

The report is published at His Majesty's Stationery Office, and is obtainable from Messrs. Eyre and Spottiswoode, or through any bookseller, price 8*d*.

FRANK BALFOUR BROWNE.

THE ANATOMY OF CORALS.[1]

THE classification of corals based upon the structure of the hard or skeletal parts alone, such as has been used by zoologists in general since the publication of Milne-Edwards and Haime's "Histoire Naturelle des Coralliaires" (1857–1860), is clearly not satisfactory. Some consideration in the system of the general anatomy of the soft tissues of the living coral polyps is clearly necessary if our classification is intended to indicate at all the natural grouping of the genera and species.

The startling discoveries made by Moseley during the voyage of the *Challenger*, that the coral Heliopora and the corals of the family Stylasteridæ do not belong even to the same order as the Madrepores, was an important, if not the principal, stimulus to the investigations of the anatomy of these zoophytes that have been published in recent years. Moseley himself, and his pupils Bourne, Fowler, and Sclater, and abroad von Heider and von Koch, contributed valuable memoirs on the anatomy of different species of Madreporaria, and slowly but without any further startling effects our knowledge grew. The result of these investigations was to confirm the belief in the close relationship of the Madrepores to the sea anemones, and to show that in the structure of the mesenteries, tentacles, and other organs there are differences between the genera of great systematic importance. But still our knowledge remained insufficient to suggest any permanent improvement on the Edwardsian system.

Some years ago Mr. Duerden, when stationed in the island of Jamaica, commenced a series of investigations upon the living corals of Kingston harbour and its neighbourhood. He took advantage of his opportunities for observing them alive on the reef and in his aquarium; he was equipped with a profound knowledge of the structure of the Actiniaria and of the modern methods of anatomical investigation. A series of papers and notes marked the period of his residence in Jamaica; but he reserved for this magnificent memoir of 200 quarto pages a general and detailed account of his work.

To say that the memoir is brilliant is to express an opinion, but to say that it is important is but to state a fact. Zoologists who are interested in the structure of corals must refer to this memoir as a great store of first-hand

[1] "West Indian Madreporarian Polyps." By J. E. Duerden. *Memoirs of the National Academy of Sciences*, vol. viii. (Washington, 1902.)

facts, and whoever attempts in the future to classify the Zoantharia must base his conclusions upon many of the anatomical details which are here for the first time adequately recorded.

No less than twenty-six species of corals, distributed among twenty genera, formed the materials of Mr. Duerden's investigations, and, although the descriptions are not exhaustive, there is a very full and interesting account of the general structure of all these forms.

The brilliancy of the colours of many corals in the living state has excited the interest and admiration of the naturalists and travellers who have visited coral reefs. These colours appear to be due to a variety of causes. In many cases the cavities of the polyps and the adjacent canals bear large numbers of the symbiotic algæ called Zooxanthellæ. The colour of these cells accounts for most of the prevailing brown and yellow-brown tints. In some few instances, such as *Astrangia solitaria* and *Phyllangia americana*, the Zooxanthellæ are nearly or wholly absent, and the polyps then are remarkably transparent and almost colourless. But there are in many cases definite pigment cells, both in the ectoderm and endoderm, which may add to or give the only colour effect of the expanded polyps. A third cause of colour is to be found in the boring filamentous red and bright green algæ with which many corals are infested.

The chapter dealing with the structure and arrangement of the tentacles is one of exceptional interest. To investigators in this country the tentacles have always offered difficulties and uncertainties. However carefully the

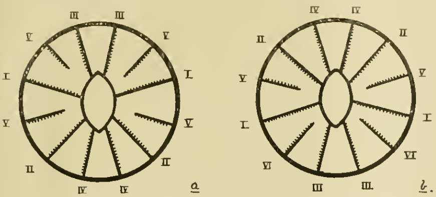

Fig. 1.—Diagrammatic figures showing the arrangement of the first six pairs of mesenteries in (*a*) Madrepora; (*b*) most other species of Madreporaria. The upper side of each is the side turned towards the axis (axial), and the lower is away from the axis (abaxial). The axial side of Madrepora is ventral, whereas in most other species it is dorsal. (The upper of the bilateral pairs marked v, v in *a* should have been vi, vi).

material they can obtain is preserved, it is impossible to prevent a great deal of retraction and shrinkage. Mr. Duerden's careful observations, therefore, of the fully expanded tentacles of his living corals form a particularly welcome addition to our knowledge.

The most elaborate, and perhaps we may say the most important, part of the author's work deals with the number and arrangement of the mesenteries. This is not the place to relate or to criticise details which are necessarily highly technical and somewhat intricate; but it may be said that it is upon the results of this part of his investigations that the suggestions he has to offer for the classification of the order very largely depend.

If we regard the Madreporaria as an order, we may divide it into two suborders:—(1) the Entocnemaria, (2) the Cyclocnemaria. In the former the mesenteries always arise in bilateral pairs, and beyond the protocnemic stage the increase takes place within one or both of the directive entocœles. In the latter the mesenteries, beyond the protocnemic stage, arise in isocnemic unilateral pairs within the primary exocœles. The Entocnemaria are represented only by the single section Perforata, the Cyclocnemaria by the two sections Aporosa and Fungacea. The arrangement of the families of the Aporosa into two groups, the Gemmantes and the Fissiparantes, based upon the method of asexual reproduction—by gemmation or by stomodæal fission—supported as it is by Mr. Duerden's later researches, can be regarded as only tentative and suggestive at present; but the facts upon which it is based are among the most interesting and important of his many results.

It is a matter for regret, which many will share with the reviewer, that in the introduction to the systematic part of the memoir Mr. Duerden has not given us his views as to the relation of the Actiniaria to the Madreporaria, a difficult matter upon which no one is more competent to express an opinion.

There are some points in the terminology employed by Mr. Duerden that appear to me to be open to some objection. "By universal acceptation," he says, "Cœnenchyme is the calcareous deposit originating from the cœnosarc." This is most unfortunate. The word was introduced by Milne-Edwards and Haime to signify the common tissue which precedes the existence of the polyps and plays a considerable part in their constitution. In a similar sense Kölliker uses the expression as the tissue that gives rise to the axis of the precious coral. It was for the soft, not the hard, parts of the "common tissue" that the word was introduced. But to say that by "universal acceptation" the word is used for the calcareous deposit is not accurate, for the writers on Alcyonarians invariably use the word to signify both hard and soft parts, other than the axis, which lie between the neighbouring zooids.

Again, the use of the word "gastro-cœlom" for the general body-cavity of the Cœlenterate, suggesting as it does a compromise with the old-fashioned gastro-vascular cavity, is to be regretted. Either of the words "enterocœl" or "cœlenteron" is preferable.

On the other hand, the discussion (pp. 443–4) on the use of terms referring to the aspects of the cœlenterate body is excellent. The aspect of the body towards which the faces bearing the musculature of the two complete bilateral pairs of mesenteries, i, ii, are turned was called by Haddon the "sulcar" aspect, and the opposite the "sulcular" aspect. This terminology was adopted by Bourne in his "Anthozoa" of Lankester's "Treatise on Zoology." Marshall, in writing upon certain Alcyonarians, had previously used the terms "abaxial" and "axial" respectively, and these terms were introduced to supersede the "ventral" and "dorsal" of Moseley, Kölliker, and others. It is quite clear now from Mr. Duerden's remarks that the use of the newer sets of terms can lead to nothing but confusion. Anything that can be called a "sulcus" occurs only in Alcyonaria and a few Zoantharia; the "sulculus" is a myth.

But of more importance is the fact that, as shown by Carlgren, the "sulcus" is dorsal in Cerianthus and ventral in the other forms where it occurs. The axial-abaxial relationship, moreover, is not constant. In the Alcyonaria and in the majority of Zoantharia the dorsal aspect of the polyp is turned towards the axis of the colony, and the ventral aspect away from the axis; but in Madrepora this arrangement is reversed. In the solitary Anthozoa the use of the terms "axial" and "abaxial" has no meaning.

The conclusion is then that, although they are open to some objections, the use of the terms "dorsal" and "ventral" for the two aspects of the bilateral anthozoon must be retained.

In conclusion, Mr. Duerden may be congratulated on the production of a really great work which marks an important step forward in the history of our knowledge of the Cœlenterata.

Sydney J. Hickson.

SEISMOLOGICAL NOTES.

In No. 10, vol. ix., of the *Boll. Soc. Sismol. Italiana*, Dr. Agamennone records the fact that his idea of taking photographs, at intervals, from fixed points, in regions suspected of bradiseismic movements, was independently suggested by F. Salmojraghi. The object is to detect slow or rapid changes of relative level in the interior of a continent, where there is no such convenient datum level as is afforded by the sea, and the paper is specially devoted to showing that the effects of refraction, being irregular, would not prevent the detection of a bradiseismic change of relative level in a regular series of photographic records.

No. 23 of the *Mittheilungen* of the Austrian Earthquake Commission is a paper by Prof. Láska on the application of earthquake observations to the investigation of the constitution of the interior of the earth. From a consideration of the observations of the Caraccas earthquake of

October 29, 1900, in Europe and Japan, he arrives at the conclusion that if the earth consists of a central core and an outer shell, each of uniform composition, the outer shell must have a thickness of not more than 500 km. This result would fall in with Milne's hypothesis, but as this is considered to be inconsistent with the facts of astronomy, he adopts the conclusion that there is a continuous increase in the rate of propagation from the surface to the centre of the earth, this increase being much more rapid near the surface than at greater depths; this condition would result in the wave motion being propagated along curvilinear paths, and give rise to a small apparent rate of propagation near the origin as compared with that found at greater distances. The value of Prof. Láska's conclusion is diminished by the fact that it is based on the consideration of only a single earthquake, the time of origin of which is not known by direct observation.

In the *Boll. dell Accademia Gioenia di Scienze Naturali in Catania* of February, 1904, Prof. Ricco returns to the consideration of the gravitational anomalies he has detected under Mount Etna, and shows that they are accompanied by corresponding irregularities in the course of the lines of equal magnetic force. Prof. Ricco merely records the fact of these magnetic irregularities, but the observation is important in its bearing on the explanation of the gravitational anomaly, which is equivalent to the removal of more than 1000 metres in thickness of rock, at sea level, from under the summit of the mountain. It is inconceivable that this can be due to the existence of huge cavities in the earth; more probably the effect is due to the existence of a "root" of the mountain, depressed into a denser magma, by the buoyancy of which the visible mountain is supported. There is independent geological evidence that Mount Etna lies over a region of special subsidence, the basis of sedimentary rock on which it was heaped up having been depressed during its formation, and if we suppose this depression to have caused the displacement of denser by less dense rocks to a considerable depth, we get an explanation of both gravitational and magnetic anomalies. A rough calculation shows that the buoyancy of the downward protuberance would, on the most favourable supposition, be inadequate to support the whole weight of the mountain, and it must be concluded that Mount Etna is not in a condition of complete isostacy, but partially supported by an upward force.

In No. 1 of the tenth volume of the *Bollettino* of the Italian Seismological Society Prof. Grablovitz discusses the vexed question of the nature of the wave motion in the third phase of the record of a distant earthquake. The occasion is the series of earthquakes which originated in the Balkan peninsula on April 4, 1904; as registered at Ischia, the great waves had a period of about 8 seconds, and, if the records of the horizontal pendula are interpreted as due to tilting, they indicate angular movements of as much as 100 seconds of arc, and this means a vertical movement of more than 2 metres; in the same earthquakes the instrument for recording the vertical component of the movement gave only negative results. From this Prof. Grablovitz concludes that the records obtained from the horizontal pendula and the *vasca sismica* are not due to tilting; he admits that there may have been a small amount of vertical movement which the instrument failed to record, but this must have been much smaller than that obtained by calculation in the ordinary way.

The same number contains a description, by Dr. Agamennone, of a new form of very delicate seismoscope, adapted for the detection of both near and distant earthquakes; and an account, by D. Vassalo, illustrated by a sketch plan, of the condition of Stromboli in June, 1904.

Dr. R. von Kövesligethy, of Budapest, has made an ingenious calculation of the work done by great earthquakes. Regarding the observed irregularities in the displacement of the poles as compounded of a regular epicycloid movement, and an irregular movement, which has been shown by Prof. Milne to vary with the frequency of great earthquakes, he calculates that each of the 200 great earthquakes registered during the eight years 1895–1902 caused an average displacement of the pole through $-0''.00275$; the negative sign is interesting, as showing that the tendency of great earthquakes is to diminish the departure of the instantaneous from the mean axis of revolution. The work done by this displacement is calculated as equivalent to that which would be required to raise a mass equal to that of the earth through 1.2 mm. at its surface (*Die Erdbebenwarte*, iii., 1904, pp. 196–202).

Prof. Omori contributes a note on the variations of sea level on the east coast of Japan to part xiii. of vol. ii. of the reports of the Tokio Physico-Mathematical Society. The curves of barometric pressure and sea level are very similar, and approximately reversed; the maximum sea level is in September and the minimum in February, while the minimum barometric pressure is in July and the maximum in November. The range of barometric pressure is 9·3 m., corresponding to 126 mm. of sea level, while the range of sea level amounts to 276 mm. at Misaki and 219 mm. at Ayukaua; these figures show that while the local variations of barometric pressure doubtless influence the level of the sea, this is also dependent on the variations of barometric pressure over the Pacific Ocean. The net result is that the variations of pressure on the bed of the sea are the opposite of those on the adjoining land, and Prof. Omori correlates this fact with the observed variations in frequency of earthquakes originating off the east coast of Japan.

The *Deutschen Rundschau*, vol. xxvii., part i., contains an interesting note, originally printed in the Honolulu *Evening Bulletin* of June 21, 1904, by Dr. Otto Kuntze on the present condition of Kilauea, which he describes as being now dormant or extinct. There are no longer any "lakes of fire"; the old lake of lava has cooled, and is covered by a sheet of rock, and though steam issues from some of the cracks in this, no molten, or even red-hot, rock is now visible. A remarkable statement in the note is that the lava lake, formerly visible, did not mark an active vent, but was merely a reservoir of slowly cooling lava, which had flowed from the crater of Halemaumau and accumulated in the lowest part of the caldera of Kilauea. There is no authentic record of this crater, which rises from the floor of the caldera, having been in eruption since June 24, 1897, and the paper contains some strongly worded comments on the mis-statements regarding the present condition of the crater, printed in the guide books issued by the tourist agencies, mis-statements which are unnecessary, as Kilauea, even in its existing condition, is nevertheless one of the most interesting sights in the world, of which Dr. Kuntz claims that few have seen more than himself.

In No. 17 of the *Publications* of the Earthquake Investigation Committee in Foreign Languages, Mr. S. Kusakabe continues his investigations of the modulus of elasticity of rocks, and publishes some interesting results. He finds that all rocks show a marked hysteresis, that is to say, when exposed to a stress they go on yielding, apparently to an indefinite extent, though after a while the effect is masked by that due to changes of temperature, and when released from the stress the recovery takes place at a continuously decreasing rate, but apparently is never complete. Rocks in a state of strain have a higher modulus of elasticity than in the unstrained condition, and if exposed to a series of alternating stresses, increasing and decreasing in opposite directions, the mean modulus for the whole cycle is distinctly greater than that obtained by the usual method of determination. The mean modulus of elasticity decreases with the increase in amplitude of the cycle, from which it is concluded that the rate of transmission of earthquake waves is a function of their amplitude, and is less for a larger than for a smaller amplitude. The modulus of elasticity was found to have a maximum value at about 9° C., and to decrease by about half per cent. of its value for each rise of one degree of temperature; from this it is inferred that there is a tendency towards a decrease in the rate of transmission as the depth of the wave path increases. On the other hand, the average rate of transmission is higher in Archæan and Palæozoic than in the newer rocks, and from these two considerations the deduction is drawn that there is a level of maximum velocity of transmission. We may point out that in arriving at this conclusion no account is taken of the increase in pressure with depth, and the consequent increase in compression of the rocks.

Prof. Imamura, in the Tokio *Sugaku-Butsurigakkwai* (Tokio Physico-Mathematical Society), vol. ii., No. 13, adopts the same notion that there is a level of maximum rate of propagation, and places this level at a depth of a few hundred kilometres. The estimate is based on the high rate of transmission, as much as 16 km. per second, obtained for near earthquakes by a calculation from the observed duration of the preliminary tremors, on the assumption that their rate of propagation is uniform. In another part of the paper he gives the results of direct calculation in the case of ten earthquakes the time of origin of which was known; for Tokio, at a mean epicentral distance of 665 km., the rates were 7·5 km. per second for the first, and 5·5 km. per second for the second, phase of the preliminary tremors, while Osaka, at a mean epicentral distance of 856 km., gave 8·2 km. and 5·8 km. per second respectively. These values may be accepted as more trustworthy than those obtained by the other method.

Globus of September 15 contains a note by Wilhelm Krebs on the distribution of submarine earthquakes, illustrated by a map of the world, on which all the recorded instances are plotted. Many of these are submarine volcanic eruptions, and their great concentration in the middle of the narrowest part of the Atlantic Ocean, between Africa and South America, is very striking. The utility of charts of this description would be much increased if they bore on their face indications of the principal trade routes of the oceans; as it is, some doubt may be felt as to whether the much greater frequency of recorded seismic phenomena in the Atlantic Ocean may not be due to a very large extent to the fact that this ocean is, proportionately, much more frequented than the Pacific. The other centres of activity, according to the map, are the West Indian islands, the west coast of South America, the south of the Bay of Bengal, the Malay Archipelago, the east coast of Japan, and the Mediterranean.

THE RACIAL ELEMENTS IN THE PRESENT POPULATION OF EUROPE.[1]

THE lecturer opened his discourse with a graceful acknowledgment of the honour conferred upon him by the Anthropological Institute, and paid a respectful tribute to the memory of Huxley, who was the first to make the two-fold division of the peoples of Europe into xanthochroid and melanochroid races. With the name of Huxley he coupled the names of Beddoe and Broca as pioneers in European ethnographical research. To the two races mentioned above a third was soon added—the Mediterranean race—and the lecturer himself had in 1897 made a further step by dividing the population of Europe into six main races. He then dealt with criticisms which had been passed upon his own theories, chiefly by the American ethnologist Ripley, and stated that the further researches upon which he had continually been engaged since that date, and of which he was about to lay the results before the audience, had confirmed him in his first opinion. During a considerable number of years he had been diligently collecting statistics concerning the stature, colour of eyes and hair, and head measurements of the various nationalities, and now, in spite of certain *lacunae,* some of which he regretted to observe occurred in Britain, he was able to say that he possessed data covering the whole of Europe.

In no part of the world does there exist such a blending of races, such an intermixture of somatic characters, as amongst the ethnic groups which constitute the present populations of Europe, even when we make abstraction of the "national" groupings, such as Austro-Hungarian monarchy, for instance, and consider only the properly called ethnic or linguistic groups, like Slavic, Roman, Germanic, &c.

In an anthropological study of the European populations it is impossible to proceed in the same way as in the case of the majority of the so-called uncivilised peoples, where the measurements of a small series of individuals (often twenty or fifty) suffices to give an idea of the whole population.

Another method is required for the study of complicated ethnic groups. It is the combination of the statistical and the cartographical methods, in which the observations taken on many thousands of individuals permit the investigator to exclude the influence of accidental variations, and to deduce one or several racial types in the population of a given region.

Such measurements concerning the principal racial characters, for instance, the stature, the colours of the hair and the eyes, the shape of the head (expressed principally by the cephalic index, *i.e.* the centesimal relation between the length and the breadth of the head), &c., have been made in nearly all the parts of Europe—especially by the examination of conscripts for the military service.

The only countries in which such measurements are now absent are Montenegro, some provinces of European Turkey and of Caucasus. Some other countries, and not of the least civilised, have not yet furnished sufficient information. For instance, there is no data concerning the cephalic index and the stature for Prussia and some other States of northern Germany; concerning cephalic index and pigmentation for Hungary, Roumania, and Servia; concerning the cephalic index for some parts of Switzerland, of Holland, of Russia, and, the lecturer regretted to have to mention that, for some parts of the United Kingdom.

The lecturer expressed then the hope that in a short time all these *lacunae* would disappear; considering this fact, that many serious efforts are made now for studying the populations in Germany, Roumania, Russia, and Great Britain. In every case this *lacunae* represent only a small part of Europe. For the rest, the details are sufficient, and furnish a basis for general deductions.

Taking the whole mass of these results (about 20,000, expressing the observations on more than 3,000,000 of individuals), and correcting them as to be comparable with each other, the lecturer explained how he put on the maps of Europe, of a comparatively large scale (1/10,000,000), district by district, this different data, and obtained in this way the distribution of every one of the principal somatic characters throughout the different regions of Europe.

Concerning the cephalic index, Europe can be divided into four regions:—

(1) A region of long-headed people with medium-headed areas in the north-west (Scandinavia, north of Germany, Holland, Great Britain).

(2) A region in the south-west (Portugal, Spain, south of Italy, east of Balkan Peninsula), characterised by even greater length of head.

(3) A very short-headed region in western Central Europe (south-eastern France, southern Germany, northern Italy, Switzerland) and in the immediate west of the Balkan Peninsula.

(4) A region comprising Russia and Poland subdivided into three, moderately long-headed in the centre, and medium-headed on the east and west.

After discussing these regions in detail, he proceeded to the subject of stature. He remarked that the great mass of his data was compiled from measurements taken on conscripts, and explained an ingenious method by which these measurements could be modified so that they represented fairly the typical stature of the full-grown male population. In Europe there are no people of very short stature according to the classification invented by Topinard (under 1,600 mm., or 63 inches); on the other hand, this continent is distinguished by the tallest race known, the Highlanders of Scotland. Hence, for the purpose of this lecture, he would speak of statures ranging between 1650 and 1675 mm. (65 inches to 66 inches) as *medium,* those below these measurements as *short,* and those above as *tall.* Tall statures are, with a very few exceptions, particularly well represented in the north-west; the rest of the population of Europe is, again with certain exceptions, chiefly in the Balkan Peninsula, of medium or short stature. People of medium stature are found grouped round the regions where the tall peoples occur, and connect the tall races of the north-west with those of the south-east. Short statures he divided into three groups, eastern (Russia), western (France), and southern (Spain and Italy), and showed how the eastern zone communicated by narrow "channels" with other centres of short stature.

In grouping the peoples of Europe with regard to colour of complexion, eyes and hair, he had taken as the basis of his classification the *brunette* type (eyes and hair *dark* brown or black), as the most easy of recognition. Those peoples among whom are found from 17 per cent. to 30 per cent. of brunettes may be called *intermediate.* Where less

[1] Summary of the Fifth Huxley Memorial Lecture, delivered before the Anthropological Institute of Great Britain and Ireland, on October 7, by Dr. J. Deniker, president of the Anthropological Society of Paris, to whom was presented the Huxley Memorial medal.

than 17 per cent. occur the population is termed *blond*, where more than 30 per cent. dark.

According to this grouping the two extremes are the Swedish (3 per cent. brunettes) and southern Italy (70 per cent.). From this point of view the map showed that north Europe was mainly blond, South Europe dark, and Central Europe intermediate. He traced the southern limit of the blond races through the various countries, showing that it nowhere reached below the 50th parallel in Central Europe, and below 55th parallel in Britain and Russia. The northern limit of the dark peoples is more irregular. In the intermediate zone blond areas are rare (one of these occur in south England, *i.e.* Berkshire, Oxfordshire, Hampshire, Sussex and Middlesex), dark areas fairly numerous, but individually very small. Intermediate areas in the blond zone are only found in the British Isles, but in the dark zone are fairly frequent in western Europe.

From these data and certain other considerations relating to shape of face and nose, character of hair, &c., Dr. Deniker had been confirmed in his theory that the present population of Europe is composed of six main races. These he proceeded to enumerate, giving their typical characteristics, tracing their positions throughout the map, and indicating the proportions in which they had intermingled to form the existing populations of the various countries. The following is an abbreviated sketch of his classification:—

(1) A race, blond, wavy-haired, long-headed, very tall, with long face, a straight prominent nose; the *northern race*, so called because its representatives are confined almost exclusively to North Europe. This is the *Cymric race* of Broca, the *Germanic* or *Reihengräber* race of German authors, the *Teutonic race* of Ripley, or the *Homo Europaeus* of Lapouge.

With this race is connected a subrace, blond or intermediate, straight-haired, medium-headed, of tall or medium stature, angular face, and *retroussé* nose, the *subnorthern race*, found in the neighbourhood of the *northern*.

(2) A race blond, straight-haired, moderately short-headed, and of short stature, broad square face, nose often *retroussé*; the *Eastern race*, so named since its principal home is in eastern Europe.

Connected with this is a subrace, blond or intermediate, medium-headed, of very short stature, named the *Vistulian race*, occurring in Poland, parts of Prussia, and probably Saxony and Silesia.

(3) A race dark, hair sometimes curly, long-headed, of very short stature, straight or *retroussé* nose; the *Ibero-insular race*. This is the *Mediterranean race*, or *Homo Mediterraniensis* of certain authors, found chiefly in the Iberian Peninsula and the islands of the western Mediterranean.

(4) A race dark, very short and round headed, of short stature, round face, broad nose, and thick-set body; the *Cevenole* or *western race*. This type occurs in its greatest purity in the extreme west of Europe, though found sporadically elsewhere. This is the race called variously by other authors *Celtic, Celto-Ligurian, Celto-Slavonic, Sarmatian, Rhetian, Ligurian*, or *Homo Alpinus*.

(5) A race very dark, moderately long-headed, and fairly tall; the *Littoral*, or *Atlanto-Mediterranean race*, situated on the coast of the Mediterranean, from Gibraltar to the Tiber, and in occasional groups on the Atlantic Littoral, but never more than 150 miles from the sea.

(6) A race dark, short-headed, tall, nose slender and straight or arched; the *Adriatic* or *Dinaric race*, which is found grouped round the northern Adriatic, particularly in Bosnia, Dalmatia, Croatia, and the centre of the Balkan Peninsula, but found also sporadically and with somewhat modified characteristics in Central Europe.

With the last two races are connected two secondary races, which are perhaps no more than types, produced by the admixture of the two former with each other or with the *northern, subnorthern*, and *western* races.

(*a*) The north-western, long- or medium-headed, situated between the *northern* and *Atlanto-Mediterranean* races, spread chiefly in Ireland.

(*b*) The sub-Adriatic, moderately short-headed, more rarely short-headed, of medium stature, found in many parts of Central Europe, probably the result of admixture between the *Adriatic* and *subnorthern* and *western* races.

REPORT OF THE SURVEY OF INDIA.

The Indian Survey report is a full record of useful work and widespread progress, but it lacks some of the interest which used to attach formerly to the very varied character of the work undertaken by the Survey department. The scientific section of the report is included within the limits of a few pages; and the narratives of individual surveyors (which always formed a most interesting chapter or two) have entirely disappeared.

The main work of the department, now, is the revision of old mapping in districts which have been sorely in need of such revision for many years. The plains of India, in fact, are being re-surveyed, and, on the whole, the work of the department is increasing, rather than diminishing, on purely utilitarian lines. It would almost seem as if the days of Indian geodetic triangulation, which once took such a strong lead amongst the scientific triangulations of the world, were numbered. Only one first-class series is in progress at present, and this is to connect the great meridional Mandalay series of Burma with a future extension following the Salwin valley. It is, however, satisfactory that the practice and training necessary for surveyors in this class of work is well maintained so far, for it is impossible to say what the future may demand in the way of similar extensions in Persia, Tibet, or even in China.

One subject of special interest dealt with in the report is the deflection of gravity. In 1901 a theory was advanced by Major Burrard that deflections of gravity in India could be classified by regions. Astronomical determinations of latitude have therefore been carried systematically through considerable arcs to prove whether this theory were sound. The results undoubtedly support Major Burrard's prediction, and it is expected that the substitution of this regional law for the old theory of local attraction will exercise a profound influence on future investigations.

The report on geographical or reconnaissance surveys (on the scale of 1/500,000) includes an out-turn of 38,000 square miles of survey of this class by one native assistant in western Tibet. This seems a remarkably large out-turn for one surveyor to secure during the progress of a "shooting expedition"; but it is only one instance amongst many of the remarkable capacity of well trained native explorers for work of this nature. In reasonably easy country there seems to be hardly any limit to their power of producing fairly accurate geographical maps so long as they have a few fixed points to work upon.

In this connection it is well to note the remarks of the Surveyor-General (Colonel St. G. Gore) on the difficulty that constantly faces him of finding qualified native assistants to meet the demands of military or political missions or geographical expeditions. He most justly observes that in the first place it is difficult to find the men who possess the necessary qualifications, and in the second that, having found them, it is impossible to train them efficiently in country which is unsuitable for instruction. It is due to a combination of natural aptitude with perfect educational environment that the native explorer of the Indian Survey becomes so extraordinarily efficient as a topographer. If these men are wanted (and they *are* wanted) for Imperial duty over half of the continents of Africa and Asia, it seems but fair that the Imperial Treasury should contribute something towards maintaining a sufficient staff to meet all demands.

T. H. H.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Cambridge.—The State Medicine Syndicate reports that during the current year there were 57 candidates for the diploma in public health, of whom 34 were successful. For the diploma in tropical medicine and hygiene there were 12 candidates, of whom 8 were successful. The syndicate has resolved to hold two examinations for the latter diploma in 1905, the first beginning on January 10, the second on August 8.

Applications for the vacant readership in botany (annual stipend 300*l*.) are to be sent to the Vice-Chancellor by Tuesday, November 15.

Mr. R. H. Lock, late Frank Smart student in botany, has been elected to a Drosier fellowship at Gonville and

Caius College. Dr. A. C. Haddon, university lecturer in ethnology, has been elected to a senior fellowship at Christ's College.

A department of experimental psychology has been established, says *Science*, in the Western University of Pennsylvania, under the charge of Dr. Edmund B. Huey.

The new medical buildings of the University of Liverpool will be opened by the Chancellor, Lord Derby, on Saturday, November 12, and on the same day Lord Kelvin will formally open the new George Holt Physics Laboratory.

The council of the University of Liverpool has just appointed Dr. J. H. Grindley lecturer in engineering, Mr. A. Leitch assistant lecturer in engineering, and Mr. G. E. Piper demonstrator in applied mechanics and engineering design and drawing.

We regret to learn of the death of Prof. D. W. Fiske on September 17. The bulk of his estate, including the great book collections, has been left to Cornell University. It is stated in *Science* that the bequest amounts to between 100,000*l*. and 200,000*l*.

Dr. E. G. Coker, of the McGill University, Montreal, has been appointed to the professorship of mechanical engineering and applied mathematics at the City and Guilds Technical College, Finsbury, vacated by the appointment of Prof. Dalby to the professorship of engineering at the institute's Central Technical College.

Mr. Francis Galton, F.R.S., has endowed a research fellowship in the University of London for the promotion of the study of "national eugenics," defined as "the study of the agencies under social control that may improve or impair the racial qualities of future generations either physically or mentally." The fellowship is of the annual value of 250*l*., is tenable for one year in the first instance, and is renewable for two subsequent years. The person appointed to the fellowship will be required to devote the whole of his time to the study of the subject, and in particular to carry out investigations into the history of classes and families, and to deliver lectures and publish memoirs on the subject of his investigations.

The report on the work of the department of technology of the City and Guilds of London Institute for the session 1903–4 has now been published. The general introduction to the report points out that the encouragement now offered by the Board of Education to the teaching of technology is among the causes contributing to the increase in the number of students in the institute's registered classes. Compared with the figures given in last year's report, those for the past session show a decided improvement. In the different branches of technology, the number of students in November last attending classes in the United Kingdom was 41,089 as compared with 38,638 in the previous year, and the number of examinees was 20,051 as against 17,989. The closer connection of the work of the department with that of the Board of Education is shown, also, not only by the recognition of the City and Guilds of London Institute as an organisation for the inspection of classes in technology, manual training, and domestic economy, but also by the stamping by the Board of Education of full certificates granted by the institute to students who pass in technology and have "qualified in the cognate science or art subjects required by the institute." It is interesting to find that the question of arranging courses of instruction adapted to the requirements of operatives engaged in ship-building is under consideration; it is intended to extend the syllabus in ship carpentry and joinery so as to make it suitable for artisans engaged in other branches of the industry. Care is to be taken not to overlap the syllabus in naval architecture of the Board of Education, and it is expected that the new examination will appeal to a different class of candidates from those who have hitherto presented themselves for examination. It should be noted that the department of technology of the institute occupies an intermediate position between the central and local education authorities and the several trade societies. The latter bodies have shown a growing interest in technical instruction, and year by year the department has grown into more intimate relationship with these trade organisations.

SOCIETIES AND ACADEMIES.

London.

Entomological Society, October 19.—Prof. E. B. Poulton, F.R.S., president, in the chair.—Dr. T. A. **Chapman** exhibited a series of *Lozopera deaurana*, Peyr., bred last spring at Hyères, a species regarded as lost, or mythical, until he re-discovered it three years ago at Ile Ste. Marguerite, Cannes. He also exhibited on behalf of Mr. Hugh Main a specimen of *Pieris brassicae*, the anterior and posterior wings of which had been symmetrically injured, probably by the girdle when in the pupal stage.—Mr. G. C. **Champion** exhibited specimens of *Nothorrhina muricata*, Dalm., from Las Navas, Spain, found trapped in the earthenware cups used to collect the exuding resin on the trunks of pines.—Mr. H. St. J. **Donisthorpe** exhibited specimens of the rare beetle, *Cis bilamellatus*, Wood, taken at Shirley on October 10 last.—Mr. W. J. **Lucas** exhibited a ♀ specimen of the rare dragonfly *Agrion armatum*. He said that a ♂ and a ♀ were taken in the Broads by Mr. F. B. Browne last year, and this year about ten more, probably all ♀♀, were taken in the same district. Besides these there are possibly no other examples in Britain. It is quite distinct from our other six blue Agrionines in form and colouring.—Mr. W. J. **Kaye** exhibited five specimens of *Dianthoecia luteago*, var. *ficklini*, from North Cornwall, taken during the first week of July, 1901, and remarked that while the typical *D. luteago* of the Continent was tolerably constant, wherever it occurred in Britain it assumed a special local form.—Prof. E. B. **Poulton,** F.R.S., exhibited a number of specimens of the genus Sphecodes, five species in all, and of *Ocyptera brevicornis*, a Tachinid, their mimetic fly, illustrative of Mr. Edward Saunders's recent paper on the aculeate Hymenoptera from the Balearic Islands and Spain.—Mr. C. A. J. **Rothney** sent for exhibition a series of the Indian ant *Myrmicaria fodiens*, from a colony established thirty-two years in the big banyan tree in Barrackpore Park; and specimens of *Monomorium salomonis*, Lin., and *Solenopsis geminata*, Fab., successfully encouraged in Madras as a protection against white ants—termites.—Mr. E. E. **Green** exhibited a spider from Ceylon mimetic of some coccinellid beetle, at present unidentified.—Colonel J. W. **Yerbury** exhibited specimens, and read notes upon, deer gadflies taken by him this year in Scotland.

Manchester.

Literary and Philosophical Society, October 18.—Prof. W. Boyd Dawkins, F.R.S., president, in the chair.—Dr. W. A. **Bone** read a paper entitled "The Mode of Combustion of Hydrocarbons," in which he gave an account of researches carried out by Messrs. R. V. Wheeler and W. E. Stockings and himself, at the Owens College, on the slow combustion of hydrocarbons below their ignition points.—Dr. Charles H. **Lees** exhibited a modification of the U-tube used in electrolysis which he had devised, and which diminishes to about one-half the correction for pressure due to the column of liquid in the unsealed limb of the tube.

Paris.

Academy of Sciences, October 24.—M. Mascart in the chair.—Stereoscopy without a stereoscope: J. **Violle.** In a camera, furnished with two objectives, directly in front of the plate is placed a grating, ruled with 100 black lines to the inch. The negative from this contains the two sets of images, each crossed with a set of fine bands. When this is looked at through a similar ruled plate the picture appears in relief.—On the modifications of glycolysis in the capillaries caused by local modification of the temperature: R. **Lepine** and M. **Boulud.** The experiments were made on dogs. Relatively to the arterial blood, the venous blood of the warmer part always contains a little more sugar. In the case of the paw kept cool, this difference is increased to about double, and is in the same direction.—On integral functions of finite order: L. **Leau.**—On certain partial differential equations of the second order: S. **Bernstein.**—On the period of antennæ of different forms: C. **Tissot.** On account of the high value of the deadening, the rotating mirror method does not give accurate figures for the period, and the author describes another method which is free from this objection. It is shown that, independently of the principal period, the antennæ give rise to oscillations of a higher order, the laws for which have been experimentally worked out.—Study of the sea bottom of the North Atlantic; the Henderson and Chaucer Banks: M. **Thoulet.** The examination of the deposits obtained from the bed of the North Atlantic by the Prince of Monaco renders the existence of the Henderson and Chaucer Banks improbable. The proportion of lime found was remarkably uniform, whilst the amount of sand was very variable. It results that the usual method of classification by sand, although very useful near the coasts, is useless for the study of great depths.—Remarks on a recent series of calorimetric determinations: P. **Lemoult.** Some recent calorimetric determinations with the Krœker bomb by E. Fischer and F. Wrede are re-calculated to constant pressure, and the results compared with the original figures of Berthelot and some later unpublished ones of Landrieu. The numbers given by the formulæ of the author are also tabulated in parallel column.—The extraction of vanadium from the natural lead vanadate and the manufacture of some alloys of this metal: H. **Herrenschmidt.** The mineral is treated in a reverberatory furnace with carbonate of soda and carbon, and a slag obtained containing the vanadate, aluminate, and silicate of soda along with oxide of iron. This is again melted, and air blown through until the vanadium is completely oxidised, and the sodium vanadate lixiviated.—On a new anhydride of dulcite: P. **Carré.** The new anhydride is obtained by heating dulcite with phosphoric acid at 135° C. It is isomeric with mannide, and is named dulcide.—A new method for preparing organic derivatives of phosphorus: V. **Auger.** The solution obtained by dissolving granulated phosphorus in alcoholic soda is heated with an alkyl iodide or bromide. An alkylphosphine is formed, recognised after its oxidation to the corresponding alkylphosphinic acid.—The influence of the products of the breaking down of albuminoid materials on the saponification of oils by cytoplasma: Ed. **Urbain,** L. **Perruchon,** and J. **Lancon.**—On the tyrosinase of the fly: C. **Gessard.** In *Lucilia Caesar*, in both stages in the life of the insect, the coloration of the integument is due to the reaction of the tyrosinase.—On a parasite of *Audouinia tentaculata*, *Angeiocystis audouiniae*: Louis **Brasil.**—Oscillations of coast-line animals synchronous with the tide: Georges **Bohn.**—On the geology of the Lower Engadine: Pierre **Termier.**—On the toxicity of the chlorohydrate of amyleine: L. **Launoy.**

DIARY OF SOCIETIES.

THURSDAY, NOVEMBER 3.

CHEMICAL SOCIETY, at 8.—Note on the Action of Nitric Acid on the Ethers: J. B Cohen and J. Gatecliff.—The Condensation of Formaldehyde with Acetone (Preliminary Note): E. A. Werner.—Union of Hydrogen and Chlorine. Rate of Decay of Activity of Chlorine: J. W. Mellor.—The Action of Phthalic Anhydride on α-Naphthylmagnesium-bromide: S. S. Pickles and C. Weizmann.—The Constitution of Nitrogen Iodide: O. Silberrad.—The Available Plant Food in Soils: H. Ingle.—The Combustion of Ethylene: W. A. Bone and R. V. Wheeler.—The Decomposition of Methylurea: C. E. Fawsitt.—The Influence of Certain Salts and Organic Bodies on the Oxidation of Guaiacum: Miss E. G. Willcock.—The Influence of Potassium Persulphate on the Estimation of Hydrogen Peroxide: J. A. N. Friend.—The Dynamic Isomerism of α- and β-Crotonic Acids (Preliminary Note): R. S. Morrell and E. K. Hanson.—The Influence of Sunlight on the Dissolving of Gold in an Aqueous Solution of Potassium Cyanide: W. A. Caldecott: (1) The Fractional Hydrolysis of Amygdalinic Acid; (2) Isoamygdaline: H. D. Dakin.

RONTGEN SOCIETY, at 8.15.—The Presidential Address: C. Thurston Holland.

CIVIL AND MECHANICAL ENGINEERS' SOCIETY, at 8.—Presidential Address, The Effect of Patent Law on Modern Civilisation: C. T. Hanssen.

FRIDAY, NOVEMBER 4.

GEOLOGISTS' ASSOCIATION, at 8.—Conversazione.

MONDAY, NOVEMBER 7.

ROYAL GEOGRAPHICAL SOCIETY (Albert Hall), at 8.30—The Work of the National Antarctic Expedition: Captain R. F. Scott, R.N.

SOCIETY OF CHEMICAL INDUSTRY, at 8.—The Trend of Invention in Chemical Industry: J. Fletcher Moulton, F.R.S.

TUESDAY, NOVEMBER 8.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Coast Erosion: A. E. Carey.—Erosion on the Holderness Coast of Yorkshire: E. R. Matthews.

WEDNESDAY, NOVEMBER 9.

GEOLOGICAL SOCIETY, at 8.—On the Occurrence of *Elephas meridionalis* at Dewlish, Dorset. No. II. Human Agency Suggested: Rev. Osmond Fisher.—Notes on Upper Jurassic Ammonites, with Special Reference to Specimens in the University Museum, Oxford. No. II.: Miss Maud Healey.—Sarsen-Stones in a Clay-Pit: Rev. E. C. Spicer.

THURSDAY, NOVEMBER 10.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—The premiums awarded for papers read or published during the session 1903–4 will be presented, and the president, Mr. Alexander Siemens, will deliver his inaugural address.

MATHEMATICAL SOCIETY, at 5.30.—Annual General Meeting.—Presidential Address on the Theory of Waves on Liquids: Prof. H. Lamb.—Note on the Application of the Method of Images to Problems of Vibrations: Prof. V. Volterra.—On the Zeros of Certain Classes of Integral Taylor's Series: G. H. Hardy.—The Linear Difference Equation of the First Order: Rev. E. W. Barnes.—Curves on a Conicoid: H. Hilton.—Remarks on Alternants and Continuous Groups: Dr. H. F. Baker.—On the Expansion of the Elliptic and Zeta Functions of $\frac{1}{2}K$ in Powers of q: Dr. J. W. L. Glaisher.—Examples of Perpetuants: J. E. Wright.—Two Simple Results in the Attraction of Uniform Wires obtained by Quaternions, with, for comparison, their Verification by the Geometry of the Complex: Prof. R. W. Genese.—On the Reducibility of Covariants of Binary Quantics of Infinite Order: P. W. Wood.—On some Properties of Groups of Odd Order: Prof. W. Burnside.

FRIDAY, NOVEMBER 11.

ROYAL ASTRONOMICAL SOCIETY, at 5.

MALACOLOGICAL SOCIETY, at 8.—Descriptions of Three New Species of Opisthostoma from Borneo: E. A. Smith, I.S.O.—Two Apparently New Species of Planispira from the Islands of Java and Gisser: Rev. R. Ashington Bullen.—The Anatomy of *Siliqua patula*, Dixon: H. Howard Bloomer.—On the Genus Tomigerus, with Descriptions of New Species: H. von Ihering.—Notes on Some New Zealand Pleurotomidæ: Henry Suter.—Notes on Some Species of Chione from New Zealand: Henry Suter.

SOCIOLOGICAL SOCIETY, at 4.—Relation between Sociology and Ethics: Prof. Höffding.

CONTENTS.

THURSDAY, NOVEMBER 10, 1904.

JUSTUS VON LIEBIG AND FRIEDRICH MOHR.

Monographieen aus der Geschichte der Chemie. Herausgegeben von Dr. Georg W. A. Kahlbaum. viii. Heft. Justus von Liebig und Friedrich Mohr in ihren Briefen von 1834–1870. Pp. viii+274. (Leipzig: Johann Ambrosius Barth, 1904.) Price 8 marks.

DR. KAHLBAUM continues to put those chemists who are interested in the personal history of their science under an obligation to him by reason of the care and assiduity which he devotes to the editing of the letters of the great leaders of chemical inquiry such as Berzelius, Liebig, Wöhler, and others, as these from time to time come into his keeping. The volume before us deals with the correspondence of Liebig and Friedrich Mohr.

Of Liebig it is unnecessary at this date to say anything. His name and personal characteristics are well known to all who are interested in science, and his position in the history of science is assured for all time. Whilst his correspondence with Mohr adds but little to our knowledge of him as a man, it throws many sidelights on incidents which occurred during the most interesting and active periods of his career. Thus, for example, we learn for the first time of the relative share of Liebig and Wöhler in the work which resulted in the classical memoir on bitter almond oil. Most of the experimental work was due to Wöhler; the interpretation of the facts and the compilation of the memoir was made by Liebig. It would appear, in fact, that Wöhler never saw the memoir until the proof of it was sent to him.

Indeed, the chief interest of the correspondence, so far as it relates to Liebig, is concerned with his work as editor of the famous periodical—the *Annalen der Chemie und Pharmacie*—which is now permanently associated with his name.

The name of Friedrich Mohr is much less familiar, at all events to the chemists of this generation; and yet the author of the "Titrier-methode"—the practical founder of the art of volumetric analysis—deserves to be had in remembrance. He was a representative of a type of man of which few examples, at least in this country, are left to-day, viz. that of the scientific apothecary. He was by instinct, training, and practice a man of science, and he brought his knowledge, experience, and aptitudes as a man of science to the exercise of his calling. In this respect he resembled many of those who laid the foundations of modern chemical science. In the early part of the last century the occupation of the apothecary was practically the only one open to the man who had his living to make, and who at the same time wished to exercise his passion for chemical inquiry. Teaching appointments were few, and even where chemistry was taught the opportunities for experimental work were very meagre.

Mohr was born in Coblenz at about the time that Dalton gave the New Philosophy to the world. His father, Karl Mohr, apothecary, town councillor and member of the Rhenish Medical College, was a person of some importance in the city, and it was probably in his house that the authors of this correspondence first made each other's acquaintance.

Coblenz, from its proximity to the French frontier, was the scene of many stirring episodes during the early years of the nineteenth century, and Mohr himself lived through the time of, and was personally witness to, the rise and collapse of French military power during the interval between Moscow and Sedan. As a little boy he might have seen the passage of the Rhine by the French troops on the occasion of Napoleon's invasion of Russia, and have spelled out the magniloquent inscription on the fountain before St. Castor which commemorates that event, as well as the caustic words which St. Priest, the Russian commander following on the heels of the retreating French, caused to be added:—"*Vu et approuvé par nous, Commandant Russe de la Ville de Coblence: Janvier 1er* 1814." As an old man he saw, after the *debâcle* of Sedan, the spectacle of a ruined and discredited War Minister skulking about in the twilight under the shade of the chestnuts in the Poppelsdorfer Allée in Bonn in just fear of the taunts and insults of the unfortunate soldiery whom he had betrayed.

In 1829 Mohr went to Heidelberg, where he came in contact with Leopold Gmelin. He had already acquired a considerable knowledge of operative chemistry and of pharmacology under his father's tuition. In those far-off days the laboratory of an apothecary was a reality, and those who practised the calling were not merely chemists by prescription, but were such in fact. They were for the most part well skilled in chemical processes, and actually made the greater number of the substances in which they dealt. The influence of this early training is to be seen in the character and scope of Mohr's subsequent work. He was essentially a *practical* chemist, and his services to the science consisted mainly in the improvements he effected in operative chemistry. Many of these humble but useful inventions were not calculated to bring their author much fame, but if his connection with them is well-nigh forgotten they at least secured for him the gratitude of his contemporaries. How many of the present generation of workers, it may be asked, associate his name with that commonest of laboratory appliances—the cork-borer?

Mohr remained at Heidelberg two years, and then repaired to Berlin to listen to Heinrich Rose's lectures. In 1832 he returned to Heidelberg and took his degree—*summa cum laude*. What a *summa cum laude* meant in 1832, so far as regards chemistry, may be inferred from the fact that the "hoch berühmten Führer," Gmelin, recorded that "the Herr Kandidat answered his questions on the chemical relations of iodine, the preparation of potassium iodide, the discovery of arsenic and on the preparation and composition of ether to his complete satisfaction." Creuzer found that he displayed considerable knowledge of what the old Greeks and Romans knew of botany and *materia medica*, and that he had a competent acquaintance with their languages; Muncke was satisfied with his answers concerning the balance, the pyrometer, and the electrical relations of bodies; Leonhard with those on mineralogy and geology; and Schweins recorded that the "Kandidat als Pharmazeut ungewöhnliche Kenntnisse in der Mathematik besitzt"—whatever that might imply.

The subjects in which Mohr took his degree continued to interest him to the end of his days. In chemistry he was no theorist; indeed, the speculative side of this science seemed to have little or no attractions for him; and this is the more remarkable when it is remembered that in other departments of human thought he let his imagination have the fullest play, as may be seen in his "History of the Earth." Further, Mohr has some claim to be regarded as an independent discoverer of the law of the conservation of energy, as his tombstone in the old "Friedhof" in Bonn testifies.

To the historian of chemistry these letters have a special interest. If, as has been said, they add little to our knowledge of Liebig as a man and as a leader in science, they nevertheless afford much valuable information concerning matters which agitated the chemical world during some of the most stirring periods of the last century. They have been most carefully annotated by the editor and his assistants, as the numerous foot-notes indicate. Many passages and allusions which might have been obscure have been elucidated by their patient research. We can heartily commend the book to all who are interested in the personal and biographical history of chemistry.

T. E. T.

THE BIONOMICS OF EXOTIC FLOWERS.

Handbuch der Blütenbiologie. Begründet von Dr. Paul Knuth. iii. Band. Die bisher in aussereuropäischen Gebieten gemachten blüten-biologischen Beobachtungen unter Mitwirkung von Dr. Otto Appel. Bearbeitet und herausgegeben von Dr. Ernst Loew. i. Theil. Cycadaceæ bis Cornaceæ. Pp. 570; mit 141 Abbildungen im Text. (Leipzig: Engelmann, 1904.) Price 17s. net.

THIS valuable summary of available information concerning the pollination of exotic flowers maintains the high standard of the preceding volumes, though it naturally deals with knowledge essentially fragmentary and only rarely founded on a statistical basis. The work does not limit itself to imparting information upon actual observations on pollination, but in some cases includes accounts of the forms and colours of flowers, the arrangement of their nectaries, and even the microscopical details of fertilisation. As examples of the various matters dealt with, the following may be cited:—Freycinetia and its suggested pollination by bats, the remarkable synchronous blossoming habits of *Dendrobium crumenatum*, parthenogenesis in Ficus, Kooders's work on tropical geocarpous plants, the fertilisation of Rhopalocnemis, the peculiar flowers of the commelinaceous Cochliostema and their morphology, species of Yucca and their relations with Pronuba.

Among the many interesting features of the work we may note that in bringing together in one work the scattered observations on ornithophilous pollination it renders possible a survey of existing knowledge concerning the inter-relations of birds and flowers. Yet the facts recorded show the rudimentary stage of our knowledge as to the significance of birds in the shaping of flowers. Scattered through the present work we find evidence of actual or possible ornithophilous flowers belonging to a considerable number of natural orders, including the Bromeliaceæ, Liliaceæ (Alöe), Scitamineæ, Orchidaceæ, Proteaceæ, Loranthaceæ, Ranunculaceæ (Aquilegia), Capparidaceæ, Rosaceæ (almond, peach, quince), Caricaceæ, Leguminosæ, Melianthaceæ, Balsaminaceæ (Impatiens), Malvaceæ, Cactaceæ, Rhizophoraceæ, Myrtaceæ, Marcgraviaceæ, and Passifloraceæ. Included among these are flowers, such as the peach and almond, obviously not originally ornithophilous, and others, such as Passifloraceæ and *Aquilegia canadensis*, the pollination of which by birds is dubious. Still others there are, such as *Carica Papaya*, the structure and creamy tint of the flowers of which scarcely suggest ornithophily. Other observations show that in different parts of the earth the same species of flower is visited by different animals. For example, the entomophilous Japanese *Eriobotrya japonica* is visited by humming-birds in South America, and by honey-birds in South Africa. On the other hand, certain natural orders, such as the Loranthaceæ and Mimosaceæ, markedly show pollination, or at least regular visitation, by honey-birds in the Old World and by humming-birds in the New World; and some flowers of remarkable structure, such as those of *Amherstia nobilis* and *Hibiscus schizopetalus*, visited by birds seem to demand correspondingly remarkable methods of pollination.

The fragmentary nature of our knowledge in regard to pollination is shown by the lack of published information in regard to some of the commonest plants. For instance, *Bombax malabaricum* is not mentioned in this work, yet it is very widely distributed, and even common in some regions; and in southern China I know that its large red flowers are visited by small birds. In some cases the omission of information is due to oversight on the part of the authors; for example, there is no reference to the Vallisneria-like pollination of the submarine Enhalus. The work also shows that additional observations are required in regard to some of the commonest tropical plants. As a case in point, it may be said that few of those who have scented *Pandanus odoratissimus* at distances of a quarter of a mile will accept without further examination the view that littoral species of Pandanus are anemophilous. Or, again, Knuth found that the flowers *Cassytha filiformis* were mostly cleistogamous on the coral islands of the Java Sea; but unpublished observations of my own on Dane's Island, near Canton (China), sufficiently showed that this is not the case everywhere.

In regard to the printing of the work, it must be confessed that misprints are too numerous, a brief examination showing the following:—Kleistoam, Magroglossa, Abitulon, Spahtiphyllum, and Bromeliaceenhlüten.

PERCY GROOM.

RECENT PHILOSOPHICAL WORKS.

(1) *A Primer of Philosophy.* By A. S. Rappoport, Ph.D. Pp. 118. (London: John Murray, 1904.) Price 1s. net.

(2) *Religion und Naturwissenschaft. Eine Antwort an Professor Ladenburg.* By Arthur Titius. Pp. 114. (Tübingen und Leipzig: J. C. B. Mohr (Paul Siebeck), 1904.) Price 1.80 marks.

(3) *Philosophische Propädeutik auf Naturwissenschaftlicher Grundlage.* By August Schulte-Tigges. Zweite verbesserte und vermehrte Auflage. Pp. xvi+221. (Berlin: Georg Reimer.) Price 3 marks.

(4) *Der Skeptizismus in der Philosophie.* By Raoul Richter. Erster Band. Pp. xxiv+364. (Leipzig: Dürr'sche Buchhandlung, 1904.) Price 6 marks.

(1) DR. RAPPOPORT'S book, which appears in Mr. Murray's new series of primers, is on the whole a very satisfactory introduction to the study of philosophy. The statement is always accurate, interesting and suggestive, and the terminology is carefully chosen. There are many interesting quotations; perhaps those from the German will not always be understood without a translation by the average reader of a primer. On p. 2 the statement "it was astonishment that first made man philosophize" is attributed to Aristotle. No doubt Aristotle said so, but Plato had the same idea before him. On p. 45 the term sociology is said to be derived from the Latin word *socius*, society (*sic*).

(2) "Religion und Naturwissenschaft" is a counterblast to a lecture given by Prof. Ladenburg of Breslau, on the influence of the natural sciences on the *Weltanschauung*. Prof. Ladenburg, as represented by the quotations from his work, appears to believe that experiment, observation, induction, are the key of all knowledge, and that all the progress of the last centuries has been caused chiefly by the enlightenment due to the natural sciences. This rather extreme position Prof. Titius assails with some success, and then proceeds to vindicate the spiritual life of man, individualisation, *Wertbestimmung*, Christianity, even miracles, on lines that are not altogether novel. But the author is no obscurantist, and the argument is probably as convincing as any popular discussion can make it.

(3) The third work on our list is intended to introduce pupils of the highest classes in *Realgymnasien* to the philosophic principles that underlie scientific method and the general scientific thought of our time. The first part deals with *Methodenlehre*, and discusses observation and experiment, induction, causal law and hypothesis, deduction. In the second part, entitled "The Mechanical View of the Universe, and the Limits of Knowledge," there is an adequate account of such things as atomism, teleology, the Darwinian theory, and the relations of psychical events and their physiological accompaniments. On this last head the author declares himself for a theory of parallelism, not as being the solution of the problem, but the problem itself. The book is excellent both in form and statement, and all the arguments both for and against a particular view are most fully and impartially stated. The quotations show a wide range of reading; but it would perhaps be well if the author's name and the title of the work in question were added in every case.

(4) The first volume of "Der Skeptizismus in der Philosophie" contains an account only of Greek scepticism, that is to say, of Pyrrhonism and of the scepticism of the Later Academy. But as many of the chief problems raised by scepticism in all ages are discussed here at considerable length, this first volume cannot safely be neglected even by those who are chiefly interested in Hume, the "partial" scepticism of Kant, or modern positivism. The author shows himself a most competent guide. He is always fair minded; even where it is most difficult to be patient with certain well-known quibbles of the Pyrrhonists he labours seriously to discover the grain of truth amid the heap of chaff. Almost a hundred pages are given to a discussion of "sensual scepticism," *i.e.* the scepticism which bases itself upon the contradictory perceptions of the same object experienced by different living creatures, by different human beings, by the same human being at different times, and the like. These arguments, according to this work, have weight only as against extreme realists, and both (extreme) idealism and moderate realism (*e.g.* the realism of Locke) are represented as able to face the situation. With which of the two last named the author's sympathies ultimately lie is not apparent from this first instalment; it will doubtless become evident in the second (and concluding) volume. It is to be hoped for every reason that so excellent a work will soon reach completion.

THE CHRISTIAN CENTURY IN JAPAN.

Geschichte des Christentums in Japan. By Dr. J. Haas. Band ii. Pp. xxvii+383. (Tokio: 1904.)

IN this second volume Dr. Haas—whom we congratulate on the well merited doctorate in theology recently conferred upon him by the University of Strassburg—pursues the history of the Christian missions in Japan from the departure of Xavier in 1549 to the year 1570 under the leadership of the Jesuit superior Cosmo de Torres, of Valencia. During that period, and, indeed, almost up to the close of the sixteenth century, the task of conversion lay entirely in the hands of the Jesuits, while the increasing trade with Japan was monopolised by the Portuguese. The sources of Dr. Haas's history are almost wholly European, and above all the famous letters of the Jesuit missionaries from Japan, of which the volume is largely a précis. These authorities are not, however, sufficient, and with the progress of the work it becomes more and more evident that the true history of the Christian century in Japan can only be written in the Peninsula, where, as Father Cros's great book on "St. François de Xavier" tells us, in the inexhaustible archives and libraries of Lisbon and Madrid, and in those of Simancas, Coimbra, Evora, and Ajuda, are to be found the original documents in vast numbers from which alone an adequate account of that most interesting chapter in the world's history can be gathered.

In the score of years covered by the present volume the faith was preached over the whole of Kiushiu and most of Central Japan, the northern and eastern Daimiates and the whole of the great island of Shikoku being untouched. This work was accomplished by eleven Jesuit fathers, assisted by four converts. In 1564 the Daimio of Ōmura, the first Christian Daimio, known as Sumitada, or Omura Risen (Risen was his Buddhist name), was baptised, and adhered to the faith until his death in 1587. It is of this convert that Crasset writes:—

"He went to the chase of the bonzes as to that of wild beasts, and made it his singular pleasure to exterminate them from his states" ("Murdoch," p. 238).

It would, however, be merely special pleading to take this language literally, otherwise than as expressing the worthy father's admiration of the vigour with which the newly made convert promulgated Christianity within his petty domain. Up to 1570, out of the fifteen or sixteen millions of Japanese, some twenty thousand had been baptised. This seems a small proportion, but the true measure would be the ratio of the baptised to the population of those parts of Japan where the gospel had been, with some adequacy, preached. As to the quality of their Christianity it is difficult to form a judgment. The steadfastness of large numbers under persecution is some guarantee of the reality of their belief; on the other hand many in becoming Christians followed the example or obeyed the commands of their feudal superiors.

Another much debated point, not easy to determine, is to what extent the native converts "provoked" the immense majority who still adhered to the Way of the Gods and the Way of Buddha. It is certain that the Buddhists were "provoked," but there is little evidence that they had any real cause of complaint during the period now considered—the provocation was of a passive, not of an aggressive character. On the whole, the fathers were far from unpopular with the common folk. They were looked upon as superior beings, and Froez says of his reception at Yokoseura:—

"All the Christian inhabitants came to meet us and were so delighted at our arrival that they would willingly have taken us on their shoulders and borne us off."

It was not until 1587 that persecution began, the result of a fit of policy of the cruel, crafty, but capable Taiko, Hideyoshi.

Dr. Haas writes lucidly, and his pages are full of interesting details; but the narrative is obscured by an over-abundance of matter that might well be relegated to notes or appendices. The Germans seem unable to distinguish between books and note-books.

F. VICTOR DICKINS.

OUR BOOK SHELF.

Lectures on the Diseases of Children. By Robert Hutchison, M.D., F.R.C.P. (London: Edward Arnold.) Price 8s. 6d. net.

IT is difficult to praise this little volume too highly. It deals with one of the most attractive and satisfactory subjects in medicine, the treatment of children's diseases; the style is excellent, and the illustrations, which, with one or two exceptions, are taken from photographs of the author's cases, are unusually good.

In some three hundred pages Dr. Hutchison describes aspects of some of the more common diseases of childhood which, as he says, "are not usually dealt with in systematic lectures." In the first instance, the lectures were given at the London Hospital; subsequently they were published serially in the *Clinical Journal*, while their present appearance in book form is in response to the request of a number of readers who wanted them in a convenient form for reference.

The early chapters deal with the problems of infant feeding, and the subject, which unfortunately is closely allied, of the various digestive disturbances which occur in hand-fed babies. Upon questions of diet Dr. Hutchison speaks with special authority, and his remarks on the difficult subject of artificial feeding are concise and practical.

In the space of a short lecture it is not possible or desirable to deal with all the conceivable methods by which children might be, or have been, fed, but it seems an omission not to mention "laboratory" milk, which, whatever its objections, certainly offers the physician a method of wonderful precision in prescribing the exact percentage of fat, proteid, and lactose which he requires for any individual patient. The establishment in London of the Walker Gordon Laboratory, at which this milk can be obtained, and the existence of a farm in connection with it at which every precaution is taken to procure germ-free milk with scientific accuracy, certainly deserve mention in any book which deals with the subject of substitute feeding. The expense of "laboratory" milk puts it beyond the reach of many babies, but it is less expensive than a wet nurse, and avoids all the disadvantages inseparable from employing one.

In succeeding chapters Dr. Hutchison deals with various common diseases of childhood. They are all delightful reading, full of common sense and helpful suggestion as to diagnosis and treatment. One would like to quote extensively, but the book is one that every student of the subject, whether he be qualified or not, should possess.

Special interest attaches to the lecture on mental deficiency in childhood, often a subject of great difficulty in practice, and one with which the ordinary text-book scarcely deals. The photographs illustrating this chapter are particularly good.

The concluding chapters are devoted to the diagnostic significance of some common symptoms, such as wasting, cough, fever, &c. It is impossible to do full justice to this delightful book in a short notice. The work forms a valuable adjunct to the good text-books already written on the subject, and it shows to the full the clinical knowledge and the literary ability of the author, whose reputation, already high, will no doubt be increased by it.

Elementary Manual for the Chemical Laboratory. By Louis Warner Riggs, Ph.D., Instructor in Chemistry in Cornell University. Pp. vi+138. (New York: John Wiley and Sons; London: Chapman and Hall, Ltd., 1904.) Price 5s. 6d. net.

THIS volume embodies the author's idea of what should be taught during a one-year course of chemistry, the time available being not less than a hundred and twenty hours for laboratory practice, and sixty for "recitation" work. It is arranged in short numbered paragraphs, each containing a direction to the student or an explanation of some point or process, and is intended to be used, under the guidance of an instructor, in conjunction with some general text-book of chemistry and physics.

About one-third of the work is devoted to preliminary experiments in general chemistry. The student is then introduced to simple volumetric analysis, the principles of which are very well explained

—this forming, perhaps, the best portion of the book. After three experiments in gravimetric work the learner passes on to systematic qualitative analysis, treated from the standpoint of electrolytic dissociation. The author recognises that, "logically," the quantitative work should follow rather than precede the qualitative; but after repeated trials he prefers the order indicated. In the present connection, however, the matter is more one of convenience than of logic.

Accepting the author's system, the experiments themselves are judiciously selected, and well fitted for their purpose. But there are educationists who would by no means agree that "theoretical explanations should be reserved for the recitation-room," and not given in the laboratory. Still less would they say that the students should "study thoroughly all the details of an experiment before attempting to perform it," and that "this should be done outside the laboratory." Whether such a system would tend to produce a hod-man or an architect would depend, as it seems to the writer, less upon its own merits than upon the personality of the instructor. C. S.

Die Einheit der Naturkrafte in der Thermodynamik. By Richard Wegner. Pp. viii + 132. (Leipzig: Von Veit and Co., 1904.)

As described in the secondary title, this pamphlet is an attempt to deduce from the kinetic energy of non-elastic atoms, corporeal and ethereal, all known physical forces, chemical, electrical, and mechanical, including gravity. Nothing Boschovichian is assumed; only the kinetic energy of moving atoms of different sizes. It is not easy to follow an argument which provisionally assumes that the atoms are held together to form molecules with regular vibration frequencies capable of propagating through the surrounding swarm of ether-atoms waves of condensation and rarefaction, by means of the reactions and interference of which (when there are two or more molecules) attractions are brought into being; and which then, in terms of this general outlook, gives reasons why the reaction of the ether atoms may be found sufficient to hold the corporeal atoms together. A necessary consequence of the investigation is that gravity is propagated in time, and should be a function of the temperature. The author has tested the latter point by experiment, and finds some evidence in favour of its truth. The source of the chemical elements is found in the different magnitudes of the atoms, with the corresponding differences in their energetic combinations. The temperature of a body is proportional to the mean molecular weight, multiplied by the square of the mean translational velocity of the molecule; divided by the relative number of molecules in unit volume; multiplied by the relative mean path of the molecule. Since, according to the theory elaborated, the kinetic energy of the elementary particles implies attraction, all bodies will be surrounded by a layer of condensed gas and ether particles. In the waves in the ether sheath is found the source of the electrical current. Electrostatic action, on the other hand, depends on chemical actions in the ether sheath. The applications to chemical and electrical phenomena are admittedly crude and imperfectly worked out; but the author claims to have proved the possibility of deducing all the recognised forces of nature from the kinetic energy of non-elastic Lucretian atoms.

The Science and Practice of Photography. By Chapman Jones, F.I.C., &c. Fourth edition. Pp. 569. (London: Iliffe and Co., Ltd., 1904.) Price 5s. net.

THIS volume, which is the fourth edition of the work, has been very greatly enlarged and rewritten since the appearance of the third edition, the number of chapters having been increased from fifty-five to sixty-eight. It may be considered as forming a most excellent guide to the practice of photography, and a perfect reference for those who so continually question one as to "the best book on photography, for a beginner, you know"; and it will doubtless prove useful as a reference book to many who have long passed the beginner stage. There is a decision of tone and clearness of exposition, combined with an intelligent anticipation of the many questions which arise at every step of the path, which render it especially suitable for this purpose.

At the same time, the scientific reader who hopes to gain from it some account of the work which has been done of late years, with a view to the clearing up in some measure of the chemical and physical problems in which photography abounds, will probably be greatly disappointed. The two most noteworthy features of this, as of almost all English works on photographic science, are found in the method in which contemporary German literature is ignored, and in which the whole of modern physical chemistry is disregarded. The fact, for instance, that development may be regarded as a reversible heterogeneous reaction occurring between ionised salts, in accordance with the mass law, seems to be entirely beyond the idea of this or any other book on the subject. Development with ferrous oxalate is here represented by the equation:—

$$3AgBr + 3FeC_2O_4 = FeBr_3 + Fe_2(C_2O_4)_3 + 3Ag,$$

which, involving as it does the existence of ferric ions in the developer after use, gives a sufficiently distorted view of the reaction. While we find the chemical theory of the book to be of this type, the information as to the progress of sensitometry is of the slightest, no mention whatever being made of the notable researches by Dr. Eder. A most original suggestion as to the nature of the developable condition is to be found at the close of the chapter devoted to that subject. In brief, this book is a most delightful manual of the practice of photography, but can scarcely claim to represent the scientific side of the subject in any sense whatever. C. E. KENNETH MEES.

Ants and Some Other Insects. An Inquiry into the Psychic Powers of these Animals. With an Appendix on the Peculiarities of their Olfactory Sense. By Dr. August Forel. Translated from the German by Prof. William Morton Wheeler. Pp. 49; figures. (Chicago, 1904.) Price 2s. 6d.

AN elaborate treatise on the senses of insects, especially ants, illustrated by numerous experiments. The book deserves the most serious attention of students of psychology and animal intelligence; but it would occupy too much space, nor would any useful object be gained, by attempting to epitomise either the body of the work or even the author's deductions. We may, however, quote the following conclusions:—

"Even to-day I am compelled to uphold the seventh thesis which I established in 1877 in my habilitation as *privat-docent* in the University of Munich:

"'All the properties of the human mind may be derived from the properties of the animal mind.'

"I would merely add to this:

"And all the mental attributes of higher animals may be derived from those of lower animals. In other words, the doctrine of evolution is quite as valid in the province of psychology as it is in all the other provinces of organic life. Notwithstanding all the differences presented by animal organisms and the conditions of their existence, the psychic functions of the nerve-elements seem nevertheless everywhere to be in accord with certain fundamental laws, even in the cases where this would be least expected on account of the magnitude of the differences."

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Archebiosis and Heterogenesis.

THE columns of the daily papers have during the last two weeks contained many references to the question of the origin of life. One of the most recent utterances has been that of Lord Kelvin, who has roundly declared himself an unbeliever in the natural origin of living matter either in the present or in the past. We must suppose, therefore, that in reference to this question he is content to believe in miracles.

Prof. Ray Lankester and Dr. Chalmers Mitchell, however, proclaim themselves, as followers of Huxley, believers in evolution generally, and in the natural origin of living matter in the past. They, like many others, refuse to believe that it takes place at the present time, because undoubted proof of its occurrence cannot be produced by laboratory experiments. The uniformity of natural phenomena would certainly lead us to believe, as Sir Oliver Lodge has intimated, that if such a process occurred in the past, it should have been continually occurring ever since—so long as there is no evidence to show cause for a break in the great law of Continuity. Certainly no such evidence has ever been produced, and if the origin of living matter takes place by the generation in suitable fluids of the minutest particles gradually appearing from the region of the invisible, such a process may be occurring everywhere in nature's laboratories, though altogether beyond the ken of man.

My point may be illustrated thus. Bacteriologists all over Europe and elsewhere have been working for the last thirty years by strict laboratory methods, and notwithstanding all that they have made out and the good that has thereby accrued to suffering humanity, they have apparently never yet seen the development from Zooglœa aggregates of Fungus-germs, of flagellate Monads, or of Amœbæ. If, however, they would only examine what goes on in nature's laboratory when a mixed bacterial scum forms on suitable fluids, they would have no difficulty in satisfying themselves as to the reality of these processes. I described such processes in your columns in 1870, more fully in the *Proceedings* of the Royal Society in 1872, and finally in my "Studies in Heterogenesis" (pp. 65–84, pls. vi. and vii., Figs. 53–71). Even during the last week I have again obtained photomicrographs demonstrating the origin of flagellate Monads from Zooglœa aggregates forming in a bacterial scum, and if you will admit an illustrated communication on this subject to your columns, proving by such a test case my position as to the reality of heterogenesis, I shall be happy to present it, and to show that something beyond the recognised strict laboratory methods of the day is needed if we are to fathom some of nature's deepest secrets.

The councils of the Royal and Linnean Societies are guided in the acceptance of papers by referees who are wedded, on biological questions, to laboratory methods. It is useless for me, therefore, again to attempt to submit such a communication to them. Their referees (probably not having worked at such subjects themselves) would not advise the acceptance of the paper, and my communication might simply be consigned to their archives. The Royal Society "for the Promotion of Natural Knowledge" on two occasions would not even allow me to submit my views to the consideration of, and discussion by, its fellows. In these circumstances, Sir, I appeal to you, in the interests of science, to allow me to send you an illustrated paper proving, so far as such proof can go, the heterogenetic origin of flagellate Monads and of Fungus-germs.

H. CHARLTON BASTIAN.

Manchester Square, October 31.

[IN reply to Dr. Bastian's appeal we will print his communication, and also any important replies from competent workers on the subject which may be sent to us.—ED.]

Average Number of Kinsfolk in each Degree.

I WAS glad to read the first paragraph of the reply by Prof. G. H. Bryan to my letter, in which he acknowledges his mistake, but I cannot allow the second paragraph to pass without protest, in which he says "the discrepancy can be accounted for more simply still" in a way he describes. I do not wholly understand his present view, but only enough of it to be assured that it is vitiated by some fundamental misconception. In these circumstances it is best to re-state my original argument in different words. We agree to start on the assumptions that boys and girls are on the average equally numerous, and that all other conditions are to be ignored. Then, if an individual be taken out of a family of $2d$ children, $2d-1$ children will be left, of whom $d-\frac{1}{2}$ will, *on the average of many experiences*, be girls and $d-\frac{1}{2}$ will be boys. The sex of the individual who was taken out in the first instance is quite unimportant; the result will be the same whether that individual be a boy or a girl.

Prof. G. H. Bryan thinks, if I understand him rightly, that the sex of the individual in question *is* of importance.

Some persecuting demon must have again caused my pen to write and my eye to overlook an absurdly erroneous figure in my last letter. The faulty passage runs ". . . is 80 ($=2\frac{1}{2}\times 16$, as it should be)"; the 16 ought to be replaced by 32. It is intended to be quoted from the right hand column of line (5) in the table which accompanies that letter.

FRANCIS GALTON.

Misuse of Words and Phrases.

IN the preface to my book on "Cubic and Quartic Curves" I have stated my views on the matters referred to in the last paragraph of T. B. S.'s letter. I am a strong advocate of the use and, if necessary, the invention of words of classical origin to express new ideas, and I consider the phrase *self-cutting* inelegant.

My objection to the phrase non-singular cubic or quartic curve is that no such curves exist, since Plücker has shown that all algebraic curves, except proper conics, possess a determinate number of singularities. Thus anautotomic quartics possess 52 simple singularities, viz. 28 double and 24 stationary tangents. It is also possible for such curves to possess compound singularities, formed by the union of one double and two stationary tangents.

With regard to the use of *an*, the rule is that before a word beginning with a vowel *an* is to be used instead of *a* for the sake of euphony, but when a word beginning with a vowel is pronounced as if it commenced with a consonant, *a* must be used instead of *an*. The phrases *such an one, an uniform rod, an wonderful sunset, an yew tree*, are all equally incorrect.

A. B. BASSET.

November 4.

The Coming Shower of Leonids.

THE pretty abundant shower of Leonids witnessed last year encourages the hope that a fairly rich return may be observed this year. There will be no moonlight to interfere with the brilliancy of the display should it occur, and the most probable time of its apparition will be before sunrise on November 15.

In 1903 the maximum occurred between 5 and 6 a.m. on November 16, and, allowing for leap year, the ensuing maximum should take place on November 15 at about noon. The shower seems likely to be observed to the best advantage at American stations, as in 1901, but it should be carefully watched everywhere, and with a special view to ascertain the hour of greatest abundance.

It is to be hoped that some further attempts will be made to determine the place of the radiant by photography. We have already a sufficient number of eye observations of the position, and the work of ordinary observers will be better directed to counting the number of meteors visible at regular intervals during the night, and registering the most brilliant objects. The meteors from other showers should also be noted, and especially any conspicuous Taurids that may appear. The latter by their slow long flights and yellow trains are readily to be distinguished from the swiftly moving Leonids with their green streaks.

W. F. DENNING.

OWING to the large numbers of shooting stars visible on the night of November 15, 1903, the expectation of witness-ing a meteoric spectacle on perhaps a more extensive scale will probably be revived on the near approach of the Leonid epoch of 1904. Reasons have already been given for supposing that last year's display was connected by the nineteen years' period with a very similar phenomenon observed on November 13, 1865, the interval between the two events representing two complete revolutions of the meteoric cycle. The present epoch, therefore, which is thus associated with the historic meteor shower of November 14, 1866, will be liable to reproduce its brilliant prototype, though only to a limited extent.

The anticipated shower, however, if it takes place, will not occur on the night of November 14, as it might naturally have been expected to do, owing to 1904 being a leap year. The meteor-swarm, according to calculations made by the present writer, has undergone considerable retardation since 1903, and as a result of this perturbation the Leonid meteor shower becomes due in 1904 on the night of November 15. It is on the latter night, therefore, that the maximum will take place, whether it culminate in a shower or not. There will occur, however, on November 14, 15h., an interesting miniature meteor display. The shower on the night of November 15, though not so intense, will be more extensive than that of 1866, as maxima fall due at 9h., 12h. to 15h., and 17h. 30m. G.M.T. JOHN R. HENRY.

The Definition of Entropy.

FROM time to time controversies have appeared in various journals regarding that most difficult of all physical conceptions—entropy. I have purposely avoided passing any opinions as to the merits of the views of different writers, as I have considered the question far too large a one to be dealt with satisfactorily by destructive criticism directed towards particular points. I have, however, now found a definition of entropy which certainly appears to meet most of the objections to the conventional treatment. That definition may be stated somewhat as follows:—

Let the available energy of any system at any instant relative to a refrigerator of temperature T_0 be defined by the condition that it is the maximum amount of energy that could be obtained from the system at that instant by reversible thermodynamic engines working between the system and the refrigerator T_0, the remaining portion of the energy being, of course, called non-available energy. Then in any change of the system the increase of entropy is the quantity obtained by dividing the increase of non-available energy by the temperature T_0 of the refrigerator.

I hope to publish a detailed treatment shortly, but in the meantime I would mention that this definition overcomes all the difficulties inherent in the conventional treatment of at least the more ordinary irreversible phenomena, such as friction, impact, gas rushing into a vacuum.

If we adopt the principle of degradation of energy as the fundamental second law of thermodynamics (as I suggested in the Boltzmann *Festschrift*), Clausius's statement that the entropy of the universe tends to a maximum now follows at once. So, too, do his inequalities. For every irreversible transformation in the interior of a system produces loss of available energy, and therefore (since it does not affect the total energy) increase of non-available energy, and therefore increase of entropy. We may say that entropy can be generated, but never destroyed. It follows that the total increase of entropy in the system is greater than the quantity of entropy entering from without. This is Clausius's inequality for an irreversible non-cyclic process. If the process is cyclic the total gain of entropy is zero, and therefore the entropy generated in the system must be exported during the cycle. This is Clausius's inequality for a cyclic process.

The introduction of the refrigerator presents no real difficulty. If non-available energy, instead of being given to the refrigerator T_0, is worked down reversibly to a refrigerator at a lower temperature T_1, its amount will be decreased in the ratio $T_1 : T_0$. G. H. BRYAN.

The Direction of the Spiral in the Petals of Selenipedium.

IN *Selenipedium grande*, *S. longifolium*, and *S. conchiferum*, the twisted petals are so arranged that the direction of the spiral is right-handed on each side.

They are not heteronymous, *i.e.* the right petal with a left twist and the left petal with a right twist, as in all antelopes' horns, nor are they arranged homonymously, as in most sheep's horns,[1] but the twisted petals have the same direction on each side, and in the cases above mentioned the right-handed spiral is always present. In trying to find a cause for the direction, I expected it to appear that before and during the unfolding of the flower the petals were twisted when lying together, and thus took the bias, which continued during growth. If two strips of paper be laid together and twisted into a pipe-lighter, each, when separated, would exhibit the same spiral twist.

Examination of the still-folded flower proves that this simple explanation is not the true one, and, at least in *S. grande*, the petals are straight when they show at first (two inches or more in length), and become afterwards spirally twisted during growth and elongation.

The necessary bias to determine the direction of the spiral evidently acts after the unfolding of the flower, and is a slight force acting continuously during growth, such as would be made by the circulation if there were a difference in the circulation of the sap in the two edges of each petal.

This difference would act alike in each, and would make each petal twist in the same way; but, of course, this is a mere conjectural suggestion. GEORGE WHERRY.

Cambridge, October 30.

Thinking Cats.

THE story of the cat that saved the cook, in your last issue, is certainly remarkable, but surely it is not unusual for cats to find out how to direct attention when they want to get into or out of a house, or for them to conceal their kittens in curious places.

Two instances of the former occur to me among many. A cat in my father's house used to rattle the letter-plate at the front door (it was in a window near the door) whenever it was shut out, and another, in my own house, would come to any *lighted* window, even on the top storey, and tap at the glass if it was shut out at night. In the same house a cat hid its kittens, after one family had been destroyed, under the boards of a lead flat, so that, as they grew, it could not get them out, and directed our attention to them by running backwards and forwards. They were released by taking up the boards.

From cats to birds seems a natural transition. I have a curious instance, at this moment, of a pair of robins mistaking their own importance. Last spring they built, and reared their family, in a hole in the wall of an old country mansion, which was being rebuilt under my supervision. The wall was inside the house, in the great hall, and the female sat on her nest, looking out at the workmen, amid all the noise and disturbance of building. They disappeared in the summer, but now that the house is finished and occupied, the pair have returned, and flit about the same hall and the adjoining drawing-room, evidently under the impression that the house was built for them.

R. LANGTON COLE.

Change in the Colour of Moss Agate.

A FRIEND of mine possesses a penholder the handle of which is made of moss agate. Originally the colour of the handle was bluish throughout, but recently the upper part of the handle has become very much lighter in colour and much more transparent.

I thought perhaps some of your readers could tell me whether it is usual for moss agates to undergo changes of this kind after having been cut and polished, and, if it is usual, to what agent or agents the change is ascribed.

W. A. WHITTON.

County School, Bridgend, November 7.

The Origin of Life.

MR. HOOKHAM ingeniously argues that experiments to evolve living out of non-living matter are inconclusive and must probably always fail because the sterilising agent used, which is commonly heat, "eliminates not only life, but its potentiality at one stroke."

Most of us believe that the earth was at one time an incandescent globe. Neither life nor the potentiality of life could have existed in such circumstances. How would Mr. Hookham, on the theory of evolution, explain their first introduction? GEOLOGIST.

[1] NATURE, December 12, 1901; *Lancet*, January 1, 1898.

ON THE OCCURRENCE OF WIDMANNSTÄTTEN'S FIGURES IN STEEL CASTINGS.

SOME little time ago, during his inspection of the metallurgical laboratories at the University College of Sheffield, Sir Norman Lockyer exhibited considerable interest in the fact then communicated to him that almost invariably small steel castings exhibited in the first stage of their manufacture the Widmannstätten figures, provided that the carbon was near the semi-saturation point of steel, namely, 0·45 per cent. The authors communicated the following brief note in the hope that it would be interesting to mineralogists and astronomers.

For many years an exhaustive research into the properties of steel castings has been proceeding at the Sheffield College. This research necessarily involves a close investigation of the influence of mass; hence the weight of the experimental castings varies from about 28 lb. to 2 tons. In such heavy castings as those last named the Widmannstätten figures are seldom found, the slow cooling of the mass exerting an influence similar to that of annealing, an operation which, as will presently be seen, causes a change in structure so profound as almost always to destroy the figures. The authors therefore selected for purposes of demonstration research casting No. 541, weighing about 30 lb. The mean analysis of drillings from this metal, taken from a portion of the casting $1\frac{3}{8}$ inches in diameter, registered the following figures:—

	Per cent.
Carbon	0·39
Silicon	0·08
Manganese	0·03
Sulphur	0·03
Phosphorus	0·02
Aluminium	0·03
Iron by difference	99·42

The structure of the metal as cast is shown in the upper half-section of Fig. 1. As usual, it exhibits two

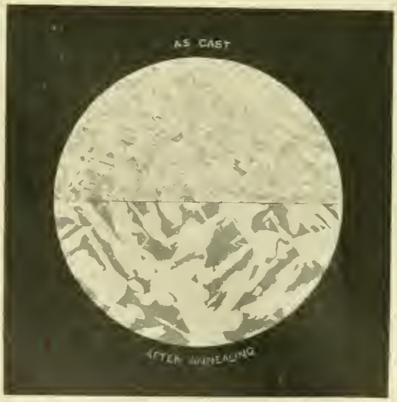

FIG. 1.—Research casting 541. Reduced from micrograph. Magnified 22 diameters.

constituents, the magnification being too low to reveal its third and fourth constituents, namely, the sulphides of manganese and iron also present in minute quantities. The dark etching constituent is pearlite $(21Fe + Fe_3C)$, its colour being due to the liberation during etching of an automatic stain composed of that dark, carbonaceous colouring matter upon which the well-known carbon colour test depends. The pale constituent is, of course, ferrite, in this case nearly pure iron, and has obviously assumed that crystalline structure characteristic of the Widmannstätten figures.

The lower half-section of Fig. 1 delineates the structure of the metal after the operation of annealing. The two stages of annealing were carried out as follows:—first, the steel, protected so far as possible

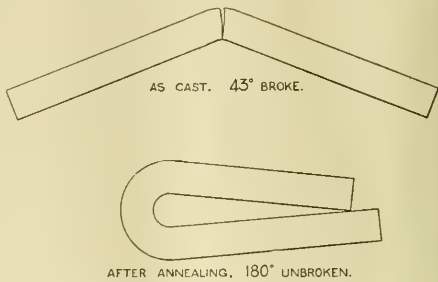

FIG. 2.—Dimensions of test-pieces:—$10'' \times \frac{3}{4}''$ diam.; bending radius, $\frac{3}{8}''$.

from the air, was maintained for about seventy hours at a temperature of about 950° C.; secondly, it was allowed to cool very slowly, occupying, perhaps, another seventy hours in falling to a temperature at which it could be comfortably handled. The result was a total re-arrangement of the pattern presented by the ferrite and pearlite, and a consequent elimination of the figures. This change in structure was accompanied by a profound change also in the mechanical properties of the steel.

Fig. 2 reproduces, before and after annealing, bending tests made on bars 10 inches long and $\frac{3}{4}$ inch in diameter. The metal as cast snapped sharply after bending through an angle of 43° over a radius of $\frac{3}{8}$ inch. The annealed steel bent through an angle of 180° without exhibiting any signs of fracture. At the request of Prof. Lewis, of Cambridge University, the authors have submitted to him duplicate sections of the steels figured in this paper. Prof. Lewis considers that an interesting point raised is as to whether the occurrence of the Widmannstätten figures in pieces of metallic iron dug out of the earth necessarily proves them to be of meteoric origin.

The authors have to thank their colleague Mr. J. H. Wreaks, demonstrator of metallography at the Sheffield College, for his patient and precise reproduction of the structures figured in this note.

J. O. ARNOLD.
A. MCWILLIAM.

FORESTRY IN THE UNITED STATES.

AMONG the professional papers of the United States Geological Survey we have already noticed the first six reports dealing with the various forest reserves in the States of Oregon, Washington, and California. The two latest reports, Nos. 7 and 8, now to hand, deal with the forest conditions in the San Francisco Mountains Forest Reserve and the Black Mesa Forest Reserve in the State of Arizona. The former report is by John B. Leiberg, Theodore F. Rickson, and Arthur Dodwell, with an introduction by F. G. Plummer; while the latter report was prepared by F. G. Plummer from notes by Theodore F. Rickson and Arthur Dodwell. Both forest reserves were first created by proclamation of President M'Kinley, dated August 17, 1898. The region in which the San Francisco Mountains Forest Reserve is situated forms a kind of plateau, traversed by numerous deep canons and dotted by several hundred

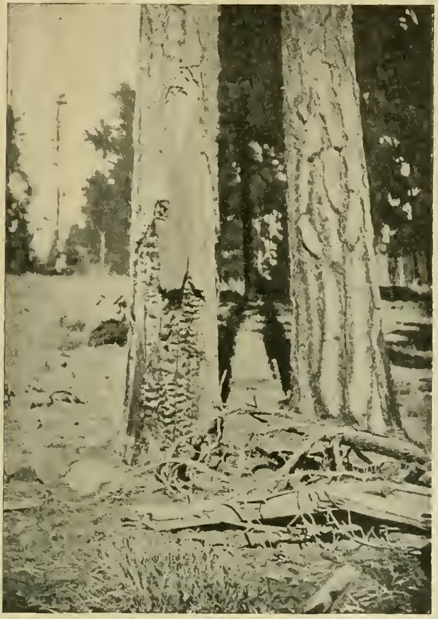

FIG. 1.—Fire Scars on Yellow Pine.

volcanic cones, which vary in height from 100 feet to 1000 feet. The soil is various, but gravelly loam is the prevailing type. On the slopes of the volcanic cones and ridges in their neighbourhood scoriaceous soils prevail. The water-retaining capacity of the latter class of soil is not very great. The loamy soils are best adapted for forest growth. As regards drainage, the visible run of permanent surface flow is small. Most of the precipitation sinks either within the reserve or in the desert or semi-desert tracks which border it.

Electric storms do considerable damage to the standing crop in the reserves, and it is estimated that in some places as many as 5 per cent. of the trees have been struck and killed by lightning. There are twelve coniferous species in the reserve, but the yellow pine predominates, producing more than 99 per cent. of the merchantable timber, and forming 90 per cent. of the total forest. About the same number of broad-leaved species occur, but a complete list of them is not available. All over the reserve the stands of yellow pine do not carry an average crop of more than 40 per cent. of the timber they are capable of producing. This unsatisfactory condition is attributable to the numerous fires which have occurred in this region within the last 200 years. In addition to the destruction caused by fire, careless cutting and grazing have done much damage in the reserve.

The reproductive capacity of the yellow pine in the reserve is extremely small there being a great deficit in seedling and sapling growth. There has apparently been a complete cessation of reproduction over large areas during the past twenty or twenty-five years. This low reproductive capacity is attributed to various causes—some depending on the operation of natural agencies, others on human intervention. The grazing value of the reserve was at one time very great. As the gramineous flora of the region is a rich one, there was formerly a luxuriant growth of grass, but owing to the persistent and excessive pasturing, especially by sheep, the turf-forming grasses were reduced in size and vegetative activity, which led to various changes in the character of the subsequent vegetation. What was formerly pasture land is now covered by exuberant growths of various low desert shrubs and herbaceous Compositæ, particularly species of sunflowers.

The agricultural value of the region is not great, there being only some 2500 acres under the plough, and these occur in the now dry beds of what were formerly Stone-man and Mormon lakes, or at the foot of ridges where local areas of seepage exist. The crops consist of oats, wheat, and potatoes. There is no fruit culture in this region. This reserve, like the others, is subdivided into townships and ranges, the detailed descriptions of which are included in the report. At the end we have a very useful summary, showing in tabular form a classification of lands in the reserve by townships. The maps and photographic illustrations are of the same high standard as those which accompany the other reports of this series.

The Black Mesa Forest Reserve comprises an area of 2786 square miles, made up as follows:—

	Square miles.		Square mil
Timbered area ...	2248·5	Burned area	5·5
Woodland	391	Logged area	1·0
Timberless area ...	140		

FIG. 2.—Large Growth of Alligator Juniper.

A very striking feature of the report is the decrease in the water supply due to successive seasons of drought, which have practically destroyed the value of the grazing and agricultural areas in the reserve. Three years ago the wheat crop yielded 5000 bushels. The following year it fell to 2500 bushels, and last season the yield was only 800 bushels. A cattle ranche in the range, which used to graze more than 100,000 head, will now support not more than 9000 head. As a remedy it is suggested to adopt stringent rules, regulating the number of stock and the areas on which they shall be grazed on each permit. Very little lumbering has been carried out within the reserve, which is apparently due to the difficulties and expense of transport. The timber species, coniferous and broad-leaved, number fifteen, the yellow pine being the principal timber tree. It is distributed uniformly throughout the extent of the reserve. In some ranges it forms a pure forest. Its average height is 125 feet, with 24 feet of clear trunk with a diameter of 18 inches at breast height. It varies in age from 125 to 150 years.

The Engelmann's spruce occupies the moister areas above an altitude of 9000 feet. It averages 70 feet in height and 10 inches in diameter. Its age varies from 50 to 75 years. Its growth is extremely rapid, but the tree is usually clothed with branches to the ground. A variety of the Engelmann's spruce, *Picea engelmannii*, var. *Franciscana*, known as the Arizona spruce, gives much better results, averaging 100 feet in height with 20 feet of clear trunk and a diameter of 18 inches. Red fir, white fir, western white pine, alligator juniper, and Arizona cypress also occur within the area. The deciduous trees are confined to the borders of streams and marshy areas. The reproductive capacity of the various species is exceptionally good, especially where the young growth is afforded shelter by the larger trees. The underbrush throughout the areas in which the yellow pine predominates is very small, and consequently this region has not suffered much injury from forest fires. The report also embodies detailed descriptions of the various subdivisions of the range, together with carefully prepared maps and beautiful photographic plates. Of the latter we have reproduced two as an example of the interesting way in which these papers are illustrated.

TECHNICAL EDUCATION IN LONDON.[1]

THE last report of the Technical Education Board of the London County Council, dealing with the year 1903–4, directs special attention to the progress made in the provision of technical, secondary, and higher education in London during the past eleven years. Under the recent Education Act (London), 1903, the administration of the whole of the education of London passed into the hands of the new Education Committee, and the Technical Education Board ceased to exist. The present report is consequently opportune, and serves to record the great services which have been rendered to education in London by the late Board.

The most striking features of the report are the evidences provided of the increase and rapid development of polytechnic institutions, the establishment and success of London County Council schools and technical institutes, and the improvement in the equipment and staffing of secondary schools. The extent of the advances made can be estimated satisfactorily by comparing the number of educational institutions providing good scientific and technical education at the time of the supersession of the Technical Board with the number in existence in 1893, when Mr. Llewellyn Smith reported on the provision made for technical instruction at that time. To take the case of the laboratory accommodation for the teaching of chemistry. In 1893 there appear to have been about fourteen chemical laboratories in London open in the evening for instruction; since that time well equipped departments for teaching practical chemistry have been opened in eleven new polytechnic institutions. The total volume of instruction in evening classes in chemistry in 1893 was only about 38,000 student-hours per session, and in polytechnics under 15,000 student-hours. In 1893, after omitting the attendances of students who did not attend for more than twenty hours during the session, the amount of time devoted to evening work in theoretical and practical chemistry amounted to 64,554 student-hours in the polytechnics alone.

The result obtained by comparing the advance made in the teaching of electricity and electrical technology is just as striking as in the case of chemistry. In 1893 there were five electrical laboratories open for evening instruction, while in 1903 there were twenty-three institutions giving evening instruction in electricity or electrical technology, or both. In practical electrical engineering there were only four centres in 1893 available for evening instruction, and only one applied for aid from the Board, and at this institution there were thirty-eight students. During the session 1902–3 there were, in polytechnics aided by the Board, a large and increasing number of students for electrical engineering, and the volume of instruction, omitting students who attended for less than twenty hours during the session, amounted to 43,909 student-hours. In addition to these, a large number attended classes in electricity and magnetism in the physics departments of the institutions. The volume of instruction here reached 32,872 student-hours.

Ten years ago there was scarcely any provision in London for pure technological teaching. From the list of evening classes for 1903 it appears that technological instruction is now available in a great variety of subjects, of which the most important are:—bricklaying and brick-cutting in twelve institutions, cabinet-making in nine, carpentry and joinery in twenty, furniture design in nine, masonry in nine, metal-plate work in eight, painting and decorating in twelve, photo-process work in four, plastering in nine, plumbing in fifteen, printing in four, smithing in six, tailors' cutting in seven, and upholstery in six. This rapid increase in the number of polytechnics and technical institutes in which adequate provision is made for practical instruction in trade subjects has had a remarkable effect in producing an interest in the scientific principles underlying the various trades concerned. As an example, the report quotes the case of the Northampton Institute in Clerkenwell, in which district there is a very large number of special trades. In order to meet the demands of the neighbourhood, classes were started in subjects in which no organised technical instruction had previously been given in London. Some of these have been remarkably successful, and in several cases it has been found necessary to increase the number of evenings of instruction in order to provide for the large number of students in attendance.

There has been also, says the report, a natural tendency during the past few years for sporadic classes in trade subjects to disappear in consequence of the increasing popularity of the polytechnics and larger technical institutes, in which are found thoroughly well equipped laboratories and workshops. The number of distinct trades in which practical instruction is provided, and also the number of centres where such courses of instruction can be obtained, have more than doubled during the past nine years,

[1] "Annual Report of the Technical Education Board of the London County Council, 1903–1904." (Westminster: P. S. King and Son, 1904.) Price 2s. 6d.

and the number of apprentices and young workmen attending them has increased four-fold.

The great success which the rapid growth of polytechnics in different parts of London, since the formation of the Technical Education Board in 1893, has had in the development of evening instruction has not, the report points out, been achieved at the expense of other institutions; it represents a new growth, not the transference of instruction from old to new institutions. Many changes have taken place in the older polytechnics to bring them more into touch with modern requirements, and this has been accompanied in nearly every case by an increase in the volume of instruction. Statistics have been compiled, with regard to the attendances which have been made, from 1893 for a period extending over eight years. It has been impossible to give particulars with regard to all the 4000 classes in the numerous subjects of instruction aided by the London County Council, but mechanical engineering, electrical engineering, carpentry and joinery, plumbing, other building trade classes, experimental physics, chemistry, and mathematics have been selected. The total volume of instruction in these subjects, taken together, shows an increase from 118,732 student-hours in 1893 to 454,363 student-hours for 1900–1. Since then the number of artisan students has been increasing steadily. The increase in the amount of work done by the students, speaking generally, appears to have been even greater than the growth in numbers. A growing proportion of the students are now, it is satisfactory to find, taking advantage of the systematic courses which have been arranged, involving attendance on several evenings a week; and it is not surprising to find the Board recording its belief that the educational value of the work done in polytechnics, especially as regards the young mechanic, has been in this way greatly increased.

As has been frequently pointed out, it was from the first the policy of the Board to avail itself of the opportunity of aiding the supply of technical instruction rather than of creating a direct supply, wherever public institutions have existed capable of responding to the Board's aid by such developments of efficient technical instruction as might be expected to meet the requirements of the district. It has been necessary, however, to provide two classes of institution, for the conduct of which the London County Council is wholly responsible, viz. :—

(*a*) Institutions which provide instruction of such a highly specialised character that it is necessary for them to draw their students from the whole of London; for it has been impossible for any institution with the ordinary sources of income to provide the equipment and the highly specialised teachers necessary.

(*b*) Local institutions, providing instruction of a more ordinary character in districts in which no public institutions under a responsible governing body existed which could be utilised for the Council's requirements.

There are many other subjects of interest included in the report, and some of them have already been dealt with from time to time in these columns. It must suffice here, by way of conclusion, to mention briefly the work the Board has accomplished in aiding and extending satisfactory instruction in science in the public secondary schools of London. Seventeen chemical laboratories have been equipped in new buildings, generally in wings added to existing school premises, and three rooms used for class purposes have been converted into chemical laboratories. Four large rooms have been fitted up for practical work in physics and chemistry. Sixteen physical laboratories have been equipped in new buildings, and ten large class-rooms have been adapted for practical work in physics, in addition to the four mentioned above, in which practical work in chemistry is also carried on. Thus fifty laboratories have been equipped in secondary schools for boys, with bench accommodation for more than 1200 pupils working simultaneously, or for 6000 pupils working one day a week. Twenty-five science lecture-rooms have been provided, sixteen of these being specially constructed for the purpose in new buildings. A large number of additional science masters have been appointed as a result of the Board's maintenance grants. In secondary schools for girls, laboratories have in some cases been provided for practical work in physics, chemistry, and botany, and some of those in existence have been equipped suitably to meet modern requirements. A. T. S.

NOTES.

THE list of appointments on the occasion of His Majesty's birthday includes the following honours conferred upon men of science :—Mr. W. H. M. Christie, C.B., F.R.S., has been promoted to the rank of Knight Commander of the Order of the Bath (K.C.B. Civil Division). Dr. J. W. Swan, F.R.S., has received the honour of Knighthood. The Hon. C. A. Parsons, F.R.S., has been appointed a Companion of the Order of the Bath (C.B.). Mr. Francis Watts, Director of Agriculture in the Island of Antigua, and analytical and agricultural chemist for the colony of the Leeward Islands, has been made a Companion of the Order of Saint Michael and Saint George (C.M.G.).

THE council of the Royal Society has made the following award of medals for this year :—The Copley medal to Sir William Crookes, F.R.S., for his long-continued researches in spectroscopic chemistry, on electrical and mechanical phenomena in highly rarefied gases, on radio-active phenomena, and other subjects. The Rumford medal to Prof. Ernest Rutherford, F.R.S., for his researches on radio-activity, particularly for his discovery of the existence and properties of the gaseous emanations from radio-active bodies. A Royal medal to Colonel David Bruce, R.A.M.C., F.R.S., for his researches in the pathology of Malta fever, nagana, and sleeping sickness, and especially for his discoveries as regards the exact causes of these diseases. A Royal medal to Prof. William Burnside, F.R.S., for his researches in mathematics, particularly in the theory of groups. The Davy medal to Prof. William Henry Perkin, jun., F.R.S., for his discoveries in organic chemistry. The Darwin medal to Mr. William Bateson, F.R.S., for his contribution to the theory of organic evolution by his researches on variation and heredity. The Sylvester medal to Prof. Georg Cantor for his researches in the theories of aggregates and of sets of points of the arithmetic continuum, of transfinite numbers, and Fourier's series. The Hughes medal to Dr. Joseph Wilson Swan for his invention of the electric incandescent lamp and various improvements in practical applications of electricity.

THE following is a list of fellows who have been recommended by the president and council of the Royal Society for election into the council for the year 1905, at the anniversary meeting to be held on November 30 :—president, Sir William Huggins, K.C.B., O.M.; treasurer, Mr. A. B. Kempe; secretaries, Prof. J. Larmor, Sir Archibald Geikie; foreign secretary, Mr. F. Darwin. Other members of the council :—Dr. Shelford Bidwell, Mr. G. A. Boulenger, Colonel D. Bruce, R.A.M.C., Mr. F. W. Dyson, Prof. Percy F. Frankland, Prof. F. Gotch, Dr. E. W. Hobson, Prof.

J. N. Langley, Mr. J. E. Marr, Sir William D. Niven, K.C.B., Prof. W. H. Perkin, jun., Prof. J. Perry, Mr. A. Sedgwick, Dr. W. N. Shaw, Prof. W. A. Tilden, Rear-Admiral Sir William Wharton, K.C.B.

WE announce with deep regret that Dr. Frank McClean, F.R.S., died at Brussels on Tuesday morning in his sixty-seventh year.

MR. JAMES COSMO MELVILL has presented his general herbarium to the Manchester Museum of the Victoria University. The herbarium has taken nearly forty years to collect, and it was formally opened in its new quarters by Sir W. T. Thiselton-Dyer, K.C.M.G., on October 31.

THE portraits of Prof. Osborne Reynolds and Prof. A. S. Wilkins, by the Hon. John Collier, will be formally presented to the Victoria University of Manchester on Friday, November 18. Dr. A. W. Ward, the master of Peterhouse, Cambridge, formerly principal of the Owens College, and Vice-Chancellor of the Victoria University, will make the presentation on behalf of the subscribers.

A CHRISTMAS course of lectures, adapted to a juvenile auditory, will be delivered by Mr. Henry Cunynghame, C.B., at the Royal Institution, on "Ancient and Modern Methods of Measuring Time."

AN inaugural dinner of Royal School of Mines men resident in South Africa was held at Johannesburg on Saturday, October 8. The chair was taken by Mr. A. R. Sawyer, president of the Geological Society of South Africa, and many old students of the school were present.

THE *Times* correspondent at Tokio reports that a serious earthquake occurred in Formosa at 4.30 a.m. on Sunday, November 6. The centre of the disturbance was at Kia-yih, where 150 houses were overthrown and 33 damaged, 78 persons killed, and 23 injured.

THE deaths are announced of Forstmeister Schering, formerly professor of mathematics and geodesy in the School of Forestry at Munich; Clemens Alexander Winkler, professor at Freiberg; and Dr. Francesco Chizzoni, professor of geometry at Modena.

THE Society of Arts will commence its fourth half-century on November 16, when Sir William Abney, as chairman of the society's council, will open the 151st session with an address. The subjects on which papers will be read at the meetings before Christmas include British trade, canals, the St. Louis Exhibition, patent law, Burma, and street architecture. There will also be a course of lectures on wind instruments, with musical illustrations.

THE *Times* correspondent at Copenhagen announces that Mr. Mylius-Erichsen's expedition returned there from Greenland on November 6, having been absent two years and a half. Mr. Mylius-Erichsen was accompanied by Mr. Knud Rasmussen and Count Harald de Moltke, a well known painter. The expedition travelled along the west coast, and drove round Melville Bay on sledges. During the whole time the explorers lived with the natives, learning their language, and studying their manners and customs of life.

IT was decided early last year, soon after the death of Mr. F. C. Penrose, to commemorate his work in Athens by building on to the Students' Hostel of the British School in Athens a library to bear his name. Mr. Penrose was the first director of the school in Athens, and was called on more than once by the Athenian authorities to advise as to the preservation of the Parthenon. The total cost of the building and fittings will be about 1150*l.*, and so far 400*l.* has been received in subscriptions toward this object. The school can, if necessary, afford out of its own resources the sum of 600*l.*, but no more, so it seems that at least 150*l.* should be raised by subscription if the building is to be opened free of debt during the archæological congress in Athens next spring. The committee will have, it is to be hoped, no difficulty in securing this further sum of money. Subscriptions may be sent to Mr. George Macmillan, St. Martin's Street, London, or may be paid into the account of the Penrose Memorial Fund at the London and County Banking Company, Ltd., Henrietta Street, Covent Garden, W.C.

MR. J. FLETCHER MOULTON, F.R.S., gave an address on the "Trend of Invention in Chemical Industry" before the Society of Chemical Industry on Monday. In the course of his remarks he said that there are two departments of great interest at the moment from the inventive development they are manifesting in their products. The first is that of pharmaceutical products. Physiologists are beginning to associate specific effects on the human organism with specific chemical groups. These groups appear in countless combinations, and their effect may be masked or hindered by the setting in which they are placed. It may thus be that many of the forms in which these effective groups have up to now been administered have influenced and distorted their normal action, and a line of genuine research and invention is now being pressed forward seeking practical solutions of the problem of the best way to use these operative groups. The second department concerns food-stuffs. A vast waste of nutritious matter is going on all round us. A substantial part of the ability now devoted to the practical solution of difficult chemical questions in existing industries could be usefully applied to the preservation of food-stuffs. The main trend of invention in chemical industry is rendering certain and complete in their action processes formerly unmanageable or unprofitable by reason of the uncertainty of the reactions that actually and locally took place. The realisation of the necessity of uniformity of conditions in order to obtain full yield manifests itself not only in the efforts to improve old processes, but also in the choice of new ones; that process is a good one which permits the necessary conditions to be secured at every point and at every moment.

A LIST of awards to exhibitors from Great Britain and Ireland at the St. Louis International Exhibition has been received from the secretary of the Royal Commission appointed for the exhibition. The number of grand prizes gained by Great Britain is 121, while 238 gold medals, 162 silver medals, and 132 bronze medals have been awarded to British exhibitors, making a total of 653. It is therefore only possible here to mention a few of the awards to men of science and scientific bodies. Among these awards are the following:—Department of Liberal Arts: photography, grand prize, Sir W. de W. Abney, K.C.B., F.R.S.; the Royal Observatory, Greenwich; the Royal Photographic Society; the Solar Physics Observatory; and Sir Benjamin Stone; gold medal, the Geological Photographs Committee of the British Association; the Cretan Exploration Fund; and the Survey of India. Maps and apparatus for geography, grand prize, Board of Agriculture and Fisheries; Ordnance Survey of Great Britain and Ireland; Royal Geographical Society; Admiralty (Hydrographical Department); the Survey of India; Palestine Exploration Fund. Chemical and pharmaceutical arts, grand prize, low temperature research exhibit of the British Royal Commission; Sir

William Ramsay, K.C.B., F.R.S.; gold medal, Dr. Ludwig Mond, F.R.S.; the Owens College; Royal College of Science, London. Awards to collaborators, gold medal, Prof. James Dewar, F.R.S. (low temperature research exhibit); Mr. T. Wilton, and Dr. A. R. Garrick. Various applications of electricity: awards to collaborators, grand prize, Lord Kelvin (for important contributions to electrical engineering); gold medal, Prof. Hugh Langbourne Callendar, F.R.S., Mr. W. du Bois Duddell. Theory of agriculture: grand prize, the Rothamsted Experimental Station (Lawes Agricultural Trust); gold medal, Board of Agriculture and Fisheries; Royal Agricultural Society. Department of Horticulture: appliances and methods of pomology, grand prize, Board of Agriculture and Fisheries; Royal Horticultural Society; the British Royal Commission; gold medal, Dr. Henry. Department of Forestry: appliances and processes used in forestry, gold medal, Forest Department, India; silver medal, the Royal Scottish Arboricultural Society. Department of Mines and Metallurgy: ores and minerals, grand prize, Home Office (Mining Department); Department of Agriculture and Technical Instruction for Ireland. Geological maps and plans of mines, grand prize, Geological Survey of India. Mining literature, grand prize, the Iron and Steel Institute; the Geological Survey of India; gold medal, the Institution of Mining Engineers. Fishing equipment and products: grand prize, Marine Biological Association of the United Kingdom, for an exhibit prepared at their Plymouth laboratory illustrating the life-history and the food of fishes, and a gold medal for publications. Department of Anthropology: ethnography, grand prize, Cretan Exploration Fund; Egypt Exploration Fund; Palestine Exploration Fund.

A CONFERENCE on the teaching of hygiene and temperance in relation to physical deterioration was held at Caxton Hall, Westminster, on November 2, under the auspices of the National Temperance League, Sir John Gorst presiding. The various speakers dealt with the evils of intemperance, and attention was directed to the petition prepared by the British Medical Association in which the medical profession urged that the teaching of the elements of the laws of health should be made compulsory in the elementary schools.

THE American Bar Association has passed a resolution in favour of establishing in the Department of Justice, Washington, a laboratory for the study of the criminal, pauper, and defective classes. In the Bureau of Education, Washington, Mr. MacDonald has for some years been carrying on work of this kind under many difficulties, and it is mainly owing to his initiative that the foregoing resolution was framed.

IN connection with the review on "Cancer Research" (NATURE, vol. lxx. p. 279), an American correspondent, Mr. Harbert Hamilton, has directed our attention to the reported occurrence of a tumour in an oyster. The original paper (Prof. J. A. Ryder in *Proc.* Acad. Nat. Sciences, Philadelphia, 1887, p. 25) records that the tumour was growing in the pericardial cavity; it consisted of alveoli containing numbers of round nucleated cells resembling the colourless blood and lymph cells of the oyster. The opinion is expressed that the growth was of mesodermal origin, and probably benign.

WITH regard to the note on anti-typhoid vaccination which appeared in these columns last week (p. 14), it may be of interest to direct attention to a statistical inquiry on the same subject contributed by Prof. Karl Pearson, F.R.S., to the *British Medical Journal* (November 5, p. 1243). Prof. Pearson analyses mathematically certain statistics submitted to him by Lieut.-Colonel Simpson, R.A.M.C., and concludes that while most of the correlations both for immunity and recovery are distinctly sensible, having regard to their probable errors, yet they are so irregular that little reliance can be placed upon them as representing any definite uniform effect. He considers that the data suggest that a more effective method of inoculation must be found before it should become a routine practice in the Army.

AT a special meeting of the Charity Organisation Society on October 31, Dr. Orme Dudfield, medical officer of health for Kensington, contributed a paper on the need for sanatoria for persons suffering from consumption. He pointed out that more than one-tenth of the total mortality from all causes was due to tuberculous diseases, and that consumption accounted for nearly three-quarters of the tuberculous mortality. He suggested that the Metropolitan Asylums Board, which, on an order by the Local Government Board, has the power to do so under the various Health Acts, should take the matter in hand and equip sanatoria, the present Gore Farm Asylum being a very suitable building and site. With regard to the expense of such institutions, Dr. Dudfield remarked that the loss caused to London by tuberculosis could not be less than $4\frac{1}{2}$ millions per annum, and he contended that the expense incurred would be amply recouped by the money saved to the community. On the motion of Sir W. Broadbent, it was resolved "That it be referred to the Administrative Committee to consider Dr. T. Orme Dudfield's paper and the discussion upon it, and to report to the Council of the Charity Organisation Society at some subsequent meeting."

DURING last week a demonstration was given at Stratford, in connection with the process invented by Mr. Powell for treating timber with a solution of sugar. The result is that all kinds of wood are made tougher, heavier, and more lasting, while the softer varieties become more useful and more ornamental when worked. Besides this it is possible to put fresh and unseasoned timber through the process without delay, and after treatment the "powellised" wood is ready for immediate use, as there is no danger of its shrinking or warping. The timber is placed in cages which are wheeled into a boiler, and after this has been closed, a solution of beet sugar is pumped in, though apparently an open tank can be utilised. The solution takes the place of the air in the timber, and is absorbed by the individual fibres, for microscopical examination fails to demonstrate the presence of sugar crystals between them. It is therefore difficult to remove the sugar, and wood blocks which have been treated are no longer porous, so that pavements made from them should be more sanitary than those in present use. After being taken from the receiver the wood is dried in ovens by artificial heat, the temperature varying with the kind of wood. When subjected to a breaking strain, "powellised" timber recovers itself to a greater extent than untreated wood, and is able, even when broken, to support a greater weight without collapsing. It is also claimed that timber so treated is not subject to "dry rot," and by the addition of some poison to the sugar it is hoped to make it withstand the attacks of termites in tropical countries.

ACCORDING to the report of the Natural History Society of Northumberland, Durham, and Newcastle-upon-Tyne for 1903–4, the "museum talks" given once a month in winter by the curator have been continued. They were fairly well attended, although most of the audience contented themselves with listening to the discourse, only a few taking the opportunity of inspecting the museum.

Some excellent photographs of rorquals "spouting" illustrate a paper on these cetaceans by Dr. G. M. Allen in the September issue of the *American Naturalist.* In height and volume the "spout" of all the species is much less than was supposed to be the case by the older observers, even that of the huge "sulphur-bottom" averaging only about 14 feet in height, although it may occasionally reach 20 feet. In the same number Dr. C. R. Eastman has an article on fossil plumage, in which it is pointed out how extremely seldom are birds' feathers preserved in marine deposits; indeed, the only formations of this nature from which they have been recorded appear to be the Solenhofen limestones, the Cretaceous of Kansas, and the Monte Bolca Eocene.

The practice of planting trees and shrubs by stockmen around their ranch-houses is advocated in a *Bulletin* of the New Mexico Experimental Station, in which the author, Mr. Wooton, describes the native ornamental plants. Poplars or cottonwood trees are recommended for shade, also the hackberry, and a maple known as box-elder. The indigenous flora contains many climbers, including species of Ipomœa, Maurandia, and clematis, while for the gardens on the Mesa native yuccas, the sotol, Dasylirion, and the ocotillo are suitable.

The latest number of the *West Indian Bulletin,* vol. v., No. 2, contains an article on the cold storage of fruit, in which it is pointed out that previous to storage it is necessary to have the fruit cool before and while it is being packed. Reference is made to the installation of Hall's system for cooling the fruit chambers on board the West Indian Royal Mail Steamers *Tagus* and *Trent.* A review of the cacao industry indicates that Trinidad and Grenada continue to show a satisfactory increase in their exports, and Trinidad stands fourth in the list of cacao-producing countries.

Continuing the "Materials for a Flora of the Malay Peninsula," Sir George King, F.R.S., with the cooperation of Mr. J. S. Gamble, F.R.S., has worked out in the latest part (No. 15) the uniovulate series of the Rubiaceæ. This coincides with the subdivision Coffeoideæ adopted by Schumann in Engler's "Pflanzenfamilien." The authors retain Cephælis as a generic name, and include under Webera only a portion of the genus as understood by Hooker in the "Flora of British India." The most important genera are Ixora and Lasianthus, for the latter of which no fewer than twenty-five new species are given. No species of the Indo-Malayan genus Myrmecodia is recorded, and only one species of Hydnophytum.

We have received from Messrs. J. R. Gregory and Co., of Kelso Place, London, W., the prospectus and first part of the "Twentieth Century Atlas of Microscopical Petrography." This elaborate work is intended to supply drawings, descriptions, and microscopic slides of typical rocks to its subscribers; while, for an additional guinea, chips of the same rocks, mounted by a smooth face on glass plates, are issued to complete the materials for study. There are many good points about the idea, and we do not know why so capable a draughtsman as the author should veil his identity under the not very attractive title of "a senior medallist and first-class honoursman in Natural Science of the University of Edinburgh." The subject is not treated systematically, and we note that, while the plates can be arranged in a portfolio according to the owner's taste, the text is paged continuously, and cannot be cut up. There are many students, especially those forced to work alone, who will welcome a book of this kind, accompanied as it is by the actual specimens that are described.

The Royal Society has published its second annual issue of that part of the "International Catalogue of Scientific Literature" dealing with meteorology, including terrestrial magnetism. Our readers generally will know that this catalogue is an outgrowth of the catalogue of scientific papers published by the Royal Society. This second issue comprises mainly the literature of 1902, but includes some works published in 1901. Not only the titles of papers appearing in periodicals or as independent works are given, but their subject-matter has been indexed. The referee of this valuable contribution is Mr. T. D. Bell (librarian of the Meteorological Office), which, we consider, is sufficient guarantee of the care that has been taken in the preparation of the work. We note that a very important addition has been made by including the contents of the *Meteorologische Zeitschrift* for 1902 as well as for 1901 which were omitted in the first issue. But we also note some important omissions which will probably be remedied in a future issue, *e.g.* the valuable papers which appear in the *U.S. Monthly Weather Review.* The Royal Society appears to receive notification of very few daily weather reports, as only those of four countries are included out of some twenty-five that are actually published.

Mr. John W. Butters, writing in the Edinburgh Mathematical Society's *Proceedings,* advocates a much more extensive use of the principle of *symmetry* in teaching geometry, a proposal with which many mathematicians will no doubt agree.

An amusing anecdote about *Linnea borealis* is told by M. V. Brandicourt in *Cosmos* for October 1. This rare plant was reported to have been discovered in 1810 by the Empress Josephine when on a visit to the Montanvert at Chamounix. But it transpired later that the specimens were planted there by a certain Bonjeau, who was pharmacist to Her Majesty, and the secret was let out by the man who planted them in a letter to her asking for help when he was incapacitated by an accident. As M. Brandicourt remarks, no one will ever again find *Linnea borealis* at the Montanvert or anywhere near—the Empress took them all!

In the *Proceedings* of the Royal Society of Edinburgh, xxv., 4, Dr. J. Erskine Murray describes a simple differentiating machine. In it the differential coefficient of a function the graph of which has been drawn is obtained by recording the slope of the tangent at each point, and to give this the machine is guided so that two near dots on a piece of celluloid shall at each instant lie along the curve, while a tracing point on a second sheet describes the required graph of the first derived function as thus obtained approximately. This method, rough as it sounds in description, is said to give valuable information in many statistical problems where existing methods would prove too laborious.

We have received parts i. to vii. of the *Rendiconto* of the Naples Academy (January to July), and in them notice obituary accounts of three members of the academy. Antonio de Martini studied medicine at Naples and Paris. In 1839 and 1840 he published with Salvatore Tommasi two papers on the organism of reptiles and one on the lamprey, and these were soon followed by many other papers. In 1847 he was appointed professor of anatomy and physiology at the veterinary college. The new morphology emanating from Germany at that period attracted Martini's attention, and he published a valuable work on embryology. About 1860 he was nominated professor of physiology, and two years later he was appointed to a newly founded chair of pathology. He was also appointed consulting physician to Princess Margherita, mother of the present King. Throughout his career he worked hand in hand with his colleague Tommasi. Gaetano Giorgio Gemmellaro was born at Catania in 1832. At the age of twenty he produced his first paper on certain volcanic minerals from Patagonia, and from then onwards published papers almost continuously for fifty years. The geological history of Sicily was almost made by him. He was professor of geology and mineralogy at Palermo, a member of the Accademia dei Lincei and of many other academies of different countries, one of the "Forty" of the Italian Society of Science, a Senator, and Knight of the Order of Savoy. Prof. Giustiniano Nicolucci was born in the island of Liri, and graduated in medicine at Naples in 1843. Under Stefano delle Chiaje he developed a taste for biological science, and in 1842 published his first paper on the structure and functions of the human cerebral nerves. During the political disturbances he left his country, and three years later returned to practise medicine. The various types of humanity with which he came in contact in his profession attracted his attention to the study of anthropology, which he continued to his last day. His researches dealt with both historic and prehistoric anthropology, his favourite theme being the prehistoric anthropology of Italy, and especially of southern Italy.

A NEW and revised edition of "Object Lessons in Elementary Science," by Mr. Vincent T. Murché, has been published by Messrs. Macmillan and Co., Ltd., in two parts at 2s. each.

THE "London University Guide and University Correspondence College Calendar" for 1905 contains in a convenient form the kind of information required by a private student desirous of taking a degree at the University of London.

MR. HEMMING's book entitled "Billiards Mathematically Treated" has reached a second edition, which has just been published by Messrs. Macmillan and Co., Ltd. In appendix iii. of the new edition Mr. Hemming institutes a comparison of strokes played through and fine, and of the margin of error in each case.

MESSRS. WHITTAKER AND CO. have published a third edition of "The Optics of Photography and Photographic Lenses," by the late Mr. J. Traill Taylor. The short chapter on lenses of Jena glass which was included in the last issue of the book has been omitted, and one on anastigmatic lenses, written by Mr. P. F. Everitt, inserted in its place.

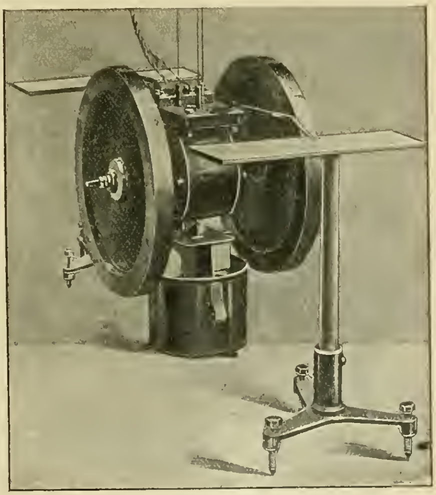
AN authorised translation, by Dr. M. Ernst, of the presidential address delivered by Mr. Balfour at the Cambridge meeting of the British Association has been published by Herr J. M. Barth, Leipzig, under the title "Unsere heutige Weltansschauung." Dr. Ernst has rendered the address into fluent German, and has added a few short descriptive notes—mainly of a biographical character—which will be of interest to readers unfamiliar with the names of Newton, Cavendish, Stokes, Maxwell, Kelvin, Rayleigh, and other natural philosophers to which reference is made. In the first note, on the foundation and objects of the British Association, the list of sections should have included the section of educational science.

THE "Notes on Shooting, with Instructions Concerning the Use of Nitro-Powders," written by "An Expert," and published by Messrs. Curtis's and Harvey, Ltd., has reached an eighth edition. This little volume of 83 pages has been completely re-written, and now contains a practical account of the results of recent researches in sporting gunnery. The actions of guns and gunpowder are based on the laws of physics and chemistry, and the results which have followed the application of the scientific method to the problems in connection with this branch of technology have been incorporated in the book. The volume provides evidence that manufacturers are coming to realise that substantial advantages in their work follow an acquaintance with results arrived at by the man of science. The six chapters into which the book is divided deal with smokeless powders and the methods of testing them, with patterns on the distribution of pellets on the target, with cartridge shooting, and aiming at moving objects.

OUR ASTRONOMICAL COLUMN.

APPARATUS FOR MEASURING THE VELOCITY OF THE EARTH'S ROTATION.—Prof. A. Föppl, of the Munich Technical High School, has devised a new gyroscopic apparatus for measuring the angular velocity of the earth's rotation.

As shown in the accompanying figure, the apparatus consists of a large top carrying at each end of a horizontal



spindle an iron wheel 50 cm. (19·7 inches) in diameter and 30 kilograms (66·1 lb.) in weight. This spindle is the axle of a small electro-motor which is capable of turning the wheels 2400 revolutions per minute. The whole framework is suspended by three fine, strong steel wires to the ceiling of the room in which the experiment is performed, and a cross piece immediately under the centre of the axle dips into a bath of oil, thereby deadening the subsidiary interfering oscillations. The angle through which the whole apparatus turns about its vertical axis is read off, on the two scales shown in the figure, to about the tenth of a degree.

To perform the experiment the current is disconnected from the motor, and the latter run as a generator for a short period, when a reading of a voltmeter placed in circuit enables the angular velocity of the revolving wheels to be found. Knowing this, one deduces the moments of inertia of the turning masses, and then by an equation which takes for its arguments the combined moment, the constant angular velocity of the wheels, the torsion of the trifilar suspension, &c., one may calculate from the observed readings, taken from the scales each minute of the quarter or half an hour that the wheels continue to revolve at a constant rate, the angular velocity of the earth's rotation.

For this quantity Prof. Föppl has obtained a value within 2 per cent. of that obtained from astronomical phenomena, and hopes, with the assistance of M. O. Schlick, the maker of the apparatus, to obtain a still more accordant value by further modifying and perfecting his device (*Revue générale des Sciences*, No. 19, October 15).

The Perseid Shower.—Mr. A. King sends an account of his observations of Perseid meteors during July and August. The observations were divided into two periods, namely, (1) July 12 to 18 inclusive at Sheffield, (2) August 3 to 18 inclusive at Leicester.

The total time spent in watching was twenty-one hours. Considerably more than 200 shooting stars were seen, of which nearly 130 were Perseids; 152 meteors were noted, about 80 being Perseids. The *maximum* of the shower seems to have occurred on August 11, or in the daylight hours of the morning of August 12. By August 14 the strength of the shower had much decreased, but on the following night there was a recrudescence of Perseid activity, for within the first fifteen minutes of a watch from 10h. to 11h. two beautiful Perseid fireballs, both nearly equalling Jupiter in brilliance, appeared, and altogether the hourly rate of Perseids was higher than on August 14. Mr. King considers that the display was scarcely so strong as of late years, but still was a fairly rich one. The following positions were obtained:—August 6, α 38, δ $+56\frac{1}{2}$ (10 meteors); August 11, α $45\frac{1}{2}$, δ $+57\frac{1}{2}$ (35 meteors); August 12, α $46\frac{1}{2}$, δ $+57\frac{1}{2}$ (13 meteors); August 14, α $50\frac{1}{2}$, δ $+58\frac{1}{2}$ (7 meteors).

The movement of the radiant is thus well shown. In conclusion, Mr. King says:—"All the brilliant Perseids had pear-shaped heads. Of 47 Perseids the colours of which were recorded 31 were yellow, a few of these having a greenish tinge. The tints of the streaks usually eluded observation, but the streak of a bright Perseid which appeared on August 13 was muddy."

The Dumb-bell Nebula.—From a special study of the various forms of nebulæ which he has photographed with the Meudon reflector, M. Louis Rabourdin has arrived at the conclusion that the dumb-bell nebula may be correctly classified as elliptical, and that the ring nebula in Lyra should also be placed in the same category.

On comparing a number of photographs of these two objects he found that they have the same elliptical form, and that the stars enclosed in each are, generally speaking, similarly arranged. Consequently, he believes them to be objects which started with the same primal form, but have arrived at different stages in the order of their evolution.

Several other well known objects are placed by him in the same class, and he suggests that the nebulæ generally may be of two general types only, viz. elliptical and spiral (*Bulletin de la Société astronomique de France*, October, 1903).

Harvard College Observatory.—In a small brochure published by the Harvard College authorities (Cambridge, Mass., 1904) the establishment, growth, and work of the college observatory is briefly recorded. The various stations and the instruments located in each are named and described, and the work already performed, the publications of the observatory, and the officers employed are mentioned in chronological order. Two reproductions of photographs show the stations at Cambridge and Arequipa respectively.

In a second similar publication Prof. E. C. Pickering outlines the second part of his "Plan for the Endowment of Astronomical Research," in which he suggests several methods of usefully spending the money he is seeking to raise for this purpose. Among other things he discusses solar eclipse expeditions, and states that the English method of organisation by means of a central permanent eclipse committee is one which might be usefully copied in other countries, where much money has been "wasted" by sending out a number of mutually independent expeditions, often in charge of incompetent persons, to attempt to obtain results which are but seldom adequately discussed or published.

IRON AND STEEL INSTITUTE.

The opening meeting of the Iron and Steel Institute was held on October 24 in New York under the presidency of Mr. Andrew Carnegie. Addresses of welcome were delivered by the Mayor, by Mr. John Fritz, chairman of the reception committee, and by Mr. James Gayley, president of the American Institute of Mining Engineers. On behalf of the council Sir James Kitson presented to Mr. Carnegie the Bessemer gold medal in recognition of his great services to the iron and steel industries of the world. On October 26 a selection of papers was read and discussed.

The first and most important read was that by Mr. James Gayley (New York) on the application of dry air blast to the manufacture of iron. The variable moisture in the atmosphere has long been recognised as a barrier to further progress in blast furnace practice. The problem of extracting the moisture has been solved by Mr. Gayley by the adoption of refrigeration by means of anhydrous ammonia. A plant was put in operation at the Isabella furnaces of the Carnegie Steel Company at Pittsburg on August 11, and remarkable results have been obtained. Prior to its adoption, the furnace from August 1 to August 11 produced on an average 358 tons of pig iron daily with a coke consumption of 2147 lb. Using dry air blast from August 25 to September 9 the daily production of pig iron averaged 447 tons with a coke consumption of 1726 lb. Similar advantages would doubtless be effected in the Bessemer converter, in the open-hearth steel process, in copper smelting, and in other processes where air in large quantities is used.

The next paper read was on the influence of carbon and phosphorus on the strength of iron and steel, by Mr. H. H. Campbell, of Steelton, Pennsylvania.

The paper by Mr. C. V. Bellamy, Director of Public Works, Lagos, was of great ethnological interest. He described the process of iron manufacture in the hinterland of the British colony of Lagos, within twenty days of London, where the methods are the same as those practised by the earliest workers in the metal. The smelting works are near Oyo, the capital of the Yoruba country, and it is only recently that they have been visited by a white man for the first time. Analyses given by Mr. F. W. Harbord, in an appendix to the paper, show that the metal is a pig iron partially decarburised by an oxidising flux. It is really a puddled steel, low in sulphur and phosphorus, its purity accounting for its good qualities.

Mr. J. M. Gledhill read a paper describing the development and rise of high-speed tool steel. Since the initiation of high-speed cutting at the Bethlehem Steel Works, great developments have been made, and results in cutting powers far beyond expectation have been attained. An analysis of one of the best qualities of rapid steels produced by Sir W. G. Armstrong, Whitworth and Co., Ltd., showed 0·55 per cent. of carbon, 3·5 per cent. of chromium, and 13·5 per cent. of tungsten.

The results of different analysts when operating on the same sample of iron or steel are far from concordant, and attempts have been made at various times to investigate the causes of difference. A further attempt has now been made to ascertain the most trustworthy methods for the determination of carbon and phosphorus in steel by a committee consisting of Mr. J. E. Stead, F.R.S., Baron H. von Jüptner (Austria), Mr. A. A. Blair (Philadelphia), and Mr. Gunnar Dillner (Stockholm), who presented an interim report covering fifty-two printed pages.

A paper on acid open-hearth manipulation was submitted by Mr. A. McWilliam and Mr. W. H. Hatfield (Sheffield), in which experimental results were recorded proving that, at about the temperatures occurring in Siemens steel-making practice, the chemical composition of the slag, particularly with regard to its acidity, is the factor which determines whether the percentage of silicon in the molten steel shall increase or decrease.

Mr. E. Demenge (Paris) submitted a paper on the utilisation of exhaust steam, from engines acting intermittently, by means of regenerative steam accumulators and of low-pressure turbines of the Rateau type. The process has been applied with conspicuous success at the Donetz Steel Works in Russia, at the Poensgen Steel Works at Düsseldorf, and at several French collieries.

The meeting concluded with the customary votes of thanks to the reception committee, proposed by Mr. E. Windsor Richards and seconded by the secretary, Mr. Bennett H. Brough. The meeting was attended by more than 300 members, and an attractive programme of visits to metallurgical works in various parts of America was arranged.

THE INTERNATIONAL ELECTRICAL CONGRESS AT ST. LOUIS.

SINCE the article on the proceedings of the International Electrical Congress at St. Louis appeared in our issue of October 27, we have received the subjoined report to the congress of the chamber of Government delegates referred to on p. 639.

It will be noticed that the resolutions ask for the appointment by Governments of one international commission, at first of a temporary character, but which, it is hoped, may become permanent, to deal with electric units.

Report of the Chamber of Delegates.

At the meeting on September 13, after discussion in the chamber, two subcommittees were appointed to deal with the questions of international electromagnetic units and of international standardisation respectively.

At the meeting on September 15 the following report of the committee on international electromagnetic units was accepted and unanimously adopted:—

Committee on International Electromagnetic Units.

The subcommittee appointed September 13 begs leave to suggest that the chamber of delegates should adopt the following report:—

It appears from papers laid before the International Electrical Congress and from the discussion that there are considerable discrepancies between the laws relating to electric units, or their interpretations, in the various countries represented, which, in the opinion of the chamber, require consideration with a view to securing practical uniformity.

Other questions bearing on nomenclature and the determination of units and standards have also been raised, on which, in the opinion of the chamber, it is desirable to have international agreement.

The chamber of delegates considers that these and similar questions could best be dealt with by an international commission representing the Governments concerned. Such a commission might in the first instance be appointed by those countries in which legislation on electric units has been adopted, and consist of (say) two members from each country.

Provision should be made for securing the adhesion of other countries prepared to adopt the conclusions of the commission.

The chamber of delegates approves such a plan, and requests its members to bring this report before their respective Governments.

It is hoped that if the recommendation of the chamber of delegates be adopted by the Governments represented, the commission may eventually become a permanent one.

The following report was also received and unanimously adopted from the committee on international standardisation:—

Committee of the Chamber of Delegates on International Standardisation.

The committee of the chamber of delegates on the standardisation of machinery begs to report as follows:—

That steps should be taken to secure the cooperation of the technical societies of the world by the appointment of a representative commission to consider the question of the standardisation of the nomenclature and ratings of electrical apparatus and machinery.

If the above recommendation meets the approval of the chamber of delegates, it is suggested by your committee that much of the work could be accomplished by correspondence in the first instance, and by the appointment of a general secretary to preserve the records and crystallise the points of disagreement, if any, which may arise between the methods in vogue in the different countries interested.

It is hoped that if the recommendation of the chamber of delegates be adopted, the commission may eventually become a permanent one.

At the meeting on September 16 the following resolutions were unanimously adopted:—

"That the delegates report the resolution of the chamber as to electrical units to their respective Governments, and that they be invited to communicate with Dr. S. W. Stratton (Bureau of Standards, Washington, D.C.) and Dr. R. T. Glazebrook (National Physical Laboratory, Bushy House, Teddington, Middlesex, England) as to the results of their report, or as to other questions arising out of the resolution."

"That the delegates report the resolution of the chamber as to the international standardisation to their respective technical societies, with the request that the societies take such action as they may deem best to give effect to the resolution, and that the delegates be requested to communicate the result of such action to Colonel R. E. B. Crompton, Chelmsford, England, and to the president of the American Institute of Electrical Engineers, New York City."

THE NATIONAL ANTARCTIC EXPEDITION.

THE narrative of the National Antarctic Expedition, related by Captain Scott to an audience of about seven thousand people at the Albert Hall on Monday, was the first account of the work of the expedition given to the Royal Geographical Society since the *Discovery* returned home. Captain Scott made a general statement of the work of the expedition, referring particularly to the various sledging journeys—nine of which were made in the first season and six in the second season—for exploration to the south, west, and east; but his remarks were chiefly of the nature of descriptions of a magnificent collection of photographs of scenes and incidents in the areas visited. These pictures themselves constitute a unique record of Antarctic conditions, and with the results of meteorological, magnetic, hydrographic, biological, and geological observations make the expedition most notable in the history of polar exploration. An exhibition of the photographs taken by Lieut. Skelton, water colour sketches and coloured drawings by Dr. E. A. Wilson, and other objects of interest connected with the voyage of the *Discovery*, is now open at the Bruton Galleries, 13 Bruton Street, Bond Street, W.

At the end of the lecture the chairman, Sir Clements Markham, K.C.B., on behalf of the Royal Geographical Society, presented a gold medal to Captain Scott and silver medals to the officers and men. The gold medal of the Geographical Society of Philadelphia for 1904 was presented to Captain Scott by the United States Ambassador in the name of that society. The medal bears on one side a medallion of Dr. Elisha Kane, their own discoverer, in whose honour the society was organised, and on the reverse this inscription:—"For eminent geographical research. *Per mare et terram.* The Philadelphia Geographical Society. Incorporated 1803. Awarded to Captain Scott in the year 1904."

As the scientific work of the expedition will be described at subsequent meetings of the Royal Geographical Society, Captain Scott only made incidental reference to it, and added little to what has already appeared in these columns (vol. lxix., p. 543, April 7). The following brief summary of the lecture is, however, of interest in showing some of the incidents and inquiries of the expedition.

The Antarctic area was divided into four quadrants, of which the Ross quadrant was allotted to the British expedition. It was there that Sir James Ross in 1840 discovered the sea that bore his name. But Sir James Ross was in a sailing ship, and only saw things dimly and in the distance. The geographical problem was therefore in brief to find out what lay to the east, to the west and to the south of what Ross had seen. In addition to the geographical problem, there were many scientific ones connected with a region so little known. The principal of these was magnetism, and the course taken by the *Discovery* was especially adapted for a magnetic survey.

Accompanied by two other members of the expedition, Captain Scott left the ship for a southern journey early in November, 1902, and on December 29 arrived at a point in latitude 80° 17′, when they were obliged to retrace their steps. Finally, the party returned safely to the ship, and found that the *Morning* relief ship had arrived in McMurdo Sound. Mr. Armitage made a journey to the westward with a large party. After one or two failures he found a good route to the main ice cap over the surface of a glacier of great length. He gradually rose in altitude until he arrived on the inland plateau at a height of 8900 feet, and was thus the first to penetrate into the interior of Victoria Land.

The expedition had hoped to accompany the *Morning* home, and it was not until the end of February, 1903, that this was seen to be impossible, because of the condition of the ice. They expected the ice in the bay in which they lay to break up, but unfortunately it got so late that there was only one thing for the *Morning* to do, and that was to return. She got home with a good deal of difficulty, but the *Discovery* was forced to remain a second winter.

Captain Scott next made a sledging expedition in a westerly direction, reaching his "furthest west" point on November 30, 1903. The party had reached the top of a mountain range some 7000 feet above the sea-level when a blizzard came on and prevented further movement for six days. The party then set out westward, rising another 1500 feet, and for another week advanced over a huge plain that extended as far as the eye could reach. The temperature was forty degrees below zero, and the lips, nostrils, and cheeks of the party were blistered by the incessant wind from the west. The rarefied air, too, had a great effect in reducing staying power. On this expedition they reached a very interesting spot—that at which the compass pointed south instead of north. They had reached for the first time the line of no variation lying between the South Pole and the south magnetic pole.

By the middle of December, 1903, all the sledging parties were ordered to be back, in order that an attempt might be made to free the *Discovery* from the ice by sawing out a channel. The attempt to clear a channel had to be abandoned, but on January 15 the *Morning* and the *Terra Nova* were sighted. They brought word that unless the *Discovery* could be freed it must be abandoned, and to obviate this hard necessity blasting operations were undertaken. But by the end of January the ice began to break up of its own accord, and by the middle of February there was a clear channel for the *Discovery*, which was then free to start on its return voyage.

MOUNT EVEREST: THE STORY OF A LONG CONTROVERSY.

THE highest mountain in the world is situated in a country from which Europeans have with few exceptions been jealously excluded; and the recent visit to the capital of Nepal of an experienced British surveyor, equipped with instruments and with full permission to use them, is an event of no small interest in the annals of Himalayan geography.[1] It is clear from Captain Wood's report that this event has been brought about by the personal intervention of Lord Curzon.

Surveyors have penetrated the Himalayas east and west of Nepal into Sikkim and Kumaon, and have from these points of view been enabled to observe a few of the Nepalese peaks; but from flanking stations the ranges of mountains are seen "end on," and the nearer peaks shut out the more distant from view. The knowledge that we possess of the heights and positions of the peaks of the Nepalese Himalayas has consequently been obtained from observations taken with theodolites at stations situated in the plains of Bengal and Oudh.

From maps of small areas we are able to estimate that the number of peaks existing in Himalayan regions, including Kashmir and Bhutan, probably exceeds 40,000, and that of these more than 10,000 are always clothed with snow. Such estimates, rough as they are, suffice to show that the problem which confronted the Indian Survey when it first undertook the determination of the positions and heights of the peaks of the Himalayas was not a simple one.

It is difficult now to discover how many of the 10,000 snow-peaks were known to the natives of India by name before the British commenced their survey. The number so named was certainly small, and possibly less than fifty. Not only were the two highest mountains of all without a name but many of the most conspicuous peaks throughout the whole length of the Himalayas were nameless. The few peaks that serve as landmarks to travellers on frequented thoroughfares have probably always had names, and the few that mark the sources of sacred rivers and indicate to weary pilgrims on distant plains the positions of the shrines that are their goals have for ages been recognised by names.

It is questionable whether some of the Hindu names now attaching to peaks were not given in the first instance by British surveyors; in the earlier days of the survey names were accepted from villagers more readily, perhaps, than would now be done. Even the celebrated name of Dhawlagiri, as attaching to a particular peak, is not altogether free from suspicion. The story of the controversy over Mount Everest shows how easy it is to find native names that have no existence in fact, and how hard it is to identify the precise peak even when a native name is current.

When 10,000 snow-peaks have to be fixed, and when but 50 of these have names, some system of classification has to be devised. The case is analogous to that of the stars; a few of the brighter stars have names of their own, the remainder are classified by constellations, and are designated by letters or numbers. The snow-peaks of the Himalayas are classified by areas, and are designated by Roman numerals or by letters with numbers attached; thus the highest mountain in the world is known in the official records as Peak XV, and the second highest is recorded as Peak K_2, both having been nameless at the time of their discovery.

The height of Peak XV, now better known as Mount Everest, is 29,002 feet, and that of K_2 is 28,250 feet. Sixty years ago Dhawlagiri, in Nepal, was considered the highest mountain in the world; Dhawlagiri is 26,795 feet high, and has since been found to be surpassed in height by six Himalayan peaks; of these K_2 is in Kashmir, and the other five, Everest (29,002), Kangchenjunga I (28,146), Kangchenjunga II (27,803), Makalu (27,790), and Peak T_{45} (27,000) are in or near Nepal.

The Discovery of Mount Everest.[1]—In 1848 trigonometrical surveyors commenced to build a line of survey stations along the plains of Oudh and Bengal from west to east, and to determine the positions of these stations in latitude and longitude by means of triangles observed with large theodolites. Sir George Everest had intended originally to carry the series along the mountains, but abandoned his design in consequence of the refusal of the Nepalese Government to allow the operations to enter their territories. Consequently, after crossing the hills of Kumaon, the stations were brought down into the plains near Bareilly, from which point they were carried for 800 miles through the deadly tracts which fringe the Himalayas. At almost every station the snowy range of Nepal was visible, and the northern horizon appeared broken by numbers of peaks. Just as some stars appear brighter to the eye than others, so do some snow-peaks against the sky-line appear loftier than others. The superior magnitude of certain stars may be due either to their greater diameter or their lesser distance, and the superior elevation of certain peaks may be due either to their greater height or their lesser distance. The most refined observations with the most perfect of instruments, if taken from a single station only, will furnish no clue as to whether a mountain-peak is conspicuous on account of its magnitude or on account of its nearness.

As the surveyors moved across Bengal from west to east they witnessed changes in the apparent positions of the peaks; the analogy of the stars no longer serves us, as owing to the great distances of the latter they appear to preserve their relative positions in the sky; but the case of mountain-peaks may be compared to what a traveller witnesses when he journeys by rail through a forest of pines—the nearer tree-trunks continually appear to pass between his eye and the more distant ones. As the surveyor moves across the plains parallel to the mountains he sees

[1] Report on the Identification and Nomenclature of Himalayan Peaks. By Capt. H. Wood, R.E., with a preface by Colonel Gore, C.S.I., R.E., late Surveyor General of India. (Published by Order of Colonel F. B. Longe, R.E., Surveyor General of India, 1904.)

[1] In order to appreciate the distance from which Mount Everest is visible, we have only to consider that if it stood in Snowdon's place, it would be seen from Land's End to Edinburgh and from Kent to Connaught.

innumerable peaks, many snow-clad, many bare, always seemingly changing their places and forms.

It is a mistaken idea that particular peaks can be identified from different points of view by their characteristic shapes. Such a course may sometimes be possible from near stations, but at distances greater than forty miles the form of a peak is its cross-section in outline against the sky, and this changes as one moves round it. The same peak is often found noted in the field records of the survey by a different letter or number at each station from which it was observed. Colonel Sir Andrew Waugh, of the Bengal Engineers, who was Surveyor-General of India from 1843 to 1861, realised from the outset the difficulties of identification. His orders were that every visible peak, great and small, was to be observed from every observing station, but that the identification of peaks, with the exception of the unmistakable few possessing native names, must be left to computers. In accordance with these orders the true direction of every visible peak and the angular elevation of every summit above the horizon were determined from every observing station.

The identification of the peaks as observed from different stations was then effected as follows:—

1st Step.—The stations of observation were carefully projected on a map, and from each were drawn lines representing the directions of all peaks observed from it.

2nd Step.—When direction-lines from three or more stations met in one point, it was tentatively assumed that the same peak had been observed on the three or more occasions.

3rd Step.—By trigonometrical formulæ the distance of this assumed peak from each of the observing stations was then calculated, and from these distances independent values of the latitude and longitude of the peak were obtained; if the several values were accordant the identification was proceeded with.

4th Step.—From the observed angle of elevation and from the calculated distance of the peak from each station the height of the peak was deduced; a separate value for the height of the peak was thus obtained from each observing station. If the several values of height were accordant the identification was finally accepted.

Numerous peaks were found to have been observed only once or twice, and could not be identified; many others failed to satisfy all the tests, and had to be rejected.

About 1852 the chief computer of the office at Calcutta informed Sir Andrew Waugh that a peak designated XV had been found to be higher than any other hitherto measured in the world. This peak was discovered by the computers to have been observed from six different stations; on no occasion had the observer suspected that he was viewing through his telescope the highest point of the earth.

The following table shows the several values of height that were obtained for Mount Everest:—

THE OBSERVED HEIGHT OF MOUNT EVEREST.

Sir Andrew Waugh had always adhered to the rule of assigning to every geographical object its true local or native name; but here was a mountain, the highest in the world, without any local or native name that he was able to discover. He determined, therefore, to name the great snow-peak after Sir George Everest, his former chief, the celebrated Indian geodesist. The name of "Mount Everest" has since become a household word, and no objection to it has ever been raised by natives of the country.

The Devadhunga Controversy.—When Sir Andrew Waugh announced that the peak was to be named Everest, Mr. Hodgson, who had been political officer in Nepal for many years, intimated to the Royal Geographical and Royal Asiatic Societies that Sir Andrew Waugh had been mistaken, and that the mountain had a local name, viz. Devadhunga. Sir Roderick Murchison, the president of the Royal Geographical Society, approved Waugh's action, but the Royal Asiatic Society supported Hodgson and repudiated the name of Everest. Seeing that the Survey officers had been debarred from entering Nepal, Mr. Hodgson was amply justified in raising the question he did; but he had made no scientific measurements, and it is known now beyond dispute that he was mistaken in his identification of Everest. He apparently assumed that the great peak, which he saw standing in the direction of Everest, and which was so conspicuous from Katmandu, where he resided, was the highest peak in Nepal;[1] but Nepal covers a large area, and Mount Everest is more than a hundred miles from Katmandu. Either Mr. Hodgson was unaware of the real distance of Mount Everest, or he failed to realise that even the highest mountain on earth will look small at so great a distance. It is probable that Mr. Hodgson never even saw Mount Everest; it is certain that if he did so he was unaware that he was looking at it.

All subsequent information goes to show that there is no peak in Nepal called Devadhunga. Mr. Hodgson's sincerity has never been doubted, and it is believed now that the name Devadhunga is a mythological term for the whole snowy range.

The Gaurisankar Controversy.—In 1854 three brothers, Hermann, Adolphe, and Robert de Schlagintweit, undertook a scientific mission to India and Central Asia at the instance of the King of Prussia, and with the concurrence of Lord Dalhousie and the court of directors. Their labours lasted until 1857, by which date they had succeeded in taking numerous astronomical, hypsometric, magnetic, and meteorological observations; they had also made geological, botanical, and zoological collections for the India House Museum; and they had explored the high mountains of India and Tibet, and had constructed many panoramic drawings of the snow-peaks of the Himalayas. Their mission unfortunately ended in the death of the second brother, Adolphe, who was killed at Kashgar.

In 1855 Hermann de Schlagintweit visited a hill in Nepal named Kaulia, near Katmandu, and from it took observations to the snow-peaks. He saw the mountain called Devadhunga by Hodgson, and he identified it as Mount Everest;[2] he, however, repudiated Hodgson's name of Devadhunga, and certified that the local native name for the peak was Gaurisankar.

Continental geographers, accepting Schlagintweit's views, have continued to this day to call the highest mountain in the world Gaurisankar; the Indian Survey, however, were unable to reconcile Schlagintweit's results with their own, and have declined to follow him.

The diagram in Fig. 1 illustrates the tour of Hermann de Schlagintweit, who visited the two stations of Kaulia and Falut, which are 175 miles apart. From Kaulia he saw a high peak to the north-east which the natives called Gaurisankar, and which he identified as Everest. From Falut he saw a high peak to the north-west, which he also identified as Everest.

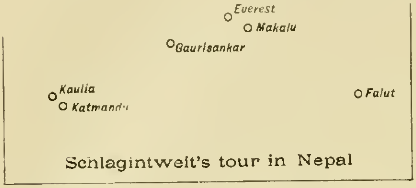
There is no doubt now that Schlagintweit was misled in his identification of Mount Everest. It is the common misfortune of all pioneers that posterity chiefly concerns itself with their mistakes. Indian geography owes much to Hermann de Schlagintweit, but she is more mindful now of his errors than of her debts. The mistakes of Schlagint-

[1] See *Proceedings* R.G.S., vol. viii., 1886, pp. 89 and 179.
[2] Schlagintweit's "India and High Asia," vol. iii. p. 193.

weit have formed the basis of controversy, and will continue to be remembered until controversy ceases.

In 1883 Colonel Tanner visited Falut, and found that Everest was barely visible from there, being almost shut out from view, and entirely surpassed in appearance by Makalu (height 27,790 feet), a lower though nearer peak; it was Makalu that Schlagintweit mistook for Everest, and it was Makalu that he drew as Everest, both in his panorama of the snows from Falut, and in his picture, which is preserved at the India Office.

In 1903 Captain Wood visited Kaulia by order of Lord Curzon; he found that Gaurisankar and Everest were



Schlagintweit's tour in Nepal

Heights in feet.		Distance from Mount Everest in miles.	
Everest	29,002		
Makalu	27,790	to Makalu	12
Gaurisankar	23,440	to Gaurisankar	36
Falut	11,815	to Falut	85
Kaulia	7,051	to Kaulia	109

FIG. 1.

different peaks thirty-six miles apart, and that Everest, far from being conspicuous, was almost obscured from view by intervening ranges. Captain Wood also discovered that an imposing peak of the snowy range, a peak long known in the records of the survey as Peak XX, height 23,440 feet, was the famous Gaurisankar of the Nepalese.

A comparison of the drawings of Schlagintweit and Wood tells us that the same peak was shown by the Nepalese to both observers as Gaurisankar. Schlagintweit was therefore right in giving the name of Gaurisankar to the great peak that is so conspicuous from Kaulia and Katmandu, but he has been proved to have been wrong in three particulars, namely, (1) in his identification of Everest from Kaulia, (2) in his identification of Everest from Falut, (3) in assuming that he had observed the same peak from Kaulia as he had done from Falut.

It is interesting to consider the magnitudes of the mistakes he made:—from Kaulia the direction of Gaurisankar differs from the true direction of Everest by two degrees; from Falut the direction of Makalu differs from the true direction of Everest by forty-two minutes.

From Kaulia the elevation of Gaurisankar differs from the true elevation of Everest by twenty-four minutes; from Falut the elevation of Makalu differs from the true elevation of Everest by fifteen minutes.

The two peaks Gaurisankar and Makalu, which Schlagintweit thought were the same, are forty-seven miles apart.

The supposed identity of Everest and Gaurisankar has rested only on Schlagintweit's evidence. It is true that successive British Residents at Katmandu have continued to regard Gaurisankar as Everest,[1] but their ideas have been based on the Schlagintweit tradition. It is also true that in a recent number of the *Geographical Journal*[2] the photographs of Dr. Boeck have been preferred as evidence to the observations of the Indian Survey; unfortunately Dr. Boeck made a mistake of thirty-two degrees in direction in his attempt at identifying Mount Everest,[3] and this initial slip led him to twist the whole area of Nepal round through a third of a right-angle.

Side Issues of the Controversy.—It is difficult to avoid the thought that this long controversy has of recent years been degenerating into a barren dispute over side issues.

(1) It has, for instance, been stated in the *Geographical*

[1] "In the Himalayas," by Waddell, 1899, p. 346.
[2] *Geographical Journal*, March, 1903.
[3] Colonel Gore's preface to Captain Wood's Report, 1904.

Journal that "the object of Captain Wood's visit to Nepal was to ascertain whether the mountain known as Mount Everest is visible from the heights in the neighbourhood of Katmandu, and forms part of the range known in Central Nepal as Gaurisankar."[1] But this statement is incorrect. The object of Captain Wood's visit to Nepal was to ascertain whether the peak known to the Nepalese as Gaurisankar was identical or not with the peak known to us as Mount Everest, and this main issue ought to be kept in view. It is also inaccurate to speak of a range in Central Nepal known as Gaurisankar: there is no range so known; Gaurisankar is a double peak.

(2) A side issue on which some argument has been expended is whether Mount Everest is visible from Kaulia or not. This point may be of interest to individuals, but it has no scientific importance; and I am surprised to see it asserted, as though some geographical issue were involved, that the Survey officers have generally held the view that Everest was not visible from Kaulia.[2]

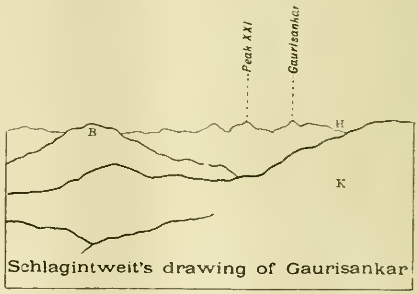
In a paper published in 1886, the late General Walker, R.E., gave some calculations of azimuth and elevation to show that the two peaks of Gaurisankar and Everest could not be identical; after proving his point in a convincing way, he added the following general remark:—"Obviously therefore Gaurisankar, the easternmost point of Schlagintweit's panorama of the snowy range, cannot have been Everest, and the great pinnacle must have lain hidden away from his view by intervening mountain masses."[3]

If we wish to discover whether a place A is visible from a place B, we have but two courses open to us: we can make calculations from contoured maps of the country, or we can send an observer to B to ascertain if A can be seen. If there are no maps, the second course alone is open.

Mount Everest is 109 miles from Kaulia; the intervening space is taken up by mountains and valleys, ridges and hollows, spurs and basins; this complicated area is unsurveyed, and questions of visibility are not mathematically arguable.

How came it, then, that an expert like General Walker expressed the opinion that Everest was not visible from Kaulia? General Walker was, of course, merely judging from Hermann Schlagintweit's recorded evidence. At Kaulia Schlagintweit made a careful drawing to scale of the snowy and nearer ranges; in Fig. 2 is given a copy of his drawing of Gaurisankar.

Schlagintweit wrote against the peak Gaurisankar on his drawing the words "Gaurisankar or Everest," but



Schlagintweit's drawing of Gaurisankar

FIG. 2.

General Walker showed by calculations that if Everest had been really visible it would have been seen by Schlagintweit as a low peak near the spot marked H. As Schlagintweit showed no low peak at this spot, General Walker concluded that it had been obscured from his view by one or another of the many unsurveyed intervening ranges.

[1] *Geographical Journal*, January, 1904, p. 89.
[2] *Geographical Journal*, March, 1903, and January, 1904.
[3] *Proceedings* R.G.S., vol. viii., 1886, where it will be seen that Schlagintweit described Everest as the easternmost point of his panorama.

When Captain Wood visited Kaulia in 1903 he was unable to discover the place from which Schlagintweit had made his drawing; he selected another spot, and made a careful drawing to scale of the snowy and nearer ranges. In Fig. 3 is given a copy of his drawing of Gaurisankar.

On the advice of the Prime Minister of Nepal, Captain Wood recorded on his drawing against the lower peak of the Gaurisankar double the name Gauri, and against its loftier companion the name Sankar.

If we compare Wood's drawing with Schlagintweit's, we see that the nearer range B appears higher in Schlagintweit's picture than in Wood's. This same peculiarity is visible throughout the panoramas of the two observers; the near ranges appear in Schlagintweit's drawing higher always with regard to the distant ranges than they do in Wood's. The inference is that Schlagintweit drew his panorama from a considerably lower point than Wood did; this may account for the fact that Schlagintweit shows no signs of Everest.

Again, in Schlagintweit's drawing the near range K cuts off laterally more of the snowy range than it does in Wood's, and obscures the shoulder of Gaurisankar just at the point where Everest should have been visible.

In Wood's drawing Mount Everest appears as a low peak at the spot where General Walker calculated that it would appear.

The omission of Everest from Schlagintweit's panorama led General Walker to believe that it was not visible from

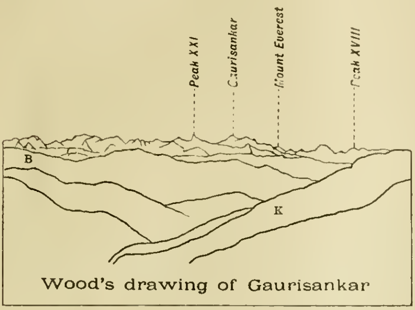


FIG. 3.

Schlagintweit's station at Kaulia. Whether it was visible or not was, I am sure, in General Walker's opinion not a question of moment.

(3) Now that Gaurisankar and Everest have been proved to be different peaks, a suggestion has been put forward [1] that they belong after all to the same "group" of peaks, and that "according to Alpine usage and precedent there is nothing to prevent the name Gaurisankar being applied to the loftiest peak of the group."

It is clear from this passage that the author is desirous of getting rid of the name of Everest, but it is not clear how his object is to be attained, whether by transferring the name Gaurisankar from the one peak to the other, or by giving the name Gaurisankar to both peaks. To displace the native name from the mountain which the natives know, and to attach it to a remote peak which they do not know, would be a course that would not commend itself to anyone interested in the preservation of local geographical names. To give the same name to both peaks would be to introduce a needless confusion.

Gaurisankar and Mount Everest, we are here told, belong to the same group; but what is a group? Controversialists give to the term different meanings to suit their own requirements. It is true that in some instances the same name has been given to different Himalayan peaks; Kangchenjunga I and Kangchenjunga II are the official designations of the two pinnacles which cap the lofty mass of Kangchenjunga; the eight peaks of a cluster in Kumaon are named Badrinath I, Badrinath II, &c.; but these peaks are slight prominences crowning the snow-clad pyramid of Badrinath, like turrets on a castle. Everest and Gaurisankar are separated by a wide interval and a deep valley, and are not spires of a single pile.

The extent to which we are justified in giving the same name to different peaks is, however, not altogether a question of intervening distance and depth; geographical significance has also to be considered. The peaks of the Badrinath cluster have a common, but no individual, significance; they are notable only as the several pinnacles of the sacred pile of Badrinath, and can therefore be classified without disadvantage under one general apellation. But the case of Gaurisankar and Everest is different: the former is remarkable in Nepal for the pre-eminence of its grandeur; the latter, screened from the gaze of man, is known only as the highest point of the earth. Would it not, then, be a mistake to include under one name two mountains the claims of which to celebrity are so different?

Before we blindly follow Alpine precedents in the settlement of Himalayan problems, we must consider well whether the conditions are identical. "It is no exaggeration to say," writes a great Himalayan authority, "that along the entire range of the Himalayas valleys are to be found among the higher mountains, into which the whole Alps might be cast, without producing any result that would be discernible at a distance of ten or fifteen miles." [1]

The Discovery of a Supposed Tibetan Name.—Colonel Waddell's book,[2] "Among the Himalayas," gives a good description of the Nepalese mountains with many interesting profiles · the author's investigations have enabled him to authenticate a Tibetan name for a high peak which he believes to be Mount Everest. This name is Jamokangkar, sometimes spelt Chamokankar.

Now let us suppose for one moment that it will be proved by future evidence—not at present forthcoming—that the mountain called Jamokangkar by Tibetans is identical with our Mount Everest. What then? Will it be incumbent upon us to abandon the name of Everest and to adopt that of Jamokangkar? I think not.

When the Gaurisankar controversy opened, the name of Everest was an interloper upon the map of Asia; but its trespass has long since been condoned. Time and usage have secured for it a right not less sacred than the right of origin; for what, after all, is the right of origin but that conferred by time and usage? To displace now this name from its lofty position in geography would seem to many of us an outrage.

It will, I think, be lamentable if former advocates of the name Gaurisankar, seeing that their cause is doomed, continue the struggle under this new flag of Jamokangkar. Already, to our regret, has Mr. Freshfield, a life-long defender of the claims of Gaurisankar, declared in favour of the Tibetan name.[3]

The old dispute has been settled; the names Gaurisankar and Everest have been proved to belong to different peaks; and it is to be hoped that Continental geographers, who have hitherto attached the name of Gaurisankar to the famous peak that we call Everest, will, in the interests of scientific harmony, now accept the name that has always been accepted by India. But before we can look for Continental acquiescence we must endeavour to show agreement at home. Few Continental geographers see the official reports of the Indian Government; the majority draw their conclusions from articles in our geographical Press.

In March, 1903, Mr. Freshfield, the late secretary of the Royal Geographical Society, wrote in the *Geographical Journal* as follows:—"The reason, for which the surveyors argued so strenuously forty-five years ago, that the 29,002 feet peak cannot be the Gaurisankar of Nepal was, of course, that their chief's proceeding in giving the mountain an English name was excused, or justified, at the time by the assertion that it had no local or native name."

The surveyors whose motives Mr. Freshfield has impugned were formed into a committee forty-five years

ago to consider the question whether the peak which Mr. Hodgson called Devadhunga was identical with the peak which Sir A. Waugh called Mount Everest; from the geographical evidence available they concluded that the two peaks were not identical, and their conclusion has been found correct.[1] In those early days there had arisen no such subtle questions as whether Mount Everest formed part of a certain range, or whether it belonged to a certain group of peaks, or whether it was just visible to those who knew where to search for it. To the clear minds of our predecessors, to Hodgson and Waugh and Schlagintweit and Walker, there was but one question at issue, namely, the identity of Hodgson's and Schlagintweit's peak with the Mount Everest of the Survey.

This question has now been answered, and after fifty years of discussion the Hindu and Nepalese names have been proved to be inapplicable; let us, then, close a controversy that has fulfilled its purpose, and let us suffer the English name to rest on our maps in peace.

S. G. Burrard.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Oxford.—The Vice-Chancellor has appointed Prof. Ray Lankester, hon. fellow of Exeter College, to be Romanes lecturer for 1905.

Sir John Burdon Sanderson, Bart., hon. fellow of Magdalen College, late regius professor of medicine, has been constituted a perpetual delegate of the university museum.

Mr. Walter J. Barton, scholar of New College, has been elected to the geographical scholarship for 1904–5.

The executive committee of the Oxford division of the British Medical Association has had the electric light permanently installed in the Pitt-Rivers Museum as a mark of their appreciation of the generosity of the university in allowing the association to make use of their various buildings and of the help the university gave them in other ways during the meeting of the association in Oxford in July last. The cordial thanks of the university have been conveyed to the Oxford division of the association for their most acceptable gift, and the curators of the university chest have been empowered to erect a suitable record of the occasion in the Pitt-Rivers Museum.

Cambridge.—Mr. J. C. Willis, of Gonville and Caius College, director of the botanic garden at Peradeniya, Ceylon, has been approved for the degree of doctor of science.

Prof. G. H. Darwin, F.R.S., and Mr. A. E. Shipley, F.R.S., have been elected members of the council of the Senate.

Mr. A. Young, tenth wrangler in 1895, lecturer in mathematics at Selwyn College, has been elected a fellow of Clare College.

Mr. R. P. Gregory, demonstrator of botany, and Mr. E. Cunningham, senior wrangler 1902, have been elected fellows of St. John's College.

Prof. Marshall Ward, F.R.S., has been elected president, and Prof. Thomson, F.R.S., Prof. Liveing, F.R.S., and Dr. Hobson, F.R.S., vice-presidents of the Cambridge Philosophical Society.

We learn from *Science* that the will of Mr. James Callanan, of Des Moines, makes bequests amounting to 27,000*l*. for educational institutions. Of this sum 20,000*l*. goes to Talladega College, Alabama.

The chair of chemistry applied to the dyeing industry at the Paris Conservatoire des Arts et Métiers, rendered vacant by the death of M. Victor de Luynes, has been given, states the *Athenaeum*, to M. Maurice Prudhomme, who acted as reporter of the section devoted to textile industries and dyeing at the Exposition Universelle of 1900.

The following deans of faculties of the University of London have been elected for the two years 1904–6:—medicine, Dr. J. K. Fowler; science, Dr. A. D. Waller, F.R.S.; engineering, Prof. J. D. Cormack; economics, Mr. G. Armitage-Smith.

[1] *Vide Proceedings* R.G.S., 1858

Mr. Andrew Carnegie, who has been Rector of the University of St. Andrews for the past term of three years, was re-elected to that office on November 4.

An open competitive examination for not fewer than twenty situations as assistant examiner in the Patent Office will be held by the Civil Service Commissioners in January next. The examination will commence on January 2, 1905, and forms of application for admission to it are now ready for issue, and may be obtained on request addressed by letter to the secretary, Civil Service Commission, Burlington Gardens, London, W.

Dr. C. Kassner has been appointed professor of meteorology at the Berlin Technical College; Dr. Maurer physicist to the German Navy; Dr. O. Lummer, from Charlottenburg, to succeed Prof. O. E. Meyer as professor of physics at Breslau; Prof. London, of Breslau, to succeed Prof. Heffter as professor of mathematics at Bonn. Dr. Augustin, of Prague, has been raised to the rank of ordinary professor of meteorology, and Dr. Karl Exner has retired from the chair of physics at Innsbruck with the title of Hofrat.

In view of the importance of German to students of science, the University College of North Wales founded a lectureship in German, to which was attached the duty of conducting a beginner's class in that language, with especial reference to the needs of students qualifying for science degrees, and Mr. Rea, of Belfast, was appointed lecturer. The experiment bids fair to be a complete success, about thirty students having joined in the first year of the new venture. The institution of classes of this kind in our university colleges will, it is hoped, remove an anomaly which, in the natural order of events, has grown up in Britain, viz. the turning out of graduates in science who are debarred from efficiently engaging in post-graduate work by their inability to assimilate readily the subject-matter of Continental scientific literature.

SOCIETIES AND ACADEMIES.

London.

Royal Society, June 2.—"Studies on Enzyme Action: The Effect of 'Poisons' on the Rate of Decomposition of Hydrogen Peroxide by Hæmase." By George **Senter**, Ph.D., B.Sc. (Lond.). Communicated by Prof. E. H. Starling, F.R.S.

In a former paper (*Zeit. physikal. Chemie*, xliv., p. 257, 1903) the author investigated the relation of the reaction velocity to peroxide concentration and amount of enzyme present, as well as the acceleration caused by rise of temperature; the results correspond almost exactly with those obtained by Bredig in his experiments on the decomposition of hydrogen peroxide by colloidal platinum. In the present paper, assuming that hæmase is also a colloid in solution, it is suggested that the velocity of reaction between the catalysor and hydrogen peroxide is great in comparison with the rate of diffusion of the peroxide to the colloidal particles, so that what is measured is really a diffusion-velocity. This would account for the analogous results obtained with platinum and hæmase, since the nature of the catalysor would be of secondary importance.

The hæmase catalysis of hydrogen peroxide, like the platinum catalysis, is retarded by small quantities of many substances, more especially by those which act as poisons towards the living organism. Thus mercuric chloride, sulphuretted hydrogen, and hydrocyanic acid, in the concentration of 1 gram-molecule to 1 million litres, reduce the reaction-velocity to half its value; they are just the substances which have the greatest retarding effect on the platinum catalysis. Iodine, mercuric cyanide, and aniline have a much smaller effect. Arsenious acid, sodium fluoride, and formaldehyde do not greatly retard the catalysis; although powerful antiseptics, they have little effect on enzyme actions in general. Carbon monoxide, although an active poison for the platinum catalysis, does not affect hæmase. Hæmase, like other enzymes, but unlike platinum, is very sensitive even to minute quantities of acids and alkalis. The retarding effect of acids is, in most cases, proportional to the concentration of hydrogen ions, in other words, to the strength of the acid. The ways in which poisons may act are discussed in the paper, and it is suggested that in many cases they enter into chemical combination with the enzyme.

Royal Microscopical Society, October 19.—Dr. Dukinfield H. Scott, F.R.S., president, in the chair.—A communication from Mr. W. D. **Colver** described the antennæ of *Pulex irritans*, on the terminal joint of which Mr. Wm. Jenkinson, of Sheffield, had discovered a lamellated structure that he believed to have an olfactory function. Mr. Jenkinson had found similar structures in several other members of the family Pulicidæ. A slide showing the entire antenna, and another showing the terminal joint, were exhibited under microscopes, and photographs of the latter slide were exhibited in the room and on the screen.—Part xvii., being the concluding part, of Mr. **Millett's** report on the recent Foraminifera of the Malay Archipelago was taken as read.—The **President** then gave a demonstration on the reconstruction of a fossil plant. The plant selected was *Lyginodendron Oldhamium*. The growth of our knowledge of its construction was illustrated by a number of actual sections and lantern slides shown on the screen. The identification of the stem of a Pinites, the fern-like petiole of *Rachiopteris aspera*, and the foliage of *Sphenopteris Höninghausi* as being corresponding parts of Lyginodendron was demonstrated. It was discovered that the stem was frequently branched, and certain fossil seeds are now, on structural evidence and association, considered to be the fruit of this plant. The reconstruction of the plant is, however, still incomplete, for the male organs have not yet been identified with certainty. The position of Lyginodendron as a seed-bearing plant allied at once to cycads and ferns was now established. A picture of the reconstructed plant was shown on the screen, and models of the seed lent by Prof. F. W. Oliver were exhibited.

Physical Society, October 28.—Dr. R. T. Glazebrook, F.R.S., president, in the chair.—An interference apparatus for the calibration of extensometers: J. **Morrow** and E. L. **Watkin.** The paper describes an apparatus for calibrating extensometers and similar instruments by comparison with the wave-length of sodium light. The apparatus is self-contained and easily made ready for use. It consists essentially of two metal cylinders of equal diameter, with their axes in the same straight line, but with a small gap between their adjacent ends. The gap is increased or decreased by the movement of a lever actuating a screw, and the alteration in its amount is measured by the interference rings produced in an optical system situated inside the gap.—A sensitive hygrometer: Dr. W. M. **Thornton.** The instrument is made by enclosing the cooled surface of a Regnault's hygrometer in a glass globe so that only the mass of vapour contained in the vessel is available for condensation. The cooled surface is made much smaller than usual—about 1 sq. cm. The surface-density of the deposited moisture depends on the total quantity of water-vapour present. If this is more than a minimum to be determined later, it will be visible either by the loss of brightness by scattering, or by observing, as in the Dines hygrometer, the scattered light itself. Little is known as to the manner in which moisture is deposited on smooth cold surfaces. Dr. Park has shown that the thickness of the deposit is of the same order as that of the black spot in interference films. The reflection of light from such a clear layer of uniform thickness backed by a bright surface is considered in the paper, and it is shown that the loss of light due to the thinnest possible films can be perceived. The opposite case to that of a smooth layer is that of clear spherical particles resting on the surface. This is also considered, and the surface-density to give a visible deposit is calculated. In connection with this an interesting note was received from Lord Rayleigh in reply to an inquiry, in which he shows that the maximum brightness of a cloud is about 4×10^{-5} that of the sun. Comparing all values, it is taken that 10^{-8} grams per sq. cm. can be detected by unaided vision with diffused light. The time taken for moisture to diffuse from a state of uniform distribution throughout the globe towards the centre is then calculated, and found to be less than ten minutes for a sphere of 20 cm. diameter. The paper is an attempt to make the somewhat neglected Regnault hygrometer an instrument of precision in the detection of small quantities of moisture.—Note on a property of lenses: Dr. G. E. **Allan.** A well known method of testing the concavity or convexity of a lens consists in holding the lens at arm's length and, while looking through it, moving it from side to side or up and down, when the image in the convex lens is found to move in the opposite direction to that of the lens, whilst in the case of the concave lens it moves in the same direction. The above facts hold if, instead of the naked eye, we employ a microscope.

PARIS.

Academy of Sciences, October 31.—M. Mascart in the chair.—Presentation of vol. xi. of the "Annales de l'Observatoire de Bordeaux": M. **Lœwy.**—Trypanosomiasis in French West Africa: A. **Laveran.** The sleeping sickness is endemic in several regions of Senegal; an examination of six specimens of biting flies from this district showed that they were all *Glossina palpalis*, the fly which, according to the researches of Dr. Bruce, propagates human trypanosomiasis. In the blood of horses from French Guinea, in two cases numerous trypanosomes were encountered. In the flies from this region, *Glossina palpalis* predominated. On the Ivory Coast, sporadic cases of human trypanosomiasis are common; here one specimen of *G. palpalis* was found, together with several *G. morsitans*. Round Lake Tchad numerous trypanosomes, having the characteristics of *Trypan. Brucei*, were found in the blood from infected horses; *G. tachinoides* here appears to be the characteristic tsetse fly.—On a case of long phosphorescence emitted by the wood of a cherry tree: M. **Clos.**—The rotation of Venus: P. **Lowell.** The results of spectroscopic observations show a velocity of about 0·005 kilometre a second, which favours a long period of rotation. For a twenty-four hour period, the velocity would be 0·450 kilometre a second.—The rotation of Mars: P. **Lowell.** The spectroscopic measurements give a velocity of 0·228 kilometre per second, as against 0·241 kilometre calculated from the previous eye observations.—On a new micrometer. History of the question: G. **Millochau.** An account of previous applications of the use of parallel glass plates as a micrometer.—On a new safety arrangement for electrical mains at high tension: L. **Neu.** Each line is furnished at its source with an interrupter which works automatically in the case of a wire breaking, of a bad insulation, or in the event of an accidental contact between the high tension wire and a telegraph or telephone wire.—On the atomic weight of aluminium: M. **Kohn-Abrest.** Aluminium, the impurities in which had been determined by analysis, was treated with acid, and the evolved hydrogen burnt to water. The mean of seven experiments gave 99·15 parts of water from 100 parts of the pure metal, corresponding to an atomic weight for the aluminium of 27·05 (oxygen, 15·88).—The action of halogen derivatives of the metalloids on halogen alkyl compounds: V. **Auger.** The alkyl iodides, bromides, and chlorides react with phosphorus iodide, giving alkylphosphinic acids. No reaction occurs with the chloride of arsenic; chloride of bismuth simply gives rise to an exchange of halogens, whilst with chloride of antimony the quantity of antimony-alkyl was too small to separate.—The tetrahydride and decahydride of naphthalene: Henri **Leroux.** These addition products were obtained from naphthalene by means of the Sabatier and Senderens reaction. Their properties and those of some halogen derivatives are described.—The action of the chlorides of phosphorus on the organomagnesium compounds of the aromatic series: R. **Sauvage.** The action of phosphorus oxychloride upon organomagnesium compounds of the aromatic series leads to the production of compounds of the type $R_3 \vdots P:O$ and $R_2=POCl$, the latter, after treatment with water, giving acids $R_2=PO.OH$. The tetraoxy-cyclohexane-rosanilines: Jules **Schmidlin.** The author quotes some experiments of Lambrecht and Weil as affording a new confirmation of his views on the quinonic structure of these compounds, and also as showing that the benzene ring of the carbinol passes through the hexahydrobenzene ring before forming the quinone ring.—The density of nitrous oxide and the atomic weight of nitrogen: Philippe A. **Guye** and Alexandre **Pintza.** The nitrous oxide used in these experiments was prepared from sodium nitrite and hydroxylamine sulphate. After weighing the flask full of the gas, the latter was condensed by connecting the flask with a side tube, well cooled, and containing charcoal. The effect of some of the impurities in the gas was thus eliminated. The atomic weight deduced for nitrogen from these experiments is 14·013. Previous values obtained in the author's laboratory by different methods are, from the limiting density of nitrogen, 14·004; by weighing nitrous oxide, 14·007; by the volume analysis of the same gas, 14·019. The mean of the four methods gives 14·011.—On the oxidation of ethyl and methyl alcohols at the temperature of their boiling points: René **Duchemin** and Jacques **Dourlen**. The rapid deterioration of some alcohol lamps had been attributed to the presence of some acid impurities in the alcohol used. It is now shown that these alcohols are rapidly oxidised at their boiling points in the presence of copper, and the effects noticed are possibly due to this action.—On the anatomy of some fishes of the genus Orestias: Jacques **Pellegrin**. The difference in the pharyngeal apparatus in these fishes is caused by a special adaptation due to the special food, small molluscs with very hard shells.—Contribution to the study of resorption of the vitellus during the embryonic development: H. **Dubuisson**.—On the coincidence between the geosynclinals and the great circles of maximum seismicity: de Montessus **de Ballore**.—On the continuity of the tectonic phenomena between the Ortler and the Hohe Tauern: Pierre **Termier**.—On the pit of Trou-de-Souci, Côte-d'Or: E. A. **Martel**.

DIARY OF SOCIETIES.

THURSDAY, NOVEMBER 10

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—The premiums awarded for papers read or published during the session 1903–4 will be presented, and the president, Mr. Alexander Siemens, will deliver his inaugural address.

MATHEMATICAL SOCIETY, at 5.30.—Annual General Meeting.—Presidential Address on the Theory of Waves on Liquids: Prof. H. Lamb.—Note on the Application of the Method of Images to Problems of Vibrations: Prof. V. Volterra.—On the Zeros of Certain Classes of Integral Taylor's Series: G. H. Hardy.—The Linear Difference Equation of the First Order: Rev. E. W. Barnes.—Curves on a Conicoid: H. Hilton.—Remarks on Alternants and Continuous Groups: Dr. H. F. Baker.—On the Expansion of the Elliptic and Zeta Functions of $\frac{1}{2}K$ in Powers of q: Dr. J. W. L. Glaisher.—Examples of Perpetuants: J. E. Wright.—Two Simple Results in the Attraction of Uniform Wires obtained by Quaternions, with, for comparison, their Verification by the Geometry of the Complex: Prof. R. W. Genese.—On the Reducibility of Covariants of Binary Quantics of Infinite Order: P. W. Wood.—On some Properties of Groups of Odd Order: Prof. W. Burnside.

FRIDAY, NOVEMBER 11.

ROYAL ASTRONOMICAL SOCIETY, at 5.—Note on the Variation of η Aurigæ: Col. E. E. Markwick.—On a very Sensitive Method of Determining the Irregularities of a Pivot; on the Pivot Errors of the Radcliffe Transit Circle, and their Effects on the Right Ascensions of the Radcliffe Catalogue for 1890: A. A. Rambaut.—The Determination of Selenographic Positions and the Measurement of Lunar Photographs: Third Paper—Results of the Measurement of Four Paris Negatives: S. A. Saunder.—Discussion of the Long-Period Terms in the Moon's Longitude: P. H. Cowell.—A Determination of the Apex of the Solar Motion and the Constant of Precession from a Comparison of Groombridge's Catalogue (1810) with Modern Greenwich Observations: F. W. Dyson and W. G. Thackeray.—Magnetic Disturbances 1882 to 1893, as Recorded at the Royal Observatory, Greenwich, and their Association with Sun-spots: E. W. Maunder.—Ephemeris for Physical Observations of the Moon, 1905: A. C. D. Crommelin.

MALACOLOGICAL SOCIETY, at 8.—Descriptions of Three New Species of Opisthostoma from Borneo: E. A. Smith, I.S.O.—Two Apparently New Species of Planispira from the Islands of Java and Gisser: Rev. R. Ashington Bullen.—The Anatomy of *Siliqua patula*, Dixon: H. Howard Bloomer.—On the Genus Tomigerus, with Descriptions of New Species: H. von Ihering.—Notes on Some New Zealand Pleurotomidæ: Henry Suter.—Notes on Some Species of Chione from New Zealand: Henry Suter.

SOCIOLOGICAL SOCIETY, at 4.—Relation between Sociology and Ethics: Prof. Höffding.

PHYSICAL SOCIETY, at 8.—Investigation of the Variations of Magnetic Hysteresis with Frequency: Prof. T. R. Lyle.—The Determination of the Mean Spherical Candle Power of Incandescent and Arc Lamps: G. B. Dyke.—Exhibition of Physical Apparatus: Robert Paul.

TUESDAY, NOVEMBER 15.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Discussion of Papers—Coast Erosion: A. E. Carey, and Erosion on the Holderness Coast of Yorkshire: E. R. Matthews.—*Succeeding Paper*:—Distribution of Electrical Energy: J. F. C. Snell.

ZOOLOGICAL SOCIETY, at 8.30.—(1) On Mammals from the Island of Fernando Po, collected by Mr. E. Seimund; (2) On Hylochœrus, the Forest-pig of Central Africa: Oldfield Thomas, F.R.S.—On the Species of Crowned Cranes: Dr. P. Chalmers Mitchell.—On the Mouse-hares of the Genus Ochotona: J. Lewis Bonhote.

MINERALOGICAL SOCIETY, at 8.—Anniversary Meeting.—New Localities for Gyrolite and Tobermorite: J. Currie.—Occurrence of Brookite with Anatase in the Cleveland Ironstone: C. R. Lindsey.—(1) Some Applications of the Gnomonic Projection to Crystallography; (2) The Construction of Crystallographic Projections: H. Hilton.—Some New Forms of Quartz-wedge and their Uses: J. W. Evans.—(1) On Three New Minerals from the Binnenthal; (2) On some Curious Crystals of Blende: R. H. Solly.

WEDNESDAY, NOVEMBER 16.

CHEMICAL SOCIETY, at 5.30.—The Isomerism of the Amidines of the Naphthalene Series: R. Meldola and J. H. Lane.—Theory of the Production of Mercurous Nitrite and of its Conversion into various Mercury Nitrates: P. C. Ray.—Amide Chloroiodides: G. D. Lander.—A New Synthesis of Isocaprolactone and some Derivatives: D. T. Jones and G. Tattersall.—The Influence of Substitution in the Nucleus on the Rate of Oxidation of the Side-chain, II. Oxidation of the Halogen Derivatives of Toluene: J. B. Cohen and J. Miller.—The Halogen Derivatives of Naphthacenequinone: S. S. Pickles and C. Weizmann. Constitution of Pyrazolidone Derivatives: B. Prentice.

ROYAL MICROSCOPICAL SOCIETY, at 8.—Theories of Microscopic Vision (a Vindication of the Abbe Theory): A. E. Conrady.

ENTOMOLOGICAL SOCIETY, at 8.

ROYAL METEOROLOGICAL SOCIETY, at 7.30.—Meteorological Observing in the Antarctic: Lieut. Charles Royds, R.N.—Decrease of Fog in London during recent Years: F. J. Brodie.—Hurricane in Fiji, January 21–22, 1904: R. L. Holmes.

SOCIETY OF ARTS, at 8.—Inaugural Address by Sir William Abney, K.C.B.

THURSDAY, NOVEMBER 17.

ROYAL SOCIETY, at 4.30.

LINNEAN SOCIETY, at 8.—On the Structure of the Stems of Plants: Lord Avebury, F.R.S.—Observations on Undescribed or Little Known Species of Membracidæ: G. B. Buckton, F.R.S.

FRIDAY, NOVEMBER 18.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—Impact Tests on the Wrought Steels of Commerce: A. E. Seaton and A. Jude.

CONTENTS.

THURSDAY, NOVEMBER 17, 1904.

THE THEORY OF CONTINUOUS GROUPS.

Introductory Treatise on Lie's Theory of Finite Continuous Transformation Groups. By John Edward Campbell, M.A., Fellow and Tutor of Hertford College, Oxford, and Mathematical Lecturer at University College, Oxford. Pp. xx+416. (Oxford: Clarendon Press, 1903.) Price 14*s*. net.

THE theory of continuous groups should appeal to all who are interested in mathematics; it is based on the fundamental ideas involved in cases of change of the algebraic notation, and as such is an illuminating synthesis of a large number of our elementary operations; and the principal notions of the theory, once laid bare, are so simple and admit of so many familiar applications that these should form an integral part of elementary teaching, particularly in analytical geometry and differential equations. As to its philosophical import, the theory is of the greatest value in the analysis of our geometrical conceptions, being an indispensable part of that algebraic scheme which, at present running parallel with these, may modify them still more than hitherto before the parallelism is recognised again as an identity.

Lie himself, though directing attention to the fact that he heard as a student, in 1863, lectures from Sylow on Galois's theory of discontinuous groups, and acknowledging his indebtedness to several writers on partial differential equations, would seem to have been interested, above all other things, in the transformations of analytical geometry; and while the precise propositions of his theory of groups must be primarily attributed to his study of systems of linear partial differential equations, his bias was at first, and largely throughout, to arrive at his conclusions by the help of geometrical intuition. Thus, though he has succeeded so extraordinarily in what he tells us was one of his objects, drawing again into organic union branches of mathematics which threatened to pursue solitary developments, there is, some may think, a certain underlying vagueness of definition as to the character of the functions to which his theories apply. This even has, perhaps, some advantages.

Of these various points of view the book now under notice gives the English student an excellent means of judging. With roughly the same purpose as the simplified German account of Lie's theory (Scheffers, 1893, 800 pages), it is briefer, and yet quite clear in statement; it contains more of the application of Lie's theory to the solution of partial differential equations, and it offers alternative proofs, due to its writer, of the fundamental theorems of the subject. Like the German book, it largely leaves aside the developments subsequent to Lie, such as the intricate theory of the structure of groups, and the application to the transformation group of systems of differential equations initiated by Picard, and leaves wholly aside Lie's criticism of the axioms of geometry, while it accepts Lie's function theory throughout; but it abounds in apt examples, chosen mainly from differential equations and geometry, so that almost any mathematical student may find something to interest him, and, with such limitations as noticed above, it is extraordinarily full and complete. Altogether a book which should be widely read.

So much so that it is both difficult and uncongenial to offer any criticisms, were only a review complete without some. To us it seems that some account of *systems* of equations which in the aggregate define a finite continuous group forms the most natural introduction to the theory; though Lie's account of them comes near the end of his third volume he is there revising his fundamental principles, and the ideas involved are very simple. Reference to Schlesinger's "Treatise on Linear Differential Equations" (Bd. ii., Teil i., p. 23) shows how this suggestion works out in detail. It seems right that the student should early learn, for instance, how far the linear transformations which leave x^2+y^2 unaltered fall under Lie's terminology. Perhaps, again, fuller references to anticipations of the ideas which Lie has coordinated into one system would have helped the student. Such may be found widely scattered in all the early masters; two that are handy to us are in Sylvester's writings. In 1852, when Lie was ten years old, Sylvester ("Collected Works," vol. i., pp. 326, 353), while ascribing the notion partly to others, writes of *continuous* or *infinitesimal* variation, and that "concomitance cannot exist for infinitesimal variations without, by necessary implication, existing for finite variations also." Or, again, the deduction, so interesting when we first came across it, of the equations for the infinitesimal motion of a rigid body, from the invariance of the expression $dx^2+dy^2+dz^2$, is in a paper of Sylvester's of 1839 (*ib.*, p. 34). Again, it appears to us, though recognising the value of Mr. Campbell's proofs of the fundamental theorems, that much would have been gained in directness, without appreciable increase of the necessarily analytical character of much of the subject, by a frank recognition of Schur's forms for the first parameter group in terms of the constants of structure; of this we are, perhaps, not impartial judges (see *Proc.* Lond. Math. Soc., vol. xxxiv. p. 91), as equally not of Mr. Campbell's use of the word *united* in his exposition of Lie's definition of an integral of a partial differential equation, having ventured elsewhere to introduce the words *connected* and *connectivity,* which latter seems better than the mere symbol M_n which Mr. Campbell adopts from Lie (see "Encyc. Brit.," vol. xxvii. p. 452). But we have a more serious contention with Mr. Campbell about a matter in which opinions will be widely divided; no doubt it is proper that a beginner's course in the theory of groups should insist primarily on the group property, and not confuse this by complicated considerations in regard to the properties of functions; but in our opinion no account can be regarded as modern which does not face the difficulties; it seems to us misleading, without careful explanations, to use language about functions in general which applies in the first instance only to the simplest algebraic functions. On p. 11 we read: "b_k can in general be expressed . . . in order that (2) may remain an analytic function of its arguments." In what way is the student to imagine the function defined after it has ceased to be an analytic function of its arguments? or does the word *analytic* mean *regular*? and what is the meaning of *expressed*? Again, on p. 98: "This transformation of the variables has only involved algebraic processes." The processes in question consist in reverting certain power series; now a power series is an entirely symbolic thing unless we have very simple rules for the law of its coefficients; how can the reversion of a power series in general be regarded as a practicable process likely to aid the effective determination of the integrals of a differential equation? and at any rate it does not seem fair to describe it as an algebraic process. Moreover, apart from such indefiniteness, and passing over such phrases as (p. 24) "where t is a constant so small that its square may be neglected," there is the question, apparently unconsidered in this book, of how far Lie's propositions can be proved for functions which are not analytic, in regard to which various investigations are already forthcoming.

But we gladly turn from such criticisms to remark again on the merits of the book, choosing two random examples, one of the practical spirit in which it is written, the other of the author's eye for a neat result. On p. 256 the author frankly uses the known theorems as to forces in three dimensions to abbreviate the reduction of the equation of a linear complex. On p. 243 the author arrives at the theorem that Ampère's partial differential equation of the second order is reducible by a contact transformation either to $s=0$ or to $rt-s^2=0$, according as it possesses two distinct systems of intermediary integrals or only two coincident systems. In conclusion, we would express our admiration for the form and printing of the volume.

TECHNOLOGICAL CHEMISTRY.

The Industrial and Artistic Technology of Paint and Varnish. By A. H. Sabin, M.S. Pp. vi+372. (New York: John Wiley and Sons; London: Chapman and Hall, Ltd., 1904.) Price 12*s*. 6*d*. net.

Food Inspection and Analysis. By Albert E. Leach, S.B., Analyst of the Massachusetts State Board of Health. Pp. xiv+787. (New York: John Wiley and Sons; London: Chapman and Hall, Ltd., 1904.) Price 31*s*. 6*d*. net.

(1) THIS is a gossipy, pleasantly discursive volume, the style of which will be indicated when we remark that the book is prefaced by an extract from Quintilian, and closes with a poetical quotation. It treats, generally in untechnical and even colloquial language, of varnishes and paints, their history, fabrication, and uses. Principles, not formulæ, are usually given by the author; the book is in no sense a collection of recipes.

If there is not much of strictly scientific value in the treatise, there is a good deal which is of practical interest. The chapter upon the protection of metals against corrosion, for instance, may be recommended to the notice of engineers, and also that on the coating of water-pipes. As regards this latter question, the author points out that the essential feature of the "Angus Smith process" has been misapprehended in modern practice. Dr. Smith's treatment resulted in a varnish or "enamel" of linseed oil and coal-tar pitch being baked on to the cleaned surface of the pipe, the oil oxidising more or less completely during the operation. The modern substitute for this is, too often, a mere dipping of the pipe in crude tar, or in tar diluted with "dead oil." From the wording of the original patent this process may, on a technicality, pass under Angus Smith's name; but our author has no doubt that if the inventor were living he would condemn the whole thing from beginning to end. It is "adulterating his invention and stealing his reputation."

Mr. Sabin describes a process of his own, which has, he tells us, been successfully applied to large pipelines in America, and is in use in the United States Navy for the protection of heavy copper mains. It is evidently based upon a study of the Angus Smith process. It consists in applying to the pipes a thin coating of a mixture of linseed oil and asphaltum, and afterwards heating the pipe to 400° F. until the oil is completely oxidised. The product is said to be a hard, elastic enamel. One result is that, whereas the aforesaid copper mains had formerly an average "life" of about six months, they have now lasted three or four years, and their ultimate durability is not yet determined.

There is some curious lore in the author's historical summary. The connection between electricity and "Berenice with the golden hair," between varnish and the Queen of Cyrene, is a good example of etymological ramifications. One quaint recipe of 1520 is worth quoting:—

"A most excellent varnish for varnishing arquebuses, crossbows, and iron armour: Take of linseed oil two pounds, sandarac one pound, Greek pitch two ounces. Boil the oil, then dissolve in it the other ingredients, and strain through a much-worn linen cloth; and when you wish to use the varnish, scrape and polish the work and heat it in a hot oven, because that is the best place to heat it . . . then lay it on thinly with an instrument of wood, so that you may not burn your fingers, and it will make a beautiful changing colour.

"And if you supplied the place of Greek pitch with naval pitch, I think it would make the work black when you varnished it."

The treatise can be read with profit either by the manufacturer who knows little of chemistry, or by the chemist who wishes to know something of paint and varnish technology.

(2) There is a Madras story of a native woman, who, charged with possessing illicit salt, would offer no defence; wherefore she was about to be mulcted in the sum of one rupee. Before closing the case, however, the magistrate thought he might just as well satisfy himself that the substance really was salt, and forthwith proceeded to taste it. Thereupon the lady raised her voice in a very effective interjection: "Not only," said she, "not only does the sahib fine me one rupee, but lo! he eats the ashes of my dead husband."

Fortunately for magistrates, such appeals to the palate are rarely either necessary or sufficient, nowadays, for disposing of legal cases relating to the identity and purity of foodstuffs. Much more cumbrous machinery has had to be devised. To summarise and explain this machinery is the aim of the work under notice. In the main it is intended for the food analyst, and the author's idea has been to give this official some information, not only on the subject of food-analysis, but also on various collateral matters with which he is brought into contact. Thus there are sections discussing the equipment of the laboratory, the storage of samples, legal precautions, the duties of the food inspector, and certain processes of food manufacture.

All the ordinary foodstuffs are dealt with, a chapter being allotted to each group of allied products, such as cereals, spices, alcoholic beverages, and so on. The descriptions are written clearly; an excellent selection of the salient facts and the best methods of examination has been made; and to each division an extensive bibliography is appended. Microscope work is a special feature, and the volume is enriched by a series of forty plates, containing about four times as many photomicrographs of the principal vegetable and animal structures met with in the examination of foods.

The chief criticism to offer on the book is that the treatment of so much material in one volume—even one of eight hundred pages—must necessarily be in the nature of a summary. Hence in many instances the information, though sufficient for routine work, is not full enough to be of much value when cases of real difficulty arise.

One notes several examples of careless transcription in looking through the work. On p. 441 the so-called "Koettstorfer's equivalent" for butter-fat is given a maximum value of 241 and a minimum of 253. It might be guessed that these two numbers have been transposed; but on the next page the value of the constant in question is given as 224. The author has, in fact, failed to distinguish between the "equivalent" and the "value" of the saponification experiment. In the table on p. 441 the values of the insoluble acids for oleomargarine are transposed; the specific gravity has no temperature of reference; and a faulty arrangement of the table makes it appear that butter-fat and margarine possess, somehow, a maximum and a minimum temperature; whilst in the data for edible oils and fats on p. 380 the limiting values are again transposed.

Nevertheless, it would be unfair to judge the book by these slips. It contains a large amount of information and, though written more particularly from the American point of view, will be found a useful conspectus of the whole field of food control.

C. SIMMONDS.

THE TRANSPIRATION OF PLANTS.

Die Transpiration der Pflanzen. Eine Physiologische Monographie von Dr. Alfred Burgerstein, A. O. Universitätsprofessor in Wien. Pp. x+283. (Jena: Gustav Fischer, 1904.) Price 7.50 marks.

THIS book is a classified analysis of the published work on transpiration from the time of Hales onward, with a running criticism by the author, who is well known to have attended to the subject for many years.

The amount of contradictory evidence is remarkable. In the case of the earlier experimenters, with more or less faulty methods, this is not surprising; but the same thing strikes one in many modern instances. The question of the amount of transpiration in moist tropical regions, as compared with Europe, is a case in point. Another instance is what the author describes as a "seven years' war" (1884–1891) between Wille and Lundström as to the absorption of water by the aërial parts of plants. Other disputed points are the effect of salt solutions supplied to the transpiring plants, and the influence of varying amounts of CO_2 in the atmosphere; and many other cases might be cited.

The relation of plants to water, though a subject of primary importance, is still to a great extent in the elementary stage of inquiry. A large number of the statements quoted by Burgerstein are little more than disconnected facts, and, in spite of the interesting book he has made of them, they still seem to us to await a somewhat different treatment.

The subject-matter of the book falls into two classes:—(1) the loss of water-vapour considered as physical phenomenon; (2) the biological inquiry into the adaptation of plants to the distribution of water considered as environment. From both points of view transpiration should be considered side by side with assimilation and respiration, and this manner of looking at the subject has not, in our judgment, been kept sufficiently in mind by the author. The point is that the same organs—the stomata—serve for gaseous exchange and for the evaporation of water. Burgerstein discusses at the end of his book the question whether, as some have supposed, transpiration is a necessary evil. This might have been discussed from a broader standpoint, and would have been in place in an earlier chapter. It does not seem necessary to treat the view referred to as entirely false. Plants undoubtedly have to strike a balance between the possession of a free stomatal connection with the atmosphere and the consequent danger of evaporating more water than they can take up from the soil. This compromise includes also the value of the transpiration-stream in supplying minerals to the aërial parts, on which Burgerstein rightly lays stress. All we suggest is that the whole problem, being of a fundamental character, might well have been dealt with more liberally, and been given a place preliminary to the details of transpiration.

A fault in Burgerstein's treatment of transpiration, though a fault difficult to avoid, is that he does not keep before the reader the fact that the condition of the stomata—whether open, half open, or shut—is far and away more important than all the other internal conditions put together. Like the rest of the world, he is well aware of this, but we doubt whether the uninstructed reader would here learn to think of the problem in this way. To take an example, he describes (p. 62) how, when part of the foliage is removed, the remaining leaves transpire more actively than before. Here we want a discussion of the possible effects, direct or indirect, of the operation on the stomata of the remaining leaves. The same thing is true of the discussion (p. 81) on the transpiration of flowers as compared with leaves, where the reader is left in ignorance of how far the facts are explicable by reference to the stomata.

But it is not merely in relation to isolated problems that we feel the want of more information with regard to the stomata. We should expect to find a full general discussion of their importance in regard to transpiration. This would have included a reference to Horace Brown's work on the static diffusion of gas through these openings, and a consideration of the question how far evaporation can be checked by the closure of the stomata. Again, we should have liked a discussion of the trustworthiness and general value of the microscopic measurements of the stomata in living plants. Burgerstein gives an interesting account of the methods depending on the yield of water-vapour, such as Stahl's cobalt test, &c., by which it can be roughly determined that the stomata are "widely open" or "nearly shut." But if we are to distinguish the stomatal factor from other factors in experiments on transpiration, numerical statements as to the condition of the stomata are wanted, and the question whether such data are available might well have been discussed. With regard to method, Burgerstein seems to us a little hard on the various "potometer" methods, by which a general idea of the transpiration curve is obtained by measuring the intake of water. He is justified in saying that these methods do not estimate transpiration but absorption; but we think he undervalues the fact that, with cut branches and for not too extended periods of time, the intake so closely corresponds to transpiration that the method cannot be neglected, and is certainly of great value for purposes of demonstration.

Though we have criticised "Die Transpiration der Pflanzen," we are far from meaning to condemn it; we have, indeed, read it with interest and profit. Anyone intending to make a study of the subject cannot do better than read it with care. He will thus be made aware of many pitfalls, and will have a guide to the chief points which need fresh investigation.

F. D.

OUR BOOK SHELF.

House, Garden, and Field; a Collection of Short Nature Studies. By L. C. Miall. Pp. x+316; illustrated. (London: E. Arnold, 1904.) Price 6*s*.

THIS admirable little work appears to be by far the best aid to the proper teaching of nature-study that has hitherto come under our notice, the author having very wisely refrained from furnishing the teacher with a manual which would do away with all necessity for original study and observation on his part, and enable him to read the various lessons to his pupils without effort or thought. The object of the writer is, indeed, as much to educate the teacher as to enable the latter to teach his pupils. For example, in the article on bananas, Prof. Miall, when he asks the reason for the peculiar shape of that popular fruit, under the guise of leaving the reply to the pupil is really testing the powers of observation and reasoning possessed by the teacher himself.

As the author observes in his introduction, teachers seem to expect a series of ready-made lessons on a variety of nature subjects, basing their demand on the ground that they have no time (or is it that they have no inclination?) to make the necessary studies for themselves. If this course were adopted, it would lead to two evils. First, all the observations (if they could be so called) would come from the teacher and not from the pupils; and, secondly, knowledge thus acquired by the teacher could not possibly raise the delights of genuine nature-study in the minds of his scholars. Prof. Miall has therefore preferred to make an effort to instil and encourage the habit of observation and inquiry in a few teachers (who will necessarily be the best of their kind) by showing them what may be learnt by careful observation of the common natural objects to be met with among their daily surroundings, rather than by pandering to the popular clamour for cut and dried lessons—which are really not nature-study at all. How he has succeeded remains to be seen. If we may venture to predict, it will be the clever and inquiring teachers who will praise and take advantage of his efforts, and the dullards and plodders who will condemn them and say that they are unsuited to their purpose.

Although the author modestly says that he gives only a few lessons, his articles or essays are no less than fifty-four in number, and cover a very wide range of subjects, including cheese-grubs, glow-worms, water-lilies, London pride, the human face and hand, and museums and their teachings. As an example of the large amount of information Prof. Miall manages to give in a very small compass, we may refer to the exceedingly interesting account of the ancestry and evolution of insects in the chapter on the "cheese-hopper." An excellent work which should be in the hands of all teachers is our verdict. R. L.

Ideals of Science and Faith. Essays by Various Authors, edited by the Rev. J. E. Hand. Pp. xix+333. (London: George Allen, 1904.) Price 5*s*. net.

"ON all sides" (to quote the preface) "is a growing recognition that the ideals common to both Religion and Science are not only numerous but are indeed the very ideals for which the nobler spirits on both sides care most." Necessarily the treatment is varied, perhaps too varied, but the editor gently deprecates criticism of this feature. Prof. Patrick Geddes has room to discourse on the excellence of teaching boys to make boxes; and the theologians, under "A Presbyterian Approach," "A Church of England Approach," and the like, hardly give one a definite view of "A Christian Approach."

In the papers of the men of science and philosophers the general position is that science does not deal with the whole of life, and that it can no longer meet the claims of faith with a "*certainly not.*" Sir Oliver Lodge defends the idea of continuous guidance on the part of the Deity, seeks to reconcile Pantheism and the belief in a personal God, and complains that religious people seem to be losing some of their faith in prayer. Prof. J. Arthur Thomson and Prof. Patrick Geddes lay stress on the altruistic side of the struggle for existence. Prof. Muirhead maintains that we must limit causation and the conservation of energy to the material world, and must look for some other conception when we come to the action of the mind itself. "We use a saw to make a fiddle; we throw it (*sic*) aside when we come to play upon it (*sic*)." The Hon. Bertrand Russell's paper—"An Ethical Approach"—is the most eloquent; much of it is Lucretius, Book iii., rewritten (could one be more complimentary?), with the difference that Mr. Russell recognises more definitely the need for religion and worship, albeit the worship of a God who is not Force but "created by our own love of the good."

Die orientalische Christenheit der Mittelmeerlände. By Dr. Karl Beth. Pp. xvi+427. (Berlin: Schwetschke, 1902.)

THE author spent five months in 1901 in the eastern Mediterranean, investigating at first hand, and at close quarters, the institutions, and the practical working of the Greek, Armenian, and Coptic Churches, and of such other fragments of Christian communions as survive in those parts. He is evidently a good observer and quick worker, and was able to elicit much interesting information, meeting everywhere, as he did, with cordial receptions and assistance. The result is a valuable handbook of an ill-explored section of ecclesiology, full of queer side-lights upon mediæval and modern history, and no less upon the workings of the religious instinct under the peculiarly unfavourable conditions which have prevailed in the Levant for so long. The author's personal knowledge of the working of these curious institutions enables him to supply a number of corrections to Kattenbusch's "Lehrbuch," and to confirm and expand the observations of Gelzer, von der Goltz, von Soden, and other recent travellers.

Tales of Sutton Town and Chase, with other Tales and some Sketches. Collected by "Tau." Pp. 86. (Birmingham: Hudson and Son, 1904.) Price 2s. 6d. net.

TWO of the narrative poems in this delightful little collection are of more than local interest. One ballad —"The Alchemist of New Hall"—refers to the moated stone mansion of New Hall, where the celebrated Dr. Sacheverell lived at one time. Another poem deals amusingly with a meeting of the Lunar Society, which met in the district in the latter portion of the eighteenth century, and included among its members Erasmus Darwin, Galton, James Watt, Priestley, Wedgwood and Baskerville. To persons familiar with Sutton Coldfield and the neighbourhood, this collection of verses describing in appropriate words and metre some of the stories of "oldest inhabitants" will be read with keen interest; and many others will find pleasure in the quaint ideas contained in this dainty little volume.

The Glamour of the Earth. By George A. B. Dewar. Pp. ix+255; with illustrations by R. W. A. Rouse. (London: George Allen, 1904.) Price 6s. net.

THE true lover of the country will enjoy this book. The author is not addressing the mere seeker after information; and such a reader will regard the volume as diffuse and unsatisfactory. But men who are weary with work and have gone to the country quietly to come into contact with nature, and so secure refreshment and recreation, will follow Mr. Dewar's notes and leisurely observations with sympathy and appreciation. The beautiful pictures by Mr. Rouse add much to the attractiveness of the volume.

Jahrbuch der Radioaktivität und Elektronik. Herausgegeben von J. Stark in Göttingen. Erster Band. 1 Heft. (Leipzig: S. Hirzel, 1904.)

THIS new magazine or "year-book," devoted to radio-activity and the electric discharge, is promised to appear in four parts yearly. The first part, now under consideration, contains two original contributions, six short summaries of recent work on special branches, and a fairly complete list of the original papers on radio-activity, &c., which had appeared in 1904 up to the date of going to press. The short summaries referred to are preceded by bibliographies, and should prove useful to specialists.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

What is Brandy?

WITH regard to the interesting article in your issue of November 3 upon this subject, I trust that I may be allowed to pass a few comments.

There can be no doubt that the word "brandy" originally connoted burnt or distilled wine; its derivation is thus stated in the "Oxford Dictionary" of Dr. Murray as from the Dutch word "brandewijn," old English "brandy wine."

Thus so late as 1719 one D'Urfey, "Pills," v. 23, wrote:—

"I was entertained, with Kisses fine and Brandy wine."

Certain spirits were introduced long before the outbreak of the phylloxera in France under the name of British brandy, still included in certain legal documents under the designation of British compounds, though, as a matter of fact, made more without than within this country. Herein a difficulty arises for those who may have to advise county or borough councils in the administration of the Sale of Foods and Drugs (Amendment) Act, as now interpreted, or those, like myself, who have to deal with cases under the Merchandise Marks Act. For on the one hand an astute chemist could make up a liquid, wholly innocent of grape juice, so that the results, obtained on analysis, were identical with those of a genuine grape-spirit, and on the other, a sample of the latter might, as pointed out in your article, if carelessly distilled be condemned, though innocent.

Again, if a genuine grape spirit, distilled not far from Cognac, were mixed with — per cent. of a spirit, not silent (I omit particular details on the ground of expediency), mere analytical results would be of little avail; such a problem (*credite experto*) requires prolonged research, and the application of methods not wholly chemical.

It is clear that professional tasting, especially by certain specially gifted persons, is a very valuable aid to analytical results and methods of research, yet, as a matter of evidence, it can be regarded only as a question of opinion, based on long experience, rather than as a definite proof.

A Government inquiry would elicit important evidence, and possibly some kind of standard might be arrived at which would not only exclude clever and fraudulent imitations, but also bring the present chaos or *impasse* to a conclusion. V. H. VELEY.

Oxford, November 5.

YOUR article published under the above heading in NATURE of November 3 raises some interesting points. The writer clearly fails to appreciate any difference between brandy and alcohol, for he says, "if the brandy is being made from damaged wine the rectification must be most carefully conducted, and may have to be pushed to a point that the alcohol is obtained almost pure, that is to say, almost free from *non-alcohol*." Now if brandy is merely alcohol, as is here plainly implied, why produce it from grapes or wine at all? Similarly, why produce whisky from malted barley, or rum from cane sugar? The fact is that the genuine article is, and has always been in history, the product of the pot still. The pot still produces alcohol plus "*non-alcohol*," the patent still pure alcohol. It is true that brandy, whisky, and rum contain alcohol, but the alcohol of the patent still or rectifying still is not whisky, brandy, or rum. Pot still spirit from "damaged" or sick wines would be nauseous and undrinkable, but pot still spirit from wines of repute possesses the qualities which distinguish genuine brandy chemically and physiologically from rectified spirit. It is well known that the effects of pure alcohol on the blood pressure and lymph circulation are modified very considerably by the presence of other constituents in spirits. These other constituents are the "*non-alcohol*" which you describe. To call rectified spirit or patent still spirit brandy is about as reasonable as calling skimmed milk milk. In England the word brandy ought to be confined to a pot still spirit produced from the wine of grapes, and should never be applied to alcohol distilled in a patent still from "damaged wine" or from likely enough worse material. Such a definition, if adopted, would be "calculated to facilitate the work of the unfortunate public analysts who may be called upon to express an opinion as to the genuineness of a sample of brandy," and the question, what is brandy? analytically speaking, would no longer "await solution." Recent analyses to which you refer have at any rate reduced a large section of the brandy trade to the confession that much of the stuff they sold never had its origin in the grape at all. The public house trade now posts notices in the bars that it cannot guarantee the brandy sold to be genuine grape spirit.

The attitude of the French committee is not difficult to understand, and there can be no objection to it so long as the trade, in the interests of which it has undertaken the inquiry, determines on issuing an honest label setting forth that either the spirit is a pot still spirit from grape wine or it is not. S. ARCH. VASEY.

Bromley, Kent, November 8.

The Origin of Life.

ALTHOUGH there are good reasons for believing that the life of our world is the product of its own physical conditions, and distinct from the life of other members of the solar system, it is hardly probable that living substance can be produced otherwise than by the same conditions that produced it in the past, and one of these conditions is a vast period of time.

We are not acquainted with any life apart from "cells." But the cell is a very complex organism, and between inorganic substance and the cell there may have been as long a course of evolution as between the cell and the highest existing animal or vegetable. Probably most biologists nowadays regard life not as an entity (*e.g.* not as a "vital force"), but rather as a coordination of many physical processes which have become more numerous and better coordinated in the course of evolution. It is not to be supposed that the *total* functions of life would be developed in not-living substances under the restricted conditions of human experiment; nevertheless, some of the *individual* functions might be brought into action, at least in a primitive form.

One of these functions, which I believe to be the most fundamental, is the deoxidation of a compound containing the elements N, O, C, H, &c., by the action of light, moderate heat, or slight electrical disturbance. This is the foundation of biosynthesis—a small beginning which in the course of ages develops mechanisms so perfect as the photosynthesis in chlorophyll-bearing cells. We ought by research to discover the conditions on which such deoxidation depends, and imitate it in our laboratories; we might even apply it to important economic purposes.

This deoxidation is probably a perfectly natural process, as natural as the opposite process of oxidation, only it must not be sought in the behaviour of mere oxides, as CO_2, but rather in that of compounds containing N, O, C, H, &c., as above suggested. In fact, it may be expected to be nearly a reversal of the process of vital oxidation, which has been more successfully investigated. Vital oxidation seems to take place in two stages, as follows:—(1) the O is taken into combination with the N in a complex molecule, (2) it is transferred from the N to a more oxidisable element. Whether complete linking occurs between O and N, as $O{=}N{=}$, we cannot say; but the linkings $\equiv C{-}O{-}N\equiv$ and $H{-}O{-}N\equiv$ are probable. The oxygen-carrying function of N seems to be assisted in many (if not all) cases by Fe.

First attempts at life may be occurring continually around us, but if any synthetic substances be formed they are sure to be seized and assimilated by the already developed organisms. F. J. ALLEN.

Cambridge, November 12.

Change in the Colour of Moss Agates.

IN connection with Mr. Whitton's inquiry (NATURE, November 10, p. 31), the following note may be of interest.

On the top of the West Cliff at Bournemouth the road is laid with material which includes a number of flint pebbles. These are, as a rule, rounded or subangular, and of a yellow or whitish-yellow colour as regards their general surface. But where exposed to the air the colour has changed to deep blue, violet, or purple, and so much so that in places the whole surface of the road has a marked blue shimmer. Or perhaps it should rather be said that this was the case last autumn; I have not seen it since.

As will be seen from the enclosed specimen, the contrast between the imbedded and the exposed portion of the pebbles is very striking.

Without giving any special study to the matter, I was inclined at the time to attribute the phenomenon either to a further oxidation and hydration of the iron which is, no doubt, present in the flints, or, possibly, to a molecular rearrangement of the silica. At some points the blue colour passes almost into black; this suggests that it may indicate a transition stage between yellow and black flints.

Possibly some mineralogist has examined the matter more thoroughly. C. SIMMONDS.

Northcroft, Deronda Road, Herne Hill, November 14.

Chemical Analysis for Beginners

IN a review on this subject (this vol., p. 5) "J. B. C." directs attention once again to the unsuitability of an extended study of analysis for a beginner. His opinions not only claim respect, but must be largely shared by all teachers of chemistry.

There is, however, a side to the question which somehow seems rather to be overlooked. The average elementary student will work patiently for hours over qualitative analysis, well taught, badly taught, or not taught at all—he is interested, and though none too willing to use brains as well as tables, he is ready under guidance to do his best. But in any logical system of elementary quantitative and preparation work calculated to build up a firm foundation in the principles of chemistry he appears to take no *natural* interest, when it comes to actual work. Possibly "J. B. C." will not agree that this is so; and it may be right that the student should be compelled (if it can be done) to think logically from the first. But it seems not unimportant to interest him in practice as well as "on paper."

I do not refer to the embryo professional chemist who soon gets through the introductory work and is nearly always interested, but to that enormous crowd of text-book consumers who spend, possibly, three hours per week in the chemical laboratory as part of their scheme of study. Does not the marked change of attitude in such students when qualitative analysis is touched upon indicate that there is still room for fundamental improvement in the method of presenting first steps in practical chemistry?

F. SOUTHERDEN.

Royal Albert Memorial College, Exeter.

Misuse of Words and Phrases.

IN Mr. Basset's book, to which he refers in NATURE of November 10 (p. 30), he speaks of the advantage of having "a concise and pointed mode of expression, which saves a great deal of circumlocution and verbosity." He thinks that this object is best gained by coining a new word from the Greek, for instance, *autotomic*, whereas I hold that the same object is better gained by adopting a word of English derivation, *self-cutting*. Mr. Basset now says that he considers this word "inelegant," and, in the absence of any standard of elegance, I can only reply that this is a matter of individual taste. Perhaps it would be better still to call a curve that has double points a "nodal curve," and one that has none a "nodeless curve." The word *binodal* is already in use.

As regards the phrase "non-singular cubic," it is clearly inaccurate if, with Plücker, we speak of "singular lines" as well as "singular points," and include all these under the term singularities; but I rather think that in English books the term singularity was formerly not applied to double tangents, or even to points of inflection.

November 14. T. B. S.

Reason in Dogs.

APROPOS of "thinking cats," perhaps the following story of a practical joke played by a dog will interest your readers.

A friend of mine, Mr. W., owns a Manchester terrier of which he is very fond, and for that reason receives rather more than doggy attention. The dog passes most of his time in the library, where a basket and rug are provided for him, but he prefers, when it is possible, to take possession of his master's easy chair. A short time ago I had occasion to call on Mr. W., and the dog was, as usual, occupying the chair, from which he was removed to his basket. He showed his resentment of this disturbance of his slumbers by becoming very restless. Presently he trotted over to the door, which he rattled by pushing with his nose, his usual method of attracting attention when he wished to go out. His master immediately rose and opened the door, but instead of the dog going out he rushed back and jumped into the chair his master had just vacated! The rapid wagging of his tail and the expression on his face showed the dog to be very pleased with the result of his ruse. The dog has repeated the same joke once or twice since, with much evident delight to himself. ARTHUR J. HAWKES.

Bournemouth.

Occurrence of a Tropical Form of Stick-Insect in Devonshire.

A FEW weeks ago I obtained through the kindness of a lady in Paignton a living specimen of a stick-insect, one of several individuals which had appeared in her garden. My example was met with on the plaster outside a window, and owing to the tenacity with which it adhered to its position required some force to dislodge it. I preserved it in captivity for about a fortnight, at the close of which period it died, having refused to feed on the foliage of any of the plants with which it was supplied.

It is an apterous female, and is, I think, referable to *Cladoxerus phyllinus*, Gray. I have not been able to obtain any clue as to the cause of its occurrence.

ROBERT O. CUNNINGHAM.

A Probable Variable of the Algol Type.

ON the evening of October 29, while examining the Pleiades with a binocular at about 9 p.m., G.M.T., I noticed that the star Atlas (27 Tauri) was slightly *fainter* than Pleione (28 Tauri), a little to the north of it. I did not remember at the time what the relative brightness of the stars was, and on looking them up in the Harvard Catalogues I was surprised to find that Atlas was measured 3·80 magnitude, and Pleione 5·19. I find that all the estimates for the last 300 years agree in making Atlas considerably brighter than Pleione. The nights following October 29 were cloudy, but on the evening of November 9 I found Atlas of its usual brilliancy, and more than 1 magnitude brighter than Pleione. The observed variation was therefore about $1\frac{1}{2}$ magnitude. As Atlas is not a long period variable, it seems probable that it is a variable of the Algol type. The star should be watched, and observations for variable radial velocity would be very desirable.

J. E. GORE.

THE PREVIOUS EXAMINATION AT CAMBRIDGE.

THE first report of the studies and examinations syndicate, issued on November 11, deals with the previous examination. This is the first public test imposed on candidates for degrees at the university, and since 1822 has included a compulsory examination in both Latin and Greek. In response to a demand for reform sent up by teachers, parents, professional men, and men of science in the direction of making Greek, at least for some students, an optional subject—a demand supported by a large majority of head-masters and assistant masters in the secondary schools—the syndicate proposes a new scheme for the examination in which this demand is recognised.

Briefly, the scheme provides that for *all* candidates the "previous" shall consist of three parts, to be taken together or separately at the convenience of the student. Part i. includes Latin, Greek, French, and German, the papers in each to require unprepared translation and composition. "Set books" are abolished. A candidate may take Latin *and* Greek, or either Latin *or* Greek together with French or German. In other words, he must take *two* languages, of which one at least is an ancient classical language. Part ii. includes arithmetic, algebra, and geometry as heretofore. The paper on "Paley's Evidences" is abolished; it is not a school subject, and it is got up largely by an effort of memory from a bare abstract or analysis. Part iii. includes English composition as a compulsory subject, and two of the following alternatives: (1) English history; (2) scripture knowledge (a Gospel and Acts in English); (3) elementary organic chemistry; (4) experimental mechanics and other parts of elementary physics. Natural science, in the shape of physics and chemistry, is thus introduced for the first time. The syndicate was urged by weighty authorities to require from all candidates some knowledge of science; but, after full consideration, it is unable to recommend more than the inclusion of science among the alternative subjects. Probably, in view of the imperfect organisation of science teaching in many public schools of the classical type, to make science compulsory at this stage would have involved the adoption of a standard so low as in effect to discredit the subject.

For the benefit of certain students, among whom students of science may certainly be reckoned, to whom the power to read French and German is more important than a special knowledge of one only of these, it is provided that the translation papers in each of the two languages may be substituted for the translation and composition papers in one alone.

For a boy from a modern school or technical institute, therefore, the examination provided might thus include, for example, Latin, French, and German translation, mathematics, English composition, elementary chemistry, and elementary physics. On the other hand, a boy from a purely classical school might take the following combination: Latin and Greek, mathematics, English composition, scripture, and English history. For him the examination would be an improvement on the old "previous" examination, not only by reason of the higher standard proposed to be required, but also on account of the wider range of literary subjects to be included.

The report represents a serious attempt to recognise and to provide for the changes which are in progress in modern English education. By asking from every aspirant evidence that he has seriously studied *one*, at least, of the classical languages, it safeguards the traditional virtue ascribed to that form of intellectual training. By admitting that modern languages (including English) and physical science are possible components of a liberal education in the twentieth century, it indicates a certain widening of academic aims and ideals that may lead to better things hereafter. There is little doubt that the report will meet with strenuous opposition from those who, in the supposed interest of ancient learning, dare not make any concession to modern knowledge. It will not escape criticism from reformers of the more advanced type, who would sweep away Latin as well as Greek. But the proposals at least remedy a genuine grievance in a practical manner, and they make for progress along the lines of a sounder and broader education than the older universities have yet sought to foster.

THE EXPLORATION OF THE TRANSVAAL.[1]

IN this first report, drawn up by Mr. H. Kynaston and his colleagues, we see the prospect of healthy rivalry between the geologists of Cape Colony and of the newly acquired territories to the north. No time has been lost in issuing one of those small folio

[1] "Geological Survey of the Transvaal. Report for the Year 1903." Pp. ii+48; with 24 plates, folding maps, and sections. (Pretoria: Printed at the Government Printing Office, 1904.)

volumes, the form of which, however unsuited to our bookshelves, probably recalls to the Government printers the blue-books of the old home-country. No time has been lost, moreover, in the prosecution of researches which furnish something worthy to record,

FIG. 1.—Waterberg sandstones near Balmoral, containing fragments of Pretoria quartzite.

and the results have here been illustrated on an excellent and liberal scale. Topographic work has been undertaken where existing surveys are deficient, and it seems probable that the geologists will run ahead, for some years to come, of the accurate mapping of the country. The beds dealt with are, firstly, the Pretoria series of quartzites and shales, which must have a high antiquity; secondly, the Waterberg sandstones and grits, which are now for the first time proved to be distinctly unconformable on the Pretoria series; and thirdly, the Karroo system, or rather systems, which opened under Glacial conditions, and were laid down on the denuded surface of the folded Waterberg series.

The two earlier series are thus clearly pre-Carboniferous. The Pretoria series is in places enormously swollen by the intrusion of diabase, which has worked its way along the bedding-planes with remarkable regularity. Where it breaks across the beds, it becomes slightly modified and charged with fragments from the quartzites. The Waterberg series near Balmoral has been invaded laccolitically by a granite, which is correlated with the red granite of the northern Transvaal. On its upper surface, which follows the planes of stratification of the overlying beds, it passes into a platy rock of the compact quartz-porphyry type.

Mr. E. T. Mellor regards the Waterberg series, with its coarse breccias and conglomerates, as deposited in waters swayed by powerful currents, torrents from the land being responsible for the earlier beds. Fragments of the Pretoria quartzites are found in these, affording additional proof of the unconformity (Fig. 1).

The Karroo beds similarly contain boulders of the rocks that preceded them, including the granite that rose beneath the Waterberg series. These boulders occur in the Glacial beds at the base of the system, corresponding with the Dwyka conglomerate of Cape Colony. These beds were laid down in a region already traversed by large streams, and it is very interesting to note that the modern Elands River, Bronkhorst Spruit, and Wilge River have cleared the Glacial beds out of the ancient channels, and have followed in the course of valleys that were long fossilised and lost to view.

As in Cape Colony, the Lower Karroo beds lie on handsomely glaciated surfaces. Dr. Molengraaff directed attention to these in 1898, and Mr. Mellor has described numerous new and admirable instances (Fig. 2). The uniform direction of the striæ from one exposure to another points to an ice-sheet, and not to local glaciers. The fact that the movement was from north to south, speaking in general terms, both in the Transvaal and in Cape Colony, only adds zest to the search for an explanation of this old Glacial epoch in the southern hemisphere. It is satisfactory to find that Dr. Molengraaff now concludes that even in the Vryheid district the ice-movement was from N.W. to S.E., *i.e.*, contrary to his previous suggestion.

Mr. A. L. Hall found in the area allotted to him an interesting series of igneous rocks, including a norite which, near Onderstepoort, has given rise to considerable masses of magnetite by a process of segregation.

FIG. 2.—Glaciated surface (Permo-Carboniferous glaciation), north of Douglas Colliery, near Balmoral.

It is not so clear, however, that similar internal processes, taking place during cooling, will account for the passage of the norite into red granite, described as occurring near the farm of Doornpoort. The facts noted, particularly the mottling of the granite near its margin, where it contains augite and decomposed hornblende, seem to point rather to the formation of a composite rock along an intrusive junction.

Messrs. Kynaston and Hall conclude this important report with an account of what they style "diamondiferous" pipes and alluvial deposits. It is suggested that the diamond-bearing vents were connected with the great uplift that followed the close of the Karroo period in South Africa.

Some of Mr. Mellor's results, now detailed in the official memoir, were communicated earlier in 1904 to the Geological Society of South Africa, and have been incorporated in Dr. Molengraaff's "Geology of the Transvaal."[1] This handy work, the publisher of which is not named, now replaces the well known paper in the *Bulletin de la Société géologique de France* for 1901. It is accompanied by a coloured sketch map on the scale of 1 : 500,000.

GRENVILLE A. J. COLE.

OUR MUSEUMS.[2]

THE object of the association, of which the manifold spheres of activity are chronicled in the *Museums' Journal*, is the promotion of the better and more systematic working of museums. That museums are destined to play a very important function in the future education of our race every curator is fully convinced. Yet anyone perusing the pages of the *Museums' Journal* will be struck by the apparent want of unanimity among those into whose charge such institutions have been placed as to the best methods to be adopted in conveying to the public the educational advantages offered. A learned German museum official thought that if artistic skill were more cultivated the public would show increased appreciation for museums. He insists that the greater the knowledge of drawing in a community, the greater the value of a museum as an educational institution for a nation. Dr. Hecht, a French museum authority, advocates placing among natural history specimens a number of attractive and pleasing exhibits so as to lead the mind of the visitor to larger ideas, and to show him by well chosen illustrations in how many ways animal life is connected with human civilisation. Another gentleman argues that the doctrine of evolution should be the key-note of museum work, while Mr. Pycraft directs attention to a real defect in many of our museums in the manner in which our animals are mounted. He gives as an instance how the train of the peacock, commonly called its "tail," is often placed as if it arose from the hinder end of the body, while in reality when erect it stands in front of the wings, as shown in the accompanying illustration reproduced from Mr. Pycraft's paper.

"Would it not be well," remarks Dr. Bather very aptly in his excellent presidential address at the Aberdeen conference of the Museums' Association, "for each of us Museum curators occasionally to ask himself the question: What exactly is the object of my Museum?" While laying stress on inspiration as one of the principal functions of a museum, by which Dr. Bather understands the selection and display of material so as to attract members of the general public, he does not, however, touch upon the really vital point to the museum curator—how can we best induce the community to enter the doors of our institutions?

FIG. 1.—Side view of the Peacock in display showing that, when erect, the train stands in *front* of the wings, and not behind them. From the *Museums' Journal*.

The scope of museums is extended from year to year, and everything is done to widen the sphere of their usefulness. A museum is no longer a place for exhibition only, but a place for research and investigation, and for the encouragement of those who desire to devote their time to such. Yet no one like the museum curator is more impressed with the fact that, in spite of all his efforts to make his collections appeal to the public, in spite of his heartfelt desire to teach both old and young, he only succeeds in attracting within the walls of the institution a comparatively small percentage of the community. What is really wanted, it seems to us, is that schools and museums

[1] "Geology of the Transvaal." By Dr. G. A. F. Molengraaff. Translated by J. H. Ronaldson, M.E. With Additions and Alterations by the Author. Pp. viii+90. (Edinburgh and Johannesburg, 1904.)

[2] *The Museums' Journal*. Edited by E. Howarth. Vol. iii. (July, 1903, to June, 1904). Pp. x+436 and 73–142. (London: Dulau and Co., 1904.) Price 12s. net.

should work hand in hand to aid one another in the supreme object of education. A beginning in that direction has been made in the United States and in some towns in England, where the young are taught in the lecture theatre and are then conducted by the teacher to the section of the museum dealing with the subject of the discourse. In this way the young are familiarised with the objects and uses of museums, to which they will surely more readily return in after life, and in the development of which they will take a keener interest than they do at present. R. F. S.

DR. FRANK McCLEAN, F.R.S.

IN Dr. Frank McClean astronomy has not only lost one of her most devoted and painstaking followers, but a generous benefactor that can ill be spared, especially in this country. His death came as a surprise to most of his friends, for, although it was known that his increasing years were beginning to tell on his general activity, it was thought that there was still much work left in him. Unfortunately, however, this was not to be, for, at the latter end of his usual trip on the Continent, he was taken ill at Brussels, and very shortly afterwards passed away on November 8 at the age of sixty-seven, surrounded by members of his family.

Dr. McClean was the son of the late distinguished engineer, Mr. J. R. McClean, F.R.S., and was born in 1837. After the completion of his education at Westminster, the College, Glasgow, and Trinity College, Cambridge, of which he was a scholar, graduating in 1859 as a wrangler, he took up the profession of his father, and became apprenticed in the same year to Sir John Hawkshaw; three years later he was taken into partnership in the firm of Messrs. McClean and Stileman.

Up to the year 1870 his energy was directed to engineering matters, but retiring from his profession, he devoted the remaining years of his life to spectroscopic researches in connection with the sun and stars. The success which rewarded his endeavours is best shown by the numerous important papers which he communicated to the Royal Society and Royal Astronomical Society, and by the fact that the council of the latter society awarded him, in 1899, the gold medal, their highest honour for astronomical research. The crowning work, which he fortunately completed, and with which his name will always be associated, was the conception and carrying out of the great spectroscopic survey of the brighter stars over the whole celestial sphere.

He commenced his spectroscopic work with several important researches, all of which were carried out with zeal, patience, and thoroughness; these were naturally closely allied, in fact preliminary steps, to the great work to which he later devoted his energies. The first of these dealt with the photography of metallic spectra by means of an induction spark, after which he turned his attention to the nearest star, the sun, and made an elaborate series of comparative photographs of the spectra at high and low altitudes. An account of this, accompanied by a beautiful atlas of plates, was submitted in 1890 to the Royal Astronomical Society. The high sun spectrum was taken as far as possible when the sun's altitude was more than 45°, and the low sun when it was under $7\frac{1}{2}$°, so that the depth of atmosphere traversed was in the proportion of one to five respectively. For securing these photographs he employed a fixed heliostat to reflect the solar light into a telescope fixed parallel to the polar axis, in conjunction with a spectroscope in which was used a large Rowland plane grating.

The investigation brought out in a striking manner the different effects of atmospheric absorption in the solar spectrum, and put one on a firmer footing as regards the variations due to atmospheric influences.

After the publication of these results, McClean turned his attention again to terrestrial spectra, and made a minute study of the comparative photographic spectra of the sun and metals. The first results were connected with the spectra of the gold and iron groups of metals. These spectra were collated by means of their common air lines with the iron spectrum, and so by means of the iron lines with the solar spectrum. In the gold group he found many lines due to these metals which up to that time had not been observed, and he also remarked some curious coincidences that existed between the air lines in the metallic spectra and lines in the solar spectrum. That he had in his mind the eventual spectroscopic study of the heavenly bodies is shown even in his brief accounts of these experiments, for in one case he writes, "the spectra of the metals appear to me to be fairly within the scope of astronomy, as our knowledge of them forms the basis of any knowledge we possess of the composition of the heavenly bodies."

At the end of 1891 he published another set of comparative spectra of the sun and metals. The two series consisted of six sections, corresponding to six sections of Angstrom's chart; they were as follows:—

Section i. contained the spectra of the sun, iron, platinum, iridium, osmium, palladium, rhodium, ruthenium, gold, and silver. The last eight constitute the platinum group of metals.

Section ii. contained the spectra of the sun, iron, manganese, cobalt, nickel, chromium, aluminium, and copper. These seven metals constitute the iron copper group.

Throughout McClean's scientific career his greatest work was undoubtedly the spectroscopic survey of every star brighter than $3\frac{1}{2}$ magnitudes scattered throughout the whole celestial sphere.

Such a programme seemed large for one man to tackle single-handed, but McClean was equal to the occasion, and succeeded not only in accomplishing it, but in discussing and publishing the results.

For the northern stars the photographs were secured at his home, Rusthall House, Tunbridge Wells. The instrument employed was a photographic telescope having an object glass of twelve inches diameter, and carrying an objective prism of the same aperture, with a refracting angle of 20°.

To secure the southern stars McClean worked at the Cape of Good Hope from May to November, 1897. He took with him the prism he had already used for the northern work, and fixed it in front of the object glass of the well-known Cape astrographic instrument, which had been placed at his disposal by Sir David Gill. Both series of photographs were thus secured with practically identical instruments, the advantage of which it is difficult to overestimate.

Space does not permit, nor is it here necessary, to enumerate at any length the results of such a far-reaching research, which were so ably discussed, and received such high praise. Mention, however, may be made of the originality he displayed in referring the stars to galactic latitude and longitude, instead of employing the usual system of right ascension and declination. The celestial sphere he divided into four equal areas by drawing a circle at a radius of 60° from each galactic pole. By means of a great circle passing through the galactic poles, he cut the sphere into two halves, so that each of the four areas was again equally divided. This apparently simple portioning of the heavens was amply rewarded.

In discussing the relation of special type stars to the Galaxy, one of the chief facts that made itself at once apparent was that "Helium" stars were not indiscriminately scattered over the heavens like the solar or other type stars, but were more thickly concentrated in the two zones north and south of the galactic equator. In addition, among many other outcomes of this survey was the discovery of oxygen in the spectrum of β Crucis, and in the helium stars generally.

The energy and stamina displayed by McClean in all his work will be best understood when it is mentioned that he employed no assistants. In his laboratory he was the sole operator, and in the observatory at night every manipulation was accomplished by his own hands. To quote the words of the president of the Royal Astronomical Society when presenting him with the gold medal, ". . . . it was his eye that measured the lines, and his was the pen that worked out the calculations. Need I add more to prove that what Mr. McClean's hand had found to do he did with all his might?"

Turning now from this very brief and incomplete summary of McClean's scientific work, reference must be made to his generosity in presenting munificent gifts for the advancement of astronomy. Being a worker himself, he was in a position to know in what direction monetary aid could be best employed. As the founder of the Isaac Newton studentships at Cambridge University, requiring an endowment of 15,000*l*., he rendered a service to astronomical science which it would be hard to overestimate, and the results that will accrue from it will, we hope, be a fitting memorial to his name.

Not content with providing in this way the means by which the study of astronomy will be encouraged, he presented the Cape Observatory, ten years ago, with a large telescope, fittings, and dome, with all the latest improvements, to accomplish work which otherwise would have been delayed possibly for many years. He saw at once the field that was open and the advance that was possible if the southern heavens were surveyed by a prismatic camera of large dimensions, and he took this opportunity to supply the necessary means.

The fact that Sir David Gill in his recent report for the year 1903 writes, "The Zeiss prism is a very perfect and transparent piece of glass, and I have no doubt that its performance will do credit to the fame of its makers. The observatory is indebted to Mr. McClean for this splendid gift, as also for the costly alterations to the spectroscope," shows that McClean's original gift has been greatly increased. As the inauguration of the "Victoria" telescope forms an epoch in the history of the Cape Observatory, may the results obtained with it play a like *rôle* in the advancement of stellar spectroscopy for the southern hemisphere.

McClean was elected a fellow of the Royal Society in 1895; the university of Glasgow conferred on him the honorary degree of LL.D., while, as previously mentioned, he obtained the gold medal of the Royal Astronomical Society.

In 1865 he married Ellen, the daughter of Mr. John Greg, of Escowbeck, Lancaster, who now mourns with her three sons and two daughters his loss. They are not, however, alone in their grief, for his death is deeply felt by a large circle of friends, among whom are many astronomical colleagues who will miss his familiar face.

The funeral, which took place on Friday last, was attended by representatives from many societies and institutions, among which may be mentioned the Cambridge University, the Royal Society, the Royal Astronomical Society, the British Association, the Institution of Civil Engineers, Greenwich Observatory, Solar Physics Observatory, and the Cambridge University Observatory.

W. J. S. L.

NOTES.

THE seventieth birthday of Prof. G. H. Quincke, the doyen of German physicists, will be celebrated at Heidelberg on Saturday next, November 19. Prof. Quincke's laboratory formed the subject of a contribution to our series of scientific centres in NATURE of April 24, 1902, and his portrait was reproduced in the article. Reference was then made to the admirable manner in which the laboratories at Heidelberg are arranged, and the many ingenious devices to be found in them, as well as to some of the investigations carried on. It is therefore unnecessary to attempt to describe again the results of Prof. Quincke's uninterrupted work in physical research for nearly half a century. Among Prof. Quincke's many pupils have been Prof. Lenard (Kiel), Prof. Braun (Strassburg), Prof. W. König (Greifswald), Profs. Elster and Geitel (Wolfenbüttel), the late Prof. Willard Gibbs, Prof. Michelson, Dr. J. T. Bottomley, F.R.S., Dr. J. McCrae (Glasgow), &c.; a complete list would include many other English and American students. To celebrate the occasion of Prof. Quincke's seventieth birthday, a committee, with Prof. Kohlrausch (Berlin) as president and Dr. R. H. Weber (Heidelberg) as secretary, has arranged for the presentation of a large and handsome album containing the autograph photographs of many of the leading physicists of all nationalities and of Prof. Quincke's former pupils. A convincing testimony of the high value set on Prof. Quincke's work in this country is supplied not only by the lists of universities and learned societies which have conferred their honours on him, but also by the fact that among the English physicists and personal friends who have contributed photographs are Lord Kelvin, Lord Rayleigh, Sir W. Huggins, Sir W. Ramsay, Sir H. E. Roscoe, Sir N. Lockyer, Sir W. H. Preece, Prof. J. J. Thomson, Sir A. Rücker, Prof. J. Larmor, Prof. J. A. Ewing, Mr. C. V. Boys, Sir O. Lodge, Prof. J. H. Poynting, Prof. G. Carey Foster, Prof. A. Schuster, Dr. W. N. Shaw, Prof. J. Perry, Prof. R. B. Clifton, Prof. J. G. MacGregor, Prof. J. T. Joly, Prof. G. H. Darwin, Prof. W. G. Adams, Prof. W. M. Hicks, Prof. H. Stroud, Prof. A. P. Chattock, Prof. A. S. Herschel, and many others.

THE American Consul at Bermuda describes in a United States Consular Report the steps which have been taken to establish there a biological station which will be to North America what the Naples station is to Europe. For several years American naturalists have carried on investigations of the natural history of the Bermudas and the surrounding sea, and have made efforts to establish a biological station in these islands. Upon the advice of the Royal Society, our Government has given its assent to the project. The Colonial Government has expressed its willingness to purchase the land and erect the building, and grants toward equipment and support of tables have been made by the Royal Society and the Carnegie Institution. Harvard University and New York University, in connection with the Bermuda Natural History Society, have already commenced work in a temporary laboratory close to what will be the permanent quarters of the station, and the United States Government has been asked to give generous support to the station. America has already founded a tropical botanical laboratory in buildings of the Government of Jamaica at

Cinchona, and has now secured a biological station, so that it appears as if the Americans are rapidly getting the control of the scientific interests of our western tropical possessions. While we cannot but admire the interest shown in the establishment of these stations by universities and colleges in the United States, it is impossible not to regret the apathy with which our home and colonial Governments regard such matters. Surely it is the duty of the State to encourage the pursuit and cultivation of natural knowledge throughout the Empire, and to realise the richness of its possessions in material for scientific study as well as in precious minerals. It is a reproach to our nation that a biological station has not been established by us in the Bermudas; for now, instead of American investigators carrying on their work in a British station, we have to face the fact that, though the station will be on British soil, it will belong to the United States, and our own countrymen will be guests in it. So far as the interests of science are concerned, probably this does not matter; for, as Mr. Balfour wrote a few days ago to the translator of his British Association address, community of aim "binds together the scientific men throughout the world into one international brotherhood." But it should be evident to some of our ministers, at least to Mr. Balfour, who has often expressed sympathy with scientific progress, that it cannot be to the advantage of the State for another nation to accept responsibilities which belong to us. Mr. Balfour is gratified at the success of the translation of his address into German, but apparently he does not consider that the interest shown in scientific matters in Germany is due to the active and practical part played by the State in helping scientific education and research. What we want here and in all parts of the Empire is more practical help of the kind given by the United States and Germany to save us from the future regret of lost opportunities.

REUTER's Agency states that a long report has been received from the members of the expedition of the Liverpool School of Tropical Medicine now investigating sleeping sickness in the Congo. Complete observations have been made on the spread and distribution of sleeping sickness along the Congo River for a distance of nearly 1000 miles between Stanley Pool and Stanley Falls. From Leopoldville to Bumba cases of sleeping sickness were present in every town visited, and a large percentage of the population harboured trypanosomes. From Basoko to the falls only imported cases were met with, with two exceptions, and trypanosomes were not found among the general population. Observation seems to show that enlarged cervical glands are an early sign of the disease, recognisable before trypanosomes make their appearance in the general circulation, and in a little fluid withdrawn from a gland with a hypodermic needle trypanosomes may be detected. Tsetse flies were incessantly present up to Basoko, the species being *Glossina palpalis*, after which they became infrequent, their distribution thus corresponding with that of sleeping sickness.

MR. W. H. PICKERING, late chief of the inspecting staff for the Yorkshire and Lincolnshire mining districts, has been appointed Chief Inspector of Mines in India.

DR. CATTO has been awarded the Craggs prize of the London School of Tropical Medicine for his discovery of a new *schistosomum* parasite of man. The Craggs prize, of the value of 50*l.*, was founded some years ago by Sir John Craggs, and is awarded annually in October to that student of the London School who is considered to have carried out the best piece of research work, or made an important discovery, in tropical medicine during the preceding year.

IN a letter to the *Speaker* of November 5, Mr. J. A. Reid urges that educationists should consider the desirability of teaching children the principles of evolution in schools. In considering how the subject might be taught, Prof. W. K. Clifford remarked in 1878: "The teacher, knowing what is to come in the end, may so select the portions of various subjects which he teaches at an earlier stage that they shall supply in a later stage a means of understanding and estimating the evidence on some question of evolution."

THE inaugural meeting of the Association of Economic Biologists was held at Burlington House on Tuesday, November 8. Mr. F. V. Theobald occupied the chair, and in the course of his introductory remarks he detailed the steps taken by Mr. Walter E. Collinge to found the association. He hoped that the association would welcome all investigators in economic biology, whether agricultural, medical, or commercial. The relationship between biology and agriculture was apparent to all, but only recently had the importance of its relationships with medicine and commerce been realised. Membership of the association will be confined to workers in economic biology. The following officers have been elected for 1904–5:—president, Mr. Fred V. Theobald; vice-president, Mr. A. E. Shipley, F.R.S.; council, Prof. G. S. Boulger, Prof. A. H. R. Buller, Prof. Geo. H. Carpenter, Dr. Francis Marshall, Mr. Robert Newstead, Major Ronald Ross, F.R.S., Mr. Fraser Storey, Mr. Cecil Warburton; hon. treasurer, Mr. Herbert Stone; hon. secretary, Mr. Walter E. Collinge. The next meeting will be held at Birmingham in April, 1905.

ON December 4, 1804, Joseph Lebon, who is considered in France as the inventor of lighting-gas, was found murdered by an unknown hand in the Champs-Elysees, near the site where is now the Grand Palais. In memory of this sad tragedy, and to pay due honour to the celebrated inventor, the Compagnie Parisienne du Gaz has given a certain quantity of gas, free of charge, to the Aero Club and Société française aérienne. Ascents will accordingly be made on December 4 by members of these two societies. On December 5 an exhibition will be held in the Grand Palais by the Automobile Club.

AT a meeting of the Société astronomique de France held in Paris on November 2, M. Lippmann being in the chair, the Comte de la Baume-Pluvinel gave an address on the forthcoming total eclipse of the sun on August 30, 1905. He mentioned the intentions of American astronomers to send expeditions to Labrador, Spain, and Upper Egypt. After the address the society decided to appoint a committee for determining the part which France should take in observing the eclipse. It is fairly certain that the principal work of this committee will be concerned with observations in Algeria and Tunis, through which the line of totality passes. This eclipse was also commented upon at the last meeting of the St. Petersburg Scientific Aëronautic Congress, officially held in the rooms of the Imperial Academy of Sciences under the chairmanship of the Grand Duke Constantin Constantinovitch, president of the academy. Colonel Vives y Vich has announced that he will make an aëronautical ascent from Burgos on this occasion, for the purpose of ascertaining the part the clouds may possibly play in the apparent brightness and shade of the corona. In addition, the international committee of *ballons-sondes* has decided that atmospheric observations shall be made at the great altitudes of the various observatories connected with the institution during August 29, 30, and 31 for ascertaining the changes the eclipse may introduce in the prevailing winds and temperatures at different altitudes.

THE *Scientific American* of October 22 contains the portrait of a white raccoon-dog from northern Japan, in the New York Zoological Park, which is regarded as representing a new species, and is accordingly named *Nyctereutes albus*. The ordinary raccoon-dog of Japan and China is an animal closely allied to the true dogs, but with a marked superficial resemblance to a raccoon. If the New York specimen really indicates the existence of a white species of raccoon-dog, the fact will be of considerable zoological interest.

IN the second part of the Bergen Museum *Aarbog* for the current year Prof. G. O. Sars describes a small crustacean (*Paracartia grani*) recently discovered in the oyster-beds of western Norway which is of great interest from the point of view of distribution, since the only other known representative of the genus inhabits the Gulf of Guinea. The author considers that the creature reached Norway from the south during a warm period, and that it survives on the bays of the west coast owing to the circumstance that a superincumbent layer of fresh water renders the subjacent salt water unusually warm. The same explanation accounts for the prolific oyster-beds on this coast.

IN the November number of the *Century Magazine* Prof. H. F. Osborn publishes *in extenso* the lecture on the evolution of the horse in America which he delivered at the recent Cambridge meeting of the British Association. Omitting reference to that portion of the article devoted to the origin of the Equidæ generally, we may mention that the author regards North America as the ancestral home of the genus Equus, the American horses passing into South America by way of Panama, and into Asia by a land-bridge across Bering Strait about the early or middle portion of the Pliocene period, giving rise in the latter area to the Siwalik horses (which, by the way, are not later than older Pliocene age). Horses of all kinds died out both in North and in South America, according to the author's belief, before the European conquest. The American Miocene and Pliocene horses are considered to have been striped; but the splitting of Equus into the true horses, asses, and zebras probably took place in the Old World. Przewalski's horse of Mongolia is regarded as representing the ancestral stock of the ordinary horses of the Old World, the long manes and tails of the latter being probably due in part to domestication. On the other hand, the author accepts the view that the blood-horse may have had a different ancestry, although he does not refer to its suggested derivation from the Indian *Equus sivalensis*.

SOME interesting experiments in blasting tree butts with gellignite—a safety explosive—have recently been carried out at Lord Leigh's Stoneleigh Abbey Estate, near Kenilworth. The usual boring was made and filled with the explosive. An electric detonator was used which enabled the operator to retire under cover at a safe distance. The butts operated upon were of various sizes and species, but in each case the method was found to give satisfactory results. It is also claimed to combine efficiency with economy.

THE comparative age of the different elements of the flora of eastern North America forms the subject of a paper by Dr. J. W. Hashberger in the September issue of the *Proceedings* of the Philadelphia Academy. Most of the flora cannot be older than the close of the Glacial period, which, from the rate of cutting of the Niagara gorge, is estimated to have occurred not more than 15,000 years ago. Some of its elements may, however, be much older, since they may be the descendants of boreal plants which flourished on unglaciated areas in the midst of the ice-sheet. Apart from these, there was firstly a wave of plant-life from the skirts of the ice-sheet. This was followed by a northern wave, many of the species of which, forming the bog-plants of the old Glacial lakes, soon occupied the tundra left by the ice; the conifers developed later, and restricted the bog-flora. Hence came the modern bog and swamp floras, while the existing Poccona flora is due to a third invasion.

THE work of the Forestry Bureau of the United States Department of Agriculture stretches far afield, and the forests of the Hawaiian Islands form the subject of one *Bulletin* by Mr. W. L. Hall, while Mr. W. L. Bray in another reviews the forest resources of Texas. The succession of the forests in Texas indicates that their distribution is primarily influenced by the amount of rainfall, and only secondarily by the nature of the soil. A remarkable instance of the spread of a successful type is furnished by the mesquite, *Prosopis glandulosa*, which has spread from the Rio Grande eastwards across the Rio Brazos, and northwards into the adjoining States of Oklahoma and Kansas. In the Hawaiian Islands a mesquite, although an alien, has established itself as a pure forest from sea-level to an elevation of several hundred feet, and is regarded as a valuable asset, because, in addition to the fuel and posts obtained from the wood, the pods furnish excellent food for stock.

IN view of the difficulties of obtaining zygospores of species of Mucor and allied genera, considerable importance attaches to a paper—"Sexual Reproduction of the Mucorineæ," by Mr. A. F. Blakeslee—which is published in the August number of the *Proceedings* of the American Academy of Arts and Sciences. The author found that the greater number of these fungi failed to produce zygospores in pure cultures, but some would do so when a mass of spores taken from an impure culture was sown together. This suggested that in the latter case zygospores were produced from different mycelia or plants, and eventually experiments demonstrated that two different strains, which may be regarded as a (+) and a (−), were required; thus two groups, the *heterothallic* and *homothallic* are distinguished. Sporodinia is homothallic, Phycomyces, Rhizopus and several species of Mucor are heterothallic. Differences of colour, luxuriance and duration of conjugating ability were noted, but the most interesting results obtained were incipient attempts at hybridisation by opposite strains of allied heterothallic forms.

WE learn from the *Standard* that, under the auspices of the Meteorological Council, a new observing station for London has just been established in St. James's Park. The station is situated in an open spot a few yards distant from the iron railings bordering on the Horse Guards Parade, and is equipped with a set of thermometers, mounted in a Stevenson screen, and two rain gauges—one of quite an ordinary kind, the other a self-registering gauge of the pattern designed by Mr. F. L. Halliwell, of Southport. Just within the park railings are placed two ornamental wooden frames one containing, for the previous twenty-four hours automatic records of bright sunshine, of rainfall, and of temperature all made in Westminster; the other copies of the latest weather charts and forecasts prepared at the Meteorological Office.

WE have received a copy of the results of the magnetical and meteorological observations made at the Royal Alfred Observatory, Mauritius, in the year 1901. The observatory has a complete equipment of instruments recording photographically the variations of the principal magnetic and meteorological elements and of earth movements, in addition to a self-registering "Beckley" rain gauge and other automatic apparatus. The tables, containing hourly and mean values, have been carefully prepared on the Greenwich pattern, and are, therefore, quite clear and convenient for reference. Mr. Claxton prints the results of an interesting investigation of the degree of accuracy of self-registering maximum and minimum thermometers. He finds that maximum thermometers read higher in a horizontal position than when inclined to the horizon; the excess may amount to 1° F. Also, that the indications of spirit minimum thermometers are untrustworthy, owing chiefly to evaporation of the spirit. They should be used in conjunction with an ordinary mercurial thermometer.

A PAPER on Britain's place in foreign markets is contributed to the *Economic Journal* for September by Prof. A. W. Flux. The author has had considerable difficulty in drawing up statistics owing to the great discrepancies which he finds in the returns from different countries. He, however, considers that the market for British goods in Germany, France, and the United States, though narrowed by the tariff policy of the third, is still of great importance, and is expansive in some degree except in the case of the United States. In all three cases, however, the trade done by other countries as a whole has grown faster than their trade with us.

DURING March, 1903, several excursions were made to the Phlegræan fields of Naples by Dr. G. de Lorenzo and Sir Archibald Geikie. At the suggestion of the latter the former has now published a short history of volcanic activity in this region (*Rendiconto* Naples Academy, May to July). Dr. de Lorenzo divides the volcanic formations into three periods, the first being represented by the pipernoid tufa of the Campagna and by conglomerate and breccia at Cuma, Camaldoli and Procida, the second by the yellow tufa of Posilipo, Nisida, Pozzuoli, Capodimonte, &c., and the trachitic masses of the Vomero, and the third period by the eruptions of the Solfatara, Monte Nuovo, the Lago d'Agnano and similar formations.

IN the *Rendiconto* of the Naples Academy for March and April, Prof. Orazio Rebuffat describes some interesting and simple experiments with radium salts. When a glass rod was rubbed with wool in the common way for producing electric sparks the author found that if the experiment was performed in a medium containing a radium salt a luminous glow followed the wool, and when the finger was brought near the excited glass a glow was again seen. By taking a vacuum tube and opening connection with a small tube containing a salt of radium, and then rubbing the outside of the glass tube with wool, a brilliant glow was seen within. By means of this experiment Prof. Rebuffat considers it possible to demonstrate the production of emanations from radium preparations of very feeble activity.

DR. R. VON LENDENFELD, of Prague, has published in *Globus*, lxxxv., 24, a discussion of the melting of glaciers in winter. The author considers that the earth's interior heat is incapable of accounting for any considerable part of the phenomenon; indeed, he only attributes about 3 per cent. to 6 per cent. of the result to this cause. Another cause which may account for a further 1 per cent. is the slow conduction of the summer heat to the interior. The main cause of the melting is attributed to the heating of the ice by the work done in its descent. This work is converted into heat in overcoming friction, viscosity, and similar resistances, just as in Joule's classical experiments. A further increase in the internal melting during the winter is probably due to the pressure produced by the winter snows.

A SPECIAL report of the seventy-sixth meeting of the German Association of Naturalists and Physicians is contained in the number of the *Physikalische Zeitschrift* for October 20. The meeting was held at Breslau from September 18 to 24, and the physical papers include the following:—E. Hoppe, constitution of magnets; H. Hartl, lecture apparatus; C. Pulfrich, coast surveying, &c.; F. Müller, vacuum apparatus; C. Dieterici, energy of water and its vapour; W. Scheffer, stereoscopic problems; A. Köhler, photomicrography by ultra-violet light; J. Stark, mercury lamps of quartz glass; O. Lummer and P. Weiss, *n*-rays; W. Nernst, chemical equilibria at high temperatures; L. Grunmach, properties of emanium and liquid nitrous oxide; A. Wehnelt, negative ions from incandescent metallic oxides; O. Lummer, resolution of fine spectrum lines; W. Schmidt, models of wave motion; H. T. Simon, a phasemeter; M. Reinganum, molecular volumes of halogen salts; L. Graetz, radiations from hydrogen peroxide; J. Rosenthal, Sprengel pumps; W. Stern, tone-variators; K. Schreber, explosion motors, also force, weight and mass; G. Bredig and F. Epstein, kinetics of adiabatic reactions; and E. Meyer, combustion engines. In addition a discussion took place on mathematical and scientific teaching in the higher schools, including addresses by K. Fricke, F. Klein, F. Merkel, and G. Leubuscher. In the general meetings papers were read on the Ice age by Messrs. Brückner, Meyer and Partsch, on the Antarctic expedition by Prof. Gazert, and on biological mechanics by Prof. Roux.

THE scientific methods which have characterised Japanese operations in the Far East are not the only results of the well developed system of education which the last thirty-five years has seen established in Japan. Some fifty years ago Japan was a hermit nation more than five centuries behind the times, to-day she constitutes a new and important factor in the problem of the distribution of the world's commerce. The story of the foreign commerce of Japan since the restoration of imperial authority in 1868 is told by Mr. Yukimasa Hattori in Nos. 9 and 10 of series xxii. of the *Johns Hopkins University Studies in Historical and Political Science*, copies of which have reached us. Mr. Hattori considers his subject under three headings: the volume of trade, the character of Japan's commerce, and the geographical distribution of trade. Two remarks towards the end of his paper will show the conclusions to which Mr. Hattori has come. "Japan must rely on industrial development rather than on agriculture, and must try to excel in the quality of the goods produced rather than in quantity." "Japan possesses all the advantages necessary to make her a great manufacturing country. Her people possess exceptional skill, and labour is relatively cheap; coal is abundant, and the raw material is easily obtainable either at home or in the neighbouring countries." Those readers who have followed the steps in Japan's development since 1868 will be prepared to agree with Mr. Hattori that his country is but "at the very beginning of beginnings" of what will yet be seen.

A SECOND edition of Mr. Drinkwater Butt's "Practical Retouching" has been published by Messrs. Iliffe and Sons Ltd., at 1*s*. net.

MESSRS. MACMILLAN AND CO., LTD., have in the press an English translation of Dr. Cohnheim's "Chemistry of the Proteids," prepared with the author's sanction from the second edition of that work by Dr. Gustav Mann, of the physiological laboratory at Oxford, and author of "Physiological Histology." Dr. Cohnheim's book, which, in its second edition, has been entirely re-modelled, deals with all recent advances made in analysing and synthetising proteids. Several special features have been introduced into the English translation, and some of the chapters have been re-written.

AN English edition of Prof. Weismann's "Evolution Theory," which has been translated, with the author's co-operation, from the second German edition (1904) by Prof. J. Arthur Thomson, of Aberdeen University, and his wife, will be published in two volumes by Mr. Edward Arnold toward the end of this month.

To commemorate the twenty-fifth anniversary of the founding of the firm of Burroughs, Wellcome and Co., Mr. Henry S. Wellcome is arranging an exhibition of historical objects in connection with the history of medicine, chemistry, pharmacy, and the allied sciences, the object being to illustrate the art and science of healing in all ages. The date of the opening of the exhibition is not yet fixed.

THE Cambridge University Press will publish very shortly in the Cambridge Biological Series "Morphology and Anthropology," by Mr. W. L. H. Duckworth. The volume will present a summary of the anatomical evidence bearing on the problem of man's place in nature. The Cambridge University Press has also in preparation "Studies from the Anthropological Laboratory in the University of Cambridge," by Mr. Duckworth.

THE November number of the *Popular Science Monthly* is devoted entirely to the St. Louis Congress of Arts and Science. The representative administrative board, it will be remembered, adopted the plan proposed by Prof. Münsterberg, of Harvard University, to hold one congress of the arts and sciences which should attempt to promote and demonstrate the unity of science. An appreciation of the work of this international congress, interspersed with portraits of representative men of science from various parts of the world, is contributed by Mr. W. H. Davis, of Lehigh University, one of the secretaries. A selection from the addresses given at the congress completes an interesting number of the magazine.

OUR ASTRONOMICAL COLUMN.

ENCKE'S COMET (1904 *b*).—A telegram from Prof. Max Wolf to the *Astronomische Nachrichten* (No. 3975) states that on October 28 the ephemeris published by M. Kaminsky in No. 3973 of that journal needed corrections of $+11s. -2'{\cdot}4$, and, further, that the magnitude of the comet was 12·5.

Visual observations have not, as yet, been fruitful. Prof. E. Millosevich vainly sought for this object on September 15 and October 5.

DESLANDRES'S FORMULA FOR THE LINES IN THE OXYGEN BAND SERIES.—Referring to a note on the results obtained by Mr. O. C. Lester concerning the oxygen bands in the solar spectrum, which appeared in these columns on October 20, Prof. Deslandres directs attention to the fact that a modification of his first formula (viz. $N = a + bn^2$), equivalent to that now proposed by Mr. Lester, was published by him in his original (*Comptes rendus*, August, 1886) and succeeding memoirs on this subject.

Mr. Lester's statement that the first law requires the modification which he proposes is obviously justified, but he appears to have omitted to study the original memoirs, and to have accepted the epitomised and generally known results as being complete. This does not, however, lessen the importance of the valuable experimental results he obtained in measuring the old and new bands on his large dispersion photographs.

ANNUAL REPORT OF THE CAPE OBSERVATORY.—In the report of the Cape Observatory for 1903 Sir David Gill records several important additions to and modifications of the instrumental equipment.

The work of the new transit circle has been greatly facilitated, and the results improved by the adaptation of a Repsold automatic transitting device to the instrument.

The line-of-sight spectroscope which is used in connection with the Victoria telescope has been re-modelled, and an extremely delicate thermostatic arrangement has been fitted so that the temperature of the prism box can be maintained constant, within $\pm 0^\circ{\cdot}05$ F., during a three or four hours' exposure.

In the astrophysical department several stellar spectra have been completely reduced in the region λ 4200 to λ 4580, and those of Canopus and Sirius have been discussed in connection with the corresponding terrestrial origins of their lines. The results of the line-of-sight work have been made more trustworthy by measuring only those lines which, on traversing either the thin or the thick ends of the prisms, show no relative displacement, and α Phœnicis has been shown to have a very large radial velocity. In December this star was apparently receding from us at the rate of 105 km. per second.

A large amount of routine work in connection with the maintenance of an efficient time service and the completion of the Cape zone for the astrographic chart was accomplished during the year. Important operations were also carried out in connection with the geodetic survey of South Africa, whilst the Government survey of the Transvaal and the Orange River Colony and the topographic survey of South Africa have been planned, the former having been commenced.

THE TRANSITION FRDM PRIMARY TO SECONDARY SPECTRA.—Some very interesting experimental results, obtained with the idea of determining as definitely as possible the points at which, under various conditions, the primary is replaced by the secondary spectrum in gases, are published by Mr. P. G. Nutting in No. 2, vol. xx., of the *Astrophysical Journal*.

The general method was to determine what current capacity caused the above named change when either the wave-length, the pressure, the nature of the gas, the inductance or the resistance was altered, and this was called the "critical capacity."

Among other results the experiments showed that this critical capacity is a function of the wave-length, and that it increases slightly as the pressure decreases down to about 1 mm. of air, when it suddenly becomes infinite. All the elements tested have the same critical capacity for the same wave-length and pressure, although the critical point is more marked in some elements than in others. The introduction of inductance always relatively weakens the secondary and strengthens the primary spectrum, although no amount of inductance will completely annul the effects of capacity. Resistance acts similarly to inductance. The critical capacity of any vapour in a mixture of vapours was shown to be the same as when no other gases were present.

NEW BUILDINGS OF THE UNIVERSITY OF LIVERPOOL.

The George Holt Physics Laboratory.

THE George Holt Physics Laboratory, which was declared open by Lord Kelvin on November 12, will be valued by the University of Liverpool as a magnificent addition to its fabric, as well as a memorial to one of the wisest and most generous supporters of that college from which the university has been developed.

The laboratory covers an area of 9600 square feet, and has an average height of 55 feet. The architects are Messrs. Willink and Thicknesse, of Liverpool, with whom there is associated Prof. F. M. Simpson, now of University College, London. The external walls, which are very substantial, are built in best common brick with broad courses of red brick and dressings of Storeton stone. The basement floors are asphalte on a bed of concrete resting on the continuous rock which is the foundation of the whole building. All the upper floors are fire-proof; they consist of a bed of concrete which encases a lattice-work of steel girders, and supports a layer of coke breeze, upon which tongued and grooved pitch-pine boards are stuck down with bitumen and nailed. The resulting surface is both noiseless and steady, and the whole building is made very rigid by the girders employed.

In the basement there is a large workshop, fully fitted with machine tools, store-rooms, a room containing a liquid air plant, a furnace room, an accumulator room, a room for the custody and comparison of standards, and a number of research rooms in which extra steadiness, complete darkness, or constancy of temperature can be respectively secured.

On the ground floor, close to the entrance hall and cloak-rooms, are the doors of the large lecture theatre, a smaller class-room, and a large laboratory for elementary students. This floor also contains the preparation room, the apparatus

FIG 1.—The George Holt Physics Laboratory, Liverpool.

room, and a sitting-room, office, and private laboratory for the professor.

The first floor is set apart for the teaching of senior students. It contains two large students' laboratories, four smaller rooms suitable for optical and acoustical experiments, a students' workshop, a library, and two sitting-rooms for demonstrators.

The second floor consists almost entirely of research rooms of various sizes. Of these some are designed for special purposes, such as spectroscopy, but the majority are planned so as to be adaptable to as great a variety of needs as possible.

A photographic dark room is provided on each floor; that in connection with the preparation room is adapted for the making of lantern slides and enlargements. There is also a small observatory on the roof, containing a four-inch equatorial telescope.

An electrically driven lift, working in the centre of a tower, is available for the conveyance of heavy apparatus from floor to floor. It can also be used to give access for experimental purposes to all points of two vertical walls which extend to the full height of the tower, about 75 feet. In another part of the laboratory access over a horizontal distance, about 90 feet, nearly equal to the whole length of the building, is secured.

The rooms are heated by low pressure hot water, and are ventilated by an exhaust fan in the roof. They are adequately supplied with gas, with sinks to which hot and cold water are led, with electric power from the corporation mains, and with wires from a switch-board in the basement to which the accumulators are connected. The wiring is run in wood casing on the surface of the walls; all pipes are fully exposed, and, wherever a floor or wall is pierced, an opening is left through which further permanent or temporary connections can be made as required.

The apparatus and preparation rooms have galleries round them, so that their whole wall-space is rendered available for cupboards and drawers. Special devices have been adopted for the ready darkening of the lecture theatre, and for the provision of rigid points of attachment above the whole length of the lecture table. The counter-shafting in the workshop is supported so as to be entirely independent of the rest of the building, and thus silence and freedom from vibration are secured.

The erection of the laboratory was rendered possible by the munificence of a small body of donors, Mrs. and Miss Holt, Sir John Brunner, the late Sir Henry Tate, the executors of the late Rev. J. H. Thom, Mr. Alfred Booth, Mr. Holbrook Gaskell, Mr. J. W. Hughes and Mr. John Rankin, who together subscribed the sum of 23,600*l.*, which by the addition of interest has increased to 25,900*l.* The cost of the building, with furniture and fittings, is 21,600*l.* A sum of 1200*l.* has already been spent upon machinery and new apparatus, and thus about 3000*l.* is available for the completion and maintenance of its equipment.

It is hoped that the general scheme according to which the laboratory is arranged will prove favourable to simplicity and economy of administration, and will allow teaching and research to flourish side by side, not hampering but supporting each other.

New Medical Buildings of the University of Liverpool.

The new medical buildings opened at Liverpool on November 12 go far to complete the university school of medicine in that city in a thoroughly efficient and modern manner. They provide accommodation chiefly for the subjects of anatomy, surgery, and materia medica, the school of dental surgery and the school offices, and forensic medicine. There are four full floors to the building, and the ground plan is of an L shape. One limb of the L-shaped figure joins the fine Thompson-Yates laboratories opened six years ago for physiology and pathology. The other limb forms a wing ending freely towards the north. In the angle of junction of the two portions of the building are placed large theatres, one on the ground floor for surgery, the other upstairs for human anatomy. The pitch of the benching is steep, and the lighting is extremely good from a series of long windows following the curve of the rounded angle of the building. In the wing, lighted by windows east and west, is a spacious museum for anatomical preparations. Above this is a large room for dissection, especially well lighted from the east. An excellent theatre for operative surgery forms a feature of the surgical equipment.

In addition to the theatres, museum, and dissecting room are rooms for a library, and for smaller classes than those the theatres are intended to accommodate. In the front portion of the building is the medical faculty meeting room for transacting the business of the faculty and of its various committees, also for meetings of the veterinary board which manages the newly started university school of veterinary medicine. Next to the medical faculty meeting room is the spacious room providing an office for the Dean of the faculty. No effort or expense has been spared in making the construction at once durable, well lighted within, and handsome from the exterior. Admirable lighting has been secured throughout, even to the basement rooms, which are particularly good, so as to provide a much needed reading room for students. The erection was begun three years ago, and part of the building has already been in occupation for more than a year. The architects are Messrs. Waterhouse, of London, who have designed most of the older buildings of the university. The group of medical school buildings now in use have cost altogether about 80,000*l*., including, with the building opened on Saturday, the Thompson-Yates laboratory and the Johnston laboratory. The Chancellor of the university, Lord Derby, formally inaugurated the new buildings on the same afternoon as Lord Kelvin opened the new university laboratory for physics. With these fresh additions to its accommodation and teaching equipment, and with the fine new laboratories for zoology and for electrical engineering now rapidly nearing completion, the University of Liverpool will rank among the best provided university institutions in the country.

PROF. MENDELÉEFF ON THE CHEMICAL ELEMENTS.

THE last half-volume (eightieth) of the new Russian "Encyclopædic Dictionary" contains a remarkable paper by Prof. Mendeléeff on the chemical elements, of which the following is a slightly abridged translation. Together with the articles on matter and on the periodic law, which Mendeléeff contributed to previous issues of the same dictionary, and a paper, "An Attempt at a Chemical Comprehension of the World's Ether," published in a Russian review, this article represents the fundamental physical and chemical conceptions of the great chemist as they now appear in connection with the discoveries of recent years.

"Human thought," he begins, "has always endeavoured to simplify the immense variety of phenomena and substances in nature by admitting, if not the full unity of the fundamental elements (Democritus, Epicurus), at least the existence of a limited number of elements capable of producing all the variety of substances. In antiquity this tendency often resulted even in confusing the phenomena with the substances (earth, water, air, and fire)." Since the time of Lavoisier such a confusion has become certainly impossible: the substances are sharply separated from the phenomena which are associated with them. Of course, there may be partial returns to the old view. "However," Mendeléeff continues, "the solidity of the now prevailing conception as to the profound difference existing between substances and phenomena is the result of such a mass of coordinated knowledge that it cannot be shattered in the least even if a small portion of the men of science return to the "dynamism" of old which endeavoured to represent matter also as one of the forms of phenomena. Consequently we are bound now to recognise the substances (the masses) and the phenomena (the movements) as two quite separate, independent categories, such as space and time, the substance of which our thought has not yet penetrated, but without which it cannot work. Thus, for example, we are far yet from understanding the cause of gravitation, but with its aid we understand many phenomena, even though up till now it is not quite evident whether attraction acts through the aid of an intervening medium or represents a fundamental force which acts at a distance. Progress in the understanding of nature depends, therefore, not upon our reducing everything to one final conception—to one 'principle of all principles'—but in reducing the great variety of substances and phenomena which act upon our senses to a small number of recognised fundamental conceptions, even though these last be disconnected. One of such conceptions is that of the recognised chemical elements.

"The simplest way of conceiving matter in this case is to consider it as the result of combinations of elements which themselves are matter; and the phenomena as the results of movements which are the property of these elements or their aggregations. It was from this point of view that the conceptions were elaborated as to the distinction, not only between phenomena and substances, but also between simple bodies and elements; because the conception of a simple body implies the idea of an impossibility of transforming certain bodies into other bodies, while the conception of a chemical element is merely determined by the desire of diminishing the number of substances which are required for explaining the great variety of the latter."

Mendeléeff passes next to the so-called "rare" elements. Leaving aside historical details concerning them, he remarks that it is the more necessary to dwell upon them as they complete to a great extent our knowledge of the periodic law. "Our information about them," he continues, "can also, in our opinion, contribute towards explaining the relations between the phenomena and the substances in nature; because for the understanding of a multitude of natural phenomena it is necessary to resort to the conception of the so-called luminiferous ether, which by all means must be considered as a ponderable substance, and consequently must have its place in the system of elements, inasmuch as it reminds us of the properties of helium, argon, and other similar elements. The conception of the ether was resorted to at the outset exclusively for explaining the phenomena of light, which, as is known, can be best understood as the result of vibrations of the ether. However, later on, ether, considered as being distributed throughout the universe, was resorted to in order to explain, not only electrical phenomena, but also gravitation itself. In consequence of that, a very great importance has to be attributed to the ether; and as it cannot be considered as anything but ponderable matter, we are bound to apply to it all the conceptions which we apply to matter in general, including also the chemical relations. But as, at the same time, we are bound to admit that this matter is not only distributed throughout stellar space (in order to explain the light which reaches us from the stars), but also penetrates all other substances; and as also we must admit that the ether has no capacity of entering into chemical reactions, or of undergoing any sort of chemical condensation, therefore the above mentioned elements, helium and argon, which are characterised precisely by the absence of that property of entering into chemical reactions with other substances, show in this respect a certain similarity with the ether.[1]"

Referring further to radium, Mendeléeff remarks that there can be no doubt as to its being a separate element, extremely rare in nature. As to the emanation of helium by radium, and the presence of the helium spectrum in the spectrum of radium, he explains these facts by the occlusion of helium in a compound of radium, and considers that "nothing gives us reason to think that radium should be transformed into helium." "Notwithstanding the extremely small quantities of radium occurring in nature, Madame Curie has succeeded in obtaining a compound of it, and in establishing its kinship with barium, as also in finding its atomic weight to be near 224, which permits us to complete the periodic system of elements by placing radium in the second group, in the 12th row, in which we have already thorium and uranium, the ores of which are possessed of radio-activity.[2]

"As to argon and its congeners—neon, krypton, and xenon—these simple gases, discovered by Ramsay, differ from all the known elements in that, up till now, notwithstanding the most varied attempts, they could not be brought into combination with any other substance, or with each other. This gives them a separate place, quite distinct from all other known elements in the periodic system, and induces us to complete the system by a new separate group, the group zero, which precedes group i., the representatives of which are hydrogen, lithium, sodium, and so on.

"The placing of these elements in a new group is fully supported by the atomic weights which are deduced for these gases on the basis of their densities, if we admit that the molecule of each of them contains but one atom.

1 "About this resemblance between argon and helium and the substance of the world's ether I have already written in a separate article entitled 'An Attempt at a Chemical Comorehension of the Ether,' in the review *Messenger and Library of Self-Education*, in the first four numbers of 1903. This article was translated into German in the *Prometheus* of 1903 by M. Tshulok, and into English by M. Kamenskiy under the title 'A Chemical Conception of the Ether' (Longmans, Green and Co., London, 1904). I must, however, remark that the German translation is a complete one, but that the editors of the English translation have omitted the introductory general philosophical remarks about the fundamental distinction between substances (masses), forces (energy), and spirit. This omission deprives the article of the realistic meaning which I intended to give it by introducing ether into the system of elements."

2 "Some later researches lead us to believe that the atomic weight of radium is slightly above the figure found by Madame Curie, but it seems to me that it still remains doubtful whether the conclusion of Madame Curie has to be altered."

Thus, helium must be placed before lithium, and argon before potassium, as is seen from the table, into which radium has also been introduced. In this table there are, in the group zero, two unknown elements, x and y, which have been introduced for two reasons: first, because in the corona of the sun, above the region of incandescent hydrogen, there has been noticed an element which has an independent spectrum, and therefore is named coronium; and although it is yet unknown (helium was also first characterised by Crookes as an element, on account of the independence of its spectrum), it must have a density, and consequently an atomic weight, both smaller than those of hydrogen (in the table, this element is marked as y); and secondly, because there is no reason to believe that the system of elements is limited in the direction of the lightest ones by hydrogen. The presence of the elements x and y in the group zero makes us think that the elements which correspond to these positions in the system will be distinguished by the absence, in a high degree, of the capacity of chemical combination—a property which belongs also, as has been already pointed out, to helium, argon, and their analogues.

"The same property must be attributed to the substance of the ether, which must possess, moreover, an extremely low density, and consequently a very great rapidity of motion of its molecules, in order to have the possibility of escaping from the spheres of attraction, not only from the atmosphere of the earth, but also from the atmospheres of our sun and other suns the masses of which are greater than that of ours. The researches concerning the double stars prove that the masses of the stars which we know do not exceed the mass of our sun more than thirty-two times, while in other cases they are equal to it; therefore, if we attribute to the ether the properties of gases, we must admit, on the basis of the kinetic theory of gases, that its specific gravity must be very much smaller than the specific gravity of hydrogen. In order that the ether may escape from the sphere of attraction of stars the mass of which is fifty times greater than the mass of the sun, it must, while it chemically resembles argon and helium, have an atomic weight not more than 0·000 000 000 053 (and a density, in relation to hydrogen, half as large, as I have proved in the above mentioned article on ether). The very small value of this figure already explains why there is little hope of isolating the substance of the ether in the near future, as it also explains why it penetrates all substances, and why it is condensed in a small degree, or collects in a physicomechanical way, round ponderable substances—being mostly condensed round such immense masses as that of the sun or of stars.[1]"

In conclusion, Mendeléeff indicates that while the conception of the chemical elements is connected in the most intimate way with the generally received teachings of Galileo and Newton about the mass and the ponderability of matter, as also with the teaching of Lavoisier concerning the indestructibility of matter, "the conception of the ether originates exclusively from the study of phenomena and the need of reducing them to simpler conceptions. Amongst such conceptions we held for a long time the conception of imponderable substances (such as phlogiston, luminous matter, the substance of the positive and negative electricity, heat, &c.), but gradually this has disappeared, and now we can say with certainty that the luminiferous ether, if it be real, is ponderable, although it cannot be weighed, just as air cannot be weighed in air, or water in water. We cannot exclude the ether from any space; it is everywhere and penetrates everything, owing to its extreme lightness and the rapidity of motion of its molecules. Therefore such conceptions as that of the ether remain abstract, or conceptions of the intellect, like the one which also leads us to the very teaching about a limited number of chemical elements out of which all substances in nature are composed."

[1] "It is worth noting that all the incandescent, self-luminous celestial bodies are immense as regards their masses, in comparison with the cooler bodies like the earth or the moon; perhaps this depends upon the distribution of the ether, which is condensed precisely round such very big masses as the sun and the stars. It is also worth noticing that the atomic weights of radium, as also of thorium and uranium, are very great in comparison with those of the other elements."

WELSH CONFERENCE ON THE TRAINING OF TEACHERS.

THE Welsh National Conference on the Training of Teachers was held in Shrewsbury on November 10 and 11, and although no special reference was made to science teaching, still the subject of education is now in a fair way to be considered a science, since it has been included as a section of the British Association.

The conference was convened by the Central Welsh Board and the University of Wales, and in addition to these bodies, representatives attended from every county education authority in Wales, from every type of educational institution, from the National Executive of Welsh Councils and from all the associations of masters and mistresses. Upwards of 200 delegates attended in all, most of whom remained throughout all four sessions.

At the first session, which was devoted to "The Special Aspect of the Problem of Training Presented in Wales," Principal Griffiths, vice-chancellor of the University of Wales, presided, and in his opening address submitted the points which it was most important that the conference should decide. Briefly they were these: What were the real demands of the Principality, and how far were they met by existing institutions? Was Wales to import the shortage of teachers, or to increase her own production? In what manner could the schools be best utilised as training grounds without injuring the schools? and should local education authorities undertake the training of secondary teachers? To these questions no uncertain answer was suggested, although the conference abstained from passing formal resolutions until an opportunity had been accorded the members to consider the verbatim report, which it was decided to publish at an early date.

At the second session Mr. Lloyd George, M.P., presided, and a paper was read by Lord Stanley of Alderley, chairman of the Anglesea Education Committee, and late chairman of the London School Board, on "The Point of View of the Local Authorities." The debate was opened by Mr. S. J. Hughes, county alderman of Glamorganshire. Both Lord Stanley and Alderman Hughes emphasised the paramount importance of training for the elementary school teacher. In summing up the debate, Mr. Lloyd George replaced the sword by the trowel, and emphasised the need for additional accommodation and for subsidising the buildings and the staffs. Enthusiasm was required, he said, to meet the increased burden on the rates, but he believed that the enthusiasm would be forthcoming. At this stage the only resolution of the conference was passed. This was moved by Principal Griffiths, and asserted "That it is the duty of the Principality to undertake the training and supply of teachers sufficient to meet the requirements of the Principality."

At the third session, which was presided over by Sir John Gorst, "The Special Aspects of the Problem of the Training of Elementary Teachers" was considered, a paper being read by Mr. T. John, vice-president of the National Union of Teachers. The experiments already being tried in the utilisation of the intermediate schools of Wales for the training of pupil teachers were described in detail, but the general opinion of the conference was unmistakable—that any half-time system should be a temporary expedient only.

As regards the question of the concurrent instruction of primary and secondary teachers, it was agreed that it is necessary for the separation of the primary teacher's professional training from his general education, and that under certain conditions it is possible and desirable that primary and secondary students should be trained together. The important question of the further training of those acting teachers whose qualifications are incomplete was introduced by Mr. Badger, director of higher education for Monmouthshire.

The relations between the various qualifying examinations were considered, and there was practical unanimity that matriculation should be a condition of entering the primary training departments of the three university colleges of Wales.

Mr. Humphreys Owen, M.P., chairman of the Central Welsh Board, presided over the fourth session, which was devoted to the "Special Aspects of the Problem of Secondary Training." Two papers were read, by Miss E. P. Hughes, late principal of the Cambridge Training College for Secondary Teachers, and Mr. Trevor Owen, Swansea, who acted as the official spokesman of the Association of Welsh County Schoolmasters. The conference was decidedly of opinion that secondary training should be post-graduate and completely differentiated from the degree course, but that the training college should be essentially attached to the university college. Representatives of the Association of Assistant Masters also addressed the conference and endorsed the views expressed by the readers of the papers.

There can be no doubt that the ultimate result of the conference will be far-reaching and beneficial. The interchange of ideas always makes for good, and it is not too much to hope that from the deliberations there may be devised a scheme which will be workable for all parts of the Principality, and will in time produce a supply of fully trained teachers of all grades, which, like her system of secondary education already established, will be a lasting and tangible proof of the enthusiasm of the Welsh people for education.

THERAPEUTIC BACTERIAL INOCULATION.[1]

ALTHOUGH the majority of diseases are produced directly or indirectly by the invasion of microbes, it has come to be generally recognised that the soil in which they grow plays a cardinal part in determining the ultimate effect or fate of the microbe. The finding of a pathogenic microbe, and even the accessory disposing factors of a disease, are, however, after all only the beginnings of the greater problem which is the end and aim of all medical science, viz. the cure of the disease.

To attack the causal agent is manifestly a solution of the problem, and this was the method originally advocated by Lister, who may be regarded as the founder of the doctrine of the ætiological curative principle. Experience has, however, shown that the attempt to destroy by means of ordinary chemical poisons the microbes in the living body is fraught with danger, for long before the protoplasm of the microbe is destroyed the cells of the body are irreparably damaged. Internal antiseptic therapy is a thing of the past. To-day we must rely on the stimulus produced by bacteria in the body whereby the cells of the latter elaborate substances which are antagonistic to these same bacteria. These substances—germicidal in the widest sense of the word—differ considerably in their mode of action. Some neutralise the bacterial poisons, others produce a solution—a lysis—of the bacteria. In other cases, again, Metchnikoff claims that the destruction takes place by a kind of digestion in the interior of certain cells of which the chief representatives are the wandering corpuscles of the blood.

The inoculation of a living microbe for the purposes of prophylaxis dates from the time of Edward Jenner, whose work was widely extended by Pasteur. It is not even necessary to use living bacteria, dead bacteria being likewise capable of conferring immunity. In any case, with the exception of diphtheria antitoxin, previous attempts have aimed at prevention rather than cure. The authors of the papers before us are the first who have utilised bacterial inoculations as a curative agent. Dr. A. E. Wright, late professor in the Army Medical School, is already widely known for his method of the preventive inoculation against typhoid fever—a method which is admitted to have led to a marked diminution of this disease in the British Army. His most important work, however, has been the discovery of therapeutic inoculation. To introduce bacteria into an individual already infected with the same bacteria would at first sight appear to be a paradox, but the results obtained justify the means. By the invention of accurate methods of testing the effects produced in the body by the inoculations, Dr. Wright has been able to demonstrate that the elaboration of protective substances follows a general law, characterised at first by a negative phase and followed by a positive phase in which the protective substances in the blood are increased in quantity.

In a series of papers he has likewise shown that in so-called phagocytosis there is really a cooperation of the cells and fluids of the body, and that in the latter there are substances—opsonins—which in some way or other act upon the microbes and prepare them for subsequent destruction by the leucocytes. This opsonic type of immunity is applicable to a number of diseases, but the present researches show that the mere presence of these opsonins is not sufficient to induce immunity. They must be in the proper place and at the required time if they are to exert their action, and a great deal of art is required on the part of the inoculator to create the most advantageous conditions for his patient. The methods advocated by Prof. Wright are so new that it is difficult to foresee how far they may go, but the striking curative results obtained justify one in prophesying that the time is not so very far distant when the abilities of the physician will be judged by his successes as an immunisator, for it must not be imagined that

[1] "On the Action exerted upon the *Staphylococcus pyogenes* by the Human Blood Fluids, and on the Elaboration of Protective Elements in the Human Organism in response to Inoculations of a Staphylococcus Vaccine." By Dr. A. E. Wright and Capt. Stewart R. Douglas, I.M.S. (*Proc.* Roy. Soc., September, 1904).

"On the Action exerted upon the Tubercle Bacillus by the Human Blood Fluids, and on the Elaboration of Protective Elements in the Human Organism in response to Inoculations of a Tubercle Vaccine." By the same Authors (*Proc.* Roy. Soc., September, 1904).

immunisation consists in the subcutaneous inoculation of some mysterious bacterial fluid prepared in the laboratory. On the contrary, it is a complex process, and it is only with the help of accurate scientific measuring methods that the physician will be able to gauge whether he is helping or injuring his patient. B.

PALÆOZOIC SEED PLANTS.

IT may be doubted if those who are not directly concerned with the study of the vegetable kingdom appreciate the full significance of the distinction which the botanist maintains between plants of seed-bearing and spore-bearing habit. For this reason the recent and important discoveries proving that the seed-bearing habit existed among more than one group of Palæozoic vegetation, discoveries which will form a historical landmark in the study of fossil plants, may not attract the attention which is their due outside the circle of workers on recent and fossil botany.

The seed-bearing habit is, from many points of view, regarded as a far higher stage in plant evolution than that attained by any known member of the vegetable kingdom in which the fertilised megasporangium remains without any integument of the nature of a seed-coat. So far, the botanist has associated the seed habit with two classes of plants, the gymnosperms (Coniferæ, Cycadeæ, &c.) and the angiosperms or flowering plants, and with these alone. It has not been suspected that members assigned to other groups, including the great race of vascular cryptogams (Pteridophyta), had at any period in their evolution attained to this high status. Yet such has recently been shown to be the case.

It is interesting to notice that these discoveries have been mainly due to the British school of palæobotany. Although it has been known for a long period that remains, obviously of the nature of seeds, occur here and there in the sandstones and shales of the Carboniferous period, Carruthers was the first to suggest, in 1872, that some of these fossil seeds may be attributed to the genus Cordaites, an extinct race, of gymnospermous affinities. This conclusion was subsequently confirmed by Geinitz, Grand'Eury, Renault, and other Continental botanists, who have greatly extended our knowledge of this Palæozoic type.

Until recently Cordaites has remained the solitary Palæozoic genus which was known to have attained the seed-bearing habit.

In 1901, however, Dr. Scott published a full description of a Carboniferous cone, Lepidocarpon, of undoubted lycopodian affinities, where integumented megasporangia are found when fully mature, and in which each sporangium contains a single embryo-sac. It has thus become clear that in the history of the lycopodian stock the evolution of seed-bearing members had taken place. More recently other evidence has accumulated which not only confirms this conclusion, but tends to show that Lepidocarpon did not stand alone among lycopods in this respect.

It is to discoveries still more recent of a similar nature, but affecting other lines of descent, that special attention may be directed. They are concerned with a synthetic type of Upper Palæozoic vegetation of great interest, which has become widely known under the name Cycadofilices. More than one genus of this group has now been shown to have reached the seed-bearing status.

The credit of the first discovery of this nature is due to Prof. Oliver and Dr. Scott, who recently published a full account of the seed and the evidence for its attribution in the *Philosophical Transactions* of the Royal Society. The more important conclusion of these authors may be briefly summarised as follows. It has been found that a seed, already recorded by Williamson as *Lagenostoma Lomaxi,* was borne by the fossil plant known as Lyginodendron. The two have not been found in continuity, but the evidence for this conclusion, although in the main indirect, is none the less conclusive. The chief point lies in the identity of the glandular structures found on an organ termed the "cupule," which envelops the seed, with those already known to occur on the stems, petioles and pinnules of Lyginodendron, which are peculiar to this genus among Carboniferous plants.

Within a few months of the earlier record of this remarkable research by Prof. Oliver and Dr. Scott, their main conclusion was confirmed in an unexpected manner by the discovery, on the part of Mr. Kidston, of the seed of another genus of the same group, Medullosa, of which an account has also appeared in the *Philosophical Transactions.* In this case the pedicel of a large seed, of the type known as Rhabdocarpus, was found to bear pinnules identical with those of the frond *Neuropteris heterophylla,* the foliage of a Medullosa.

Here absolute continuity, an extremely rare circumstance among fossil plants, exists between a foliar and a reproductive organ.

Further evidence, but more inconclusive and indirect, also exists, but space forbids any notice here. Attention may, however, be directed to an interesting and suggestive communication published by M. Grand'Eury in the *Comptes rendus* during the present year on the same subject.

The discoveries under discussion have made it clear that at least two genera of the Cycadofilices possessed the seed-bearing habit, and evidence is also available which suggests that Lyginodendron and Medullosa did not stand alone in this respect.

Prof. Oliver and Dr. Scott have concluded that "the presence in the Palæozoic flora of these primitive, Fern-like Spermophytes, so important as a phase in the history of evolution, may best be recognised by the foundation of a distinct class which may suitably be named Pteridospermeæ." This suggestion would seem to be a happy one, even though it may eventually involve the absorption of the whole group now familiar as the Cycadofilices.

In connection with these researches of Prof. Oliver, Dr. Scott, and Mr. Kidston, many further points of interest, and in some cases of criticism, might be discussed, but it must suffice here to direct attention to one or two valuable clues which these discoveries afford. The phylogeny of the cycads, a race with a great past, and still existing though in greatly diminished numbers, is in its main outlines now clear. There can be little doubt that the cycads are sprung from this same pteridospermous stock, which in its turn originated from a truly fern-like ancestor.

In the investing envelope of the young seed of Lagenostoma, which Prof. Oliver and Dr. Scott have spoken of as the "cupule," it is not improbable that homologies may eventually be recognised with protective structures existing among members belonging to other lines of descent, which may have great value as a contribution to other phylogenetic problems.

In conclusion, the existence of the seed-bearing habit among certain members of three out of the six great groups of Upper Palæozoic times raises the interesting speculation whether other groups may not eventually be found to have attained to the same status. The Calamites, the representatives of the Equisetales, are at present above any real suspicion in this respect, yet it would now be hardly surprising if further discoveries revealed the existence of seed-bearing members in this group, although it is by no means safe to assume that the seed-bearing habit must necessarily have existed in any group. E. A. N. ARBER.

ANTHROPOLOGICAL NOTES.

THE *Reliquary and Illustrated Archaeologist* for October contains, as is usual with this journal, interesting and well illustrated articles, among which may be noted one on "the funambulist," or rope-walker, by Mr. Arthur Watson; some Norman and pre-Norman remains in the Dove-Dale district, by Mr. G. le Blanc Smith; medallic portraits of Christ in the sixteenth century, by Mr. G. F. Hill; a carved bone of the Viking age, by Mr. J. Romilly Allen.

All who are interested in primitive technology will welcome the new instalment of Dr. Walter E. Roth's monograph on North Queensland ethnography. *Bulletin* No. 7 deals with domestic implements, arts, and manufactures, and is illustrated by twenty-six plates containing 250 figures. Dr. Roth not only describes the objects in daily use of the Queensland blacks, but, what is of very much greater importance, he usually describes how and of what they are made. Of especial interest and importance is his description of the manufacture of stone implements. He says:—

"I am afraid that too much importance has been hitherto attached to the differentiation of stone-celts into axes, adzes, wedges, scrapers, &c.: the savage certainly does not recognise the fine distinctions embodied on the labels attached to these articles in an ethnological museum. . . . The actual manufacture of a celt is now a lost art in Queensland. . . . The original celt in its simplest form is a water-worn pebble or boulder, an adaptation of a natural form; otherwise, it is a portion removed from a rock, &c., *in situ*, either by fire, indiscriminate breakage or flaking."

A record of a careful excavation of Jacob's Cavern, McDonald County, Missouri, by Messrs. Charles Peabody and W. K. Moorehead, is given in *Bulletin* i., department of archæology, Phillips Academy, Andover, Mass. The implements are of well known types, and nothing suggestive of Palæolithic culture was discovered; it is possible that the cave-dwellers were different from the Osages and from the lower Mississippi tribes. The paper is illustrated by eleven plates. The Phillips Academy is to be congratulated on its activity.

An interesting and well illustrated *résumé* of the recent archæological discoveries in Crete is given by M. S. Reinach in *l'Anthropologie* (Tome xv., Nos. 3–4, p. 257). The author tentatively proposes the following chronology of the development of the Cretan civilisation:—(1) 4500 (at least) to 2800, Neolithic period. Black pottery, with angular designs and no spirals; numerous stone vessels; no metal; rudimentary figurines of burnt clay. (2) 2800 to 2200, period of Kamares or Minoan I. About 2800 first certain contact with Egypt (twelfth dynasty); introduction of copper and bronze into Crete; painted pottery derived from Neolithic pottery. (3) 2200 to 1900, period of transition or Minoan II. Building of first palace. Continuation of relations with Egypt and commercial dealings with the islands of the Archipelago, notably with Melos. (4) 1900 to 1500, culmination of the period of Kamares or Minoan III. Building of the second palace; great development of ceramics, glyptics, and painting. An artist of Knossos went to Phylakopi, in Melos, and executed the "flying-fish fresco"; the linear Cretan writing occurs on Melian pottery. An insular confederation (?) took possession of Knossos and there established a new dynasty (?). (5) 1500 to 1200, Mycenæan period. Ceramics with zoomorphic and curvilinear designs. The centre of civilisation passed to the Peloponnesos; decadence and abandonment of the palace. The last king of the Minoan dynasty, Idomeneus, left Crete about 1200 for Italy, and founded Salentium; shortly afterwards the Dorians conquered Crete, and the island entirely retrogressed into barbarity.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—The report of the studies and examinations syndicate on the previous examination, in which it is proposed that a modern language may be substituted for Greek or Latin, will be discussed in the Senate House on December 1.

Dr. H. F. Baker, F.R.S., St. John's, and Mr. F. H. Neville, F.R.S., Sidney, have been appointed members of the general board of studies. Prof. J. J. Thomson, F.R.S., has been appointed a manager of the Gerstenberg studentship in moral philosophy for students of natural science.

Dr. Myers has been appointed demonstrator of experimental psychology.

The Isaac Newton studentship in astronomical physics and optics, value 200*l*. a year for three years, will be vacant next term. Candidates must be B.A.'s of the university, and under twenty-five years of age on January 1, 1905. Application is to be made to the Vice-Chancellor before January 26.

Additional benefactions to the university, amounting to some 3500*l*., have been paid or promised since February of the present year. A considerable number are ear-marked for the endowment of a Huddersfield lectureship in special pathology.

Two Walsingham medals in biology have been awarded this year, one to Mr. R. P. Gregory, fellow of St. John's College (for botany), and one to Mr. K. Lucas, fellow of Trinity College (for physiology).

NEW buildings of the Borough Polytechnic Institute, including buildings for engineering, building trades, domestic economy, &c., are to be opened as we go to press by Mr. J. W. Benn, M.P., chairman of the London County Council.

LORD REAY will deliver the prizes at the Northampton Institute for the session 1903–4 on Friday, December 9, at 8 o'clock. The prize distribution will be followed by a conversazione, which will be continued on Saturday, December 10.

DR. FREDERIC ROSE, His Majesty's Consul at Stuttgart, and the author of a series of diplomatic and consular reports on technical instruction in Germany, has been elected assistant educational adviser to the Education Committee of the London County Council.

THE committee in charge of the fund for the development and better equipment of the science schools in Trinity College, Dublin, has announced that 15,886*l*. has now been subscribed towards the 78,000*l*. necessary for the annual up-keep of the new schools. It will be remembered that Lord Iveagh offered to provide the sum of 34,000*l*. required to erect the new buildings if the amount required for up-keep were obtained by public subscription. The committee, in making an earnest appeal for further subscriptions, points out that the next most urgent need of the university is the development of the school of botany and plant physiology.

IT may be taken as indicative of the widespread interest in higher education among the Welsh people that large sums of money are contributed in a great number of small amounts towards the expenses of the university colleges. For instance, in the preliminary list of subscriptions, paid or unpaid, towards the permanent buildings fund, published in the calendar of the University College of North Wales for the session 1904–5, we notice that more than 6500*l*. is made up of amounts under five pounds, and, in addition to this, there are more than two hundred gifts of five guineas or five pounds. The total amount of subscriptions up to the present towards the permanent buildings fund reaches 27,190*l*.

THE Education Committee of the County Council of the West Riding of Yorkshire arranged last summer for the attendance of a group of art-masters from the schools in their administrative area to attend for six weeks at the School of Industrial Arts, Geneva. The committee has now published extracts from the report received from the administrator of the Geneva school on the work of the Yorkshire teachers, and a summary of the reports submitted by the art-masters who studied at Geneva. The teachers seem to have benefited greatly by their visit, and there can be little doubt that a first-hand acquaintance with Continental methods is of great value to English teachers. One interesting way in which scientific observation may be rendered useful in art instruction comes out in the report of one of the visiting masters, who writes of the Geneva School of Industrial Arts that: "Another very useful adjunct is a garden where Nature is allowed to have very much of her own way. Here the form and colour of plants and flowers and their growth at various stages can be carefully and leisurely studied."

SPEAKING at the Birmingham Municipal School on Tuesday, Mr. Alfred Mosely referred to some lessons taught by the American educational system. He remarked that America differs from us in an intense belief in education, and the realisation by manufacturers of the value of the thoroughly trained college student in their factories. We are face to face with a condition of things which is somewhat alarming. A scientific education has become an absolute necessity if we are to hold our place industrially. We have an Empire such as those who have not travelled do not realise, an Empire teeming with natural resources in every direction, merely awaiting the skilled hands of the mechanic and farmer to develop them. What we have in Canada and our other colonies makes the United States pale by comparison, but the United States have learnt to develop their resources, while we have been quarrelling over the village pump. It is Mr. Mosely's intention at an early date to approach some of the steamship companies to see whether facilities can be arranged for some school teachers to visit the United States and observe what is done there.

SOCIETIES AND ACADEMIES.

LONDON.

Chemical Society, November 3.—Prof. W. A. Tilden, F.R.S., in the chair.—The following papers were read:—Studies on the dynamic isomerism of α- and β-crotonic acids, part i.: R. S. **Morrell** and E. K. **Hanson**. Preliminary experiments on the freezing points of mixtures of the two acids furnish no evidence as to the existence of a compound of α- and β-crotonic acids between 100° and 168°, and between 15° and 71°·9.—The constitution of nitrogen iodide: O. **Silberrad**. In the interaction of zinc ethyl with nitrogen iodide it was found that trimethylamine was produced. This confirms Chattaway's view that the iodide has the constitution $NH_3:NI_3$.—The available plant food in soils: H. **Ingle**. Extraction with a 1 per cent. solution of citric acid for seven days renders a soil much less fertile, especially at first, but chemical changes in such soil, during the growth of the plants, gradually render it again capable of supplying plant food.—The basic properties of oxygen: compounds of the ethers with nitric acid: J. B. **Cohen** and J. **Gatecliff**. It is shown that with aliphatic ethers unstable compounds of the type X_2O,HNO_3 are formed.—Note on the influence of potassium persulphate on the estimation of hydrogen peroxide: J. A. N. **Friend**. It is shown that a secondary reaction, represented by the following equation,

$$H_2O_2+K_2S_2O_8=K_2SO_4+H_2SO_4+O_2,$$

probably takes place in addition to the main reaction.—The influence of sunlight on the dissolution of gold in aqueous potassium cyanide: W. A. **Caldecott**.—The fractional hydrolysis of amygdalinic acid, *iso*-amygdalin: H. D. **Dakin**.—The effect of anhydrides on organo-magnesium bromides, part i., the action of phthalic anhydride on magnesium α-naphthyl bromide: S. S. **Pickles** and C. **Weizmann**.—The combustion of ethylene: W. A. **Bone** and R. V. **Wheeler**. The principal results of these experiments are as follows:—(1) there is no preferential combustion of either carbon or hydrogen; (2) formaldehyde is the most prominent intermediate oxidation product; (3) there is no separation of carbon or liberation of acetylene.—The decomposition of methylcarbamide: C. E. **Fawsitt**. The decomposition of methylcarbamide by acids is due to a transformation of the methylcarbamide into methylamine cyanate, which is subsequently decomposed by the acid.—Position isomerism and optical activity; the methyl and ethyl esters of di-*o*-, -*m*-, and -*p*-nitrobenzoyltartaric acids: P. F. **Frankland** and J. **Harger**. The authors describe the preparation and properties of the six esters in question.—The action of nitrogen sulphide on organic substances, part ii.: F. E. **Francis** and O. C. M. **Davis**.—Reduction products of $\alpha\beta$-dimethylanhydracetonebenzil, and condensation products of benzaldehydes with ketones: F. R. **Japp** and W. **Maitland**.—Interaction of sodium phenylglycidate with phenylhydrazine: F. R. **Japp** and W. **Maitland**.—α-Benzoyl-β-trimethacetylstyrene: F. R. **Japp** and W. **Maitland**.—Olefinic ketonic compounds: S. **Ruhemann**.—Δ^α-Oleic acid: H. R. **Le Sueur**.—Action of magnesium alkyl halides on derivatives of camphor: M. O. **Forster**.—Sulphonchloroalkylamides: F. D. **Chattaway**.

Linnean Society, November 3.—Prof. W. A. Herdman, F.R.S., president, in the chair.—Mr. G. Claridge **Druce** showed specimens of a new British grass, *Koeleria valesiaca*, Gaud., which he had found in the herbarium of Dillenius at Oxford, and recently re-found in the original locality at Brent Down, Somersetshire.—The Rev. John **Gerard**, S.J., brought specimens of a proliferous plantain (*Plantago major*) from the neighbourhood of Clitheroe, Lancashire.—Mr. Frank **Crisp** brought for exhibition a flower of *Schubertia graveolens*, Lindl., an asclepiad, which, deprived of its corolla and with a portion of its calyx cut away, viewed from the side, presented the genitalia in the shape of a skull.—A note on some points in the structure of the gill of the Ceylon pearl-oyster: the **President**.—Notes on the "sudd" formation of the Upper Nile: A. F. **Broun**. The author gives a list of the plants forming the mass of vegetation, which, favoured by the silt brought down by the White Nile, helps to block the shallow channels.—Bryozoa from near Cape Horn: A. W. **Waters**. The paper deals with specimens which were collected by the French "Mission scientifique du Cap Horn," but were not mentioned by Jullien in his report on the "Bryozoaires" of that expedition, published in 1888. From this material, which Jullien had presumably not handled, Mr. Waters adds twenty-eight species to the original list of fifty-six. He gives further particulars in regard to some of those named by his predecessor, and points out that eight species established by Jullien had been already described under other names. He rectifies two erroneous identifications, enlarges the range of distribution for several species, and for six of them calls to mind that they were first discovered by the *Challenger*.

Mathematical Society, November 10.—Prof. H. Lamb, president, in the chair.—The council and officers for the ensuing session were elected. They are as follows:—president, Prof. Forsyth; vice-presidents, Prof. Burnside, Prof. Elliott, Prof. Lamb; treasurer, Prof. Larmor; secretaries, Prof. Love and Mr. Grace; other members of council, Mr. Berry, Mr. Campbell, Dr. Glaisher, Dr. Hobson, Major MacMahon, Mr. Mathews, Mr. Western, Mr. Whittaker, Mr. A. Young.—Prof. Forsyth having taken the chair, Prof. **Lamb** delivered an address on deep-water waves. He reviewed the theory of the waves produced on deep water by a local disturbance of the surface. The theory developed independently by Poisson and Cauchy had often been regarded as obscure, and it had never been interpreted completely. The problem has a deeper significance in that it offers perhaps the simplest example of the propagation of waves in a dispersive medium, and was the origin of the theory of group velocity, which has so many applications in various branches of physics. After tracing the history of the problem, the author proceeded to disengage the essential results of the theory from the clouds of analysis in which they had been involved; he pointed out the connection of the analytical results with the analysis which was used at a later date for the investigation of the phenomena of diffraction; he traced the forms of the waves due to a local initial elevation both at considerable and at small distances from the source of disturbance; and he pointed out the significance of the results when interpreted by means of modern notions concerning waves of approximately simple harmonic type and the propagation of groups of such waves. Finally, he discussed the solution of the problem of waves generated by a local and periodic variation of pressure.—The following papers were communicated:—Note on the application of the method of images to problems of vibrations: Prof. **Volterra**. It is shown how to obtain by means of the method of images a complete solution of the problem of vibrations of a membrane, and it is pointed out that although the train of images may be infinite, yet the number of terms in the solution is finite.—The zeros of certain classes of integral Taylor's series, two papers: G. H. **Hardy**. The nature of the zeros of some particular classes of functions, allied to the exponential function, is determined with much greater precision than can be attained by any of the known general theorems. If $\phi(n)$ is an integer when n is an integer, and the increase of $\phi(n)$ is regular and sufficiently rapid, there are exactly $\phi(n)$ zeros of $\Sigma\frac{x^{\phi(n)}}{\phi(n)!}$ within the circle $|x|=\phi(n)$, and their positions can be determined very precisely. In the second paper similar investigations are given for other functions of which $\Sigma\frac{x^n}{(np+1)^{\alpha n}!}$ is an example.—On the reducibility of covariants of binary quantics of infinite order: P. W. **Wood**. The paper contains the conditions that any covariant linear in the coefficients of each of δ binary quantics of infinite order should be expressible in terms of products of covariants of lower total degrees. The reducibility of covariants of degree 4 is determined completely, and certain classes of reducible covariants of degree δ and weight $\geqslant(2^{\delta-1}-1)$ are discussed.—The linear difference equation of the first order: Rev. E. W. **Barnes**. The questions to be considered relate to the existence of solutions, their analytical expression, and their place among transcendental functions. These questions are discussed from the point of view of the theory of functions of complex variables, the arguments of the functions which occur in the difference equations being assumed to be complex.—Curves on a conicoid: H. **Hilton**.—Remarks on alternants and continuous groups: Dr. H. F. **Baker**.—Expansions of the elliptic and Zeta functions of $\frac{2}{3}K$ in powers of q: Dr. J. W. L. **Glaisher.**—Examples of perpetuants: J. E. **Wright.**—Two simple results in the attraction of uniform wires obtained by quaternions: Prof. **Genese.**—A theorem relating to quotient groups: Prof. **Miller.**—On certain classes of syzygies: A. **Young.**

CAMBRIDGE.

Philosophical Society, October 31.—Annual general meeting, Dr. Baker, president, in the chair.—Prof. Marshall Ward, F.R.S., was elected president for the session 1904–5. —On the dimorphism of the English species of Nummulites: J. J. **Lister,** F.R.S. The author gave an account of his examination of the characters of three English species of Nummulites, *N. laevigata* (Brug.), *N. variolaria* (Lam.), and *N. elegans* (Sow.), with respect to dimorphism. It appears that these species, far from invalidating the conclusion that the species of Nummulites are dimorphic, are in complete accord with it.—A problem concerning wood and lignified cell-walls: Prof. Marshall **Ward,** F.R.S. Dr. W. J. Russell some time ago showed that if a block of wood is laid on a photographic plate, and kept in the dark for some time, a photographic image will be found on the plate after ordinary development, although no light has had access; and he has summarised his numerous and important observations in a recent paper in the *Philosophical Transactions.* Since resinous woods were found especially active, Russell suggested that some active body of resin-like nature was the agent concerned, and that hydrogen peroxide was developed. Prof. Marshall Ward's paper describes experiments which were directed to the questions, (1) can this photographic contact-method be utilised to obtain images of thin and microscopic sections of wood? and (2) what other substances, *e.g.* in woods devoid of resin, are active? The author showed photographs, obtained without light, of thin sections of many different kinds of wood, and demonstrated that in most cases resin and allied bodies cannot be the active agents. He also showed that a thin section which gives a very faint image, or even no recognisable image at all, if used dry and untouched, may give a very deep one if soaked in a weak solution of tannin, gallic acid, pyrogallol, &c., and then dried before being placed on the plate. A striking result is obtained if such solution is streaked across the section; the treated streak or figure comes out deep black on a pale ground-work of the part untreated. Xylol, clove oil, tannic acid, and some other bodies are also active. The author thinks that a careful comparative investigation of all kinds of woods might lead to important results regarding that very difficult question, the constitution of lignified cell-walls.—The pine-apple gall of the spruce: note on the early stages of its development: E. R. **Burdon.** The galls are caused by certain Aphidæ belonging to the genus Chermes. The insect drives its proboscis into the bud, and sets up an irritation which results in the young shoot becoming modified into a gall. The early stages of the gall take place whilst the shoot is still enclosed in the winter bud scales. The cells are forced into precocious growth, and a parenchymatous tissue, consisting of swollen cells with vacuolated protoplasm and enlarged nuclei, is formed. The chlorophyll, tannin, resin, resin canals, and secretory cells all disappear, but an abundant supply of starch is laid down which may possibly arise as the ultimate product of the disintegration of the tannin. The chromatin network of the nuclei becomes aggregated into wart-like nucleoli. The mitotic figures appear to be of the usual somatic type, and no indication of heterotypical mitoses has yet been found. There is reason for believing that the ultimate cause is an injection by the insect, and that this injection will cause a gall growth only when it acts on embryonic tissues which are not confined by other lignified or cuticularised tissues.—On certain quintic surfaces which admit of integrals of the first kind of total differentials: A. **Berry.**

MANCHESTER.

Literary and Philosophical Society, November 1.—Prof. W. Boyd Dawkins, F.R.S., president, in the chair.—On alkaline borates: C. H. **Burgess** and A. **Holt,** jun. The authors found that nearly all the glasses obtained by fusing boric anhydride with varying quantities of sodium carbonate could be transformed, wholly or in part, into stable, crystalline forms, which invariably melt at a higher temperature than the glasses from which they were derived. The study of the melting points of these mixtures, and the analyses of the crystals and glasses, point to the probable existence of both sodium metaborate and a further compound containing only a quarter equivalent of sodium. Anhydrous borax itself does not appear to be a definite compound; it is almost a eutectic mixture of the solid solution of the two above mentioned compounds. The glasses appear to be a superfused state of the crystals. The familiar colours of borax beads seem to be due to the formation of a complex sodium ion, and can be changed in tint by increasing or decreasing the amount of alkali present.—Note on the electrolytic preparation of titanous sulphate: W. H. **Evans.** The results show that a low current density, high concentration, and a temperature of about 70° C. are the most favourable for obtaining an efficient yield in this reduction process. Moreover, the author has found that the preparation can be carried out without the use of any diaphragm to separate the anode from kathode chambers of the cell.

DUBLIN.

Royal Irish Academy, November 14.—Prof. R. Atkinson, president, in the chair.—On the discovery of hyæna, mammoth, and other extinct Mammalia in a Carboniferous cavern in the county of Cork: R. J. **Ussher.** After recapitulating the work that has been done in Irish caves, Mr. Ussher described an extensive cavern in county Cork, near Doneraile, in every portion of which that he has examined remains of extinct Mammalia have been found. Mammoths, old and young, have been met with in several places; bears and reindeer were abundant; Irish elk, wolf, and hyæna were also found; the last, identified by Dr. Scharff from a portion of a skull with teeth, is an addition to the Irish fauna. These remains were in red sand beneath a floor of crystalline stalagmite, which was present in the various chambers and galleries.

PARIS.

Academy of Sciences, November 7.—M. Mascart in the chair.—Researches on the desiccation of plants and vegetable tissues: final equilibrium, under average atmospheric conditions: M. **Berthelot.** The rate of loss of moisture is proportional at any instant to the quantity of water remaining in the plant. A further amount of moisture is driven off at 110° C.—On the absolute desiccation of plants and vegetable materials: period of artificial desiccation. Reversibility by atmospheric moisture: M. **Berthelot.**—On the preparation in a state of purity of boron trifluoride and silicon tetrafluoride, and on some physical constants of these compounds: Henri **Moissan.** The boron fluoride was prepared in two ways, by heating a mixture of boric anhydride and calcium fluoride with sulphuric acid, and by direct synthesis from boron and fluorine. After purification, the gas was frozen by liquid air, foreign gases pumped off, and the solid allowed to volatilise. The boron fluoride melted at $-127°$ C. and boiled at $-101°$. Silicon fluoride, purified in a similar manner, melts at $-97°$, and passes into the gaseous state without melting. The experiments establish the physical identity of BF_3 and SiF_4 prepared synthetically with the compounds prepared by the ordinary chemical methods.—On the nature of *charriage*: Ed. **Suess.** —Remarks by Michel **Lévy** on the preceding paper.—On a hyperelliptic surface: M. **Traynard.**—On the complementary geodesic triangulations in the higher parts of the French Alps: P. **Helbronner.**—On a new mode of constructing aërial helices: Ch. **Renard.** The helices described are 2·5 m. in diameter, and are perfectly rigid when rotated by power, although their weight is only 3 kilograms. —On explosions in boilers: L. **Lecornu.**—Retrograde diffusion in electrolytes: E. **Bose.** The author points out that the results obtained experimentally by Thovert were predicted by Abegg and Rose on Nernst's theory.—On the estimation of temporary radio-activity for its therapeutic utilisation: Th. **Tommasina.**—The proof of a radio-activity peculiar to living beings, vegetable and animal: Th. **Tommasina.**—The action of low temperatures on colouring matters: Jules **Schmidlin.** An alcoholic solution of rosaniline chlorohydrate shows a clear diminution in the intensity of the red colour, and at the same time developes a fine greenish-yellow fluorescence.—Heats of combustion of triphenylmethyl and some derivatives of triphenylmethane: Jules **Schmidlin.**—The preparation of iodide of gold by the action of iodine on gold: Fernand **Meyer.** The iodide AuI can be obtained by the direct action of iodine upon gold at temperatures between 50° and 100°. Below 50°, or above 200°, there is no action. In the presence of water in a closed vessel iodine gives with gold the same aurous iodide.—On a yttrium earth near to gadolinium: G. **Urbain.** An attempt to isolate an element characterised by the band $\lambda = 488$.—On β-bromobutyric acid: M. **Lespieau.** The amide of this acid is obtained by saturating allyl cyanide with hydrobromic acid in the cold. A crystalline mass separates, which, when dissolved in concentrated hydrobromic acid solution, deposits white crystals of the amide.—The oxidation of acetol: André **Kling.**—On the formation of formaldehyde during the combustion of tobacco: A. **Trillat.** The experimental results show that aldehydes are formed during the combustion of tobacco, notably formaldehydes. The toxic effects, however, are modified by the fact that these aldehydes immediately combine with the nitrogenous bases given off at the same time.—On the germination of the spores of *Atrichum undulatum* and *Hypnum velutinum*, and on their nutrition in sterilised liquid media: Paul **Becquerel.**—On the development of the kidney and Leydig's gland in the Elasmobranchs: I. **Borcea.** The kidney of the Elasmobranchs has the same value as that of the higher vertebrates.—The influence of the feeding on the length of the intestine of the larvæ of *Rana esculenta*: Émile **Yung.**—On an infectious disease of horses, with alterations in the bones, observed at Madagascar: MM. **Charon** and **Thiroux.**—On the general structure of the Tyrolese Alps west of the Brenner Railway: Pierre **Termier.**—Modifications undergone by the nutritive exchanges in skin disease: A. **Desgrez** and J. **Ayrignac.**

NEW SOUTH WALES.

Royal Society, September 7.—Mr. C. O. Burge, president, in the chair.—Notes on the theory and practice of concrete-iron constructions: F. M. **Gummow.** The author outlined the theory from the present standpoint of scientific research, and after reviewing the principal applications, concluded his paper by giving particulars of a test of concrete-iron plate beams, carried out on a large scale.—Further experiments on the strength and elasticity of reinforced concrete: Prof. W. H. **Warren.** The author stated that the paper consisted of an experimental investigation of the physical properties of Portland cement mortars and concrete when reinforced with steel.

Linnean Society, September 28.—Dr. T. Storie Dixson, president, in the chair.—Monograph of the Australian Cicadidæ: Dr. F. W. **Goding** and W. W. **Froggatt.** Descriptions of all the Cicadidæ attributed to Australia, amounting to 115 species, comprised in 21 genera, are given. In connection with the geographical distribution of the species it may be mentioned that though many are strictly confined to the coastal forests of eastern Australia, others are found sporadically over a very large area, reappearing in widely separated districts if the suitable class of country presents itself. For example, *Tibicen willsi*, Dist., described from Rockhampton, ranges up the Queensland coast to Townsville, occurs also at Bourke, N.S.W., and reappears at King's Sound, N.W.A. Indo-Malayan affinity is indicated by the occurrence of the genera Gæana and Huechys.—Notes on Neuroptera, with descriptions of new species: W. W. **Froggatt.**—Ngarrabul and other aboriginal tribes, part ii., distribution of the tribes: J. **MacPherson.** The distribution of twenty-four tribes in north-east New South Wales and South Queensland, in accordance with the languages spoken and as gleaned from Ngarrabul sources of information, is discussed and mapped.—Notes on the native flora of New South Wales, part i., the Tumbarumba and Tumut districts: R. H. **Cambage.** These notes comprise observations on the conspicuous vegetation of the country between Wagga, Tumbarumba, Tumut, and Gundagai during the drought of 1903, and serve to show the striking differences between the flora of the low country round Wagga (600 feet above sea-level) and that of Laurel Hill or Bago, near Tumbarumba (about 3300 feet), where the vegetation presents a recognisable Tasmanian facies.

DIARY OF SOCIETIES.

THURSDAY, NOVEMBER 17.

ROYAL SOCIETY, at 4.30.—Air Resistance Encountered by Projectiles at Velocities up to 4500 Feet per Second: A. Mallock, F.R.S.—Theory of Amphoteric Electrolytes. Part II.: Prof. J. Walker, F.R.S.—Enhanced Lines of Titanium, Iron, and Chromium in the Fraunhoferic Spectrum: Sir Norman Lockyer, K.C.B., F.R.S., and F. E. Baxandall.—On the Group IV. Lines of Silicium: Sir Norman Lockyer, K.C.B., F.R.S., and F. E. Baxandall.—The Electrical Conductivity and other Properties of Sodium Hydroxide in Aqueous Solution, as Elucidating the Mechanism of Conduction: W. R. Bousfield, K.C., M.P., and Dr. T. Martin Lowry.—On the Wetting of Cotton by Water and by Water Vapour: Prof. D. Orme Masson, F.R.S.

LINNEAN SOCIETY, at 8.—On the Structure of the Stems of Plants: Lord Avebury, F.R.S.—Observations on Undescribed or Little Known Species of Membracidæ: G. B. Buckton, F.R.S.

FRIDAY, NOVEMBER 18.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—Impact Tests on the Wrought Steels of Commerce: A. E. Seaton and A. Jude.

EPIDEMIOLOGICAL SOCIETY, at 8.30.—The Inaugural Address on the Epidemiological Aspects of Industrial Diseases: the President, Dr. Whitelegge, C.B.

TUESDAY, NOVEMBER 22.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Distribution of Electrical Energy: J. F. C. Snell.

WEDNESDAY, NOVEMBER 23.

NATURDENKMÄLER.

Die Gefährdung der Naturdenkmäler und Vorschläge zu ihrer Erhaltung. By H. Conwentz. Pp. xii+207. (Berlin: Borntraeger, 1904.) Price 2 marks.

READERS may naturally ask, "What is a Naturdenkmal?" and, since the word is a comparatively new one to the German vocabulary, necessitating its elucidation by the author even for German readers, it may not be out of place if we explain its meaning, as near as possible, in his own words. The usual meaning of "Denkmal" to the German mind suggests a monument or memorial to commemorate some famous personage or victory (for example, Gœthe-Denkmal, Sieges-Denkmal). But in addition to this the title is often applied to outstanding works in science, literature, music, &c. Further, the remains of ancient buildings or works of art of whatever kind which have a historical, technical, or educative value, are spoken of as Bau- and Kunst-Denkmäler. Also the term is applied to prehistoric remains, such as lake-dwellings, burying mounds, urns, tools and weapons of stone or metal; however, the author points out that all those Denkmäler are of artificial origin, that is, the result of man's work and ingenuity. The term Naturdenkmal has a wider application, and includes certain results of nature's handiwork, for example, the elaborately carved stone obelisk is a Denkmal of recent times, and the rough stone-block, erected by the hand of man to commemorate the dead, forms a prehistoric Denkmal; while the Glacial boulder, carried from afar in a former epoch and deposited on the plain by natural forces, forms a Denkmal of nature, or as the artificially built up cairn and rampart wall of a former age may form prehistoric Denkmäler, so the hill and mountain range, formed without man's intervention, are Denkmäler of nature.

Also the whole natural landscape, with its various soil formations, with its water courses and lakes, with its special plant and animal communities, as well as single rare species and individuals of the original flora and fauna, represent "Naturdenkmäler." Although only virgin lands, together with their plants and animals undisturbed by man, should come within the strict sense of the term, still we must here and there allow a certain latitude in its application, because undisturbed localities are scarcely to be found in many of the modern cultured States. For example, any striking feature in the landscape, even if it is a deserted valley or village, must not be struck off the list. Also a natural forest growth which, by self-seeding, has followed the destruction of the original forest by man, must also be reckoned a Naturdenkmal.

On the other hand, artificially planted trees, such as are found in many villages, avenues, and parks, no matter how interesting they may be, cannot be regarded in the strict sense of the term as Naturdenkmäler. In many cases the local conditions must be taken into account in reckoning any natural phenomenon as a Denkmal, for example, a part of the forest which has remained unexploited by man (virgin forest) or the still living representatives of a disappearing species of plant or animal, is universally regarded as a Naturdenkmal; but in other cases, according to the country and locality, we find certain exceptions, for example, in north Germany the traces of glaciers on the rocks are among the greatest rarities, and must, therefore, be regarded as Naturdenkmäler. But on the coast of Scandinavia their occurrence in places is so frequent that there they are no longer Naturdenkmäler. In like manner the Cornel (*Cornus Suecica*) occurs in a few localities in north-west Germany, and in the east it is only found in one place, hence here it is a Naturdenkmal; but in north Russia, Finland, Sweden, &c., its occurrence is frequent over large areas, hence there it is no longer a Naturdenkmal. Similar examples may be given for many other plants and birds. From the foregoing it will be seen that a number of different factors determine whether a natural object can be reckoned a Naturdenkmal or not, and a decision can only be come to by taking the surrounding conditions in each case into account.

The dangers which threaten those natural curiosities and rarities are many, and the author devotes almost one-half of the above memorial to an enumeration of many cases where, through ignorance, indifference, or natural causes, many unique Naturdenkmäler have been considerably damaged, if not entirely destroyed. As an example of the damage which may be done through ignorance or indifference, the author points out the way in which the most beautiful parts of the forests, within reachable distance from Berlin, are often rendered anything but attractive by the traces which trippers and picnic parties so commonly leave behind them. Frequently, also, the most beautiful spots are disfigured by unsuitable and unattractive buildings, principally for the accommodation of visitors. The author also complains that many of the most picturesque hill-tops are disfigured by monuments and towers which are entirely out of harmony with their beautiful, natural surroundings. Then, again, the landscape is subjected to considerable disfiguration by the many devices employed by the advertising agent. Those in high authority are themselves not always free from blame. In one of the German Federated States it was at one time proposed that, in order to preserve the banks and channels of the water-courses, all trees and shrubs should be removed from the sides of brooks and streams. This movement was, however, happily frustrated, otherwise not only the æsthetic features of the landscape would have been entirely destroyed, but also many plant and animal communities would also have disappeared.

The author then brings a long list of charges against tourists and visitors, showing how in many places characteristic plants of the coast and mountains have been almost entirely rooted out. The so-called sportsman, too, is responsible for the wanton destruction of many song-birds in certain parts of the Continent, especially Italy. The author further mentions the extremely regrettable manner in which the reindeer, now confined to Spitsbergen, Nova Zembla, Greenland, Siberia, &c., is systematically hunted and wantonly destroyed in the name of sport. Two cases are mentioned where well educated people in high positions organised expeditions to the native haunts of the reindeer, where in one or two days more than 100 head were killed, and the greater number of them allowed to lie and rot on the ground. The author further gives a long list of birds which are threatened with extinction unless something is done for their preservation. The dangers to which Naturdenkmäler are exposed through the drainage and reclamation of lands, utilisation of water-power, stone-quarries, exploitation of moors for peat, &c., also the dangers of scientific forestry, leading to the disappearance of all the virgin forest, the uprooting of certain plants for commercial purposes, trapping of birds for cages, and collecting by ornithologists, are too numerous to mention in detail.

Around the ever-increasing centres of industry in Germany the pollution of air and water is becoming greater every day, with the result that plant and animal communities, as well as the whole natural landscape, are undergoing a rapid and radical change, which is necessarily accompanied by the disappearance of rare and valuable Naturdenkmäler. The proposals put forward by the author for their preservation occupy the larger part of the book. Generally speaking, they fall into three groups, viz.:—making a record of the various Naturdenkmäler for the different States throughout the Empire; providing for their protection in the various places; and making them generally known. In carrying out these proposals, it is necessary that the Government should take an active part by the passing of certain laws and allowing the active cooperation of different officials in the various departments. Also communities, societies, and private individuals are called upon to lend their aid. The various details in this proposed organisation for the protection of nature's "monuments" seem quite reasonable and eminently practical, but with laudable modesty the author does not insist that they should be accepted in their entirety. He puts them forward more as a working basis, the details of which may be subject to alteration from time to time as experience and trial should suggest. He is, however, confident that the time will come when the "monuments" of nature will receive the same care and reverence as that which has for long been bestowed upon the monuments of early art and civilisation.

PRINCIPLES OF FUEL COMBUSTION.

Smoke Prevention and Fuel Economy. By Wm. H. Booth and John B. C. Kershaw. Pp. 194. (London: Archibald Constable and Co., Ltd., 1904.) Price 6*s.* net.

IN the preface the authors state their object to be the "bringing before the fuel using public the principles of fuel combustion," more especially in relation to the smoke question and the economic use of fuel. They express their belief in the possibility of burning bituminous coal perfectly, and that black smoke is merely so much evidence of improper design. "Both on humanitarian and economic grounds its suppression is called for."

The general principles are clearly stated, and a brief description of selected types of furnace arrangement, stokers, &c., illustrated by good diagrams, makes the whole a useful compilation. It cannot be claimed that any addition has been made to our general knowledge of the subject, for the importance of proper air supply, perfect mixing of the gases and air for combustion, the maintenance of a sufficiently high temperature for unchecked combustion, and other points have long been recognised in books dealing with boiler management. Smoke, in fact, is possibly not so much the result of ignorance as of conservatism and false economy.

The book contains many statements in reference to water-tube boilers which few who have had practical knowledge of their working will altogether agree with. Thus "when moderately worked, some degree of safety, or at least a danger much less than attached to the discarded Howard boiler." Surely the rapid adoption of boilers of this type in the large electric lighting and power stations, engineering works, &c., is a sufficient answer to this.

After a reference to the development and satisfactory working of water-tube boilers with anthracite coals in America, the authors refer to the same boilers being erected in this country to burn bituminous coal, and "being set exactly as in America, the results have been hopelessly bad, *and the present smoke of London is due to this boiler more than anything else*" (p. 19). It cannot be denied that the total sum paid in fines for permitting smoke from steam plant of this type has been fairly large, but does the total number of water-tube boilers in London, many of them giving grand results, bear any large proportion to boilers of the old pattern, in spite of the rapid adoption of the former in recent years? The statement we print in italics is far too sweeping and altogether unjustified.

As the authors point out, in many cases boilers, presumably those in which the tubes are more nearly horizontal than vertical, were often set too near the fire, so that combustion was checked by the chilling action of the tubes; but this certainly does not apply to another type of water-tube boiler in use where the tubes are more nearly vertical than horizontal, for here ample combustion space is provided. Several excellent furnace arrangements are described and illustrated which provide for the maintenance of a high temperature until combustion is complete with these boilers, including the excellent one due to Mr. Miller. Engineers, however, do not seem very favourably disposed to much firebrick in the furnace, for it is not easy to ensure its standing the high temperature for any length of time, and water-tube boiler makers rather fight shy of such arrangements owing to the excessive heating of the lower tiers of tubes.

Closely connected with this question is that of the chain grate. As mentioned by the authors, this practically fell into disuse until the advent of the water-tube boiler resuscitated it, and yet we find the statement "it (the chain grate) must fail under the straight ascending flow of the usual setting of the water-tube boiler." Everything turns on the *usual* setting. There must be a number of unusual settings about, or it is not easy to understand why this grate has been so extensively adopted for these boilers. Certain it is that with no further elaboration of the furnace than a short firebrick arch at the fore-part (illustrated in Fig. 15) they will perform their work very efficiently, and with practically no smoke when using a bituminous coal.

A chapter is devoted to the chemistry of the combustion process. In referring to the hydrogen in fuels, the statement occurs, "it is generally assumed to be present combined with carbon to form hydrocarbons. The most important of these for the fuel user are —methane, ethylene and acetylene." A small amount of at least the first may be present in coal, but are we to assume the authors to mean that these are the important hydrocarbons existing in the coal before it has been heated?

In view of Bone's work (mentioned in a short footnote) it is a pity the authors did not revise their theory to account for the formation of smoke, seeing that the book was not published until a twelvemonth after Bone and Wheeler's paper appeared in the *Journal* of the Chemical Society (August, 1903), and Armstrong's paper in the same number, in which it is definitely stated "neither hydrogen nor carbon being burnt preferentially." PART II. of Messrs. Pendlebury and Robinson's "New School Arithmetic" has followed quickly on the publication of part i., and this excellent text-book is now complete. The second part is concerned mainly with the application of arithmetic to the transactions of commerce, dealing with such subjects as interest, discount, commission, stocks and shares, profit and loss, &c. Ratio and proportion find a place, and they are illustrated largely by this class of problem. The authors devote a little space to the training of youths in computations suitable to experimental work in the laboratory. Thus we find that algebraical symbols are freely introduced, and chapters are given on averages, approximations, graphs, elementary mensuration, and logarithms. This portion of the book might well have been extended even at the expense, if necessary, of some of the chapters relating to purely business matters. But the subjects treated are very numerous, affording considerable ground for selection, and many teachers will no doubt, and with advantage, omit some of the technical commercial chapters. At every stage examples are introduced in great abundance, the answers to which extend to nearly fifty pages. The book concludes with a collection of test papers, and a large number of miscellaneous problems. Parts i. and ii. are published separately, and also in one volume. The examples and answers may also be obtained without the other text. Altogether the book is one that deserves, and will no doubt obtain, an extended circulation.

With the issue of part vi. of Messrs. Hall and Stevens's "School Geometry," this popular text-book must now be nearing its completion. The present section corresponds, substantially, with Euclid, Book xi., 1–21, and it further deals with the mensuration of the simpler geometrical solids. In establishing the theorems of pure solid geometry, the authors follow Euclid rather closely, but there are some useful additions. Thus it is shown how a point in space is located by means of rectangular coordinates; but it is not shown how position and form may be exhibited graphically by means of projections. In dealing with areas and volumes, elementary trigonometry is used. The prismoidal formula is also introduced, but its value is scarcely made sufficiently manifest, and it is not shown how to deal approximately with irregularly shaped figures, by means of Simpson's or other rules. The book is printed in very distinct type, and the figures and diagrams are beautifully designed and executed. The subject-matter is presented and developed in the clear and attractive style which is always found in the authors' text-books, and is illustrated by well chosen examples.

Part iv. of Mr. Allcock's "Theoretical Geometry for Beginners" treats, in the first instance, of ratio and proportion, with geometrical applications. The propositions correspond roughly with Euclid, Book vi., but the style of proof is different. The reader is first introduced to the conception of ratio and proportion by means of numerical and algebraical examples, and his knowledge of arithmetic and algebra is drawn upon in establishing some preliminary theorems, which are subsequently used in demonstrating the various theorems. The latter half of the book is devoted to modern geometry, including chapters on harmonic pencils, the complete quadrilateral, poles and polars, centres of similitude, inversion, maxima and minima, and envelopes. Some numerical examples are given at intervals, but, as the title implies, the propositions and the exercises thereon are almost entirely confined to deductive geometry, and from this point of view the treatment is eminently satisfactory. The book is got up and printed in a way that leaves nothing to be desired.

The "Elementary Plane Geometry" by Mr. Turnbull is intended for youths who have already had a course of experimental geometry, and is almost entirely devoted to demonstrative geometry. It is divided into four sections, dealing respectively with triangles and quadrilaterals, circles, areas, and with ratio, proportion, and similar figures. Most of the propositions contained in the volume belong to Euclid, but the author has allowed himself that freedom of treatment that is now happily prevalent. The book shows no conspicuous merits such as would render its general use either likely or desirable.

In the volume by the Rev. E. M. Radford, the author has compiled and arranged a hundred test or examination papers, each containing twelve problems; a large number of the latter are stated to be original, and many are taken by permission from published examination papers. The collection is "intended primarily for the use of candidates for mathematical entrance scholarships at Oxford and Cambridge," and the subjects on which problems are set comprise "pure geometry, algebra, trigonometry, analytical conics, and elementary mechanics," with the addition in the last fifty papers of elementary theory of equations and elementary differential calculus. The book will no doubt prove useful to the class of student for whom it is intended, but the problems show no sign whatever of having been influenced by the reform in the teaching of mathematics which is now in progress. The author hopes shortly to publish a volume of solutions, and this will be very acceptable to teachers who may use the work.

OUR BOOK SHELF.

Handbuch der Laubholzkunde. Charakteristik der in Mitteleuropa heimischen und im Freien angepflanzten angiospermen Gehölz-Arten und Formen mit Ausschluss der Bambuseen und Kakteen. By Camillo Karl Schneider. Erste Lieferung, pp. 160; Zweite Lieferung, pp. 161–304. (Jena: Gustav Fischer, 1904.) Price 4 marks for each Lieferung.

THESE two parts form the commencement of a work intended to render possible the identification of the hardy species of angiospermous trees and shrubs indigenous to, or cultivated in, Central Europe. Such a work invites comparison with Koehne's well known book on the same subject rather than with the more comprehensive descriptive works by Koch and Dippel. From the first named it differs in the vastly greater number of illustrations, and in the fuller details given regarding the characters of buds and twigs. These additional details contained in Schneider's book go far towards removing the uncertainty of diagnosis involved in the provisional identification by means of the dichotomous keys employed throughout the work. The present Lieferungen, dealing with the Salicaceæ, Myricaceæ, Betulaceæ, Fagaceæ, Ulmaceæ, Moraceæ, Urticaceæ, Santalaceæ, Loranthaceæ, Aristolochiaceæ, Polygonaceæ, Chenopodiaceæ, Phytolaccaceæ, Caryophyllaceæ, Trochodendraceæ, Ranunculaceæ, Lardizabalaceæ, and some species of Berberis, nominally include 197 illustrations, but in reality contain quite 2000 figures of buds, twigs, leaves, inflorescences, flowers, fruits, and their parts. In addition, the free use of abbreviations and of small print has rendered possible the condensation into small compass of much information concerning not only diagnostic characters of species, varieties, and forms, but also concerning their nomenclature, distribution, and phenology. To illustrate the method of treatment adopted by the author, *Populus alba* may be selected from the twenty-three species of Populus considered in this work. Three varieties of this tree are sufficiently described as regards their distinctive features; figures are given of resting-buds, twigs and their transverse sections, four forms of leaves, flowers, seed, embryo, and seedling; information is tendered as to the times of flowering, of flushing of the vegetative buds, and of fruiting, also as to the germination, distribution, and age attained by this species; and finally hybrids including this species are noted. In so thorough a work it is exceedingly difficult to avoid making statements not universally applicable, but the solitary one that the reviewer has observed is to the effect that *Carpinus Betulus* has a trunk with a light grey coating of cork. The work may be strongly recommended to all engaged in the study of dicotyledonous woody plants growing in the open in this country.

PERCY GROOM.

The Cancer Problem in a Nutshell. By Robert Bell, M.D. Pp. 39. (London: Baillière, Tindall and Cox, 1904.) Price 1s. net.

DR. BELL in this pamphlet ascribes the development of malignant disease to a withdrawal of some controlling influence exerted by the thyroid gland upon the cells of the body, caused by some toxic state of the blood. He therefore advocates the administration of thyroid gland or of its active principle in the treatment of the disease, and claims to have obtained successful results. Little or no evidence is given in support of these views, and since malignant disease occasionally, though unfortunately rarely, undergoes spontaneous cure, the apparent success of any form of medical treatment has to be carefully controlled before such a result can be admitted. Dr. Bell's suggestions for the prevention of malignant disease may be of some value.

R. T. H.

Photography on Tour. Pp. 132. (London: Published for the *Photogram*, Ltd., by Dawbarn and Ward, Ltd., n.d.) Price 1s. net.

IN these pages, the sizes of which are only $3\frac{3}{4}$ inches by $4\frac{3}{4}$ inches, we have a number of useful hints and instructions which are well worth an amateur's time to read. When the photographer is away from his base, and has to invent all sorts of makeshifts, he may find many a useful wrinkle given here for which he may later be very thankful. The author seems to have brought into a very small compass a great deal of information covering a wide field, and this pocket book for the touring photographer should serve a useful purpose.

The Story without an End. From the German of Carové. By Sarah Austin. Illustrated by Paul Henry. Pp. vii + 77. (London: Duckworth and Co.) Price 1s. 6d. net.

IN this allegory a child is introduced to the beauties of plants, birds, insects, and other forms and aspects of nature. It pleases children to imagine themselves in close communion with inanimate nature, and they have no difficulty in endowing all the objects around them with human attributes. Poetic feelings, and sympathetic interest in plant and animal life, are appealed to by this daintily bound and gracefully illustrated contribution to literature.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

On the Origin of Flagellate Monads and of Fungus-germs from Minute Masses of Zooglœa.

BACTERIAL scums are exceedingly common in ditches and ponds, nature's laboratories, and it is a matter of much importance to know what goes on therein. Some light may be thrown upon this subject by making infusions or macerations from cut fragments of various plants, and then examining, at different periods, the scum or pellicle that forms on such fluids. What I have now to say will refer almost exclusively to infusions made from hay. The hay employed may be either fresh or old, but it does not do to substitute for hay mere unripe grasses. I have elsewhere shown how remarkably different are the products derivable from living unripe grasses and from ordinary hay.[1]

In making such an infusion I have been accustomed to cut the hay into short pieces, to place these in a little beaker, and then to add water so as well to cover the fragments. After maceration for three or four hours at a temperature of about 86° F. (30° C.), the infusion has been filtered through two or three layers of the finest Swedish filtering paper into another small beaker. In this way all but the smallest particles, 1/12,000 of an inch or thereabout, will be excluded. For observation of the changes now to be described it is best that the bacterial scum, which soon forms on the surface of the fluid, should be very thin, therefore the depth of the fluid ought not to be more than about one and a half inches—though if one is seeking to make out the origin of ciliated Infusoria infusions of greater depth should be employed in order that a fairly thick pellicle may form.

When such an infusion is kept under a bell-jar (to exclude dust) at a temperature of about 65° F. (18° C.), the pale sherry-coloured fluid in less than twenty-four hours becomes lighter in colour and very turbid. Soon a scum, almost invisible, begins to form on the surface, composed of several different kinds of bacteria, and in about thirty-six hours small Zooglœa masses of the most varied sizes and shapes begin to appear therein. In Fig. 1, A, a portion of such a scum is shown as it appeared at the end of the third day on a hay infusion in which the masses of Zooglœa were exceptionally numerous. The portion of this scum here represented had been transferred on the tip of a sterilised scalpel to a drop of a dilute solution of eosin, which stained the surrounding bacteria a pale red tint, but left the Zooglœa masses unstained, so that they were rendered very distinct. Had logwood been used the results would have been reversed—that is, the Zooglœa areas would have been more or less deeply stained, while the surrounding bacteria would have remained unstained.

Examination of one of these masses with a high power will show its constitution, and reveal the fact that we have to do with an aggregation of separate bacteria imbedded in a jelly-like material. This may be seen from Fig. 1, B, which shows a highly magnified portion of one of the Zooglœa masses from the same pellicle after it had been immersed in a drop of a weak solution of Ehrlich's eosinophyle fluid, which stained the surrounding bacteria a yellow tint, while it left the Zooglœa mass unstained. The slightly altered bacteria within the Zooglœa mass are at this early stage plainly to be seen, though later on they become more or less obscured by reason of progressive molecular changes taking place in the mass during its subsequent transformation.

Some of these Zooglœa masses are destined ultimately to be converted into numbers of flagellate Monads or of Amœbæ, while others become resolved into heaps of Fungus-germs. I have found it impossible to tell from the mere microscopical appearance of the Zooglœa masses whether they are destined ultimately to yield Monads or Fungus-germs. The latter transformation is undoubtedly by far the commoner of the two, and when I was working for many months at this subject during 1899 I was unable to find any good specimens, capable of being photographed, showing the conversion of Zooglœa masses into Monads, although I many times saw and photographed Monads originating from the pellicle as discrete motionless corpuscles—especially when the infusions were kept at a temperature of about 72° F. (22° C.).[1] But one day last month, on October 19, desiring to make certain observations, I made a weak infusion from a portion of a small handful of hay gathered in Norway more than two months previously, which had since been kept in a small cardboard box. The infusion was prepared and filtered in the manner already indicated, and divided into two portions: one, which we may name A, being placed in a small open beaker and left beneath a bell-jar at the end of the mantelpiece in my study; while the other (a very small portion), which we may name B, was put into a small half-ounce earthenware pot, over which the cover was placed. The two specimens of the infusion, covered and uncovered, were then left side by side beneath the bell-jar, so that the temperature to which they were exposed might be as nearly as possible similar. Some of the changes in the scums that formed on the surface of these fluids are now to be described.

Origin of Flagellate Monads from Minute Masses of Zoogloea.

A. When examined fifty-one hours after the time of filtration the scum on this infusion was found to be very thickly crowded with small masses of Zooglœa varying much in shape and actual size, as shown in Fig. 1, A.

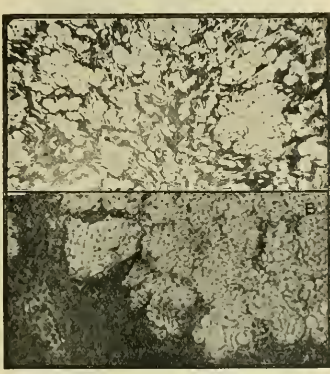

FIG. 1.—A, Zooglœa masses in the scum on a hay infusion (×100); B A portion of one of these masses showing the contained bacteria (×500)

In the course of the fourth day very many of the smallest masses were seen to be undergoing segmentation into small motionless spherical bodies, while multitudes of active flagellate Monads of the same size were for the first time seen in the fluid and in the midst of the portion of the scum under examination. When a similar examination had been made twelve hours previously not a single Monad was seen; now there were swarms of them, and all were of about the same size.

In Fig. 2, A (×500), some of these small masses are shown together with their contained bacteria; B (×375) shows a number of the small masses undergoing segmentation; while C (×700) shows one of these bodies more highly magnified, in which the segmentation into embryo Monads, still in a motionless condition, is almost complete.

In the course of the next day the Monads were found in prodigious numbers. They were spherical or ovoidal in shape, and provided with a single flagellum about twice the length of the body. Under a high power a nucleus could be distinctly seen, generally surrounded by a circle of very minute granules. In addition, two or three larger granules were to be seen—one of them, larger and more highly refractive than the others, being often present in the

[1] "Studies in Heterogenesis," p. 87 (1904).

[1] "Studies in Heterogenesis," pp. 69-73, Figs. 53-55.

posterior half of the body of the organism, and there showing faint oscillations. Numbers of the Monads that were aggregated between three small contiguous air bubbles are shown in Fig. 2, D (×125), as they appeared under a low power of the microscope. Many of them were in active

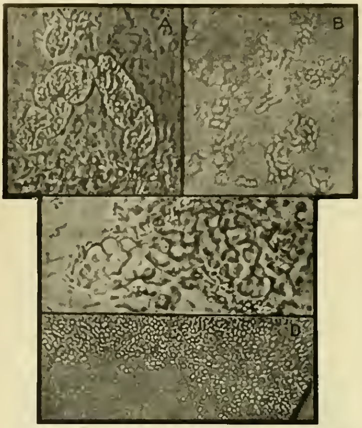

FIG. 2.—A. Small Zooglœa masses from the hay infusion (×500); B, Other of these masses undergoing segmentation (×575); C, One such mass the segmentation of which is nearly complete (×700); D, Monads derived from products of segmentation (×125).

movement and are not shown, but those that were stationary were photographed by a very brief exposure. I found it impossible to photograph these particular Monads under a high power because they were mixed up with active bacteria, and were themselves very delicate in texture. The movements of these bacteria could not be arrested except by a

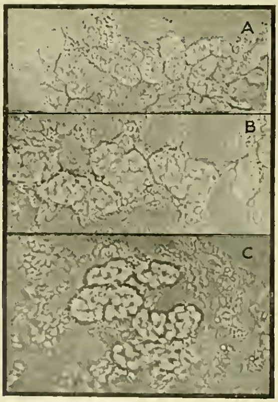

FIG. 3.—A, Portion of pellicle taken from the pot (×500); B, Small Zooglœa masses about to segment (×500); C, Small Zooglœa masses which have undergone complete segmentation (×500).

comparatively strong osmic acid solution, or by exposure to the vapour of a 1 per cent. solution for more than half a minute, and in either case the result was to make the Monads almost invisible, if it did not cause their complete diffluence.

B. The closed pot was not opened until the end of the fifth day, and I then found the surface of the infusion covered with a very thin, scarcely perceptible film of bacteria, which on microscopical examination was seen to be densely crowded with very minute Zooglœa masses such as are shown in Fig. 3, A (×500). Not a single Monad was to be seen, but many of the masses were found to be about to segment as in B, or actually segmenting as in C, into a number of motionless spherical corpuscles.

During six subsequent days I uncovered the pot for a moment to take up on the tip of a sterilised scalpel a portion of the scum for examination, and on each occasion found the minute Zooglœa masses presenting similar characters, except that day by day a rather larger number of them showed evidences of segmentation, though not a single active Monad was to be seen.

The Zooglœa masses formed in the dark, and in a comparatively airless pot, were not only different in character from those formed in the open vessel, but it would seem that their process of change was slower and was in part arrested by the opening of the pot, since after eleven days there was still not a single active Monad to be seen, though in the open vessel swarms of them were found during the fourth day.[1] This arrest of the process of change recalls the similar arrest which was always found to occur when the pot was opened in which Hydatina eggs were being transformed into ciliated Infusoria of the genus Otostoma.[2]

It so happened that on the very day that I first observed the segmentation of the small Zooglœa masses in A I had

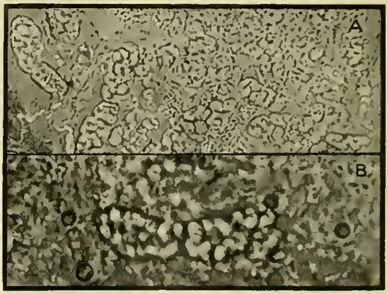

FIG. 4.—A, Minute Zooglœa masses in various stages of change (×500); B One of these masses in which segmentation has been nearly completed (×700).

on my work-table under a bell-jar a small petri dish in which a tuft of dead lichen had been soaking for a few days in distilled water. There was a very thin scum here and there on the surface of this water, and on examining a portion of it I was surprised to find that it also was crowded with small Zooglœa masses, many of which were apparently in different stages of segmentation into Monads, though the majority of them showed no signs of segmentation. Being busy with what seemed at the time to be the more important A infusion, I did not examine this new scum again until after the expiration of two days, and then I found crowds of active Monads, and all the Zooglœa masses now in different stages of segmentation such as are shown in Fig. 4, A (×500). The only portion of an unaltered mass that I could find is seen on the left hand side of this figure, contiguous to the black speck. In the two days all the small Zooglœa masses had either

[1] Examinations of the scum taken from the pot have since been made at intervals during another week and still, up to the eighteenth day, not a single Monad has been met with, though very many of the small Zooglœa masses have been found segmenting into pale brown Fungus-germs. But nine days ago (in order to test the question whether the *premature* opening of the pot had caused an arrest of the formation of Monads) I made another similar infusion from the same hay, and placed some of it in another small half-ounce pot, which was opened for the first time to-day. In the first portion of the scum obtained from this second pot I found swarms of active Monads, and also heaps of the small brown Fungus-germs resulting from the segmentation of other of the Zooglœa masses.—*November* 14.

[2] "Studies in Heterogenesis," pp. 49-51, and xiv.

become converted into Monads or altered in a more or less irregular manner. I attempted to stain some of the masses with a dilute solution of gentian violet. One of these, in which segmentation is pretty complete, is shown in B (×700), while the scattered products of another mass are

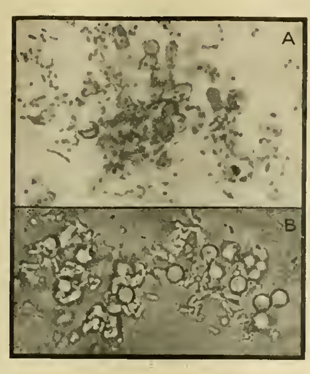

FIG. 5.—A, Products of segmentation stained, and appearing as minute spherical nucleated cells (×900); B, Monads in a resting stage (×700).

shown in Fig. 5, A (×900), after they had been lightly stained with Westphall's mastzellen fluid. In this embryonic condition the future Monads are seen as spherical nucleated cells, either single or in pairs. Some of the

FIG. 6.—A, Monads developed from Zoogloea masses in a hay infusion (×500); B, Amœbæ stained with logwood, from an egg and water emulsion (×200); C, Amœbæ originating in the scum from an egg and water emulsion (×125).

Monads which were found a few days later in a motionless, resting condition, are shown in B (×700).

On other occasions I had been a little more successful in photographing Monads produced from Zooglœa areas in a hay infusion. Thus Fig. 6, A (× 500), shows some such Monads, found on the third day, which had been developed from discrete corpuscles, and which were rendered motionless by a very weak osmic acid solution. These discrete corpuscles, as well as the motionless corpuscles derived from the segmentation of Zooglœa masses, sometimes become converted into Amœbæ rather than into Monads. What the conditions are that favour this particular change I have

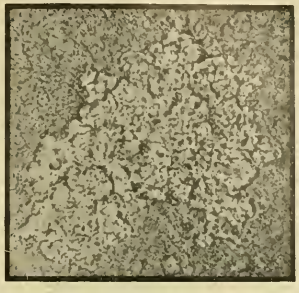

FIG. 7.—A Zooglœa mass undergoing change (×375).

been unable to ascertain, though I know that in rare cases swarms of minute Amœbæ rather than Monads appear in this way in hay infusions. The production of swarms of minute Amœbæ is, however, the rule in the pellicle that forms on an emulsion made by pouring about eight ounces of water on a teaspoonful of mixed white and yolk of egg. Such Amœbæ, slightly stained with logwood, are shown in Fig. 6, B (×200), taken from a pellicle on the seventeenth day, while in C (×125) they are seen, as I believe, originating in another egg and water emulsion on the eighteenth day, in the midst of irregular clumps of bacteria. These aggregates of bacteria had been noticed for several days, but when first observed not a single Amœba had, up to this time, been seen either in them or in the surrounding

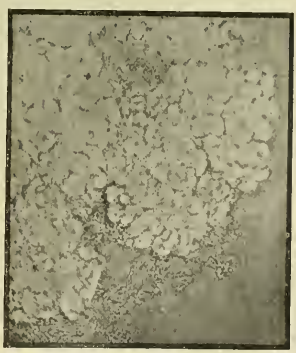

FIG. 8.—Portion of a Zooglœa mass about to segment (×500).

fluid. Then there were appearances as though changes were taking place within the aggregates, followed in two or three days by the presence of swarms of minute sluggish Amœbæ around, and issuing from, the bacterial aggregates, as shown in the figure under a low magnification.

In reference to the occurrence of these swarms of minute Amœbæ, I may say that I have never seen one of them multiply by fission, and certainly their vast numbers are not to be accounted for in this way. I make these remarks concerning Amœbæ without pretending that what I have here said in regard to them is quite conclusive, or in any way comparable to the convincing evidence above adduced concerning the heterogenetic origin of Monads from the transformation of Zooglœa masses—a transformation in which we have vegetal organisms giving rise to animal organisms of a totally different kind, though between these two forms of life no relation of kinship has ever been admitted, or even suspected, by the great majority of biologists.

Origin of Fungus-germs from Masses of Zoogloea.

It has seemed to me, as I have said, impossible to say from the mere microscopical characters of the masses of Zooglœa whether they are likely to yield Monads or Fungus-germs. It will be observed, however, that in the three cases to which I have just referred the masses giving rise to embryo Monads have all been small, and that they have tended to go through their metamorphoses with some rapidity.

It is certain, however, that the great majority of the larger Zooglœa masses tend rather to produce Fungus-germs of one or other kind, and to go through their changes at a slower rate. These statements may be illustrated by a record of the changes taking place in the larger Zooglœa masses that were found in great abundance in the pellicle forming on infusion A. These larger masses of Zooglœa, and also all the later changes which I am now about to

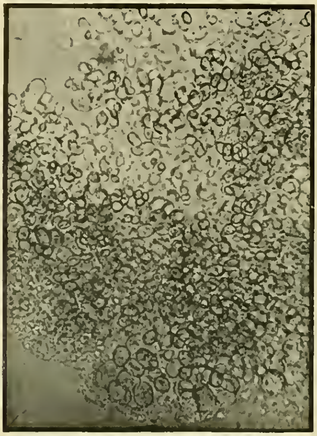

FIG. 9.—Development of small brown Fungus-germs from a mass of Zooglœa (×500).

describe, were, however, wholly absent from the pellicle on infusion B, up to the eleventh day.[1]

Where the changes occur to which I would now direct attention the Zooglœa masses gradually become larger and much more refractive, while they also stain much more deeply with logwood, gentian violet, or other of the aniline dyes. At the same time the constituent bacteria, which are so very distinct in the early stages, seem to become enlarged and gradually more or less hidden as the molecular changes taking place in the mass increase. One of these aggregates in this refractive, glistening stage, which was found and photographed on the fifth day, is shown in Fig. 7 (×375).

The next stage of change is revealed by distinct indications of segmentation beginning to show themselves through the mass, such as may be seen in Fig. 8 (×500), which represents a portion of a large Zooglœa mass that was found on the sixth day. This condition may persist for several days, but occasionally further changes occur rapidly, as may be seen by Fig. 9 (×500), showing a portion of another large Zooglœa mass found on the seventh day, in which minute ovoid germs of different sizes are separating from the mass, and at the same time assuming a brown colour. This change was proceeding more rapidly at the edge of the mass; but further in, as may be seen in the upper portion of the figure, the mass shows more of the appearance to be seen in Fig. 8. Although the germs seem to separate from the metamorphosed Zooglœa mass as bodies of varying size, I think there can be no doubt that some of the separate units subsequently increase distinctly in

FIG. 10.—A portion of the brown mycelium (×125).

size—though whether they undergo segmentation is not so clear. On the following day numerous heaps of brown Fungus-germs were found derived from these Zooglœa masses, forming clusters so thick and dense that their constituents could only be shown by pressing upon the cover glass firmly and thus breaking up the masses of germs. Portions of such a broken up mass are represented in Fig. 11, A (×500).

As a rule, these bodies show little tendency to germinate,

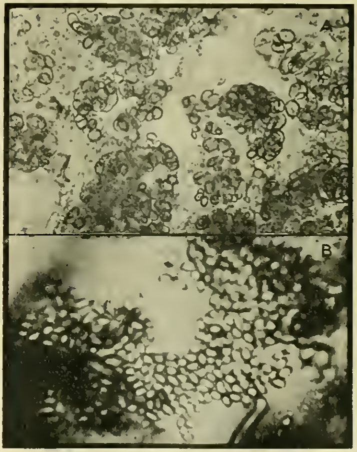

FIG. 11.—A, Heterogenetic Fungus germs (×500); B, Acrospores produced from the mycelium (×500).

but occasionally they do so, and two or three masses of mycelium to which they had given rise (also of a brown colour) were found on the eighth day. One of them had sent a hypha above the surface, and there produced a great number of ovoid acrospores having a bluish-black appearance. Some of the mycelium is shown in Fig. 10 (×125), while the acrospores are represented in Fig. 11, B (×500)

[1] See note on p. 78.

It will be noted that the acrospores are comparatively uniform in size, and are wholly different from the extremely variable brown Fungus-germs produced from the Zooglœa masses.

What has just been illustrated is only one of the ways in which Fungus-germs are produced in the pellicle from Zooglœa masses. Anyone working at this subject will have no difficulty in recognising many other modes in which they originate. Sometimes the germs separate from the Zooglœa masses as colourless units, and then take on an almost black colour before they begin to germinate, as in the specimen shown in Fig. 12, which was taken on the twelfth day from another pellicle on a hay infusion.

I have frequently found that these heterogenetic Fungus-germs are small ovoid bodies with one, or sometimes two, nuclear particles such as may be seen in this case, and also in some of the small brown units shown in Fig. 9. It is interesting, moreover, to find that the immediate products of segmentation which are about to develop into flagellate Monads present, except for their spherical shape, very similar characters, as may be seen by reference to Fig. 5, A.

It seems to me impossible to doubt that we have in the processes which I have just described definite instances of heterogenesis. The fact of the individualisation and the segmentation of these Zooglœa masses cannot be denied. It is plain, indeed, that from such aggregates of bacteria, by common consent regarded as belonging to the vegetal kingdom, we have the production of typical animal organisms, and that, as I have said, no kinship between

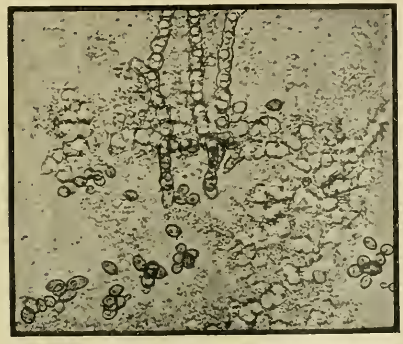

FIG. 12.—Heterogenetic Fungus germs becoming black and germinating (×500).

bacteria and flagellate Monads has ever been recognised, or even suspected, by the great majority of biologists; and, though it cannot be said that there is the same lack of kinship between bacteria and Moulds, it can certainly be said that the majority of biologists have never suspected any such relation between these two forms of life as that which has now been made known.

I care little what names may be given to the bacteria, though I am certain that many different varieties are prone to form zooglœal aggregates, and to go through one or other variety of such changes as have just been described. Being much interested with these processes that go on in nature, and under more or less natural conditions, I have been familiar with such phenomena for more than a generation[1]; but although they were made known so long ago I am not aware that any bacteriologist in Europe, America or elsewhere has ever repeated my observations. Bacteriologists to whom I have personally mentioned the subject have, with only one exception, shown not the least desire to examine specimens or to follow up the inquiry. They seem wedded to their strict laboratory methods, and seemingly prefer to have dealings with nothing but pure cultures and sterilised media. I do not deny for a moment the enormous increase of knowledge, and the benefit which has accrued to the human race, from their studies, but should like to see a little more toleration displayed for those who prefer to work in a different way, and strive to find out what goes on under more natural conditions—undeterred by the much talked of but much over-rated risk of "infection." Assuredly, in the future, much of what is now ascribed to "infection" will be differently regarded as the "origin of species" by heterogenesis becomes more and more known.

If such processes as have just been described are continually going on in nature, but are not to be met with in the laboratories of bacteriologists, it should make us hesitate to repudiate a natural origin of living matter at the present day simply because undoubted proof of its occurrence cannot be produced by laboratory experiments. If it occurred in the past the law of Continuity would lead us to expect that it has been continually occurring ever since, and, as I said in my letter of November 10, "if the origin of living matter takes place by the generation in suitable fluids of the minutest particles gradually appearing from the region of the invisible, such a process may be occurring everywhere in nature's laboratories, though altogether beyond the ken of man."

H. CHARLTON BASTIAN.

The Temperature of Meteorites.

DURING the early part of the year 1901, when I was on the staff of the Elswick Works, it occurred to me that it would be useful and interesting if a connection could be made between the conditions of the flight of artillery shells and of meteorites. Later in the same year I made a preliminary mathematical investigation into the matter, and as a result a paper on the temperature of meteorites was sent in as an essay to compete for the Smith prizes at Cambridge. It was distinguished from other essays sent up in not receiving a prize.

It has since remained a strong wish on my part some day to work up the subject into a form fit for presentation to a scientific society, but the pressure of other matters has prevented this. In order, therefore, to preserve at least its outlines, I give here a brief exposition of the premises, the procedure, and the conclusions of the essay.

Ordinary ballistic tables contain a wealth of information as to the retardation experienced by projectiles of all sizes and of one general shape. The shape of the shell is well known. If the same rules can be made to fit the motion of meteorites it is clear that the velocity at any time can be obtained, and thence the loss of energy due to the obstruction caused by the air. This energy reappears as heat, sound, electrical energy, chemical energy, &c. Of these by far the most important is heat. Thus the conditions under which a meteorite "heats up" can be ascertained, and if it be assumed that all the energy is so spent, it is obvious that a superior limit to the resulting temperature may be obtained. One further point should, however, be mentioned—a meteor which reaches the earth is called a "meteorite," and the velocity necessary for this is such that the time of passage through the material part of the earth's atmosphere is so short, say five seconds, that chemical burning will not, in general, introduce any sensible error. Such error as might be introduced would be of the opposite sense to radiation losses, themselves small for much the same reason.

Meteorites may be of almost any shape. I have only considered the shell shape, as it is the only one the flight of which has been thoroughly investigated by exhaustive experiment.

According to Ingall's "Exterior Ballistics," the law of the resistance of the air is a function of the velocity which, for velocities above 1380 feet per second, is the velocity squared. For meteoric problems, velocities less than this are unimportant. Whether this simple law would hold good for velocities of, say, 20 miles a second, or even the 7 miles a second which the earth can impose, is not known, but for lack of a better it has been necessary to employ it.

The next difficulty, and of difficulties there is no small number, lies in the varying density of the air. A few thousand feet is the upward limit of ordinary projectiles. Even for howitzer shell the correction for rarefaction is so slight that the simplest kind of correction is enough. For meteorites, however, more extended treatment is required. I have taken the resistance to be in direct proportion to the density of the air. To do even this requires a knowledge of the density at all altitudes, and for this I have assumed an isothermal distribution of temperature. The theory of adiabatic distribution makes the atmosphere cease at distances well within twilight and meteor phenomena, and is therefore of no use. Probably something between these two would be most accurate, but its precise form is not of great importance in this investigation owing to the very slight influence of the uppermost reaches of the air on the motion of meteorites.

I now come to the meteorites themselves. Many sizes have been considered, but chiefly diameters of 0·10 inch and 12·0 inches. I refer to these as the "small" and the "large" meteorites. When other sizes are mentioned their diameters are given. I have further taken two materials, viz. iron and stone (trap rock), representing holosiderites and asiderites. The thermal constants for the materials are those found by Forbes.

I stated above the circumstances in which a knowledge of the heat energy given to the meteorite might be taken to be known. To find the temperature distribution in the *interior* of the iron or stone I have adopted the approximation of considering the meteorite to be cylindrical, and then utilising ordinary cylindrical coordinates. During the investigation a good many results were obtained which indicated methods by which the simple labour of the work could be lightened. Some of the more cumbersome expressions could be simplified by dividing the distance between the earth's surface and infinity into two regions, that within the sensible effect of the atmosphere and that without.

Many results were obtained during the investigation. In the large meteorite it was found that for all velocities of approach the temperature at the centre was a most minute fraction of that at the surface. For the small meteorite it was found that the final velocity was always very small and the time of flight correspondingly great, with the result that the whole of the material would be consumed before reaching the earth's surface—this would then properly be termed a meteor, not a meteorite. In its turn this consideration gives the altitude at which incandescence would occur. The small iron meteor would burst into brilliance at 45 miles up, and the stone one at 68 miles. To obtain a superior limit to the point of incandescence I assumed a meteor the diameter of which was only a millionth of an inch. For iron, brilliancy is obtained at 106 miles, and for stone at 129 miles. These figures are obtained by assuming the meteors to have the maximum velocity which the earth could impose. If, however, an initial velocity of 250 miles per second be assumed, surely a superior limit, incandescence would occur some 35 or 40 miles further off, so that the greatest height for visibility would lie well within some 170 miles.

An iron meteorite 3 inches in diameter falling to the earth from an infinite distance would begin to get warm about nine seconds before reaching the earth, and continue to increase in temperature for about seven seconds, after which its velocity would be practically "killed," and two seconds later it would reach the earth at about two-thirds of a mile per second. This represents a typical case for what might be termed the "twelve pound shell" size.

In the "twelve pound shell" size the internal temperature falls off very rapidly towards the interior. Thus, taking the mean temperature in the severest case as 1·00, the surface temperature was 2·2, and at a depth equal to a fifth of the radius (0·30 inch) the temperature was about 0·3 only, whilst at the centre it was 0·0016. So that for the most excessive surface temperatures the central temperature would be well below the temperature of liquid air, assuming, of course, that the initial temperature of the meteorite is at the absolute zero.

The steepness of the heat gradient at or near the surface is the probable cause of the nodular appearance of meteorites. Great resistance to the inward flow of heat would be offered by any internal veining, and as a result such surfaces of separation would tend to become the limiting surfaces for any burning which might occur.

The various formulæ used to obtain the above results were suited to a subsidiary investigation, viz. that of the problems connected with the ejection of rock from terrestrial volcanoes. The results of such an investigation may be briefly summarised as follows:—Had the earth no atmosphere all masses shot off vertically at 7 miles a second and over would fail to return. With the existing atmosphere the large meteorite would require a velocity of 13 miles per second, and the "twelve pound shell" would want a velocity of 78 miles per second. These velocities are not without interest in view of the theory that meteorites originated from terrestrial volcanoes. Smaller velocities would suffice were the masses discharged from high altitudes. Thus, from a height of 5 miles, the velocity for the large iron meteorite would be only $8\frac{3}{4}$ miles per second, and for the "twelve pound shell" only 18 miles a second. Further calculation shows that with an initial velocity of 7 miles a second the large meteorite would rise to only some 120 miles, and the "twelve pound shell" to between 40 and 50 miles, and both would then fall back to the earth.

In conclusion, the result of the investigation may be said to have created a strong presumption in favour of the following general deductions:—

(*a*) That the velocities of meteorites are materially changed by the resistance of the atmosphere, and, in general, by a fractional part of the velocity which is independent of the velocity of approach.

(*b*) That the superior limit for incandescence is probably about 150 miles above the earth's surface.

(*c*) That no iron meteor the original weight of which was less than 10 to 20 lb. reaches the earth's surface, and that when a meteor does do so the temperature of its centre is not in general above that of liquid air (assuming the temperature of space to be zero).

I am aware that the whole structure of the investigation rests on the evil principle of extrapolation, but until man is capable of experimenting with velocities of 10 or 20 miles a second, and surviving thereafter to record his results, no other manner of investigation seems possible.

London, November 13. H. E. Wimperis.

Mount Everest: the Story of a Controversy.

I have read with interest in your columns under this title a carefully compiled and instructive account of the discussions that have from time to time during the past fifty years broken out with regard to the naming of the highest measured point on the earth's surface, Peak XV of the Indian Survey.

I have long maintained it to be a matter for regret that the monarch of mountains should be called after any individual, however eminent, and I am still of this opinion, which is shared by most mountaineers and mountain lovers. We should prefer that Peak XV should bear a Nepalese or a Tibetan name, even had one to be invented for it, as twenty years ago Alpine Clubmen, in accord with Russian surveyors, found or invented native names for many of the great peaks of the Caucasus.

But, since your correspondent appeals to me not to prolong the controversy further, I must remind him that the opinion I have expressed is an individual and not an official opinion. For ten years I have had no official connection with the Royal Geographical Society.

Should the council of that body resolve that, considering the length of time the title "Mount Everest" has been more or less in use in this country for Peak XV, the absence of any evidence that that individual peak is designated as, or included in the designation of, Gaurisankar by the Nepalese, and the practical inconvenience (whether the name be authentic or not) of introducing a new Tibetan name such as Chomo- or Jamokangkar, it is expedient that the title Mount Everest should be generally accepted, I shall acquiesce. For I attach greater importance to the general principle than to the particular case, and I believe the protracted discussion and many protests summarised in your columns have served their purpose in helping to discourage the practice of giving personal names to mountains.

I should add that foreign geographers are not, as your correspondent suggests, mainly dependent on the *Geographical Journal* for information in this matter. Captain Wood's report has been noticed in that well known periodical *Petermann's Mitteilungen*.

Douglas W. Freshfield.

Observations of the Leonid Meteors, 1904.

Observations by the writer this year go to show that the intensity was much below that of last. Briefly, the nights of November 12 and 13 were heavily overcast, but the night of November 14 and early morning of November 15 were fortunately clear. The display lasted about an hour, say from 12.30 until 1.30 a.m., maximum 1 o'clock a.m. (local times), hourly rate, low, 20 to 25. Bright meteors, however, continued to appear at intervals up to 3 a.m., when clouds coming on stopped further observation. A couple of hours' watch before and after midnight of November 15 gave only two Leonids, while another two hours' watch on the night of November 16 showed the radiant, which was sharply defined the previous nights, at $150° + 23°$, near Zeta, to be quite quiescent. Other radiants active were :—

	R.A. Dec.	
	° °	
(1) Leonids (No. 2) ...	165 + 25 ...	Strong, bright.
(2) Ursids	155 + 47 ...	,, ,,
(3) Præsepids	125 + 20 ...	Slow, small, wiry.
(4) Cancrids	130 + 5 ...	Short, bright.
(5) Geminids	108 + 28 ...	(One) short, bright.

It would be interesting to hear of observations made during the hour or so before daybreak on the morning of November 15, as it is just possible the increased intensity noticed in previous years may not be real, but due rather to the fact of the radiant being near the meridian, and the smaller meteors coming down more direct at that time are the better able to penetrate to the lower layers of the atmosphere.

The Discovery of Argon.

In your translation of Prof. Mendeléeff's interesting paper on the chemical elements (November 17, p. 94) I see that he attributes the discovery of argon and its congeners to Ramsay. Am I not right in believing that it was Lord Rayleigh who discovered argon, and that it was he who gave that impulse to chemistry which Sir William Ramsay has carried forward to such remarkable results?

November 20. G. H. Darwin.

Blue-stained Flints.

Some years ago there were many blue-stained flints on a road near Cambridge. Lime from gas-works was about to be mixed with the flints used as road-metal, and the two different materials had lain for some time in heaps by the roadside. The blue colour, in some instances very intense, was developed wherever a heap of flints and one of lime touched each other; from which I surmised that the calcium sulphide of the gas-lime had reacted with an aluminium compound present in the flints, producing a substance akin to ultramarine.

Cambridge, November 19.

Inheritance of Acquired Characteristics.

It may be worth noting that since my letter to you of some months back, in which I gave an instance of fox-terrier pups being born with short tails, I have heard of two similar cases. In one of these cases the dog was owned by one of the managers of the Rhodes' Fruit Farms, near Cape Town. The other case occurred in the Transvaal at Sabi, one out of a litter of four being born with a short tail.

DR. KOENIG'S METHOD OF COLOUR PHOTOGRAPHY.

In the methods of three-colour photography hitherto practised the colours are used as inks, stains, or pigments already prepared, and their distribution is effected indirectly by the action of light. In the imbibition process three thin gelatin reliefs are prepared (using potassium bichromate to sensitise the gelatin), and after each relief is stained with its appropriate colour the three films are superposed. The method recently described by Dr. Koenig is of the multiple film kind, but the colours are produced by direct exposure to light.

Many organic colouring matters yield by reduction colourless bodies that are more or less easily re-oxidised with the production of the original colours. The oxidation of these leuco colouring matters is generally if not always quickened by light. If, therefore, the leuco-compound produced from a dye of a suitable red colour is caused to impregnate a film, and this is exposed beneath the negative made to give the red image in three-colour work, the red image may be produced by direct exposure to light. A similar procedure will of course give the yellow and blue images, and so the complete colour print may be obtained. Such are the general principles upon which Dr. Koenig's process depends, but to elaborate the details of a successful process on these lines it was necessary to overcome many practical difficulties.

It was necessary, in the first case, to select only those dyes (of suitable colours, of course) that yield leuco-derivatives of sufficient stability to stand the necessary manipulations. Then it was found that the leuco-bases selected as otherwise suitable gave but a feeble image even after long exposure; but it was observed that when collodion was used as the medium the sensitiveness was greatly enhanced, and the vigour of the image very much improved. This improvement was traced to the action of the nitrocellulose, and other nitric acid esters were found to have a still greater effect. Nitromannite especially is useful for sensitising purposes. Dr. Koenig emphasises the fact that the leuco-bases in an inert film are useless, as the action of aërial oxygen, when it has reached its maximum, gives only a flat and feeble image.

The fixing of the image was the next difficulty, for obviously it is necessary to remove the excess of the leuco-body without interfering with its coloured oxidation product. It is well known that many dyes show a great tendency to remain attached to a fabric or film in spite of the application of solvents, but the leuco-bases employed also have a similar tendency. Dilute mineral acids, though they dissolve the greater number of the leuco-bases, would not remove them from collodion films. A 10 per cent. solution of monochloracetic acid was found to be the best fixing agent.

The various solutions required are supplied ready for use, and the following summary of the instructions issued with them will give a general idea of the manipulation required. A piece of baryta coated paper rather larger than the negative has its edges turned up, and is coated with a $1\frac{1}{2}$ per cent. collodion to which has been added the leuco-derivative of the blue dye and a solution containing the necessary additions. When dry it is exposed under the appropriate negative (for, say, twenty to forty seconds in bright sunshine), soaked in the fixing bath for a few minutes, washed for a few minutes, dipped into a gelatin solution that contains a little chrome alum, and hung up to dry. The print is then turned so that its lower edge shall be uppermost, again dipped into the gelatin solution, and again allowed to dry. The gelatin coating is applied to isolate the collodion film so that it may not be interfered with by the application of the second collodion. The print is then coated with collodion to which the materials for the blue image have been added, exposed under the proper negative, fixed, and coated twice with gelatin as before. A similar procedure follows for the yellow image, and after the final gelatin coating it is well to varnish the print. It is claimed for the dyes employed that the blue, which is the one most liable to change, is more permanent than Prussian blue.

THE NEW WHALE FISHERIES.[1]

IN the story of the rise and fall of the whale fisheries history has many times repeated herself. The Basque fishery, the oldest of all, the fragmentary records of which go back beyond the middle ages, which extended centuries ago to the other side of the Atlantic, which long furnished harpooners to our own fleet, and which has left us the harpoon and its name, finally passed away during last century with a practical extinction of the object of its pursuit. Our own Greenland, or right whale, fishery, in which for one hundred years some 250 vessels were employed, hailing from almost every east coast port, has been now for nearly another century on the decline, and some half dozen whalers from Dundee are all that is left of the once great argosy. A few fine old American ships, with dark-skinned harpooneers from the Cape Verdes, still chase the sperm whale throughout its world-wide habitat, in place of the 700 sail that followed the business sixty years ago. Zorgdräger, Scoresby, Scammon, and a host of lesser men have left us records of these old fisheries, of the methods employed, and of the marvellous success achieved; but, nevertheless, the naturalist has much to regret in the passing away of these great industries, in the near approach to extermination of the most valuable and most interesting species, and in the scantiness of the material that has as yet been saved. Our chief museum contains, I believe, neither skeleton nor even skull of the Greenland whale, and the difficulties in the way of procuring one now-a-days seem to be very great indeed. We have to go to Stockholm or St. Petersburg to see the entire skeleton of such a whale, with the huge fringes of whale-bone still in place in the jaws. Nor, by the way, would our knowledge seem to be more adequate than our anatomical material, for a writer in a standard text-book told us only the other day that a single whale may yield us "several tons" of whale-bone!

While the fisheries before mentioned, and others like to them, are passing or have passed away, a new fishery has sprung up that has for the object of its pursuit a class of whales that formerly had been left in peace. This is the fishery for the great rorquals, or finner whales, first instituted by Captain Svend Foyn at Vadsö in 1864. The fishery is carried on by means of small steamers, carrying at their bows a harpoon gun which discharges a line and explosive bullet. The steamer tows the fish home, to be flensed and worked up in the factory ashore. Twenty years after Svend Foyn's small beginning there were more than thirty such factories on the coasts of Finmark, but all of these have very recently been disestablished by the Norwegian Government, which, in deference to temporary and local prejudice, is robbing its country of a profitable and ill-spared industry. The great success and profit of this fishery has led to its extension to Iceland, Færöe, Newfoundland, and lastly, to Shetland and the Hebrides; but it is still almost wholly in Norwegian hands, and a factory at Tonsberg enjoys a practical monopoly of the machinery employed.

One consequence of the growth of this new industry has been to impress upon us, or to remind us of, the fact that at least certain species of whales exist in their native seas in prodigious numbers, seldom though the occasional traveller has the luck to see them. Once, in the North Pacific, on a calm summer's day, I saw for an hour the ship surrounded on every side by great whales to the number of many hundreds, and a somewhat similar display is said to have been witnessed to the north of Shetland during the past summer. Dr. Hjort calculates that from the beginning until 1901 the finner whale fishery resulted in the capture of some 27,000 fish, a vast number in itself, though not great in comparison to the yield of the Arctic fishery in its palmy days, for the Dutch alone are reckoned to have taken no less than about 575,900 Greenland whales and "Nordkapers" or Biscayan whales, between 1669 and 1778. Probably long lived, but certainly slow breeding, the whale must in the end give way before a wholesale persecution; but meanwhile several species are still immensely numerous, and the naturalist has at least the consolation that pursuit tends to cease as scarcity becomes manifest, and long before actual extermination is achieved.

FIG. 1.—The Common Rorqual, Snook's Arm, Newfoundland.

The new industry has many attractions and opportunities for the naturalist. The stations are in many cases within reach of easy travel, and the manner in which the carcases are drawn up for flensing on the shore affords a perfect spectacle of the entire creature. The volume which has suggested the present article, by Dr. F. W. True, of the U.S. National Museum, is the outcome of a careful use of the opportunities afforded by the Newfoundland whaling stations, supplemented by abundant use of literature and study in American museums. Dr. True, who is already well known as a student of the Cetacea, seems to have made it his first object to investigate the specific characters of the larger whales, with the exception of the Greenland whale, and to determine, once for all, whether specimens of the various forms from the two sides of the Atlantic be specifically identical.

[1] "The Whalebone Whales of the Western North Atlantic." By Frederick W. True. (Smithsonian Contributions to Knowledge.) Pp. iv+332, and plates. (Washington: Smithsonian Institution, 1904.)

This question is answered, in general, in the affirmative, with some reservation as to the possible existence of varietal or subspecific differences in the case of the humpback, Megaptera, and the lesser piked whale, *Balaenoptera rostrata*, or *acutorostrata*, as our author, following Lacépède, prefers to call it. Furthermore, additional evidence is adduced in support of the identity of the North Pacific species with those of the North Atlantic. This conclusion is entirely confirmatory of the views of European naturalists, and Dr. True's remarks on the distribution of the various forms deserve to be read in connection with Dr. Guldberg's recent very interesting papers on the probable course of the annual migrations of several species around the circuit of the North Atlantic.

But Dr. True has given us other things besides a careful account of specific characters. He has given us, in the first place, a singularly interesting epitome of the early history of whaling in America, downwards from the mythical days of the Saga of Thorfinn. It will be news to the citizens of New York that, in the seventeenth and eighteenth centuries, there was a not unimportant whale fishery on Long Island and in Delaware Bay, and that so late as 1823 (?) there was a family on Long Beach, N.J., who every winter sought for and "sometimes captured" whales, in which business they had been engaged, father and sons, ever since the Revolution. In the next place, and of still more popular interest, Dr. True has enriched his book with fifty large plates, for the most part taken directly from photographs, of whales as they lay on the beach at the Newfoundland factories. A few similar photographs have recently appeared from Norwegian and Scottish sources, but no such excellent and comprehensive series as Dr. True's has yet been made, though, by the way, one series of *B. musculus*, published about twenty years ago by M. Yves Delage, could scarcely be surpassed.

Five or six species of whales are obtained, more or less abundantly, at the various whaling stations. These are the great "sulphur-bottom," or Sibbald's rorqual, the blue whale of the Norwegians, which, rare on our own coasts, is the chief source of profit to the Icelandic and Newfoundland whalers; secondly, the common rorqual; thirdly, Rudolphi's rorqual, the Seihval of the Norwegians, which seems to be rare on the other side of the Atlantic, but which in certain years has bulked very largely in the Finmark catch; lastly, the humpback, Megaptera. Besides these a sperm whale is caught every now and then, and the Icelanders still take an occasional Nordkaper, or Biscayan whale. Thus the "finner" industry furnishes not only a large number of individuals, but a great variety of species to the observation of the naturalist. Several curious points crop up in regard to the relative commercial value of the several forms. Thus, for instance, Rudolphi's whale, a species very similar to the common rorqual, long overlooked and afterwards considered very rare by naturalists, is now a most valuable element in the fishery, its whale-bone, though no bigger and longer than that of the common species, being worth, from its intrinsic quality, just about ten times as much.

Dr. True's photographs show us, with a wealth of illustration, Sibbald's whale, the common rorqual, the humpback, and the Nordkaper as they lie upon the beach. Many interesting points are excellently well shown the distribution of colour, the curious pleatings of the ventral skin, the contrast in form between the long, slender, lanky Sibbald's whale and the shorter, stouter body of the common species, the tubercles on the head of Megaptera, the huge flippers with their garniture of barnacles in the same species.

Fig. 2.—The Humpback, Balena Station, Newfoundland.

It is a common practice of American naturalists, and Dr. True is no exception, to deal somewhat harshly with received nomenclature in the quest after "priority." Rightly or wrongly, the common rorqual is invariably known to us as *B. musculus*, but that name is here transferred to what we call *B. sibbaldii*; the former is here designated *B. physalus*, L., and *B. biscayensis* figures as *B. glacialis*, Bonnaterre. The work as a whole does not lend itself to epitomisation, and the foregoing brief account does not do justice to its scientific interest.

D. W. T.

NOTES.

The directors of the Ben Nevis Observatories, which were closed on October 1, have just issued a circular describing the circumstances in which these observatories have at last been discontinued. The maintenance of the two stations at Fort William and on the summit of Ben Nevis has involved an average yearly expenditure of 1000*l*. Of this sum, 350*l*. has been supplied by the Meteorological Council, and the remainder has been obtained from various private sources. It was hoped that the Treasury Committee which was appointed to consider the question of the annual grant to the Meteorological Council would deal adequately with the position of the Ben Nevis Observatories in its report, but in their circular the directors express disappointment that this was not done. The directors remark:—"Some of their number, including the two secretaries, were examined, and fully stated their case, besides handing in detailed memoranda regarding the history, work, and cost of maintenance of the observatories. Yet, with all this information before them, the committee state in their report that 'it appears that only 350*l*. per annum is required to ensure the continued maintenance of the observatories.' The directors lost no time in calling the attention of the First Lord of the Treasury to this 'inexplicably erroneous' statement, and in appealing to him that means should be found to prevent the abandonment of the observatories. The Treasury, however, could not see its way to any further increase of the contribution from the Parliamentary Grant, but offered to continue the allowance of 350*l.* a year hitherto received from the Meteorological Council. As this arrangement would have left the directors exactly where they were before, face to face with the impossibility of continuing to raise 650*l.* every year, and with the obvious hopelessness of obtaining adequate pecuniary support from the Government, there was no alternative but to close the observatories."

IT is announced in the *Times* that a donor, who desires to remain anonymous, has placed a sum of 1000*l.* in the hands of the treasurer of the Royal Society, to be devoted to the advancement of science. By his wish 500*l.* of this gift is to be placed to the credit of the "Catalogue of Scientific Papers Account" of the Royal Society, and the remainder to the credit of the "National Physical Laboratory Account" of that body, with the request that the executive committee of the laboratory will accede to any personal wish of the director as to its expenditure.

A STRONG, detailed indictment of the department of the War Office which should be responsible for the production of necessary maps appeared in Saturday's *Times* from the military correspondent of that journal. The war in the Far East has lasted now for nearly nine months, and not a single map of the seat of war has been issued by the Government department which is the chief recipient of the results of our geographical research. The vexatious thing is that the information, even the maps, exist, but that no endeavour has been made to utilise them for the public benefit. The Russian and Japanese Staff maps of Manchuria exist in London, but neither map can be purchased by the public through the trade, though, as both are in the hands of individuals in London, and whole sheets of the Japanese map have been reproduced by the Japanese Press, the presumption is that the mapping section of the director of military operations also stands possessed of them. A map intended to be of use to the public must be a compilation of these and other materials; but no such map has been issued officially at all. The only excuse for this deplorable want of sense is the lack of staff and of time to produce the map for which there is a public demand. In this case nothing could be simpler than to provide some house in the trade with the information available, and allow suitable maps to be produced by private enterprise. Our official maps are, the article affirms, nothing less than a national disgrace. Not only all the Great Powers, but even those of the second and third rank, are infinitely superior in cartography. These facts are then employed to direct attention to the whole question of the teaching of geography, and to warn us of a serious defect in our system of national education. We have suffered in the conduct of military operations because the teaching of geography has not assumed its proper place in the education of our army officers.

THE death is announced of Dr. Karl H. Huppert, emeritus professor of physiological chemistry in the University of Prague, at seventy-two years of age.

THE scientific committee of the Royal Horticultural Society met recently and received with regret the resignation of Prof. Henslow, who for more than a quarter of a century has acted as its secretary. Mr. F. J. Chittenden, who has been for some time a member of the scientific committee of the society, has undertaken to discharge the duties of secretary until the end of the current session.

IT is stated by the *Pioneer Mail* that the Burma Government has decided to discontinue the experiments for the improvement of the indigenous silk industry in the more important silk centres of the Province by the importation of silkworm eggs from France. Owing to climatic and other causes, rearing has failed with foreign imported eggs, and it is not considered worth while pursuing the experiments without the aid of an expert.

MR. J. N. HALBERT has been appointed assistant in the Dublin Museum in succession to Mr. G. H. Carpenter, who held the post for many years. Mr. Halbert is known as the author, in collaboration with the Rev. W. F. Johnson, of a list of the beetles of Ireland (*Proc.* R. I. Acad.). He has also published some papers in the *Zoologischer Anzeiger* and the *Annals and Magazine of Natural History*, on freshwater mites.

THE applications for space in the forthcoming automobile exhibition at Paris on December 4 far exceed the space available in the Grand Palace of Fine Arts, so it may be necessary to hold the exhibition at the Galerie des Machines. One of the curiosities of the exhibition will be the *Lebaudy II.* exhibited in a reduced model. To November 18 the Lebaudy dirigible balloon had executed not less than fifty-four ascents, and on the fifty-first the return to the Moisson Aërodrome, the starting point, was accomplished. From the last day of October to November 18 ten ascents were successfully executed.

THE first meeting of the annual session of the German Society of Naval Architects was held at the Technical High School at Charlottenburg on November 17. The Emperor William, the honorary president of the society, the Grand Duke of Oldenburg, the Secretary of State for the Imperial Navy, Admiral von Tirpitz, and the secretary of the British Institution of Naval Architects were present. Prof. Ahlborn, of Hamburg, read a paper on the spiral formation of water under the action of a ship's screw, and on the movements produced in the water by the revolution of the screw; and Prof. Braun, of Strassburg, dealt with the methods and aims of wireless telegraphy.

THE *Journal* of the Society of Arts states that among the congresses arranged in connection with the Liège International Exhibition of next year, and with which the cooperation of the Belgian Government is ensured, one on chemistry and pharmacy, convoked by the Belgian Chemical Society and the Liège Pharmaceutical Association, will be held at the end of July. The congress is to be divided into the following sections:—(1) general chemistry, physicochemistry; (2) analytical chemistry, apparatus and instruments; (3) industrial mineral chemistry, including metallurgy; (4) industrial organic chemistry (sugar-boiling, fermentation, tanning, dyeing, &c.); (5) pharmaceutical chemistry; (6) the chemistry of food substances; (7) agricultural chemistry, manures; (8) biological and physiological chemistry (application to hygiene and bacteriology); (9) toxicology; (10) practical pharmacy; and (11) legislation and professional interests, deonthology. The president of the organising committee is Prof. A. Gilkinet, of Liège.

A CONFERENCE on physical education was held on November 16 at the Education Offices of the London County Council, the Bishop of Bristol presiding. Miss Johnson, of the Swedish Institute, Clifton, advocated the organisation of physical education on the lines of the Royal Central Institute of Sweden, which she described. Sir W. Church, president of the Royal College of Physicians, moved a resolution to the effect that it is desirable that a national system of physical education should be established in the United Kingdom. This was seconded by Sir Lauder Brunton, and supported by other speakers, including Lord Londonderry and Sir W. Broadbent. The *Times* of November 17, in a leading article on the subject of the conference, while acknowledging our supineness in this respect in the past, rightly deprecates any hasty action in the matter, and remarks that while Swedish and other systems have their merits, what we want here is not a system borrowed from Sweden, Denmark, or Japan, but a British system growing out of the British character, and suited, as no borrowed system can ever be, to British needs, and considers that we must begin with the children in our elementary schools.

IN the *Times* of November 17 appeared a letter stating that skulls and limb-bones of horses of known pedigree, no matter what their breed, are required by the natural history branch of the British Museum, and the cooperation of horse-owners is invited in the endeavour to bring together a large series of such specimens. No mention is made in the letter of the special purpose for which a collection of this nature is required. Those who have kept abreast of zoological literature for the last year or two will, however, have scarcely failed to notice how much attention has been directed by naturalists to the problem of the origin of the various breeds of domesticated horses, and especially to the idea that thoroughbreds and Arabs have a different parentage from the "cold-blooded" horses of western Europe. The circumstance that some horses of eastern origin show a vestige of the cavity for the "tear-gland" of the hipparions has been recently brought to notice as an important factor in the problem. To ascertain the frequency of this feature is probably one of the objects of making the collection, while a second may be to ascertain the constancy of certain proportionate relations between the limb-bones of racers and cart-horses. The museum already possesses the skeleton of "Stockwell," from whom are descended most of our best thoroughbreds, and likewise the skull of "Bend Or," presented by the Duke of Westminster, and Mr. W. S. Blunt has promised a skull of one of his famous Arabs.

WE have received from Messrs. Friedlander, Berlin, a catalogue of books on comparative anatomy, which is divided into three sections, the first dealing with vertebrates and the second with invertebrates, while the third is devoted to comparative embryology and morphology.

No. 9 of vol. xxxi. of the *Proceedings* of the Boston Natural History Society is devoted to the North American parasitic funguses of the group Ustilagineæ. These organisms, which have been hitherto very imperfectly known, infest various parts of herbaceous flowering plants, and are represented by twenty-four genera included in two families. Much still remains to be done in determining their distribution, and some of the hosts of certain species are given on the authority of observers other than the author of this paper, Mr. G. P. Clinton.

AN account of the method of preparing *clayed* cocoa appears in the *Bulletin* of the Trinidad Botanical Department for July. The cocoa-beans, after being fermented and dried, are collected in heaps, upon which men are set to dance, while others replace the beans as they scatter. Meantime the heaps are dusted over with powdered clay which adheres to the gummy surface of the beans and acts as a polish, so that finally the beans assume the appearance and colour of polished mahogany; careful drying completes the process, which results in the beans carrying and keeping better on account of the protective covering formed.

THE Cosmo Melvill herbarium, now the property of Owens College, Manchester, is estimated by the donor to contain five thousand genera, or two-thirds of the total number recorded in the "Genera Plantarum," exclusive of others since instituted, and the phanerogams alone amount to 36,000 different species. From a geographical point of view nearly every country appears to have furnished a quota. Amongst the more important collections mention should be made of Sir Joseph Hooker and Dr. Thomson's Indian plants, Dr. Henry's Chinese collections, Mr. C. G. Pringle's Mexican plants, and the specimens collected by Dr. Nuttall in North America.

THE Deutsche Seewarte has added another to its many useful publications, *Tabellarische Reiseberichte*, a collection of tabular reports of the meteorological logs received during the year 1903 from observers on ships. It has several times been suggested that observations made at sea should be published in a tabular form, similarly to those made at land stations; the late Admiral Makaroff was the last to urge the importance of doing so, but the question of expense has always stood in the way. The work in question does not attempt such a regular tabulation of observations, but gives a useful summary of some of the principal phenomena recorded on each voyage, *e.g.* the limits of the trade winds and monsoons, the force of wind, the storms experienced and the behaviour of the barometer during their occurrence, noteworthy currents, sudden changes of sea temperature, &c. Each report also gives the length and nature of the voyage, so that any person interested in the meteorology of any particular part of the ocean can determine approximately the amount of materials available. It is proposed to issue a similar volume for each year.

DR. H. HERGESELL, president of the International Aëronautical Committee, has contributed to *Beiträge zur Physik der freien Atmosphäre* an interesting account of his kite observations on the Lake of Constance. The ascents were first made in the year 1900, and subsequently in the years 1902 and 1903, on both occasions with the assistance of Count Zeppelin, who lent his motor-boat for the purpose. It is understood that such observations are somewhat difficult at an inland station, as the wind velocity necessary for raising the kite (about 8 metres per second, or 18 miles per hour) is not always available without the artificial wind produced by the motion of a boat. Dr. Hergesell's experiments clearly show that, frequently, inversions of temperature and humidity occur at certain levels, which are not exhibited by observations made on mountain peaks, and the opinion is expressed both by Prof. Mascart (president of the International Meteorological Committee) and by himself that however useful in various ways, observations on mountain stations have not led to the results that were expected from them. He is of opinion that if any improvement is to be made in what he terms the present stagnant condition of meteorological science, it will be by the investigation of the upper strata of free air rather than by piling up observations made at ordinary meteorological stations—in other words, by making meteorology a study of the physics of the atmosphere.

IN a communication to the Institution of Mechanical Engineers Mr. R. M. Neilson discusses the possibilities of gas turbines from a scientific standpoint, a region of study to which up to the present little systematic attention has been given. The author considers that there are four different cycles which could be applied with advantage to a gas turbine, giving efficiencies of from 0·25 to 0·84, and two of them admitting of several different cases. The necessity of keeping the temperature of the blades of the turbine down to about 700° C. to a certain extent limits the efficiency, but, as the author points out, a decrease in the temperature of the source in a Carnot's cycle affects the efficiency less than an increase in the temperature of the refrigerator of the same amount.

We have received from the Stanley Electric Manufacturing Co., of Pittsfield, Mass., an interesting wall map showing the long distance power transmission lines in California. There are six power houses situated on the western slopes of Sierra Nevada from which power is transmitted electrically to San Francisco and the surrounding district. The longest transmission is from the De Sabla power house to Sansaulito, which is to the north of San Francisco, on the opposite side of the Golden Gate; the length of this line is 232 miles. More than 10,000 h.p. is being supplied to San Francisco itself from the electric power house which is 147 miles away. An additional power house is proposed, and also several additional lines.

At a recent meeting of the Faraday Society, among other papers was one by Miss B. Pool on a suggested new source of aluminium. This consists of the vast deposits of laterite which occur in several parts of India; these laterites are closely analogous to bauxite, from which aluminium is at present manufactured. The paper gives analyses of several of the laterites in different districts, and the author concludes that this raw material, on account of its purity, ready accessibility, and association with flowing water should be almost an ideal source of aluminium. Mr. W. M. Morrison, in the discussion, questioned whether it was probable that the Indian laterites would be used in this country, as the supply of bauxite near at hand was plentiful, though it was not unlikely that at some future date they might be worked *in situ*.

We have received from Messrs. Christy and Co., of Old Swan Lane, Lower Thames Street, E.C., a few samples of the several varieties of Dr. Schleussner's dry plates, and have found them to vindicate, practically, the commendations bestowed upon them by many Continental men of science, including several well known astronomers. The "ordinary" plates are characterised by their great sensitiveness and the evenness of their emulsion. The "special rapid" plates, intended chiefly for stellar photography and general scientific work, were found excellent, especially in stellar work, even faint stars giving fairly dense trails when the plates were exposed in a stationary camera. The results in this direction especially are enhanced by the very smooth grain of the finished negative. On testing the "orthochromatic" plates in terrestrial and stellar spectroscopic work they were found to be extremely sensitive, and, with relatively short exposures, gave spectra extending well up into the orange with only a short break on the less refrangible side of the "F" line. The "Viridin" are especially sensitive in the green, with reduced sensitiveness in the blue and violet, and should be found very useful in landscape work where the use of a screen is inconvenient or likely to lengthen the exposure unduly. All the plates were easy to develop with normal pyro-soda, and gave excellent, fine-grained negatives free from any trace of fog. Messrs. Christy are the sole agents for these plates in Great Britain.

No. 9 of vol. cvi. of the *Bulletin de la Société d'Encouragement* contains several papers of metallurgical interest. M. H. Le Chatelier describes a photographic method of recording the temperature of pieces of steel at every instant during the rapid cooling which accompanies hardening, and investigates the law of this cooling in the case of the commoner baths, such as water, oil and mercury, which are employed in industry. Contrary to the usually accepted view, the rate of cooling by means of mercury is much smaller than that due to water; the specific heat of the quenching material, and not its thermal conductivity, is obviously the principal factor to be considered in such cases. The cooling by oil is relatively very slow, owing to its low specific heat and to its viscosity, which prevents loss of heat by convection. M. L. Guillet describes in the same part the properties of tin and titanium steels, and M. P. Mahler discusses the reversible actions occurring in the blast-furnace.

We have received a copy of the "British Standard Specification and Sections for Bull Headed Railway Rails," issued by the Engineering Standards Committee. It has been resolved that the steel used in these rails shall be of the best quality, the constituents conforming to the following limits:—carbon from 0·35 to 0·5 per cent., manganese from 0·7 to 1·0 per cent., silicon not to exceed 0·1 per cent., phosphorus 0·075 per cent., and sulphur 0·08 per cent. The manufacturer shall make and furnish to the purchaser a carbon determination of each cast, and a complete chemical analysis representing the average of the other elements present shall be given for each rolling. A table of the general dimensions of the "B. S." rails is given, with illustrative sections. For straight lines, the committee recommends the adoption of the following as the normal lengths of the rails, namely, 30 feet, 36 feet, 45 feet, and 60 feet. The tensile strength must not be less than 38 tons per square inch nor more than 45 tons per square inch, and a 5-feet length of rail shall respond satisfactorily to the blows of a falling weight of 2240 lb. The inspection and testing of the rails by the purchaser during the course of their manufacture are suitably provided for.

An interesting paper by Mr. L. Gilchrist on the electrolysis of acid solutions of aniline appears in the November number of the *Journal of Physical Chemistry*. On electrolysing a hydrochloric acid solution, aniline black is formed, the depolarising effect amounting to about 0·3 volt. Substituted chloranilines are not formed to any appreciable extent. Electrolysis of a hydrobromic acid solution, which has a considerably smaller decomposition voltage, leads on the other hand to bromanilines, and no aniline black is produced.

The *Proceedings* of the Royal Dublin Society (vol. x., No. 23) contain a report by Dr. E. J. McWeeney on the cases of carbon monoxide asphyxiation which have occurred in Dublin since the addition of carburetted water gas to the ordinary coal gas. It appears that from 1880 to 1900, before the addition of carburetted water gas was practised, there was no recorded case of death from coal gas poisoning, whilst during the four years that have elapsed since the addition was made, there have been ten cases with seven deaths due to that cause.

In a paper published in the *Manchester Memoirs* (vol. xlix., 1904) Mr. W. Thomson describes experiments which show that arsenic is rapidly eliminated from the system by kidney secretion. After the administration of one-fiftieth of a gram of arsenious oxide, about 16 per cent. was found to be eliminated in this way within twenty-four hours. The amount of arsenic in the secretions of people in towns where large metallurgical operations are carried on is found in some cases to be as high as one-thirtieth of a grain per gallon.

A SECOND edition of Prof. Hantzsch's "Grundriss der Stereochemie" has just been published by J. A. Barth in Leipzig. The rapid advances which have taken place in this branch of chemistry during the last ten years have rendered considerable additions necessary. Sections are now included dealing with the stereochemistry of diazo-compounds and complex inorganic bodies, and with the molecular asymmetry of nitrogen, sulphur, selenium, and tin compounds. The connection between configuration and biological activity, the reciprocal transformation of optical antipodes, and the phenomenon of steric hindrance are also treated in the new edition, which should be welcomed by all classes of chemists.

A THIRD edition of the "Elements of the Mathematical Theory of Electricity and Magnetism," by Prof. J. J. Thomson, F.R.S., has been published by the Cambridge University Press. A new chapter on the properties of moving electrified bodies has been added, and other minor changes have been made.

MESSRS. BELL AND SONS have published separately, under the title "Examples in Algebra," a selection of the examples in the recently published "Elementary Algebra," by Messrs. W. M. Baker and A. A. Bourne. The price is 3s., and the new volume may also be had in two parts at 2s. each.

THE yearly volume for 1904 of the *Reliquary and Illustrated Archaeologist* has now been published. The four separate issues, which have been referred to from time to time in these columns, together form a handsome volume. Some articles in the volume will appeal to students of science who are not archæologists. Among these may be mentioned a well illustrated article by Mr. W. H. Legge "About Almanacs," and Mr. F. W. Galpin's "Notes on a Roman Hydraulus."

IN order to meet the requirements of the new syllabus in chemistry of the matriculation examination of the University of London, Dr. G. H. Bailey has taken advantage of the demand for a second edition of his book on chemistry to re-write and enlarge it. In its present form "The New Matriculation Chemistry" contains everything that a candidate at the matriculation examination is likely to require. An introductory course of experimental work has been inserted in addition to other new matter. The volume is published by Mr. W. B. Clive, and edited by Dr. William Briggs.

OUR ASTRONOMICAL COLUMN.

ENCKE'S COMET (1904 *b*).—On a photograph obtained on October 28 with two hours' exposure, using the Bruce telescope, Prof. Max Wolf discovered a faint image of Encke's comet, the apparent position of which at 28d. 7h. 13m. 48s. (Konigstuhl M.T.) was

$$\alpha = 23h.\ 37m.\ 51{\cdot}41s.,\ \delta = +26^\circ\ 0'\ 38''{\cdot}0.$$

A faint tail, extending in a northerly direction, was suspected.

On the same night Prof. Millosevich at Rome was able to find the comet with the 39 cm. equatorial of the Roman College Observatory. The object was extremely faint, and had the following position at 6h. 30m. (October 28, Rome M.T.), $\alpha = 23h.\ 37m.\ 58s.$, $\delta = +26^\circ\ 1'{\cdot}4$.

Prof. E. Hartwig also observed the comet visually, using the large refractor of the Bamberg Observatory, at 9h. 18m. 11s. (Bamberg M.T.) on October 30, and determined the following as its position :—

$$\alpha\ (\text{app.}) = 23h.\ 28m.\ 1{\cdot}01s.,\ \delta\ (\text{app.}) = +25^\circ\ 23'\ 25''{\cdot}1.$$

The comet was very diffuse with a faint central condensation, and a diameter of more than 10′ (*Astronomische Nachrichten*, No. 3977).

OBSERVATIONS OF PERSEIDS.—The results of a large number of independent observations of the Perseid shower of last August, together with a detailed exposition by M. Chrétien of the process by which the positions of meteor radiants may be determined from the observed data by the method of least squares, are published in the November number of the *Bulletin de la Société astronomique de France*.

Among other results, those obtained by M. Perrotin at Nice and by M. G. A. Quignon at Mons are given. The former have already been summarised in these columns; the latter are as follows :—

During a total watch of 7h. 15m. between August 7 and 12, M. Quignon observed 110 meteors, chiefly Perseids, and determined the position R.A. = 44°, dec. = +59°, as the mean radiant point of the shower. The maximum display took place between 22h. 40m. and 23h. 10m. on August 11, when 21 meteors, or 42 per hour, were seen.

HEIGHTS OF METEORS.—In a letter to the November number of the *Observatory* Mr. Denning publishes some data regarding the observed heights of the appearances and disappearances of several different classes of meteors.

He states that, generally speaking, the swift meteors become visible at a greater height than the slower ones, and do not approach so near to the earth's surface before disappearing. Thus for the Leonids and Perseids, both of which are characterised by their comparative swiftness, it has been determined that the former are generally more lofty than the latter, the average heights being as follows :—

	Height at beginning	Height at ending	No. of meteors
Leonids ...	84 miles ...	56 miles ...	25
Perseids ...	80 ,, ...	54 ,, ...	40

On the other hand, the mean heights of the very slow meteors appear to average about 65 miles at the beginning to 38 miles at the end of their appearance. These, however, appear to form two distinct classes :—(1) those having very low radiants, extending from 64 miles to 48 miles; and (2) those having fairly high radiants, extending from 66 miles to 28 miles.

The swiftest meteors apparently become visible when nearly 20 miles higher than the very slow meteors, whilst those of the latter which have high radiants come 20 miles nearer the earth than those having very low radiants.

Seven Quadrantids and four Lyrids gave mean heights of 67 miles to 52 miles and 84 miles to 50 miles respectively.

THE PHOTOGRAPHIC SPECTRUM OF JUPITER.—Using the large refractor of the Meudon Observatory in conjunction with a spectrograph containing one 60° prism and having a focal length of 292 mm., M. G. Millochau obtained a number of photographs of the spectrum of Jupiter during December and January.

A study of the resulting spectra, which were obtained on Lumière panchromatic plates and extend from F to C, showed a number of bands at λλ 618, 607, 600, 578, and 515, which are apparently the same as those observed by Keeler in the spectrum of Uranus. It further disclosed the facts that the water vapour and α bands were greatly strengthened in the planetary spectrum, and that all the bands were relatively more intense in that part which was produced by the light from the south equatorial band of the planet's apparent disc.

The appearance of the band at λ 618, which has been previously observed in the spectra of the superior planets, and of several new faint bands in the Jovian spectrum, indicates the existence of a gas in the atmospheres of the outer planets which does not exist at all, or only in much feebler proportions, in the atmospheres of the inferior planets.

M. Millochau intends to prosecute this research further at the Mont Blanc Observatory, where the clearer atmosphere should permit of better results being obtained (*Bulletin de la Société astronomique de France*, November).

SCIENCE AND THE STATE.[1]

I HAVE long held that there is a certain class of work performed by institutions which should undoubtedly be carried on by some department of the State, specially devoted to such work.

The work to which I refer is such as is not suitable, or to be expected from societies or individuals. It is work which is continuous and must expand in the flux of time, which is recognised by the public as useful, which is not and cannot be remunerative, which requires a staff larger than is required by the ordinary demands of a society, and cannot be dropped without serious detriment to the public.

When there is some pressing need Government does administer branches of a department which has to carry out scientific investigation. Thus the medical branch of the Local Government Board has been laboriously and gradually built up. It is far otherwise, however, with that scientific work which has no department specially interested in or needing it, though it is for the public weal; as the State departments only exist for ministering to that weal, it appears that some department should be created or enlarged to take charge of such work. This view, which I have long held, has been more than confirmed by the evidence given before a recent committee, which the Treasury practically appointed, to consider the present position of the Meteorological Office, but limiting the recommendation to be made so far as the grant made to it is concerned.

Meteorological science has been greatly retarded in Great Britain by want of funds. Perhaps the latest example occurred in 1902, when there was a proposal to obtain further information about atmospheric currents and conditions by the use of balloon and kite observations, an international scheme of work being contemplated. The small sum of 500*l*. a year would have been necessary to carry out this research, but the Royal Society was obliged, on behalf of the Meteorological Office, to reply that they had no funds, a reply which it would have been difficult to make had the Meteorological Office been part of a Government department. Let us look across the water at our American cousins and see how they regard the science of meteorology, and whether or not it is important enough to attach it to the State. According to evidence given to the committee, the Weather Bureau in America, corresponding to our Meteorological Office and forming part of the Department of Agriculture, was spending 230,000*l*. a year on the same work as that of the Meteorological Committee, whose funds at the maximum were confined to 15,300*l*. In Germany, where very large sums are spent on the oceanic part of meteorology, it is a part of the Navy Department. We, with our splendid navy and mercantile marine, surely ought to see that this part of meteorology is as well cared for as it is in Germany, and that there is no lack of funds. The evidence given before the committee showed that without the help of the hydrographic branch of the Navy the work could not have been carried on with anything like success. I am not intending to enter into a discussion of meteorological science, but it has been pointed out that if forecasts are any good (and we have it on record that from 68 per cent. to 75 per cent. of them are successful) they ought to be made as good as possible. There is no doubt that kite and balloon observations, and the use of wireless telegraphy in mid-ocean, would give a still higher percentage of successful forecasts. But the additions must remain in abeyance owing to the money limit which has been fixed at the same standard for so many years.

Again, we find that a very large item of expenditure by the Meteorological Office is the cost of telegrams. It has to pay the same price for the use of the Post Office telegraphs as any private individual, whereas every Government office has the free use of the wires, and has not to consider whether a telegram runs to 12 or 120 words, or whether it sends 1 or 100. The main object of the Meteorological Office is to assist the public, and this is the same as that of Government departments, yet the one is hampered by the cost of publishing information (which to be of the greatest use must be transmitted at once), whilst the other is not. The view of the committee which sat was strongly that this disability ought to be removed, so that wide publicity to weather reports, especially in harvest time, should be given. Finally, the committee almost unanimously reported in favour of the office being attached to some Government department, and proposed that this should be the Board of Agriculture, a department which at present is not overweighted.

I must remind you that our great Indian dependency has been more alive to the question of meteorology than we have at home; but I trust that, backward as we are, we may, before long, attain that excellence of administration which the Indian Meteorological Department has exhibited under its present and past able administrators.

What the Government intends to do with the committee's report I do not know. Judging from previous history, there seems to be a dread at the Treasury of any of the present departments having more to do with science than is absolutely forced upon them. Perhaps this is natural. The lay official mind has, with some few exceptions, never fully grasped the importance of orderly and continued scientific investigation in order to increase national prosperity. It recognises this in a way, for the need is continually brought into prominence by the Press, but to it the easiest plan is to leave all such investigation to societies. In Great Britain it has never been realised that to foster such work is a duty of the nation. We have ignored the very patent fact that in free America and in other countries the necessity of annexing to the State all utilitarian research (when such research is carried out with the definite object of public usefulness) is fully recognised. I am not proposing for an instant that the work which is carried out by individuals or societies should be curtailed, but there are questions which are too large, too expansive, and bearing too much on the public weal which should be dealt with in Great Britain as they are in (say) America.

I have only so far referred to the Meteorological Committee, but, at all events, there is another institution, the National Physical Laboratory, which should come into the same category of quasi-public departments.

The Government has given the National Physical Laboratory buildings, and a sum of 19,000*l*. to make the additions to them, which were absolutely necessary to commence with. It granted 4000*l*. a year for four years, and afforded assistance to it through the Office of Works. The term of years for which the grant was made runs out in March next, and its financial position has to be reviewed by the State through the Treasury. Its existence and development has become a necessity through the excellent work that it has already done. But there is work of first-class importance to the public which the laboratory has been forced to refuse owing to lack of funds. Standardising is not a luxury in the present day, and England has suffered much in its trade owing to the want of it.

The table on p. 91 will show the amounts granted by the different States in regard to these laboratories.

Here we have a direct comparison of grants and turn-out of work. Great Britain, I think I may say, has no reason to be ashamed of the work, though it has of the grants. In connection with the results given in the table, I may point out that France and the United States started their institutions after the inauguration of our own laboratory.

The idea of making any such institution a State institution, it may be supposed, was never entertained by the Government, such a notion being foreign to existing precedent. The precedent—bad precedent too—had to govern the situation. We have only to look across the Atlantic to see how our Anglo-Saxon cousins treat such matters. There, institutions such as I have here described are part and parcel of a State department, and have a handsome annual grant allotted to them. The Government of the United States recognised the public need, and so did Congress, with the result that the public need is catered for by a public department, as it should be.

In regard to the National Physical Laboratory, it is no secret that at the present moment it is hampered by want of funds for equipment and staff. Its refusal of work has only proceeded from this cause. The report which it issued showed that its expenditure had been larger than its income

[1] Abridged from the inaugural address delivered at the Society of Arts on November 16 by Sir William Abney, K.C.B., F.R.S., vice-president and chairman of the council of the Society.

of 9000*l.*, an income which is derived from a variety of sources:—Treasury grant, 4000*l.*; Gassiot Fund, 400*l.* (about); from Meteorological Committee, 400*l.*; fees, &c., 4200*l.* (about). In addition to this there has been 1200*l.* in donations.

Whether the laboratory can become self-supporting is a matter of doubt to my mind. Even if it should be so, that is no reason for taking it away from State control, which always gives an impress to decisions, and it is a pledge that gain is not its only object. Certainly it would never arrive at the proportions that the huge, more than self-supporting department, the Post Office, has arrived at. The example of Germany, where the State takes the fees, and supports the institution, is worth following.

Country	Name	Cost: Building	Cost: Equipment	Annual Grant	Receipts from annual work	No. of tests made	Staff
Germany	Reichsanstalt	£200,000		£16,000	£3,000[2]	22,469	112
	Aichungs-kommission	48,000		8,500	—	—	—
	Versuchsanstalt	137,000		15,000	8,000[2]	5,000	140
		£385,000		£39,500	£11,000	27,469	252
France	Laboratoire de l'état	£27,000 and some buildings.	£20,000	5,500	—	—	12
U.S.A.	Bureau of Standards	£70,000	45,000	19,000	114[3]	1,666[3]	22
Great Britain	National Physical Laboratory	£19,000 including some buildings.	[1]	4,000	4,042[4]	30,807[4]	50

1 The annual grant was made before the work was started, and any balance left after paying salaries I believe was available for apparatus.
2 In these cases the State takes the fees. 3 For the first year. 4 Includes the Observatory Department.

I might refer to researches in solar physics also, which are carried out in the iron shanties at South Kensington, under the control of the Board of Education. The sum of 700*l.* is allotted as a grant in aid for the work that is carried out there, and some of the staff are borne on the estimates; but if, as is to be believed, some of the tremendous problems of the causes of famine and plenty are dependent on the solar phenomena, then this work should be enlarged and encouraged. The expenditure of ten times the sum in one year may enable millions of pounds and lives to be saved which may be lost from the scant supply of needful means. It is true that the Solar Physics Observatory is under the Board of Education, but if its history were written, I doubt not that it would be found that from its very first inception (due to the repeated recommendation of a host of scientific men who foresaw something of what might be expected from it) the State wanted none of it. It may be said that if the Meteorological Office and the National Physical Laboratory were attached to a Government department, they might be starved in the same way. I do not believe it possible that such would be the case, for these two are of ostensible use to the ordinary public, and appeal to that most sagacious and popular person the man in the street, in a way that solar physics does not. The last deals with problems which are for future use, but it is intimately, most intimately, connected with meteorology. If the Meteorological Office becomes attached, as it eventually must be, to a Government department, the Solar Physics Observatory and staff should be attached to the same department.

If the Government will recognise the two institutions as doing essentially public service, and ask for the necessary funds, I believe Parliament would vote the supplies in the same ungrudging manner that Congress has done, as they would look upon them as a paying investment. Parliament realises most frequently before Government does the importance of any public work. The most happy solution of the problem would be (1) to have some department of State to which these and other kindred scientific institutions should be attached; (2) to have a scientific advisory board; (3) to distinguish clearly between grants for research, equipment, and material, and those for staff.

THE BEN BULBEN DISTRICT.

THE region lying north of Sligo, which was visited by a large party of naturalists last July on the occasion of the fourth triennial conference of the Naturalists' Field Clubs of Ireland, is one of much beauty and interest. In its general aspect it recalls the best features of the Yorkshire Carboniferous Limestone area. Its setting, with the great limestone plain of Ireland stretching away on one hand, and the Atlantic Ocean on another, adds a dignity and impressiveness to this group of cliff-rimmed, flat-topped hills which might not be bestowed by their height alone, though they are of no mean elevation (Truskmore, the highest point, rises to 2113 feet). The Ben Bulben range, which derives its name from that of one of its spurs which projects boldly towards the Atlantic, represents the wreck of the Upper Limestone of this district. The fertile undulating low grounds all around are occupied by a lower and more argillaceous series, through which one of the old Caledonian folds of Ireland projects as a knobby ridge, its rugged outlines forming a charming contrast with the green and grey tabular forms of the limestone. The Upper Limestone, 700 feet or 800 feet thick, massive and strongly jointed vertically, rests on the lower series as a cliff-bound plateau, intersected by several grand glens, which are cut through the limestone deep into the less resisting rocks underneath. The mural precipices are the result of the characteristic weathering of the massive limestones. Below them, where not obscured by talus, the Middle Limestones and shales fall away in steep concave slopes into the plain. The exquisite valleys of Glencar and Glenade cut right through the plateau, the first in an east and west direction, the other north and south. Each is from one to two miles wide from cliff-top to cliff-top, and about a thousand feet deep (Fig. 1). The floors of these valleys are undulating, and the scenery is much enhanced by the fact that each embosoms a lake at the point where the cliff scenery reaches its best.

On some parts of the plateau-edge denudation has been more severe, as in the beautiful wedge of Ben Whiskin (1666 feet), the western side of which displays a characteristic precipitous front, while the eastern side has been worn down to a uniform steep slope which drops into Gleniff.

The uniformity of the post-Carboniferous uplift is shown by the almost absolute horizontality of the beds of limestone throughout the region. The surface of the plateau, while retaining in a general way this horizontality, is seen on a nearer approach to be undulating, a feature chiefly due to the fact that patches of the Yoredale sandstone still remain here and there isolated on the surface of the limestone. The whole plateau, limestone as well as sandstone, has in general a thick covering of peat.

To the botanist the Ben Bulben range is well known as the only British habitat of *Arenaria ciliata*, a species with a high northern and alpine distribution, which is locally abundant on these hills. This plant strikes the key-note of the flora of the district, which is essentially northern and alpine in its characters. Adjoining on the south, in Mayo, the Lusitanian heaths, *Erica mediterranea* and *Dabeocia polifolia*, and other plants fully represent the remarkable southern flora which characterises the western sea-board of Ireland, and a few miles on the northern side the same features are repeated in Donegal in the occurrence of *Saxifraga umbrosa*, *Euphorbia hiberna*, and *Trichomanes radicans*. But in the Sligo flora the southern element is absent, saving the occurrence of *Adiantum Capillus-Veneris*, which may be found growing at sea-level in company with *Draba incana* and *Saxifraga aizoides*.

As it is with the plants, so with the animals. The characteristic southern forms of western Ireland are scarcely represented, while northern animals are conspicuous. The Field Club entomologists found *Pelophila borealis* literally to swarm on the shores of Lough Gill, which is only a few feet above sea-level; *Xenylla brevicauda*, an Apteron new

FIG. 1.—Entrance of Glencar. Showing the southern cliff-wall of Carboniferous Limestone, which rises a thousand feet above the valley.

to the British Isles, which accompanied it here, is likewise northern; and other instances might be quoted. Among other results of the Field Club visit (which are fully described in the September number of the *Irish Naturalist*) may be mentioned the discovery of three water-mites, one of which, *Eylais bicornuta*, is new to science, and the two others new to Britain.

COAST EROSION AND PROTECTION.

TWO papers on this subject were recently read at the Institution of Civil Engineers, one by Mr. A. E. Carey on coast erosion, and the other by Mr. E. R. Matthews, the borough engineer of Bridlington, on the erosion of the Holderness coast of Yorkshire.

The first paper deals generally with the whole coast of England, and briefly enumerates the salient geological features of the coast line and points out their connection with the relative rates of erosion. The second paper is confined to the erosion taking place on the Yorkshire coast between Bridlington and Spurn, and the works that have been carried out in constructing promenades, sea walls, and groynes at Bridlington.

There is no novelty in the descriptive parts of these papers. It is a well known and recognised fact that on certain parts of the coast of this country considerable loss of land is taking place by the erosion of the sea. The subject occupied the attention of the geological section of the British Association in 1885, when a committee was appointed to investigate the subject of coast erosion, and reports of experts having local knowledge were obtained from all parts of the coast and printed in the reports issued from time to time, the last, which was confined to recent evidence obtained from the coast guards, being published in the report of the meeting held at Southport in 1903. We have ourselves dealt with the subject in articles in NATURE in our number for June, 1899, and on sea coast and destruction in August 23, 1900. The destruction of the Holderness coast and the protective works put up to stop the erosion at Hornsea, Withernsea, and Spurn were dealt with in a paper by Mr. Pickwell on the encroachments of the sea from Spurn Point to Flamborough Head printed in the *Minutes of Proceedings* of the Institution of Civil Engineers, vol. li., 1878.

The whole subject, both as descriptive of the coast of England, the losses that have taken place, and the works that have been carried out to prevent erosion, is also very fully dealt with in the work on "The Sea Coast" published by Messrs. Longmans in 1902.

Mr. Matthews in his paper makes a statement that has frequently been made before, but for which there does not appear to be any warrant, to the effect that the material eroded from the Holderness coast is carried into the estuary of the Humber. This subject was very fully dealt with in a paper read at the British Association at Glasgow in 1901 on the source of warp in the Humber, in which it was conclusively shown that it is physically impossible for this material to be carried into the Humber, and that, as a matter of fact, no warp is carried into the river from the sea, but that the warp in suspension is derived entirely from the solid matter brought down by the various tributaries of the river. The paper describes this matter as oscillating backwards and forwards with the tides in a zone confined to the lower reaches of the Ouse and the Trent, except that when heavy freshets are running it extends into the Humber and is then partly carried out to sea. This peculiar action is made use of to improve the value of the land adjacent to the rivers by the process of "warping." Any solid matter brought into the Humber on the flood tide consists entirely of clean sand, and has no relation to the waste of the Holderness coast.

The only novel features, therefore, in these papers is the suggestion of Mr. Carey that the matter should be taken up by Parliament, and that a body of commissioners should be created with the special function of dealing with the foreshores of England and Wales. He proposes that the coast should be divided into districts placed under commissioners, each having an engineer to act as coast warden, with power to deal with the material on the beach, and the general control and management of all foreshore lands, the costs incurred by this commission to be divided between the Treasury, the local authorities, and the landowners.

Mr. Matthews confines his ideas of Government interference to the coast of Yorkshire, and suggests that this ought to be protected against the inroads of the sea by the Government, quoting as a precedent for this that the Board of Trade protects the Spurn Peninsula. He loses sight, however, of the fact that this is done for the protection of the lighthouses which stand on the peninsula, and for the preservation of the entrance to the Humber. Mr. Matthews gives an estimate for protecting this reach of coast by sea walls and groynes, and shows, as has been done by others on previous occasions, that the value of the land swallowed up by the sea within a reasonable period would not amount to one-third of the first cost of the protective works, apart from their maintenance.

It will be remembered that recently, owing to the great destruction of sea protective works that occurred at Lowestoft and Southwold, the representatives of the sea coast towns on the east of England held a conference at Norwich and appointed delegates to interview the Prime Minister and the officials of the Government departments more particularly concerned in this matter, urging that the preservation of the coast and the sea defence works ought to be a national charge. So far, however, they do not appear to have justified their claims for such aid. It has been pointed out that most of these towns have gradually emerged from mere fishing villages into sea-side resorts, and have erected promenades and other similar works for the purpose of making their places popular, and have by this means increased the value of the land in the neighbourhood from a mere agricultural price to that of building land, very greatly to the profit of the owners of such land. It appears therefore manifestly unfair to ask the owners of the agricultural land at the back, whose rents have already been greatly depleted by the fall in value of agricultural produce during the last few years, to contribute towards works for the improvement of their neighbours' land on the coast, which they would have to do if these works were made a charge on the national revenue, and it would be equally unjust to levy contributions on inland towns which have borne the costs of large improvements for sanitary and health purposes out of their own rates.

Mr. Carey describes in his paper the evolution of a sea-side village, subject to intermittent inundation, into a watering place, in front of which the local authority charged with the works not only encloses within the sea wall nearly the whole of the shingle beach which afforded a natural protection to the shore, but also by groynes traps the whole of the travelling shingle, with disastrous results to the owner of the land to leeward. It may also be pointed out, as stated in the British Association report for 1895, that many of the disasters that occur to the sea walls and promenades of these sea-side towns are due to defective engineering and a complete disregard of the laws of nature.

It is obvious that it would be very desirable to set up some better control over the works now carried on along the sea shore either by increasing the powers of the Board of Trade or by the appointment of a special commission, as suggested by the author of the paper. The great difficulty will be in dealing with the rights of the persons claiming the ownership of the beach material, which in many cases is sold and removed in very large quantities for concrete making, road repairs, or other purposes. The Board of Trade occasionally, on being applied to, intervenes and issues notices prohibiting the removal of sand and shingle, but its power to do so is not so well defined as it ought to be, and the whole subject requires investigation, and legislative action for regulating and controlling works carried out on the sea shore and the removal of beach material; but the preservation of the property of landowners and urban authorities out of funds provided from the national exchequer would be entirely contrary to the methods of administration hitherto pursued in this country.

THE NOVEMBER METEORS OF 1904.

THOUGH there was no prospect of a brilliant display this year, there seemed the probability of a pretty conspicuous shower. In 1838—five years after the great meteor-storm of 1833—Mr. Woods, of London, reported in the *Times* that on the night of November 12, between 15h. 25m. and 15h. 55m., "nothing could exceed the grandeur of the heavens. Meteors fell like a shower of bombshells in a bombardment and in such rapid succession as to defy every attempt to watch their particular directions or to ascertain their numbers." Mr. Woods estimated that he saw 400 or 500 meteors during the half-hour mentioned.

In 1872 also, about five years after the brilliant displays in 1866, 1867, and 1868, the Leonids returned pretty abundantly, for on November 13, 12h. to 18h., several observers at Matera, Italy, counted 638 meteors, and the display was regarded as having been much brighter than usual.

In these circumstances it was expected that the return of 1904 would be deserving of careful observation, and so it has proved, though the shower was perhaps not quite so rich as expected. The earth, however, probably passed through the denser part of the stream at about Greenwich noon on November 15, and thus it must have escaped observation in England. Reports from American stations are awaited with interest. In this country fogs were very prevalent at the important time, and at some places appear to have obliterated the phenomenon.

At Bristol during the night of November 13 there were very few meteors visible, with only occasional Leonids, but the stars were dim in the fog.

On November 14 the conditions were more favourable. Between 13h. 30m. and 15h. 45m. about 55 meteors were seen (including 33 Leonids) by the writer during a watch extending over $1\frac{1}{2}$h. of the period named. It was considered that Leonids were appearing at the horary rate of 25 for one observer. After 16h. increasing fog interfered with observation. The Rev. S. J. Johnson at Bridport had, however, a very clear sky after 16h., and noted a fairly numerous display of Leonids, including one as brilliant as Venus and several equal to Jupiter. He does not mention the exact number seen.

Mr. C. L. Brook at Meltham, near Huddersfield, watched on November 14 between 16h. and 18h., and counted 69 Leonids, of which number 17 were observed in the first quarter of an hour. Other results have come to hand which corroborate Mr. Brook's figures, and show that the maximum was attained between 15h. 50m. and 16h. 20m., when the rate of apparition was 1 Leonid per minute in the sphere of vision commanded by one observer.

There appear to have been very few Leonids seen either on the nights of November 13 or 15.

As observed at Bristol, the radiant seemed to be an area 4 or 5 degrees in diameter, with its centre slightly west of γ and ζ Leonis, or at $151^\circ+23^\circ$. There were several minor showers visible, and two of these were well pronounced at $43^\circ+21^\circ$ and $144^\circ+37^\circ$.

W. F. DENNING.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—The Rhodes trustees have decided to add 200*l.* a year for the next five years to the stipend of the reader in pathology. Mr. Alfred Beit and Mr. Wernher have supplied sufficient money to endow a professorship of colonial history, and to appoint an assistant professor in the same subject. They have also made a gift to the Bodleian Library.

Magdalen College has made a grant to the delegates of the university museum of 250*l.* a year for the next two years for the purpose of the payment of scientific assistants. The following examiners have been appointed:—in chemistry, W. H. Perkin, jun.; in preliminary physics, E. S. Craig; in preliminary chemistry, J. E. Marsh; in preliminary animal physiology, W. Ramsden; in preliminary zoology, E. S. Goodrich; in medicine, organic chemistry, N. V. Sidgwick; in human anatomy, A. Thomson; in materia medica, R. Stockman; in midwifery, J. S. Fairbairn; in pathology, G. Sims-Woodhead; in forensic medicine and public health, J. D. Mann and A. L. Ormerod; and in human physiology, L. E. Hill.

THE Treasury, at the instance of the Colonial Office, has made a grant of 500*l.* a year to the Liverpool School of Tropical Medicine.

THE prizes and certificates gained by students at the Sir John Cass Technical Institute during the past session will be distributed by Sir William H. White, K.C.B., F.R.S., on Thursday, December 1. The laboratories and workshops of the institute will be on view, and there will be exhibitions of students' work.

AT Bedford College for Women two occasional lectures, open to the public without fee, will be delivered on November 25 and December 8. The first lecture will be by Prof. Karl Pearson, F.R.S., on "Recent Work and some Unsolved Problems in Heredity," and the second by Miss C. A. Raisin on "London, its Early Foundation and Later Growth, a Geological Study."

THE alumni of the Massachusetts Institute of Technology are collecting, says *Science*, a fund for current expenses, which now amounts to more than 20,000*l.*, to be used in the course of the next five years. We learn from the same source that Harvard University has received from Miss Whitney a gift of 1000*l.*, the income of which is to be applied as a scholarship to aid meritorious students in the study of field geology or geography in the summer months, preferably in the mountain region of the western United States.

APPLICATION will be made to Parliament in the ensuing session for an Act to transfer University College, London, exclusive of the North London or University College Hospital, the medical school, and the boys' school, to the University of London, and to dissolve or provide for the dissolution of the college itself. The Bill will contain a clause authorising and providing for the making by the Senate of the university, or by such other body or persons as the Act may prescribe, of statutes and regulations for the management of the college; and provision will also be made for carrying on the work of the hospital, the medical school, and the boys' school.

THE new buildings of the Borough Polytechnic Institute were opened by Mr. Benn, chairman of the London County Council, on November 16. The buildings, which were urgently needed for the large number of students, have cost with equipment more than 24,000*l.* Toward this amount the central governing body of the City of London Parochial Charities contributed 3000*l.*, the London County Council 16,000*l.*, with a promise of a further sum. The council also meets the cost of installation of the electric light and equipment, amounting to 2950*l.* The total cost of the land, about $1\frac{3}{4}$ acres, buildings and equipment, by the end of the year will be not less than 96,000*l.*

WITH the object of giving to the school children of the United Kingdom better knowledge of the colonies, and of giving to the school children of each colony better knowledge of the United Kingdom and of other parts of the Empire, a syllabus of seven lectures on the United Kingdom, each to be illustrated by about forty lantern slides, has been drawn up by a committee connected with the Colonial Office. The subjects of the lectures are:—(1) the journey from the East to London; (2) London the Imperial city; (3) scenery of the United Kingdom; (4) historic centres and their influence on national life; (5) country life and the smaller towns; (6) great towns, the industries, and commerce; (7) defences of the Empire. Mr. H. J. Mackinder will give an account of the scheme, and exhibit some of the slides which have been prepared to illustrate it, at the Whitehall Rooms, Hôtel Métropole, on Wednesday, December 7, at 5 p.m. The Colonial Secretary has consented to preside.

AT the inaugural meeting of the new session of the Royal Statistical Society on November 15, the new president, Sir Francis Sharp Powell, Bart., M.P., delivered an address on education in which he presented specially impressive figures to illustrate prominent educational features of various countries. The activity in educational matters of to-day was commended, and attention directed to the growing conviction that a more liberal education than that provided by purely technical instruction is necessary in this country. Among other interesting comparisons instituted in the address was one dealing with the average expenditure on education per child in Prussia and in England. Exclusive of central and local administration, it appears that the average expenditure per child on the register is in Prussia 1*l.* 15*s.* 6*d.* if buildings are included, and 1*l.* 10*s.* 8*d.* exclusive of buildings. The corresponding figures in England are 2*l.* 12*s.* 9*d.* and 1*l.* 17*s.* Further, the number of scholars per teacher is 66 in Prussia and 57 in England, excluding pupil teachers. It seems clear from these figures that Germany, with a smaller expenditure per child than our own, succeeds in securing better results, and it is to be hoped that English education soon may be conducted more scientifically, so that the value of our education may be more in accordance with our expenditure. The address also pointed out that in secondary education German activity is shown in the provision of technical schools for special branches of metal industries, for wood-working, engineering, and textile industries, and for agriculture.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, June 16.—"Hydrolysis of Cane Sugar by *d*- and *l*-Camphor-β-Sulphonic Acids." By R. J. **Caldwell**, B.Sc.

The rates of inversion of cane sugar by two stereoisomeric acids were determined in order to compare the results with the case of inversion by enzymes, which are apparently all asymmetric substances. Wilhelmj's law holds accurately for half normal solutions of both dextro- and lævo-camphor-β-sulphonic acids. The velocity constant κ (equal to $10^4/t \log_{10} a/a-x$, where a is the initial cane sugar concentration, and x the concentration of the inverted sugar at the end of t minutes) was found to be 10·07 and 10·13 in two experiments with the dextro-acid, and 10·05 and 10·08 for the lævo-acid. The author concludes that there is no difference in the inverting power of the two acids attributable to their asymmetric structure. This result is in accord with the conclusion arrived at by Emil Fischer regarding the *d*- and *l*-camphoric acids (*Zeits. Physiol. Chem.*, 1898, vol. xxvi. p. 83). The relative activities of hydrochloric acid and camphor-β-sulphonic acid towards cane sugar are 100 : 90, whereas for milk sugar the ratio is 100 : 70.

November 17.—"Enhanced Lines of Titanium, Iron, and Chromium in the Fraunhoferic Spectrum." By Sir J. Norman **Lockyer**, K.C.B., LL.D., F.R.S., and F. E. **Baxandall**, A.R.C.S.

In this paper the authors give the results of a detailed study of the enhanced lines of Ti, Fe, and Cr in relation to the lines of the Fraunhoferic spectrum. In previous Kensington publications it had been shown that the enhanced lines of some of the metals are prominent in the spectra of α Cygni and the sun's chromosphere, whilst it has been generally recognised that the lines in the Fraunhoferic spectrum are mainly the equivalents of lines in the arc spectra of metals. In connection with the work on enhanced lines, it has been noted that some of them, at least, appear to correspond with comparatively weak solar lines to which Rowland has attached no origin. With the object of possibly tracing some of the unorigined solar lines to their source, a careful comparison has been made between the enhanced lines shown in the photographic spark spectra of Ti, Fe, and Cr and the solar lines. The photographs used for this purpose were all taken with a Rowland grating, and on such a scale that the length of spectrum between K and F is about 14 inches (35 cm.). The chemical elements named were first selected for investigation because they furnish by far the greater number of enhanced lines which have been shown to occur in the spectrum of α Cygni.

It was found that many of the enhanced lines fell exactly on isolated lines of the solar spectrum, and in these cases the solar wave-lengths were adopted and the identification considered established. If, however, for any of these solar lines Rowland had given alternative origins, special comparisons were made of the enhanced line photograph with those of the metals given by Rowland. Notes (given at the end of the tables) were made as to the agreement or non-agreement of the metallic lines involved, and also of the relative intensities in their individual spectra, so that due weights could be given to the respective metallic lines which were thought conjointly to produce compound solar lines.

Where there was any doubt as to the exact coincidence of a metallic and solar line, or where by the close grouping of several solar lines it was not possible to say by direct comparison to which solar line the metallic line corresponded, careful measures were made of the metallic line, and its wave-length found by interpolation between closely adjacent lines of known wave-length. The resulting wave-lengths were then compared with Rowland's solar wave-lengths, and in cases of close agreement with solar lines it was deemed probable that the two lines were really identical.

A final table is given of the enhanced lines of the three elements which are considered, as a result of the analysis, to be identical with lines in the Fraunhoferic spectrum. Forty-two of these agree with solar lines unorigined by Rowland, and as the majority of them are conspicuous lines in stellar spectra of certain types, it has been thought that these results will be of importance in standardising the wave-lengths of many stellar lines.

Physical Society, November 11.—Dr. R. T. Glazebrook, F.R.S., president, in the chair.—Investigation of the variations of magnetic hysteresis with frequency: Prof. T. R. **Lyle**. The experiments were made on two rings of laminated annealed iron, in one of which the radial breadth of the iron was considerable relative to its mean radius. These rings were magnetised by alternating currents of different strengths and periods; both the magnetising-current wave and the magnetic-flux wave were quantitatively determined by a wave-tracer (described by the author in the *Phil. Mag.*, November, 1903), and the wave-forms so obtained subjected to harmonic analysis. The experiments were divided into series, in which the period and wave-form of the magnetising current were kept as nearly constant as possible throughout any one series, while its strength was varied. The analytic expressions for the associated current and flux waves for a few series are given in tabular form. From the analytic expressions for each pair of associated waves it was found that when the magnetising current was approximately sinusoidal the total iron loss (I) was, within certain limits of the induction, given by a formula $I=(a+bn)\mathfrak{B}^{1\cdot57}$ where n is the number of periods per sec., $\mathfrak{B}$ the "effective induction," and a and b are constants. When from the total iron loss per c.c. per cycle the sum of the statical hysteresis and the value that theory assigns to eddy-current loss was subtracted, a considerable quantity remained, which increased both when the frequency and the flux-density increased. This quantity, called by Fleming the kinetic hysteresis, has been obtained for each experiment.—On the practical determination of the mean spherical candle-power of incandescent and arc lamps: G. B. **Dyke**. Mr. Dyke points out the need of an improved method of expressing the efficiency of glow-lamps, and adopts the suggestion of Dr. Fleming of expressing the whole flux of light in lumens per watt. The expression of the efficiency in this manner involves the determination of the mean spherical candle-power (M.S.C.P.), and the paper describes a method of doing this. The objects of the paper are:—(1) to obtain curves showing the variations of candle-power of glow-lamps in a horizontal plane; (2) to obtain reduction factors by which the mean horizontal candle-power (M.H.C.P.) may be calculated from the maximum horizontal candle-power (C.P.); and (3) to obtain reduction factors for deducing the M.S.C.P. from the M.H.C.P. and from the C.P.—Exhibition of apparatus: R. W. **Paul**. The construction of highly sensitive pivoted electrical instruments has been rendered difficult by the fact that delicate pivots will not admit of transporting without injury. A number of galvanometers were shown in which the design was based upon the use of a moving coil, supported on one pivot in a powerful and uniform magnetic field, and controlled by a spring. A simple non-reflecting, suspended-coil galvanometer for the student's use, with a sensibility of 1 division per micro-ampere, was also exhibited. A new design of lantern, adapted for science lectures, and for use with three Nernst filaments arranged closely together, was shown in action. It is capable of being instantly changed from horizontal to vertical projection, can be fitted with a reversing prism, and has a wide adjustment for focusing. Another exhibit was an Ayrton Mather reflecting electrostatic voltmeter with a magnetic damping device. The instrument shown had a sensibility of 500 mm. at 1 m. for 30 volts, but similar instruments are made to give this deflection with pressures as low as 8 volts.

PARIS.

Academy of Sciences, November 14.—M. Mascart in the chair.—Researches on the desiccation of plants: the period of vitality. Moistening by liquid water: imperfect reversibility: M. **Berthelot**.—New researches on the Cañon Diablo meteorite: Henri **Moissan**. A very careful and complete examination was made of a block of this meteorite weighing 183 kilograms. It was found to be distinctly heterogeneous in structure, containing iron, nickel, sulphur, phosphorus, silicon, and carbon. The latter element was present in several forms: amorphous carbon, graphite, and diamonds, both the black and transparent variety of the diamond being separated. Characteristic green hexagonal crystals of silicon carbide were also isolated, the author remarking that this is the first time that this compound has been met with in nature.—The measurements of the velocity of propagation of earthquakes: G. **Lippmann**. An instrument is described capable of determining to 1/5 of a second the exact time of the commencement of a seismic shock at any given point. The author also discusses the following problem: to find the direction of the seismic wave front at the surface of the earth, in a given region, and to measure the velocity of its horizontal propagation.—On the inscription of seismic movements: G. **Lippmann**. In the photographic self-recording apparatus in common use for earthquake phenomena, owing to the considerable expense of the strip of sensitised paper, its velocity through the apparatus is very slow, about 12 cm. per hour. In the modification now proposed, the slit through which the ray of light falls on the paper is closed by a shutter, and this is operated electrically by the seismic shock. By this means the speed may be greatly increased, since the paper is only used up during the period of the earthquake shocks.—On the seeds of the Neuropterideæ: M. **Grand'Eury**. As the result of the examination of more than 1000 specimens of fossil seeds, usually attributed to ferns, the author distinguishes 15 genera or subgenera of Neuropterideæ, and 25 specific types.—Remarks on Hugoniot's adiabatic law: M. **Jouguet**.—On the use of helium as a thermometric substance and on its diffusion through silica: Adrien **Jaquerod** and F. Louis **Perrot**. An attempt to determine the melting point of gold with a thermometer of fused silica, and containing helium, failed owing to the rapid diffusion of the gas through the silica at the high temperature. The velocity of diffusion appears to be proportional to the pressure of the gas, and is very considerable, since after six hours' heating at 1100° C. the pressure of the helium had fallen to about one-seventh of the initial pressure. Below a red heat, at about 510° C., the diffusion is still fairly rapid, and a very slow effect could even be traced at 220° C. For practical purposes, therefore, the nitrogen thermometer remains the best instrument for high temperatures.—Researches on dielectric solids: V. **Crémieu** and L. **Malcles.** In the course of his researches on electric convection, Crémieu observed some anomalies of electrical influence through solid dielectrics. The authors have commenced a systematic study of these phenomena, and give an account in the present paper of the apparatus used, reserving the results for a future communication.—On the conductivity of gases from a flame: Paul **Langevin** and Eugène **Bloch.** The coefficient of re-combination of the ions from a flame has been measured, and found to be equal to about 0·7. This value is less than one, as the theory requires, and is much greater than in the case of the Röntgen rays.—On the absorption of hydrogen by rhodium: L. **Quennessen.** Contrary to the statement given in the text-books, the absorptive power of rhodium for hydrogen is nil. Rhodium is not analogous with palladium in this respect.—The action of boric acid on the alkaline peroxides and the formation of perborates: George F. **Jaubert.** By the action of boric acid upon sodium peroxide a perborate of sodium is formed, the analysis of which leads to the composition $Na_2B_4O_8,10H_2O$. On re-crystallising this a substance possessing more oxygen, $NaBO_3,4H_2O$, is formed, and this is very stable at the ordinary temperature, although decomposed rapidly at 100° C. The latter substance, treated with 50 per cent. sulphuric acid, gives after filtration through guncotton a solution of hydrogen peroxide of a strength of 150 to 200 volumes.—On thioformic acid: V. **Auger.** The author has shown in a previous paper that the substance regarded by Wöhler and Limpricht as thioformic acid is in reality trithioformaldehyde. The method which was found to give the best yield of sodium thioformate was the interaction of sodium hydrogen sulphide with phenyl formate. The latter substance was incidentally obtained in the pure state for the first time, and details of its preparation are given.—The synthesis of $\beta\beta$-dimethyladipic acid: G. **Blanc.**—On a new sugar from the berries of the mountain ash: Gabriel **Bertrand.** The sugar is isomeric with, but distinct from, sorbite and mannite, and is provisionally named sorbierite. Its physical properties are given, and its composition as a hexahydric alcohol determined by the production of a hexacetate.—The development of the organic material in seeds during their ripening: G. **André.**—On the detection of cotton seed oil in olive oil: E. **Milliau.** The test proposed is a modification of the reduction test with silver nitrate.—Anhydrobiosis and tropisms: Georges **Bohn.**—On the growth of man and of living beings in general: Charles **Henry** and Louis **Bastien.**—The evolution of the weight and organic material of the leaf during necrobiosis in white light: L. **Beulaygue.**—On heterogeneity in the Stichodactyline group: Armand **Krempf.**—The comparative influence of some organic compounds of phosphorus on the nutrition and development of animals: A. **Desgrez** and A. **Zaki.**—On the inoculation of cancer: M. **Mayet.**—On the bleaching of flour by electricity: M. **Balland.** The treatment of flour by electrified air has a bleaching action, and produces chemical changes corresponding to the effect of age.

DIARY OF SOCIETIES.

THURSDAY, NOVEMBER 24.

ROYAL SOCIETY, at 4.30.—On the Refractive Indices of the Elements: C. Cuthbertson.—The Flow of Water through Pipes. Experiments on Stream-line Motion and the Measurement of Critical Velocity: Drs. H. T. Barnes and E. G. Coker.—On Galvanic Cells produced by the Action of Light. Preliminary Communication: Dr. M. Wilderman.—Some Physical Characters of the Sodium Borates, with a New and Rapid Method for the Determination of Melting Points: C. H. Burgess and A. Holt, jun.—On the Convergence of Infinite Series of Analytic Functions: H. A. Webb.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Hydrodynamical and Electromagnetic Investigations regarding the Magnetic-Flux Distribution in Toothed-Core Armatures: Prof. H. S. Hele-Shaw, F.R.S., Dr. Alfred Hay, and P. H. Powell.

FRIDAY, NOVEMBER 25.

PHYSICAL SOCIETY, at 5.—The Measurement of Small Differences of Phase: Dr. W. E. Sumpner.—On the Curvature-method of Teaching Geometrical Optics: Dr. C. V. Drysdale.—(1) Exhibition of Specimens of Crystals showing the Phenomenon of Luminous Rings; (2) On a Rapid Method of Approximate Harmonic Analysis: Prof. Silvanus P. Thompson.—Exhibition of Apparatus by Prof. Dalby, Mr. Darling, Dr. Drysdale, and Prof. Thompson.

SATURDAY, NOVEMBER 26.

ESSEX FIELD CLUB (at Essex Museum, Stratford), at 6.30.—Delegate's Report British Association: F. W. Rudler.—Notes on Supposed Lake Settlement at Skitt's Hill, Braintree: F. W. Reader.—Coast Erosion in East Anglia: John Spiller.

MONDAY, NOVEMBER 28.

SOCIETY OF ARTS, at 8.—Musical Wind Instruments: David J. Blaikley (Cantor Lecture I.)

INSTITUTE OF ACTUARIES, at 5.—Inaugural Address by the President, Mr. Henry Cockburn.

TUESDAY, NOVEMBER 29.

ZOOLOGICAL SOCIETY, at 8.30.—Some Observations on the Field Natural History of the Lion: Capt. Richard Crawshay.—On some Nudibranchs from East Africa and Zanzibar. Part VI.: Sir Charles Eliot, K.C.M.G.—The Altai Lynx: R. Lydekker, F.R.S.—On Old Pictures of Giraffes and Zebras: R Lydekker, F.R S.—On the Morphology and Classification of the Asellota Group of Crustaceans, with Descriptions of the Genus Stenetrium and its Species: Dr. H. J. Hansen.—On the *Lacerta depressa* of Camerano: G. A. Boulenger, F.R.S.

INSTITUTION OF CIVIL ENGINEERS, at 8.—*Discussion*: Distribution of Electrical Energy: J. F. C. Snell.

WEDNESDAY, NOVEMBER 30.

SOCIETY OF ARTS, at 8.—The British Canals Problem: Arthur Lee.

THURSDAY, DECEMBER 1.

ROYAL SOCIETY, at 4.30.—*Probable Papers*:—The Ascent o Water in Trees: Dr. A. J. Ewart.—On the Presence of Tyrosinases in the Skins of some Pigmented Vertebrates. Preliminary Note: Miss F. M. Durham.—On Chemical Combination and Toxic Action as Exemplified in Hæmolytic Sera: Prof. R. Muir and C. H. Browning.—Histological Studies on Cerebral Localisation. Part II.: Dr. A W. Campbell.

CHEMICAL SOCIETY, at 8.—The Nitrites of the Alkali Metals and Metals of the Alkaline Earths, and their Decomposition by Heat: P. C. Rây.

RONTGEN SOCIETY, at 8.15.

LINNEAN SOCIETY, at 8.—Proteid Digestion in Animals and Plants: Prof. Sidney H. Vines, F.R.S.

FRIDAY, DECEMBER 2.

AERONAUTICAL SOCIETY, at 8.—The Aëronautical Exhibits at the St. Louis Exhibition: the President, Major B. Baden-Powell.—Kites, Kite-flying and Aëroplanes: W. H. Dines.—The Work of the International Aëronautical Commission: Dr. M. H. Hergesell.—Captive Balloon Photography: Griffith Brewer.

DAI NIPPON.

Dai Nippon, the Britain of the East, a Study in National Evolution. By Henry Dyer, D.Sc., &c. Pp. xvi+450. (London: Blackie and Son, Ltd., 1904.)

THE story of how Japan jumped from what she was to what she now is will always form one of the most remarkable episodes in the history of material civilisation. Not only is it this, but it is also a remarkable illustration of the results that can be achieved by occidental education fostered by and implanted on a system of oriental ethics.

This story, under the title of "Dai Nippon," or "Great Japan," is told by Dr. Henry Dyer, who for about ten years was principal of the College of Engineering in Tokyo. From it we learn that Japan has taken from Europe and America every concrete aid to progress on which she could lay her hands, and in return for this she now offers a code of morals. When we realise that it is Japanese ethics which are at the base of Japanese character, and that these ethics led to the desire to acquire European knowledge, they commend themselves for close consideration.

We may give water to a horse, but to make him drink is another matter. In a similar manner we may cover a country with schools, but to induce people who have neither the ability nor desire to learn to take advantage of such schools is a formidable task. The Japanese had ability in a marked degree. Their extraordinary power of memorising, which the few Europeans who have noticed the same have only regarded as an abnormal curiosity, may possibly be the resultant of committing to heart the sayings of eastern sages and endless idiographs. A philosophy which had sunk into the hearts of the people while many Europeans still revelled in a feral state no doubt played its part in the suggestion that it was advisable to fall in line with western progress. The main lever, however, which forced Japan from its insular Utopia into the never-ending struggle amongst the comity of nations was the feeling that national and personal honour had been affronted. A civil war was ended, the Tokugawa party had been defeated, and the feudal barons had been united under the Emperor who still reigns. Internal dissensions had ceased, but western demands had settled like a cloud upon the nation. Treaties had been made with thirteen States, each of which had its courts of justice; Japan was powerless to fix its tariffs; Yokohama was policed by a British regiment, and legations kept their guards. In these and other directions Japan felt that, notwithstanding she possessed a culture about which the man in the street is yet profoundly ignorant, she was humiliated and looked down upon as an inferior. Buddhism and Shintoism had resulted in an extraordinary patriotism and loyalty, while the "Bushido" of the "Samurai" gave a system of moral principles "which entered more deeply into the national life of Japan than do those of the religion we profess into Western civilisation."

Among these ethical teachings those bearing upon wisdom, benevolence, and courage were preeminent. Wisdom meant intellectuality rather than mere knowledge. Benevolence resulted in social relationships, so that beggars are practically unknown, whilst State aid for the poor is seldom sought. Courage embodied the idea that it is better to die for one's country rather than yield. Commerce had always been looked down upon as a low pursuit. A nation saturated with such ethical teachings was naturally proud of her autonomy, and sought to escape from occidental restrictions. The escape she chose was by an education in western utilitarian knowledge, wisely backed by an army and a navy.

In 1868, when the present Emperor ascended the throne, he took an oath embodying five principles, the objects of which were to act as beacons in the ocean of international struggles of the world. In the fourth of these we read that "all purposeless principles and useless customs" were to be discarded, whilst the fifth directs that "knowledge and learning shall be sought after throughout the whole world, in order that the status of the Empire of Japan may be raised ever higher and higher." When this announcement was made the education of Japan chiefly consisted in memorising Chinese classics and characters, learning to reckon on the abacus, and studying history and edicts. Knowledge relating to science and its applications was almost non-existent, and we can well imagine the doubts of those who were entrusted with the administration of the imperial command as to the courses they should follow. In 1871 a department of education was created, and with it schools of various grades were established throughout the country. The children of the lower classes, including females, were admitted, while the schedules of study of preexisting schools were re-modelled. At the present time it may be said that Japan bristles with schools, and that there is not an ignorant family in the country.

A child, possibly commencing at a kindergarten, is admitted to a common school at the age of six. After four years he passes to a higher grade school, where there is also a four years' term. Above this there is a middle school with a five years' term. Graduates from this school can by competitive examination pass to one of six higher middle schools, above which stand two imperial universities, in connection with which there are colleges of literature, science, medicine, engineering, law, and agriculture. The number of elementary schools is 27,109. Usually no fees are charged, but in special cases the local governor may allow charges varying between $2\frac{1}{2}d.$ and $5d.$ per month.

In the training of children moral education takes precedence of instruction in facts of practical use in daily life. Bodily development is not neglected, but good manners and etiquette rank higher than minds stored with information.

In the secondary schools, although mathematics, natural history, physics, chemistry, and other subjects are taught, we again find—and find in institutions of all grades—that "morals" (without religious dogma) head the list. It is clear that the Japanese want good citizens, citizens who recognise the symbol of authority

F

rather than practical demonstrations of the same. In Japan a crowd will halt before a straw rope on which flutters a tiny paper notice. In Europe police and truncheons might be required. The good manners of the East are hardly so superficial as popularly imagined. They are the outcome of their philosophy emphasised by special training, the end of which is "to cultivate your mind that even when you are quietly seated not the roughest ruffian can dare make an attack on your person."

The higher secondary schools are preparatory to the universities, the objects of which are to teach "such arts and sciences as are required for purposes of the State." To each is attached a university hall, which is established for purposes of original research. In the six colleges forming the university the professors and assistants number 245, and the students 3121. The entrance fee is 2 yen, and the annual tuition fee is 25 yen (1 yen = 2*s*.). For those who cannot proceed to the universities, industrial, agricultural, commercial, and other technical schools have been established. In 1902 there were 845 such schools, attended by 55,596 scholars. The expenditure on these in 1902 was 2,739,297 yen, of which 285,253 yen was State aid. The total annual expenditure by the Government in connection with the educational department is roughly six million yen (600,000*l*.).

In addition to the schools mentioned, Japan has its naval, military, art, and music schools. Over and above these, again, we find educations in departments of life which in Europe have received but little attention. Chess, or rather "*go*," clubs are common throughout the country, and for proficiency in the game certificates are awarded. Certificates can also be obtained in the art of flower arrangement, an art which has its terminology and canons, but which in Europe finds its perfection in "studied negligence."

In connection with education, a point which Dr. Dyer has not emphasised, but which is in strict accordance with the imperial edict of 1868, is that the Government keeps up a stream of its best educated men flowing round the world, each being a specialist, visiting countries and institutions with the object of gathering together what is valuable in his own vocation. Originally it was the Japanese student who was sent abroad; now it is the professional man. You may not know it, but often he may be able to give more information than he receives. Generally speaking, in Dr. Dyer's words, the Japanese Government finds that money spent on education is a good national investment.

The chapters devoted to industrial development, the army and navy, commerce, politics, and other subjects are as interesting and full of information as those bearing upon education.

With regard to the future of Japan, Dr. Dyer tells us that his ideas are decidedly optimistic, and he believes "that in material, intellectual and moral influence Japan will fully justify her claim to be called the Britain of the East." So far as the concrete adjuncts of civilisation are concerned, Japan might be pleased could she be on the same platform as her ally, but it is doubtful if she aspires to much more. Her 46 millions of people have smiling faces, their courtesy and politeness have attracted the attention of all travellers, they are scrupulously clean and see a bath-tub every day, to show anger is to put yourself on a level with a dog, and should two persons have an altercation, for one to dub the other as a "shaba fusagi" or an "impeder of the world's progress" would be an epithet not to be forgiven. The courage of her soldiers needs no comment, while the endurance of a "jinricksha" man, who for a week can pull a heavy European with his baggage 40 or 50 miles per day, is, from an occidental point of view, quite phenomenal.

The Japanese are temperate, frugal, modest, and happy, while the world knows that they possess artistic instincts. In many directions a Japanese is distinctly superior to the European. The nation has a soul, and if we reflect on the components which make up that soul—the soul of Ruskin—it seems that in certain directions European countries might be benefited if only they were able to raise themselves to the level of Dai Nippon. Although by the opening of the country much has been gained, there are many signs indicating that the blessings have not been unalloyed. Commerce, competition, and the accumulation of wealth have been accompanied by increasing poverty, whilst those whose vocations have been at the open ports have acquired the manners of those with whom they came in contact. So far is this marked that a Japanese who has been a servant in a European house may be handicapped in obtaining similar employment amongst his own people. To say the least, he has become too brusque. Side issues of this nature may cause a nation to regard with regret the disappearance of old conditions, but, taking all in all, Japan has gained more than she has lost. She is no longer a pupil, but a teacher.

SYLVESTER'S MATHEMATICAL PAPERS.

The Collected Mathematical Papers of James Joseph Sylvester. Vol. i., 1837–1853. Pp. xii+650. (Cambridge: University Press, 1904.) Price 18*s*. net.

THE appearance of this volume is very welcome for more reasons than one. Sylvester's papers were published in a variety of journals, and generally contained a considerable number of misprints; they will now be available in an attractive form, with their accidental blemishes removed by a very careful and competent editor. The work of preparing these papers for the press must be troublesome and tedious, and the thanks of mathematicians are due to Dr. Baker for having undertaken it. Special attention should be directed to the note at the end of the volume on Sylvester's theorems about determinants, some of which require correction.

The papers here published range in date from 1837 to 1853. The first three relate to mathematical physics; but Sylvester soon followed his natural bent, and all the rest of this volume is pure analysis, mostly algebra. Historically, the most notable results are those on elimination, canonical forms, and the theory associated with Sturm's method of locating the real roots of equations. Moreover, there is the paper on the contacts of lines and surfaces of the second order, where the invariant factors of a matrix are recognised, and the system of two quaternary quadratics is considered in detail with reference to the simplest simultaneous reduction of the forms.

Appreciations of Sylvester's character and of the value of his mathematical work have been written by able hands, and it is unnecessary to enlarge upon them here. His egotism was obvious and often amusing, but never offensive; his enthusiasm was refreshing, and though his temper was touchy, he was very generous and kind. As a master of formal analysis he has few equals; the birth of the calculus of invariants occurred just at the right time to attract his attention, and his contributions to this subject alone are enough to make him famous. He had the instincts of an architect, and it is well, on the whole, that he did not always trouble to clear away the chips. The casual remarks scattered about his papers and the fragmentary nature of some of them, help to make the reading of them very stimulating; he takes us into his confidence, shows us how his ideas arose, and gives us hints of unexplored regions. He was eminently original, and spent little time in studying the works of his contemporaries; thus he did not even realise that his theory of reciprocants had been more than anticipated by others, especially by Lie. But any misunderstanding arising from this source must have been long since dissipated, and his place among the great mathematicians of his time is quite secure.

Sylvester's occasional notes on the theory of numbers and his lectures on partitions suggest problems to those who are interested in arithmetic. The present volume, for instance, contains three notes on cubic Diophantine equations, a subject not yet exhausted, though Sylvester's own theory of resideration throws much light upon it. The late Henry Smith once referred to this problem as being one which might be hopefully attacked with the engines of modern analysis; perhaps the appearance of this edition of Sylvester's works may lead to the discovery of a complete theory.

A good example of Sylvester's power of illuminating and drawing general conclusions from the simplest mathematical problem is the note (p. 392) on an elementary geometrical theorem for which no direct proof had been discovered. He observes that the proof may be made to depend on showing that a certain analytical equation has no real root, and suggests that in all such cases where the analytical proof consists in demonstrating the *non-existence* of roots, the geometrical proof must necessarily be indirect, while in other cases the *reductio ad absurdum* may be convenient, but is not necessary. This observation reminds us at once of Gauss's discussion of the division of the circle, and if Sylvester's conjecture is true it gives another case of the curious points of contact that exist between analysis and geometry.

It is not to be expected, or even desired, that many should share Sylvester's keen delight in the beauty of formal analysis; but it is a mistake to discourage those who are inclined to enjoy it, however unpractical parts of the subject may be. Quite apart from other reasons, the study of pure mathematics may be defended, like that of music or chess or painting, from the merely æsthetical side, and this Sylvester does in terms both vigorous and quaint. For example:—

"The fortunate proclaimer of a new outlying planet has been justly rewarded by the offer of a baronetcy and a national pension, which the writer of this wishes him long life and health to enjoy. In the meanwhile, what has been done in honour of the discoverer of a new and inexhaustible region of exquisite analysis?" the latter reference being to Cayley's discovery of the calculus of invariants. Fortunately Cayley was saved in another way from the cares of money-making, and he lived long enough to realise to the full his great reputation among those who would appreciate his work. Sylvester in his early life suffered unjustly from the current prejudice against his race; so far as it was possible this was afterwards atoned for, and it is to be hoped that no bitter feeling was left behind.

G. B. M.

MENTAL AND SOCIAL MEASUREMENTS.

An Introduction to the Theory of Mental and Social Measurements. By Edward L. Thorndike, Professor of Psychology in Teachers' College, Columbia University. Pp. xii+212. (New York: The Science Press, 1904.) Price 1.50 dollars net.

AMERICAN colleges seem more awake than our own to the fact that the newer methods of statistics have made it possible to deal with facts with which they are directly concerned, and to discuss them with far more completeness than was practicable a few years ago. They are making in consequence large collections of anthropometric data to serve as tests of health and development, and for comparisons between colleges. Again, there are more teachers in America than in this country who, appreciating the fact that the above methods have far wider applicability, extend the range of their measurements to psychophysical subjects. They are also eager to deal with purely psychical matters that elude direct measurement but admit of being arranged by mutual comparison into their proper class places, or to utilise a third and still more general method, which deals with such objects as can be sorted into a few distinct classes without regard to their internal arrangement. The author is fully justified in saying that

"The obscurest and most complex traits, such as morality, enthusiasm, eminence, efficiency, courage, legal ability, inventiveness, can be made material for ordinary statistical procedure, the one condition being that the general form of distribution of the trait in question shall be approximately known."

In these circumstances a system of elaborate measurements has come into vogue in many American colleges. Whether the authorities have always planned their measurements wisely, and whether they discuss them adequately and accurately, will not be considered here. The volume is written to direct and to warn, in doing which it reveals some grave blunderings. Unfortunately, it is composed chiefly for those persons who are ignorant of even simple mathematics. The author is fully conscious of the serious embarrassments of the position he has chosen, but bravely attempts the well-nigh impossible task of overcoming them. Thus he says:—

"If this book were written by a mathematician for the mathematically minded, it would not need to be one fifth as long. If read by such a one it may well seem intolerably clumsy and inelegant."

Whether he succeeds under these difficulties in giving easily intelligible explanations may well be doubted; indeed, his language, though frequently lucid, is often quite the reverse. Still, if the volume were used as a text-book in the hands of an enthusiastic and capable teacher good results might follow, but it requires an optimistic disposition to believe that it would prove more than superficially instructive, if it were intelligible at all, to the mass of ordinary and unassisted readers. The author might, however, claim a higher rank for it than he has done on the ground that it teems with instructive illustrations by which everyone may profit, and that it presents familiar ideas from slightly new points of view, much to the advantage of even well instructed readers.

There is no science more handicapped by cumbrous and repellent terminology than that of the higher statistics. Its ideas are not always intrinsically difficult to grasp, but the phrases by which they are expressed are both ugly and unexpressive. The writer believes that a student, however mathematically minded he may be, would save himself time and annoyance if he prefaced his earliest studies by a few hours of what might be called *kindergarten* exercises with beans, acorns, or the like. By the process of sorting them into arrays and picking out the medians, quartiles, &c., then by measuring them individually and extracting from the measures the remaining statistical constants, he would soon obtain a serviceable familiarity with the more elementary technical terms and the ideas they represent. It would be easy to devise a suitable course that would prove a welcome help to students who are enthusiastic about measurements, and it is to be hoped that the next writer on popular statistics will elaborate one.

The author gives a large number of frequency polygons, derived from a wide variety of data, which are of interest. It is to be wished that attempts were more frequently made to reduce the variously shaped polygons obtained by experience into a few classified types, to append to each type the names of the objects that had been found to conform to it, and to analyse the causes of its shape in each instance. It is difficult to doubt that by so doing some desirable help would be given to the interpretation of any new polygon. It is perfectly true that almost any curve or polygon *may* be built up in various ways by different types of curve or polygons appropriately superposed, but experience alone will tell whether there is not a much greater probability of such and such a type being due to such and such combinations rather than to others. Through these means many hypothetical sources of origin might be found so rare as to be hardly worth considering, and so the field of probable interpretations would be narrowed. Speaking generally, the interpretation of results is a branch of statistics that has hitherto received less attention than it deserves. It is no doubt a great thing to be able to describe groups and to determine correlations between them with precision, but this is not all that is wanted. It is another and even more important achievement to dissect and analyse results and to discover the dominant causes that produced them, but the art of doing this seems as yet inadequately developed and to offer a promising field for research.

F. G.

OUR BOOK SHELF.

Practical Chemistry, a Second Year Course. By G. H. Martin, M.A. (N.D.). Pp. 41. (Bradford: G. H. Martin, The Grammar School.) Price 1s.

MR. MARTIN has arranged in an unpretentious form a most excellent syllabus of experiments and examples suitable for boys beginning the study of chemistry.

It is satisfactory to find that, in a school of such high standing as the Bradford Grammar School, the science master has seen the wisdom of devoting a whole year (it is to be hoped it will be extended to a second year) to teaching the simple facts which underlie important principles without recourse to tests and tables.

One suggestion may be offered. If the book is to have a wide circulation, which it certainly deserves, it will be necessary to fill in the outline of experiments, and perhaps to illustrate the results by actual examples, possibly in a companion volume.

Boys cannot be expected to work out details of apparatus in the short time allotted to science during school hours if substantial progress is to be made. No doubt the author has his apparatus set up and gives an appropriate demonstration to the class, but this will not help those teachers who wish to profit by the book unless their technical difficulties are solved for them.

J. B. C.

Retouching. By Arthur Whiting. Pp. xvi+91. (London: Dawbarn and Ward, Ltd., 1904.) Price 1s. net.

IT very often happens that photographic negatives require a certain amount of careful manipulation owing to defects caused by photographic methods, scratches, &c. It is also desired sometimes to eliminate small defects due to slight movement of the object, or to alter or improve portions of the picture to attain a desired end. The author has endeavoured in these few pages to place before the reader the different methods and devices that are in use to cope successfully with the various defects that may be encountered. In the first instance the tools required are described, and the special objects of each explained. The reader is then shown how, in the case of portraits, to preserve the likeness but yet to eliminate the blemishes caused by optical or chemical or other action; he is here introduced in a few words to the elements of facial anatomy. The author has considered it necessary to insert a special chapter on retouching portraits of professionals, in which the main principle to be kept in view is to produce a beautiful face. To attain such an ideal, mouths are reduced, jaws cut down, ears knifed, eyes enlarged, and various other surgical operations performed. Working up draperies, retouching landscapes, preparing prints for the press, and how to make a portable retouching desk, form other topics for treatment. The book should serve as an admirable guide to amateurs, and will be found useful to those who go more especially into this class of work. Numerous illustrations accompany the text.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* Nature. *No notice is taken of anonymous communications.*]

Average Number of Kinsfolk in each Degree.

As Dr. Galton has completely misunderstood the point of my last remark, I fear it will be necessary again to re-open a discussion which I had thought was satisfactorily closed.

My point is this: If we take a large number n of families containing in the aggregate nd sons and nd daughters, and remove on an average one child *of specified sex* from each family, we shall have a preponderance of the opposite sex in those that remain. The *average* numbers under this condition will be d and $d-1$, and not $d-\frac{1}{2}$ and $d-\frac{1}{2}$, and this was how I was originally led to my first conclusion.

If, however, we wish to test the question whether a girl has the same average number of brothers as sisters, we are only concerned with families containing at least one girl, and therefore families containing only boys must be left out of account, as I stated. When these have been removed there will be a preponderance of girls in the families that are left. It is this cause which enables us to reconcile the fact that, while the probable total numbers of girls and boys in any family may be equal, the probable numbers of brothers and sisters of a single individual of specified sex, say a girl, may still be equal. This may not be such a rigorous method as Dr. Galton employs, but it at least shows that the result is not necessarily opposed to what one would naturally infer from general considerations. G. H. Bryan.

Compound Singularities of Curves.

The compound singularities of algebraic curves may be divided into three *primary* species. First, *point singularities*, or multiple points, which are exclusively composed of nodes and cusps; secondly, *line singularities*, which are exclusively composed of double and stationary tangents; thirdly, *mixed singularities*, which are composed of a combination of simple point and line singularities. Amongst compound line singularities may be mentioned (α) a double tangent which osculates a curve at one of its points of contact, the constituents of which are one stationary and two *ordinary* double tangents; (β) a tangent having a contact of the fourth order with a curve, the constituents of which are three double and three stationary tangents.

The third species comprises the majority of compound singularities, and may be divided into the following subsidiary ones:—

(1) Nodes and multiple points, any tangent at which has a contact of a higher order than the first with its own branch, and does not touch the curve elsewhere. The flecnode and biflecnode are the most familiar examples of this species.

(2) Nodes, cusps, and multiple points, any tangent at which has a contact of the first or some higher order at some other point or points on the curve. For example, it is possible for each of the six nodal tangents of a trinodal quintic to touch the curve elsewhere, and it can be shown that the six points of contact lie on a conic.

(3) Two or more nodes, cusps or multiple points may have a common tangent. Thus the reciprocal of a biflecnode is a pair of cusps having a common cuspidal tangent, whilst a septimic curve may possess a node and a rhamphoid cusp having a common tangent.

(4) Singularities of the tacnode and oscnode type. When the number of constituent double points is unequal to $\frac{1}{2}n(n-1)$, where n is a positive integer, the singularity cannot be a multiple point, but must be of the tacnode type; and since the constituents of a tacnode are two nodes and two double tangents, every singularity of this species must contain double or stationary tangents, or both. When the number of double points is equal to $\frac{1}{2}n(n-1)$, the singularity *may* be a multiple point, but when it contains line as well as point singularities, it is of the same type as the oscnode, which is composed of three nodes and three double tangents.

(5) A tangent at a node or a multiple point, which has a contact of a higher order than the first with its own branch, may coincide with some other tangent at the singularity. When both tangents at a flecnode coincide, the resulting singularity is a tacnode; but the coincidence of two or more tangents at a multiple point, any of which possess this property, gives rise to a variety of peculiar singularities which do not appear to have been completely examined.

It is also possible for a mixed singularity to be formed in more than one manner; in other words, it may possess more than one penultimate form. Thus an oscnode may be formed by the union of two cusps and two stationary tangents, and additional singularities of this character are possessed by quintic and sextic curves.

To call a cissoid or a cardioid a *nodal* curve appears to me a glaring misuse of language, since both curves are *nodeless*. A. B. Basset.

The Origin of Life.

No doubt "Geologist" points out a literal flaw in my statement, but I thought it would be obvious that by the "potentiality of life," which would be destroyed by heat, I meant potentiality of life, appearing within the time of the experiment. Given countless ages, then, on the evolution hypothesis, the potentiality of life, as of the rest of nature as we know it, existed in the fluid mass of the uncooled earth, and I did not mean to say anything inconsistent with this. Nor, on the other hand, did I mean to say that by the heat applied the potentiality of life in the matter under test would be destroyed for all time. I meant potentiality of appearing within a given time, the time of the experiment, and I cannot help thinking this was the natural sense of my words.

In asking me to explain the introduction of life or its potentiality into this planet, "Geologist" shows that he has entirely mistaken the purport of my letter. My aim was only logical, not constructive. If I could explain how life first appeared on the earth, I should probably be able to suggest a more promising line of experiment than that hitherto followed, which I find myself unable to do. My sole object was to point out a logical error, as it seemed to me, in the view commonly taken by men of science of the results of these experiments, an error, if my memory serves me, fully shared by Huxley—in admiration for whom, I hasten to say, I yield to no one. Huxley, if I remember rightly, was so impressed with the strength of the evidence against the contemporary origination of life that he practically gave up the idea, and put the date back. In this, I am venturing to suggest, he was illogical; through having overlooked the fact that in all the experiments the agent, which was used to destroy actual life and its germs, would probably be efficacious in destroying the potentiality of life in non-living matter on the point of assuming life, if any such there were, and, consequently, the positive result having artificially been made impossible, the negative result meant nothing, and should not be allowed to influence opinion. George Hookham.

Change in Colour of Moss Agates.

The following observations may perhaps throw light on the colour changes in moss agate and flint noted by Messrs. Whitton and Simmonds in your issues of November 10 and 17. Specimens of the flints from Bournemouth referred to by Mr. Simmonds were brought to this laboratory some months ago, and, though they were not submitted to any very searching examination, it was found that the colouring matter could be removed on boiling a fragment with hydrochloric acid, while the solution gave well marked reactions for iron and phosphoric acid. Now the compound $Fe_3(PO_4)_2.8H_2O$, whether prepared in the laboratory or occurring as the mineral vivianite, is colourless when pure, but becomes oxidised to ferrosoferric orthophosphate, and turns blue, when exposed to the atmosphere. It seems probable, then, that the change of colour of these flints is due to a layer of vivianite which alters on exposure.

In considering the case of the agate penholder, it should be noted that such objects are but rarely made of agate in its natural condition, it being the practice of the manufacturers to colour the stone artificially by chemical treatment. Thus a fine blue colour can be developed by soaking the stone first in a solution of potassium ferrocyanide and then in a solution of a ferric salt. Now as exposure to the action of alkalies, or in some cases to direct sunlight, suffices to destroy the blue colouring matter, it would seem probable that it is in this direction that an explanation of the change observed by Mr. Whitton is to be sought.

In conclusion, I may add that a very instructive series of specimens illustrative of the artificial colouring of agate is on exhibition in the mineral gallery of the British Museum (Natural History). A. HUTCHINSON.

Eocene Whales.

IN NATURE for September 29 (p. 543) "R. L." reviews Dr. Fraas's paper on the Egyptian zeuglodonts, dissenting from the conclusions that the zeuglodonts are not whales, and that the ancestors of the whales are at present unknown. I trust "R. L." will pardon me for in turn dissenting from these assertions, and for agreeing entirely with Dr. Fraas. So long ago as 1900, in discussing the pelvic girdle of Basilosaurus, I pointed out that the vestigial femur suggested that of a creodont, while later, in *Science* for March 11, I recorded my utter disbelief in any relationship between Basilosaurus and existing whales. Consequently, while greatly pleased at the results of Dr. Fraas's study of the small zeuglodonts, I was not at all surprised. It seems to me that our knowledge of Eocene mammals is really very small, and that it will be many years before we will be able to trace the line of descent of many existing forms with any degree of certainty. This is most emphatically true of the whales, the ancestry of which is still obscure. At the same time I have pointed out (*Science*, March 11) that the Eocene deposits of the southern United States contain remains of a large cetacean that is at present known to us by a few caudals alone. This form is undescribed, because it seemed to me best to await the discovery of better material than caudals. So while the ancestors of whales are still unknown, we have a hint that they may be discovered any day. F. A. LUCAS.

Brooklyn Institute Museum, November 4.

The Discovery of Argon.

IN reference to the slip indicated in the last issue of NATURE by Prof. G. H. Darwin, permit me to mention that the slip was mine—not Mendeléeff's. In Mendeléeff's text it stands: "As to argon and its congeners—helium, neon, krypton and xenon—these simple gases discovered *mainly* (*preimuschestvenno*) by Ramsay. . . ." I am sorry to see that I had omitted the word "mainly."

In reality, my manuscript (which I enclose) contained, as you see, the words "discovered chiefly by Ramsay," but as "chiefly" was not the proper word it was struck out, probably by myself, in the proof. THE TRANSLATOR.

The Leonids, 1904.

WATCHING was begun on November 14, when between 18h. 10m. and 18h. 40m., in a sky rapidly brightening with approaching sunrise, one certain Leonid, of magnitude excelling that of Sirius, shot from Cancer into Gemini.

November 15.—Watch from 12h. 5m. to 12h. 40m., and 14h. 5m. to 15h. 45m. The heavens were very clear at the start. I had just commenced looking out when a beautiful tailed Leonid, of mag. 3, shot from $85\frac{1}{2}°+2\frac{1}{2}°$ to $74°-2°$. At 12h. 17m. thin, broken clouds began to pass over, the sky becoming completely covered at 12h. 40m. At 12h. 38m. a huge-headed Leonid, outrivalling Venus in brilliancy, was seen travelling behind small, broken clouds from $129°+35\frac{1}{2}°$ to $107°+43°$ in three-quarters of a second. The path here given is probably a little too long. About 13h. 30m. the sky began to clear again, and was pretty good by the time of the commencement of the second watch. There were many thin clouds, but the interspaces were large and very clear. At 15h. 25m. the heavens became quite unclouded. In this last look-out Leonids were more numerous, six being between 14h. 45m. and 15h. 38m. The increase in frequency of meteors of the dominant shower at this period was not due to improvement of seeing conditions.

In the latter watch three shooting stars coming from $160°+48\frac{1}{2}°$ were mapped. The radiant point of the Leonids of November 15, as determined from eight tracks, was at $151°+20°$. The meteors were swift, and mostly left streaks. There was a decided tendency towards green in their colouring.

Below are particulars of some of the most interesting Leonids, other than those mentioned above:—

November 15.

G.M.T.	From	To	Mag.	Duration	Length	Remarks
h. m.	° °	° °		secs.	°	
14 46	$181\frac{1}{2}+28$	$186+28\frac{1}{2}$	>1	$\frac{1}{4}$	4	Swift. Greenish-yellow. Directed from 1° N. γ Leonis.
15 6	$71-9\frac{1}{2}$	$64-11$	>1		$7\frac{1}{2}$	Very swift. White, tinged blue.
15 26	$101+16\frac{1}{2}$	$88+12\frac{3}{4}$	$<$S	1	14	Green-yellow.
15 38	$172+34\frac{1}{2}$	$179\frac{1}{2}+37\frac{3}{4}$	S − ♃		7	White, tinged green. Streak.

Sheffield, November 24. ALPHONSO KING.

Intelligence in Animals.

HAVING recently seen in NATURE some accounts of the sagacity of cats, I trust that the following facts, for which I can personally vouch, may also be interesting to your readers.

We have a cat, an ordinary tabby, which, when out and anxious to gain admittance into the house, not only lifts the weather-board of either our front or back hall-doors three or four times in succession, thereby causing a loud knock each time, but has also instructed her young kitten to perform the same feat.

Both mother and daughter now regularly knock in this manner in order to be let in. J. E. A. T.

MY room opens by a door to a hall; when our fox-terrier wants to come into my room from the hall he *scratches* at my door. When he finds himself in the hall and wants to go out by another door to the garden or back-hall, he *whines* for me, and, going out, I find him by the door he wants opened. This—my leisure regrets—is of daily occurrence. F. C. CONSTABLE.

Wick Court, near Bristol, November 27.

PATAGONIA.[1]

THE dispute between the Argentine Republic and Chile with regard to the boundary line of their Patagonian possessions threatened at one time to result in a prolonged and sanguinary struggle. Happily this misfortune was averted by the decision, honourable to both nations, to refer the differences that had arisen to the arbitration of our Sovereign. A British Commission was accordingly appointed to examine the geographical features of the country and judge how far they could be reconciled with the terms of the treaties the interpretation of which was in question. As the head of this commission was chosen Sir Thomas Holdich, who had served his country as boundary commissioner in the wild inaccessible lands that lie to the north and west of our Indian possessions, and this selection was abundantly justified by the tact and skill with which a frontier more than 800 miles in length was traced in such a manner as to accomplish the almost unprecedented feat of satisfying both parties.

In the present volume Sir Thomas Holdich has given us his impressions of the progressive republics of Chile and the Argentine, and of the scene of his

[1] "The Countries of the King's Award." By Sir Thomas Holdich K.C.M.G. Pp. xv+420. (London: Hurst and Blackett, Ltd., 1904. Price 16s. net.

labours in Patagonia—impressions all the more valuable because they are those of a distinguished soldier and man of science who has spent the greater part of his life in the East, and whose principal achievements have been amongst the great mountain masses and plateaux of Central Asia, which find their only parallel in the Andes. Again and again he dwells on the likeness and on the contrasts between the new lands that he was visiting and those with which he had long been familiar.

We have only space to quote one passage (p. 149):—"One could not see the stiff rows of poplars streaking the stony slopes of the eastern Andes near Mendoza without being forcibly reminded of the Indian frontiers; and the plains of Chile round about Santiago might be the plains of Afghanistan round about Kabul. Standing on the slopes of the hills near Kabul, where Baber's tomb overlooks the Chardeh valley and the flat range of the Hindu Kush fills up the western horizon, where interlacing lines of poplars chequering the purple and yellow fields mark the course of the irrigation channels, an impression once drifted in upon my mind of a land of promise set in the midst of barren hills, specially designed to illustrate man's ingenuity in making green things to grow where no green thing had been before. It was the wealth of the poplars and the willows which produced the impression, contrasted with the sterility of the mountains which formed their background and which were only faintly visible through the summer haze, with just the glint of snowpatch here and there. The impression was reproduced with the first view of the plains stretching from the foot hills of the Andes outwards to the Pacific. For twenty-five years Time might have stood still, and Chardeh, Maidan, and the road to Ghazni were all back again before me."

It is, however, the pages that describe the author's experiences in Patagonia that will appeal most strongly to the scientific reader. The international differences have borne at least some good fruit. In the hope of finding evidence to support one view or the other the interior of Patagonia has been so energetically explored that there are few countries of which there has been so rapid an increase of our geographical knowledge in recent years. Comparatively little of the tract examined by Sir Thomas Holdich had been trodden by the foot of civilised man a dozen years before his visit.

We follow with absorbing interest the author in his rapid journey through the varied scenery of the central depression between the Andes on the one hand and the pampas on the other—a fertile land of hill and valley, with here and there great lakes that occupy the deeper hollows and overflow, some to the Atlantic and others through deep breaks in the mountains to the Pacific. Everywhere there are evidences of important changes in the still recent past—the shrinkage or complete disappearance of lakes, the diversion of the drainage from the Atlantic to the Pacific, and the retrocession of the glaciers.

Elsewhere we read of cruises amid the channels and inlets of the Pacific coast, which form the submerged continuations of the central valley of Chile, and of the glens of the rivers that traverse the Andean chain. Further inland these latter are filled with alluvium overgrown with impenetrable jungle. On this side, too, of the Andes there is evidence of recent changes, for—as Darwin was the first to point out—high above the sea-level are raised beaches and deposits containing shells of forms that still live in the neighbouring ocean.

But although the axis of the Cordillera and the outer

Fig. 1.—Corcovado Valley. From "The Countries of the King's Award."

chain of islands appear to be rising from a position of depression, the line of the great Chilian valley is probably still sinking, for near the head of the Gulf of Penas, and south of the isthmus of Ofqui, that connects the peninsula of Taitao with the mainland, are found forests so recently submerged as to render it necessary to be cautious in steering amongst the tree tops. Future generations of mankind, the author thinks, may see the isthmus submerged beneath the ocean, above which it is even now but slightly raised.

Part of this isthmus is occupied by Lake San Rafael, which is remarkable as the "terminus of an enormous glacier that scatters huge icebergs about its waters." "Is there any other glacier," the author asks, "descending to sea level in latitude 47° either N. or S.?" We know of none; but however that may be there are several that reach the sea between this point and the Straits of Magellan; and yet southern Patagonia is a land of luxuriant vegetation, at least on its western coasts. "Forest was everywhere about us, dense, shadowy, dark and generally dripping. The long lines of the higher sierra were thick with it up to the point where the granite cliffs polished and smoothed by ice-cap and glacier gave foothold to vegetation only on their flat ledges. The little islets that seemed to chase one another through the streaky grey sea were rounded and packed with it." In the Ultima Esperanza district in latitude 52° there are grazing grounds where the sheep fatten quickly on the tufted grass of the country, and are left to find their own shelter, while in the neighbouring woods the puma waits his opportunity as he does in the tropical forests of Brazil. And over the whole country, mountains, valleys, and pampas alike, blow untiringly the strenuous western winds, for the most part in blustering gales that succeed one another in quick succession. "In no country in the world," remarks our author, "must 'weather' and climate be so differentiated as in Patagonia. The weather is bad as bad can be—wild and boisterous, bursting into fury, breaking into sunshine, freezing the blood in one's veins with a biting blizzard, or suffocating the system with the still steady glare of a noonday sun, and it may do all this and more in the course of a few hours' interval; but whether storming or shining, tearing one's tent to rags or bathing the landscape in sunshine, who can describe the life-giving, purifying, sweetening, strengthening effects of the climate."

Such is Patagonia, a land that seems destined to nourish a hardy race woven of many strands, among which the sturdy Welsh colonists of the 16th of October Valley, of whom the author has much to tell us, will not be least important. To the man of science it is a land of striking illustrations of long established principles and of problems that will require many years of research to solve, for of the story of its making scarcely the first chapter a chapter of which Darwin wrote the opening pages—is yet complete.

J. W. E.

LORD KELVIN AND GLASGOW UNIVERSITY.

THE installation of Lord Kelvin as Chancellor of Glasgow University, which took place in the Bute Hall on Tuesday, is an event which has few, if, indeed, it has any, precedents in the recent annals of our universities. The Chancellor is the head of the whole university, but in practice he is rarely present except on ceremonial occasions, and a great part of the work which he has had to do officially is done for him in Scotland, as it is at Oxford, Cambridge, London, or in the newer English universities, by the Vice-Chancellor. Many occasions arise, however, when it is of importance to the universities concerned that statesmen, such as the Prime Minister, who is Chancellor of Edinburgh, Mr. Chamberlain, who is Chancellor of Birmingham, Lord Rosebery, who is Chancellor of London, and Lord Spencer, who is Chancellor of Manchester, should represent their universities in Parliament or elsewhere, and such men have usually been elected not so much on account of their own connection with the universities they preside over as of the eminent place they have taken in the State, and the weight which must on all occasions be attached to their considered opinions. Lord Kelvin has been connected with the University of Glasgow since his early boyhood, he has spent his life within her walls, and he built up his enduring fame during the fifty-three years when he was professor of natural philosophy in the university.

Lord Kelvin's father was a north of Ireland man, preparing for the ministry of the Presbyterian Church. In his day, and until the foundation of the Queen's Colleges in Ireland, Glasgow was the university to which many north of Ireland men resorted, and Lord Kelvin's father was a distinguished student in Glasgow, gaining prizes in many classes more than ninety years since. About eighty years ago he gave up his studies for the ministry and became professor of mathematics in the Belfast Academical Institution. Eight years later—in 1832—he was elected to the chair of mathematics in Glasgow, which he filled for sixteen years with eminent success. There were no better text-books anywhere than those which he published on the subjects of his chair, and the small number of his students who remember him can testify that they never met a clearer or better teacher of mathematics. Prof. James Thomson had a genius for teaching other things besides mathematics, and both Lord Kelvin and his elder brother, who was professor of engineering first in Belfast and afterwards in Glasgow, owed the best of their education to their father. Lord Kelvin was only twenty-two years old when the university had the courage to elect him to the chair of natural philosophy, on the strength of his quite exceptional brilliancy as a student first in Glasgow and afterwards in Cambridge. How he has discharged the duties of his chair and how wide and fruitful have been his conception of its duties is known to the whole world of science.

On Tuesday, after Lord Kelvin had been formally installed as Chancellor of the University, he proceeded to confer the following honorary degrees of LL.D. on the recommendation of the Senate.

Princess Louise (Duchess of Argyll), who was president of Queen Margaret College until the college was incorporated with the university in 1893. The Marquess of Ailsa, who has taken a great interest in naval architecture, and in its practical application to the building of yachts and other vessels. Dr. J. T. Bottomley, F.R.S.; Dr. James Donaldson, principal of the University of St. Andrews; Admiral Sir John Charles Dalrymple Hay, G.C.B., F.R.S.; Dr. J. M. Lang, principal of the University of Aberdeen; Mr. G. Marconi; Mr. Andrew Graham Murray, M.P., Secretary for Scotland; the Hon. C. A. Parsons, F.R.S.; and the Lord Provost of Glasgow, Sir John Ure Primrose, Bart.

After conferring these degrees Lord Kelvin delivered an address, in the course of which he spoke as follows:—

To be Chancellor of one of the universities of our country is indeed a distinguished honour. For me to be Chancellor of this my beloved University of Glasgow is more than an honour. I am a child of the University of Glasgow. I lived in it sixty-seven years (1832 to 1899). But my veneration for the ancient Scottish university, then practically the university for Ulster, began earlier than that happy part of my life. My father, born in County Down, was for four years (1810 to 1814) a student of the University of Glasgow, and in his Irish home, first as professor of mathematics in the newly-founded Royal Belfast Academical Institution, his children were taught to venerate the University of Glasgow. One of my earliest memories of those old Belfast days is of 1829, when the joyful intelligence came that the Senate of the University of Glasgow had conferred the honorary degree of Doctor of Laws on my father. Two years later came the announcement that the faculty of Glasgow College had elected him to the professorship of mathematics.

In 1834, two years after my father was promoted from Belfast to the Glasgow professorship of mathematics, I became a matriculated member of the University of Glasgow. To this day I look back to Prof. William Ramsay's lectures on Roman antiquities and readings of Juvenal and Plautus as more interesting than many a good stage play that I have seen in the theatre. Happy it is for our university, and happy for myself, that his name, and a kindred spirit, are with us still in my old friend and colleague, our senior professor, George Ramsay. Greek, under Sir Daniel Sandford and Lushington, logic under Robert Buchanan, moral philosophy under William Fleming, natural philosophy and astronomy under John Pringle Nichol, chemistry under Thomas Thomson (a very advanced teacher and investigator), natural history (zoology and geology) under William Couper, were, as I can testify by my own experience, all made interesting and valuable to the students of Glasgow University in the 'thirties and 'forties of the nineteenth century. Sandford, in teaching his junior class the Greek alphabet and a few characteristic Greek words, and the Scottish pronunciation of Greek, gave ideas, and something touching on philology, to very young students, which remains on their minds after the heavier grammar and syntax which followed have vanished from their knowledge. Logic was delightfully unlike the Collegium Logicum described by Goethe to the young German student through the lips of Mephistopheles. Even the dry bones of predicate and syllogism were made by Prof. Buchanan very lively for six weeks among the students of logic and rhetoric in Glasgow College sixty-seven years ago; and the delicious scholastic gibberish of "Barbara, Celarent" remains with them an amusing recollection. A happy and instructive illustration of the inductive logic was taken from Wells's "Theory of Dew," then twenty years old. My predecessor in the natural philosophy chair, Dr. Meiklebam, taught his students reverence for the great French mathematicians, Legendre, Lagrange, Laplace. His immediate successor in the teaching of the natural philosophy class, Dr. Nichol, added Fresnel and Fourier to this list of scientific nobles; and by his own inspiring enthusiasm for the great French school of mathematical physics, continually manifested in his experimental and theoretical teaching of the wave theory of light and of practical astronomy, he largely promoted scientific study and thorough appreciation of science in the University of Glasgow. In this hall you see side by side two memorial windows presented to the university to mark permanently its admiration of three men of genius, John Caird, John Pringle Nichol, and his son, John Nichol, who lived in it, and worked for it and for the world, in the two departments of activity for which universities exist, the humanities and science. As far back as 1818 to 1830 Thomas Thomson, the first professor of chemistry in the University of Glasgow, began the systematic teaching of practical chemistry to students, and by aid of the faculty of Glasgow College, which gave the site and the money for the building, realised a well equipped laboratory, which preceded, I believe, by some years Liebig's famous laboratory of Giessen, and was, I believe, the first of all the laboratories in the world for chemical research and the practical instruction of university students in chemistry. That was at a time when an imperfectly informed public used to regard the University of Glasgow as a stagnant survival of mediævalism and to call its professors the Monks of the Molendinar!

The university of Adam Smith, James Watt, and Thomas Reid was never stagnant. For two centuries and a quarter it has been very progressive. Nearly two centuries ago it had a laboratory of human anatomy. Seventy-five years ago it had the first chemical students' laboratory. Sixty-five years ago it had the first professorship of engineering of the British Empire. Fifty years ago it had the first physical students' laboratory—a deserted wine cellar of an old professorial house, enlarged a few years later by the annexation of a deserted examination room. Thirty-four years ago, when it migrated from its four hundred years old site off the High Street of Glasgow to this brighter and airier hilltop, it acquired laboratories of physiology and zoology, too small and too meagrely equipped. And now every university in the world has, or desires to have, laboratories of human anatomy, of chemistry, of physics, of physiology, of zoology. Within the last thirty years laboratories of engineering, of botany, and of public health have been added to some of the universities of the British Empire, with highly beneficent results for our country and the world. All these the University of Glasgow now has. During the last fifty years our university has grown in material greatness and in working power to an extent that its most ardent well-wishers in the first half of the nineteenth century could scarcely have imagined possible. Two successive legislative commissions (1858 and 1889) have re-formed its constitution and broadened its foundations, and added to its financial resources, and admitted women to its membership, with all the privileges of students and graduates. Splendidly liberal subscriptions by the people of Glasgow and by a world-wide public outside, backed by powerful aid from the National Treasury, enabled the university, on leaving its ancient site, to enter into the grand group of buildings on Gilmorehill, in which it has happily lived ever since. A few years later the generous gift of 45,000*l*. by the late Marquis of Bute built the hall called after his name, in which we are now met. At the same time the adjoining Randolph Hall and staircase were built by a portion of the legacy left to the university by the late Mr. Randolph. The Queen Margaret College and grounds were presented to the university by Mrs. Elder, who also added largely to the endowment of the engineering professorship, and founded the professorship of naval architecture. Other generous donors have given an engineering laboratory with lecture-rooms, and botanical buildings, and great and much needed extensions in the anatomical department. The Carnegie Trust and the principal's university equipment scheme are at present providing two new buildings; one of these is for extensions in the medical school. The other, in which I naturally take the most personal interest, is for the natural philosophy department, including lecture-rooms and a physical laboratory, all designed and at present being realised under the able direction of my successor in the natural philosophy chair, Prof. Andrew Gray.

In the province of the humanities the working power of the university for instruction and research has been largely augmented during the last fifty years by the foundation of new professorships, conveyancing, English language and literature, Biblical criticism, clinical surgery, clinical medicine, history (in my opinion the most important of all in the literary department), pathology, political economy. In mathematics and in the science of dead matter, professorships of naval architecture and geology; lectureships of electricity, of physics, and of physical chemistry; and demonstratorships and official assistantships in all departments have most usefully extended the range of study, and largely strengthened the working corps for research and instruction. I venture to congratulate the city of Glasgow on having for her god-daughter a university so splendidly equipped and so admirably provided with workers.

ANNIVERSARY MEETING OF THE ROYAL SOCIETY.

THE report of the council of the Royal Society was presented at the anniversary meeting held yesterday, November 30, and the president, Sir William Huggins, K.C.B., F.R.S., delivered the annual address.

The council refers to the second general assembly of the International Association of Academies last Whitsuntide as one of the chief events of the year. At the close of the meeting, Vienna was chosen by a unanimous vote as the place of meeting of the next general assembly. A complete protocol of the proceedings of the assembly has been drawn up, and will be issued before the end of this year. Other matters referred to in the report are the African geodetic arc, the international congress of aëronautics held at St. Petersburg in August, the international laboratory of physiology on Monte Rosa, the Royal Society "Catalogue of Scientific Papers," the "International Catalogue of Scientific Literature," the Government grant for scientific investigations, and the expenses of special Government inquiries.

The Royal Society is frequently requested by various departments of the Government to advise upon, or in some cases to undertake the supervision and control of, and in others the entire responsibility for, scientific investigations of national importance, but no provision has been made by Government to meet expenses to which the Society has been put in acceding to these requests. As the result of pointing out this unsatisfactory position, H.M. Treasury has approved of an alteration in the regulations for administering the Government grant of 4000*l.* for scientific purposes which will permit a sum to be set aside out of the reserve fund of the grant for printing and office expenditure incurred "in undertaking, controlling, supervising or advising upon matters which the President and Council may, at the request of the Government, undertake, control, supervise or advise upon." That is to say, the Royal Society is graciously permitted by the Treasury to use a part of the annual Government grant for scientific investigations to meet expenses incurred in answering Government inquiries.

Mention is also made in the report of the radium research grant of the Goldsmiths' Company, the Treasury inquiry into the Meteorological Office, and the letter on scientific education sent by the council to all British universities last January. The following extracts from other parts of the report of the council are of interest:—

Sleeping Sickness.

The investigation of this disease in Uganda was continued after Colonel Bruce's return to England by Dr. Nabarro and Captain Greig, of the Indian Medical Service. A further report (No. 4) by Colonel Bruce has been published, and its general conclusions, briefly stated in the last report of the council—namely, that the sleeping sickness is caused by the entrance into the blood and thence into the cerebro-spinal fluid of a species of Trypanosoma (*T. gambiense*), and that these trypanosomes are transmitted from the sick to the healthy by a species of tsetse fly (*Glossina palpalis*)—have been confirmed by subsequent observations. The efforts of the observers are now being directed to the attempt to discover a means of eliminating the trypanosomes from the blood and tissues of the infected in the early stages, and before severe damage has been done to the nervous centres. In the meantime the Royal Society Committee has advised the Government to adopt such preventive measures as are found practicable for protecting a non-infected area where the carrier fly is found from the incursion of emigrants from the infected areas.

Antarctic Expedition and Investigation.

The Antarctic ship *Discovery*, accompanied by the relief ships *Morning* and *Terra Nova*, returned safely in March last to Lyttelton, and a "Summary of Proceedings" was forwarded thence by Captain Scott by post to the presidents of the Royal and Royal Geographical Societies. The *Discovery* arrived in England at the beginning of September, when a joint letter of welcome from the president and the president of the Royal Geographical Society was dispatched to Captain Scott.

The natural history specimens and notes and drawings have been sent to the British Museum (Natural History Department), to be preserved there as part of the national collection, the trustees of the museum having agreed to organise and undertake the publication of these results of the expedition, under the editorship of the director of the museum.

The laborious duty of arranging for the reduction and publication of the magnetic and meteorological observations made by the expedition has been undertaken by the Royal Society. Two special expert committees have been appointed, and are already dealing with these two classes of material.

As regards the magnetic observations, the Hydrographic Department of the Admiralty has undertaken the reduction of about one-third of the material, and the remaining two-thirds, consisting of the slow-run magnetograms, remain to be dealt with. The committee for magnetism have accordingly arranged that these observations shall be reduced, under the superintendence of Dr. Chree, their secretary, in the observatory department of the National Physical Laboratory; and the Royal Society has undertaken responsibility for the cost of these reductions, to the extent of 400*l.*, by an advance from the donation fund, in the full hope that this expenditure will be refunded out of the proceeds of the sale of the *Discovery*.

Committees have been arranged for dealing with other observations. The reduction of the meteorological observations has been undertaken by the Meteorological Council with the aid of a sum of 500*l.* guaranteed by the Royal Geographical Society in anticipation of the sale of the *Discovery*. It is hoped that the publication of these results will be undertaken by H.M. Stationery Office.

The committees are working as far as possible in concert with the authorities engaged in the reduction of the observations of the German and Scottish Antarctic Expeditions, which in part covered the same period of time.

It is proposed that the special scientific results of the expedition shall be published in a uniform series of volumes similar to the published records of the *Challenger* Expedition.

Mediterranean Fever.

In February last a letter was received from the Colonial Office asking whether the Royal Society would be willing to appoint an advisory board in this country for the purpose of supervising investigations into Mediterranean fever, to be carried out by a commission representing the Navy, the Army, and the Civil Government of Malta.

The matter was referred to the tropical diseases committee of the society, which had superintended the investigations into malaria and sleeping sickness, and upon their advice the council decided to accede to the request of the Colonial Office, provided that the appointment of investigators rested with the Royal Society, and that all expenses in connection with the investigation were borne by the Government. These conditions were accepted by the Government with a modification, which the council acceded to at the particular request of H.M. Treasury, viz. that the Royal Society should participate by defraying (out of the Government Grant Reserve Fund) the cost of scientific equipment to an amount not exceeding 200*l.* The advisory board was constituted as a subcommittee of the tropical diseases committee, with Colonel Bruce, F.R.S., as chairman. Members of the commission of investigation were nominated, with the approval of this committee, by the Navy, the Army, and the Civil Government of Malta, and Colonel Bruce himself went out to Malta on behalf of the committee to start the inquiry, which is now in active progress.

National Physical Laboratory.

The National Physical Laboratory has continued its work with success during the year, the last of the five for which the original annual grant of 4000*l.* was made by the Treasury.

This fact has been prominently before the committee at its various meetings. In reply to an inquiry by the chairman, a letter was received from Sir E. W. Hamilton to the effect that while there was no idea of stopping the grant, the question before H.M. Treasury was whether there should be an increase in its amount, and suggesting that the committee should formulate "constructive proposals" with detailed estimates of the expenditure, both capital and recurring, required to put the laboratory on a satisfactory footing. Accordingly this was done, and a memorandum on the future organisation and expenditure of the laboratory, which was drawn up by the executive committee on February 19, was sent to the Treasury by the president and council, who strongly supported the proposals of the committee.

The main recommendations of the memorandum were (1) that a sum of nearly 30,000*l.* was required for capital expenditure, and (2) that the annual grant should be raised in the course of four years to 10,000*l.*; while, with a view to supporting these proposals, a request was made for an official inquiry into the work and organisation of the laboratory.

To this request the Financial Secretary of the Treasury replied, stating that the question of the increase must stand over until the estimates for 1905–6 were under consideration, and suggesting that meanwhile the executive committee should consider which of the new works were of the most pressing importance, and make application accordingly.

In answer, a further memorandum was prepared, pointing out that the question at issue was whether the laboratory is to be allowed to remain undeveloped in its present condition, with its limited powers and opportunities, or whether it is to be adequately developed, and ultimately placed on a footing similar to that of the corresponding institutions in other countries, and asking that the First Lord of the Treasury would receive a deputation to support the request already made, "That an inquiry might be instituted into the work and organisation of the National Physical Laboratory with a view to laying down the lines that ought to be followed in its future development."

In consequence of this request, a conference took place early in August at the House of Commons between the Prime Minister, the Chancellor of the Exchequer, and the President of the Board of Trade on the one hand, and Lord Rayleigh, Sir F. Hopwood, the treasurer and senior secretary of the Royal Society, with the director, representing the laboratory, at which the matter was discussed.

The donations and subscriptions promised to the laboratory, in most cases for five years, have increased, and now reach a total of about 2000*l.*

While the report is one of progress, the committee of the laboratory feel that with adequate financial support they might do much more. It is not yet sufficiently recognised how substantial is the assistance the laboratory can render to commerce and manufactures. The grant made by the Government is treated by them as one in aid of science itself, although it is applied under the highest scientific direction to facilitate the applications of science to manufacture. This distinction is an important one, which needs to be emphasised; when it is fully grasped the progress of the laboratory, as an aid to national industry, will be much more rapid.

In his anniversary address the president referred at first to the scientific careers of the thirteen fellows of the Society lost by death since the previous anniversary. He then gave a sketch of the work the society has done and is doing for the nation, and showed how the generous intentions of the founder, Charles II., were never fulfilled. From this survey of the history of the society, we have taken the following extracts, with the descriptions of the scientific work of this year's medallists:—

During the last few years a very large amount, increasing each year, of work outside the reading, discussion, and printing of papers, of a more or less public character, has been thrown upon the Royal Society—so large indeed as at present to tax the society's powers to the utmost. A not inconsiderable part of this work has come from the initiation by the society itself of new undertakings, but mainly it has consisted of assistance freely given, at their request, to different departments of the Government on questions which require expert scientific knowledge, and which involve no small amount of labour on the part of the officers and staff, and much free sacrifice of time and energy from fellows, in most cases living at a distance.

There is little doubt that this largely-increased amount of public work has arisen, in part naturally from the greater scientific activity of the present day, but also, and to a greater extent, from the fuller recognition by the Government and the public of the need for scientific advice and direction in connection with many matters of national concern.

It may not be inopportune, therefore, for me to say a few words on the advisory relation in which the society has come to stand to the Government, and to review very briefly the great work which the society has done, and is doing, for the nation.

Among academies and learned societies the position of the Royal Society is, in some respects, an exceptional one. In the British dominions it holds a unique position, not only as the earliest chartered scientific society, but in its own right, on account of the number of eminent men included in its fellowship, and the close connection in which it stands, though remaining a private institution, with the Government. The Royal Society is a private learned body, consisting of a voluntary and independent association of students of science united for the promotion of natural knowledge at their own cost.

The Royal Society, while remaining a purely private institution for the promotion of natural knowledge, has been regarded by the Government as the acknowledged national scientific body, the advice of which is of the highest authority on all scientific questions, and the more to be trusted on account of the society's financial independence; a body, which, through its intimate relations with the learned societies of the Colonies, has now become the centre of British science. The society's historical position and the scientific eminence of its fellows have made it naturally the body which the scientific authorities of foreign countries regard as representing the science of the Empire, and with which they are anxious to consult and to cooperate, from time to time, on scientific questions of international importance.

On their part, the fellows of the Royal Society, remembering that the promotion of natural knowledge is the great object for which it was founded and still exists, and that all undertakings in the home and in the State, since they are concerned with nature, can be wisely directed and carried on with the highest efficiency only as they are based upon a knowledge of nature, have always recognised the fundamental importance of the society's work to national as well as to individual success and prosperity, and their own responsibility as the depositories of such knowledge. They have always been willing, even at great personal cost, ungrudgingly to afford any assistance in their power to the Government on all questions referred to them which depend upon technical knowledge, or which require the employment of scientific methods. In particular the society has naturally always been eager to help forward, and even to initiate, such national undertakings as voyages of observation or of discovery of any kind, or for the investigation of the incidence of disease, which have for their express object the increase of natural knowledge.

At the same time, as the society is dependent upon the voluntary help of its fellows, whose time is fully occupied with their own work, the society may reasonably expect the Government not to ask for assistance on any matters of mere administration that could be otherwise efficiently provided for. The hope may be expressed that in the near future, with increased official provision in connection with the recognition of science, the position of the society to the Government may not extend beyond that of a purely advisory body, so that the heavy responsibilities now resting upon it, in respect of the carrying out of many public undertakings on which its advice has been asked, may no longer press unduly, as they certainly do at present, upon the time and energy of the officers and members of committees. The society regards this outside work, important as it is, as extraneous, and therefore as subordinate, and would not be justified in permitting such work to interfere with the strict prosecution of pure natural science as the primary purpose of the society's existence, upon which, indeed, the society's importance as an advisory body ultimately depends.

The society has accepted heavy responsibilities at the instance of the Government in respect of the control of scientific observations and research in our vast Indian Empire. In 1899, the India Office inquired whether the Royal Society would be willing to meet the wishes of the Indian Government by exercising a general control over the scientific researches which it might be thought desirable to institute in that country. A standing committee was appointed in consequence by the council for the purpose of giving advice on matters connected with scientific inquiry, probably mainly biological, in India, which should be supplementary to the standing observatories committee which was already established at the request of the Government as an advisory body on astronomical, solar, magnetic, and meteorological observations in that part of the Empire.

An investigation, onerous indeed, but of the highest scientific interest and of very great practical importance, has been carried on by a series of committees successively appointed at the request of the Government for the consideration of some of the strangely mysterious and deadly diseases of tropical countries. In 1896 a committee was appointed at the request of the Colonial Secretary to investigate the subject of the tsetse-fly disease in South Africa. Two years later Mr. Chamberlain, Secretary of State for the Colonies, requested the society to appoint a committee to make a thorough investigation into the origin, the transmission, and the possible preventives and remedies of tropical diseases, and especially of the malarial and "blackwater" fevers prevalent in Africa, promising assistance, both on the part of the Colonial Office and of the Colonies concerned. A committee was appointed, and, under its auspices, skilled investigators were sent out to Africa and to India. In the case of the third committee the society itself took the initiative. An outbreak in Uganda of the disease, appalling in its inexorable deadliness, known as "sleeping sickness" having been brought to the knowledge of the society, a deputation waited upon Lord Lansdowne at the Foreign Office, asking him to consider favourably the dispatch of a small commission to Uganda to investigate the disease. He gave his approval, and a commission of three experts, appointed on the recommendation of the committee, was sent out to Uganda, 600*l.* being voted out of the Government grant towards the expenses of the commission.

The investigations in tropical diseases, promoted and directed by these committees, have largely increased our knowledge of the true nature of these diseases, and, what is of the highest practical importance, they have shown that their propagation depends upon conditions which it is in the power of man so far to modify, or guard against, as to afford a reasonable expectation that it may be possible for Europeans to live and carry on their work in parts of the earth where hitherto the sacrifice of health, and even of life, has been fearfully great. A general summary of the work already done on malaria, especially in regard to its prevention, and also on the nature of "blackwater" fever, has been published in a Parliamentary paper, which records Mr. Chamberlain's acknowledgment to the Royal Society for its cooperation in the work undertaken by the Colonial Office. The reports on sleeping sickness up to this time form four whole numbers of the *Proceedings*, giving evidence in support of the view that this deadly disease is caused by the entrance into the blood, and thence into the cerebro-spinal fluid, of a species of Trypanosoma, and that these organisms are transmitted from the sick to the healthy by a kind of tsetse fly, and by it alone; sleeping sickness is, in short, a human tsetse-fly disease.

In 1897, the council was requested to assist the Board of Trade in drawing up schedules for the establishment of the relations between the metric and the imperial units of weights and measures. A committee was appointed, which, after devoting much time and attention to the matter, drew up schedules which were accepted by the Board of Trade and incorporated in the Orders of Council.

Soon after the reports were received of the appalling volcanic eruptions and the loss of life which took place in the West Indies in 1902, the council received a letter from Mr. Chamberlain to ask if the society would be willing to undertake an investigation of the phenomena connected with the eruptions. The council, considering that such an investigation fell well within the scope of the objects of the society, organised a small commission of two experts, who left England for the scene of the eruption eleven days only after the receipt of Mr. Chamberlain's letter, the expenses being met by a grant of 300*l.* from the Government Grant Committee. Six weeks were spent in the islands, including Martinique, by the commission, which was successful in securing results of great scientific interest. A preliminary report was published at the time, and a full report has since appeared in the *Transactions*.

Time forbids me to do more than mention the successive expeditions sent out by the society, conjointly with the Royal Astronomical Society, for the observation of total solar eclipses; and the onerous work thrown upon the society for several years in connection with the National Antarctic Expedition, undertaken jointly with the Royal Geographical Society, which has this year returned home crowned with success; but the society's labours are not at an end, for the prolonged and responsible task of the discussion and publication of the scientific results of the expedition is still before them.

To the Royal Society is entrusted the responsible task of administrating the annual Government grant of 4000*l.* for the purpose of scientific research, and a grant of 1000*l.* in aid of the publication of scientific papers.

In addition to these permanent responsibilities, which are always with the society, its advice and aid are sought from time to time both by the Government and by scientific institutions at home and abroad, in favour of independent objects of a more or less temporary character, of which, as examples, may be taken the recent action of the society for the purpose of obtaining Government aid for the continuation through Egypt of the African arc of meridian, and for the intervention of the Government to assist in securing the fulfilment of the part undertaken by Great Britain in the International Astrographic Catalogue and Chart.

Upon the present fellows falls the glorious inheritance of unbounded free labour ungrudgingly given during two centuries and a half for the public service, as well as of the strenuous prosecution at the same time of the primary object of the society, as set forth in the words of the Charter: "the promotion of Natural Knowledge." The successive generations of fellows have unsparingly contributed of their time to the introduction and promotion, whenever the opportunity was afforded them, of scientific knowledge and methods into the management of public concerns by departments of the Government. The financial independence of the Royal Society, neither receiving, nor wishing to accept, State aid for its own private purposes, has enabled the society to give advice and assistance which, both with the Government and with Parliament, have the weight and finality of a wholly disinterested opinion. I may quote here the words of a recent letter from H.M. Treasury:—"Their Lordships have deemed themselves in the past very fortunate in being able to rely, in dealing with scientific questions, upon the aid of the Royal Society, which commands not only the confidence of the scientific world, but also of Parliament."

In the past the Royal Society has been not infrequently greatly hampered in giving its advice by the knowledge that the funds absolutely needed for the carrying out of the matters in question in accordance with our present scientific knowledge would not be forthcoming. Though I am now speaking on my own responsibility, I am sure that the society is with me, if I say that the expenditure by the Government on scientific research and scientific institutions, on which its commercial and industrial prosperity so largely depend, is wholly inadequate in view of the present state of international competition. I throw no blame on the individual members of the present or former Governments; they are necessarily the representatives of public opinion, and cannot go beyond it. The cause is deeper, it lies in the absence in the leaders of public opinion, and indeed throughout the more influential classes of society, of a sufficiently intelligent appreciation of the supreme importance of scientific knowledge and scientific methods in all industrial enterprises, and indeed in all national undertakings. The evidence of this grave state of the public mind is strikingly shown by the very small response that follows any appeal that is made for scientific objects in this country, in contrast with the large donations and liberal endowments from private benefaction for scientific purposes and scientific institutions which are always at once forthcoming in the United States. In my opinion, the scientific deadness of the nation is mainly due to the too exclusively mediæval and classical methods of our higher public schools, and can only be slowly removed by making in future the teaching of science, not from text-books for passing an examination, but, as far as may be possible, from the study of the phenomena of nature by direct observation and experiment, an integral and essential part of all education in this country.

I proceed to the award of the medals.

Copley Medal.

The Copley Medal is awarded to Sir William Crookes, F.R.S., for his experimental researches in chemistry and physics, extending over more than fifty years. Ever since his discovery of the element thallium in the early days of spectrum analysis, he has been in the front rank as regards the refined application of that weapon of research in chemical investigation. Later, the discrepancies which he found in an attempt to improve weighings, by conducting the operation in high vacua, were tracked out by him to a repulsion arising from radiation, which was ultimately ascribed by theory to the action of the residual gas. This phenomenon, illustrated by the radiometer, opened up a new and fascinating chapter in the dynamical theory of rarefied gases, which the genius of Maxwell, O. Reynolds, and others, has left still incomplete. The improvements in vacua embodied in the Crookes tube led him to a detailed and brilliant experimental analysis of the phenomena of the electric discharge across exhausted spaces; in this, backed by the authority of Stokes, he adduced long ago powerful cumulative evidence that the now familiar kathode rays, previously described by C. F. Varley, must consist of projected streams of some kind of material substance. His simple but minutely careful experiments on the progress of the ultimate falling off in the viscosity of rarefied gases, from the predicted constant value of Maxwell, at very high exhaustions, gave, in Stokes's hands, an exact account of the trend of this theoretically interesting phenomenon, which had already been approached in the investigations of Kundt and Warburg, using Maxwell's original method of vibrating discs.

These examples, not to mention recent work with radium, convey an idea of the acute observation, experimental skill, and persistent effort, which have enabled Sir William Crookes to enrich physical science in many departments.

Rumford Medal.

The Rumford Medal is awarded to Prof. Ernest Rutherford, F.R.S., on account of his researches on the properties of radio-active matter, in particular for his capital discovery of the active gaseous emanations emitted by such matter, and his detailed investigation of their transformations. The idea of radiations producing ionisation, of the type originally discovered by Röntgen, and the idea of electrified particles, like the kathode rays of vacuum tubes, projected from radio-active bodies, had gradually become familiar through the work of a succession of recent investigators, when Rutherford's announcement of a very active substance, diffusing like a gas with a definite atomic mass, emitted by compound of thorium, opened up yet another avenue of research with reference to these remarkable bodies. The precise interpretation of the new phenomena, so promptly perceived by Rutherford, was quickly verified, for radium and other substances, by various observers, and is now universally accepted. The modes of degradation, and the enormous concomitant radio-activity, of these emanations, have been investigated mainly by Rutherford himself, with results embodied in his treatise on radio-activity and his recent Bakerian lecture on the same subject. It perhaps still remains a task for the future to verify or revise the details of these remarkable transformations of material substances, resulting apparently in the appearance of chemical elements not before present; but, however that may issue, by the detection and description of radio-active emanations and their transformations, Prof. Rutherford has added an unexpected domain of transcendent theoretical interest to physical science.

Royal Medal.

A Royal Medal is awarded to Prof. W. Burnside, F.R.S., on the ground of the number, originality, and importance of his contributions to mathematical science. The section of our "Catalogue of Scientific Papers" for the period 1883–1900 enumerates fifty-three papers by Prof. Burnside, the first dated 1885, and the "International Catalogue of Scientific Literature" thirteen more. His mathematical work has consisted largely of papers on the theory of groups, to which he has made most valuable additions. In 1897 he published a volume "On the Theory of Groups of Finite Order," which is a standard authority on that subject. Two recent papers on the same theory, published in 1903, may be specially mentioned. In one of these he succeeded in establishing by direct methods, distinguished by great conciseness of treatment, the important subsidiary theory of group-characteristics, which had been originally arrived at by very indirect and lengthy processes. In the other he proved quite shortly the important result that all groups of which the order is the product of powers of two primes are soluble.

Besides the treatise and papers relating to group theory, Prof. Burnside has published work on various branches of pure and applied mathematics. His work on automorphic functions dealt with an important and difficult special case which was not included in the theory of these functions as previously worked out. The paper on Green's function for a system of non-intersecting spheres was perhaps the first work by any writer in which the notions of automorphic functions and of the theory of groups were applied to a physical problem. He has also made important contributions to the theory of functions, non-Euclidean geometry, and the theory of waves on liquids. His work is distinguished by great acuteness and power, as well as by unusual elegance and most admirable brevity.

Royal Medal.

The other Royal Medal is awarded to Colonel David Bruce, F.R.S., who, since 1884, has been engaged in prosecuting to a successful issue researches into the causation of a number of important diseases affecting man and animals. When he went to Malta in 1884 the exact nature of the widely prevalent "Malta," "Rock," or "Mediterranean" fever was entirely unknown. After some years' work at the etiology of this disease, he discovered in 1887 the organism causing it, and succeeded in cultivating the *Micrococcus melitensis* outside the body. This discovery has been confirmed by many other workers, and is one of great importance from all points of view, and perhaps more especially as, thanks to it, Malta fever can now be separated from other diseases, *e.g.* typhoid, remittent, and malarious fevers, with which it had hitherto been confounded.

During the next few years he was engaged in researches of value on cholera, and on methods of immunisation against this disease. He also carried out some work on the leucocytes in the blood, published in the *Proceedings* of the Royal Society, 1894.

In 1894 he was requested by the Governor of Natal to investigate the supposed distinct diseases of "nagana" and the tsetse-fly disease. In the short time of two months he made the most important discovery that these two diseases were one and the same, and dependent upon the presence of a protozoan organism in the blood, known as a trypanosome. Some six months later Bruce was enabled to return to Zululand, and remained there two years, studying the disease and making the discovery that the tsetse fly acted as the carrier of the organism which caused it. He was thus the first to show that an insect might carry a protozoan parasite that was pathogenic. This observation was made in 1895.

Bruce not only determined the nature and course of "nagana," but in addition he studied the disease in a large number of domestic animals, and also observed the malady in a latent form in the wild animals of South Africa. Subsequent observers have found but little to add to Bruce's work on this subject.

In 1900 Bruce was ordered to join a commission investigating the outbreak of dysentery in the Army in South Africa, and a great part of the laboratory work performed by this commission was carried out by him.

In 1903 Colonel Bruce went, at the request of the Royal Society, to Uganda, to investigate further the nature of sleeping sickness. It was very largely, if not entirely, owing to him that the work of the Royal Society's commission was brought to a successful issue. At the time when he arrived a trypanosome had been observed by Castellani in a small number of cases of this disease; thanks to Bruce's energy and scientific insight, these observations were rapidly extended, and the most conclusive evidence obtained, that in all cases of the disease the trypanosome was present. He showed further that a certain tsetse fly, the *Glossina palpalis,* acted as the carrier of the trypanosome, and obtained evidence showing that the distribution of the disease and of the fly were strikingly similar.

Bruce has therefore been instrumental in discovering and establishing the exact nature and cause of three widespread diseases of man and of animals, and in two of these, nagana and Malta fever, he discovered the causal organism. In the third, sleeping sickness, he was not the first to see the organism, but he was quick to grasp and work out the discovery, and he made the interesting discovery of the carrier of the pathogenic organism, and thus discovered the mode of infection and of spread of the malady, matters of the highest importance as regards all measures directed to arrest the spreading of the disease.

All this research work has been done whilst serving in the Royal Army Medical Corps, and engaged in the routine work of the Service.

Davy Medal.

The Davy Medal is awarded to Prof. W. H. Perkin, jun., F.R.S., for his masterly and fruitful researches in the domain of synthetic organic chemistry, on which he has been continuously engaged during the past twenty-five years.

Dr. Perkin's name is identified with the great advances which have been made during the past quarter of a century in our knowledge of the ring or cyclic compounds of carbon. Thus, in the year 1880, the cyclic carbon compounds known to chemists were chiefly restricted to the unsaturated groupings of six carbon atoms met with in benzene and its derivatives, whilst the number of compounds in which saturated carbon rings had been recognised was very limited, and it was indeed considered very doubtful whether compounds containing carbon rings with more or less than six atoms of carbon were capable of existence.

The starting point for Dr. Perkin's researches in this field of inquiry was his investigation of the behaviour of the di-halogen derivatives of various organic radicals with the sodium compounds of malonic, aceto-acetic, and benzoylacetic esters, which led to the synthesis of the cyclic polymethylene compounds up to those of hexamethylene, whilst heptamethylene derivatives were obtained by an adaptation of the well known reduction of ketonic bodies leading to pinacones. The reactions thus introduced by Perkin are now classical, having proved themselves of the highest importance for synthetical purposes, and having been instrumental in stimulating the further investigation of the cyclic compounds of carbon.

Dr. Perkin also extended the same methods to the synthetical formation of carbon rings of the aromatic series, obtaining by means of ingeniously designed reactions derivatives of hydrindonaphthene and tetrahydronaphthalene.

But whilst the above achievements depend mainly on happily conceived and brilliantly executed extensions of the malonic and aceto-acetic ester syntheses, Perkin has, by a remarkable development of the Frankland and Duppa reaction for the synthesis of hydroxyacids, been successful in building up the important camphoronic acid in such a manner as to place its constitution beyond doubt (1897).

Dr. Perkin has further devoted much attention to the important subject of the constitution of camphor, towards the elucidation of which he has contributed valuable experimental evidence embodied in a most important and elaborate paper, containing the results of many years' work in conjunction with numerous pupils, entitled "Sulphocamphylic Acid and Isolauronolic Acid, with Remarks on the Constitution of Camphor and Some of its Derivatives" (1898). Bearing on the same subject are later communications on camphoric acid and isocamphoronic acid.

About the year 1900, Perkin, in prosecuting his researches on the constitution of camphor compounds, succeeded in devising synthetical methods for the production of what he has termed "bridged rings," of which a simple example is furnished by the hydrocarbon dicyclopentane

$$CH_2\left\langle\begin{array}{l}CH-CH_2\\ \;|\qquad\;\;|\\ CH-CH_2\end{array}\right.$$

The universal admiration of organic chemists has been called forth by these investigations; they reveal, indeed, a wonderful capacity for devising reactions which coerce carbon atoms to fall into the desired groupings.

Of other publications displaying not only extraordinary experimental skill but close reasoning and the power of interpreting results, mention may be made of Dr. Perkin's memorable researches on the constitution of dehydracetic acid, berberine, brasilin, and hæmatoxylin respectively.

During the present year (1904), Dr. Perkin has made perhaps the most remarkable addition to the long list of his achievements by successfully synthesising terpin, inactive terpineol, and dipentene, substances which had previously engaged the attention of some of the greatest masters of organic chemistry.

In conclusion it may be stated that Prof. Perkin is not only the author of the above and numerous other important researches which are outside the scope of this brief summary, but that he has also created a school of research in organic chemistry, which stands in the very highest rank.

Darwin Medal.

The Darwin Medal is awarded to Mr. William Bateson, F.R.S., for his researches on heredity and variation.

Mr. Bateson began his scientific career as a morphologist, and distinguished himself by researches on the structure and development of Balanoglossus, which have had a far-reaching influence on morphological science, and which established to the satisfaction of most anatomists the affinity of the Enteropneusta to the Chordate phylum. Dissatisfied, however, with the methods of morphological research as a means of advancing the study of evolution, he set himself resolutely to the task of finding a new method of attacking the species problem. Recognising the fact that variation was the basis upon which the theory of evolution rested, he turned his attention to the study of that subject, and entered upon a series of researches which culminated in the publication in 1894 of his well-known work, entitled "Materials for the Study of Variation, &c." This book broke new ground. Not only was it the first systematic work which had been published on variation, and, with the exception of Darwin's "Variation of Animals and Plants under Domestication," the only extensive work dealing with it; but it was the first serious attempt to establish the importance of the principle of discontinuity in variation in its fundamental bearing upon the problem of evolution, a principle which he constantly and successfully urged when the weight of authority was against it. In this work he collected and systematised a great number of examples of discontinuous variation, and by his broad and masterly handling of them he paved the way for those remarkable advances in the study of heredity which have taken place in the last few years, and to which he has himself so largely contributed. He was the first in this country to recognise the importance of the work of Mendel, which, published in 1864, and for a long time completely overlooked by naturalists, contained a clue to the labyrinth of facts which had resulted from the labours of his predecessors. He has brought these results prominently forward in England in his important reports to the Evolution Committee of the Royal Society, and in papers before the Royal and other societies, and also before horticulturists and breeders of animals. He has gathered about him a distinguished body of workers, and has devoted himself with great energy and with all his available resources to following out lines of work similar to those of Mendel. The result has been the supporting of Mendel's conclusions and the bringing to light of a much wider range of facts in general harmony with them. It is not too much to say that Mr. Bateson has developed a school of research to which many biologists are now looking as the source from which the next great advance in our knowledge of organic evolution will come.

Sylvester Medal.

The Sylvester Medal is awarded to Georg Cantor, professor in the University of Halle, on account of his researches in pure mathematics. His work shows originality of the highest order, and is of the most far-reaching importance. He has not only created a new field of mathematical investigation, but his ideas, in their application to analysis, and in some measure to geometry, furnish a weapon of the utmost power and precision for dealing with the foundations of mathematics, and for formulating the necessary limitations to which many results of mathematics are subject.

In 1870 he succeeded in solving a question which was then attracting much attention—the question of the uniqueness of the representation of a function by Fourier's series. The extension of the result to cases in which the convergence of the series fails, at an infinite number of suitably distributed points, led him to construct a theory of irrational numbers, which has since become classical. From the same starting point he developed, in a series of masterly memoirs, an entirely new branch of mathematics—the theory of sets of points.

Having established the fundamental distinction between those aggregates which can be counted and those which cannot, Cantor showed that the aggregates of all rational numbers and of all algebraic numbers belong to the former class, and that the arithmetic continuum belongs to the latter class, and further, that the continuum of any number of dimensions can be represented point for point by the linear continuum. Proceeding with these researches he introduced and developed his theory of "transfinite" ordinal and cardinal numbers, thus creating an arithmetic of the infinite. His later abstract theory of the order-types of aggregates, in connection with which he has given a purely ordinal theory of the arithmetic continuum, has opened up a field of research of the greatest interest and importance.

Hughes Medal.

The Hughes Medal is awarded to Sir Joseph Wilson Swan, F.R.S., for his invention of the incandescent electric lamp, and his other inventions and improvements in the practical applications of electricity. Not as directly included in the award, his inventions in dry-plate photography, which have so much increased our powers of experimental investigation.

NOTES.

THE council of the Royal Society of Edinburgh at its recent meeting decided to award Sir James Dewar, F.R.S., the Gunning Victoria Jubilee prize for 1900–4 for his researches on the liquefaction of gases extending over the last quarter of a century, and on the chemical and physical properties of substances at low temperatures.

THE *Times* reports that a telegram by wireless telegraphy has been transmitted by Mr. Marconi from the Marconi Company's station at Poldhu, Cornwall, to a station belonging to the Italian Government at Ancona, Italy. The distance between Poldhu and Ancona, about 1000 miles, is almost entirely overland, and in order to reach their destination the ether waves had to pass over nearly the whole of France and a considerable part of Italy, including some of the highest mountains of the Alps.

THE will of the late Dr. Frank McClean, F.R.S., includes the following bequests:—5000*l.* to the University of Cambridge to be expended in improving the instrumental equipment of the Newall Observatory, 5000*l.* to the University of Birmingham (in addition to his previous subscription) to be applied in the department of physical science, 2000*l.* to the Royal Society, 2000*l.* to the Royal Institution, 2000*l.* to the Royal Astronomical Society, and to the University of Cambridge for presentation to the Fitzwilliam Museum all the testator's illuminated or other manuscripts and early printed books, and all objects of mediæval or early art which the director of the museum may select as being of permanent interest to the museum.

IN a recent letter to the *Times* Prof. T. Clifford Allbutt directs attention to the paramount importance of considering the question of diet in all schemes of physical education. It is important that there should be no hasty legislation in this matter, especially in view of the important researches which are now approaching completion. Prof. Allbutt gives in his letter a brief account of the results at which Prof. Atwater, of Middletown, Connecticut, and Prof. Chittenden, of Yale University, have arrived. Prof. Atwater has measured accurately, upon healthy persons in uniform circumstances, the intake of food, and the output of waste and work, and has endeavoured to determine the modes and rates of conversion of foods into bodily and mental energy. Much of this expenditure of energy is upon an excess of food taken beyond the needs of the individual. Such excess (or not more than 4 per cent. of it) does not escape mechanically and cheaply from the body, but is absorbed, distributed, and excreted; to this process no little energy is diverted. In this useless effort energy is chiefly wasted by the nitrogenous foods. Excessive starches and sugars are burned off in the lungs almost directly, and at far less cost. Prof. Atwater teaches that the ordinary man eats too much, and in so doing wastes energy which he might have used to profit. Prof. Chittenden comes to a like conclusion by somewhat different methods. He will publish shortly tables to show how, on a closer adjustment of kinds and quantities of food to the useful work required, not only is this much work still sustained, but, by release of energy ordinarily dissipated in the demolition of food excess, the sum of work put out is prodigiously increased, in some cases even by so much as 60 per cent. or 70 per cent. It is clear enough already that one of the chief factors of physical well-being is to know what to eat, and what quantity of it results in the production of the maximum of useful energy. Until this is known with more exactitude than is common to-day, systems of physical education must be tentative and imperfectly conceived.

PROF. S. NEWCOMB has been elected corresponding member of the Berlin Academy of Sciences.

PROF. FEHR contributes to *l'Enseignement mathématique* for November 15 a list of the principal exhibits of models and books at the mathematical congress last August. Among the publishing firms exhibiting books, Germany was represented by six, Austria by two, France by four, Italy by five, Switzerland, Belgium and Denmark each by one. This is exclusive of books exhibited by societies and individuals, under which category we find the solitary British exhibit, by the Royal Irish Academy. Among the exhibitors of models our country was represented by Prof. Greenhill.

THE Belgian Government has decided upon the construction of a turbine steamer for its Channel fleet. Gradually the 19-knot steamers on this international service will be replaced by new turbine boats, with a speed of 23 knots, so that eventually even the slowest mail boats under the Belgian flag will have a speed of 21½ knots, or 24 miles an hour. The steamer which will inaugurate this departure in the progress of the service is at the present moment on the stocks at Hoboken, near Antwerp, and it will shortly be launched. Until quite recently, all steamships in the Channel and Irish Sea services were of the paddle-wheel type, a class admirably adapted for these comparatively short journeys. Drawing little water, they were able to enter any of the shallow harbours, and, at the same time, were capable of developing a speed altogether out of proportion to their draught. Since the introduction of turbines the diminution of the diameter of the propeller and of the weight of the engines has been rendered possible, so that what was until lately considered a mechanical impossibility, namely, to construct a steamer drawing only 9¾ feet and developing 12,000 indicated horse-power, may now be taken as a problem solved. The new Dover-Ostend mail boat will be a triple-screw steamer driven by Parsons' marine steam turbines. There will be three turbines—a high-pressure one in the centre, receiving the steam direct from the boilers, and a low-pressure one on each side, driven by the exhaust from the central engine. The Marconi system of wireless telegraphy will be installed, and remain at the service of the travelling public, as on all the Belgian mail steamers.

The articles in the fourth part of vol. xxxii. of Gegenbaur's *Morphologisches Jahrbuch* are two in number, the one, by Dr. Böse, on variations in certain muscles of the human thorax, and the other, by Mr. A. Gierse, on the brain and cephalic nerves of the small deep-sea teleostean fish *Cyclothone acclidens.* The latter is remarkable for possessing a median cephalic sympathetic nerve-cord, apparently unknown in any other vertebrate.

According to the report of the annual meeting held in May last, the Boston Society of Natural History (U.S.A.) is devoting attention to the display in its museum of the fauna of New England. New England palæontology is to be shown in the eastern end of the building between the rooms devoted to the palæontology of the rest of the world, while the remaining available space will be devoted to the recent birds and mammals. In the galleries will be arranged the lower vertebrates and the invertebrates. Accordingly, the local fauna, which is to be the leading feature of the museum, will occupy the most prominent and central position, from which the various portions of the general collection will diverge. This is as it should be, and when complete the museum promises to be a model for other local institutions of a similar nature.

The first part of vol. lxxviii. of the *Zeitschrift für wissenschaftliche Zoologie* is devoted to the fourth and apparently concluding section of Dr. E. Rohde's valuable and exhaustive account of the structure of the organic cell, and to an article by Mr. D. Deineka on the constitution of the swim-bladder of fishes. In the second of these articles the author supports the view that the main function of the swim-bladder is hydrostatic; fish in which this organ has been pierced, and the whole or part of its contained gas withdrawn, or replaced by water, completely lose their balance, in some cases falling on one side, in others standing nearly perpendicular in the water with the head downwards, and in others, again, floating belly upwards. Whether, however, the swim-bladder has a double function, and acts also as a respiratory organ, is, in the author's opinion, extremely doubtful.

In the September issue of the *Proceedings* of the Philadelphia Academy Miss A. M. Fielde records three instances of curious traits displayed by ants kept under observation in the laboratory at Woods Holl, Mass. In the first case the actions recorded suggest something akin to hypnotism, while from the third there seems a possibility that these insects may be able to remember and recognise individuals of their own kind after a separation of several years. The reactions of ants to vibrations form the subject of a second article by the same author in conjunction with Mr. G. H. Parker. In this it is urged that it is misleading to ascribe or to deny hearing to these insects. They are very sensitive to the vibrations of solids, but not to those of air, and their reactions to these might as well be described as due to touch as to hearing.

The appearance of a bark disease among the Para rubber trees in certain districts in Ceylon during 1903 created some alarm among rubber planters, but prompt measures for its treatment were carried out under the advice of the Government mycologist. Mr. J. B. Carruthers, the officer in question, gives an account of its occurrence in his report, which forms No. 16 of vol. ii. of the *Circulars and Agricultural Journal* of the Royal Botanic Gardens, Ceylon, and states that the disease was due to a canker fungus; further details with regard to structure and treatment will form the subject of a separate circular.

The *Journal of Botany* (November) contains the first part of a detailed description of the plants collected in Patagonia by Mr. Hesketh Prichard, of which a preliminary list was given in his book "Through the Heart of Patagonia." The identification has been undertaken by Dr. Rendle, who prefaces the list of plants with a short account of the region in which the collections were made, and the typical elements which are represented. The new species belong chiefly to characteristic temperate South American genera. To the same number Mr. A. B. Jackson contributes some notes on Leicestershire plants which summarise observations made since the year 1886, when the "Flora of Leicestershire" was published.

Dr. W. E. de Korté, at a meeting of the Pathological Society of London on November 15, described what he believes to be the parasites of small-pox and vaccinia. In the lymph of the eruptive spots in both these diseases he has detected bodies measuring about 1/2500 inch in diameter, amœboid, and containing refractile granules; these he regards as amœboid protozoa. They are extremely delicate, breaking up and disappearing on all but the gentlest manipulation, and on attempts to stain or preserve. They seem to be very similar to the bodies described by Funck some years ago under the name of *Sporidium vaccinale.*

In an article on trypanosome diseases (*Brit. Med. Journ.*, November 26) Prof. Robert Koch advances arguments in favour of the view that the trypanosomes of mammals at present known belong to about three species, viz. the rat trypanosome and the *T. Theileri* of South African cattle, both of which are distinguished morphologically and by unchanging virulence and inoculability from the other trypanosomes, *i.e.* those of nagana, surra, mal de caderas, and sleeping sickness, all of which show considerable variation in morphology, virulence, and inoculability, and are therefore regarded by Prof. Koch as being probably varieties of one type.

The new number of the *Mitteilungen aus den deutschen Schutzgebieten* contains papers on the north-western boundary region of Togoland, by Count Zech, and on the results of an exploration of the healthy plateau region of the Kamerun, north of the Manenguba mountains, by Dr. Hans Zieman. The information in the former paper, and the map accompanying it, are of particular interest on account of the immediate proximity of the district to British territory.

The July number of the *Bulletin* of the Italian Geographical Society contains the concluding portion of Prof. Brocherel's report on the expedition to Central Asia in 1900. Signor Carlo Rossetti writes on the political and economic conditions of Korea, and Signor Eugenio Barbarich makes an important contribution to the physical geography and geology of Albania. Another paper deals with the award of the King of Italy in the arbitration as to the boundary between Brazil and British Guiana.

Prof. Penck's account of the progress made during the last five years in the execution of a map of the world on a scale of 1 : 1,000,000, which was presented to the International Geographical Congress at Washington, is published in the October number of the *National Geographic Magazine.* During the last four years France, Germany, and Britain have issued three series of maps, containing sixty-one sheets worked out on the same scale and in the same style of division of sheets. These maps cover nearly 10,000,000 square miles, and will ultimately embrace the whole of Africa, and large parts of Asia and America. It will be remembered that the congress adopted a resolution proposing to the Government of the United States the execution of a similar general map of America.

In a recent number of the *Bulletin* of the Italian Aëronautical Society Dr. L. Palazzo, director of the Italian Meteorological Service, gives a very interesting account of the scientific experiments in Italy with unmanned balloons. The paper contains photographic illustrations of the balloons employed, of the methods of filling them, of their flight in mid-air, and of the records of the instruments. The place chosen for the aëronautical station is Pavia, principally owing to its geographical suitability and its distance from mountains and sea. The balloons used are a preparation of india-rubber, and are made by the Caoutchouc Company, of Hanover. They are sent up in tandem fashion, and are spherical and closed, and have the faculty of expanding to about seventy times their original volume, rising rapidly to an altitude of 20,000 metres and upwards, where a temperature of 60° C. below zero may be recorded. The upper balloon eventually bursts; the second balloon, which is smaller and not fully inflated, does not burst, but acts as a kind of parachute, which commences to fall rapidly at first and afterwards more gradually. It carries the registering apparatus attached to it by a line, and is intended to attract the attention of persons in the neighbourhood of its descent. The instruments generally reach the ground somewhat gently, and are seldom broken. Dr. Palazzo acknowledges the assistance he has received from Profs. Hergesell and Assmann in inaugurating these important experiments.

We have received a reprint of a paper published by Prof. A. Righi in the *Atti dei Lincei*, vol. xiii., ii., 233, under the title of "Certain Phenomena Observed in Air which is Ionised by Radio-active Substances"; experiments are described which show the necessity that exists in making measurements of the ionising power of radio-active substances by means of the various forms of gold-leaf electroscopes to take into account the position of the leaves relatively to the walls of the electroscope, and to the direction of the ionising rays.

In a paper published in the *Physikalische Zeitschrift* (No. 20), C. Liebenow calculates that the presence of 1/5000 of a milligram of radium per cubic metre distributed uniformly throughout the earth's volume would be sufficient to compensate for the loss of heat which is caused by conduction through the crust, and thus to maintain the earth's interior at a constant temperature. The concentration which is here assumed is considerably less than that actually observed by Messrs. Elster and Geitel to hold for radium in various kinds of natural earths, but it may perhaps be assumed that the proportion of radium is greater in the crust of the earth than at the interior. In any case, the need becomes apparent of making allowance in all calculations dealing with the earth's rate of cooling, for the remarkable thermal effects of radio-active substances.

In No. 17 of the *Revue Scientifique*, Prof. R. W. Wood's recent letter to Nature (vol. lxx. p. 530) calling into question the existence of the *n*-rays is reprinted, and in No. 18 an editorial article discusses in detail the character of the evidence on which they are alleged to exist. In No. 19 of the *Revue* the opinions of Profs. Berthelot, Bouty, Pellat, Langevin, and Abraham have been ascertained with regard to the matter. Of these expressions of opinion, that of M. Langevin is the most emphatic; after making many experiments, he concludes that in no case in which the observer is unaware of the result he is to obtain is there the slightest evidence of the existence of these rays, whilst on the other hand the experimenter can readily so dispose his mind as to see whatever he wishes to see. The general attitude which is taken up in these articles is that the observed phenomena are purely subjective, and due to suggestion; they are consequently more likely to prove of importance to the psychologist than to the physicist.

In the October number of the *Gazzetta* G. Bruni and A. Callegari have established by means of cryoscopic measurements the remarkable fact that in many cases the nitroso-group in organic substances is isomorphous with the nitro-radical. The formation of solid solutions in such cases is also made evident by peculiar colour phenomena. Whilst, for instance, a solution of nitrosobenzene in benzene is green, but becomes colourless when frozen, a solution in nitrobenzene, which has the same colour, remains green after solidification. In the former case solid colourless nitrosobenzene has separated, whilst in the latter a solid solution of the substance in the solidified solvent is formed, which, like the liquid solution, is coloured green.

The numerous attempts which have been made to decide by physical methods the nature of isodynamic substances such as ethyl acetoacetate and acetylacetone have given rise to widely differing opinions. Thus Brühl, for instance, has considered that the optical properties of acetylacetone between 0° C. and 100° C. prove that, between these temperatures, it exists solely in the di-enolic form

$$CH_3.C(OH) : C : C(OH).CH_3,$$

whilst Dr. W. H. Perkin, from a study of the magnetic rotatory power of the same substance, considers that at 16° C. it consists of a mixture of this form with the keto-enolic modification, and at 93° C. of a mixture of the keto-enolic and diketonic varieties. In the October number of the *Gazzetta* F. Giolitti shows that at about 70° C. a remarkable change in the expansibility of acetylacetone occurs which conforms with Perkin's view of a change of structure at a temperature between the limits 16° C. and 93° C. The variation in the expansion of ethyl acetoacetate between −10° C. and 100° C. is, however, perfectly linear, apparently indicating that at these temperatures only one form exists, or that the rate of change of one form into another is uniform between these limits.

A correspondent points out that in Nature of November 24 (p. 88, line 19 from top, first column) the name Sansaulito is a misspelling for a well known locality near San Francisco. The correct spelling is Saucelito, which means "little willow," from *Sauce*, willow, in Spanish.

We have received from Messrs. F. Darton and Co., of 142 St. John Street, E.C., a well illustrated catalogue of electrical novelties. The pieces of apparatus, toys, and household devices of which particulars are given are ingenious in design, and some of them would make instructive presents for boys with a mechanical turn of mind.

Messrs. Watts and Co. will issue on December 7 for the Rationalist Press Association an English translation of Prof. Haeckel's "Die Lebenswunder," under the title of "The Wonders of Life." The chief aim of Prof. Haeckel in this work is to present a mass of biological evidence for the views as to the origin and nature of life which he briefly advanced in the "Riddle of the Universe."

MESSRS. GEORGE BELL AND SONS have published a revised re-issue of "Cities and Sights of Spain," by Mrs. Aubrey Le Blond (Mrs. Main). This handbook for tourists is meant as a supplement to the ordinary guide-book, and the information supplied shows that the writer has an intimate first-hand knowledge of the country. The advice as to hotels, expenses, what to do and what not to do, is of just the kind to be of assistance to visitors to Spain, of which country the writer says, "no other part of Europe offers so varied and attractive a field to nearly every type of traveller." The appearance of this re-issue is particularly opportune just now, since astronomers and others will be visiting Spain next year to view the total eclipse of the sun, as the central line of the eclipse runs in a direction N.W. to S.E. across that country. Mrs. Le Blond's book may be commended to those scientific visitors who will have time to visit some of the beauty spots of the land in which their observations will be made.

WE have received vol. xxxvi. of the *Transactions and Proceedings* of the New Zealand Institute, which contains details of the work of the year 1903. The transactions are divided into five sections—miscellaneous, zoology, botany, geology, and chemistry and physics. The total number of papers contributed in these subjects reaches fifty. Among the contributions to the miscellaneous section may be mentioned several statistical studies by Prof. H. W. Segar and an exhaustive consideration of Maori marriage customs by Mr. Elsdon Best. The president of the institute, Captain F. W. Hutton, F.R.S., is the largest contributor to the section of zoology. He describes a new fish, two new flies, a new blow-fly from Campbell Island, and has papers on a new Weta from Chatham Islands and on the occurrence of the curlew sandpiper (*Ancylochilus sub-arquatus*) in New Zealand. Prof. Benham writes of a new species of leech (*Hirudo antipodum*) recently discovered in New Zealand, of the Oligochæta of the New Zealand lakes, and of an apparently new species of Regalecus (*R. parkeri*). Prof. Park contributes to the section of geology five papers on different aspects of New Zealand geology. Of the six papers in chemistry and physics, three are the work of Mr. J. S. S. Cooper. The proceedings, which make up the second part of the volume, provide interesting particulars of the year's work of each of the seven scientific societies affiliated to the New Zealand Institute. The volume as a whole demonstrates conclusively that the men of science in New Zealand are doing successfully their part to extend the bounds of natural knowledge.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN DECEMBER:—

Dec. 1. 10h. 9m. to 12h. 8m. Transit of Jupiter's Sat. III.
,, 10h. 22m. Minimum of Algol (β Persei).
,, 13h. 56m. to 14h. 8m. Moon occults η Virginis (Mag. 4·0).
4. 7h. 11m. Minimum of Algol (β Persei).
8. 13h. 43m. to 15h. 45m. Transit of Jupiter's Sat. III.
10–12. Epoch of Geminid meteoric shower (Radiant $108^\circ + 33^\circ$).
11. 12h. 0m. Saturn in conjunction with Moon (Saturn 3° 28′ S.).
12. 1h. Juno in conjunction with Moon (Juno 0° 49′ S.).
13. 10h. 19m. to 11h. 12m. Moon occults λ Aquarii (Mag. 3·9).
,, 21h. 0m. Mercury at greatest elongation (20° 30′ E.).
16. 17h. Jupiter in conjunction with Moon (Jupiter 1° 47′ N.)
20. 6h. 1m. to 7h. 4m. Moon occults γ Tauri (Mag. 3.9).
,, 11h. 25m. to 11h. 58m. Moon occults θ' Tauri (Mag. 3·9).

Dec. 20. 12h. 21m. to 13h. 31m. Moon occults BAC 1391 (Mag. 4·9).
,, 15h. 19m. to 16h. 12m. Moon occults α Tauri (Mag. 1·1)
21. 21h. 0m. Uranus in conjunction with Sun.
24. 8h. 54m. Minimum of Algol (β Persei).
26. 9h. 2m. to 9h. 13m. Moon occults A Leonis (Mag. 4·6).
27. 5h. 43m. Minimum of Algol (β Persei).
,, 21h. Venus in conjunction with Saturn (Venus 0° 48′ S.)
28. 10h. Neptune in opposition to the Sun.
29. 12h. 0m. Neptune's Satellite at max. elong. west (distance 17″).

ENCKE'S COMET (1904 *b*).—No. 3980 of the *Astronomische Nachrichten* contains the results of further observations of Encke's comet.

Prof. Millosevich, observing at the Roman College Observatory at 6h. 26m. 15s. (M.T. Rome) on November 7, determined the position of the comet to be

$$\alpha \text{ (app.)} = 22\text{h. } 50\text{m. } 39{\cdot}93\text{s.}, \quad \delta \text{ (app.)} = +22^\circ\ 19'\ 20''{\cdot}1,$$

and recorded the object as an extraordinarily difficult one with the filar micrometer of the 39 cm. equatorial; no nucleus could be definitely seen.

On November 15 Herr Moschick, using the 6-inch telescope of the Konigstuhl Observatory, Heidelberg, found the comet to be a very faint and diffuse object with a doubtful nucleus. The position at 13h. 12m. (Konigstuhl M.T.) was α (app.) = 22h. 13m. 37·6s., δ (app.) = + 18° 14′ 26″.

The following is a corrected ephemeris, by M. Kaminsky, given in the November number of the *Observatory*:—

Ephemeris (Berlin Midnight).

1904	R.A. h. m. s.	Dec. ° ′
Nov. 29	21 18 30	+10 30
Dec. 3	21 3 50	+ 8 9
,, 7	20 49 20	+ 5 36
,, 11	20 34 10	+ 3 1
,, 15	20 16 32	+ 0 17
,, 19	19 56 38	− 2 58
,, 23	19 35 12	− 6 31

On the last mentioned date the comet will be a little north of κ Aquilæ, and owing to its proximity to the sun in right ascension will be a difficult object to observe.

As pointed out by Dr. Smart, the comet will approach very near to Mercury in January, and it is hoped that an opportunity of testing the mass of Mercury, by observations of the comet after the approach, will therefore be available.

VARIATIONS ON THE MOON'S SURFACE.—In No. 4, vol. liii., of the Harvard College Observatory *Annals* Prof. W. H. Pickering publishes a number of photographs illustrating the changes which take place in the regions about the lunar crater Eratosthenes during the commencement, the duration, and the passing of sunlight on that region of the moon's surface.

There are sixteen figures in all, the longest interval of time between the taking of any two successive figures being 1·6 days, and it is hoped that, by publishing these together with the detailed descriptions by Prof. Pickering which accompany them, the work of other selenographists may be greatly facilitated, by the possession of the knowledge of what to look for.

The mean diameter of the crater of Eratosthenes is 37 miles, that of the floor 28 miles, and measures of the shadows cast indicate that the western wall has a height of 12,000 feet, whilst the indicated height of the eastern wall is something less than 15,000 feet.

As evidence in favour of the vegetal origin of these phenomena, Prof. Pickering suggests that although water could not exist at the low pressures obtaining on the lunar surface, yet it might be retained in the soil by capillary attraction and thence feed the vegetation, which at each return of sunlight would develop and thus cause the changes illustrated in the photographs.

CELESTIAL PHOTOGRAPHY AT HIGH ALTITUDES.—An interesting account of the work performed by Prof. Payne and Dr. H. C. Wilson during their sojourn at Midvale (Montana), illustrated by reproductions of two of the photographs obtained, is given by the latter observer in No. 8, vol. xii., of *Popular Astronomy*.

The altitude of the observing station was 4790 feet above sea-level, and the results lead Dr. Wilson to the conclusion that the increase in altitude, from Northfield to Midvale, reduced the necessary exposures, other conditions being the same, by about one-half. The two reproductions accompanying the account show excellent photographs of the America nebula and of the region between β and γ Cygni taken with a $2\frac{1}{2}$ inch Darlot lens with exposures of three hours and of two hours respectively.

DISTRIBUTION OF STELLAR SPECTRA.—In No. 1, vol. lvi., of the Harvard College Observatory *Annals* the distribution of stellar spectra, mainly in reference to the Milky Way, is discussed.

The spectra dealt with are those examined by Mrs. Fleming for the Harvard catalogues, and the work is not yet complete, the present publication dealing only with the results already obtained.

The number and proportion of each class of spectra in definite regions of the heavens, as determined from the discussion of 276 plates containing the spectra of 32,197 stars, are given in a series of tables and shown on a number of curves.

The results indicate that the universe consists of two portions, (1) the first-type stars, which occur in all regions, but preponderate in the formation of the Milky Way; (2) the stars having second- or third-type spectra, which show, in general, a uniform distribution over the whole sky.

The proportion of first-type stars increases as fainter objects are included, but with the Orion stars the opposite seems to be the case. Stars with peculiar spectra seem to congregate in the Milky Way, whilst, contrary to expectation, those having spectra of class F appear to be relatively fewer in the galactic regions.

ABSORPTION BY WATER VAPOUR IN THE INFRA-RED SOLAR SPECTRUM.—An interesting series of experiments has been made at the Smithsonian Astrophysical Laboratory, by Mr. F. E. Fowle, jun., in order to test the correctness of Bouguer's formula for calculating the amount of solar energy received after atmospheric absorption.

The results, so far as they go, show that the selective absorption of water vapour is well represented by Bouguer's formula and seems to depend only on the amount of the absorbent present, that is to say, the amount of the absorption produced by a given quantity of water vapour is the same, whether the radiations pass through a *great* thickness of *small* density or *vice versâ*.

The absorption increases as the wave-lengths of the bands increase, and varies from about 10 per cent. near A ($0{\cdot}76\mu$) to nearly 100 per cent. at about $1{\cdot}80\mu$.

No indication of a general water vapour absorption has been found in the region $0{\cdot}68\mu$ to $2{\cdot}00\mu$.

Mr. Fowle's complete results, illustrated by some of the bolograms obtained, are published in No. 1, vol. ii., of the quarterly issue of the *Smithsonian Miscellaneous Collections*.

THE SUPPLY OF VALUABLE FURS.

FEW persons, other than those in some way connected with the fur trade of this country, or who have had occasion to make statistical inquiries on the subject, have any conception of its enormous volume and value. Yet every thoughtful observer who strolls along the fashionable shopping streets of the metropolis at this season can scarcely fail to be struck with the number of establishments for the sale of furs and the richness and variety of their contents, or with the great extent that furs are worn by ladies. Any real and comprehensive idea of the magnitude of the trade can, however, only be gained either by attending the great London quarterly fur sales, such as those of Messrs. C. M. Lampson and Co., or by a study of the catalogues and price-lists of such sales. By a perusal of these documents the inquirer will gain some conception of the immense number of skins of the more valuable kinds of fur-bearing animals imported into this country alone; and when the great Continental sales, such as the Leipzig and Nijni-Novgorod fairs, are also taken into consideration, he will marvel where the supply comes from, and wonder that a clean sweep has not long ago been made of the chief fur-producing species. Nevertheless, the supply of most descriptions of furs seems to be well kept up, and, with the exception of a few species, such as the sea-otter, the beaver in many districts, the West African guereza monkeys, and certain kinds of fur-seal, it does not appear that any of the valuable fur-bearing mammals are in present danger of extermination, or even of becoming unduly scarce. The truth is that we have probably little real conception of the abundance of such creatures in the more remote districts of North America and in the fur-producing countries of northern Asia.

To attempt, within moderate limits, any general account of the mammals which yield the more valuable kinds of furs is impossible, as it would be with the means at our disposal to give a survey of the world's fur trade, and we shall accordingly content ourselves with referring to some of the more striking items in trade circulars for the current year, and with making such notes on certain of the species there mentioned as may seem desirable. Here it may be recalled that there appeared in 1892 a valuable and interesting work on "Fur-Bearing Animals" by Mr. Henry Poland. This work, needless to say, is now altogether out of date, and it is much to be hoped that the author could see his way to the issue of a new edition, especially, if we may say so without offence, if he would seek the assistance of a professed naturalist in the revision.

We commence our brief review of the more interesting items in the 1903–4 sale-lists by referring to some of the most valuable descriptions of furs employed as articles of dress or as carriage rugs, a large proportion of which are yielded by the Carnivora, and especially by members of the family Mustelidæ. One of the foremost places in this respect is occupied by the sea-otter (*Latax lutris*), an animal which formerly abounded on the coasts of Kamchatka and the Aleutian Islands, but which now stands in imminent jeopardy of extermination unless prompt measures are taken for its protection. Between the years 1772 and 1774 some 10,000 skins of this species were taken in the Aleutians, while at the end of the eighteenth century the annual take was 120,000 in certain newly discovered haunts in Alaska. This number, however, soon fell to 15,000, and when Alaska was ceded to the United States it had sunk to 700. A temporary improvement then took place, but in 1901 the number had fallen to 406. In 1903 Messrs. Lampson sold 463 skins, but they had none to offer in January, 1904, and there are none down in their October list, the latter deficiency being perhaps due to the recent loss of a whole cargo of furs from the Kommandorski Islands and Kamchatka. Of late years 100*l*. is no uncommon price for a sea-otter pelt, while from 200*l*. to 300*l*., and even, it is said, 500*l*., have been paid for unusually fine skins.

These prices are, however, paralleled by those given for American silver or black fox (*Canis vulpes argentatus*). Nowadays the trade distinguishes the pure black from the silver or white-tipped skins. Black skins are said to have been sold in St. Petersburg at from 300*l*. to 800*l*. each. In London a pair of silver skins realised 480*l*. and an inferior pair 200*l*. in 1902, but single skins are reported to have fetched 200*l*. Messrs. Lampson offered 670 skins of this fox in 1903, and have 55 in their current October list. The white and blue phases of the Arctic fox (*Canis lagopus*), which are the winter dress of different animals, although often regarded as the winter and summer coats of the same form, have of late years become very fashionable. Of the former 20,341, and of the latter 3685, were sold by Messrs. Lampson last year, but none of the blue variety appear in this autumn's catalogue, against 57 in October, 1903, and it would accordingly seem that the demand is telling on the supply. White fox skins, which some years ago sold for between 2*s*. 6*d*. and 15*s*. each, have recently risen to from three to five guineas, although they are now declining; on the other hand, blue fox, which has long fetched from ten to fifteen guineas per skin, appears to be rising in value. Both white and blue fox come from the northern parts of both hemispheres; the blue should be a pure bluish French grey.

Of lynx skins 5828 were sold by Messrs. Lampson in 1903, and 6316 were offered this autumn, the catalogue prices ranging between 22*s*. and 42*s*. for good samples. Probably most of these skins belong to the circumpolar *Felis lynx*, although they may include some of the American *F. rufa*.

Another handsome fur now in considerable demand is that of the glutton or wolverine (*Gulo luscus*), of which 47,139 skins were sold last year by one firm, the catalogue price ranging this autumn from 16*s.* to 34*s.* for good samples. The sales of Russian sable (*Mustela zibellina*) by the same firm last year reached the enormous total of 29,547, which compares with a total of 9247 for the whole of London in 1891, an increase which seems to imply either the tapping of a fresh source of supply or an undue drain on the normal stock. The catalogue prices range from 10*s.* to 15*l.* per skin, but specially fine skins will fetch from 50*l.* to 70*l.* each. As its trade name implies, all the best sable comes through Russia. "Kolinsky" or Siberian sable (*M. sibirica*) is the trade name of an allied species of which enormous numbers of skins come into the market, Messrs. Lampson quoting 472,796 for last year; the price is, however, low, usually less than two shillings, and now declining.

Ermine (*M. erminea*), of which the returns for 1903 are not given in the list before us, has recently risen 30 per cent. in value; 1379 skins were sold in January, 1903, and 461 this October. From 20*s.* to 180*s.* per "timber" of 40 skins was the price some years ago. Ermine is imported both from Russia and America. When made up with specks of black fur instead of with the black-tipped tails, it is called minever. Japanese sable, of which only 179 skins were sold by Messrs. Lampson in 1903, is represented by 1211 this autumn, a circumstance which may indicate that our allies are endeavouring to make as much as possible out of their exports.

A similar increase is noticeable in the case of Japanese mink (a species it is a little difficult to identify zoologically, but which would appear to be allied to *M. sibirica*), of which 13,728 skins were disposed of at the sales in 1903, while 7228 were offered this autumn, against 3543 at the corresponding sale of last year. Of American mink (*M. vison*) the imports are always heavy, and for 1903 Messrs. Lampson record 253,001 skins, this being about 100,000 less than the total number sold in London in 1901. Prices range from 1*s.* to 13*s.*, but are on the decline. The various kinds of real marten, such as *M. martes* and *M. americana*, with 55,106, and the inferior sorts known in the trade as "baum" and "stone" (*M. foina*), with 10,940 and 8323 in the past year, bulk less large, although prices range higher, fine pelts of the pine or American marten realising from 30*s.* to 40*s.*

Leaving certain others of the marten group, we pass on to otters (*Lutra vulgaris, L. canadensis*, &c.), of which 14,757 pelts were disposed of in sales last year, the catalogue prices in January ranging to as much as from 50*s.* to 60*s.* With modern methods of curing, the handsome black and white fur of the various species of skunk (Mephitis and Conepatus) has come into extensive and fashionable use, no less than 948,447 skins having been sold last year, the price ranging from about 1*s.* to 7*s.* each. Of badger skins (*Meles taxus*) the number sold by the same firm was 13,543; formerly the price was from 1*s.* to 2*s.* per skin, but the range in the list varies now from 4*d.* to 13*s.*

Of the larger land Carnivora, the skins of which are used for fur rather than for floor rugs, we may mention the sale last year by Messrs. Lampson of 47,139 wolf skins and 12,834 bear skins. Of the former the catalogue price ranges from 1*s.* or less to 30*s.*, while for the latter, which include the brown, black, grizzly, and white species, prices up to 4*l.* are quoted. Reference has already been made to the silver, white, and blue foxes; in addition to these are quoted 62,052 skins of red fox (*C. vulpes*, &c.), 2957 of the cross-fox (*C. v. pennsylvanicus*), 64,431 of the American grey fox (*C. cinereo-argentatus*), and 2186 of the kit-fox (*C. velox*). Raccoon skins number 268,190 in the list under consideration, while 9650 civet skins are quoted in the January list.

Among rodents, beaver skins total 16,504 in the list before us, while the Hudson Bay Company sold in January last 34,806, the latter number comparing badly with the 63,419 sold by the same company in January, 1891, which was greatly inferior to the sales of half a century or so earlier. In 1891 the price varied from 5*s.* to 69*s.* per skin; in Messrs. Lampson's list quotations range up to 30*s.*, but there had been a fall of 12½ per cent. from the previous year. The next largest fur-bearing rodent is the South American coypu (*Myopotamus coypu*), known in the trade as nutria, of which 80,269 skins appear in last year's sale-list. Far more valuable are, however, the much smaller beautiful silver-grey pelts of "real" chinchilla, of which 23,587 were sold last year by Messrs. Lampson, 60*s.* to 240*s.* per dozen being the price quoted by Mr. Poland in 1891, but a maximum of 310*s.* appearing in the list before us. I take it that by "real" chinchilla is meant the typical *Chinchilla lanigera*, although the latter name is applied by Mr. Poland's book to the "bastard chinchilla" of the trade, which one would have thought meant one of the species of Lagidium. Be this as it may, "bastard chinchilla" is represented by no less than 132,996 pelts in Messrs. Lampson's 1903 sales, the maximum price being 145*s.* per dozen.

Of the smaller and less valuable rodent furs briefer notice must suffice, the chief interest connected with these being the enormous numbers in which they are imported. Thus musquash (*Fiber zibethicus*) is represented by no less than 2,979,460 pelts of the normal, and by 117,412 of the black phase, while 1,678,667 skins of the former were disposed of at the January sale this year. Squirrel (of various kinds), on the other hand, totalled only 142,501. Rabbit and hare skins are not of sufficient value to find a place in these sale-lists. Among marsupials, skins of the so-called Australian opossums, that is to say, various species of phalangers, press hard on musquash skins in point of numbers, 2,455,765 being the quotation in last year's list. True, or American, opossum (Didelphys), on the other hand, totals only 168,396. Of kangaroo skins the number in the same list is 21,963, while wallaby skins (that is to say, those of the smaller kinds of kangaroos) reach 520,087, and wombat skins 255,332.

An item of considerable interest in the sale-list of January, 1904, is 343,996 mole skins, ranging in price from 1*s.* to 7*s.* 3*d.* per hundred, such prices being stated to be exceptionally low, and not, one would think, paying for the trouble of collecting. No year's total for mole skins is given, but since Mr. Poland mentions "several thousands" as being the annual collection in 1891, it would seem that the demand—perhaps for motoring coats—has vastly increased of late years. Another item evidently connected with motoring is that of 403 musk-ox skins at the March sale of last year. The trade in these skins has only lately been developed, and it cannot but be looked upon with suspicion by naturalists, as the musk-ox might easily be exterminated.

Although the total numbers of skins offered at sales in January last compared well with those of the preceding year, prices ruled lower, which may be accounted for by the general commercial depression.

In addition to Messrs. Lampson's sales, it should be mentioned that there are the Hudson Bay Company's sales, as well as several smaller fur sales in London. In January of the present year (after the loss of a valuable cargo of furs at sea) the Hudson Bay Company sold 34,806 beaver skins, as already mentioned (against 47,777 the preceding year), and 923,053 musquash pelts (against 1,482,670 in 1903). The skins disposed of at the smaller sales we have not space to quote. We may refer, however, to the following items in Messrs. Culverwell, Brooks, and Co.'s sale catalogue of this October. These are 9280 Australian opossum, 3214 "wallarine" (smaller kangaroos), 673 chinchilla, 934 fox, 2772 wolf, and 2313 African monkey skins.

The latter probably belong in great part to the West African guereza (*Colobus vellerosus*), the species already referred to as, according to consular reports, being in danger of extermination on account of excessive pursuit.

As regards the prospects of the trade in fur-seal pelts for the current season, Messrs. Lampson, after referring to the loss by shipwreck of the Kamchatka Commercial Co.'s vessel already mentioned, and adding that in consequence they may have no Copper Island fur-seals to offer, write as follows:—

"The Alaska seal-catch this year amounts to 13,134 skins, as against 19,378 last year. . . . The North-west catch is not yet completed, but our receipts to date are about the same as at this time last year. With regard to the Lobos Island seals, no news has been received so far. . . . The total supply of seals this season is likely to fall considerably short of last year's quantity."

From the introductory statements this diminution may, however, be merely temporary, and need not necessarily indicate a permanent falling off in the supply of fur-seal pelts.

In respect to skins used solely for rugs or ornamental purposes, very few words must suffice. In Messrs. Culverwell, Brooks, and Co.'s list for October of this year appear 100 South American guanaco skins (from which the beautiful orange carriage-rugs are made), 24 tiger, and 266 leopard skins, while Messrs. Lampson's January list gives 184 tiger and 557 leopard skins (inclusive of snow-leopard and "leopard-cat").

The leopard skins range in price from 10*s*. or less to 34*s*. (55*s*. for snow-leopard), while tiger skins vary from 2*l*. to 60*l*. each.

Imperfect and sketchy as this review of recent London fur sales necessarily is, it serves to give some idea of the enormous—we may almost say appalling—number of wild animals annually slaughtered for the sake of their pelts. What, however, it does not—and cannot—give is the effect that this continuous slaughter is having on the numbers of the various species of fur-bearing animals throughout the world.

This is what naturalists want to know from the point of view of zoology, and it is also what the fur trade community ought to desire to know from the point of view of their own and the world's interest. Of late years furs have become increasingly fashionable, with a corresponding appreciation in price; but as to whether this increased demand is having any serious effect on the numbers of fur-bearing animals in general we appear, except in the case of a few species, such as the sea-otter, the beaver, the West African guereza, and the fur-seals, to be in a state of utter and hopeless ignorance. R. LYDEKKER.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—The new statute, the object of which is to exempt candidates for honours in mathematics or in natural science from Greek in Responsions, was brought before Congregation on Tuesday, November 29. The changes proposed in the statute were in strict accordance with the resolutions passed by Congregation in Hilary Term, 1904, except in one small detail. Candidates for honours in mathematics or in natural science have two courses open to them under the proposed statute. They may offer the subjects required by the present regulations, viz. Greek, Latin, arithmetic, and elementary algebra or Euclid, or in place of Greek they may substitute French or German, together with a mathematical or scientific subject to be prescribed by the board of studies for Responsions. Candidates who had not offered Greek would be allowed to substitute an additional knowledge of the subject-matter of the Bible for that part of the examination in Holy Scripture which involves a knowledge of the Greek text of the Gospels. The statute was lost by 200 votes to 164.

Dr. William Osler, F.R.S., regius professor of medicine, has been elected to a studentship at Christ Church.

A NEW professorship of applied chemistry has been established at Trinity College, Dublin. Mr. Emil Alphonse Werner, assistant to the professor of chemistry, has been appointed as the first occupant of the new chair.

WE learn from *Science* that Park College, near Kansas City, has received an additional endowment of 20,000*l*., of which 5000*l*. has been given by Dr. D. K. Pearson; and that at a recent meeting of the trustees of Columbia University gifts amounting to about 9400*l*. were announced by the trustees. Among these was the sum of 3000*l*. from General Horace W. Carpentier.

THE Minister of Public Instruction for Austria has issued a decree concerning the admission to the universities of students from the Realschulen, according to which those wishing to be on the same footing as candidates from the Gymnasia are required to pass an additional examination, held twice a year, in Greek, Latin, and philosophy. Candidates may prepare for this examination either by private study or by courses held at certain secondary schools.

IT would do much good if everyone spoke their minds on the subject of free libraries as straightforwardly as did the Countess of Jersey last Saturday afternoon. When laying the foundation stone of a library which the generosity of Mr. Carnegie is providing for Hanwell, she touched on the great usefulness of books of reference, especially with regard to the particular life-work of the reader. In fact, one would judge that novels would find but a small place on the shelves if Lady Jersey were to choose all the books, for she very sensibly pointed out that the best volumes of fiction can now be bought for a few pence, and that more expensive books and those more difficult to get should form the bulk of a public library.

AT the winter session of the General Medical Council last week a report was considered from the Education Committee on the proposals for a school certificate submitted to the council recently by the Board of Education. After discussion it was decided to inform the Board of Education (1) that any well considered plan which would tend to a diminution in the number of examinations in preliminary subjects of education, and to a unification of standard of those which remain, would meet with the hearty approval of the Medical Council. (2) That if the standard of the examination contemplated in the scheme were such as to be generally accepted for matriculation by the universities, the council would be prepared to recognise it as qualifying for entrance on a course of professional study. (3) That, pending the general adoption of a uniform system of unification of educational tests, the council would welcome the establishment under the Board of Education of a central board for the purpose of classifying examinations according to standard and arranging for the mutual recognition of certificates; and, further, that they regard the establishment of such a board as highly desirable from an educational point of view.

SOCIETIES AND ACADEMIES.

LONDON.

Entomological Society, November 2.—Prof. E. B. Poulton, F.R.S., president, in the chair.—Mr. J. E. **Collin** exhibited a specimen of *Platyphora lubbocki*, Verr., a species of Phoridæ parasitic upon ants. No specimen has been recorded since the one originally bred by the present Lord Avebury in 1875, and described for him by Mr. G. H. Verrall in the *Journal* of the Linnean Society for 1877.—Mr. P. J. **Barraud** exhibited an aberrant *Epinephele jurtina (janira)*, ♂, taken by him this year in the New Forest, in which the usual apical spots were absent from the fore-wings, giving the specimen a curious appearance, noticeable even when flying.—Mr. J. **Edwards** sent for exhibition three specimens of *Bagous lutosus*, Gyll., one found by himself on Wretham Heath, Norfolk, on August 4, 1900—the first authentic British example—and two taken in the same locality by Mr. Thouless on May 22, 1903; also *Bagous glabrirostris*, Herbst., from Camber, Sussex, for comparison.—Dr. T. A. **Chapman** exhibited bred specimens of *Hastula* (*Epagoge*, Hb.?) *hyerana*, Mill., from larvæ taken at Hyères last March, and said the fact that the pale forms only have hitherto been known, whereas of those bred nearly half are dark, suggests either that really very few specimens are in collections—which is the most probable case—or that melanism is now affecting the species.—Mr. W. J. **Kaye** exhibited specimens of the moths *Castnia fonscolombei* and *Protambulyx ganascus* showing protective and warning coloration of the two species.—Mr. H. W. **Andrews** exhibited specimens of *Eristalis cryptarum*, F., and *Didea alneti*, Fln., two species of uncommon Syrphidæ from the New Forest.—Mr. Edward **Harris** exhibited a brood of *Hemerophila abruptaria* reared by him this season, together with the parents, a dark male and a normal female, showing considerable variation.—Mr. Gervase F. **Mathew**, R.N., exhibited some beautiful and interesting examples of *Leucania favicolor*, Barrett, including the varieties described by Barrett in the current volume of the *Entomologist's Monthly Magazine* (p. 61), and, more recently, by Tutt in the *Entomologist's Record* for this year. He also exhibited a series of twenty-four *Camptogramma fluviata*, the descendants of a wild pair captured on September 22, 1903, showing a wide range of colour variation.—The **President** exhibited a photograph taken by Mr. A. H. Hamm to illustrate the protective flower selection of *Pieris rapae*. He also exhibited four specimens of *Conorrhinus megistus*, Burm., the large South American Reduviid which is well known to attack man; these were brought back by W. J. Burchell in the year 1828, and still have the original labels affixed to them.

Geological Society, November 9.—Dr. J. E. Marr, F.R.S., president, in the chair.—Mr. E. T. **Newton**, in exhibiting, by permission of the director of H.M. Geological Survey, a specimen of Fayolia near to *Fayolia grandis*, found by Dr. L. Moysey, of Nottingham, in the Coal-measures of Ilkeston (Derbyshire), pointed out that Fayolia was first described by Profs. Renault and Zeiller in 1884, in their monograph on the "Houiller de Commentry." In 1894 Mr. Seward described the first British specimen, from Northumberland, in the Leeds *Naturalist*, but thought that it was not a plant. There was some resemblance to certain spiral egg-cases of Elasmobranchs, but Dr. Günther was unwilling to accept the Northumberland fossil as the egg-case of a fish. Mr. Kidston had not yet seen the specimen now exhibited, but from a sketch he recognised its relation to Fayolia. At present there was still uncertainty as to the exact nature of this fossil.—Notes on Upper Jurassic Ammonites, with special reference to specimens in the University Museum, Oxford, ii.: Miss Maud **Healey.** This paper gives a re-description of the types of *Cardioceras vertebrale*, Sow., *C. scarbrugense*, Y. and B., *C. cordatum*, Sow., and *C. excavatum*, Sow., and their varieties. Four varieties of the first, nine of the second, three of the third and fourth are defined, and a description is given of a new species of Cardioceras belonging to the same group. Notes on species allied to the group and on others which have been wrongly confused with it are added. These species are so closely connected by innumerable transitional forms that their limits cannot be definitely fixed. The term "species" is therefore used as equivalent to Prof. J. W. Gregory's *circulus*: "It includes a number of 'forms,' which vary along lines radiating outward from a central type."—Sarsen-stones in a clay-pit: Rev. E. C. **Spicer.** Near to Bradenham, midway between High Wycombe and Prince's Risborough, certain clay-pits yield a clay for brick-making, in which are embedded large angular sarsen-stones, white saccharoidal sandstones with a siliceous cement.—On the occurrence of *Elephas meridionalis* at Dewlish (Dorset). Second communication: human agency suggested: Rev. Osmond **Fisher.** This paper is in continuation of one published by the author in 1888. The site in which the elephant-remains were found is a narrow trench, examined to a depth of 12 feet in places, with nearly vertical sides, a smooth, chalk bottom, and an abrupt end. It was not a fault or a stream-course, and it was partly filled with fine dust-like sand which may have been wind-borne. The trench cuts diagonally across the scarp; and, even if it could be accounted for by natural agencies, it is difficult to explain how it happened that so many elephants fell into it. The author points out that in Africa elephants are caught by the natives in pitfalls of similar character constructed on the tracks leading to watercourses. This trench is in a corresponding position with regard to a stream, and it is suggested as possible that the trench may have been of human origin. There is, however, no conclusive evidence elsewhere that man was contemporary with *Elephas meridionalis*, which is characteristic of the Pliocene age.

Royal Astronomical Society, November 11.—Prof. H. H. Turner, president, in the chair.—The long-period terms in the lunar theory: P. H. **Cowell.**—Determination of selenographical positions from measurement of lunar photographs: S. A. **Saunder.** This was the author's third communication on the subject, and in it he discussed the measures, made by Mr. J. A. Hardcastle, of four negatives taken at the Paris Observatory. The methods employed were explained, and a comparison was given with the results of other determinations, showing that a considerable increase in accuracy had been obtained.—The magnetic disturbances, 1882 to 1903, as recorded at the Royal Observatory, Greenwich, and their association with sun-spots: E. W. **Maunder.** From the examination and tabulation of the more considerable disturbances recorded, it had been found that disturbances succeeded each other at intervals corresponding to a synodical rotation of the sun. This occurred with too great frequency and regularity to be the result of chance coincidence, and it was concluded that the magnetic influence radiates from very restricted areas on the sun's surface, certain streams reaching the earth with each solar rotation. The relation of the magnetic disturbances with sun-spots was discussed, and it was pointed out that the theory threw light on the cause of the long straight rays, seen proceeding from the corona at some solar eclipses, and which sometimes reach a distance of several degrees.—Determination of the apex of the solar motion in space, and of the constant of precession, from a comparison of Groombridge's catalogue (1810) with modern Greenwich observations: F. W. **Dyson** and W. G. **Thackeray.**—The discussion on a paper by Dr. Rambaut on a very sensitive method of determining the errors of a pivot, with special reference to the pivot errors of the Radcliffe transit circle, was deferred, and other papers were taken as read.

Mineralogical Society, November 15.—Prof. H. A. Miers, F.R.S., president, in the chair.—Dr. J. W. **Evans** described two new forms of quartz-wedge by means of which approximate quantitative estimations can be readily made of the double refraction of minerals in small grains or in rock-sections.—Mr. J. **Currie** contributed a note on some new localities in Scotland and the Færöes of gyrolite and tobermorite, and Mr. C. R. **Lindsey** one on the occurrence of microscopic crystals of brookite with anatase in the Cleveland ironstone.—Mr. R. H. **Solly** exhibited and described various minerals from the Lengenbach quarry, Binnenthal. Three of these were new, viz. marrite and bowmanite, of which the chemical composition has not yet been determined, and lengenbachite, which has been shown by Dr. Hutchinson to be a sulpharsenite of lead containing some copper and antimony, and having a specific gravity of 5·8. Marrite occurs in small lead-grey crystals resembling modified cubes, and lengenbachite in thin lead-grey blade-shaped crystals, some as long as 40 mm., showing a highly perfect cleavage. Marrite crystallises in the oblique system with $a:b:c=0{\cdot}57634:1:0{\cdot}47389$ and $\beta=88^\circ\ 45'$, while lengenbachite is probably anorthic. Bowmanite occurs in small honey-yellow rhombohedral crystals with $111:100=53^\circ\ 50'$. It has a highly perfect cleavage parallel to 100, and a specific gravity of about 3·2. The author also described twinned crystals of seligmannite dispersed over large crystals of dufrenoysite and baumhauerite, and curious highly modified crystals of blende showing a thin metallic lead-grey coating.—Mr. H. L. **Bowman** described crystals of a mineral from Cornwall which had been sent to him for determination by Mr. F. H. Butler. They were found to be bertrandite, a mineral new to the British Isles.—Mr. G. F. Herbert **Smith** exhibited a slightly modified form of the hand refractometer which he had previously described.—Mr. H. **Hilton** contributed notes on some applications of the gnomonic projection to crystallography, and on the construction of crystallographic projections.

Zoological Society, November 15.—Dr. W. T. Blanford, F.R.S., vice-president, in the chair.—The mammals collected by Mr. E. Seimund in Fernando Po: Oldfield **Thomas**, F.R.S. Twenty-four species, of which two were new, were enumerated and remarked upon. Mr. Oldfield Thomas also exhibited some skulls and a piece of skin, and gave an account, of a new species of pig from the forests of Central Africa.—The crowned cranes of the genus Balearica, and a new species obtained on the White Nile by Lady William Cecil: Dr. P. Chalmers **Mitchell.**—The mouse-hares of the genus Ochotona inhabiting the Palæarctic region: J. Lewis **Bonhote.** These numbered sixteen species, one of which was described as new.—Twelve new species of earthworms from the north island of New Zealand: Prof. W. Blaxland **Benham.**

Chemical Society, November 16.—Prof. W. A. Tilden, F.R.S., president, in the chair.—The following papers were contributed:—The isomerism of the amidines of the naphthalene series (fifth communication on anhydro-bases): R. **Meldola** and J. H. **Lane.** When 2:4-dinitroaceto-α-naphthalide is reduced (1) by tin and hydrochloric acid, and

(2) by iron and hydrochloric acid, two isomeric amido-amidines are produced, the former giving rise to that having the α-NH constitution, and the latter to the β-compound. This difference in action is explained by assuming that in presence of iron the two nitro-groups are fractionally reduced while with tin both are reduced simultaneously.—Theory of the production of mercurous nitrite and of its conversion into various mercury nitrates: P. C. **Rây.** Mercurous nitrite is the first product of the action of nitric acid (containing nitrous acid) on mercury. This is converted into nitrate by the nitric acid, and finally, under suitable conditions, there ensues an accumulation of nitrite owing to the occurrence of the reaction represented by the following equation:—

$$4Hg + 4HNO_3 = Hg_2(NO_2)_2 + Hg_2(NO_3)_2 + 2H_2O.$$

—Amidechloroiodides: G. D. **Lander** and H. E. **Laws.** Benzoylaniline imidechloride reacts with hydrogen iodide furnishing an amidechloroiodide to which the constitution Ph.CClI.NHPh is provisionally assigned.—A new synthesis of *iso*caprolactone and certain derivatives: D. T. **Jones** and G. **Tattersall.** The lactone was obtained by the interaction of magnesium methyl iodide with ethyl lævulate.—The influence of substitution in the nucleus on the rate of oxidation of the side-chain, part ii., oxidation of the halogen derivatives of toluene: J. B. **Cohen** and J. **Miller.** The authors have studied the behaviour of the dichloro-, chlorobromo-, and dibromo-derivatives, and the comparative oxidisability of these compounds is discussed.—The halogen derivatives of naphthacenequinone: S. S. **Pickles** and C. **Weizmann.**—The constitution of pyrazolidone derivatives; β-phenylazo*iso*valeric acid and *s*-β-phenylhydrazidobutyric acid: B. **Prentice.**—Preliminary notice of some condensations of phenanthraquinone with ketonic compounds: F. R. **Japp** and J. **Wood.**—The decomposition of ethylene iodide under the influence of the iodide ion: A. **Slator.**—The spectrum generally attributed to chlorophyll, and its relation to the spectrum of living green tissues: W. N. **Hartley.** The author confirms his previous observations on the difference in the absorption spectra of alcoholic extracts of (*a*) fresh green leaves and (*b*) dried green leaves.—Studies on comparative cryoscopy, part ii., the aromatic acids in phenol solution: P. W. **Robertson.** The influence of various substituents on the molecular association of aromatic acids is discussed.—Isomeric change of diacylanilides into acylaminoketones. Transformation of dibenzoylaminobenzophenone into 1-benzoylamino-2-4-dibenzoylbenzene: F. D. **Chattaway** and W. H. **Lewis.**

Royal Meteorological Society, November 16.—Capt. D. Wilson-Barker, president, in the chair.—Meteorological observing in the Antarctic: Lieut. Charles **Royds,** R.N.—Decrease of fog in London during recent years: F. J. **Brodie.** The author had discussed the number of days of fog reported at Brixton, the London station of the Meteorological Office, for the thirty-three years 1871–1903, and found that the mean annual number of fog days was 55, of which 45 occurred in the winter half of the year, and only 10 in the summer half. December is the foggiest month with 9·5, the next being November with 8·5, January with 8·2, and October with 7·8. The clearest months are July with 0·4, June with 0·6, and May with 0·8. The greatest number of fog days was 86 in 1886 and 83 in 1887, and the least 13 in 1900 and 26 in 1903. Dividing the thirty-three years into three periods of eleven years each, the author showed that the mean for 1871–1881 was 55, for 1882–1892 it was 69, while for 1893–1903 it was only 41, there being thus a very marked decrease in the number of days with fog during the last eleven years.—Hurricane in Fiji, January 21–22, 1904: R. L. **Holmes.**

PARIS.

Academy of Sciences, November 21.—M. Mascart in the chair.—On the changes in dimensions and volume that the organs and tissues of plants undergo under the influence of desiccation: M. **Berthelot.** The length of the stem is not greatly affected, but the lateral dimensions, and therefore the capacity, diminishes to a considerable extent during drying.—Remarks on the necessity of studying the variations of dimensions and volume of organs and parts of living or extinct beings in anthropological and palæontological work: M. **Berthelot.**—On a general theorem concerning algebraic surfaces of linear connection superior to unity: Émile **Picard.**—On the removal of moisture from the air blown into the Isabella blast furnace, near Pittsburg, by freezing: Alfred **Picard** and M. **Heurteau.** The efficiency of a blast furnace is dependent to a considerable extent on the amount of moisture in the air supplied to the furnace. An account is given of a plant for removing this moisture by passing the air through a refrigerating chamber cooled to about $-10°$ C. The results obtained show a surprising economy of fuel, the saving in the coke used amounting to 20 per cent.—On the constitution of ricinine: L. **Maquenne** and L. **Philippe.** The authors have shown in a previous communication that ricinine is converted by the successive action of caustic potash and hydrochloric acid into a methyloxypyridone. In the present paper a detailed study of this substance is given.—New experiments on the photographic registration of the action of the *n*-rays on a small electric spark: R. **Blondlot.** A refinement of the method given in a previous paper, and an investigation of the possible sources of error. The photographic negatives obtained are regarded by the author as establishing beyond cavil the action of the *n*-rays on the electric spark.—On continued algebraic fractions: R. de Montessus **de Ballore.**—The generalisation of a theorem of Weierstrass: Maurice **Fréchet.**—Fourier's series and Taylor's series on its circle of convergence: P. **Fatou.**—On the chemical composition of the radio-active gaseous mixtures given off from the water of some thermal springs. The presence of helium: Ch. **Moureu.** The gases evolved from twelve different springs were analysed, and the figures given for the amounts of carbon dioxide, oxygen, nitrogen, and gases of the argon group.—The influence of the nature of the anode on the electrolytic oxidation of potassium ferrocyanide: André **Brochet** and Joseph **Petit.** The nature of the metal used as the anode has a very considerable effect on the electrolytic oxidation of potassium ferrocyanide, the yields varying from 75 per cent. in the case of copper to nil in the case of metals forming a soluble anode.—On the complexity of dissolved sulphates: Albert **Colson.** On the assumption that the lowering of the freezing point of a solution of sulphuric acid is due to the single molecule H_2SO_4, the author draws the conclusion that the sulphates of the bivalent metals in aqueous solution are present as double molecules.—The stimulating and paralysing influence of certain bodies in the production of rust: L. **Lindet.**—On the purification of solutions of vanadate of soda; observations relating to the methods of double decomposition for the industrial separation of metals: M. **Herrenschmidt.** An explanation of the use of vanadic acid in preference to sulphuric acid in the separation of silica and vanadic acid.—The action of iodine and yellow oxide of mercury on unsaturated acids. The separation of isomers: J. **Bougault.** The results obtained depend upon the position of the ethylene linkage in the molecule. Acids with the $\beta\gamma$ linking fix hypoiodous acid in a very stable manner, giving rise to iodolactones.—Researches on the action of hydrobromic and hydrochloric acids on triacetin. Formation of some new halogen derivatives of triacetin: R. **de la Acéña.**—The addition of hydrogen to some aromatic ketones by means of reduced nickel. A new method of synthesis of aromatic hydrocarbons: Georges **Darzens.** With nickel reduced from its oxide at a temperature of 300° C., and working the Sabatier and Senderens reaction at 190° C. to 195° C., aromatic ketones of the formula C_6H_5—CO—R are reduced to hydrocarbons of the type C_6H_5—CH_2—R, without the production of any appreciable amount of the hexahydro-derivative. If, on the other hand, the nickel is reduced at the lowest possible temperature, so that it is very active, the addition product makes its appearance. Details are given of the application of this reaction to several ketones, and the method appears to be a general one for the production of hydrocarbons.—The action of pyridine and quinoline bases on bromosuccinic and dibromosuccinic esters: Louis **Dubreuil.**—The theory of colouring matters: Jules **Schmidlin.**—On trehalase, its general presence in fungi: Em. **Bourquelot** and H. **Hérissey.** Trehalase appears to be an enzyme generally present in fungi, the times of its appearance and disappearance being possibly in close relation with the utilisation of trehalose or the storage of the latter in the form of reserve material.—On the measurement and the laws of variation of the energy shown by the ergograph according to the frequency of the contractions and the weight raised: Charles **Henry** and Mlle. J. **Joteyko**.—On the law of variation of weight of *Penicillium glaucum* as a function of its age: Mlle. W. **Stefanowska**. The results are expressed graphically, and show that the evolution of the weight of these fungi as a function of the time presents two well marked phases: a phase of rapid ascent up to the period of fructification, and a phase of decrease appearing suddenly after fructification.—Transformations of the new secreting apparatus in Conifers: G. **Chauveaud**.—On vegetation in atmospheres rich in carbon dioxide: E. **Demoussy**. With one exception, there is a marked advantage in supplying plants with an additional amount of carbonic acid, the average increase in the weight of the aërial parts of the plant being 60 per cent. greater in the case of the artificial atmosphere.—On the experimental production of radishes with starchy reserves: Marin **Molliard**.—*Solanum Commersoni* and its variations in relation to the origin of the cultivated potato: Edouard **Heckel**.—A new theory of phototropism: Georges **Bohn**.—On the geology of the Salzkammergut: Emile **Haug** and Maurice **Lugeon**.—On the mountain chains to the south of the Guadalquivir: Robert **Douvillé**.—The tension of carbonic acid in the sea and on the reciprocal influence of the carbonic acid of the sea and that of the atmosphere: August **Krogh**. From a study of the equilibrium between sea-water and the carbonic acid of the air, the conclusion is drawn that the proportion of carbon dioxide in the air tends to increase, the sea, by absorbing the gas, opposing this tendency.—The measurement of the sensitiveness of taste in men and women: N. **Vaschide**.—The elimination of sulphur and of phosphorus, the demineralisation of the organism, and the magnitude of the average molecule elaborated in persons suffering from skin diseases: A. **Desgrez** and J. **Ayrignac**.—On the relations between Surra and Mbori: MM. **Vallée** and **Panisset**.—Remarks by M. **Laveran** on the preceding communication.

DIARY OF SOCIETIES.

THURSDAY, DECEMBER 1.

ROYAL SOCIETY, at 4.30.—The Ascent of Water in Trees: Dr. A. J. Ewart.—On the Presence of Tyrosinases in the Skins of some Pigmented Vertebrates: Miss F. M. Durham.—On the Structure and Affinities of the Fossil Plants from the Palæozoic Rocks. V.—On a New Type of Sphenophyllaceous Cone (*Sphenophyllum fertile*) from the Lower Coal Measures: Dr. D. H. Scott, F.R.S.—On Chemical Combination and Toxic Action as Exemplified in Hæmolytic Sera: Prof. R. Muir and C. H. Browning.—Histological Studies on Cerebral Localisation. Part II: Dr. A. W. Campbell.

CHEMICAL SOCIETY, at 8.—The Nitrites of the Alkali Metals and Metals of the Alkaline Earths, and their Decomposition by Heat: P. C. Rây.

RÖNTGEN SOCIETY, at 8.15.—The Perspective Nature of X-Ray Projection: Dr. W. Cotton.—The New Ultra-violet Glass recently produced by Messrs. Schott and Genossen, of Jena: J. H. Gardiner. Both will be illustrated by the Epidiascope.

LINNEAN SOCIETY, at 8.—Proteid Digestion in Animals and Plants: Prof. Sidney H. Vines, F.R.S.

FRIDAY, DECEMBER 2.

AËRONAUTICAL SOCIETY, at 8.—The Aëronautical Exhibits at the St. Louis Exhibition: the President, Major B. Baden-Powell.—Kites, Kite-flying and Aëroplanes: W. H. Dines.—The Work of the International Aëronautical Commission: Dr. M. H. Hergesell.—Captive Balloon Photography: Griffith Brewer.

GEOLOGISTS' ASSOCIATION, at 8.—On the Superficial Deposits of Central and Parts of Southern England: Dr. A. E. Salter.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Midland Railway, West Riding Lines: The Construction of Contract No. 1: R. T. McCallum.

MONDAY, DECEMBER 5.

SOCIETY OF ARTS, at 8.—Musical Wind Instruments: D. J. Blaikley. (Cantor Lecture II.—Brass Instruments.)

SOCIETY OF CHEMICAL INDUSTRY, at 8.—(1) Raschig's Theory of the Lead Chamber Process; (2) Theory of the Action of Metals on Nitric Acid: Dr. E. Divers, F.R.S.—A Rapid and Accurate Method for the Estimation of Phosphorus in Iron Ores: L. J. Davies.—Fluorescope for Comparing Substances under the Influence of Radium Rays: C. S. S. Webster.

VICTORIA INSTITUTE, at 4.30.—The Right Way in Psychology: Rev. F. Storrs Turner.

TUESDAY, DECEMBER 6.

ANTHROPOLOGICAL INSTITUTE, at 8.—Exhibition of a Slate Adze and Other Objects: Rev. R. Ashington Bullen.—Lantern Illustrations of Native Types from South India: Edgar Thurston.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Distribution of Electrical Energy (*Discussion*): J. F. C. Snell.—On the Construction of a Concrete Railway-Viaduct: A. Wood-Hill and E. D. Pain.

WEDNESDAY, DECEMBER 7.

SOCIETY OF ARTS, at 8.—The International Exhibition at St. Louis: W. F. Reid.

SOCIETY OF PUBLIC ANALYSTS, at 8.

GEOLOGICAL SOCIETY, at 8.—The Chemical and Mineralogical Evidence as to the Origin of the Dolomites of Southern Tyrol: Dr. E. W. Skeats.—Certain Genera and Species of Lytoceratidæ: S. S. Buckman.

ENTOMOLOGICAL SOCIETY, at 8.—On *Erebia bejarensis* and *Erebia stygne* in Spain, with an Exhibition of Specimens: Dr. Thomas A. Chapman.

THURSDAY, DECEMBER 8.

ROYAL SOCIETY, at 4.30.—*Probable Papers*:—Memoir on the Theory of Partitions of Numbers. Part III: Major P. A. MacMahon, F.R.S.—Note on a Means of Producing a High-voltage Continuous or "Pertinacious" Current: Sir Oliver Lodge, F.R.S.—The *Rôle* of Diffusion during Catalysis by Colloidal Metals and Similar Substances: Dr. H. J. S. Sand.—The Effect of Liquid Air Temperatures on the Mechanical and other Properties of Iron and its Alloys: Sir James Dewar, F.R.S., and R. A. Hadfield.

CIVIL AND MECHANICAL ENGINEERS' SOCIETY, at 8.—Notes on Portland Cement: H. E. Bellamy.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Hydrodynamical and Electromagnetic Investigations regarding the Magnetic-Flux Distribution in Toothed-Core Armatures: Prof. H. S. Hele-Shaw, F.R.S., Dr. A. Hay, and P. H. Powell. (Conclusion of Discussion).—Studies in Magnetic Testing: G. F. C. Searle.

SOCIETY OF ARTS, at 4.30.—Burma: Sir Frederic Fryer, K.C.S.I.

MATHEMATICAL SOCIETY, at 5.30.—On Groups of Order $p^{\alpha} q^{\beta}$: Prof. W. Burnside.—On the Linear Differential Equation of the Second Order: Prof. A. C. Dixon.—On a Deficient Multinomial Expansion: Major P. A. MacMahon.

FRIDAY, DECEMBER 9.

EPIDEMIOLOGICAL SOCIETY, at 8.30.—Ticks and Tick-transmitted Diseases: Dr. Nuttall, F.R.S.

MALACOLOGICAL SOCIETY, at 8.—Description of a new species of Trachiopsis from British New Guinea: H. B. Preston.—A Correction in Nomenclature: E. A. Smith.—Notes on the American Cyclostomatidæ and their Opercula: W. H. Dall.—Note on the Dates of Publication of the Various Parts of Moquin-Tandon's "Hist. Moll. terr. fluv. de France": J. W. Taylor.

ROYAL ASTRONOMICAL SOCIETY, at 5.

PHYSICAL SOCIETY, at 8.—On a Rapid Method of Approximate Harmonic Analysis: Prof. S. P. Thompson, F.R.S.—A High-Frequency Alternator: W. Duddell.—Exhibition of Experiments to show the Retardation of the Signalling Current on 3500 miles of the Pacific Cable between Vancouver and Fanning Island.—Exhibit of Ayrton-Mather Galvanometers, Universal Shunts, and Electrostatic Instruments.

CONTENTS.

THURSDAY, DECEMBER 8, 1904.

THE MILLAIS BRITISH MAMMALS.

The Mammals of Great Britain and Ireland. By J. G. Millais. Vol. i. Pp. xx+363; illustrated. (London: Longmans, Green and Co., 1904.) Price 6 guineas net.

IN two important features this magnificent work, of which the first volume is now before us, may lay claim to special preeminence. First, the illustrations, alike in number, size, truthfulness to nature, and artistic excellence, are unrivalled; and secondly, as regards the main and most important part of the subject, namely, the habits and local distribution of the various species, the work is in no sense a compilation, but the result of long and patient personal observation on the part of the author. Indeed, the only matter for regret connected with the work is that its price puts it out of the reach of a large percentage of field naturalists; bearing in mind, however, the style in which it is got up and the wealth of illustration, it is difficult to see how it could have been offered to the public at an appreciably lower figure.

As an author of a work like the present, Mr. Millais has one incomparable advantage over the great majority—if not, indeed, over all—of his fellow-naturalists in this country, namely, that he is a great painter. In this double capacity of artist and naturalist he is consequently able to present the public not only with exquisite artistic pictures of the animals he describes, but also with portraits which emphasise and bring into prominence their special generic and specific characteristics. It is, indeed, this judicious blending of the artistic with the zoological aspect that confers on the coloured illustrations in this work such peculiar value. Too often in paintings of this description we find either zoological details more or less completely sacrificed to artistic effect or the former brought into undue prominence to the destruction of all that is really artistic and pleasing. In hitting off the happy medium between these extremes, Mr. Millais and the other two artists who have assisted in the work have been remarkably successful. In addition to the coloured pictures, there are a number of sketches, and in some cases photographs, showing the various animals in characteristic attitudes, in pursuit of their prey, &c., which illustrate their natural history almost without the necessity for letter-press. Nor is this all, for there are several sketches illustrative of the mammalian life of our island in prehistoric times; and although some of the details of form and colour assigned to certain of the extinct forms may be open to criticism, these certainly convey a good idea of the richness of this fauna as compared with that of the present day. No illustrations are given in the text of either skulls or teeth, which is perhaps somewhat to be regretted, as the latter receive mention in the text.

As regards the amount of time and labour the author has devoted to the work, it may be mentioned that, according to a statement in the preface, he made four successive expeditions, during as many years, in order to acquire a full knowledge of the grey seal alone, and that the best part of five years has been spent on the task in general.

The present volume contains the preface and introduction to the entire work, together with the text and illustrations relating to the orders Chiroptera, Insectivora, and Carnivora exclusive of the Mustelidæ. The relegation of the latter to the second volume is rather a pity, as it involves the intercalation of the seals and walruses between the bears and the weasels, which somewhat mars the systematic arrangement. The author states, however, that he found it impossible to complete his account of the Mustelidæ in time for it to come in its proper place.

In his introduction the author takes a cursory survey of the history of the British Islands during the prehistoric and later Tertiary periods, and as he is not a professed palæontologist he may perhaps be allowed a little license here, especially as it does not affect the general subject of the work. The statement as to the occurrence of ungulates in the Cretaceous (perhaps due to the author having been misled by a certain South American writer) is, however, open to exception, while the alleged first appearance of marsupials and Insectivora at the same time is perhaps an error in the opposite direction. The assertion that many types of mammals have been but little altered since the (Lower) Eocene might also be modified.

While on the subject of errors, it may be mentioned that the author (and quite justifiably) is very much "down" on other writers on British mammals for their various sins of omission and commission—whether trivial or otherwise. He must therefore take it in good part if similar slips of his own are brought to notice. For example, we fancy Sir Archibald Geikie will feel somewhat surprised to find himself described as a distinguished palæontologist and zoologist. Again, the initials of Dr. Smith Woodward are not A. B., neither is Dr. R. Ball (p. 238) the designation of the late director of the Dublin Museum, while Hermann, and not Herman, is the proper designation of the author of the name *Sorex vulgaris* (p. 141). Lack of classical knowledge seems to be implied in the translation of Chiroptera as "hand-bearers" (p. 12). More serious is the discrepancy between the number of teeth in Rhinolophus as given in the text (p. 23) and in the formula (p. 24), while another error of the same nature occurs on p. 143, where the number of premolars in the shrew is given as 2/4 instead of 4/2. Exception may also be taken to the statement (p. 230) that bears, as a whole, are a more primitive type than dogs, and the fact that the plate of the walrus is lettered *Trichechus rosmarus* while the creature is described in the text as *Odobaenus rosmarus* is another instance of want of care.

Reverting to the merits of the volume before us, attention may be directed to the value of the work accomplished by Mr. Millais in regard to the bats. Although the distinctive features of the various British representatives of the group can be gleaned by a careful study of technical treatises, the nature of the illustrations given in previous works on British mammals rendered it very hard for the amateur (to say

G

nothing of the professed) naturalist to identify such specimens as might come under observation. All such difficulties vanish with Mr. Millais's life-sized coloured figures as a standard for comparison, the distinctive features of each species being brought clearly before the reader both in the text and in the plates. Much important work has also been done with regard to the local distribution of several of the species, notably as to the occurrence of the lesser horseshoe bat and the noctule in Wales. Whether Mr. Millais has been well advised, at all events in a work of this nature, in generically separating the noctule and Leisler's bat from the pipistrelle may, however, be open to question. Moreover, seeing that the author refuses to admit "*Myotis myotis*" into the British list, the propriety of assigning a separate heading to this species may perhaps likewise be doubtful.

Among the Carnivora, the account of the wild cat is of special interest, largely owing to the fact that the author does not endorse the views of the late Dr. Hamilton as to the practical extermination of this species in the British Islands. Not that it is anywhere common, even in the wilder parts of Scotland, where in many districts it has long since been killed off. At the present day, owing to a special cause, west Ross-shire appears to be its main stronghold. As to the extermination of the wolf and the bear from our islands, the author has much to say—and all that he says is worth reading. Very interesting, too, is his account of two distinct types of the fox in Scotland, namely, a dark and grey form in the mountains, and a smaller red or pale form in the lowlands. Apparently, however, he does not allude to the "greyhound fox" of the Lake District, which Cumberland sportsmen insist is entitled to be regarded as a distinct local race.

The most original and therefore the most valuable part of the section on the Carnivora is that relating to the British seals, of the characteristics and habits of which Mr. Millais has made himself thoroughly master as the result of personal observation in their native haunts; and no longer will naturalists find any difficulty in distinguishing between the common and the grey seal at all ages. Special interest attaches to the recognition of four distinct colour-phases in the adult male of the grey seal, although, since every intermediate stage between these may occur, and they are found together, they cannot be regarded as local races. Even more interesting is the statement that the young hooded seal is not, as commonly reported, white, but of the same mottled colour as the adult. It is, however, to be wished that the author had given the full reasons for this assertion.

The author has expressed the hope that his work may be found a fitting companion, as regards illustration, to Lord Lilford's volumes on British birds. So far as he has gone at present, he may be congratulated on having attained his ambition, and there is every reason to expect that the second and third volumes will be fully equal in this respect to the one before us. For many years this splendid work will probably remain one of the standard authorities on British mammals, and in the matter of illustration it will most likely be always without a rival. R. L.

FIRE RISKS.

Fire and Explosion Risks. By Dr. von Schwartz. Translated by C. T. C. Salter. Pp. xxi+357. (London: Charles Griffin and Co., Ltd., 1904.) Price 16*s*. net.

IN estimating the risks of fire due to the storage of goods of varying descriptions, the insurance companies are met by the difficulty that the knowledge necessary to gauge the comparative safety or otherwise of the materials present is of so technical a nature that but few possess it, and in many cases substances of apparently the most innocuous character become active sources of danger under conditions likely to escape the notice of any but those who have made a special study of the subject. As a result risks are often taken at far too low a premium, whilst the distrust born of the loss incurred afterwards leads to excessive charges in utterly wrong directions, very few insurance offices being fortunate enough to possess inspectors or assessors with the necessary knowledge to safely guide them in the adjustment of their scale of fees.

In Germany several works by such authorities as Dr. Richter, Prof. Hapke, and Dr. von Schwartz lend valuable aid to the scientific side of the question, but in England, with the exception of some valuable little works compiled by Mr. W. A. Harris, the able secretary to the Phœnix Fire Office in Liverpool, the literature of the subject has been entirely neglected, although the fact that on an average 10,000,000*l*. is annually paid by British fire insurance companies on fire claims alone, whilst the loss probably is nearly double this amount, suggests that the subject is well worth the deepest consideration.

Under these conditions it is a matter for congratulation that Mr. C. T. C. Salter has now given us an excellent translation of Dr. von Schwartz's valuable book on "Fire and Explosion Risks," a handbook which deals in a thoroughly practical way with the investigation, detection, and prevention of dangers arising in the manufacture and storage of the most widely used chemico-technical substances.

The author has had a very wide experience as a consulting chemist and factory inspector, and has brought his almost unique experience in manufacturing methods to bear upon the various risks which they entail, with the result that he has produced a work in which practice is so blended with theory as to make the book of the utmost value, not only to chemists, but also to those who, without much chemical knowledge, yet wish to master the mysteries of a very intricate branch of technical application.

In dealing with the various substances the raw material is fully described in each case, its origin, physical character, and behaviour under all conditions is freely discussed, whilst cautions and suggestions for the safe manipulation and storage of each are clearly stated.

The arrangement by sections of those bodies likely to react on each other is particularly useful, and the works chemist and insurance surveyor can find the information he seeks in relation to the particular class of goods with the minimum of trouble.

Taking the book as a whole, the reader's interest is fully sustained, and although one finds instances of duplication of cautions, this is evidently the result of the sectional arrangement and so unavoidable.

In so excellent a work detailed criticism is a somewhat thankless task, but it might be suggested that in discussing the risks attendant on the use of petroleum lamps, some notice might be taken of the views of Sir James Dewar, Dr. Boverton Redwood, and the late Sir Frederick Abel, as to increase of the flash point not being so complete a solution of the trouble as the author leads one to believe.

It might be well to note in a future edition that barium peroxide, which on p. 117 is said to become dangerous at 800° C., may also give rise to fire at atmospheric temperatures when exposed to friction with organic matter.

On p. 187 it is stated that one pound of calcium carbide furnishes 4 to $4\frac{1}{2}$ cubic feet of acetylene, which is perfectly true of the inferior carbide made on the Continent, but with material of the quality until recently made at Foyers the yield rarely fell below 5 cubic feet per pound.

Occasionally one finds slight discrepancies in the statement of temperatures in different parts of the book, the temperature at which lead fuses being given at p. 291 as 325° C., whilst in the appendix, p. 343, it is stated to be 334° C. Such details as these, however, detract but little from the value of a book which is an important and most valuable addition to the technical literature of the day.

THE DETERMINATION OF MINERALS.

Mineral Tables—for the Identification of Minerals by their Physical Properties. By Arthur S. Eakle, Ph.D. Pp. 73. (New York: John Wiley and Sons; London: Chapman and Hall, Ltd., 1904.) Price 5s. 6d. net.

STUDENTS of mineralogy, miners, prospectors, and others interested in the determination of minerals by methods which do not involve the use of elaborate apparatus, will find this little book a useful addition to the literature of the subject.

The tables, though forming a volume of only 73 pages, include nearly 250 minerals, comprising all the commonly occurring ores, veinstones, and rock-formers, as well as a few species of more restricted occurrence. They are designed for the identification of unknown minerals by the examination of their physical properties alone; blowpipe reactions are not employed at all in the scheme. It is claimed by the author that the determination of minerals by blowpipe analysis is less apt to become merely mechanical if it has been preceded by practice in identification by physical properties. This is no doubt true; and if, as is often the case, the beginner is tempted to rely upon blowpipe analysis alone, that intimate acquaintance with minerals which is only gained as the result of the systematic observation of their physical properties, and which is so valuable for their ready recognition in the field, is either missed entirely or is only very imperfectly acquired. Indeed, in most cases blowpipe reactions are best employed by the determinative mineralogist in confirming conclusions already arrived at from the evidence of physical properties. They are, however, so invaluable for this purpose, and afford such an indispensable aid to identification by physical properties, that any determinative scheme from which they are entirely excluded must be in a sense deficient. The author would have greatly added to the value of the tables by including for each species a brief statement of its distinctive blowpipe reactions, and we venture to suggest this extension of the scope of the work to him for future editions.

As in all tables of this kind, the identification of an unknown mineral is effected by a process of elimination. The minerals dealt with in the book are first divided into categories according to their colour in the powdered condition; these groups are then subdivided into minor groups according to the colour of the mineral in mass; and finally, the species in each of these divisions are arranged in order of hardness.

In general plan the tables are similar to those of Weisbach; but they differ from them in certain respects, notably in their greater simplicity, and in the abandonment of that indefinite and unsatisfactory property lustre, as an important means of discrimination. The tables are preceded by an "analytical key," by reference to which it is possible, after preliminary observations of streak and colour, to see at a glance in which table the mineral under examination will be found; it is then only necessary to determine the hardness and one or two other characters, such as crystalline form, structure, cleavage, specific gravity, and so forth—all of which are described in columnar form in the tables—to complete the identification.

The omission of the great majority of those rare minerals which the ordinary student or prospector is scarcely likely to meet with, and which by their insertion render so many books of this kind dear and unnecessarily complicated, is to be commended. The tables are certainly to be regarded as among the most satisfactory that have yet appeared.

OUR BOOK SHELF.

Die Sinnesorgane der Pflanzen. By G. Haberlandt. Pp. 46. (Leipzig: Barth, 1904.) Price 1 mark.

THIS little book, which is appropriately dedicated to the memory of Darwin, was given as a lecture before the recent Versammlung deutscher Naturforscher und Aertzte at Breslau. The author devotes the chief part of his space to a semi-popular account of the various types of structures, such as bristles, hairs, papillæ, which serve for the perception of mechanical stimulus. This is necessarily, to a large extent, a recapitulation of his own interesting work on the subject, and is followed by an account of the *statolith* theory—the hypothesis independently put forward by himself and Němec as explaining the sensitiveness of plants to the force of gravity. The most interesting part of the lecture is, however, Haberlandt's concise discussion of his recent theory of the mechanism by which the direction of incident light is perceived by plants. He believes that the epidermic cells are, so to speak, the eyes of the plant. Thus, according to his view, when light strikes a leaf at right angles to the surface it results, from the plano-convex form of the epidermic cells, that the inner wall of each cell is illuminated more brightly in the centre than at the periphery. This makes it possible for the leaf to orientate itself in regard to light. Thus, suppose the plant to be moved so that the light now strikes the leaf obliquely, the bright patches of light on the inner cell walls will no longer be central. This change may be believed to constitute a stimulus calling forth a curvature of the leaf stalk by which the leaf is brought again to its normal position at right angles to the incident light. Thus the leaf moves when the bright patch is not central, and comes to rest when each of its epidermic cells is centrally illuminated. This attractive theory cannot be said to be as yet established, and botanists will look with interest to its further development by its author. The appendix of six pages is devoted to the literature of the subject and to short discussions of points which probably seemed too technical for the text of the lecture.

Electricity in the Service of Man. By R. M. Walmsley. Pp. viii + 1208. (London: Cassell and Co., Ltd., 1904.) Price 10s. 6d. net.

WHEN the first edition of this book was published in 1888, it was doubtless a comparatively easy matter to write a treatise covering all the practical applications of electricity to the service of man. As each successive edition appeared the task must have become one of increasing difficulty, and now that the fourth has been reached Dr. Walmsley no longer finds it possible to condense all his material into one volume. He has therefore wisely confined himself to certain branches, and left the others for treatment in a supplementary volume. The book before us is divided into two parts, the first being more or less theoretical, dealing with the principles, and incidentally with the history, of the subject, and the second dealing with the technology of electricity. The first part is clearly written, and forms a good introduction to the study of electricity and magnetism which should be valuable to the beginner or to the amateur interested in scientific progress. The second part is confined in the present volume to generators and motors, with a chapter on measurements. The writer is of opinion that these more advanced subjects are best studied by means of the many very excellent treatises specially devoted to them; but still, there can be no doubt that a general review such as the one before us appeals to a large class of readers and serves a useful purpose. The book is plentifully illustrated with drawings and diagrams, which are for the most part good, though several, especially in the earlier part, are rather crude and out of date. M. S.

The Flora of the Presidency of Bombay. By T. Cooke. Vol. ii. Part i. Compositæ to Boraginaceæ. Pp. 216. (London: Taylor and Francis, 1904.) Price 9s.

THIS volume begins in the middle of the series *inferae* belonging to the gamopetalous division. The indigenous species of Compositæ are numerous, but for the most part are not so important as the introduced composites, of which a list is given. In the series *heteromerae* the cohort Ericales is unrepresented, but the orders Myrsineæ, Sapotaceæ, and Ebenaceæ include several interesting genera. Under Bassia Dr. Cooke explains how the synonym Illipe has been erroneously introduced. Illipe is the Tamil name for *Bassia longifolia*, and is applied commercially to the fatty product obtained from the fruit; this species replaces in southern India the better known mahua tree, *Bassia latifolia*, of which the flowers furnish a favourite food, also a spirit to the natives of Central India. The province is rich in species of Diospyros, amongst them *ebenum*, *melanoxylon*, the calamander-like *oocarpa*, and *crumenata*. The author agrees with Hiern in uniting *D. ebenum* and *D. assimilis*, but separates *D. cordifolia* and *D. montana*. The Apocynaceæ include *Cerbera Odollam* of the salt marshes, an endemic Beaumontia, and a species, also endemic, of Ervatamia, a genus cut off by Dr. Stapf from the original genus Tabernæmontana. Another dominant order is that of the Asclepiadaceæ, which furnishes mostly twining shrubs or climbers, and of which a good many, as, for instance, the four species of Hoya, and seven species of Ceropegia, are confined to the western side of the peninsula. This part gives every indication of the same care and accuracy which distinguished the first volume.

Quadratic Partitions. By Lieut.-Colonel Allan Cunningham, R.E. Pp. xxiv + 266. (London: F. Hodgson, 1904.) Price 12s. net.

THIS contains a complete list of primes p up to 99991, with the factors of $p-1$, and resolutions of

$$p=a^2+b^2=c^2+2d^2=A^2+3B^2=\tfrac{1}{4}(L^2+27M^2);$$

of $p=e^2-2f^2$ up to $p=24977$; together with other resolutions of the type $mp=x^2\pm Dy^2$ for selected values of m, D, and all primes p up to a certain limit. Besides this, there are tables relating to the Pellian equation, and others directly connected therewith. The introduction explains the nature and use of the tables, and gives an account of their preparation. Though some of the contents have already been published (as explained in the introduction), a substantial part appears for the first time in print; the whole forms a varied as well as extensive series of arithmetical records which will be found of great value by those who are interested in the theory of numbers, especially in connection with the theory of residues and of quadratic forms. Great care has been taken to ensure accuracy, and the appendix contains lists of errata detected in various preceding tables. The new part of the work represents a very large amount of labour, which is henceforth spared to those in search of material for induction, and the grants made by the Royal Society towards the expenses of computation and publication have been worthily bestowed. It may be added that the paper and type used are satisfactory; in the case of tables this is a matter of real importance. All serious students of the theory of numbers ought to procure this work, as well as Lieut.-Colonel Cunningham's "Binary Canon," for, independently of their use in solving special problems, these tables may suggest or confirm new theorems of real importance.

Advanced Hand-camera Work. By Walter Kilbey. Pp. xvii + 98. (London: Dawbarn and Ward, Ltd., 1904.) Price 1s. net.

IN this series of photographic books already published the present author is responsible for the popular volume on "Hand Colour Photography," which is now in its second edition. In the issue before us he deals with the higher flights of hand-camera work, more especially in connection with its use with the focal plane shutter. The subject-matter treats of the selection of apparatus, the behaviour and efficiency of the focal plane shutter, and practical work with the camera, the last mentioned consisting of hints on focusing, exposing, and the treatment of moving objects. No less important are the subjects of the last two chapters, which concern the plates and developers suitable for such work, and the employment of hand cameras in telephoto, stereoscopic, and orthochromatic photography. A great number of excellent and appropriate illustrations from the author's own negatives accompany the text.

The easy and clear style of the author, and his thorough acquaintance with the subject he is treating, render the book not only delightful to read, but a valuable guide to those who wish to work successfully with hand cameras.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Definition of Entropy.

THERE is, I fear, a difficulty in drafting Prof. Bryan's definition so as to be clear as well as accurate. This arises when the definition is first given with reference to the entropy of the working substance, because the non-available energy is not necessarily a portion of the energy of the substance. The terms available energy, free energy, bound energy, and non-available energy are continually used loosely in thermodynamics as if they referred to portions of the energy of the working substance. I know from experience the difficulty of defining the entropy of the working substance in terms of dissipation or degradation, without reference to the state of things outside the substance, and in a paper on the factors of heat I adopted the notion of reduction of "transfer credit," so that increase of entropy went with lessening of capacity for transforming heat into work with change of volume. In my book on "Entropy" the whole treatment is essentially from the dissipation or degradation point of view, but entropy is first defined in connection with the irreversible increase of entropy in an isolated system. It is thus defined: "Increase of entropy is a quantity which, when multiplied by the lowest available temperature, gives the incurred waste."

May I say that I am exceedingly glad to find Prof. Bryan treating the subject from the same point of view, as it is strong evidence that my treatment is essentially right.

41 Palace Court, W. J. SWINBURNE.

MR. SWINBURNE has directed attention to an obscure point in my letter of November 10 which is calculated to produce quite the contrary impression to what I intended. In defining available energy relative to a given temperature, it was not my intention to exclude work that the system was capable of producing by expansion or otherwise without using the reversible engines, and instead of "maximum amount of energy" I meant maximum amount of *work*. By work I refer to ordinary mechanical energy as opposed to what Mr. Swinburne calls "waste energy." The point to which I wished to direct attention was the desirability of basing a definition of entropy on non-available energy, and the use of the term "relative" in this connection, or at least some equivalent language (as implied in my words, "The definition may be stated *somewhat* as follows").

So far as I am able to judge, both from Mr. Swinburne's book and from some correspondence with the author, it would appear that the conclusions to which I am being led by independent working in regard to entropy agree closely in many substantial points with those at which he has arrived. Since the controversy referred to there have been one or two papers published on the subject by other writers with which I altogether disagree. G. H. BRYAN.

Craniology of Man and the Anthropoid Apes.

IN reading Mr. Macnamara's Hunterian oration of February, 1901, I find these words:—

"Prof. Deniker in his work on the embryology and development of the anthropoid apes has shown that *in consequence of the early closure* of the anterior sutures of the skull of these animals the fore part of their brain does not increase beyond the size it had attained at the end of the first year of life; but in man these sutures do not consolidate until a much later period, so that the anterior lobes of his brain are enabled to expand, and actually become far more perfectly developed than the corresponding lobes among anthropoid apes."

This being so, I ask:—

(1) Has the experiment ever been tried of keeping the sutures of an infant ape open by artificial means? And if it has,

(2) Has the brain been found to expand and become more perfectly developed?

For if so we should expect the ape to manifest an intelligence not far short of that of a man. A. T. MUNDY.

IN answer to Mr. A. T. Mundy's questions, it seems to me that it would be impossible in a young living ape, by artificial means, to prevent his frontal suture from closing, and if we could succeed in keeping it open I question if any marked increase in the size of the animal's frontal lobes would augment his intellectual capacity. It is not only the great size of man's cerebrum as compared with that possessed by anthropoid apes which gives him greater intellectual power, but, as I have stated in the passage quoted by Mr. Mundy from my Hunterian oration, the frontal and parietal lobes of the human brain are "far more perfectly developed than the corresponding lobes among anthropoid apes." This is especially the case with respect to those motor and psychical areas of man's cerebral convolutions which control his power of intelligent speech; these areas of the brain are deficient in the anthropoid apes. It is probable that man's ability to make use of articulate language, and through this means to think, has led to the great development of the psychical elements of his brain. A comparison of the size and conformation of the cranium of Tertiary man with that of existing Englishmen is an indication of the length of time it has taken for the human cerebrum, and therefore intellect, to reach its present stage of evolution. Man and anthropoid apes we hold to be derived from a common ancestral stock; the former, under the action of natural selection and other causes, including, I think, not only an inherent capacity of cerebral but also of cranial growth, have gradually developed, whereas anthropoid apes, from arrest of cranial and cerebral growth, have not reached the standard attained by human beings; the difference between these two orders of beings, however, is one of degree, and not of kind. N. C. MACNAMARA.

November 26.

Pinnipedia a Sub-order of Cetacea!

ONE is so much accustomed to encounter strange assertions in regard to zoology in the non-scientific Press that one takes little notice of them; but when one reads under the head of "Science," as may be read in this day's *Athenaeum* (p. 767), a reviewer of Mr. Millais's "Mammals of Great Britain and Ireland" complaining of that work that "Nowhere is it stated, as it should be, that the Sub-order Pinnipedia belongs to the order Cetacea," one is tempted to ask to what end have writers on classification laboured, if such an assertion as this is to pass unchallenged? If, by a slip of the pen, "Cetacea" was written for "Carnivora," one can sympathise with the reviewer, for all are liable to such unhappy accidents; but the general drift of his remarks seems to forbid that charitable construction, for in the preceding paragraph it is expressly stated that the Carnivora, except the Mustelidæ, are dealt with in the volume. F. Z. S.

December 3.

The Late Mr. Assheton Smith.

THE man of ample means, and who is a lover of living creatures, has a great opportunity. Mr. Assheton Smith had this opportunity, and he used it not only to gratify his own pleasure, but to share it with others. There was nothing that he liked better than to go the round of his park with a guest, and to point out and discuss the characters and habits of the animals which he had gathered together from various quarters of the globe. With the late squire such a ramble was no ordinary treat. One felt, too, that in this man the beasts had a true friend, that he had studied them and knew their ways, and that he would do his utmost to make their lot as happy as possible. To such a man science owes a great debt. Not only does he afford the student an opportunity of studying animals in favourable circumstances, but he is able to place material at the disposal of the laboratory and museum when these animals have paid nature's last demand. For a number of years I have had the good fortune to act, as it were, as prosector to his menagerie, and both my students and I have been able to carry out not a few studies in comparative anatomy. Sometimes, playfully, he would accuse me of possessing the "evil eye," as he said that an animal was not likely to survive long should I express a desire to have it eventually for the college museum. I am grateful that my liking for natural history brought me in touch with him. It is in the small actions of life that one can best read character. A gentleman to the core, he was never fearful of giving himself away by showing the utmost courtesy to the humblest. An unfastened door or gate, a watertap left trickling he would not abide. Everything at the park must be precision and finish to the smallest details. Over his many acts of private charity he ever kept the veil tightly drawn. A few of them have incidentally come to my knowledge, and they reveal the vastness of his sympathy. His many zoological donations, and his gift to the college of a site on the Menai Straits for a biological station for the study of marine life, bear eloquent testimony to his desire to advance science. May the pile to be raised on this fine site—let us hope at no distant date—be at least one grateful tribute to his memory. PHILIP J. WHITE.

University College, Bangor, November 28.

The Leonid Meteors of 1904.

FROM results of observations of this shower as published in NATURE of November 24 it seems that Leonids were found to be somewhat numerous on the night of November 14. It is to be regretted that those observers who were able to count so many shooting stars on this night had not the following night equally clear, as at Dublin both November 14 and 15, though not to the same degree, proved favourable for observations, and it was on the latter night that the maximum occurred. Owing to the unsuitable weather that appears to have prevailed in many places on November 15, some details of the observations made on the successive nights of the epoch at the same place may prove interesting.

The night of November 14 turned out ideally fine here, the temperature also being very mild for the season. During a watch on this date from 10h. 15m. to 13h. 45m. (Dublin time) 16 meteors were counted, of which 7 or 8 were referred to the Leonid radiant. The meteors, especially the Leonids, did not appear very bright, only 1 of the first and 2 or 3 of the second or third stellar magnitudes having been seen. No particulars of their paths were noted, as doing so might have interfered with the observations of other meteors. Shooting stars were more numerous in the early part of the watch than after midnight, 5 having been counted between 10h. 45m. and 11h., of which 2 shot from the direction of Leo. Another, though feebler, maximum occurred about 13h.; but, as it was considered from the declining meteoric rate that the anticipated miniature shower of this night was already over, observations were discontinued shortly before 14h.

The night of November 15 began very inauspiciously; clouds in the early evening covered the heavens, totally concealing both moon and stars. Subsequently, however, the sky partially cleared at intervals, and when observations were begun at 10h. 15m. passing clouds in the east left clear tracts of considerable area. Though the seeing was thus far from good, yet meteors were considered to be rather scarce, only 1 shooting star, a third magnitude Taurid, having been seen during a watch extending over nearly an hour. About 11h. the clouds passed off, leaving the eastern sky clear until nearly 14h. Meteors now began to be more numerous. A fine Taurid at 11h. 25m. passed down straight towards Leo, which, however, was partly invisible in a bank of fog along the horizon. When about twenty minutes later the "Sickle" emerged clear in the heavens, a succession of fine Leonids left no doubt as to the superior character of the coming display.

From 11h. to 13h. 30m. 32 meteors were counted; at 14h. 55m. the number had increased to 50 meteors, the total result at 16h. 45m. amounting to 60 meteors. But owing to clouds observations were greatly hindered from 13h. 45m. to 14h. 15m., and a second interruption of nearly equal length, arising from the same cause, occurred about 15h. During the last hour of the watch the sky was fairly clear, and it was noted that the meteor shower was now rapidly declining. The majority of the meteors were observed to emanate from Leo as soon as the latter had become visible near midnight.

The shower was also observed at the Paris Observatory on the night of November 15 with the following results[1]:—

From 10h. 30m. to 13h. 15m. ... 21 meteors observed
,, 13h. 15m. ,, 16h. 30m. ... 29 ,, ,,
,, 16h. 30m. ,, 17h. 35m. ... No shooting star seen

As no mention is made of the state of the weather, it seems the display terminated very abruptly at Paris, slightly more so than in Dublin or elsewhere, as Mr. T. R. Clapham, on November 15, from 15h. 45m. to 17h. 45m. counted 19 Leonids with 3 three doubtful ones, notwithstanding two brief interruptions from clouds, this result, it may be added, indicating a meteoric rate almost exactly equal to that of the preceding night as given by Mr. Hector Macpherson, who on November 14, from 15h. to 18h., recorded 35 meteors (*English Mechanic*, November 25, p. 365). The rate on the latter night seems, however, to have been even higher than this to judge from some results, but more observations are, no doubt, desirable. JOHN R. HENRY.

Dublin, November 29.

[1] The results are of course given in Paris mean time.

Blue-stained Flints.

Two years ago I found large patches of an intense blue colour, with some black spots, on flints on the quay at Great Yarmouth. I looked for a possible cause, and discovered other patches similar in all respects but colour. The latter patches were black, and had been made by tar spilt by fishermen when tarring their fish skips. I kept some pieces, both black and blue, in a box until some months ago, and no appreciable change had taken place, so I came to the conclusion that the blue colour was produced by the action of the tar on the flint when exposed to sunlight.

This occurrence is interesting in view of the action noticed by Dr. Allen between gas-lime and flint, and points to the action on the flint of some substance common to the tar and gas-lime.

May I suggest to your former correspondent that the blue flints seen at Bournemouth were produced from the black, and not *vice versâ*. THOMAS L. D. PORTER.

County School, Ilford, Essex.

"FIND" OF ROYAL STATUES AT THEBES.

THE "land of surprises and paradoxes," as Egypt has well been called, has once again justified its reputation, and out of the ruins of one of its most ancient cities there has come to light a mass of historical evidence which, if we mistake not, will be found to be of more importance the more it is studied. It will be remembered that for many years past M. G. Legrain has been carrying out a series of repairs of a very far-reaching character on the mass of buildings of various styles and ages which is commonly known as the "Temple of Karnak." In the course of this work he has collected a number of important facts which, when duly arranged, will be of considerable use to the student of ancient Egyptian architecture, and, side by side with these, he has brought together a considerable amount of information of value historically. It is not our purpose even to outline the broad facts of the works of restoration which he has carried out, and we therefore pass on to state briefly the facts which relate to his last "find" of monuments at Karnak.

Early in the present year M. Legrain was continuing the excavation of a portion of the temple precincts near one of the great walls when he accidentally came upon a large pit or well which, it was evident, had been filled up by the ancient Egyptians. Soon after he began to dig out the well the workmen came upon a layer of statues made of hard stone of various kinds, and when the mud was removed from them many of them were found to be inscribed. Beneath this layer of statues was a layer of earth, and beneath the earth was another layer of statues, and the clearing out of the pit showed that it was filled with layers of statues and earth, arranged alternately. The statues were usually found face downwards, and it thus became clear that they had been so placed in order that their faces might be protected by the soft earth and mud in which they were buried. The total yield from the pit or well was about 450 statues.

As soon as the pit was emptied M. Legrain began to examine the objects which he had found, and he saw that many of the statues were royal, and that, speaking generally, the oldest belonged to the second or third dynasty, and the latest to the twenty-sixth dynasty. The greater number of them were, of course, made for high officials, generals, architects, priests, &c., and we may be certain that from first to last they represent the men who, during a period of about 3500 years, were the principal benefactors of the great temple of Amen-Rā, the "king of the gods," at Thebes. The question which naturally arises is, How came these statues to be in the place in which they were found? The answer is not far to seek. We know that it was a custom among the Egyptians for the kings and their nobles to dedicate statues of themselves to the temples of the god or gods whom they loved to worship, and they did so with the idea that, after death, their spirits would come from their graves and inhabit them, and would enjoy in their new existence the worship which had been their delight when upon earth. As the spirits of the gods also dwelt in the statues which were dedicated to them in the temples, the spirits of the kings and their nobles would thus dwell in divine company, and would participate in the happiness which disembodied spirits were believed to derive from the chants and hymns of the faithful, and the offerings and incense which were offered up by the priests. How these statues were arranged is not quite clear, but it is pretty certain that they were placed in niches or on pedestals in the chambers adjoining the sanctuary. As time went on, chamber after chamber would become full, and at length it would be as difficult to find a site for a new statue as it is to find a site for a monument to some illustrious dead person in our own Westminster Abbey.

It has been the custom to say that the temple of Amen-Rā at Karnak was founded by the early kings of the twelfth dynasty, about B.C. 2500, but it is clear from the statues which M. Legrain has brought to light that a temple to Amen must have existed at Karnak at least some 1500 years earlier. Some archæologists, basing their opinion on the evidence derived from religious texts, have always maintained that the twefth dynasty temple of Amen was merely a new foundation, and not the original temple, and this was the view which Sir Norman Lockyer, K.C.B., arrived at in his investigations of the systems of the orientation of Egyptian temples. We now know that so early as B.C. 4000 an important temple of Amen stood at Karnak, and that even in that early period it was already so old that kings held it to be one of the highest honours attainable to have their statues included among the monuments of the "glorious and mighty dead" who were commemorated there. The temple of Amen represented the roll of fame for the Egyptians, and M. Legrain's "find" helps us to understand why Karnak was declared by the priests to be the "throne of the two lands" (*i.e.* Egypt), and the "seat beloved of the heart of the god." Now the fortunes of the god Amen and of his temple varied with those of the king, and the glory of his sanctuary waxed and waned according as the prosperity of the country increased or decreased. During the fourth, fifth, and sixth dynasties the chief centre of power lay between Heliopolis and Memphis; from the twelfth to the twentieth dynasty it rested at Thebes, and the temple of Amen between B.C. 2500 and B.C. 1050 was the greatest in the land, just as Amen himself was the greatest of the gods.

Between B.C. 1000 and B.C. 650 evil times came upon Thebes, and the formerly wealthy capital became poverty-stricken. A serious trouble between the priests and the people resulted in the departure of the former to Nubia, and in consequence the temple of Amen fell into a state of decay. Worse than all, soon after his accession, B.C. 668, Ashur-bani-pal, King of Assyria, invaded Egypt, and, marching up the country, plundered Thebes and its temples. This blow the city seems never to have recovered, and for about 300 years it held a position of no importance in the country. Under the Ptolemies some attempt to rebuild certain portions of the Temple of Amen was made, and it is probable that the work was begun under the wise rule of that astute ruler Ptolemy I. It was, of course, impossible to restore the worship of Amen to its original glory, and the extent of the buildings of the god must have been considerably curtailed.

Whilst the work of restoration was going on, the question of the disposal of the statues which M. Legrain has unearthed came up for decision. It was felt that to destroy the statues would be a sacrilegious and profane act, and therefore an old well was chosen in which to bury them; as we have seen, they were carefully placed in layers of earth or mud, and it is entirely to the religious instinct of the restorers of the temple of Amen that we owe the preservation of such a unique series of statues. In his "Notes prises a Karnak," recently published in the *Recueil*, M. Legrain directs special attention to the statues of three kings, of whom previously no monuments have been known; these are:—Mer-ḥetep-Rā, Mer-sekhemRā Mer-ānkh-Rā. It is early yet to attempt to assign exact places to these kings, but the discovery of their monuments is a striking contradiction of the assertion which has been made recently to the effect that our knowledge of Egyptian history is complete, and that there are no more important discoveries to be made in Egypt. Already M. Legrain's examination of the statues from Karnak enables us to correct our views on Egyptian history, and we must be prepared to admit that the kings of Egypt were considerably more in number than the king-list of Manetho would lead us to suppose, and that some of the dynasties were contemporaneous. M. Legrain's "find" also proves beyond all doubt the futility of limiting dynastic history to a period of 3000 years, as some of the German *savants* have done, and the evidence which is accumulating rapidly all goes to show that the assertions concerning the great antiquity of Egyptian civilisation made by Herodotus and other Greek writers, and the opinions of modern experts like Mariette, Chabas, and our own Hincks, are generally correct.

The statues recently found belong to all the dynasties which are most famed for the production of fine artistic efforts in sculpture and statuary, and many of them may well be considered to represent with great fidelity the features of the men they commemorate. Nearly all the great kings of Egypt took care to have their portrait-statues added to the Karnak collection, and down to the Ptolemaïc period the lover of antiquity in Egypt could look upon contemporaneous portraits in stone of the kings of the Archaic period, of Cheops, the builder of the Great Pyramid, of the great warriors of the eleventh, twelfth, and eighteenth dynasties, of the bombastic Rameses II., and of the Nubian king Tirhakah, who, to his credit be it said, left the shrine of Amen at Karnak uninjured, and humbly worshipped in that great symbol of the solar worship of the ancient Egyptians. It is greatly to be regretted that the Ptolemies did not cause portraits of themselves and their queens to be included among the statues of the great kings and priests of the country over which a strange fate called them to rule.

COMPULSORY GREEK AT OXFORD AND CAMBRIDGE.

THE statute enabling students of mathematics and natural science to proceed to a degree at Oxford, without previously passing in Greek, has been rejected in the larger house by 200 votes to 164. At an earlier stage the proposal was adopted in the smaller assembly by the narrow majority of two votes. The discussion accorded to the statute was brief, for the voters had probably made up their minds; but it revealed the fact that, while the familiar arguments as to culture and the humanities held sway with those who have "learned nothing and forgotten nothing," some condemned the proposal, at least ostensibly, because it was too narrow. It would shut up school boys with a bent for mathematics or science to a "premature specialism," if they alone had to be segregated, years before the university stage, from their happier fellows on the "classical side."

The Cambridge proposals avoid at least this latter objection. They recognise that the examination which admits to the university should be one, in the sense that it allows the student who has passed it to enter any faculty or department of the university. He need not, while still at school, decide finally as to his special subject or subjects; and if he changes his mind as to the course he desires to pursue he need not retrace his steps, and begin to "get up" a new set of "little-go" subjects after he has entered the university. For three days high debate on the new scheme was held in the Cambridge Senate House, and so far as argument goes the impression produced is that the *placets* have the best of it. The official defenders of compulsory Greek spoke, naturally and properly, of the ennobling influence of Greek literature and philosophy. They scornfully derided the lack of culture disclosed by the false quantities of the mere man of science who is Greekless. But they failed to make clear the connection between the paltry rudiments, half grammar and half "crib," by which Greek is now represented in the previous examination, and humanistic culture or literary training of any sort. It was practically admitted that half the boys, even from classical schools of the straitest sect, might spend eight formative years over Greek and be no Hellenists in the end. But the conclusion was that time must be given for the improvement of school-teaching in classics, and that, in order to secure this improvement, the artificial support of the subject afforded by the present regulations is a necessity. The monopolists asked for more protection that they might mend their machinery.

One or two headmasters pleaded their helplessness before the uncultured parent if the shelter of academic compulsion were denied them, and the inconvenience they would suffer if they had to rearrange their time-tables to make room for science and modern languages, with all their complexity. Greek for all who aspire to enter the university is so much simpler than French and German and science for some, mere "modern-siders," and Greek and Latin for others, the "pick of the school." "If compulsion is done away with, schools will soon give up Greek altogether; in ten years it will be as dead as Hebrew," was the cry of these despairing headmasters. There were not wanting others to answer them, no less distinguished as scholars and teachers. The masters of Trinity and Christ's, the president of Queens' and Dr. Jackson, and other Grecians of established fame had such faith in the vitality of Greek—in its undying charm and its unrivalled power over the human spirit—that in their opinion it needed no such paltry prop to hold it upright. To force upon students of another bent the wasteful drudgery of six months' cramming in Greek accidence and the perfunctory conning of a set book with the help of a translation, was not only an educational blunder, but a grave moral wrong. It was bad for the student, it was bad for the master, it was bad for the university, and it was worst of all for the cause of Greek learning itself. It was breeding a race of students who, able and brilliant and influential in other paths, cherished a positive hostility to the distasteful subject that had raised itself as a needless obstacle in their way. But for compulsion they might have remained at worst indifferent, at best distant admirers of Greek. Now their only thought of it was associated with grievance and injustice. Times had changed, were changing fast; new methods of education were afoot in the schools. The bifurcation of studies—classical and non-scientific on the one hand, modern and scientific on the other—had become an accomplished fact. It was for the university frankly to recognise the change, and to give equal opportunity for both curricula. Cambridge had amply provided for the needs of the modern and scientific student once the barrier of the classical previous was passed. Why should the student, whose school and university course alike bore in one and the same direction, say towards natural science, be obliged to deviate during the last months of his school-time in order to pass through a wicket that lay straight in the path of his classical comrade, but far out of his own? True, a great teacher, a Porson or an Arnold or a Gow, might make even "Little-go Greek" a thing of life and light for his pupils; but what of the schools the head of which was a "mere Newton or Darwin"? Must the many be sacrificed for the few?

Then another issue was raised by the clerical members of the Senate, an issue on which, seeing the actual composition of the register, more will ultimately turn than on the educational question. If Greek is not compulsory, it will cease to be taught to and cease to be learned by candidates for ordination. The bishops of the Church of England will no longer be able to require a knowledge of the Greek Testament from the aspirant to holy orders. It is admitted that the Presbyterian Church exacts both Greek and Hebrew as a condition of admission to its theological schools. But the heads of the Anglican Church are weaker than the General Assembly; the university must reinforce them, whatever the consequences to sound learning and unfettered research.

Grave warnings were uttered that the *non possumus* of the Senate on this question would not be the final word. Revolution, in other words a Royal Commission, would be the inevitable Nemesis of reform denied. And there is no doubt that this thought will weigh with some waverers, who love learning and fear for its displacement by modern studies, but who love the university more and dread the changes which a liberal government might impose on it from without.

The report of the syndicate will doubtless be referred back for reconsideration of details in the light of the discussion. But the principle that modern subjects shall be recognised will certainly be retained, and on this principle issue will be joined early next term. The result no man can predict, for it lies with the silent voters who will flock from the country to the poll. But the debate has cleared the air, and the reformers are sanguine that this time something will be done.

PROF. KARL SELIM LEMSTRÖM.

As has already been announced, Prof. Karl Selim Lemström, whose name is known to our readers by his investigations on the aurora borealis and the influence of electricity on plant growth, died on October 2 after a short illness.

He was born in 1838 not far from Helsingfors, and entered the university in 1857, where he devoted himself to studies of physics and mathematics. His first scientific work, published in 1868, was founded on experiments made in Stockholm under the guidance of the late E. Edlund, the celebrated physicist, and dealt with the intensity curve of induction currents in relation to time, the intensity of the inducing current, &c. A summary was published in French in the *Proceedings* of the Swedish Academy of Sciences in 1870.

Lemström joined the late Baron A. E. Nordenskjöld's expedition to Spitsbergen in 1868 as physicist. In the two following years he worked in the laboratory of V. Regnault in Paris; in 1871 he made a journey to Lapland; in 1872 he continued his researches on the induction currents at the St. Petersburg Academy of Sciences. His papers during these years are printed in the *Proceedings* of the Swedish Academy and of the Finland Society of Sciences.

During the journey to Spitsbergen Lemström was engaged in observations on atmospheric electricity, terrestrial magnetism, and the aurora borealis. These observations, continued in Lapland, suggested to him a new theory of the last named phenomenon, so enigmatic even after the investigations of De la Rive, Loomis and others. This theory he expounded in a dissertation entitled "The Electrical Discharge in the Aurora and the Auroral Spectrum" (1873).

His next work, on the causes of terrestrial magnetism, was published in 1877. Starting from Edlund's well known theory on the nature of electricity, he argued that the rotation of the earth in an atmosphere of non-rotating ether causes the electric currents of which the terrestrial magnetism is a manifestation, and he described several experiments in confirmation of these views.

Appointed in 1878 professor of physics at the Helsingfors University, he continued his investigations on the aurora borealis in Lapland in 1882–4, where he organised two stations for taking part in the international polar exploration of these years. The investigations carried on by this expedition were published in a large work, "Exploration internationale des Régions polaires, &c.," of which vol. iii. (1898) contains his auroral researches.

One very interesting work by Lemström is devoted to the study of night frosts and the means to prevent their devastations, so frequent in Finland. Lemström emphasised the nocturnal radiation of heat as the principal cause of the night frosts, and showed that in calm and clear summer nights the air, cooled by the radiating soil and plants, must remain at the surface of the earth, and, flowing like water, gather on lower grounds, which generally are most exposed to frost. He proposed to prevent the radiation by artificial clouds of smoke, and invented for this purpose "torches" or tubes of peat (described in *Acta Societatis Scientiarum Fennicae*, Tome xx.).

Moreover, Lemström made important experiments on the influence of electricity on growing plants, on which subject he read a paper before the British Association at Bristol in 1898. The influence in question was found by exposing the plants to electric tension from a metallic wire net, provided with points and connected with the positive pole of a Holtz machine, the negative pole being conducted to the earth.

His frost experiments directed attention to the prevention of frost damage in several countries, and also gave rise to new scientific investigations (for instance, by Th. Homén). It is to be hoped that further work may be devoted to this important subject as well as to the electrocultural question, which have both but very little advanced from the point to which they were brought by the warm-hearted, indefatigable pioneer, Selim Lemström. Arthur Rindell.

NOTES.

It was announced last week that the Royal Society of Edinburgh has awarded the Gunning Victoria Jubilee prize for 1900–4 to Sir James Dewar, F.R.S. We now learn that the following additional awards have been made:—the Keith prize for 1901–3 to Sir William Turner, K.C.B., F.R.S., for his memoir entitled "A Contribution to the Craniology of the People of Scotland," and for his "Contributions to the Craniology of the People of the Empire of India": the Makdougall-Brisbane prize for 1902–4 to Mr. J. Dougall for his paper on an analytical theory of the equilibrium of an isotropic elastic plate; the Neill prize for 1901–4 to Prof. J. Graham Kerr for his researches on *Lepidosiren paradoxa*.

A valuable collection of specimens illustrative of the fauna of the deep sea has recently been received at the British (Natural History) Museum as a gift from H.M. the King of Portugal. The collection is reported to include a number of deep-sea fishes, among which are sharks of considerable size, captured during His Majesty's recent cruise in Portuguese waters. Several of these may prove to have been previously unrepresented in the British Museum collection. King Carlos, like the Prince of Monaco, is much interested in the fauna of the deep sea, of which he himself has done much to increase our knowledge. The collection sent to the museum is also stated to contain a series of contributions to our knowledge of the deep-sea fauna from the pen of His Majesty.

The sale of Chartley Park, Staffordshire, the hereditary seat of Lord Ferrers, involves also a change of ownership of the remnant of the celebrated herd of white cattle which have been kept there for the last 700 years. It is much to be regretted that the cattle could not have gone with the park, and have been maintained there by the new owner; but as this is not to be, it is to be hoped that they will be given a safe home elsewhere, where they will flourish and increase. It was long considered that the herds of wild cattle in various British parks were direct descendants of the wild aurochs, but it is now generally admitted (largely owing to the writings of Mr. Lydekker) that they are derived from domesticated albino breeds nearly allied to the Pembroke and other black Welsh strains, some of which show a marked tendency to albinism. This view, as pointed out by a writer in the *Times* of November 29, is strongly supported by the fact that the Chartley cattle frequently produce black calves. The theory advocated by a later writer in the same journal that the British park cattle are the descendants of a white sacrificial breed introduced by the Romans rests upon no solid basis. The Chartley cattle, believed to be reduced to nine head, are to be captured by the purchaser—no easy task.

The anniversary dinner of the Royal Society was being held last week as we went to press. In proposing the toast of the Royal Society, Mr. Arnold-Forster said that every day he has lived in a public office he has been more and more impressed with the need for a greater knowledge in our public life of what men of science are thinking, what they are doing, and what they hope and mean to accomplish in all the great departments of scientific life throughout the globe. There is absolutely infinite opportunity for the work of trained minds in that important department of our national life, the public service. Even in his short official life he had lived to see some progress made in the direction in which he wished to see this nation travel. Sir William Huggins responded; and among other speakers were Lord Strathcona, Sir J. W. Swan, Mr. W. Bateson, and Mr. Leonard Courtney.

The annual dinner of the Institution of Electrical Engineers was held on Thursday last, December 1, Mr. Alexander Siemens, the president, being in the chair. In proposing the toast of the institution, Lord Alverstone remarked that its high standing among scientific organisations was due to the fact that it had kept pace with the times, had been the first to promulgate and promote among its members all the information about electrical science that could be obtained, had been willing to welcome electricians from all parts of the world, had kept its students and its members acquainted with every modern development, and had given them the means of cultivating the technical knowledge of their science to the highest extent. In the course of his response to the toast, the president announced that telegrams of congratulation and sympathy had been received from the Belgian and Italian Societies of Electrical Engineers. In their visits to foreign countries the international character of electrical engineering had come out, and it was this which had contributed not a little to the development of electricity throughout the world.

The death is announced of Dr. T. M. Drown, president of Lehigh University, and previously professor of chemistry at Lafayette College and the Massachusetts Institute of Technology.

It is reported in the *Pioneer Mail* that the Secretary of State for India has sanctioned the creation of the appointment of electrical adviser to the Government of India, with headquarters at Calcutta. The present post of electrical engineer to the Government of Bengal will be abolished.

According to the correspondent of the *Daily Chronicle* (November 25) the German Commission that is investigating tuberculosis has come to the conclusion that two distinct forms of tubercle bacilli exist, the human and the bovine. Out of fifty-six cases of human tuberculosis examined fifty showed human bacilli only, five (three being children) showed bovine bacilli, while the remaining one showed both human and bovine bacilli.

A movement has been initiated in Denmark for the erection of a monument to the late Prof. Finsen, the inventor of the light cure for lupus. It has been thought that many outside Denmark would desire to join in doing honour to one who did so much for his fellow-men, and a British committee has been formed for the furtherance of the scheme. The Hon. Sydney Holland, Sir Francis Laking, Sir Frederick Treves, and Mr. Malcolm Morris, members of this committee, announce that subscriptions may be paid to the Finsen Memorial Fund at the National Provincial Bank, 112 Bishopsgate Street, E.C.

The Bradshaw lecture was delivered at the Royal College of Surgeons on December 1 by Mr. Mayo Robson, who took for his subject the treatment of cancer. He pointed out that in many instances, perhaps in all if we only knew it, there was a pre-cancerous stage in which operation ought to be performed, and would be the means of saving many lives. In early operation with complete removal of disease, together with a wide margin of healthy tissue, our hope of cure must depend. Medical treatment could not cure, and could do little to prolong life. There was hardly any situation in the body in which an operation for removal could not be performed provided the disease were recognised sufficiently early, and the results of surgical treatment were by no means so hopeless as generally supposed.

We learn from the *Athenaeum* that M. Paul Tannery, whose death is announced, was born at Mantes on December 20, 1843, was president of the Congrès d'Histoire Générale des Sciences held at Paris in 1900, and had written extensively on philosophical subjects since 1876. His principal works include "Pour l'Histoire de la Science Hellène," 1887, and "Recherches sur l'Histoire de l'Astronomie Ancienne," 1893; he edited with M. Ch. Henry the works of Fermat, and with M. Ch. Adam an edition of Descartes.

Prince Roland Bonaparte has resumed the presidency of the committee of the Aëro Club of Paris, which he had previously to relinquish on account of ill-health. At the meeting of the club on November 28, the report of the St. Petersburg congress was read. The suggestion was made to ask the Government to lend a torpedo-boat for experiments in starting sounding-balloons over the Mediterranean when the scientific congress meets at Algiers next April. In connection with proposed ascents during the solar eclipse of August 30, 1905, it is unfortunate that one of the towns having the best situation on the line of totality—from Philippeville to Sfax—Batna, with a population of 6000 or 7000, is lighted by electricity, and there is no gas reservoir. It will therefore be necessary for the aëronauts to manufacture hydrogen on the spot, or else to bring it from a distance.

The following are among the lecture arrangements at the Royal Institution, before Easter:—a Christmas course of lectures (experimentally illustrated and adapted to a juvenile auditory) on ancient and modern methods of measuring time, by Mr. Henry Cunynghame; Prof. L. C. Miall, adaptation and history in the structure and life of animals; Prof. Karl Pearson, some recent biometric studies; Prof. W. E. Dalby, engineering; Mr. A. H. Savage Landor, exploration in the Philippines; Prof. W. Schlich, forestry in the British Empire; Mr. J. J. H. Teall, recent work of the Geological Survey; Prof. H. H. Turner, recent astronomical progress; Prof. R. Meldola, synthetic chemistry (experimental); Mr. D. G. Hogarth, archæology; Prof. J. J. Thomson, electrical properties of radio-active substances; and Lord Rayleigh, some controverted questions of optics. The Friday evening meetings will begin on January 20, when a discourse will be delivered by Sir James Dewar on new low temperature phenomena; succeeding discourses will probably be given by Dr. E. A. Wilson, Mr. Cecil Smith, Mr. J. W. Gordon, Prof. H. Marshall Ward, Chevalier G. Marconi, Prof. J. J. Thomson, Prof. G. H. Bryan, Prof. J. Wright, Prof. T. Clifford Allbutt, Lord Rayleigh, and other gentlemen.

The new board of anthropological studies in Cambridge is now organised, and commenced work last October with nine courses of lectures. Sir Richard Temple, Bart., C.I.E., delivered an inaugural address at Cambridge in the museum of archæology and ethnology on "The Practical Value of Anthropology." In the course of his most interesting and suggestive address he said:—"Now, when we are started on a new line of research, when we add a new course of studies to a university curriculum, there is a question that we cannot help facing—a question, in fact, that ought to arise—What is the good of it all?" From his long experience as an administrator in the East, Sir Richard Temple drew, from facts that had come under his own observation, examples of the desirability, one would like to add the necessity, of a knowledge of ethnology for those who are brought into contact with alien peoples, and he dealt severally with merchants and planters, administrators and magistrates, and missionaries. He also pointed out that stay-at-home critics require training and information, as by their ignorant criticism they are liable to do a great deal of actual harm. "But mischievous as uninformed criticism is, there is nothing of greater value and assistance than the criticism of the well informed." He alluded to the value of anthropological study to history, and after dealing with the value of an early anthropological training to a man in his work, he pointed out the value it is in his private life, even if it is pursued merely as a hobby. "Not only will it enable the student to do the work of the world and to deal with his neighbours and those with whom he comes in contact, throughout all his active life, better than can be otherwise possible, but it will serve to throw a light upon what goes on around him, and to give an insight into human affairs, past and present, that cannot but be of benefit to him, and it will provide him with intellectual occupation, interest and pleasure, as long as eye can see, or the ear can hear, or the brain can think." The address is printed in full in the *Cambridge Reporter* (vol. xxvi., No. 643).

ACCORDING to "Notes for Visitors to the Gezira Aquarium," issued by the Public Works Department of Cairo in November, the tanks at that establishment contained specimens of no less than twenty-nine species of native fishes, including the Nile perch, the electrical cat-fish, and the elephant-fish (Mormyrus).

WE have received from the author, Dr. W. G. Ridewood, two papers on the osteology of the skull in some of the more generalised families of bony fishes, the one published in the *Proceedings* of the Zoological Society, and the other in the *Journal* of the Linnean Society. Some remarks on the general morphology of the skull are appended to the former paper.

THE *Emu* for October contains reproductions of two very interesting photographs, the first showing the "run" or "play-house" of the great bower-bird (*Chlamydera nuchalis*), and the second a flight of bare-eyed cockatoos (*Cacatua gymnopis*), estimated at between sixty and seventy thousand in number. Considerable interest attaches to a note on bird-sanctuaries in New Zealand, where, it appears, all the surviving flightless species are now protected by Government. The want of such sanctuaries, both for birds and mammals, in Australia forms the subject of comment in another paragraph.

To vol. lxxviii., part ii., of the *Zeitschrift für wissenschaftliche Zoologie*, Mr. A. Voss, of Dusseldorf, contributes the first instalment of an essay on the comparative anatomy and mechanics of insect structure, especially in relation to flight, commencing with the thorax of the house-cricket in relation to the attachment of the wings and their movements. The other articles include one by Dr. P. Dugener on the scent-organ of the butterfly *Phassus schamyl* and the function of the same; a second, by Dr. H. Jordan, on the digestive organs of the sea-mouse (*Aphrodite aculeata*); a third, by Mr. L. von Graff, on the marine turbellarian worms of Orotava and the coast of Europe; and a fourth, by Dr. S. Gross, on the perineal sac and its glands of the guinea-pig.

IN the *Zoologist* for November Mr. O. V. Aplin announces that the black-necked grebe (*Podicipes nigricollis*) should be added to the list of birds nesting in the British Islands. It appears that during the past summer several pairs of these grebes successfully reared their young within our islands, but for obvious reasons neither the locality where this interesting event took place nor the name of the observer by whom it was recorded are revealed to the public. Pennant, it seems, stated that the black-necked grebe nested in the Lincolnshire fens near Stamford in his time, and the late Mr. E. T. Booth had a pair of nestlings brought to him by a marshman; but the observations of this year form the first definite record of the nest having been actually seen. A second article in the same journal is devoted to notes on natural history made during the cruise round the world of Lord Crawford's yacht *Valhalla* in 1902–3 by Mr. M. J. Nicoll. Among new forms obtained during the voyage, the author refers to *Pyroderces crawfordi*, belonging to the Microlepidoptera, and the fish *Corvina crawfordi*. He also records his own observations on the flight of flying fish, and is one of those who believe that they move their "wings."

THE Danish Commission for the Study of the Sea, which is charged with carrying out the Danish portion of the cooperative international investigations, has issued the first memoirs of its report, which is published under the title "Meddelelser fra Kommissionen for Havundersøgelser." The report, which is to be written in English or German, and is issued in quarto form, uniform with the *Bulletin* of the Central Bureau of the International Council, is divided into three series, dealing respectively with fisheries, with hydrography, and with plankton. Of the fisheries series one memoir is now published, viz. C. G. Joh. Petersen, on the larval and post-larval stages of the long rough dab and the genus Pleuronectes (with two plates); of the hydrographic series three memoirs, Martin Knudsen, on the organisation of the Danish hydrographic researches, H. J. Hansen, experimental determination of the relation between the freezing point of sea-water and its specific gravity at 0° C., Niels Bjerrum, on the determination of chlorine in sea-water and examination of the accuracy with which Knudsen's pipette measures a volume of sea-water; and of the plankton series two memoirs, Ove Paulsen, plankton investigations in the waters round Iceland, C. H. Ostenfeld, on two new marine species of Heliozoa occurring in the plankton of the North Sea and the Skager Rak. The memoirs are of interest as being amongst the first fruits of the international scheme of cooperative research. They are, however, all short memoirs, dealing with what may be considered as side issues of the main investigations, the reports upon which must be looked for at a later date. The Danish Commission, which is appointed by the Danish Board of Agriculture, consists of Prof. C. G. Joh. Petersen (chairman), C. F. Drechsel, C. H. Ostenfeld, and Martin Knudsen (secretary).

THE important preliminary results of the National Antarctic Expedition have already been utilised by Mr. W. Krebs in the communication of a useful paper to *Das Weltall* (vol. iv., Heft 24). By comparison of the yearly temperature at the English, German, and Swedish stations during the year 1902–3, he finds that the average decrease of temperature amounted to 0°·5 C. for each degree of latitude; and by applying this value to the results obtained by the five stations established round the Antarctic Pole during the years 1898–1903, he has constructed approximate isotherms between 50° and 80° S. latitude, and thus made an important addition to the valuable yearly isothermal charts published in Dr. Hann's "Handbook of Meteorology." Dr. Hann's southernmost isobar is 4° C., just below Tierra del Fuego; Mr. Krebs continues the isotherms for each 4° C. as far as −16°, which runs near the 70th parallel between longitude 60° E. and 60° W. He also draws portions of the isotherm of −20° C., reaching nearly to the 80th parallel.

THE *Times* of November 29 contains an interesting article on London fogs; although it deals principally with the most elementary physics of the atmosphere, and with the part played by aqueous vapour, the subject is very ably handled and is made both attractive and instructive. The author points out the well known facts that the amount of invisible vapour in the air varies directly with the temperature; by whatever process the cooling of the air takes place, the capacity of the vapour to remain invisible diminishes until the "dew point" or "saturation point" is reached; any further cooling produces cloud or fog. He states that it is more than twenty years since it was shown that the vapour molecules cannot of themselves combine to form cloud or fog particles, but that solid nuclei of dust, or other impurities, are necessary, on which the vapour molecules can condense. Taking this for granted, it is seen at once why fogs in London (or other large towns) are so much denser than in the open country. For instance, at an elevation of 6000 feet, say on the Alps, the number of dust particles per cubic centimetre may amount to less than 200, while in towns the number may reach 100,000 or 200,000. The vapour in the country, condensed on a few particles of dust, will result in a coarse grained form of condensation, whereas in town the same quantity of vapour being distributed over a very large number of dust particles, there results a fine grained fog. The author points out that it is not the large-sized visible dust that does the damage, but the infinitely small, ultra-microscopic particles produced by combustion of fuel and light; that, in fact, experiments have shown that it is possible for cloudy condensation to take place in the absence of dust. In 1897 (*Trans.* Roy. Soc. Edin., vol. xxxix.) Mr. Aitken stated that dust particles are not absolutely essential for the production of fog, but that, as the air is full of dust and condensation takes place on these by preference, therefore practically all our cloud particles have dust nuclei. The author concludes, justly, we are afraid, that London will always be liable to fogs, owing to its situation and meteorological conditions; all that can be hoped for is a reduction in the more disagreeable constituent elements; there seems to be, so far, no way of appreciably reducing their frequency or their bad effects. We hope that the experiments begun by Sir Oliver Lodge, with a view to their possible ultimate dissipation by electricity, will be energetically continued.

THE *Revue Scientifique* (Nos. 20 and 21), in continuing its inquiries as to the existence of the *n*-rays, publishes a letter from M. Blondlot stating that the photographic exposures, the results of which he considers prove the reality of these radiations, were made by a laboratory assistant who was ignorant of the effects he ought to obtain, and was therefore not unconsciously biassed. The obvious rejoinder is made that the results obtained in this way are less to be trusted than if they were due to M. Blondlot himself. M. Lambert claims that his experiments showing that the *n*-rays exist were made in a manner excluding subjective phenomena. On the other hand, MM. Cailletet, Lippmann, Berget, Turpain, and Perrin have all failed to obtain experimental proof of their existence.

PART X. of the *Transactions* of the Royal Dublin Society contains a continuation of the researches of Messrs. W. F. Barrett, W. Brown, and R. A. Hadfield on the physical properties of a series of alloys of iron. It is shown that a remarkable similarity exists between the diminution of the electrical conductivity and the change in the thermal conductivity of iron, which are caused by the addition of other elements. Not only is the general order of the electrical and thermal conductivities the same for all the alloys, but equal increments of any given element appear to produce a corresponding diminution of conductivity for both heat and electricity. It is remarkable that the effect of alloying iron with another element, even a better conductor, is always to reduce both the thermal and the electrical conductivities. The ratio of the two conductivities is, however, not exactly the same for all alloys; on plotting the electrical against the thermal conductivity, a fairly smooth parabolic curve is obtained showing that the ratio increases in magnitude as the conductivity of the alloys increases.

THE October part of the *Physical Review* contains an account by Messrs. C. W. Waidner and G. K. Burgess of a number of measurements which they have made by photometric methods of the temperature of the electric arc. Wien's law of the distribution of energy in the spectrum was assumed as a basis of calculation, and three distinct types of photometers, namely, those of Holborn and Kurlbaum, of Wanner, and of Le Chatelier, were employed. The values obtained for the "black body" temperature of an arc of pure graphite by the three methods agreed within 30° C., the average being about 3700° abs. The true temperature of the arc must be higher than this by an amount depending on the departure of the radiation from true "black body" radiation, and may possibly be between 3900° and 4000° absolute. Contrary to the usually accepted view, the temperature of the arc does not appear to be independent of the current, and it is undoubtedly influenced by the degree of purity of the carbons forming the arc. With impure carbons, the temperature is lower by 40° C. than in an arc of highly purified graphite. Such variations would appear to preclude the suggested use of the brightest part of the positive carbon of the electric arc as a standard source of light.

THE second number of the *Extensionist*, which is a record of the University Extension Guild, has reached us. In addition to numerous descriptive notes on the work of the guild, this issue contains addresses by Sir Arthur Rücker, F.R.S., Mr. Hilaire Belloc, and Mr. Banister Fletcher.

THE Infants' Health Society has published a pamphlet entitled "The Present Conditions of Infant Life, and their Effect on the Nation," which directs attention to the almost complete failure of our present method of rearing the infants of the working class. In the poorer parts of the larger towns and cities it is not uncommon for nearly *half* the children born to die in infancy. The dominating cause of this appalling mortality is the improper feeding of the infant.

MESSRS. A. AND C. BLACK have published the 1905 issues of three useful annuals—"Who's Who," "Who's Who Yearbook," and the "Englishwoman's Yearbook." "Who's Who" has been enlarged again this year, nearly a hundred pages having been added, bringing the total up to 1796. Due prominence is given to men of science and their work, not only of those in this country, but in other parts of the world. There is a want of uniformity in the amount of detail given concerning the careers of the notabilities included, and something might be done with advantage to reduce the lengths of some of the biographies, and thus to keep the volume of a convenient size. The "Who's Who Yearbook" contains the tables which were formerly included in "Who's Who" itself. "The Englishwoman's Yearbook" will in its revised form continue to lighten the labours of women sharing in the useful work of the world.

OUR ASTRONOMICAL COLUMN.

RE-DISCOVERY OF TEMPEL'S SECOND COMET.—A telegram from the Kiel Centralstelle announces that Tempel's second comet was re-discovered by M. Gavelle at Nice on November 30, and that the observation showed the daily ephemeris published in No. 3971 of the *Astronomische Nachrichten* to be nearly correct.

The following is an extract from the above named ephemeris, which was published by M. J. Coniel:—

12h. M.T. Paris.

1904	α (app.) h. m. s.	δ (app.) ° ′	log Δ	$1:r^2\Delta^2$
Dec. 8	20 7 38	−24 19	0·29671	0·126
,, 10	20 15 4	−24 8	0·29913	
,, 12	20 22 26	−23 56	0·30161	0·122
,, 14	20 29 47	−23 42	0·30414	
,, 16	20 37 4	−23 28	0·30672	0·117
,, 18	20 44 19	−23 12	0·30936	
,, 20	20 51 30	−22 55	0·31206	0·113

PARALLAX OF A LOW METEOR.—Whilst exposing on the Andromeda nebula with two Voigtlander objectives on August 12 Herr P. Götz, of Heidelberg, photographed on each plate the trail of a remarkably low Perseid. From measurements of the trail on the two plates it was possible to determine the parallax of the meteor at definite points in its flight where the trail was considerably strengthened. The result showed a mean parallax of 28″·12, whilst for six distinct points on the trail the following parallaxes were determined:—

28″·26, 37″·31, 27″·78, 25″·20, 17″·14, 10″·0.

The base of the triangle Meteor—Voigtlander I.—Voigtlander II. measured 68 cm., and it therefore follows that the distance of the meteor at each of these points was 4·98, 3·78, 5·05, 5·57, 8·27, 14·03 kilometres respectively, the coordinates of the meteor at each point being respectively:—

α = 0h. 28·2m., 0h. 22m., 0h. 19·2m., 0h. 16·8m., 0h. 10·7m., 0h. 7·7m.

δ = +43° 13′, +42° 1′, +41° 28′, +40° 58′, +39° 47′, +38° 59′.

The path of the meteor was apparently rectilinear, but the observations indicated that it described a sharp curve in the third dimension with the convex side towards the observer.

The path of the meteor extended from α = 0h. 33·6m., δ = +44° 17′ to α = 23h. 52·2m., δ = +35° 28′ (*Astronomische Nachrichten*, No. 3975).

DATE OF THE MOST RECENT SUN-SPOT MINIMUM.—From a discussion of the observations of solar phenomena made at the Roman College Observatory during the period November 25, 1900, to January 4, 1902, Signor E. Tringali deduces the date of the latest sun-spot minimum to have been June 15, 1901, or 1901·45.

In Table i. of the communication the relative daily frequencies of spots, &c., are given for the years 1878–9 and 1888–1903, and it is seen that the frequency of days without spots during 1901 was greater than obtained during the previous minimum (1889), but less than in the 1878 minimum. The numbers given for 1878 and 1901 are 0·76 and 0·73 respectively (*Memorie della Società degli Spettroscopisti Italiani*, No. 8, vol. xxxiii.).

OBSERVATIONS OF PERSEIDS, 1904.—In No. 9, vol. xxxiii., of the *Memorie della Società degli Spettroscopisti Italiani*, Prof. S. Zammarchi, director of the meteorological observatory at Brescia, gives in tabular form the results of the observations of Perseids made at that observatory during the nights of August 9–14. 531 Perseids were seen, and the observations are recorded in the order of the appearance of the objects, the time, the points of appearance and disappearance, and the general characteristics of each meteor being given.

THE ORBIT OF SIRIUS.—In No. 3981 of the *Astronomische Nachrichten* Prof. Doberck gives the results of a discussion of the observations of Sirius and its faint companion, and includes a set of elements, an ephemeris for the period 1903·2–1917·2, and a table showing the differences between the observed and calculated values of position angle and distance. Owing to the great difference between the magnitudes of the two components, the systematic errors of observation are unusually large.

The following are the elements determined from the discussion:—

☊ = 225° 49′	P = 49·49 years
λ = 29° 54′	T = 1894·28
γ = 43° 20′	a = 7″·513
e = 0·5871	

The orbit is referred to the equinox of 1900. The motion is retrograde, and the anomalies are considered as positive before and negative after periastron.

The consideration of the errors of observation shows that they are inversely proportional to the aperture of the object glass employed.

HARVARD OBSERVATIONS OF VARIABLE STARS.—Part ii., vol. xlvi., of the Harvard College Observatory *Annals* is devoted to the observations, chiefly of variable stars, made by Prof. E. C. Pickering with the meridian photometer during the years 1892–8.

The first chapter gives the results of the observations of short-period variables, and then discusses the phases of the light-variations and the corrections to their ephemerides. Chapter ii. deals similarly with the observations of variables of the Algol type, chapter iii. collates the observations of various miscellaneous objects, and the fourth chapter gives, and discusses, the observations of planets and asteroids. The early observations of variable stars, at Harvard, are collected into tables in the fifth chapter, whilst the last chapter discusses the observations of long-period variables, and describes the eight light-curves given on the two plates at the end of the volume.

CORRECTION OF THE LONGER TERM IN THE POLAR MOTION.—In a previous communication to the *Astronomische Nachrichten* Mr. Kimura, of the Mizusawa International Latitude Station, showed that the cycle of the polar motion might be approximately represented by two principal terms of 365 and 438 days.

In No. 3981 of the same journal, however, he discusses the latter term more fully, from observations made during the period 1890–1904, and finds that it is probably a day or two too long. Taking the two periods 1890–1896 and 1896–1902, he derived the value 437·1 days, whilst from the periods 1892–1898 and 1898–1904 the value 436·6 days was obtained. The latter value, Mr. Kimura thinks, is likely to be the more correct, and consequently the cycle is not exactly six years as was indicated by the former discussion.

The values given in the paper show that for the years 1890 and 1891 the radius of the circular motion was especially large, but from 1892 to last year it remained nearly constant.

ARC SPECTRA OF THE ALKALI METALS.—In No. 9, vol. xl., of the *Proceedings* of the American Academy of Arts and Sciences Mr. F. A. Saunders, of Syracuse University, gives the results of a series of researches on the arc spectra of lithium, sodium, potassium, rubidium, and cæsium.

The salts were vaporised on nearly pure carbon poles, and the spectra were taken with a grating camera, special arrangements being made to photograph the spectra well up into the red.

Several new lines, which fit into the respective series, were discovered, and in the lithium spectrum Mr. Saunders believes that the dual character of the lines is real and not simply due to reversals as has been supposed by Hagenbach and other spectroscopists.

A comparison of the arc spectra with spark spectra of the same substances showed no relative enhancement of any of the lines in passing from the conditions of the arc to those of the spark.

INVAR AND ITS APPLICATIONS.

Preliminary.

DESCRIPTION of Phenomena.—A new material requires a new name; that of "*invar*" has been adopted, on the suggestion of Prof. Thury, to avoid the periphrase "steel containing about 36 per cent. of nickel, which is characterised by possessing an extremely small coefficient of expansion or by the fact that its specific volume is practically invariable when considered as a function of the temperature." The name has been universally adopted, and the title of this article is thus justified.

The discovery of invar, as is the case with most discoveries, was preceded by observations indicating the direction of the researches from which it had its origin. As early as 1889 the late Dr. John Hopkinson noted the singular fact of the existence of a ferro-nickel containing about 25 per cent. of nickel, the density of which was found to have diminished by about 2 per cent. after cooling to the temperature of solid carbon dioxide; and in 1895 M. J.-R. Benoît, director of the Bureau international des Poids et Mesures, having to determine the length of a metre scale composed of an alloy of iron with 22 per cent. of nickel and 2 per cent. of chromium, was extremely surprised to find that his measurements, made with an extreme range of temperature of about 2 degrees C., gave concordant results only on assuming for the alloy a totally abnormal coefficient of expansion, equal to that of brass, and consequently half as

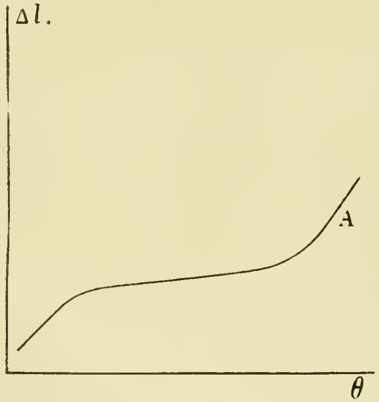

FIG. 1.—General form of the expansion curve for a reversible nickel-steel.

great again as that required by the law of mixtures generally applicable to such cases. This alloy was not magnetic, and thus resembled Hopkinson's alloy before cooling, although the latter after exposure to a low temperature became endowed with magnetism.

It was natural to coordinate these two anomalies and to consider the non-magnetic iron of the second alloy as being very expansible. At the time I considered that the alloy, after being rendered magnetic by cooling, would possess a normal coefficient of expansion; but as the alloy studied by M. Benoît did not become magnetic either in carbon dioxide or in liquid air, I was forced provisionally to renounce this hypothesis. For the liquid air I was indebted to the kindness of Sir James Dewar at a time when liquid air was not obtainable in Paris. I did not, however, abandon this research, and it was in seeking for alloys capable of a transformation similar to that observed by Hopkinson that I was led to examine alloys possessing a negatively abnormal coefficient of expansion. I may add that I was able later perfectly to reproduce Hopkinson's discoveries and to extend them in various directions, but I am unwilling to linger over the details in an article of a practical character, these discoveries having hitherto been fruitless of industrial applications. It will be sufficient to consider later in a brief manner the common cause of the anomaly observed by Hopkinson and of the phenomenon which I have studied.

Reversible Alloys.—The alloys of iron and nickel which contain more than 25 per cent. of the latter metal may or may not be magnetic, according to the temperature at which they are studied. The passage from one state to another is gradual, the magnetism declining continuously as the temperature is raised, whilst on lowering the temperature the reappearance of the magnetism follows the same curve. The temperature at which the magnetism totally disappears depends on the composition of the alloy. For alloys containing from 26 per cent. to 27 per cent. of nickel it is little above 0° C.; as the proportion of nickel increases it rises very rapidly until a maximum, corresponding with 70 per cent. of nickel, is reached at a temperature fixed by M. Osmond at 550° C., when the curve falls to the transformation point of nickel at 340°. This curve of variation is, so to speak, an *indicatrix* of the properties of the alloys; above the curve the expansion is abnormally great, but at the moment of crossing it with descending temperature the rate of the contraction diminishes, and a region is soon reached in which the anomalous negative expansion exists. Subsequently at a much lower temperature the normal state is reached. The curve given in Fig. 1 shows the general character of the variation for alloys of this class; its phases are more or less elongated, the different regions more or less inclined, but the curve always consists of a region of negative abnormality with two confluent curves, one side being characterised by large expansions at high temperatures, the other by a normal expansion. The abnormal region covers generally several hundred degrees.

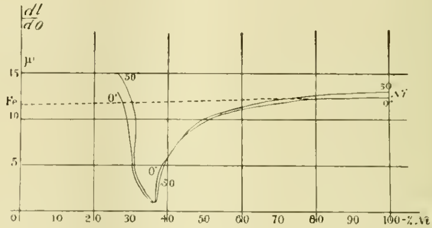

FIG. 2.—Coefficients of expansion at 0° and 50° C. of the various reversible nickel-steels.

The temperature indicated by the abscissa of the point A corresponds sensibly with the ordinate of the indicatrix in question at the point belonging to the same alloy; in other words, it is at this point that the magnetism finally disappears as the temperature rises.

Curve 1 shows that it is impossible to assign a general value to the expansion of a particular nickel-steel; the value chosen must always apply to a definite region and to a more or less extensive range of temperature. If we consider, for instance, the temperatures 0° and 50° C., the two curves of Fig. 2 can be traced, representing at these two temperatures the inclination of the tangent to curve 1 for all the reversible alloys of iron and nickel. It is the minimum of this curve which corresponds with invar, strictly so-called. This minimum will be displaced toward the left for alloys considered at lower temperatures and conversely.

It should be noted that beyond the minimum the curves cross; we are then in the region corresponding to the left-hand side of curve 1, where the true expansion diminishes with rising temperature. This result of the measurements is of interest because, independently of its being observed for the first time, it has given rise to an interesting application.

Theoretical Views.—Without entering into the details of a theory for the development of which I may refer to an article in the *Revue générale des Sciences* (July 15 and 30, 1903), I will indicate at least the source of the phenomena which have been described.

In the two transformations which take place successively in iron in passing from the α condition to the β and γ conditions of Osmond, the metal undergoes different apparent changes, of which the most characteristic are the transitions, in two distinct stages, into the non-magnetic state and a

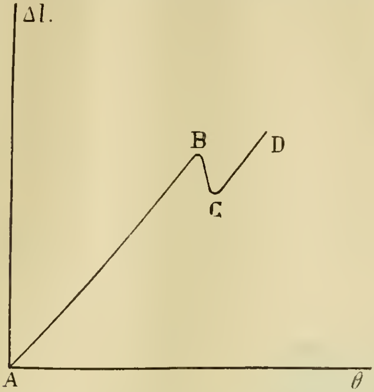

Fig. 3.—Expansion of iron.

sudden diminution of the specific volume of the iron at the moment it reaches the higher condition. The expansion of iron up to high temperatures is indicated by a curve such as ABCD, Fig. 3. The addition of a little carbon modifies this curve considerably, as was observed especially by M. Le Chatelier and MM. Charpy and Grenet. The addition of nickel begins to separate the change more and more into two inverse transformations, which commence at very different temperatures (Hopkinson's phenomenon); as the proportion of nickel increases, the change again becomes simple, but instead of being sudden, as with pure iron, it is spread out over a wide interval of temperatures, at each of which the reciprocal solution of iron in its two extreme states and of nickel strives to attain a stable equilibrium. For the greater part the attainment of equilibrium is practically instantaneous; it is much more rapid, for example, than that which is observed in an aqueous solution in which large crystals are placed, and resembles rather that which would occur in a saturated solution containing an infinite number of crystalline nuclei of the same density as the solution. In a medium thus constituted equilibrium is reached almost instantaneously. The perfect dissemin-

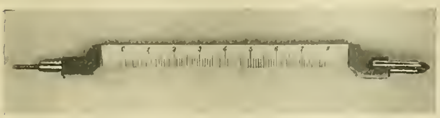

Fig. 4.—Scale at the end of a wire (the divisions are millimetres).

ation of iron throughout the nickel or the converse is evidently a very important factor of the phenomenon. For Hopkinson's phenomenon the same transformation is still produced, but with an enormous thermal hysteresis.

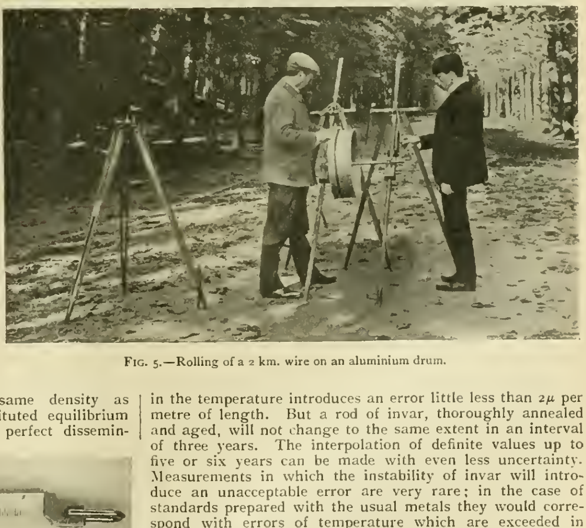

Fig. 5.—Rolling of a 2 km. wire on an aluminium drum.

It is necessary to mention, however, a retardation in a minor part of the change which follows very slowly the principal instantaneous phenomenon. This retardation, due perhaps to a migration of some of the molecules engaged in the change, is rendered visible in the case of invar, strictly so-called, by a gradual elongation with time. It is enormously accelerated by heating the alloy, for example, at 100° C.[1] Nevertheless, when a bar of invar has been heated thus it still increases in length very slightly after several years at the ordinary temperature. At the end of five or six years the total elongation is nearly 1/100 mm. per metre, but the subsequent lengthening each year does not exceed a fraction of a micron.

This phenomenon is of theoretical interest. Practically it restricts the use of invar, and although, by systematic heating, a much smaller limit of variation can be reached than that above indicated, such a change prevents the alloy from being employed in the preparation of *standards of the first order.* It is necessary to point this out before proceeding to consider the apparatus in which invar has introduced decided elements of progress. For a consideration of other qualities which may render it valuable I will refer to information already given in this Journal.[2] I can describe here only a few of the uses of invar, and will choose three of the most typical.[3]

Applications.

Standards of Length.—If the slight defect of stability referred to above prevents the employment of invar in the preparation of fundamental standards, the requirements of which are infinite, a wide field of application still remains in the construction of standards which can be referred from time to time to fundamental units, and during these intervals are employed at temperatures which are not readily ascertained, as is the case with the majority of measuring instruments which cannot be maintained in a liquid bath. With a brass scale, for instance, an uncertainty of 0·1 degree C. in the temperature introduces an error little less than 2μ per metre of length. But a rod of invar, thoroughly annealed and aged, will not change to the same extent in an interval of three years. The interpolation of definite values up to five or six years can be made with even less uncertainty. Measurements in which the instability of invar will introduce an unacceptable error are very rare; in the case of standards prepared with the usual metals they would correspond with errors of temperature which are exceeded in nearly all ordinary measurements.

But the greatest claim that invar can make to utility is in its application to geodesy; working in the open air under extremely variable atmospheric conditions makes the deter-

[1] The variation of the rapidity of the change with temperature seems to follow van 't Hoff's law of geometrical progression.

[2] Nature, No. 1822, September 29, vol. lxx. p. 527.

[3] A more complete description will be found in my recent work, "Les Applications des Aciers au Nickel."

mination of temperature very uncertain, and, on the other hand, a control on returning, by means of a standard of reference in a geodesical or metrological establishment, is always possible. With this idea M. Benoît and myself, at the request of General Bassot, have designed for the use of the Geographical Service of the French Army a scale of 4 metres which is made of invar, and has been found so practical by the surveyors that four other scales of the same type have been constructed for other countries.

This scale has an H-section with a side of 40 mm.; its direction lies in the plane of the neutral fibres, and it has such rigidity that the flexure is quite admissible in an accurate standard supported at only two points. As a consequence, the scale can be placed on a light support which is subjected to no especial conditions of rigidity, since it has not, as in most of the older apparatus, to assure the rigidity of the standard. The support which we have adopted is an aluminium box that completely envelops the scale and protects it from shocks, dust, and accidents of all kinds, as well as from rapid changes of temperature. The complete apparatus weighs 56 kg., whilst the old form of Brunner, consisting of two scales and a rigid support, weighs 72 kg., and affords no protection for the standards.

For direct employment in the field, especially when the apparatus has to be carried to great distances (the scale will, in the near future, be used in the Andes), the facilities introduced, compared with those existing in older apparatus, are considerable, and if they constituted the sole progress in geodesy they would deserve serious consideration. But the use of invar has permitted a more complete transformation in the measurements of bases. Twenty years ago M. Edw. Jäderin made trial of a method which consisted of the use of long wires stretched under a constant load and serving the purpose of fixing between two limits of the base the distance of a series of movable bench-marks, ranged between these limits. The advantage of this method, the rapidity of measurement, lightness of material, and facility in the choice of ground, will be readily appreciated, but it will also be recognised that the uncertainty of the temperature of the wires made the method doubtful in cases where greater accuracy was required than that usual for the ordinary requirements of topography or land-surveying. M. Jäderin has diminished these uncertainties by employing two wires of brass and steel respectively, by means of which each of the ranges was successively measured. The difference observed for the two wires was taken as an indication of their common temperature, whence the temperature of the steel wire, considered as the principal standard, was deduced. Without going into the details of the calculations necessary to the method, it is easy to see that small inevitable errors influence the result; the real difference of temperature of the two wires at the time of the measurements and errors of reading reappear in the result, multiplied by factors of a variable nature, but all greater than unity.

FIG. 6.—Reading the position of the end scale of the wire against a movable mark.

These uncertainties disappear completely with a wire made of invar, especially as the greatest care can be given to the manufacture of comparatively small quantities of the alloy when it is required for particular purposes in which the price, between certain limits, is a secondary consideration; samples may be chosen so as finally to descend below the minimum of the curve in Fig. 2 and cut the axis of the abscissæ. Zero and even negative expansions have thus been realised. The specimens having a minimum expansion are strictly reserved for geodetic purposes, and considerable quantities of wire have thus been obtained of which it is unnecessary to know the temperature within about 10 degrees even for the most precise measurements of base lines. Commonly, a knowledge of the temperature within 5 degrees is sufficient; an error of this magnitude hardly makes a difference of 1 part in 1,000,000.

These advantages could not escape surveyors. As early as 1898, M. Jäderin himself requested me to obtain for him wires[1] made of invar for the purpose of perfecting his method, at a time when M. Benoît and myself were undertaking, at the Bureau international des Poids et Mesures, experiments to ascertain their suitability for such a purpose. The trials were so encouraging that the following year it was decided to equip the Swedish-Russian expedition to Spitsbergen with similar wires, by means of which all its base lines were measured. At this time, however, the experiments were not sufficiently advanced to obviate the need of taking many precautions, and the expedition acted very wisely in not considering the wires as standards of length. The true standards were two iron bars, previously verified at the Bureau international, which served to measure the short bases (the Swedish base was 96 metres long) on which were standardised the wires of 24 metres, which subsequently served to measure the true bases of several kilometres in length. This was the first practical trial of invar in the field, and, according to the reports which I have received from several members of the expedition, notably from M. Jäderin, the success exceeded every hope. Two independent measurements of the Swedish base showed a difference of 19 mm. per 10 kilometres, that is, of 1/500,000 *without introducing any correction for the temperature.*

The same sense of safety in the employment of these wires is felt after reading the report by M. Backlund, of the Russian expedition, and of Commandant Bourgeois, on the measurements of the French Survey in the territory of the Republic of Ecuador. The difference in the measurements of a base made in 1901 with a bimetallic scale and with a wire of invar was 1/3,300,000; the agreement is so good that it must be attributed partly to chance, but such chances are rare when the systematic elimination of errors has not been pushed to extremes.

In any case a more complete study of the wires of invar became necessary, and, on the ground of the studies already commenced by M. Benoît and myself, the International Committee of Weights and Measures entrusted to us, at the end of 1900, on the request of the International Geodetic Association, a detailed investigation of this question.

We therefore erected against a thick basement wall, protected by the building of the laboratory of the bureau, a series of bench-marks spacing out a length of 24 metres at intervals of 4 metres, measured by means of an invar standard. On the outside of the last uprights are two pulleys on ball bearings over which pass two cords that carry weights of 10 kilograms and are attached to the wire on which observations are to be made at the distance of

[1] These wires were manufactured at the steel works of Imphy belonging to the Société de Commentry-Fourchambault and Decazeville, by whose collaboration I was enabled to carry out the work described in this article.

the extreme marks. These wires carry at their extremities scales of invar, having the form represented in Fig. 4, with their edges in the same line as the axis of the wire. This arrangement, somewhat complicated in appearance, is necessary to ensure constancy of length, whatever be the inclination of the scale in a transverse direction.

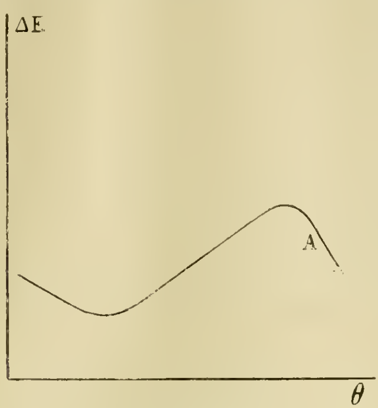

FIG. 7.—General form of the curve of change of Young's modulus for a reversible nickel-steel.

During four years measurements have been made weekly with a great number of wires which have been submitted to different treatment. Owing to the complexity of the subject, more than a hundred thousand comparisons between the wires and the base were necessary to elucidate all the questions relating to the stability of the wires and the precision that they guarantee. After four years, and after the method of treatment of the wires has been gradually modified so as to ensure the greatest possible degree of stability, we can emphatically assert the excellence of the method of measurement by wires constructed of invar. When a wire of the usual diameter of 1·65 mm. is stretched by loads varying from an insignificant weight to that of 20 kilograms, the permanent elongation which it undergoes is not measurable; moreover, it can be rolled as often as desired on a drum (Fig. 5) of sufficient diameter (at least 50 cm.), or kept rolled for months without showing on subsequent measurement a variation greater than that due to errors of observation. Several wires which were measured at the bureau were returned after use in the field; in the beginning, variations in the length of the order 1 in 200,000 were observed in several instances, but recently the constancy of the length has become much more decided. Whilst reserving the results obtained by long trials in severe climates, it may be concluded from the results obtained in the laboratory that a surveying expedition equipped with several wires constructed of invar and subject to mutual control will be able to measure several long bases without fearing a departure from accuracy in the wires greater than that permissible in such measurements, assuming, of course, that the wires are always handled with due care.

The considerable increase in the accuracy of geodetic measurements, caused by the substitution of wires of invar for those of steel or brass, necessitated a corresponding improvement in the apparatus. We have therefore proposed certain new principles which have been realised in instruments constructed with the aid of M. Carpentier, of which a provisional model has been already mentioned in NATURE.[1] A description of the final types which have been adopted would carry me too far; Fig. 6, which indicates one of the measures, may take its place. It will be sufficient to add that, thanks to the new material which has been discovered, the measurement of a base by means of wires answers all the needs of a surveyor; the relative error of the base has fallen below that of the angles; bases can be measured across broken ground, cultivated land, streams and rivers. Above all these advantages, the complete staff, including auxiliaries, need not exceed ten men for a rate of progress of 5 kilometres per day. This arrangement, compared with that by which ten years ago fifty men using rules and microscopes could advance 500 metres a day, exhibits an economy of 98 per cent.! To-day the measurement of a base with all the accuracy required in geodesy costs little more than chaining, and the proof has been so thorough that the French Survey finds its advantageous to measure all its bases by the new method.

The advantages of measurements by wires have been quickly recognised by surveyors. Several departments of survey have requested the Bureau international to standardise wires suitable for base measurements; we have thus had the satisfaction of examining the apparatus for use by the Argentine Republic, Australia, Cape Colony, France, Germany, Japan, Mexico, Roumania, Russia, Servia, and Switzerland.

This simplification in the fundamental measurements of the survey will lead to a reversal in the future of the respective positions of the base and angular measurements. In the old method of surveying measurements of bases were reduced as much as possible and angles multiplied indefinitely; in the new geodesy angles will be controlled by frequent measurement of numerous long bases. This general plan has already been introduced in the United States in the fine work carried out during the determination of the length of the 98° meridian.

Horology and Chronometry.—The possibility of constructing a compensated pendulum with its rod of invar is so obvious that it is hardly necessary to emphasise it. It will be sufficient to observe that the slight change which invar undergoes is not for this purpose a serious defect. As it is necessary to determine the rate of a clock at frequent intervals, variations in the daily rate of the order

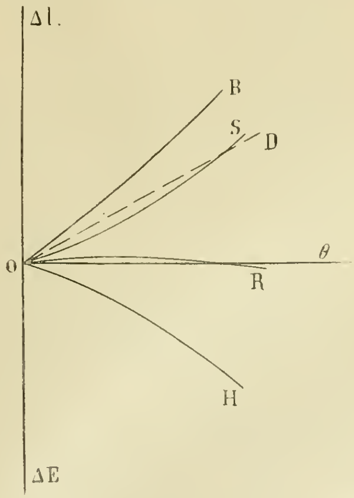

FIG. 8.—Diagram of the compensation of a chronometer with a steel-brass balance.

of a few hundredths of a second in a year will be merged in the variation of the longer period, and will give rise to an error hardly to be feared; but other applications will need some explanation.

In order not to prolong the preliminary part of this article, I omitted to mention a singular property of the nickel-steels,

[1] June 2, 1904, vol. lxx. p. 104.

which for ordinary watch-making is of prime importance. To resume those considerations. At the end of 1896 I found that when an alloy containing 24 per cent. of nickel passes from the non-magnetic to the magnetic state, its modulus of elasticity undergoes a diminution of 10 per cent. This change is the more remarkable inasmuch as the limit of elasticity is simultaneously raised, as was shown by Hopkinson. I was intending to study the same change in invar when M. Thury at Geneva and M. Paul Perret at La Chaux de Fonds, after my first publication, established for the alloy the singular fact of a positive variation of Young's modulus with increasing temperature. A systematic investigation of the change by M. Perret and myself led us to results which, completed by the theoretical views which were developed, permitted me to assign to the total variation of the modulus of a nickel steel endowed with reversible properties a course indicated by the curve in Fig. 7. Point A has the same significance as in the curve of Fig. 1, and two regions of variation in a normal sense are shown, between which lies a region of abnormal variations connected with the first by two confluent curves.

The existence of these confluent curves has a great importance for horology. The necessity of fitting good watches with a bimetallic compensation balance arises

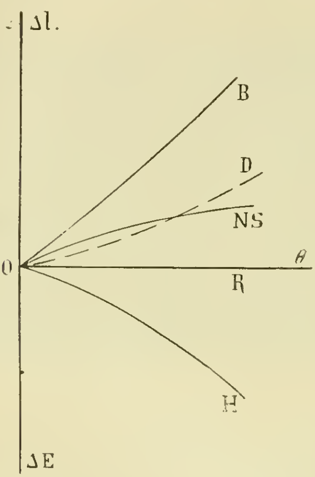

FIG. 9.—Compensation with nickel-steel-brass balance.

almost exclusively from the need of securing comparable rates at different temperatures owing to the variation in the modulus of elasticity of the steel spring. This variation is sufficiently great to cause a retardation of five minutes in the day in a watch fitted with a steel spring and a monometallic balance, the temperature of which undergoes a change from 0° to 30° C. The employment in the spring of a nickel-steel the properties of which are represented by one of the confluent curves (that is, of an alloy having Young's modulus a maximum or minimum at the average temperature to which the watches are submitted) will obviate the need of a costly compensation. The compensation is, of course, not perfect; the difference between the form of the curve and a straight line, and still more, the difficulty of obtaining an alloy passing through a maximum or minimum at ordinary temperatures, limit the application of these springs to ordinary watches, and preclude their use in accurate chronometers. But in their own province they represent a real advance, as they reduce the error of an uncompensated watch by 90 per cent., and the cost of watches which were approximately compensated by a rough balance by 6*d*. in the shilling. The trade of watchmaking gains as much by direct economy as from an increase in quality; the annual saving is certainly 10,000*l*., and is likely to become 20,000*l*. or 30,000*l*. Competition, moreover, is so keen in the trade that a diminution of prices passes at once from the manufacturer to the consumer, so that the public gains the whole advantage of it.

Another application in chronometry, although its advantages from a monetary aspect are insignificant, seems to me of greater interest, because it appeals to a higher range of thought, and represents an advance in a region in which perfection had apparently been reached.

In 1833 the celebrated English watchmaker Dent discovered that a chronometer regulated for two extreme temperatures gains at intermediate ones, and the correction of "*Dent's error*," as it is called, has exercised the ingenuity and invention of the best watchmakers. In England particularly, the country *par excellence* of marine chronometry, great efforts have been made to introduce corrections for this error. The auxiliary systems of Loseby, of Kullberg and others have permitted the attainment of great accuracy, but at the expense of a considerable increase in price and of complications which are not exempt from inconveniences. The cause of Dent's error is almost entirely the non-linear variation of the elasticity of the steel of which the hair spring is composed. The curve OH, Fig. 8, represents this variation. The action of the balance is proportional to the difference of the expansions of the metals composing the bimetallic ring; if we represent the expansions of steel and brass by the curves OS and OB it

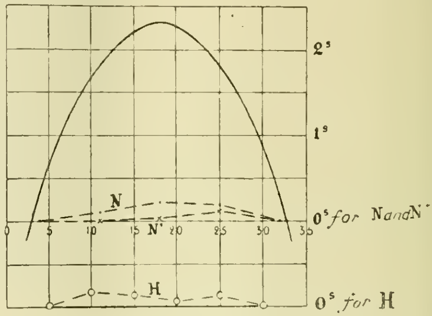

FIG. 10.—Results obtained at Neuchâtel and Hamburg with Nardin chronometers fitted with nickel-steel-brass balances.

will be seen on referring to the numerical formulæ whence these curves are obtained that, whilst their average inclination is very different, the variation of this inclination is nearly the same. The variation of the difference of inclination is therefore nearly zero, and the curve giving the difference of the expansions practically becomes the straight line OD. The rate of the chronometer at different temperatures is given by the algebraical sum of the ordinates of the curves OH (natural variation) and OD (corrective function), that is, by the curve OR. Such is the reason of Dent's error, which has been corrected hitherto by adding to the natural corrective function of the balance a term of great curvature given by an auxiliary system.

But the same result would be attained by substituting for one of the metals of the double ring another metal or alloy of which the increase of expansion is much greater than that of brass, if that metal is rejected, or much less than that of steel, and preferably negative, if the brass is retained. The curve of Fig. 1 offers in this respect numerous possibilities. Practical reasons lead one to retain the brass and to associate with it an alloy having an expansion which is a retarded function of the temperature. Fig. 9, in which the curve OS belonging to steel has been replaced by ONS referring to nickel-steel, shows a curve OD that can be rendered symmetrical with regard to OH; the sum OR of the curves is then always zero, and the problem has a practical solution.

I had established this theory in the year 1899, when two of the principal Swiss watchmakers, M. P. Nardin, of Le Locle, and M. P. Ditisheim, of La Chaux de Fonds, expressed a wish to make a trial of the new balance. The first attempt gave so perfect a result that the balance has not since been modified; its adoption by Swiss watchmakers was very rapid, and to-day it is employed in the majority of their best timepieces. It was with a pocket chronometer fitted with this balance that M. P. Ditisheim beat in 1903 all records at Kew with a total of 94·9 points, the previous best being 92·7. The compensation was awarded 19·7 points, the maximum of ideal perfection being 20. The dark-lined curve of Fig. 10 shows the theoretical variations of a perfect chronometer compensated by the usual method; the curves N, N′, and H represent the average results obtained at Neuchatel with two groups comprising in all sixteen chronometers, and at Hamburg with six chronometers, all made by M. Nardin.

Incandescent Lamps and Crookes's Tubes.—In conclusion, a few words may be given to an application, less scientific in its nature than the preceding, but likely to be welcomed by all who regret the systematic destruction of the world's store of platinum. The curve in Fig. 2 shows that two nickel-steels of definite composition have an expansion equal to that of glass; but only one of these can be practically considered, namely, that containing about 45 per cent. of nickel; the alloy which contains 29 per cent., at a slightly higher temperature passes the point A of Fig. 1 and enters the region of high expansion.

For a metal to fuse in glass it is indispensable, but insufficient, that it should possess the same expansibility as glass; fortunately the alloy containing 45 per cent. of nickel possesses all the other properties which are necessary, provided that it be not unduly oxidised during the softening of the glass. As a matter of fact, several manufacturers of incandescent lamps have adopted, under the name *platinite*, this welcome substitute for platinum, thereby economising several hundred kilograms of the precious metal. If this economy spreads, a ton of platinum may be saved annually for science and those industries in which its use is indispensable.

Conclusions.

It is time to conclude this over-long article. The applications which have been described are not the only ones which might be predicted or have been attempted with these curious alloys, the properties of which for a time seemed so paradoxical that a number of physicists and metallurgists refused to believe in their existence. All the applications which to-day give new resources to science and new economies, representing large sums, to industry arise from a peculiar phenomenon of equilibrium in the mutual solution of two isomorphous metals; that is one interesting side of the question. There is another on which I would insist in concluding; it is that these results have been obtained as a sequel to a long series of delicate measurements in which the thousandth of a millimetre was the ordinary unit, and without which no discovery in this domain would have been possible.

CH. ÉD. GUILLAUME.

SHOWER OF ANDROMEDIDS FROM BIELA'S COMET (?)

WHAT certainly appears to have been a well defined shower of Andromedids occurred on November 21 and following nights to November 28. Yet this display, if it really represented the débris of Biela's comet, like the meteors seen in November 1872, 1885, 1892, and 1899, was not true to its time, for no return was to be expected, in ordinary circumstances, until 1905 or 1906. The period is about 6·7 years, and if the shower displayed itself this year it must mean that the swarm has been much disturbed, or that the meteors are rapidly distributing themselves round the orbit, and will soon form a continuous stream, visible annually as the earth intersects it in the third week of November.

Dr. Schulhof and Prof. Abelman (*Astr. Nach.*, 3516) pointed out some years ago that a convulsion of the orbit-motion of the Andromedids would occur in 1901, as Jupiter would approach the group to within 0·5 of the earth's distance from the sun in March of the year named. The effect would be a displacement of the node to the extent of 6°, which would bring the maximum on November 17, or ten days earlier than in 1872 and 1885.

The Rev. W. F. A. Ellison, of Enniscorthy, Ireland, writes me that the most remarkable meteoric shower he witnessed in November was furnished by the Andromedids. He was extremely surprised to find the radiant of this stream very active on November 21. At 7 p.m. he counted 8 meteors in fifteen seconds, and although this rate was not maintained, he continued to observe numerous Andromedids until midnight. From 7h. to 8h. 24 were seen, from 8h. to 9h. 22, after which the number decreased. Until November 28 meteors continued to fall from this radiant, and many of them were objects of remarkable brilliancy, quite equal to the Leonids, but the motions were slower and the paths shorter. The prevailing colour was pure white, the trains being greenish. The radiant seemed further north than Mr. Ellison expected to find it, the position being at about $21° + 50°$.

The following are some of the larger meteors recorded by Mr. Ellison:—

Nov. 21. 8h. 2m. G.M.T. = Vega. From a point a little above α Cygni exactly across δ and about 15° further, directed precisely from Vega.
,, 21. 8h. 49m. = ♀. Low down in west where no stars could be seen to fix the path, but evidently Andromedid.
,, 21. 9h. 8m. = ♃. From $337° + 7°$ to $329° - 7°$.
,, 21. 9h. 16m. = ♃. From $354° + 30°$ to $348° + 18°$.
,, 26. 7h. 35m. = ♀. From $52° + 27°$ to $64° + 8\frac{1}{2}°$. Duration 2 sec., vivid flash at end.
,, 28. 8h. 50m. > ♀. From about $215° + 50°$ to $215° + 46°$ Very short path, swift and flashing. Impossible to fix path accurately.

It seems desirable to inquire whether any other observers noticed an abundance of meteors on about November 21, and if so whether their paths were directed from the usual radiant point of the Andromedids.

W. F. DENNING.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—Mr. J. H. Jeans, of Trinity, has been appointed university lecturer in mathematics in the place of Prof. Macdonald, now of Aberdeen University.

The late Mr. G. T. B. Wigan has bequeathed to the university some 9000*l.*, the interest of which is to be used for the purpose of promoting scientific education and research. It is proposed to divide the fund equally between the board for physics and chemistry and the board for biology and geology. Each board will administer the income of its moiety subject to the condition that no portion is to be applied to one specified purpose for longer than five years at a time.

The name of the late Frank McClean, F.R.S., the founder of the Isaac Newton studentships in astronomy, and a generous donor to the observatory, has been added to the university roll of benefactors.

Dr. Donald MacAlister, the representative of the university on the General Medical Council for the last fifteen years, has been elected president of the council in succession to Sir William Turner, K.C.B., principal of Edinburgh University.

Mr. F. F. Blackman, of St. John's, has been appointed reader in botany in the place of Mr. Francis Darwin.

A university lectureship in botany, stipend 100*l.*, is vacant by the resignation of Mr. F. F. Blackman, recently appointed reader. Application is to be made to the Vice-Chancellor by December 17.

Prof. E. Waymouth Reid, F.R.S., has been approved for the degree of doctor of science.

Prof. Woodhead has obtained from friends resident in or connected with Huddersfield a sum of more than 1600*l.* for the endowment of a Huddersfield lectureship in special pathology. The general board proposes that the gifts be gratefully accepted by the university, and that the lectureship be forthwith established.

The museums and lecture rooms syndicate reports that the zoological collections have outgrown their present accommodation, and suggests that a new zoological museum should be arranged for on the site recently acquired from Downing College, in the neighbourhood of the new Sedgwick Geological Museum.

A new diploma is proposed in mining engineering for students who have resided nine terms and have attained a prescribed standard in certain subjects of the natural sciences and mechanical sciences triposes.

The board of geographical studies has published a report submitting regulations for the special examination in geography for the ordinary B.A. degree, and for the diploma in geography. The range of subjects is comprehensive, and the standard contemplated is obviously high. The regulations are given at length in the *University Reporter*, pp. 301–3. Dr. D. MacAlister and the Right Hon. Sir G. D. T. Goldie, K.C.M.G., have been appointed members of the board.

The memoir of Mr. A. Wood, advanced student of Emmanuel College, on the spontaneous ionisation of air in closed vessels, and its causes, has been approved as qualifying for the certificate of research.

The Rev. Francis Bashforth, second wrangler 1843, formerly fellow of the college, and distinguished for his researches in ballistics, has been elected to an honorary fellowship at St. John's College.

LORD REAY will distribute the prizes to the students of the Northampton Institute, Clerkenwell, on December 9.

PROF. HELE-SHAW has accepted the post of principal organiser under the Transvaal Technical Council for one year, and has in consequence resigned the chair of professor of engineering at Liverpool.

THE registrar of the University of Leeds announced, at a Mansion House meeting held at York on November 30 in support of the university, that 61,825*l*. has been subscribed toward the 100,000*l*. required to make the necessary additions to the buildings and to increase the endowment of the university, so as to satisfy the financial requirements laid down by the Committee of the Privy Council.

LORD LONDONDERRY will receive a deputation from the Association of Chambers of Commerce of the United Kingdom on Monday next, when the following resolution on commercial education will be submitted:—"That in order to retain our industrial positions and to introduce into this country such further industries as may be profitably developed it is absolutely necessary to establish or acquire public secondary schools of the highest standard, and to provide sufficient inducements by bursaries, exhibitions, scholarships, or otherwise to make the efficient boys stay long enough to take full advantage of the provisions made for higher technical and higher commercial education."

THE third annual meeting of the North of England Education Conference will be held in the St. George's Hall, Liverpool, on January 6 and 7, 1905. The subject to be discussed on the first morning is "Leaving Certificates." Lord Stanley of Alderley will preside, and papers will be read by Mr. G. Alexander, Mr. Owen Owen, and the Rev. J. B. Lancelot. The discussion will be opened by Sir Oliver Lodge and Mr. G. Sharples. In the afternoon of the same day there will be three separate conferences dealing respectively with "Manual Training," the "Teaching of Geography," and "Child Study." Principal Reichel will read a paper on the first subject, Mr. Mackinder on the second subject, and Prof. Sherrington on the third. The subject for discussion by the conference as a whole on the morning of the second day is "Scholarships, with Special Reference to the Coordination of Education." Sir William Anson will take the chair, and papers will be read by Miss S. A. Burstall and Dr. T. J. Macnamara. Messrs. Gore and Edwards will open the discussion. In the afternoon the conference will be divided into three parts to discuss the "Teaching of Domestic Science," "School Games, with Special Reference to Day Schools," and the "Teaching of English." Domestic science will be dealt with in papers by Miss Fanny Calder and Miss E. Pycroft, school games by Messrs. J. L. Paton and F. W. Augell, and the teaching of English by Miss E. Drummond and Mr. G. C. Steel. An exhibition of geographical appliances, apparatus, maps, books, &c., will also be held on the days during which the conference meets.

FROM a long list of recent appointments in such journals as the *Physikalische Zeitschrift*, *l'Enseignement mathématique*, and similar sources, we extract the following professorships, mainly mathematical and physical:—Germany, Austria, &c.—S. A. Arrhenius (Stockholm) for meteorology and cosmical physics at Berlin; H. Battermann for astronomy, and directorship of observatory at Königsberg; K. Cranz (Stuttgart) at technical college, Charlottenburg, Berlin; O. Eggert (Berlin) for geodesy at technical college, Danzig; Dr. Furtwangler for mathematics at agricultural college, Bonn-Poppelsdorf; Grassmann (Halle) at Giessen; L. Hefter (Bonn) at technical college, Aachen; G. Landsberg (Heidelberg) extraordinarius for mathematics at Breslau; K. Oertel for astronomy at Munich; R. Prantl (Hanover) extraordinary at Göttingen; Rohn (Dresden) for descriptive geometry at Leipzig; C. Runge (Hanover) at Göttingen; K. Schreber at Greifswald; J. Sommer for mathematics, technical college, Danzig; P. Stäckel (Kiel) at technical college, Aachen, to replace Prof. van Mangoldt, who is transferred to Danzig; Vahlen (Königsberg) at Greifswald; Wellenstein (Giessen) extraordinary for mathematics, Strassburg. France.—Cartan for calculus at Nancy; Cotton for mechanics at Grenoble; Drach for mechanics at Poitiers; Lecornu for mechanics at polytechnic college, Paris, in place of the late M. Sarrau; H. Poincaré for astronomy at polytechnic, Paris; Raffy for analytical geometry, Paris; Jules Tannery for calculus at Paris. Italy.—F. Guardacci (Florence) for geodesy at Bologna; Mich. Rajna for astronomy, and directorship of observatory, Bologna; in addition, F. Amadeo has been appointed recognised teacher for history of mathematics at Naples. America.—G. H. Hallett and C. A. Holden (extraordinary), Pennsylvania; D. N. Lehmer (extraordinary), California; James MacMahon, Cornell; Robert E. Moritz for mathematics, Washington; H. L. Rietz (extraordinary), Illinois; J. H. Tanner, Cornell; A. W. Whitney, California; besides the following instructorships in mathematics:—J. W. Bradshaw, Michigan; A. B. Coble, Baltimore; L. C. Karpinsky, Michigan; E. B. Lytle, Illinois; C. L. F. Moore, Massachusetts; A. Ranum, Wisconsin; F. C. Touton, Illinois.

THE annual dinner of the past and present students of the Queen's Faculty of Medicine in the University of Birmingham was held on November 29. In proposing the toast of "The Medical School," Sir F. Treves said:—"It is very much to be regretted that very little heed is given to science in this country. There was a time when the man of science—Galileo, for example—was cast into prison; now he is simply allowed to starve. There is no kind of encouragement offered to science. In every university throughout the country the same story is told. I think that those men who devote themselves to science in this country deserve rewards infinitely beyond any they have ever received." Mr. Chamberlain, who was present in his capacity of Chancellor of the university, in proposing the toast of "Students, Past and Present," referred to the remarks of Sir F. Treves. Mr. Chamberlain said:—"I am afraid that for all time to come probably science, and the conferring of great benefits upon one's fellow-creatures, must be, to a large extent, its own reward. But the pursuit of research is an impossibility so long as the actual means of existence are wanting, and the professional practitioner when he starts is, in very many cases at any rate, so tied by the necessity of providing an actual subsistence for himself and his family that anything like original and continuous research is in his case impossible. That can only take place when there are in this country schools established where for a year or two, perhaps in their younger time, men of ability and of interest in school subjects can be brought together under capable heads, and can carry out on the most extended scale that series of researches which already, in the hands of some of our most distinguished men of science, have led to such important results." During the course of his remarks Mr. Chamberlain also said that three classes of people are essential to the success of a modern university—students, teachers, pious benefactors. "Unfortunately," he said, "we have fewer pious benefactors in this country than they have in the United States of America, where, by their munificent donations, counting by millions, they have covered the land with a net-work of universities which have brought higher education within the reach of almost every citizen. I hope the time is coming when men who have more than they want, more, perhaps, than is good for them, can find no better opportunity of disposing of the surplus than by benefactions which not only are of present usefulness, but, what is of more importance, are of permanent advantage to the community amongst which they live."

ON Thursday last, December 1, the prizes and certificates gained by students of the Sir John Cass Technical Institute during the session 1903–4 were distributed by Sir William White, K.C.B., F.R.S., when the chair was taken by Sir Owen Roberts, chairman of the governing body. Sir William White, in the course of his address, said that during his recent visit to America he had had the opportunity of studying the methods of technical education in vogue there, and he must certainly confess that both America and Canada can teach us a great deal so far as technical colleges in general, and the interest taken by employers of labour in the future employment of men trained in technical institutions, is concerned. The essential advantage which America and Canada, and also Germany, possess over this country is that they are all imbued with the idea that it is a wise investment on the part of a nation to provide for all kinds of education from the elementary up to the highest. It is almost impossible to make expenditure on education too lavish, provided it is well directed, if the nation is to be well educated. This country, in his opinion, will never reach a truly healthy condition until every man or woman, in whatever position the accident of birth may place them, shall, if they possess the capabilities, have also the opportunities of self-culture. Nevertheless, there is one respect, he thought, in which this country stands supreme. It is in the provision of evening classes for the working man and the working woman who, from the very nature of their circumstances, are compelled to work all day to get a living. Employers should assist these educational classes more than they do at present. The London and South-Western Railway Company are doing what may well be done by other large employers. They grant to the apprentices in their works at Nine Elms the necessary time to attend the early morning classes at the Battersea Polytechnic. The apprentices are allowed to go to these classes twice a week, and are paid for the time that they are away from the company's service, on the condition that they do a certain amount of study at home, thus completing in the evening the training which they receive during the day at the polytechnic. This is not altogether an experiment. The Admiralty has done the same thing for fifty years or more, with the result that the Admiralty, from the apprentices in its own dockyards, has trained not only many of its principal shipbuilding officers and naval architects for the Royal dockyards and the Admiralty service, but has also furnished to the private shipbuilding industry of the country some of its most famous shipbuilders. The leaders and managers in those great private establishments to-day are in no small proportion drawn from men who were trained in the Admiralty service under the system which has been in operation, and by which every apprentice who cares to improve his mind has the opportunity to do so. If employers will give the utmost encouragement to institutions like the Sir John Cass Institute, they will be rewarded by having capable men on their staff who will know the principles of their business.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, November 17.—"The Electrical Conductivity and other Properties of Sodium Hydroxide in Aqueous Solution, as Elucidating the Mechanism of Conduction." By W. R. **Bousfield,** K.C., M.P., and T. M. **Lowry,** D.Sc.

The original object of the research was to investigate the decay, as the temperature rises, in the "ionising" properties of water, which is manifest in the inflected character of the curves expressing the relation between temperature and conductivity in aqueous solutions of the alkalies.[1] The principal results of the investigation are as follows:—

(1) In the most dilute solutions, in which "ionisation" is nearly complete, and again in the most concentrated solutions, the curves expressing the relation between molecular conductivity and temperature in aqueous solutions of sodium hydroxide are not inflected between 0° C. and 100° C. In each case the form of the curve appears to be determined mainly by the rapid changes of viscosity which accompany changes of temperatures. Moderately dilute solutions give curves that are inflected between 0° C. and 100° C.; the temperature of inflection reaches a minimum, at 48° C., in the case of a normal (4 per cent.) solution, but rises to 100° C. when the concentration is raised to 30 per cent.

(2) The inflected conductivity-temperature curves can be represented by the formula

$$\kappa_t/\kappa_0 = \rho_t/\rho_0 \, (1+bt)^n \, e^{-at}.$$

This formula is applicable to conductivity-temperature curves of all kinds, and gives expression, not only to the inflection now under consideration, but also to the maximum conductivity and the second inflection in the general conductivity-temperature curve.[2]

(3) The maximum conductivity of caustic soda at 18° C. is 0·3490 in a 15 per cent. solution, the value given by Kohlrausch being 0·3462. At higher temperatures the maximum conductivity is considerably greater, rising to more than 1·4 at 100° C., and occurs in solutions of greater concentration.

(4) The viscosity of a 50 per cent. solution of sodium hydroxide is approximately seventy times as great as that of water. The influence of this factor may be to some extent eliminated by dividing the molecular conductivity by the fluidity, and this ratio it is proposed to call the "intrinsic conductivity" of the solution. Whilst the molecular conductivity of sodium hydroxide solutions decreases steadily as the concentration is increased, the intrinsic conductivity falls to a minimum at about 8 per cent. NaOH, and then rises, until at 50 per cent. NaOH, the value is considerably greater than in the most dilute solutions. It is believed that this increase is due to the fact that liquid soda is an electrolyte, *per se*, and that, in concentrated solutions, the current is conveyed partly by the soda alone, as if it were in the fused state.

(5) In re-determining the densities of aqueous solutions of sodium hydroxide, quantities of sodium, amounting to about 150 grams at a time, were weighed, and converted quantitatively into concentrated solutions of sodium hydroxide by the action of steam in a platinum vessel. Eleven determinations, made with six different standard solutions, gave, as the density of a 50 per cent. solution at 18° C., the value 1·5268, with an average error of 0·0001. Solutions of known concentrations having been prepared by dilution, their densities were determined with a probable error of not more than 0·0001; the values recorded by previous observers were derived from solutions standardised by titration only, and appear to contain errors in the third or even in the second place of decimals.

(6) In the formula

$$\rho_t = \rho_0 + \alpha t + \beta t^2 + \gamma t^3,$$

which represents the influence of temperature on the density of water and aqueous solutions of soda, the coefficient of t^3 vanishes when a concentration of 12 per cent. NaOH is reached, whilst the coefficient of t^2 vanishes at 42 per cent. NaOH; at the latter concentration there is a simple linear relationship between density and temperature.

(7) The molecular volume of sodium hydroxide in dilute aqueous solution has a large negative value, a litre of water dissolving 140 grams of sodium hydroxide at 0° C., 100 grams at 18° C., or 60 grams at 50° C., without increasing in volume. The molecular volume does not increase continuously as the temperature rises, but reaches a maximum value at about 70° C. In a 50 per cent. solution the temperature has little effect on the molecular volume, the extreme variation being only about 10 per cent.

[2] *Loc. cit.*, p. 52.

Entomological Society, November 16.—Prof. E. B. Poulton, F.R.S., president, in the chair.—Mr. H. St. J. **Donisthorpe** exhibited the second recorded British specimen of *Orchestes sparsus*, Fahr., taken by him on August 28 in the New Forest.—Mr. H. W. **Andrews** exhibited specimens of *Atherix crassipes*, Mg., from the New Forest, the only previously recorded locality in Britain being near Ticehurst, Sussex.—Mr. G. O. **Sloper** exhibited aberrant forms of *Melitaca athalia* from Luan, Switzerland, and Martigny, in which the tendency of the black markings to supersede the fulvous was particularly noticeable.—The **President** exhibited cases containing Diptera, and a case containing the skins of African Sphingid larvæ, dried in botanical paper, and after seventy years still preserving their colours, from the Burchell collection in the Hope Museum, Oxford.—Mr. C. O. **Waterhouse** exhibited a gall of some lepidopterous insect found on the califate bushes in Patagonia. The gall resembled that of *Cynips kollari*, but was hollow, the walls being about ⅛ inch in thickness. The circular door prepared by the larva was about ⅛ inch in diameter. The pupa was lying free, without any silk cocoon. It was suggested that the insect was perhaps allied to Œcocecis.—Mr. G. H. **Kenrick** communicated a paper entitled "Natural Selection Applied to a Concrete Case."—Mr. J. C. **Kershaw** communicated papers on enemies of butterflies in south China, and a life-history of *Gerydus sinensis*.—Mr. Nelson **Annandale** communicated a paper on the eggs and early stages of a Coreid bug, probably *Dalader acuticosta*, with a note on its hymenopterous parasites.

Royal Microscopical Society, November 16.—Sir Ford North, F.R.S., in the chair.—Mr. Hugh C. **Ross** exhibited and described a new electric warm stage of his invention.—Mr. C. L. **Curties** exhibited two new designs of the Nernst lamp suitable for use with a current of 100 and 200 volts respectively, adapted for use with the microscope, and fitted with ground glass or blue glass fronts and mounted so as to be used at any height or angle required.—A paper on theories of microscopic vision, a vindication of the Abbe theory, which contained some new views on the subject, was read by Mr. **Conrady.**

Linnean Society, November 17.—Prof. W. A. Herdman, F.R.S., president, in the chair.—Mr. H. E. H. **Smedley** exhibited forty-one models of Palæozoic seeds and cones. The models of the seeds show the complexity of their internal structure, whilst the models of the synthetically re-constructed calamitean and other cones display the high organisation of the vascular cryptogams of Palæozoic times.—Note on the shape of the stems of plants: Lord **Avebury.** The author pointed out that while most plants had round stems, in some they were triangular, some quadrangular, &c., but that, so far as he knew, no attempt had been made to explain these differences. He thought they could, however, be accounted for on mechanical principles. In building, when the main object was to meet a strain in one direction, the well known girder was the most economical disposition of material. In a tree-stem it was necessary to resist strain coming from all directions, and the woody tissues acted as a circular series of girders. In herbs with opposite leaves the strains were mainly in two directions, and were met by two opposite girders, thus giving the quadrangular stem. Taking our native flora he showed that all herbs with quadrangular stems had opposite leaves, and as a rule herbs with opposite leaves had quadrangular stems. Sedges had triangular stems and grasses round stems, and while sedges had the leaves in threes, those of grasses were distichous. Pentagonal stems might be accounted for in a similar way, and incidentally this threw light on the petals of so many flowers. Thus plants had adopted, millions of years ago, principles of construction which have gradually been worked out by the skill and science of our architects and engineers.—Observations on some undescribed or little known species of Hemiptera Homoptera of the family Membracidæ: G. Bowdler **Buckton.** Prof. Poulton has explained the significance of the strange forms of some of the Membracidæ by their dependence on environment, and the requirements of mimicry; and the Rev. Canon Fowler has also given information respecting the economics of the species, and their maintenance during the struggle for life. The present paper may be regarded as supplementary to Canon Fowler's work on the Membracidæ in the "Biologia Centrali-Americana," and to Mr. Buckton's monograph, in which latter work an attempt has been made to classify the family so far as at present known. The specific descriptions are chiefly founded on specimens from the museums of Madrid and Brussels. Most of the new species are from Mexico and Central America, six from Africa, and one each from India, Ceylon, Sumatra, and the Philippines. Mr. Buckton then characterises twenty-four new species, five of which are made the types of new genera, and the paper concludes with general observations on the habits, economy, and transformations of the Membracidæ.

Physical Society, November 25.—Dr. R. T. Glazebrook, F.R.S., president, in the chair.—The measurement of small differences of phase: Dr. W. E. **Sumpner.** Hitherto, in order to measure the differences of phase between alternating-current quantities, it has been necessary to use some method involving the simultaneous reading of three deflectional instruments, such as the wattmeter method, or the three-voltmeter method either in its original or in some modified form. These methods cannot be successfully applied when the phase-differences to be determined are small. The author describes new voltmeter methods which may be used for the purpose, and gives the results of a number of measurements on alternating-current plant.—Dr. C. V. **Drysdale** exhibited and described apparatus for the direct determination of the curvatures of small lenses, such as the objectives of microscopes. Parallel light from a distant source falls upon a plane unsilvered mirror inclined at an angle of 45°. Some of the light is reflected and brought to a focus by an ordinary convex lens. The surface to be tested is placed at this point, and the reflected rays proceed as if they had come from a point on the surface. They pass through the plate glass into a telescope focused for parallel rays, and an observer sees an image of the distant source. If the surface is convex and is brought nearer to the lens, then, when it reaches such a position that its centre of curvature is at the focus of the rays emerging from the lens, the light will again retrace its former path and a distinct image of the source will be seen in the telescope. In order to obtain the two images the surface has therefore been moved through a distance equal to its radius of curvature. If the surface is concave it must be moved away from the lens. Dr. Drysdale showed how the method could be carried out by means of an auxiliary piece fitted to an ordinary microscope. He also described a method of testing the spherical and chromatic aberration of microscopic objectives. Light from a distant point is partially reflected by means of a piece of plate-glass down the axis of the microscope. In passing out of the objective it is brought to a focus upon a mirror, and retraces its path along the axis of the instrument until it reaches the plate glass. This it passes through, and by means of a telescope an observer can view the distant source. The light having passed twice through the lens to be investigated, the effects of chromatic and spherical aberration are doubled, and at the same time the effect of coma is eliminated.—Prof. S. P. **Thompson** gave an exhibition of specimens of crystals showing the phenomenon of luminous rings. He said it was well known that when a source of light was viewed through certain samples of calc-spar the field of vision contained two luminous rings each of which passed through the image of the luminous point. The subject had been investigated by Dr. Johnstone Stoney, who had attributed the phenomenon to a minute tubular structure in the crystal. There were, however, certain crystals which when cut in the ordinary way across the axis and used to view a distant source of light exhibited a single luminous ring passing through the image of the source. Looking down the axis of the crystals no ring is visible, but on tilting it a ring can be seen in the direction of the tilt which grows in diameter as the tilt is increased. So far as he knew, no explanation of these phenomena had been offered. At the meeting a piece of calc-spar showing the two rings, and pieces of beryl and tourmaline showing the single ring were exhibited.

EDINBURGH.

Royal Society, November 7.—Lord M'Laren in the chair.—In a paper on Prof. Seeliger's theory of temporary stars, Dr. J. **Halm** gave some important extensions bearing especially upon the characteristics of Nova Aurigæ (1892) and Nova Persei (1902). Seeliger's theory, broadly stated, is that a temporary star results from the collision of a dark body with a nebula, the chances of such a collision being much greater than the collision of two dark bodies. A necessary consequence will be an intense superficial heating with an atmospheric expansion in all directions. In whatever direction an observer may be situated, spectroscopic observations will show, (1) a displacement violet-wards of absorption lines or bands due to the absorptive action of the expanding and cooling atmosphere advancing in the direction of the observer with the hotter interior parts of the star as background; and (2) bright bands due to the expanding atmosphere to right and left of the body of the star, there being in this case no brighter background and no spectral shift. Dr. Halm now imagines that the collision is due to the advance of the dark body into a stream of nebulous matter passing obliquely across the dark body's path. This will at once give rise to a circulation of parts of the nebula round the star, and these, of course, will also be highly heated. The portions moving transverse to the line of sight across the face of the star will produce absorption bands in their normal position in the spectrum, while the marginal portions moving on the one side towards the observer and on the other side from him will produce a shift of bright bands both towards the red and towards the violet end of the spectrum. By compounding the effects of these two conditions, namely, the simple expansion of the atmosphere equally in all directions and the swirl of incandescent matter due to oblique collision, Dr. Halm showed that the two types of spectra obtained in the cases of the recent Novæ were at once obtained.—Three papers by Dr. Thomas **Muir** were also communicated, the titles being "The Sum of the Signed Primary Minors of a Determinant," "Continuants Resolved into Linear Factors," and "The Three-line Determinants of a Six-by-Three Array."

November 21.—Lord M'Laren in the chair.—Mr. George **Romanes**, C.E., read a paper on a possible explanation of the formation of the moon. The general idea was that the moon had grown to its present form and size by the gradual agglomeration of what was originally a ring of satellites broadly similar to what we know to exist in the case of Saturn. On this hypothesis it was easily shown that the process of agglomeration of a comparatively small body like the moon could not be accompanied with an evolution of heat sufficient to produce a molten globe, and that in consequence the ordinary assumption of intense volcanic action to explain the so-called craters was difficult to accept. But it seemed possible to account for the rugged mountainous surface of the moon with the "seas," ridges, "craters," and peaks by means of the bombardment of those meteoric masses, large and small, which in virtue of the combined action of moon, earth, and sun were precipitated from time to time upon the lunar surface. In the absence of an atmosphere the masses so precipitated would impinge upon the surface with high enough velocities to render the material in the immediate vicinity liquid, the impinging mass also itself being liquefied wholly or partially according to circumstances. The author entered into a detailed examination of some of the most striking features of the moon's surface, and showed how this hypothesis accounted for them. He also exhibited a mass of lead into which small bullets had been shot at various incidences. The indentations reproduced the leading characteristics of the lunar "craters," even to the small hill in the middle of the main depression. It was also noticed that at the instant of impact the rim of lead thrown up all round was made red hot. The mysterious streaks so characteristic of Tycho in certain aspects were explained as due to great splashes of material which settled down in thin crystalline layers capable of throwing off the reflected sunlight in definite directions.—Prof. **Coker** described a laboratory apparatus for measuring the lateral strains in tension and compression members. By a well designed combination of levers and mirror attachment an apparatus capable of being fixed to the bar itself had been constructed, which was sufficiently rigid and yet sensitive enough to measure a change of 1/20,000th of an inch. Some experiments on steel, iron, and brass bars were described, in which the new apparatus was used in conjunction with Ewing's extensometer, and values of Poisson's ratio were given to three significant figures. The values varied from one-third to one-fourth.

PARIS.

Academy of Sciences, November 28.—M. Mascart in the chair.—On the possibility of chemical reactions: M. **de Forcrand.** The author contends that the rigid application of the thermodynamical condition of the possibility of a chemical reaction is neither practical nor necessary, and that the empirical rule that the disengagement of heat settles the course of a reaction is the only possible experimental criterion of the possibility of chemical reactions.—On the prediction of chemical reactions: M. **de Forcrand.** In general, accurate prediction of the course of a chemical reaction is impossible, but there are two rules or principles, one rigorous the other approximate. The latter, the principle of maximum work, is a simplification of the first, and ought to be considered as the only practical guide.—M. Dastre was elected a member in the section of medicine and surgery in the place of the late M. Marey.—The Leonids in 1904: Lucien **Libert.** Details of observations made at Havre on the nights of November 14, 15, and 15, 16. 111 meteors were observed and the trajectories measured.—On the singularities of uniform analytical functions: D. **Pòmpeiu.**—On a new class of ions: G. **Moureau.** In a previous paper it has been shown that a saline vapour becomes conducting after passing through a porcelain tube heated to about 1000° C., and remains conducting at much lower temperatures, possessing the properties of an ionised gas. In the present paper the mobilities of these new ions have been measured. It was found that in the neighbourhood of the region of ionisation the mobilities of the vapours are of the same order as the ions of the gases issuing from a flame.—On the genesis of temporary radio-activity: Ed. **Sarasin,** Th. **Tommasina,** and F. J. **Micheli.** The authors conclude from the results of their work that a very close relation appears to exist between ionisation and the production of temporary radio-activity. The two phenomena would appear to be reversible, the production of the temporary radio-activity of a body being due to the absorption, or, perhaps, adsorption of an emanation which is formed during the ionisation of a gas. On this view, the radio-activity would consist in the loss by radiation of the emanation adhering to radio-active bodies, this causing, in its turn, the ionisation of a gas.—Stereoscopy without a stereoscope: A. **Berthier.** The author points out that he has already published a description of a method similar in principle to that given by M. Ives in the *Comptes rendus* of October 24 last.—On the colloidal state of matter: G. E. **Malfitano.** The author regards colloidal matter as a system formed of an electrolyte dissociated into ions and insoluble molecules grouped round these ions.—The influence exerted by the removal of the moisture from the air supplied to the blast furnace: A. **Lodin.** The results obtained by Gailey at the Isabella blast furnaces, near Pittsburg, on he effect of drying the air forced into the furnace, have attracted much attention in Europe, not unmixed with scepticism. The author makes a comparison of the heat balances in the two cases, and shows where the economy is effected. One indirect effect of the drying process is to increase the temperature of the ingoing air, and a considerable portion of the economy effected may be attributed to this cause. In Europe, where it is usual to work with the air entering the tuyeres at a much higher temperature than at the Isabella furnaces, the relative economy which would be produced by drying the air would be too small to justify the capital expenditure required to introduce the necessary plant.—On the use of dry air in blast furnaces: Henri **Le Chatelier.** The economy claimed for the use of dry air is ascribed by the inventor of the process to the fact that the moisture of the undried air transforms a certain proportion of the coke into hydrogen and oxide of carbon. From the figures of the amount of water removed it is possible to calculate exactly this loss; it is 5 per cent., or only one-fourth of the amount claimed. It is certain, then, either that the economy claimed is incorrect, or else that the true cause is to be sought for elsewhere. The author shows that the quality of the iron produced, especially as regards its sulphur impurity, is an important factor, and that when the sulphur is to be kept down to a certain percentage the economy of fuel claimed by Gailey may be real.—On wood spirit from *Thuya articulata*, Algeria: Emilien **Grimal.** Carvacrol, thymohydroquinone, and thymoquinone were isolated from the product of the distillation of this wood with steam.—The formation and distribution of the essential oil in an annual plant: Eug. **Charabot** and G. **Laloue.** During the formation of the flower the increase of essential oil by the flower corresponds to a loss of oil by the green parts. After the seed is formed, and there is no longer a flow of nutritive principles towards the flower, the essential oil returns to the green organs.—Floral abnormalities produced by parasites acting at a distance: Marin **Molliard.** The atrophy of the stamens, and the conversion of the sepals, petals, and carpels into green foliaceous leaves, a phenomenon frequently met with in *Trifolium repens*, is shown to be due to the burrowing of a larva (probably of *Hylastinus obscurus*) at the base of the stem of the plant.—*Xylotrechus quadrupes* and its ravages on the coffee plant of Tonkin: L. **Boutan.**—The individuality of the complex particle in a crystal: M. **Wallerant.**—On the lakes of the Grimsel and of the St. Gothard massif: André **Delebecque.**—The degree of saline concentration of the blood serum of the eel in sea water and in fresh water, after its experimental passage from the former to the latter: René **Quinton.** The percentage of salt in the blood serum of the eel varies in accordance with the degree of salinity of the water in which it is placed, and is an example of the fact that the saline concentration of fresh water fishes is that of their marine ancestors, reduced simply by the influence of the new medium in which they live.—The elimination of urea in healthy subjects: H. **Labbé** and E. **Morchoisne.**—Contribution to the study of acid dyscrasia: A. **Desgrez** and J. **Adler.**—On the bleaching of flour: E. **Fleurent.**

DIARY OF SOCIETIES.

THURSDAY, DECEMBER 8.

ROYAL SOCIETY, at 4.30.—Memoir on the Theory of the Partitions of Numbers. Part III: Major P. A. MacMahon, F.R.S.—Note on a Means of Producing a High-voltage Continuous or "Pertinacious" Current: Sir Oliver Lodge, F.R.S.—The Effect of Liquid Air Temperatures on the Mechanical and other Properties of Iron and its Alloys: Sir James Dewar, F.R.S., and R. A. Hadfield.—The *Rôle* of Diffusion during Catalysis by Colloidal Metals and Similar Substances: Dr. H. J. S. Sand.

CIVIL AND MECHANICAL ENGINEERS' SOCIETY, at 8.—Notes on Portland Cement: H. E. Bellamy.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Hydrodynamical and Electromagnetic Investigations regarding the Magnetic-Flux Distribution in Toothed-Core Armatures: Prof. H. S. Hele-Shaw, F.R.S., Dr. A. Hay, and P. H. Powell. (Conclusion of Discussion).—Studies in Magnetic Testing: G. F. C. Searle.

SOCIETY OF ARTS, at 4.30.—Burma: Sir Frederic Fryer, K.C.S.I.

MATHEMATICAL SOCIETY, at 5.30.—On Groups of Order $p^\alpha q^\beta$: Prof. W. Burnside.—On the Linear Differential Equation of the Second Order: Prof. A. C. Dixon.—On a Deficient Multinomial Expansion: Major P. A. MacMahon.—The Application of Basic Numbers to Bessel's and Legendre's Functions (second paper): Rev. F. H. Jackson.—On the Failure of Convergence of Fourier's Series: Dr. E. W. Hobson.—An Extension of Borel's Exponential Method of Summation of Divergent Series Applied to Linear Differential Equations: E. Cunningham.

FRIDAY, DECEMBER 9.

ROYAL ASTRONOMICAL SOCIETY, at 5.—(1) Dark Nebulosities; (2) Detached Nebula in Cygnus: W. S. Franks.—On the Relative Brightness of Binary Stars: J. E. Gore.—(1) On the Completion of the Main Problem in the New Lunar Theory; (2) The Final Values of the Coefficients in the New Lunar Theory: Prof. E. W. Brown.—On the Relative efficiency of Different Methods of Determining Longitudes on Jupiter: A. Stanley Williams.—On the Temperature of Sun-spots, and on the Spectrum of an Artificial One: W. E. Wilson.—On the Validity of Meteor Radiants deduced from Three Tracks: H. W. Chapman.—*Promised papers*:—Observations of the Leonid Meteors of 1904 November: Royal Observatory, Greenwich.—Radio-activity of Matter the Possible Cause of Heat Energy in Sun and Stars: W. E. Wilson.—Mean Areas and Heliographic Latitudes of Sun-spots in the Year 1903: Royal Observatory, Greenwich.—The Coefficients of 145 Terms in the Moon's Longitude derived from Greenwich Meridian Observations, 1750–1901: P. H. Cowell.

EPIDEMIOLOGICAL SOCIETY, at 8.30.—Ticks and Tick-transmitted Diseases: Dr. Nuttall, F.R.S.

MALACOLOGICAL SOCIETY, at 8.—Description of a new species of Trachiopsis from British New Guinea: H. B. Preston.—A Correction in Nomenclature: E. A. Smith.—Notes on the American Cyclostomatidæ and their Opercula: W. H. Dall.—Note on the Dates of Publication of the Various Parts of Moquin-Tandon's "Hist. Moll. terr. fluv. de France": J. W. Taylor.

PHYSICAL SOCIETY, at 8.—On a Rapid Method of Approximate Harmonic Analysis: Prof. S. P. Thompson, F.R.S.—A High-Frequency Alternator: W. Duddell.—Exhibition of Experiments to show the Retardation of the Signalling Current on 3500 miles of the Pacific Cable between Vancouver and Fanning Island.—Exhibit of Ayrton-Mather Galvanometers, Universal Shunts, and Electrostatic Instruments.

MONDAY, DECEMBER 12.

SOCIETY OF ARTS, at 8.—Musical Wind Instruments, Reed Instruments: D. J. Blaikley.

SOCIETY OF DYERS AND COLOURISTS, at 8.—Bleaching Agents: and the Methods of Application: F. W. Walker.—The Application of Sulphide Colours in the Dyeing of Chrome Leather.

ROYAL GEOGRAPHICAL SOCIETY, at 8.30.—Explorations in Bolivia: Dr. H. Hoek.

TUESDAY, DECEMBER 13.

ZOOLOGICAL SOCIETY, at 8.30.—Some Notes on Anthropoid Apes: Hon. Walter Rothschild.—On the Cranial Osteology of the Clupeoid Fishes: Dr. W. G. Ridewood.—The Characters and Synonymy of the British Species of Leucosolenia: Prof. E. A. Minchin.

SOCIOLOGICAL SOCIETY, at 8.—The School in Some of its Relations to Social Organisation and to National Life: Prof. M. E. Sadler.

INSTITUTION OF CIVIL ENGINEERS, at 8.—On the Construction of a Concrete Railway-Viaduct: A. Wood-Hill and E. D. Pain.

WEDNESDAY, DECEMBER 14.

CHEMICAL SOCIETY, at 5.30.—Hydrolysis of Ammonium Salts. V. H. Veley.—The Viscosity of Liquid Mixtures. Part ii.: A. E. Dunstan.—The Diazo-reaction in the Diphenyl Series. Part ii.: Ethoxybenzidine: J. C. Cain.—The Sulphate and the Phosphate of the Dimercurammonium Series: P. C. Rây.—A Method for the Direct Production of certain Aminoazo-compounds: R. Meldola and L. Eynon.

SOCIETY OF ARTS, at 8.—The Patent Laws: C. D. Abel.

THURSDAY, DECEMBER 15.

ROYAL SOCIETY, at 4.30.—*Probable Papers*:—An Analysis of the Results from the Falmouth Magnetographs on "Quiet" Days during the Twelve Years 1891 to 1902: Dr. C. Chree, F.R.S.—The Halogen Hydrides as Conducting Solvents. Part iii.: B. D. Steele.—The Halogen Hydrides as Conducting Solvents. Part iv.: B. D. Steele, D. McIntosh, and E. H. Archibald.—Effects of Temperature and Pressure on the Thermal Conductivities of Solids. Part i., The Effect of Temperature on the Thermal Conductivities of some Electrical Insulators: Dr. C. H. Lees.—The Basic Gamma Function and the Elliptic Functions: Rev. F. H. Jackson.—On the Normal Series satisfying Linear Differential Equations: E. Cunningham.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Discussion on Mr. Searle's Paper, Studies in Magnetic Testing; Followed by The Combination of Dust Destructors and Electricity Works, Economically Considered: W. P. Adams.

LINNEAN SOCIETY, at 8.—The Ecology of Woodland Plants: Dr. T. W. Woodhead.—Experimental Studies on Heredity in Rabbits: C. C. Hurst.

FRIDAY, DECEMBER 16.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—Heat Treatment Experiments with Chrome-Vanadium Steel: Capt. H. Riall Sankey and J. Kent-Smith.—Messrs. Seaton and Jude's Paper on Impact Tests on the Wrought Steels of Commerce will be further discussed.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Folkestone Harbour: Cylinder-Sinking at the Root of the Old Pier: R. H. Lee Pennell.

CONTENTS.

THURSDAY, DECEMBER 15, 1904.

HUMAN ANATOMY.

(1) *A Treatise on Applied Anatomy.* By Edward H. Taylor, M.D., F.R.C.S.I. Pp. xxvii+738; 178 figures and plates. (London: Charles Griffin and Co., Ltd., 1904.) Price 30s. net.

(2) *The Human Sternum.* By Andrew Melville Paterson, M.D. Pp. 89; 10 plates. (London: Published for the University Press of Liverpool by Williams and Norgate, 1904.) Price 10s. net.

(3) *Der Gang des Menschen.* v. Teil. Die Kinematik des Beinschwingens. By Otto Fischer. Price 5 marks. vi. Teil. Ueber den Einfluss der Schwere und der Muskeln auf die Schwingbewegung des Beins. By Otto Fischer. Price 4 marks. (Leipzig: B. G. Teubner, 1904.)

(1) TO those unfamiliar with the ways of modern medicine the continual appearance of new works on human anatomy must cause some surprise. No subject should be better known, for it has been a matter of almost universal study for centuries. At the best, many will conclude, a new text-book on applied anatomy—the kind of anatomy the surgeon and physician more especially need—can only be a re-setting of old facts, and an examination of Dr. Taylor's work will show that, to a large extent, the conclusion is justified. The steady advance of surgery necessitates a continual rearrangement of anatomical perspective; the areas of the body which were under a surgical taboo to the septic surgeons of former days are open to the clean operator of modern times. The brain and spinal cord, the cavities of the ear and nose, the organs within the thorax and abdomen, and the great joint cavities of the limbs, have come, one after the other, within the field of everyday surgical procedure during the last thirty years. In his treatment of these parts of the body Dr. Taylor is quite up to date; his pages reflect accurately the best opinion that is to be found in modern text-books of anatomy and surgery. Still, modern advances will not altogether explain the rapid appearance of new works on anatomy or on any other subject; every generation demands its books on science or literature wet from the press.

The study of this work, containing more than half a million words, furnished with highly finished figures, written with clearness and accuracy, raises the question: is the modern surgeon, as seen in a text-book such as this, a more scientific man than his predecessor of fifty or a hundred years ago? A consideration of a number of subjects in this work, in the treatment of which Dr. Taylor is neither better nor worse than other rising surgeons, will show that, as thinking men, they compare unfavourably with surgeons of past periods. The subjects referred to deal with (1) the appendix vermiformis, the seat of appendicitis; (2) the prostate, which becomes so frequently enlarged in old men; (3) the epididymis, a structure connected with the testicle and very liable to disease; (4) the gall bladder, interesting in connection with the formation of gall-stones; (5) the antrum of the mastoid, an air space connected with the middle ear; (6) the air spaces opening into the cavity of the nose. These six structures are selected because, during the last twenty or thirty years, they have been the subjects of the keenest inquiry, and surgeons have published their observations concerning them in thousand upon thousand of treatises and articles. One would expect that the basis of their treatment would rest on an intimate knowledge of the normal use of these structures. John Hunter, Everard Home, and John Hilton would certainly have sought a complete knowledge of the functions of these parts to serve as a foundation for a rational treatment. Dr. Taylor adopts the orthodox view as regards these structures; he describes their shape, position, and relationships, and the routes by which they may be reached, but not a word is said of their use. Perhaps it is unfair to blame Dr. Taylor for this omission, because it must be confessed that we know much more of the diseases of these structures than of their normal function. Yet in a text-book written for house and operating surgeons surely it is the duty of the author to point out essential gaps in our knowledge rather than to gloss them over by a multitude of unessential details. This criticism is the more pertinent because the author in this case has not taken a narrow view of applied anatomy; he devotes a very large part of his space to a description of operative procedures, pathological processes, embryological defects, and introduces here and there points in physiology.

A great part of this work consists not of applied, but of purely descriptive anatomy. Some years ago Waldeyer, of Berlin, gave an elaborate description of some ten or twelve areas he distinguished within the human pelvis—all of which have been adopted in this book; yet not a word is said as to what manner of use a surgeon can possibly apply them. Again, as regards a small peritoneal recess, which may occur to the left of the terminal part of the duodenum, all the various forms which have been described by hair-splitting surgeons are reproduced in detail. An elaborate description of the condition known as knock-knee is supplied, yet no mention is made of how bones react in their growth to the forces which are brought to bear on them, nor is there any allusion to the forces which normally act on the knee joint.

Surgeon-anatomists have a fondness for the application of certain proper names to surgical procedures and anatomical structures—such as the "pouch of Prussak," the "fossa of Landzert," "Gosselin's fracture," &c. An examination of the index of this work shows that more than one hundred such terms are used, yet, in comparison with many works, the number is indeed very moderate; but one feels they are still rather many. Many terms introduced by surgeons are not words which may be used easily, such as "cholecystotomy" (opening the gall-bladder), "cholecystectomy" (excision of the gall-bladder), "cholecystenterostomy" (making a communication between gall-bladder and intestine), "choledochotomy" (opening the bile duct).

(2) In this monograph, a companion to one on the human sacrum, published in 1893, Prof. Paterson

gives the facts gathered and the conclusions reached during a prolonged research into the development, comparative anatomy, and nature of the human sternum. Leaving aside the convenience of having our scattered knowledge on this subject summarised, and the value of the mass of evidence collected during the examination of hundreds of individuals, the main importance of the work lies in two conclusions which Prof. Paterson draws concerning the nature of the sternum:—(1) that it is fundamentally part of the shoulder girdle; (2) that it is not a segmental structure. Both these inferences are at variance with accepted opinion.

At the present time it is universally taught that the sternum in mammals, birds and reptiles—that is to say, in all vertebrates which use the body wall for the purposes of inspiration—is a composite bone derived from a fusion of the ventral ends of the ribs. The sternum is thus regarded as a structure of costal origin, and having only a secondary connection with the shoulder girdle. In Amphibia, on the other hand, it is recognised that the sternum is developed in continuity with the shoulder girdle, of which it forms an intrinsic part; it is in them a shoulder-girdle sternum. That the shoulder-girdle sternum represents the more primitive type, and that from such a type the costal sternum of the Reptilia was evolved, are assumptions which comparative anatomists will freely grant. At present, however, there is a distinct break in our knowledge of the history of the sternum; no intermediate forms between those two types are believed to occur, and no one, with perhaps the exception of the late Prof. T. J. Parker, has ever formulated a definite theory as to the manner in which the costal sternum of Reptilia could have arisen from the amphibian shoulder-girdle sternum. Prof. Paterson's investigations help us very materially to trace the origin of the costal or, as it may more truly be named, the "respiratory" sternum of the three higher classes of vertebrates from the simple sternum of Amphibia. He shows that the "respiratory" sternum arises developmentally in continuity with the precoracoid element of the shoulder-girdle, and quite independently of the ribs, and that it is therefore merely a modified form of the amphibian shoulder-girdle sternum. Further, the various forms assumed by the "respiratory" sternum in reptiles, birds, and mammals do not, when rightly interpreted, favour Gegenbaur's conception of its evolution by a fusion of the ventral ends of ribs. The sternum of amphibians is the median ventral element of their shoulder girdle, and when Prof. Paterson states that no corresponding element is developed elsewhere in the median ventral line, he overlooks the cartilage developed as a median ventral element in the pelvic girdle which in every sense exactly corresponds to the sternum.

The origin of the "respiratory" sternum is part of a wide problem, viz. in what manner and under what conditions did the body wall become modified to serve as an active inspiratory agent in higher vertebrates, thus replacing the "pharyngeal pump" of amphibians? Whatever may have been the exact manner in which the one form of respiration was evolved from the other, there can be no doubt that the ribs, the intercostal muscles, and the sternum as we know them in higher vertebrates appeared during this phase of evolution. Their appearance is directly due to the introduction of a new type of respiration; the sternum which serves in the higher forms as an element of the respiratory thorax is totally unlike the bone which merely served as part of the shoulder girdle in the more primitive type. With this evidence clearly in view it is difficult to understand how Prof. Paterson concludes that even in mammals the sternum is still—what it was when it first appeared in vertebrates—functionally and fundamentally an adjunct or element of the shoulder girdle. We are surprisingly ignorant of the part played by the sternum in the movements of respiration, even in man, but a cursory examination of its respiratory movements in various groups of birds, and in several orders of mammals, quickly serves to show that its form and size depend chiefly not on the movements of the forelimbs, but on the part it plays in the respiratory movements of the thorax. In our opinion the key to the morphology of the sternum is an accurate investigation of its function.

Prof. Paterson is undoubtedly right in regarding the sternum as primarily a continuous unsegmented median bar. The conception of the sternum as a segmental structure he characterises as "a nebulous transcendental notion." Yet his own evidence shows that the greater part of the mammalian sternum, at the commencement of the cartilaginous and osseous stages of development, is laid down as a truly segmental structure, each segment corresponding exactly to a body segment. Much more "nebulous and transcendental" appears to us his explanation of the occurrence of bony segments or sternabræ as "due to the traction or pressure on the part of the ribs and costal cartilages." In support of this theory Prof. Paterson cites the fact that centres of ossification appear in bones at points of traction and pressure. In the case of the sternum, however, the centres of ossification appear not opposite such points, but exactly between them.

This monograph is well got up; the figures are numerous and highly finished. There is evidently a slight error in Fig. 35, plate v.; the centre of ossification for the fourth segment (if the term may still be used) of the mesosternum is stated to be present in 71 per cent. of cases, whereas in the text (p. 18) the proportion is given as 26 per cent. A curious misprint occurs on p. 33, where the centre just alluded to is said to appear in 59 per cent. of children before birth, and 15 per cent. *after death*—probably meaning after birth.

(3) The brothers Weber were of opinion that in the forward swing of the leg in walking the lower extremity acted as a pendulum, the chief force in action being that of gravity. Duchenne, on the other hand, as the result of a special investigation, came to a totally different conclusion, viz. that the forward swing was almost wholly due to the direct action of muscle. In the fifth and sixth parts of his research into the mechanics of the human gait, Prof. Fischer concludes, after an elaborate analysis of the force expended during

the movement, that Duchenne comes much nearer the truth than the brothers Weber, muscular action playing a much larger part than the force of gravity. Those who have watched the passive movements of a paralysed leg during attempts at progression will have no difficulty in accepting Prof. Fischer's results.

The problem of estimating theoretically the force necessary to produce the forward swing of the lower extremity in walking is an extremely complicated one. Prof. Fischer regards the lower extremity as a pendulum made up of three segments, each of which undergoes certain secondary movements during the swing of the entire extremity. Further, the hip joint, from which the pendulum is suspended, undergoes an irregular forward movement during the swing of the limb. The resistance and elasticity of the muscles and ligaments and the friction at the various joints are factors which can only be approximately estimated.

By means of photographic records Prof. Fischer was able to subdivide the forward swing into forty and forty-one equal phases of time, and by estimating the amount of force in action during each phase he shows that gravity alone can account for only a minor fraction of the force necessarily expended in the movement. Further, the positions assumed by the foot, leg, and thigh during a forward swing show distinctly that various groups of muscles are then in action. He recognises four periods in the forward movement of the limb, each of which is characterised by the action of a distinct group of muscles. In the commencing phase the ilio-psoas bends the thigh on the body, the rectus femoris extends the leg forwards, the tibialis anticus bends the foot upwards; in the second phase the gluteus maximus and hamstring muscles draw the thigh backwards; in the third phase the knee is flexed by the gastrocnemius and short head of the biceps; in the final phase the muscles in front of the leg are again in action, and remain powerfully contracted until the sole of the foot is again planted on the ground.

These results are certainly much more in keeping with clinical and everyday experience than those of the brothers Weber. Many who only occasionally take long walks must have observed that one of the first groups of muscles to give out are those in front of the leg, and that they feel painful only at the end of the forward swing, when the heel reaches the ground—the period at which Prof. Fischer shows these muscles come most powerfully into action.

A. KEITH.

EARTHQUAKES.

Earthquakes. By Clarence Edward Dutton, Major, U.S.A. Pp. xxxiii + 314; 63 illustrations. (London: John Murray.) Price 6*s.* net.

EPITOMISED and carefully digested accounts of seismological investigations made during the last twenty-five years are few in number. Two have been published in England, a compilation has been "made in Germany," and now we have a volume from the distinguished geologist, Major C. E. Dutton, of the United States. All told, therefore, we have only four books which give the uninitiated some idea of what the new seismology means and what it has accomplished. About the old seismology, volumes, papers, and particularly sermons exist in thousands. But if we except a few, and amongst the few the works of Mallet stand high above the rest, all they give are reiterated narratives of what people saw and heard, now and then enlivened by some wild hypothesis or pious reflection.

Major Dutton's work belongs to another category, and rather than telling us what earthquakes do, his main object has been to tell us what they are, and while doing this he has kept abreast with the work of others which his own inquiries in the domain of seismic and volcanic activities have enabled him to present in a terse and accurate form.

Everything is discussed with a minimum of mathematics from a strictly scientific standpoint, whilst that which is sensational has properly been most carefully put under taboo. A justification for the exclusion of what is of practical importance, which gives not only to the man in the street but to Governments some inkling as to the use of earthquakes, is not so apparent. It is extremely likely that a Prime Minister may not care a twopenny-bit whether the inside of the world on which he lives is red hot or stone cold, while he might be extremely interested to know that seismograms may afford a satisfactory explanation for the interruption of his cablegrams. The importance of earthquake writings to communities who have been alarmed by accounts of disasters in foreign countries is self-evident, while it would at least be consoling to those who were suddenly cut off from the outer world by the failure of their cables to learn whether such failures were the result of an operation of war or of nature. A knowledge of how to construct so that earthquake effects should be minimised means the saving of life and property in countries subject to seismic disturbances. Seismic charts indicate positions where it is dangerous to lay deep-sea cables, whilst they tell the hydrographer where he may expect to find changing depths. In these and in a variety of other directions seismology helps to make communities comfortable, and at the same time acts as incentive to create a popular interest in and to obtain support for a young science. But as Major Dutton defines his standpoint, and as a volume of 300 pages cannot contain everything, our remarks on omissions must only be taken as indications of the hydra-headed nature of seismology.

The first four chapters are chiefly devoted to the cause of an earthquake, which is defined as anything that "calls suddenly into action the elasticity of the earth." Explosions at volcanic foci produce a local trembling, but they are comparatively of rare occurrence and seldom disturb large areas. When a long fault line is produced, and a large territory carrying perhaps mountain ranges drops down along its length, instrumental observations have revealed the fact that the world may be shaken as a whole. Subsequent adjustments along such a line due to intermittent recovery from overstrain and settlements of disjointed materials give rise to numerous after-shocks which are only sensible over areas of small size, and it seems likely that the greater number of earthquakes felt in the world belong to this latter class. All of them represent a relief of stress, and the discussion on the sources of earth stresses, commencing with the contractional hypothesis and concluding with the results of investigations by Prof. George Darwin, are attractive not only to seismologists but to all who wish to learn something about the inside of the world on which they live.

Some fifty pages are given up to descriptions of seismoscopes and seismographs, attention being particularly directed to those which record unfelt teleseismic movements. We cannot say that the concepts relating to seismic wave motion put forward are generally accepted, but such as they are we may say that they represent modern views. About the amplitudes and periods of earthquake waves seismologists have certain definite information, but about the magnitudes of these elements, particularly for waves which have travelled over long paths, much has yet to be learned. For this latter class of movement it is pointed out that discordant results are found in tables showing the speeds at which they were propagated. The author inclines to the view that the differences which have been noted are due to variability in the delicacy of instruments employed to pick up a wave or wave group. In great measure this may be true, but it seems to us that marked errors may also arise in consequence of inaccuracy in determining the time at which waves were generated at their origin.

Then, again, there are those who incline to a belief, which they sustain with arguments deserving close consideration, that within our earth convection currents exist; it would follow from this that along similar paths, or even along the same path, earthquake speeds should vary.

Notwithstanding these uncertainties, the author holds the opinion that remarkable and unexpected results which fit well within errors of observation have been reached.

Two serious difficulties, for the explanation of which we are asked to wait patiently, relate to the lengthening of wave periods and the total duration of a disturbance as it radiates. We will suggest that the former phenomenon may perhaps be at least partially explained by assuming that in the vicinity of an origin the records refer to forced vibrations, while at a distance the motion represents a periodic natural movement of the crust which varies with its heterogeneity. With regard to the second difficulty, now and then we have evidences that a disturbance recorded at a station far removed from an origin may be reinforced and lengthened by a repetition of the first disturbance which has reached the station by travelling in an opposite direction round the world. Generally, however, the record from a horizontal pendulum near to an origin appears to move as long as, if not longer than, a similar instrument at a distant station, which means that in certain instances the author's difficulty is non-existent. Finally, it must be borne in mind that a single impulse at an origin results in the birth of a series of waves which reach a distant station along different paths and with different speeds, with the result that a blow at an epicentre may at a distance from the same be recorded as a long train of waves.

When Major Dutton suggests to his readers that the Seismological Investigation Committee of the British Association carries on its work in consequence of financial aid received from the British Government, we recognise that he shares a widespread misapprehension.

Much is said relating to the elasticity of rocks, in connection with which an elaborate table, the result of investigations made by Prof. Nagaoka, of Tokio, is reproduced. A second long table is that drawn up by M. Montessus de Ballore relating to the distribution of seismicity.

The illustrations, of which there are sixty-three, are for the most part excellent, but there are one or two photomechanical reproductions of instruments which we imagine will give more delight to their authors at the sight of their own shaky caligraphy than to the ordinary reader.

Taken as a whole, the work is one to be read by all who wish to know what is known respecting the propagation of wave motion in our earth since the invention of the seismograph, and it is destined to receive a hearty welcome.

TECHNICAL MECHANICS.

Die technische Mechanik: elementares Lehrbuch für mittlere maschienentechnische Fachschulen und Hilfsbuch für studierende höherer technischer Lehranstalten. By P. Stephan, &c. Erster Teil: Mechanik Starrer Körper. Pp. viii+344. (Leipzig: Teubner, 1904.) Price 7 marks.

IN the very early part of this excellent work there is a certain lack of system, inasmuch as, although the author very properly treats first of the equilibrium of a *particle,* he assumes the nature of the stress exerted in such rigid bodies as the bars of a framework, the crank and connecting rod of an engine, &c. The nature of such forces is never properly appreciated by the student who is truly a beginner in the subject of dynamics—and, indeed, there is no part of statics in which students of even very considerable experience are so apt to go wrong as that relating to the forces exerted by jointed bars. The author treats from the outset the equilibrium of forces acting in space of three dimensions without having previously disposed of the simpler two dimensional case, a course which meets with the approval of many teachers, although it seems to the reviewer to be the less simple method. Herr Stephan enunciates the parallelogram law for the composition of forces (or vectors generally) at the outset, and assumes it as a result of experiment—which, on the whole, is perhaps the wisest plan for a teacher. Near the end of the book, however, he gives the ordinary Newtonian proof of the proposition.

He gives very early and very clearly the method of determining the resultant of a system of coplanar forces acting on a body (other than a particle) by means of the force and funicular polygons—a subject in which English students are, as a rule, extremely weak. There is a section on the determination of the centres of gravity of all the bodies usually figured in our

English books, followed by a discussion of all the ordinary simple machines—with this difference, that Herr Stephan's figures are much better than those of our text-books. Then follows a discussion of friction, in which, although the author almost invariably solves his problems by introducing the normal force N and the friction μN, he does not omit to point out the utility of the *total resistance* and the angle of friction. He underestimates this utility, however, in solving a simple problem by the N and μN method, and in his final results (p. 118) substituting the angle of friction—a process which simply obscures the merit of the second (and much shorter) method—with the remark that the example shows the advantage which the introduction of the angle of friction "occasionally offers." The truth is that in the hands of a skilful student the geometrical method founded on the employment of the angle of friction and the total resistance is almost always more neat, direct, and simple than the analytical, or N and μN, method. It can be conceded, however, that for engineering students, and technical students generally, this analytical method is the safer, although the longer, and requires less of the *esprit mathématique*. The nature of rolling resistance, which seldom finds mention in our English books, is well explained and illustrated by several applications (pp. 147, &c.). Indeed, the whole of Herr Stephan's treatment of the machines (screw presses, cranes, friction band-brakes, &c.) commonly discussed is excellent, and occupies a very large part of the treatise; it is, in fact, the best and most useful portion of the book.

The only kind of catenary treated of in this volume is the parabola of suspension bridges, to which only two pages and two illustrative examples are devoted. Doubtless the subject will receive more consideration in some subsequent volume.

Herr Stephan is very careful to avoid errors in his figures, and to represent the lines of action of three forces when they keep a body in equilibrium as meeting in a point—a very elementary condition not always observed in our text-books. Once, however, he overlooks this necessity, and represents the lines of action of three forces acting on a bar in a framework (Fig. 164) as forming a triangle of very respectable area.

In the section dealing with the equilibrium of frameworks of jointed bars, he directs attention to the obvious fact, which is not usually mentioned in our books, that even if the bars are loaded throughout their lengths (by their own weights or otherwise) the stresses can be calculated by taking any of the bars as unloaded and weightless, and then superposing the calculated results (p. 197). This simple principle he applies in a special case, and it is one which on many occasions might be employed with great advantage.

The last hundred pages are devoted to kinetics of an elementary kind—including the theory of direct collision of spheres, the compound pendulum, &c.—together with a section on the moments of inertia of various figures and solids. There is no mention made of the very simple and useful rule that a triangular area can be replaced by three equal particles placed at the middle points of its sides—a rule which saves an enormous amount of trouble in the calculation of moments of inertia for all plane areas bounded by right lines. In the absence of this simple rule, a ponderous application of the integral calculus is the only refuge of the student. A somewhat similar "particle rule" saves reams of ponderous calculus work in hydrostatics; but these rules are not widely known.

Herr Stephan very properly makes short work of D'Alembert's principle, deducing it directly from Newton's axioms ii. and iii., so that, although he employs the term "centrifugal force," he is careful, except in one instance, to show that it is a force exerted *by*, and not *on*, a moving particle. The exceptional instance occurs at p. 281, where he is calculating the tension in a driving belt which passes over the surfaces of two revolving cylinders. Here he speaks of a small element of the band as "experiencing" a centrifugal force, which is duly represented, in the usual way, by a centre-flying arrow. His subsequent teaching, however, removes the erroneous notion herein contained.

The book is wonderfully well printed and illustrated, as well as free from mistakes. On p. 15 "Punkte" should clearly be "Kräfte," and on p. 187 the reference should be to Fig. 131 and not to Fig. 135. The theory is illustrated by nearly 200 examples.

To all students who desire to attain a real and physical conception of the subject Herr Stephan's work can be very strongly recommended.

GEORGE M. MINCHIN.

OUR BOOK SHELF.

Machine Drawing. By Alfred P. Hill. Pp. 83. (London: P. S. King and Son, 1904.) Price 2*s.* 6*d.* net.

IN this text-book the author presents a course of instruction which he considers suitable for students attending elementary drawing classes who are unable to spare more than one evening per week, and whose technical training is thus confined to the one subject of machine drawing. Three dozen plates are given, affording a choice of examples to be copied to scale from the dimensions figured, some of which are proportional dimensions covering a range of sizes. Accompanying the plates are descriptive accounts of the construction and uses of the machine parts drawn, with sets of questions founded thereon. At intervals, where space is available, formulæ and physical data are introduced and used in making calculations illustrating machine design. This crude attempt to teach applied mechanics along with elementary machine drawing seems to us a mistake, as, in the absence of a knowledge of mechanical principles, such formulæ as are given become mere rules of thumb, and any attempt to apply them independently cannot fail to be disastrous, as, for instance, in the author's method of estimating the limiting speed of a fly-wheel on p. 42. The time wasted on these premature calculations might very profitably be spent with rule, callipers, and squared paper, in measuring and making careful and complete dimensioned sketches of actual machine parts, and so cultivating the habit of closely and accurately observing constructional details.

Errors abound throughout the book. The author is not a safe guide even in such a small detail as the projection of a hexagonal nut, while his statement on p. 44 that "heat and work are mutually controvertible" is a fair index of the scientific value of the work. The volume is somewhat redeemed by a few good plates prepared from working drawings supplied by makers, but in many cases the figures indicating dimensions are, unfortunately, so small as scarcely to be legible.

An Elementary Class-book of Practical Coal-mining. By T. H. Cockin. Pp. xii+428. (London: Crosby Lockwood and Son, 1904.) Price 4s. 6d. net.

In general character this useful volume resembles the text-books already available for students of coal-mining. The work is, however, carried to a rather more advanced stage than has hitherto been considered necessary for an elementary class-book, and chapters are given dealing with allied subjects, such as chemistry, mechanics, the steam-engine, and electricity. The order of treatment differs from that usually adopted, the subjects dealt with being:—(1) geology; (2) structure of stratified rocks; (3) coal and coalfields; (4) search for coal; (5) sinking; (6) opening out; (7) miners' tools; (8) explosives; (9) methods of work; (10) working by long wall; (11) methods of working by pillar and stall; (12) special methods of work; (13) timbering; (14) coal cutting by machinery; (15) mechanics; (16) steam; (17) gases; (18) ventilation; (19) instruments; (20) lighting; (21) winding; (22) haulage; (23) pumping; (24) surface arrangements; (25) coke making; (26) accidents; and (27) electricity. This arrangement is not so logical as that adopted by the late Sir C. Le Neve Foster in his elementary work. For example, sinking with rock-drills is described before mining tools, coal-cutting machinery before the elements of mechanics, and electric signals before electric terms are defined. The brief chapter on coke making is hardly necessary, as this subject is usually dealt with in metallurgical treatises. It is doubtful, too, whether the chapters on chemistry, mechanics, steam, and electricity are sufficiently full to give an insight into the allied subjects, for the study of which excellent text-books are available. The illustrations are clear and diagrammatic, and possess the advantage of having been specially drawn for the book.

Bird Notes from the Nile. By Lady William Cecil. Pp. xii+113; illustrated. (London: Archibald Constable and Co., Ltd., 1904.) Price 2s. 6d. net.

THREE claims to high commendation present themselves on the first glance at this elegant little popular work. In the first place, the numerous illustrations are simply exquisite; secondly, technical names are banished from the text; and, thirdly, in the long list of species forming the appendix such names appear to be correctly spelt, and are thoroughly up to date, even to the adoption of the so-called "Scomber scomber" system of alliteration. In her preface Lady William confesses that the notes were written originally solely for her children, who doubtless were desirous of possessing a memento of their parents' Nile trip, but that friends persuaded her to offer them to the public. The adoption of this advice is, in our opinion, fully justified, and while the book has no doubt been found delightful by the young people of the family, it can scarcely fail to be a pleasant companion to the many bird-lovers who make a winter excursion up the Nile. Although no attempt (and very properly) is made at technical descriptions of the various species encountered during the voyage, such notes as are given are in most cases sufficient to render identification an easy matter, to say nothing of the instances when this is rendered self-evident by the illustrations.

Education and National Efficiency in Japan.

THE notice of my book "Dai Nippon, the Britain of the East," which appeared in NATURE of December 1, directed attention to a nation from which much may be learnt at the present time, and it may interest your readers if I supplement your article by a few notes from my personal experience and observation. In the memorandum issued by Sir Norman Lockyer suggesting the formation of a British Science Guild, it is stated that the people of this country do not manifest that interest in and belief in the power of science which are noticeable among the peoples of the Continent or of America, and that, in spite of the efforts of many years, the scientific spirit essential to all true progress is still too rare, and, indeed, is often sadly lacking in some of those who are responsible for the proper conduct of many of the nation's activities. The British Science Guild has been proposed with the view of attempting to remedy this evil, and to bring home to all classes the necessity of applying scientific treatment to affairs of all kinds.

The objects of such a guild have been attained, to a very remarkable degree, in Japan, not so much by the formation of a special organisation for the purpose, as by the awakening of the national consciousness to the necessity of keeping in mind certain definite aims, and by the earnest cooperation of the various departments of Government, of scientific associations, and of private organisations of many different kinds. There is, indeed, a danger at the present time in this country of too much importance being attached to mere organisation and machinery, and too little to the spirit which pervades them. Mr. Matthew Arnold, in one of his last official reports on elementary schools, pointed out that "our existing popular school was far too little formative and humanising, and that much of it to which administrators point as valuable results is in truth mere machinery." This applies with far greater force to a great deal which has been done in recent years in the way of scientific and technical education. Instruction and knowledge are too often confounded with education, and mere machinery and organisation prevent the development of the scientific spirit. Many of the men who are supposed to have had a complete technical education are very poor specimens of humanity, wanting in individuality and character, devoid of all originality, and with a very narrow view of the world. Some of them may manage to pile up fortunes for themselves, but they will do little to make their country great. Even from a practical point of view, success in any trade or profession does not depend so much on the amount of information which may have been crammed into the learners' heads as is often supposed. It depends incomparably more upon their capacity for useful action than upon their acquirements in knowledge. All experience proves that the spiritual is the parent and first cause of the practical, and especially the economic history of the Middle Ages shows us that an ounce of manly pride and enthusiasm is worth more than a pound of technical skill.

The recent history of Japan has emphasised this fact. While attention has been paid to details, the spirit which has animated the leaders of public opinion and action has been the chief cause of the great developments which have taken place. The complete study of this aspect of Japanese national life would take us into many interesting psychological discussions, but it is sufficient for our present purpose to note that the Japanese mind, unlike the British (which is strongly individualistic), is dominated to a very great extent by collective opinion. At the same time, while Japanese philosophy and their former social order were essentially communistic in their nature, still (contradictory as it may seem) their genius is individualistic, and they impress their personal qualities on their work, although they are willing to sacrifice results to a rigid organisation. The outcome of it all is that the national consciousness is directed to the attainment of national objects by men whose individual powers have been trained to make effective use of western science, and the results have been simply wonderful.

These results have been most apparent in the operations of war. It was the sound of the cannon on the Yalu River, in the war with China ten years ago, which awoke Europe and America to a knowledge of the fact that a new nation had been born in the Far East, and which at the same time started many of the political problems which have led up to the present war with Russia. That war, whatever its ultimate results may be, has shown that the Japanese have not only been able to take full advantage of the applications of western science, but that they have been animated by the spirit of old Japan, which has made them regardless of personal sacrifices. The Army and Navy have been organised and worked on scientific methods, and with a completeness of arrangements which has won for them the admiration of all impartial critics. Their intense patriotism has caused them to perform deeds of daring which are unequalled in the history of war, while their skill in strategy and in the applications of the latest scientific methods to all they have done has made them almost uniformly successful in their operations. They have demonstrated the importance of the work of the engineer. The railways which have been built in Japan have been fully utilised to convey men and materials, and the ships to transport them oversea. The telegraphs have been used to communicate instructions and to keep the authorities informed regarding movements and requirements. The dockyards and shipbuilding yards have been ready to undertake repairs, and the arsenals and machine shops to turn out war material of all kinds, as well as appliances which aid operations in the field. Light railways have been laid down on the way to battlefields, and wireless telegraphy and telephones to convey instructions to soldiers; in short, all the latest applications of mechanical, electrical, and chemical science have been freely and intelligently employed.

The ships of the Japanese Navy are probably the best illustrations of the Japanese methods of procedure. In naval matters they accepted all the guidance the western world could give them, but at the same time they struck out a line of their own, and the fleet which they have created is unique in the character of its units. British designs have in many respects been improved upon, with the result that they have obtained in their latest ships many features which have won the admiration of the naval world. The inventions and improvements which have been made by Japanese officers, engineers, and scientific men disprove the charge which is very often made, that the Japanese have no originality. Even in the matter of pure science Japanese investigators have shown that they are able to take their places among those who have extended the borders of knowledge. The memoirs and papers published by Japanese students and teachers, both on scientific and literary subjects, will bear very favourable comparison with those of any other country, and while no Japanese Newton, Darwin, or Kelvin has yet arisen, there are men connected with Japanese universities and colleges of whom any learned institution in the world would have no reason to be ashamed.

I must refer to my book for details of the developments which have taken place in engineering and industry. Suffice it to say that roads and rivers have been improved, railways to the extent of between four and five thousand miles have been constructed, a large mercantile marine has been created, docks and harbours have been made, telegraphs and telephones are in use all over the country, excellent postal arrangements are in operation, and there are few departments of mechanical and chemical industry in which there are not many establishments doing very efficient work. The result of it all has been that commerce has been immensely extended, and the financial resources of the country developed in such a manner as to enable Japan to take her place among the powerful nations of the world.

At the root of all these developments has been the very complete system of education which has been established in the country. Elementary schools are to be found in every district, and secondary and technical schools in populous centres, while the universities of Tokyo and Kyoto supply the highest training required for the national life; but for details of these I must again refer to my book. The motive underlying all the efforts is what I wish chiefly to emphasise. Shortly after the Emperor succeeded to the throne, he issued a proclamation which contained the following sentence:—"Knowledge and learning shall be sought after throughout the whole world, *in order that the status of the Empire of Japan may be raised ever higher and higher.*" The recent history of Japan is the most striking illustration of the influence of a wisely directed system of education on national affairs when those who are responsible for it are infused with high national ideals.

At the same time it should be noted that some of the most thoughtful and influential men in Japan doubt whether the official system of education is likely to lead to the best results. They feel, like Matthew Arnold, that too often the machinery and organisation receive more attention than the real education, and, moreover, they dislike the idea of all educational institutions being of the same type. Probably the most influential educationist in Japan was Yukichi Fukuzawa, and he never failed to point out the possible evils which are likely to arise from a too strictly official routine. His own college, the Keio Gijuku, has been a great school for statesmen, lawyers, and public men, and many of the leading men in Japan have been his pupils. Count Okuma, the distinguished statesman, has also established what is essentially a private university, and there are many other schools of different kinds, all of which supplement the Government institutions. Even in the technical and professional establishments, however, attention is not confined to the subjects required for strictly utilitarian purposes or for examinations; the first object is to train *men* who will be able to serve their country, in the fullest sense of that term. Many discussions are now being carried on with regard to the future of education in Japan, and the general tendency of these was indicated a short time ago by a distinguished Japanese author when he said, "No system of education which is not based on sociological conditions can be thoroughly successful, and therefore a study of ethnology, sociology, and of evolution generally is absolutely essential to a thorough understanding of the educational questions awaiting solution." The Japanese are now face to face with many problems which confront all industrial nations, and it is to be hoped that, having organised their education generally, and in some respects given an example to western nations, they will go a step further and show that it is possible to combine industrial development with the welfare of all classes of the community.

The chief lessons which the British Science Guild has to learn from Japan is that if it is to be of any real influence in the life of the Empire, the term *science* must be used in its broad sense, as including all knowledge required for individual and collective life, and that all efforts must be guided by a consciousness of the real aims of national life.

Glasgow, December 6. HENRY DYER.

The Heating Effect of the γ Rays from Radium.

IN a recent communication to the *Physikalische Zeitschrift* (No. 18, September) Paschen has described some experiments which indicate that the γ rays from radium supply a large proportion of the total heat emission. It is known that the heating effect of radium when surrounded by an envelope of sufficient thickness to absorb both the α and β rays is about 100 gram calories per hour per gram. Paschen, however, found that if the radium was surrounded by a sufficient amount of lead to absorb completely the γ rays the heating effect was increased 2·26 times. This large heating effect of the γ rays was so unexpected, and of such great importance in connection with the nature of these rays, that we decided to verify this result by an independent method. In Paschen's experiments, the heating effect was determined in a special Bunsen ice calorimeter, in the central tube of which the radium, surrounded by a lead cylinder about 4 cm. in diameter, was placed. In order to correct for the natural melting of the ice mantle a differential method was employed. In our experiments we decided to use a differential air calorimeter, similar to the one described in our previous work on the heating effect of radium and its emanation (*Phil. Mag.*, February). In each flask of the differential air calorimeter there was placed a narrow glass tube, closed at the lower end and extending to about the centre of the flask. The radium bromide weighing 23·7 milligrams was enclosed in a small metal capsule supported by a thread, and was inserted alternately in the glass tubes. The flasks, originally at atmospheric pressure, were immersed in a water bath kept in a constant temperature room, and were connected by a xylene tube which served as a manometer. The heating effect was measured by the movement of the xylene column, observed by a telescope with micrometer eye-piece, and the scale was calibrated by a small heating coil of approximately the same dimensions as the radium. Two sets of experiments were carried out, in one of which the ends of the glass tubes were inserted in lead cylinders 3 cm. in diameter and 3 cm. high, and in the other with aluminium cylinders of exactly the same dimensions.

The lead envelope absorbed more than half the γ rays, while the aluminium absorbed only a few per cent. The readings were found to be very steady and consistent, but no appreciable difference in heating effect could be detected in the two experiments. As a check, the heating coil was employed in both experiments to calibrate the readings, the means of which agreed to about 1 per cent.

According to Paschen's results, the heating with the lead cylinders should have been at least 50 per cent. greater than with the aluminium cylinders. In our experiments we could not have failed to detect a difference of 5 per cent. We conclude from this that the γ rays do not supply more than a small percentage of the total heating effect of radium.

Singularities of Curves.

THE compound singularities of algebraic curves offer a wide field for discussion, but the naming of the simple singularities has not yet been placed on an entirely satisfactory footing. The latter consist of (1) point singularities, which are nodes and cusps; (2) line singularities, which I prefer to call bitangents and inflections. Mr. Basset calls them double and stationary tangents; but if this is done, symmetry requires that the point singularities should be called double points and stationary points, and this is not admissible, because the phrase double points (as now used) includes cusps as well as nodes. If a curve has a double point Mr. Basset calls it *autotomic* (self-cutting); but this term is incorrect when all the double points in the curve are cusps (as in the cardioid), for the curve does not then cut itself. If it is really desirable to have a means of distinguishing curves that have nodes or cusps from those that have none, they may perhaps best be described respectively as curves with or without point singularities.

A CHRISTMAS BIRD-BOOK.[1]

THE success which attended his last children's bird-book has induced Mr. Kearton to cater once more for the wants of young people interested in the animal life around them, and the result is the present charming little volume, illustrated, as usual, by reproductions from photographs taken direct from nature by the author and his brother. In the guise of a narrative told by "Cock Robin" to his offspring, the author has contrived to convey in his own inimitable manner a vast store of information concerning bird-life, interspersed with observations relating to other animals. Although, as already said, intended primarily for juvenile readers, the volume contains a certain amount of information which may be new to some of their seniors, including those to whom natural history is not an unknown study. For instance, until we learnt it from Mr. Kearton's pictures, we ourselves were ignorant of the marked and easily recognised difference between the foot-prints of a rabbit and those of a hare, despite the number of times they have come under our notice in the snow.

Generally Mr. Kearton conveys his information in simple language, but he is very prone to speak of a bird picking up food between its two mandibles when it would be "shorter, simpler, and better understood" (to quote from a well known Bar story) if he said beak. Apparently old fables connected with animals die hard, for, according to the author, many young people at the present day believe that a wren is a female robin, and that male robins lose their red breasts in summer.

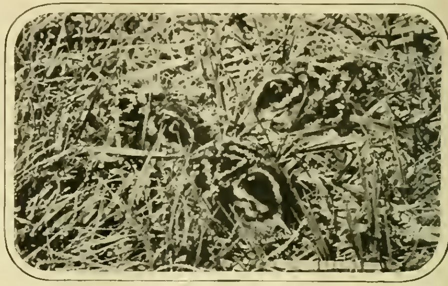

FIG. 1.—Young Dunlins in their natural surroundings. From Kearton's "Cock Robin." (Cassell and Co.).

These and other old wives' legends Mr. Kearton does his best to replace by accurate and interesting accounts of the mysteries of bird-life.

The best (if there can be a best where all is so interesting) of the five chapters are the two on nesting and the clamour of chicks, both being illustrated by a number of photographs of nests and young birds. Very graphically does the author bring out the remarkable difference in development at the date of hatching between a young sparrow, for instance, and that of a woodcock, and he also shows how much this difference depends on habit, a young skylark showing a somewhat intermediate stage. Very striking are the two photographs here reproduced, the one showing young dunlins skulking amid their native covert, and

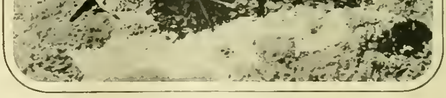

FIG. 2.—The same birds in unnatural surroundings. From Kearton's "Cock Robin." (Cassell and Co.)

the other the same birds removed to an uncongenial environment.

"Nature-teaching" could not be conveyed in a better manner, or in one less free from affectation and faddism, and we trust that the "Kearton annual" will enjoy the extensive patronage that it certainly merits among those on the look-out for suitable Christmas presents for their young friends.

[1] "The Adventure of Cock Robin and his Mate." By R. Kearton. Pp. xvi+240; illustrated. (London: Cassell and Co., Ltd., 1904.) Price 6s.

THE PRESENT CONDITION OF THE SEA-FISHING INDUSTRY.[1]

"THE methods employed in the capture and transport of fish, the great combinations of capital, the trade organisations, the disputes between the trade and the railway companies, local upheavals, like those of Newlyn and Grimsby, which temporarily paralysed the industry, the efforts of science to unveil the secrets of the sea, and of Parliament first to encourage such investigation and then to act upon its results; these have in turn been briefly dealt with. Lastly, we visited most of the important fishing ports." Such in the author's words is an outline of the plan of this book.

Historically the work is of interest as being the first popular and general account of the sea-fishing industry which has appeared since Holdsworth's "Deep-Sea Fishing," an admirable treatise of similar scope published thirty years ago. A good idea of the rapid progress of the industry in the interval may be gathered from a comparison of the two. Curiously enough, Holdsworth doubted the probability of any extensive adoption of either steam power or the otter trawl in relation to commercial fishing. Contrary to this forecast these very two factors, together with ice and railway facilities, have effected nothing short of a revolution in the industry. It is possible that the next decade or so may also have surprises in store as the result of trade enterprise on the one hand and scientific investigation on the other.

Mr. Aflalo wisely refrains from pronouncing any strong opinions as to future developments.

After a short sketch on "Life in the Sea," in which the chief of the facts known about the life-histories of the edible fishes are mentioned, the author proceeds to describe the various processes involved in the capture and distribution of fish. These subjects receive adequate if not exhaustive treatment, and are made as interesting as possible by Mr. Aflalo's well-known popular style of writing. Then follow two important chapters on legislation and scientific investigation. The final section consists of interesting notes on the different kinds of fishing practised at each important station along the coast, the condition of the harbours (usually defective), railway facilities, local modifications of the share system of wage-payment, and the general prosperity, or otherwise, of the port in question. The contrasts in some cases are very striking, as, for example, between the mushroom-like development of steam-trawling in the hands of syndicates, as at Grimsby, and the moderate but steady prosperity associated with private enterprise at a typical smack-trawling port like Brixham. The former may be safely described as the busiest and least picturesque port in the kingdom, while Brixham, which three-quarters of a century ago supplied the pioneers of the North Sea fishery, and still breeds a notably hardy and resourceful type of man, remains attractive in the old-fashioned way.

In dealing with such controversial matters as legislation and scientific investigation, Mr. Aflalo represents the two sides of a question with some skill, and, absolutely committing himself to neither, has a good word to say for both. Nevertheless, this attempt to steer a sort of middle course among the different opinions leads to no very definite results. The latest Sea-Fisheries Bill he appears to regard as a measure which might do some good, and cannot, in view of its elastic and unbinding character, do much harm; it has, in fact, its good points. International scientific investigation is strongly advocated, "although effectual investigation of the vast bed of the North Sea is out of the question," and "however faulty the Christiania programme may be when analysed on a purely economic basis."

The continued participation of Britain in the international investigations is recommended for the following reasons:—"As a piece of scientific work on an elaborate scale, the North Sea scheme is not unworthy of a century which opened with the discovery of radium and the *n*-rays. As a measure of high politics it is at least equal to the Anglo-French Agreement of which so much more has been heard."

Apart from purely diplomatic considerations, such as the above, the flat-fish problem, which is understood to be receiving special attention at the hands of the international experts, is surely very largely an international one, if only on account of the well-ascertained fact that by far the most important nurseries of the plaice are on the Continental side. One awaits with interest the full details of these researches, especially of certain experiments on the marking of plaice, as a result of which it has been stated (in a short report recently issued by the council of the Marine Biological Association) that the species performs seasonal migrations of considerable extent and definite direction, and further that 20 per cent. of the English marked plaice have been recovered and returned by the fishermen within a year. The latter result indicates an intensity of fishing such as may conceivably affect the supply of this fish. Still more interesting economic possibilities—standing, perhaps, in relation to the last as the antidote to the evil—are suggested by some reports recently circulated in the newspapers. These speak of the phenomenal growth of small plaice liberated on the Dogger Bank, to which they had been transplanted from certain crowded inshore "nurseries." Investigations such as these bear directly on questions of

FIG. 1.—The *Huxley*, specially commissioned to carry out fishery investigations. From Aflalo's "Sea-fishing Industry of England and Wales."

[1] "The Sea-fishing Industry of England and Wales. A Popular Account of the Sea Fisheries and Fishing Ports of Those Countries." By F. G. Aflalo, F.R.G.S., F.Z.S. With a sea-fisheries map and numerous photographs by the author and others. Pp. xx + 386. (London: Edward Stanford, 1904.) Price 16s. net.

supply, and are evidently inspired by a determination to give something like concrete value for public money.

While awaiting the verdicts of science and the deliberations of legislators, it is useful to have to hand a work such as this, which gives a concise statement and accurate picture of the present condition of the great sea-fishing industry.

The book is abundantly supplied with interesting photographs. There is also a sea-fisheries map, in which, however, is one glaring defect. From this map it would appear that Yarmouth and Lowestoft are given over entirely to the drift-net fishing, and that neither of these places has any connection by rail with the metropolis. This is inconsistent with what is stated in the text, and is opposed to common knowledge.

THE ELEVENTH EROS CIRCULAR.[1]

THE appearance of this volume brings us definitely face to face with a new situation in the derivation of accurate positions of the heavenly bodies from photographs. It will be remembered that in the winter of 1900–1 the recently discovered small planet Eros made a very near approach to the earth, and a large number of photographs were taken with the view of determining the distance of the planet, from a knowledge of which that of the sun, and the dimensions of the solar system generally, could be inferred with (it was hoped) considerably improved accuracy. The measurement of the plates involves enormous labour, and has only been partially accomplished in the intervening four years; and the discussion of the measures has necessarily proceeded even more slowly. But the present publication of more than 400 quarto pages represents a notable addition to the tabular statement of measures, and contains an important contribution to the discussion.

It appears that the plates taken at different observatories are liable to disagreement in a serious manner. Putting aside the planet itself for a moment, when the positions of the stars found from plates taken at the Algiers Observatory are compared with those found from plates taken at Paris, there is a difference varying with the brightness of the individual stars. Such a difference is not altogether new in astronomy; it was pointed out by Sir David Gill a dozen years ago or more that eye observations of stellar positions made by different observers were likely to differ systematically in this manner; but this was attributed to human defects in the observer, and it was hoped that photography would free us from the embarrassment. So it probably will when rightly used; but we have apparently not yet completely realised the necessary precautions. The instruments for taking the photographs at Algiers and at Paris are as precisely similar as the constructor could make them; they were used in the same way; the plates were measured similarly and with careful attention to certain known sources of error, and yet the resulting star places show the following differences in seconds of arc in the mean of 5 groups of 87 stars each:—

Mean magnitude	Difference ″
8·8	−0·27
9·4	−0·42
10·4	−0·57
11·2	−0·72
11·6	−0·83

There is a range of more than half a second, and we want to measure the hundredth of a second! This is probably an exceptional case; but what may occur once may occur again, and in view of this fact it is not too much to say that a very serious addition has been made to the labour of determining the quantity sought—the solar parallax—by this revelation.

It is disappointing to find no satisfactory suggestion of the cause of error in the paper which gives an account of it. A suggestion is indeed made, viz. that in measuring a plate the presence of an adjacent image (for the exposure is repeated on the same plate so as to show all the images more than once) may disturb the eye of the measurer. All our experience hitherto is against such a possibility. It seems more likely to the writer that the cause may be sought in the object glass of the photographic telescope, and, to be more precise, in an error of centreing of the crown lens relatively to the flint. Such an error is well known to opticians, and is easily detected in a visual telescope by the fringe of colour on one side of a star image when slightly out of focus. But the images formed by a photographic telescope are not examined by the eye in the regular course of work, and such an error might therefore escape detection until revealed by such a comparison of measures as is given above. The stray light on one side of the image would not be strong enough to affect the sensitive film in the case of faint stars, but for a bright star it would spread the image in that direction, and so introduce a spurious displacement of the centre. If this explanation be correct, the error can be both detected and eliminated by turning the object glass through 180° (with most forms of telescope mounting it is only necessary to turn the telescope to the other side of the pier), and this can easily be done. Indeed, it ought to have been done before now, under the admirable maxim for physical work, "reverse everything that can be reversed," but, so far as is known to the writer, the point has hitherto escaped notice.

If on examination this explanation will not fit the facts, some other must be found. A few additional details in the volume before us would have made it possible to test this hypothesis; if, for instance, it had been specified which plates were taken on one side of the pier and which on the other, a comparison of the two sets would have given very definite information. Mr. Hinks has already given cogent reasons (see *Observatory* for September, 1903) for regretting the lack of information as to the identity of the individual plates, and we have now to add this further reason. For the systematic difference described is not confined to Algiers-Paris. If we turn to the paper following that in which M. Trépied gives the figures above quoted and arrange the differences found at the Goodsell Observatory (Carleton College, Minnesota) according to stellar magnitude, we find a well marked effect in R.A. and a smaller one in dec.; and probably other cases, when duly examined, will give similar results, though it does not seem to have occurred to astronomers generally to make a properly searching inquiry. For instance, at the end of the volume M. Lœwy tabulates a series of differences between two lists of star places prepared with great care by himself and by Prof. Tucker, of the Lick Observatory, and he comments with satisfaction on the close accordance of the two lists. But a very slight examination suffices to show that the differences are affected with "magnitude-equation," though in this instance the effect may be due to the visual observations.

In fact, while duly admiring the energy and diligence with which this vast mass of material has been collected and published, a result due in great part to the powers of organisation of M. Lœwy, the director of the Paris Observatory, we may well feel some doubts whether it will turn out to be, as he hopes, a "collection of *homogeneous* material, susceptible of being immediately used without the necessity of undertaking,

[1] Conference astrophotographique internationale de Juillet, 1900. Circulaire No. 11. (Paris: Gauthier Villars, 1904.)

as in the past, long and tedious preliminary investigations" (p. 3). Homogeneity for such a purpose cannot be secured by mere similarity in publication of results; indeed, this very process tends to cover up vital differences of detail, and it is to be feared that, unless these can be unearthed again, the work will suffer in accuracy.

There is an appendix at the end of the volume professing to give a bibliography of the already large literature on the Eros campaign, but containing no reference to the *Monthly Notices* or other English work. Is not this rather a strange oversight?

H. H. TURNER.

NOTES.

BRITISH science has been honoured by the award of the Nobel prize for physics to Lord Rayleigh, and the prize for chemistry to Sir William Ramsay, K.C.B., F.R.S. Prof. Pavloff, of the Military Academy of Medicine at St. Petersburg, has been awarded the prize for physiology. The distribution of the prizes took place at Stockholm on December 10 in the presence of King Oscar and the Royal Family, foreign ministers and members of the Cabinet, and many leading representatives of science, art, and literature. After speeches had been delivered by the vice-president and other representatives of the Nobel committee, and of the Academies of Science, Medicine, and Literature, King Oscar personally presented Lord Rayleigh, Sir William Ramsay, and Prof. Pavloff with their prizes, together with diplomas and gold medals. The sum of money attaching to each prize amounts to about 7825*l*. The distribution of the prizes was followed by a banquet, at which the Crown Prince presided; and among the company were Prince and Princess Charles, Lord and Lady Rayleigh, Sir William and Lady Ramsay, and M. and Mme. Pavloff. Count Mörner proposed the health of Prof. Pavloff, Prof. Petterson that of Sir William Ramsay, and Prof. Hasselberg that of Lord Rayleigh. On Monday Sir William Ramsay delivered a lecture on argon and helium at the Academy of Sciences, and King Oscar gave a dinner party to the prize winners. On Tuesday Lord Rayleigh delivered a lecture at the academy on the density of gases. Both lectures were highly appreciated and greatly applauded. It is announced that Lord Rayleigh proposes to present to Cambridge University the value of the Nobel prize for physics awarded to him.

SIR NORMAN LOCKYER, K.C.B., F.R.S., has been elected a corresponding member of the Imperial Academy of Sciences at St. Petersburg.

THE Lavoisier gold medal, which has been awarded by the French Academy of Sciences to Sir James Dewar, F.R.S., for his researches on the liquefaction of gases, was founded in 1900, to be given, without distinction of nationality, at such times as the French Academy should elect in recognition of eminent services rendered to chemistry by scientific men. The present is the first occasion on which the medal has been awarded to a British man of science.

THE Wislicenus memorial lecture will be delivered before the Chemical Society by Prof. W. H. Perkin, F.R.S., on Wednesday, January 25, at 8.30 p.m.

MR. A. SILVA WHITE, formerly secretary to the Royal Scottish Geographical Society, and editor of the *Scottish Geographical Magazine*, has been appointed assistant secretary of the British Association, and has already taken up the duties of the post.

PROF. BOYCE, of Liverpool University, has proposed to the Liverpool Chamber of Commerce a scheme for the establishment of a commercial museum and bureau of scientific information. The object is to correlate the various scientific forces in the city in order to utilise them for commercial advantage. The scheme has been referred to a committee of the Chamber of Commerce.

ON the invitation of the director, Dr. J. J. Dobbie, F.R.S., and Mrs. Dobbie, a large and representative gathering assembled in the Royal Scottish Museum, Edinburgh, on Monday evening, December 12, to celebrate the jubilee of the museum. The museum embraces three departments—natural history, art and ethnography, and technology, under their respective keepers, Dr. Traquair, F.R.S., Mr. D. J. Vallance, and Dr. Alex. Galt. In the natural history department the collection of fossil fish is one of the most important in the world. Other special features of this department are the hall of British zoology and the zoological type collection, the aim of the latter being to illustrate the bearing of comparative anatomy on the classification of the animal kingdom. The ethnographical collection is one of the most extensive of its kind, and contains many specimens brought home by explorers of the end of the eighteenth and early part of the nineteenth centuries. The technological department contains a large and fine collection of machine and engineering models, most of them made in the museum workshops, together with mining and metallurgical specimens and models. There is also a large collection of economic botany attached to this department. The collections of H.M. Geological Survey of Scotland are housed in the museum, and with these is associated the Heddle-Dudgeon collection of Scottish minerals, which has been described as the finest collection of the minerals of any one country in existence. The museum is supported by a Parliamentary grant, and is under the Scotch Education Department, which was represented at the conversazione by Sir Henry Craik, K.C.B., and Mr. Macdonald, assistant secretary.

A MEETING was held in the geological lecture theatre of the Owens College, Manchester, on December 8, at which it was resolved to establish a Manchester University Geologists' Association. The object of the association is to afford a centre of social reunion for the discussion of geological subjects. Prof. Boyd Dawkins was elected president, Mr. B. Hobson and Mr. Winstanley vice-presidents, Mr. W. J. Hall secretary, and Mr. O. B. Leigh treasurer.

A SHORT time ago Dr. Doyen claimed to have discovered the microbe of cancer, and to have prepared with it a curative serum for the disease. A committee was appointed to investigate Dr. Doyen's claims (see NATURE, October 27, p. 631), and, according to the daily Press, has now reported favourably on them. The *Standard's* correspondent telegraphs, however (December 14), that the committee has not yet arrived at any conclusion.

ON the recent retirement of Sir William Macgregor from the Governorship of Lagos, the Liverpool School of Tropical Medicine decided to mark its appreciation of his valuable services to the cause of health and sanitation by raising a fund, to which Sir Alfred Jones contributed 500*l*. and Mr. John Holt 200*l*. It has been decided to expend this fund on two medical expeditions to the west coast of Africa, one in charge of Prof. Boyce, who, with Dr. A. Evans and Dr. H. H. Clarke, sailed from the Mersey on Wednesday, the other under Colonel Giles. These expeditions will study the various health problems presented by the districts they visit, the distribution of biting insects, and related matters.

A DEMONSTRATION of the Pollak-Virag high-speed writing telegraph was given on December 9 at the Carlton Hotel in the presence of the Austro-Hungarian Ambassador. The Pollak-Virag high-speed telegraphic system was described upwards of three years ago in a detailed article published in NATURE for May 2, 1901, and readers may be referred to that account for particulars of the instruments used. Very high speeds—reaching 100,000 words an hour—were reported as having been attained in America in 1901 by this system, using several perforating machines to prepare the message being sent; but it now appears that these estimates were too high. The postal authorities in Hungary in recent experiments carried out between Budapest and Pozsony, a distance of some 218 kilometres, with two copper telephone wires of 3 mm. diameter, secured the transmission of 45,000 words an hour. In another series of experiments, conducted between Berlin and Königsberg, a maximum transmission of 40,000 words an hour was attained over a distance of 710 kilometres with wires 4·5 mm. in diameter. It is stated that our Post Office department is about to carry out some trials of the Pollak-Virag system.

THE performances of an intelligent horse—"Clever Hans"—at Berlin two or three months ago attracted much attention. In a letter which appeared in NATURE of October 20 (vol. lxx. p. 602) the Rev. J. Meehan pointed out that the performances of the horse were much the same as those of the horse "Mahomet" shown at the Royal Aquarium twelve or thirteen years ago, and depended entirely upon the animal's observation of movements of the trainer or the tones of his voice. Much the same opinion has been reached by a commission of psychological experts, headed by Prof. Stumpf, of Berlin University, that has subjected "Clever Hans" to a scientific examination. The conclusion arrived at is that the horse is not capable of independent thought. According to the Berlin correspondent of the *Daily Chronicle*, Prof. Stumpf found that this horse is gifted with remarkable powers of observation, which four years of patient and skilful treatment have developed. When asked a question "Hans" knows he has to beat with his hoof in reply, but he does not know when to cease beating until he detects some movement on the part of the person questioning him. The commission expresses the opinion that, so far as Herr von Osten, the owner, is concerned, these movements are given involuntarily, and are sometimes of so imperceptible a nature as to be undetected, save by highly trained human observers. There has been no trickery, says Prof. Stumpf, but, on the other hand, there have been no reasoning powers on the horse's part. The whole secret is in von Osten's skill, patience, and judicious reward, and, on "Hans's" part, in keen powers of observation.

VISITORS to the Zoological Gardens in the Regent's Park will miss the old Indian rhinoceros "Jim," which had been a denizen of the menagerie since July 25, 1864, on which date it was presented to the society by the late Mr. A. Grote. It died on December 7, after having been out of health for many months. Such a long sojourn in captivity in this country is probably unparalleled for an animal of this kind. As a statement has appeared in the Press that the skin might perhaps be mounted in the British (Natural History) Museum, it may be well to state that His Highness the Maharaja of Kuch-Behar recently presented the skin of a wild specimen of the great Indian rhinoceros to the museum, which has been set up, and is exhibited. The "Zoo" specimen will therefore not find a home in the national collection.

THE December number of the *Century Magazine* contains a most interesting account, by Mr. G. H. Grosvenor, of the new method of purifying water—both in small quantities and when stored in large reservoirs—by means of blue vitriol (copper-sulphate). It has long been known that copper is fatal to bacteria, but the fear has hitherto been that the amount required to effect the destruction of such organisms would likewise be injurious to man. Dr. G. T. Moore has, however, announced in an American official publication that he can employ copper in such a diluted form as to be quite harmless to the higher forms of animal, and yet sufficiently potent to destroy the germs of cholera and typhoid, as well as mosquito larvæ, in a few hours. The method of introducing the copper-salt into the water is fully explained in the article. It may be added that the treatment is stated to be equally efficacious and safe for sterilising milk. As an illustration of the effects of copper in destroying bacteria, it is mentioned that such organisms are never found on copper coins, although abundant on those of silver, and it is mentioned that artisans in copper-works are immune to bacterial diseases. Whether we have been wise in abolishing the old-fashioned copper tea-kettle is one of the questions raised by the new operations.

THE discovery of the existence of an anterior rudimentary pair of gills in the Continental fresh-water crayfish *Astacus fluviatilis*, which is not present in the common *A. pallipes* of the Thames, was described by Prof. Lankester in NATURE of January 21 (vol. lxix. p. 270), and is recorded in the November issue of the *Quarterly Journal of Microscopical Science* by Miss M. Moseley, who appears to have inherited her father's love for biological studies. The other four papers in the same number are of a very technical nature, the longest and perhaps the most important being a detailed account by Mr. J. W. Jenkinson of the maturation and fertilisation of the egg of the axolotl (*Amblystoma tigrinum*). More general interest attaches, however, to the article by Prof. L. Rogers on the development of flagellated organisms or trypanosomes from the protozoic parasites found in the spleen in cases of cachexial fevers and certain other diseases. Of the two remaining articles, the one by Dr. J. Rennie discusses the so-called epithelial islets in the pancreas of bony fishes, while the second, by Dr. H. G. Fowler, is devoted to the description of the anatomy of a radiolarian of the genus Gazeletta.

IN an article entitled "A Flamingo City," which appears in the December number of the *Century Magazine*, Mr. F. M. Chapman, of the American Museum of Natural History, gives a graphic and well illustrated account of one of the great breeding-places of the American flamingo in the Bahamas. Although previous observers, both in those islands and in Europe, have published descriptions of flamingo colonies, and have refuted the old error that the birds sat straddle-wise on their nests, the author claims to be the first to have seen nestling flamingoes in their native haunts, and likewise to have brought the camera to bear on one of the breeding-places of these birds. Flamingoes, as Mr. Chapman remarks, are more brightly coloured than any other large bird, and their gregarious habits and the open nature of their resorts are admirably suited to bring their gorgeous hues into prominence. The visit to the nesting-grounds was made at the latter end of May, when both eggs and young birds were to be found in the nests.

At first the birds—estimated at 2000 in number—rose in a flock, and fears were entertained that they would permanently forsake their nests, but after a time—despite the erection of a "blind" for the camera—they returned in a body. The sight of such an army of large birds, both in flight and when marching, is described as magnificent and imposing, if not, indeed, appalling. The young remain in the nest for about three days, and for the first three weeks after leaving it feed like ordinary birds. By that time, however, the beak has attained its characteristic flexure, and the young birds then search for their food with the lower mandible upwards. Molluscs of the genus Cerithium form almost the sole food of the Barbados species. It is sincerely to be hoped that a movement to prevent these "rookeries" from being raided by the plumage-hunter will be attended with success.

In vol. iv. of the *Bulletin* of the Imperial Botanic Garden at St. Petersburg, Mr. J. Palibin describes the plankton which he collected in Barents Sea, and also gives a historical *résumé* of other collections made in the Arctic Ocean. In a series of letters Mr. Boris Fedtschenko communicates the botanical observations made during a journey through the Sir Daria region of Turkestan.

In a pamphlet entitled "Notes on the Commercial Timbers of New South Wales," Mr. J. H. Maiden describes the principal woods, their characters, and uses. The information is primarily suited to practical men who supply or use timber in the colony. The majority of the timbers are hard woods, and different species of Eucalyptus give ironbarks, stringy barks, varieties of box, mahogany, and gum. The timbers recommended in lieu of pine are white beech, *Gmelina Leichhardtii*, a genus of the order Verbenaceæ, and red cedar, *Cedrela australis*, and rosewood, *Dysoxylon Lessertianum*, both included in the Meliaceæ.

The establishment of "biologic forms" of species of Erysiphaceæ and Uredineæ is based upon the restricted powers of infection of the spores upon allied species of the host plant. But the immunity of a species of the host plant is not absolute, because, as pointed out by Mr. E. S. Salmon in No. 3 of vol. ii. of the *Annales Mycologici*, another host plant may act as a bridging species. Thus the form of *Erysiphe graminis* which grows on *Bromus racemosus* will infect *Bromus hordeaceus*, but will not infect *Bromus commutatus*, although the spores found on *Bromus hordeaceus* will infect *Bromus commutatus*. If spores from *Bromus racemosus* are sown on *Bromus hordeaceus*, then the spores produced on *Bromus hordeaceus* as a result of that sowing are found to be capable of infecting *Bromus commutatus*.

The daily weather report issued by the Meteorological Office on Tuesday, December 6, showed that on the morning of that day the winds and sea in the Channel were still very heavy, and, further, that a rapid fall of the barometer at Scilly pointed to the approach of a fresh disturbance. This storm developed very rapidly, and by 2h. p.m. a deep disturbance lay over Dorsetshire, and another to the north of the Helder. These disturbances were accompanied by very heavy rainfall, amounting in twenty-four hours to 2·25 inches at Cuxhaven, 1·25 inch at St. Aubins (Jersey), and 0·94 inch in London, while severe thunderstorms occurred generally in Devon and Cornwall. Much damage to property is reported from various districts, and in parts of Dorsetshire a veritable tornado occurred; rain and hail fell in torrents, accompanied by heavy thunder and lightning. At Beaminster roofs and trees suffered severely; the path of the storm was well defined, and, as is usually the case in these local whirlwinds, was limited to a very small area. The region of heavy rainfall over the country generally was sharply defined on its northern side; at Nottingham and Spurn Head no rain was reported to the Meteorological Office on the morning of December 7.

A volume of monthly wind charts for the South Atlantic Ocean, prepared by the marine branch of the Meteorological Office, has just been published by the Hydrographic Department of the Admiralty. The region covered extends from the equator southward to the 65th parallel, and from the 20th meridian of east longitude to the 90th of west longitude, so that a portion of the Pacific is included. Nearly a million sets of observations, extending over a period of forty-five years, have been used. The winds have been discussed in areas of 5° of latitude by 5° of longitude, and the results are exhibited by means of roses showing the relative frequency and strength at the sixteen even points of the compass. The distribution of mean atmospheric pressure is shown by means of isobaric lines, and the mean air temperature by isotherms, while along the African and American coasts are numerous notes bearing upon the characteristic climatic features of the various months. A striking feature on every chart is the area of high barometric pressure covering the whole of the area between Africa and the east coast of America, its central space being usually more on the western side of the ocean, as is the case with the anticyclone of the North Atlantic. The wind circulation of the South Atlantic is associated with its dominating high pressure system. On the eastern and northern portions of the ocean the south-east trade is very constant, is never interrupted by storms, nor attains the force of a gale. On the western side the winds are more variable, but gales are very rarely experienced northward of the 35th parallel. Except near the land fogs seldom occur northward of the 30th parallel, and the south-western part of the ocean is the only region where ice is ordinarily met with. Statistics of the rainfall at a number of places within the area of the charts show that the annual amount ranges from 0·31 inch at Walfisch Bay and 1·54 inches at Serena (Coquimbo) to 93·41 inches at Pernambuco and 100·63 inches at Valdivia. It may be recalled that at the Cambridge meeting of the British Association Commander Hepworth read a paper on the results of the discussion of the observations for these charts.

In No. 22 of the *Physikalische Zeitschrift* Messrs. Elster and Geitel reply to Mr. J. R. Ashworth's recent letter to Nature (vol. lxx., p. 454) suggesting that the human breath may be considered as a source of the ionisation of the atmosphere. Their measurements of the conductivity of air charged with ordinary human breath show that such air is not more conducting than ordinary air. On the other hand, the breath of a person who has been working continually with radium preparations has decided ionising power, and the nature of the ionisation shows that it is due to the emanation of radium.

Nearly all the physicists who have been approached hitherto by the *Revue Scientifique* in the course of its inquiries as to the existence of the *n*-rays have unequivocally stated their inability to observe the effects which these rays are alleged to produce. It is therefore particularly interesting to note in the *Revue* for November 26 that M. D'Arsonval has been able to reproduce these effects in many instances, and to show that they are not due merely to thermal causes. M. Mascart is stated jointly to have observed with him the same phenomena. M. Poincaré, although himself unable to verify the existence of the radiations, adversely criticises Prof. Wood's objections. M. Weiss, from his failure to observe the rays, simply concludes that he was physically unfitted for such observations.

PART xii. of the *Transactions* of the Royal Dublin Society consists of an investigation by Mr. Richard J. Moss of the state in which helium exists in pitchblende. The total quantity of helium in a sample of pitchblende was 0·107 c.c. per gram, and of this 1·17 per cent. was liberated by simply grinding the mineral in a vacuum. The quantity of carbon dioxide separated by completely decomposing the mineral was 4·686 c.c. per gram, of which only 0·0085 per cent. was obtainable by grinding. As a similar proportion of the total occluded carbon dioxide can be separated from calcite, in which the gas is undoubtedly present in minute cavities, by simply pulverising the crystals, it is probable that the whole of the carbon dioxide of pitchblende, and possibly the helium also, are present similarly occluded. It is evident that the proportion of the gases liberated by roughly grinding must necessarily be only a small proportion of the total volume.

THE Christmas number of *Photography*, published by Messrs. Iliffe and Sons, Ltd. (1*s*. net), is restricted to many kinds of work with the camera which can be accomplished indoors during the winter months. It might be said further to deal with the lighter side of photography as well, as will be judged by reading the second portion of this number. Part i., by Mr. C. J. Harrison, deals with the working up of negatives and prints for the removal of mechanical and other defects from negatives. The methods and dodges employed are, as the author states, the outcome of his own experience, but nevertheless they are interesting reading, and may prove serviceable to many photographers. The illustrations accompanying the text and chosen to represent various stages of these methods are also well worth examination. In part ii. Mr. W. L. F. Wastell discourses on bye-paths of photography. Here the reader is made acquainted with methods for producing what may be termed "freak" photographs. Thus we have illustrated examples of the so-called "spirit" photograph, distortions due to the object being too near to the camera, two images of the same person in one picture, combination portraits, silhouettes, and many others of a similar character. The supplement to this number consists of designs, covering sixteen pages, of photographic mounts to serve as Christmas cards.

THE articles in the October number of the Johns Hopkins Hospital *Bulletin* (xv., No. 163) are mainly of medical interest. Dr. Packard, however, writes an interesting account of some famous quacks, including Valentine Greatrakes, who claimed the healing touch for the King's evil in the seventeenth century, no other than Robert Boyle testifying to his powers; Joshua ("Spot") Ward, who discovered a cheap way of making oil of vitriol; and John St. John Long, who devised a famous liniment which possessed not only curative powers, but also revealed hidden disease, and from his practice is said to have derived 13,000*l*. a year.

MR. W. B. CLIVE has published a revised and enlarged edition of "First Stage Building Construction," by Mr. Brysson Cunningham.

MESSRS. DAWBARN AND WARD, LTD., have published in their "Home Worker's" series a booklet by Mr. R. H. S. Williams with the title "How to Build a Bicycle," and one on "How to Build a Petrol Motor," by Mr. J. F. Gill.

THE separate parts (parts i.–vi.) of "A School Geometry," by Messrs. H. S. Hall and F. H. Stevens, which have been reviewed in these columns from time to time, have been published together in one volume by Messrs. Macmillan and Co., Ltd., at 4*s*. 6*d*.

A FOURTH edition of Prof. Olof Hammarsten's "Textbook of Physiological Chemistry" has been published by Messrs. John Wiley and Sons, New York (London: Messrs. Chapman and Hall, Ltd.). This issue is an authorised translation by Prof. John A. Mandel from the author's enlarged and revised fifth German edition.

THE 1904 issue of the "Year-book of the Scientific and Learned Societies of Great Britain and Ireland" has now been published by Messrs. Charles Griffin and Co., Ltd. This is the twenty-first annual issue of a useful list of organisations for the advancement of science, literature, and art, and of work done year by year. Comprehensive as the compilation is, it is not quite complete, for there appears to be no reference either to the Sociological Society or to the Geographical Association.

Erratum.—In the inscription of Fig. 5 (p. 135) of the article on "Invar" in last week's NATURE, "a 2 km. wire" should read "a 24 m. wire."

OUR ASTRONOMICAL COLUMN.

RELATIONS BETWEEN SOLAR AND TERRESTRIAL PHENOMENA.—In a paper communicated to the Royal Society of New South Wales, Mr. H. I. Jensen, of Sydney University, discusses the more recent data concerning sun-spot frequencies and the occurrence of volcanic outbursts, earthquakes and climatic variations, with the view of illustrating further the dependence of the terrestrial upon the solar phenomena.

In a previous paper communicated to the same society in June, 1902, he arrived at the conclusion that the maxima of volcanic and seismic activity coincided, in point of time, with the sun-spot minima, but the discussion of the later data has led him to a confirmation of the views expressed by Sir Norman Lockyer, viz. that the maximum activity of the terrestrial takes place at both the minima *and the maxima* of the solar phenomena. His observations show, however, that the action at sun-spot maxima is less marked than, and of a different character to, that which takes place at the minima.

The differential action of lunar attraction is also discussed, and although the author concludes that this cause is only one of secondary importance, he shows that volcanic outbursts and earthquakes seem to occur most frequently at those times when the moon is in perigee.

In discussing the connection existing between solar and meteorological variations, Mr. Jensen refers to the work performed in this direction by Sir Norman and Dr. Lockyer, and in general agrees with their results, although he inclines to the belief that the epochs of sun-spot *maxima* are generally the epochs of excessive rainfall. Further, he strongly insists upon the necessity of attaching more importance to geographical position when considering the prevailing meteorological conditions of any place (*Proc.* Roy. Soc. New South Wales, vol. xxxviii.).

SUN-SPOT SPECTRA.—In No. 4, vol. xx., of the *Astrophysical Journal* Father Cortie brings together the results of all the sun-spot spectra observations made at the Stonyhurst College Observatory during the period 1883–1901.

Using a Browning automatic spectroscope containing twelve 60° prisms, the widened lines in the region B–D of the solar spectrum were picked out, and the intensity of their relative widening recorded on an arbitrary numerical scale. The present catalogue results from 5486 individual observations of 349 lines, and the results generally confirm the observations made at South Kensington as recorded by Sir Norman Lockyer in a paper ("On the Relation between the Spectra of Sun-spots and Stars") recently communicated to the Royal Society, viz. that vanadium and titanium are the elements chiefly affected in sun-spot spectra.

Father Cortie states that the widening of some oxygen lines in sun-spot spectra, particularly in the α band, seems to be a real phenomenon.

ECLIPSE OBSERVATIONS.—Vol. iii. of the *Annalen* of the Royal University Observatory of Strassburg, edited by Dr. E. Becker, the director, contains the results of the heliometer observations of the total solar eclipse of May 28, 1900, and of the lunar eclipses which took place on January 28, 1888, May 11, 1902 (partial eclipse), and April 11, 1903, respectively.

In the first part Prof. Kobold gives the results of a number of observations made in order to determine the reduction elements of the heliometer, and then applies them to the observational results obtained during the solar eclipse of 1900. Finally, he gives the corrections to the previously determined positions. In part ii. the same observer discusses the observations of the 1888 and 1892 eclipses of the moon, and gives the values obtained for the radius of the earth's shadow, &c., finally comparing them with the calculated values.

In the third part Herr C. W. Wirtz discusses the observations of the lunar eclipse of April 11, 1903, including the corrections to the moon's place, the figure and size of the earth's shadow, and the variations of the diameter of the crater Linné during the eclipse. The curve on which are plotted the values of the last named quantity shows a considerable increase in the diameter during the approach of the earth's shadow to the crater, the maximum value evidently occurring during the actual eclipse of Linné.

THE APPEARANCE OF SPARK LINES IN ARC SPECTRA.—An interesting discussion of the conditions which lead to the appearance of "spark" lines in arc spectra is published in No. 4, vol. xx., of the *Astrophysical Journal* by Dr. Henry Crew, of the North-western University, Ill. Dr. Crew made a number of experiments in which the Mg line at λ 4481 appeared in the arc spectrum, and examined the arc, simultaneously, with a Rowland grating spectrograph and a Duddell high-frequency oscillograph.

The various conditions under which the arc was produced were as follow:—(1 and 2) current with negligible and with large amount of inductance respectively; (3) arc broken by air blast; (4) arc in atmosphere of coal gas.

The reproductions of the oscillograph curves show the current conditions during each experiment, and from a discussion of the results Dr. Crew arrives at the following conclusions:—(1) A rapidly changing, high E.M.F. is a probable *conditio sine qua non* for the appearance of spark lines in arc spectra. (2) The effect of hydrogen and other atmospheres in introducing spark lines is explained by the fact that these atmospheres produce a more rapid break, and this, in turn, introduces an extra E.M.F., which in some way, as yet unknown, is responsible for the radiation of the spark line. A possible explanation of the stellar conditions which produce spark lines in the spectra of stars is also discussed.

THE ROYAL ASTRONOMICAL SOCIETY OF CANADA.—Founded as the Astronomical and Physical Society of Toronto, the name of this society was changed in 1900 to that of the Toronto Astronomical Society. In 1903 it was decided to change its name to the Astronomical Society of Canada, and in response to a petition the privilege of prefixing the word "Royal" to its name was granted, so that the full title of the society is now the above heading. We hope that this now national society will be a stimulus to the promotion and diffusion of astronomical science, and that its influence will be greatly extended. We have before us the volume containing the selected papers and proceedings for the years 1902 and 1903, edited by A. Harvey; the varied topics there dealt with bid fair for the future of the society. Among some of the papers may be mentioned the address of the president, R. F. Stupart, director of the Magnetic and Meteorological Observatory of Toronto, in which is an account of the history and work of the institution. W. H. S. Monck gives a catalogue of aërolites, arranged in order of the months in which they fell. There is a brief account of the present astronomical equipment of Canada as a whole, and a discussion on papers dealing with solar phenomena and terrestrial effects. The volume concludes with an account of women's work in astronomy, by Miss E. A. Dent.

THE FIRST TRUE MAPS.

IN the history of cartography, in the development of maps and map-making, there is perhaps nothing quite comparable to the first appearance of the "portolani" or "handy charts" at the close of the thirteenth and the beginning of the fourteenth century. For the portolani, the first true sea-charts, are also the first true maps of any kind—the earliest designs in which any part of the earth-surface is laid down from actual observation of close and continuous character.

By the term "portolani" we intend, of course, to refer to that great series of coast-plans of which the earliest known examples belong to the first decade of the fourteenth century (A.D. 1300–1310); which are traceable to a very few, perhaps to two or three (now lost), originals; which may be extended to cover at least 500 designs (reaching down to the end of the sixteenth century); and were primarily intended to serve as practical guides to mariners and merchants in the seaports of the Mediterranean and Black Sea.

These plans of practical navigators—of men whose livelihood largely depended on their knowledge of nature and their close observation of natural features—are a remarkable contrast, in their almost modern accuracy, to the results of the older literary or theological geography as we have them in the Hereford or Ebstorf maps (both of the very same period as the oldest existing portolans, *c.* A.D. 1300). They have never yet received adequate attention from English geographers (as from Nordenskjöld the Swede, Fischer the German, or Uzielli the Italian), and the problem of their sudden appearance in such comparative perfection is surely deserving of more study, and capable of fuller explanation, than it has yet received. Certain assumptions may perhaps be made without danger. The portolano type was not the invention of one man, of one year, of one decade. It did not spring from any school or any example of mediæval student-map. It was the final result of centuries' experience—the outcome of the notes, plans, and oral tradition of generations of pilots and captains. Skipper-charts of certain important and much-frequented sections of the coast trade-routes were probably combined, by slow degrees, into a coast-chart of the Mediterranean basin as a whole. It may be that the sketches of small portions of shore-line which we have in fifteenth century manuscripts of Leonardo Dati's poem "La Sfera" are really copies, but slightly modified, of such old skipper-charts—reaching back, perhaps, to the eleventh century, and forming the very earliest indications of that new scientific geography in which the compass played so great a part. If this surmise is correct, the opening of the mediæval Renaissance, in the generations immediately preceding the Crusades, was accompanied by the oldest embryonic forms of modern cartography.

Once more, it may be that the sea-chart which is mentioned in connection with the Seventh Crusade (of A.D. 1270), and which St. Louis apparently employed to aid his attack on Tunis, was a portolan, or a sectional chart of the North African coast of portolan type. It may be that the *charta* noticed in Raymond Lulli's "Arbor Scientiæ" (about A.D. 1300) as necessary for sailors—along with the compass, needle, and "star of the sea"—was a work of the same kind. It may be that Andrea Bianco's planisphere of 1436 is a re-edition of a "handy-map" of the thirteenth century. But the oldest certain examples of the type we are concerned with, which have been discovered up to the present, are the *Carte pisane* and the first design of Giovanni de Carignano, both belonging to the opening years of the fourteenth century, while the oldest dated portolan is the first of Pietro Vesconte (or Visconti), executed in 1311.

And when, with these and the next few examples, we get at last our full coast-chart of the Mediterranean basin, what is its character?

It is a map without graduation, embracing only the coast lines and the towns and natural features in the immediate neighbourhood of the coast. But though it is restricted, it has extraordinary merits in its own field. Its delineation of the shores of the *Mare Internum*, from the Straits of Gibraltar to the extreme east of the Black Sea, is markedly superior to anything of earlier date—even to the Madaba mosaic of the sixth century or to Matthew Paris's thirteenth century "England." The chief errors which Ptolemy had imparted to the shape of the Mediterranean are corrected. The main features of the great inland sea are presented with a correctness and a minute detail which, at the most casual glance, immediately distinguish portolan work from any preceding variety of cartography. No attempt is made to fill up the interior of the lands—continental or insular—of which the coasts are portrayed; such attempts are made later, it is true, but they are obvious and confessed additions to the primitive, normal, or typical portolan. But, along the shores in question, all points important for navigation are drawn with great care; small islands, bays, cliffs, and headlands—of no great general importance, but vital to the coaster—are often depicted in disproportionate size; all the ports especially suitable for calling, watering, and revictualling are indicated with the especial honour of *red* colouring; even shallows are frequently marked, denoted by a sign still used at the present day; the very large number of shore-names testifies to the minute knowledge underlying the work. Thus along the north coast of the Mediterranean we have (by A.D. 1320) about 620 names; on the coasts of the Black Sea and Sea of Marmora about 260; on the coasts of Asia Minor and Syria about 160; on the north coast of Africa about 240; in all some 1280, without counting island names—which are very numerous—or the names which fringe the western coast of Europe to the mouth of the Elbe, and the western coast of Africa to Cape Nun, or Non, at the extreme south-west of Morocco. In respect to these shores—let us say from Hamburg almost to the Wady Draa, and from Gibraltar to Azov, Poti, Batum, Alexandretta, Jaffa, and the Nile—the portolani soon become fixed in the pattern they permanently retained, a pattern which gradually triumphs over every other—even the revived Ptolemaic, to which scholars clung so desperately and so unhappily. We may therefore regard the great mass of these works as mere copies of a few normal or typical designs which were completed (at least in all their essential parts) before the outbreak of the Hundred Years' War, and a good twenty years before the battle of Crecy. How closely the original type was followed may be guessed from the fact that the portolan *colours*—used according to certain definite rules—are unaltered for long periods of years, and through scores of examples. Thus red or reddish-brown is always kept for the Red Sea, and long after the Turkish conquest of Rhodes that island regularly appears in white with a black cross.

Instead of lines of latitude and longitude (or substitutes for such lines, as we find in the "Palestine" of Marino Sanuto, *c.* A.D. 1310), a net of loxodromes is employed on (or has, at any rate, been added to) the portolani even of the earliest time. These loxodromes are straight lines in the direction of the various winds, proceeding from a number of crossing-points regularly distributed over the map. But in this loxodrome net-work, in sharp contrast to all other features of the portolan map-type, there is almost infinite variation; one seldom comes across two designs of exactly similar character in this respect.

A distance-scale, with the same unit of length, occurs on all the portolani; this unit (which has been called the *portolan mile*) is estimated with much care by Nordenskjöld at 5830 metres; while of all known mediæval measures, that which corresponded most nearly with the "portolan mile" seems to have been the Catalan *legua*. A Catalan league therefore, it is suggested, may have furnished the basis of the portolan measure, and the portolan type of map may have originated (in part at least) among Catalan mariners.

Baron Nordenskjöld, indeed, does not hesitate to ascribe to the portolani an entirely Catalan parentage. But, admitting that one germ of the first true maps may have existed at Barcelona or some other centre of Catalonian trade and seamanship, I cannot but think that another germ still more active and important was to be found in Italy, and above all in the north-west—in Genoa and Pisa. For, remembering the indications in Dati's "Sfera," we may agree with Theobald Fischer that map sketches of portolan type, and with the practical object of helping navigation, were almost certainly drawn *in Italy, and by Italians,* before 1300. Remembering, also, that of the existing portolani all the earliest examples are unquestionably Italian—and that, of some 500 known, 413 were executed by the countrymen of Carignano and Vesconte—we shall not be ready to deprive Italy of the first place in the creation of the oldest scientific maps. Even if that creation was, as seems probable, an "Homeric" feat—the piecing together (with additions and improvements) of a great number of small sectional coast-surveys—yet this earlier stage, only recorded in Italian manuscripts, seems no less due to the seamen of the peninsula.

Can we throw any other light upon the origin of the portolani?

In 1881 Fiorini suggested that West-European mariners, such as those of Italy, learnt from the Byzantines the art of making and using maps founded on careful draughtsmanship and close study of distance (*i.e.* portolani of a kind) as early as the eleventh century. This idea has been accepted by Theobald Fischer, and has been treated with great respect by other scholars. Yet it is surrounded by difficulties. For no Greek portolan has yet been found, nor is Greek influence anywhere to be detected in the language, legend-allusions, contours, or other details of the early portolani. Fragments of Latin, fragments of Italian and Catalan dialects, fragments of a *lingua franca* composed of various Romance tongues—these are the media through which the early portolan draughtsmen convey information. But of Greek they make no use, and of Byzantine geography, history, harbours, or coast routes they show no *special* knowledge. We may give weight to the fact that the Byzantine navy was one of the chief Christian weapons in the ninth, tenth, and early eleventh centuries; that Constantinople was then the greatest trade centre in Christendom; and that the seamen of the Greek islands were very prominent in Mediterranean navigation in the age of the Byzantine revival (*c.* 860–1060 A.D.). But all this is far from proving a Byzantine right to the "invention" of the portolan coast-chart,[1] even in the primitive form of sectional pilot-maps of limited areas.

It only remains to say that all genuine progress in geographical delineation followed the lines of the portolani; that the accurate methods employed by them for coast-work were gradually applied to the interior of countries; that in spite of the contempt shown for them by most of the learned in the so-called Renaissance period, they were at last known by their fruits and vindicated by the success of their type.

Ancient classical or pre-Christian maps were not without certain merits, though we can only judge of them by the two remaining examples, the Peutinger table, originally a road-map of Augustus's Empire, and the designs illustrating the "Geography" of Claudius Ptolemy of Alexandria—both surviving only in manuscripts of the central mediæval period. After the modern age of oceanic discovery had passed through its earliest and most difficult stages, the Renaissance editions of Ptolemy (from 1474) played a very important part in delaying geographical progress and retarding the history of civilisation. But in the time of the early portolani (say from 1300 to 1400) neither the work of the Alexandrian astronomer nor the road-maps of the Roman Empire were adequately known in western Europe. The sixteenth and seventeenth centuries were not so innocent.

Designs of the portolan type do not seem to have existed even in the best ages of classical geography and exploring activity; the old *peripli* were sailing directions, not drawn, but written; and the only Arabic scheme of the sort which has yet been found is certainly copied from a Christian—and Italian—original.

It is in the portolani, and especially in such a work as the Laurentian design of 1351, with its revelations of the Azores and the Madeira group, and its still more startling suggestion of the true shape of Africa, that we may find, perhaps, the chief geographical teachers of Henry the Navigator and his Portuguese. Never better than in these long-neglected charts does the history of civilisation illustrate man's change from empirical to scientific, from traditional book-learning to the investigation of nature. The portolani long

[1] To Nordenskjöld's wild theory, "Facsimile Atlas," p. 48, that Marinus of Tyre is the real original portolan draughtsman, and that the Marinus maps which Masudi saw before A.D. 956 were really portolani, we need not pay attention.

suffered, in general appreciation, from the fact that—in their essential features—they never attempted to gratify popular taste; that they did not, with rare exceptions, illustrate[1] the works of fashionable writers, whether classical philosophers or mediæval prelates; that they had no connection with the legends and dreams of chivalry and romance; that they were not the work of schools or courts; and that they owed nothing to Ptolemy or Strabo. But we know their worth better now.

They first record for us the new discoveries among the Atlantic islands and along the African mainland; they guide and accompany the faltering steps of our race in the outward, oceanic, movement of European life; in them true cartography, the map-making of the civilised world, begins.

C. RAYMOND BEAZLEY.

[1] Some of the atlases founded on portolani, such as the *Carte Catalane* of 1375, really illustrate the travels of the thirteenth and fourteenth centuries, *e.g.* Marco Polo's. But this is strictly in the way of explanation of a great eographic text.

GEOLOGICAL NOTES.

STATISTICS of mineral production in India in the ten years 1894 to 1903 have been issued by the Government of India (Department of Revenue and Agriculture, 1904). In the report for 1903 satisfactory progress in the mining industry is recorded. There has been a remarkable development in the production of petroleum and manganese ore, and a continuation of the progress previously recorded for coal and gold.

From the Geological Survey of India we have received part ii. of the newly re-issued *Records*. Mr. T. H. Holland, director, contributes a short appreciative memoir of the late General C. A. McMahon, and among other articles there is a well illustrated report by Mr. J. Malcolm Maclaren on the auriferous occurrences of Chota Nagpur, in Bengal. The conclusion is that there is little scope for the legitimate investment of capital in the recovery of gold, whether from the quartz veins or from the superficial deposits, but that the greater portion of the gold must be left to the native washer, "forming for him a reserve that, though it will never raise him to affluence, will always lift him beyond the grasp of famine." Two minerals, thenardite and cancrinite, are recorded for the first time from India. We have also received a report on the geology of Spiti, by Mr. H. H. Hayden (*Mem.* Geol. Surv. India, vol. xxxvi., part i.). Hitherto no systematic survey had been made of the region, and the results of this work, which was carried out by Mr. Hayden with the assistance of the late Dr. von Krafft, are depicted on a map to the scale of one inch to four miles, and further illustrated by some striking pictorial views and sections. The formations represented are Cambrian, Silurian, Carboniferous and Permian, Trias, Jurassic, and Cretaceous, with also intrusive rocks. The oldest sedimentary rocks belong to the Middle Haimanta division of Mr. Griesbach; they are unfossiliferous, and are overlain presumably by the Upper Haimantas, in which Lingulella and Olenus have been found. Lower and Upper Silurian rocks are recognised, and from these and the later formations many fossils are recorded.

The ammonite fauna of the Spiti shales forms the subject of a monograph by Dr. Victor Uhlig (*Mem.* Geol. Survey, India, ser. xv., vol. iv.). Only the first portion of this work has at present been issued, and in it the author deals with the genera and species of Ammonoidea. With regard to the classification, the author remarks that as no universally satisfactory agreement has yet been reached, he gives the descriptions of the various forms in unclassified sequence, while indicating their approximate position. In the course of his work he has studied as far as possible all the old as well as new material, and he has found it necessary to re-figure and describe many of the species previously published.

In mineralogical notes contributed by Mr. A. K. Coomaraswamy (*Spolia Zeylanica,* August), reference is made to the occurrence in Ceylon of thorium-bearing minerals, of corundum-sillimanite rocks, kyanite, serendibite, &c. The same author, in dealing with the geology of Ceylon (*Geol. Mag.*, August), proposes the name Balangoda group for a series of granitic and pegmatitic rocks intrusive in the Charnockite series. The group includes granites with zircon, allanite, magnetite, &c.

The summary of progress of the Geological Survey for the year 1903 contains the usual particulars of the field work which has been carried on in Cornwall, Derbyshire and Nottinghamshire, Carmarthenshire and Pembrokeshire, in various parts of Ross-shire and the western highlands, in the Edinburgh coal-field, and in the neighbourhood of Cork in Ireland. Special attention is directed to the discovery in Ross-shire of a rock essentially composed of magnetite and cassiterite—the occurrence of tin-ore being new; but it is stated that at present there is no reason to believe that the tin-bearing rock occurs in any large masses. In an appendix Dr. J. S. Flett contributes first notes on the petrography of western Cornwall, dealing with some of the garnetiferous greenstones, the granites and greisen veins, and the phenomena of contact alteration; Mr. H. B. Woodward writes on the Geological Survey in reference to Agriculture, with report on the soils and subsoils of the Rothamsted estate; and Mr. H. A. Allen continues the important catalogue of types and figured specimens of fossils in the Museum of Practical Geology, with a record of Oolitic Gasteropoda and Scaphopoda.

The general report and statistics on mines and quarries for 1903, part iii. (output), has been issued by the Home Office. The total value of the minerals raised during the year showed a decrease of $5\frac{1}{4}$ million pounds as compared with 1902—a decrease arising from the fall in price of coal. The total output of coal was the highest hitherto recorded. The outputs of ores of iron, copper, and lead show increase, while those of manganese, tin, and uranium ores show decrease.

In the *Proceedings* of the Bristol Naturalists' Society (n.s., vol. x., part iii.) Prof. Lloyd Morgan and Prof. S. H. Reynolds give particulars of the field relations of the Carboniferous volcanic rocks of Somerset. There is also an interesting article by Mr. W. H. Wickes on the Rhætic bone-beds, the author pointing out that there is no regular and persistent bed, but thin layers of varying extent occur on different horizons, due to the former presence and destruction of shoals of carnivorous fishes and saurians, while the occurrence of small pebbles in the bone-beds is attributed to the fact that large sea fish often have stones in their stomachs. Mr. H. B. Woodward contributes a memoir on the late Robert Etheridge, dealing more especially with his work in the Bristol area.

In the *Proceedings* of the Cotteswold Naturalists' Field Club (vol. xv., part i.) Messrs. J. W. Gray and G. W. S. Brewer direct attention to the evidence of a Celtic settlement on Cleeve Hill, prior to the Roman occupation of that part of the country; among the domestic animals were the horse, ox, sheep, pig, dog, and fowl. Mr. L. Richardson contributes an article on the Rhætic beds of Worcestershire.

A study of sands and sediments has been commenced by Mr. T. Mellard Reade and Mr. Philip Holland (*Proc.* Liverpool Geol. Soc., 1904). So far as their investigations have proceeded, they are led to believe that purely mechanical micro-sediments may constitute a much larger proportion of the rocks than has been hitherto suspected. Moreover, their experiments show the persistent retention of detrital carbonate of lime in extremely fine subsidence-matter, and suggest that deep-sea limestones may sometimes be formed as detrital accumulations.

The twenty-eighth annual report of the Department of Geology and Natural Resources, Indiana, under the direction of Mr. W. S. Blatchley, State geologist, is accompanied by an excellent geological map of the State on the scale of an inch to four miles, with explanatory descriptions by Dr. T. C. Hopkins and Dr. A. F. Foerste. The formations represented are Ordovician, Silurian, Devonian, Lower Carboniferous, and Coal-measures. The petroleum producing areas are specially marked, that industry having become one of the greatest in the State. Special reports are contributed on this and on the lime industry, and there is also an article on the stratigraphy and palæontology of the Niagara formation by Mr. E. M. Kindle, with twenty-five plates of fossils.

A comprehensive memoir on the geology and ore-deposits of the Bisbee Quadrangle, Arizona, by Mr. F. L. Ransome, appears as one of the "professional papers" of the United States Geological Survey (1904). This district became famous for its production of copper-ore in 1880, and was connected with the railway system as recently as 1902. Hence Mr. Ransome has found himself obliged to invent names—and pleasing ones of Spanish origin—for several topographic features. His plates show how the geological structure of the country can be read on many of the hill-sides with the clearness of a diagram; in several respects they remind one of the bare dry landscapes in the Mesozoic areas of the Basses Alpes. The fossiliferous beds include Middle Cambrian, Devonian (apparently conformable on these), Lower and Upper Carboniferous (both marine), and Cretaceous, resting unconformably on the preceding beds. The affinities of the strata are with those of Texas. The paper concludes with a discussion of the origin of the copper-ores, in which stress is laid on their concentration from cupriferous iron-pyrites, deposited in metamorphosed limestone.

In the *Proceedings* of the Royal Society of Victoria (vol. xvii., n.s., part i.) Messrs. F. Chapman and G. B. Pritchard commence an article on the fossil fish-remains from the Tertiaries of Australia. They deal with the description, range in time, and distribution of the sharks, and they observe that Asteracanthus, hitherto known only from Secondary strata, extended beyond question into the Tertiary seas round southern Australia. In other articles the Silurian Ostracoda and Phyllocarida, and the Tertiary Polyzoa and Mollusca of Victoria receive attention. Prof. J. W. Gregory contributes a paper on the antiquity of man in Victoria, and concludes (contrary to his previously expressed opinion) that, however ancient the Australian aborigines may be, there is no evidence of the long occupation of Victoria by man.

We have received the annual report of the Geological Survey of Canada for the year 1900, issued in 1903; it is accompanied by geological maps, dated 1904, of parts of British Columbia (Atlin Gold-fields), Labrador, Saskatchewan, and Quebec.

A revision of the Palæozoic Palæechinoidea, with a synopsis of all known species, has been contributed by Mary J. Klem (*Trans.* Acad. Science, St. Louis, vol. xiv., No. 1). She remarks that the prevailing characters which may be taken as a basis for classification are:—(1) number of columns in the ambulacra; (2) position and number of the ambulacral pores; (3) ornamentation of the plates; (4) imbrication of the plates; (5) apical system; (6) general shape of the body; and (7) geological position.

An interesting article on the occurrence and distribution of copper in the United States, by Mr. W. H. Weed, appears in the *Mining Magazine* (New York, September). Nearly 700 million pounds of metallic copper were produced in the States during 1903, and in the previous year nearly 300 million pounds were obtained from an area a mile long and half a mile wide at Butte, in Montana, where the Anaconda Mine produces more copper than any other mine in the world. The ores occur in well defined veins in quartz-monzonite, associated with white granite or aplite, which forms dykes and small masses. Dykes of quartz-porphyry also occur, and seem to have some genetic association with the ore-bodies. Several mines are 2200 feet deep.

The Geological Survey of Queensland has commenced the issue of *Records*. In No. 1 Mr. B. Dunstan, the acting Government geologist, contributes notes on the occurrence of gold nuggets near Mount Morgan, on phosphate-bearing rocks, asbestos, oriental rubies, &c. Mr. R. Etheridge records the occurrence of Halysites in the Chillagoe limestones. We have received also *Publications* Nos. 191 and 192, on the tin, copper, and silver mining in the Stanthorpe district, by Lionel C. Ball, and on the Herberton tin field, by Mr. W. E. Cameron.

Some Upper Devonian fish-remains, obtained by Dr. Whitman Cross from Colorado, are described by Mr. C. R. Eastman (*Amer. Journ. Sci.*, October). The remains belong to the genera Bothriolepis and Holoptychius. In the same journal a number of fossil turtles belonging to the Marsh collection in Yale University Museum are described and figured by Mr. O. P. Hay. Many of the specimens are from the Laramie deposits of Wyoming.

SCIENTIFIC RESEARCH IN THE PHILIPPINE ISLANDS.

THE occupation of the Philippine Islands by the United States has been quickly followed by the establishment of laboratories, and already a large amount of scientific work has been done, and several valuable reports have been issued.

The report[1] under review deals with the year ending September, 1903. The permanent buildings of the Government laboratory at Manila were completed last April, and comprise a serum laboratory for the preparation of therapeutic sera and vaccine lymph with attached paddocks and animal houses, a chemical laboratory, a biological department for the prosecution of pathological, entomological, and botanical research, a marine biological station, a bureau of weights and measures, and a library.

About one-third of the volume is occupied with a report on trypanosomiasis by Dr. Musgrave and Mr. Clegg, with special reference to the existence of surra among the horses in the Philippines. At the same time a very complete review of our present knowledge of trypanosomiasis is given, the various species are described, and the symptomatology and prophylaxis are discussed. The report, which is a very valuable one, is copiously illustrated with excellent photographs, temperature charts, &c. Several other papers of pathological interest are included in the volume; also an account of rinderpest inoculation.

Another valuable report is on the gutta-percha industry and the various gutta-percha-producing trees, and is illustrated with a number of photographs of species of Palaquium and Payena, methods of collection of the gutta-percha, maps of geographical distribution, &c.

The final third of the volume contains the report of Mr. Charles Banks, the Government entomologist, and gives an account of the insect pests attacking the cacao. This, like the rest of the papers, is copiously illustrated with excellent photographs.

The volume reflects the greatest credit on the staff of the laboratory, but the complete omission of a table of contents and an index should be remedied in future issues.

R. T. HEWLETT.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

BIRMINGHAM.—A chair of music has been established by an endowment of 10,000*l.* given for that purpose by Mr. Richard Peyton, of Birmingham. The chair has been accepted by Sir Edward Elgar; but the intention of the university authorities is by no means to interfere in any way with his work as composer, and he will be left free to develop the chair gradually and on such lines as he, in consultation with other members of the Senate, may think fit.

Dr. Arthur Robinson, of King's College, London, has been elected to the chair of anatomy, vacated by the appointment of Dr. Windle to the presidency of Queen's College, Cork. The new professor will assume office in January.

A new chair of electrical engineering has been established as a supplement to the lectureship in the same subject held by Dr. D. K. Morris. The first occupant of the chair will be Mr. Gisbert Kapp, now lecturer at Charlottenburg. He is not expected, however, to return to this country until the autumn of next year, and his appointment will not take effect until October, 1905. Meanwhile, and subsequently, Dr. Morris and his staff will continue their work as before. The new and large buildings for the department will be ready by that time. A competent assistant will have to be elected to assist Prof. Kapp in the drawing office for dynamo and central station design.

Prof. Burstall will continue to occupy his chair, the title of which will be changed to "Mechanical Engineering," and he will have control over a great engineering block and the power station.

It is not improbable that a special chair of civil engineering in the narrower sense will be established.

[1] Report of the Superintendent of Government Laboratories in the Philippine Islands for the Year ended September 1, 1903.

EDINBURGH.—Sir Donald Currie has subscribed the sum of 25,000*l.* toward the fund which is being raised by the university to enable a site to be purchased on which laboratories and other educational buildings could be erected, and for making further financial provision for an extension of the teaching staff and for the promotion of research in the university. To the principal, Sir William Turner, Sir Donald Currie stated that he wished the revenue from this money to be applied by the university court to the remuneration of a staff of lecturers, such as the authorities of the university might find it advisable from time to time to appoint. An option was also given to the university court to apply 5000*l.* of the amount towards the purchase of a site for the new laboratories, should it be necessary to use a portion of his gift for that purpose. In addition to this gift, subscriptions amounting to 15,000*l.* have been promised by other friends of the university.

ACCORDING to a report mentioned in *Science*, it is proposed to move the Western University of Pennsylvania from the suburbs of Allegheny to Pittsburg proper, near the new Carnegie Technical School. About fifty acres of ground, sufficient for twenty large university buildings, are being secured at a cost of about 400,000*l.*, and the work of construction will be begun before long. Fifty citizens of Pittsburg have agreed to give each from 8000*l.* to 20,000*l.* for the school. From the same source we learn that the general assembly of the State of Vermont has appropriated 12,000*l.* for the use of the agricultural department of the university. The money is to be expended in the erection and equipment of a building to be known as Morrill Agricultural Hall, in memory of the father of the agricultural colleges of the country, the late Senator Justin S. Morrill.

IT may be remembered that the authorities of University College, Sheffield, were informed by the committee of the Privy Council that, subject to a substantial realisation of the hopes entertained in connection with the movement for the establishment of a Sheffield University, their Lordships would be prepared in due course to recommend to His Majesty the grant of a charter. We learn from the calendar of the University College for 1904–5 that of the sum of 170,000*l.*, which efforts are being made to raise, 54,134*l.* has been promised since 1903. In addition, 52,908*l.* was promised in 1902 to the new buildings fund, so that some 107,042*l.* has been raised for higher education in Sheffield within a short period. It is to be hoped that little difficulty will be experienced in securing the amount which must be provided still before the University of Sheffield can be incorporated.

Two technical State scholarships have been just placed at the disposal of the local government of the Punjab, says the *Pioneer Mail*. These scholarships will enable natives of India to pursue a course of study in Great Britain or other western countries with the object of qualifying them to assist in promoting the improvement of existing native industries and the development of new industries wherever this may be possible. In the case of the Punjab the industries allowed to be taken up are tanning, metal-work, and pottery, and the local government has decided to confine its efforts to the first two, at any rate for the present. The value of each scholarship has been fixed at 150*l.* a year, and it will be tenable for two years, but it will be open to the Government of India to increase the value of any scholarship, and to extend the period during which it will be tenable. Commissioners and superintendents of divisions have been asked to make the scheme publicly known, and to enlist in its behalf the interest of the commercial classes.

THE annual prize distribution and students' conversazione at the Northampton Institute, E.C., was held last week, when the prizes and certificates were distributed by Lord Reay. The principal's report showed that the work of the institute has in several important departments overtaken the accommodation, and that there is urgent necessity for extension. A special note was made of the recent recognition of the work of the institute by the Board of Education; and the necessity for a "British Institute of Technical Optics" was pointed out. Lord Reay, in his address, dwelt upon the desirability of reviving, so far as modern conditions would allow, the old system of apprenticeship, and pointed out how the polytechnics and technical institutes could be made useful in connection therewith. The vote of thanks to Lord Reay was moved by Mr. Alexander Siemens. After the distribution the various laboratories and workshops were thrown open, and a series of lecturettes, exhibits, and demonstrations was given. The most interesting demonstration was perhaps that of a new submersible boat in the swimming bath. These boats, invented by Mr. Middleton, of Brighton, are propelled, directed, controlled, and governed by fins actuated by prime movers, in such a fashion that they can move any way in tri-dimensional space in the fluid in which they are immersed. By altering the inclination of the plane of the fins, these can be made to propel the boat forwards or backwards, to sink it below the surface, to raise it again, and, in fact, to direct it along any course, whether inclined to the horizontal or otherwise.

THE proceedings of the Institute of Chemistry of Great Britain and Ireland for 1904, which have now been published, show that the council of the institute has had under consideration the recommendations of the Consultative Committee to the Board of Education for a scheme of examinations for school certificates. It will be remembered that it is proposed that these school certificates should take the place of the many professional preliminary examinations now held; that a central board should be constituted for England, consisting of representatives of the Board of Education and of the different examining bodies, to control the standard of the examinations for school certificates; and that the proposed examinations should be under the control of independent external examiners, although conducted by internal and external examiners jointly. The council of the Institute of Chemistry has informed the Board of Education (*a*) that the council considers it desirable to substitute some such system as is proposed in lieu of the various professional preliminary examinations now held; (*b*) that if such a system be established, the council will be prepared to accept the proposed senior certificate examination, passed in the subjects required by the regulations of the institute; and (*c*) that the council will be pleased to be represented on the proposed central board. A scheme for school certificates submitted by the University of Birmingham has also met with the approval of the council of the institute, and it has also been decided to accept the matriculation examination held jointly by the Victoria University, the University of Liverpool, and the University of Leeds, as an approved preliminary examination, provided the certificate include the subjects required by the regulations of the institute.

A DEPUTATION from the Association of Chambers of Commerce of the United Kingdom waited upon Lord Londonderry, President of the Board of Education, on Monday to urge that increased Government aid should be given to higher technical and higher commercial education. The views of the deputation were expressed in the following resolution, which was passed at the meeting of the association on September 28, and was now laid before Lord Londonderry:—"That, in order to retain our industrial position and to introduce into this country such further industries as may be profitably developed, this association is of opinion that it is absolutely necessary to establish or acquire public secondary schools of the highest standard, where efficient means of such education do not exist, with fees low enough to make them accessible to all grades, and to provide sufficient inducements by bursaries, exhibitions, scholarships, or otherwise to make the efficient boys stay long enough in these schools in order to thoroughly train and adequately prepare a very much larger number than is at present available for taking full advantage of the provisions made for higher technical and higher commercial education, the facilities for which ought also to be largely extended and the standard considerably raised." In introducing the deputation, Sir W. H. Holland, M.P., said the chambers of commerce might be fairly taken to represent the organised commercial opinion of the country, and they were convinced that the Board of Education would encourage them to take a keen interest in secondary and technical education. Mr. Ivan Levinstein said the want of secondary education was the cause of our present most deplorable position. What we wanted, in the first instance, was a far larger number of high-class public secondary schools. We must be prepared to face a great financial sacrifice, for some years at any rate, if we were to put secondary education in this country on anything like the level it had reached in America, Switzerland, and Germany. After other speakers had put forward similar claims for consideration of the subject, Lord Londonderry, in reply, said that he felt the weight of the arguments put forward, but the opinions of his colleagues of the Board of Education and himself on this vitally important matter were expressed in such detail and so definitely in the reply forwarded by Mr. Morant to the chamber on September 26 (see NATURE, October 13, p. 595) that on the present occasion he proposed to devote attention rather to the question of commercial education than to that of technical education. The whole matter was one to which the Board were fully alive, and he was very glad to learn from the representations which they had made that day that there was on the part of the chambers of commerce a keen appreciation of the value of that special advanced instruction in the several sections of mercantile practice which the Board had felt it their duty to encourage in the evening schools serving the more important commercial communities.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, February 11.—"On Certain Properties of the Alloys of Silver and Cadmium." By Dr. T. K. **Rose.**

Attention was directed to these alloys on account of the advantages of using them as the material for trial plates for testing the fineness of silver coin and plate. An examination of the curves of equilibrium between the liquid and solid states of the alloys proved the existence of several compounds of silver and cadmium, some of which have already been recognised in other ways. Horizontal branches of the curve mark the solidification of the compounds Ag_3Cd_2, AgCd, and $AgCd_3$, and the solidification of Ag_2Cd_3 corresponds to a cusp on the curve of initial freezing points.

There is a strong tendency for mixtures of the compounds to form solid solutions. This is strikingly shown in the case of alloys containing more than 80 per cent. of silver. At temperatures in the short range of a few degrees between the initial and final freezing points of these alloys, two bodies exist side by side, but at a lower temperature they coalesce to form a single solid solution provided that sufficient time is allowed for complete mixing by diffusion. For example, in the standard alloy, which contains 7·5 per cent. of cadmium, solidification begins at about 945°, and is completed at about 913°. If the alloy is maintained at some temperature between these points a network of a silver-poor body is gradually formed surrounding crystals of a silver-rich body. If the alloy is subjected for some hours to a temperature a little below 913°, large crystals with regular boundaries are formed occupying the whole area of the field. These alloys are remarkably ductile.

The alloy corresponding to the formula Ag_2Cd is fine-grained and apparently homogeneous. If heated for some time to a temperature of 750°, somewhat below its point of solidification, the cadmium from the surface is volatilised, leaving a layer of pure silver. On removing this during the operation of polishing a black layer is met with, coloured by oxide of cadmium, and underneath this the original alloy is found to exist. The layers are not everywhere of the same thickness, so that in the course of polishing alternate rings of black and white are produced, resembling the well known Japanese decorative metal-work called Mokumé, which is used in jewellery.

The alloy containing about 50 per cent. of silver consists of crystals of a silver-rich body, often pinkish in colour, set in a white matrix composed of $AgCd_3$. The 40 per cent. alloy is a hard, brittle substance, the compound Ag_2Cd_3. As the percentage of silver decreases, a matrix, consisting mainly of $AgCd_3$, makes its appearance surrounding the crystals of Ag_2Cd_3, and specimens containing less than 25 per cent. of silver consist of crystals of $AgCd_3$ set in a matrix of cadmium.

Several similarities to the silver-zinc series of alloys have been noted.

November 24.—"The Refractive Indices of the Elements." By Clive **Cuthbertson.**

In a letter addressed to NATURE in October, 1902, attention was directed to the fact that the refractivities of the five inert gases of the atmosphere, He, Ne, A, Kr, and X, as determined by Ramsay and Travers, were, within narrow limits of accuracy, in the proportion of 1, 2, 8, 12 and 20; or, more simply, of $\frac{1}{4}$, $\frac{1}{2}$, 2, 3, and 5.

In a second letter it was shown that the refractivities of the halogens, Cl, Br, and I, stand also in the relation of 2, 3, and 5 to the same degree of accuracy; but it was pointed out that the figures for P, As, and S, as measured by M. Le Roux in 1861, did not show any similar relation; and it was observed that a re-determination of them would be interesting.

With a Jamin's refractometer, adapted for use with high temperatures, results have now been obtained for Hg, P, and S, which differ widely from those of M. Le Roux. The index of mercury, calculated for a molecule containing two atoms, is placed at 1·001857, a number which agrees closely with the value given by the refractive equivalent of Gladstone. The index of P_2 is found to be 1·001197, and that of S_2 is 1·001101.

In all three cases it is estimated that the margin of error does not exceed $1\frac{1}{2}$ per cent. Comparing these values for P_2 and S_2 with those of N_2 and O_2, it is shown that the simple relations found in the case of the inert gases and the halogens also hold in the case of nitrogen and phosphorus, oxygen and sulphur; and that an atom of phosphorus retards light four times as much as an atom of nitrogen, an atom of sulphur four times as much as an atom of oxygen.

Efforts have also been made to measure the index of fluorine in the gaseous state, but, owing to the experimental difficulties, success has not yet been attained.

It appears then, that, out of fourteen elements the index of refraction of which has been measured in the gaseous state, twelve conform to the rule that in each chemical group the refractivities of the elements are in the ratios of small integers. The other two, Hg and H, have no allied elements with which they can be compared.

It is pointed out that N, O, and Ne are each followed, in their respective families, by an element the refractivity of which is four times as great, and that, consequently, there are reasons for believing that the elements composing the series N, O, F, and Ne, and P, S, Cl, and A are, in some sense, homologous. Comparing the refractivities of the latter series we see that the power to retard light appears to be closely connected with the valency, increasing as it increases, in spite of the decrease in atomic weight, as shown in the following table:—

	Element			
	P	S	Cl	A
Atomic weight ...	31	32	35·5	40
Refractivity ...	299 × 4	275 × 4	192 × 4	141 × 4

The series Ne, O, N, show the same relation, and it is probable that the refractivity of C is even higher than that of N.

The refractivity of B, estimated from BCl_3 and BBr_3, is certainly very great; but whether it exceeds that of C there is not sufficient evidence to determine.

December 1.—"On the Structure and Affinities of Fossil Plants from the Palæozoic Rocks.—V. On a New Type of Sphenophyllaceous Cone (*Sphenophyllum fertile*) from the Lower Coal-measures." By Dr. D. H. **Scott,** F.R.S.

The class Sphenophyllales, of which the fossil described is a new representative, shows on the one hand clear affinities with the Equisetales, while on the other it approaches the Lycopods; some botanists have endeavoured to trace a relation to the ferns. The nearest allies among recent plants are probably the Psilotaceæ, which some writers have even proposed to include in the Sphenophyllales.

The new strobilus appears to find its natural place in the type-genus Sphenophyllum, as at present constituted, but it possesses peculiar features of considerable importance, which may probably ultimately justify generic separation. The specimen, of which a number of transverse and longitudinal sections have been prepared by Mr. Lomax, is from one of the calcareous nodules of the Lower Coal-measures of Lancashire, and was found at Shore Littleborough, a locality rich in petrified remains, now being opened up by the enterprise of the owner, Mr. W. H. Sutcliffe.

The close affinity of the strobilus with Sphenophyllum is shown by the anatomy of the axis, which has the solid triarch wood characteristic of that genus, and by the fact that the whorled sporophylls are divided into dorsal and ventral lobes, as in all other known fructifications of this class. But whereas, in all the forms hitherto described, the lower or dorsal lobes are sterile, forming a system of protective bracts, while the ventral lobes alone bear the sporangia; in the new cone, dorsal and ventral lobes are alike fertile, and no sterile bracts are differentiated. On this ground the name *Sphenophyllum fertile* is proposed for the new species.

Each lobe of the sporophyll divided palmately into several segments, the sporangiophores, each of which consisted of a slender pedicel, terminating in a large peltate lamina, on which two pendulous sporangia were borne. In the bi-sporangite character of the sporangiophores, and in other details of structure, *Sphenophyllum fertile* approaches the *Bowmanites Römeri* of Count Solms-Laubach, while in the form and segmentation of the sporophylls there is a considerable resemblance to the Lower Carboniferous genus Cheirostrobus.

The wall of the sporangium has a rather complex structure, the most interesting feature in which is the well defined small-celled stomium, marking the line of longitudinal dehiscence.

The spores, so far as observed, are all of one kind; they are ellipsoidal in form, with longitudinal crests or ridges; their dimensions are 90–96μ in length by 65–70μ in width.

The most characteristic point in the structure of the new cone—the fertility of both dorsal and ventral lobes of the sporophyll—is regarded as more probably due to special modification than to the retention of a primitive condition.

"On the Presence of Tyrosinases in the Skins of some Pigmented Vertebrates.—Preliminary Note." By Florence M. **Durham.**

An extract can be made from the skins of certain pigmented animals (rabbits, rats, guinea-pigs and chickens) which will act upon tyrosin and produce a pigmented substance. This action suggests the presence of a tyrosinase in the skins of these animals.

The action of the tyrosinase is destroyed by boiling, does not take place in the cold, is delayed by time, requires a temperature of about 37° C., and also the presence of an activating substance such as ferrous sulphate to start it.

The coloured substances produced are in accordance with the colour of the animals used. Black substances are obtained, when animals with black pigment in their skins are used, and yellow substance, when the skin contains the orange pigment. The coloured substances are soluble in alkalis, but insoluble in acids.

Anthropological Institute, November 22.—Mr. H. Balfour, president, in the chair.—Dr. Ed. **Westermarck** read a paper on the magic origin of Moorish designs. The designs are largely derived from charms against the evil eye. A Moor protects himself against the evil eye of another person by stretching out the five fingers of his right hand, saying, "five in your eye." The object of this gesture is to throw back the evil power, *l-bas*, which has emanated from the other person's eye. The number five by itself has thus come to be regarded as a charm against the evil look. This was illustrated by a number of lantern slides, showing charms, and designs grown out of charms. Silver amulets containing a double five grouped in the form of a cross, with a piece of blue glass as a common centre, are in frequent use. Magic efficacy is attributed to the cross, not only because it represents a five, but also, as it seems, because it is regarded as a conductor for baneful energy, which is dispersed by it in all the quarters of the wind. The double five is often represented as an eight-petalled rosette, or a double cross, with or without a well marked centre. By joining the extremities of the lines which form each of the two crosses, two intersecting squares are produced; they are probably intended to represent a pair of eyes. By painting over all the lines which fall within the two intersecting squares, or by hollowing the two squares, the artist produces an empty octagon. The two crosses may also be of different lengths, and then the joining of the extremities of each cross gives rise to two squares, of which the one is inscribed in the other. The tendency to produce the number five double as double five, an eight petalled rosette, a double cross, or a double square seems to be due to the fact that the protective gesture is sometimes performed both with the right and left hand. By doubling each petal in the eight-petalled rosette, the sixteen-petalled rosette has been produced. The image of an eye or a pair of eyes is also used to throw back the baneful energy emanating from an evil eye. The eye is sometimes represented as round, sometimes as a triangle (the two intersecting triangles seem to represent a pair of eyes), sometimes with a triangular eyebrow. A row of triangular eyes and eyebrows, or of eyebrows alone, is a common design on carpets.

Geological Society, November 23.—Dr. J. E. Marr, F.R.S., president, in the chair.—On an ossiferous cavern of Pleistocene age at Hoe-Grange Quarry, Longcliffe, near Brassington (Derbyshire): H. H. **Arnold-Bemrose** and E. T. **Newton,** F.R.S. The quarry is situated near the top of the plateau, at about 1100 feet above Ordnance-datum. The cave is evidently a master-joint in the limestone, enlarged by water, and, besides being a swallow-hole, has served as a hyæna-den. The large number of mammalian remains found includes lion, hyæna, rhinoceros, Elephas, and other Pleistocene forms; but, besides these, there were numerous bones and teeth of fallow-deer, mixed with the Pleistocene remains at all horizons in the cave. The physical conditions are such as to preclude, as the authors think, any idea of a re-deposition of the bones at any date subsequent to the Pleistocene period; and it is concluded, therefore, that the fallow-deer (*Cervus dama*) was a Pleistocene species, although hitherto supposed to be a much later introduction.—The superficial deposits and pre-Glacial valleys of the Northumberland and Durham Coalfield: D. **Woolacott.** Six volumes, published by the North-of-England Institute of Mining and Mechanical Engineers, contain a large number of borings made in the northern coalfield. A considerable proportion of these are most valuable in showing the nature and distribution of the superficial deposits. From them and from field-mapping it is possible to form a fairly accurate conception of the pre-Glacial floor of the district and its drainage, and also of the relative changes of level before, during, and after the Glacial period.

Zoological Society, November 29.—Mr. G. A. Boulenger, F.R.S., vice-president, in the chair.—Observations on the field natural history of the lion made during seventeen years of travel and residence in Central Africa: Captain Richard **Crawshay.**—Some nudibranchs from East Africa and Zanzibar, part vi.: Sir Charles **Eliot.** The paper contained an account of thirty species and varieties, of which eight of the former and one of the latter were described as new.—Some photographs of giraffes and a zebra taken from pictures in the art collection at Windsor Castle, and an old print of a zebra dated 1762: R. **Lydekker.** Mr. Lydekker was of opinion that the picture and print of the zebra had been taken from the same animal.—Two specimens of lorises, one a slow loris (Nycticebus) and the other a slender loris (Loris), recently acquired by the British Museum: R. **Lydekker.** The latter specimen was pointed out to be sufficiently different from the typical *L. gracilis* to be entitled to subspecific rank.—The morphology and classification of the Asellota group of crustaceans, with descriptions of the genus Stenetrium and its species: Dr. H. J. **Hansen.**—The lizard *Lacerta depressa* of Camerano and its varieties: G. A. **Boulenger,** F.R.S. A small collection of fresh-water Entomostraca from South Africa: R. **Gurney.** The collection comprised examples of five species, three of which were described as new.—The cranial osteology of the Egyptian mastigure (*Uromastix spinipes*): F. E. **Beddard,** F.R.S.

Chemical Society, December 1.—Prof. W. A. Tilden, F.R.S., in the chair.—The nitrites of the alkali and alkaline earth metals and their decomposition by heat: P. C. **Rây.** These nitrites are shown to be comparatively stable, and their aqueous solutions can be evaporated to dryness without decomposition or oxidation taking place. When barium nitrite is heated it is first converted into barium oxide and barium nitrate, the latter finally also being decomposed into baryta.—Metallic derivatives of nitrogen iodide and their bearing on its constitution: O. **Silberrad.** Guyard's supposed copper derivative of nitrogen iodide is shown to be a cuprosamine periodide. The silver derivative described by Szuhay is found to be a true nitrogen iodide derivative of the formula NI_3,NH_2Ag.—Synthesis of 1:1-dimethylhexahydrobenzene: A. W. **Crossley** and Nora **Renouf.**—The formation and reactions of imino-compounds, (i.) condensation of ethyl cyanoacetate with its sodium derivative: H. **Baron,** F. G. P. **Remfry,** and J. F. **Thorpe.** This is a preliminary communication regarding the properties of compounds containing the group —C(=NH)—, which in some respects closely resembles the =CO group in reaction.—The affinity constants of aniline and its derivatives: R. C. **Farmer** and F. J. **Warth.** These constants are best measured in such cases by determining the distribution of the salts between two immiscible solvents applied simultaneously. The following substituents exert a decreasing electronegative action, in the order in which they are given, on the affinity constant of aniline:—NO_2,COOH,—N=NPh,Br,Cl,Me,OMe. — The attractive force of crystals for like molecules in saturated solutions: E. **Sonstadt.** Crystals of a salt were placed in saturated solutions of the same salt, and the amount of the latter withdrawn from the solution by the attractive force of the crystals was determined periodically.—The Grignard reaction applied to the esters of hydroxy-acids: P. F. **Frankland** and D. F. **Twiss.** A substance which is probably $\alpha\alpha\delta\delta$-tetraphenylerythritol was obtained by the action of magnesium phenyl bromide on dimethyltartrate.—Note on the addition of hydrogen cyanide to unsaturated compounds: A. **Lapworth.** It is shown that in spite of Knoevenagel's assertion to the contrary, there is no experimental evidence that mesityl oxide unites directly with hydrogen cyanide except in the presence of alkalis. The author is now engaged in the examination of a number of products obtained by the interaction of aldehydes with chloroacetates in presence of potassium cyanide.

Mathematical Society, December 8.—Prof. Forsyth, president, in the chair.—The following papers were communicated:—On a deficient multinomial expansion: Major **MacMahon.** A generalisation of the binomial theorem, made by Abel and restated by Cayley, leads to the consideration of the series that is obtained from an ordinary multinomial expansion by restricting the indices of the terms to obey certain Diophantine inequalities. The paper contains investigations of the number of terms in such a series, the sum of the coefficients, and a syzygetic theory of the distinct terms.—The application of basic numbers to Bessel's and Legendre's functions: Rev. F. H. **Jackson.** The author generalises various functions that are expressed by power series by replacing n in the coefficient of x^n by $(p^n-1)/(p-1)$. Two generalisations are obtained of Bessel's functions, one being derived from the other by inversion of the "base" p. In the present paper the author shows that these two functions are connected by a relation containing basic exponential functions. He obtains also generalisations of a number of results which bear on the relations between Legendre's functions and Bessel's functions, and he connects the theory of the generalised Legendre's functions with that of the Theta functions.—On groups of order $p^\alpha q^\beta$: Prof. W. **Burnside.** In a previous paper the author had proved that these groups are soluble. In the present paper it is shown that, subject to certain specified exceptions when the order is even, a group of the specified order in which $p^\alpha > q^\beta$ must have a characteristic subgroup of order p^a, where a is such that p^a is greater than $p^\alpha q^{-\beta}$.—On the failure of convergence of Fourier's series: Dr. E. W. **Hobson.** Fourier's series formed for a continuous function may not converge at a point, and then it does not represent the function at the point. In the paper attention is directed to a class of series which fail to converge, but can be made to converge to any assigned value by enclosing suitable sets of terms in brackets and treating the terms in a bracket as a single term. No example has ever been found of a non-convergent Fourier's series which cannot be included in this class. The nature of the set of points in the periodic interval at which a Fourier's series fails to converge is discussed, and it is shown that, when the function to be represented by the series is continuous, this set has the "measure" zero.—An extension of Borel's exponential method of summation of divergent series applied to linear differential equations: E. **Cunningham.** The object of the paper is to make more precise the connection between Laplace's solution of linear differential equations in terms of definite integrals and the asymptotic expansion of the solution as the product of an exponential function and a descending power series. The latter series, with the exponential factor omitted, is shown to be "summable" in a sense analogous to that of Borel's theory; and it is proved that the fundamental properties of summable divergent series, such as differentiation term by term, addition and multiplication term by term, are valid for the series in question.—On the linear differential equation of the second order: Prof. A. C. **Dixon.**

CAMBRIDGE.

Philosophical Society, November 14.—Prof. Marshall Ward, president, in the chair.—The charge of the α rays from polonium: Prof. **Thomson,** F.R.S. A bismuth disc covered with polonium (or radio-tellurium), as supplied by Sthamer, was mounted on pivots in a vacuum tube. In front of the disc and about 3 cm. from it was a very carefully insulated gold-leaf electroscope which could be charged with either positive or negative electricity. The vacuum tube was exhausted by first pumping out as much air as possible by a mercury pump, and then using Dewar's method of extracting the remainder of the air by dense charcoal cooled by liquid air. In this way vacua were obtained very much superior to those got by pumping alone. It was found that at these very low vacua the electroscope in front of the polonium if negatively charged leaks so slowly that it is hardly possible to measure the leak with accuracy; while if the electroscope is positively charged its leak is very rapid, certainly more than 100 times the leak when charged negatively. Thus the polonium gives out large quantities of negative electricity, but not enough positive to be detected; this is very remarkable, as polonium is generally supposed to give out nothing but α rays. In order to see that the positive electricity had not been swamped by the negative the instrument was placed in a strong magnetic field; this stopped the negative corpuscles coming out of the polonium from reaching the electroscope, and it was found that now the latter no longer leaked when charged with positive electricity; but though the negative particles had been stopped no positive ones could be detected, for there was no leak from the electroscope when negatively electrified. The author was never able to be sure of any *increase* in the charge of a negatively electrified body placed near the polonium; this he thinks is due to the negative particles from the polonium moving so slowly that they are unable to make headway against the repulsion exerted by a negatively electrified body. The α rays of polonium are deflected by a magnet, hence they must be positively charged at some part, at any rate, of their course, yet no trace can be found of this charge when the rays strike against an electroscope. The question is discussed whether the α particles lose their charge when they pass through the cloud of negative ones near the polonium, or whether they are alternately charged and discharged, the time during which they are uncharged being much longer than the time they are charged.—On the dynamical significance of Kundt's law of selective dispersion in connection with the transmission of the energy of trains of dispersive waves: Prof. **Larmor,** F.R.S.—The chlorination of α picoline: W. J. **Sell,** F.R.S.—An attempted synthesis of uric acid: H. J. H. **Fenton,** F.R.S.—The diffusion of hydrogen through palladium: O. W. **Richardson.** The paper is chiefly a criticism of the conclusions drawn by Mr. G. N. St. Schmidt (*Drude's Ann.*, vol. xiii. p. 747) from his experiments on this subject. The author shows that the known facts can be explained on the hypothesis that the hydrogen inside the metal is dissociated, in the same way as for platinum.—Optically active nitrogen compounds: Miss M. B. **Thomas** and H. O. **Jones.** The work was undertaken in order to find out what connection exists between the constitution of optically active nitrogen compounds and the numerical value of their rotatory power. The rotation for a basic ion may be determined by preparing the salt with an acid of known rotatory power, and subtracting the rotation due to the acidic ion from the total rotation of the salt in aqueous solution. The series of substituted ammonium salts under investigation contain the phenyl, benzyl, and methyl radicals with ethyl, *iso*propyl, *iso*butyl or *iso*amyl. The paper contains a brief account of the resolution of the *iso*propyl compound by means of its dextro-brom-camphor-sulphonate.

DUBLIN.

Royal Dublin Society, November 15.—Dr. R. F. Scharff in the chair.—Prof. T. **Johnson** gave an account of a disease of swedes which has caused considerable loss in different parts of Ireland, especially in the west. The small leaves become "spotted," turn yellow, and fall off. The attack is due to *Cercospora Bloxami*, Berk. and Br., which causes disease in swedes in Germany and Switzerland. Associated with the Cercospora from different localities, the author found a Phoma-stage, suggestive of *Phoma Brassicae*, Thüm., and in one locality, associated also with Cercospora, *Pleospora herbarum*, *β Brassicae* (Lasch), Sacc. The swede disease shows a curious parallelism with the disease of the sweet chestnut investigated by Berlese in Italy, where Cercosporella, Phoma or Phyllosticta, and Sphærella stages are associated.—Prof. W. F. **Barrett**, F.R.S., read a paper on a method of protecting the hands of the operator from X-ray burns. The author stated that in taking some radiographs of surgical cases during the first three months of 1896 (shortly after Röntgen's discovery) he noticed the extreme opacity to the X-rays of any bandages which contained a dressing of iodoform. This led to a series of experiments on the relative transparency of bodies to the X-rays, and it was discovered, early in March, 1896, that all bodies of high molecular weight, such as iodoform, were opaque to these rays. If, then, the burns produced by the X-rays be due to those rays which cannot penetrate a layer of iodoform, it is easy to construct gauntlets with an inner lining filled with iodoform which would entirely protect the hands of the operator. Such gloves would be far more flexible and far lighter than gloves with a lead lining. The author added to his paper an historical note on the relative transparency of bodies to the X-rays, giving a brief summary of the work done.

MANCHESTER.

Literary and Philosophical Society, November 15.—Prof. W. Boyd Dawkins, F.R.S., president, in the chair.—Dr. W. E. **Hoyle** exhibited specimens of certain rare Cephalopoda:—(1) *Ancistrochirus lichtensteini* from the Maldive Archipelago, the type specimen in the Paris Museums being the only one previously known. (2) A species of Cirroteuthis from the neighbourhood of the Cape of Good Hope, beautifully preserved in formol, and exhibiting the gelatinous appearance and rounded stumpy form of the animal in a way never seen in examples preserved in alcohol. (3) Section of an octopod embryo from Zanzibar showing a number of peculiar chitinous rods in the epithelium.—Mr. F. **Nicholson** communicated a note on the mistaken idea that birds are seed-carriers, in which the author stated that he had found no evidence from his own observations, extending over many years, that entire seed can pass through a healthy bird. In confirmation of this view Mr. Nicholson quoted two passages from Macgillivray's "A History of British Birds," in which the author states that of many hundreds of berry-eating and seed-eating birds which he had opened there were only two which showed the presence of whole seed in their intestines, and these two were in all probability cases of diseased action.—Mr. R. W. **Ellison** exhibited a number of birds' eggs, including specimens of the following:—the great black-backed, the lesser black-backed, the herring, and black-headed gulls, the Sandwich and lesser terns, the ring sand plover, and the guillemot. The selection was made with the view of demonstrating certain facts as to the coloration of the eggs and its relation to that of their surroundings.

PARIS.

Academy of Sciences, December 5.—M. Mascart in the chair.—On the general formula giving the number of double integrals of the second species in the theory of algebraic surfaces: Émile **Picard**.—On the nepheline rocks of Tahiti: M. **Lacroix**. A detailed examination of a series of rocks from Tahiti constitutes a continuous series from a petrographical point of view, in which the mineralogical variations are essentially the result of an increase in the amount of lime, iron, and manganese, accompanied with a corresponding reduction in the amount of silica and alkalis.—On differential equations of a parabolic type: Vito **Volterra**.—Observations on the Perseids for 1904, and the determination of their heights above the ground: V. **Fournier**, A. **Chaudot**, and G. **Fournier**. The observations were carried out on the nights between August 9 and 16. 274 meteors were registered, 180 of which were Perseids. Only 27 of these were of the first magnitude, the greater part being of the third or fourth order. With the view of determining the heights of some of the meteors simultaneous observations were carried out on the night of August 16 at Rouvray and at Morvan (Côte d'Or), two stations 10·1 kilometres apart. 32 shooting stars were noted at the first station, and 52 at the second, 13 of these being common to both, and of these 4 have been reduced. The height at the first appearance varied from 107 to 283 kilometres, at disappearance from 35 to 66 kilometres, and the length of the trajectory from 56 to 245 kilometres. The average height for the first appearance was 168 kilometres, and of disappearance 53 kilometres, these figures being greater than those obtained by M. Chrétien in 1901.—On groups of the order p^m(p prime, $m>4$) of which all the divisors of the order p^{m-2} are Abelian: M. **Potron**.—The design of high-speed vessels: Vice-Admiral **Fournier**.—On telestereoscopy: Paul **Helbronner**. The object of the experiments was, whilst preserving the strong magnification of the telescope objective, to get the details standing out in clear relief. The arrangement described has been used in geodesic work in the French Alps, and has been found very useful.—Researches on dielectric solids: V. **Crémieu** and L. **Malclès**. By means of a quantitative study of the phenomena described qualitatively in a previous note, the diminution of electrical influence through solid dielectrics by the production in the dielectric of a reactive charge is clearly established.—Experiments permitting of the demonstration of the n-rays: H. **Bordier**. With the view of removing objections to the purely subjective experiments which are used for the detection of the n-rays, the author has applied with success a photographic method, very long exposures being employed on account of the feeble intensity of the light emitted.—On the composition of colloidal granules: Victor **Henri** and André **Mayer**. The composition of the colloidal granules of copper ferrocyanide studied by J. Duclaux may be considered as a particular case of the phenomenon of adsorption. The granules may be looked upon as formed by copper ferrocyanide which has adsorbed a certain quantity of potassium ferrocyanide. It is not necessary that compounds of indefinite chemical composition should be assumed.—The action of methylene chloride upon toluene in the presence of aluminium chloride: James **Lavaux**. It is shown that the ditolylmethane and dimethylanthracene isolated by previous workers on this reaction are mixtures. From the former the author has isolated dimeta- and dipara-ditolylmethane, and β-methylanthracene, and from the latter three isomeric dimethylanthracenes.—On the retrogradation of some cyclic secondary amines: P. **Lemoult**. Amines of the type R—NHR′ on heating with PCl_5 give some of the primary amine RNH_2, together with R′Cl. The reaction was best marked with the methylanilines.—On the organic combinations of metals in plants: MM. **Schlagdenhauffen** and **Reeb**.—On the synthesis and chemical nature of sorbierite: Gabriel **Bertrand**. It is shown synthetically that the sorbierite described by the author in a previous paper is identical with the d-idite of Fischer and Fay.—The biological *rôle* of the diffusion of liquids: Stéphane **Leduc**.—Researches on the germination of the spores of some yeasts: A. **Guilliermond**.—On the anatomical modifications which are produced in the course of the evolution of certain rhizomes: André **Dauphiné**.—Biospeleology: Armand **Viré**. A discussion of the bearing of the evidence of the animals found in caves on the theory of evolution.—Osmotic communication between the vital and exterior media in certain marine Selacian fishes: René **Quinton**.—*Lernaeenicus Sprattae*, a parasite of the sardine on the coasts of Vendée: Marcel **Baudouin**.—The action of calcium permanganate on alkaloids, and in particular on strychnine: G. **Baudran**.—The nutritive value of cows' milk, sterilised at 108° C., for artificial feeding: G. **Variot**. As the result of work carried on over a period of twelve years, on an average of 150 to 200 infants daily, the conclusions are drawn that milk sterilised at 108° C. preserves all its nutritive value, and is in no way inferior to milk pasteurised at 80° C. or simply heated to 100° C. No appreciable decrease in the readiness with which the milk was assimilated could be noticed, and not a single case of infantile scurvy occurred. The percentage of infants incapable of utilising sterilised milk was between 3 per cent. and 4 per cent.

NEW SOUTH WALES.

Royal Society, October 5.—Mr. C. O. Burge, president, in the chair.—Ethnological notes on the aboriginal tribes of New South Wales and Victoria: R. H. **Mathews**.—Preliminary observations on radio-activity and the occurrence of radium in Australian minerals: D. **Mawson** and T. H. **Laby**. A brief summary of observations on the radio-activity of minerals and occurrence of radium is given, showing that comparatively intense activity is only found associated in minerals with thorium and uranium. A torbernite and euxenite were found highly active, but the specimens were too small to examine for radium. A Western Australian gadolinite, found by Prof. Norman Collie to contain one bubble of helium in ten grams, was expected to contain radium, but none could be detected. Twelve monazites were found radio-active; one, with double the average activity of the others, from Pilbarra, Western Australia, gave on heating the radium emanation; five monazite and zircon sands were also active. No relation between thoria contents and activity was found, which points to the presence of uranium.—The flood deposits of the Hunter and Hawkesbury Rivers: Prof. F. B. **Guthrie** and Prof. T. W. Edgeworth **David**.

CAPE TOWN.

South African Philosophical Society, September 28.—Dr. J. D. F. Gilchrist, president, in the chair.—A new South African cypress, *Callitris schwarzii*, Marl.: Dr. R. **Marloth**. The two species of cypress hitherto known from South Africa belong to the genus Widdringtonia, which, however, is now mostly merged into the genus Callitris. Until recently only one other species of Widdringtonia was known, viz. *W. Commersoni* from Madagascar, but lately a fourth species has been found by Whyte on the Shire Highlands, called by Sir H. H. Johnston the Malanje cedar. The South African species are *C. juniperoides*, the so-called Cape cedar, and *C. cupressoides*, the saprechout. The former is a tree from 30 to 40 feet high, and occurs only on the Cedar Mountains, while the latter is only 10 to 12 feet or rarely 15 feet high, but is common on all the mountains of the south-western districts. When recently the author heard that some "Sapree" trees in the Baviaanskloof Mountains were 50 to 60 feet high, he suspected at once that this must be a different species, and an examination of some ripe cones proved that this tree is quite distinct from the common *C. cupressoides*.—The Glacial conglomerate in the Table Mountain series near Clanwilliam: A. W. **Rogers**. This communication is an extension of one read before the society in 1901. The conglomerate with glaciated pebbles has now been traced through a distance of about 23 miles near Clanwilliam.—South African Verbenaceæ, supplementary note: H. H. W. **Pearson**.—Further note on factorisable continuants: Thos. **Muir**.—South African Hymenoptera: P. **Cameron**.—On the structure of the endothiodont reptiles: R. **Broom**.

October 26.—Sir David Gill, K.C.B., F.R.S., vice-president, in the chair.—The rocks of Tristan d'Acunha, brought back by H.M.S. *Odin*, Commander Pearce, R.N., and their bearing on the question of the permanence of ocean basins: E. H. L. **Schwarz**. Through the courtesy of Commander Pearce, of H.M.S. *Odin*, a number of specimens were recently obtained for the South African Museum from the island group of Tristan d'Acunha. The islands are described in the *Challenger* reports, and from the accounts published in them it is evident that while Inaccessible Island and Tristan d'Acunha itself are ordinary volcanic islands, Nightingale Island is a gigantic agglomerate neck like those that the author has described from Griqualand East, on the flanks of the Drakensberg Mountains. Two rocks of a type unusual to volcanic islands were brought back by the expedition; one was a white mica and biotite gneiss from Tristan d'Acunha, the other a lava containing foreign fragments from Nightingale Island.

DIARY OF SOCIETIES.

THURSDAY, DECEMBER 15.

ROYAL SOCIETY, at 4.30.—On the Ultra-violet Spectrum of Gadolinium: Sir William Crookes, F.R.S.—An Analysis of the Results from the Falmouth Magnetographs on "Quiet" Days during the Twelve Years 1891 to 1902: Dr. C. Chree, F.R.S.—The Halogen Hydrides as Conducting Solvents. Part iii. Preliminary Note: B. D. Steele.—The Halogen Hydrides as Conducting Solvents. Part iv. Preliminary Note: B. D. Steele, D. McIntosh, and E. H. Archibald.—Effects of Temperature and Pressure on the Thermal Conductivities of Solids. Part i. The Effect of Temperature on the Thermal Conductivities of some Electrical Insulators: Dr. C. H. Lees.—The Basic Gamma Function and the Elliptic Functions: Rev. F. H. Jackson, R.N.—On the Normal Series satisfying Linear Differential Equations: E. Cunningham.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Discussion on Mr. Searle's Paper, Studies in Magnetic Testing; Followed by The Combination of Dust Destructors and Electricity Works, Economically Considered: W. P. Adams.

LINNEAN SOCIETY, at 8.—The Ecology of Woodland Plants: Dr. T. W. Woodhead.—Experimental Studies on Heredity in Rabbits: C. C. Hurst.

FRIDAY, DECEMBER 16.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—Heat Treatment Experiments with Chrome-Vanadium Steel: Capt. H. Riall Sankey and J. Kent-Smith.—Messrs. Seaton and Jude's Paper on Impact Tests on the Wrought Steels of Commerce will be discussed.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Folkestone Harbour: Cylinder-Sinking at the Root of the Old Pier: R. H. Lee Pennell.

MONDAY, DECEMBER 19.

SOCIETY OF ARTS, at 8.—Musical Wind Instruments, Flutes: D. J. Blaikley.

INSTITUTE OF ACTUARIES, at 5.—On the Retrospective Method of Valuation: Frederick Bell.

FARADAY SOCIETY, at 8.—The Electric Furnace; its Origin, Transformation, and Applications. Part ii.: A. Minet.—Electrolytic Analysis of Cobalt and Nickel: F. Mollwo Perkin and W. C. Prebble.—(1) The Electrolytic Preparation of Tin Paste. (2) Note on the Electrolytic Recovery of Tin: F. Gelstharp.

TUESDAY, DECEMBER 20.

ROYAL STATISTICAL SOCIETY, at 5.

INSTITUTION OF CIVIL ENGINEERS, at 8.—*Discussion* on the Construction of a Concrete Railway-Viaduct: A. Wood-Hill and E. D. Pain.

WEDNESDAY, DECEMBER 21.

GEOLOGICAL SOCIETY, at 8.—Certain Genera and Species of Lytoceratidæ: S. S. Buckman.—(1) The Leicester Earthquakes of August 4, 1893, and June 21, 1904. (2) The Derby Earthquakes of July 3, 1904. (3) Twin-Earthquakes: Dr. C. Davison.

ROYAL MICROSCOPICAL SOCIETY, at 8.—The Theory of Highly Magnified Images: J. W. Gordon.

ROYAL METEOROLOGICAL SOCIETY, at 7.30.—Discussion of Mr. F. J. Brodie's paper, Decrease of Fog in London during Recent Years. Followed by The Study of the Minor Fluctuations of Atmospheric Pressure: Dr. W. N. Shaw, F.R.S., and W. H. Dines.

THURSDAY, DECEMBER 22, 1904.

A ZOOLOGICAL TRIBUTE.

Mark Anniversary Volume. To Edward Laurens Mark, Hersey Professor of Anatomy and Director of the Zoological Laboratory at Harvard University, in Celebration of Twenty-five Years of Successful Work for the Advancement of Zoology, from his former Students, 1877–1902. Pp. xix+513; 36 plates and portrait. (New York: Holt and Co., 1903.)

THIS stately volume is a tribute to a notable personality in the history of American zoology. It has been inspired by the affection and loyalty of about one hundred and fifty of his former students, twenty-six of whom contribute the memoirs which fill its 500 quarto pages. To their esteemed master, these students—now themselves in many cases well known teachers and investigators—express their gratitude for his rigorous discipline in methods of work, for his critical skill, and for his stimulating sympathy. They recall with pride the service that was done to science by the publication of Mark's work on the maturation, fecundation, and segmentation of the egg of Limax—

"a work that introduced into America the then new cytological methods in the application of which this country has since reached an elevated position. It likewise introduced into zoology a proper fulness and accuracy of citation and a convenient and uniform method of referring from text to bibliography. It marked a step forward, also, in thoroughness and detail, and in the full recognition that, even in zoology, as in physics and chemistry, method is hardly less important than matter."

The tribute of twenty-five memoirs is one to make a teacher proud, especially as they exhibit many of the features which have distinguished his own work.

Seitaro Goto leads off with a description of a new Craspedote medusa—*Olindioides formosa*, n.g. et sp., from Misaki, like Haeckel's Olindias in some ways, yet strikingly different, *e.g.* in having six radial canals instead of four. Along with Gonionema and Halicalyx, Olindiopsis and Olindias represent the subfamily Olindiadæ, which must rest meanwhile under the Eucopidæ among the Leptomedusæ. H. S. Pratt describes four new Distomes—a new genus (Ostiolum) from the frog, related to Hæmatotœchus of Looss, and three new species of Renifer (=Styphlodera) from the mouth and air passages of common North American snakes. W. A. Locy takes us into a different domain in elaborating his discovery (1899) of a "new nerve" in Selachians, which arises on the dorsal summit of the fore-brain, before and apart from all other olfactory radices, and runs to the olfactory epithelium. A similar nerve has been recorded in Protopterus by Pinkus, and in Amia by Allis; elsewhere it has remained undetected. Jacob Reighard takes us into the open air in his fascinating and most instructively careful study of the breeding habits of *Amia calva*. The sexes differ obviously in colour, but spawning is usually at night; there are about three times as many males as females on the spawning ground; the male builds the nest, guards and defends it; he excites the female by biting and rubbing; he may induce two females at different times to spawn in the same nest; he leads the young black larvæ forth, re-unites the school when it loses scent, and guards them until they begin to assume orange and green hues; he is a model of paternal care.

Charles A. Kofoid describes an interesting Opalinid, *Protophrya ovicola*, the least specialised member of the family, which he found in the brood-sac of *Littorina rudis*. An interesting item is the presence of a micronucleus, which has only been observed in one other Opalinid, *Anoplophrya branchiarum*. It is obvious that the question of the micronucleus in Opalinids should be looked into, and that this new genus should be searched for in other localities. The next memoir brings us back to "new-fangled" methods, for C. B. Davenport compares a lot of Pectens from Tampa, Florida (*Pecten gibbus*, var. *dislocatus*), with another lot from San Diego, California (*Pecten ventricosus*). These are closely analogous species, and if environmental facts are similar, the variability should be the same. But in all the proportions measured, the San Diego Pectens show themselves from 50 per cent. to 100 per cent. more variable than those of Tampa. The San Diego forms represent a plastic race in a varied present environment. It seems to us that the concepts of variability and modifiability must be analysed out before such statistics as those offered in this memoir can be of much value in ætiological discussion. Observed differences have to be recorded, but it is only when demonstrable modificational differences are subtracted from the observed differences that we can draw secure conclusions as to variability in the strict sense. Gertrude Crotty Davenport discusses the longitudinal division and fragmentation of the sea-anemone *Sagartia luciae*, and shows that numerous intermediate forms may occur while the individuals are always tending by means of regeneration in the direction of twelve stripes and forty-eight mesenteries. Again, we must emphasise the desirability of distinguishing between modificational and variational divergences from the norm of the species.

Frank W. Bancroft describes an interesting seasonal modification of the compound Ascidian *Botrylloides gascoi*; the colony died down and the zooids degenerated, but with the assistance of a "yellow lobe" containing no zooids recuperation was effected. Carl H. Eigenmann discusses another mode of degeneration in telling the whole history of the eyes of the blind Amblyopsid fishes. The foundations of the eye in the embryos, which develop in the gill-cavity of the adult, are normally laid, but the stages beyond the foundations are cœnogenetic or direct; in fact, there is a developmental degeneration corresponding to the degeneration of the eye in the adult. Somewhat surprising is H. P. Johnston's account of three fresh-water Nereids—*Nereis limnicola*, n.sp., *Lycastis hawaiiensis*, n.sp., and *Lycastroides alticola*, n.g. et sp.—from indubitably fresh-water habitats. The author discusses the conditions which will admit of marine forms becoming denizens of fresh water, and gives a useful synopsis of recorded cases of fresh-water Polychæta. Then follows an interesting study in ethology, H. R. Linville's account of the tube-formation in *Amphitrite ornata* and *Diopatra cuprea*, the particular point of which is the minute adaptations of structure to function, an illustration of a kind of research which is always welcome and valuable.

W. E. Ritter discusses the structure and affinities of a new type of Ascidian from the Californian coast, which he calls Herdmania after a well known ascidiologist. The colony is composed of crowded but entirely free zooids arising by budding from short, much branched, closely interwoven stolons. The zooid is long and narrow, with three regions—thoracic, digestive, and cardiogenital. It is quite unique in having two epicardiac tubes, separate throughout their length; the oviduct serves as a uterus in which the embryos go through their development to nearly the period of metamorphosis; there is a peculiar grouping of the numerous branchial tentacles. It seems to be a divergent offshoot from the Polyclinid branch. R. M. Strong brings us back to a familiar subject and an old problem; he analyses the iridescence or metallic coloration of the dorsal surfaces of the distal portions of the feathers from the sides of the neck of grey domestic pigeons. The coloration is not due to diffraction, and Gadow's refraction-prism hypothesis will not work. The colours are probably thin-plate interference colours or Newton's rings, effects which are produced where spherical pigment granules come in contact with the outer transparent layer. C. R. Eastman takes us back to Palæozoic sharks, showing that the much-debated Edestus fossils are genuine teeth, and represent a stage in an interesting evolution series from Campodus to Helicoprion. We can hardly do more than refer to H. V. Neal's careful study of the development of the ventral spinal nerves in Selachians, but we may note that while the neuraxones of these nerves develop like those of Amniota as processes of neuroblast cells, there is a migration of medullary cells in early stages of development, which, though they take no part in the formation of the neuraxones or ganglia of the ventral nerves, participate in the formation of the nerve-sheaths, which have usually been regarded as of mesenchymatous origin.

H. S. Jennings elaborates his interesting thesis that the asymmetry of most flagellate and ciliate Infusorians, as also of the Rattulid Rotifera, is correlated with the habit of swimming in spirals. The spiral course is the simplest device for permitting an unequally balanced organism to progress in a given direction through the free water, and the method of reaction to most stimuli is closely correlated with the unsymmetrical or spiral type of structure. Rolfe Yorke contributes a study of the nerve cells of the cockroach and of the substance within these that seems to correspond to the chromophilous material in the nerve cells of higher animals. R. M. Yerkes shows by elaborate experiments that *Daphnia pulex* is strongly positively phototactic to all intensities from 0 to 100 candle-power, and is negatively thermotactic at a temperature of about 28° C.

In a very interesting paper on Mendel's law and the heredity of albinism, W. E. Castle and G. M. Allen show that complete albinism, without a recorded exception, behaves as a recessive character in inheritance, and that the facts are in general accord with Mendelian principles. P. E. Sargent discusses the structure and functions, development and phylogeny of that archaic portion of the mesencephalic roof known as the torus longitudinalis which is characteristic of Teleosts. T. G. Lee attacks a not less difficult problem —the implantation of the ovum in the gopher, which he finds to be quite unique as regards the nature and history of the pre-placental "fixation-mass" formed by the trophoblast. J. H. Gerould makes a comparison of the early stages of Sipunculus and Phascolosoma, and seeks to show that the "serosa" of the former represents the remains of a degenerating prototroch equivalent to that of the latter, which is in turn homologous with the primitive condition seen in mesotrochal Annelids.

G. H. Parker takes us once more into the open air in his study of the positive and negative phototropism of the mourning-cloak butterfly (*Vanessa antiopa*). It is interesting that the negative phototropism is only seen in intense sunlight and after the butterfly has established a certain state of metabolism by flying about for a while, and that the position assumed in negative phototropism exposes the colour patterns of the wings to fullest illumination, and has probably something to do with bringing the sexes together during the breeding season. Ida H. Hyde presents a new interpretation of the structure of the eye of Pecten, supplementing and correcting previous descriptions. The long series of memoirs ends with one by H. B. Ward on the larvæ of *Dermatobia hominis* —an Oestrid or bot-fly, widely distributed in America, though not in the States, which occurs commonly in the skin of cattle, pigs, and dogs, and less frequently in some other creatures, including—unfortunately—man.

We cannot conclude our rapid review of this huge volume without directing attention to the great range of zoological territory which the memoirs cover, to the high standard of workmanship which they exhibit, and to the unanimity with which the various authors recognise their indebtedness to their master, Edward Laurens Mark.

J. A. T.

SYNTHESIS OF VITAL PRODUCTS.

The Chemical Synthesis of Vital Products, and the Inter-relations between Organic Compounds. By Prof. Raphael Meldola, F.R.S. Vol. i. Hydrocarbons, Alcohols and Phenols, Aldehydes, Ketones, Carbohydrates and Glucosides, Sulphur and Cyanogen Compounds, Camphor and Terpenes, Colouring-matters of the Flavone Group. Pp. xvi + 338. (London: E. Arnold, 1904.) Price 21s. net.

IN spite of the long and daily increasing list of successful chemical syntheses of substances which are primarily produced as the result of processes occurring in living organisms, one constantly hears from physiologists the complaint that the synthetic work of chemists, wonderful as it may be in itself, throws no light on the biochemical problem of how the same substances are generated in the bodies of plants or animals. The points of view of the organic chemist and the physiologist are entirely distinct. The chemist, in studying a biochemical product, starts by dissecting it into a number of known atomic groups, and when this analytic work is complete, he seeks to confirm his conclusions as to the constitution of the substance by piecing these atomic groups together again, so as to reproduce the substance synthetically. In accomplishing the latter part of his task, the question of imitating biochemical conditions never even occurs to him, inasmuch as for his purpose the simplest and most efficient laboratory processes are the best; and when he has solved the problem from his point of view he is satisfied. That alizarin and indigo can not only be synthesised, but that they can be synthesised so cheaply that the natural products cannot compete with them in the market, is doubtless a triumph both for the chemist and for the technologist; but so long as each step of these syntheses is effected either by means of such chemical agents or under such conditions of temperature as would be fatal to life in any form, it is evident that the results are devoid of any biochemical bearing, and that the physiologist is justified in disregarding them. Meanwhile, therefore, so far as the important subject of the synthesis of vital products is concerned, there is no helpful interaction between chemistry and physiology. Each goes its own way.

It is with the object of endeavouring to remove this reproach from these sciences and of bringing about a better understanding between them that Prof. Meldola has written the present work, of which the first volume is now before us. The work is, as the author states, "a record of the synthetical achievements of generations of workers arranged with a distinct biochemical bias." In fact, the title of one of the introductory chapters, "Organic Chemistry from the Bio-centric Standpoint," might have served as a subtitle for the entire work.

This biocentric standpoint has, as the author indicates, necessitated an arrangement of the subject-matter differing materially from that usually followed in works on organic chemistry. In these the derivatives are arranged under the parent compound, or chemical type, from which in many cases they can be produced by processes of laboratory synthesis. But,

"According to the present scheme each vital product is in itself a biochemical type quite independently of the chemical type to which it may be referred, and the synthesis of each product, instead of being mentioned incidentally in connexion with the group to which it belongs as a point of minor interest, is here brought into the first rank of importance. In other words, the chemical type is in this work subordinated to the individual compound—a mode of treatment for which every justification will be conceded when it is pointed out that in vital syntheses there are unquestionable genetic relationships between compounds of quite different types" (p. 12).

Another necessity arising from the biocentric standpoint has been the recognition of "down-grade synthesis" as well as of "up-grade synthesis"—of the synthetic products obtained from complex generators by fission as well as of those obtained from simpler generators by union. Thus a number of substances generally recognised as vital products do not occur as such in the living organism, but are produced by hydrolytic fission, sometimes during the process of isolating them: thus alizarin from the glucoside ruberythric acid. The justification for registering these as vital products lies in the fact that their atomic complexes are pre-existent in the glucosides and similar compounds from which they are obtained.

The details of these classifications are worked out by the author with very great skill and with exhaustive knowledge of the subject. References are everywhere given, no fewer than forty-five periodicals, not to mention the patent literature, being quoted from. Among the syntheses enumerated we have not succeeded in detecting any omissions. The author does not claim to have sifted critically the enormous mass of experimental records which he has brought together; he leaves to the investigators themselves the responsibility for their statements. His object is "to bring practical workers, whether chemists, physiologists, or technologists, into communication with the various authorities quoted."

The author admits that we are at present profoundly ignorant of the modes of synthetic action which go on within the living organism, and he points to the necessity for a more systematic study of the chemical stages in which such action occurs—a branch of investigation for which plant life offers especial facilities. He points to Charabot's researches on the development of the terpene alcohols and ketones as examples of the pioneering work required. He is firm in his belief that such work will not only increase our knowledge of biochemistry, but will place us in a position to imitate the conditions of biochemical synthesis. He writes:—

"If, some decades hence, a work on similar lines to the present should ever be compiled, it may be anticipated with confidence that the laboratory methods for synthesising vital products will have approximated more closely to the physiological processes" (p. 9).

This confidence in the future powers of the chemist is closely connected with the author's attitude towards Neovitalism. He says:—

"I think it advisable to place on record the opinion that the present achievements in the domain of chemical synthesis furnish no warrant for the belief that the chemical processes of the living organism are in any sense transcendental, or that they must be regarded as belonging to a class of special material transformations which human science will never be able to reproduce. Such an admission as the latter would be tantamount to a proclamation of Neo-vitalism. . . . There is no warrant for the belief that the physics or chemistry of animals and plants is ultra-scientific" (Preface, p. vi).

To the present reviewer the terms "transcendental" and "ultra-scientific" seem to beg the question. It is surely a matter for legitimate and entirely "scientific" inquiry, whether our present laws of chemistry and physics, which have been deduced solely from the study of dead matter, apply without qualification to living matter. Possibly, when the conditions of the biochemical problem are more thoroughly understood, it may be, contrary to Prof. Meldola's belief, just as easy to show that we can never, in our beakers and retorts, imitate the biochemical conditions of vital synthesis as it is for a mathematician to prove the transcendence of π.

This view, like its opposite, is, however, in the present state of our knowledge, rather a matter of opinion than of proof.

In conclusion we congratulate the author on having produced a most useful work—a work of almost ultra-German thoroughness—and one which will be an immense boon to all interested in the subject with which it deals.

IONISATION AND ABSORPTION.

The Becquerel Rays and the Properties of Radium. By the Hon. R. J. Strutt. Pp. vii + 214. (London: Edward Arnold, 1904.) Price 8s. 6*d*. net.

A NUMBER of books dealing with radio-activity and the kindred phenomena have already appeared; and it is a bold thing on the part of an author to place another before the public. However, with the exception of Prof. Rutherford's inimitable treatise on the subject, none of the previous works have been characterised by any striking individuality, so that there is, or rather was, still room for a vigorous statement of the general features of the subject from a popular point of view. This the author of the present work has accomplished in a manner that leaves little room for criticism. He possesses to a remarkable degree the faculty of stating difficult questions in a simple way, and of expressing the answers in a language which is easily understood.

In a book of this kind there is usually a good deal of treatment which appears somewhat slipshod when regarded from a strictly scientific standpoint; but such a charge cannot with justice be maintained against the present volume. Naturally some of the most intricate points, such as the effect of a magnet on a moving electric charge, have to be treated analogically to make them represent anything real to a mind inexpert in dealing with this class of phenomena; but here the author has not only been fortunate in choosing familiar instances, but those chosen have been true analogies, and accurately represent the physical features of the case. The whole treatment is characterised by vigour and interest, and is such as we should have every reason to expect from the pen of so well-known an investigator in this branch of physical science as the author.

It is scarcely necessary to analyse in detail the contents of the book, but the whole forms a clear and concise presentation of the great question of the relationship between electricity and matter, which is of overpowering interest to physicists at the present time. In the first chapter we are made familiar with the various phenomena accompanying electric discharge in rarefied gases, and are thus placed in a position to understand the working of what may be regarded as a miniature discharge tube, viz. a radio-active atom. After describing the various manifestations of radio-activity and the properties of the radiations, the author considers the various products of radio-active change. We are thus led to a probable view of the mode of origin of the chemical elements, in the evolution of which the inert gases seem to form the final stage. The last chapter forms a very lucid account of the electrical theory of mass and the various views of atomic structure based thereon.

Unfortunately there is one serious blot on the general excellence of the book, and that is the treatment of absorption in chapter iv. Almost at the outset (p. 87), the author contradicts himself owing to the word "greater" having crept in where he doubtless intended to say "less." This uncorrected error is not likely to cause much trouble to those who are familiar with the subject, but we imagine the beginner will be greatly perplexed by trying to reconcile this statement with what follows.

Apart from this, it seems a great pity that so much stress should be laid on Madame Curie's experiments on the absorption of the α-rays from polonium, as it is doubtful what conclusion can be drawn from them except that practically all the rays are stopped by about four centimetres of air. In the experiments referred to a quantity of polonium was placed at a variable distance below two parallel plates three centimetres apart. A hole in the lower plate covered by wire gauze allowed the α-rays from the polonium to penetrate the region between the two plates, and the ionisation it produced there was taken to measure its "intensity." Madame Curie then investigated the diminution in the ionisation produced by placing a sheet of aluminium foil 0·001 cm. thick (equivalent to 2 cm. of air) over the lower plate, when the polonium was at different distances below it. When the polonium was 0·5 cm. away the aluminium cut down the radiation to one-quarter its previous value, whilst when the distance was 1·9 cm. the ionisation was reduced to one-twentieth. This shows clearly, as Madame Curie pointed out, that the α-rays which have passed through a certain thickness of matter are less penetrating than those which have not. The question, however, which is of most interest in the present state of the subject is how the ionisation per centimetre of path varies with the amount of matter previously passed through. These experiments furnish no very certain answer to this question, since when the aluminium foil is inserted the whole of the radiation is absorbed long before it reaches the upper plate, so that the different experiments are not strictly comparable. The whole question of absorption is very intricate, and it is undesirable to dwell further upon it here. There is still plenty of room for experimental investigation on this subject. For instance, Townsend's experiments on ionisation by collision and Durack's on that produced by the Lenard and Becquerel rays show that the number of ions produced per cm. by a moving corpuscle increases with the velocity up to a certain point, and then decreases. It would be of interest to see whether, as is probably the case, this holds for the positively charged α-rays as well.

The book contains three useful appendices. The first describes a number of simple experiments illustrating the essential features of radio-activity; the second gives the simple theory of the deflection of kathode rays, for the benefit of those not entirely unacquainted with mathematics; while the third describes the chemical processes involved in the extraction of the radio-active products from pitchblende residues.

The general arrangement is good, but there appears to be more than the usual allowance of uncorrected errors in spelling and composition. We hope that a second edition will give the author an opportunity of correcting these.

On the whole the book may be thoroughly recommended to the general reader as an accurate and attractive account of the latest aspect of scientific thought on the structure of matter; whilst the specialist will find numerous passages which are suggestive and stimulating.

O. W. Richardson.

LABORATORY EXERCISES IN BREWING.

Laboratory Studies for Brewing Students. By A. J. Brown, M.Sc., &c. Pp. xviii+193. (London: Longmans, Green and Co.) Price 7s. 6d. net.

THE brewing school at Birmingham is fortunate in possessing Prof. Brown as its head, and we hail the appearance of his book as extending its advantages to students of brewing generally.

These Laboratory Studies describe a systematic series of experiments illustrating the scientific principles underlying brewing. The author is careful to point out that he does not aim at dispensing with a teacher. Assuming a knowledge of chemical manipulation, he gives the detail necessary for the successful performance of each experiment, and draws the appropriate conclusion. He frequently connects the conclusions with others from allied experiments, and even to some extent with brewing practice, but at each step more and more scope is left for the teacher to discuss the bearing of the results on one another and on large scale work. If the author published his own lectures we should doubtless find them an exceedingly valuable complement to the work before us.

The book is divided into four sections:—(1) barley and malting; (2) principles of the mashing process; (3) fermentation; (4) hops. These sections are further subdivided into parts and paragraphs, the latter corresponding to each experiment.

The first section follows the changes in outward appearance from the flowering stage to the ripe barley corn, and thence passes on to the anatomy of the corn and to its conversion into malt.

Under the heading dealing with the varieties, we find one of the many instances of the way in which the author equips his men for taking their part in the controversies of present day brewing but avoids all dogmatising on points still *sub judice*. The experiments are planned so that the student will know all the characteristics of, *e.g.*, Chevallier (we adopt Mr. Beaven's spelling of the rev. gentleman's name) and Goldthorpe, but he is left with an open mind as to the vexed question of their rival merits.

Dealing with the technical examination of malt (and, indeed, also of barley and hops), we are glad to find due recognition given to expert knowledge—the student being specially commended to the teacher for instruction in it. For we are apt nowadays to underrate the knowledge accumulated by the practical man—what corresponds to the "farmer's eye" is still of immense value to the brewer.

Section i., part v., devoted to the chemical examination of malt, is as good as any in the book. Heron's method of determining the yield of extract is very fairly criticised, and we leave the subject with a full appreciation of its value and difficulties. The footnote of p. 46, that "a thoroughly satisfactory malt mill is yet to be introduced," should appeal to all interested in brewing.

Section ii., the principles of the mashing process, deals with the changes which take place when malt and water are brought together at various temperatures and sketches the analysis of wort as far as the carbohydrates (much the largest constituents) are concerned. We were sorry that, in giving the experiment showing that the influence of heat in restricting starch transformation is due to modification of the diastase, no reference is given to Kjeldahl's "Recherches sur les ferments producteurs de sucre" (*Résumé du Compte rendu des Travaux du Laboratoire de Carlsberg*, i, 109), but this is perhaps on account of its being in a foreign language and so unsuitable for students.

Section iii. is devoted to fermentation, but, as there are already books, chiefly by the Hansen school, dealing with this important subject, this section is a good deal curtailed. We are, however, glad to see (even if they are in small print) experiments on the author's important discovery that the maximum number to which yeast cells multiply in a nutritive solution depends, not on the number of cells with which the solution is seeded, but on the volume of the solution, granted, of course, a sufficiency of food.

Section iv., on hops, concludes the volume. We wish an experiment had been included to show the restrictive action of hops on the acid-forming bacteria, but such an experiment is not a very easy one for students.

It will have been noticed that the book adheres to the usual plan of beginning with barley and ending with beer. This seems inconsistent with the custom of passing from the well known to the less well known, and we should like to see tried the opposite plan of starting with beer and tracing it back into its constituents.

In training men for technical work the course should be; first, a general grounding in science; secondly, practical experience of the art in question; thirdly, a study of the scientific principles involved. If this be so the work before us should not only be of service to students but also to those brewers who desire to look into the experiments on which the principles of their art are founded.

OUR BOOK SHELF.

Morphologie und Biologie der Zelle. By Dr. Alexander Gurwitsch. Pp. xix+437. (Jena: Gustav Fischer, 1904.)

We are told in the preface that this book is intended for the use of beginners. The author must, however, have had Macaulay's omniscient schoolboy looming large in his imagination when he thus appraised the character of his completed work. Many of the topics discussed are quite the reverse of elementary, and the general treatment adopted throughout is lacking in that quality of lucidity which is essential to success, especially in a work that is written for the use of beginners. The fact is the author has attempted too much, and although his book may be serviceable to readers already tolerably familiar with cytology, it can, we imagine, hardly hope to appeal to the class for which it is stated to have been designed.

The general plan of the work is somewhat novel and has much to recommend it, whatever one may think of the manner in which Dr. Gurwitsch has actually executed his task. Thus, whilst a considerable description of cell-structure is naturally included, it is on the physical and physiological aspects of the problems that attention is mainly concentrated. Some of the sections, in particular those dealing with metabolism, are suggestive and well worth reading, although one not seldom misses expected allusion to recent work. Indeed, it almost seems at times that the author is rather needlessly attacking positions which have already ceased to possess any real importance.

A considerable number of pages are devoted to the subject of nuclear and cell division, as well as to a discussion of conflicting theoretical explanations of the process of mitosis. The advanced student will here find much to interest him if he will take pains to dig it out. But the whole question of reduction is omitted, on the ground that the author regards it as foreign to the main purpose of his book. We cannot but regret his decision, since the processes therein concerned serve to throw light on many difficulties connected with an ordinary mitosis that are not otherwise easily cleared up.

The last portion of the book is given up to a discussion as to whether the cell is to be regarded as an elementary organism or as the unit of organisation, and the question is treated both from the view of the Protozoa and Metazoa. The discussion is difficult to follow, and the answer really depends on what meaning is attached to the somewhat elusive definitions employed. It is, of course, obvious that the significance attaching to the unit will not always be the same, for this will have a different value for the morphologist and the physiologist respectively.

We confess that, whilst the book as a whole possesses undoubted merits, it nevertheless strikes us as the result of a premature effort. There is much evidence of undue haste, for example in the amazing number of glaring typographical errors; the names of authorities quoted, no less than ordinary words, repeatedly assume an unfamiliar appearance. But however irritating this may be to the reader, it would after all be a trifling matter if the subject as a whole had been presented in a well digested fashion. J. B. F.

A New Geometry for Senior Forms. By S. Barnard, M.A., and J. M. Child, B.A. Pp. xv+331. (London: Macmillan and Co., Ltd., 1904.) Price 3s. 6d.

This text-book is intended primarily for the use of students who are reading for the Oxford and Cambridge local examinations; the London intermediate examinations; mathematics, stages iii. and iv., South Kensington, and examinations of like nature. The first half of the book is a very happy combination of practical work and deductive reasoning. Much scale drawing is done, it is to be hoped with proper appliances in a proper manner, and teachers and students can select from a large number of graphical exercises appearing at short intervals, many of which have been taken by permission from recent examination papers. Trigonometrical ratios for acute angles are introduced and formulæ established relating to triangles, a short table of sines, cosines, and tangents being employed for numerical calculations. This section also deals with the geometry and mensuration of the simple solids, the formulæ used being all proved. The prismoidal formulæ and suggestions for the treatment of irregularly shaped figures seem unfortunately to have been overlooked. There are a few pages on the geometry of plane motion where the idea of a vector might have been appropriately and very usefully introduced.

The second or "theoretical" half of the book is mainly concerned with the formal establishment of theorems relating, amongst other matters, to the connection between algebra and geometry (after Euclid ii.), to circles, to ratio, proportion, and similar figures, and to solid geometry as in Euclid xi. A little modern geometry is given, but there is no description of how form and position in space are defined and exhibited by scale drawings.

The authors have produced one of the best of the new text-books which are following closely the progress of reform rather than leading the way. The volume can be heartily recommended to students who are preparing for mathematical examinations under recently revised schedules.

Studien über die Albuminoide mit besonderer Berücksichtigung des Spongin und der Keratine. (Studies on Albuminoids, with Special Reference to Spongin and the Keratins.) By Dr. Eduard Strauss. Pp. 128. (Heidelberg: C. Winter, 1904.) Price 3·20 marks.

This little book does not treat, as its title might lead some to suppose, of the albuminous substances in general, but of that limited group of them to which the term albuminoid is usually restricted by physiologists. This group includes spongin, cornein, gorgonine, onuphine, conchiolin, spirographin, and silk, which are products (mainly skeletal in function) of the invertebrate world; and collagen, reticulin, elastin, and the keratins, which are found among the vertebrata. One notes in this list the absence of chitin among the invertebrate products, the reason being that this material has now been shown not to be a member of the proteid group at all. Reticulin, also, which is mentioned, and was originally described by Siegfried, does not really exist. Miss Tebb conclusively proved it to be an artifact from collagen, and this view is accepted by Dr. Strauss.

The first seventy pages deal with a general account of these substances taken one by one. The remainder of the book deals with some original work on the digestion products of spongin and the keratins. The proteoses so formed were separated by Pick's method, and their properties differ somewhat from, though in the main resemble, the similar products of proteolysis derived from other and better known sources. Among them two gluco-albumoses are described. Iodine occurs not only in gorgonine, the organic substratum in certain corals, but also in spongin.

This contribution to science is interesting, but deals with such a small corner of biochemistry that it will appeal to very few. We doubt whether it is wise to magnify its importance by making it the subject of a special book. The first part of the work is dealt with, though perhaps not quite so fully, in all text-books of physiological chemistry, and the second part might quite well have formed the subject of a brief paper in one of the numerous journals devoted to such subjects.

W. D. H.

Pages from a Country Diary. By P. Somers. Pp. vi+280; illustrated. (London: Edward Arnold, 1904.) Price 7s. 6d.

THIS is one of those delightful books written in the form of a discursive diary, somewhat after the style of Sir Herbert Maxwell's "Memories of the Months," which may be taken up and read during every spare half-hour until the reader finds with regret that he has come to the last page. Almost every kind of topic and pursuit connected with country life receives a share of attention, among them, to a brief extent, the habits and ways of birds and other animals. Among statements connected with natural history is one (on the authority of a well known taxidermist) that albino pheasants always have diseased liver; this, however, if true, can scarcely be cause and effect, since such birds have white plumage from the first, and they surely cannot be hatched with liver-disease. Special interest attaches to the statement that a hen grouse of normal colouring produced an entire brood of cream-coloured chicks, since this seems to afford an instance of how a new colour-phase might be produced by discontinuous variation. The subsequent history of the brood is not recorded—probably its members were all shot.

Several references are made to otters and their habits, and, although he is a thorough sportsman, the author cannot refrain from uttering a word of sympathy with these beautiful animals when surrounded in the water by a pack of hungry otter-hounds. On the other hand he has nothing but scorn for the sickly sentimentality of those who would forbid such manly sports as hare-hunting and stag-hunting, even when the deer is a so-called tame animal.

A Scheme for the Detection of the more common Classes of Carbon Compounds. By Frank E. Weston, B.Sc. Pp. viii+56. (London: Longmans, Green and Co., Ltd., 1904.) Price 2s.

THIS little book is intended for students who are preparing in chemistry for the final B.Sc. examination of the University of London. The author, who is lecturer on chemistry at the polytechnic in Regent Street, has elaborated the scheme now offered as the result of many years' experience with his own classes. There certainly has been a dearth of "systematic schemes" for the detection of carbon compounds, and from this point of view the book should be useful. Whether it will have any real educational value will depend very much upon the manner in which it is used. If, as in the case of the "systematic schemes" for the detection of inorganic substances, the identification of organic compounds is to be reduced to a purely mechanical series of operations involving no real scientific knowledge on the part of the student, the present book will do more harm than good to the cause of education, although it may help candidates through the final B.Sc. as intended. On the other hand, if used intelligently in connection with the scientific treatment of organic chemistry, it may be made of some educational use. The selection of compounds has on the whole been judiciously made, and we have no fault to find with the treatment excepting to point out that certain crudities of style and inconsistencies of spelling seem to indicate either imperfect knowledge or imperfect revision. What quantity, for example, is meant by "a pinch"? Why should the word "monohydricphenols" appear on one page and "trihydric phenols" on another? There are too many slips of this kind in such a small book to enable us to recommend it unhesitatingly to students in its present form.

Photograms of the Year 1904. By the Editors and Staff of the *Photogram*, assisted by A. C. R. Carter. Pp. xlviii+176. (London: Dawbarn and Ward, Ltd., 1904.) Price 2s. net.

IN these pages we have typical photographic pictures of the year reproduced and criticised. This statement does not apply simply to British productions, but extends to those made in many lands where pictorial photography is practised. Robert Demachy discourses on the pictures exhibited at the annual series of photographic events in France. British Columbian progress is recorded by H. Mortimer Lamb. The editor of the Australian *Photographic Journal* gives some notes of the advances made in his country, while "A new Departure in American Pictorialism" is written by Savakichi Hartmann. These are followed by articles on the work of the year, suggestions to would-be picture-makers by H. Snowden Ward, and "Royal and Ring." The two great exhibitions, the Photographic Salon and the Royal, are dealt with by A. C. R. Carter. The "American Salon" and "Western Workers in the United States" conclude the volume. It may be mentioned that this publication is the tenth annual issue, and equals, if it does not exceed, both in quality and number of illustrations, those that preceded it. Most of the reproductions are the work of Messrs. Carl Hentschel, Ltd.

It seems scarcely necessary to add that those of our readers who follow this special branch of photography will find in this volume material which should prove of great value to them.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Heterogenetic Fungus-germs.

THE development of brown fungus cells in connection with Zooglœa, as described in NATURE, November 24, by Dr. Bastian, is very familiar to me, and probably to all who attempt pure cultures of fungi.

Various species of microscopic fungi belonging to the genus Cladosporium are everywhere present on fading and dead leaves. The spores, and also the vegetable portions of these fungi, constantly assume the form called *Dematium pullulans* by De Bary. Such forms produce exceedingly minute colourless conidia, which can pass through thick filter paper. Under normal conditions these minute conidia on germination form delicate hyaline hyphæ which give origin to a Cladosporium. If cultures of these conidia become infested with bacteria that form Zooglœa the hyphæ become invested with a comparatively thick, brown cell-wall, and form either compact masses of cells or irregular hyphæ consisting of short cells, constricted at the septa, exactly as shown in Dr. Bastian's Fig. 12. In a disease of *Prunus japonica*, caused by a Cladosporium, large masses of gum, just sufficiently dense to prevent dripping, issued from the wounds. The mycelium of the fungus spread into this gum, and produced myriads of brown cells arranged in chains.

The semi-liquid gum caused the same abnormal development as that produced by Zooglœa. A plate showing the entire course of development of the fungus in the gum is contained in the *Kew Bulletin*, December, 1898. As these fungi only develop on fading leaves, it was not to be expected that they would appear in infusions of young grass.

Herbarium, Kew. GEORGE MASSEE.

Note on Radio-activity.

In the course of some experiments on the chemical behaviour of the β and γ rays from radium (Ramsay and Cooke, NATURE, August 11) solutions were obtained containing a radio-active substance which could sometimes be removed from the solution by the formation in it of a suitable precipitate. Sometimes when such a solution, containing ammonium salts, and in which several precipitations had already taken place, was evaporated to dryness on the lid of a porcelain crucible the residue was found to be capable of lessening the rate of leak of the electroscope, *i.e.* it behaved in the opposite way to an active residue, which would increase the rate of leak. This "anti-activity" has been observed on several occasions, and seems to be a specific property of the matter examined, and not to be due to any variable condition of the electroscope; thus the natural leak taken before is the same as that taken immediately after such an experiment.

I have not found any mention of a similar phenomenon in the literature on radio-activity, but should be glad to know if like results have been noticed by other observers. An explanation of the "anti-activity" would seem to be either that the leaf of the electroscope, which was always negatively charged, receives particles carrying a similar charge, which particles cause little ionisation of the air, or that the rays exert a de-ionising power on the air, if one can conceive of such an action. W. TERNENT COOKE.

Gower Street, W.C.

Blue Flints at Bournemouth.

THERE is an old man living here, in Bournemouth, who years ago was employed in re-laying a part of the Poole Road, some little distance within the western boundary of the borough. He says that he helped to put down a quantity of refuse from the gas-works mixed up with flints, &c.—for this was before the days when the Poole Road began to be mended with granite. Now it so happened that this very man was employed to dig up and remove the surface of the road in preparation for the laying down of the tram lines, and of the wood pavement with which the whole road is now covered; and he says that he helped to dig up the very stuff which years ago he had helped to put down, and that this old road material was carted off to the new road then in course of construction upon the common and along the top of the cliff close by this part of the Poole Road. The flints, he says, came out blue, and are the blue flints now to be seen in patches upon this new road along the west sea-front. J. W. SHARPE.

Bournemouth.

Intelligence of Animals.

As some stray remarks of mine seem to have set this discussion agoing, I should be glad if you would kindly allow me to supplement your correspondents' interesting letters by two or three further stories which have come directly under my own observation. They are intended to be illustrative of methods of *reasoning about reason* in animals, particularly dogs. It will be observed that each story has its own distinctive shade of inaccuracy, and that the shade grows deeper as you proceed.

I trust, however, I shall by no means be taken as doubting the correctness of the facts sent you by your scientific readers, though I admit I might plead guilty to an indictment for suspecting seriously their interpretation. In the case of one or two of them I should not be surprised if some much more simple explanation than the one put forward might have been overlooked.

(1) Some years ago I had a favourite Irish terrier, Tim. Tim was a brave little chap, and would not quail before a lion. Like all of his strain, he had, I may say in passing, the rather human habit of grinning when amused, and would smile back at you in quite a comical fashion. This not too common trait is, I think, noteworthy.

When a mere puppy, Tim, in one bound, leaped into the household's good graces, and by no less meritorious an action than by saving us all from being burned alive. It was this way. Some newspapers thrown carelessly near the library grate caught fire; but Tim, who was snoozing on the hearthrug, bounded up and rushed to the cook, making such a row that that good lady dashed upstairs and tramped out the budding conflagration.

I am loth to point out that the young terrier could have had no more idea of a conflagration than Juno's geese when they cackled had of the Gallic invasion, from which by so doing they are said to have saved the Roman Capitol, and, further, I am greatly afraid that on the occasion showed not the foresight set down to his credit, but for once in his life—cowardice. The results, indeed, as not rarely happens from that species of wisdom, were satisfactory, and the appropriation of the praise on Tim's part quite after the manner of fully acknowledged rationals.

(2) In adult life Tim used to earn his breakfast of mornings by carrying my boots up to my room. Where his astuteness and "reasoning power" came in was by always fetching up polished boots, though he might have three or four pairs to pick and choose from. Of polished pairs he would invariably seize my light ones if they were at hand—a hint, the housekeeper used to insist, that he wished that I should "go off with myself" and visit friends.

When "doggie" stories are circling I seldom fail to extract this from my budget, and I am always tempted to add little flourishes. At all events, I never feel called upon to explain that Tim possessed no acquired taste for bog-mud, and accordingly he discarded soiled shoes. Further, though Tim was by no means lazy, he set store by Helmholtz's great principle of the conservation of energy. He had experimented and discovered for himself that there was far less using up of brawn and muscle in bearing along and aloft a thin than a heavy, thick-soled boot. All this by no means appeared on the surface, and so his superlative judiciousness was a source of delight to the cook, and of bewilderment to her visitors, all the year round.

(3) A farmer residing near me has a strong, useful mongrel, Major by name. Though Major is a cur of low degree, his wisdom is great and "uncanny." Like every other dog around here he would almost know your thinking—to use the pet phrase—and certainly would understand your talking. The latter statement can be proved, and I beg to undertake the demonstration.

For agriculturists in these parts fairs are the grand monthly carnivals. Some months ago, on the eve of one, our farmer said to his wife as they sat by the fireside, "Jane, I think I must chain up Major to-night and not have him follow us to-morrow as he did on the last occasion." "Would you believe it," so the farmer relates it, "on hearing his sentence out marched Major, most indignant." Next morning at an early hour, as Jane and himself proceeded to the fair, there he was sitting on his tail on a fence looking out for them more than a mile from home! And so he was at the fun of the fair as well as another.

Our farmer never conjectured there might have been in the meantime for the mongrel an attraction of his own in the direction of the town, though the torn ear was there to set him thinking. *Qui vult decipi, decipiatur.*

(4) Another neighbour possesses a spotted dog which he calls a water spaniel. Though he, no less than every other puppy, whelp, and hound in the country, may be distinguished for intelligence, he and they are certainly not noted for good looks or long pedigrees. This particular thoroughbred, amongst many things, (*a*) can go on a message to any house he is directed to within a radius of three miles! (*b*) can catch any hare he sets his eyes upon! and yet (*c*) will be fifteen years old to a day if he lives until January 2 next!

Explanation:—His owner sometimes gives a loose rein to a splendidly vivid imagination.

I yield to no one both in my respect and liking for our canine friends and in my admiration for their affection, their highest developed quality. But I am inclined to think their good points and "thinking powers" are often vastly exaggerated by friendly and carelessly observing eyes. Much that surprises may be of the type of one or other of the four stories above given. Imperfect, ill-trained observation, reading into actions motives and purposes which were never dreamt of, setting aside the simple for the marvellous, assisted by a heavier or lighter dash of Munchausenism, would turn folly into wisdom and wisdom into folly. By the help of any one of these principles one is quite capable of seeing in the most aimless action the profundity of the gods.

Creevelea, co. Leitrim. JOSEPH MEEHAN.

SOME SCIENTIFIC CENTRES.

VI.—The Physical Laboratory at the Museum d'Histoire naturelle.

The Museums d'Histoire naturelle, in the beautiful surroundings of the Jardin des Plantes in Paris, founded in 1793, form an institution of acknowledged eminence; whilst the lectures delivered there are by the most renowned professors, and on most, if not all, branches of the natural sciences. It was Cardinal Richelieu, as we know, who founded the Jardin des Plantes somewhere about 1626, not long before the establishment of the French Academy by the same great Minister of State.

The physical laboratory in particular of these museums has been the seat of many discoveries and the centre from which has radiated some of the best thought, as well as some of the best work, that has animated the academy and through it the scientific world for three-quarters of a century. It is not often the case with science, nor, indeed, with other branches of learning, that in a single family there should be found for three generations a series of distinguished men of the highest order of intellect who have devoted their lives and best energies to its pursuit and attained to universal fame. More seldom is it, then, that when the lineage is thus preserved unbroken, the members thereof should all be devoted to the one and to the self-same calling. For three generations the Becquerels have occupied in succession the same chair at the same institution, namely, the Museum d'Histoire naturelle in Paris. The number of papers which have been read before the Academie des Sciences by the Becquerels extends to seven or eight hundred.

Henri Becquerel, whose portrait in his laboratory at the Museum d'Histoire naturelle is here reproduced, is, we venture to think, perhaps the most distinguished of his race. His father, Alexander Edmond, is known as the inventor of the phosphoroscope and the author of "La Lumière," a work of great value in its day, whilst his grandfather, Antoine César, was likewise famous for a long series of researches, chiefly on chemical dynamics and electrocapillary phenomena. His electromagnetic balance is of historic interest in the development of the galvanometer, although long since abandoned for practical purposes.

Thus the history of the physical laboratory at the Museum d'Histoire naturelle may be said to run parallel with the history of the Becquerels, and the two to be so closely interwoven that to describe the part played by one and the influence exerted by it in the development and advancement of knowledge is perhaps equivalent to writing that of the other in detail. It was not so with other scientific centres of this series; there there were many discontinuities, here the continuity is one.

The technical process of gilding due to de la Rive was based upon Becquerel's observation in 1834 of the deposition of metals on the negative electrode when the poles of a pile are immersed in solutions of various metallic salts; that the two solutions needed could be kept apart by the use of animal membranes without preventing the passage of the current, and that with very feeble currents the deposition of metal is even

Fig. 1.—Prof. Henri Becquerel in his Laboratory at the Paris Museum d'Histoire naturelle.

and uniform on the surface of the electrode. Although rivalled by many others in the application of these principles, many were the facts and many the methods which he announced with rapid succession in laying the foundations of the art of electro-plating.

It was to the study of electrocapillary phenomena, which he was the first to observe in 1867, that his later years were devoted. The discovery was a curious one, the result, if we mistake not, of the deposition of metallic copper on a crack in a test-tube containing a solution of cupric sulphate, and immersed in another solution of sodic sulphide. The investigation of this phenomenon was full of interest, and not the least was the suggestion that the deposition of metals in veins in rocks is due to the same cause as that which he observed in the broken test-tube.

A member of the French Academy from 1829, eight years before being called to the chair which he filled to the end of his life, he was also a corresponding member of the Royal Society, and received from it its greatest honour, the Copley medal, and from the Emperor Napoleon III. the Cross of Commander of the Legion of Honour. Thus with him there closed a chapter, a long, an interesting, and an eventful chapter, in the history of the Museums d'Histoire naturelle.

Edmond Becquerel, although a pupil of his father and for a considerable time his assistant at the museums, did not teach there, and, indeed, as Sir William Crookes has said in his obituary notice of him in the *Proceedings* of the Royal Society, of which he was a foreign member, it may "be remarked that though he had early distinguished himself by scientific works of high value, and as the son of an eminent and much respected Academician he was not without influence, yet none of the great scientific establishments of his country offered him an appointment." He finally, however, secured a permanent position at the Conservatoire des Arts et Métiers, and there the abilities so long latent had full play, and manifested themselves by the success of his subsequent career.

At the death of his father, in 1878, he succeeded to the chair of physics at the museum, and this important position he continued to hold until his death in 1892. Brought up as he was in a scientific atmosphere, he evidently inherited from his father his "acute power of observation," and that "infinite capacity of taking pains which seems to be the essential characteristic of the Newtons, the Faradays, and the Darwins, and, in short, of all the great leaders of science."

Since 1892 Henri Becquerel has been professor at the Museum d'Histoire naturelle, and has continued those studies which his ancestors in days gone by pursued with ardour and with success, not the less marked, although perhaps, on the whole, notwithstanding their brilliant achievements, less fruitful in revealing that knowledge which was to come; for by his memoirs on the radio-activity of matter Henri Becquerel has given to the world of science the results of a very remarkable series of researches.

There are four methods of studying the infra-red parts of the spectrum: the thermopile, as employed by Tyndall and others, the radiomicrometer of Boys, the bolometer as used by Langley, and the phosphorescent screen of Becquerel. After exposure to the violet rays, and if the screen is subjected to the action of the infra-red, the phosphorescence becomes so intense that the energy accumulated is radiated so rapidly that the parts thus acted upon become quite dark relatively to the other parts of the screen. Thus a map of the infra-red can be produced and studied at leisure so long as the phosphorescence of the screen lasts, or, indeed, photographs of the screen thus affected may be taken. The effect is due most probably to heat, and is therefore a case of thermoluminescence. Under the influence of heat the collisions between molecules become more frequent and more violent, and the energy absorbed from the more refrangible rays, and stored up in the substance, by some means at present not very clearly understood, is once more yielded up to the æther and radiated away. The energy is stored up in unstable molecular aggregates which gradually disintegrate, as radio-active molecules have been found to do,[1] the change of absorption which accompanies fluorescence being due to the formation of these molecular groups.

The absorption spectrum of crystals exhibits many anomalies, from which Becquerel has extracted a most important principle. If a crystal is composed of two isomorphous substances the molecular elasticity of which varies in different directions, so that the absorption varies too, the absorption spectrum will likewise vary in different directions, so that it is thus possible to detect the presence of different substances, since in two isomorphous substances the directions of molecular elasticity do not correspond, and therefore the directions of absorption would likewise differ. Each chemical substance, therefore, affects the direction of propagation and of absorption.

If the directions of absorption do not coincide with the optic axes, it is due to the presence of different isomorphous substances in the crystal. The absorption spectrum of each substance remains different and in its own particular direction, whilst that of refraction is the resultant effect. By this contrivance the composition of crystals has been examined and afterwards confirmed by chemical means, whilst in many instances the presence of substances in quantities too minute for the chemist to notice has been detected by this elegant method of analysis.

But the most striking work that has issued from Becquerel's laboratory relates to the radio-activity of matter. Of this great discovery, separating as it does the ideas of this century from those of the last, so much has been written, upon their far-reaching importance, so many ideas have been discussed in these columns, that to discourse upon them here would be but vain repetition of all that has been said before; yet, paradoxical though it may seem, it is unquestionably the work of all works that most definitely separates, and at the same time most closely unites, the two sciences of physics and chemistry, whilst it brings into prominence what may appropriately be called a new science—that of radio-activity—a science which neither physics nor chemistry can claim within its old province, and yet neither can disclaim, nor would it very readily do so if it could.

What is the influence which these laboratories have exerted and exert? We may ask, what is the influence of the Royal Institution? Is it not to be measured by the work which has been done there and by the ideas which have been scattered from those great fountains of thought—if they can be measured? How many youthful imaginations, how many enthusiastic aspirations have been aroused within those venerable halls, of the Becquerels as of the Davys, the Faradays, and the Tyndalls? Parisian lecturers are *savants*, philosophers, and orators. For although the Teuton regards the gift of eloquence (we hope it is his own) as the gift to be designated as "gab," the southerner or the Celt thinks it indispensable in the expression of a clear mind and of a great soul, at once saturated with thoughts and the grandeur of its subject; and in France this counts for more than it usually does among us.

These lectures are a source of inspiration to the multitude as well as to the grave, and their importance cannot be overrated.

Having said thus much of the laboratories of the Museum d'Histoire naturelle, we may perhaps be permitted to add a word as to the central figure in this centre of scientific thought, of M. Henri Becquerel; from none need we expect greater freedom, greater ease, or kindlier consideration. The brief summary

[1] British Association and *Electrician*, 1900-02; and *Phil. Mag.*, 1901 *Phil. Trans.*, 1897[5]

of his researches and of that of his predecessors is the record of this branch of the museums, and also of the debt which knowledge owes, and must ever owe, to the influence of one of the most remarkable of the pioneer laboratories and great European centres of scientific work.

JOHN BUTLER BURKE.

THE "NATURE-STUDY" OF BIRDS.[1]

THIS book fulfils the chief conditions we have previously insisted upon as being essential in all new works relating to the birds of the British Isles, in that it is original, interesting, exquisitely illustrated from living subjects, and not burdened with technical names. Indeed, the latter are conspicuous by their complete absence, thereby, no doubt, rendering the volume much more acceptable to readers of all classes than it would have been had it included the usual superfluous intercalations in bracketed italics. Mr. Boraston, it appears, took to the "nature-study" of birds comparatively late in life, and in his case it may be truly said "better late than never," for had he never done so lovers of nature in general, and of birds in particular, would have been deprived of a very charming volume containing a number of fresh ideas and suggestive observations. Having once decided to take up the outdoor study of bird-life, the author entered on his task with characteristic energy, and at once saw how essential it was for him to follow in the steps of the Messrs. Kearton and to employ the camera to perpetuate the scenes that he so much enjoyed if his work was to be one that would appeal successfully to the public.

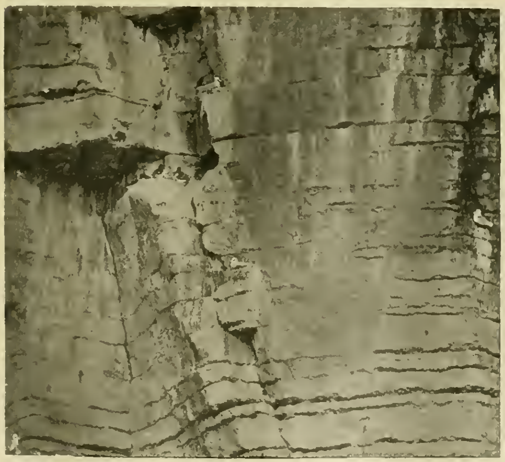

FIG. 1.—Kittiwakes on an Anglesea Cliff. From "Birds by Land and Sea."

How successful have been the results, both from the literary and the artistic point of view, readers of his book will not, we venture to think, be long in deciding. To whet their appetites, we herewith reproduce a couple of the illustrations, all of which, by the way, are taken from the author's own photographs.

FIG. 2.—Young Ringed Plovers crouching. From "Birds by Land and Sea."

The volume opens with the latter of what the author terms the two critical periods of bird-life, namely, March and September, when the migratory species are in the thick of their departure from or arrival at the British Islands. From September until May the seasonal observations of the year forming the subject of the volume relate to the bird-life of the neighbourhood of the author's home at Stretford, near Manchester, but during June the scene is transferred to the wild coast of Anglesea and Puffin Island, while in July and August we once more return to the home district. Perhaps the Anglesea interlude forms the most interesting part of the volume; but whether on a holiday or whether at home, the author seems to be endowed with a marvellous capacity for work, both in the matter of making and recording observations and in taking photographs.

On the wild cliffs of Anglesea, as we are told on p. 210, "stalking" birds for the purpose of taking their portraits by a well planned snap-shot demands a considerable amount of coolness and steadiness on the part of the observer, as if he becomes too much absorbed in the object of his pursuit awkward accidents are likely to occur; and even if such undesirable contingencies are successfully avoided, disappointments from unsuspected or unavoidable causes are only too likely in many instances to annul the results of all the toil and trouble. Who, for instance, will fail to commiserate the author on having lost the chance of "snapping" a sitting nightjar (p. 202), from the fact that he actually did not see the bird for some seconds, and then, when "his eyes were opened," the camera slipped?

[1] "Birds by Land and Sea: the Record of a Year's Work with Field glass and Camera." By J. M. Boraston. Pp. xiv+282; illustrated. (London: John Lane, 1905.) Price 10s. 6d. net.

As an example of the successful accomplishment of a difficult task, we reproduce (Fig. 1) the photograph of kittiwake gulls nesting on the precipitous face of a cliff, approach to which was effected by climbing down a narrow gulley and then scrambling over seaweed-clad boulders, to the imminent peril of the camera.

As a specimen of really excellent bird-photography, we present to our readers the picture of a group of young ringed plovers (Fig. 2), the mottled down of which harmonises so admirably at a short distance with their surroundings.

If it be said that this notice is purely commendatory, and contains nothing in the way of criticism, the reply is that we have found nothing to criticise or to condemn. It is real nature-study. R. L.

THE ARTIFICIAL PRODUCTION OF RUBIES BY FUSION.[1]

THIS memoir opens with a short historical account of the attempts previously made to produce rubies by fusion, starting with the researches undertaken by Gaudin with the view of obtaining fused alumina in a transparent state. He obtained by fusing potassium or ammonium alum, together with a little chrome alum, small globules, which became opaque on solidification, but had the composition of the ruby. These were shown by Becquerel to have the cleavage of corundum, and contained small cavities lined with crystals of ruby. Gaudin concluded that alumina could not exist in the vitreous state, and this view was supported by C. Sainte-Claire Deville, on account of the uniform density of the oxide before and after fusion. The facts at present known are in support of this view, for the transparent alumina obtained by fusion is a completely crystalline mass. The problem was not further investigated until, in 1886, Charles Friedel described an experiment by which corundum was obtained by fusion, presenting most of the properties of the ruby, but differing from the natural product by the presence of certain included bubbles, and by a rather low density.

As the production of the so-called "Geneva rubies" remained a trade secret, M. Verneuil started a series of investigations, following up the work of Gaudin. He found that to obtain the fused material in a transparent state certain conditions must be rigorously fulfilled. He compares the solidification of alumina to that of water, which forms according to the method of cooling transparent or opaque ice. An important observation which appears to have escaped Gaudin is that it is only the portions of alumina which are fused in the cooler parts of the flame which remain transparent on solidification. One of the greatest experimental difficulties is that, however carefully the cooling is conducted, the fused mass is excessively brittle. This brittleness is least marked when a very small supporting surface is employed. The apparatus devised by M. Verneuil is very ingenious. The blow-pipe and furnace tube must be absolutely vertical. The finely powdered alumina, containing the requisite quantity of chromic oxide, and specially purified, is admitted by means of a fine sieve, which is given a series of regular taps, controlled by an electromagnet, so that the material falls down the tube intermittently in a series of thin layers. It forms a cone at the bottom, and as soon as this cone reaches a hot enough part of the tube the apex fuses, and the fused material then extends gradually upwards in a long filament. This eventually reaches a still hotter part of the furnace, and develops a spherical mass instead of growing further; this spherical globule when solidified forms the ruby. The cooling has to be very gradual, so that the crystalline particles have time to become regularly arranged, or an opaque product is obtained. If the ovoid mass is carefully detached when cold, it splits up into two nearly equal portions, but not along a cleavage-plane. The product so obtained is an individual crystal, and the direction of its principal optic axis is never very different from that of the major axis of the ovoid.

The product when cut cannot be distinguished by its chemical, physical, or optical properties from a stone cut from a natural ruby. The operation may be considered successful when the clear product weighs 12 to 15 carats, and has a real diameter of 5 or 6 millimetres. It is, however, impossible to obtain stones larger than $\frac{1}{4}$ carat free from included bubbles and cracks, and experts can therefore readily distinguish the artificial gems from natural ones. These flaws do not in any way detract from the beauty of the stones; they are often clearer than many natural rubies, which are seldom found perfect.

The paper is illustrated by diagrams of the very ingenious apparatus devised by the author.

[1] "Memoire sur la Reproduction artificielle du Rubis par Fusion." By A. Verneuil. (*Annales de Chimie et de Physique*, 8e série, t. ii., September.)

CALCIUM METAL.

ELECTROMETALLURGY has at last succeeded in producing metallic calcium in commercial quantities, and at what must be considered a relatively low price. Until within a few weeks ago this metal had only been available in very small amounts, and remained a rare laboratory specimen; it is now obtainable at a price per kilogram less than that charged by most chemical dealers for a small one-gram sample. Humphry Davy first formed the amalgam by electrolysing lime, mixed with mercuric oxide and slightly moistened, with a mercury kathode; he isolated the metal in small quantities by distilling off the mercury. Since then many chemists have tried in vain to find a method suitable for its preparation on a larger scale. Matthiesen, making use of Bunsen's suggestion of applying high current density at the kathode, only succeeded in obtaining a few grams at a time by electrolysis of the fused chloride, or of mixtures of calcium and other chlorides having a lower fusing point. Henri Moissan, as the result of a critical study of the numerous proposed methods, was able to prepare somewhat larger quantities of the metal. His method was essentially a modification of that proposed by Liès-Bodart and Jobin in 1858, which consisted in reducing fused calcium iodide with metallic sodium. Moissan found that molten sodium forms an excellent solvent for calcium, and by heating calcium iodide with a large excess of sodium obtained on cooling a cake of the sodium-calcium alloy resting on the sodium iodide. Small quantities of the alloy were thrown into well cooled absolute alcohol, which reacts with the sodium leaving the calcium pure, but in the state of a fine crystalline powder. This powder can be agglomerated by pressure and fusion, and thus Moissan prepared the fine specimen ingots of this metal which so greatly interested visitors to the Paris Exhibition of 1900. It is largely to him that we are indebted for a knowledge of the properties of the pure metal, of which he prepared some 1 kilos. by this process. Contrary to the earlier descriptions, calcium is a white metal, the yellow coloration being due to a film of nitride; its melting point is about 760° C., and its density 1.85. The definite compounds which it forms directly with hydrogen and nitrogen promise useful applications in the laboratory in cases where it is necessary to remove these gases.

The next advance was made almost simultaneously by Borchers and Stockem at Aix-la-Chapelle, and

Ruff and Plato at Berlin. The method employed by these workers was in principle that of Matthiesen, but by suitable construction of apparatus and regulation of temperature much better yields were obtained, and the metal was thus prepared in larger quantities. Borchers and Stockem electrolysed molten calcium chloride, which was maintained at a temperature below the fusing point of calcium; they ascribe the low yields at higher temperatures to the reaction of fused calcium with calcium chloride to form a subchloride. Using an iron rod as kathode, they obtained a metal sponge which was pressed with tongs before removing from the electrolyte. The raw material prepared in this way contained some 10 per cent. of calcium chloride, which could, however, be almost entirely removed by subsequent fusion of the metal.

The final step in the evolution of the commercial process was taken by Suter and Redlich, of the Elektrochemische-Werke, Bitterfeld. By the ingenious employment of a kathode which only just touches the surface of the fused calcium chloride, they obtain a small layer of fused calcium under the kathode; before the calcium has collected in sufficient amount to flow away the electrode is very slightly raised; the metal thus comes into a cooler zone and solidifies. By continuing the process a rather irregular rod of calcium is built up, which itself forms the kathode. The metal is supplied in these rough rods, which in outward appearance strongly resemble cabbage stalks, but show a white metallic surface when cut through.

The present price quoted in Germany is about 20*s.* a kilogram retail, or 12*s.* a kilo. in 100 kilogram lots, which quotation alone proves the feasibility of the process. The technical product is said to contain about 97·11 per cent. pure calcium, 1·64 per cent. calcium chloride, and 0·4 per cent. sodium. If one may judge by the case of metallic sodium, there will doubtless be difficulties in finding any large demand for the metal, but it will obviously be much appreciated for experimental purposes in many chemical and physical laboratories.

R. S. Hutton.

NOTES.

We regret to announce that Sir Lowthian Bell, Bart., F.R.S., died on Tuesday, at eighty-eight years of age.

The death of Mr. Norman Maccoll, late editor of the *Athenaeum*, at sixty-one years of age, will be deeply regretted by many men of science. Mr. Maccoll did much to further the interests of science, and to cultivate sympathy with the pursuit of natural knowledge among readers not actively engaged in scientific work.

On Saturday last, direct telegraphic communication was established between Liverpool and Teheran, in Persia, a distance of four thousand miles. The line belongs to the Indo-European Telegraph Company.

On Tuesday next, December 27, Mr. Henry Cunynghame will deliver at the Royal Institution the first of a Christmas course of six lectures adapted to a juvenile auditory on ancient and modern methods of measuring time, experimentally illustrated.

At the December meeting of the Astronomical Society of France an address was given by Mr. de Watteville on the temperatures of stars. The lecturer described a series of experiments made by him in the Count de Labaume Pluvinel laboratory, and exhibited a series of photographs of spectra obtained by him, reproducing the principal types described by Sir Norman Lockyer. The president congratulated the speaker on having obtained such brilliant results, on the subject of which he has already delivered a thesis at the Sorbonne.

It is announced by the *Athenaeum* that the Circolo Matematico di Palermo intends to offer an international prize for geometry at the fourth International Mathematical Congress, which will meet at Rome in 1908. The prize will consist of a small gold medal, to be called the Guiccia medal, after its founder, and of 3000 francs, and will be given by preference, though not necessarily, to an essay which advances the knowledge of the theory of algebraical curves of space. The treatises may be written in Italian, French, German, or English, and must be sent to the president of the Circolo Matematico before July 1, 1907.

We learn from the *Times* that on Friday last President Loubet received Dr. Otto Nordenskjöld, who was presented by the Minister for Sweden and Norway in Paris. On the evening of the same day Dr. Nordenskjöld delivered a lecture on his Antarctic explorations before the French Geographical Society. Prince Gustav Adolph and Prince William of Sweden were present, and several Ministers were represented. Dr. Nordenskjöld was the guest on Saturday afternoon of the Paris Municipal Council at the Hôtel de Ville. He was welcomed by the president of the council, who presented him with a silver medal commemorating his visit to the city. On Saturday evening Dr. Nordenskjöld delivered a lecture before a large and distinguished audience at the Sorbonne.

The death is announced of Mr. C. G. Barrett, one of the editors of the *Entomologist's Monthly Magazine*, at the age of sixty-eight years.

It is stated that at a meeting of the French Surgical Society held on December 14 a report of the committee appointed to investigate Dr. Doyen's researches on cancer and its microbe was read, and that some of the conclusions support Dr. Doyen's claims. No authentic details have, however, as yet been published.

The following recent deaths are announced in the *Bulletin* of the French Physical Society and the *Popular Science Monthly*:—M. Jeunet, late professor of physics; Prof. Lespiault, of the University of Bordeaux; Prof. Joseph Thimont, of the École Ste.-Geneviève and other institutions; Prof. Clemens A. Winckler, professor of chemistry at Dresden; Prof. Max Berbels, of Berlin, noted for his publications on ethnology; Major Henry F. Alvord, chief of the dairy division of the U.S. Department of Agriculture.

In the *Bulletin* of the French Physical Society, No. 219, the death is announced of Prof. Macé de Lépinay, of Marseilles, a former member of the council of the society. Prof. Macé de Lépinay's researches were mostly connected with optics, and had special reference to the determination of wave-lengths by means of interference phenomena, on the lines first laid down by Fizeau. The methods used were interference due to double refraction, interference of a direct ray with one passing through a lamina of the crystal, and interference of two rays, one passing once and the other twice through the lamina. A further series of researches dealt with the inverse problem of determining the specific mass of water. Most of the experiments were performed with sodium light. Prof. Macé de Lépinay's latest researches were conducted conjointly with M. Buisson, who proposes to complete them.

Glass hives for the observation of bees at work have been in use for many years, and latterly ants' nests have been on view at the Crystal Palace; but it may be new to many of our readers to learn that Messrs. A. W. Gamage, Ltd., of Holborn, have actually put on sale a contrivance called "The Lubbock Formicarium," which is really a portable ants' nest, which can be moved anywhere without trouble or inconvenience, and which, it is claimed, will last for upwards of six years with ordinary care. The species selected is the small yellow ant, *Formica flava*, and the nest is enclosed in a frame 10 inches square, resembling a picture frame, except that it must, of course, be laid flat, and the cover must be kept over it except when the ants are under observation. The nest contains ants in their various stages, and some of the other insects which are associated with them; and it is supplied with or without a queen, and accompanied by full directions as to management. This novelty has attracted considerable attention already, and the visitors, many of whom are children, show much interest in this novel exhibition.

Dr. Charles Waldstein gave a lecture on "Herculaneum and the Proposed International Excavation" at the Royal Academy on December 14. He remarked that from Herculaneum many beautiful works might be expected. The city and district of Herculaneum were overwhelmed with volcanic material, but this is not the impenetrably hard lava commonly supposed. Geologists have shown that, apart from actual contact with air, the material is perfectly friable and manageable for the excavator. The beautiful works from the city which are to be seen at Naples show that the disaster was not destructive of the beauty of the works of art at Herculaneum. Manuscripts which can be unrolled and read, as well as glass and marble, with no trace of fire on them, give good hope of what may be expected from thorough excavation. The catastrophe was a marvellous preservation of a provincial city's life at the moment of arrest. The King has expressed approval of the proposed international excavation, and the King of Italy, as well as his Prime Minister, promise support. The President of the United States, the German Emperor, the President and Government of the French Republic, the Emperor of Austria, and the King of Sweden encourage the undertaking. There is already a committee in Vienna, and it is hoped to secure the cooperation of many other national committees. Mr. Neville Rolfe, our Consul at Naples, has told Dr. Waldstein that there is ample work for many years without infringement of private rights.

Our Norwegian namesake—*Naturen*—for November contains an illustrated account of the mammoth discovered in the Kolyma district in 1901, and now mounted in the St. Petersburg Museum. The monster has been set up in the position in which it was found, namely, endeavouring to struggle out of a quicksand or crevasse.

In the issue of the *Sitzungsberichte* of the Vienna Academy for November 10 Dr. F. Werner gives an account of the zoological results of his recent expedition to Egypt and Nubia. The most important part of the collection appears to consist of orthopterous insects—a group hitherto very imperfectly known from the countries in question, and of which a large series of specimens was obtained. Very noteworthy is the discovery of certain Central Asian species of the group in the heart of this part of Africa. A fish and a fresh-water mussel previously supposed to be confined to the Upper Nile are recorded from the delta, and some interesting observations with regard to certain reptiles have also been made.

We are indebted to the publisher—G. Freytag, of Leipzig—for copies of the two issues of the new (twenty-sixth) edition of Pokorny's "Naturgeschichte des Tierreiches," a well known zoological text-book for schools. The present enlarged edition has been supervised by Mr. M. Fischer, of Mülhausen. The book is issued in two forms, one more expensive than the other. In the cheaper issue (of which the price is 3*s*. 6*d*.) there are only five coloured plates, whereas in the more expensive one (price 4*s*. 6*d*.) the number of illustrations of this description is twenty-nine. Some difference in the arrangement and number of the cuts distinguishes the two issues. Considering the price of the volume, the coloured illustrations are all that could be desired. The fact of the work reaching its twenty-sixth edition is a sufficient guarantee of its fitness for its special purpose.

We have received a copy of a new monthly publication, *Indian Public Health* (No. 4, vol. i.), which is to be devoted to the discussion of public health questions in our Indian Empire. We cannot help expressing the opinion that it is undesirable to multiply small journals, of which there are already too many. It would be better to enlarge the scope of the existing journals.

In the *Journal* of the Quekett Microscopical Club (ix., No. 55) Mr. T. B. Rosseter gives a good description of the anatomy of *Taenia sinuosa*, a tapeworm of geese, and proves by feeding experiments that the cysticercoids inhabit certain copepods and ostracods; and Mr. Wesché investigates some new sense-organs of Diptera, concluding that where the antennæ are not particularly sensitive, the palpi have structures to compensate, and may bear organs of touch, taste, and smell, but not more than two of these at the same time. He also describes certain organs, probably of sense, on the legs of many species, the function of which is doubtful.

We have received "Researches in Helminthology and Parasitology," by Prof. Joseph Leidy, edited by his son, Dr. Joseph Leidy (*Smithsonian Miscellaneous Collections*, part of vol. xlvi.). It gives a summary of Prof. Leidy's contributions to science, with bibliography, and should prove of considerable value to those engaged in these branches of research. Commencing in 1849, Prof. Leidy's contributions were continued without intermission down to 1889, and are no less than 578 in number, many being of considerable importance, and embracing parasites of all kinds, as well as some papers on comparative anatomy.

In the report for the year 1903–4 on the administration of the Government Museum and Connemara Public Library, Madras, amongst other interesting matter the following paragraph appears:—"A prolonged tour was made in the Mysore province in connection with the ethnographic survey, with the primary object of continuing my researches into the character of the Canarese cranium (*vide* Museum *Bulletin*, iv., 2, 1901). The work was carried out under conditions of considerable difficulty, caused by the terror of the natives, who mistook me for a recruiting sergeant bent on seizing them for employment in South Africa or for the Somali war, and fled before my approach from town to town. The little spot, which I am in the habit of making with Aspinall's paint to indicate the position of the fronto-nasal suture when measuring the nose, was supposed to possess blistering properties, and to turn into a number on the forehead, which would serve as a means of identification. The untimely death of a Korava outside a town where I was halting was attributed to my evil eye. Villages were denuded of all save senile men, women and children. The vendors of food-stuffs in one bazaar finding business slack owing to the flight of their customers, raised their prices, and a missionary complained that the price of butter had gone up. My arrival at one important town was coincident with a temple festival, whereat there were not sufficient men left to drag the temple car in procession. The headman of another town, when he came to take leave of me, apologised for the scrubby appearance of his chin, as the local barber had fled. One man, who had volunteered to be tested with the tintometer, was suddenly seized with fear, and, throwing his body-cloth at my feet, ran away and was no more seen. An elderly municipal peon wept bitterly when undergoing the process of measurement. Such are a few examples of the results which attend the progress of the Government anthropologist." Mr. Edgar Thurston finds that the average cephalic index of various groups of natives in the southern (Tamil and Malayalam) districts of the Madras Presidency ranges from 72·6 to 76·5, while that in the Canarese and Maratha area ranges from 77·1 to 81·8. The significance of this brachycephalic element is not yet elucidated.

In the *Transactions* of the Academy of Science of St. Louis, vol. xiii., No. 8, Mr. J. A. Harris gives some details of polygamy and floral abnormalities in species of Solanum. A collection of flowers of *Solanum carolinense* showed about twenty staminate to eighty perfect flowers. A second paper by the same writer describes the germination of seedlings with unequal cotyledons of *Pachira campestris*, a genus sometimes allied with Bombax.

The formation of a botanic garden in sandhills does not perhaps suggest utility or success, but in the *Gardener's Chronicle* (November 19) Dr. Masters gives an account of the practical results obtained by experiments carried out in the garden, or, as it may be called, the experimental station established in the Belgian dunes at Coxyde. As an instance of the way in which experimental results are sometimes opposed to theoretical supposition, the writer describes the successful formation of a forest of dwarf poplars in the sandhills, and even suggests that they would act as nurses to seedling pines.

It is characteristic of the scattered groups of islands which lie between the parallels of 45° and 60° south that in their flora they all contain a proportion of what has been termed a Fuegian element. Amongst these are the so-called Southern Islands of New Zealand, of which the latest account is that given by Dr. Cockayne in the *Transactions* of the New Zealand Institute, vol. xxxvi. The plant associations of the Auckland Isles include a forest formation, with *Olearia lyallii* as the dominant tree, which Dr. Cockayne regards as the primitive forest, and one that was previously more extensive, but which has been curtailed by the spread of a *rata* forest similar to the rata forests found in New Zealand. This fact, and the existence of a well marked New Zealand element in the flora are points of evidence in favour of a former extension of New Zealand to the south.

Mr. A. Tingle, of the Imperial Provincial College, Chinanfu, Shantung, has sent a further communication upon the flowering of the bamboo, in which he supplements—in view of the letters of Prof. J. B. Farmer, F.R.S., in our issue for August 11, and of Mr. J. S. Gamble, F.R.S., in Nature for September 1—the information supplied in his previous letter. Mr. Tingle is unable to tell the species of the bamboos that flowered, but he reports that they were small, growing to a height of about 4 metres, and that the stems averaged about 4 cm. in circumference near the ground. All the bamboos have died since flowering. Mr. Tingle points out that the bamboo will grow in Shantung only if carefully cultivated in a garden. The seasons, he remarks, have been in no way exceptional in Shantung.

Among the interesting collection of models of Palæozoic seeds and cones exhibited by Mr. H. E. H. Smedley at a recent meeting of the Linnean Society, a few are of special interest to palæobotanists. The example selected for illustration here is that of the group of three models of the sporophylls of the lycopodiaceous cone, Lepidocarpon, from the Carboniferous formation. The model on the left shows the general morphology of a single sporophyll, from which will be seen the peculiar shape of the integument and micropyle, much resembling a hand-bag. The centre model demonstrates the general anatomy as seen in the

Fig. 1.—Palæozoic cones.

transverse section, and shows the complete lamina of the sporophyll, while that on the right clearly exhibits the complex internal structure of the sporangium containing four megaspores, one of which has developed a seed-like formation filling nearly the whole of the sporangium, the other three being abortive. In urging an affinity between the lycopodiaceous cones and the gymnosperms, the author submitted the following points of agreement :—Integument and micropyle, the single functional megaspore in the sporangium, and the detachment of the seed-like organ as a whole.

The report of the Meteorological Council for the year ending March 31, 1904, shows increased activity, and is somewhat more bulky than its predecessors, extending to more than 200 pages; the report proper embraces only some 30 pages; the remainder is composed of appendices which contain details of the operations of the office. No change has taken place in the constitution of the council during the year, nor is any clue given to the future of the office resulting from the deliberations of the Meteorological Grant Committee; their report, however, was not issued until after the period to which the council's report refers. While the work of a former Government department is arduously performed, the Meteorological Office continues to hold a very anomalous position compared with similar establishments in other countries; it performs valuable public duties, but has not the status of a Government office, although supported by a Government grant. The operations may be summarised under four principal heads :—(1) ocean meteorology, the collection, tabulation, and discussion of meteorological data for all parts of the ocean, and the preparation and issue of charts and the supply of instruments to the Royal Navy and mercantile marine; (2) the issue of storm warnings to all seaports willing to receive them, of daily weather forecasts, and of forecasts for agriculturists during harvest seasons; (3) the climatology of the British Isles, statistics relating to British colonies and dependencies, and replies to numerous meteorological inquiries from all sources; (4) the discussion of automatic registers received from the observatories and other stations in connection with the office. The library contains weather maps and other publications received from all parts of the world, and these are available to all persons wishing to consult them.

PART X. of the *Bulletin* of the Department of Agriculture of Jamaica contains an interesting article by Mr. H. H. Cousins, the Government chemist, on the possibility of manufacturing starch from cassava on such a scale as to undersell German potato starch in the English market. The high proportion of starch in cassava makes the latter twice as valuable as the potato as a raw material, and cassava has the additional advantage that it is not liable to fungoid diseases such as produce extraordinary variations in the annual potato crop in Germany. The seasons of its growth and harvest are, moreover, perfectly unrestricted.

SOME apparatus left by the late M. Félix Worms de Romilly has been offered by the French Physical Society for distribution to its members.

THE Association of Engineers of the School of Liège is organising, under Government patronage, a congress of mining, metallurgy, applied mechanics and geology, to be held at Liège from June 26 to July 1, 1905, on the occasion of the Universal Exhibition.

IN the *Physikalische Zeitschrift* for December 1 Mr. Hermann Bonin contributes an interesting report on steam turbines, based on the writings of Stodola, Feldmann, Gutermuth, and Boveri. In it the Laval, Curtis, Rateau, Zölly, and Parsons turbines are figured, and their peculiar features discussed.

PROF. R. W. WOOD contributes a paper on *n*-rays to the *Physikalische Zeitschrift* for December, and suggests that those experimenters who obtain positive and those who obtain negative results should arrange to make a series of joint experiments in the way that has been done in a similar case by Crémieu and Pender.

WE have received a thesis by Messrs. H. C. Crowell and G. C. D. Lenth on the "Doble" needle-regulating nozzle for fire hoses and other jets. This nozzle is furnished with a convergent mouth-piece in the centre of which is a peculiarly shaped "needle," the effect of which on the stream lines is to obviate the spraying noticeable with ordinary jets, and thus to increase the efficiency. The paper is printed by permission of the Massachusetts Institute of Technology.

PROF. N. UMOW contributes to *Terrestrial Magnetism and Applied Electricity* an ingenious method of constructing magnetic charts. It consists in developing the magnetic potential in a series of spherical harmonics, and representing on a Mercator's chart the poles of the various harmonics and curves showing their zeros and so forth. The advantage of this system is that instead of drawing a large number of magnetic curves, it is possible to convey more exact information by drawing a comparatively small number of curves indicating the various terms in Gauss's expansion.

IN a paper read before the Institution of Mechanical Engineers on November 18 Messrs. A. E. Seaton and A. Jude emphasise the need of testing materials which are to be subjected to rapidly repeated or to alternating loads by other methods than by merely determining the tensile strength and elastic limit. A form of apparatus is described by means of which the ability of a notched bar of the material to withstand impact can be measured, and it is shown that although a high tensile strength may be accompanied by a small resistance to shock, a bar which responds satisfactorily to the impact test always has sufficient tensile strength and elasticity. The best results as regards resistance to shock are obtained with those steels which contain only a small proportion of carbon, an extraordinarily rapid increase of brittleness occurring with an increase in the percentage of carbon. The line of fracture of the metal follows the direction of the ferrite and avoids the perlite. Oil quenching has the effect of increasing the shock strength of steel to a value which is 500 per cent. to 600 per cent. greater than that of the natural steel in its best condition.

A NEW and revised edition of stage iii. of Mr. Vincent T. Murché's "Object Lessons in Elementary Science based on the Scheme issued by the London School Board" has been issued by Messrs. Macmillan and Co., Ltd.

IN the November, 1904, issue of the *Central*, the magazine of the Central Technical College Old Students' Association, Prof. H. E. Armstrong, F.R.S., continues his papers on the mechanism of combustion, and there is an illustrated description of the Manhattan railway power station of New York, contributed by Mr. W. A. Del Mar.

IN addition to the enumeration of classes and other administrative matter, the *Johns Hopkins University Circular* for November, 1904, contains one or two original papers. Among these may be mentioned one by Prof. W. B. Clark on the Matawan formation of Maryland, Delaware, and New Jersey, and its relations to overlying and underlying formations.

THE Department of Agriculture and Technical Instruction for Ireland has issued a pamphlet entitled "Notes for Manual Instructors." Manual instruction is comparatively new in Ireland; the conditions are different from those in other countries, and there are initial difficulties to be overcome. For these reasons the notes here brought together should be of real assistance to teachers of the subject.

A COPY of an almanac for the year 1905, compiled at the offices of the Egyptian Survey Department, and published by the National Printing Department at Cairo, has been received. The almanac provides full particulars of the dates of all the important meetings of the various Government departments, and gives information on points in connection with the Government regulations which should be of service to tourists and residents.

IN view of the largely increased facilities provided within the past few years by the publication departments of various institutions, and more especially by the Carnegie Institution, for the promotion of original research with its incident publications, the Wagner Free Institute of Science, Philadelphia, has decided to discontinue for the present its work in this department, and to devote its energies more exclusively to other purposes indicated by its founder.

WE have received a copy of the "Guide to the Archives of the Government of the United States in Washington," just published by the Carnegie Institution of Washington. The guide was begun by Mr. C. H. Van Tyne and Mr. W. G. Leland, and completed by the newly organised Bureau of Historical Research. The original purpose of the guide was to gather information of the whereabouts of important historical materials, but as the work proceeded it was found desirable carefully to deal with all administrative records. The work, in fact, developed into a survey of all the branches, bureaus, and divisions of the Federal Government in Washington.

Two new volumes have been added to Ostwald's series of scientific classics, published by Mr. W. Engelmann, Leipzig (London: Williams and Norgate), bringing the number of reprints and translations in the collection up to 145. One of the volumes is a translation, by Herr F. Plehn, of Kepler's "Dioptrice," with an introduction, notes, and sketch of Kepler's life and work. The second volume (No. 145) contains reprints of two papers by Kekulé, edited with notes by Herr A. Ladenburg; the papers are:—"Über die Constitution und die Metamorphosen der chemischen Verbindungen und über die chemische Natur des Kohlenstoffs" and "Untersuchungen über aromatische Verbindungen."

THE annual report of the Smithsonian Institution for the year ending June 30, 1903, has been received. As usual, the general appendix makes up the greater part of the volume. The excellent and varied selection of beautifully illustrated papers by men of science of all nationalities, constituting the general appendix, provides a trustworthy indication of the extent and nature of the progress in science during the twelve months with which the report deals. It is impossible here to give even the titles of the fifty-three papers included. Some of the papers have been reprinted from NATURE and other periodicals, some are addresses delivered before scientific bodies, and a few are new contributions. In addition to these works there are a number of translations of papers originally published in other languages. The first place is given to a reprint of the general description of the moon included by Prof. N. S. Shaler in the introductory chapter of his memoir on "A Comparison of the Features of the Earth and the Moon." This paper is illustrated by ten magnificent plates. The work done on radium and radio-activity is chronicled in papers by M. E. Curie, Prof. J. J. Thomson, Sir William Ramsay, Mr. Soddy, Sir Oliver Lodge, Sir William Crookes—the names being mentioned in the order in which the papers are printed. Geographical research is represented by contributions by Captain E. W. Creak, Mr. Alfred H. Brooks, Commander Peary, Sir Clements R. Markham, Dr. Otto Nordenskjöld, M. G. Ts. Tsybikoff, and others. The articles on geographical and zoological subjects are illustrated very profusely, and the volume will make a valuable addition to reference libraries fortunate enough to secure copies of it.

OUR ASTRONOMICAL COLUMN.

DISCOVERY OF A NEW COMET (1904 *d*).—A telegram from the Kiel Centralstelle announces that a new comet was discovered by M. Giacobini at Nice on December 17·11. Its position at 17h. 41·3m. (M.T. Nice) was

R.A. = 16h. 14m. 40s., dec. = $+27°\ 28'$,

and its movement was in a north-easterly direction.

This position is situated on the western boundary of the constellation Hercules, about 44m. east of α Coronæ, which has approximately the same declination (27° 2′), and is favourably situated for observation during the three or four hours preceding dawn.

A second telegram from Kiel informs us that the comet was again observed at Nice on December 18. Its position at 16h. 44m. (M.T. Nice) was as follows:—

R.A. = 16h. 17m. 3·4s., dec. = $+27°\ 54'\ 8''$.

TEMPEL'S COMET (1904 *c*).—The following details of M. St. Javelle's re-discovery of Tempel's second comet are given in No. 3984 of the *Astronomische Nachrichten*:—

	M.T. Nice h. m. s.	R.A. (app.) h. m. s.	Dec. (app.) ° ′ ″
Nov. 30	... 6 7 48	... 19 36 39·89	... −24 48 37·3
Dec. 1	... 5 55 10	... 19 40 23·58	... −24 46 17·5

The comet was a feeble and ill-defined object as seen in the Nice equatorial of 0·76 m. aperture, and had the appearance of a whitish spot 1′·5 to 2′·0 in extent; no nucleus was visible.

A continued abstract of M. Coniel's daily ephemeris (*Astronomische Nachrichten*, No. 3971) is given below:—

12*h*. *M.T. Paris.*

1904	α (app.) h. m. s.	δ (app.) ° ′	log Δ	$1 : r^2\Delta^2$
Dec. 20 ...	20 51 30 ...	−22 55 ...	0·31206 ...	0·113
,, 22 ...	20 58 39 ...	−22 36 ...	0·31480	
,, 24 ...	21 5 43 ...	−22 17 ...	0·31760 ...	0·108
,, 26 ...	21 12 44 ...	−21 57 ...	0·32044	
,, 28 ...	21 19 41 ...	−21 35 ...	0·32333 ...	0·103
,, 30 ...	21 26 35 ...	−21 13 ...	0·32626	
1905 Jan. 1 ...	21 33 24 ...	−20 50 ..	0·32924 ...	0·c98

ENCKE'S COMET (1904 *b*).—An observation of Encke's comet was made by Herr van d Bilt at Utrecht on December 8. At 8h. 3m. 46s. (M.T. Utrecht) the position of the comet was

α (app.) = 20h. 46m. 22·11s., δ (app.) = $+5°\ 12'\ 29''\cdot5$,

and its magnitude was estimated as 7·5. This observation indicated that a correction of +41s., +1′·2 was necessary to the ephemeris published by Messrs. Kaminsky and Ocoulitsch in *Astronomische Nachrichten*, No. 3981 (*Astronomische Nachrichten*, No. 3985).

OBSERVATIONS OF OCCULTATIONS BY PLANETS.—Dr. T. J. J. See, writing to the *Astronomische Nachrichten* (No. 3984), explains the futility of making observations of occultations by planets for the purpose of determining the extent of the planetary atmospheres. He points out that the extent of the irradiation about a planet's disc, at night time, in every case exceeds the probable extent of the planet's atmosphere, so that the star is lost in the irradiation zone before the interposition of the atmosphere between it and the observer.

Thus observations of this character, made during the hours of darkness when the irradiation affects the observation, can never succeed in determining the amount of refraction suffered by the star light in passing through the planet's atmosphere, because the star is always hidden before it reaches even the outer limit of that atmosphere.

RELATIVE DRIFT OF THE HYADES STARS.—In a paper communicated to the British Astronomical Association Dr. Downing, F.R.S., discusses the resulting values obtained by Herr Weersma, and published in No. 13 of the Groningen Astronomical Laboratory *Publications*, in order to determine the relative drift of the sixty-six Hyades stars dealt with by the latter observer.

The results of the discussion show that these stars may be arranged in three chief groups as regards the amount and direction of their annual motion. The first group contains thirty-eight stars, including most of the bright ones except Aldebaran, having a mean motion of 0″·096 per year in the mean direction 106° from north towards east. In the second group Aldebaran and three faint stars are included, and the annual mean motion is as much as 0″·160 in the mean direction 160°. In both these groups the magnitudes are in no way related to the amounts of movement, some of the fainter stars, in fact, having a greater apparent motion than the brighter ones in the same group. The values for the third group are 0″·036 and 254° respectively, and it is reasonably conjectured that this group is at a greater distance from our system than the others (*Journal* British Astronomical Association, No. 1, vol. xv.).

DESIGNATIONS OF THE VARIABLE STARS DISCOVERED DURING 1904.—In No. 3984 of the *Astronomische Nachrichten* the Variable Star Commission of the Astronomischen Gesellschaft publish a catalogue of fifty-eight new variables, discovered by various observers during the present year. They give for each star the number by which it will in future be known, the temporary designation which this replaces, its coordinates and the amount of precession in each coordinate, for 1900, and the magnitude. The catalogue is followed by a detailed account of the discovery, variations, and general characteristics of each variable.

THE "COMPANION TO THE OBSERVATORY."—The 1905 edition of the well known "Companion to the Observatory," published at 1s. 6d. by Messrs. Taylor and Francis, contains its usual complement of useful data for all kinds of astronomical observations. Ephemerides for the planets and their satellites, the Greenwich magnetic elements, the times of maxima and minima and the periods of numerous variable stars and data relating to a number of double stars are given amongst the mass of information contained.

As in previous years, Mr. Denning gives the dates and radiant points of the principal meteor showers and Mr. Maw has supplied the double-star tables, whilst the ephemerides of an ever-increasing number of variable stars have been taken from advance proofs generously contributed by M. Lœwy.

GLACIATION IN NORTH AMERICA.[1]

THIS volume, which has only recently reached us, is by no means of merely local interest. The first 226 pages form a treatise on glacial geology in general, and represent the author's views after some twelve years of study of drift deposits in the field. No one who examines plates i. to vi. can mistake the character of these deposits; these excellent photographic pictures would meet, indeed, with international acceptance. On p. 30 we have some suggestive figures given as to the area of existing glaciers, from which it appears that the whole drift-covered country in North America is only ten times as large as that still covered by ice in Greenland. The Antarctic ice-sheet, moreover, is as extensive as that postulated for North America in "Glacial" times, a fact that effectually "removes the element of incredibility which, at first thought, attaches to so striking a theory as that of the glacial origin of the drift." The northern ice, however, as Mr. Salisbury immediately points out, extended into temperate latitudes, and special explanations must thus be sought. New Jersey, we may observe, lies on the latitude of Lisbon and Sicily in the northern hemisphere, and corresponds with Cape Town and Melbourne in the southern and more glacial hemisphere. Mr. Salisbury at present seeks the cause of older widespread glaciations (p. 192) in Chamberlin's hypothesis of variations in the amount of carbon dioxide in the atmosphere. Elevation accelerates rock-decay, and this process promotes refrigeration by withdrawing carbon dioxide from the air. The possibility of variation in the constitution of the atmosphere, owing to the emanations of volcanoes, is also touched on as one of many other causes controlling the supply of carbon dioxide.

FIG. 1.—Side of a glacier in Greenland, showing the moraine-débris in the lower part, while the upper ice is almost free from it.

Plates xviii. and xix. are valuable for the comparison they afford between the landscapes formed by the uniform ice-cap of Greenland and the protrusion of peaks through a dwindling ice-area in the familiar scenes of Switzerland. Other interesting photographs from Greenland occur on plates xxv. and xxvi., and one of them is here reproduced (Fig. 1).

The general propositions stated by the author are illustrated by examples of moraine-material, striated surfaces, &c., from New Jersey, so that dwellers in that State may now acquire a new insight into the topographic features round them. Mr. Salisbury restricts the word *kame* to material washed out from and left against the irregular margin of a glacier (p. 116), while *eskers* represent the channels of subglacial streams. Seeing how these two terms have been interchanged, as the author's references show (p. 136), it might have been well to invent a new word for the special type of water-formed terminal moraine which the author describes here as a kame. Chapter v., on changes in drainage resulting from glaciation, contains a very suggestive study of the former glacial lakes in the flat basin west of Newark. The concluding 550 pages are concerned with "local details," the meaning of which becomes clear after so excellent an introduction. One of the most striking illustrations is that facing p. 537 (Fig. 2), where the "plucking" away of blocks along the joint-planes of a glaciated surface is clearly shown by the step-like structure and abrupt details of the lee side of a *roche moutonnée*. This term, by the by, does not seem to be defined in the earlier portion of the book.

FIG. 2.—Glaciated surface of "trap" at Weehawken, New Jersey.

In conclusion, we could wish that some "State Survey" would give us a similarly comprehensive memoir for the glacial provinces of the British Isles. G. A. J. C.

[1] "The Glacial Geology of New Jersey." By Rollin D. Salisbury. Vol. v. of the Final Report of the State Geologist. Pp. xxviii+802; plates and folding maps. (Trenton, N.J.: MacCrellish and Quigley, 1902.)

THE PEOPLE OF THE NORTH-EAST OF SCOTLAND.[1]

IT is to the credit of the Anatomical and Anthropological Society of the University of Aberdeen that it can issue *Proceedings* in a form far superior to those of the Anatomical Society of Great Britain and Ireland—the only other anatomical society in this country. Even in the contents of its *Proceedings* the younger society, founded and fostered by the professor of anatomy in the university, compares not unfavourably with the older society.

Naturally one turns first to those papers which deal with the people in the north-east of Scotland. By common repute they are a shrewd, "hard-headed" race. In a well written paper on the contents of short cists found in Aberdeenshire and neighbouring counties, Dr. Alexander Low tells all that can at present be known of their ancestors, the prehistoric inhabitants of this part. The picture drawn by Dr. Low is founded on the broken skeletons of eight men and

[1] *Proceedings* of the Anatomical and Anthropological Society of Aberdeen University, 1902–04. Pp. 155, 28 plates, 22 figs. in text. (Aberdeen: University Press, 1904.)

two women which, owing to the foresight of the late Prof. Struthers and of Prof. Reid, have been slowly accumulated and safely preserved in the anatomical museum of the university. These prehistoric Aberdonians were of low stature (5 feet 2 inches to 5 feet 4 inches), with rounded heads which measured in breadth from 82 per cent. to 85 per cent. of their length. One can see, by referring to "An Analysis of Anthropometric Statistics," a contribution made to this volume of the *Proceedings* by Mr. John Gray, that only about 12 per cent. of the present inhabitants of Aberdeenshire possess heads which, in the proportion of their diameters, resemble those of the prehistoric race. Further, it is evident that the present inhabitants of Aberdeenshire stand, as regards the diameter of the head—the only racial characteristic that can be dealt with—in an intermediate position between the long-headed highlanders of the west of Scotland and the short-headed prehistoric people of the east coast. The natural inference appears to be that the present race of the north-east of Scotland is the result of a fusion of the east and west types—but the west has exerted the stronger influence. One of the two female skulls described by Dr. Low is that of a woman who, in shape of head, belonged to the west rather than to the east type. She may have been an exceptional member of the "short-cyst" race, but it is more probable that she was a western woman captured by the eastern invaders. Those who seek to discover the factors which determine the shape of the head will find most valuable material in the fourteen plates contributed by Prof. Reid. They represent serial sections of the heads of two subjects which had been very successfully prepared.

In these *Proceedings* one can recognise the influence that the Anatomical Society exerts on the medical graduates of Aberdeen. A skeleton of a Chinese coolie sent from Singapore, a Boxer's skull brought from north China, five Wa Kamba skulls and ten Wasoga crania collected in Uganda, provide material for the junior members to examine and report on. A paper contributed by Dr. F. W. Moir contains the results of a prolonged study of the people of Ashanti. Is it not strange that the University of London, in the very centre of the Empire, offers no such stimulus to its medical graduates as is given in Aberdeen? When the board of studies for human anatomy and morphology was recently constituted in the University of London the study of human races was, for all practical purposes, completely excluded.

The eyesight of the people in the north-east of Scotland is remarkably good. Drs. Usher and Stoddart found, from the examination of 400 students, that 15 per cent. were myopic or short sighted; Fuchs found in Germany that 60 per cent. of students at a corresponding age were myopic; Norris and Oliver give 28 per cent. as the corresponding figure for American students. About three in every hundred of the Aberdeen school children are myopic; the proportion in Edinburgh is almost twice that number. Seven per cent. of the Aberdeen police are short-sighted.

In conclusion, it is to be hoped that the oblivion which so frequently overtakes the *Proceedings* of local societies, because of their inaccessibility to other workers, will spare the *Proceedings* of which this volume is but one of a series.

HYDROLOGY IN THE UNITED STATES.

THE Geological Survey Department of the United States embraces much wider duties than those covered by the similar department in this country, and the following notes upon some of the various matters with which it deals, and of the trouble taken to afford information as to the mineral resources and water supply of America, may be of interest.

The United States Geological Survey Department was created by an Act of Congress in 1879. From time to time its duties, as originally set out, have been considerably extended. For administrative purposes the survey is now divided into branches and divisions, comprising geology, topography, hydrography, with offices charged with administration and the publication of maps and reports.

The department of the Geological Survey has charge and classification of all public lands; the examination of the geological structure, mineral resources, and the products of the national domains; the survey of forest reserves and the preparation of topographic and geologic maps. The hydrographic and hydrological branch has charge of all investigations relating to the occurrence of water as a mineral and as a source of wealth to the country. It is engaged in making systematic measurements of the rivers and streams throughout the States, and of the flow of water and the supply available, whether for domestic use or as a source of power. It also, through the Reclamation Service, prepares plans for the construction of reservoirs, canals, and other works for the irrigation of arid lands, of which there are very large areas in America, and superintends the carrying out of works that have been decided on for reclamation.

To show the thorough way in which the work of the department is carried out and the pains taken to ensure efficiency, recently a conference was called by the chief engineer for the purpose of enabling the heads of the engineering staff of the Reclamation Service (twenty-five in number) to become acquainted with their work, and of exchanging views and information as to the works in hand and those planned for the future, and so secure uniformity of method in carrying out their work. At this conference an address was given by the chief engineer on the duties of the officers engaged in the work, and papers were read by the engineers having charge of the various works in execution. A record of these proceedings, with copies of the papers and other information, is given in one of the State papers issued by the department.[1]

Nearly two hundred engineers, hydrographers, and topographers are in the employ of the Reclamation Department alone, and comprehensive instructions are issued as to the management of the works, rates of pay for assistants and workmen, and other matters. One condition laid down by the State is that in all constructive work eight hours shall constitute a day's work for all labourers and mechanics.

For the use of the staff engaged in the hydrological department a manual[2] has been issued containing instructions as to the proper method of taking observations and the best form of float and current meters to be used under different conditions, with illustrations of the different kinds of meters in use and the method of using the same from bridge, cable, and boat stations; forms of reports, diagrams of discharge and current observations; with formulæ and tables to be used in computations.

From time to time the reports sent in by the staff as to the results of the various surveys and works going on are issued by the department, some of which, relating to water supply and irrigation, the relation of rainfall to run off and the floods in the Mississippi, have been noticed in NATURE of January 7, July 28, and November 3, the last reports, Nos. 89, 90, 91, being on the water resources of the Salinas Valley, the geology and water resources of the lower James River Valley, and on the natural features and economic development of drainage areas in Ohio.[3]

A BIBLIOGRAPHY OF AGRICULTURAL SCIENCE.[1]

THE yearly increasing output of scientific workers, like the fleas that have "lesser fleas to bite 'em," has called into being another class of workers who have to abstract the papers into Jahresberichte, Centralblatter, records, and the like, the next step in the *ad infinitum* process being represented by the indexes which appear every decade or so to the abstracts themselves. By no other means would the investigator be able to "read up the literature" before attacking a new problem, and though there may be two opinions as to the wisdom of so doing, there can be none as to the desirability of having the power if need be. The present volume consists of a subject index to the first twelve volumes of the *Experiment Station Record*, the well known series of abstracts of both American and European papers in agricultural science which is issued monthly by the United States Department of Agriculture, and distributed so liberally to all foreign workers. The *Experiment Station Record* is, indeed, something more than a journal of abstracts; it contains from time to time special articles resuming the current state of knowledge about particular subjects, and written by some acknowledged expert; for example, in this index we find mentioned special articles by Kühn, Stohmann, Kellner, Zuntz, and Hagemann on nutrition investigations alone.

The abstracts proper in the *Experiment Station Record* are generally very full; like all abstracts, they vary much in value, but generally they fulfil their real purpose of telling one whether it is worth while to read the original paper or not. Naturally, with a subject like agriculture, touching on so many sciences, the abstracts cover a very wide field; chemistry, botany, zoology, geology, all have their special journals which must be looked through lest any article bearing on agriculture escape; meteorology, bacteriology, veterinary science, horticulture also contribute, in addition to the great volume of journals in every country which are devoted solely to agricultural topics. The present index only adds to the debt of gratitude which all British workers in this field have long owed to the United States Department of Agriculture; in fact, if one wants to find the reference to some English experiment, by far the best if not the only way of tracing it is to hunt up its abstract in the *Experiment Station Record*. Such a pursuit will now be greatly facilitated by the present general index, which represents a putting together of the very full indexes to each of the annual volumes. A further feature of value is a complete list of *Bulletins* issued by the various divisions of the U.S. Department of Agriculture, with references to the abstracts in the *Record*. When we add that the department has also published card indexes to the more important foreign agricultural publications, as, for example, to the well known *Landw. Versuchsstationen*, we get a further idea of the completeness with which the United States Department of Agriculture is pursuing its self-imposed task of bibliography.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

AT the Darmstadt Technical College Mr. Clarence Feldmann has been appointed professor of electrotechnics.

PROF. W. NERNST, director of the departments of physical chemistry and electrochemistry at Göttingen, has accepted the chair at Berlin previously occupied by Prof. Landolt.

PROF. ARRHENIUS has declined the appointment offered him at Berlin, the Swedish Academy of Sciences having founded a Nobel Institute of Physical Chemistry with Prof. Arrhenius as director.

DUBLIN University has conferred the degrees of Master in Surgery and Doctor in Medicine *honoris causa* on Sir Frederick Treves, C.B., and the degree of Doctor in Science *honoris causa* on Major Ronald Ross, C.B., F.R.S.

DR. E. W. SKEATS, demonstrator in geology at the Royal College of Science, has been appointed to the chair of geology and mineralogy in the University of Melbourne in succession to Prof. J. W. Gregory, F.R.S., now professor of geology at Glasgow University.

CHAIRS for research and teaching in protozoology and in helminthology are about to be established at the London School of Tropical Medicine, the funds being provided by certain colonial Governments. The importance of these branches of research in tropical medicine is unquestionable, and it is gratifying to know that this is appreciated by the Governments which have thus assisted the study of the subjects.

DR. JOLY has been appointed ordinary professor of mathematics at Lausanne; Dr. Heinrich Liebmann, hitherto recognised teacher in mathematics, has been appointed assistant professor of philosophy at Leipzig; Dr. Roland Scholl, assistant professor of chemistry at the technical college, Carlsruhe; Dr. Arthur Wehnelt assistant professor of theoretical and applied physics at Erlangen; Dr. Georg Edler von Georgievics, hitherto professor of chemical technology at Bielitz, is to succeed Prof. Karl Zulkowski at the German Technical College at Prague.

THE annual conference of teachers, arranged by the London County Council, will be held on January 5–7 next at the Medical Examination Hall, Victoria Embankment. At the first meeting, addresses on the teaching of arithmetic will be given by Mr. C. T. Millis and Mr. S. O. Andrew, and the discussion will be opened by Mr. A. W. Siddons. Other subjects to be brought forward at subsequent meetings are:—the psychology of dictation, the teaching of reading, art teaching in Japan, the influence on handicraft of art teaching in elementary and secondary schools, the art training of the artisan, and true and false applications of Froebel's principles.

THE promoters of the movement for providing the University College of North Wales with new buildings on the site presented by the Corporation of Bangor have within the last few days been greatly encouraged in the task by an announcement that Mr. Owen Owen will contribute 1000*l*. to the building fund. This donation, taken in conjunction with the recent bequest to the college by the late Dr. Isaac Roberts of the sum which is expected to reach about 15,000*l*., and by the late Mr. John Hughes, of Liverpool, and Mr. Richard Hughes, of Llanfwrog, Anglesey, of 5000*l*. and 1500*l*. respectively for the purpose of establishing scholarships, affords a welcome indication of the interest which is now being taken in the fortunes of the college by Welshmen having the like means and wish to benefit the cause of higher education.

AT a recent meeting with reference to Swanley Horticultural College, presided over by Lady Brassey, Mr. J. C. Medd urged the claims of the college to recognition by the Board of Agriculture, and showed how the institution now fulfilled the conditions which it ought to do, if it were to expect an annual grant from that Government department. He also alluded to the nature-study course for teachers which was held at Swanley during the summer holidays. Sir John Cockburn pointed out that all educational establishments that did their duty were in need of funds, and that Swanley College was no exception. Mr. Buckmaster, chief inspector to the Board of Education, spoke of the efficiency of Swanley College at the present time, and thought that all energy should be directed towards maintaining and improving the position which Swanley had attained rather than to inaugurating similar undertakings.

ADDRESSING the boys at St. Clement Danes' Holborn Estate Grammar School on Monday, Lord Alverstone remarked that it was the knowledge acquired in youth which lasted longest. The effort to retain impressions in later life was in marked contrast to that made when the brain was younger. Modern languages, therefore, should be earnestly and carefully studied at school. He was glad to see a considerable number of pupils had gained honours in English literature. In the hurry and race of modern life there was a tendency to advocate education which would be of immediate assistance to professional life; but he was strongly of opinion that up to the age of sixteen or seventeen a boy's education should be general, and the temptation to specialise too much should be resisted. A boy would be a better student and would make a better man of the world if up to seventeen he received a liberal education rather than one directed to any special object. Most educationists would agree with Lord Alverstone in his objection to specialisation at school; but in connection with this subject it is pertinent to ask whether the study of Greek is not specialisation to a boy who is taught English and Latin properly.

At the annual speech day of Scarborough Municipal School on Tuesday, the Right Hon. A. H. Dyke Acland, chairman of the governing body of the school, remarked that if he were asked what the secondary schools of the country needed most he would say more money, fewer examinations, and a more effective instruction in English language and literature. They wanted the means which would enable them to try to follow the example of other countries in the matter of secondary education. The culprit in this case was not the Board of Education but the Treasury. If it had to put down ten millions for elementary education it tried to take it out of secondary education, and at this present moment of our country's history there was nothing which needed more assistance than secondary education. With regard to examinations, Mr. Acland strongly contended that the old system of paper examinations was not a true test of the efficiency of a school, and was often altogether deceptive. The true test was when half a dozen inspectors spent four days and watched the work of the pupils, as was done at Scarborough. In America there were almost no examinations, and in Germany the ordinary paper examination of which we thought so much was unknown.

SOCIETIES AND ACADEMIES.

London.

Royal Society, October 27.—"Some Physical Characters of the Sodium Borates, with a New and Rapid Method for the Determination of Melting Points." By C. H. **Burgess** and A. **Holt**, jun.

The glasses obtained by fusing sodium carbonate with boric anhydride can be transformed either wholly or in part on prolonged heating into stable, crystalline varieties, which invariably melt at higher temperatures than the glasses from which they were derived.

A study of the melting points of the crystalline and vitreous forms of mixtures of different compositions leads to the conclusion that only two sodium borates can be obtained by fusion—$Na_2O.4B_2O_3$ and $Na_2O.B_2O_3$.

The addition of Na_2O to boric anhydride produces in the first place a solution of the borate $Na_2O.4B_2O_3$ in boric anhydride. This then becomes supersaturated, and the borate in excess separates on heating for some time. The amount which separates continues to increase until the mixture has the composition of nearly pure $Na_2O.4B_2O_3$, when complete crystallisation occurs. Between this point and the compound $Na_2O.B_2O_3$, the crystalline forms appear to be solid solutions of the two above mentioned borates, anhydrous borax itself being almost the eutectic point. In mixtures containing more sodium than $Na_2O.B_2O_3$, the crystals seem to be solid solutions of this compound with sodium carbonate. The glasses appear to be the superfused and metastable forms of the crystals.

Analyses of glasses and crystals of various composition confirm the observations derived from the melting points. The melting point method employed consisted essentially of a platinum wire which was heated electrically, to which a small bead of the substance under investigation was hung. A light weight was attached to the bead. When the wire was heated to the melting point of the substance the bead and weight fell off. The resistance of the wire was determined at this moment, and thence the temperature. The method proved good for substances like glass, which have hitherto not been supposed to melt at any definite temperature.

November 17.—"On the Group IV. Lines of Silicium." By Sir Norman **Lockyer**, K.C.B., LL.D., Sc.D., F.R.S., and F. E. **Baxandall**, A.R.C.Sc.

In previous communications to the Royal Society an account has been given of the behaviour of the lines of silicium under varying experimental conditions, and as a result of the inquiry the lines were divided into four distinctive groups. The genuineness of the lines of group iv., as silicium lines, has recently been questioned by M. de Gramont, of Paris. He concludes that, as the lines of group iv. always disappear from his spectra with the air lines, they are really due to oxygen or nitrogen. This is so much at variance with the Kensington conclusions that it has been considered necessary to give, in the present paper, the photographic evidence on which those conclusions were based. Reproductions of photographs of silicium spectra under various electrical conditions are given, and from the behaviour of the Si iv. lines in the different photographs it is claimed that they cannot be due to anything other than silicium.

In the vacuum-tube spectrum of SiF_4 the Si iv. lines are seen to be stronger than even the strongest of Neovius's air lines, which appear in the same spectrum.

In one of the reproductions, the spark spectrum of sodium-silico-fluoride, volatilised between platinum poles, is compared with the spark spectrum of air, also made incandescent between platinum poles. In each spectrum the ordinary lines of nitrogen and oxygen are well seen. The silicium lines in question are shown in the former spectrum, but have no corresponding lines in the air spectrum. It is also mentioned that these lines do not occur in the Kensington spark spectrum of any element other than silicium.

There are, according to Neovius, very weak lines of oxygen or nitrogen near the positions of the silicium lines (4089·1 and 4116·4). These faint air lines are possibly the lines which Gramont gets in his spectra, but from the evidence adduced in the present paper they are not the lines which appear so strongly in the Kensington silicium spectra.

In another reproduction the SiF_4 spectrum is given alongside that of ϵ Orionis, and the identity of position of the Si iv. lines and strong lines in the stellar spectrum is shown.

Linnean Society, December 1.—Prof. W. A. Herdman, F.R.S., president, in the chair.—Proteid digestion in animals and plants: Prof. S. H. **Vines**, F.R.S. In this discourse Prof. Vines first remarked that the foundation of our knowledge of gastric digestion in animals was laid by van Helmont so long ago as early in the seventeenth century ("Ortus Medicinæ," 1648), who held that it was effected by an "acid ferment." But in spite of continued research by Réaumur, Stevens, Spallanzani and others, it was not until two hundred years later that the ferment was actually detected. This important discovery was made in 1836 by the celebrated Schwann, who gave to the ferment the name "pepsin." In the course of subsequent investigation, it came to be recognised that the digestion of the food is not by any means completed in the stomach, but that the greater part of the digestive process is carried on in the small intestine (duodenum) by the pancreatic secretion. Claude Bernard ascertained in 1856 that the pancreatic juice contains a ferment that digests proteids; to this ferment the name "trypsin" was given by Kühne in 1876. These two were the only proteases known until quite recently (1901) a new protease, termed "erepsin" by Cohnheim, its discoverer, was added to the list. Like trypsin, this protease peptolyses peptones, and is active in alkaline liquids; but its peptonising power is much less marked, as it is without action on albumin and fibrin, though it can peptonise casein. The discovery of erepsin suggested the possibility that trypsin might be, not a single enzyme, as had hitherto been thought, but a mixture of enzymes, possibly of peptonising with peptolysing enzymes. Research in this direction has, in the hands of Dr. Vernon, already (1903) shown that what is generally known as trypsin is a mixture of erepsin (pancreato-erepsin) with what may be termed trypsin proper. It is not inconceivable that analysis may be carried still further, and that trypsin proper may itself be found to be a mixture of a peptonising with a peptolysing enzyme. Prof. Vines next turned to proteid-digestion in plants. His own contribution, made within the last three years, consists of a number of observations on many different plants or parts of plants, showing that a protease of some kind is probably to be found in all parts of all plants at one stage or other of their development. It appears that whilst all plants that have been investigated can effect peptolysis, only a limited number have been found capable of digesting fibrin. Prof. Vines has ascertained that in certain cases (yeast, mushroom) the tissues contain a mixture of erepsin with a fibrin-digesting enzyme, a result which finds its analogue in Vernon's researches on pancreatic trypsin.

Entomological Society, December 7.—Prof. E. B. Poulton, F.R.S., president, in the chair.—Mr. H. St. J. **Donisthorpe** exhibited *Quedius nigrocoeruleus*, taken by Mr. H. C. Dollman in a rabbit-hole at Ditchling, Sussex, this being the fourth recorded British specimen.—Prof. T. Hudson **Beare** exhibited a specimen of the rare Longicorn *Tetropium castaneum*, taken about two years ago in the vicinity of the quays at Hartlepool, and probably introduced from abroad.—Mr. G. J. **Arrow** exhibited a series of the Lamellicorn beetles from the Burchell collection, and remarked that Burchell had at the time of their capture, some seventy years ago, already noted their powers of producing musical sound.—Mr. C. O. **Waterhouse** exhibited drawings illustrating the development of the front wing in the pupa of the Tusser silk moth, showing the relation of the tracheæ to the veins, prepared for exhibition in the Natural History Museum. He also exhibited some coffee berries from Uganda injured by a small beetle belonging to the Scolytidiæ, and two coleopterous larvæ from the Burchell collection from Brazil, submitted to him for determination by Prof. Poulton. One was a heteromerous larva two inches long, much resembling the larva of Helops. The more interesting one was noted by Burchell to be luminous, and appeared to be the larva of an Elaterid.—Mr. J. J. **Walker** exhibited the type-specimen of *Haplothorax burchelli*, G. R. Waterhouse, from the Hope collection, a remarkable Carabid discovered by Burchell in St. Helena. It is now exceedingly rare, if not entirely extinct, in its sole locality, the late Mr. Wollaston, during his visit to the island in 1875–6, having entirely failed to find the beetle alive, though its dead and mutilated remains were often met with.—The **President** exhibited cases showing the results of breeding experiments upon *Papilio cenea* conducted by Mr. G. F. Leigh, who had for the first time bred the *trophonius* form from *trophonius* itself. He also exhibited a photograph, taken by Mr. Alfred Robinson, of the Oxford University Museum, showing the Xylocopid model and its Asilid mimic, exhibited by Mr. E. E. Green at a recent meeting. The example was particularly interesting, inasmuch as Mr. Green's record of the mimic circling round its model tended to support the view that the bee is the prey of the fly.—*Erebia palarica*, n.sp., and *Erebia stygne*, chiefly in regard to its association with *E. evias*, in Spain: Dr. T. A. **Chapman**. The author described *Erebia palarica*, a new species from the Cantabrian range; he said it was phylogenetically a recent offshoot of *E. stygne*, and the largest and most brilliant in colouring of all the known members of the family.—Entomological experiences during a tour through India and Ceylon, October 10, 1903, to March 26, 1904: Dr. G. B. **Longstaff**.

Geological Society, December 7.—Dr. J. E. Marr, F.R.S., president, in the chair.—The chemical and mineralogical evidence as to the origin of the dolomites of southern Tyrol: Prof. E. W. **Skeats**. Recent work on modern coral-reefs has shown that these limestones contain very little, if any, insoluble residue. The study of the relative proportions of the organisms composing these reefs, and the alterations that they undergo, has further shown that corals play a subordinate part in them, and that calcareous algæ, foraminifera, and other organisms form the bulk of the rocks of the reefs. The author has applied this information in the examination of collections from the much debated area of the dolomites of southern Tyrol. The chemical examination of numerous specimens from the Schlern dolomites of the Schlern, the Langkofl, the Marmolata, the Sella, the St. Cassian district, the Richthofen Reef, and numerous other localities is described, so far as relates to the proportions of lime and magnesia and of insoluble residue. These results are compared with similar analyses of limestones from lower and higher horizons.

Physical Society, December 8.—Dr. R. T. Glazebrook, F.R.S., president, in the chair.—On a rapid method of approximate harmonic analysis: Prof. S. P. **Thompson**. For the study of alternating electric currents and for several other applications, harmonic analysis is simplified by the consideration that all the even terms in the Fourier expansion are absent. In this case the second half-period is similar to the first half-period, but with the ordinates of the corresponding angles reversed in sign. Given a complicated harmonic curve containing constituents of the odd orders only, the zero-line can always be drawn so that the constant term vanishes from the Fourier series, the mean ordinate being zero; and it is then always possible to choose as origin a point for which the ordinates at 0° and 180° are zero. The paper gives a *résumé* of the various methods which have been employed for harmonic analysis by reduction from simultaneous equations, graphical means, and by harmonic analysers. The method adopted by the author is a simplification of a general method of analysis published by Prof. Runge.—A high frequency alternator: W. **Duddell**. The author described and showed in action a high-frequency alternator which he had constructed in 1900 for some experiments on the resistance of the electric arc, and with which frequencies up to 120,000 ~ per second had been obtained. An illustration will perhaps convey some idea of how high a frequency of 120,000 ~ per second really is. In plotting curves for ordinary frequencies of 50 to 100 ~ per second, a scale often adopted is 10 inches for 100 ~. If it were attempted to plot a curve up to 120,000 ~ per second to this scale, the curve paper would require to be 12,000 inches, or nearly *one-fifth of a mile long*.—Exhibition of experiments to show the retardation of the signalling current on 3500 miles of the Pacific cable between Vancouver and Fanning Island: Prof. W. E. **Ayrton**. The experiments were performed upon a cable electrically equivalent to the portion of the Pacific cable between Vancouver and Fanning Island, the product of the capacity (in mfds.) and the resistance (in ohms) being nine millions. Three dead-beat galvanometers were employed to indicate the current at the beginning, in the middle, and at the end of the cable. It was shown that upon applying an E.M.F. at one end of the cable the current at that end was enormously greater than its steady value, and that one-fifth of a second elapsed before any indications of current were shown at the far end of the cable. By that time the current at the sending end was 3·7 times its steady value, and after two-fifths of a second it had fallen to 2·3 times its steady value. In about five seconds the current became steady.

Royal Astronomical Society, December 9.—Prof. H. H. Turner in the chair.—On a very sensitive method of determining the irregularities of a pivot, and on the influence of the pivot errors of the Radcliffe transit circle upon the right ascensions of the Radcliffe catalogue: Dr. **Rambaut**. The method is a modification of that of M. Hamy, a small steel pin being inserted in each pivot; by means of a lever arrangement horizontal as well as vertical displacements, due to pivot irregularities, can be observed. The apparatus, which had been found entirely satisfactory, was fully described and illustrated.—On the validity of meteor radiants as determined from three observed tracks: Mr. **Chapman**.—A note accompanying a photograph of the detached nebula in Cygnus: W. S. **Franks**. The nebula was the one recently photographed by Dr. Max Wolf; the present plate, taken with the late Dr. Isaac Roberts's 20-inch reflector, showed the details of the nebula on a larger scale. A second note by Mr. Franks upon dark nebulosities was also read; it was illustrated by four photographs of long lenticular nebulæ, each of which was sharply divided longitudinally throughout its entire length by a dark line. The author suggested that these nebulæ, probably spirals seen edgeways, were cooler at their extreme edges, and that this band of cooler matter absorbed their light and caused the appearance of the dark bands seen in the photographs.—Two papers on the lunar theory, one being a note on the completion of the solution of the main problem: Prof. Ernest W. **Brown**.—An analysis of 145 terms in the moon's longitude: P. H. **Cowell**.—On the decline in the magnitude of the variable 159, 1904 Pegasi: Mr. **Wickham**.

Zoological Society, December 13.—Mr. Herbert Druce, vice-president, in the chair.—Some specimens of a gazelle from Palestine: a new species: Oldfield **Thomas**, F.R.S.—The anthropoid apes, illustrated by a large collection of mounted skins, skeletons, and skulls: the Hon. Walter

Rothschild. The gorilla from South Cameroon and the white-faced chimpanzee of the Gaboon were characterised as new.—The cranial osteology of the clupeoid fishes: Dr. W. G. **Ridewood.**—Characters and synonymy of the British species of sponges of the genus Leucosolenia: Prof. E. A. **Minchin.**—Descriptions of eighteen species of land-shells belonging to the genus Macrochlamys and its allies: Dr. W. T. **Blanford,** F.R.S.—Descriptions of a new genus and thirty-two new species of phytophagous Coleoptera of the family Halticidæ from South and Central America: M. **Jacoby.**

Cambridge

Philosophical Society, November 28.—Prof. Marshall Ward, president, in the chair.—Remarks on Piroplasmosis with exhibition of specimens: G. H. F. **Nuttall.**—Note on some peculiar features in seedlings of Peperomia: A. W. **Hill.** The seedlings of *Peperomia umbilicata* were found in the Andes of Bolivia at about 13,500 feet above sea-level. The species is a geophilous one with small bulbs and peltate leaves. The peculiarity of the seedlings lies in the fact that, though they are dicotyledonous in structure, only one of the two cotyledons leaves the seed to function as an assimilating organ; the other remains permanently in the seed as an absorbent organ. The other bulbous species from the Andes apparently show the same features of germination, and several other species from Central America, preserved in the herbaria of Kew and South Kensington, whilst differing in their vegetative habits, show a similar type of germination.—Exhibition of new and rare Arachnids taken near Cambridge: C. **Warburton** and N. D. F. **Pearce.**—The inheritance of tortoiseshell and related colours in cats: L. **Doncaster.** Tortoiseshell cats are heterozygotes, containing the two colours black and orange. They can be produced by mating orange with black, but a tortoiseshell paired with either orange or black may throw all three colours. Male tortoiseshells are exceedingly rare, and the normal colour of the black-orange heterozygote in the male is orange, the black in this case being completely recessive. When a male tortoiseshell is paired with a female, all three colours may be produced in the kittens. Cream and blue are dilute forms of orange and black, and behave similarly when crossed, the females being "blue tortoiseshells," the males creams. Creams may be obtained by pairing blue with orange, the dilution being transferred from one colour to the other. Blue is recessive to black, and so probably is cream to orange; it appears also that blue may be completely recessive to orange in the female, although black by orange in the female gives tortoiseshell.

Manchester.

Literary and Philosophical Society, November 29.—Prof. W. Boyd Dawkins, F.R.S., president, in the chair.—Determination of wave-lengths in the extreme ultra-violet part of the spectrum: H. **Morris-Airey.** After a brief historical sketch of the work of earlier investigators, the classical experiments of Schumann were described. Schumann was not able to measure the wave-lengths of the new lines beyond $185\mu\mu$, which he photographed, on account of our defective knowledge of the dispersion of the material of which his prism was constructed. The author attempted to do this by producing the spectra by means of a concave grating *in vacuo*, but without success. However, using a plane transmission grating ruled on a plate of white fluorspar, to resolve the light from a powerful induction coil discharge between aluminium electrodes four new standard wave-lengths were measured extending to the wave-length $169\mu\mu$. The experiments were carried out, after Schumann, *in vacuo*, and the spectra recorded on photographic plates specially designed for the work.

Paris.

Academy of Sciences, December 12.—M. Mascart in the chair.—Remarks on some thermochemical rules relating to the possibility and the prediction of chemical reactions: M. **Berthelot.** The author discusses the statement that a chemical reaction must always be accompanied with an evolution of heat, and refers to his earlier works to show the exact meaning to be attributed to the words chemical reaction.—The determination of the difference in longitude between Greenwich and Paris made in 1902: M. **Lœwy.** A detailed account is given of the precautions necessary for the accurate determination of this constant. Particular care was given to the study of the personal equation of each observer, and to reduce still further the errors due to this source, the English and French observers changed stations. The mean result obtained by the latter for the difference of longitude between Paris and Greenwich was 9m. 20·974s.—On the element Z_δ: Lecoq **de Boisbaudran.** In discussing the presence of a band $\lambda = 488$, M. Urbain regards the existence of a new element corresponding to this band as hypothetical. The author gives reasons for his statement that this band is really due to a new element, and maintains the accuracy of his work published in 1895.—Observations of the sun made at the Observatory of Lyons with the 16 cm. Brunner equatorial during the third quarter of 1904: L. **Guillaume.** The results are summarised in three tables giving the numbers of spots, their distribution in latitude, and the distribution of the faculæ in latitude.—On the approximation of incommensurables and of trigonometric series: M. **Fatou.**—On continuous space groups, finite and infinite: M. **Le Vavasseur.**—Remarks on a method for the study of the convergence of certain continuous fractions: H. **Padé.**—The detonation of explosive substances under water: M. **Jacob.**—An electrically driven nickel-steel pendulum: Jean **Mascart.** A preliminary account of the results obtained with a pendulum of invar, driven by the electrical arrangement devised by M. Lippmann. Its rate was about two seconds per day. The author regards it as preferable to use several pendulums of this kind, which can be set up with ease, to attempt an absolute compensation.—On the registration of the *n*-rays by photography: G. **Weiss** and L. **Bull.** A description of the arrangement adopted is given in detail, the object being to produce three squares in contact with each other, the centre one corresponding to the effect produced by the phosphorescent surface when not exposed to the rays. The two outer squares should have been darker if an increase of the light intensity had been produced under the action of the rays. The experiment was repeated a great number of times, varying the nature of the plates, the time of exposure, and the intensity of lighting. The shortest exposure was twenty seconds, and the longest five minutes. In no case was a positive result obtained, there being no difference between the intensity of the squares corresponding to the time of action of the rays.—On some new derivatives of tetrahydrobenzene: Léon **Brunel.** By the simultaneous action of iodine (in the presence of mercury oxide) and acetic anhydride upon tetrahydrobenzene an iodoacetate is formed, $CH_3.CO_2.C_6H_{10}I$.—The synthesis and study of cyclic substituted thio-hydantoins: Emm. **Pozzi-Escot.** The method of preparation adopted consisted in acting upon the *a-b*-disubstituted thio-ureas with a monoalkyl fatty acid.—On the possibility of producing a non-brittle steel, tempered blue: Ch. **Frémont.** It is generally supposed that all irons and steels, whatever their quality, become brittle under shock at temperatures between 200° C. and 450° C. An example is given showing that this is not necessarily the case.—On a method of decomposition of complex statistical curves into irreducible curves: Charles **Henry.**—On the accessory glands of the larvæ of the Lepidoptera: L. **Bordas.**—The development of the tentacles of the Campanulariidæ and the Plumulariidæ: Armand **Billard.**—The resistance to desiccation of some fungi: Mme. Z. **Gatin-Gruzewska.** It has been found that certain fungi, including three species of Polyporus, are not killed by a prolonged drying at 37° C., as the dried fungi, when moistened, possess the same respiratory coefficient as the undried plant. The amount of carbon dioxide given off per hour is, however, less in the former case than in the latter.—On the constitution of arable earth: A. **Delage** and H. **Lagatu.** By the application of the methods of petrography to the smallest particles of arable earth, the authors come to the conclusion that instead of the earth being, as is usually represented in classical works on the subject, the result of a disaggregation followed by a decomposition of the mineral constituents of rocks, it simply consists of the various minerals of the rocks from which it is derived in a very fine state of division. The mica, quartz, felspar, calcite, tourmaline, apatite, &c., are perfectly normal, and show no signs of decomposition or of localised corrosion. The advantages of this method of examining arable earths, when used to supplement the results of a chemical examination, are pointed out.—On a new potato suitable for cultivation in damp soils: M. **Labergerie.** *Solanum Commersoni*, which up to the present has been regarded as only good for forage, has been found to give an excellent edible tuber, and it possesses the great advantage of preferring a damp soil for its growth.—On the gasification of vegetable combustibles and the generation of an economical motive power in agriculture: L. **Bordenave.** An account of the production of gaseous fuel from agricultural refuse, used in conjunction with a gas engine designed for gas of low calorific value.—The Coal-measures in French Lorraine: Francis **Laur.** The views of the author regarding the prolongation of the Saarbruck basin into France, following an axial line Neukirchen-Pont-à-Mousson, have been confirmed by two borings 700 metres deep. Further borings are in progress for the thorough exploration of the coal field. The coal contains 2 per cent. of moisture, 36 per cent. of volatile matter, 49 per cent. of coke, and 13 per cent. of ash.—Glacial growth at the end of the nineteenth century, and the different factors which have determined the anomalies of this growth in the massif of Pelvoux: Ch. **Jacob** and G. **Flusin.** The observations put forward furnish an explanation of the anomalies of glacier growth in this region indicated in 1900 by Kilian.—On subterranean corrosion at Wells (England), and the chronometry of subterranean erosion: E. A. **Martel.**

NEW SOUTH WALES.

Linnean Society, October 26.—Dr. T. Storie Dixson, president, in the chair.—Notes on Australian Lycænidæ, part iv.: G. A. **Waterhouse** and R. E. **Turner.**—Revisional notes on Australian Carabidæ, part i., tribes Carabini, Pamborini, Pseudozænini, Clivinini, and the genus Nebriosoma: T. G. **Sloane.**—Notes on the native flora of New South Wales, part ii.: R. H. **Cambage.** The route traversed—Boggabri to Tingha, *via* Narrabri, Moree, Warialda, and Inverell—offers sufficient variations in altitude and geological formation (including portion of the black soil plains) to provide interesting examples of the results traceable to these factors in the distribution of species under Australian conditions. Thus the effect of climatic influence is exhibited by such species as *Eucalyptus sideroxylon* (ironbark or mugga), *E. conica* (a box-tree), and *E. melanophloia* (silver-leaved ironbark), which in the south grow at lower elevations than is the case towards the north, where they are able to ascend the mountains owing to the warmth of northern latitudes being tempered by the increased elevation. The same influence also allows certain eastern and western species to mingle on the northern highlands, while in the south the Great Dividing Range serves as a cold barrier to keep them apart. As an instance of the influence of geological formation, the case of a sandstone area between Boggabri and Narrabri was mentioned; here *Angophora lanceolata* is a conspicuous feature of the flora.—Notes from the Botanic Gardens, Sydney, No. 10: J. H. **Maiden** and E. **Betche.**—Miscellaneous notes (chiefly taxonomic) on Eucalyptus, part i.: J. H. **Maiden.** The author deals with some plants formerly included under *E. amygdalina*, Labill. The confusion which has gathered around *E. radiata*, Hook. f. (non Sieb.), is finally cleared up. That "white gum" included under *radiata* by Bentham and others is described as a new variety or species under the name *E. numerosa*, from the number of fruits in an umbel.

GÖTTINGEN.

Royal Society of Sciences.—The *Nachrichten* (physico-mathematical section), part v. for 1904, contains the following memoirs communicated to the society:—

July 23.—A. **Sommerfeld**: Contributions to the theory of electrons; (2) bases of a general dynamic of the electron. G. v. d. **Borne**: Seismic records in Göttingen, July–December, 1903. W. **Voigt**: The action of electric vibrations upon optically active bodies. M. **Laue**: On the propagation of radiation in dispersive and absorptive media.

September 10.—J. **Thomae**: On a Gaussian series in various parts of its region of convergence.

INDIA.

Asiatic Society of Bengal, November 2.—Some archæological remains in Bishnath: W. N. **Edwards.** The old earthworks round Bishnath and Pertabghur are described, as well as the Buroi Fortification.—Noviciæ Indicæ, xxiii., four orchids new to the Indian flora: D. **Prain.** Descriptions of two new species, *Microstylis Cardoni* from Chota Nagpur, and *Eulophia Campbellii* from Manbhum and Singbhum; and also of *Lecanorchis japonica*, Bl., and *L. malaccensis*, Ridl., orchids now first added to the Indian flora.—Noviciæ Indicæ, xxiv., some new Indian plants: D. **Prain.** Some notes on species of the orders Anonaceæ, Sterculiaceæ, Celastraceæ, Leguminosæ, Rosaceæ, Combretaceæ, Orobanchaceæ, Labiatæ, and Monotropeæ, together with descriptions of new species.—A language map of west Tibet with notes: A. H. **Francke.** The distribution is given of the Rong, Leth, Sham, Purig, and Balti dialects in the Indus and Shayog valleys, and in Zangskhar and Rubshu.—Additions to the collection of oriental snakes in the Indian Museum, Calcutta: Nelson **Annandale.** A paper adding to our knowledge of the distribution of Typhlopidæ, Uropeltidæ, Colubridæ, and Viperidæ in India.—On *Dioscorea deltoidea*, Wall., *D. quinqueloba*, Thunb., and their allies: D. **Prain** and I. H. **Burkill.**

THE FUTURE OF THE HUMAN RACE.

(1) *Mankind in the Making.* Pp. viii+429. Price 7s. 6d. (2) *Anticipations.* Pp. 122. Price 6d. (London: Chapman and Hall, Ltd., 1903.) (3) *The Food of the Gods.* Pp. 317. (London: Macmillan and Co., Ltd., 1904.) Price 6s. By H. G. Wells.

MR. WELLS is a man of imagination, and he has let his imaginative faculty play about the great problems that obtrude themselves when we contemplate the new conditions under which civilised man is now living, conditions which must inevitably undergo further change as science advances. Three books of his more especially claim to forecast the future of our race, and to lay down the lines on which education should proceed. These three are "Anticipations," a very bold attempt to peer into the future; "The Food of the Gods," a lively romance full of humour that does not pall from beginning to end of the book; and "Mankind in the Making," a series of essays dealing mainly with education, and advocating radical changes in our methods.

As to style, Mr. Wells is a hard hitter. He pounds at all classes or professions or trades which fall below his standard of efficiency, or who represent, as he thinks, mouldering ideas and systems. He cannot talk patiently of bishops, schoolmasters, army men or plumbers. His philosophy has had its origin in the theory of evolution. He looks at the race of men in the past, the present, and the future, and he sees a long series of births. The individual is trustee for the race of the principle of life. The idea of this trusteeship is to Mr. Wells a great and ennobling one. A man must not look upon his individual life as the all-important thing, but must find his true happiness in the propagation and education of offspring. Nevertheless, we find in "Anticipations" that this ideal will be shared only by a limited number of people. In the world he pictures are many childless *ménages*, and Mr. Wells himself is prepared to tolerate relaxation of the marriage law and even "sterile gratification." But in this new world there will be also many men of strenuous earnestness and of religious purpose, though not professing a definitely Christian faith, who will be the leading spirits. As a rule they will be fathers of families, for the childless *ménages* will not fit in with their theory of things.

These men of energy—men of science, engineers, doctors, and so forth—will shape policy and administration. The result will be marvellous efficiency, such as is rarely if ever seen now. There will be no king. Monarchy will have given place to the New Republic. Royalty is connected with all things out of date, with aristocratic privileges, ridiculous costumes and decorations. Therefore it must go. In the New Republic, though so efficiently managed, there will be many idlers. There will be an enormous development of irresponsible wealth, great numbers of people living on invested money, having no cares of management and no duties in connection with their property. It is among this class mainly that will be found the childless *ménages*. The class that supplies unskilled labour, the old servile class, will tend to disappear. The invention of machines capable of performing more cheaply all the work that has hitherto fallen to the unskilled will make such men unnecessary. Peasant proprietors and all small land-holders must pass away. They represent stagnation, and there is room only for go-ahead, adaptable people. Those who fail to adapt themselves will fall into the abyss, the great sink in which wallow all those who are unfitted for the new conditions. The people of the abyss are to be encouraged to extinguish themselves, to practise what would commonly be called vice without offspring resulting.

Mr. Wells is quite alive to the need of an antiseptic in a wealthy society such as he foresees. To keep down excessive accumulations of wealth he proposes heavy death duties, and heavy graduated duties upon irresponsible incomes, "with, perhaps, in addition, a system of terminable liability for borrowers." But besides this there will be at work for many years to come "that most stern and educational of all masters —war." In its methods war will be very unlike anything of which we have as yet had experience. There will be marksmen few in number, but possessed of skill altogether beyond that of the marksmen of to-day. The army will no longer be officered by men too stupid and indifferent to use properly the inventions of science. No masses of raw, unskilled lads will be driven on to the slaughter.

Some greater synthesis will emerge. Mr. Wells reviews the various large groups of peoples which make up the greater part of the population of the earth. There is the Russian group, the German, Latin, and English groups, and there are the Yellow Races. Mr. Wells does not think the Russian or the German likely to predominate. In the French he has a great belief, though they do not "breed like rabbits." The richness and power of their literature make him think their language will extend itself far. He laments the comparative poverty and meagreness of our literature. Still, he inclines to the belief that a great dominant synthesis of the English-speaking peoples may be formed. Germany will be cowed by the combined English and American Navies, and Anglo-Saxonism will eventually triumph.

There remain the Yellow Races. Their star, too, will pale before that of the Anglo-Saxons. But all syntheses, however great, will eventually fuse into one. There will be a World State, and rival nationalities will be a thing of the past. "Against these old isolations, these obsolescent particularisms, the forces of mechanical and scientific development fight and fight irresistibly."

All these speculations are very interesting reading, but we cannot help regretting that Mr. Wells did not study and reflect a little longer before writing. His imagination, unclogged by knowledge, is apt to run away with him. Though he expresses the greatest reverence for Darwin and his successors, he does not show a very thorough grip of the principles of evolution. To begin with, he seems unaware of the part in the national life that is played by the lower stratum of society, the "stagnant" masses as he would call them. From this stratum emerge the men of energy so dear to Mr. Wells's heart. Occasionally the son of a poor man, say in Scotland or Yorkshire, rises to eminence. Far more often it takes more than one generation to climb the ladder. But this does not alter the fact that this substratum is an absolute necessity. For the upper strata do not keep up their numbers, and society has been truly described as an organism that is perpetually renewing itself from its base. But Mr. Wells knows only of the abyss into which tumble all the failures of modern life. Such a valuable national asset as peasant land-holders he despises and wishes to abolish. Yet from such "stagnant" classes spring the families that work upward and produce the men of energy that do the highest work of the nation. The downward movement of which Mr. Wells talks so much is comparatively but a puny stream. No doubt there is an abyss, no doubt there are in our big towns not a few degraded families which are tending to die out. Yet even the most degraded produce here and there a man of grit, a man, for instance, who enlists and rises to be a non-commissioned officer. The pick of the slum-bred men make fine fighters.

Mr. Wells wishes all citizens to be energetic and up to date. The unadaptable masses must be got rid of. They must be instructed so that the indulgence of their sexual instincts may not lead to their having offspring. Reckless parentage must be in every way discouraged. And yet Mr. Wells declares that he cannot devise any system of selection by which it would be possible to breed good citizens; the qualities demanded are too diverse. So we are to get rid of the reckless classes and depend solely on the careful classes. We are to introduce careful parentage, that is, put a stop to natural selection; but there is to be no scientific selection to take its place. The result would indeed be disastrous. As it is, our national physique may be poor, but what there is in the nation of physical vigour is due to the great amount of elimination, probably not far short of 50 per cent., that still goes on.

Here is another strange forecast. War is "the most educational of all masters," and yet after many years a great world state will arise and there will be a kind of millennium. If war the great educator, the great antiseptic, is no more, surely the world is likely to be the worse for its absence. What is to make the world better? No doubt Mr. Wells would say, "The advance of science." Science is his sheet anchor. It is to ennoble the national life so that even the idle holders of irresponsible wealth will be powerless to degrade it. But will this be so? No doubt the inventor is ennobled by his brain labour, by his striving to make his dream a reality. And the men of energy who find practical applications of his discoveries are doing work of a kind that often, though not always, elevates the character. But what of the people who merely make use of the discoveries and inventions of others? The man who invents a locomotive engine is likely, at the lowest, to be above the pettiest meannesses. But the mere travelling in railway trains leaves men morally no better and no worse. The striving after knowledge is the ennobling thing, and not the knowledge itself, the making of discoveries, not the enjoyment of them.

This being so, there is a fallacy running all through that very humorous romance "The Food of the Gods"; in the story those who are fed on this food in their infancy and youth grow to a height of some forty feet. The inventors do not add to their inches. In its application this is not true. The mass of mankind remain small in brain and character—they grow, but do not grow much, when their youth is nurtured on the clearest and noblest ideas. The few thinkers, discoverers, inventors are the giants. As to education, Mr. Wells has much to say that is worth pondering. He wishes boys to make a real study of the English language and literature. On our success in teaching English and producing good literature depends the answer to the question: Will English retreat before the tongue of some rival synthesis, or will it become the language of the world? For educational purposes, the dead languages, as we might expect, are tried and found wanting. Those who teach them are "fumbling with the keys at the door of a room that was ransacked long ago." F. W. H.

BRITISH FRESHWATER ALGÆ.

A Treatise on the British Freshwater Algae. By Prof. G. S. West. Pp. xv+372. (Cambridge: At the University Press, 1904.) Price 10*s.* 6*d.* net.

A Monograph of the British Desmidiaceae. Vol. i. By W. West and Prof. G. S. West. Pp. xxxvi+224. (London: Printed for the Ray Society, 1904.) Price 25*s.* net.

WHOEVER has sought to gain a practical knowledge of the British freshwater Algæ has in the past been often checked by the impossibility of determining, by the aid of English works, many of the forms met with. During the twenty years that have elapsed since the issue of the latest large English work on the group (Cooke's "British Freshwater Algæ") very great progress has been made in most countries of Europe, in North America, and to some extent in other countries also, in the study of these plants. Very many species previously unknown have been detected, and much light has been thrown on obscure life-histories, on the effects of environment, and on the relationships of the various Algæ to one another, and to other organisms of simple structure. But while so much new knowledge has been gained, it is dispersed in various languages and in numerous volumes; and there has been, in English, no trustworthy guide even to the published results of these years dealing with the British freshwater Algæ. Thus it has become more and more difficult to pursue the study with success, and the need of adequate presentation of the subject has been felt to be very urgent. The works just issued by the Messrs. West are most welcome, and mark a very great advance on earlier books in English dealing with these Algæ. The authors possess a unique knowledge of the species and of their distribution in Britain, the result of personal investigations carried on unweariedly in many and varied districts of the British Islands. They have added largely to previous records in species new to science, in others new to British lists, and in the fuller knowledge of the life-histories of species already known. The task was no easy one, but none more competent could have undertaken it, and it has been accomplished in a way to deserve the gratitude of all interested in the freshwater Algæ of Great Britain and Ireland.

The "Treatise" is one of the well known and excellent Cambridge Biological Series. Its aim is stated as "to give the student a concise account of the structure, habits and life-histories of Freshwater Algæ, and also to enable him to place within the prescribed limits of a genus any Alga he may find in the freshwaters of the British Islands." To do this within the limits of an octavo volume of less than 400 pages, in which are numerous illustrations, is a task possible of accomplishment only by one very familiar with the subject and skilled in concise expression; but that it has been successfully done will, we think, be the verdict after testing the book thoroughly. The views and labours of others receive due attention, and footnotes direct the student to the original publications; but Prof. West is no mere follower of the views of others, and much of the excellence of his book is due to his personal researches and to the conclusions he has drawn from them. In the preface we read that "there is no single book, or accessible set of books, by means of which a student can hope to accurately identify one-third of the freshwater Algæ he may find in a single day's ramble through a reasonably productive part of the country." With the aid of this guide he may hope to determine the genus of all save the more critical forms, and even the species in some of the genera. But the book is much more than a guide to the identification of genera and species. The introduction gives a very readable and interesting general account of freshwater Algæ in respect of their habitats, distribution, relations to and associations with certain other plants, and even with the lower animals, some of these correlations being of very curious kinds. Their relations to temperature (some thriving on ice and snow, while others can live around hot springs at 94°.5 C.), to surface conditions and exposure, and to geological strata are discussed; and the author's wide experience in field work gives much interest to the discussion. Mountainous districts are the richer, especially in Myxophyceæ and Conjugatæ, of which latter the desmids and Mougeotia are peculiarly numerous in species in these regions. The older Palæozoic and Igneous regions are preeminent in this respect, and the richest localities in Britain, "and perhaps in the whole of Europe," are tarns and peat-bogs in hollows of the Lewisian gneiss of north-west Scotland, while the fen district of eastern England is the poorest in Britain in freshwater species of Algæ.

The methods of collection, of cultivation (so important as a means of study), and of preservation for future use are described. The structure, cell-contents, nutrition and growth of the cells and plant-bodies, the methods of multiplication by division and of reproduction (asexual and sexual), the alternation of generations, the range of polymorphism observed in some species, and alleged to occur in others, are considered, and the belief is stated that the higher types have originated by gradual evolution from the more lowly types, but that the latter still persist, and must not be confounded with stages in the life-histories of the higher forms, as the author believes has been done by some. The phylogeny and scheme of classification take full note of the discoveries and views of Blackman, Bohlin, Borzi, Chodat, Wille and others, combined with the author's own discoveries.

Six great classes are recognised, of which four (Rhodophyceæ, Phæophyceæ, Bacillariaceæ or diatoms, and Myxophyceæ) are of the usual compass, the two former including few species in fresh waters. The Heterokontæ, a group proposed a few years ago by Luther for a few families characterised by yellowish-green chromatophores and the production of oil as a reserve of food, are separated off from the other green Algæ; but all the remaining green types are included in the class Chlorophyceæ, the methods of reproduction not being accepted as justifying their separation into different classes. Chlamydomonas is regarded as nearest to the origin from which all have sprung, scarcely different from the Flagellata, and the divergent lines of increasing complexity are traced, three chief tendencies, as pointed out by Blackman, showing themselves, and resulting in three types of structure, viz. the motile cœnobium, the multinucleate unicellular cœnocyte, and the multicellular aggregate, the cells of which become more and more intimately related and specialised to form the definite organism. This last type has resulted in the most complex structures among Algæ, and is regarded as having given origin through them to the archegoniate plants.

All grades of classification of the British freshwater Algæ down to genera are defined in this "Treatise," and each genus is well illustrated by drawings from the plants themselves, with few exceptions original. The number of British species is stated under each genus, and information is often added regarding the more representative species. For each genus also the synonymy is given, along with references to the literature.

Prof. West's treatment of his subject is instructive and stimulating, and the book will do much to extend the study of these plants. But it also excites the hope that he will supplement this work by giving us one descriptive of all the species and varieties of these Algæ that have been found in Britain, with, if practicable, indications of those likely to be added to the flora. He has pointed out the need of such a guide, and has proved that it could be attempted by none more fit to make it a success.

The volume on "British Desmidiaceæ" also illustrates the extraordinary advance in the study of British freshwater Algæ in recent years, due to the researches of but a few workers, among whom the authors are in the front rank. In this monograph will be brought together not only much information that, though published, was often scarcely accessible, but also much acquired through researches in many regions, from Shetland to Cornwall, in Wales and Ireland, and not yet published. Nearly 700 species and 450 varieties are now known from the British Islands (being rather more than one-third of all named species). Of these many have been discovered and made known by the authors. Cooke's "British Desmids," issued in 1886–7 as a compilation of all the forms then known, included less than 300 species and less than 50 varieties. In this first volume rather more than one-fifth of the British species and varieties are included, so that the "Monograph" will probably extend to five volumes.

Each form is described, with references to its synonyms and its bibliography; and its distribution in the British Islands is detailed, the authority for each locality being stated. The figures are original, except where it was not possible to procure specimens. When borrowed the sources are always acknowledged. A very full list of books and papers on desmids adds to the value of the work.

The "Monograph of British Desmidiaceæ" is worthy of a place among the numerous valuable works issued by the Ray Society, and will be indispensable in the study of these plants.

THEORY OF RAPID MOTION IN A COMPRESSIBLE FLUID.

Leçons sur la Propagation des Ondes et les Équations de l'Hydrodynamique. By Jacques Hadamard. Pp. xiii+375. (Paris: Hermann, 1903.) Price 18 francs.

THE theory of fluid motion, as ordinarily worked out, presents several *lacunae*. One notable omission is the absence of any detailed discussion of the effects of compression and rarefaction of air owing to the rapid motion of bodies through it. An artillerist, seeking by the aid of the theory for principles that would help him to understand the resistance of the air to the motion of projectiles, would be likely to be disappointed. He would find an explanation of the effect of rifling in keeping the points of projectiles forward; but, while he might admire the ingenuity displayed in the development of the theory, he would feel that, with this exception, it shed but little light upon his business. The present book represents the outcome of efforts made in recent years by some French mathematicians, and especially by Hugoniot and P. Duhem, to widen the scope of the traditional hydrodynamics so as to include rapid motions in compressible fluids.

Our hypothetical artillerist would need to exercise much patience in order to get on with the book. He would probably soon give it up as too intensely mathematical. The first chapter is devoted to an account of an existence theorem in the theory of potential. It is to be proved that, provided a certain condition is satisfied, there exists a function which is harmonic in a given region and has a given normal rate of variation at the boundary of the region, in other words, that irrotational motion of incompressible fluid is possible within a closed surface which changes its form in a prescribed manner without changing its volume. The author gives a proof which is very interesting from the point of view of analysis. He also expresses the required function by means of a subsidiary function which he calls "Fonction de Franz Neumann," and of another which he calls "Fonction de Klein." The latter is the velocity potential due to a source and a sink within the given surface, and the former also can be interpreted physically, but the interpretations are not recorded. In the case of a spherical boundary, which is worked out, the results are attributed to Bjerknes and Beltrami. It would seem that these writers, therefore, virtually anticipated Hicks's discovery of the image of a source with respect to a sphere. One misses the interpretation in terms of images. The mathematics is there, but the author does not tell us what it means. Nevertheless the mathematics is excellent.

In chapters ii. and iii. we have so much of the ordinary theory as is requisite for the purpose of setting out the equations and conditions which govern the motions of fluids, and we have also an extension to discontinuous motions. The fact that was emphasised by Hugoniot is that the motion is not necessarily continuous. He paid especial attention to the case in which the velocity is everywhere continuous, but the differential coefficients of the components of velocity are discontinuous at a moving surface. The discontinuities at such a surface are not arbitrary, but are subject to three sorts of conditions. The surface moves through the fluid like a wave. One set of conditions connects the discontinuities with the direction of the normal to the surface. A second set connects them with the velocity of propagation. These two sets of conditions are kinematical. To determine the velocity of propagation the dynamical equations must be introduced. The kinematical conditions are called "conditions d'identité" and "conditions de compatibilité," and they are expressed by means of some elegant geometry. The necessity for such conditions has been recognised by other writers in the case of discontinuities that affect the velocity. The latter are here called "waves of the first order." The origin of Hugoniot's discontinuities, called "waves of the second order," is found in an analytical paradox. If the pressure is a function of the density, the equations of motion determine the acceleration of every particle; but, if the motion of a boundary is prescribed, the normal component of the acceleration of the particles that are in contact with the boundary is prescribed also. The two values thus obtained for this acceleration are in general different. Waves of the second order originate at the boundary, and are propagated through the fluid.

Chapter iv. deals with rectilinear motion in a gas, and is mainly occupied with the problem, first attacked by Riemann, of discontinuities that affect the velocity. Riemann's theory was condemned by Lord Rayleigh on the ground that it violated the principle of energy, and the problem remained in an unsatisfactory state for many years. It was taken up again by Hugoniot in 1887 without knowledge of Riemann's work. Hugoniot introduced expressly the condition that the increment of energy—kinetic and internal—of the portion of fluid which undergoes a sudden change of state is equal to the work done upon it by the pressures of neighbouring portions, and he concluded that the law connecting pressure and density ($p=\kappa\rho^{\gamma}$) cannot be maintained during the passage of the discontinuity. This conclusion is opposed to Riemann's theory. H. Weber, in his recent edition of Riemann's "Vorlesungen über die partiellen Differentialgleichungen der mathematischen Physik," has contended that a complete calculation of the energy supports Riemann's theory against Lord Rayleigh's objection, but he did not refer to Hugoniot. In the book under review no mention is made of Lord Rayleigh's objection or of H. Weber's contention, but Riemann's theory and Hugoniot's are developed side by side, and the results are compared both with each other and with the results of certain experiments by Vieille. Much of the analysis is worked out and interpreted by the aid of geometrical constructions, but the reader wishes often for a more physical interpretation.

Chapters v. and vi. contain extensions of the theories of the preceding chapters to motion in three dimensions and to waves in elastic solid media. The physical value of a theory of rapid motions, accompanied by strains that are not "small," in an elastic solid, supposed to have a strain-energy function, is extremely doubtful; but no exception can be taken to the analytical methods by which the theory is developed. Chapter vii. brings the theory of waves that do not involve discontinuities of velocity or strain into relation with the theory of characteristics of partial differential equations. The discovery of the relations between these two theories has attracted a good deal of attention recently, and we may be grateful to M. Hadamard for his masterly exposition of the subject. A few notes are appended to the volume. Of these the most interesting is the one in which it is shown that discontinuities of the first order may give rise to vortex motion, even when the pressure and density in the undisturbed state are uniform throughout the fluid.

It is a sign of the healthy state of mathematics in France that the ablest analysts are bringing their powerful methods to bear upon recondite physical questions. The book under notice is a very valuable contribution to a most important and, at the same time, a most difficult subject. It breaks fresh ground, and it cannot fail to stimulate inquiry. It may be expected to conduce to the further advance of our knowledge of aërodynamics A. E. H. L.

THE GREAT ST. BERNARD PASS.

Across the Great St. Bernard. The Modes of Nature and the Manners of Man. By A. R. Sennett. Pp. xvi+444 and 111; illustrated. (London: Bemrose and Sons, 1904.)

A FLUENT but not too accurate pen, and a general knowledge of the more frequented districts of the Alps appear to be Mr. A. R. Sennett's chief qualifications for writing this book. It has a comprehensive title, and needs it, for the St. Bernard Pass is hardly more than a thread to connect, if possible, quotations in prose and verse, scraps of science and history, descriptions of scenery, and moralisings on things in general. The author has nothing new to tell us about the St. Bernard, which is not surprising, for the pass has been often described, and a carriage road now goes the whole way from Martigny to Aosta. Mr. Sennett, however, informs us that Hannibal crossed it "with his vast army," of which he proceeds to describe the sufferings. Notwithstanding what has been written by Law, Ellis, Freshfield and others, we are well aware that it is not easy to determine what route Hannibal did follow, but thought that the Great St. Bernard was no longer advocated by anyone who had studied the question.

Other statements are disputable. We are told the soldanella flower protrudes through the edge of the *névé* (which does not mean the winter snow); that the edelweiss dwells "in snow, owning a habitat where no other flowering plant may survive," and as "its haunt is far removed from all verdant vegetation and in the most craggy and inaccessible positions," we cannot expect to see it growing at the botanical station in Bourg St. Pierre, and so forth. This village is rather more than 5300 feet above sea-level, and the plant is often found between this and 6000 feet; indeed, it can be cultivated in England. As for the craggy and inaccessible positions, we had thought newspaper correspondents now enjoyed a monopoly of this fiction. Like any other Alpine plant, it may grow in a breakneck place, but its favourite habitat is a rough slope of grass and stone. It used to grow profusely on a place of this kind, where it could be gathered in perfect safety, on a mountain ridge about a thousand feet above San Bernardino.

But Mr. Sennett, though prone to discuss scientific questions, does not always win our confidence. The "Tertiary period of the London Clay" is an odd phrase, and adamantine an inappropriate epithet for the *firn* or upper basin of a glacier; and in what respect the Lago di Garda resembles a diadem we fail to perceive. To his vision of a Europe the glacier fields of which only just failed in reaching the Alps we are perhaps accustomed, but think that most geologists at the present day would speak less confidently of glaciers having scooped out the Alpine lake basins, or having "cut out gorges for themselves through the solid mountain, divided enormous peaks in twain, planed down and levelled great asperities." The Märjelen See does not lie in a lake basin, but simply at the head of a glen, blocked by the great Aletsch Glacier, and after seeing it one day full and the next empty, we utterly disbelieve Mr. Sennett's explanation that it is emptied on the principle of a syphon. The name Mörjelen, which he prefers, may be patois, but the other form is more usual; so also is Gondo for Gonda, Guttannen for Guttenen, Meiringen for Meyrengen, and, notwithstanding Baedeker, Penninus for Pœninus (the title of the Alpine Jupiter). The science is discursive and commonplace, where not enriched by extracts from Tyndall or Ruskin, or yet more ornamental writing. Mr. Sennett may think in English, but is so prone to translate into journalese that we suspect he was trained in a certain Fleet Street haunt of young lions. We cannot welcome the verb "resurrect," the adjective "riverian" (of or belonging to a river), or "lithic" (a favourite one) when plain folks would say stony or rocky. The book, however, contains numerous illustrations, often pretty, but it is tiresome to have them (except in the appendix) only numbered, and to be obliged to consult a list to see what they are, especially when we are sometimes greeted with fanciful titles instead of place-names. "Dame Nature's Painters" does not much enlighten us, but it looks very like a view down the lower part of the Via Mala. But the author has tried the dangerous experiment of mingling poetry and science, and we cannot honestly congratulate him on his success.

T. G. B.

TRACHOMA.

Trachoma. By Dr. J. Boldt. Translated by J. Herbert Parsons, D.Sc., F.R.C.S., and Thomas Snowball, M.B., C.M. With an introductory chapter by E. Treacher Collins, F.R.C.S. Pp. lii + 232. (London: Hodder and Stoughton, 1904.)

DR. BOLDT'S monograph on "Trachoma," published at the end of last year, deals with a subject presenting many problems to which no satisfactory solutions can at present be offered. It is therefore a matter for congratulation that an English translation of such an excellent *résumé* of the subject has been prepared. Dr. Boldt has been working for many years in one of the trachoma infested centres of Germany, and has been constantly faced during that time with these unsolved problems, and in the book before us he clears the ground of all the lumber which gathers round any subject of discussion, and states clearly the present condition of our knowledge and the lines on which future investigation must go.

The first and most important difficulty met in dealing with trachoma is that at present the ætiological factor is unknown. The discussion of this question in chapter iv. particularly, and incidentally in chapters iii. and v., will be, to ophthalmic surgeons, the most interesting part of the book. The author distinctly inclines to the view that there is a specific organism, the primary cause of trachoma, as yet undiscovered, but that also an individual predisposition and a number of subsidiary causes, such as climate, soil and race, overcrowding, uncleanliness, and other social evils, are also contributing causes.

Many workers at the present time are inclining to lay much greater stress on the importance of the individual predisposition and to hold the view that the disease may be set up by any bacterium which is pathogenic for the conjunctiva. The large number of cases in which some scrofulous taint can be traced is distinctly in favour of this view. It has been frequently shown that in such people any infection will give rise to a lymphoid hypertrophy, and the essential pathology of trachoma is primarily a hypertrophy of lymphoid follicles with subsequent degeneration of the lymphoid tissue and formation of scar tissue. Dr. Boldt, with absolute fairness, gives both hypotheses and the arguments which have been advanced by various writers in support of them.

It would be of undoubted benefit to the community if this book were to get into the hands of two classes in particular, the men who are concerned in the administration of the Poor Laws of the country, and those concerned in the medical and sanitary administration of the Army. The excellent introductory chapter by Mr. Treacher Collins gives details of the most useful work which is being carried on at Swanley, and of the influence that proper hygienic measures have had generally in checking the disease. Dr. Boldt gives similar details of the progress and subsequent checking of trachoma throughout the various countries of Europe. It would indeed be well if the last chapter were separately printed and distributed as a pamphlet to the various boards of guardians and health officers throughout the Empire.

We have nothing but praise for the way in which the translators have carried out their work. We could nowhere detect a trace of German origin in the style.

OUR BOOK SHELF.

The Cyclones of the Far East. By Rev. José Algué, S.J. Second (Revised) Edition. Pp. 283. (Manila: Bureau of Public Printing, 1904.)

IN the present edition the author has extended the area dealt with in the earlier editions, and as abundant additional data have been collected, not only from the Philippines themselves, but also from the surrounding coasts, this information has now been embodied. The author says that, "owing to the opening up of the Far East in recent years, an endeavour has been made to extend the usefulness of the work by giving a greater compass to the study of the phenomena which cause, accompany, and follow the atmospheric perturbances which are experienced in the various seas of the Far East." The title of the revised edition is changed from "Cyclones of the Philippines" to "The Cyclones of the Far East." The present edition appears in English, and is freed from the formidable list of errors found in the English version of an earlier edition. Among the many additions contained in this new edition may be mentioned some practical rules for navigating in case of encountering a typhoon, and a list and description of the ports of refuge during storms in the Far East, especially in the Philippine Archipelago.

Commendation should certainly be given of the careful arrangement and division of the whole work, which aid much the general study and grip of the valuable material, whilst numerous illustrations add much to the elucidation of the subject. Father Algué must be credited with what is only too commonly overlooked. At the conclusion of each chapter reference is given to the works which may be consulted in connection with the branch of the subject dealt with. The references appear to have been chosen with the greatest impartiality and with the sole desire to render the work as complete as possible. This example may commend itself to authors of other branches of scientific work.

The principal cause which influences the progressive movement of typhoons is said to be the general movement of the atmosphere in which they take place, not of that part only which overlies the land and sea over which they pass, but especially of that portion of the atmosphere which moves at higher altitudes, as we are to look there for the seat of the greater part of the energy and power which nourish and sustain the atmospheric whirls. This opinion is endorsed by all who discuss the nature and law of storms, but, unfortunately, too little light can be thrown on the movement of the upper air, although praiseworthy efforts are being made in this direction.

The storms which visit the Philippine Archipelago vary greatly in frequency according to season, the months with the greatest number being July, August, and September, whilst the months with the least frequency are January, February, and March. Much good work is done in the classification of cyclones, and diagrams are given showing the paths of eleven different types. Considerable attention is paid to the precursory signs of cyclones, and naturally much importance in this direction is attached to the form and movement of clouds.

The whole treatise is suggestive of further scientific inquiry, and Father Algué has done much by this work to advance our knowledge of the law of storms.

C. H.

The Animals of New Zealand: an Account of the Colony's Air-breathing Vertebrates. By F. W. Hutton and J. Drummond. Pp. xiv+381; illustrated. (Christchurch and London: Whitcombe and Tombs, Ltd., 1904.)

Some months ago, when noticing Captain Hutton's valuable "Index" of the New Zealand fauna, we had occasion to refer to the impending issue of the present volume; now that it is before us, we are happy to be able to state that it fully realises our expectations, and forms a most valuable history of the air-breathing vertebrates of the colony, written in a pleasant style which cannot fail to make it acceptable to a large circle of readers. At starting, the authors refer to their indebtedness to the late Mr. T. H. Potts, who did such good work in describing a fast vanishing fauna before it was too late. The melancholy story of the waning of this curious and interesting fauna forms, indeed, the key-note of the introduction of the volume. From the time that Captain Cook, in 1773, turned down pigs in Queen Charlotte's Sound, the native fauna has had to contend with competitors from Europe of a stronger and more aggressive type, the natural result being that many forms, like the tuatera lizard, have already disappeared from the mainland, although in some instances surviving in the adjacent islets, and many more are destined to go ere long. Among the latter (if, indeed, it be not already extinct) is the short-tailed bat, the sole representative of the genus Mystacops, its rarity, or extermination, being attributed to the destruction of insect life caused by the introduction of European birds.

From a purely commercial standpoint the authors do not, however, by any means condemn the introduction of many of the foreign species, having even a good word to say for the much abused sparrow. "Without the sparrow, or some other bird equally common," they write, "residents in the colony would be over-run with the insects again, and life would be insupportable." The phrase concerning insects, it may be explained, refers to the "plagues" of various species which occurred when European food-crops were first introduced into the colony. On the other hand, the introduction of certain species, such as the greenfinch and, above all, the rabbit, is most strongly condemned. The acclimatisation of several kinds of deer is considered to be of considerable advantage to the general prosperity of the islands, as it leads to the visits of European sportsmen.

Among the species which have suffered most severely from foreign competition may be mentioned the two bats, the kiwis, the weka rail, and the tuatera. The moas appear to have been completely and the Notornis all but exterminated by the Maories before the European advent.

Limitations of space alone prevent further commendation of a very excellent, interesting, and beautifully illustrated work.

Zellenmechanik und Zellenleben. By Prof. Dr. Rhumbler. Pp. 43. (Leipzig: J. A. Barth, 1904.) Price 1 mark.

This little work represents a sketch of the author's views on the causes and means of manifestation of cellular activity. The point of view adopted is a materialistic one. It is considered that the whole subject should be dealt with from the physical or the physico-chemical aspect, even when this fails to present a complete solution of all the difficulties that may arise. It is becoming more and more recognised that many of the acts which used to be regarded as specially the outcome of vital activity find their parallel in inorganic nature. An amœba when ingesting a filament of oscillatoria much longer than itself is able completely to enclose it because the algal thread becomes coiled up within the protoplasmic body of the protozoan. But an exactly similar state of things is produced if a drop of chloroform is placed in water and a filament of shellac be then presented to it. The filament is drawn into the chloroform, and coiled up much as the alga in the amœba; and if a short glass thread be coated with shellac, it is also "ingested," but as the lac becomes dissolved the glass thread is gradually extruded. The whole question here resolves itself into one of surface tension, and perhaps the processes of ingestion and excretion may ultimately prove to be essentially similar in nature.

Again, the remarkable uniformity in the details of nuclear divisions (karyokinesis), from whatever source the cells may originate, strongly suggests that a comprehensive physical explanation of the process will one day be forthcoming.

But although the physical aspects of cellular activity will certainly become more clear and definite, this is only the first step on to the threshold of the temple in which the secret of life is guarded. Behind the proximate physical phenomena lies a vast complex of changing chemical conditions, and it will be long before we are likely to be able exhaustively to analyse them. The more successfully we do so, however, the more nearly shall we be able to grapple with the physical problems of movement and the like. Rhumbler regards changes of surface tension, and the reactions that affect it, as constituting one of the most profitable of the many possible lines of cytological investigation.

Studies in Astronomy. By J. Ellard Gore, F.R.A.S., M.R.I.A. Pp. xi+336. (London: Chatto and Windus, 1904.) Price 6s.

In this book the reader is presented with a series of disconnected essays on a variety of astronomical subjects, many of which include interesting and suggestive results of calculations made by the author. The subjects range from "giant telescopes" to the "construction of the visible universe," but Jupiter is the only planet to which any detailed reference is made, and the sun is only dealt with from the point of view of its stellar magnitude and its motion in space. The chapter on "Messier's nebulæ," bringing together all the recent information with regard to these objects, will be of considerable value to those who possess telescopes, and the notes comprising "recent advances in stellar astronomy" give a useful summary of the state of our knowledge of the subjects dealt with at the beginning of the present year.

Most of the papers have already appeared as magazine articles, and, notwithstanding the revision which has been made for the present purpose, there is necessarily a considerable amount of repetition. Apart from this, however, the book provides a very acceptable course of not too difficult reading for those who have a general elementary acquaintance with the subject.

Salts and their Reactions. By Dr. L. Dobbie and H. Marshall. Pp. 198. (Edinburgh: James Thin, 1904.) Price 3s. 6d. net.

THIS book is intended to serve as an introduction to the study of practical chemistry, and has for its basis a series of notes intended for use in the Edinburgh classes. In an interesting preface Prof. Crum Brown states his belief in the possibility of devising a course that would be "something better than a mechanical training to enable students to pass a mechanical examination consisting in the detection of simple salts in solution." Notwithstanding this assurance, one finds that about half the book consists of descriptions of the ordinary tests and schemes of analysis common to most books treating of elementary practical chemistry.

The first part of the work consists of a short and very clear account of the general physical properties of salts and salt solutions. An outline is given of the ionisation hypothesis and of its applications, some of which are practically illustrated at a later stage. After a short account of the nature and use of indicators, a chapter is devoted to alkalimetry and acidimetry. The experimental part of the book, excluding the sections on qualitative analysis, is only represented by about twenty-five pages, and although the selection of experiments has evidently been carefully made, it seems a pity that the practical illustration of a really excellent theoretical introduction should be so meagre.

The remainder of the book is taken up with a description of the reactions of metallic and salt radicals, and with schemes for analysis. In several small particulars a departure from the conventional methods has been made with distinct advantage. Dry-way reactions, which so few chemists appear to appreciate, are relegated to an appendix, which also contains the inevitable and perfectly useless description of the reactions of the so-called rare elements. Teachers who have the management of large practical classes should find the volume of value.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Radiation Pressure.

ON p. 515 of your issue of September 22 I stated that there is a retarding force on the earth as it moves along its orbit amounting in all to about 20 kgm. The calculation was made on the supposition that the earth is a full radiator of uniform temperature. I have found on revising the calculation that there was an error in the arithmetic, and that the force is considerably greater, though still too small to have an effect worth considering. The following is a simple method of obtaining its value. It assumes that the earth may be treated as a black sphere exposed to sunlight, radiating as much as it receives, and with all its surface at one temperature.

If the stream of solar energy falling normally on 1 sq. cm. is S per second, a black sphere, radius a, receives $\pi a^2 S$ per second. If it radiates R per second per sq. cm. its total radiation is $4\pi a^2 R$, and the assumption of equal receipt and expenditure gives $R = S/4$. The total repulsive force exerted by the sun's radiation is $S\pi a^2/U$, where U is the velocity of light. The total retarding force due to velocity u in the orbit is $4/3\ Ru/U^2 . \pi a^2$. This is the Doppler effect due to crowding of energy in front and opening out behind (*Phil. Trans.*, A, ccii. p. 546, corrected by final note). Hence we have

$$\frac{\text{Retarding force}}{\text{Solar repulsion}} = \frac{u}{3U}.$$

At the earth's distance u/U is about 10^{-4}, so that the retarding force is about 1/30,000 of the solar repulsion.

If we take S/U as 5.8×10^{-5} dyne/sq. cm. (*Phil. Trans., loc. cit.*, p. 539), and the radius of the earth as 6.37×10^8 cm., the total solar repulsion is about 75×10^6 kgm., say 75,000 tons, and the retarding force is about 2500 kgm.

But another effect comes in which will more than counterbalance this. The hemisphere of the earth which is advancing in the orbit is on the whole colder than that which is retreating, owing to the lag in the warming of the surface exposed to the sun. I find that if one hemisphere is at 301° A. and the other at 300° A., the greater radiation from the warmer side gives a net push directed from that side to the colder of about 165,000 kgm. Of course this hemispherical distribution of temperature is only a rough approximation to the real condition, and even if the force be as large as 165,000 kgm. only a component of it acts along the orbit tending to accelerate the motion. Still, that component must almost certainly be much greater than the retarding force due to the Doppler effect, and on the whole, therefore, there is probably a small acceleration in the orbit. A force of 2500 kgm. would destroy about $4/10^{16}$ of the earth's momentum in one year. Even if the accelerating force were twenty-five times as great as this it would only generate $1/10^{16}$ of the present momentum in one year. This illustrates the insignificance of radiation pressure on the larger bodies in the solar system.

I take this opportunity of correcting another error in the address in NATURE of September 22, which has been pointed out to me by Mr. C. T. Whitmell. It arose from some very faulty arithmetic on p. 541 of the paper in the *Philosophical Transactions* already referred to. Apparently in the formula giving the radius of each of two equal spheres the mutual radiation-repulsion of which balances their gravitative attraction, a square root of 10 was omitted, and the value of that radius should be $a = 0.69\theta^2/10^4\rho$. A wrong value was also assigned to the density of the sun. Mr. Whitmell has very kindly re-calculated the results depending on this formula, and I have worked them out independently. We now find that two equal spheres will have equal radiation-repulsion, and gravitative attraction with radii as given below:—

Temperature absolute		Density		Radius in centimetres
6200°	...	1·375	...	1930
300	...	1	...	6·1
300	...	11	...	0·5645
300	...	5·5	...	1·13

The last was given previously as 3·4 cm.

The effect of radiation pressure on terrestrial dust is worthy of consideration, for it may be quite appreciable when the particles are small and are among surroundings at different temperatures. For simplicity of calculation, let us suppose a very small dust particle, of density ρ, to be cylindrical with radius a and length a, and let its flat ends be black and let its curved surface be perfectly reflecting. Let it be situated between two indefinitely extended parallel vertical walls, one at a temperature θ_1° A., the other at a lower temperature θ_2° A., and let its ends be parallel to the walls. The two faces of the dust particle will, if it is small enough, be at very nearly the same temperature, so that we may leave out of account the pressures due to the emitted radiation and consider only those due to that received from the walls. If σ is the radiation constant 5.32×10^{-5}, and if U is the velocity of light, the difference of pressure on the two sides will be $2\sigma(\theta_1^4 - \theta_2^4)/3U$, and the acceleration due to this on area πa^2 and mass $\rho\pi a^3$ is $2\sigma(\theta_1^4 - \theta_2^4)/3U\rho a$. When $\rho = 1$, $a = 10^{-3}$, $\theta_1 = 400°$ A., $\theta_2 = 300°$ A., this acceleration is 0·02 cm./sec.^{2}.

If the law of radiation pressure can be taken as still holding when the radius is reduced to $a=10^{-5}$, the acceleration is 2 cm./sec.^{2}. This implies that such a particle of dust, in a vacuum, and between vertical walls respectively at 27° C. and 127° C. would not fall vertically, but would deviate about 2 mm. per metre towards the colder wall.

The effect found by Prof. Osborne Reynolds (*Phil. Trans.*, ii., 1879, p. 770) on a silk fibre exposed to radiation from a hot body, and assigned by him to "radiometer" action, is far larger than this. The radius of the fibre was 0·000625 cm., and its length was probably about 15 cm. When it was hung up in a test tube containing hydrogen at atmospheric pressure, and was exposed to radiation from a neighbouring jar filled with boiling water, the lower end of the fibre moved through 0·01 cm. This would imply an acceleration of about 0·7 cm./sec.^{2}, about sixty times the acceleration on a dust particle of the same radius under the conditions assumed above. The action detected by Reynolds increased, too, very rapidly as the pressure fell, being ten times as great when the pressure was reduced to 1 inch of mercury.

The University, Birmingham, December 15.

The Date of Easter in 1905.

Already queries have been addressed to me on the subject of the date of Easter in 1905, owing to the fact that, according to the almanacs, the moon is full at 4h. 56m. Greenwich mean time on the morning of March 21 next, and that therefore, according to the Prayer Book rule, it would appear that Easter Day should be the Sunday following March 21, viz. March 26. As the misunderstanding on the subject seems widely spread, perhaps you will allow me to explain that the "moon" referred to in the ecclesiastical calendar is not the actual moon in the sky, which is full at a definite instant of time, but a fictitious moon, the times of the phases of which are so arranged as not to differ much from those of the actual moon. These phases are held to occur, vaguely, on certain days, and therefore hold good for all longitudes, and so avoid a practical inconvenience that would arise from the use of the actual moon. Thus, in the instance before us, in which the actual moon is full at 4h. 56m. a.m. Greenwich mean time, the same moon is full at 11h. 48m. p.m. (*on the preceding day*) Washington mean time. The people adopting Greenwich time would, therefore, in the supposed circumstances, keep Easter Day on March 26, whilst those adopting Washington time would keep it on April 23.

Perhaps the simplest expression for the date of the Paschal full moon is March (44 − epact), which gives the date directly when the epact is less than 24. When the epact is equal to or greater than 24, this expression gives the date of the preceding full moon, and the Paschal full moon is found by adding 29 to this date.

Thus in 1905 the epact is 24, therefore the calendar moon is full on March 20, and again on April 18. The latter is, by the rule, the Paschal full moon, and Easter Day is the following Sunday, viz. April 23.

Lepidocarpon and the Gymnosperms.

The concluding sentence in your note on Mr. H. E. H. Smedley's admirable models of the fructifications of Palæozoic plants (Nature, December 22, p. 183) may possibly be misleading to some of your readers. As the models of Lepidocarpon shown in your figure were prepared from my instructions, I may be supposed to share the responsibility for the hypothesis of an affinity between the lycopodiaceous cones and the Gymnosperms, stated to have been urged by "the author," especially as the points of agreement mentioned are quoted, with some slight abridgment, from my paper on the seed-like fructification of Lepidocarpon in the *Philosophical Transactions*.[1] Such an affinity has never appeared to me to be probable. The characters cited—the presence of an integument and micropyle, the single functional megaspore, and the detachment of the indehiscent, seed-like organ as a whole—are important points of analogy with true seeds, but in Lepidocarpon "these organs differ too much in detail from the seeds of Gymnosperms to afford any evidence of affinity."[1] I doubt whether my friend Mr. Smedley really intended to suggest anything more than an analogy.

As regards the Gymnosperms, evidence has been accumulating for some time past indicating their connection with the fern-phylum rather than with the Lycopods. Some account of this evidence will be found in my discourse at the Royal Institution on the origin of seed-bearing plants (1903),[2] while a more recent summary is given in Mr. Arber's article on Palæozoic seed-plants in Nature for November 17, p. 68.

The seed-like organs of some Palæozoic Lycopods, such as Lepidocarpon and Miadesmia,[3] seem to be cases of homoplastic modification, and not to be indicative of any affinity with those groups of seed-plants which have come down to our own day.

Fishing at Night.

The notice in your Journal of the "Sea Fishing Industry," written by Mr. Aflalo, suggests to me that he or some other of your readers may inform me why sea fishing takes place for the most part at night. I have heard the subject discussed all my life, and the answers have been of the most opposite and unsatisfactory character, such as to obtain a supply of fish for the morning markets, and because fish come nearer to the surface in the dark. Everyone must be familiar with the sight of our fishing boats preparing to take their departure as the evening approaches in the different harbours on our coasts. Some of the masters, unfortunately, like the Apostle Peter, have toiled all night and caught nothing.

December 20.

A New British Bird!

A fine example, a male, of the Pacific eider-duck, *Somateria v-nigrum*, was killed at Scarborough on December 16. This is the first recorded instance of the occurrence of this bird on our shores. Closely resembling the common eider, *Somateria molissima*, it may yet be readily distinguished therefrom by the bright orange colour of the bill, and the sharply defined, black V-shaped mark on the throat—hence the specific name *v-nigrum*.

The Pacific eider occurs in abundance along the coasts of north-western America and north-eastern Asia.

Intelligence of Animals.

In reference to the question of intelligence in animals, it may be of interest to mention a case of distinct reasoning power in a cat which for nine or ten years associated himself with our family; he would have scorned the suggestion that he belonged to it. When he found himself on the wrong side of a closed door—a very constant occurrence—he stood up and, catching the handle in his fore paws, *rattled* it. I do not think he tried to *turn* the handle, but he certainly knew that it played an essential part in the opening of the door. He is now no more, and *de mortuis nil nisi bonum* bars any further reference to his career, for he was a dissipated old scoundrel; but it is a pleasure to me to pay, with your permission, the above little tribute to his memory.

Greenock, December 17. T. S. Patterson.

FAUNA OF THE HIGHLANDS.[1]

THIS handsome new addition to Mr. Harvie-Brown's "Vertebrate Fauna of Scotland" maintains the high standard of excellence which has marked the preceding volumes. It is punctiliously accurate and at the same time picturesque and full of interest. One of the authors, the Rev. H. A. MacPherson, sacrificed himself too whole-heartedly to an enthusiasm for ornithology, and died in 1901 at the age of forty-three, and Mr. Harvie-Brown has also to deplore the loss of another collaborator, Mr. T. E. Buckley, who died in 1902. Of both these naturalists there are appropriate *in memoriam* sketches.

This volume deals specially with the western parts of the counties of Sutherland and Cromarty—west of the great "watershed"—and with similar portions of Ross-shire and Inverness-shire down to the boundary of "Argyll." In the introductory matter we find terse physiographical accounts of Skye, the Ascrib Islands, Handa, Priest Island, and the coast of the mainland, designed to illustrate the most outstanding faunal feature of the area, namely, its isolation. Mr. Lionel W. Hinxman contributes a brief account of the geology of the north-west Highlands, and there is another interesting section dealing with climatic and other changes, including those due to the hand of man. Few of these can be said to do man's intelligence much credit.

Mr. Harvie-Brown confesses that the chief interest of the area in question is the comparative poverty of its fauna. "The true faunal value lies in its isolation by sea and mountain ranges." "It appears to me to be almost the poorest and least favoured of our Scottish Faunal Areas, both as regards species and in its paucity of individuals of many of them." But it includes some old frequented haunts of some of our now rarer birds, it illustrates faunistic changes traceable to climatic changes, and it gives evidence of a keen struggle for existence amid which some species are still advancing. What Mr. Harvie-Brown particularly seeks to show is that the hemmed-in nature of the area is a main reason for its faunal poverty; thus some of the more prominent land-features of the country, such as the long tongue of land of Ardnamurchan, act as deterrents to the advance of land birds from south to north. The nature of the soil, the vegetation, the distribution and character of wooded areas, and the climatic conditions have also to be borne in mind, but Mr. Harvie-Brown has not done justice to himself or to his theme in his treatment of this aspect of the problem. Of course it is not given to everyone to be a Humboldt, but without attaining to his compre-

FIG. 1.—Fulmar's first nesting-place on Handa (at small white ×). From "A Fauna of the North-West Highlands and Skye."

[1] "A Fauna of the North-West Highlands and Skye." By J. A. Harvie Brown and H. A. MacPherson. Pp. civ + 378; illustrated. (Edinburgh: David Douglas.) Price 30s

hensiveness of outlook it would not have been difficult to improve the chapter on the "Faunal Position" of the area in question; and even in regard to the particular factors which Mr. Harvie-Brown emphasises in his interpretation of the faunistic peculiarities of the areas, his "argument," as he calls it, appears to us too jerky and elliptical to win conviction. But he gives some references to papers dealing with the physiographical conditions in some detail.

Turning to the list of mammals—which is somewhat mournful—we find that there is only one bat, the pipistrelle; the hedgehog, the lesser shrew, and the water-shrew are rare; the true wild cat still lingers; foxes, once *very* numerous, are now scarce; the marten, once abundant, is trembling in the balance between rarity and extinction; the polecat has become decidedly rare; a colony of badgers still persists; the rabbit, introduced about 1850, is in many places taking a rapid—lamentably rapid—hold of newly afforested grounds; and so on. The chief value of such information lies in the precision with which it records increase or decrease, *e.g.* of squirrel and polecat, within a term of years, and thus illustrates evolutionary processes going on around us.

We need hardly refer to the records of adder, lizard, and slow worm, of frog and toad, and two newts; but we may be allowed to note, without being captious, that the title on the back of the book and on the beautiful frontispiece, "A Fauna of the North-West Highlands and Skye," is somewhat too big for the volume, which deals with mammals, birds, reptiles, and amphibians, and no more.

The most entertaining part of the book is that which deals with the birds, in regard to which the authors speak from rich experience and with infectious enthusiasm. There is naturally enough a dominant *note personnel,* but it is always pleasant, even when the information given does not seem very important. Among the rare visitors we may mention the lesser whitethroat, the barred warbler, the nuthatch, the golden oriole, the great grey shrike, the waxwing, the rose-coloured pastor, the roller, the hoopoe, the osprey, the bittern, Pallas's sand-grouse, the red-necked phalarope, the great crested grebe, and the fulmar. Among the most interesting residents are the chough, the raven, the hen-harrier, the sea-eagle, the rock dove, and the ptarmigan. This section is rich in historical material, *e.g.* in regard to the starling, the golden eagle, the sea-eagle, the osprey, the grey lag goose, and the fulmar. Apart from their historical interest, the notes on the birds are full of interesting observations, and some of the descriptions by the late Mr. MacPherson are fine pieces of picturesque writing. Mr. Harvie-Brown gives here and there an inkling of his strong views on bird protection; thus, "the Bird Acts require steady and relentless revision and change. The idea of saving trouble at Westminster and County Council and Sheriff Courts, by dividing Great Scotland into two divisions—north and south—for all species mentioned in these Acts, is absurd, and appears to me to be eminently calculated to defeat all useful purposes of the Acts."

The book is beautifully got up and illustrated, and though, unfortunately, somewhat of a luxury, is sure to be welcomed by those who are interested in the wild life of Scotland. Its mood is one that will foster interest in open-air natural history, and the thoroughness of its lists should help to lessen the ruthless killing of supposed rarities. J. A. T.

A NATURALIST IN SARAWAK.[1]

NEARLY forty years ago Dr. Beccari, the well known traveller-naturalist, made extensive journeys in Sarawak, but not until now has he published an account of his experiences; indeed, for this volume we have to thank the Ranee, H.H. Lady Brooke, who wisely urged Dr. Beccari to give the public the benefit of his knowledge, for, as she justly stated, the conditions have practically remained unchanged from times unknown.

Fig. 1.—Adult Male Mayas Tjaping. From "Wanderings in the Great Forests of Borneo."

Dr. Beccari collected in the land of the Land Dyaks, of the Sea Dyaks, and of the Kayans, not to mention less numerous peoples, and he gives a first-hand account of the people, their houses, dress, weapons, and ways. All this is very interesting reading, but there is little, if anything, that has not been recorded in Ling Roth's great compilation "The Natives of Sarawak and British North Borneo," or in the writings of more recent travellers. Indeed, it is the great fault of this book that the numerous contributions that have of late years been made to the natural history and

[1] "Wanderings in the Great Forests of Borneo: Travels and Researches of a Naturalist in Sarawak." By O. Beccari. Translated by Dr. E. H Giglioli, and revised and edited by F. H. H. Guillemard. Pp. xxiv+424 illustrated. (London: A. Constable and Co., 1904.) Price 16*s.* net

ethnology of Sarawak are one and all ignored. A few references are given to older publications or the *Sarawak Gazette*, and to some of the papers based on the collections sent home by Dr. Beccari. The reader must consequently bear in mind that there is a considerable amount of information about the animals and people of Sarawak which, to say the least of it, supplements Dr. Beccari's book. To the ethnologist the chief value of the book lies in the identification of animals, and especially of plants, employed by the natives, as the author not only gives their uses, but their native and scientific names.

The general naturalist will find the book packed with interesting information. Dr. Beccari is an enthusiastic and keen witted field naturalist. The intending traveller will pick up many valuable suggestions, and the stay-at-home naturalist will gain an extremely good idea of the conditions of life in the jungles of Borneo. The author not only describes what he saw, but he seeks to trace the interdependence of organisms upon one another and their relations to the environment. As Dr. Beccari is a professional botanist, the botany of a tropical forest is dealt with more fully and with greater knowledge than is usual in similar books, and those botanists who are interested in ecology will find much that will be of service to them.

The most important zoological observations are those on the orang-utan. The Dyaks recognise several varieties of orang, the two more important being the "Mayas kassa" and the "Mayas tjaping," with a laminar lateral expansion of naked skin in front of each ear. (In a foot-note we read that *tjaping*, in Malay, is the term applied to a small, nearly triangular piece of silver which is hung in front of baby girls as a fig-leaf.) Wallace and others have expressed the opinion that at least two species of orang-utan exist in Borneo. Dr. Beccari has come to the following conclusions:—There is no well authenticated case of a female with lateral face-expansions, though there is some evidence that such do occur; but there are young orangs with milk dentition which have them well developed, and adult male individuals are found with the expansions rudimentary. Not associated with the above character is the frequent absence of the terminal phalange of the hallux with the total or partial suppression of the nail. Evidently there is great variability in the orang, but Dr. Beccari holds that there is only one species of *Simia satyrus* with two main varieties, "tjaping" with lateral adipose cheek-expansions and highly developed cranial crests, and "kassa" with no lateral cheek-expansions and its skull devoid of strongly pronounced crests. Nevertheless, he suggests "that in a remote past the Mayas tjaping and the Mayas kassa were two quite distinct species, perhaps having their origin in separate regions, and only later coming into contact on the same area . . . at present it seems hardly likely that the two races should remain distinct." Dr. Beccari brought home a large number of skins, skeletons, and heads of these animals, and he confesses to have killed and wounded others which he could not take away. He adds practically nothing to our knowledge of their habits.

FIG. 2.—Rafflesia Tuan-Mudæ, Becc. (flower 22 inches in diameter). From "Wanderings in the Great Forests of Borneo."

Dr. Beccari does not hesitate to throw out a number of hypotheses, many of which will by no means be implicitly accepted by biologists; for example, he suggests (p. 32) that the prominent nose with narrow nostrils directed downwards of the Semitic people is associated with living in an open country, "whilst Negroes and Malays, for the most part dwellers in the forest, have snub noses with wide nostrils turned upwards, such as characterise most monkeys." Again, he says, "I have always thought that there must have been a formative epoch, in which every creature had the power of special adaptation to its own needs—nay even to its own wishes or caprice. In this epoch of 'plasmation' when the so-called force of heredity—which tends to reproduction according to the type of the progenitor—had but little power, the world being still young, the organism must have been far more susceptible of modification by external forces (p. 36). . . . The actual power of adaptation in organisms is at the present day well nigh non-existent as compared with what they must have possessed in the past (p. 211). . . . The varied forms assumed by those groups of individuals called by naturalists species, would be merely the result of a plasmative force exerted by surrounding conditions on primitive beings (p. 208). . . . May it not be that the Rafflesia, and a host of other aberrant species, both animals and plants, are examples of the autocreation of organisms (derived from exceptional circumstances of the environment) and suddenly appeared *à l'improviste,* as it were, in that primitive epoch during which organic matter was easily plasmated, so as to adapt itself with facility even to extraordinary conditions of existence? (p. 389). . . . Therefore, contrary to the present prevailing tendency to attribute a powerful action to variability during the existing period, and to consider every species as inconstant, I hold the opposite opinion, namely, that at the present time species do not vary in Nature, returning thus to the old idea of the nearly absolute fixity of existing species (p. 210)." It is interesting to compare these views with those arrived at by Alfred Wallace, who wandered in the same jungles; and, as Dr. Guillemard, the English editor, rightly observes, "Whether the scientific reader does or does not admit the validity of all Dr. Beccari's theories concerning species-formation, he cannot call in question his abundant experience of the country, or his knowledge of the subjects of which he treats." A. C. H.

OILS FOR MOTOR-CARS.

POSSIBLY this article may be of interest to readers of NATURE who are not chemists, and therefore no apology need be made for treating certain parts of the subject in an elementary manner. The commercial names for motor-oils are numerous and confusing, and the automobilist may well be puzzled to discriminate between them, even if his chemistry has by no means become a mere schoolboy reminiscence.

The various liquids in use at the present time as fuels for motors are derived from three sources, namely, crude petroleum, coal tar, and alcohols. By far the largest quantity is furnished by the petroleum. Coal-tar "spirit" is scarcely beyond the experimental stage. Alcohol is somewhat largely used abroad, but at present is almost out of the question in this country.

Products from Crude Petroleum.—These, so far as motor fuel is concerned, are two: a *light oil* and a heavier or *"burning" oil.* The light oil, in one grade or another, is variously known as gasoline, petroleum spirit, petrol, petrol spirit, motor spirit, mineral spirit, motol, moto-essence, naphtha, petroleum-benzine, and benzoline. Of these, gasoline has the lowest density, benzoline the highest. The oil is obtained in the distillation of American crude petroleum, and may be said generally to be the portion of the distillate passing through the still between the temperature-limits of 60° C. and 150° C., and having a specific gravity ranging from 0.68 to 0.74. The limits, however, vary somewhat with the different refineries. To obtain a good motor "spirit" this fraction of the distillate is purified with sulphuric acid and with soda, and rectified by re-distillation. Such a spirit is clear, has no strong odour, and leaves no residue when evaporated from the hand. Two or three years ago the best English petrol had a specific gravity of 0.680; but, for reasons to be mentioned later, the density has been gradually raised, and is now generally about 0.720 or more.

Chemically, light oil or petrol is a mixture of several members of the homologous series of paraffin hydrocarbons, C_nH_{2n+2}. It is generally assumed to be mainly heptane, C_7H_{16}, and octane, C_8H_{18}, but both lower and higher members are usually present, and some analyses indicate that the range may commonly be from hexane, C_6H_{14}, to undecane, $C_{11}H_{24}$. A point to notice is that whilst petrol as a whole is a light, volatile oil, it is by no means a homogeneous liquid. The different hydrocarbons composing it have not the same volatility as one another, and they require different quantities of air for their complete combustion.

The heavier oil obtained from crude petroleum corresponds to what is ordinarily known as kerosene, petroleum oil, or paraffin. It is obtained by refining the fraction which distils between 150° and 200°, and has a density of about 0.78 to 0.81. This product contains higher members of the paraffin series than those of petrol. It is consequently less volatile, and has a higher flash-point.

Kerosene is not only cheaper than petrol, but safer in the handling. Why, then, is petrol used so largely as a motor fuel instead of kerosene? And why are some kinds of petrol better than others? To answer these questions we have to remember that, to form the proper explosive mixture for the engine, it is necessary to have the vapour of the liquid mixed with a particular proportion of air. With too little air the mixture burns too gently; with too much there is a diluent effect, and liability to failure of ignition. The ready volatility of petrol allows of the requisite mixture being made more easily, more certainly, and with a simpler form of carburetter than when kerosene is used. Failure to ignite is less frequent, and the combustion is cleaner.

Nevertheless, since the supply of petrol is not limitless, attempts are being made, with some success, to utilise kerosene as a source of motor energy. The principle employed is that of heating up the vapour of the kerosene, or the liquid itself, in order to allow of a readier admixture with the air in the carburetter. This is effected either by the heat of the exhaust or by some other special contrivance. A "smokeless petroleum engine" has recently been described which is said to run without smoke or smell, and without "sooting" the cylinder. It will not, however, start with the cold kerosene. Petrol is used for the first revolutions in order to heat the vaporiser and raise the kerosene to the necessary temperature.

As regards differences of quality met with in motor spirits (petrol), the first thing to notice is that the higher the density of the liquid the nearer does it approach to the character of kerosene and to the possession of the disadvantages peculiar to the latter. To meet the growing demand, makers have been more and more inclined to eke out their supply of petrol by including a portion of the heavier fractions that were formerly rejected. Hence many of the present oils are to that extent of inferior quality. Next, the density alone is not an infallible criterion, because a spirit having a density of, let us say, 0.700, may be made up in different ways. Ideally, it might consist of a single hydrocarbon having the density in question. On the other hand, it might be compounded of two hydrocarbons having widely different densities, such as 0.660 and 0.740 respectively. In the first case it would distil completely at one uniform temperature, in the second there would be a difference of perhaps a hundred degrees between the initial and the final boiling points. With homologous hydrocarbons the lower-boiling member vaporises more readily than the higher; consequently, in practice, the vapour from the second spirit would in the early stages of a run contain an excessive proportion of the more volatile constituent, and in the later stages too much of that which is less volatile. For satisfactory combustion these two constituents require very different proportions of air; hence if the carburetter was initially arranged to give the proper quantity it would not do so in the later stages. The practical bearing is that, to avoid waste of fuel or loss of heat, more attention must be paid to the carburetter when the petrol has a wide range of boiling points than when it is more nearly homogeneous.

As already mentioned, the petrols in actual use consist of several hydrocarbons; there is none containing only one, or even only two. But the foregoing examples typify the better and the inferior qualities respectively.

Products from Coal-tar.—These are known commercially as benzol or benzole, benzine, and coal-tar spirit, all of which terms mean nearly the same thing, and toluol, which is a very similar liquid of lower density. (Benzol or benzine should be distinguished from benzoline, the petroleum product previously referred to.) In the first group the aromatic hydrocarbon benzene, C_6H_6, is the chief constituent, but toluene, C_7H_8, and xylenes, C_8H_{10}, also accompany it. Benzol is commercial benzene, *i.e.* benzene with some impurities and homologues; benzine is a cruder variety; these differ only in the proportions of the admixtures, and are often indistinguishable the one from the other. Coal-tar spirit is a general term for either. In America and in France, as well as sometimes in this country, the term "benzine" refers to the petroleum naphtha, not to the coal-tar product.

Benzol has a greater density than petrol (about 0.883 at 15°.5 C.), and a higher boiling point, viz. about 90° C. Nevertheless, it has the advantage of distilling, as a whole, within much narrower limits than most varieties of petrol do. Thus, while there may be a difference of more than 100° C. between the initial and final boiling points of petrol, a good sample of "90's benzol" will distil completely within a range of about 55° C. or less, *i.e.* between 90° and 145°. Benzol is consequently more like the ideal homogeneous fuel than petrol is, and this, together with the necessity of supplementing the supply of petrol by some other fuel, has led to its frequent employment abroad and to experimental trials in this country. Deutz benzol locomotives have been used for some time in Germany, and the tram-cars of the Saalgau-Herbertingen-Riedlingen line are worked by a 14 h.p. benzol motor, whilst a mixture of benzol and alcohol is used in some of the French racing cars. So far as the German experience has gone, the results are said to indicate that the benzol motor is about 10 per cent. cheaper in working than the alcohol engine. The British trials seem to show that benzol works more uniformly than petrol, and is generally satisfactory, except that with too great a compression in the cylinders there is a liability to pre-ignition.

One disadvantage of benzol is the presence in it of sulphur compounds, chiefly carbon disulphide and thiophene. These not only give an evil-smelling exhaust, but may conceivably corrode the metal of the cylinder through the formation of acid vapours in the combustion. Probably at a cost of about a penny per gallon the benzol could be sufficiently freed from sulphur, and it is thought that, with a good demand, the purified liquid might be supplied at a price of about 7*d*. a gallon, or less. Unfortunately, however, the supply of benzol is even more limited than that of petrol; the yield from coal-tar is only some 0.6 per cent., and much of what could be produced is already absorbed by the chemical and dye industries. It seems, therefore, very unlikely that benzol will ever largely supplant petrol, though it may usefully supplement this fuel.

Toluol (crude toluene), of lower density but higher boiling point than benzol, has also been recently tried, though not on a sufficiently extended scale to give much practical information. Benzol is essentially a mixture of pure benzene and toluol, and in one respect the mixture is better than pure benzene, because the latter freezes at 0° C., and this is prevented by the presence of toluol.

Alcohols as Fuels.—The industrial side of the question has encouraged the use of alcohol in France and Germany, since, other things being equal, it is better to support home agriculture than foreign oil-fields. Strong alcohol can be bought in Germany at a cost of 8½*d*. to 10*d*. per gallon, and at this price its use is said to be economical compared with petrol. Pure alcohol, of course, is heavily taxed—in this country the duty amounts to 17*s*. per gallon of 90 per cent. alcohol—and that used for motor purposes is "denatured" by the addition of foreign substances. In England the denatured product is methylated spirit, obtained by mixing "spirits of wine" with not less than one-ninth of its bulk of wood-naphtha, and when intended for retailing, with 0.38 per cent. of mineral naphtha or petroleum oil in addition. In France the denaturant is a mixture of heavy "benzine" and malachite green. Ordinary methylated spirit, in some experiments made a short time ago, was said to give an exhaust with an odour so vile as would preclude its general use; this is attributed to the denaturant, and to obviate it one suggestion is that alcohol intended for motor-fuel should be denatured with petrol. There are, however, some fiscal difficulties in the way.

Alcohol is a substance already partly oxidised; it contains rather less hydrogen than does petrol, and only about one-half as much carbon, the difference being made up of oxygen. Consequently its available heat-energy, viz. the heat developed by the complete oxidation of its carbon and hydrogen, is not much more than one-half that of good petrol. Nevertheless, it has some compensations. It is of nearly uniform composition, and distils within much narrower limits than petrol; in fact, strong alcohol, not denatured, is an almost homogeneous body, which boils away completely at a practically constant temperature. Moreover, it is claimed that the alcohol engine has a much greater efficiency than the petrol motor. To get the best results, however, it has been found necessary to use a higher compression than that given by the ordinary petrol engine. In some cases both petrol and alcohol are employed, with two carburetters; the petrol is used for starting, and is automatically cut off by a governor when the motor is sufficiently hot. The net result of the alcohol trials at present seems to be that, for equal volumes, petrol is appreciably more efficient than denatured alcohol; but the difference is not considerable, and fluctuations in price may yet make alcohol a serious competitor with petrol where the fiscal difficulties can be overcome.

The cheaper higher alcohols of fusel oil (chiefly amyl and butyl alcohols) have also been proposed for use as motor-fuels. But practical trials are lacking, and in any case the supply of fusel oil is only a limited one. For the principal motor-fuel of the future it is probably to kerosene that we must look.

C. Simmonds.

ADMIRAL SIR ERASMUS OMMANNEY, K.C.B., F.R.S.

A WELL-KNOWN figure has been lost to scientific circles by the death of Admiral Sir Erasmus Ommanney, K.C.B., F.R.S., which occurred on December 21, at ninety years of age.

Erasmus Ommanney was born in London so long ago as the year 1814, and entered the Navy in 1826. He became Lieutenant Ommanney in 1835, and at once volunteered to serve under Sir James Ross in the voyage for the relief of a number of missing whalers reported to be caught by the ice of Baffin's Bay, and on the coasts of Greenland and Labrador. The objects of the expedition were successfully carried out, notwithstanding the extreme danger of the navigation during the winter months.

In 1850 he was appointed second in command under Captain Horatio Austin on the Arctic expedition in search of Sir John Franklin; and in August of that year was the actual discoverer of the first winter quarters of Franklin's ships. He also directed an extensive system of sledge journeys, by which the coast of Prince of Wales Land was laid down. After his return from the Arctic he was elected a Fellow of the Royal Society for his services to science.

After his retirement in 1877, he threw himself with zeal into the work of numerous learned societies, of which he was an energetic member. He was a Fellow of the Royal Geographical Society, and had been a member of the council. He was also a Fellow of the Royal Astronomical Society. An active member of the British Association, he had served upon its council, and went with it to Canada in 1884 as treasurer, receiving on that occasion the honorary degree of LL.D. from the McGill University, Montreal.

The funeral took place at Mortlake Cemetery on Tuesday afternoon. Among the wreaths placed upon the coffin was one from the president and members of the Royal Geographical Society.

NOTES.

It is proposed to establish in the University of Liverpool a memorial to Mr. R. W. H. T. Hudson, late lecturer in mathematics, whose brilliant career was so tragically cut short at the end of last September. The memorial will probably take the form of an annual prize in mathematics, to be awarded for distinction in geometry, the subject in which Mr. Hudson's work chiefly lay. For this purpose a sum of 100*l.* would be required. Contributions to the fund should be sent to Mr. Alexander Mair, the University, Liverpool.

Dr. J. MacIntosh Bell, a nephew of Dr. Robert Bell, F.R.S., has just been appointed Government geologist of New Zealand. Dr. MacIntosh Bell has seen much active service on the Canadian Geological Survey, having worked during four seasons under his uncle, the director. In the spring of 1899 he went with Dr. Robert Bell to Great Slave Lake, where he spent the following winter, and in 1900 he was sent to Great Bear Lake, several hundred miles further north. On his return he was employed in 1901 and 1902 as geologist by the Lake Superior Commercial Co., and in 1903 by the Ontario Bureau of Mines.

Replying to a vote of thanks, after laying the foundation-stone of the Chelmsford Free Library, School of Art, and Museum on December 21, Lord Rayleigh said that the visit to Stockholm from which he had just returned was of great interest. His colleagues and he received almost a royal welcome, and at the banquet which formed part of the proceedings it was very much impressed upon them that what Nobel had in view in providing his prizes was to bring scientific men of the various countries together not merely for the advancement of science, but to promote good feeling and the cause of peace between the nations of the world. Lady Rayleigh afterwards distributed the prizes to the students of the local science and art classes.

Lord Kelvin has accepted the nomination of the council for the presidency of the Faraday Society, in succession to Sir Joseph Swan, F.R.S.

The death is announced of the Rev. J. M. Bacon at the age of fifty-eight. Mr. Bacon had made a number of balloon ascents for scientific purposes, and some of the results of his studies are described in his works "The Dominion of the Air" and "By Land and Sky."

According to the *Patria*, negotiations have been entered upon by the Italian Minister of Posts and Telegraphs and the British Postmaster-General with a view to establish wireless telegraphic communication between the stations of Poldhu and Bari.

We are informed that the constitutional amendment exempting the California Academy of Sciences from further taxation was carried at the election, November 8, by a majority of nearly 11,000.

The bog-slide reported in several newspapers as having occurred on December 7 between Frenchpark and Castlerea, in the north part of the county of Roscommon, appears now to have come to rest, after invading a village and covering a large area of agricultural land. Local information reaches us to the effect that clefts still remain visible in the bog, but that the hollow formed at the origin of the slide is gradually closing in. The flow is attributed to heavy rain, with which existing means of drainage were unable to cope. Lord de Freyne is erecting huts for the dislodged tenantry, and about twenty men were still engaged at Christmas in clearing the main road from its peaty covering.

On December 22 the airship *Lebaudy II.* made its thirtieth experiment in aërial direction at Moisson, near Mantes. In these voyages the *Lebaudy II.*, the volume of which has been brought up to 2063 metres, returned each time to the shed which shelters it, after having gone away to distances so great as ten miles. The length of the balloon is 64 metres, and its regular crew consists of three people. Several times, however, it has taken passengers, as many as six persons having ascended at one time. The speed attained by its own propulsion, measured with a registering anemometer, may be estimated at 40 kilometres per hour. The airship has been taken out in wind blowing at 5 or 6 kilometres, and in rain. It has risen to the altitude of 500 metres. The ascent of December 22 was the last of the autumn campaign, eighteen ascents having been made during the months of November and December. During this season experiments were made to decide whether an astronomer aboard an airship can know the precise geographical position of the balloon when he makes his observation. An ascent was made between 1 and 2 a.m. on a foggy morning. In the car had been taken an acetylene searchlight equalling 100,000 lamps of ten candles each, like those at the Exposition of the Grand Palais. The balloon was invisible to persons on the earth, and the earth itself could not be seen by the aëronauts. But the light could easily be distinguished, and its movements followed. Next year new voyages to considerable distances will be undertaken, like that from Moisson to Paris, or to the Crystal Palace from London. In its last trial the *Lebaudy II.* remained inflated for sixty-four days.

WITH Mr. C. G. Barrett, whose death was announced last week, has disappeared one of the last of the old school of British lepidopterists, contemporary with Doubleday and Newman. The first mention we can find of Mr. Barrett's name is in the list of entomologists in the "Entomologist's Annual" for 1857, but from that time onwards he became a frequent contributor to the *Entomologist's Weekly Intelligencer*, and afterwards to its successor, the *Entomologist's Monthly Magazine*, the first number of which appeared in June, 1864, so that the fortieth year of this periodical has been marked by the demise of two out of the seven editors whose names appear on the early numbers of 1904, Robert McLachlan, the last of the original staff who still continued to act, and C. G. Barrett, who joined the staff of that magazine in 1880, and became a member of the Entomological Society of London in 1884. Mr. Barrett was an enthusiastic and very successful collector of British Lepidoptera, and as he held a position in the Excise which involved his being moved from one station to another, he had great facilities for investigating the insects of widely separated localities. Perhaps the most important of his captures was the extremely interesting moth which he obtained on the Hill of Howth, near Dublin, and was named *Dianthoeia Barrettii* after him. Mr. Barrett's contributions to entomology, with one notable exception, were published almost exclusively in magazines, but in 1892 he commenced his great work, "The Lepidoptera of the British Isles," in serial parts, and he had completed the Macro-Lepidoptera at the time of his death. Mr. Barrett's last paper, a description of the larva of *Doryphora palustrella*, Douglas (one of the Tineina), appeared in the *Entomologist's Monthly Magazine* for the present month, so that he may be said to have died in harness.

THE *Standard's* correspondent states (December 26) that the Vienna Veterinary Institute has just opened a laboratory for the study of the diseases of fish, which will be in charge of Prof. Fiebinger.

THE Paris correspondent of the *British Medical Journal* details some of the conclusions of the committee appointed to investigate Dr. Doyen's claims respecting the cause and treatment of cancer (December 24, p. 1720). M. Metschnikoff, one of the committee, states (1) that in culture tubes inoculated by Dr. Doyen with cancerous material in his presence the *Micrococcus neoformans* developed; (2) that the characters of the microbe so obtained agreed with those described by Dr. Doyen as characteristic of the *M. neoformans*; (3) it is not yet possible to report on the specificity or pathogenic characters of the microbe; (4) it is not possible yet to state whether Dr. Doyen's serum has a curative action or no. It will be seen that this report is a very guarded one, and very different from the details published in the daily Press.

WE learn from the *Times* (December 21) that a considerable number of beautifully worked flints have recently been discovered at Culmore, which is said to be in the south of Scotland, but we have been unable to find the locality on maps. The spot where the flints were found has the appearance of having been surrounded by marshy ground, and it is possible that the flint-tools may have belonged to lake-dwellers. Arrow-heads, scrapers, anvil and hammer stones, are abundant among the worked flints. The collection has been acquired by Mr. Ludovic Mann, and will be exhibited for a few weeks in the People's Palace, Glasgow.

THE annual conversazione of the Royal College of Science and Royal School of Mines was held at the college as we went to press last week, and was attended by about five hundred guests. The company included Sir Norman Lockyer, Sir Arthur Rücker, Mr. Morant, Prof. Judd (the dean), Prof. Tilden, Prof. Perry, Prof. Callendar, Prof. Gowland, and Mr. G. W. C. Kaye (secretary). There were many interesting exhibits in the various departments in chemistry, physics, astrophysics, mechanics, metallurgy, mining, geology, and biology, under the direction of their respective professors. The Solar Physics Observatory was open by permission of Sir Norman Lockyer, and a kinematograph exhibition was given, while the college company of the Corps of Electrical Engineers showed a searchlight. Dr. W. Watson, F.R.S., delivered a lecture during the evening on radium and twentieth century alchemy.

Spolia Zeylanica for October contains the description by Mr. Boulenger of a new snake of the genus Aspidura, and an illustrated account by Mr. J. L. Hancock of the Cingalese representatives of the grasshoppers of the family Tettigidæ.

THE October number of the *American Naturalist* is entirely devoted to botanical subjects, even the usual pages of notes being omitted. In the first article Prof. Penhallow completes his account of the anatomy of conifers, in the second Dr. B. M. Davis contributes the fourth instalment of his studies of the plant-cell, while in the third Prof. D. H. Campbell discusses the affinities of the ferns of the groups Ophioglossaceæ and Marsilaceæ.

AT the meeting of the Zoological Society held on December 13 Mr. Rothschild exhibited a wonderful series of mounted skins and skulls of gorillas and chimpanzees, most of which had been set up by Rowland Ward, Ltd. A long paper was also read on this unique collection, in the course of which the author stated that he recognised four different forms of gorilla, two of which constituted species. Unfortunately, in our opinion, he advocated the transference of the name *Simia satyrus*, so long applied to the orang-utan, to the chimpanzee. Surely a title to a name ought to become valid after such a long period of unchallenged use.

TWO articles from the twentieth volume of the *Journal* of the Imperial University of Tokyo were received by last mail. In the first Mr. T. Fujita discusses the mode of formation of the germinal layers in gastropod molluscs. More general interest attaches, however, to the second, in which Mr. H. Yabe describes a number of cephalopod remains from the Cretaceous rocks of Japan, this being his second contribution to the subject. Most of the species belong to European genera, and the large size of some of the specimens of turrilites is very noticeable. We have also received article 8 from vol. xviii. of the same serial, in which Mr. B. Hayata gives a list of the plants of the order Compositæ found in Formosa.

IN the December number of *Bird Notes and News* the Royal Society for the Protection of Birds records its efforts in regard to the late osprey case in Surrey. It may, however, be asked whether it would not be well to admit that the preservation of such stragglers is a practical impossibility, and that ospreys and motors are incompatible. Similarly, in view of recent letters in the *Field*, the question as to whether birds are or are not harmful requires discussion on a business footing, altogether apart from sentiment. If they are proved harmful, we can decide whether we will put up with the damage for the sake of the attraction they add to the landscape; but let us abandon attempts to gloss over charges of damage and to defend birds at all costs. The society urges the advisability of establishing a "bird and tree day" throughout the country; possibly an excellent way of developing interest in nature—but this time will show.

WE have received four zoological papers from American serials. The first (from the *Proceedings* of the Boston Natural History Society) contains a list of molluscs from Frenchman's Bay, Maine, by Mr. D. Blaney, while in the second (from the same journal) Mr. W. R. Coe discusses the terrestrial nemertean worms of the genus Geonemertes from Bermuda. These worms, it may be remembered, were first discovered, dwelling in company with ordinary earthworms, during the *Challenger* cruise, but the specimens were lost, and no others were ever collected until 1898 and 1901. In the third paper (from the *Proceedings* of the U.S. National Museum) Mr. P. Schmidt re-determines a Japanese fish, while in the fourth (from the *Proceedings* of the American Academy) Messrs. Parker and Starratt record some interesting experiments with regard to the effect of heat on the colour-changes of the American chamæleon-iguana (*Anolis carolinensis*).

MESSRS. Jordan, Russell, and Zeit publish details of experiments on the longevity of the typhoid bacillus in water (*Journ. of Infectious Diseases*, i., No. 4, p. 641), from which it appears that under conditions probably closely simulating those in nature the vast majority of typhoid bacilli introduced into a water perish within three or four days. This is rather opposed to the views now generally prevailing, and needs confirmation before it can be absolutely accepted.

AT a meeting of the Institute of Mining and Metallurgy held on December 15 Messrs. Thomas and Macqueen read a paper on methods of dealing with dust in the air and gases from explosives in a Cornish mine (Dalcoath). Miners' phthisis is especially due to inhalation of stone dust, and it is found that the use of a water-jet with machine drills entirely prevents dust if used from the commencement of operations and properly directed, a coarse spray being more efficient than a fine one, but is difficult to apply when the drill-holes become deeper than about two feet. James's water blast was found particularly effective for laying the dust caused by shovelling and blasting.

AN interim report has been issued by a committee appointed by the British Association to inquire into ankylostomiasis in Britain. The Ankylostoma is an intestinal parasite producing serious and sometimes fatal effects. The report states that there are many channels by which the Ankylostoma might be introduced into British coal mines (it has been introduced into the Westphalian coal fields and into the Dalcoath tin mine in Cornwall, as already recorded in these columns). The conditions existing in our mines are such that it would probably flourish and become firmly established. Once introduced it is doubtful if it could ever be eradicated, and therefore it is recommended that proper sanitary regulations should without delay be formulated and enforced to prevent infection of the pits.

A REPORT by Drs. Haldane and Wade has been issued by the Local Government Board on the destruction of rats and disinfection on shipboard, with special reference to plague. For destroying rats the burning of sulphur, the use of liquid sulphurous acid, carbonic oxide, carbonic acid, and the Clayton process are discussed. Carbonic oxide, while very fatal to rats, has no effect on insect vermin and no disinfecting action, and having no odour may be dangerous to man, and may form an explosive mixture with air. Carbonic acid, while fatal to rats, is similarly without lethal effect on vermin, has no disinfecting action, and a large quantity is required, which makes it expensive, but it is less dangerous to man than carbonic oxide. Burning sulphur is tedious and only applicable in empty cabins and holds, but is cheap and fairly effective. Much the same may be said of liquid sulphurous acid, but it is quicker though more costly. The Clayton process consists in burning sulphur in a furnace, the fumes from which are pumped into the holds, &c., and is probably the best of the methods discussed. Properly carried out it is fatal to rats and all vermin, has considerable disinfecting and penetrative power, is not likely to cause accident as its odour is so marked, but it damages certain articles, especially if damp, and does not diffuse well in a closely packed hold.

THE area planted with cotton this season in the West Indies is estimated in the *Agricultural News*, November 19, at from eight to ten thousand acres, excluding Carriacou, where four thousand acres were planted mostly with Marie Galante cotton. Of this amount Barbados and St. Vincent each have sixteen hundred acres under cotton, and in St. Kitts the acreage exceeds two thousand acres. The crops generally are much healthier than in the previous year, and an output of about 5000 bales may be expected.

THE *Quarterly Record* of the Royal Botanic Society of London for the second quarter of this year contains an account of the horticultural exhibition held in June, and most of the papers read at the conferences have been published. The educational section attracted a number of speakers and visitors when nature-study and horticulture formed the subjects of addresses by Sir George Kekewich, Mr. F. Verney, and others. At the forestry conference Prof. W. R. Fisher delivered the address, in the course of which he discussed the selection of seeds of forest trees, and advocated the formation of experimental stations in order to study the suitability of different trees for particular districts and soils.

THE morphological nature of the ovary in the genus Cannabis has engaged the attention of many botanists, including Payer, C. B. Clarke, and Briosi and Tognini; finally, Dr. Prain, having been deputed by the Government of India to report upon the cultivation of *gánjá*, has upon the evidence of certain abnormal forms contributed a new explanation in No. 12 of the Indian *Scientific Memoirs*. Previously the views had been expressed that the pistil consists either of a single carpel, or of two carpels of which the anterior alone is developed, and bears an ovule; the bicarpellary nature of the ovary is, in Dr. Prain's opinion, fully borne out by specimens showing phyllody of the gynœcium, but it is the posterior carpel which is fertile. With respect to the character of the diclinism of the flower, this is shown to be primitive and not vestigial.

WE have received from the Rev. J. de Moidrey, S.J., of the Zi-ka-wei Observatory, an interesting and useful memoir on the climate of Shanghai, based upon observations made between 1873 and 1902. The coldest weather occurs about the beginning of February, and the warmest about August 1, nearly forty days after the solstices. The mean temperature for thirty years at Zi-ka-wei was 59°·2 F., and the mean range 43°·2. The extreme readings were:—maximum 102°·9, minimum 10°·2. A variation of the climate is not apparent. The average monthly relative humidity is 78 per cent.; the annual variation is insignificant, averaging only 4 per cent. The average yearly rainfall is 43·6 inches; June is preeminently the rainy month, both for frequency and amount, while December is the driest month. The paper contains useful remarks upon the cyclones experienced over the China seas.

WE have received a copy of "Meteorology in Mysore" for 1903, being the results of observations at Bangalore, Mysore, Hassan, and Chitaldrug; these observing stations lie at the corners of a quadrilateral comprised between 12° 18′ and 14° 14′ N. latitude and 76° 10′ and 77° 36′ E. longitude, Bangalore being 190 miles west of and 3000 feet higher than Madras. The results, including the means for eleven years, 1893–1903, have been very carefully worked out by the director, Mr. John Cook, and contain some interesting features. The highest reading for eleven years of air temperature in shade was 103° at Chitaldrug in April 1901 and 1903, and the lowest 42°·7 at Hassan in December, 1895. The mean relative humidity varied from 57 per cent. to 62 per cent., but extreme dryness was occasionally experienced, the humidity varying between 4 per cent. and 6 per cent. Rainfall is fairly uniform throughout the province, varying from $26\frac{1}{4}$ to $37\frac{3}{4}$ inches per annum. The value of the report would be enhanced by a key-map of Mysore and surrounding districts.

IN the *Sitzungsberichte* of the Vienna Academy, cxiii., 3 and 4, Dr. Fritz Hasenöhrl discusses the laws of reflection and refraction of light as applied to a body which is moving relative to the ether, in connection with the thermodynamical aspects of the principle of reciprocity, and also the variations in the dimensions of matter due to motion through the ether.

IN No. 86 of the *Communications* from the Leyden Physical Laboratory Dr. H. Kamerlingh Onnes and Dr. H. Happel discuss the application of Gibbs's volume-energy-entropy model to the representation of the continuity of the liquid and gaseous states on the one hand, and the various solid aggregations on the other. For this purpose models have been constructed for an ideal substance, showing the continuity of the solid and liquid as well as of the liquid and gaseous states.

A SERIES of experiments on the influence of abnormal position upon the motor impulse is described in the *Psychological Review* for November 1 by Mr. Charles Theodore Barnett. Without going into the theoretical aspect of these investigations, we notice that the author refers to the well known puzzle of drawing a rectangle and its diagonals in front of a looking-glass, and the difficulty of playing the piano with crossed hands, as Beethoven so often requires in his sonatas, is another illustration which suggests itself.

PART i. of vol. xlviii. of the *Transactions* of the Institution of Engineers and Shipbuilders of Scotland contains a paper by Mr. F. J. Rowan on the smoke problem, which is of especial interest on account of the recent inquiry by Sir John Ure Primrose at the sanitary congress in Glasgow into the connection of smoke with the production of rain and fogs in large cities. It is pointed out that although domestic fires are principally responsible for atmospheric pollution in a large town, only the smoke issuing from factory chimneys is subject to municipal control, and that many kinds of industrial furnaces, other than those used for raising steam, are employed in operations of such a nature that they cannot but necessarily produce large volumes of smoke. In dealing with the question of the prevention of smoke from furnaces used in connection with steam boilers, the employment of smoke-consumers, smoke-washers, and similar appliances is condemned, and a system of gas firing is advocated. Mr. Fyfe, the sanitary inspector of Glasgow, in the course of the discussion of the paper, stated that although the Public Health Act empowered prosecution in the case of "any chimney (not being the chimney of a private dwelling house) sending forth smoke in such quantity as to be a nuisance," it was customary in Scotland, under the Burgh Police Act, not to proceed against other kinds of furnaces than those used for heating boilers. His own experience had convinced him that gas firing was not absolutely necessary in such cases, but that by means of a suitable and inexpensive smoke-consumer, consisting of ignited jets of producer gas, all the smoke could be got rid of, and an additional supply of heat given to the boiler.

SAMPLES of an improved form of crucible lid have been sent to us by Messrs. J. J. Griffin and Sons. It is made slightly convex towards the crucible, and has been designed to obviate the loss of substance which so readily occurs in simple gravimetric experiments, such as the conversion of copper into copper oxide by means of nitric acid, when the ordinary form of crucible lid is employed.

ACCORDING to a paper by M. Bertrand in the *Comptes rendus* (No. 20, p. 802) mountain ash berries not only contain the alcohol sorbitol, but an isomeric alcohol, sorbierite, is also present. To obtain it the sorbitol is completely converted into sorbose by the action of the sorbose bacterium, and the sorbose is removed by crystallisation. Sorbierite has been obtained from the mother liquor in the form of deliquescent crystals. That the new alcohol is hexahydric has been established by the cryoscopic determination of its molecular weight, and by the preparation and analysis of the di- and tri-benzoic acetals.

A VERY interesting paper dealing with the primary formation of optically active substances in nature is contributed by Dr. A. Byk to the *Zeitschrift für physikalische Chemie* (vol. xlix. p. 641). It is shown in an indirect experimental manner that it is possible to effect the resolution of racemic substances by a purely physical agent—circularly polarised light. The reflection of the plane polarised rays of sunlight from the surface of water under the influence of the earth's magnetism is supposed to give rise to a predominating quantity of one form of circularly polarised light, and this is the cause which determines the production of optically active substances in the photochemical processes taking place in animal and plant life.

WE have received Williams and Norgate's "International Book Circular." An article on some contemporary foreign chemists, illustrated by twenty portraits, is contributed by Dr. M. O. Forster.

PROF. M. W. TRAVERS's work on the experimental study of gases has been translated into German by Dr. T. Estreicher, and the translation has been published by Messrs. F. Vieweg and Son, Brunswick.

AN authorised translation, into German, of Prof. J. J. Thomson's lectures on "Electricity and Matter," reviewed in NATURE of May 26 (vol. lxx. p. 73), has been made by Herr G. Siebert, and published by the house of F. Vieweg and Son, Brunswick. The work forms the third volume of a series of monographs issued under the general title "Die Wissenschaft."

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN JANUARY, 1905.

Jan. 2–3.	Epoch of January meteors (Radiant $230° + 53°$).
6.	4h. 52m. to 7h. 5m. Transit of Jupiter's Sat. III. (Ganymede).
8.	2h. Saturn in conjunction with Moon (Saturn 3° 3′ S.).
9.	3h. Venus in conjunction with Moon (Venus 2° 13′ S.).
,,	11h. Juno in conjunction with Moon (Juno 0° 11′ S.).
10.	5h. 9m. to 6h. 23m. Moon occults ϕ Aquarii (Mag. 4·4).
11.	Perihelion Passage of Encke's Comet.
13.	8h. 52m. to 11h. 6m. Transit of Jupiter's Sat. III. (Ganymede).
,,	10h. 36m. Minimum of Algol (β Persei).
15.	Venus. Illuminated portion of disc = 0·650, of Mars = 0·903.
16.	7h. 25m. Minimum of Algol (β Persei).
24.	12h. 43m. to 13h. 40m. Moon occults β Virginis (Mag. 3·8).
27.	10h. Mars in conjunction with Moon (Mars 2° 45′ S.).
28.	15h. 7m. to 16h. 11m. Moon occults γ Libræ (Mag. 4·1).

ELEMENTS AND EPHEMERIS OF COMET 1904 *d*.—*Circular* No. 69 from the Kiel Centralstelle contains a set of elements, calculated by Herr M. Ebell from the observations made on December 17, 18, 19, and a short ephemeris, for comet 1904 *d*, recently discovered by M. Giacobini at Nice. They are as follows:—

Elements.

T = 1905 Jan. 3·2814 Berlin.

$$\left.\begin{aligned} \omega &= 75° \;\; 9'·8 \\ \Omega &= 225° \;\; 1'·2 \\ i &= 103° \;\; 27'·3 \end{aligned}\right\} 1904·0$$

$\log q = 0·27173$

Ephemeris 12h. (M.T. Berlin).

1904–5		α h. m. s.		δ ° ′		log Δ		Brightness
Dec. 26	...	16 37 56	...	+31 45	...	0·3328	...	1·12
,, 30	...	16 49 48	...	+33 53	...	0·3234	...	1·17
Jan. 3	...	17 2 37	...	+36 8	...	0·3146	...	1·22

Brightness at time of discovery = 1·0.

From the above it will be seen that both the northern declination and the brightness of the comet are increasing, but at the same time its right ascension is approximating more closely to that of the sun, thereby rendering observations increasingly difficult, and only possible during the few minutes preceding dawn.

OBSERVATIONS OF BRIGHT METEORS.—During a sea voyage undertaken in 1903–4, Dr. J. Möller, of Elsfleth, observed a large number of meteors, and in No. 3984 of the *Astronomische Nachrichten* he records the essential data regarding the observations of the sixteen brightest objects seen during November–December, 1903, and March, 1904. Of these, two were as bright as Jupiter, and five were brighter than Saturn. The latitude and longitude of the place of observation are given in each case, so that in the event of duplicate observations having been made the real paths may be computed.

The same observer recorded in No. 3971 of the same journal an authenticated naked-eye observation of Jupiter's third satellite on November 1, 1903.

THE GREAT RED SPOT ON JUPITER.—In a note to No. 3983 of the *Astronomische Nachrichten* Mr. Denning gives the results of his own and the Rev. T. E. Phillips's observations of the Great Red Spot since the last conjunction of Jupiter. They show that for the seven months prior to last September the motion of the spot indicated a rotation period, for the zone wherein it is located, of 9h. 55m. 38·6s., a shorter period than any observed since 1883, when it was 9h. 55m. 38·2s.

In the same publication Mr. Stanley Williams gives the results of his observations of this phenomenon, and shows that from his eye-estimates of the times of transit, during the period August, 1903, to January, 1904, the average time of rotation was 9h. 55m. 41·52s.

He points out that this is a remarkable increase on the rotation period (viz. 9h. 55m. 39·66s.) of the preceding year.

REPORT OF THE UNITED STATES NAVAL OBSERVATORY.—Rear-Admiral Chester's report of the work done at the United States Naval Observatory during the fiscal year ending June 30, 1904, shows that the observatory and the staff are still maintaining their reputation as regards the number and excellence of the observations made. In all 15,287 observations were made, including photographs of the sun taken on 210 days which show an increase of 93 days on which spots and faculæ were recorded on the solar disc. A new photo-visual triple objective with an aperture of 7·5 inch and a focal length of 65 feet, giving a 7-inch image, is to be obtained for the photoheliograph, and will also be used on future eclipse expeditions for photographing the corona. In regard to next year's eclipse the superintendent asks for a special grant of 1200*l.* and recommends the employment of a man-of-war and its crew to assist in the observations, which he suggests should be made at two widely separated stations in Spain.

The report also contains individual reports from the assistant in charge of each department, and records the personnel, the routine work performed with each instrument, and the publications issued during the period with which it deals.

The branch observatory at Tutuila, Samoa, has now been established, and placed under the supervision of assistants from Washington.

MATHEMATICAL DRAWING.[1]

THE appearance of a useful little book by Prof. Gibson may be made the occasion of emphasising the importance of drawing in mathematics, whether pure or applied, especially as the University of London has recently made a paper on drawing compulsory for all mathematical candidates for the B.Sc. degree. It was not without due consideration of the attendant difficulties that this step was taken. For the last two years the paper on drawing was left optional for the candidates in order that teachers as well as students should have time to obtain some definite notion of what is required; but even now, in the absence of well established text-books, a considerable amount of uncertainty exists as to the nature and scope of the subject. Time will, no doubt, set this right, and we welcome Prof. Gibson's text-book as assisting towards the desired object.

There are three prominent conceptions of mathematical drawing which may be noticed. These are:—(1) plotting, which means the construction of curves by taking a set of successive values of an abscissa and from them calculating (by a book of tables or otherwise) the values of the corresponding ordinate, and finally marking the positions of the points on squared paper; (2) the construction of curves—usually conic sections—from certain geometrical data; (3) what is generally called "geometrical drawing," embodying the principles and processes of projective geometry, and including problems in three dimensions. This is, perhaps, a rough division, but it will suffice.

Plotting may be a very humble process—"mere" plotting, as it is sometimes contemptuously called—or it may be what has long been known as curve tracing, and is to be found in treatises on the differential calculus. But even in this latter and higher character it is not (at least as usually employed by students) a system of accurate drawing. The construction of circles, and conics generally, from assigned data is certainly not a pure exercise in drawing, because it involves a very large knowledge of theorems on the part of the student. An exercise in this subject is apt to be, in reality, a severe examination in Euclid or in the theory of conic sections, and it cannot be what was intended by the advocates of a paper on drawing. With regard to projective geometry the case is somewhat different; the principles involved are not very numerous, and it cannot be said that a

[1] "An Elementary Treatise on Graphs." By George A. Gibson, M.A., F.R.S.E., Professor of Mathematics in the Glasgow and West of Scotland Technical College. Pp. x + 183. (London: Macmillan and Co., Ltd.) Price 3*s.* 6*d.*

knowledge of a large assortment of theorems is necessary; but the practical value of the study to students who are neither engineers nor architects is another matter.

There is, however, another kind of mathematical drawing which does not fall under any of these heads, and which consists in the invention of graphic solutions of equations which can be solved with great difficulty, if at all, by the stock processes of accurate mathematics. This branch is at once the most useful and the most vague; it is impossible to lay down its principles in systematic order—it must be learnt by abundant exemplification.

The ordinary academic problems of statics and hydrostatics furnish many examples of this subject, but only a few of these can be noticed here.

If AB and BC are two ladders freely jointed together at B, of different weights and lengths, placed with the ends A and C resting on a rough horizontal plane, A being prevented from moving while C is drawn out along the plane, the inclinations, θ, ϕ, of AB and BC to the ground when the limiting position is reached are determined from two equations of the forms

$$a \sin \theta - b \sin \phi = 0; \; m \tan \theta + n \tan \phi = k,$$

where a, b, m, n, k are all given quantities. The graphic solution of these equations is effected with great ease thus:—draw a line OH equal to m, and produce OH to O′ so that HO′ $= n$; at H draw HC perpendicular to OO′ and equal to k; through O draw any line OQ meeting HC in Q; take a point R in CH such that CR = HQ, and draw O′R; then the point, P, of intersection of OQ and O′R is a point on the locus represented by the second of the above equations, the angles θ, ϕ being POO′ and PO′O. These points, P, are therefore constructed with great ease and rapidity. Also the locus represented by the first equation is a circle having for diameter the line joining the points which divide OO′ internally and externally in the ratio $a : b$, and the points of intersection of these two loci give the required values of θ and ϕ.

The following problem leads to precisely the same equations as the above:—rays of light emanate from a fixed point P in one medium separated by a plane surface from a second medium; find the ray proceeding from P which will be refracted to a given point, Q, in the second medium.

Again, the fact that when a uniform chain hangs with free extremities over two fixed supports of equal heights there are either two figures of equilibrium or none results from the solution of an equation of the form $xe^{a/x} = k$, which is effected by drawing the curve $y = e^x$ and the right line $y = kx/a$, and then it is at once seen that there are either two points of intersection or none.

When a heavy wire rope has its ends fixed at two points in the same horizontal line, and a load is suspended from the lowest point of the rope, the rope forms parts of two distinct catenaries, and the determination of these curves leads to an equation of the form

$$e^{k/x} = [(x^2 + a^2)^{\frac{1}{2}} + a]/[(x^2 + b^2)^{\frac{1}{2}} + b],$$

in which x alone is unknown. The tracing of the curve obtained by putting y equal to the right-hand side of this equation is quickly effected by means of two fixed circles and the drawing of right lines.

The figure of equilibrium of a revolving self-attracting liquid spheroid gives an equation which is a particular case of $x(a + bx^2)/(c + x^2) = \tan^{-1}x$, and this is best solved by the tracing of two curves. If we put y equal to the left-hand side we have a curve of the third degree the geometrical construction of which is exceedingly simple, and requires only a fixed circle and right lines.

Whenever a problem involves two unknown angles in two equations one of which is of the form $m \cos \theta + n \cos \phi = c$, where m, n, c are given, all angles satisfying this equation can be represented as the base angles of a triangle the base of which, AB, is fixed, and the vertex of which describes what may be called a quasi-magnetic curve, the geometrical construction of which is this: take any two fixed points, A, B; about A as centre, with radius m.AB/c describe a circle; about B describe a circle with radius n.AB/c; draw any line perpendicular to AB meeting these circles in Q and R respectively; then the lines AQ and BR intersect in a point on the required curve. When $m = n$ we have the common magnetic curve the construction of which is not nearly so well known as it should be.

The solutions of the above examples have all been of a purely geometrical kind, and have not involved the plotting of points by coordinates arithmetically calculated. There are other problems of a slightly different kind, still independent of plotting, but involving *trial*; the value of a certain unknown quantity which has to satisfy a certain geometrical condition is found by trial to do so very nearly if not completely. In all such cases Taylor's theorem furnishes a still closer value than the observed one, and completes the solution with all desirable accuracy.

For example, many problems lead to the equation $a \sin 2(\theta - \alpha) = b \sin \theta$ for an unknown angle θ, the other quantities being all given. This can be solved by two circles thus:—draw a line AB equal to b, and on it as diameter describe a circle the centre of which is C; draw AD making the angle BAD $= \alpha$ and cutting the circle in D; draw CD and produce it to E so that CE $= a$, and on CE as diameter describe a circle. Now find on the circumference of the first circle a point P such that if CP meets the second circle in Q we have BP = EQ. This is done with great accuracy by the eye, and Taylor's theorem will improve the solution.

An equation which can be solved also very easily by trial is $a \sin^2 \theta = b \cot \theta$, which may be taken in the form $a \sin^3 \theta = b \cos \theta$, and a graphic solution suitable to each form is easily found.

Finally, we may notice equations of the form

$$\tan x = ax/(c - x^2),$$

which we obtain from Bessel functions in certain problems relating to vibrations. Such an equation is easily solved by the intersections of the curve $y = \cot x$ with the hyperbola $y = (c - x^2)/ax$, and the construction of the hyperbola belongs to the most simple case of this curve, viz. given one point on the curve and the asymptotes. As compared with the graphic solution of equations given by physical problems, the graphic solution of algebraic equations is unimportant, though not devoid of interest, because Horner is always available for numerical cases.

Prof. Gibson gives many examples of the solutions of quadratics and of cubics by graphic methods; but as regards quadratics it must be confessed that there is no utility in the process, and too much space is usually devoted to it. For cubics in general he gives a graphic solution and an interesting discussion. In a second edition of his book he might treat the biquadratic similarly, because its graphic solution can be easily effected by means of a circle and a parabola, or by means of a right line and a curve easily derived from a parabola. Many curves occurring in physics are dealt with in the book—such as isothermals and adiabatics; there is also a useful discussion of Fourier's theorem, and a treatment of the curves belonging to vibrations, damped as well as undamped. The graphic method is also applied to the solution of some of the simpler mixed trigonometric and algebraic equations, and the book concludes with a chapter on the properties of conic sections.

GEORGE M. MINCHIN.

CENTRAL AMERICAN MAMMALS.[1]

THREE years ago the author of these volumes published, in the same serial, a valuable synopsis of the mammals of North America and the adjacent seas. In the present larger work he has taken in hand the mammals of the tract generally known in this country as Central America, but on the other side of the Atlantic termed, at any rate by zoologists, Middle America, together with those of the West Indian islands. The greater bulk of the present work is accounted for, not so much by the greater number of species (690 against 606) as by the increased elaboration of the mode of treatment, the addition of diagnostic "keys" to the various genera, and by a fuller account of the habits of many species, the latter feature rendering these volumes proportionately more valuable to the naturalist, and at the same time of more general interest. The illustrations, too, are more numerous, comprising, besides crania, figures of the external form of a considerable number of species.

[1] "The Land and Sea Mammals of Middle America and the West Indies." By D. G. Elliot. *Field Columbian Museum Publications*, Zoological Series, vol. iv., parts i. and ii., pp. xxi+850 illustrated.

the addition of the latter likewise tending to popularise the work.

In his preface Dr. Elliot reiterates and emphasises the remarks made in the companion volume as to "the excessive and probably unwarranted multiplications of species and races (made easy by the too liberal application of the trinomial system)" of American mammals in general. Many of the forms, he adds, which have received separate names are separated on the evidence of comparative instead of distinctive characters. That is to say, their differences from other types are so slight as to be incapable of definition except by comparison with the latter, often, indeed, involving the necessity of placing specimens of each side by side. Consequently, in many instances specimens cannot be referred to their respective species or races without access to museums.

Perhaps it is rather unfortunate that the author did not see his way to go one stage further, and mention what species and races are entitled, in his opinion, to recognition. A step would then have been made towards the elimination of the forms named on insufficient distinctive characters. Nowadays it is the fashion to assign a distinct name to every recognisable form, however slight may be its points of difference; but some limit in this direction will apparently have to be imposed before long, unless zoology is to become an impossible science. In our opinion, one way of mitigating the difficulty is by using specific terms in a comparatively wide sense, thus leaving the subspecies, or races, to be recognised or not according to the discretion of the individual student.

Nomenclature is another point on which the author has a good deal to say, and he mentions that some of the names employed in the companion volume have been changed in the present work. He hopes, however, that as the result of such changes "a nomenclature that at least will approach stability may, in the distant future, be expected to be reached." Possibly it may—at the cost of rendering all the older standard works on zoology, palæontology, distribution, and scientific travel worse than useless—but a proposal like that of emending such a name as Odocoileus (in universal use among his naturalist countrymen) to Odontocœlus scarcely seems calculated to pave the way to such a happy millennium!

Among changes in nomenclature that we specially regret to see is the substitution of Agouti for Cœlogenys as the name of the paca, largely on the ground that the former is the popular title of a totally different group of rodents, for which reason we think its use in the scientific sense should be barred. It is also distressing to see the familiar

FIG. 1.—Lord Derby's Opossum and young. From Elliot's "Mammals of Middle America."

name Hapale, for the marmosets, banished in favour of Callithrix, so long used for the titi monkeys, which now figure as Saimiri. On a par with the latter is the substitution of Tayassu for Dicotyles, of Coendu for Cercolabes, and of Potos for Cercoleptes, which is like an invasion of zoological Goths and Vandals into the sacred precincts of classic Rome. One point in regard to the plan of the work—whether intentional or accidental it is not easy to say—strikes us as unsatisfactory. In the case of certain species, such as *Odontocoelus americanus* and *Ovis cervina* (pp. 69 and 84), for example, of which the typical form does not occur within the limits of the area under consideration,

FIG. 2.—Long-tailed Skunk. From Elliot's "Mammals of Middle America."

the species-name itself does not appear in the list at all, but only the subspecies, such forms consequently lacking a distinctive number, and thus rendering the census of specific types occurring within the area inaccurate.

Otherwise we have nothing but commendation to bestow on the general mode of treatment of the subject, and it may be safely affirmed that the author has earned the gratitude of all naturalists on this side of the Atlantic by putting in a convenient and easily accessible form such a vast amount of information with regard to the mammalian fauna of an extremely interesting region. The illustrations (two of which are reproduced), it may be added, are, for the most part, beyond praise.

R. L.

THE FISHERIES OF SCOTLAND.

THE twenty-second annual report of the Fishery Board for Scotland, for the year 1903, is issued in three parts as usual, the first dealing with the sea fisheries, the second with the salmon fisheries, and the third being concerned with marine research.

With regard to sea fisheries, tables are given showing the results of the trawl fishing and the line fishing. The number of steam trawlers has been increasing steadily for the last seven years, and rose from 109 in 1896 to 280 in 1903. The average catch per vessel increased from 5030 cwt. to 5594 cwt., while the value of the catch per cwt. was practically the same in 1903 as it was in 1896.

In the line fishing the number of steam liners increased from 39 vessels in 1898 to 91 vessels in 1903, the number having varied somewhat in the intermediate years, 23 vessels having been added in 1903. The total number of boats was slightly less than in 1898, owing to a steady decrease in the number of sailing craft. The catch, since

1898, has steadily decreased from 1,050,000 cwt. to 602,600 cwt., and the value per cwt. has slightly decreased. The reason given for the reduction in value of line-caught fish is that the trawlers have been landing large quantities of cod. Thus, in spite of the large increase in the number of steam liners, which are, of course, independent of wind in getting to the fishing grounds, the catch per boat fell from about 182 cwt. to about 121 cwt.

It is interesting to note that for the herring fishing in the Buckie and Peterhead districts experiments have been made with sailing boats fitted with auxiliary steam power. The value of steam power is shown in another part of the report, where the catch of the Scotch boats (sailing craft) working from English ports during October and November is compared with that of the English boats, a large number of which are steamers. The Scotch boats caught more than 65½ per cent. of the total catch, but only got 46⅝ per cent. of the total value, the steamers always being able to make the market first.

The west coast mackerel fishing has shown great improvement, the catch in 1903 being 57 per cent. better than in 1902. The trade apparently only requires development, as "shoals of mackerel almost every year visit the coast."

In the report on salmon fisheries we learn that during the year Mr. Calderwood, Inspector of Salmon Fisheries for Scotland, made inquiries as to the views of the various fishery boards with regard to the limitation of netting in narrow waters, this move being an outcome of the report of the Royal Commission on Salmon Fisheries.

Some of the boards have already taken steps to reduce the netting in their rivers. In the Annan all nets have been removed, while in the Spey only about three miles of water is now netted. In the Aberdeenshire Dee an association has, for about thirty years, annually bought off the nets on some sixteen miles of water, and now both upper and lower proprietors are seeking to secure the permanent removal of these nets.

While eleven of the boards consulted passed resolutions in favour of reducing the netting, six were unable to express an opinion, and only one, the North Esk Board, passed a resolution against any such reduction. In Mr. Calderwood's words:—"The resolution was prepared and agreed to by the lower proprietors—who are in the majority—before the meeting took place, and was based upon the argument, supported by good evidence, that the present amount of netting in the district—which netting has been constant for a great number of years—has not produced a decline in the stock of fish. The question of improving the general interest of their *whole* district is complicated by other considerations which need not be referred to here."

One of the most important papers in this report is Mr. Calderwood's contribution to the life-history of the salmon as observed by means of marking adult fish, the first part of which appeared in the report for 1901. Since then 62 additional re-captures of marked fish have been made, which, with those previously caught, gives a total of 252 re-captured fish. From this material, and also from other results obtained in Scotland, Ireland, and Norway, Mr. Calderwood has been able to draw some important conclusions. We now have evidence bearing out the commonly accepted view that the great majority of salmon after visiting the sea return to the river they left.

The marking experiments seem to show that grilse spend less time in fresh water than salmon, running up and down from the redds more quickly than the latter.

Another very interesting fact brought out is that a grilse kelt after running down to the sea may return within a few months as a summer salmon of about 10 lb., or may remain in the sea until the following year, returning to the river as a spring salmon. This partly upsets the belief that spring salmon are old fish, for, although there is no doubt that old fish do run up in the spring, we now know that a fish of 18 or 20 lb. may only be five years old, according to Mr. Calderwood, and on its second return from the sea.

There is evidence showing that some fish spawn in two successive seasons, and one case, No. 7298, seems to suggest that the fish was spawning for the third year in succession.

There is a diagram, in which fish of various weights are considered as being of various ages, which shows the interesting facts observed as to the "dual migration" which exists, perhaps, in all stages of the salmon's life-history.

We know that all the fish of one hatching do not migrate to the sea at the same time. Some migrate at one year old, the great majority at two years, and some again at three years.

For the smolt to grilse stage Mr. Calderwood mentions three cases in which the smolts returned after a year and some months as grilse of 3½, 3½, and 6½ lb. respectively, and says "we have no data to show any other seasonal migrations which may occur at this stage." We do not know whether the authority for the cases is untrustworthy, but we recollect records of smolts marked and released being re-caught after a few months as grilse up to 8 lb. weight. Such cases are mentioned by Fraser ("On the Salmon, &c.," 1833, pp. 15, 16) and by Brown ("Stormontfield Experiments," p. 92), who says "the experiments here have shown . . . that all the smolts of one year do not return the same year as grilse, the one half returning next spring and summer as small salmon."

Mr. Calderwood shows that what he considers five-year-old fish do not increase in weight in the way that four-year-olds and six-year-olds do, and he suggests that this may represent the period in the life of the adult salmon when the reproductive function is at its best, and thus asserts itself at the expense of the body-growth.

Surely this classing of fish into ages by size can only be roughly correct at best. We do not yet know to what extent fish spawn annually or biennially, or whether a fish may rest several seasons after spawning. Yet if Mr. Calderwood's suggestion that the activity of the reproductive organs checks growth is sound, surely a fish spawning three years in succession—as No. 7298 suggests may happen—would be considerably smaller than a fish of the same age which spawned in alternate years or less often.

There are several other interesting papers in this part, but space precludes us from referring to them.

Part iii., scientific investigations, contains eight papers on various subjects connected with marine fisheries. Dr. T. Wemyss Fulton, the superintendent, gives an account of the trawling investigations, and in another paper continues the report of his investigations on the rate of growth of fishes. He also reports upon the operations of the Nigg Marine Hatchery, and has another paper entitled "Ichthyological Notes" on the various interesting species taken during the year.

An important paper is that by Dr. Williamson on the life-histories of the edible crab and other decapod Crustacea. Dr. Williamson has discovered that the ova of the crab are not attached by mucilage to the long hairs of the spinnerets as was supposed, but that the eggs are actually pierced by the hairs, and are thus spitted in rows, the eggs not being attached to one another.

Dr. Thomas Scott contributes a paper on some rare and interesting marine Crustacea, and another upon some fish parasites new to the Scottish marine fauna.

The report is published at His Majesty's Stationery Office, and can be obtained through any bookseller.

FRANK BALFOUR BROWNE.

PRIZE AWARDS OF THE PARIS ACADEMY OF SCIENCES.

AT the annual meeting of the Academy of Sciences the list of prizes awarded for the year 1904 was announced as follows:—

Geometry.—The Bordin prize to M. Servant, for his memoir on the determination of surfaces applicable to the paraboloid of revolution which pass through a given contour; the Vaillant prize, divided between M. Emile Borel (3000 francs), and M. Bricard (1000 francs); the Francœur prize to M. Émile Lemoine; and the Poncelet prize to M. Désiré André.

Mechanics.—A Montyon prize to M. Gustave Richard.

Navigation. The extraordinary prize, of 6000 francs, divided in equal parts between M. Jacob (for his theoretical researches on the transmission of submarine explosions), M. Gayde (for a study of the resistance of hulls to submarine explosion), and M. La Porte (for hydrographic work on the coast of Brittany); the Plumey prize to M. Lucien Mottez, for important services to submarine navigation.

Astronomy.—The Pierre Guzman prize is not awarded;

the Lalande prize to Mr. S. W. Burnham, for his work on double stars; the Valz prize to M. de Campos Rodrigues, for work done at the Lisbon Observatory, with especial reference to the determination of the solar parallax by means of the planet Eros; the Janssen medal to M. Hansky.

Geography.—The Binoux prize, divided between M. Baratier (for his work in connection with Colonel Marchand's expedition in Central Africa), M. Bénard (for his work on Arctic exploration), and M. Alphonse Berget (for his book on the physics and meteorology of the globe); the Gay prize to Mr. Bell Dawson, for his hydrographic work in eastern Canada; the Tchihatchef prize to Lieut.-Colonel Lubanski, for his explorations in Indo-China; the Delalande-Guérineau prize to M. Auguste Pavie, for work in French China.

Physics.—The Hébert prize to M. Georges Claude, for his book on electricity for general readers; the Hughes prize to Lieut.-Colonel E. Ariès, for his publications on the theory of heat and chemical statics; the Kastner-Boursault prize to Captain Ferrié, for his work on wireless telegraphy.

Chemistry.—The Jecker prize, divided between MM. Freundler, Minguin, and Lespieau; the Cahour prize, divided between MM. Chavanne, Kling, and Binet du Jassoneix; a Montyon prize (unhealthy trades), divided between MM. Dupont and Détourbe.

Botany.—The Desmazières prize to M. Guilliermond, for his work on cryptogams, especially fungi; the Montagne prize to M. Camille Sauvageau, for his work on algæ; the de la Fons-Melicocq prize is not awarded.

Anatomy and Zoology.—The Savigny prize to M. Krempf; the Thore prize to M. d'Orbigny.

Medicine and Surgery.—A Montyon prize to M. Paul Reclus, for his memoir on the proper use of cocaine in surgery; to M. Kermogant, for his work on exotic pathology and hygiene; and to M. Cazalbou, for his researches on the trypanosomiases of the French Soudan. Mentions are also accorded to MM. P. Launois and Roy, for their biological studies on giants; MM. F. Bezançon and M. Labbé, for their treatise on hæmatology; and to M. Odier, for his work on the action of electricity and certain poisons on nerve cells. MM. F. Marceau, P. Briquel, J. Gagnière, and R. Voisin are accorded citations. The Barbier prize to MM. Prenant, Bouin and L. Maillard, for their book on histology, and a mention to M. Pierre Lesage; the Bréant prize (accumulated interest) to M. Frédéric Borel, for his memoir on cholera and plague in relation to Mahometan pilgrimages; the Godard prize to MM. J. Albarran and L. Imbert, for their memoir on tumours of the kidney; the Baron Larrey prize to M. Conor, for work on typhoid fever, M. E. Lafforgue receiving a mention; the Bellion prize to M. Jules Delobel, for his book on hygiene in schools, M. Gabriel Gauthier receiving a mention; the Mège prize to M. G. Delamare, for his experimental researches on morbid heredity.

Physiology.—A Montyon prize to M. J. Jolly, for his memoir entitled "Experimental Researches on the Indirect Division of the Red Blood Corpuscles," a very honourable mention being accorded to M. C. Fleig, for his work on the mode of action of chemical stimulants on the digestive glands; the Philipeaux prize to M. Cristiani, for his work on thyroid grafting, an honourable mention being accorded to M. Joseph Noé; the Lallemand prize, divided between M. Maurice de Fleury (for his works on the nervous system) and MM. J. Camus and P. Pagniez (for their memoir on psychotherapy); the Pourat prize to M. J. Tissot, for a study of the physical and chemical phenomena at high altitudes; the Martin-Damourette prize, divided between M. A. Frouin (1000 francs) and M. Manquat (400 francs).

Among the general prizes, the Lavoisier medal was awarded to Sir J. Dewar, for his work on the liquefaction of gases; the Berthelot medal to MM. Freundler, Minguin, Lespieau, Kling, Binet du Jassoneix, Dupont, and Paul Villard; the Jerome Ponti prize to M. Maurain; the Trémont prize to M. A. Guillemin; the Gegner prize to M. J. H. Fabre; the Lannelongue prize to Mme. Vve. Nepveu; the Leconte prize to M. René Blondlot, for his work taken as a whole; the Wilde prize to M. Paul Villard, for his work in physics; the Houllevigue prize to MM. Henri de la Vaulx and Henri Hervé, for their work in aëronautics; the Saintour prize to M. Charles Frémont, for his experimental researches on the elasticity of metals; a Montyon prize (statistics), divided between M. V. Lowenthal, for twelve memoirs relating to the depopulation of France, and M. Paul Razous, for his memoir on the mortality and liability to disease in dangerous professions, MM. Henry Guégo, E. Maury, and Ott receiving mentions; the Jean-Jacques Berger prize is divided between MM. J. Resal (6500 francs), A. Alby (3500 francs), Laurent (2000 francs), Grimaud (1500 francs), and Retraint (1500 francs).

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Liverpool.—The arrangements for excavations to be made during the winter under the auspices of the university institute of archæology, in Upper Egypt, have been completed, and the work will be begun at Hierakonpolis before the New Year. The excavations have been placed as in previous years at Beni-Hasan, Negadeh, and elsewhere under the care of the university reader in Egyptian archæology.

Dr. Norman Moore has been appointed a member of the consultative committee *vice* Prof. Bertram C. A. Windle, F.R.S., who has resigned his membership upon appointment as president of Queen's College, Cork. Dr. Moore is chairman of the board of advanced medical studies of the University of London, and represents the Royal College of Physicians upon the General Medical Council.

The annual meeting of the Geographical Association will be held at the Royal Colonial Institute, Northumberland Avenue, London, W.C., on Friday, January 6, at 4 p.m. The president, Mr. Douglas W. Freshfield, will be in the chair. A report on the eighth international geographical congress will be read by Mr. H. Yule Oldham, and there will be a discussion on practical geography in schools.

On December 20 Lady Warwick distributed the prizes gained by the students of the evening classes and of the day secondary school of the Carpenters' Company at Stratford. In the course of some remarks upon the school, she said that England needed a better system of secondary education, and it was now acknowledged that the State should take the matter in hand. But in the meantime the city companies were doing a good work in bringing secondary education to the doors of the people.

The annual conference of the Public Schools Science Masters' Association will be held at Westminster School on Saturday, January 14, 1905. The following are among the subjects to be discussed:—(1) the importance of including both Latin and natural science in a scheme of general education; (2) recent proposals for school leaving certificates; (3) the use and misuse of terms in science teaching; (4) the possibility of teaching "scientific method" to boys whose education is almost entirely literary and who have no time for a regular course in chemistry and physics. Sir Michael Foster, K.C.B., is the president of the association for the year.

New buildings of the Willesden Polytechnic, erected at a cost of about 10,000*l.*, were formally declared open by Sir W. Anson on December 21. After distributing prizes to the successful students, Sir W. Anson remarked that polytechnics marked what he hoped was becoming the modern view of education, that it did not consist of independent sets of studies, but was a composite whole, no part of which did not rest upon or form a foundation for another part. It should be borne in mind that a polytechnic did not merely train a student in a handicraft. The object of such an institution was to combine theory and practice, to teach the student not only how to do a thing, but why it was done in a particular way, so that he became not only skilful in the craft upon which he was engaged, but got to understand the scientific principles underlying his work.

Mr. L. L. Price read a paper at the meeting of the Royal Statistical Society on December 20 entitled "Accounts of the Colleges of Oxford, 1893–1903, with Special Reference to their Agricultural Revenues." The paper is based on the accounts, published annually, of the colleges (and the university) of Oxford, and is a continuation of one read in 1895. The gross external receipts of the colleges (and the university) in 1903 exhibited an increase on 1893 of 29,797*l.*, and on 1883 of 16,343*l.* The net external receipts of the colleges alone showed an increase of 16,566*l.* on 1893, and a decrease of 10,311*l.* from 1883. Later in his paper Mr. Price states that it hardly seems extravagant to affirm that during a quarter of a century the colleges (and the university) have lost between a third and a fourth of their agricultural revenues. Had it not been for an increase in revenues derived from other sources, they would have been crippled yet more seriously. The most noticeable feature is the large increase in the receipts from houses and sites of houses. Between 1883 and 1903 these receipts were doubled, and between 1893 and 1903 they increased from 56,877*l.* to 91,388*l.* On the whole this gross increase has more than balanced the gross diminution in the receipts from lands and tithe. The internal receipts of the colleges increased by 5814*l.* between 1883 and 1893, and by 11,428*l.* between 1893 and 1903.

THE annual conference of headmasters of public schools was held this year at Christ's Hospital, West Horsham, on Thursday and Friday last, December 22 and 23. Among the subjects discussed on Thursday were the recommendations of the consultative committee of the Board of Education for the establishment of school certificates, and the policy of the Board of Education in encouraging the sending of intending elementary school teachers to secondary schools in lieu of pupil teacher centres. The following resolutions were adopted:—"That the question of school certificates be referred to the committee of the conference with a view to immediate action, and that it be an instruction of the committee to obtain in writing the opinion of every member of the conference on the various points involved in the scheme of the consultative committee." "That this conference pledges itself to support the education authority in its policy of providing that candidates for pupil teacherships in public elementary schools shall receive a substantial portion of their education in a public secondary school, and considers it desirable that as many recruits as possible for teacherships in public elementary schools should be obtained from the ranks of ordinary pupils of secondary schools." On Friday a discussion took place on the subject of Greek, with special reference to the proposals of the Cambridge Syndicate, and the following resolution was carried by twenty-one votes to eight:—"That, without committing itself to details, the conference generally disapproves of the Cambridge Syndicate with regard to Greek in the Previous Examination." The conference also expressed itself against some of the reforms of the new Army entrance examinations, and carried the following resolution unanimously:—"That this conference hopes that the scheme for qualifying certificates in the examination for Woolwich and Sandhurst will be so amended as to encourage the study of Latin." A strong representation is to be made to the War Office on this subject. It was also agreed that the committee of the conference should consider the syllabus issued by the Board of Education on the teaching of English literature, and should include their recommendations in the annual report.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Meteorological Society, December 21.—Capt. D. Wilson-Barker, president, in the chair.—Decrease of fog in London during recent years: F. J. **Brodie** (*Discussion*).—The study of the minor fluctuations of atmospheric pressure: Dr. W. N. **Shaw**, F.R.S., and W. H. **Dines**. The authors described an apparatus called the "microbarograph," which they have designed to magnify the minor fluctuations, and at the same time to disentangle them from the general barometric surges. They also showed some records from three of these instruments. The authors wish to obtain information as to the nature of the disturbances and the causes to which they may be assigned. Among the causes which suggest themselves as likely to produce temporary fluctuations of the barometric curves are stated by the authors to be (1) atmospheric billows passing along surfaces where there is discontinuity of density in a manner somewhat similar to ocean waves; (2) the passage of minute whirls or cyclonic depressions of small scale; (3) variations of pressure due to the attraction or repulsion produced by electric stress as masses of air at different potential pass over; (4) the mechanical effects of wind; and (5) the mechanical effects of rapid condensation of aqueous vapour.

DIARY OF SOCIETIES.

MONDAY, JANUARY 2.

VICTORIA INSTITUTE, at 4.30.—Confucianism: Rev. A. Elwin.

WEDNESDAY, JANUARY 4.

GEOLOGICAL SOCIETY, at 8.—The Marine Beds in the Coal Measures of North Staffordshire: J. T. Stobbs.—The Palæontology of the Marine Bands in the North Staffordshire Coalfield: Dr. Wheelton Hind.—The Geology of Cyprus: C. V. Bellamy, with Contributions by A. J. Jukes-Browne.

THURSDAY, JANUARY 5.

RONTGEN SOCIETY, at 8.15.—Description of an Automatic Vacuum Pump: C. E. S. Phillips. (The apparatus will be shown at work.)—Exhibition of a Method by which Strongly Adherent Films of Aluminium may be applied to Glass.—A Note on the Coloration of Glass by Radium Radiation.

FRIDAY, JANUARY 6.

GEOLOGISTS' ASSOCIATION, at 8.—The Third Issue of the British Association Geological Photographs: Dr. C. G. Cullis.

MODERN OPTICAL METHODS.

Die Bilderzeugung in optischen Instrumenten, vom Standpunkte der geometrischen Optik. By the Scientific Staff of Carl Zeiss's Works. Edited by M. von Röhr. Pp. 588; with 133 woodcuts. (Berlin: Julius Springer, 1904.)

Grundzüge der Theorie der optischen Instrumente nach Abbe. By Dr. Siegfried Czapski. Second edition. Edited by Dr. O. Eppenstein, with the assistance of M. von Röhr. Pp. 490; with 176 woodcuts. (Leipzig: Johann Ambrosius Barth, 1904.)

THE old geometrical optics which we used to read at Cambridge was a delightful subject. It would have been a still more delightful subject had examiners set better questions on it. Probably no other branch of mathematics would lend itself so well to the kind of treatment which is now fortunately coming into fashion, viz. the use of graphical and experimental methods. If the German system of Lehrfreiheit prevailed in this country I would rather teach geometrical optics to an elementary class than geometry adapted to modern requirements.

This elementary optics, however, bears about the same relation to the optics treated in the first of these books that Newton's deductions from Kepler's laws bear to the planetary theory. The analogy is the more complete in that both the optician and the astronomer have found it impossible to obtain an exact solution by direct methods, and they have therefore been led to employ the method of trial and error in order to obtain successive approximations giving the desired results to closer and closer degrees of accuracy. As Messrs. Czapsky and Siedentopf point out (p. 25), the exact determination of the forms of the refracting surfaces required to produce exact images subject to given conditions has never been effected, except in a few cases, such as the Cartesian oval, in which rays from one focus converge to a point in the other. We therefore take spherical surfaces, and by calculating the various kinds of aberration, show how they may be corrected. It is, however, interesting to learn that the theory of non-spherical surfaces has quite recently been put into practice in the Zeiss works for the first time in the construction of lenses other than large reflectors and refractors for telescopes. It has, in fact, been found possible to correct certain residual aberrations by applying finishing touches to the lenses giving them a slight deviation from sphericity.

The analogy between the problems of the optician and the astronomer is made still closer by observing how different specialists have confined their attention to particular kinds of aberration in the one case and of perturbation in the other, and have devised special methods for simplifying the calculation of the corresponding terms.

In his preface Dr. Czapski tells us that the present work owed its origin to the demand for a revised edition of his "Theorie der optischen Instrumente nach Abbe," published in 1893. Being unable to undertake the work himself, the idea suggested itself that a better purpose would be served by obtaining the collaboration of a number of joint authors, and that no better body of men could be found for the purpose than the scientific staff of the Zeiss firm.

The work has been divided among the seven joint authors as follows:—The first chapter, dealing with the fundamental principles of optics, including the laws of refraction, the principle of minimum path, and the characteristic function, is contributed by Drs. Czapski and Siedentopf; Drs. König and von Röhr contribute the second chapter, on formulæ of calculation, and the fifth, on spherical aberration, in which latter is contained a complete exposition of Abbe's method of invariants and its application to the determination of the ten corrections determined by the problem of Seidel. The chapters on chromatic aberration and on determination of optic systems according to the theory of aberrations (chapters vi., vii.) are contributed by Dr. König alone. "The Geometrical Theory of Images after E. Abbe" is the title of the third chapter, by Dr. Mandersleb. In the fourth chapter, by Dr. P. Culmann, on the realisation of optical images, we actually do find our old friend the formula

$$\frac{\mu}{v}-\frac{1}{u}=\frac{\mu-1}{r},$$

in a position, however, of subsidiary importance. Dr. Löwe contributes a chapter on prisms, while Dr. von Röhr is responsible for the last two chapters, dealing with the breadths of pencils, penetration, brightness of images, and similar matters.

The second of these books is of a more elementary and practical character. It contains a general discussion of images formed by small pencils, and illustrated descriptions of the principal optical instruments. The corrections are discussed, but the discussions are less mathematical. The theory of conjugate foci receives fairly full treatment, and among the interesting features which we notice at a first glance, attention may be directed to the series of sections of a pencil of light on p. 24, and the figures of an object and its image on p. 40, where the object is an arrow in a plane through the axis of a lens, and is bisected by the focal plane of the lens.

This is the second edition of a book of which the first edition was written for Winkelmann's "Handbuch der Physik." Of matter new in this edition, Dr. Eppenstein contributes chapters on screens, on projection apparatus, and on the illumination of objects; chapters on vision, on photographic objectives, and on spectacles are contributed by Dr. M. von Röhr.

The perfection to which the manufacture of optical instruments has been brought by the Zeiss firm is well known, and it is also pretty generally realised that the results attained could not have been accomplished by an establishment run on purely business lines by "practical men" falsely so-called. The usual stock form in which the last named class of individual recommends his wares to the public is the stereotyped statement that "The materials used in the preparation of these goods are of the best quality obtainable."

The present books furnish abundant proof that this statement is particularly applicable to the Zeiss instruments in regard to the quality of those materials most essential for the production of good optical apparatus, viz. brains and knowledge of advanced mathematics.

G. H. Bryan.

AMERICAN CYTOLOGY.

Fecundation in Plants. By David M. Mottier, Ph.D. Pp. viii + 187. (Washington: Published by the Carnegie Institution, 1904.)

Contributions to the Knowledge of the Life-History of Pinus, with Special Reference to Sporogenesis, the Development of the Gametophytes and Fertilisation. By Margaret C. Ferguson, Ph.D. Pp. 153. (Washington: Published by the Washington Academy of Sciences, 1904.)

MR. MOTTIER'S "Fecundation in Plants" gives to those who are interested in cytology an account of the phenomena of fertilisation throughout the vegetable kingdom, written by one who has carried on investigations in several branches of the subject with success. His practical acquaintance with his subject confers even on his descriptions of the investigations of others a freshness which makes his work a pleasure to read. The first chapter is perhaps the most generally interesting. In it he gives an account of some of the vexed problems of karyology which are at present calling out so much controversy among cytologists. Among these problems may be mentioned the existence of centrosomes, the homology of centrosomes and blepharoplasts, the nature of synapsis, the significance of the sexual process, and the numerical reduction of chromosomes. The author's method of discussion is candid. He avoids being dogmatic in expressing his own views, although he criticises somewhat severely the observations of others. He holds that centrosomes and centrospheres do not occur in plants higher than the liverworts, and are, indeed, only well established in a few of the Thallophyta. It is remarkable that he does not allude to the possibility that the radiations at the poles of mitoses may be in part artefacts produced by the fixing agents. He considers Belajeff hasty in coming to the conclusion that the centrosome is the homologue of the blepharoplast; but he admits later on that certain "facts lend encouragement to the belief that centrosome and blepharoplast may be homologous structures." Mottier regards synapsis as due in a large measure to the action of reagents. He accepts Strasburger's theory of the numerical reduction of chromosomes as a good working hypothesis, and he holds now that there is no evidence for Weismann's "reduction" to be found in the mitoses of plants. His candid expression of doubt as to the persistent individuality of the chromosomes preserved through the successive mitoses—so often assumed, though almost involving a miraculous resurrection—is typical of his attitude of independence.

The succeeding chapters give an account of fertilisation in types taken from the various subdivisions of the vegetable kingdom. These descriptions are most useful in bringing together what is scattered sporadically through botanical literature into the compass of a short, well written book. The work is illustrated by blocks in the text, which show in a satisfactory manner the points to be brought out.

Miss Ferguson's memoir has a more limited scope, but this allows her to devote more space to her own researches, which have been very extensive in the cytology of the spore-production of conifers. It is quite remarkable to see how two cytologists, writing almost simultaneously, can hold so divergent views on fundamental subjects. While Mottier sees in the fusion of sexual nuclei the blending of two lines of descent, Miss Ferguson's researches lead her to believe that no fusion-nucleus, combining the paternal and maternal hereditary substances, is formed. Rather the processes of mitosis allow these to be kept apart during the life of the offspring, and the "reduction" or qualitative division occurring some time during the life-cycle secures that the gametes shall be "pure." It is evident that the later writer is concerned with the relation of mitosis to Mendel's views rather than to Weismann's hypothesis. With regard to synapsis, Miss Ferguson believes it to be a normal stage in heterotypic mitosis. Another point of difference is the mode of origin of the double chromosomes of heterotypic mitosis. Miss Ferguson finds confirmation in her preparations for the view (first published by the writer of this review in 1896, *Proc.* Roy. Irish Acad.) that the two arms of the chromosomes are approximated pieces of the nuclear thread, and do not arise by longitudinal cleavage as Mottier believes. This interpretation seems to be gaining ground, and the Louvain school, once so much opposed to it, has recently accepted it, putting the folding back, however, to the synaptic stage. The reviewer's investigations seem to suggest the possibility that two distinct foldings take place, one during synapsis and another between that stage and the differentiation of the chromosomes. Whatever views are held on these disputed matters, all cytologists are indebted to the author for her beautiful drawings, which are reproduced in a series of twenty-four plates.

There is no doubt that the publication of these two memoirs, the one by the Carnegie Institution and the other by the Washington Academy, will be of much service to those engaged in cytological research.

H. H. D.

PHYSICAL RESEARCH AT LEYDEN.

Het Natuurkundig Laboratorium der Ryks-Universiteit te Leiden in de Jaren 1882–1904. Gedenkboek aangeboden aan den Hoogleeraar H. Kamerlingh Onnes, Directeur van het Laboratorium, by gelegenheid van zyn 25-jarig Doctoraat op 10 Juli 1904. Pp. viii + 288. (Leyden: Eduard Ydo, 1904.)

THIS volume was prepared by colleagues and pupils of Prof. Kamerlingh Onnes, of Leyden University, and presented to him on the twenty-fifth anniversary of his receiving the degree of Ph.D. It differs in character from the usual collections of scientific papers which it has become the fashion on the Continent to present to eminent men of science on similar occasions. Since 1882 Prof. Onnes has been director of the physical laboratory at the University of Leyden, and the book gives a description of the growth of the institution since his accession to the directorship, of its present condition, and of the work carried out by himself and by his pupils under his supervision. In a sense it is a matter for regret that by the nature of the case he himself had to be excluded from the list of contributors; on several of the subjects dealt with it would be interesting to have the director's personal views.

After an eloquent dedication from the hand of Prof. Bosscha, we find in the first chapter, compiled by Prof. Haga and others, a detailed description of the laboratory and of the more important machinery and fittings, particularly those belonging to the "cryogenic" department, to which Prof. Onnes has devoted most of his personal labours; the low temperature baths prepared here are extensively used throughout the laboratory for various researches.

In an appendix to this chapter Dr. Siertsema gives an interesting account of the training school for apprentice mechanics instituted by Prof. Onnes in connection with the laboratory. This institution is probably unique; it was started in 1886 with one pupil, and the number has risen steadily until this session no less than thirty-three boys are receiving systematic instruction in the various mechanical arts, with the object of qualifying themselves as instrument makers, glass-blowers, electricians, and for similar professions. The boys are supposed to assist to a certain extent in the routine work of the laboratory and earn corresponding small wages, while in the evening they have to attend classes in the municipal technical institute. A better training for the purpose could hardly be imagined, and one is not astonished to learn that after the completion of the three years' course the boys appear to be much in request in laboratories and various engineering and technical works.

In chapter ii. thermodynamical investigations are reviewed; Prof. van der Waals gives an account of Prof. Onnes's researches on thermodynamical surfaces, Prof. Kuenen writes on the phenomena of condensation of binary mixtures, and there are further articles on accurate isothermals of gases, on the construction of models of surfaces, and on capillarity and viscosity of liquids up to the critical region.

The third chapter, edited by Prof. Lorentz and others, is devoted to optical and magneto-optical work; here we find a discussion of experiments on the reflection of light by mirrors, on the magnetic rotation of the plane of polarisation in gases, liquefied gases and other liquids, on the influence of pressure on the rotation of sugar solutions, on the reflection of light by magnetised mirrors (Kerr's phenomenon), and an account of Zeeman's discovery of the modification in spectra by magnetic forces. The phenomenon discovered by Egoroff and Georgiewsky, that a sodium flame placed in a magnetic field emits partially polarised light, was investigated by Prof. Lorentz himself, and appears to be closely connected with Zeeman's phenomenon.

In the last chapter Prof. Zeeman gives a description of researches on Hall's phenomenon in bismuth at various temperatures down to the boiling point of oxygen, measurements of the dielectric constant of liquid oxygen and liquid nitrous oxide, and of the absorption of Hertz vibrations by salt solutions.

A detailed account of all the research work is published regularly in the *Communications* from the physical laboratory at Leyden, the issue of which was commenced in 1892, but the present papers give a useful general summary of the work carried out, presented in a manner which should make it intelligible to the uninitiated.

The volume bears ample testimony to the success which has attended Prof. Onnes's manifold labours for his laboratory, which owes to him its position as one of the best known institutions of its kind. It is well illustrated, and contains as a frontispiece a striking likeness of Prof. Onnes, apparently after a drawing.

PRACTICAL SILICATE ANALYSIS.

Manual of the Chemical Analysis of Rocks. By H. S. Washington, Ph.D. Pp. ix+183. (New York: Wiley and Sons; London: Chapman and Hall, Ltd., 1904.) Price 8s. 6d. net.

Of late years greatly increased attention has been directed to the chemical investigation of rocks, and the science of petrology has been enriched by many excellent analyses. Among these the work of the United States Geological Survey deservedly holds the highest place, both on account of its abundance and its thoroughness. The present treatise arises from an endeavour to make the methods used by Clarke, Hillebrand, and other chemists in the United States laboratory available to all workers. It is excellently clear and detailed, and though the experienced analyst will not find in it much that is not already published in more succinct form in the official *Bulletins* of the Survey, he will glean a few details of manipulation and discussions of the bearings of chemical petrology that will at any rate repay perusal.

The author intends his book to be used mainly by the rather numerous class of geologists and petrologists who combine a fair knowledge of chemistry with a desire to make their own rock analyses. Undoubtedly this is a far more satisfactory proceeding than, as is usually done, to have the analyses executed by some analyst who has no special knowledge of the intricacies of this part of practical chemistry, and follows methods which are discredited or discarded. In any case such a worker will do well to place himself, for a time at least, under some teacher who is thoroughly at home in the subject; we hope that this book will not stimulate the production of analyses of rocks by students in course of training. Much of the worst analytical work with which chemical petrology is burdened has been executed in that way. If it helps to spread the knowledge of the methods used by Clarke and Hillebrand this book will do much good, as it is desirable that these should henceforward be recognised as standards, from which any important departure should be notified when the results are published.

In a few respects Dr. Washington has simplified the standard American procedure. We think this is wise, and, while we endorse his opinion that only the best work should be aimed at, we do not think that this means that the very elaborate American analyses should be emulated by the ordinary worker. From twenty to twenty-five elements are usually sought for by the American chemists, and nearly one-half of these may be present in less than 1 per cent. of the total rock. Such analyses look exceedingly well on paper, but require the greatest experience and manipulative dexterity if they are to be trustworthy. Moreover, their value is as yet not beyond question. Certainly an analysis in which ten or twelve elements are determined as exactly as possible is more welcome than an analysis which is more elaborate but less accurate. We notice that the author discourages the routine execution of duplicates. No doubt this is right; they take up much time, and may be useless or misleading; it is better for the experienced chemist to occupy himself in the most thorough testing of his reagents, the purity of which is never above suspicion. Still, there can be no doubt that duplicate analyses do show how far it is possible for the results to vary when two samples of the same powder are analysed. They help to check any exaggerated confidence in analytical refinements. In this respect it would be interesting to know what are the probable limits of error in analyses executed by the methods given in this book. The author gives his opinion (apparently not founded on any special investigations), and it strikes us that he is more sanguine in this respect than the majority of experienced silicate analysts in Britain or on the Continent.

OUR BOOK SHELF.

Application of some General Reactions to Investigations in Organic Chemistry. By Dr. Lassar-Cohn. Translated by J. B. Tingle, B.A. Pp. 101. (New York: Wiley and Sons; London: Chapman and Hall, Ltd., 1904.) Price 4s. 6d. net.

It would be difficult to say with what object and for what class of readers this little volume (it is scarcely more than a pamphlet, and may be read in an hour) was written. Yet anyone engaged in the practical pursuit of organic chemistry cannot fail to be interested in it. One may say roughly that the book treats of the unsystematic part of organic chemistry, *i.e.* of the ordinary reactions which do not succeed, and how they may be made to do so.

Without always offering a very satisfactory explanation of the causes of success or failure, for the terms "protective influence" and "contact action" are after all merely names, the author points out how an apparently unimportant modification may affect the whole course of a reaction and convert an unprofitable method into a successful or commercially lucrative one. Incidentally, he urges the systematic study of these anomalous reactions.

As an example may be mentioned the well known fact that the accidental introduction of a few drops of mercury into the experimental vessel, in which the preparation of phthalic acid from naphthalene was in progress, rendered the operation and consequently the production of artificial indigo a success.

As a rule the difficulties encountered by the anomalous behaviour of organic compounds are met not by more drastic treatment, but by milder reagents. The whole trend of modern organic synthesis seems to lie in this direction. Thus the caustic alkalis have been replaced in many cases by alcoholic solutions of sodium ethoxide, by diethylamine, pyridine, or chalk, the strong mineral acids by phosphoric, boric, or one of the organic acids. High temperatures have given place to lower ones. The days of so-called "pyrogenic synthesis" are past. No one nowadays makes organic compounds by the aid of a red-hot tube.

In this connection it is suggestive that the fundamental reactions of living matter which embrace oxidation and reduction of a far-reaching kind, as well as synthetic processes more complex than anything achieved in the laboratory, are all effected at ordinary temperatures and with the mildest reagents.

It follows, therefore, that the more closely organic chemists succeed in imitating these conditions the more surely will those mysterious contact or fermentation problems usually associated with living protoplasm, but not unknown in the laboratory, approach solution. J. B. C.

A Further Course of Practical Science. By J. H. Leonard and W. H. Salmon. Pp. ix+224. (London: John Murray, 1904.) Price 2s.

In this book the principles of natural science are taught and enforced in a scientific manner by means of a course of experimental work, simple in character, but involving quantitative measurements, and carried out personally by the student. To begin with, lengths are measured with an ordinary rule, and tests are made in order to find out the limits of accuracy within which the measurements may be relied on. These measurements serve as an introduction to "physical arithmetic," or simple arithmetical computations specially suitable for dealing with numbers which are avowedly only approximately correct. Then follows a chapter on elementary mensuration involving the estimation of angles, lengths, areas, and volumes, the balance very wisely sharing in this work.

Experiments are devised to illustrate some of the fundamental properties of matter, such as those of indestructibility, inertia, porosity, ductility, &c. The next six chapters deal with mechanics, the subjects including uniform linear acceleration, Newton's laws, relative motion, statical equilibrium of uniplanar forces, and simple machines. This difficult section is not treated in a very satisfactory manner. The method is too deductive, the experiments are somewhat scanty and not very well chosen. Thus there is no direct verification of the fundamental principle of the conservation of momentum. Vectors, though introduced, are not made sufficiently prominent, and in the so-called "simple machines" it seems rather antiquated to find the three kinds of levers, the three systems of pulleys, the wedge, &c., introduced.

In the concluding chapters relating to the properties of liquids and gases, and the nature of heat, the authors are happier in their treatment, notwithstanding an occasional looseness in the statement of a principle. The book deserves to be very favourably received, and teachers will find that arrangements have been made to facilitate the purchase of the apparatus necessary for conducting the experiments.

Die drahtlose Telegraphie. By Dr. Gustav Eichhorn. Pp. x+256; numerous figures. (Leipzig: Veit and Co.) Price 5 marks.

This is an elementary exposition of the principles and practice of wireless telegraphy with especial reference to the systems developed by Dr. Braun. It is evidently intended to enable a practical man to become acquainted with this method without, at the same time, any attempt being made to give such a complete account as would warrant its use as a class text-book. By means of the first five chapters a reader who knows a little about the elements of electricity and magnetism will be able to appreciate the nature of electric waves and of Hertz's achievement in producing them. Then, after briefly alluding to the early system of Marconi, the writer passes on to the particular devices of Dr. Braun. The book is well and clearly written, but is in no sense a complete compendium on the subject, and the reader who derives all his knowledge from it will be inclined to think that there is only one system in the world, and that Eichhorn is its prophet. More recent methods of detecting waves by means of effects arising from hysteresis in iron are dismissed in a couple of pages, where there is no reference to Rutherford's early detector working on the same principle, while Lodge's steel-mercury-contact detector does not appear even to be mentioned, although the "Literature" appendix at the end includes the year 1903. In appendix ii. the Thomson-Kirchhoff theory of the oscillatory discharge of a condenser is given; the credit, of course, belongs to Thomson (Lord Kelvin).

Notes on the Natural History of the Bell Rock. By J. M. Campbell. Pp. xv+112; title-piece. (Edinburgh: David Douglas, 1904.) Price 3*s.* 6*d.* net.

As a record of the various types of aërial and marine life commonly seen by the guardians of the lonely lighthouses of the east coast of Scotland in particular, and of the British coasts in general, these random notes are worthy of all commendation, more especially as they are written by a man who does not appear to have had a scientific training. Mr. Campbell was assistant light-keeper on the Bell Rock for the long period of nine years, and he is therefore well qualified to know all that is to be known with regard to the general habits of the commoner and more conspicuous species frequenting the environment of his station; while a period of such a length is sufficient to include the visits of many of the rarer stragglers. Most or all of the notes, it appears, have been previously published in the local Press of the neighbouring mainland, and they are certainly worthy of rescue from such oblivion. The only point for regret is, perhaps, that the author does not say more about bird migration. Mr. James Murdoch, late secretary to the Board of Northern Lighthouses, has contributed an interesting introduction on lighthouses and lighthouse-men in general.

R. L.

The British Journal Photographic Almanac, 1905. Edited by Thomas Bedding. Pp. 1612. (London: Henry Greenwood and Co., 1904.) Price 1*s.* 6*d.* net.

THIS bulky volume, with its mine of miscellaneous photographic information, is compiled on the same lines as the earlier issues, and will be found to be a necessary adjunct to the studio and library. Among the host of articles in these pages may be mentioned a condensed summary of the story of the *British Journal of Photography* and the almanac which appeared in the jubilee number of the above mentioned journal, and also a selected number of the jubilee articles. Recent novelties in apparatus, &c., by the editor, forms also a conspicuous feature, and represents the progress in this branch of photography. No less important are the practical notes on numerous subjects, the formulæ, tables, list of photographic societies of the United Kingdom, &c., all of which add to the utility of the volume. The full indices to advertisers and contents make a quick reference to any portion of the book quite an easy matter, an important consideration in a book containing 1612 pages. The processed illustrations and woodcuts are as numerous as ever.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Mean Temperatures of High Southern Latitudes.

ON p. 131 of NATURE of December 8, 1904, you give an approximate calculation of the mean temperatures of high southern latitudes, by Mr. Krebs, based upon the observations of the most recent Antarctic expeditions.

For the new edition of my "Lehrbuch der Meteorologie" I have made a similar calculation, and have made use of the observations in order to calculate afresh the mean temperature of the southern hemisphere. My preliminary results are as follows:—

S. latitude	50°	60°	70°	80°
Yearly temperature	5·5	−2·0	−11·5	−19·8 C.
January	8·3	3·2	−0·8	−6·5 ,,
July	2·9	−7·6	−22·2	−31·5 ,,

Mean temperature of both hemispheres:—

	January	July	Year	Annual variation
S. hemisphere	17°·3	10°·3	13°·6	7°·0 C.
N. ,,	8·0	22·5	15·2	14·5 ,,
Whole earth	12·6	16·4	14·4	3·8 ,,

Ferrel and myself formerly determined the mean temperature of the southern hemisphere to be 15° C. (from temperatures up to 55° S. lat.). The new observations in high southern latitudes have now shown that the southern hemisphere is considerably colder than the northern, viz. by about 1°·5 C. The publication of the temperature observations of the *Discovery's* second year will be very important for this question; in my calculations I could only make use of the observations relating to the first year.

Vienna, December 30, 1904. JULIUS HANN.

Reversal of Charge from Electrical Induction Machines.

LAST week, while working with a small Voss machine, I accidentally observed, on stopping the machine, giving about two turns in the wrong direction and then re-starting the machine in the original direction, that the poles had reversed. I repeated the experiment a dozen times, and invariably the reversal occurred. The reversal was observed by examining the spark between the knobs.

I mentioned the fact to Prof. Gray, and we then tried the effect with a vacuum discharge tube connected to the knobs. While the tube was fresh the reversal occurred, but after a little time the reversal occurred but seldom. It was found, however, that if the discharge was made to pass by connecting one terminal of the tube to earth, the other terminal to one pole of the machine, while the second pole of the machine was kept insulated, then the reversal invariably occurred when the procedure mentioned was followed.

We next tried the large Wimshurst machine in the laboratory with the same results. It was noticed, however, when the induction rods were so arranged that the machine excited both ways, that the reversal did not occur.

As I do not remember to have seen the experiment mentioned before, I think it worth directing attention to, as it provides a simple way of getting the discharge to pass in whatever direction it is required.

GEORGE W. WALKER.

Physical Laboratory, The University, Glasgow.

Fishing at Night.

THERE are, as I have explained in the book referred to by "S. W." in NATURE of December 29, 1904 (p. 201), many reasons for night-fishing by our pilchard and other fishing fleets. He quotes one, however, which is quite unsatisfactory, namely, the convenience of catching the morning market. To a few ports this might apply, but as a general rule the fish-train for Billingsgate leaves the coast towns about six or seven in the evening, the fish reaching the central market by van first thing in the morning. The actual reasons for this preference for night-fishing are many. In the case of pilchards taken in drift-nets, the habits of the fish themselves furnish the explanation. In the case of trawlers, the reasons are diverse. In some cases the water is so shallow that the nets would be seen and avoided by the fish in daylight, and this, in fact, is still more the case with the drift-nets. Elsewhere, they trawl at night because they want soles, just as many Plymouth boats trawl by day because their best market is for the rougher kinds of fish. There is no night-trawling in Cornwall by reason of the local regulations, which clear the sea by night of other fishing craft in order that the drifters may work without interruption or risk. F. G. AFLALO.

14 Westover Villas, Bournemouth, Hants.

The Cost of Chemical Synthesis.

IN your review of Prof. Meldola's "Synthesis of Vital Products," your reviewer argues that though certain products, viz. alizarin and indigo, "can be synthesised so cheaply that natural products cannot compete with them in the market"; yet this is of little interest from the biochemical point of view.

May I point out that this argument is even stronger than it seems, for the *cheapness* is quite accidental, and due to the fact that the world requires coal gas, and iron.

If the syntheses above were dependent on anthracene and naphthalene obtained from coal treated strictly *ad hoc* this cheapness would disappear. R. J. FRISWELL.

43-45 Great Tower Street, London, E.C., January 2.

"Bastard" Logwood.

THE Jamaica *Bulletin* of the Department of Agriculture for November, 1904, prints a very interesting article on this subject by B. C. Gruenberg and William Gies, contributed originally to the *Bulletin* of the Torrey Botanical Club.

During the past few years the growers of logwood in Jamaica have been greatly disturbed by an apparent increase on their properties of an unmerchantable variety of the plant known as "bastard" logwood; the exportation of this wood along with real logwood has served to condemn all the logwood from the districts which have shipped it.

"Bastard" logwood differs from the genuine varieties, from the dyer's standpoint, in yielding little or no hæmatoxylin, but instead a yellowish-green pigment which is of no value, and which, when mixed with the commercial extract, reduces the characteristic tinctorial properties. Chips of the "bastard" logwood present a yellow, pale pink, white, or even chocolate coloured surface, instead of the dark red or deep purple bronze-tinted colour of the best logwood. There appears great uncertainty, even when the trees are cut down, as to whether a tree is really a "bastard" tree or not. What is known as a "bastard" tree is frequently dark enough when first cut to lead one to believe that it is a good red-wood tree, but instead of darkening with age it remains the same colour, or becomes lighter rather than darker. "Bastard" wood is not the result of disease or of any lack of vigour; the trees producing it are perfectly healthy and normal.

It is not the result of soil or climatic conditions, since bastard and normal trees are found growing side by side under absolutely identical conditions.

It is not the result of immaturity; aged trees may produce bastard wood.

These facts point to heredity as the probable cause of the trouble, that is, certain trees produce "bastard" wood because they grow from seed of a "bastard" tree; in other words, "bastard" logwood is a variety of *Haematoxylin Campechianum* that normally produces little or no hæmatoxylin. The chemical differences existing among all these logwoods are quantitatively very slight, and there are no striking structural differences among all the varieties of logwood.

There can be no doubt that "bastard" logwood is a distinct variety or subspecies of *Haematoxylin Campechianum*, notwithstanding the slight morphological difference that distinguishes it from the "red" logwood and blue logwood.

The Jamaica *Bulletin* has done good service to the colony in bringing the fact prominently before the planters that the admixture of useless wood which has been the source of unnecessary loss to them may be avoided.

Intelligence of Animals.

THE instance of intelligence in a cat recorded by Mr. T. S. Patterson on p. 201 is not unusual. I have known several cats, all of them males, that were accustomed to rattle the handle or some part of the lock in order to get a door opened. F. J. ALLEN.

Cambridge.

A NEW CONTRIBUTION TO ASSYRIAN HISTORY.[1]

IN a handy little volume, to which we have much pleasure in directing the attention of our readers, Mr. L. W. King, of the British Museum, has published the cuneiform text and a translation of a very important historical Assyrian document, which has been recently exhibited in the Assyrian and Babylonian room in the British Museum. This document is a slab of limestone, about 15½ inches long and 11½ inches wide, which is inscribed with sixty-seven lines of cuneiform text, thirty-seven lines being on the obverse and thirty on the reverse. The writing is in bold, well formed characters, but it seems to have been cut somewhat hurriedly, for the mason was obliged to make nine erasures, and in two passages he has left out a sign, apparently without having detected the omission. We need not discuss the palæographical importance of the text, which is of considerable interest, and it is only necessary to state that it exhibits the style of Assyrian characters employed in monumental inscriptions in the early part of the thirteenth century before Christ.

The contents of the text, which is actually the official summary of the principal events in the reign of Tukulti-Ninib I., King of Assyria about B.C. 1275, fall readily into four divisions, which respectively record the king's name and titles, his military expeditions, the foundation of the city Kar Tukulti-Ninib, and an appeal to future rulers. The stone tablet or slab which supplies this information was either placed in a niche in the wall or laid in a box of stone or clay, and then built up in the foundation of the city Kar Tukulti-Ninib. In passing, Mr. King discusses briefly but clearly the question of foundation deposits, both in Egypt and Assyria, and shows how the ideas concerning them in the two countries agree in some respects and differ in others.

Turning now to the campaigns of Tukulti-Ninib I., we find that in the first he conquered the Kuti and the inhabitants of four other districts; in the second he became master of the land of Shubari, and ten other provinces; in the third he vanquished forty kings of the land of Na'iri; and in the fourth he defeated Bibeashu, King of Babylon, and completely subjugated the regions of Sumer and Accad. The last campaign was undoubtedly the most important of all, for with

[1] "Records of the Reign of Tukulti-Ninib I., King of Assyria, about B.C. 1275." By L. W. King, M.A., F.S.A. Pp. xvi+185, and 11 illustrations. (London: Luzac and Co., 1904.) Price 6s. net.

the fall of Babylon Tukulti-Ninib became master of all Mesopotamia. The resistance offered by the Babylonians was stubborn in the extreme, and the Assyrian king slew large numbers of them and destroyed their city wall. Tukulti-Ninib looted the city and plundered the treasuries of E-sagil, the great temple of Marduk, and he carried off to Assyria not only Bibeashu himself, but the statue of his god Marduk. No victory could have been more complete, and even at this distance of time it is impossible not to feel some sympathy with the vanquished Babylonian king when we read that he, a prisoner and bound in chains, was led, with his god Marduk, into the presence of Ashur, the great god of Assyria, as witnesses of the comprehensive manner in which Tukulti-Ninib had performed Ashur's commands.

The account of the conquest of Bibeashu and of the capture of Babylon by Tukulti-Ninib is especially important from a chronological point of view, for it establishes beyond a doubt the fact that these two kings were contemporaneous. For some time past it has been known from the "Babylonian Chronicle" that Tukulti-Ninib conquered Babylonia, but the name of the Babylonian king, although it occurs on this document, was not recognised. Both Mr. Pinches, who published a translation of this "Chronicle," and Dr. Winckler, who published a copy of the text, misread the passage in which the name occurs. The identification of Bibeashu and the correct reading of his name we owe to Mr. King, who has succeeded in establishing a new and very important synchronism in Assyrian and Babylonian history. Thus the system of chronology which made Bibeashu to live sixty or seventy years after Tukulti-Ninib I. is proved to be incorrect.

In connection with the conquest of Babylon by Tukulti-Ninib I., mention must here be made of the copy of an inscription which is found on a small clay tablet (K. 2673), now in the British Museum. This copy was made from a lapis-lazuli seal, on which the original inscription was engraved by a scribe of Sennacherib, who caused some lines to be added to commemorate his conquest of Babylon and the recovery of the seal by himself. The lapis-lazuli seal, as Mr. King tells us, was not made for Tukulti-Ninib I., as was once generally thought, but for Shagarakti-Shuriash, a Kassite king. When Tukulti-Ninib captured Babylon he found the seal there, and carried it off to Nineveh, and he had his own inscription engraved upon it without erasing that of Shagarakti-Shuriash. The seal was subsequently, in circumstances unknown to us, carried back to Babylon, where Sennacherib found it about 600 years later, and he, of course, restored it to Nineveh, and, having added his own inscription to it, had a copy of the inscription of the Kassite king, that of the King of Assyria, and of his own made on a tablet. The first to translate the copy of Tukulti-Ninib's inscription on the tablet was Mr. George Smith, but that of Shagarakti-Shuriash baffled him, and he failed to read the characters of which it was composed. Profs. Hommel, Bezold, and Schrader were likewise unable to translate it, and Mr. King has been the first to prove that, in addition to the words added to the seal by the order of Sennacherib, the copy contains two distinct inscriptions, namely, one of Shagarakti-Shuriash and one of Tukulti-Ninib I. The copy of Sennacherib's inscription is very important, for it enables us to assign the date of Tukulti-Ninib's reign provisionally to about B.C. 1275; its length cannot at present be stated with exactness.

In addition to the interesting text of Tukulti-Ninib, of which a general summary has been given above, Mr. King adds the inscriptions of Shalmaneser I. from the fragments of inscribed bowls now in the British Museum, a passage from the synchronous history, the inscriptions from the lapis-lazuli seal of Shagarakti-Shuriash, and Sennacherib's accounts of his capture of Babylon both in 702 B.C. and 689 B.C.; in fact, every bit of evidence which relates to the period of which his book treats, and is found in the cuneiform inscriptions, is appended for the assistance of the reader, with full transliterations and translations. That Mr. King has published not only a new, but important historical inscription is clear, and all who are in any way familiar with the subject will find his sober and concise observations on its contents helpful and stimulating. Messrs. Harrison's large cuneiform type has been used for printing the text, and paper and binding leave nothing to be desired. We note that the volume is the first of a series of "Studies in Eastern History" which Luzac and Co. are about to publish, and we feel that if the succeeding volumes are as valuable as the "Records of the Reign of Tukulti-Ninib I." the success of the undertaking is assured.

SEISMOLOGY IN JAPAN.

UNDER the title of "Recent Seismological Investigations in Japan," Baron Dairoku Kikuchi, former Minister of Education, has issued for private circulation only an "address" prepared for the late exposition in St. Louis. When we look at this address, which is a quarto volume of 136 pages filled with illustrations, we feel that its author should have doffed his modesty and called it seismology as developed in Japan. To describe the work more closely, we shall not be far from the mark if we say it is an epitomised translation of a number of publications which to Europeans have hitherto been cryptogramic. It gives us not only a *résumé* of sixteen numbers of the publications of the Tokyo Earthquake Investigation Committee—called for short the E. I. C.—which have been published in a European language, and with which we are more or less familiar, but there is added an abstract of forty-seven numbers or volumes published in Chinese idiographs. Many seismologists have looked at them and wondered what they meant. The contents of these sixty-three publications have been epitomised, mixed, and systematised.

FIG. 1.—Model of a Farmer's Cottage. Showing the essential points of construction recommended by the Earthquake Investigation Committee. The chief points to be observed are diagonal bracing, the use of iron straps, and the avoidance of mortices and other cuts at joints.

After an introduction to the "recent" investigations, which tell us that the first earthquake recorded in Japan was in A.D. 416, and reference to various investigations made by Europeans in Japan, we are introduced to the system under which investigations and their results have been classified and discussed.

Under the heading "Statistical" we find data relating to the distribution of earthquakes in space and time, their relation to meteorological conditions, and various phenomena. Earthquakes which have a submarine origin are most frequent in summer, when the level of the Pacific Ocean bordering Japan is higher than in winter. Those originating on the land are most frequent in winter, at which season barometric pressure is at a maximum. Out of forty-seven destructive earthquakes which originated beneath the Pacific, twenty-three were accompanied by *tsunami* or sea waves, which probably means that on these occasions marked and sudden changes had taken place in the configuration of the sea bed.

Among the instruments which are described we notice a horizontal pendulum the bob of which is controlled by a small inverted pendulum. Although the vertical and horizontal dimensions of this apparatus are each only 1 metre, Prof. Omori tells us that a period of one minute can be obtained without difficulty. Macroseismic motion is described, and after this reference is made to microseisms or pulsations. These two classes of movement Prof. Omori finds alternate in their frequency, so that when the small movements are at a minimum the larger ones may be expected. This observation, we learn, has enabled him on several occasions to predict within ten or twelve hours the occurrence of an earthquake.

The geological investigations which have been made chiefly refer to the survey of volcanoes, which is a work outside that done by the Geological Survey.

The investigations of relationships that may exist between earthquakes and various physical phenomena which affect or are affected by strain in the earth's crust are particularly interesting. At present continuous magnetic observations are being made in Japan at five stations, from which, amongst other things, it has been observed that on several occasions magnetic

FIG. 2.—Nagoya Spinning Mill. Showing the effects of the Mino-Owari Earthquake of 1901 on a brick building and on a chimney constructed according to European practice.

needles have been disturbed before or at the time of large earthquakes. Speaking generally about these investigations, Baron Kikuchi considers that they promise to throw light upon the state of underground stress, and as one of the chief objects of the E. I. C. is to devise means to predict earthquakes which may be taken as announcements that stress has been relieved, it will be recognised that the inquiries relating to local magnetic disturbance are of a promising nature.

Other phenomena which receive attention are variations in latitude, the determination of gravity, underground temperatures, *seiches*, changes in the level of water in wells, and the elastic constants of rocks.

The last section of this interesting volume is an account of investigations which have been made with the object of reducing the disastrous effects of earthquakes to a minimum. To the practical person this is no doubt the most important branch of all seismological research. Already it has accomplished much, and after a severe shaking we have learned that in Japan new types of structures are to be seen standing amongst the ruins of older types.

We welcome Baron Kikuchi's volume, and trust that although its circulation is private it may also be wide.

THE FOUNDER OF AUSTRALIAN ANTHROPOLOGY.[1]

DR. A. W. HOWITT is our highest authority on the native tribes of Australia. Ever since the publication of "Kamilaroi and Kurnai," in 1880, he has been adding to our knowledge of the most instructive and interesting aboriginal population in the world. The present work, therefore, which summarises the data collected by him during forty years of personal intercourse with the "blackfellows," is of the greatest importance. Most of the material here incorporated was written up before 1889; a few modifications of theory and many new facts have been introduced, and some corrections made, but the broad deductions remain unaltered.

The main body of the work is preceded by a useful summary and criticism of the principal views that have been put forward as to the origin and ethnological affinities of the Tasmanian-Australian stock; Dr. Howitt rejects both the Dravidian and the Malayan hypotheses. The tribes here dealt with came into contact with the white man at a date too early, perhaps, to allow them much chance of survival; many of them are now practically extinct, and most of them are at least deorganised. The area they occupied is about one-quarter of the continent, extending on the north to near the tropic of Capricorn, and on the south bordered by the Southern and Pacific Oceans, connected by Bass Strait. This area has a wide range of climate and temperature, and the tribes themselves present almost every variety of social organisation, from that of the Dieri and central districts through the ordinary Australian types to the unique system of the Kurnai in Gippsland. Excellent maps, very numerous and complete, illustrate both the tribal areas and the range of the various social systems.

In this matter of organisation Dr. Howitt traces the gradations in a way conclusive enough to point to the probable course of evolution. In particular he reduces the problem of exogamy to the bisection of the community into two exogamous intermarrying moieties—the typical Australian system—which bisection is based, as he implies, on the prohibition of marriage between brothers and sisters. It is to be regretted that he does not fully discuss this ground of exogamy. He quotes Dr. Frazer and the present writer as having independently reached the same conclusion, and it seems that we are at last approaching unanimity as to this primal law of human social relations. He

Fig. 1.—One of the Krauatungalung Clan of the Kurnai Tribe. From Howitt's "The Native Tribes of South-East Australia."

agrees with Spencer and Gillen that the primary functions of totemism were in existence before exogamy became established, and that the relation between totemism and exogamy is secondary only. On the other hand he sees no reason to modify his original view that the bisection was a reformatory measure, instituted after a long reign of the "Undivided Commune." It is doubtless impossible to deny some purposiveness to the innovation, if innovation it was; Mr. Lang is here inclined to agree. But to engineer such bisection in a large undivided commune seems beyond the powers even of primitive man. A shorter way may be easily suggested:—the moieties practically correspond to two groups of intermarrying relatives; we may suppose, then, to begin with, two small families or fire circles, A and B, making inter-

marriage, and continuing to do so in successive generations. Now here we have in A and B not only the two moieties of the future tribe, but the tribe itself, in the making. The bisection *grew* out of a quasi-purposive exogamous instinct against marriage within the fire-circle.

There seems to be nothing against Aristotle's view that the tribe grew out of the family, except the curious but fashionable prejudice in favour of an organisation for primitive man of the baboon type. Mr. Atkinson in a remarkable paper has dealt the latest and one of the shrewdest blows at this prejudice, and doubtless anthropologists may in time revert to Darwin's suggestion that the earliest form of the human family resembled rather that of the unsocial anthropoids, such as the gorilla. It is noteworthy that Dr. Howitt modifies considerably the earlier conception of the Undivided Commune, and regards it as having been originally something like "what occurs when the modified Communes of the Lake Eyre tribes reunite." The battleground of the two schools is, of

FIG. 2.—The *Bret* or Dead Hand. From Howitt's "The Native Tribes of South-East Australia."

course, the so-called group-marriage of the tribes last named. In this connection the author does good service by putting together a full and revised account of the Dieri marriage-system, with its *Tippa-malku* or individual marriage, and its *Pirrauru* or group-union. We are thus enabled with some certainty of data to compare the notorious Urabunna and Arunta systems. But when Dr. Howitt says, "the germ of individual marriage may be seen in the Dieri practice; for as I shall show later on, a woman becomes a *Tippa-malku* wife before she becomes a *Pirrauru* or group-wife" (p. 179), the logic strikes one as curious. The inference should surely be that the group-marriage has been evolved from the individual system, and not the other way about.

The author still regards the practice, as amongst the Wiimbaio, of exchanging wives on the approach of a pestilence, as a survival of group-marriage, and the right of access as a survival of the *jus primae noctis* and an "expiation" for individual marriage. One had thought that these two last categories had been relegated to the limbo of outworn fictions anthropological. Noticeable details are that the action of jealousy is very strong in the Dieri tribe; that, as the Rev. O. Siebert puts it, "the practice of *Pirrauru* is worthy of praise for its strength and earnestness in regard to morality, and in the ceremonial with which it is regulated, since no practice could be less in accord with the hetairism which Lord Avebury has imagined for the Australian aborigines" (p. 186).

It is disappointing to find that no mention is made of Cunow's theory of the four and eight subclasses; it would have been instructive to see what light an unrivalled personal knowledge of the system and an acquaintance, doubtless extensive, with the dialects might have thrown on the view that these classes are age-divisions, and have primarily nothing to do with marriage-restrictions. The Kurnai with their totems which do not affect marriage, and their local, not class-divisions, present a fascinating problem, and no one knows more about the Kurnai than does Dr. Howitt. Their marriage by elopement, and the systematic use therein of priestly assistance, are remarkable customs. "It was the business of the *Bunjil-yenjin* to aid the elopement of young couples. For instance, when a young man wanted a wife, and had fixed his mind on some girl, whom he could not obtain from her parents, he must either go without her, persuade her to run off with him, or call in the aid of the *Bunjil-yenjin*. In the latter case his services were retained by presents of weapons, skin-rugs, or other articles." The *Bunjil-yenjin* then sang a magic song until he thought his magic strong enough to secure the "covering up" of the parents in a state of coma.

The author in a very interesting essay applies the facts of "maternal descent" to the Teutonic Salic Laws. Among the more important features of the book is the masterly and final settlement of the vexed questions of the native headmen, and the belief in supreme beings, like *Daramulun*. The connection between the two questions is that the headman in the sky is the analogue of the headman of the tribe on the earth. Among the Kurnai—to note another difference between many of the south-eastern tribes and those studied by Spencer and Gillen—the knowledge of *Mungan-ngaua* is confined to the initiated men, who impart it in all sincerity to their novices; the Arunta, as Spencer and Gillen inform us, take this opportunity of explaining their deity away as a being only believed in by women and children. Among further details of interest are the Kurnai custom of the Dead Hand, the performance of the Indian Rope Trick by Kurnai medicine-men, the magical influence which exists between opposite sexes, and the belief that the initiated elders infuse their own magical power into boys at confirmation.

The book is a fitting crown to Dr. Howitt's labours, and is, in effect, the most considerable and important of all studies of the Australian race.

A. ERNEST CRAWLEY.

CHANGES UPON THE MOON'S SURFACE.

UNTIL within the last few years there has been a very general opinion that the moon was a cold, dead world, or, as it has been sometimes expressed, a burned out cinder, upon which nothing ever happened. This view was apparently due to the fact that the men who wrote the text-books on astronomy were not the men who studied the moon. Among the selenographers themselves, those astronomers who made a special study of the moon, there is not one, so far as the writer is aware, who has not expressed his belief that changes of some sort, volcanic or otherwise, occasionally occur upon our satellite. Reference is made to such men as Mädler, Schmidt, Webb, Elger, and Nieson.

As the result of his lunar observations in Peru, Jamaica, and California, the writer has come to the conclusion that physical changes do occur upon the moon, and that they may be classified under three heads, those due to volcanic action, those due to the formation and melting of hoar frost, and those due to vegetation.

In the first class the classical example is that of Linné, which, according to the measurements of Lohrmann, Mädler, and Schmidt, prior to 1843, had a diameter of between four and seven miles. Its diameter at present is three-quarters of a mile. A few years ago a new crater was announced by Klein in the vicinity of Hyginus. The writer is not sufficiently familiar with this region to speak from personal experience, having but a few sketches of it, but he believes that a change there of some sort is generally admitted by selenographers.

Perhaps no area of its size upon the moon has been so thoroughly examined as the floor of Plato. It has been studied at intervals of about eleven years, first in 1870 by a committee of the British Association, next by A. S. Williams and others in 1881, and again a few years later, then by the writer at Arequipa in 1892, and again this past summer in California. In each survey about forty craterlets have been mapped, and each time some new ones have been discovered, while at the same time a few of those previously observed had ceased to be visible. The original trigonometrical survey of 1870 was based upon four craterlets located near the centre of the floor, and selected as primary stations. The easternmost of these was last seen as a crater in 1888. A trace of it was suspected in 1892, but a search for it this past summer with a 16-inch telescope working under most favourable climatic conditions failed to reveal any trace of it whatever. Even the large white area upon the floor which formerly marked its position has partially disappeared.

A map of the floor of Plato, based on a survey made in 1892, is given in the Harvard *Annals* (xxxii., plate x.). On this map the craterlet numbered 3 corresponds to craterlet number 22 of the older surveys. This craterlet was tenth in order of conspicuousness in 1870. In 1881 it had risen to the seventh place. In 1892, although carefully looked for, it could not be found, and it was entered on the map as a missing crater. A study of this region during the past summer revealed the presence of what appeared to be a large crescent-shaped bank of sand, six miles in length by from one to two miles in breadth. Its height was computed at not far from 1000 feet. It is the only object of the sort upon the floor, and the writer has so far found no previous record of its existence. When the sun is setting upon Plato it is by far the most conspicuous object within the crater walls, and was readily revealed by a 6-inch objective in Cambridge, Mass., working under very unfavourable atmospheric conditions. At sunrise it was also in part seen without difficulty under fair conditions. It seems incredible that so conspicuous an object as this should have been overlooked by all the earlier observers, had it then been visible.

I accordingly wrote to Mr. Williams, and he kindly sent me a list of forty-two observations made during the years 1879 to 1890, dealing with the particular portion of the crater floor where this formation was situated. Five of these observations were made during that portion of the lunar day when the object is now conspicuous, and when it is much more so than any of the craterlets upon the floor. Three of Mr. Williams's observations record that nothing was visible upon this portion of the floor. One observation records two small white spots, one of which he thinks may have been the original crater, and the other is possibly a neighbouring hill. Both of them as shown by this sketch were evidently very small objects as compared to the present formation. The fifth observation records a bright streak passing through the spot in question and extending for about thirty miles across the floor. Evidently if the present sandbank had been in existence at that time Mr. Williams could not have failed to have seen it and recorded it upon his sketches. Between this sand heap and the crater wall a large craterlet now exists. It is, in fact, the largest upon the floor, measuring about two miles in diameter, but owing to its peculiar position, and also to the fact that it is never bright like most of the others, it can only be seen at lunar sunset, and even then is not conspicuous.

Turning now to the second class of physical changes visible upon the moon, those due to the formation and disappearance of hoar frost, we find numberless examples scattered over the surface, but in most cases favourable atmospheric conditions and a large glass are necessary to render them clearly visible. Before dealing with any specific cases, however, it may be well to endeavour to answer some of the objections raised on theoretical grounds to the possibility of the existence of water vapour upon the moon.

The writer believes that he himself was one of the first to point out that if water vapour existed upon the lunar surface, it must sooner or later be dissipated into outer space (*Astronomy and Astrophysics*, 1892, xi., p. 781). That such a dissipation must have been going on in times past seems to be inevitable, but before reaching a conclusion as to the present existence of water vapour upon the moon, there are one or two important considerations that must be taken into account.

Vulcanologists are now generally agreed that the vast quantity of water, amounting to thousands, and sometimes to millions of tons, given off during volcanic eruptions is not rain water, nor yet water that has reached the interior from the ocean, but is water that either is being expelled for the first time from the earth's interior or is being expelled by heat from the rocky materials of the earth's crust with which it was previously united by the forces of crystallisation. If the earth is still discharging such large quantities of water from its interior there is no reason why the moon should not be doing the same thing. It is true the moon is smaller, but then also it began life later than the earth. The reason why the earth has oceans is that it is large enough and massive enough to retain the expelled water in that form. The moon, on the other hand, is too small to do so, and the water therefore appears scattered widely over its surface in the form of hoar frost before being dissipated into outer space.

Another objection to the theory of the existence of water vapour that has been raised is the statement that there is no evidence of erosion upon the moon. This statement is clearly a mistake, but the eroded valleys are small, and it requires good atmospheric conditions to detect them. Fairly conspicuous examples, however, exist upon the central peaks of Theophilus and Eratosthenes. Although the valleys are small, it is hard to understand how the comparatively minute amount of hoar frost at present found in these regions could have produced so great an effect, and we must conclude that formerly there must have been a great deal more of it. The only strong evidence that water in the liquid state ever existed upon the surface of the moon lies in the dry river-beds. The best example of these lies on the eastern slopes of Mt. Hadley, at the base of the Apennines. Another river-bed, partially fragmentary, discovered this past summer lies sixty miles due south of Conon. Although difficult objects, the former has been seen in Cambridge, Mass. A sketch of it is given in the Harvard *Annals*, xxxii., plate vii.

Turning now from theory to fact, one of the clearest evidences of hoar frost upon the moon is found in connection with the pair of small craters known as Messier and Messier *A*. Sometimes one of these craters is the larger and sometimes the other. Sometimes they are triangular and sometimes elliptical in shape. When elliptical their major axes are sometimes parallel and sometimes nearly perpendicular to one another. When the sun first rises on them they are of about the same brilliancy as the *mare* upon which they are situated, but three days later they both suddenly turn white, and remain so until the end of the lunation. When first seen the white areas are comparatively large, especially that surrounding Messier itself, but it gradually diminishes in size under the sun's rays. By the eighth day little is left outside the crater itself, while at the end of the lunation only the bottoms and interior western walls remain brilliant. The general character of these changes can be followed even with a 4-inch telescope working under only moderate atmospheric conditions. Photographs of these craters showing their varying shapes and sizes will be found in the Harvard *Annals* (li., p. 28). Those to whom the *Annals* are not accessible will find these photographs and most of the other illustrations referred to in this article in my book "The Moon."

FIG. 1.—1901, July 26, 2·6 days, 43°.

FIG. 2.—1901, March 31, 3·5 days, 54°.

The white area surrounding Linné also shows evidence of change in size during the lunation. Soon after sunrise it measures 4″ in diameter, at noon 2″, and at sunset 3″·5. The change is evidently analogous to that shown by the polar caps of the earth and Mars, lunar noon in this case corresponding to midsummer for the planets, and sunrise and sunset to spring and autumn.

In the crater Eratosthenes there is a brilliant white area on the summit of the central mountain range. When the sun first rises on it it measures five miles in length by two in breadth. It soon, however, begins to dwindle, and two and a half days later all is gone save two little spots, each about a mile in diameter. They reach their minimum size five days after sunrise, when the smaller is about half a mile in diameter. They then begin to increase, the northern one attaining a length of five miles shortly before sunset. If these markings are due to white quartz, or some similar rock, it is difficult to account for their change in size.

The third class of physical changes with which we shall deal the writer believes to be due to the presence of vegetation. Changes of this class are more conspicuous than those of either of the other two, and if the explanation of vegetation is admitted, both the other explanations almost necessarily follow. It is therefore important to study these changes with the greatest care.

Before describing the facts, it may be well first to deal with the principal objection that has been made to the suggested explanation, namely, the lack of water on the moon in the liquid form. The reason that we believe liquid water to be lacking is that it is known that as we reduce the atmospheric pressure the boiling point of water is gradually lowered, until when we reach a pressure of 4·6 millimetres the boiling and freezing points coincide. Below this pressure ice changes at once into the gaseous form without passing through the liquid state. While, therefore, there can be no free water upon the surface of the moon, there is yet nothing to prevent it from occurring beneath the surface of the ground, retained by the capillary action of the soil. This action is so strong that, as has recently been shown by Cameron (*Science*, 1903, xviii., p. 758), it is capable of extracting water from a membrane against a calculated osmotic pressure of 36 atmospheres.

Since on the earth plants can live on moisture which they have in turn extracted from such a soil, there seems to be no difficulty in understanding how they could live on the moon, in a soil which could thus retain considerable moisture in spite of the low atmospheric pressure. Although in a state of nature, even in desert regions, all plants are occasionally exposed to water in the form of rain or dew, yet under artificial conditions we know that even such highly organised structures as house plants can flourish on water that in the liquid form reaches them only by capillary absorption from the soil.

Turning now to our observations, as early as 1837 it was pointed out by Mädler that there were two small spots in the crater Alphonsus which always became very dark at about the time of full moon, while earlier and later they were much lighter. A similar observation had been made by him regarding a region just to the south of the Mare Crisium. Little else was known regarding the matter until 1892. Since that date spots presenting these characteristics have been found all over the moon's surface, except in the vicinity of the poles. The most northern spot known is in latitude +55°, the most southern in latitude −60°. It is possible that some of the *maria,* notably Tranquillitatis, and part of the borders of Serenitatis and Vaporum, are covered with these spots, but in any case they do not cover more than 5 per cent. of the moon's visible surface, and possibly it is very much less.

It should be mentioned here that the western spot shown by Mädler in Alphonsus is now comparatively inconspicuous, but that north and south of it lie two others, which with Mädler's eastern spot form a very striking isosceles triangle at full moon.

We will now direct our attention to the crater Eratosthenes, which has been more carefully studied than any other region presenting these phenomena, and which exhibits the changes on a sufficiently large scale to enable us to make use of photography. The four photographs here shown were taken in the Island of Jamaica in 1901, and are enlargements from some of the negatives used in printing the Harvard "Atlas of the Moon." Beneath each figure is given the date on which it was taken, the number of terrestrial days that had elapsed since the sun rose upon it, and the colongitude of the sun, taken from Crommelin's ephemeris. The photographs are all on the same scale of 1/2,000,000, or about thirty-two miles to the inch. Upon this scale the moon would be 68.5 inches in diameter.

When the sun rises upon this formation the whole of the floor is at first of a light grey tint, whatever detail there is being but faintly marked. This tint is maintained by the south-western quadrant of the floor throughout the lunation. About three days after sunrise a dark spot appears on the north-western slopes of the central mountain range. The regions at its immediate base darken at about the same time, and an irregularly mottled dark sector appears as the result. On the fourth day the centre of the sector lightens, leaving two canal-like forms radiating from the central peaks. Although in a small telescope these canals appear straight, yet when well seen with a large glass they are found to present considerable irregularity of structure. On the eleventh day the southern one fades out, and just before sunset the northern one also disappears.

A faint X-shaped marking distinguishes the north-eastern quadrant of the floor at sunrise. The centre rapidly darkens as the sun rises upon it, and soon becomes intensely black. Three branches of the X successively fade away, leaving only the south-eastern one, which on the seventh day becomes very pronounced. A new branch or canal forms by gradual darkening on the east, while the canal on the north-east, which had disappeared, forms anew by a progressive growth downwards from the crater rim. This growth progresses for five days at a nearly uniform rate of 250 feet per hour, or about 4 feet a minute.

FIG. 3.—1901, April 2, 5·6 days, 79°.

FIG. 4.—1901, March 5, 7·0 days, 97°.

The south-eastern quadrant, while very light at first, soon surpasses all the others in darkness. The dark area on the outer wall, which in the first figure is undoubtedly in part due to shadow, must very soon be partly due also to something else, for it still shows upon the third figure, which was taken but 0.8 day before full moon, when shadows are geometrically impossible. The last figure was taken 0.8 day after full moon, and the darker portion of the spot is seen to have rapidly increased in size and to have grown downwards with considerable velocity towards the central peaks.

Since this dark area cannot be shadow, our only alternative seems to be that we have here a real change in the character and brightness of the lunar surface. Since we do not know of any mineral which gradually darkens as the sun shines upon it, and later fades out again, our only alternative seems to be to call in the aid of vegetation. At all events nobody has ever cared to propose any other explanation of the facts, so far as the writer is aware.

As the lunation progresses the western portion of this dark area slowly fades out, while the eastern is absorbed in the gathering shadows of the lunar night.

In various parts of the crater, but especially in the south-eastern and northern portions, numerous small canals and lakes present themselves. These markings are practically identical in appearance with those seen upon the planet Mars. They are too small to be well shown in the photographs, and seem to be of much more regular structure than the larger markings, which are here also called canals. It is possible that this difference is due merely to the fact that the larger markings are better seen. A more detailed account of the phenomena here described will be found in the Harvard *Annals* (liii.).

WILLIAM H. PICKERING.

SIR LOWTHIAN BELL, BART., F.R.S.

SIR Lowthian Bell, whose death at the age of eighty-eight has already been announced, studied physical science at the University of Edinburgh and the Sorbonne at Paris, and at the age of twenty-four entered the Walker ironworks, near Newcastle. There, we learn from the obituary notice in the *Times*, he remained until 1850, when he became connected with the chemical works at Washington, in North Durham. He greatly enlarged the works and laid down extensive plant for the manufacture of an oxychloride of lead introduced as a substitute for white lead by his father-in-law, Mr. H. L. Pattinson, F.R.S., with whom he was associated in the business at Washington. There, too, was introduced in 1860 almost the first plant in England for the manufacture of aluminium by the Deville sodium process.

Soon after the discovery of the main bed of Cleveland ironstone near Middlesbrough, Sir Lowthian Bell, in conjunction with his brothers, Thomas and John, started ironworks in 1852 at Port Clarence, on the north bank of the Tees. The Clarence works was one of the earliest and is now one of the largest iron-smelting works on the Tees. About half a century ago the Tees then flooded ground where iron furnaces now stand. Sir Lowthian Bell and his brothers acquired their own ironstone mines, collieries, and limestone quarries, while they were always prompt to adopt any improvement in process or apparatus that seemed likely to be advantageous.

In the development of the Cleveland iron industry the Bell firm played a very important part, and what has been the extent of that development may be judged from the fact that whereas the district in 1850 produced less than 25,000 tons of pig iron, at the present time Middlesbrough produces about one-quarter of the total output of this country. The firm was active in prosecuting those technical studies by which processes have been devised enabling Cleveland ores to compete as raw material for the production of iron and steel with others possessing greater natural advantages. In regard to steel, the great trouble with those ores is the high percentage of phosphorus (1.8 to 2.0 per cent.) contained in the cast iron which they yield; yet Middlesbrough, largely as a result of experiments carried on under Sir Lowthian Bell's direction, at a cost, it is said, of between 40,000*l.* and 50,000*l.*, produces steel rails in which this percentage is reduced to 0.07 or less.

When the British Association met at Newcastle in 1863, Sir Lowthian Bell contributed a paper on the manufacture of iron in connection with the Northumberland and Durham coalfields. In 1870 he wrote a paper on the sanitary condition of Newcastle, and more recently he compiled an elaborate account of the iron trade of the United Kingdom, compared with that of the other chief iron-making countries. On the chemistry of iron he was a high authority. The establishment of a chemical laboratory in connection with the Clarence works shows how fully he realised the importance of the scientific study of industrial processes, and his own researches on the chemistry of iron and steel have become classic. Many of these appeared first in the form of papers read before the Iron and Steel Institute, and a number of them were subsequently collected and published in a volume entitled "The Chemical Phenomena of Iron Smelting." Sir Lowthian was also the author of a book on the "Principles of the Manufacture of Iron and Steel," as well as of many papers contributed to other scientific societies.

He was one of the original founders, in 1869, of the Iron and Steel Institute, and filled the office of president from 1873 to 1875, and in 1874 became the first recipient of the gold medal instituted by Sir Henry Bessemer the year before. He was a member of the Institution of Civil Engineers and of the Chemical Society, and a past president of the Institution of Mechanical Engineers. In 1874 he was elected a fellow of the Royal Society. In recognition of his services as juror of the international exhibitions at Philadelphia in 1876, and at Paris in 1878, he was elected an honorary member of the American Philosophical Institution, and an Officer of the Legion of Honour. He was elected on the council of the Society of Arts in 1876, and in 1895 was awarded the Albert medal of the society "in recognition of the services he has rendered to arts, manufactures, and commerce by his metallurgical researches, and the resulting development of the iron and steel industries." The honour of a baronetcy was conferred on him in 1885, and in 1893 he received the degree of LL.D. from Edinburgh University.

NOTES.

A SELECTION from the specimens recently presented to the British (Natural History) Museum by His Majesty the King of Portugal has recently been placed on public exhibition in the north hall.

THE annual meetings of the American Association for the Advancement of Science and of the American Physical Society were held in Philadelphia, Pa., in "Convocation Week," from December 26, 1904, to January 2.

THE International Botanical Congress will meet at Vienna in June next, when a discussion will take place on the important question of uniformity of nomenclature, regarded both from a scientific point of view and in connection with international reports.

UNDER the title "Lichtenstein Prize," the Montpellier Academy of Sciences offers a prize for the best essay dealing with any question of zoology not referring to man. The last day is November 1, 1905. Printed memoirs more than three years old, or papers which have gained previous prizes, are excluded.

THE third International Congress of Philosophy will be held at Heidelberg in 1908. Among the English speaking members of the organising commission the name has been added of Prof. Strong, of Columbia University. A detailed account of the congress held this year at Geneva is given in a special number of the *Revue de Métaphysique et de Morale* for November, 1904.

The Postmaster-General has made provisional arrangements with the Marconi International Marine Communication Company for the acceptance and prepayment at telegraph offices in the United Kingdom of telegrams for transmission from wireless stations on the coast to ships at sea. The arrangement came into operation on January 1.

Prof. R. S. Woodward, dean of the faculty of pure science, Columbia University, has been elected president of the Carnegie Institution. Prof. C. A. Young, who has held the chair of astronomy at Princeton University since 1877, will retire at the close of the present academic year.

Captain R. F. Scott, leader of the National Antarctic Expedition, has been awarded a gold medal by the Royal Danish Geographical Society.

We learn through *Science* that Mr. Andrew Carnegie has given 108,000*l.* for the establishment in Boston of an institute similar to Cooper Institute, which is to be added to a fund of 54,000*l.*, which has grown from 1000*l.* left one hundred years ago by Benjamin Franklin.

The twenty-second annual dinner of the old students of the Royal School of Mines will be held on Thursday, February 9. The chair will be taken by Mr. T. A. Rickard. Applications for tickets should be made to Mr. D. A. Louis, 77 Shirland Gardens, London, W.

A correspondent of the *Times* states that Frédéric Mistral, the Provençal poet recently awarded 2000*l.* as half share of the Nobel prize for literature, intends to devote this sum to the development and adequate installation of the ethnographical museum—Le Musée Arletan—founded by him some years ago at Arles. For this purpose the municipal authorities agree to make over an old palace, now used as a college, the restoration and adaptation of which will cost 10,000*l.* An American resident at Avignon, Mr. Edward Leon, has offered 2000*l.* as a subscription, and will arrange for five lectures in the United States to help on the fund thus inaugurated.

The prizes for the year 1904 have been awarded, we learn from *La Nature*, by the Paris Society for the Encouragement of National Industry. The grand prix of the Marquis d'Argenteuil has been awarded to MM. Auguste and Louis Lumière for their discoveries in photography. The "chemical arts" gold medal has been awarded to M. Héroult for his works on electrometallurgy, and the "constructions and fine arts" medal to M. Arnodin. Gold medals have also been awarded to M. Boulanger for his micrographic work, to M. Grey for a rolling-mill, to M. Guillet for his work in metallurgy, and to M. Schwœrer for his system of superheated steam.

An optical convention will be held, under the presidency of Dr. R. T. Glazebrook, F.R.S., at a date toward the end of May next, at the Northampton Institute, Clerkenwell, London, E.C. The object of the convention is to bring into cooperation men interested in optical matters. A subcommittee has been appointed to consider the subjects of papers on optical questions which should be brought before the convention, and suggestions as to subjects for discussion will be welcomed. It has been decided to organise an exhibition, of a scientific character, of instruments manufactured in this country, with a view to show the progress recently made and to stimulate further efforts. In order that interest in the convention may be not confined to London workers in optics, a subcommittee is being formed to secure the assistance of local representatives. The honorary secretary of the convention is Mr. F. J. Selby, Elm Lodge, Teddington.

Writing on the subject of "Greek at Oxford," a correspondent of the *Times* again expressed the common belief that "Darwin regretted not having learnt Greek." A letter from Mr. Francis Darwin in the *Times* of December 29, 1904, shows that the statement is altogether opposed to Darwin's views. Darwin says of his education at Shrewsbury School:—"Nothing could have been worse for the development of my mind than Dr. Butler's school, as it was strictly classical, nothing else being taught, except a little ancient geography and history" ("Life and Letters," i., 31). He was, in fact, a victim of that "premature specialisation" which is generally referred to in a somewhat one-sided spirit, and from which the public schoolboy is not yet freed. Mr. Darwin adds:—"If the name of Charles Darwin is to be brought into this controversy it must not be used for compulsory Greek, but against it. In 1867 he wrote to Farrar, 'I am one of the root and branch men, and would leave classics to be learnt by those alone who have sufficient zeal and the high taste requisite for their appreciation' ('More Letters of Charles Darwin,' ii., 441)."

The Aëro Club of Paris has asked permission from the municipal authorities to make experiments in aviation in the Galerie des Machines next February. Under the head of aviation, among other experiments will be some in mechanical aërial direction. The building is so large that the results will be almost the same as would be obtained in the open air, with the difference that the disturbing effect of wind need not be feared.

St. Catherine's Lighthouse, situated on the south coast of the Isle of Wight, has just been provided with a new light of 15,000,000 candle-power, as against 3,000,000 obtained with the old apparatus. Seen from the land there are three distinct beams of light revolving in view, one just on the point of disappearing behind the "blank" or shield, while the others pass rapidly over the waters of the English Channel. The new lens is by Messrs. Chance Brothers, Birmingham; and the whole of the revolving part floats in a trough of mercury, instead of being on rollers, which has hitherto been usual, about 816 lb. of mercury being required to float it. Hitherto chain has been used in lighthouses for suspending the weights, but in this case a fine steel cable, about $\frac{1}{4}$ inch in diameter, has been adopted.

The annual report of the Russian Geographical Society gives the full list of medals awarded by the society at its annual sitting. The following medals were awarded:—the Constantine medal to the veteran geologist Friedrich Schmidt, the Count Lüthe medal to Sir John Murray, and the Semenoff gold medal to Prof. N. I. Kuznetsoff. Five small silver medals were awarded, to V. A. Vlasoff, Th. N. Panaeff, and W. M. Nedzwiedski for meteorological work, to M. M. Siazoff for the part he took in the expedition of Grum-Grzimailo, and to E. L. Byakoff for the support he gave to the same expedition.

According to information communicated by the Meteorological Observatory of Irkutsk, the earthquake which took place in Transbaikalia on September 28 last covered an area of about 4500 square miles, representing an imperfect oval elongated from N.W. to S.E., its furthest points being Troitzkosavsk in the south-east and Balagansk in the north-west. The centre of this earthquake, which was undoubtedly of tectonic origin, was located in the neighbourhood of the station Pereyemnaya, on the south-east shore of Lake Baikal. No less than three earthquakes have had their origin at this centre during the past three years.

In the *Zoologist* for December Mr. A. H. Patterson records a number of more or less remarkable specimens of fishes captured off Great Yarmouth during the year. Several examples of flat-fish with the two sides of the same colour are recorded, a plaice of this type being further remarkable from the fact that the dorsal and anal fins united beneath the tail. In a second article Mr. G. Dalgleish directs attention to the recent migration into India of birds native of eastern Central Asia—notably the mandarin-duck.

The October issue of the *Proceedings* of the Philadelphia Academy contains two papers devoted to the histology and early development of invertebrates. In the first Dr. J. A. Nelson discusses that puzzling creature Dinophilus, referred by some authorities to the turbellarians, and by others to the annelids. If the "trochophore" be regarded as a larval form common at least to all annelids, the development of Dinophilus cannot be considered as primitive. Rather it may be looked upon as an annelid the larval stage of which has become one towards which development tends, and which has consequently become specially modified. In the second of the two papers Mr. T. H. Montgomery gives the results of his investigations into the development and structure of the larva of the parasitic thread-worm Paragordius.

The December issue (vol. vii., No. 2) of the *Journal* of the Marine Biological Association of the United Kingdom contains a full list of the marine invertebrate fauna of Plymouth, compiled from the records of the association. An excellent map of the Plymouth district accompanies the list, together with notes on the various dredging-grounds and their characteristic zoological products. Some of these grounds, which formerly yielded rich harvests, have been more or less completely spoiled by being made the receptacle for rubbish and refuse from the neighbouring towns. Attention is directed to the large number of species of marine organisms attacking the limestone of which the Plymouth breakwater is constructed. To such an extent, indeed, is the stone eaten into by these creatures that considerable damage is done to the structure, and constant repairs are rendered necessary.

We have received copies of three papers by Dr. J. E. Duerden dealing with the morphology, development, and relations of corals and sea-anemones. Their titles are respectively "The Antiquity of the Zoanthid Actinians" (*Rep. Michigan Acc.*, No. 6, pp. 195–8), "Recent Results on the Morphology and Development of Coral-Polyps" (*Smithson. Miscell. Contrib.*, vol. xlvii. pp. 93–101), and "The Morphology of the Madreporaria," No. 5 (*Biol. Bull.*, vol. vii., No. 2). The main thesis of the first two papers is that, since ordinary hexamerous coral-polyps differ from sea-anemones to a great extent only by the absence of a skeleton, and the presence of such skeleton is a secondary development, the second group must be older than the first. From this basis it is argued that the tropical polyps known as zoanthids, which differ in regard to the number of their septa from the hexamerous group, bear a similar relationship to the Palæozoic tetramerous "rugose" corals, and are consequently of still more ancient origin. In the author's own words, "The Rugosa and Zoantheæ undoubtedly constitute a common group of skeleton-forming and skeletonless polyps, just as do the modern Madreporaria and ordinary hexamerous Actiniaria."

Three papers by Dr. R. Broom on the fossil reptiles of South Africa and their relationship to mammals appear in vol. xxv., part iii., of the *Transactions* of the South African Philosophical Society. In the most important of these the author discusses the origin of the mammalian carpus and tarsus. After a brief review of the nature of these two portions of the skeleton in other groups, Dr. Broom points out that in dicynodonts and theriodonts the mammalian approximation is most marked. To quote his own words, "In these latter we find more or less approximation to the mammalian type, but if we take into consideration the extreme mammalian specialisation—the presence of a large tibiale and fibulare, with a centrale which is not in the centre but comes between the tibiale and the first tarsale, then we are driven to the conclusion that the mammalian ancestor must have been a dicynodont, a theriodont, or a form belonging to a closely allied order. From the examination of the skull we have good reason to believe that the ancestor was a theriodont, and the evidence of the tarsus fully confirms that drawn from the skull and other parts of the skeleton; and the carpus, while it does not add any very strong evidence, certainly does not afford any evidence that is not in harmony with this conclusion."

A remarkable instance of what the author thinks may be true mimicry among plants is described by Dr. R. Marloth in the *Transactions* of the South African Philosophical Society, vol. xv. p. 97. Years ago, it appears that the traveller Burchell picked up on stony ground an object he mistook for a pebble, but which on exaimnation proved to be a plant of the genus Mesembrianthemum. Both in colour and in form this plant, previously named *M. truncatum*, presented a remarkable resemblance to the stones among which it grew. A second species, *M. bolusi*, growing on the hills around the Karru, generally produces two leaves about the size of a duck's egg, which have a surface like weathered stone, and a brownish grey colour tinged with green. In this state it closely resembles the surrounding stone, although for a short time its bright yellow flowers render it conspicuous enough. *M. nobile* is very similar. A fourth species of the same genus, together with *Anacampseros papyracea* (in which the leaves are covered with white papery stipules), resembles the quartz pebbles among which it grows. In the author's opinion, *M. bolusi*, *M. nobile*, and perhaps *M. truncatum* (which, unlike some of the other plants mentioned, do not change their characters under cultivation), may afford instances of true mimicry, or "homoplasy."

We have received a report on forestry in the Transvaal by Mr. D. E. Hutchins, conservator of forests, Cape Town. The report deals with the immediate necessity for the afforestation of those large tracts of land in the colony which are unsuitable for agriculture. The importance of forestry in the Transvaal cannot be over-estimated, as a perusal of this report will show. After a tour of inspection, Mr. Hutchins has been able to indicate in his report the organisation and equipment necessary for the scheme. A list of trees suitable for cultivation in the Transvaal is given, together with short notes on their sylvicultural characteristics and uses. It may be interesting to mention that the common ash, *Fraxinus excelsior*, does not thrive in the Transvaal.

Messrs. F. Darton and Co., St. John Street, E.C., have submitted to us a very handy and portable little instrument, the "Piesmic" barometer, invented by Mr. A. S. Davis. It consists of a glass tube about seven inches long, bent in the form of a syphon, the longer arm being of strong capillary tubing of one-tenth inch bore, the shorter arm being of thin quill tubing. The end of the longer tube opens into a small cast iron cistern, containing mercury;

when the instrument is out of action the tube lies horizontally, and the mercury lies on one side of the cistern, leaving the open end of the tube exposed to the air. When the tube is brought into a vertical position the mercury flows over and closes the mouth of the tube, and then flows down the tube to a greater or less depth, dependent upon the atmospheric pressure at the time. We have made a number of comparisons with a mercurial standard barometer, and find that its indications are correct to within about 0·12 inch. The readings, to the nearest tenth of an inch, or, by interpolation, to the hundredth of an inch, can be rapidly obtained. As a weather-glass it appears to be very useful, and even less likely to get out of order than an aneroid, but it would not be suitable for accurate scientific observations like an ordinary mercurial barometer. It has the advantage of being less costly, small in size, and easier of transport than an ordinary barometer.

WE have received from Messrs. C. F. Adolph and Co., of 14 Farringdon Road, E.C., their new price list of selenium cells and apparatus. This firm has introduced a new type of selenium cell which possesses the advantage over the old form of cell that it is exposed to the light on two surfaces with a consequent increase in the sensibility of fully 75 per cent. Complete sets of apparatus for demonstrating the sensitiveness of selenium to light and the transmission of sound by means of light are also described and illustrated in the list.

IN No. 21 of the *Physikalische Zeitschrift* Mr. Josef Rosenthal describes a number of improvements which he has introduced in the construction of mercury air-pumps of the Sprengel type. These pumps usually suffer from the disadvantage that the glass tube in which the mercury falls is liable to sudden fracture after the pump has been in action during a few weeks. The fracture appears to be due to the friction of the mercury on the glass producing an electrical charge which, by influencing the moist air without, converts the glass wall of the tube into the insulator of a condenser. The possibility of a discharge through the glass is eliminated by surrounding the dropping tube with a larger glass tube filled with oil, which acts as an efficient insulator. It is stated that a tube protected in this way lasted five months, although in daily use.

THE *American Journal of Science* for November, 1904, contains an investigation by Mr. Bertram B. Boltwood of the radio-activity of natural waters which is of particular interest because of an attempt that is made to explain its origin. It is shown that neither hot nor cold water dissolves any appreciable quantity of radium, as such, from a mass of finely powdered uranium minerals consisting principally of uranophane, although a brief contact with these minerals is sufficient to impart to water enough of the radium emanation to produce a very marked radio-activity. Water can also acquire a measurable quantity of the radium emanation by simple contact with gaseous mixtures which contain it. It is considered that an extremely minute trace of uranium minerals in the rocks and soils through which a water percolates would be sufficient to impart to it a measurable radio-activity. But waters such as those of Bath and Baden Baden, which contain true dissolved radium, must owe the presence of the latter to a special decomposition taking place under the influence of high temperature and great pressure.

MESSRS. LONGMANS AND CO. have in the press a translation, by Mr. J. Garcin, of M. Blondlot's papers on *n*-rays communicated to the Paris Academy of Sciences. The volume will contain additional notes and instructions for the construction of phosphorescent screens.

MESSRS. MACMILLAN AND CO., LTD., have published an edition of "An Elementary Course of Mathematics," by Messrs. H. S. Hall and F. H. Stevens, in which parts i. and ii. of the authors' "School Geometry" have been substituted for the parts of Euclid's elements contained in previous editions.

MESSRS. F. VIEWEG AND SON, Brunswick, have issued the fifth edition of Wiedemann and Ebert's comprehensive work on practical physics—"Physikalisches Praktikum." The book contains a good systematic course of practical work in physics, the experiments being well arranged and clearly illustrated.

THE issue of the *Antiquary* for January commences the first volume of a new and enlarged series. The magazine, which is devoted to the study of the past, has been enlarged by the addition of eight pages. A new section, called "At the Sign of the Owl," has been introduced, and consists of about two pages of notes concerning books of archæological interest. A good selection of articles is promised for the present year.

THERE has now been published at the Patent Office a subject list of works on the fine and graphic arts (including photography), and art industries, in the library of the Patent Office. The list consists of two parts—a general alphabet of subject headings, with entries in chronological order of the works arranged under these headings, and a key, or summary, to these headings shown in class order. The catalogue includes some 2916 works, representing 5373 volumes.

OUR ASTRONOMICAL COLUMN.

ANOTHER NEW COMET (1904 *e*).—A telegram from the Kiel Centralstelle announces the discovery of a new comet by M. Borrelly at Marseilles on December 29, 1904. The position of the object at 9h. 7m. (Marseilles M.T.) was

R.A. = 1h. 13m. 40s., dec. = $-10°\ 0'$,

and its apparent daily movement was found to be +1·6m. in R.A. and $-54'$ in declination. A nucleus was seen.

A further telegram states that the comet was observed by Dr. Cohn at Königsberg on December 31 at 6h. 22·2m. (Königsberg M.T.), when its position was as follows:—

R.A. = 1h. 15m. 56·53s., dec. = $-8°\ 29'\ 59''$.

The position of the comet is near to that of θ Ceti.

COMET 1904 *d* (GIACOBINI).—Further observations of comet 1904 *d* are published in No. 3986 of the *Astronomische Nachrichten*, together with Herr Ebell's elements and ephemeris. A photograph taken at the Konigstuhl Observatory, Heidelberg, on December 19d. 17h. 37·3m. (Konigstuhl M.T.) showed a short tail and a complex nucleus, whilst the position of the object for 1904·0 was

R.A. (app.) = 16h. 19m. 38·8s., dec. (app.) = $+28°\ 23'\ 9''$.

OBSERVATIONS OF LEONIDS AT HARVARD, 1904.—Several observers at Harvard kept the eastern part of the sky under observation for meteors from 12h. to 17h. on the night of November 14–15. As a rule, four observers kept watch, whilst a fifth wrote down their results, and between them they saw 275 meteors, of which 183 were Leonids.

The following table shows the horary rate, for a single observer, at intervals of twenty minutes:—

Nov. 14–15 h. m.	Rate	Nov. 14–15 h. m.	Rate	Nov. 14–15 h. m.	Rate
14 40	40	15 40	28	16 40	24
15 0	36	16 0	26	17 0	28
15 20	29	16 20	25		

Of the total number 35 were of the first magnitude or brighter, but none exceeded magnitude $-2·0$. At the moment of explosion the heads were generally blue or white, but in two cases, at least, the colour was clearly red or orange, probably indicating, according to Prof. W. H. Pickering, a different chemical constitution.

The radiant appeared to cover a considerable area, about 8° in diameter, and seemed to be double, the two principal centres being situated at R.A. = 9h. 56m., dec. = +24°, and at R.A. = 9h. 40m., dec. = +26°.

Although elaborate preparations were made for securing photographs, only two trails appeared on the resulting negatives. One, due to a Leonid, commenced at R.A. = 9h. 17·2m., dec. = +28° 57′, and ended at R.A. = 9h. 8·8m., dec. = +29° 52′, a more careful measure showing that the meteor passed through a point having the position R.A. = 9h. 57·0m., dec. = +24° 14′ (1855). The other trail extended from R.A. = 4h. 52·5m., dec. = +0° 52′, to R.A. = 5h. 10·7m., dec. = −4° 39′ (1855), and was, therefore, not due to a Leonid (Harvard College Observatory *Circular*, No. 89).

LIGHT-CURVE OF δ CEPHEI.—Employing the method used by Dr. W. J. S. Lockyer in his discussion of the observations of η Aquilæ (Göttingen, 1897), Dr. B. Meyerman has reduced the observations of δ Cephei.

As a result he obtained the following as the formula for determining the epochs of maxima:—

1840 September 26·3588 + 5·366404 E. (Bonn).

A comparison of the phases determined from this formula with observed values gives small differences which compare favourably with those previously obtained by other observers. The new observations are consistent with an invariable period (*Astronomische Nachrichten*, No. 3985).

STRUCTURE OF THE THIRD CYANOGEN BAND.—Some interesting results concerning the structure of the third cyanogen band have been obtained by Herr Franz Jungbluth at Bonn. By employing the third order of a Rowland grating having 630 lines to the millimetre (*i.e.* about 16,000 to the inch) and a focal length of 6·6 metres (about 21·6 feet), he obtained a greater dispersion than has hitherto been used for this purpose.

His results, stated briefly, are as follow:—(1) the third cyanogen band consists of double lines; (2) the maximum intervals between successive lines in the four strongest series form an arithmetical progression; (3) the view of King, that the inverted "heads" are to be regarded as "tails" of the bands connected with the known "heads," possesses a high degree of probability; (4) the connection of groups of "heads" and "tails" is such that the *first* "head" and the *last* "tail" belong to the same series, the second "head" to the penultimate "tail," and so on; (5) the hypothesis of Thiele, that the intervals between successive lines in a band increase only to a certain point and then *decrease* until the series ends in a tail, *appears to be correct*; (6) the lengths of the successive series form an arithmetical progression (*Astrophysical Journal*, vol. xx., No. 4).

NEW REFRACTION TABLES.—A set of new refraction tables whereby one may find the refraction correction to 0·01 of a second of arc are given in No. 3983 of the *Astronomische Nachrichten* by Dr. L. de Ball, of Vienna. The tables are adaptable to a range of atmospheric temperatures and pressures and of zenith distances. Knowing the temperature and pressure at the place of observation, one finds the logarithm of the actual density of the atmosphere from table i., and with this and the known zenith distance finds the refraction correction to the second decimal of a second of arc from table ii.

THE "ANNUAIRE" DU BUREAU DES LONGITUDES.—Continuing the scheme inaugurated in last year's "Annuaire" for the alternation of various subjects in the successive issues, the volume for this year contains, in addition to the astronomical data, tables regarding statistics, geography, &c., to the exclusion of data for chemistry and physics.

The astronomical section contains, among many other things, the following useful information: A table for calculating the altitude from readings of the barometer, a complete table of the elements of variable stars of known periods, tables of stellar parallaxes, double stars and proper motions, and an article of stellar spectroscopy by M. Gramont, whilst the sun-dial, solar physics, the table of minor planets, &c., are reserved for the issue of 1906.

ECLIPSE RESULTS AND PROBLEMS.—In the December (1904) number of the *Bulletin de la Société astronomique de France* M. le Comte de la Baume Pluvinel reviews the results obtained during the total solar eclipses of the last thirty years, and in connection with the study of each eclipse phenomenon he outlines the problems which yet require further elucidation. To those interested in eclipse work the article will be found to be a useful *résumé*.

BIBLIOGRAPHY OF CONTEMPORARY ASTRONOMICAL WORKS.—We have received from Prof. Ernest Lebon, of the Lycée Charlemagne, Paris, an extract from a plan of an analytical bibliography of contemporaneous writings on historical work in astronomy, as submitted by him to the International Congress of Historical Science held at Rome in April, 1903. Judging from the list of authors named in the plan and the specimen extracts given therein, the bibliography will be found extremely useful by those workers in astronomy who have occasion to refer to previous results obtained since 1846.

PRIZES PROPOSED BY THE PARIS ACADEMY OF SCIENCES FOR 1905.

GEOMETRY.—The Francœur prize (1000 francs), for discoveries or work useful for the progress of pure or applied mathematics; the Poncelet prize (2000 francs), for work in applied mathematics.

Mechanics.—A Montyon prize (700 francs), for the invention or improvement of instruments useful in the progress of agriculture, the mechanical arts or sciences; the Poncelet prize (2000 francs), for a work on applied mathematics; the Fourneyron prize (1000 francs), for a memoir on the theoretical or experimental study of steam turbines.

Navigation.—The extraordinary prize of 6000 francs as a recompense for any work tending to increase the efficiency of the French naval forces; the Plumey prize (2500 francs), for an improvement in steam engines or any other invention contributing to the progress of steam navigation.

Astronomy.—The Pierre Guzman prize (100,000 francs), for the discovery of a means of communicating with any celestial body other than the planet Mars; failing the award of the capital sum, the interest will be awarded every five years for a work important to the progress of astronomy. The Lalande prize (540 francs), for the observation, memoir, or work most useful to the progress of astronomy; the Valz prize (460 francs), and the G. de Pontécoulant prize (700 francs), under similar conditions. The Damoiseau prize (2000 francs); the question proposed for this prize is as follows:—there are a dozen comets the orbit of which, during the period of visibility, is shown to be of a hyperbolic nature. The problem set is to find out whether this was the case before the arrival of the comet in the solar system, going back to the past history of the comet, and allowing for the perturbations of the planets.

Geography.—The Gay prize (1500 francs), for an explorer in Africa who has determined with great precision the geographical coordinates of the principal points on his journey; the Tchihatchef prize (3000 francs), as a recompense or encouragement for naturalists of any nationality who have most distinguished themselves in the exploration of the Asiatic continent, more especially in the lesser known regions; the Binoux prize (2000 francs).

Physics.—The Hébert prize (1000 francs), for a discovery or treatise on the popular applications of electricity; the Hughes prize (2500 francs), for a work contributing to the progress of physics; the Gaston Planté prize (3000 francs), for a discovery, invention, or important work in the field of electricity; the L. la Caze prize (10,000 francs), awarded in one sum for works important in physics.

Chemistry.—The Jecker prize (10,000 francs), for work in organic chemistry; the Cahours prize (3000 francs), for the encouragement of young chemists; the Montyon prize, unhealthy trades (2500 francs and a mention of 1500 francs), for a means of rendering a trade less unhealthy or dangerous; the L. la Caze prize (10,000 francs), for the best work on chemistry during the last two years; the Bordin prize (3000 francs), for a memoir on the silicides and the part played by them in metallic alloys.

Mineralogy and Geology.—The Delesse prize (1400 francs), for a work concerning geology, or, failing that, mineralogy; the Fontannes prize (2000 francs), for the best publication on palæontology; the Alhumbert prize (1000 francs), for a memoir on the period of the last volcanic eruptions in France.

Botany.—The grand prize of the physical sciences (3000 francs); the question proposed is the demonstration of the various modes of formation and development of the egg in the Ascomycetes and the Basidiomycetes. The Desmazières prize (1000 francs), for the best work published during the preceding year on Cryptogams; the Montagne prize (1500 francs), for work having for its object the anatomy, physiology, development, or the description of the lower Cryptogams; the Thore prize (200 francs), for work on the cellular Cryptogams of Europe.

Anatomy and Zoology.—The Savigny prize (1300 francs), for the assistance of young travelling zoologists, not receiving Government assistance, who have especially occupied themselves with the invertebrates of Egypt and Syria.

Medicine and Surgery.—A Montyon prize (2500 francs and a mention of 1500 francs), for works and discoveries useful in the art of healing; the Barbier prize (2000 francs), for a valuable discovery in surgical, medical, or pharmaceutical science, or in botany having relation with medicine; the Bréant prize (100,000 francs), for the discovery of an absolute specific against Asiatic cholera, or to point out in an irrefutable manner the causes of Asiatic cholera, so that the suppression of the disease will follow. Failing the award of the capital sum, the annual interest will be given for a rigorous demonstration of the existence in the atmosphere of matter capable of playing a part in the production or propagation of epidemic diseases. The Godard prize (1000 francs), for the best memoir on the anatomy, physiology, and pathology of the genito-urinary organs; the Baron Larrey prize (750 francs), for the best work dealing with the subject of military medicine, surgery, or hygiene; the Bellion prize (1400 francs); the Mège prize (10,000 francs); the Serres prize (7500 francs), for a memoir on general embryology applied as far as possible to physiology and medicine; the Dusgate prize (2500 francs), for the best work on the diagnosis of death and the prevention of premature burial.

Physiology.—A Montyon prize (750 francs), and the Philipeaux prize (900 francs), for work in experimental physiology; the Lallemand prize (1800 francs), for work on the nervous system; the Pourat prize (1000 francs), for an essay on the origin of muscular glycogen.

Statistics.—A Montyon prize (500 francs), for a memoir on French statistics.

Among the general prizes offered in 1905 are the following:—the Binoux prize (2000 francs), for a work on the history of science; the Trémont prize (1100 francs), the Gegner prize (3800 francs), the Lannelongue prize (1200 francs), the Wilde prize (4000 francs), the Saintour prize (3000 francs), the Petit d'Ormoy prizes (two of 10,000 francs), all for work useful in the promotion of scientific knowledge. Of these prizes those bearing the names of Pierre Guzman, Lalande, Tchihatchef, La Caze, Delesse, and Desmazières are especially mentioned as being awarded without distinction of nationality.

GEOLOGICAL NOTES.

VERY little geological information appears to have been published on the State of Durango, in western Mexico. The observations therefore recorded during a brief journey by Dr. O. C. Farrington are of considerable interest (Field Columbian Museum, No. 89, geological series, vol. ii., No. 5). His route extended from the city of Durango, which is situated upon an alluvial plain hemmed in by low and rugged hills, to the silver-mining town of Villa Corona or Ventanas, distant about seventy miles in a direct line. The ground, which forms part of the interior plateau of Mexico, rises from about 6000 feet at Durango to 9000 feet. While large tracts of the area are semi-arid and sparsely covered with soil and vegetation, in some places corn is successfully grown, and elsewhere there occur extensive pine forests with oaks. Views of the scenery are given. Eruptive rocks prevail, and near the Ciudad ranch, on one of the highest parts of the plateau, there is a tract of weathered masses known as La Ciudad de Rocas ("The City of Rocks"). The outlines of the rocks are domed and rounded, and they appear to be due to the weathering of fairly homogeneous rhyolitic materials.

Particular attention is directed by the author to the famous Cerro Mercado or Iron Mountain, a hill largely made up of solid iron-ore, and situated less than a mile north-east of Durango City. It rises abruptly from the alluvial plain to an average height of about 300 feet, with single peaks 50 feet to 100 feet higher. The length of the hill is about $1\frac{1}{3}$ miles, and its average width about one-third of a mile. The ore appears to be chiefly hæmatite, although some magnetite also occurs; in physical characters it varies, being hard and soft, black, red, specular, and earthy. Hard, solid black ore, however, forms the chief mass of the "mountain," the black colour being in striking contrast to the yellow and green of the surrounding plain. The ridge is almost bare of vegetation, except for straggling cacti, and its outline is bold and rugged. Steep cliffs 10 feet to 20 feet high are not infrequent, and in places they exhibit a distinct columnar structure like that of basalt (see Fig. 1). The existence of this hill appears to have been made known in 1552 A.D., but the first serious attempt to work the iron-

FIG. 1.—Cliff showing columnar structure of iron-ore at western end of the Cerro Mercado or Iron Mountain of Durango, Mexico.

ore was made in 1828. Successful operations were not conducted until 1888, and only within the last five years has a steady production been maintained. The amount of ore exposed above the level of the plain is estimated at 360 million tons. The author briefly discusses the origin of the iron-ore, regarding it as probably igneous. The associated rocks of the district are rhyolites, probably of later Tertiary age, but the relation, either in time or manner of origin, between the associated eruptive rock and the iron-oxide, and the origin of the iron-oxide itself, seem as yet difficult to determine.

A geological description of the Baraboo iron-bearing district of Wisconsin, by Dr. Samuel Weidman, has been issued by the Wisconsin Geological and Natural History Survey (*Bulletin* No. 13, economic series No. 8). The area is formed mainly by pre-Cambrian quartzites, which stand out in bold north and south ranges, so connected both on the east and west as to constitute a cordon of bluffs enclosing a depressed drift-covered interior. Isolated areas of still older rocks, rhyolite, granite, and diorite, occur along the outer borders of the ranges. Potsdam sandstone is found beneath the drift, and on the slopes of the Baraboo quartzites, while later Palæozoic strata are met with at higher levels. Special interest has recently been aroused by the discovery of large deposits of iron-ore beneath the drift-covered valley, a discovery made while digging or drilling the farm wells in this otherwise well settled agricultural district. The iron-bearing rocks, termed the Freedom formation, from the town of North Freedom, comprise slate, chert, dolomite, and iron-ore, and all gradational phases between these kinds of rock, including banded ferruginous chert like that in the iron-bearing series of Lake Superior. The author points out that the Baraboo pre-Cambrian series may be compared with the upper portion of the Lower Marquette series, the Freedom formation corresponding with the Negaunee iron-bearing formation. Detailed accounts are given of the various rocks and drift deposits, and of the circulation of underground water.

The recent numbers of the *Boletin del Cuerpo de Ingenieros de Minas del Peru*, issued during 1904, continue to testify to the energy and activity of the Government officers charged with the development of Peru. No. 8, by Señor Venturo, describes important deposits of hæmatite in the extreme north of the country, the ore appearing on the surface, and being probably derived from the dehydration of an old lake-iron deposit. Fragments of rocks from the margins of the former lake are found surrounded by the iron oxide, and the iron itself seems to have been dissolved out from the acid igneous masses in the neighbourhood.

In view of the demand for nickel for plating, for alloying steel, and for coinage, Señor Eduardo de Habich was sent to report on the nickeliferous veins of the province of La Mar, which present practically a virgin field. His memoir (No. 11) seems encouraging, the chief ores being ullmannite and nickeline (kupfernickel), occurring mostly in veins of quartz, which may also contain both gold and silver. No. 12 has probably the widest interest for geologists in general, giving as it does the results of a visit to central Peru by Dr. Gustav Steinmann, of Freiburg-im-Breisgau, early in 1904. Señor Elmore is the author of *Boletin* No. 13, on the water-supply of the Rimac valley. It is shown that the permeable subsoil in the valley-floor, from Chosica downwards, becomes charged with a good potable water by infiltration from the River Rimac, and this is capable of furnishing a healthy supply wherever it may be desirable to tap it. The marked rise of this underground water in Callao is interestingly attributed to the obstacle furnished by the neighbouring island of San Lorenzo. The economic aspect of Señor Elmore's report is sure to be widely welcomed in a populous and practically rainless district.

The fourteenth volume of the *Berichte der naturforschenden Gesellschaft zu Freiburg-im-Breisgau* (1904) contains several papers of geological interest. A. Freiherr von Bistram's studies on the dolomitic region of the Alps of Lugano were commented on when they first appeared in separate form (NATURE, vol. lxix. p. 112). Walther Schiller and W. Paulcke are both concerned with the structure of the Engadine, the former giving a detailed account of the region south-east of Schuls, of which the Piz Lischanna forms the centre, while the latter examines the structure of a wider area, from Landeck to the basin of the Po.

Palæontological papers seldom contain so much personal revelation as is to be found in Herr Georg Boehm's first section of his *Beiträge zur Geologie von Niederländisch-Indien* (*Palaeontographica*, supplement iv., Stuttgart, 1904). The splendid series of ammonites therein described, probably from a Tithonian horizon, were obtained for the most part from the collection of a postmaster of Sula Besi, and from one of "die Alfuren," the latter name being applied to any uncivilised natives. Some specimens were even extracted from concealment in the scanty clothing of the boatmen. The postmaster and his allies appear, consciously or unconsciously, to have lost touch with the true locality of their finds, and to have opened up a delusive route through the forest in Taliabu, whereby Herr Boehm was led to a spot where he found abundant belemnites and Nuculæ, but none of the highly prized ammonites. The "Alfuren-Sammlung" proves to be of unusual interest, and may perhaps grow in the course of time, if judicious sums are expended on the "uncivilised" population. The inclusion of fossils smuggled in from other places is now, however, a possibility against which it will be difficult to guard.

Part ii. of the seventh volume of the *Transactions* of the Geological Society of South Africa (Johannesburg, 1904) bears witness to the prevalence of research in Africa in all branches of geology. Dr. Hatch contributes two papers, one in conjunction with Prof. Corstorphine, who has been drawn off from the service of Cape Colony into a more adventurous field. Mr. J. P. Johnson shows that two types of stone implements are found in the Taaibosch Spruit, the older and rougher lying beneath 15 feet of alluvium, and the newer type upon the surface. Mr. F. W. Voit furnishes a paper of general interest on the geology of German South-West Africa, in which a large series of ancient metamorphic rocks is dealt with; these are accompanied by intrusions of granite. The author urges that some of what might be regarded as ordinary contact-phenomena are here carried out on a regional scale, and must be referred to the action of pressure rather than to the invasion of the granite. The metamorphic rocks are impregnated with important deposits of copper-ore, sometimes localised in quartz veins, and sometimes spread in cloud-like masses through the schists.

In the first part of the *Jahrbuch der k.k. geologischen Reichsanstalt* for 1904 (September 15), Franz Toula describes the results of his journey to the Dobrudscha in 1892, and discusses in particular the forms of Exogyra met with. Dr. Petrascheck, in examining the granitic mass near Brixen, in the Adige valley, reviews the nature of Sederholm's "Myrmekite," an intergrowth of triclinic felspar and quartz, and concludes that it is a primary product of the consolidation of the igneous magma. Dr. Ampferer's important examination of the terraces along the valley of the Inn (pp. 91-160) should be considered by all who seek to explain the topography of glaciated areas. The author finds that the terraces of gravel rest on an earlier series of terraces cut in the rock, which are at very different levels on opposite walls of the valley. He summarises his results in a series of fifty-six propositions, among them being the conclusion that the Inn valley, on the retreat of the ice, exhibited a succession of shallow basin-like excavations, which were filled in later by a continuous deposit of alluvium. These hollows, like the smaller details of the ice-erosion, were formed independently of the hardness of the rocks concerned, and Dr. Ampferer believes that the variation in the activity of a glacier as an abrading agent depends in reality on variations in the local pressure and velocity. With reduced pressure and greater velocity the same amount of erosion can be performed as with greater pressure and less velocity. The author opposes the view that rock-obstacles on the walls of a valley are inevitably worn away by the passage of glacier-ice; he urges, on the other hand, that such irregularities may be left standing out, while others are actually produced by the lack of uniformity in the forces of erosion, to which he specially directs attention.

The *Verhandlungen der k.k. geologischen Reichsanstalt*, Nos. 9-12, for 1904, continue to be rich in papers on Bohemia and Moravia, and students of petrology in the broad sense, as well as of Palæozoic and Mesozoic faunas, must endeavour to keep pace with the monthly observations furnished by Dr. Katzer, Jaroslav J. Jahn, Friedrich Trauth, and others. The Dalmatian islands also receive attention in Dr. Waagen's reports of his recent journeys.

AGRICULTURAL EDUCATION AND RESEARCH.

THE writings of Henry, Babcock, King, and others have made the University of Wisconsin familiar to English agricultural students, so that considerable interest attaches to the twentieth annual report of the experiment station, which contains a short history of the College of Agriculture, and summarises the results of twenty years' research. The college is one of the best known in the United States, and its record is typical of many similar institutions. A professor of agriculture was appointed in 1866, there was the usual attempt to teach before the materials for a course of university grade existed, and there was the usual failure. Then, when the indignation and forcible action of "some thirty representative farmers" led the regents of the university to realise the need of "better directed measures," there was a change of policy. The farmer's educational requirements were studied, suitable courses were devised, and research in his interests was begun. The success of this changed policy is testified to by every chapter of the report, and is strikingly shown by the material progress of the institution. When the present director took charge in 1880 the buildings consisted of a dwelling house and two barns, worth about 1000*l.*; the present buildings are worth more than 60,000*l.* In 1881 the income of the agricultural department was represented by the salary of the professor and a grant of about 1000*l.* for experiments. In 1903 the College of Agriculture had an income of 10,000*l.* for administrative and teaching purposes, and of 6000*l.* for research; and in addition free instruction in languages, mathematics, and pure science was provided for agricultural students in other departments of the university.

But the "better directed measures" of the regents of Wisconsin University have had an influence outside the College of Agriculture. At the jubilee of the university last summer, Prof. Chamberlin, of Chicago, delivered an address on "The State University and Research." In this address it was argued that "the fundamental promotion of education lies in an increase in the intellectual possessions of a people, and in the mental activities and attitudes that grow out of the getting, the testing, and the using of these possessions" (*Experiment Station Record*, xvi., 3). As an illustration of the effects of properly directed research on a community, the work of the Wisconsin Experiment Station was referred to in the following words:—"It was my privilege to compare the Agricultural conventions of this State at two periods separated by a decade, within which the experiment station became a potent influence. The dominant intellectual and moral attitude of the earlier period was distinctly disputatious and dogmatic. . . . In the second period the dominant attitude was that of a scientific conference. . . . The whole was characterised by a notable approach to the methods of approved scientific procedure. The intellectual and moral contrast of the two periods was one of the most pronounced expressions of advance in the higher education in a great mass of people in the midst of a practical life which it has ever been my privilege to witness."

The educational value of research may be traced here and there in our English shires, where agricultural experts have won the confidence of farmers by conducting well devised experiments in their midst. But our education authorities still view research with suspicion, and one finds agricultural experiments, for example, labelled "demonstrations" for no other reason than to satisfy the county auditor! One wishes that our education committees, entrusted as they are with funds for the encouragement of agriculture, would study the "better directed measures" which have been so successful in Wisconsin, and not in Wisconsin only, but throughout the States. They would probably find in the American institutions confirmation of a view expressed by Prof. Chamberlin in the above quoted paper.

He remarks that while it is a good thing to provide technical instruction in agriculture, it is "a much higher and truer function to develop the science of agriculture, to increase the intellectual activity of every farmer, to improve the agricultural art on every farm, and by such improved art to furnish better and safer food to every citizen."

T. H. MIDDLETON.

SCIENTIFIC REPORTS OF THE LOCAL GOVERNMENT BOARD.[1]

As is customary, the report under notice is divided into three portions, (1) an excellent digest by the principal medical officer, Mr. Power, of the contents of the volume; (2) statistics of vaccination and details on outbreaks of disease investigated by the board's inspectors; and (3) the reports of scientific investigations carried out for the board, and of the board's vaccination department.

It is reassuring to learn that abstention from vaccination seems to be steadily diminishing, the percentage of births remaining unvaccinated being 20·8 in 1899, 19·9 in 1900, and 17·3 in 1901. The epidemic of small-pox which raged in London in 1901–2 again directs attention to the danger of small-pox hospitals in disseminating this disease in their vicinity. Practically all the London cases were removed to the hospital ships moored in the Thames at Long Reach, opposite to which is the village of Purfleet, containing a number of unvaccinated persons, and an excessive incidence of small-pox prevailed there attributable to aërial conveyance of infection from the ships. The populations of Purfleet garrison and of the training ship *Cornwall* close by were, however, thoroughly vaccinated and re-vaccinated, and not a single case of small-pox occurred in these communities, another instance of the protective power of vaccination. The report by Dr. Bulstrode on outbreaks of typhoid fever at Winchester and Southampton attributable to infected oysters has already been noticed in these columns (see NATURE, vol. lxviii. p. 303).

An outbreak of throat illness at Lincoln attributable to milk was the subject of investigation by Dr. Mair. Although bearing considerable resemblance to scarlatina the outbreak was conclusively proved not to be one of this disease. From a few of the cases a yeast was isolated from the throat by Drs. Klein and Gordon which proved pathogenic to mice, and reproduced on inoculation some of the features of the human disease.

Dr. Bulstrode's report on the excessive incidence of typhoid fever at Bridgend (Glamorgan) supplies an instructive instance of the superiority of properly conducted bacterioscopic examination over chemical analysis for detecting a *slight* degree of pollution of water supplies. Turning to the scientific investigations carried out for the board, it is difficult in a short space to give adequate notice of their contents and importance.

Dr. Klein records some observations on the bacteriological diagnosis of plague, and the manifestations of this disease in the rat. He regards the natural disease in this animal as one of slight virulence and feeble infectivity, and considers that it is spread from rat to rat mainly through their fighting propensities. Dr. Klein, in continuation of his study of agglutinins, also details experiments made to test the ability of two or more agglutinins to coexist in the blood of the same animal. Cultures of *B. typhosus* and *B. enteritidis* (Gärtner) injected simultaneously in an animal were found to produce agglutinins corresponding to each of these microbes. But if the cultures were injected not simultaneously, but in sequence, the agglutinin of the first microbe was to a large extent replaced by that of the second microbe injected.

Dr. Sidney Martin has continued his investigations of the toxic substances elaborated by diarrhœa-producing bacteria, dealing in the present instance with those of the *Proteus vulgaris*. He finds the toxin to be proteid in nature, but not albumose, and readily extractable from the bacterial cells by distilled water. An injection of the toxin produced diarrhœa with depression of temperature.

The report by Dr. Mervyn Gordon on a bacterial test for the estimation of pollution of air is one of great interest and importance. First examining the natural bacterial flora of the saliva, he found that a streptococcus having the power of producing acid in glucose and in lactose media, acid and clot in milk, and of changing the colour of an anilin dye neutral red, was extremely abundant, no less than 10,000,000, and in some cases 100,000,000, being contained in 1 c.c. of saliva, and by using a neutral red broth and incubating anaërobically minute traces of saliva may be detected. By placing, therefore, dishes of neutral red broth at varying distances from a speaker, and subsequently incubating and examining, the distance to which particles of saliva may be carried can be ascertained. It was found that particles of saliva were present in the air no less than 40 feet in front of and 12 feet behind the speaker during loud speaking. Dr. Houston has carried out an exhaustive study of the bacterial flora of human dejecta, with special reference to the colon bacillus. He finds that not less than 90 per cent. of the total number of this organism present have the characters of the typical *B. coli*.

The same observer details the results of the chemical and bacteriological examination of Tunbridge Wells deep well waters, and, in conjunction with Dr. Klein, reports on the use of nutrose agar for the identification of the typhoid bacillus.

[1] Supplement containing the Report of the Medical Officer for 1902–03. (Thirty-second Annual Report of the Local Government Board, 1902–03.)

The remainder of the volume is occupied with reports of scientific investigations carried out in the board's vaccine laboratories by Dr. Blaxall, Mr. Fremlin, and Dr. Green, and a number of excellent plates illustrating the various researches. R. T. HEWLETT.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—During the first fortnight of last month some four hundred candidates were being examined at Cambridge for entrance scholarships. The majority of the larger colleges are now combined into two groups, the larger of which includes Pembroke, Gonville and Caius, Jesus, St. John's, Christ's, King's, and Emmanuel, whilst the smaller comprises Peterhouse, Clare, Trinity Hall, Trinity, and Sidney Sussex. Queens' examined alone, and a week later than the two large groups. As a result of the examination of these thirteen colleges a sum amounting to a little more than 6000*l.* was awarded in scholarships to 108 successful candidates. This total does not include the sum, which amounted to some hundreds of pounds, given in exhibitions, sizarships, and subsizarships, and in certain extra scholarships offered by some of the colleges after the result of the first selection had been published. It is interesting to note the number of scholars and the value of the scholarships given in the different subjects. Out of a little more than 6000*l.* awarded to 108 candidates, classics gained 2850*l.*, divided amongst 49 scholars, mathematics, with 34 scholars, earned 1945*l.*, and the natural sciences divided 990*l.* amongst 20 successful competitors, whilst candidates in history and oriental and modern languages were successful in only five instances, and these 5 divided amongst them 220*l.*

AMONG the papers down for reading at a conference of the National Federation of Head Teachers' Associations, arranged to be held at Cambridge yesterday and to-day, is one by Sir Lauder Brunton, F.R.S., on "The Proposed National League for Physical Education and Improvement."

Science announces that Mr. E. D. Adams has given 10,000*l.* to Columbia University for the foundation of a research fellowship in physical science. The gift is accompanied by a valuable collection of scientific apparatus to be allotted to the electrical, physical, and psychological laboratories of the university.

THE prospectus for 1904–5 of the Colorado School of Mines shows that much importance is attached in the metallurgical courses to visits arranged for the students to works where typical processes in metallurgy can be seen in operation under commercial conditions. Immediately after taking up the study of metallurgy, trips extending throughout the junior and senior years are begun. These excursions, intended to illustrate the lectures, are taken while the particular topics are under discussion, and tend to aid greatly in an appreciation of approved machinery and practice. By means of outlines with which the student is provided, which he is required to fill out, care is taken that all the important points in connection with each plant visited are studied and reported upon.

THE following recent educational appointments are announced:—Dr. Foster P. Boswell assistant in psychology and Mr. Edwin Lee Norton instructor in philosophy at Wisconsin. Miss Florence Fitch associate professor of philosophy in Oberlin College. Prof. F. S. Luther, who occupies the chair of Trinity College, Hertford, Conn., has been elected president of the college. Dr. J. Stebbins has been appointed assistant professor of astronomy, and Mr. A. H. Wilson instructor in mathematics, at Illinois; Dr. H. B. Evans assistant professor of mathematics at Pennsylvania; Mr. C. P. Weston assistant professor of mechanics, Mr. H. R. Willard instructor in mathematics, and Mr. R. K. Morley tutor in mathematics, at Maine; Mr. W. D. Cairns associate professor of mathematics, and Mr. J. R. Luckey assistant in mathematics and physics, at Oberlin; Mr. E. D. Grant associate professor of mathematics at the Michigan College of Mines; Dr. K. Schmidt professor of mathematics and astronomy at Lake City, Florida.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, November 17, 1904.—"Theory of Amphoteric Electrolytes." Part ii. By Prof. James **Walker**, F.R.S.

In a previous paper (see NATURE, April 7, 1904, vol. lxix. p. 545) it was shown that it is possible to express the concentrations of the ions present in the aqueous solution of an amphoteric electrolyte in terms of the concentration of the un-ionised substance, the dissociation constants of the substance acting as acid and as base respectively, and the ionisation constant of water. In the present paper the values for the aminobenzoic acids have been re-calculated, and a closer concordance obtained between theory and experiment than was apparent in the former calculations. As a knowledge of the concentration of the un-ionised proportion of an amphoteric electrolyte in solution is of fundamental importance in the application of the theory, a table is given of the values of this magnitude with varying constants and total concentration. From this table it appears that when the acidic and basic constants approximate in value, dilution has little effect on the total ionisation of an amphoteric electrolyte, although the proportions of the two positive ions, and consequently the molecular conductivity, may vary greatly.

For a series of amphoteric electrolytes with a constant product $k_a k_b$, where k_a is the acidic and k_b the basic constant, it may be shown that the simultaneous alteration of $1/k_a$, k_b, and v in the same ratio has no effect on the total ionisation. From this and the preceding result it may be deduced that in such a series, beginning with an infinitely small value of k_b the total ionisation falls off as k_a diminishes and k_b increases, the fall being at first rapid, thereafter becoming slower until, through a comparatively long range, it is practically constant at the minimum value, which is actually reached when $k_a = k_b$. At this point the substance is absolutely neutral. As k_a still further diminishes, and k_b correspondingly increases, the ionisation begins to increase, very slowly at first, and the substances considered become more and more basic in character. Finally, the ionisation increases rapidly, and we deal at last with a practically simple base for which k_a is infinitely small.

The theory has been applied to cacodylic acid and to asparagine with satisfactory accordance with the experimental results.

December 1, 1904.—"On Chemical Combination and Toxic Action as exemplified in Hæmolytic Sera." By Prof. Robert **Muir** and Carl H. **Browning**.

This paper deals with the mode of action of complements—those comparatively labile bodies which are present in the serum of normal animals, and which are the active substances in hæmolysis and bacteriolysis. Towards red corpuscles treated with the suitable immune-body (the anti-substance developed by the injection of such corpuscles into an animal of other species) a complement may be regarded as a toxin, and already many points of similarity in the constitution of toxins and complements have been brought forward. The hæmolytic dose of a particular complement varies greatly in the case of different corpuscles, when each variety is treated with the corresponding immune-body, and the question dealt with in this communication is whether such variations in dosage are due to variations in the combining affinities of complements or to variations in their toxic action. For example, the hæmolytic dose of guinea-pig's complement is ten times greater in the case of its own corpuscles than it is in the case of the ox's corpuscles, and the writers show by quantitative methods that in the former case the whole of this large dose of complement enters into combination with the guinea-pig's corpuscles (through the medium of the immune-body); there is no want of combining affinity of complement, but its toxic action is slight. A similar result was obtained with each of three sera investigated—a relative non-sensitiveness of the corpuscles of an animal to its own complement; in one case there was also a deficiency in the combining power of the complement. All the results go to emphasise the importance of distinguishing these two factors in the action of a complement, which correspond with the two chief atom groups designated by Ehrlich "haptophore," or combining, and "zymotoxic." As bearing on the general biology of the subject, the following may be quoted:—"No one has yet succeeded in producing an anti-substance or immune-body by injecting an animal with its own corpuscles or cells—such a body as with the aid of complement would produce destruction of these cells. This is manifestly a provision against self-poisoning, and Ehrlich has applied to it the term *autotoxicus horror*. The results which we have brought forward, if they were found to hold generally, would go to show that even if some substance should appear which acted as an immune-body, there is a provision whereby the complement of an animal should produce comparatively little harmful effect."

Chemical Society, December 14, 1904.—Prof. W. A. Tilden, F.R.S., president, in the chair.—The following papers were read:—Hydrolysis of ammonium salts: V. H. **Veley**. It is shown that when aqueous solutions of ammonium salts are heated the evolution of ammonia and the concomitant acidity of the solutions are due not to dissociation, but to hydrolysis.—The viscosity of liquid mixtures, part ii.: A. E. **Dunstan**. The author's conclusions, given in a previous paper (Chem. Soc. *Trans.*, 1904, lxxxv., 817), are confirmed by the present series of viscosity-concentration measurements for a number of binary mixtures containing hydroxy-compounds.—The diazo-reaction in the diphenyl series, part ii., ethoxybenzidine: J. C. **Cain**. The author has examined the action of heat on the solution of the diazonium salt prepared from ethoxybenzidine, and has shown that the diazonium group, adjacent to the ethoxy-group, is normally substituted by hydroxyl, whilst the other remains intact.—The sulphate and the phosphate of the dimercurammonium series: P. C. **Rây**. When dimercurammonium nitrite, NHg_2NO_2, is treated with an oxyacid, the dimercurammonium complex remains intact. In this way, the author has succeeded in preparing the sulphate and the phosphate of the series.—A method for the direct production of certain aminoazo-compounds: R. **Meldola** and L. **Eynon**. The authors have found that most diazotised amines when treated in aqueous solutions with a strong solution of sodium dichromate give crystalline precipitates of diazonium chromates. These chromates are more or less explosive when dry, and it is suggested that some of them might find technical application as high explosives.—The combination of mercaptans with olefinic ketonic compounds: S. **Ruhemann**. Studies in optical superposition, part i.: T. S. **Patterson** and F. **Taylor**. Menthyl acetate, *l*-menthyl *d*-tartrate, and *l*-menthyl diacetyl-*d*-tartrate have been prepared and their rotations examined between 0° and 100°. It is shown to be possible by analogy to trace the separate effects of the different active groups composing menthyl tartrate and its diacetyl derivative.

Linnean Society, December 15, 1904.—Prof. W. A. Herdman, F.R.S., president, in the chair.—The ecology of woodland plants in the neighbourhood of Huddersfield: Dr. T. W. **Woodhead**. The plant-associations of this portion of west Yorkshire having been dealt with on broad lines by Smith and Moss, the author has endeavoured to carry the study a stage further by paying special attention to a very limited area. A small wood (Birks Wood, near Huddersfield) was examined in great detail, and the main factors determining the distribution of the more important plants of the undergrowth studied, such as soil, shade produced by the dominant tree, moisture, exposure, and wind. The results thus obtained were then tested by an examination of the woodlands in an area of 66 square miles to the south and west of Huddersfield; special attention was also paid to the distribution of these species beyond the limits of the woodlands.—Experimental studies in heredity in rabbits: C. C. **Hurst**. The studies were based on breeding between a Belgian "hare" and an albino Angora; the second generation showed but little outward variation from the Belgian parent, but the third generation displayed great diversity of colour—albino, grey, black, and variegated. These experiments tallied in a very close degree with the numbers expected according to the Mendelian laws.

Faraday Society, December 19, 1904.—Mr. J. Swinburne, vice-president, in the chair.—The electric furnace: its origin, transformations, and applications, part ii.: M. Adolphe **Minet**.—Electrolytic analysis of cobalt and nickel: Dr. F. Mollwo **Perkin** and W. C. **Prebble**. *Cobalt.*—The aim of the experiments was to obtain bright deposits of the metal that should be quantitatively accurate. The most satisfactory results were obtained with a solution containing an alkali phosphate and a little phosphoric acid, the latter to prevent the precipitation of the double sodium cobalt phosphate. *Nickel.*—Similar solutions were tried for nickel deposition. In this case good results were obtained with a borate solution, while a phosphate solution, which gave good figures in the case of cobalt, was not at all satisfactory.—(1) The electrolytic preparation of tin paste; (2) note on the electrolytic recovery of tin: F. **Gelstharp**. The electrolytic process is less costly than other processes in spite of the low current efficiency (50 per cent.), and it can be worked continuously. The process consists in dissolving anodes of tin, roughly cast from commercial ingots, in dilute hydrochloric acid, and depositing the metal in the form of sponge on kathodes of block tin or tinned iron. In the second note an experiment is described that has some bearing on the conditions necessary for electrolytically stripping tin plate.

PARIS.

Academy of Sciences, December 26, 1904.—M. Mascart in the chair.—On the theorem of areas and conservative systems: Paul **Painlevé**.—Groups of negative bands in the air spectrum with a strong dispersion: H. **Deslandres**. A detailed examination under high dispersion of the ultra-violet band λ 3914. This band is intense round the negative pole in vacuum tubes filled with air or nitrogen, and it constitutes nearly exclusively the kathode light of gases; it is found in the aurora borealis and in the radium light.—On the constitution of the sodium salts of certain methenic and methinic acids: A. **Haller** and P. Th. **Muller**. A differential optical method has been employed in this work, comparing the molecular refraction of the sodium salt with its corresponding acid, so far as possible in the same solvent and at equal concentrations. The substances studied included cyanacetic ester, propionyl-cyanacetic ester, malonic and cyanomalonic esters, malonitrile, and cyanocamphor. The results indicate that all the sodium salts examined have a different constitution from that of the generating acid, and hence that the latter should be classed as pseudo-acids.—On some new geological discoveries in the Soudan: A. **de Lapparent**. The fossils found present a fresh proof of the existence of an arm of the sea penetrating into the Soudan.—On the new Giacobini comet: M. **Giacobini**. Observations, the elements and ephemeris of the new comet, discovered on December 17, 1904, at the Observatory of Nice.—The provisional elements of the Giacobini comet (December 17, 1904): G. **Fayet** and E. **Maubant**.—Observations of the Tempel comet (1873, 2) made at the Observatory of Algiers with the bent equatorial of 31·8 cm. aperture: MM. **Rambaud** and **Sy**.—On the stability of aërostats fitted with steering apparatus: G. A. **Crocco**.—On the fragility of certain steels: A. **Perot** and Henri Michel **Levy**. A study of the effect of shock on notched test-pieces, a photographic method of recording the results being adopted.—On the kathode rays and the laws of electromagnetism: P. **Villard**. Diagrams are given showing the comparison of the theoretical curves with those actually obtained, and it was found that none of the experimental results present anomalies requiring the assumption of a magnetic friction.—On the thermoelectricity of the aluminium alloys: Hector **Pécheux**. Alloys of aluminium with tin, lead, bismuth, magnesium, antimony, and zinc were studied at 100°, 180°, and 380° C.—On the theory of magnetism: P. **Langevin**. An application of the hypothesis of electrons to the explanation of the phenomena of para- and dia-magnetism.—On a phenomenon of retinal adaptation relating to visual perception of faintly illuminated colours: A. **Polack**.—On the reduction by amorphous boron of the oxides of manganese, and on the preparation of a new boride of manganese: Binet **du Jassonneix**. The composition of the new boride studied is represented by the formula MnB. It fits into the series of well defined and crystallised borides FeB, NiB, and CoB prepared by M. Moissan by means of the electric furnace.—On quadrivalent oxygen: E. E. **Blaise.** Ethyl ether and magnesium iodide form a well defined, crystalline compound from which the ether is only driven off when heated to temperatures approaching 190° C. Its probable constitution is given as

$$\begin{array}{ccccc} C_2H_5 & & I\ \ I & & C_2H_5 \\ & \rangle O & & \langle O & \\ C_2H_5 & & Mg & & C_2H_5 \end{array},$$

in which the oxygen must be tetravalent. If this substance is treated with an ether containing an alkyl group of higher molecular weight, as amyl ether, the latter replaces the ethyl ether, and a vigorous reaction ensues.—On the reduction of the anhydrides of the dibasic acids: G. **Blanc.** The anhydrides of pyrotartaric, αα-dimethylsuccinic, αα-dimethylglutaric, ββ-dimethylglutaric, and camphoric acids, when reduced with sodium and absolute alcohol, give good yields of the corresponding lactones.—A general method for the synthesis of aldehydes with the aid of substituted glycidic acids: Georges **Darzens.** A mixture of monochloracetic ester with any ketone is treated with sodium ethylate in powder. The acid formed by this condensation is unstable, and splits up easily into carbon dioxide and an aldehyde of the type RR′CH—CHO, where the original ketone was RR′ : CO. The reaction has been applied to a considerable number of ketones and found to be quite general.—On the diastatic coagulation of starch: A. **Fernbach** and J. **Wolff.** It is shown that the diastatic coagulation of starch is only possible if it is in a state of liquefaction, this being produced either by a liquefying diastase or artificially.—On the combustion of sulphur in the calorimetric bomb: H. **Giran.** The heat of combustion of sulphur has been determined in the Berthelot bomb at pressures varying between 2·5 and 45 atmospheres, with the unexpected result that the heat of formation of sulphur dioxide increases with the pressure. This result is regarded as being possibly due to the formation of the persulphuric anhydride of Berthelot.—On the electrical conductivity of colloidal solutions: G. **Malfitano.** In order to eliminate the effect possibly produced by the presence of minute traces of electrolytes in solution, the conductivity of the colloidal solutions was taken both before and after filtration through a thin film of collodion, it having been shown by preliminary experiments that solutions of pure electrolytes undergo no appreciable change after such filtration. It was found that the conductivity due to the fine particles in suspension was practically nil.—On the comparative production of alcohol and carbonic acid during fermentation: M. **Lindet** and P. **Marsais.** The ratio of alcohol to carbonic acid has been followed throughout the whole course of a fermentation, the effect of varying temperature being also studied.—Study of calcium carbide used as an explosive in mining work: Marcel P. S. **Guédras.** The cartridge used consisted of a charge of calcium carbide separated by an insulating membrane from water. The membrane is broken by a cap controlled electrically, and after five minutes the explosive mixture is fired also by electrical means. The explosion takes place in a manner well adapted for mining work.—On the histology of the myocardium in the primitive molluscs: P. **Vigier** and Fr. **Vlès.**—Intranuclear fat in the suprarenal capsules of mammals: P. **Mulon.**—On the migration of glucosides in plants: W. **Russell.**—On the destruction of the winter egg of Phylloxera by lysol: G. **Cantin.** An account of experiments demonstrating the practical efficacy of a 1 per cent. solution of lysol against the disease.—On the mineral species of arable earth: A. **Delage** and H. **Lagatu.**—The geology of Sahel, Algeria: General **de Lamothe.**—The culture of the parasite of dysentery of warm countries: A. **Lesage.**—On infectious anæmia of the horse: MM. **Carré** and **Vallée.**

DIARY OF SOCIETIES

THURSDAY, JANUARY 5.

RONTGEN SOCIETY, at 8.15.—Description of an Automatic Vacuum Pump: C. E. S. Phillips. (The apparatus will be shown at work.)—Exhibition of a Method by which Strongly Adherent Films of Aluminium may be applied to Glass.—A Note on the Coloration of Glass by Radium Radiation.

CIVIL AND MECHANICAL ENGINEERS' SOCIETY, at 8.—Thames Barrage: James Casey.

FRIDAY, JANUARY 6.

INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH, at 7.30.—The Report of the Inter-Departmental Committee on Physical Degeneration: Sir Lauder Brunton, F.R.S.

GEOLOGISTS' ASSOCIATION, at 8.—The Third Issue of the British Association Geological Photographs: Dr. C. G. Cullis.

ROYAL GEOGRAPHICAL SOCIETY, at 3.30.—National Antarctic Expedition: Capt. R. F. Scott. (Lecture to Young People.)

MONDAY, JANUARY 9.

SOCIETY OF CHEMICAL INDUSTRY, at 8.—Some Chemical Aspects of the St. Louis Exhibition: Walter F. Reid.

ROYAL GEOGRAPHICAL SOCIETY, at 8.30.—Mr. Reginald Enock's Journeys in Peru: the President.

TUESDAY, JANUARY 10.

INSTITUTION OF CIVIL ENGINEERS, at 8.—The Recent Visit to the United States and Canada: Sir William Henry White, K.C.B. (The Address will be repeated on the following day at 3.30 p.m.)

WEDNESDAY, JANUARY 11.

SOCIETY OF PUBLIC ANALYSTS, at 8.—Brandy: Otto Hehner.

THURSDAY, JANUARY 12.

MATHEMATICAL SOCIETY, at 5.30.—Generational Relations for the Abstract Group simply Isomorphic with the Abstract Group LF $[2, p^n]$; Dr. W. Bussey.—On a Class of Expansions in Oscillating Functions: Prof. A. C. Dixon.—Isogonal Transformation and the Diameter Transformation: H. L. Trachtenberg.—A Generalisation of the Legendre Polynomial: H. Bateman.—Current Flow in Rectangular Conductors: H. Fletcher Moulton.—Basic Generalisations of some well known Analytic Functions: Rev. F. H. Jackson.

SCIENTIFIC THOUGHT IN EUROPE.

A History of European Thought in the Nineteenth Century. By John Theodore Merz. Vol. i., pp. xiv + 458; vol. ii., pp. xiv + 807. (Edinburgh and London: William Blackwood and Sons, 1903–4.)

A NEWSPAPER review of this book has come into our possession, which gives the impression that its most prominent feature is the treatment of biological questions such as the Darwinian theory. Doubtless the reviewer was a biologist. His remark that "the book is not a very easy one to read" is, however, very true.

Now to the present writer the feature which appears most noteworthy is the author's intimate knowledge of *mathematics*, as revealed in his masterly expositions of the development of all branches of mathematical thought during the last century. Probably an exhaustive account of this work could only be given by a number of different reviews written by specialists in different subjects, and such reviews would be so different that it would be difficult to realise that they all referred to the same book. The course we propose to follow is to give a general outline of the scope and subject-matter of the book, to scrutinise a little more closely the portions devoted to mathematics and mathematical physics, and to subject such branches as thermodynamics and kinetic theory to a still closer scrutiny.

At the outset (pp. 24–27), Dr. Merz is confronted with the difficulty that he can find no precise equivalent in French or German for our English word *thought*; for instance, he says:—

"No other language has a word so comprehensive, denoting at once the process and the result, the parts and the ideal whole of what is felt and meant. . . ."

"And yet I think I am right in saying that the conception of thought in the sense in which I am using it is truly an outcome of international, not of specifically English progress, and belongs mainly to the period of which I am treating. . . ."

What thought precisely is the author considers impossible to define, but it is only thought which renders the phenomena of nature intelligible, as he says (p. 2):—

"That which has made facts and events capable of being chronicled and reviewed, that which underlies and connects them, that which must be reproduced by the historian who unfolds them to us is the hidden element of thought."

It is the object of these volumes, as the author remarks on page 13,

". . . . . to rescue from oblivion that which appears to me to be our secret property; in the last and dying hour of a remarkable age to throw the light upon the fading outlines of its mental life; to try to trace them, and with the aid of all possible information gained from the written testimonies or the records of others to work them into a coherent picture, which may give those who follow some idea of the peculiar manner in which our age looked upon the world and life, how it intellectualised and spiritualised them."

On p. 34 he says:—

"A history of this thought will be a definition of thought itself."

In order to limit the scope of the inquiry, Dr. Merz confines his attention to European thought, and of this, again, he only selects the central portion, the thought embodied in French, German, and English literature. Accordingly the first three chapters deal with the scientific spirit in France, Germany, and England respectively. This order of arrangement is a fitting one, and well brings out all that has been said by various writers about "England's neglect ot science." Thus (p. 75):—

"Compared with Germany in philosophy and with France in science, England during the early part of the century appears remarkably unproductive. English science and English philosophy had flourished in the seventeenth and eighteenth centuries and leavened the whole of European thought, but in the beginning of our period we find neither represented by any great schools. The great discoveries in science belonged to individual names who frequently stood isolated; the organisation and protection which science could boast of in France was then unknown in England; into popular thought it had hardly entered as an element at all."

It is to France that we must turn in order to find what might be described as a *national* scientific spirit, and this spirit was very largely the outcome of the foundation of the Paris Academy of Sciences.

"Whilst the Royal Society of London only received a charter, and existed by the entrance payments and contributions of its own members, augmented by private donations; the Paris Academy had as far back as 1671 received the funds with which to commence its labours in connection with the survey of the kingdom and its extensive dependencies." . . . "It was almost exclusively by these observations that the data were found with which to substantiate Newton's mathematical reasoning; in his own country that fruitful cooperation which can only be secured by an academic organisation and the endowment of research was wanting" (p. 99). "In two important departments—the popularisation and the teaching of science—France for a long period led the way. A general interest was thus created in the proceedings and debates of the Academy. . . . ."

In the present connection are cited Laplace's "Mécanique Celeste," and the development of the analytical methods rendered possible by Leibnitz's invention of the calculus, about which we are told (p. 101),

"No learned body did more than the Paris Academicians to perfect (with purely scientific interest) this new calculus, which in the course of the eighteenth century had in the hands of Lagrange been adapted to all the purposes and problems contained or suggested in Newton's Principia."

As another illustration we take the popular interest which centred round Laplace's discovery of the calculus of probabilities (pp. 120 *et seq*).

Passing on to Germany we find national interest converging towards another equally important centre, namely, the university system, which is unique of its kind. This system was perfected in the eighteenth, and fully developed at the beginning of the present century. It is essentially a training school of research

M

and its ideal is expressed in the word *Wissenschaft*. This word, Dr. Merz considers, "cannot be defined by any single word of the English language."

"In fact, the German word for science has a much wider meaning than *science* has in French or English, it applies alike to all the studies which are cultivated under the roof of an 'alma mater'; it is an idea specially evolved out of the German university system, where theology, jurisprudence, medicine and the special philosophical studies are all held to be treated 'scientifically' and to form together the universal, all-embracing edifice of human knowledge" (p. 170).

It was not, however, until the second quarter of the century that the scientific spirit had entered the universities.

"During these twenty-five years Gauss lived and soared in solitary height—a name only to the German student as Euler had been before him." "The man to whom Germany owes its first great school of mathematics was Jacobi" (pp. 184–5).

"German science was essentially cosmopolitan, and the absence of a central body like the Paris Academy, led to an important result, the publication of a large number of periodicals devoted to special branches of science."

Turning to Great Britain the author says (p. 225):—

"Considering that the great scientific institutions of the Continent—the Paris Institute, the scientific and medical schools in Paris and the German universities—have done so much for the furtherance of science and the diffusion of the scientific spirit, it is natural that we should ask, What have similar institutions done in this country?"

A perusal of this chapter leads to the general conclusion that a "national" scientific spirit has never existed in our country. The records of the great discoveries made in Britain during the half-century ending 1825 (given in a footnote on p. 229) show that in that period hardly a year passed without some great scientific discovery being made by an Englishman, and fully justify the statement that

"England had during the early part of the century in all but the purely mathematical sciences a greater array of scientific names of the first order than Germany, and nearly as great an army as France."

And yet we find the works of these writers quite unknown in their own country, and in many cases only rescued from oblivion by falling into the hands of the Continental schools of science. We have only to instance Dr. Merz's references to the difficulties encountered by Young, Green, Babbage, Boole, Dalton, Faraday, and a host of others, and then to refer to foreign opinions on English science, as expressed by Cuvier and Prof. Moll, and quoted (pp. 235–7), as evidence of the high estimation in which British scientific work was held on the Continent. The lack of stimulus to scientific research, the absence of higher mathematical studies, were peculiarly noticeable in the two older universities, where traces of the same spirit survive to this day in spite of the internationalising influences which have played such an important part in recent scientific work. If Britain played a prominent part in the origination of the metric system, and if Continental nations base their zone system of time on the meridian of Greenwich, no better evidence of the general *national* apathy to science could be adduced than the fact that Britain is one of the few European States which have not yet universally adopted either of these systems.

The last two chapters of vol. i. are devoted to "The Astronomical View of Nature" and "The Atomic View of Nature," while chapters vi. to xii. in vol. ii. deal with the "kinetic or mechanical," the "physical," the "morphological," the "genetic," the "vitalistic," the "psycho-physical," and the "statistical" views of nature. These chapters refer more especially to the second half of the present century, and it is in them that we feel ourselves compelled to single out a few selected points rather than attempt to cover the whole range of subject-matter.

It is well known that many of our leading scientific ideas can be traced back to very ancient sources; as instances, Dr. Merz refers to the law of gravitation and the atomic theory as known to the Greeks and Romans, the kinetic theory as suggested by Heraclitus, the vortex atom theory as forestalled by Descartes and Malebranche (pp. 312–4). In passing judgment on these prior claims, Dr. Merz very rightly remarks:—

"It is the scientific method, the exact statement, which was wanting, and which raises the vague guesses of the philosophical or the dreams of the poetic mind to the rank of definite canons of thought, capable of precise expression, of mathematical analysis and of exact verification." "In every case the awakening touch has been the mathematical spirit, the attempt to count, to measure, or to calculate."

Those who flood our breakfast tables with "new" theories of the ether or designs of flying machines only constructed on paper will do well to bear these remarks in mind.

Let us now examine how Dr. Merz treats the second law and the ideas of temperature and entropy. In commenting on the work of Lord Kelvin and Clausius, he says (p. 128):—

"The result was the doctrine of the 'conservation of energy'—not of heat as Carnot had it—and the embodiment of the two correct ideas contained independently in Carnot's and Joule's work in the two well-known laws of thermodynamics—viz. the conservation, equivalence and convertibility of energy as expressed in the first law and the doctrine of the availability of energy as expressed in the second law."

In speaking of entropy (p. 169) he is no less definite in associating that conception with unavailable energy, and he only falls into a pitfall on p. 594, where he speaks of "entropy (or energy which is hidden away)" as if the two were identical and did not differ by a temperature-factor. But the footnote on p. 189 of Maxwell's "Heat," seventh edition, shows that in this he has erred in good company. In the footnote on p. 315, in discussing the absolute scale of temperature, he is more unfortunate. The scale "in which every one degree had the same dynamical value" was not the *present* absolute scale (which approximates fairly closely to the gas scale), but Lord Kelvin's *first* absolute scale, published in 1848, in which the absolute zero is not $-273°$, but minus infinity.

Of the application of statistical methods to the kinetic theory we can speak equally well in regard to the completeness with which the author has traversed the literature of the subject. We do not find any reference to the underlying *assumption* which has up to the present been unearthed in every attempt to treat the problem mathematically. But this is hardly a point on which anyone but a specialist could be expected to light, and the majority of specialists make the assumption without knowing it (*pace* Burbury's criticisms).

The last chapter but one deals with the development of mathematical thought. We have selected for special examination the portions dealing with Cantor's researches on the transfinite and the continuum, and we find the subject treated in such a way as to present a clear and definite picture to one who has not specialised in this difficult branch of mathematical thought. The last chapter contains a retrospect and prospect.

We must not omit to mention what is, perhaps, as important a feature as any, namely, the footnotes, which occupy a considerable proportion of the whole book, and constitute a kind of historic encyclopædia.

We do not believe in filling reviews with lists of misprints, but the "Racket" (index, p. 800) may perhaps better describe Stephenson's locomotive than its correctly spelt name. A more serious defect is that these two large and bulky volumes have been issued with the pages uncut, and readers have to waste much time in doing what is the proper work of the guillotine before they can begin the book. This want of thought on the part of the publisher (on his own head be it—*i.e.*, the guillotine) constitutes a serious obstacle to the attempts made by scientific workers of the present day in endeavouring to cope with the ever-increasing mass of literature that accumulates before them.

G. H. BRYAN.

THE PROBLEMS OF VARIATION.

Variation in Animals and Plants. By H. M. Vernon, M.D. The International Scientific Series. Pp. ix + 415. (London: Kegan Paul and Co., Ltd., 1903.) Price 5*s*.

THIS little book meets a real want. The frequent discussions of recent years upon the problems of evolution have been followed with much interest by an increasing number of readers and listeners, with the desire but often the inability to understand. A very large amount of interest and stimulus has been excited by such questions as acquired characters and their transmission or non-transmission by heredity, the continuity of the germ-plasm, physiological selection, continuous or discontinuous evolution, De Vries's experiments and views on mutation, the Mendelian hypothesis as opposed to that of Galton and the bearing of the great array of facts, the fruits of observation and experiment conducted by those who take opposite sides in the controversy. The present writer has often been surprised at the keenness of the interest which can coexist with an almost complete lack of knowledge of the essential details, and he feels that the present work provides precisely the information that is required—a clear, accurate, and dispassionate statement, not too long or too detailed, of researches and reasoning upon problems connected with variation.

The notable success of Section D during the late meeting of the British Association at Cambridge provides an excellent illustration of the wide and deep interest excited, at the present moment, by the last of the subjects mentioned above, and was in itself in some measure an answer to the complaint in the presidential address that insufficient attention was paid to the re-discovered discoveries of Mendel. The subject was new to probably a large proportion of the audience: those among them who had taken the opportunity of reading the fourth and fifth chapters (on blastogenic variation) of this work must have felt that they were thoroughly prepared to follow the discussion in all its detail.

The book is divided into three parts, of which the first, dealing with the *facts of variation*, contains three chapters, on the measurement of variation, dimorphism and discontinuous variation, and correlated variation respectively; the second, the *causes of variation*, includes two chapters on blastogenic variations, one on certain laws of variation, and four respectively treating of the effects of temperature and light, moisture and salinity, food and products of metabolism, and conditions of life in general; the third, *variation in its relation to evolution*, is considered in chapters on the action of natural selection on variation, and on adaptive variations.

The author wisely uses the word "hybridisation" very prominently in his account of Mendel's researches and conclusions. In the comparison between the Galtonian and Mendelian views of heredity an important difference is sometimes lost sight of—the present writer does not remember hearing it expressly mentioned, although it was certainly implied, at Cambridge. The former view is, at any rate chiefly, built upon the results of interbreeding between individuals separated by ordinary differences, the latter upon interbreeding between individuals separated by differences comparatively large. "Ordinary" differences are the points of distinction—generally small, mainly differences of degree—by which we discriminate between the individuals of a species forming a single compact mass, or if the species be broken up into two or more masses—then between the individuals within each of them. The larger differences alluded to are the points of distinction—generally large, frequently differences of kind—between the individuals of one mass ("species," "race," or "breed") and those of another, or between the ordinary individuals of a mass and those sudden large departures from its type which are apt to appear spontaneously in its midst. Even when breeds or races are distinguished by a test apparently so superficial and unimportant as colour, we are probably often confronted by the mere outward sign of inward and important distinction.

If the Mendelian view should hereafter be established beyond the possibility of doubt, there will still remain the interesting question of the part it has played in evolution. This is very largely the attempt to decide whether Darwin's earlier or later views were correct, whether evolution proceeds from the selection of large variations, "as when man selects," or from the selection of ordinary individual differences as defined above. The question cannot be discussed on the present occasion, but it is well to bear in mind that however completely the *causes* of evolution in the past may evade our attempts at demonstrative proof, the *history* of evolution is a subject which can be brought to the test. For many years it has seemed to the writer that palæontology can settle decisively whether evolution has been continuous or discontinuous. Those who desire to bring conclusive evidence to bear upon this important controversy would do well to follow the example of Prof. W. B. Scott, of Princeton, who told us at Cambridge that he was "just crazy" over the fossil mammals of Patagonia.

In the last chapter, on adaptive variations, the author would have done well to place in the forefront the warning that a superficially apparent example "of direct adaptation to surroundings in the ordinary acceptation of the term . . . may be the calling up, in response to one of two stimuli, of one of two groups of characters long since acquired by the plant protoplasm." The principle contained in these words should be prominently before the mind of the naturalist who attempts to investigate the response of an organism to its environment. He should remember that the species which he investigates are "heirs of all the ages," thoroughly inured to experimental research, past masters in the art of meeting by adaptive response the infinite variety of stimulus provided by the environment. If he remember this he will always be on his guard against a too hasty interpretation based upon the fundamental properties of protoplasm.

The discussion of the question, are acquired characters inherited? (pp. 351 *et seq.*) is a particularly interesting and suggestive introduction to the subject. A few well chosen examples of the evidence chiefly appealed to in support of such transmission are followed by a brief but well balanced discussion. The author supports the conclusion that the soma, and through the soma the environment, exert a chemical influence upon the germ-cells, and he makes effective use of the "internal secretions" which have marked an epoch in physiological research.

Several examples, generally believed to supply evidence of the "cumulative action of conditions of life" (pp. 352 *et seq.*), would be more satisfactory and convincing if they were re-investigated as a piece of special research. Too often they bear the impress of an off-hand opinion without any secure foundation upon specially directed inquiry. Thus, in the transport of adult sheep or dogs to a different climate, it may be expected that less change will be manifest in the hairy covering of the parent than in that of the offspring which has been born and passed the whole of its life in the new conditions. Thus the appearance, but by no means necessarily the reality, of an accumulated effect may be produced. In order to test the hypothesis of accumulation, it would be necessary to neglect the generation which has been subjected to two very different environments and to determine quantitatively with all possible accuracy the characters of those which follow. The often repeated statements about the telegonic effect of mating "Lord Moreton's mare" with a male quagga, when compared with the results of Prof. Cossar Ewart's researches, prepare us for the belief that many a general impression which has been produced as evidence will collapse when it has become the subject of searching and critical investigation.

In the preface the author speaks with some diffidence of the prominence given to his own researches. Investigations such as those into the effect upon offspring of the relative freshness or staleness of the parental germ-cells would, in any circumstances, be an unfortunate omission from a book on variation. They are, moreover, described in the publications of scientific societies not always freely accessible to the general reader. For another reason also the book would have suffered if these researches had been treated less fully. When the author of a general work is not altogether wanting in the sense of fitness and proportion, the account of his own contributions to science will probably be the salt of his book. These subjects stirred his own enthusiasm for research, and in writing of them he is likely to stir the enthusiasm of others.

E. B. P.

MATHEMATICAL THEORY OF ECLIPSES.

The Mathematical Theory of Eclipses, according to Chauvenet's Transformation of Bessel's Method. Explained and illustrated by Roberdeau Buchanan, S.B. Pp. x+247. (Philadelphia and London: J. B. Lippincott Co., 1904.) Price 31*s.* net.

WHEN a practical man devotes himself to the task of explaining to others the difficulties of any specialised subject on which he has been engaged for many years, the result is likely to be satisfactory. There is always the chance that the prolonged study of one particular subject has had the effect of unduly exalting its importance, with the consequent loss of a proper perspective, and when one sees a comparatively narrow branch of astronomical inquiry, like eclipses, occupying a rather ponderous volume, he may be led to think that the subject has been indiscreetly expanded. We therefore hasten to say that there is no evidence of disproportionate treatment in Mr. Buchanan's book. He himself has been employed for twenty-three years in the office of the "American Ephemeris and Nautical Almanac," and during that time has been responsible for the accurate preparation of the necessary information connected with eclipse prediction. His practical acquaintance with the subject eminently fits him for the task he has undertaken, and his book is a success. The moon's nodes have made more than one complete revolution since he began his work, and an entire series of eclipses has revealed to him their peculiarities and oddities.

The theory of eclipses has been well explained by various astronomers, and practical rules given by some. Hallaschka, in his "Elementa Eclipsium," following the method of orthographic projection, has worked out an example in full. Woolhouse, in the appendix to the "Nautical Almanac" for 1836, not only discussed the subject with great fulness, but gave practical rules for the determination of the phenomena, which for many years were followed in the preparation of the English ephemeris, and perhaps are so still. Bessel gave a more thoroughly consecutive discussion, which Chauvenet followed in his treatise, and this last forms the basis of Mr. Buchanan's work. The practical part of the arrangement does not seem to be easily systematised. A computer finds some difficulty in translating the formulæ into numbers. There are to the uninitiated continual ambiguities about the quadrants; and the manner in which angles are to be reckoned is frequently a stumbling block to the unwary. Perhaps these little difficulties are more noticeable in Woolhouse's method than in Bessel's, but it is with the view of limiting these troubles and of giving a convenient arrangement to the whole of the work that Mr. Buchanan has written his book. In his time he must have met with all the difficulties with which a young computer has to contend, and must have removed these out of the path of many. Knowing these pitfalls, he has done his best to get rid of them by suitable explanations, and probably with success. But those who have conducted pupils through carefully worked examples know only too well that a fresh set of difficulties is apt to reappear with a new case.

The author has divided his book into two parts. In the first he treats of solar eclipses and the method of deriving the various curves which are necessary for the exhibition of the whole circumstances of the phenomenon on a map. Here we get the north and south limits of total and partial eclipses, the position where the eclipse begins and ends with the sun in the horizon, and one can follow the method by which are drawn those weird curves on the eclipse maps that accompany every nautical ephemeris. By way of adding a little lightness to a rather dreary subject, we may notice some curiosities the explanation of which is not very readily seen without the assistance of a competent guide, such as the occurrence of a north limiting curve of totality falling south of the south limiting curve. Ingenuity might construct some further troublesome problems of this nature when the clue is furnished, and one can imagine an examiner exulting over the discovery of such oddities, affording as they do opportunity for worrying unhappy candidates who fall into his hands.

In the second part of the book we have detailed the method of computing the circumstances of lunar eclipses, occultations of stars by the moon, and of the transits of Venus and Mercury. These are practically particular cases of the same problem as that treated in the first part, simplified by certain conditions. In the case of the lunar eclipse, the absolute position of the moon and shadow are independent of the position of the observer on the earth, and therefore the effects of parallax can be treated much more simply. We notice that the semi-diameter of the shadow is increased by the fiftieth part of its amount, in preference to the older estimate of 1/60, but the whole question of semi-diameters is a troublesome one, which will soon have to be treated with great rigour. The occultation semi-diameter is not altogether satisfactory, and some international convention is needed to secure uniformity. From a letter from Dr. Downing, quoted by the author, we gather that the occultation diameter of the moon, as used in the preparation of the English "Nautical Almanac," differs $2''.36$ from that employed in eclipse calculations. But we find a little difficulty in following the author in his reference to authorities. In the matter of lunar parallax, Adams is not quoted, and Lardner's "Handbook of Astronomy," or Proctor on "The Moon," can scarcely be considered original and trustworthy sources.

W. E. P.

ENGLISH FIELD-BOTANY.

Flora of Hampshire, including the Isle of Wight. By Frederick Townsend, M.A., F.L.S. Second edition. Pp. xxxviii+658. (London: Lovell Reeve and Co., Ltd., 1904.) Price 21s. net.

ENGLISH field botanists frequently complain that the British flora has not yet received the careful critical attention which has been lavished on Continental floras. To a certain extent this is doubtless true. We have no manual that for thoroughness of treatment and wealth of reference to original descriptions and type-specimens can compare with Rouy and Foucault's "Flore de France"; at the same time there is an abundance of valuable information scattered through our numerous natural history journals only waiting for some energetic and widely experienced systematist to collate and bring together in a really satisfactory British flora. There are several botanists eminently fitted for such an undertaking, and it is urgently to be desired that one or more of them should take the matter in hand. Meanwhile, our numerous and rapidly accumulating county floras are paving the way to a complete botanical survey of the British Isles.

In Mr. Townsend's "Flora of Hampshire and the Isle of Wight" we have one of the best books of its class, and the work and careful attention expended upon its production must have been very considerable. The volume opens with a chapter on topography and climate. This is followed by an account of the geological structure of the district, including a summary of Mr. Clement Reid's researches on the fossil seeds of the Stone and Silchester beds of the newer Tertiary formation. In his list it is particularly interesting to notice the names of several plants usually regarded as weeds of cultivation, or as colonists, such as *Brassica alba*, Boiss., *Thlaspi arvense*, L., *Linum usitatissimum*, Linn., and also damson and plum.

The now generally approved method of dividing a district into botanical areas according to its river-systems is here in the main followed, and a useful map of the county is appended. Turning to the systematic section—by far the larger portion of the book—so many points call for attention that it is quite impossible within the limits of a short notice to mention more than a few of them. In the section devoted to Ranunculus, what appears to be a satisfactory account of the forms of *R. acris* is given; this will be appreciated by many collectors. The name *Nymphaea alba*, Linn., is retained instead of *Castalia speciosa*, Salisb., which found favour in the eyes of the editors of the "London Catalogue" (ninth edition). *Viola calcaria*, Bab., appears as var. β of *V. hirta*, Linn., though the author admits an inclination to regard it as a starved or stunted form rather than a variety. No mention is made of *V. calcaria*, Gregory, which has been cultivated, and appears to be a good species.

V. canina, Linn., is given as synonymous with *V. flavicornis*, Sm., non Forster, while *V. ericetorum*, Schrader, appears as a hybrid *canina* × *lactea*. All botanists will not find themselves in agreement with Mr. Townsend upon this point, for *V. ericetorum* is sometimes abundant where *V. lactea* is extremely scarce. Perhaps it may be hoped that cultivation will settle the question, especially if it be found that hybrid violas obey Mendel's law of segregation.

The list of Rubi brings the number up to eighty-five, making the county, with one exception, the richest in brambles of any in the British Isles. Some useful notes on the genus Erythræa are given, and the variety *sphaerocephala*, Towns., of *E. capitata*, Willd., is beautifully figured; the author now considers that the plant does not merit a varietal name.

Among the Monocotyledons, the Rev. E. F. Linton's *Orchis ericetorum* is fully described. It appears to be a well marked plant, and the fact that it grows only on heaths while the chalk plant is typical *O. maculata* cannot be said to militate against its claim to specific rank in view of the parallel case of distribution of the two plants included under the name *Valeriana officinalis*, Linn. But here again there may be great virtue in cultivation. It is satisfactory to find the truth told about *Ruscus aculeatus*. The plant with staminate flowers has narrower cladodes than the pistillate plant, and there is no evidence for a narrow-leaved and a broad-leaved variety.

In an appendix appear notes on several plants, amongst which are *Stellaria umbrosa*, Opiz, and *S. media*, Linn. (both of which are fully diagnosed), *Prunus spinosa*, Linn., *P. fruticans*, Weihe, *P. insititia*, Linn., and *P. domestica*, Linn. An account of Murbeck's arrangement of the gentians is given, and all the forms of Euphrasia and Salicornia noted in the county are described. So much matter of general interest is brought together that no field botanist, be he a native of the district or a worker in any other part of the country, can afford to neglect this volume.

SANITARY ENGINEERING.

Small Destructors for Institutional and Trade Waste. By W. Francis Goodrich. Pp. 127. (London: Archibald Constable and Co., Ltd., 1904.) Price 4s. net.

MR. GOODRICH'S book on "Refuse Disposal and Power Production," which dealt with the problems arising in the disposal of civic waste, was recently reviewed in these columns (May 12, 1904, vol. lxx. p. 25); in the present volume the same author treats of the equally important subject of the disposal of institutional and trade refuse, that is, with the design and working of small destructors. The aim has been to make clear the fact that high temperature working is as vital in the small as in the large destructor.

In an introductory chapter Mr. Goodrich lays down the principles which must be observed in the design of small destructors, and he points out that it is possible to operate at a low working cost such destructors when built on modern lines. The weak points in the design of the earlier forms were precisely those which were found in the early forms of large municipal destructors, namely, low temperature system of working, slow combustion, and inadequate and unsatisfactory methods of feeding the refuse into the cells; these difficulties, however, have all been overcome, and at the present day small destructors for use in institutions such as isolation hospitals, hotels, &c., can be obtained as satisfactory in every respect as the large ones now so commonly employed. On account of the unpleasant substances which have to be dealt with in many of these institutional destructors, they are often neglected, and proper supervision over them is not maintained; this leads to the refuse being improperly fed into the destructor; in a good modern type there is no risk of this misuse, as it is impossible to feed the destructor in any other way than that originally provided by the designer.

A number of typical destructors suitable for such institutions are described and illustrated, the drawings being fairly complete. In thinly populated districts it is often advisable to have a portable destructor, and two very successful ones of this type, namely, a Horsfall and a Meldrum, are described. Such portable destructors would be invaluable during campaigns and in our home training-camps. How dangerous the waste from a large camp may become to health was vividly shown during the inquiry by the Royal Commission into the war in South Africa. Many of the medical witnesses expressed the opinion that hundreds of lives might have been saved had the necessary steps been taken to destroy camp refuse properly and to supervise thoroughly the sanitary condition of camps. In America, which, strangely enough, has lagged behind in the adoption of municipal destructors, there has been a considerable development in the utilisation of the smaller forms, both for hospitals and for hotels. The latter portion of the book treats of the disposal of trade refuse, and the author points out how valuable from the point of view of generation of power this trade refuse often is. Such trade refuse can only be burnt in boilers specially designed for fuel of low calorific power, and where the boilers are properly designed there is no difficulty in utilising it. A number of different types of furnaces and boilers suitable for use with trade waste are described and illustrated in these chapters.

The last few pages of the book are devoted to a discussion as to the advantages of disposing of carcases of diseased and condemned beasts by means of suitably designed destructors. The book will be found, like Mr. Goodrich's other books upon this important branch of sanitary engineering, extremely valuable by all who are engaged in dealing with the disposal of solid refuse. T. H. B.

OUR BOOK SHELF.

La Statique chimique basée sur les deux Principes fondamentaux de la Thermodynamique. By E. Ariès. Pp. viii+251. (Paris: A. Hermann, 1904.) Price 10 francs.

Die heterogenen Gleichgewichte vom Standpunkte der Phasenlehre. Zweites Heft, erster Teil. By H. W. Bakhuis Roozeboom. Pp. xii+467. (Brunswick: F. Vieweg and Son, 1904.) Price 12.50 marks.

THE two volumes under review are concerned with the application of thermodynamics to the problems of general chemistry, but are yet so different in material and in treatment that few points of resemblance may be found between them.

In the book by Lieut.-Colonel Ariès the mathematical derivation of the laws of equilibrium from the fundamental principles of thermodynamics are stated in the most abstract and general form with just sufficient exemplification to indicate the bearing of the deductions on the practical work of physical chemistry. The author uses as characteristic function the thermodynamic potential at constant pressure, and it may be said in a word that his deductions are as simple and concise as the case will allow, the introduction of useless conceptions and formulæ being scrupulously avoided. One noteworthy feature which might with advantage be imitated in other works on thermodynamics applied to chemistry is the postponement of the discussion of the perfect gas to a point in the last third of the volume. The student is only too apt in dealing with the involved formulæ of certain cases of chemical equilibrium to introduce unconsciously into his equations some result which has its origin in a consideration of perfect gases, thereby obtaining a simple result apparently general, but in reality not so. The temptation to do this is greatly lessened by the simplification of the perfect gas being delayed until the general formulæ are well developed. The book is well and clearly written, and those interested in mathematical chemistry will be thankful for this lucid exposition of the subject.

The first part of Prof. Roozeboom's book has already been noticed in NATURE. It dealt with the equilibria of systems of one component. The present volume deals with the equilibria of binary systems, though such is the wealth of material that it has been found necessary to reserve the discussion of many systems presenting special features for a subsequent volume. In contradistinction to the work of Colonel Ariès, there is scarcely a mathematical formula to be found in Prof. Roozeboom's treatise; the graphic method is used to the practical exclusion of others. In the present part there are 150 diagrams, chiefly of curves the co-ordinates of which are pressure, volume, temperature, and composition in some combination. As in the first part, the various equilibria are carefully classified according to the nature of the phases involved, and each class is discussed in detail with the most pains-taking completeness, and with full reference to the original sources of the experimental work used in illustration. In general terms the volume may be said to deal with simple solutions, and no one whose interest lies in this direction can afford to dispense with the aid of such a valuable guide to the work already accomplished, and to the theory of the practical work still to be performed. J. W.

The Timbers of Commerce and their Identification. By H. Stone. Pp. xxviii+311. (London: William Rider and Son, Ltd., 1904.) Price 7s. 6d. net.

THIS work is sure to meet with a cordial reception and to be welcomed by all branches of the timber trade. The information contained in its pages is such that only an enthusiast and expert could bring together with the cooperation of others interested in the growth and utilisation of timber in every part of the globe. In all 247 different species are described, even to the minutest detail. In each case the specific name and authority are stated, and, wherever necessary, to avoid confusion, the synonyms have also been added. Then comes a list of the alternative names, or what we might call the common names. It is a well known fact that frequently one and the same kind of timber receives two different names, whereas two totally different species may be known by the same common name. The vernacular names in foreign languages, so far as they are not to be found in dictionaries, have also been quoted. Following this comes a paragraph dealing with physical characters, &c., such as recorded dry weight, hardness, taste, combustion, character of ash constituents, &c. The grain and bark are next described. The following paragraph deals with the uses to which the timber may be put. The colour is also given as a means of identification, and the anatomical characters, as seen in transverse and longitudinal sections, are fully described.

The author seems to have spared no pains in collecting and authenticating the vast amount of information and details necessary for the above purpose. A very valuable feature of the book are the illustrations, numbering 183 photomicrographs, which represent all the genera mentioned in the text, except where a single illustration serves for more than one genus. In most cases the photographs are taken from transverse sections, though in many cases longitudinal sections are also given. It is stated that the scale of magnification is three times the actual size, and is designed to show the appearance of a transverse section as seen by means of an ordinary hand lens. For those desiring further general information about wood a very useful bibliography is given at the end of the book. Also two appendices are added, which respectively describe the method and apparatus for measuring the amount of resistance in timber to impact and the absorption of water by a given area on any surface of a piece of wood.

At the beginning of the book a very interesting chapter, entitled "Practical Hints," is included, which we are sure will be read with much interest and profit by all those who work with wood. The index is a very complete one, and will render the book invaluable as a ready work of reference.

Verhandlungen der deutschen zoologischen Gesellschaft, for 1904. Pp. 252; illustrated. (Leipzig: Engelmann.) Price 11s. net.

THIS valuable publication contains the papers read at the twenty-fourth annual meeting of the society, held at Tübingen on May 24–26, 1904. The congress was opened by an address from Prof. Spengel, in which the society was congratulated on the good work it continued to produce, and especially on recent investigations on the structure of the Protozoa and on the relations of the nucleus to the general mass of protoplasm. To Prof. Blochmann was assigned the pleasant task of welcoming the society to Tübingen. The published papers are sixteen in number, in addition to which were numerous exhibits and demonstrations. Most of the former are of an extremely technical character, and to a large extent interesting chiefly to specialists. Among them we may refer to Prof. A. Brauer's account of recent investigations into the structure of the light-organs of the bony fishes, more especially of the deep-sea forms, in which the question of the relation of these structures to the lateral line system is discussed at considerable length. Dr. von Buttel-Reepen's article on the mode in which the larvæ of the honey-bee are made to assume a particular sex is also one of considerable importance. In the course of a discussion on the zoological system as commonly taught, Prof. H. E. Ziegler emphasises the view that the rhizopod and flagellate animalcules, together with the Sporozoa, form an allied assemblage, while the ciliated animalcules, both as regards the nature of the nucleus and the mode of reproduction, are altogether different. In a fourth important communication Dr. Bresslau amplifies and illustrates his discovery that the marsupium of the marsupials, in place of being a simple organ, is really formed by the amalgamation of a number of small pouches. These pouchlets, which at first form solid ring-like growths of the epidermis, soon begin to degenerate, and are merged in the wall of the marsupium. R. L.

The Optical Dictionary. Edited by Charles Hyatt-Woolf, F.R.P.S. Pp. x+77. (London: The Gutenberg Press.) Price 4s. net.

THIS is an optical and ophthalmological glossary of English terms, symbols, and abbreviations, together with the English equivalents of some French and German terms arranged alphabetically. The meanings are, as a rule, very clearly given, and the book should prove of use to students (especially medical students) who suddenly come upon an unfamiliar term in the course of their general reading. Of course, it must be understood that it is practically impossible to explain properly any scientific term in a line or two, and this is all that is attempted; the meanings given must therefore in most cases be somewhat unsatisfactory. But the book will doubtless succeed in its aim, especially in the translation of foreign terms. As regards accuracy—the *sine quâ non* of a dictionary—we only notice a very few actual errors, *e.g. dioptrically* does not mean *by reflection,* and in the definition of *numerical aperture* the words *refractive index of the medium in which the object is immersed* scarcely indicate that the medium must extend into contact with the objective. *Underlant* is apparently a misprint for *undulant,* and one-third of p. 70 has got into its wrong place.

But these are not very important blemishes, and we cordially recommend the book to those whom it may concern.

Practical Professional Photography. Vols. i. and ii. By C. H. Hewitt. Pp. 126 and 114. (London: Iliffe and Sons, Ltd., 1904.) Price 1s. net each.

THESE two volumes form a very useful addition to the *Photography* bookshelf series, of which they form Nos. 17 and 18. Although the author does not profess to go into any great detail, he gives an excellent account of the necessary requirements of the professional photographer, from the choice of business premises, the handling of customers, book-keeping, &c., down to the packing up of the finished pictures and their dispatch. The chapters on portraiture, composition, and lighting are especially satisfactory, and many a valuable hint is contained therein.

A great number of illustrations accompany the text. and serve the useful purpose of illustrating the author's remarks on many lines of work.

Solutions of the Exercises in Godfrey and Siddons's Elementary Geometry. By E. A. Price. Pp. 172. (Cambridge: The University Press, 1904.) Price 5s. net.

THIS book will be found very useful to all, both pupils and teachers, who use the well known work of Messrs. Godfrey and Siddons. The solutions, 1836 in number, contain not only the deductive, but the drawing exercises, the figures being all such as the pupil is required to construct. We cannot refrain from pleading for a better figure of a hyperbola than that given on p. 143, which a trained eye rejects at once, although it is not essential to the pupil's work.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Average Number of Kinsfolk in Each Degree.

MAY I ask you to insert yet another brief communication on the above subject, because private correspondence shows that paradoxical opinions are not yet wholly dispelled? The clearest way of expressing statistical problems is the familiar method of black and white balls, which I will now adopt.

Plunge both hands into a dark bag partly filled with black and white balls, equal in number, and well mixed. Grasp a handful in the right hand, to represent a family of boys and girls. Out of this unseen handful extract one ball, still unseen, with the left hand. There will be *on the average* of many similar experiments, as many white as black balls, *both* in the original and in the residual handful, because the extracted ball will be as often white as black. Using my previous notation, let the number of balls in the original handful be $2d$. Consequently the number in the residual handful will be $2d-1$, and the average number in it either of white or of black balls will be half as many, or $d-\frac{1}{2}$. It makes no difference to the average result whether the hitherto unseen ball in the left hand proves to be white or black. In other words, it makes no difference in the estimate of the average number of sisters or of brothers whether the individual from whom they are reckoned be a boy or a girl; it is in both cases $d-\frac{1}{2}$. The reckoning may proceed from one member of each family taken at random, or from all its members taken in turn; the resultant average comes out the same.

This, briefly, is my problem. FRANCIS GALTON.

On the State in which Helium Exists in Minerals.

IN 1898 I published in the *Proceedings* of the Royal Society the results of some experiments on the evolution of gases from minerals on heating them. I succeeded in proving that the hydrogen and carbon monoxide in the gases could be accounted for quantitatively by the reduction of water vapour and carbon dioxide by ferrous oxide, or by similar substances, and that, except in cases in which cavities could be proved to exist, the evolution of a gas from a mineral implied chemical change at the moment of heating. In the cases in which helium was evolved on heating a mineral, I pointed out that by the action of heat it is possible to obtain only half the helium, though the evolution of this gas never really ceases, but only becomes very slow. This I took to be evidence of the existence of a chemical compound of helium with some constituent of the mineral.

Recently (*Trans.* Roy. Dublin Soc., 1904) Mr. Moss has shown that by grinding pitchblende *in vacuo* helium is evolved, and considers this result as certain evidence of the existence of the gas in the free state in cavities. Since, however, helium is evolved, though slowly, from the crushed mineral at a temperature not above 300° C., the liberation of the gas in Mr. Moss's experiment may be attributed to local heating set up in the process of grinding.

In view of recent discoveries it appears to me that both of us have been on the wrong track in looking for an explanation of the phenomenon. As Sir William Ramsay and Mr. Soddy have shown, the presence of helium in the minerals may have resulted from the decomposition of radioactive matter, formerly present in them. Recently Dr. Jaquerod, of Geneva (*Comptes rendus*, 1904, No. 20, p. 789), has found that when helium is heated in a quartz bulb to a temperature above 500° C. the gas passes out through the quartz with a velocity which increases with the temperature. At 1100°, in a comparatively short time the pressure in the bulb fell considerably below that of the atmosphere. Hydrogen appeared to behave similarly.

This experiment shows that quartz, and probably substances of the nature of the minerals we are considering, though impermeable to helium at low temperatures, become permeable at moderately high temperatures, and furnishes us with a solution of the second part of our problem.

I think that we are now justified in assuming that the helium, a product of radio-active change, is present in the minerals in a state of supersaturated solid solution; that the mineral substance being impermeable to the gas at ordinary temperatures, the velocity with which equilibrium is established between the helium in solution and the helium in the gaseous phase is infinitely small, but increases very rapidly with rise of temperature; that as the solubility of helium in the mineral substance is probably very small, the mineral cannot be made to re-absorb the gas. Grinding even to an impalpable powder, if unaccompanied by local heating, should result in the evolution of minute quantities of helium only.

I may point out in conclusion that the "deflagration" which takes place when "fergusonite" is heated, and was taken by Sir Wm. Ramsay and myself to indicate the presence of a chemical compound of helium, also takes place in the case of some minerals which contain no helium.

University College, Bristol. Morris W. Travers.

The Pollination of Exotic Flowers.

In connection with Prof. Groom's article on the pollination of exotic flowers (November 10, 1904, p. 26) the following notes may be of interest. The inflorescence of *Marcgravia Umbellata* is described in Schimper's "Plant Geography," where Belt's description is quoted from the "Naturalist in Nicaragua." The plant is common here, climbing to the summit of the forest trees, and is frequently visited by humming birds. The bird settles on the top of the flowers and inserts its long curved beak into the pitchers below to suck the sweet juice which they contain. I have not seen insects visiting the flowers, neither have I found them in the pitchers, and conclude that the birds are attracted by the sweet juice itself rather than by insects in search of it as Belt suggests.

Flowers with strong scent and brush-like stamens are very common, and one of them, the Pois Doux (*Inga laurina*), is surrounded when in blossom by a motley crowd of bees, large beetles, and insects of every description, as well as by humming birds of several species. The latter certainly visit very different plants, but are most familiar hovering round the banana flowers, sucking the drops of sweet liquid continually oozing from them.

Flowers like the Pois Doux are easily destroyed by heavy rain, and blossom only for a short period. A large number of others are provided with horned stamens, with barren anthers or anther lobes. May not this be a protection against loss of pollen by rain and wind, it being kept in a sheltered situation, and only set free when an alighting insect moves the stamens? It would be interesting to observe how far the abundance of flowers with horned stamens is correlated with heavy rainfall and constant wind.

Dominica, December 13, 1904. Ella M. Bryant.

Reversal of Charge in Induction Machines.

I have tried Mr. G. W. Walker's experiment with a small Wimshurst, with 8″ plates, and find that the reversal he mentions generally takes place, but not always. In my case, however, the machine is made so as to excite either way, and the reversal will not take place unless excitation has occurred while the motion is reversed.

R. Langton Cole.

Sutton, Surrey, January 6.

EVIL SPIRITS AS A CAUSE OF SICKNESS IN BABYLONIA.[1]

In a former number of Nature (vol. lxix., p. 26) the attention of our readers was directed to the appearance of the first volume of a work which Mr. Campbell Thompson, of the British Museum, was devoting to the consideration of the important function which devils and evil spirits were believed to play in the production of disease by the early inhabitants of Babylonia. It was impossible at that time to state the final conclusions at which Mr. Thompson had arrived, for the publication of his work was not completed; but now that we have the second volume in our hands our readers are in a position to judge for themselves of the character and importance of the results, which have now been clothed in the dress of a modern language for the first time. The sources of such results, we need hardly say, are the terra-cotta tablets of the royal library at Nineveh, now preserved in the British Museum, and after a careful examination of Mr. Thompson's volumes we are able to say that the translator has done his best to reproduce the meaning of the documents which he places before us without unnecessary comments or theories.

It must be said at the outset that we do not regard Mr. Thompson's work as final in all particulars, for in respect of many Assyrian texts this work is the *editio princeps*; but none can fail to be pleased with the manifest honesty of the translations, which quite justifies us in overlooking the baldness and crudity of expression which sometimes characterise them. In studies of this kind we want the texts and the best rendering of them possible, but the most important point of all is that the editor should not read meanings into the words of his texts or twist them to suit preconceived notions. It goes without saying that Mr. Thompson's translations will not be accepted by other labourers in his field without reservation. Indeed, we may note in passing that M. Fossey has already animadverted upon them in the *Recueil de Travaux*, in the *Revue Critique*, and in the part of the *Journal Asiatique* just issued. It is no part of our duty here to attempt to vindicate Mr. Thompson's renderings or to belittle M. Fossey's knowledge of the science of ancient magic, but it must in common fairness be stated that the latter *savant* is not skilled in dealing with cuneiform documents except through the medium of the copies of other scholars who have been trained in making transcripts direct from the original tablets, and the mere fact that he condemns Mr. Thompson's derivations from the Syriac proves that he does not comprehend the importance of one northern Semitic dialect in helping to explain another. On the other hand, Mr. Thompson has spent some years in the task of copying the various classes of tablets which he is now editing and translating, and though some may admire M. Fossey's tempting renderings, and prefer them to those of Mr. Thompson, it should be remembered that the translations set forth in the volume before us are those of the skilled workman who is working at his trade, whilst those of M. Fossey are the product of a student of magic and religion in general.

The groups of tablets published by Mr. Thompson are five in number. The first are inscribed with exorcisms and spells which are directed against the disease of ague or fever; the second contain charms and incantations which were intended to do away with headache; the third deal with a series of diseases of an internal character, but it cannot at present be said exactly what those diseases were; the fourth are inscribed with texts written with the view of destroying the "taboo" to which, it seems, man was thought to be peculiarly liable; and the fifth supply descriptions of supernatural beings, among whom may be mentioned a creature who was half woman and half snake. Mr. Thompson identifies her with the goddess Nin-tu, who was the Babylonian equivalent of the Egyptian goddesses Hathor, Isis, Mer-sekert, &c., and the Virgin Mary among Oriental Christian peoples. Like each of those goddesses she was a form of the World-mother, or chief Mother-goddess who plays such an important part in many mythologies. By way of supplement, Mr. Thompson has added the

[1] "The Devils and Evil Spirits of Babylonia." By R. Campbell Thompson. Vol. ii. Pp. liv+179. (London: Luzac and Co., 1904.) Price 12s. 6d. net.

translation of an ancient prescription for curing the tooth-ache. The sufferer was ordered to mix some beer with oil and with another unknown ingredient, and, having rubbed it on his tooth, he recited the following words three times:—"When Anu had created the heavens, the heavens created the earth, the earth created the rivers, the rivers created the canals, the canals created the marshes, the marshes created the Worm, which came and wept before Shamash and cried out before Ea, saying:—'What wilt thou give me for my food? What wilt thou give me to eat?' To this the Sun-God replied:—'I will give thee dry bones and scented . . . wood.' To this the Worm made answer:—'Of what use are dry bones and scented . . . wood to me? Let me drink between the teeth and let me be at the gums, that I may drink the blood of the teeth and sap the strength of the gums, then shall I be master of the bolt of the door.'" When the patient had said the above, he was ordered to address the Worm and say, "May Ea smite thee with

FIG. 1.—Bronze animal-headed figure of one of the Babylonian Powers of Evil. From "The Devils and Evil Spirits of Babylonia."

the strength of his fist, O Worm!" We can only hope that these potent words relieved the sufferer.

The bulk of Mr. Thompson's present volume is, of course, occupied with the transliterations and literal translations of the documents of which he treats; but, as these are manifestly intended for the expert in cuneiform only, we may briefly note the summaries of their contents, which appear in the preface. The texts which refer to words of power show that they possessed much in common with a similar class of document found in Egypt and elsewhere. The Sumerian magician having found out the name of the devil which caused the sickness he was called upon to cure, proceeded to deal with it by means of sympathetic magic. He employed ceremonies of various kinds, in which magical figures, loaves of bread, pieces of hair, water, a virgin kid, &c., played prominent parts. Sicknesses could be transferred to the dead bodies of kids and pigs, and devils could be made to disappear into masses of water collected in pots, whereupon the vessels themselves would break. In Sumer and Accad knotted cords were much used for purposes of witchcraft, and knotted locks of hair were held to be all-powerful. The section which treats of the ban and taboo is especially suggestive, and we hope that Mr. Thompson will say more on these subjects when he has collected a larger number of examples. Finally, he directs attention to the existence of the word "*Kuppuru*," which is the equivalent in meaning to the Mosaic idea of "atonement," and the texts printed in the volume before us show conclusively that the acts which formed the atonement removed the taboo which man had incurred. The Sumerian ceremonies of atonement were certainly developed out of sympathetic magic, and the examples of atonement given in the Bible show that the ceremonies mentioned were, in more than one case, closely connected with primitive Hebrew magic. Those who are interested in the study of magic in all its forms will find Mr. Thompson's book of considerable interest and importance.

SPEECH CURVES.

AN interesting lecture[1] was recently delivered in the psychological institute of the University of Berlin by Prof. Scripture, of the University of Yale, whose investigations in phonetics are well known. Prof. Scripture's method is that first employed by Fleeming Jenkin and Ewing, and afterwards developed by Hermann, the writer and others, namely, to record on a moving surface, either by photography or by a direct system of levers, the curves imprinted by speech on the cylinder of a phonograph or on the disc of a gramophone. Dr. Scripture has recently improved the mechanism of his apparatus so as to obtain an amplification of the curves, about three times in the horizontal and three hundred times in the vertical direction, while the speed of the movement of his gramophone plate was reduced 126,300 times that at which it rotates during the acoustical reproduction of the sound. His curves have been submitted to analysis, and it shows the energy with which the research is being prosecuted when he is able to state that in America he has twenty persons engaged in this special bit of work.

In the discussion of his results, Prof. Scripture, in the first instance, refers to some remarks by Prof. Sievers, of Leipzig, on what may be called the "melody" of vowels and words. Prof. Sievers says that each line and verse of a poem has its own melody, and that this will be determined by the psychological condition of the individual at the time of its vocal expression. An author, too, while writing a poem, say one of a dramatic character, may give a certain "melody" to the expressions of one individual. Goethe, for example, causes Faust to drop his voice at the close of a sentence, while the voice of Mephistopheles rises and falls in a variable manner. Sievers also points out, as a curious fact, that when Goethe completed the poem, many years after he wrote the earlier portions, he had forgotten these melodic effects, and the later portions have not the same melodic characteristics. Prof. Scripture supports Prof. Sievers's view. This melodic character will thus affect the quality of a vowel sound.

Prof. Scripture holds that the movement of the vocal cords does not produce a sinuous curve, and herein he agrees with Marage, of Paris. By the movements of the cords a number of sudden and more or less violent shocks are given to the air, and each shock is communicated to the air in the resonators. In this way

1 "Über das Studium der Sprach Kurven." By E. W. Scripture. *Annalen der Naturphilosophie*. (Leipzig: Veit and Co.).

we can interpret the groups of marks made on the wax cylinder of the phonograph. Each group corresponds to a "shock" from the cords, and the smaller curves making up the group are due to the movements of the air in the resonators. Prof. Scripture is not satisfied with the theory of Helmholtz that the resonators develop overtones in a harmonic series, nor with that of Hermann, who asserts that the resonance tones need not necessarily be harmonic. He states that he cannot interpret his tracings by the rigid application of either of these theories, and he lays stress on the fact that the walls of the resonating cavities above the cords are not rigid like the resonators of musical instruments, but are soft, as if the wall were fluid. Such a resonator, he says, will give its own tone in response to all tones. We confess that here we are not able fully to comprehend the author's meaning.

Prof. Scripture endeavours also to establish a close relationship between the form of the vibration of the cords and the action of the resonators. According to him, the form of the vibration of the cord may be altered by changes in the action of the muscular fibres that tighten the cord, so as to produce a tone of a given

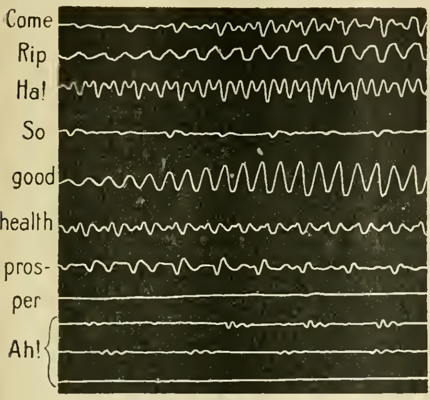

FIG. 1.—Curves of Rip van Winkle's Toast, spoken by the American actor, Joseph Jefferson.

pitch. Assuming that each muscle fibre has a separate nerve fibre (which is highly improbable), one can see that the tension of the cords, even when adapted to the production of a tone of a given pitch, might be so modified as to give out a tone-wave of a special form, and that thus an almost infinite variety of qualities of tone (tone-colours) might be produced. The special quality of tone would thus in the first instance depend on the psychical condition of the individual at the moment. In the next place, according to Prof. Scripture, the "water-wall" resonators, as he calls them, will develop their own tones, independently of the cord-tones, and thus, again, by a summation of these tones, the quality of the vowel-tone may be almost infinitely varied. In this way there is a *physiological* association between the movements of the cords and the action of the resonators.

Prof. Scripture also notes that each vowel has its own harmony, depending on the resonators, and that if it is sounded for even a short time its "melody" may change. This is why it is that when we examine the waves corresponding to a vowel as transcribed from the gramophone they are often seen to change in character as we approach the end of the series of waves. The writer can corroborate this view from his observations by his own method of recording directly the vibrations of a phonograph recorder on a rapidly moving glass plate.

Prof. Scripture also points out a fact that was soon apparent to all observers in experimental phonetics, namely, that in the records of the phonograph or gramophone there are neither syllables nor intermediate glides, but a succession of waves, infinitely diverse in form, corresponding to the tones of the voice or the sounds of any musical instrument. The sound of a single vowel may be in a groove a metre long on the wax cylinder of the phonograph, and in the bottom of this groove there may be thousands of little groups of waves. The writer possesses records of songs that if drawn out would be 100 metres in length. Finally, Prof. Scripture lays emphasis on the effect of varying intensity as influencing quality. Apart from the theory of vowel-tones advanced by the author, this interesting lecture owes its value to the way in which Prof. Scripture approaches the problem from the physiological and psychological side. The mode of production of vowel-tones is in this sense not entirely a physical problem. We are dealing with living cords moved by living muscles, and with curiously shaped resonators having living walls.

JOHN G. MCKENDRICK.

GEOLOGY OF SPITI.[1]

THERE are spots, insignificant in themselves, which have a world-wide celebrity among those interested in certain pursuits or investigations. Such is Gheel to the alienist, Shide to the seismologist, or Bayreuth to the musician, and such, too, is Spiti, a barren and sparsely inhabited valley in the centre of the Himalayas, which has long been known to geologists for its extensive series of richly fossiliferous rocks. A district like this could not long escape the notice of the Geological Survey of India, and one of the earliest volumes of its memoirs is that by Dr. F. Stoliczka and F. R. Mallet. Published in 1864, this remained the standard, and practically the only, description of the geology of Spiti until the publication, in 1891, of Mr. C. L. Griesbach's memoir, in which, while adopting his predecessors' mapping in the main, he introduced great modifications in the sequence. Neither of these descriptions, however, is entitled to rank as more than a reconnaissance, but now we have the results of what may fairly be described as a survey of this region, and, in an interesting and clearly expressed memoir, Mr. Hayden has gone far towards clearing up the points which were in dispute. In all cases where he has found himself at variance with his predecessors' conclusions he has produced good evidence, and it is in one way satisfactory that he is generally in agreement with the one who can no longer defend his views.

The Spiti valley contains representatives of every series from Cretaceous to Silurian, and a Cambrian age is inferred for a series of sedimentary, but unfossiliferous, beds underlying the latter. In all these Mr. Hayden not only collected from known, but also discovered several previously unknown, fossil-horizons, among the most interesting of which we may mention that of the land plants of Culm age. In the Silurian he has restored Stoliczka's correlation and fully supported it by fossil evidence; on the other hand he has confirmed Mr. Griesbach's discovery of Lower Triassic beds, and his conclusion that there is, in Spiti, a continuous conformable sequence from Permian to Upper Trias, and in this connection has rendered ample

1 "The Geology of Spiti, with Parts of Bashahr and Rupshu." By H. H. Hayden. (*Memoirs* of the Geological Survey of India, vol. xxxvi, part i.). Pp. vi+129; illustrated (Calcutta: Government Printing Office, 1904.)

acknowledgment of the work of the late Dr. A. v. Krafft, by whom it had been intended that the description of the Triassic rocks should be undertaken.

A chapter is devoted to the correlation of the unfossiliferous sequence of the outer Himalayas with that in Spiti, and an impartial account is given of the guesses—they are nothing more—which have been made. Mr. Hayden does not attempt to deliver judgment on this vexed question, but seems inclined towards Dr. Stoliczka's view; in this we think that he has not taken sufficient account of what may be called extra-Himalayan considerations. The differences between Spiti and the outer Himalayas, the long sequence of fossiliferous rocks in the one, the complete absence of fossils in the other, seem to admit of only two explanations—either the rocks of one area are unrepresented in the other, or the conditions of deposition were so dissimilar that lithological similarity in the two areas is not to be looked for, and either supposition precludes all hope of direct correlation.

Fig. 1.—Muth Quartzite at Head of Teti River, Bashahr. 6, Daonella Shales; 5, Muschelkalk; 4, Lower Trias; 3, Productus shales; 2, Muth Quartzite; 1, Silurian limestone. From "The Geology of Spiti."

The memoir is indexed and illustrated by plates, several of which are reproductions of photographs by the author; it bears the stamp of careful work, and is worthy of the reputation of the Geological Survey of India. We regret that we cannot say as much for the method of stitching adopted by the Calcutta Government Press; the book may be re-bound, but the torn and mangled leaves can never make a seemly volume.

SIR LAUDER BRUNTON ON THE NEED OF PHYSICAL EDUCATION.

The report of the inter-departmental committee on physical deterioration, while in the absence of scientifically ascertained data it hesitated to pronounce the evil it investigated to be widespread, has pointed us all to a better way, and Sir Lauder Brunton in these two addresses[1] drives home the lesson.

In speaking at Cambridge to the Head Teachers' Association on the National League, which owes its inception to his statesmanlike grasp of the psychological moment at which to enlist the sympathy and interest of the nation, half alarmed, half repentant of its easy optimism and *laissez-faire*, Sir Lauder Brunton went direct to the point—

How can we alter most surely and speedily those conditions which tend to physical deterioration?

The answer lies in a nutshell. By training the young to open-air work and play, to care of teeth and exercise of muscles, the girls in preparation of appetising food, the boys in such drill as will make them real defenders of their country.

We may not go so far as Sir Lauder in his belief in the educative value of the wall picture of the ravages of the tubercle bacillus—we remember the fearful joy with which we contemplated a ghastly picture of volcanic colouring which an old lady assured us was an accurate delineation of a drunkard's stomach—nor do we think his picture of the country cottage altogether accurate; but he has seized the fact that the master of the situation is the teacher, and to the teacher he turns, confident in his zeal, his devotion, his stimulating propaganda, his patient training, confident, too, in the plastic material our schools bring to his hand.

To another large class of workers in the public service, the medical officers of health, Sir Lauder Brunton also appeals. He pointed out to the Incorporated Society that physical efficiency is more than doubtful in the mass of people even if physical deterioration is unproved.

For accurate data as to height and weight, growth and physical development of the youth of the nation, we must look to the teachers in daily touch with them. Such data have hitherto been conspicuous by their absence, but once in existence they will enable the statesman and statistician alike to realise the problem they have to solve.

This involves periodical measurement, and to render their task effective the teachers will need instruction, and the most likely person to be called in to give that instruction is the M.O.H. Without trenching on the medical profession the teacher may learn from them to detect signs of fatigue or mental strain, to note defective vision and physical weakness, all of which too often escape notice until irremediable mischief is done.

Sir Lauder Brunton dwelt on the question of the milk supply, the feeding of underfed school children, and the housing question, and warmly endorsed the committee's recommendation that the medical officer of health should have security of tenure in view of the local jealousies he may arouse, the local prejudices he may cross. Discussing the report, Sir Lauder Brunton approved the desire for a Board of Health to undertake some of the duties of the over-worked Local Government Board; failing such a board, he cordially welcomed the idea of an advisory council for matters concerning the national physique, such council to consist of representatives of the Departments of State reinforced by men of science and by experts in questions of health and of physical development.

He is assured of the readiness of the medical profession to do their part in the educative work; he believes in equal readiness of the teachers to learn and teach what it is of vital importance the coming generation should acquire, not only theoretically, but practically—a knowledge of the laws of health.

The National League for Physical Education and Improvement has so far been mainly confined to the medical profession, but now that its aims are focused and defined Sir Lauder looks to a wider public. He

[1] January 5.—National Federation of Head Teachers' Associations, "The Proposed National League for Physical Education and Improvement." January 6.—Incorporated Society of Medical Officers of Health, "The Report of the Inter-Departmental Committee on Physical Degeneration."

hopes that before long not only every medical officer of health and every school teacher, but every man and woman who knows what is needed, will join its ranks. Thus will be formed that body of enlightened public opinion which is the moving power in every reform worked, in every advance made by nation, district, or parish, and thus the gospel of physical culture and healthy environment may win its way to every British home. No more patriotic work can be imagined, even though "the foes be they of our own household."

NOTES.

THE council of the Geological Society of London has decided to award the medals and funds this year as follows:—Wollaston medal to Dr. J. J. Harris Teall, F.R.S.; Murchison medal to Mr. Edward John Dunn, of Melbourne; Lyell medal to Dr. Hans Reusch, director of the Geological Survey of Norway; Bigsby medal to Prof. J. W. Gregory, F.R.S.; Wollaston fund to Mr. H. H. Arnold-Bemrose; Murchison fund to Mr. H. L. Bowman; and Lyell fund to Mr. E. A. Newell-Arber and Mr. Walcot Gibson.

ST. MARGARET'S BAY, Dover, where great falls of cliff frequently occur, was the scene of another landslip on Tuesday, January 10, when an enormous slice of the cliff, estimated by the coastguard at about a quarter of a million tons, fell into the sea. The fall occurred a little to the eastward of the bay, where the cliff is about 250 feet high. When the fall took place, about 9.30 a.m., it is said that a very sharp earth tremor was felt throughout the village, and was at first believed to be an earthquake. A further fall occurred at noon. As the result of these landslips a gap about 200 feet wide and 50 feet deep appears in the cliff. The débris at the foot of the cliff covers a large area with some very large fragments of rock. The mass is 20 feet or 30 feet high, and extends seawards about a quarter of a mile.

WE learn from the *Times* that an International Archæological Congress will be opened at Athens by the Crown Prince of Greece on April 7. The opening meeting will be held in the Parthenon, and M. Carapanos, the Minister of Public Instruction, will address the members of the congress. The director of Greek antiquities and the directors of the foreign schools will give an account of the progress of archæological research in Greece. The congress will be divided into seven sections:—(1) classical archæology; (2) prehistoric and oriental archæology; (3) excavations, museums, and preservation of monuments; (4) epigraphy and numismatics; (5) Byzantine archæology; (6) instruction in archæology; (7) geography and topography.

A SLIGHT earthquake shock which lasted a few seconds was felt at Gibraltar on January 7, at 5 a.m. No damage was done. The disturbance was also felt in the Spanish towns of Algeciras, Campamento, and San Roque. At La Linea there were two severe shocks, each lasting about five seconds, the first occurring at 4.40 a.m., and the second at 4.52 a.m.

ON Tuesday next, January 17, Prof. L. C. Miall will begin a course of six lectures at the Royal Institution on the "Structure and Life of Animals." The discourse on Friday, January 20, will be delivered by Sir James Dewar on "New Low Temperature Phenomena," and on January 27 by Dr. E. A. Wilson on "The Life of the Emperor Penguin."

WE regret to see the announcement of the death of Mr. G. W. Hemming, K.C., in his eighty-fourth year. In addition to contributions extending over many years to various magazines and periodicals, he was the author of a "Differential and Integral Calculus," which appeared in 1848, and also of a work entitled "Billiards Mathematically Treated" (1893), of which a second edition was recently published.

THE death is announced of Mr. Robert Harris Valpy at the advanced age of eighty-five. Although a keen geologist, he published very little, but he made a very fine collection of fossils from the Devonian rocks of North Devon, and his assistance was acknowledged in the late Mr. Etheridge's work on the "Physical Structure of West Somerset and North Devon" (1867). Mr. Valpy was the author of "Notes on the Geology of Ilfracombe and the Neighbourhood," published anonymously by Twiss and Sons, of Ilfracombe.

THE first award of the Henry Saxon Snell prize will be made this year by the Royal Sanitary Institute. The prize was founded to encourage improvements in the construction or adaptation of sanitary appliances, and is to be awarded by the council of the institute at intervals of three years. The first prize, which will consist of 50*l*. and a medal of the institute, is offered in the year 1905 for an essay on "domestic sanitary appliances, with suggestions for their improvement." Essays must be delivered on or before March 30, addressed to the secretary of the Royal Sanitary Institute, 72 Margaret Street, W.

THE Association for Maintaining the American Women's Table at the Zoological Station at Naples and for Promoting Scientific Research by Women announces the offer of a third prize of 200*l*. for the best thesis written by a woman, on a scientific subject, embodying new observations and new conclusions based on an independent laboratory research in biological, chemical, or physical science. The theses offered in competition are to be presented to the executive committee of the association, and must be in the hands of the chairman of the committee on the prize, Mrs. Ellen H. Richards, Massachusetts Institute of Technology, Boston, Mass., before December 31, 1906. The prize will be awarded at the annual meeting in April, 1907.

THE death is announced of Mr. Beauchamp Tower, who was associated for some years with Mr. W. Froude, F.R.S., in the experiments made for the Admiralty on the models of ships and on full-sized vessels and engines of the Navy, from which experiments much of the present knowledge of the scientific design of ships has been derived. While working as a consulting engineer, says the *Times*, Mr. Tower developed several ingenious inventions, notably a machine to carry out Mr. Spencer Deverell's idea of obtaining work from wave motion, the well known "spherical" steam-engine, largely employed for some years where high rotary speeds were needed, a centrifugal pump revolution indicator for ships, and a gyroscopic steady platform for guns at sea, all of which afford good examples of originality and scientific acumen. He also undertook for the Institution of Mechanical Engineers, and carried to a successful issue, an extremely complete series of experiments on friction, by which much new knowledge on the subject was gained.

LONDONERS probably began to realise that the electrification of the "underground" railways was nearing completion when, last week, a partial electrical service was started on the section of the lines running from Baker Street to Harrow and Uxbridge. This marks the first step in the change which will be carried out by degrees over the whole system, the electrical trains being at first run in place of some only of the regular trains, their numbers being increased until eventually the complete service is electrical. When this has been effected, and the steam trains entirely displaced, the cleaning of the stations and tunnels will be taken in hand; it is not until this is complete that the public will derive the full benefit of the alteration, so it is to be hoped that no difficulties will be experienced to cause delay. It has been no small undertaking to prepare everything for the conversion of these lines, and the actual change itself must necessarily be carried out with care, especially as it has to be effected without interruption of the traffic.

M. H. BOURGET, of the University of Toulouse, writes to ask what is the form of the surface of a fowl's egg, and if precise measures have been made of eggs in order to determine whether the shape is constant and approaches that of any known geometrical figure. In reply to this inquiry, Prof. G. H. Bryan, to whom the matter was referred, remarks:—"I believe it is generally recognised that the shape of the meridian section of an egg is most approximately a Cartesian oval, that is, a curve given by the equation $ar_1+br_2=c$, where r_1 and r_2 are distances from two fixed points. For $a=b$ this becomes an ellipse, but with a and b unequal we get a figure with one end more rounded and one more pointed, very like an egg. But anyone who tried to find mathematical equations for the curves occurring in the forms of organic life would have a difficult task, especially if he were to tackle the Diatomaceæ. It should also be remembered that the number of curves which have an equation is infinitely small compared with the number of curves that cannot be so represented."

THE annual report of the Russian Geographical Society for 1903 has only just reached us. Among the scientific explorations accomplished during the year we notice the explorations of Lake Balkhash by M. L. S. Berg, of Lake Kosogol by M. V. S. Elpatievsky, of Lake Ladoga by M. J. M. Shokalsky, and of various lakes in European Russia, as also of Lake Gokcha, by several students under Prof. D. N. Anuchin. M. V. I. Lipskiy has continued to study the flora of Central Asia, in connection with his forthcoming work on this subject, and has made for this purpose interesting journeys in the Tian-Shan, while the range of Peter I. has been further explored by M. V. Th. Novitzkiy. The botanist, M. J. N. Voronoff, explored north-western Mongolia, M. N. B. Grinevetskiy the flora of Transcaucasia, V. A. Faussek the Transcaspian fauna, and V. E. Petersen the Lepidoptera of the Urals. A journey in the Pechora region, by P. P. Mataftin, is also worthy of notice. Several expeditions—Dr. Zarudnyi in Persia, Syeroshevskiy, explorer of the Ainos, in Yezo, Karskiy in White Russia—were at work during the same year, as also the committee for the scientific collection of folk-songs, with their music.

AT the meeting of the Institution of Civil Engineers held on January 10 Sir William White, K.C.B., delivered an address on the recent visit of the institution to the United States and Canada. He described the visits made to the principal engineering works in New York City and district, to those in Canada, and to similar enterprises in Chicago. In Canada, many opportunities were afforded to see examples of the utilisation of water power, and no one could fail to realise the enormous possibilities of development in the pulp and paper industry, with cheap power and a good supply of labour. The visitors were informed that within a few miles of Ottawa there is 200,000 h.p. of water power, and within a radius of forty-five miles nearly a million horse-power. At Niagara on the Canadian side three new undertakings are being rapidly advanced, together giving more than 400,000 h.p., while a fourth will yield 40,000 h.p. When these are completed the grand total of power derived from Niagara on both sides of the river will be about 700,000 h.p. These particulars were followed in the address by an account of the International Engineering Congress at St. Louis organised by the American Society of Civil Engineers. Concluding, Sir William remarked that there can be no doubt but this visit enabled American and Canadian engineers to give practical proof of their fellowship with British engineers. The visit must tend to strengthen the friendly feeling already existing between the United States and the British Empire. It must result also in a better understanding between the mother-country and Canada.

A VALUABLE report by Dr. Musgrave and Mr. Clegg on pathogenic amœbæ, the cultivation of amœbæ, and amœbic dysentery, has been issued by the Bureau of Government Laboratories, Manila (No. 18, 1904). It is considered that all amœbæ are, or may become, pathogenic. Pure cultures of amœbæ were obtained by a modified plate culture method, but it was not found possible to cultivate the organisms unless bacteria were present in the cultivations, and the amœbæ were often found to exhibit a preference for certain species of bacteria.

THE United States Department of Agriculture has added to its valuable memoirs on food and diet a report by Messrs. Woods and Mansfield on the food of the Maine lumbermen (*Bulletin* No. 149, 1904). These men perform hard manual labour, and are much exposed to cold, wet, and hardship, and the staple daily fare consists of pork or beef, sour dough biscuits made of dough which undergoes fermentation with a "wild" yeast, tea and molasses, and beans which are first parboiled in the forenoon, and are then packed with alternate layers of salt pork in a pot which is covered with hot ashes and earth, and allowed to cook over night. It is considered that the dietary, as regards protein and energy, is the highest yet recorded for any American labouring men, is well digested, and costs about 23·5 cents per person per diem.

WE have received a copy of the third and final part of a "Catalogue of Canadian Birds," by Mr. J. Macoun, issued by the Geological Society of Canada, which deals with such families of the Passeres as were not included in the preceding part. Owing to the fuller knowledge of the habits of most of the birds recorded in this part, as compared with those in its predecessors, a larger amount of space is devoted to the majority of the species, thereby enhancing the value of the work. Otherwise the method of treatment is the same as that adopted in parts i. and ii., which have been previously noticed in our columns.

IN the eighteenth annual report of the Liverpool Marine Biology Committee, dealing with the new biological station at Port Erin, Isle of Man, the director deplores that while there have been more students than in any previous year (who have worked harder than their predecessors) and more investigators engaged on original work, to say nothing of the success of the public meetings and the excellent result of the fish-hatching, yet the number of subscribers does not increase; and, in truth, the list of subscriptions to such an admirable institution is but a pitiful one—a total of 89*l.* 3*s.* 6*d.* The marvel, indeed, is how so much good work is accomplished and the establishment kept in going order on an income of 176*l.* 14*s.* 1*d.* Apparently, however, there must be some other fund for the up-keep of the building, as there are no items in the account for caretaker's wages or for repairs. The committee has been unfortunate in losing several influential friends and supporters, among them Dr. Isaac Roberts, during the past year, and regret is expressed that it becomes increasingly difficult to find men of the same stamp among the younger generation to fill their places. The report is illustrated with figures of the early stages of the development of the lobster and of the plaice. Although plaice-hatching was fairly successful, results were by no means so good as regards the rearing of lobsters. After one failure 5000 larvæ were successfully hatched; but of these, despite every care, very few attained the "lobsterling" stage. It is incidentally recorded that the female spiny lobster (*Palinurus vulgaris*) destroys her eggs in captivity. The general interest of the report is much enhanced by an illustrated account of Manx (or "Manks") antiquities, inclusive of fossil mammals, by Messrs. Kermode and Herdman.

In the *Sitzungsberichte*, No. 22, of the Imperial Academy of Sciences in Vienna, Mr. J. Dörfler gives an itinerary of a six months' tour in the island of Crete, undertaken for the purpose of collecting botanical specimens. From this point of view the journey was very successful, as 1200 plants were obtained, including *Triadenia Sieberi*, *Senecio gnaphalodes*, and the tiny *Bellium minutum*.

Two rare seaweeds, Rhipidosiphon and Callipsygma, both referred to the Codiaceæ, form the subject of a short article contributed by Mr. and Mrs. A. Gepp to the *Journal of Botany* (December, 1904), and Mr. Salmon presents a second instalment of his notes on Limonium. The second supplement (1898–1902) to the biographical index of British and Irish botanists, compiled by Mr. J. Britten and Mr. C. S. Boulger, is concluded in the same number.

In addition to the maintenance of the more ornamental gardens, the director of the Public Gardens, Jamaica, in his report for the year 1903–4, describes a number of experiments which have been carried on at the Hope Experiment Station. With the view of combining the good qualities of different varieties of pineapples, a number of hybrid seedlings have been raised by crossing the Cayenne, Ripley, and Queen varieties. The method of growing Sumatra wrapper-tobacco under tent-cloth, as practised in the Connecticut valley in America, was tried with good results, but the climate at Hope was found to be too dry for curing the leaf satisfactorily. Considerable success has attended the budding of mango, nutmeg, cocoa, and other trees, and the process is strongly recommended, both as a means of rapid propagation and also with the object of improving the fruit.

We have received a further instalment of the States gazetteers, already noticed, in the "Gazetteer of West Virginia," by Mr. Henry Gannett, published by the United States Geological Survey.

The August and September (1904) numbers of the *Bollettino* of the Italian Geographical Society contain an extremely interesting and suggestive memoir by Prof. Gustavo Coen on the supposed decadence of Great Britain and the awakening of eastern Asia. The conclusions of the paper, which cannot be briefly summarised, are obviously the result of wide study and research, and should be of great value to geographical and political students in this country.

In a paper published recently in the Hungarian *Mathematischen und naturwissentschaftlichen Berichte* Dr. von Kalecsinszky gives an account of further observations and experiments on the warming of different layers of liquid by the sun's rays. Observations in lakes in which salt water is covered over with a stratum of fresh water show that the salt water may be warmed to a much higher temperature than the overlying fresh water. Experiments with solutions of magnesium sulphate, sodium sulphate, ammonium chloride, and sodium carbonate, and with fresh water covered with petroleum and with olive oil, gave similar results. It is concluded that the phenomenon is of general occurrence, and that it is a factor of geological importance in the formation of certain deposits.

The United States Weather Bureau has reprinted Mr. W. L. Moore's article on climate, written for the "Encyclopedia Americana," as No. 34 of its *Bulletins*. It embraces only thirteen pages of large octavo size, and is written in clear, simple language that can be understood by all. It contains in this small space a large amount of useful information relating to the effects of solar energy, distribution of land and water, and mountain ranges. With regard to secular variations, the author is of opinion that there has been no appreciable change in the climate of any large area within the period covered by authentic history.

We have received from the observatory of the University of Odessa a copy of its *Annals* for the years 1901–3. The observatory having then completed the tenth year of its existence, the volume in question includes, in addition to observations taken thrice daily, and the monthly and yearly results for 1901–3, a valuable series of means for the ten years 1894–1903. The observatory is situated in latitude 46° 26′ N.; the mean temperature is given as 28°·8 in January and 72°·1 in July. The absolute maximum was 94°·3, and the minimum −10°·3 F.; the temperature of the ground is observed at various depths. The annual rainfall is only 13 inches; the wettest month is June (2·3 inches).

We have received a copy of the report of the International Meteorological Committee's meeting at Southport in September, 1903. The meeting was well attended, and various subjects of interest were discussed, including the valuable reports by subcommittees and by individuals; these reports are printed *in extenso* in the appendix. Five of them refer to the arrangements existing or proposed for the exploration of the upper air by means of balloons and kites, and to the results hitherto obtained. Much credit is due to M. Teisserenc de Bort, who, in addition to the stations he has established at Trappes and Itteville, near Paris, has been chiefly instrumental in establishing similar stations at Moscow and Viborg (Denmark). This latter enterprise is acknowledged to be a most important contribution to meteorological science. Appendix vii. is a very valuable report by Sir Norman Lockyer on simultaneous solar and terrestrial changes, which may have an important influence on the meteorology of the future. After summarising the investigations made from earliest times, he points out the considerable advances made during the last quarter of a century. Among the other appendices we may specially mention two by Prof. Pernter (chief of the Austrian Meteorological Service) and by M. Rykatcheff (director of the Russian Service) on the use of the hair hygrometer instead of the wet-bulb thermometer. This instrument is found to be of much service in times of severe frost. M. J. Violle contributes a valuable report on radiation. The author points out that the question is exceedingly complex, and demands a complete study of each of the simple radiations which go to make up the total solar radiation. The International Meteorological Committee voted for the convening of a conference of all directors of meteorological offices, to be held at Innsbruck in September, 1905.

MESSRS. J. J. GRIFFIN AND SONS have sent us specimens of "Vitro-Ink," which is a non-corrosive ink for writing on glass, celluloid, wood, or other material. The ink may be used with an ordinary pen, and flows quite readily. A useful property is that it may be completely removed by means of a damp cloth at any time before it has set hard, so that mistakes can be rectified without difficulty. The ink will be found of especial service in labelling such things as laboratory or photographic dark room bottles, where labels of ordinary type quickly become discoloured or worn away. When written on with vitro-ink the inscriptions entirely resist strong acids, and it is only prolonged action of strong alkalis or boiling water which may efface the material. Microscopic slides, lantern slides, and glass or celluloid photographic negatives may be labelled and numbered direct, and as the ink is quite unaffected by alcohol it can also be employed for biological or other specimens which it may be necessary to preserve in spirit. Another useful field for this ink will be in the rapid production of diagrammatic lantern slides for class or lecture illustration, as the design may be drawn direct on the glass during actual projection, thereby placing considerable facilities in the hands of lecturers or others desiring to employ the screen in place of a blackboard or prepared wall diagrams. The ink can be especially recommended to photographers as an efficient labelling agent, showing good contrast in the dark room light, and capable of being washed clean instantly whenever the names become stained from the unavoidable oxidation of the various solutions employed.

MR. A. HENRY SAVAGE LANDOR'S new book, "Tibet and Nepal," will be published within the next few days by Messrs. A. and C. Black.

MESSRS. GEORGE BELL AND SONS have published a teacher's edition of part i. of "Elementary Algebra," by Messrs. W. M. Baker and A. A. Bourne. The arrangement by which the answers are printed on the page opposite to the examples which are to be given to pupils to work out should prove convenient for the teacher during class work.

OUR ASTRONOMICAL COLUMN.

DISCOVERY OF A SIXTH SATELLITE TO JUPITER.—A telegram received from the Kiel Centralstelle announces the discovery of a sixth satellite to Jupiter by Prof. Perrine. The existence of the object was suspected in December, 1904, and was confirmed by an observation made on January 4. The position angle on that date was 269°, and its distance from the planet 45′, the latter quantity decreasing 45″ daily, whilst the apparent motion was retrograde.

A later communication from Kiel states that the discovery was made with the Crossley reflector, observations of the satellite having been made on December 3, 8, 9, and 10, 1904, and January 2, 3, and 4.

COMET 1904 *d* (GIACOBINI).—Another set of elements and an ephemeris for comet 1904 *d* have been calculated by Herr M. Ebell from positions determined on December 17, 21, and 26, 1904, and are given below.

Elements.

T = 1904 November 4·22 (Berlin).

$$\left.\begin{aligned} \omega &= 41^\circ\ 15'{\cdot}6 \\ \Omega &= 218\ \ 32{\cdot}0 \\ i &= 99\ \ 39{\cdot}1 \end{aligned}\right\} 1904{\cdot}0$$

$\log q = 0{\cdot}27536$

Ephemeris (12h. Berlin).

1905	α (h. m. s.)	δ (° ′)	log Δ	Brightness
Jan. 12	17 29 10	+40 37	0·3451	1·01
,, 14	17 36 1	+41 42		
,, 16	17 43 2	+42 47	0·3438	1·00

(Kiel *Circular*, No. 71).

ELEMENTS AND EPHEMERIS FOR COMET 1904 *e*.—The following elements and ephemeris for Borrelly's comet (1904 *e*) have been calculated by Dr. Elis Strömgren from the positions determined on December 31, 1904, January 1 and 2:—

Elements.

T = 1905 January 1·2710 (Berlin).

$$\left.\begin{aligned} \omega &= 341^\circ\ 23'{\cdot}22 \\ \Omega &= 69\ \ 54{\cdot}82 \\ i &= 35\ \ 30{\cdot}70 \end{aligned}\right\} 1905{\cdot}0$$

$\log q = 0{\cdot}19344$

Ephemeris 12h. (Berlin).

1905	α (h. m. s.)	δ (° ′)	log Δ	Brightness
Jan. 12	1 33 39	+1 17·4	0·0870	0·83
,, 16	1 40 8	+4 18·7	0·0985	0·78
,, 20	1 46 56	+7 13·6	0·1107	0·73

Brightness at time of discovery = 1·0.

According to the above the comet will pass through the south-eastern corner of the constellation Pisces into Aries, and will be about twenty-five minutes west of α Piscium on January 12 (Kiel *Circular*, No. 72).

COLOURS OF STARS IN THE SOUTHERN HEMISPHERE.—During the period October, 1903–March, 1904, Dr. J. Möller, whilst cruising in the tropical regions of the Atlantic and Pacific Oceans, made a number of observations of the colours of 169 stars situated between declination −20° and the South Pole, all of which were about magnitude 3·5.

The results of these observations are published in No. 3980 of the *Astronomische Nachrichten*, where the observer also shows the reduction of his colour values to Osthoff's scale and the differences between his own results and those obtained by the latter observer.

"THE HEAVENS AT A GLANCE."—The handy card calendar, "The Heavens at a Glance," published by Mr. Arthur Mee, Llanishen, price sevenpence, post free, is full of useful information for amateur astronomers. Among other things it contains a "celestial diary" which gives all the more important astronomical events during each month, a table showing the elements of the sun and planets, and a mass of information relative to the brighter stars, variable and double stars, and star clusters and nebulæ.

Intended to hang on the observatory wall, the calendar forms a most useful adjunct to the more voluminous almanacs which it epitomises.

ASTRONOMICAL "ANNUARIO" OF THE TURIN OBSERVATORY.—The first annual publication of the Turin Observatory appeared in the year 1787, but for various reasons their appearance has not been continuous. A new series commences with the "Annuario" for the present year, and in the preface Signor Boccardi, the director, explains its *raison d'être* by the statement that it does not contain the ephemerides, star-places, &c., published in the larger national almanacs, but deals more especially with the calculations and researches made at the Turin Observatory, and fills up the gaps left by those almanacs.

As examples of this we may mention the tables which contain the mean positions and the apparent positions at upper culmination (Greenwich meridian) of 202 stars not included in the "Nautical Almanac," the "American Ephemeris," or the "Connaissance des Temps." The heliocentric coordinates of Jupiter and Saturn (for 1905 and 1906), the elements and ephemerides of various minor planets, a mass of meteorological data, and a review of the meteorology of 1903 are also given.

ORIGIN OF LUNAR FORMATIONS.—In a paper on "A Possible Explanation of the Formation of the Moon," read before the Royal Society of Edinburgh on November 21, 1904 (see NATURE, December 8, 1904, p. 143), Mr. G. Romanes showed that there had never been sufficient heat developed in the interior of the moon by gravitational compression to account for volcanic action on its surface; and he explained how lunar markings could be accounted for on his hypothesis by the impact of meteoritic masses. Dr. Johnston-Lavis writes to say he has long held this view, and reminds us that Dr. G. K. Gilbert developed the impact theory of the formation of lunar craters several years ago (see *Bull.* Phil. Soc. of Washington, vol. xii., pp. 241–292, and NATURE, vol. xlviii., p. 82, May 23, 1893).

PLANT ASSOCIATIONS IN MOORLAND DISTRICTS.

DURING the last four years systematic observations have been made on the distribution of the various associations of vegetation covering the moorland region lying to the east of the Vale of Eden.[1] The boundaries of each plant association have been traced out in the field and laid down on the six-inch Ordnance map, and reduced to the one-inch map for publication. The factors governing the distribution of plant associations over such a limited area are mainly edaphic, although the differences in altitude, which amount to about 2500 feet in the area in question, produce changes in the vegetation which are chiefly due to climatic conditions. Much of the vegetation at present covering cultivated areas in Britain owes its distribution to artificial agencies, edaphic and climatic factors being to a great extent masked. The more remote moorland districts of the north of England and Scotland, however, give opportunities for studying plant associations the distribution of which is chiefly determined by edaphic and climatic factors, the artificial factors due to the influence of man being secondary.

FIG. 1.—Succession of moorland vegetation. Eriophorum Bog on the summit plateau. Nardus Grass Heath developed on the slopes below, changing to Grass Heath with Eriophorum as the wet, gently sloping foreground is reached. From the *Geographical Journal.*

The most important artificial agencies tending to modify the natural distribution of vegetation covering our moorlands at the present day appear to be drainage operations and grazing of cattle. On many of the alpine moorlands these factors are almost negligible, and any change in the vegetation has been caused, not by artificial agencies, but by secular changes in climate. The evidence of a change in vegetation, both on the alpine moorlands of England and Scotland, is unmistakable, and it is possible to a certain extent to reconstruct the waves of vegetation which have occupied the areas mentioned since the passing away of the last ice sheet.

[1] "Geographical Distributions of the Vegetation of the Basins of the Rivers Eden, Tees, Wear and Tyne." (*Geographical Journal*, March and September, 1904.)

The district in which mapping has been carried on by the author consists of a great extent of bleak, gently sloping moorland, of which about 10 per cent. lies above 2000 feet. The author has found that considerable and marked changes take place in the plant associations at about 2000 feet; tree vegetation ceases, and many alpine plants make their appearance which are absent from the lower moorlands.

The geological formation in the south and west of the district is chiefly Carboniferous limestone yielding only a small amount of detritus, whilst in the north and east the limestone thins out and is replaced to a great extent by sandstones, grits, and shales which yield a much larger amount of detritus. This feature has an important effect upon the vegetation, the wetter types of associations being developed upon those rocks yielding a large amount of detritus.

The moorlands first resolve themselves into two chief types, grass moorland and heather moorland, and these are frequently linked together by several intermediate plant associations. Dry heather moors or heaths do not cover any great extent of ground, and are chiefly found in the limestone districts of the south. The wetter types of heather moors are well developed, and the whole district can be briefly described as a wet heather and dry grass moorland country. These features are well shown in many of the "hopes" and gills leading out of Weardale and South Tynedale. The steep lower slopes of the hills are covered with an association having *Nardus stricta* as the dominant plant. Above 1500 feet to 1800 feet the slope of the ground becomes more gradual, and shales and grits make their appearance. At the same time the *Nardus stricta* association yields to heather associations in which Eriophorum is always a prominent plant. The

FIG. 2.—Calluna and Vaccinium association on a dry wind-swept summit at 2320 feet. The lower vegetation developed on wet peat shows a great increase in Eriophorum. From the *Geographical Journal.*

succession of different types of moorland is often well shown along some of the "edges" in the north-east of the district. At Redbourne Edge the almost flat, poorly drained summit is entirely covered by Eriophorium bog, developed on deep wet peat. As the edge of the bog is approached the peat becomes drier, and Eriophorum is replaced by a narrow band of Calluna moor. Peat is absent on the slope below, and the ground is tenanted by Nardus grass heath, yielding to a wetter type of grass heath dominated by Molinia and Eriophorum. Such a succession of terraces of Eriophorum bog, Calluna moor, Nardus grass heath, and Molinia-Eriophorum moor can be distinguished from a distance of many miles in the later months of the year, when the bleached Nardus stands out in vivid contrast to the sombre hued Calluna and Eriophorum associations.

The lower slopes of the alpine moorlands are generally covered by heather associations, which yield to pasture and grass heath as the summits are approached. The drier hills are covered by an association consisting of Calluna, *Rubus Chamaemorus*, *Vaccinium Myrtillus*, and *V. Vitis-Idaea*; the wetter hills are characterised by a much greater development of *Eriophorum vaginatum* and *E. angustifolium*.

The summits of the hills are generally tenanted by a few stunted members of the lower associations; in some cases, however, the vegetation only forms patches separated by bare stony soil or peat. Part of the summit plateau of Cross Fell at 2900 feet is entirely tenanted by *Racomitrium lanuginosum*, which forms low mounds of peat frequently broken by patches of stones and bare soil, a formation bearing a close resemblance to a moss-tundra of northern latitudes.

A considerable portion of the higher ground is covered with a deposit of peat varying in thickness from a few inches to nearly 20 feet. The peat appears to be undergoing rapid denudation at the present day—in many places large areas are quite unoccupied by vegetation, and exhibit the channelled and wasted appearance characteristic of peat-hags. These features can be seen on all the peat covered hills of the Pennines, the Cheviots, and the Scottish southern uplands, being particularly well marked on the Moorfoot Hills and in the Tweedsmuir district, and again appear in most of the peat districts of the Highlands. Many of the lowland mosses, particularly those bordering on the Solway Firth and along the west coast, exhibit no such denudation. How far the denudation of the mosses in the hill districts is due to drainage operations it is difficult to say, but the fact that the peat is generally wasted away quite as much on the more remote moorlands where artificial drainage has scarcely been carried on at all as on the drained areas lends strong support to the view that denudation is due to climatic changes. This is further supported by a detailed examination of the deeper peat beds, which frequently show many alternating beds of wet and dry condition plants. The peat beds on the Cross Fell chain are evidently of very ancient origin, as the author [1] has found the remains of an Arctic flora at the base consisting of Arctic willows, and the peat above contains the remains of extensive woodlands up to an altitude of 2700 feet. The area in which woodland remains in the peat have been observed is about 140 square miles, whilst only 11 square miles are forest clad at the present time.

Gunnar Andersson [2] has shown that the destruction of some of the woodlands buried in the peat of Sweden has been caused by artificial retention of drainage water and a gradual exhaustion of food supply in the upper layers of the peat, thus bringing about a gradual swing from woodland conditions to moss conditions, and again to heath conditions. These causes may have produced alternations of woodland, moss, and heath in some of our low-lying mosses, but an examination by the author of the peat lying between the woodland beds suggests that the destruction of much of the buried forest growth has been due, not to local alterations in drainage and failure of food supply, but to climatic changes acting over very long periods of time.

FRANCIS J. LEWIS.

THE ABNORMAL TIDES OF JANUARY 7.

AN abnormally high tide was experienced down the east coast of Britain on Saturday last, January 7, extensive areas being flooded and considerable destruction wrought. At 6 p.m. on Friday, January 6, as shown in the Meteorological Office reports, a very deep cyclonic system appeared over the upper part of the North Sea, the barometer at Sumburgh Head having fallen quickly to 28·7 inches. There was a steep gradient for north-westerly winds, and in the course of the night a more or less severe gale from that quarter was experienced over the North Sea, and as the south-going tide from the Pentland Firth was then on the flood, both its velocity and its volume were greatly increased, so that it reached the Thames estuary some hours ahead of its time, and was several feet above the calculated height. While the low barometer of Friday night may have caused the tide level in the far north to have been raised about a foot, the very rapid increase of pressure to 29·83 inches at 8 a.m. on Saturday at Sumburgh Head, a rise of 1·13 inches in fourteen hours, may have done something towards swelling the volume of the tide further south. Except for the hard gale, the conditions were very similar to those which prevailed with the great tide experienced on the southern and south-western coasts at the beginning of February, 1904 (NATURE, vol. lxix. p. 348).

Much damage was done all along the coast from Scarborough to the Thames. At the former place the pier was entirely washed away, and at Hull, Goole, Boston, Yarmouth and Lowestoft, and other places the low-lying parts of the towns were flooded. The damage was not due to unusual violence of the wind alone, but to the combined effects of wind and tidal waves. From the returns of the Meteorological Office it appears that the force of the gale from Wick to Yarmouth varied from 7 to 10 on the Beaufort scale. The tide was the third after the new moon, and laid down in the tide tables as less than a full spring tide. At Boston 28 feet 5 inches was recorded on the gauge at the dock, or 116·47 feet above Ordnance Datum, being 4 feet 8 inches above the height expected. The following tide in the evening was 21 feet 11 inches, or 1 foot 10 inches below the tide table height, the difference in the two tides being 6 feet 6 inches. The highest tide recorded there previously was in 1883, when the tide rose to 29 feet, the great record tide of 1810 rising to 29 feet 4 inches. Notwithstanding the great height to which the tide rose, it ceased flowing nearly half an hour before its proper time.

The tidal wave had fortunately somewhat expended its energy before reaching the Thames, but the water was in a very disturbed condition. By mid-day the water at Putney Bridge had risen as high as it should have been at full tide, which was not due until 3.45. At 1.30 it was a foot higher than any spring tide in recent years. Shortly after this the water began to recede, and continued to do so for half an hour. Then the water again rose, and at 3.15 the ebb again set in. The water in the Thames and Medway estuaries was kept from receding by the gale, and on the morning of Saturday it was 8 feet above its normal height. At 9 a.m., when the tide had still $4\frac{3}{4}$ hours to flow, it was running up the Medway 6 feet above the anticipated height at this stage. By 11 o'clock the level of high water was reached, but during the remaining $2\frac{3}{4}$ hours the flow was very slight compared with the earlier stages, and although the water rose from 2 to 3 feet above the normal height, there was no overflow or breaches in the banks.

THE ELECTRO-THERMIC MANUFACTURE OF IRON AND STEEL.[1]

THIS report is of great interest and importance to iron and steel metallurgists, and the appointment of the commission which has drawn it up suggests that Canada has an enterprise in fostering metallurgical knowledge which the Government of the mother country might well imitate for the advantage of British metallurgical industries. The English metallurgist attached to the commission was Mr. F. W. Harbord.

Three processes were experimentally examined :—(1) the Kjellin process at Gysinge, Sweden (this is an induction process not involving the use of electrodes); (2) the Héroult process at La Praz, France (this is a resistance method involving the use of electrodes); (3) the Keller process (also a resistance method in which electrodes are employed).

On p. 15 of the report Dr. Eugene Haanel, the chief

[1] British Association Reports, 1904, Section K.

[2] "Svenska Vaxtvarldens Historia." (Stockholm.)

[1] "Report of the Commission appointed by Mr. Clifford Sifton, Minister of the Interior, Ottawa, Canada, to Investigate the Different Electro-thermic Processes for the Smelting of Iron Ores and the Making of Steel in Europe." (Ottawa: Department of Interior.)

commissioner, remarks that he considers "By far the most important experiments witnessed by the Commission were those made by Keller, Leleux and Company at their works at Livet."

It is a little difficult to realise upon what grounds the above conclusion was arrived at. Putting aside the speculative calculations of M. Keller and descending to experimental facts, it appears that the commission saw smelted several tons of pig-iron, as a rule remarkably high in manganese (1·5 per cent. to 4 per cent.), and hence of limited commercial interest, and as it is evidently not thought by the commission that the electric furnace is to become a serious competitor with the blast furnace, the specified exceptional value of these results from an industrial point of view is not quite clear.

As regards steel, only one not very satisfactory and untested heat was made (see pp. 77–78), yet upon such evidence the report states that this process is capable of producing steel equal to the best products of Sheffield's crucibles. Such premature conclusions based on such scanty data are not calculated to carry conviction to the experienced metallurgical mind.

The commission also describes a series of experiments made by M. Héroult at La Praz works. The analyses of the steels obtained appear quite satisfactory, but this process is hardly capable of competing with the ordinary open-hearth furnace even from the rosy point of view taken by the commissioners based on costs calculated (in all good faith) by the patentee.

From a British point of view Kjellin's induction process deserves the most serious attention in view of (under certain conditions) its probable competition with the crucible steel process.

Analytically, mechanically, and micrographically this steel leaves nothing to be desired, but unfortunately chemical and tensile tests, and the indications of the microscope, have a limited value in determining the working capabilities of tool-steel.

In his "conclusions" on p. 115 of the report, Mr. Harbord states that "Steel, equal in all respects to the best Sheffield crucible steel, can be produced, either by the Kjellin or Héroult or Keller processes, at a cost considerably less than the cost of producing a high-class crucible steel."

The above statement, so sweeping and involving issues of profound industrial import, should have been made only as the result of a series of exhaustive working tests. For such, in the report, the reviewer has sought in vain.

It is true that a series of tests of turning tools made from Kjellin and Héroult steels has been carried out at Woolwich by Mr. H. F. Donaldson, but the results are quite inconclusive, because of the steels employed hardly one was fit for turning tools.

Cold sett steel, carbon 0·8, cold chisel steel, carbon 0·9, tap-steel, carbon 1·1, and drill steel, carbon 1·2, have all been set to do the work of a comparative turning tool steel of carbon 1·38 per cent.

The natural consequence is that in the Woolwich results, where "E" means equal to the ordinary Woolwich turning tool steel of carbon 1·38, and "NE" means not equal to that steel, we find in the report, pp. 87 and 88, five "equals" and no less than fourteen "not equals."

As to whether Kjellin electric steel is or is not equal to crucible steel time alone can show. The conclusion of the commission may be accurate, but it is certainly not based on any scientific evidence worthy of the name.

Such evidence on a commercial scale can be conclusively obtained only by at least two comparative years of shop practice, employing all kinds of tools, and recording the average wear and waste of the steels as evidenced by the ratio between the work turned out and the annual cost of the tool steels purchased.

In the micrographic section of the report the reviewer notes with regret a recrudescence of the use (in this connection) of the meaningless and unscientific term "grain" in describing the allotrimorphic crystals of ferrite.

These crystals, although usually lacking idiomorphic external faces, nevertheless present that internal molecular symmetry associated with individual crystals, and hence should be classed as such.

Prolonged tests on Kjellin steel of all carbons, compared with similar crucible steels, have been inaugurated at the University College of Sheffield, and the erection of a Kjellin furnace capable of making one ton of steel per day is under consideration.

Without in any way compromising one's industrial attitude as to the exact capabilities of the respective methods devised by Messrs. Héroult, Keller and Kjellin, one can cordially congratulate these gentlemen on the scientific ability displayed in the development of their several methods, all of which, within their legitimate spheres, are undoubtedly of great metallurgical value. It is the more necessary to say this because such value is liable to be discounted by the hasty and ill-digested conclusions drawn by the Canadian commission.

J. O. ARNOLD.

LONDON FOG INQUIRY, 1901–3.[1]

THE Meteorological Council have issued their final report on the above inquiry, which had to be terminated at the end of the winter 1902–3 as the London County Council were unable to make any further contribution to its cost beyond the 250*l.* originally assigned. A short account of the chief results obtained by Captain Carpenter from the observations of the winter 1901–2 has already appeared in these columns (vol. lxvii. p. 548). During the succeeding winter records of the duration and intensity of fog were continued at forty-six stations in and around London, and in addition to this the scope of the inquiry was extended to include a detailed study of the distribution of air temperature over the London area. With this object thermometer screens and dry bulb thermometers were issued to thirty fire brigade stations, and daily observations of the air temperature were made at fixed hours.

The material so accumulated has been utilised to determine so far as possible the physical causes most active in producing fog in each case. The guiding principles adopted in the classification are those suggested in an article by the secretary to the Meteorological Council which appeared in NATURE (vol. lxiv. p. 649) at the time when the inquiry was started. The majority of our fogs were found to be due to radiation from the earth's surface during calm nights. Others, among them the most persistent fog of the winter, were caused by the passage of warm air over a previously cooled surface, while a third group were identified as "cloud" fogs. A certain number of fogs could not be included in any of the above categories. They appeared to be mere accumulations of the products of combustion in an almost calm atmosphere, and as such were termed "smoke" fogs. Full particulars of the thirty-nine most serious fogs of the winter are given in an appendix.

Among the chief results of the inquiry must be reckoned the establishment of a workable scale for the estimation of fog intensity by different observers, based on the extent to which traffic is impeded by land, river, and sea.

Comparison of the fog statistics from the various stations confirms Captain Carpenter's results. With a few possible exceptions which need further investigation, there is no evidence to show that, in London, geological formation has any influence on liability to fog. Again, as was to be expected, the fog frequency on the river and in the parks is very high, but the evidence does not support the view that the fog there found drifts far into the neighbouring districts.

With regard to the main purpose of the inquiry, greater precision in fog forecasts, Mr. Lempfert points out that a first step would be the establishment of a night service at the Meteorological Office. As the majority of fogs are caused by nocturnal radiation, and the intensity of this radiation depends largely on the accident whether the sky is free from cloud or not, it is manifest that forecasts issued at the suggested hour of 5 a.m. would have a much greater chance of proving correct than the present ones, which are based on observations taken at 6 p.m. on the previous evening. As most fogs become thick soon after sunrise, several hours' warning could still be given, though the hour would

[1] Report of the Meteorological Council upon an Inquiry into the Occurrence and Distribution of Fogs in the London Area, during the Winters of 1901–2 and 1902–3, with Reference to Forecasts of the Incidence and Duration of Fogs in Special Localities, to which is appended the Report by R. G. K. Lempfert, M.A. on the Observations of the Winter 1902–3.

be too late for the dissemination of the forecasts by the morning papers. Under the existing arrangements it was found that sixteen out of twenty-four "radiation" fogs and four out of eight "smoke" fogs were anticipated. The three "cold surface" fogs and four "cloud" fogs were not forecasted. The present forecasts rarely, if ever, contain any indications of the intensity of the fog expected.

The problem of the issue of fog warnings for individual districts has been approached from two points of view. As was pointed out in the previous report, the observations of drift smoke, during the incidence of fog usually show an indraught of air to some central district of London, but this is rarely symmetrical; a preponderating direction, usually identical with that due to the barometric gradient, can in most cases be identified, and plays a most important part in determining the region of thickest fog. Out of forty-four days of fog twenty-seven showed the thickest fog to leeward, five showed it to windward, while in the remaining twelve cases no particular preference for any one locality could be identified. Captain Carpenter had suggested that a more detailed study of the distribution of temperature might prove useful in this connection, and Mr. Lempfert reproduces diagrams which show conspicuous differences of temperature within the London area, in which the thickest fog is also to be found in the coldest region. Four out of the five apparently exceptional cases in which fog was thickest to windward show the lowest temperatures also on the windward side. It is the more to be regretted that the inquiry has had to be discontinued as the winter proved to be singularly free from fog. Investigation of the thick fogs of the present season from this point of view would probably have yielded interesting results.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

EDINBURGH.—The annual report for 1904 shows that the total annual value of the university fellowships, scholarships, bursaries, and prizes now amounts to about 18,270*l*. In addition, a sum of upwards of 600*l*., being the income of the Earl of Moray endowment fund, is annually available for the encouragement of original research. As already announced, in response to the appeal for subscriptions to provide for the further development of the university, Sir Donald Currie has made the munificent gift of 25,000*l*. He has expressed a wish that the revenue from his money should be applied to the remuneration of a staff of lecturers such as the authorities of the university may find it advisable from time to time to appoint. The university court, being desirous of permanently associating his name with the fund, has resolved to designate it "The Sir Donald Currie Lectureship Endowment Fund." Other contributions to the extension scheme have also been intimated to the extent of 15,000*l*., including a sum of 5000*l*. given by Sir John Jackson to the Tait memorial fund, for the encouragement of physical research.

LIVERPOOL.—The committee of the institute of archæology has been enabled by the munificence of Sir John Brunner to take in hand the publication of a "History of Egypt," to include all the results of modern research, and to be, so far as possible, a complete history of the Egyptian civilisation from the earliest times down to the conquest by Alexander the Great. It is estimated that the work will take two years to complete, and it will be published with full photographic illustrations.

A CONFERENCE on school hygiene has been arranged by the Royal Sanitary Institute, to be held in the University of London, under the presidentship of Sir Arthur W. Rücker, F.R.S., on February 7–10.

A COURSE of ten lectures on "Enzymes" will be given by Dr. W. M. Bayliss, F.R.S., at University College, London, commencing on January 18. The lectures are open to all internal students of the university, and also to medical men on presentation of their cards.

THE sixteenth issue of the "Public School Year Book" that for 1905—with its select list of preparatory schools, as useful as ever. The information given respecting each public school connected with the Headmasters' Conference is of just the kind to help parents to a decision as to where to send their boys to be educated.

PROF. FRITZ HEISE, of the Berlin School of Mines, has been appointed director of the Bochum School of Mines, and Mr. Georg Baum, the author of several works on coal-mining, has been appointed to succeed him in the Berlin chair. Mr. August Schweman, mine manager of Neurode, has been appointed professor of mining at the Aachen Technical High School to fill the vacancy caused by the death of Mr. Lengemann.

IN view of the educational and scientific progress which Japan has made in recent years, the two lectures on "The Japanese Spirit," which will be delivered by Mr. Y. Okakura, of the Imperial University, Tokyo, at the London School of Economics, Clare Market, W.C., on January 17 and January 20, should be of special interest. Tickets of admission may be obtained free from the secretary of the school.

Science reports that Mr. W. A. Riebling, of Newark, N.J., has sent an additional 2000*l*. to the Rensselaer Polytechnic Institute, Troy, N.Y., to be used in replacing the building destroyed by fire. Mr. Riebling gave 2000*l*. last June. A gift of 1000*l*. from Mr. George B. Cluett is also announced. Wellesley College has received 3600*l*., we also learn, from the Robert Charles Billings fund, the income of which is to be applied to the department of botany.

THE West Riding Education Committee has resolved, says the *British Medical Journal*, subject to certain conditions, to make grants, which will doubtless be renewed annually, to the Universities of Leeds and Sheffield of 4500*l*. and 1500*l*. respectively. In thanking the county council for the grant to Leeds, the Pro-Chancellor, Mr. A. G. Lupton, stated that of the 100,000*l*. for which the university was now asking a sum of 64,000*l*. had already been subscribed.

THE 1905 edition of the "Schoolmaster's Yearbook and Directory" follows on the same excellent lines as the issue of last year. It contains an immense amount of well arranged information, and has become indispensable to all engaged in educational work. If the publication continues to increase in size, as it seems to do annually, the section on the books of the year might be dispensed with, as information of the same kind can be obtained from many educational periodicals. The editor is to be congratulated on the fact that this useful work of reference has become established so securely.

A RESEARCH scholarship or scholarships, founded by Mr. Andrew Carnegie, will be awarded shortly on the recommendation of the council of the Iron and Steel Institute. Candidates, who must be under thirty-five years of age, must apply on a special form before the end of February to the secretary of the institute. The object of this scheme of scholarships is not to facilitate ordinary collegiate studies, but to enable students, who have passed through a college curriculum or have been trained in industrial establishments, to conduct researches in the metallurgy of iron and steel and allied subjects, with the view of aiding its advance or its application to industry. There is no restriction as to the place of research which may be selected, whether university, technical school, or works, provided it be properly equipped for the prosecution of metallurgical investigations.

A CONFERENCE of teachers from elementary and secondary schools and technical institutes was held under the auspices of the London County Council at the Medical Examination Hall, Victoria Embankment, on January 5, 6, and 7. On the first of these days, under the presidency of Sir William Collins, the teaching of arithmetic was discussed. Mr. C. T. Millis, principal of the Borough Polytechnic, said that what is needed in the teaching of arithmetic is that some of the time now spent in teaching special rules in money sums should be devoted to giving a sound knowledge of general principles. Mr. S. O. Andrew, during the course of a paper on the same subject, remarked that whatever part of arithmetic may be given up or postponed, there is a general agreement that it must still include a knowledge of the standards of measurement necessary for the investigation of physical phenomena. The need for a co-ordination of the elementary instruction in arithmetic and geometry was emphasised by subsequent speakers.

THE third annual meeting of the North of England Education Conference was held in Liverpool on January 6 and 7. More than 2000 members of education committees, teachers, and others attended. The question of leaving certificates was discussed at the first meeting, and during the course of the discussion Sir Oliver Lodge said the use and not the abuse of examinations is admitted by all as an adjunct to teaching, but the point is to determine the relation between teachers and examiners, also between teachers and inspectors. People are no longer going to be satisfied with purely external examinations imposed from above upon the schools. It is not a dignified position for the schools, and they have rebelled. Prof. Sherrington, F.R.S., read a paper later on child study, in which he urged that this study could not devote itself more profitably at the present time than to what may be termed the natural history of the child. In healthy school life lay the first line of defence against race deterioration. It would help society if teachers and physiologists could combine to examine into the mischief to growth resulting from hours of breathing vitiated air, from want of warm clothing that economised food, from semi-starvation, from improper food, from chronic fatigue, and from insufficient rest and sleep in bed. Among other subjects dealt with were the teaching of geography, the teaching of domestic science, and the place of handwork in the school curriculum.

A DEPUTATION from the executive committee of the Association of Education Committees (England and Wales) recently waited upon the Board of Education to urge the adoption of a more liberal scale of grants for secondary schools, to ask for a larger share from the Government of the cost of training pupil teachers, and to urge the necessity for the compulsory attendance up to the age of fourteen at evening continuation schools of all children who do not continue as whole-day scholars up to that age. Sir William Anson, in reply to the deputation, agreed that more money should be allowed to secondary schools, but though such a demand would have his support, Sir William Anson said he was by no means sure of obtaining the necessary funds. He expressed the opinion that the question of cost made it almost impossible to enforce a system of compulsory attendance at evening continuation schools up to fourteen years of age for children leaving the day school before that time. Until we have better security that the education given in the elementary school lasted, and a better secondary education system with larger grants for secondary schools, Sir William added, he would not be a party to asking for another penny for elementary education, as such. It is satisfactory to find it recognised officially that this country must spend more money on secondary and technical education if we are to have an educational system which will assist national progress.

THE annual meeting of the Geographical Association was held on January 6. Mr. Douglas Freshfield presided, and an interesting discussion took place on the teaching of practical geography in schools. Prof. Dryer, of the State Normal College, Terre Haute, Indiana, opened the debate, and said that practical geography meant in America laboratory work. This work is not necessarily done in a special room, and, indeed, the best part of it is done out of doors. The study of maps plays a large part in this laboratory work. Contoured topographical maps are also much used, together with raised models illustrating different forms of the earth's surface. Pictures, photographs, and lantern slides also have a conspicuous place in the school's equipment. The instrumental study of the earth's atmosphere is taken next by the students, who keep records of their own observations for a period of three months. The official weather charts can be obtained daily at every school, and, owing to the area covered by them, it is possible to follow cyclonic and anti-cyclonic disturbances for several days together, and sometimes to predict in the school itself the arrival at a particular time of an atmospheric disturbance. Field excursions are regarded as the most important part of geographical study. Mr. B. B. Dickinson described an experiment in the teaching of practical geography carried out by him at Rugby School. The report of the association shows that 123 new members have been added to the roll, making the total membership 448. The members now include teachers of every grade, school inspectors, directors of education, technical education committees, and others interested in geographical education, both at home and abroad.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, December 1, 1904.—"The Ascent of Water in Trees." By Dr. Alfred J. **Ewart**, Lecturer on Botany in the University of Birmingham.

Since the time when Strasburger's researches seemed to show that the ascent of water in trees was a purely physical phenomenon, attempts have been made by Dixon and Joly, as well as by Askenasy, to prove that the ascent of water is due to a tensile stress set up by transpiration in the leaves, and transmitted downwards by continuous water-columns which are practically suspended from them. A knowledge of the resistance to the transpiration current in the stems of trees, and of the influence of various factors upon it, forms, however, an essential preliminary to any such explanation.

The author finds that when the vessels are completely filled with water and are open at both ends, the flow through them takes place in accordance with Poisseuille's formula, the rate of flow being directly proportional to the pressure and inversely proportional to the viscosity of the liquid and the square of the radius of the vessel. Hence in climbing plants where a rapid rate of flow is required the vessels are large, approaching 1 mm. in diameter, and in such cases the total viscosity resistance during average transpiration is equal to a head of water considerably less than the height of the stem. Under normal conditions, however, air bubbles always appear in the conducting vessels of angiospermous trees, and each bubble exerts a resistance to flow which is directly proportional to the surface tension of water against air and inversely proportional to the radius of the tube. In a tall tree the theoretical resistance due to this cause alone might amount to as much as 300 atmospheres, whereas calculations from direct experiments gave total resistances for the tallest trees of 100 atmospheres during active transpiration.

No leaf could produce or maintain an osmotic suction of this intensity, nor could the water columns in the vessels transmit it without rupture. In addition, actual observation showed that although differences do occur in the osmotic concentration of the cell-sap in the leaves at different levels, these are not sufficient to overcome the resistance to average flow in the intervening portions of the trunk. It appears, therefore, that a staircase pumping action must be exercised in the wood of a tall tree, which enables the leaves to obtain the water they require without their being forced to exercise tensions of more than $\frac{1}{2}$ to $\frac{2}{3}$ of an atmosphere. No satisfactory physical explanation of such action has yet been given, but the author points out that by appropriate surface-tension action along the length of a Jamin's chain the water could be led upwards from water-column to water-column, and maintained in a labile condition ready to flow in any direction where moderate suction was exercised. Various indirect estimations have been made which lend support to this view, but direct observations have not hitherto yielded satisfactory proof, so that further investigations are still needed in this direction, and these are, in fact, in progress.

December 15, 1904.—"An Analysis of the Results from the Falmouth Magnetographs on 'Quiet' Days during the Twelve Years 1891 to 1902." By Dr. Charles **Chree**, F.R.S.

The paper contains an analysis and discussion of the results obtained from the declination and horizontal force magnetographs at Falmouth on quiet days from 1891, when the records commenced, until 1902.

The total secular changes of declination from 1891 to 1900 at Kew and Falmouth were identical, and the changes from year to year were closely alike. In horizontal force the annual changes recorded at the two stations did not agree so closely, and on the average the change at Falmouth was somewhat the greater.

Whilst the mean daily range of temperature at Falmouth—a seaside station—is notably less than at Kew, the daily ranges of declination at the two places are as nearly as possible equal, and the daily range of horizontal force is somewhat larger at Falmouth.

The annual variation of diurnal temperature range is again notably less at Falmouth than at Kew, the winter range at the former station being relatively high, and the summer range low. There is in this case a somewhat analogous state of matters in magnetics, the difference between the diurnal ranges at midsummer and midwinter being relatively less at Falmouth than at Kew.

Analysing the diurnal inequality of temperature into harmonic terms, General Strachey (*Phil. Trans.* for 1893) found that the local time of occurrence of the maxima was distinctly earlier at Kew than at Falmouth, the difference being greatest for the 24-hour term, for which it amounted to nearly an hour. When the declination and horizontal force diurnal inequalities are similarly analysed, the local times of occurrence of the maxima are so nearly alike at the two stations that it is impossible to say with certainty which is the earlier. This result applies to the average year of a sun-spot cycle.

When the annual variations in the amplitudes of the daily ranges in declination and horizontal force at Kew, and of the 24, 12 and 8-hour terms in the diurnal inequality, were expressed as Fourier series, with an annual and a semi-annual term, there proved to be a remarkably close agreement between the dates of occurrence of maximum in the annual terms, and also in those of the semi-annual terms for the several elements. The same phenomenon appears at Falmouth, and there proves, moreover, to be a remarkably close agreement between corresponding Kew and Falmouth dates. This result again applies to the average year of a sun-spot cycle.

Applying Wolf's formula $R = a + bS$, associating the range R of a magnetic element with sun-spot frequency S, results are obtained for the variation of b and b/a throughout the year at Falmouth very similar in character to those previously obtained for Kew.

Taking the above formula, but making S represent in turn the areas of whole sun-spots, umbræ and faculæ as given by the Astronomer Royal, values are calculated for a and b in the case when R represents the range of declination or horizontal force in the mean diurnal inequality for the year. A comparison is then instituted between the ranges for individual years of the 12-year period as calculated from the values of a and b thus found, and the Astronomer Royal's mean yearly data on the one hand, and as actually observed on the other. When S represents areas of whole sun-spots or of umbræ, the agreement between observed and calculated ranges is nearly though not quite so good, especially in horizontal force, as when S represents Wolfer's sun-spot frequencies; but when S represents areas of faculæ the agreement is much inferior, especially in years of sun-spot maximum.

"The Effect of Temperature on the Thermal Conductivities of some Electrical Insulators." By Dr. Charles H. **Lees.**

The substance the thermal conductivity of which is to be determined has the form of a cylinder about 8 cm. long, 2 cm. diameter, surrounded by a thin cylinder of brass and placed in a Dewar tube. The heat is supplied by the passage of an electrical current through a platinoid wire embedded in the substance parallel to the axis of the cylinder, and about 0·4 cm. distant from it. The temperature is measured by the electrical resistance of two short spirals of No. 40 pure platinum wire, down the centre of one of which the heating wire passes.

The difference of temperature of the two spirals is determined by making them two arms of a resistance bridge, the other two arms of which are equal. By means of mercury cups resistances may be placed in series with either of the spirals until a balance is obtained.

A few values of the conductivities in C.G.S. units for a portion of the range of temperature on the hydrogen scale are given in the following table:—

	At 120° abs.	At 180° abs.	At 240° abs.
Ice	0·0062	0·0058	0·0052
Naphthaline	0·0013	0·0011	0·00091
Aniline	0·0011	0·00086	0·00070
Nitrophenol (para)	0·0010	0·00085	0·00070
Glycerine	0·00078	0·00082	0·00076
Paraffin wax	0·00060	0·00065	0·00061
β-Naphthol	0·00067	0·00065	0·00063
Diphenylamine	0·00058	0·00054	0·00052

Geological Society, December 21, 1904.—Dr. J. E. Marr, F.R.S., president, in the chair.—On certain genera and species of Lytoceratidæ: S. S. **Buckman.** This paper deals with certain specimens sent by Mr. Beeby Thompson from the Northampton Sands, one of which is remarkable for its homœomorphy with Phylloceras.—The Leicester earthquakes of August 4, 1893, and June 21, 1904: Dr. C. **Davison.** The earthquake of 1893 was a twin, with its principal epicentre between Markfield and Woodhouse Eaves, and the other near Tugby, about seventeen miles to E. 34° S. Its disturbed area contains about 2200 square miles. On June 21, 1904, two shocks were felt: the first, a very slight one, at about 3.30 a.m., the second at 5.28 a.m. The epicentre of the earlier shock was in the neighbourhood of Markfield and Groby, or near the south-eastern margin of the north-western focus of 1893. The distance between the epicentres of the earthquakes of 1904 was about twelve miles. Thus the foci of 1904 appear to have occupied the nearer margins of the foci of 1893.—The Derby earthquakes of July 3, 1904: Dr. C. **Davison.** Although weaker than the earthquake of March 24, 1903, this shock, owing to its occurrence at 3.21 on a Sunday afternoon, was felt over a much wider area (about 25,000 square miles). As in 1903, the earthquake was a twin, the epicentres being almost exactly coincident with those of that year, one being situated near Ashbourne, and the other, about six or seven miles from it, near Wirksworth and Matlock Bath.—Twin-earthquakes: Dr. C. **Davison.** In a twin-earthquake, the shock consists of two maxima of intensity, or of two distinct parts separated by a brief interval of rest and quiet. In Great Britain, one in every twenty earthquakes is a twin, and our strongest shocks (the Colchester earthquake of 1884, the Hereford earthquake of 1896, &c.) belong to the same class. The phenomena show that twin-earthquakes cannot be caused by reflection or refraction of the earth-waves, or by the separation of the waves of direct and transverse vibrations, or by the repetition of the impulse within the same or an overlapping focus. They must therefore be due to impulses in two detached, or practically detached, foci; and it is shown that all the known phenomena of twin-earthquakes can be thus accounted for. In British twin-earthquakes, the distance between the epicentres varies from four to twenty-three miles, the average for seven recent earthquakes being between ten and eleven miles. As a rule, the foci are elongated approximately in the direction of the line joining them, showing that they are portions of the same fault. The foci appear to be situated at different depths, and, in two cases, the fault probably changes hade in the region between them.

Royal Microscopical Society, December 21, 1904.—Mr. G. C. Karop in the chair.—Mr. **Conrady** read a short paper explaining an experiment he exhibited to prove the phase-reversal in the second spectrum from a grating of broad slits, the mathematical proof of which he gave in his paper on theories of microscopical vision read before the society at its last meeting. The object consisted of two gratings one above the other, similar in every respect except that one had broad slits and the other had narrow slits. In accordance with what was theoretically predicted by the author, the difference was brought out when the direct light plus the first and second spectra of *one side* were admitted, but when the direct light was cut off by the movement of a shutter the image of the *broad slits* underwent a startling change. The lines jumped across to positions mid-way between the correct ones, showing there was an antagonism of phase between the light of the first and that of the second spectrum. Some photographs showing the effects produced by cutting out the various spectra of one side were exhibited by Mr. Rheinberg, who suggested to Mr. Conrady that the experiment should be made to test the correctness of the theory.—Mr. J. W. **Gordon** then gave a summary of his paper on the theory of highly magnified images.

EDINBURGH.

Royal Society, December 5, 1904.—Dr. R. H. Traquair in the chair.—The igneous geology of the Bathgate and Linlithgow Hills: J. D. **Falconer.** Five successive zones of igneous rocks were described in detail, and important conclusions drawn as to their geological age and to the relations between the intrusive rocks and dykes so characteristic of the region. The region has been very recently re-surveyed by the Geological Survey, and Dr. Horne, Dr. Peach, and others of the staff were able to corroborate many of Mr. Falconer's results, the value of which could not be over-estimated. A further paper was promised dealing with the petrology of the district.—Experiments on the simultaneous removal of spleen and thymus: Drs. Noel **Paton** and **Goodall.** Already the authors had found that the removal of either had no apparent deleterious effect upon the life of the animal, and now they proved that the removal of both in no way affected the vitality. The experiments were made on guinea-pigs.—Crystallographical notes: Dr. Hugh **Marshall,** F.R.S. The author suggested (1) that the "axis of compound symmetry of second order" should not be used in crystallographical work, as it is not a definite direction in the crystal, and that the "centre of symmetry" should be used instead; (2) that in order to simplify the classification of crystals for teaching purposes, the rhombohedral and scalenohedral classes should be treated as members of the hexagonal and not of the trigonal system.

December 19, 1904.—Sir John Murray in the chair.—A supplementary note on the Lower Devonian fishes of Gemunden: Dr. **Traquair.** The author brought forward further evidence in support of his original description, which had been criticised by Prof. Bashford Dean.—A specimen of salmon caught in the Galway River which appears to be intermediate between the smolt and grilse stages: W. L. **Calderwood.**—Networks of the plane in absolute geometry: D. M. Y. **Sommerville.** Networks built up of the various regular figures in the Euclidean plane were discussed at considerable length, and the investigation was then extended to non-Euclidean planes.

PARIS.

Academy of Sciences, January 2.—M. Troost in the chair.—The cooling power of a current of fluid on an ellipsoid with unequal axes immersed in the current: J. **Boussinesq.**—Interference fringes produced by a system of two perpendicular mirrors: G. **Lippmann.** The system of fringes formed, possessing a white central fringe, is parallel to the intersection of the plane of the mirrors. The experimental arrangement for the production of these fringes, which is described in detail, is simpler than that required for the Fresnel fringes.—On the alkaline microgranites of the Zinder territory: A. **Lacroix.** The rocks are ægyrine and amphibole microgranites, and are characterised chemically by their extreme poorness in lime and magnesia, and by the quantity of alkali, the potash being slightly in excess of the soda.—On limiting functions and functional operations: Maurice **Fréchet.**—On substitutions with three variables and invariant curves by a contact transformation: S. **Lattès.**—On invariant subgroups of index p^2: G. **Miller.**—On the deviation of freely falling bodies: M. **de Sparre.** It is shown that the formulæ usually given for this deviation are based on incomplete data, and a new expression is deduced. It is, however, impossible to check the calculations by experiment, on account of the smallness of the deviations, which would amount at most to 0·1 mm. for a fall of 1000 metres.—On a fundamental formula in the kinetic theory of gases: P. **Langevin.** The formulæ given by Maxwell and Boltzmann for the diffusion of gases is re-investigated, and the results applied to the diffusion of ionised gases. The author arrives at the conclusion that the conductivity of flames is, for the most part, due to the presence of free kathodic particles arising from spontaneous corpuscular dissociation in the flame, under the action of the high temperature.—The measurement of the conductivity of dielectrics by means of ionised gases: Charles **Nordmann.** One of the faces of the dielectric, the other of which is connected with earth, is supplied with known quantities of electricity per unit of time, and the variation of the potential of this face is observed with an electrometer. The constant charge is produced by means of a radio-active substance placed between the plates of an air condenser, and the stationary potential is measured. Details of the measurements will be communicated in a later paper.—The influence of steam on the reduction of the oxides of iron by carbon monoxide and dioxide: O. **Boudouard.** With the view of throwing some light on the results of employing dried air in the blast furnace, the author has made experiments on the influence of moisture on the reducing action of carbon monoxide, either pure or mixed with the dioxide, upon ferric oxide. It has been found that the dry gases exert a more energetic reducing action than the moist gases, but that this difference, which is considerable at low temperatures, becomes negligible at high temperatures.—On the existence of a normal green chromic sulphate: Albert **Colson.**—The separation of the three dimethylanthracenes obtained by the action of methylene chloride upon toluene in the presence of aluminium chloride: James **Lavaux.** Modifications of the Friedel and Crafts method are described, by means of which larger and more constant yields are obtained. These modifications appear to be not only advantageous in this particular case, but are applicable to any reaction carried out in the presence of aluminium chloride.—Observations of the Giacobini comet (*d* 1904) made at the Observatory of Algiers with the 31·8 cm. equatorial: MM. **Rambaud** and **Sy.**—On the crystalline rocks collected by the Sahara expedition: F. **Foureau** and L. **Gentil.**—The resistance of water to the motion of vessels. Hulls of least resistance: Vice-Admiral **Fournier.**—Hydrogen peroxide in the nascent state and its bactericidal activity on organisms in water: Ed. **Bonjean.** It is shown that whilst 0·291 gram of hydrogen peroxide per litre was required to sterilise a litre of Seine water in six hours when commercial hydrogen peroxide was employed, under the same conditions, 0·060 gram was sufficient to produce sterilisation in four hours when the hydrogen peroxide was in the nascent state from calcium peroxide.—Hyphoids and bacteroids: Paul **Vuillemin.** Hyphoids and bacteroids are not purely parasitic formations, but are symbiotic products.—Research on plant radio-activity: Paul **Becquerel.** No trace of radio-activity of plant products could be observed if precautions were taken to prevent the moisture transpired by the plant from reaching the electrometer. The author therefore regards the positive results announced by M. Tommasina as being due to a neglect of this precaution.—On the accentuation of the alpine characters of leaves in juniper galls: C. **Houard.**—On the increase of weight of organic and mineral substances in oats as a function of the age: Mlle. M. **Stefanowska.**—Respiratory measurements on marine fishes: J. P. **Bounhiol.** By means of a specially devised tank the author has been enabled to determine the carbon dioxide per gram-hour, the oxygen per gram-hour, and the ratio CO_2/O_2 for several fishes. The effect of captivity in diminishing the respiratory exchanges was well marked.

NEW SOUTH WALES.

Linnean Society, November 30, 1904.—Dr. T. Storie Dixson, president, in the chair.—Contributions to the study of Australian Foraminifera, part i.: H. I. **Jensen.** This paper, for the most part, is a compilation of the species which have been identified in samples of sand or other materials obtained from various sources.—Revision of Australian Lepidoptera, part ii.: Dr. A. Jefferis **Turner.** Some supplementary remarks on the family Notodontidæ (revised in a previous paper) are offered, and the family Syntomidæ, comprising four genera with forty-four species (of which eight are described as new), is reviewed.—A yellow race of *Bacillus pseudarabinus* from the quince: Dr. R. Greig **Smith.** The organism is identical in its morphological and cultural characters with the white race previously isolated from the sugar-cane. The gum obtained from the slime was also identical in giving the reactions of arabin and in yielding only galactose upon hydrolysis. While the cultivations of the sugar-cane race were always white, those of the quince race were yellow.—The bacterial origin of Macrozamia gum: Dr. R. Greig **Smith.** An organism, *Bacillus macrozamiae*, n.sp., isolated from the tissues of *Macrozamia spiralis* which was exuding a gum, produced, upon lævulose media, a slime from which a gum was obtained.—On a new species of Rhizophyllum from the Upper Silurian rocks of Yass, New South Wales: A. J. **Shearsby.** A third species of Calceola-like, operculate, rugose corals is described.

DIARY OF SOCIETIES.

THURSDAY, JANUARY 12.

MATHEMATICAL SOCIETY, at 5.30.—Generational Relations for the Abstract Group simply Isomorphic with the Abstract Group LF [2, p^n]; Dr. W. Bussey.—On a Class of Expansions in Oscillating Functions: Prof. A. C. Dixon.—Isogonal Transformation and the Diameter Transformation: H. L. Trachtenberg.—A Generalisation of the Legendre Polynomial: H. Bateman.—Current Flow in Rectangular Conductors: H. Fletcher Moulton.—Basic Generalisations of some well known Analytic Functions: Rev. F. H. Jackson.—On the Kinematics and Dynamics of a Granular Medium in Normal Piling: J. H. Jeans.—On Alternants and Continuous Groups: Dr. H. F. Baker.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—The Combination of Dust Destructors and Electricity Works Economically Considered: W. P. Adams. (Conclusion of Discussion.)—Fuel Economy in Steam Power Plants: Wm. H. Booth and J. B. C. Kershaw.

FRIDAY, JANUARY 13.

ROYAL ASTRONOMICAL SOCIETY, at 5.—On the Temperature of Sun-spots and on the Spectrum of an Artificial One: W. E. Wilson.—On Terms of Long Period in the Complete Expression for the Moon's Longitude: E. Nevill.—The Longitude of the Moon's Perigee: P. H. Cowell.—On the Relative Brightness of Stars: J. E. Gore.—On the Variable Star Y Aurigæ: A. S. Williams.—The Spiral Nebula H I. 153 Ceti: W. S. Franks.—Sun-spots and Magnetic Storms: A. Schuster.—*Promised Papers*: Magnetic Storms and Associated Sun-spots: Rev. A. L. Cortie.—On the Possible Effect of Radiation on the Motion of Comets: H. C. Plummer.—Note on the Re-determination of the Paris-Greenwich Longitude (communicated by the Astronomer-Royal).—Observations of the Spectra of Sun-spots, Region C to D (communicated by the Astronomer-Royal).—*Probable Discussion* of Mr. Maunder's Paper in the *Monthly Notices*, on the Connection of Magnetic Storms with the Rotation of the Sun.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Theory of Electricity and Magnetism: James Swinburne.

MALACOLOGICAL SOCIETY, at 8.—A Review of the Genera of the family Mytilidæ: A. J. Jukes-Browne.—Note on the Type of Geomelania, with Description of New Species: E. R. Sykes.—On Three Species of Dyakia from Sumatra: E. R. Sykes.—Some Nudibranchs from the Pacific, including a New Genus, Chromodoridella: Sir C. Eliot, K.C.M.G.—Notes on Two Rare British Nudibranchs, *Hero formosa*, var. *arborescens*, and *Staurodoris maculata*: Sir C. Eliot, K.C.M.G.—Description of a new Achatina from the Zambesi: H. B. Preston.

MONDAY, JANUARY 16.

VICTORIA INSTITUTE, at 4.30.—The History of Rajputana: Col. T. Holbein Hendley.

TUESDAY, JANUARY 17.

ROYAL INSTITUTION, at 5.—The Structure of Animals: Prof. L. C. Miall, F.R.S.

ROYAL STATISTICAL SOCIETY, at 5.

INSTITUTION OF CIVIL ENGINEERS, at 8.—The River Hooghly: L. F. Vernon-Harcourt.

ZOOLOGICAL SOCIETY, at 8.30.—On a Collection of Sipunculids made at Singapore and Malacca: W. F. Lanchester.—On a Collection of Gephyrea from Zanzibar: W. F. Lanchester.—On the Sipunculids and Echiurids collected during the "Skeat Expedition" to the Malay Peninsula: W. F. Lanchester.—On the Oral and Pharyngeal Denticles of Elasmobranchs: A. D. Imms.—A Contribution to the Anatomy of Chlamydosaurus and some other Agamidæ: F. E. Beddard, F.R.S.—A Note on the Brain of *Cynopithecus niger*: F. E. Beddard, F.R.S.

WEDNESDAY, JANUARY 18.

CHEMICAL SOCIETY, at 5.30.—(1) Nitrogen Halogen Derivatives of the Sulphonamides. Part i.: Sulphondichloroamides and Sulphonalkylchloroamides.—(2) Nitrogen Halogen Derivatives of the Sulphonamides. Part ii.: Sulphondibromoamides and Sulphonalkylbromoamides: F. D. Chattaway.—Electrolytic Oxidation of Aliphatic Aldehydes: H. D. Law.—The Diazo-derivatives of the Benzenesulphonylphenylenediamines: G. T. Morgan and F. M. G. Micklethwait.—The Molecular Condition in Solution of Ferrous Potassium Oxalate: S. E. Sheppard and C. E. K. Mees.—The Formation of Magnesia from Magnesium Carbonate by Heat, and the Effect of Temperature on the Properties of the Product: W. C. Anderson.—Transformations of Derivatives of *s*-Tribromodiazobenzene: K. J. P. Orton.—The Addition of Sodium Bisulphite to Ketonic Compounds: A. W. Stewart.

ENTOMOLOGICAL SOCIETY, at 8.—Annual Meeting. Address by the President, Prof. E. B. Poulton, F.R.S.

GEOLOGICAL SOCIETY, at 8.—The Geology of Arenig Fawr and Moel Llyfnant: W. G. Fearnsides.

SOCIETY OF ARTS, at 8.—Wireless Telegraphy and War Correspondence: Capt. Lionel James.

ROYAL MICROSCOPICAL SOCIETY, at 8.—What were the Carboniferous Ferns? the President's Annual Address.

ROYAL METEOROLOGICAL SOCIETY, at 7.40.—Annual General Meeting. Address on the Connection of Meteorology with other Sciences: the President, Capt. D. Wilson-Barker.

THURSDAY, JANUARY 19.

ROYAL SOCIETY, at 4.30.—*Probable Papers*: On the "Blaze Currents" of the Gall Bladder of the Frog: Mrs. A. M. Waller.—The Dual Force of the Dividing Cell. Part i.: The Achromatic Spindle Figure illustrated by Magnetic Chains of Force: Prof. M. Hartog.—Note on the Effects produced on Rats by the Trypanosomata of Gambia Fever and Sleeping Sickness: H. G. Plimmer.—Further Histological Studies on the Localisation of Cerebral Function. The Brains of Felis, Canis and Sus compared with that of Homo: Dr. A. W. Campbell.

LINNEAN SOCIETY, at 8.—Botanical Collecting: Dr. A. Henry.—On the Cranial Osteology of the Families Osteoglossidæ, Pantodontidæ, and Phractolæmidæ: Dr. W. G. Ridewood.

SOCIETY OF ARTS, at 4.30.—The Gates of Tibet: Douglas W. Freshfield.

FRIDAY, JANUARY 20.

ROYAL INSTITUTION, at 9.—New Low Temperature Phenomena: Sir J. Dewar, F.R.S.

EPIDEMIOLOGICAL SOCIETY, at 8.30.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—Some Impressions of American Workshops: A. J. Gimson.—Waterworks Pumping Engines in the United States and Canada: J. Barr.—Some Features in the Design and Construction of American Planing Machines: A. Kenrick, Jun.: Engines at the Power Stations, and at the St. Louis Exhibition: A. Saxon.

CONTENTS.

THURSDAY, JANUARY 19, 1905.

ZOOLOGICAL BOOKS FROM GERMANY.

(1) *Anthropogenie oder Entwickelungsgeschichte des Menschen; Keimes- und Stammes-geschichte.* By Ernst Haeckel. Fifth revised and enlarged edition. 2 Vols. Pp. xxviii+992; with 30 plates, 512 text figures, and 60 genetic tables. (Leipzig: Engelmann, 1903.) Price 25*s*. net.

(2) *Morphologische Studien. Als Beitrag zur Methodologie zoologischer Probleme.* By Tad. Garbowski. Pp. vii+189; 6 chromolithographic plates. (Jena: Fischer, 1903.) Price 28 marks.

(3) *Untersuchungen über den Phototropismus der Tiere.* By Dr. Em. Rádl. Pp. viii+188. (Leipzig: Engelmann, 1903.) Price 4*s*.

(4) *Graber's Leitfaden der Zoologie für höhere Lehranstalten.* Bearbeitet von Dr. Robert Latzel, k.k. Gymnasial-Direktor. Fourth revised edition. Pp. 232; illustrated. (Leipzig: G. Freytag, 1904.) Price 3.80 marks.

(1) THE first edition of Prof. Haeckel's book appeared thirty years ago, and the fourth edition in 1891. With each reappearance the book has increased in size and in stateliness, and this is particularly true of the new edition. The sequence of editions reads like a developmental process, say in crustaceans; there is some ecdysis, there is addition of new parts, there is a growing beauty, but the essence remains the same. The veteran evolutionist has gone over the whole work again; he has incorporated new discoveries, he has added fresh arguments and illustrations, but the gist of the book remains unaltered. Our familiar old acquaintances—the Monera and the Gastræadæ, the biogenetic law and its helpmate cœnogenesis, dysteleology and monism, and so on—are all as alive as ever, and with much to say for themselves. As Haeckel says, the book may have its faults; but has anyone given a better popular presentation of the concrete facts as to the position of the human organism in its place in nature, or, for that matter, has anyone else ever tried? We may object to some of his embryology and to some of his phylogeny and to all his philosophy, but here is a vivid, picturesque account of man's development and of his plausible pedigree. It is a historic document which will occupy an honourable place among the archives of biology. It is an achievement on the author's part to have made this revision now—adding about 100 pages, three score and ten figures, ten plates, and eight genetic tables; we could not expect him to change his cherished convictions. Nor, as he says, has he seen any reason to do so. The parts we like least are where he brings in new or relatively new discoveries somewhat casually, as we may illustrate by referring to the centrosome which he calls a "nicht färbares Körperchen." What is it, then, that stains so intensely with iron hæmatoxylin?

(2) Dr. Garbowski has ceased to find satisfaction in the conventional formulæ often used in seeking to interpret phylogenetic advances. He has ceased to believe in the homology of the germinal layers, in the gastræa theory, and in the cœlome theory; and he thinks that the usual application of the so-called biogenetic law is for the most part fallacious. In all this he is not so solitary a sceptic as some of his sentences would lead one to suppose.

There is a branch of ætiological inquiry in which the zoologist interprets the whole organism as a system of adaptations, and seeks to show how the various items in this system may have arisen in the course of variation, and may have persisted by enhancing the survival-value of their possessor. There is another branch of ætiological inquiry which tackles the deeper problems of morphogenesis, which inquires into the formative conditions leading to various big steps in organisation-progress—such as the origin of an enteron, the establishment of metamerism, the development of a cœlom, or the institution of a vertebral axis. It is with these morphogenetic problems that Dr. Tad. Garbowski is mainly concerned, and he wishes to find a *via media* between the use of what he believes to be obsolete verbal formulæ and the extreme of biomechanics.

"Darwin and his school sought to discover the nature of transformation without knowledge of the internal processes, and the 'Entwickelungsmechaniker' are trying to interpret the latter apart from the immanent effects of the former."

It is easy enough to say that sponges are quaintly inverted primitive Metazoa, that annelids represent ancestral Chordates on their backs, that Trochophora have sprung from Ctenophora—the illustrations are the author's—but what we must get at is an observational or experimental knowledge of the actual way in which architectural changes of moment are brought about. In short, we must deepen our physiological-morphology, getting beneath mere form-changes to the functional changes which condition them. This, so far as we can see, is what Dr. Tad. Garbowski is driving at. We are surprised, by the way, that he does not include Rauber's "Formbildung und Formstörung" in his huge bibliography.

The first chapter is devoted to a study—full of interest—of *Trichoplax adhaerens*, with subsections on Treptoplax and Salinella; the second chapter discusses the Mesozoa in general; the third chapter describes various processes of gastrulation, and ends with a rejection of the gastræa theory; the fourth chapter deals with the two primary germinal layers, the mesoderm and the cœlom, and ends with a rejection of the germ-layer theory. In conclusion, the author expounds the scope of physiological morphogenetic studies. There are six fine plates.

Dr. Garbowski is iconoclastic, and his recoil from some familiar theses is thorough-going, but his scepticism is neither unexpected nor unwelcome. The late Prof. Claus had promised to protect him if the Thames caught fire, so to speak, but the author is quite able to look after himself, and his theses will find as much acceptance as opposition. We have all been having our doubts about the homology of the germ-layers and the like; morphological concepts are every day becoming more kinetic, less static. The only question is how far we can go with the little that we know of physiological morphology. In so far as Garbowski has increased the data his memoir is very welcome.

(3) Dr. Em. Rádl has made many experiments on the phototropism of animals, that is to say, on the manner in which they orientate themselves in relation to light stimuli. Phototropic phenomena have been most studied in plants, but there is already much literature relating to their occurrence among animals, and the author begins with a historical survey. He goes on to the reactions of animals on a revolving turn-table, the compensatory head-movements of insects, nystagmus in insects, and phototropic orientation in insects with one eye blackened.

After showing that phototropic orientation or movement occurs widely among animals, *e.g.* in Cœlentera, echinoderms, planarians, annelids, arthropods, and molluscs, and that it may be exhibited in eyeless forms, Rádl discusses various phenomena which cannot be set down as simply phototropic. Thus it cannot be safely said that the movement of pigment in the eye or in the skin is phototropic, and there are many details in the behaviour of butterflies and dragon-flies in relation to light and shade which seem to be more than phototropic. A simple reflex may become complicated by the association of accessory reflexes. In unnatural conditions the established phototropic reflex may lead the animal astray, as when the moth, circling nearer and nearer, finally finds its death in the candle —an interesting and much discussed subject to which Rádl devotes some attention.

Sedentary animals, like plants, orientate themselves to the direction of the light; freely moving animals move into the direction of the light. The author discusses the question whether these two kinds of response are merely different aspects of phototropism, and comes to the conclusion that the two are not directly dependent on one another. He also regards the difference between positive and negative phototropism as a secondary matter; in both there is orientation to the direction of light, but the locomotor muscles are differently stimulated.

In the more general part of his book, Rádl discusses the relations between phototropism and other tropisms —or the more legitimate of these—geo-, stereo-, rheo-, galvano-, chemo-, and thermo-tropisms. There is a chapter, all too short, on the ethological importance of phototropism. The author is clear that organisms are systems of adaptations and that phototropism is a physiological adaptation, but he looks askance at teleological phraseology, and does not follow up the subject. The book closes with a discussion of the general theory of orientation; this must be based on study of tropisms; there is no "Orientierung überhaupt," but the organism seeks for a state of equilibrium in relation to various external stimuli—an equilibrium which consists not merely in the position of the body, but in its functioning.

Dr. Rádl is cautious in stating his own theory of phototropism; he restricts himself to the following propositions:—

(1) Phototropic orientation means the capacity of assuming a definite position of the axis of the body in the field of light.

(2) A phototropically orientated organism is in a state of physiological equilibrium in relation to the light.

(3) The orientation can only be brought about by the operation of paired or coupled forces, which are partly external, partly internal.

(4) In the orientations or tropisms of organisms there is always at least one internal force operative, and this is usually muscular.

The conclusions strike one as disappointing, for they seem to be practically summed up in the conception of "physiological equilibrium"; those who are prepared to advance other theories will find this book of great service. It summarises the subject, describes many new experiments, and criticises many untenable positions.

(4) About twenty years ago we were familiar with a little book, "Outlines of Zoology," by Graber, which had a wide use if not popularity in Gymnasien. Its features were brevity, accuracy, lucidity, and comprehensiveness. We suppose, in the absence of any prefatory note, that the volume before us is our old acquaintance in a glorified edition, in which Dr. Latzel has preserved the characteristics of the original. The book begins with a short introduction on metabolism, the cell, and protoplasm—which must be difficult pabulum for even "höhere Lehranstalten"; it proceeds to the structure and functions of the human body, and thence to a survey of the whole animal kingdom from mammals to the Protozoa. As a systematic summary to be associated with more vital studies in natural history the book is admirable; it is clear, direct, accurate, and most copiously illustrated. It is so ambitiously all-inclusive that we are almost startled to find no mention of Balanoglossus, Peripatus, or the okapi; but these will doubtless find their place in the next edition. A book of this sort, tightly packed with information, without, in many cases, even the padding of verbs to the sentences, must be judged by its intention. If that be, as we charitably suppose, to serve as a terse *index rerum* or synopsis, associated with practical work and open-air studies, it deserves to be encouraged. But if it is meant as a book to be "got up"—and there are unpleasant suggestions of the cram-book about it—then it is emphatically not in the line of progress. It stands in direct antithesis to the natural history text-books for high schools which find favour in America and are securing their place in this country. There is almost no suggestion of the evolution or affinities of the great types; there is almost no hint of initiation into scientific methods of observation and reasoning; and there is very little open-air. It seems to us more like a revisal-book for a student going up for his first professional examination in medicine or natural science than a book for schools. At the same time, it is a very effective book of its sort; the illustrations are admirable, and the coloured plates are as fascinating as the text is dry. J. A. T.

AN AMERICAN TEXT-BOOK OF GEOLOGY.

Geology. By Thomas C. Chamberlin and Rollin D. Salisbury. Vol. i. Geologic Processes and their Results. Pp. xix+654; with 24 plates and 471 figures in the text. (New York: H. Holt and Co., 1904.)

THE work of which this is the first volume, bearing the names of two well known professors in the University of Chicago, is addressed to the mature student, and is designed "to present an outline of the salient features of geology, as now developed." The present instalment, dealing with the nature and results of the processes now in operation upon the globe, will naturally prepare the way for the second volume, to be devoted to tracing the history of past ages. Agreeing with other writers in approaching the science from this side, the authors have been led by their own experience as teachers to depart somewhat from the beaten track in their general plan of treatment, as well as in the relative importance assigned to certain specific subjects. They tell us in their preface that they have laid little stress on the generally recognised divisions of geology, "dynamical," "structural," "stratigraphical," &c., but have tried rather to emphasise the historical element even in the discussion of special themes, thus bringing out the essential unity of the science. Again, some subjects, such as the development of drainage-systems, the ultimate cause of crust-movements, and others, receive here fuller treatment than has been customary in works of this scope.

Most of the original features of the book we heartily welcome. We think, too, that the authors have generally been happy in their treatment of the more dubious and debatable problems of physical geology. Their design in this has been freely to introduce the theoretical element when necessary, and at the same time "to avoid confusing the interpretations based on hypothesis with the statements of fact and established doctrines." Where important differences of opinion exist, the alternative hypotheses are set forth and their consequences compared. In some instances this candour is pushed rather far, as when the cause of vulcanism is discussed on seven distinct hypotheses. Having regard to the class of students for whom the book is primarily intended, we think that the authors have needlessly hampered themselves by trying to make it intelligible to one who has had no previous acquaintance with the rudiments of geology. How far they have succeeded in this it is not easy to judge. Thus the technical terms of the field-geologist, "dip," "anticline," "dyke" and the like, are not formally defined until we reach a late section of the volume, but the conceptions implied have necessarily been introduced much earlier. Such difficulties inevitably confront the writer of an elementary class-book, but they might safely be ignored in a work like the present.

After a preliminary outline of the general scope of geology, the authors proceed to discuss in turn the geological effects of the atmosphere, of running water, of underground water, of snow and ice, and of the ocean. Their clear exposition of the mechanism of rain- and river-erosion, with due regard to the controlling conditions, is an admirable summary of a fundamental part of geology which in most of our text-books receives very inadequate treatment. It is written on modern lines, the fertile conception of the "base-level of erosion," with its important consequences, being introduced at an early stage. The subject is one which American geologists, with their unrivalled opportunities, have made peculiarly their own, and it could scarcely have fallen into better hands. The other geological agents are discussed in the same comprehensive but concise manner, and the chapter dealing with glacial action is, as might be expected from the authors, of special interest.

The chapter on movements and deformations of the earth's body contains much material which is not elsewhere accessible to the student in a connected shape, and some originality appears in matter as well as in treatment. Consideration of the possible causes of the great crust-movements leads to an inquiry into the original and present distributions of temperature in the globe, and to a comparison of the nebular hypothesis with that of "accretion." The comparison is presented in a judicial manner, and the enunciation of the accretion hypothesis is tantalisingly brief; but a fuller discussion is promised in the second volume. Geologists sometimes need to be reminded that cosmogony is a legitimate part of their province, not to be surrendered without good reason shown. At least it is well that students should see just how much of accepted physical principles and how much of arbitrary assumptions go to the building of dogmas which have carried alarm into some quarters.

The treatment accorded to igneous action seems to us in some respects unsatisfactory. Descriptive petrography is, no doubt wisely, represented by a brief summary, an appendix to a generalised account of "the origin and descent of rocks." But what follows seems to lack due proportion. "Vulcanism" is used to include intrusive as well as extrusive action, but the chapter is occupied almost exclusively with the latter. The plutonic and other igneous intrusions, the varied forms which they assume, and their intimate relation to crust-movements and to geological history in general, are dismissed almost without notice. The full and admirable discussion of volcanoes might thus give a student the impression that these superficial phenomena are the only important effects of igneous activity.

The volume concludes with a chapter on the geologic functions of life, and a good index is added. The book is issued in handsome form; but the highly glazed paper, presumably adopted for the sake of the figures, is irritating to the reader. The abundant figures, selected from various sources, are well chosen to illustrate the text, and well reproduced. The subjects are for the most part American. A useful feature is the illustration of various types of topography by actual maps, taken from the beautifully contoured sheets of the United States Geological Survey.

A. H.

THE TOPOGRAPHY OF BRITISH INDIA.

India. By Colonel Sir Thomas Holdich, K.C.M.G., K.C.I.E., C.B., R.E. Pp. 375; 8 maps in colours. *The Regions of the World.* Edited by H. J. Mackinder. (London: Henry Frowde, Oxford University Press, n.d.) Price 7*s.* 6*d.* net.

WITH climates varying from the ice-bound deserts of the higher Himalayas and the rain-steeped forests of Tenasserim, to the desolation of Makran, where at one time of the year fire is almost unnecessary, even for cooking, and at another the cold blasts almost defy human endurance; the inhabitants of which number races unsurpassed as brave and stubborn fighters, and races among whom physical cowardice is regarded as no disgrace; where in one part music is produced by stamping on a piece of wood, and in another has been carried to a refinement which requires sixty-four tones to our octave—both extremes, it may be added, equally unmusical to the European ear; where there is found a system of laws so elaborate that the cashier who has confessed to embezzlement may yet succeed in escaping punishment, and a system of government so paternal that it imprisons the husband, whose domestic happiness has been ruined, to prevent his committing the crime of murder; the territories known as British India may be a country for political purposes, but in no proper sense of the word do they constitute a nation, they are hardly even a "region of the world," and the name is nothing but a geographical expression for the area which is administered by the British Government through the agency of the Governor-General of India in Council. To write a description which, in a book of moderate compass, will convey a clear and fairly proportioned conception, requires a master hand; not to have failed is in itself high praise, but Sir Thomas Holdich has done more than this, he has produced a topographical description of the Indian Empire which, in spite of minor errors—such as the reference to the Kasmur bund as intended for the storage of water, and a general inaccuracy where he ventures into geology—is not only interesting to read, but accurate and well proportioned on the whole.

With all its manifold diversity in detail, the Indian Empire is composed of two parts, each of which may be regarded as a geographical unit, and each geographically distinct from the other. The larger and more important of the two may be regarded as India proper, and consists of the alluvial plains of the Indo-Gangetic river system, and the triangular area known, though incorrectly, as the Peninsula. It is cut off from Burma by a tract of mountains, impassable by reason of the deep-cut network of valleys and the dense vegetation with which their slopes are covered, and on the north it is bounded by the mighty range of the Himalayas. Both these barriers have proved effective against either ethnical or military invasion, but on the west are the semi-desert hills and open plains of Afghanistan and Baluchistan, which have repeatedly been traversed by invaders. It is in the description of this region that Sir Thomas Holdich is at his best, partly, no doubt, because it is that of which he has the most intimate personal knowledge, but largely, too, because of the intrinsic interest attaching to it; for across this region came not only the great prehistoric Dravidian and the semi-historic Aryan invasions of India, but also the military invasions of Alexander the Great, and of the successive Mohammedan conquerors of India. Until the improvement of navigation brought in the nations of the west, it was the only way by which invasion and conquest were possible, and it is through this region alone that we need look for a serious attack on India, so long as we hold the command of the sea.

Of this long series of invasions all the historical ones, from Alexander onwards, have been purely military; they have left their impress, more or less deeply marked, on the religion, the administration and the political geography of India, in buildings and in public works, but they have hardly affected the great bulk of the people, who derive their origin from the earlier invasions. In these it was no mere conquering army that came, but nations, with their wives and families, their flocks and herds, their household goods and gods, who absorbed or exterminated the inhabitants of the land, and whose descendants are found over the length and breadth of India, constituting nine-tenths of the total population.

The other unit in the Indian Empire is Burma, which belongs, geographically, rather to Indo-China than to India. Cut off from the latter by a band of forest-clad mountains, which has rarely been traversed even by marauding expeditions, it received centuries ago its religion and philosophy from India, but has remained unaffected in all other respects, and maintained its ethnical distinction untouched. This isolation of Burma is now at an end; the establishment of steamer lines across the Bay of Bengal has rendered it easy of access, the Hindu prejudice against crossing the sea has given way to the stronger claims of pecuniary gain, and the gay, picturesque, pleasure-loving Burman, who had evolved an epicurean philosophy and regarded life merely as something to be enjoyed, is being ousted by the plodding, but joyless and unattractive native of Behar or Madras.

Across the north of the Empire runs the great mountain barrier of the Himalayas, the highest and greatest mountain range of the world, which separates the Mongolians of Thibet from the races of India, and has left its impress on their mythology and folklore. This naturally gets a chapter to itself, and it is satisfactory that the author recognises the futility of an attempt to trace any limited number of continuous chains in a mountain range of so great an extent, and wisely abstains from formulating any theory of the Himalayas. We cannot, however, accept the statement, repeated more than once, that the eastern Himalayas are older than the western; it is true that the rocks of which they are composed are older, but the rise of the Himalayas, as a mountain range, belongs to the great period of mountain formation which commenced at the close of the Secondary era, and there is no reason for supposing that the two halves of the range differ materially in the age of their elevation.

The book is provided with a large number of blocks in the text, nearly all maps, in which, with very few exceptions, but one method of representing relief is adopted—that of shaded areas bounded by contour lines. The method is valuable for some purposes, but as a means of representing the form of the ground is, in most cases, inferior to the much abused "caterpillar" method of delineation, and frequently conveys a misleading impression. The figure intended to represent the lower Brahmaputra valley and Gangetic delta is an instance of this, while that intended to represent the orography of the Hindu Kush looks more like an ink-maker's advertisement. In the coloured maps the complete absence of hill shading gives to the Thibetan plateau an air of flatness which it is far from possessing in reality, yet it would be unfair to conclude this notice without a word in their praise. Mr. Bartholomew has accustomed us to a high standard of workmanship, but his map of India, reproduced in this book, has seldom been equalled for intricacy and accuracy of colour printing, and for success in showing the leading features of the relief of the land.

PHYSICAL AND PHYSIOLOGICAL ASPECTS OF LIGHT.

Light Energy; its Physics, Physiological Action, and Therapeutics. By Margaret A. Cleaves, M.D. Pp. xiv+827. (London: Rebman, Ltd., 1904.) Price 21*s.* net.

WHILE this book is written primarily to further our knowledge of the properties and uses of that form of energy called light, in the treatment of disease, yet it will be found of great interest to those whose study is mainly confined to the purely physical aspects of light phenomena. The subject is treated from the modern view of energy in the form of waves of a certain length and direction, but at the same time the emission theory is not entirely ignored on account of the peculiar behaviour of some of the recently discovered radio-active substances, notably radium. About 130 pages are devoted to a description of the various kinds of rays, their origin and physical properties. The part dealing with the electric arc is very complete and clear, and embraces all one could wish to know to ensure an intelligent application of the arc lamp in the treatment of disease.

Following this is a series of chapters dealing with the action of light on the various forms of life, from the most elementary to the highly complex human subject. In this section the action of light from both natural and artificial sources is treated very thoroughly. It is quite evident that the author has devoted herself to a large amount of painstaking experiment, the valuable results of which are recorded in the present volume. According to her, the mercury vapour lamp has not justified the expectations regarding it as a therapeutic agent.

The second half of the book is taken up with the therapeutic applications of the various forms of light. This part will be of special interest to medical men, especially those who are engaged in this line of work. Sun, arc, and incandescent light baths are treated most fully, together with their use in those diseases in which the author has found them respectively useful. The indications are, in every instance, based on spectroscopic analysis, and full details of the proper technique are given for every variety of application. Several forms of bath cabinet are described, as well as arc and other lamps for local treatment with concentrated light.

While the author is rather emphatic on the necessity for employing lamps of large amperage—quantity being as essential as quality—yet she speaks highly of certain small lamps the efficiency of which was such as to necessitate their replacement by lamps of greater power in the light department of the London Hospital. The reason for this praise is seen, later on, to be related to the comparative cost of the lamps—the smaller being sold and maintained at a fraction of the cost of the Finsen, and their efficiency is at least in proportion to this cost. According to the author, the great advantage of a lamp of high amperage, like the Finsen, is that we get not only the short and high frequencies of intense chemical activity, but also the frequencies of long wave-lengths having great amplitude and penetrability—a combination which is essential to ensure the best success. In the smaller lamps these long wave-lengths of great amplitude are not present in such abundance because of the lesser amperage and smaller carbons. The results which the author has obtained in many diseases not generally subjected to light treatment will come as a surprise to those who have not kept closely in touch with modern light therapeutics.

The applications of the various coloured lights, as also those of the invisible spectrum rays, are fully discussed. A short chapter is given to the consideration of *n*-Rays and one to the Alpha, Beta, and Gamma rays of radio-active substances, their physical properties, actions, and therapeutic uses. An interesting chapter is that on fluorescence, fluorescent stimulation, and sensitisation of tissues, and the book closes with a chapter on the pernicious effect of sunlight and the pathological effects of electric lighting. The book can be confidently recommended. It will be found of great interest to most students of natural science.

REGINALD MORTON.

A BOOK ON INK.

Inks: their Composition and Manufacture. By C. Ainsworth Mitchell, B.A. (Oxon.), F.I.C., and T. C. Hepworth. Pp. xiv+251; with 46 illustrations, including 4 plates. (London: Chas. Griffin and Co., Ltd., 1904.) Price 7*s.* 6*d.* net.

LITERA scripta manet; but the permanence of the writing depends upon the quality of the ink. Certain papyri of ancient Egypt, now deposited in the British Museum, contain the earliest ink-written records so far brought to light. A roll dating from 2500 B.C. still bears decipherable characters, and fragments of papyri have been found by Prof. Flinders Petrie in a tomb to which the date 3500 B.C. is ascribed. If the origin of the use of ink is 'ost in antiquity, at least one thing is certain—the writing-fluid used by the ancient scribes for such records as the foregoing must have possessed in a high degree the property of durability.

In one form or another, the basis of these early writing-fluids was carbon. For example, Chinese ink, the so-called "Indian" ink of the modern artist, which according to the native historians has been made since 2600 B.C. or thereabouts, was at first a vegetable varnish, and later a mixture of lampblack and glue. Inks containing gallate of iron did not come into use until a much later period. Thus Sir Humphry Davy, examining some documents recovered from the ruins of Herculaneum, "looked in vain amongst the MSS. . . . for vestiges of letters in oxide of iron," and he concludes that the Romans up to the time of Pliny had never used "ink of galls and iron" for writing purposes. Gradually, however, in the early centuries of the Christian era, there came a transition from carbon inks to those containing iron; and Blagden, in "Some Observations on Ancient Inks," communicated to the Royal Society in 1787, records that the writing fluid employed in various MSS. on vellum, dating from the ninth to the fifteenth centuries, was an iron and gall ink. Somewhat earlier than the date of Blagden's paper logwood began to find employment as a constituent of inks, and soon after the middle of last century came the next notable modification, namely, the use of aniline dyes in the manufacture of both black and coloured writing-fluids.

Of these and other matters bearing upon the history, composition, and methods of preparing the various kinds of inks, Messrs. Mitchell and Hepworth have much to tell us in the volume under notice. They have brought together, and made convenient for reference, material that has been hitherto chiefly scattered amongst periodicals and isolated dictionary articles. In so doing they have saved their contemporaries some labour, and earned for themselves much gratitude.

The book is divided into three sections. The first of these deals with writing inks, including those of which carbon, tannin, logwood, and aniline respectively form the characteristic ingredients. It comprises chapters upon the sources of the tannin materials, the chemical nature of iron-gall inks, and the best methods of examining both the fluid itself and the characters on the written page. Printing inks form the subject of section ii., in which an interesting chapter treats of colour work, including three-colour printing and inks for use in the production of cheques and bank-notes. In the concluding section there is a description of inks intended for miscellaneous purposes; these comprise copying, marking, safety, and sympathetic inks, and fluids for writing on glass, wood, ivory, or leather. Many formulæ are given, some of which the authors have personally tested, and the work closes with a list of English patents relating to the subject.

Despite occasional incoherency of style, the two collaborators have produced a useful and attractive little volume. One or two slips may be pointed out; thus the equation on p. 101 is incomplete, and the specific gravity of dilute hydrochloric acid is given wrongly on p. 208. In the historical introduction we are told, *apropos* of a certain document (p. 11), that "it was probably written at the end of the sixteenth century by a man past middle age, who learned to write just about the time that Shakespeare was born (1504)." At first it seems an unnecessarily cautious understatement to call such a man "past middle age," but a little reflection shows that it is those kittle cattle the figures that are to blame.

The book is a serviceable addition to the literature of chemical technology. C. Simmonds.

OUR BOOK SHELF.

Naturbegriffe und Natururteile. By Hans Driesch. Pp. viii+239. (Leipzig: Wilhelm Engelmann; London: Williams and Norgate, 1904.) Price 4*s.* net.

This book deals chiefly with three topics. Starting on a Kantian basis, it seeks to state the *a priori* principles of pure physical science. (*A priori* is conveniently defined as "independent of the amount of experience.") Next, the leading principles of "energetics" are discussed, and their relation on the one hand to the *a priori* principles of pure physical science, and on the other hand to the ordinary laws of thermodynamics. Incidentally, the "laws" of conservation (of substance and the like) are examined, and entropy has a good deal of attention. Last of all the results attained are carried over to a discussion of biology. The point of view is neo-vitalistic. It would be hazardous to say that the author has run to earth the *x* which is the object of all our search, the vital principle or whatever other name may be applied to it; the term which he uses is the blessed word *entelechy*.

Herr Driesch is well known to be at his best a clear, original and suggestive writer. Much of the present work is excellent, but we doubt if the last eighty pages are either clear or convincing. Perhaps one would require to read the author's other works in order to accustom oneself to his point of view and his independent modes of statement. He is occasionally unsatisfactory as well when dealing with the theories of others, for example, with Prof. Clerk Maxwell's "sorting demon." The discussion occurs under the heading "Declarations of Physicists regarding Biological Subjects," and Herr Driesch almost seems at times to suppose or to imply that the conception may have been formed in order to limit the second law of thermodynamics to inanimate bodies. True, Lord Kelvin's statement of the second law has the words "in inanimate material." But Lord Kelvin's declaration is explicit ("Popular Lectures and Addresses," 1889, vol. i. p. 141):—"The conception of the 'sorting demon' is merely mechanical and is of great value in purely physical science. It was not invented to help us to deal with questions regarding the influence of life and of mind on the motions of matter." On p. 103 the accurate reference to Helmholtz's work is Ostwald's *Klassiker* Nr. 124, p. 30, Anm.

Higher Text-book of Magnetism and Electricity. By R. Wallace Stewart, D.Sc. Being vol. iv. of "The Tutorial Physics." Pp. viii+672. (London: W. B. Clive, University Tutorial Press.) Price 6*s.* 6*d.*

We have several times noticed this work as successive editions have appeared, and can speak as appreciatively of it as we have on other occasions. The present volume is based on the older one, but it has been wholly re-cast, and a very considerable quantity of new matter has been added in view of the rapid advance which has been made in electrical theory in the last few years.

In this edition the author has followed several other text-books in laying stress upon the importance of the electric field as the real seat of the energy of an electric circuit. It should be clearly brought out, however, that part of the energy must flow in the conductor, following there, as elsewhere, the direction of the equipotential surfaces; the forward flow is, however, in the dielectric itself. The figures exhibiting this flow of energy on pp. 344, 525, and 528 are very far from satisfactory. It is sufficient to point out that in every ordinary case of steady transfer the lines of force are convex *forwards;* indeed, if it be borne in mind that in accordance with Poynting's theorem the flow of energy takes place at right angles to the lines of force, there would be energy flowing out from and not into a conductor if the lines were as shown.

Too much care cannot be exercised in the construction of diagrams. They catch the eye; and just as nothing is better than a good diagram for inculcating truth, nothing can be worse educationally than one that is slipshod.

This remark applies equally to a figure illustrating the action of the keeper of a magnet on p. 227, where about twice as many lines of "force" are shown in the keeper as are represented in the magnet itself. Is the keeper supposed to be independently magnetised?

Again, on p. 401, if the equipotential lines on the plate exhibiting the Hall effect were really as shown, some of the current would flow over the edges of the conductor.

This slovenliness is almost wholly confined to the figures. The text is exceedingly lucid and painstaking in the endeavour to give a student a sound knowledge of physics. The large number of worked out examples, which have always been a distinguishing feature of the book, have no doubt contributed largely to the appreciation which it has received, especially from those who are compelled by circumstances to work without a teacher.

Life and Energy—Four Addresses. By Walter Hibbert. Pp. xiv+182. (London: Longmans, Green and Co., 1904.) Price 2s. 6d. net.

THE thesis of these four addresses—originally delivered at the Polytechnic Institute, London—is that life is not matter, is not energy, but an unceasing non-factorial directive control of energy and its transformations. "Directive control," *i.e.* in the same sense in which "temperature" in the case of heat, or "potential" in the case of electricity, controls the direction in which the energy shall flow. "Non-factorial," because while temperature, potential, and the like are factors of energy, life is not a factor.

Mr. Hibbert puts most of his points clearly, and much of what he says has considerable force. But it is doubtful if the range of ideas within which the book moves is adequate to the problem. The main position is not unassailable, and the deductions from it in regard to morals and religion are occasionally fanciful.

To descend to details. (1) It is difficult to see how the terms factorial and non-factorial describe precisely the difference between the directive control of energy manifested in inorganic and in organic bodies respectively. The discussion on p. 50 rather begs the question. (2) In describing God's directive control as being purely non-factorial, in saying (p. 144), "It is not the office of prayer to seek any direct disturbance of the course of material nature," but "its office is to secure a renewed faith in non-factorial control," Mr. Hibbert lays himself open to the retort, "Then non-factorial control is no control at all." (3) "Provided that life is a physical entity, it must be either matter or energy" (p. 16). "If it is a form of matter, it must weigh something" (p. 17). But what if it were ether? (4) "The living plant opens out a new path in which physical law can operate" (p. 39)—"it has, in a sense, directed the energy into special channels" (p. 38). But is this a differentia of life? Surely to one acquainted only with other manifestations of energy the path opened out by the dynamo is as new as anything can be.

Glossary of Geographical and Topographical Terms. By Alexander Knox, B.A., F.R.G.S. Pp. xl+432. (London: Edward Stanford, 1904.) Price 15s.

THIS work, which is intended as a supplementary volume to Stanford's "Compendium of Geography and Travel," is evidently the outcome of a vast amount of industrious research on the part of the author. The amount of labour involved in the collection of some 10,000 geographical terms derived from the most diverse languages all over the world can readily be imagined, and it can only excite our admiration that so much should have been successfully accomplished by a single individual. The book will be a decided boon to readers of works of geography and travel, who, in the absence of deep linguistic attainments, must constantly be puzzled by the terms employed in the place-names of foreign countries. It will also be valuable to the more scientific geographer as supplying a useful basis for the complete dictionary of geographical terms, which has long been felt to be a desideratum. Mr. Knox's book, useful as it is, can hardly be said to supply this need, being concerned rather with the general and popular, than with the scientific and technical usage of geographical terms. It was undertaken in the first instance, as the author explains, with a view to elucidate the terms in use in extra-European countries, and this object it certainly fulfils with success. European geographical terms, which naturally include the majority of those with which the scientific geographer is concerned, are less fully dealt with, and we not only miss many such technical terms as "Karst," "Kar," "Horst," "Schrund," "Aven" (to take a few only at random), but we find little attempt made at discrimination between the terms in use for closely allied features, or at the definition of nice shades of meaning, such, e.g., as are involved in the words "dale" and "dell," both of which are explained merely as a "valley." Many English local terms are missing, and the definition of others is not always quite satisfactory. On the other hand various Spanish topographical terms are carefully explained, and the recent definitions by the International Commission for the Study of the Sea of the main features of suboceanic relief are correctly given.

But the special value lies in the fact that the information supplied is just that which is most out of reach of the ordinary reader, terms derived from the languages of Africa, Asia, and the less known parts of the world generally, being particularly well represented. The introduction includes some useful hints, by Dr. A. H. Keane, on the laws of interchange of letters in various languages.

Blackie's Handy Book of Logarithms. Pp. 128. (London: Blackie and Son, 1904.) Price 2s.

Vier- und fünfstellige Logarithmentafeln. Pp. 24. (Brunswick: F. Vieweg and Son, 1904.) Price 0.80 mark.

IN order that mathematical tables intended for common use may serve their purpose, it is essential that great attention be paid to the labour-saving arrangements which authors have from time to time introduced, such as the careful grouping of the figures in rows and columns, the use of varied type or of differently coloured inks, marginal or thumb indexes, proportional differences, inverse functions, &c. On opening Blackie's "handy" volume, the reader will be disappointed to find that the compiler of the tables has paid little attention to the points enumerated above. A table of six-figure logarithms of four-figure numbers occupies twenty-two pages; the average difference for each row of figures is given, but there is no room found for proportional differences, so that the taking out of the logarithm of a five- or six-figure number involves an irritating calculation. Anti-logarithms are not included, but there is a table of hyperbolic logs. Sixteen pages are allotted to tables of natural and logarithmic functions of angles, for increments of one-sixth of a degree, without differences. Other tables include reciprocals, squares and square roots, cubes and cube roots, circumferences and areas of circles, heights and areas of circular segments, and rhumbs in degrees. There is an appendix giving some simple mensuration rules, some old-fashioned practical geometry, and definitions of the functions of angles, not as ratios, but as lengths.

The German tables are specially suitable for use in the chemical laboratory. The main feature is an eighteen-page table of five-figure logarithms of five-figure numbers, arranged, with proportional differences for each row of figures, like the four-figure logarithms contained in the first two pages. The collection of physical constants at the end is such as a chemist would be likely to require. There are no anti-logarithms, nor is there a marginal index. The size of page is ample, allowing of bold and effective type.

Second Report on Economic Zoology: British Museum (Natural History). By Fred. V. Theobald, M.A. Pp. x+197. (London: Printed by Order of the Trustees of the British Museum, 1904.) Price 6s.

The recent development of British Museum activities in the line of economic zoology, for which the insight of the director is largely to be thanked, is re-expressed in a second report, following quickly on the heels of the first (see Nature, January 28, 1904, vol. lxix. p. 290). We congratulated Mr. Theobald on his first report, and we repeat our congratulations, for the volume does credit to his energy and ability, and to the expertness of those inside and outside the national museum who have given him assistance. Everyone who has had even a little experience of the amount of work which is often required in order to answer apparently simple questions from outside will appreciate the skill which this report displays. The volume contains a large part of the information furnished by the director of the natural history departments of the British Museum to the Board of Agriculture and Fisheries between November, 1902, and November, 1903, besides replies to other correspondents and some special notes of present-day interest. The British Museum of Natural History is not only one of the greatest world-treasure-houses of scientific material, it has also, in its staff, an almost unrivalled wealth of learning, and we cannot refrain from giving expression to the widespread gratification that these resources of material and knowledge are now being utilised in behalf of the practical queries of the nation. The volume deals with mosquitoes, sheep scab, weevils, aphides, wire-worm, mites, leather-jackets, warbles, ring-worm, liver-fluke, and a hundred other economically interesting pests—and always in a way that leads us to respect Mr. Theobald's wide knowledge and practical shrewdness. We hope that there will be many such reports, for they are of a kind that enrich the nation as well as science. That they also contribute to art may be illustrated by the report on the grubs causing damage at Rye Golf Links.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of Nature. *No notice is taken of anonymous communications.]*

The Heterogenetic Origin of Fungus-germs.

An attempt has been made in Nature (December 22, 1904, p. 175), by Mr. George Massee, of Kew, to question the validity of my conclusions because of certain observations of his own of a totally different kind, which have little or no bearing upon what I have brought forward.

What he says is this:—*Dematium pullulans* of de Bary produces exceedingly minute colourless conidia which are most widely distributed and are capable of passing through "thick" filter paper. "Under normal conditions," he adds, "these minute conidia on germination form delicate hyaline hyphæ which give origin to a Cladosporium. If cultures of these conidia become infested with bacteria that form Zooglœa, the hyphæ become invested with a comparatively thick, brown cell-wall, and form either compact masses of cells or irregular hyphæ consisting of short cells, constricted at the septa, exactly as shown in Dr. Bastian's Fig. 12." He then refers to an illustrated paper in the *Kew Bulletin* for December, 1898, in which he has shown this process as it occurs in a certain disease of *Prunus japonica.* He thinks his observations exactly illustrate some of the facts which I have brought forward, while I, after carefully reading his paper and studying his illustrations, think they are altogether beside the mark.

He supposes the widely distributed conidia are not only present in the hay infusion (which of course they may be), but that they are able to pass through two layers of very fine Swedish filter paper (not merely "thick" paper, as he loosely puts it). Looking to his Fig. 5 and the size of the conidia there shown, this, I think, is more than doubtful. It is, however, altogether immaterial whether such conidia are present in the original hay infusion and are able to pass through the filter used by me or not, because the next necessary step in his suggested explanation is altogether wanting in my observations. This step is that the conidia assumed to be present shall produce delicate hyphæ, and that these hyphæ, coming into contact with masses of Zooglœa, shall "become invested with a comparatively thick, brown cell-wall, and form either compact masses of cells or irregular hyphæ consisting of short cells constricted at the septa." But I had already privately assured Mr. Massee that all the phenomena which I have described may be witnessed without its being possible to meet with a single hypha of any kind or a single one of the thick-walled, brown cells to which he refers.[1] Yet for his explanation to have any weight "delicate hyphæ" should always be seen in relation with the Zooglœa masses, and as for the "thick-walled cells" which are then formed being exactly like what I have shown in my Fig. 12, I can assure Mr. Massee he is absolutely mistaken. What I have represented in that figure are colourless products of segmentation of a Zooglœa mass (wholly unlike the colourless conidia shown in his Fig. 5) which speedily assume a brownish-black colour, and then, *without any intervention of delicate hyphae,* at once grow out into mycelial filaments of the same colour. In accordance with his explanation, the production of delicate colourless hyphæ should be the commonest thing possible, and should always be met with at an early stage of the changes that I have been describing; but, as a matter of fact, nothing is more remarkable than the rarity with which any of the myriads of Fungus-germs produced in a bacterial scum undergo a further stage of development, with the production of hyphæ either colourless or coloured, and I can assure Mr. Massee that he might work for three weeks or more with such infusions as I have described without finding a single specimen at all comparable with my Fig. 12. It seems deplorable that in regard to such an

[1] This was in reply to a private letter to me very similar to that which he subsequently sent to Nature. In this reply I asked him to come and examine my specimens for himself, which he did not do.

important subject as the reality or unreality of heterogenesis, persons like Mr. Massee, who could speak authoritatively, should not think it necessary to make personal observations, and should be content to offer in reply to real and prolonged work only loose explanations which will not bear any serious examination.

A further instance of the same lack of care is afforded in the last sentence of Mr. Massee's letter. Referring evidently to my remark (NATURE, November 24, 1904, p. 77) as to the very different products that may be met with in the scum forming on an infusion made from unripe grasses as compared with that forming on an ordinary hay infusion, he says:—"As these fungi only develop on fading leaves it was not to be expected that they would appear in infusions of young grass." This sentence must have been penned without the writer having taken the trouble to look at p. 87 of my "Studies in Heterogenesis," to which reference was made when I directed attention to the differences in question. Had he done so he would have seen how little he had explained the differences noted on that and on the following page, and he would also have seen that the most striking difference recorded is the complete absence of Zooglœa masses (spoken of there as "areas") in the scum forming on infusions of unripe grasses. Of course if the Zooglœa masses are not there it is easy for me to understand the absence of the Fungus-germs which, as I maintain, are produced therefrom.

This point, as well as others in Mr. Massee's letter, shows the great importance of bearing in mind two wholly distinct aspects of my observations, corresponding with different stages in the processes described. We have to do (1) with the growth, the individualisation, and the processes of segmentation taking place in masses of Zooglœa. We have also to do (2) with the question of the ultimate destination, or the transformation, of the products of such segmentation. These are two parts of the subject which are to some extent distinct, and are well worthy of further separate consideration.[1]

In conclusion I would ask, Why do the bacteriologists not tell us what they know about Zooglœa—whether they are or are not aware of its developmental tendencies, and why it should undergo processes of minute segmentation, unless such processes are a result of an organising tendency destined to have some definite outcome? Why, again, should it or its segments so often tend to assume a brown colour, while it is still nothing but Zooglœa, either segmented or unsegmented? Again, why, if the brown Zooglœa does not yield the brown Fungus-germs, should there be this constant association of myriads of brown Fungus-germs (in the absence of hyphæ) in association with brown masses of Zooglœa? How can they explain, other than I have done, the actual organisation of a Zooglœa mass, and the stages by which the brown Fungus-germs seem to be formed therein? What process of "infection" in a filtered hay infusion contained in a closed pot could cause thousands of small Zooglœa masses to go simultaneously through similar processes of this kind—producing myriads of brown Fungus-germs—when not a single hypha is anywhere to be found, and when at first no Fungus-germs are to be met with outside the Zooglœa masses themselves? I trust the bacteriologists will vouchsafe to give us some information on these points, or, if they cannot reasonably explain them, that they may be induced to work at the subject, and satisfy themselves that something important can be learned concerning bacteria, even though it be outside their laboratories and by methods other than their own.

H. CHARLTON BASTIAN.

[1] My further observations on this subject will be found in the February number of the *Annals and Magazine of Natural History*.

Compulsory Greek at Cambridge.

As a corrective to much vague discussion, perhaps the following record of facts may be of interest.

Entering the University of Cambridge in 1886, entirely ignorant of the Greek language, I was, of course, obliged to pass the "Little-go" in order to proceed to the natural sciences tripos. The Greek subjects prescribed were the Gospel of St. Mark, the Pluto of Aristophanes, and the usual grammar papers, and, in conjunction with a friend similarly circumstanced to myself, I set to work to "cram" these by as "scientific" methods as we could devise, in order to pass with as little waste of time as possible.

Purchasing a copy of Wordsworth's "Primer of Greek Grammar," we read the nouns, adjectives, and the active voice of τυπτω—no more, and then started on the prescribed books. These we translated by aid of a good lexicon, word by word—thus learning the parts of the irregular verbs, which form a favourite subject in the grammar papers. Having been once through the books by this method, we procured the translations, and read these through five or six times, in order to become so familiar with the subject-matter of the books that we could translate most passages easily at sight after making out the leading words in them.

The actual time expended by us in the preparation of Greek for the examination was carefully recorded, and amounted to $105\frac{1}{2}$ working hours, and we passed the examination in the second class, with, I believe, a considerable margin of safety even in Greek. I need hardly add that my present knowledge of the language is *nil*.

December 28, 1904.

Polyhedral Soap-films.

THE fact that polyhedral wire frames can be used for the purpose of forming films across them is well known, but there are some features of this subject, which I have investigated, which may be of interest.

If a frame of wire representing the edges of one of the simpler polyhedra, such as a cube or octahedron, is dipped into soap solution, then on taking it out it will have films attached to its edges and meeting roughly at a point in the centre of the figure, forming a number of pyramids standing on the faces of the figure. If, however, a more complex figure, such as the rhombic dodecahedron or the eicosihedron, be taken, then the effect will be quite different; the film will then simply cover all the faces except the one which was drawn out of the solution first. The former thing will happen if the area of the $(n-1)$ faces is greater than that required to form the pyramids, while the latter will occur if the reverse is the case.

If, now, in the case of the cube, for instance, after the pyramids have been formed, a film be applied to one of the faces, then a certain amount of air becomes entirely enclosed by film, and the bubble so formed settles in the centre of the frame, forming roughly a cube suspended in the frame by twelve sheets of soap-film. On closer inspection, however, it will be seen that the faces of this cube are convex, thus showing that the air in it is compressed. By inserting a tube this cubical bubble can be inflated or reduced in size, all the time retaining its convexity, so that if thus left in communication with the air it will collapse of its own accord. A little consideration shows the reason for this, namely, that three films meeting one another cannot be in equilibrium unless their planes are inclined to one another at 120°, since the tensions in all three are equal. But since the dihedral angle of a tetrahedron, cube, or octahedron is less than 120°, therefore in these figures the internal polyhedral film must always have convex faces.

From this I expected to get an exact polyhedron with plane faces in the case of the rhombic dodecahedron, since its dihedral angles are all 120°. On trying this it was found to agree remarkably with my assumption, only, as may be gathered from what has gone before, it was not quite so simple to obtain the central bubble as in the former case. After the $(n-1)$ faces had been covered with film the figure was again immersed so as to displace about one-half the air contained in it, and while thus immersed it was turned round so as to cover the one open face with liquid. On withdrawing it there was seen the plane-faced rhombic dodecahedron. The same result can be obtained by applying a film to the nth face and then exhausting some of the enclosed air by means of a tube. By using a tube, as in the former cases, the bubble can be enlarged or reduced at will by blowing or suction, and it will retain its size constant when placed in open communication with the outer air by means of this tube. This is, of course, the only plane-faced polyhedron which can thus be formed, faces, edges and vertices being entirely made out of soap films. If, on the other hand, a figure has its dihedral angles greater than 120°, then the internal bubble will have concave faces, and will, if placed in communication with the outer air, increase in size until it coincides with the faces of the frame, and will then be kept in equilibrium by their rigidity. This I verified in the case of the eicosihedron.

There is one important law which must be mentioned. I found a certain irregularity in the behaviour of the films in the case of the octahedron and rhombic dodecahedron. This was due to the fact that two films cannot cross one another at right angles, a law which can be put to the test by placing two plane loops covered with film at right angles, when a small lanceolate film will be formed making two curved lines of intersection with the film on the loops, instead of allowing them to intersect in a single straight line. In the case of the rhombic dodecahedron this slightly modifies the form of the internal bubble, introducing a small edge and a little curvature at each of the acute vertices. This defect causes a serious convexity if the bubble is small, but in general we have double curvatures at the points in question, the remaining portion of each face being plain while the figure retains the form of a rhombic dodecahedron. W. F. WARTH.

Reversal of Charge from Electrical Induction Machines.

THE reversal of the poles of a Voss machine by giving some turns in the wrong direction, as observed in NATURE of January 5 (p. 221), is not an unknown phenomenon. It is described in my paper "Essai sur la Théorie des Machines électriques à influence" (Gauthier-Villars, Paris, 1898), p. 38, together with a much more trustworthy and simpler means—an improvement, in theory and in fact. This consists in discharging by hand, at the same time, both the inductors of the fixed disc. Then the reversal is invariably observed without stopping the machine.

V. SCHAFFERS.

Louvain (Belgium), 11 rue des Récollets.

THE CONSTRUCTION OF SIMPLE ELECTROSCOPES FOR EXPERIMENTS ON RADIO-ACTIVITY.

THE electrical method, where it is applicable, is now by far the most sensitive method of detecting small quantities of matter; and the recent advances in physical science made by the method of measuring small leakages of electricity, especially in connection with the phenomena of radio-activity, have excited a very general interest in the experimental arrangements employed. The writer hopes that the following account of simple electroscopes for this kind of work will be found to be of a practical nature and of service to those who, though unfamiliar with many of the devices in general use in a physical laboratory, are nevertheless desirous of making quantitative experiments on radio-activity or some other subject where the electrical method is employed.

In general the final shape of the instrument will depend very much on the purpose for which it is required; in fact, it is one great advantage of the gold-leaf electroscope that it can usually be fixed up in any odd corner of the apparatus which happens to be convenient. There is, however, one part of the apparatus which is always the same in sensitive instruments, and that is the gold-leaf system itself. Before describing this it will perhaps make things clearer if we consider for a moment one or two points about the theory of the instrument.

What we observe usually is the rate of decrease of the deflection of a charged gold leaf from a vertical metal support to which it is attached. Now the deflection in question depends only on the shape and size of the leaf and of the metal support, and on the electrostatic potential of the system, so that the rate of collapse of the leaf measures the rate of decrease of the electrostatic potential. But what we wish to measure is the current or rate of alteration of electric charge, and this is equal to the rate of decrease of potential multiplied by the electrostatic capacity of the system. Thus for a given current the rate of movement of the gold leaves is greater the smaller the capacity of the system. For a sensitive instrument it is therefore absolutely necessary to have the parts which are metallically connected with the gold leaf as small as possible.

Cutting gold leaves is a process which requires a considerable amount of patience, especially from the beginner. The process I always adopt is to take a plate of glass and lay a sheet of smooth note paper on it. On this the gold leaf is spread out flat by blowing gently if necessary, and is cut by means of a razor. To do this, all except a narrow strip at the edge is covered with a second sheet of note paper, the straight edge of which is pressed down with the fingers so as to hold the gold leaf. A fine strip outside the edge of the paper is then cut off from the leaf by dragging the razor gently backwards parallel to itself and to the edge of the paper. It is not necessary to exert any great pressure during this operation, but a little practice will be necessary to get into the way of doing the saw-cut stroke at the proper speed. Mr. C. T. R. Wilson has succeeded in this way in cutting uniform strips one-tenth of a millimetre across, but for most purposes strips one millimetre wide are good enough. In working with gold leaf much trouble will be saved by working in a room which is free from draughts and disturbances generally.

For the metal support to which the gold leaf is attached it is convenient to use a piece of wire of about the same diameter as the thickness of the gold leaf. To fix the leaf on to the wire it is sufficient just to moisten the latter at the point of attachment with the tip of the tongue; on allowing the end of the gold leaf to come in contact with the very slightly moist wire it will be found to attach itself sufficiently firmly for all that is required of it. For obvious reasons the cutting and mounting of the gold leaf should be the very last operation in the construction of the electroscope.

In constructing an electroscope it is of the utmost importance to have trustworthy insulation. When the apparatus has not to be raised to a high temperature, and great mechanical strength is not required, sulphur is a long way better than anything else for this purpose. Generally speaking, it is better to have as small a quantity of insulating material as possible in order to diminish irregularities caused by the superficial charging up of the dielectric. Suppose we wish to insulate the wire carrying the gold leaf from another wire which supports it mechanically we should proceed as follows:—Take a porcelain crucible and gently heat a quantity of pure flowers of sulphur in it until it just melts and forms a clear yellow limpid liquid. It is important that it should not be heated so strongly as to become dark coloured and viscous, as this appears to diminish its subsequent insulating properties. The end of one of the wires is then dipped into the liquid sulphur, when a coating of sulphur forms on the wire. This is allowed to cool until it has solidified, and the operation is repeated a number of times until a bead of sulphur like that shown in Fig. 1 A has formed on the end. The end of the other wire is now heated gently in the flame and applied with a slight pressure to the point *a*, when it melts its way into the sulphur;

and if the operation has been successfully carried out the result will be as indicated in Fig. 1 B.

In this sort of work it is often necessary to make sulphur stoppers, &c., of various shapes. To do this it is only necessary to make paper models of the required shape, into which the sulphur is cast. The paper generally sticks to the sulphur, but may be taken off with a clean knife without impairing the insulation. It is advisable to do this, and also any cutting away of the sulphur that may be necessary, immediately after it has set, since it becomes very hard and brittle soon afterwards.

For ordinary work with radio-active substances it is not necessary to employ the most sensitive type of electroscope, and for such work the design shown in Fig. 2 is very convenient. It consists of a brass cylinder of about the proportions shown and 10 cm. high. The top is closed by a flat plate with a narrow tubular opening *a*, into which a sulphur stopper *b*, cast as above, fits fairly tightly. The sulphur is best cast round the wire destined to carry the gold leaf. For examining the properties of various radiations the bottom may be made in the form of a ring, as shown. This is fixed by the slot and pin indicated or some

Fig 1

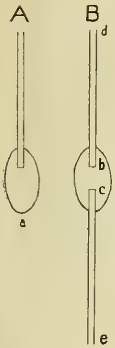

Fig 2

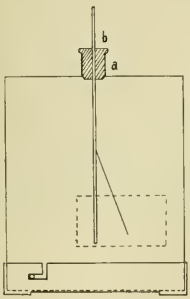


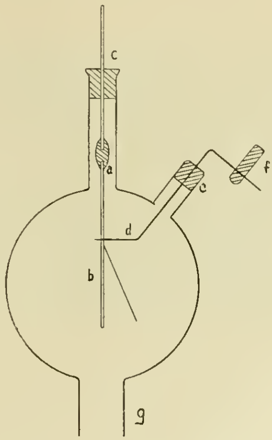
similar arrangement, and the circular hole in the base can be covered with sheets of foil, &c., if it is desired to examine the penetrating power of the rays under investigation. In all these instruments a hole has to be cut in the metal both in front and behind the gold leaf to illuminate it and to read its position. The holes are conveniently of about the relative size shown; they may be covered up with glass, mica, or transparent celluloid, whichever is most convenient. A suitable illumination is obtained by placing a sheet of white paper in front of a paraffin lamp about twelve inches behind the electroscope. The movement of the leaves is most conveniently read by means of a microscope of about 6 cm. focal length furnished with a micrometer eye-piece. It is advisable to have a microscope with as short a focal length as possible to increase the magnification, and therefore the sensitiveness.

The final appearance of the electroscope will depend very much on the appliances at the disposal of the experimenter. An instrument of this character could quite well be made out of a cigarette tin, but it would probably be more satisfactory to have the metal parts made by a competent mechanic.

If cells are not available the above instrument is readily charged by allowing a rubbed sealing wax or ebonite rod to spark to the outside wire. In measuring leaks the gold leaf should always be charged to about the same extent, as the sensitiveness depends a good deal on the amount of the deflection. The instrument will not keep its charge indefinitely, but will show a small leak even if no radio-active substances are present; this is nearly all due to the so-called spontaneous ionisation of the air. There is practically no leakage across the sulphur if the instrument is properly made.

For some purposes a more convenient arrangement is that indicated in Fig. 3, where the figure is drawn so as to exhibit the electroscope in its most sensitive form, *i.e.* with the minimum capacity. A piece about 4 cm. deep is cut off a wide brass cylinder, and the side tubes fitted on as shown. The gold leaf is carried by the wire *b*, and is insulated by the sulphur bead *a*, formed in the manner already described. Thus the insulation leak can only take place to the support *c*, and can be entirely prevented by keeping *c* at the same

Fig 3



potential as *b* by means of cells. The insulation of the wire *c* from the tube which supports it need not be of a very high order; it is sufficient to fix it in with a rubber stopper in the manner shown. So far we have all our charged system enclosed, so that there arises the difficulty of charging it. This is done by means of the wire *d*, which can be rotated about an axis through the centre of the ebonite stopper *e*. It is advisable to remove the wire *d* from the gold-leaf system when once this has been charged. By means of the sealing-wax handle *f* this may be accomplished without discharging the electroscope. The instrument is so far open. It is conveniently closed by two squares of window glass cemented on to the brass cylinder with sealing wax. The whole of the outside is then covered with thin lead sheet or tin foil to obviate effects due to the glass getting charged. Suitable windows must be cut in this to allow the position of the gold leaf to be read.

The above arrangement is as sensitive as this type of instrument can conveniently be made, since its capacity is only that of a short piece of wire and the gold leaf. Generally speaking, the capacity in electrostatic units is found to be of the same order as the length of the wire. In this or a slightly altered form, the instrument is suitable for experiments on spontaneous ionisation and the radio-activity of ordinary materials.

In experiments on emanations, induced activity, and very penetrating rays it is often convenient to increase the magnitude of the effects by allowing them to ionise a large volume of air. For this purpose the arrangement last described is particularly convenient. It is only necessary to solder a long straight wire upon the lower end of *b* and to fix *g* by means of a rubber stopper into the neck of an oil can. The leak then measured is due to the ionisation produced throughout the volume of the can. The sensitiveness, though greater than before, is not increased in the ratio of the volumes, as would otherwise be the case, owing to the increased capacity produced by the additional wire. This arrangement is especially useful for examining the induced activity which may conveniently be deposited on the wire.

A still more sensitive type of electroscope was recently invented by Mr. C. T. R. Wilson. It does not, however, appear to be an instrument which can be safely recommended to the inexperienced, so that it scarcely comes within the scope of this article. It is described in the Cambridge Phil. Soc. *Proc.*, vol. xii. p. 135, and may be bought from the Cambridge Scientific Instrument Company. Much further information about electroscopes and electrometers for radio-active work will also be found in Prof. Rutherford's book on radio-activity, chapter iii.

O. W. RICHARDSON.

GEOLOGICAL SURVEY OF CANADA.

THE Geological Survey of Canada, which was established in 1842 under the direction of Mr. (afterwards Sir) William E. Logan, commenced its labours with 1500*l.*, which was voted by the Provincial Legislature. The sum seems to have been granted without any clear idea of the length of time which the survey would take, but apparently it was expected to last about two years.

In the winter of 1844–5 the amount was expended, and Logan was more than 800*l.* out of pocket. Eventually provision was made for the continuance of the survey for five years with an annual grant of 2000*l.* Notwithstanding many difficulties and disappointments vigorous progress was made in the field work and office work, and this has been continued for upwards of sixty years under the successive directors, Selwyn, George Dawson, until now, when the survey, under Dr. Robert Bell, is provided for better than at any previous time. Thus the total votes for the present financial year amount to 22,800*l.* for general purposes, and to about 8000*l.* for the salaries of permanent officers.

We gather from the last summary report by Dr. Bell that while the Canadian Geological Survey, like that of the United States, has been engaged in palæontological, zoological, botanical, ethnological, and archæological investigations, by far the largest proportion of the work has been of an economic and practical character. Thus the justification for the increased support given to the survey is amply supplied by the investigations which have been carried on with the view of aiding the development of the mineral resources of the country. Up to the end of 1903 the publications of the survey included about 350 maps, of which 100 relate especially to mining districts; and about 250 reports and bulletins, amongst which nearly 100 are exclusively economic. During the four years of Dr. Bell's directorship, the field parties have been increased, and during the past year they have worked in many interesting districts, from the Yukon and British Columbia in the west to New Brunswick and Nova Scotia in the east, and from southern Ontario and Quebec to Lancaster Sound in the Arctic regions. Their researches have had reference to gold, silver, lead, copper, graphite, corundum and mineral pigments; to coal, peat, petroleum and natural gas; to various building and ornamental stones, clays and cement ingredients. Hitherto unknown sections of the country have been explored and surveyed, and observations have been made on the timber, soils, and water supply, as well as on the general natural history.

The palæontological work of the survey has been carried on by the veteran palæontologist Dr. J. F. Whiteaves, aided in the department of vertebrates by Mr. Lawrence M. Lambe. In the "Contributions to Canadian Palæontology" (vol. iii.), recently issued by the survey, Mr. Lambe has described some remains of the carnivorous dinosaur *Dryptosaurus incrassatus* (Cope), from the Edmonton series of Alberta, in the North-West Territory. The strata belong to the Lower Laramie (Cretaceous) formation. The importance of a more intimate knowledge of the fauna of the Edmonton series is apparent when it is borne in mind that the beds of this series in Alberta constitute the principal coal-bearing horizon of the district.

Dr. Bell himself has been partly occupied, in conjunction with other leading geologists in Canada and the United States, in investigating the crystalline rocks in Upper Michigan, in Wisconsin and Minnesota, and in the Rainy River, Thunder Bay, and other districts of Ontario, with the view of settling disputed questions. The controversies on these rocks have long been occupying attention without any definite result. A few years ago Dr. Bell urged upon the International Committee of Geologists the desirability of forming a small central committee, the members of which should go to the ground together and look at the facts. This was carried out, and as a result the members have come to an almost complete agreement on all the vexed points. The standing committee consists of Dr. Bell and Dr. F. D. Adams (professor of geology in McGill University) for Canada, and Dr. C. W. Hayes (chief geologist of the U.S. Geological Survey) and Prof. C. R. Van Hise (president of the State University of Wisconsin) for the United States. By invitation there were also associated with them Prof. Leith (of the University of Wisconsin), Dr. Lane (State geologist of Michigan), Prof. Seaman (professor of geology in the College of Mines at Houghton, Michigan), Messrs Sebenius and Merriam (geologists of the Iron Ranges), and Prof. W. G. Miller (provincial geologist of Ontario). It is anticipated that the joint report will shortly be published.

RECENT EXPLORATION IN THE MENTONE CAVES.

PROF. MARCELLIN BOULE has recently been studying the deposits in the well known caves of the Rochers rouges (Baoussé-roussé of local patois) near Mentone, and read a paper on his results before the Société géologique de France in the early part of last year, which is published in the society's *Bulletin* (No. 1). Since the original discovery by M. Rivière of a human skeleton in one of these caves, the question of the age of their deposits has been debated with much warmth, but without any satisfactory result. In recent years the caves have been carefully and systematically explored under the direction of the Prince of Monaco, with the result that a great number of fossils have been obtained. Prof. Boule's researches were conducted chiefly from the geological standpoint with the view of determining the age of the deposits, and of throwing light upon the much debated question of the oscillations of sea-level in recent times on the Mediterranean seaboard.

Prof. Boule's attention was directed in the first instance to the Grotte du Prince, which was almost intact when excavation was commenced. Here the deposits attain a thickness of more than 20 metres, and consist of basal beds of marine origin upon which strata of continental origin are superimposed. The latter can be subdivided into a number of layers, both by their physical characters and by their fossil contents, but the point of importance is that the upper and middle beds contain remains of reindeer (never previously recorded in this region), ibex, marmot, and woolly rhinoceros, that is, the fauna of the cold period of the Quaternary, while the lower beds contain quite a different fauna—*Elephas antiquus*, *Rhinoceros mercki*, and hippopotamus, that is, species belonging to the lower Quaternary fauna. The last named deposits lie upon an old raised beach which is also discernible outside the cavern, along the shore rocks, at a mean altitude of 7 metres. Almost all the contained fossils belong to the existing Mediterranean fauna, but Prof. Boule has found some beautiful examples of *Strombus mediterraneus*, which has been regarded as characteristic of the raised beaches of the Quaternary period in the Mediterranean area. But the Prince's cave contains other traces of marine action of a much earlier date. In its upper part, at a height of 28 metres, there is a calcareous encrustation due to the action of the waves, below which the wall of the cavern is perforated by boring molluscs. The sequence of events is therefore explained by Prof. Boule as follows:—

The sea formerly stood at the 28-metre level, and then gradually retired until it stood at a height of 7–8 metres. At this level the shell deposit was laid down on the floor of the cavern. Subsequently the movement of elevation was continued. Its extent is difficult to determine, but the oceanographical researches of the Prince of Monaco have shown that there extends along the rochers rouges at a slight depth an extensive submarine platform. This suggests that the movement—whether of the land or of the sea—continued until there was laid bare between the sea and the present irregular shore line a plain sufficiently extensive to become the home of such large animals as elephants, hippopotami, and rhinoceroses, for which the present topography allows no space. It is at least certain, according to Prof. Boule, that the 7-metre beach, described at other parts of the Mediterranean littoral by MM. Depéret and Caizot, and regarded by them as of late Quaternary date, really belongs to a much more distant period, for it is anterior to the subaërial deposits containing fossils belonging to the older period of the Quaternary. If this conclusion be correct, it affords a means of fixing the age of the last oscillation of sea-level in this region. It should, however, be noted that in the discussion which followed the reading of the paper M. Depéret protested against the proposed homologising of the low raised beach (height 5–7 metres) studied by him on the French coast of the Mediterranean (*e.g.* in the Bay of Pierre-Formique) with the Strombus beach in the Mentone caves. The former type of beach contains a fauna very different from that of the Strombus layers, Strombus being absent, and all the fossils belonging to living species.

At the conclusion of his paper Prof. Boule referred to the three new human skeletons which have been recently discovered in the Grotte des Enfants. The first of these has been studied by MM. Gaudry and Verneau, and proves to be markedly Australoid in type. It was obtained in a bed containing *Ursus spelaeus*, *Hyaena spelaea*, *Felis spelaea*, &c., and rested upon a bed containing molars of *Rhinoceros mercki*. It must therefore belong to the earlier part of the Quaternary period. The second skeleton was found about 0.60 metre above the first, and was accompanied by remains of the same species of mammals. The third skeleton, on the other hand, found 6 metres above the first, seems to belong to the period of the reindeer, that is, to the end of the Quaternary epoch.

Fig. 1.—Skeleton from the Grotte des Enfants.

THE SCIENTIFIC EXPLORATION OF LAKE TANGANYIKA.

THE committee for the scientific exploration of Lake Tanganyika (consisting of Sir John Kirk, Dr. Sclater, Sir W. Thiselton-Dyer, Prof. Lankester, Dr. Boulenger, and Mr. J. E. S. Moore) has lately received news of the progress of its envoy, Mr. W. A. Cunnington, who left England in March, 1904, under directions to continue the researches carried out by Mr. J. E. S. Moore during his two expeditions to Lake Tanganyika. Proceeding by the Zambesi and Shiré route, Mr. Cunnington was most kindly received at Zomba by Sir Alfred Sharpe, who granted him the assistance of two native collectors. Mr. Cunnington had instructions to devote his special attention to the lacustrine flora and fauna of Lake

Tanganyika, and, as he passed up Lake Nyassa, began his investigations in that lake, in order to be able to compare its products with those of Tanganyika. On Lake Nyassa Mr. Cunnington was able to get a good number of tow-nettings from different parts of the lake's surface, and obtained, on the whole, a large quantity of its characteristic phytoplankton, besides a considerable amount of zooplankton, consisting mostly of Copepoda, Cladocera, and insect-larvæ. The temperature of the water of Lake Nyassa was observed to fall seldom below 70°, while the temperature at 76 fathoms below the surface was ascertained to be about three degrees higher.

Mr. Cunnington arrived at Karonga, at the head of Lake Nyassa, at the end of June, 1904, and travelled on to Tanganyika by the ordinary route of the Stevenson road. His last letters from Tanganyika are dated at Vua, on October 29, 1904. He had obtained a dhow from Ujiji, which enabled him to make his stay at different places on the lake longer or shorter according as he found much or little to collect. A good series of fishes had been preserved, and many freshwater crustaceans. As regards the vegetable life, Mr. Cunnington had been much struck by the near resemblance of all the forms obtained in Tanganyika to those which he had collected in Nyassa, though he could not, of course, say that they were specifically identical. From Vua, Mr. Cunnington had arranged to cross to the east coast of the lake, and to go some distance further north before returning to the western shore. Mr. Cunnington may be expected to return to England before the end of the year.

NOTES.

SIR JAMES DEWAR has presented the proceeds of the Gunning prize, amounting to one hundred guineas, recently awarded to him by the Royal Society of Edinburgh, as a contribution to the fund for the encouragement of research, now being founded in the University of Edinburgh in memory of the late Prof. Tait.

WE regret to learn from the London branch of the Zeiss optical firm that Prof. Abbe, of Jena, died a few days ago. We also announce with regret the death of M. Paul Henry, astronomer at the Paris Observatory. His brother, M. Prosper Henry, with whom he was associated for many years in celestial photography, died about eighteen months ago.

THE Paris Société d'Encouragement pour l'Industrie nationale has awarded the grand prize of the Marquis d'Argenteuil to MM. Auguste and Louis Lumière for their photographic discoveries. M. Héroult has been awarded a grand gold medal for his works on electro-metallurgy.

THE two Antarctic ships *Terra Nova* and *Morning* were sold at Portsmouth on January 11. Messrs. W. Ziegler and Co., New York, bought the *Terra Nova* for 9600*l*., and she will probably be used for North Polar exploration. The *Morning* was sold for 1600*l*. The *Discovery* has been sold privately to the Hudson's Bay Company for 10,000*l*.

M. L. BONNAMÈRE has been elected president for 1905 of the Prehistoric Society of France.

THE death is announced of Dr. Anton Müttrich, professor of physics and mathematics in the Academy of Forestry at Eberswald.

SIR WILLIAM THISELTON-DYER, K.C.M.G., will take the chair at a lecture to be delivered at the West India Committee Rooms, Seething Lane, on Wednesday, January 25, by Mr. W. G. Freeman, superintendent of the colonial economic collections at the Imperial Institute, on "The West Indian Fruit Industry."

THE next competition for the Howard medal of the Royal Statistical Society will take place in the ensuing session. The essays must be sent in on or before June 30. In addition to the medal, a grant of 20*l*. will be awarded to the successful competitor. The subject is:—"A Critical Inquiry into the Comparative Prevalence of Lunacy and other Mental Defects in the United Kingdom during the Last Fifty Years."

THE death is announced of Mr. T. W. Shore, author of a number of papers on geological and archæological subjects. Mr. Shore was for a long time resident at Southampton, where he acted as curator of the Hartley Institution and secretary of the Hampshire Field Club. At the Southampton meeting of the British Association in 1882 he was one of the secretaries of the section of geology. On removing to London, he founded the Balham Antiquarian Society, and became its secretary; he was also secretary of the London and Middlesex Archæological Society.

WE have received a letter from Mr. C. E. Stromeyer, of Manchester, in which he suggests that irregularities of the earth's surface might be detected by special observations for determining the position of the northern and southern limits of totality during the coming total solar eclipse of August next. Unfortunately there are many practical difficulties in the way which the author has not discussed, but he makes one suggestion which might be carried out. He proposes to place soldiers at short distances along the northern and southern borders of the shadow's path, who, by marking the positions where the eclipse was total, might determine with greater accuracy than is known the breadth of the moon's shadow.

A CORRESPONDENT writes:—The death of Dr. Thomas Woods occurred on January 5 in Birr (or Parsonstown). Dr. Woods was born in February, 1815, and graduated as doctor of medicine in Glasgow in 1838. He spent all his long life as a medical practitioner and as medical officer of the union and dispensary in Birr. So it is, perhaps, not to be wondered at that his scientific work belonged largely to a former generation. He was a chemist, and as such took part in the early development of photography, originating in the 'forties a new wet plate process, the "catalysotype," a detailed description of which may be found in Hunt's "History of Photography." In 1852 and 1853 he published in the *Philosophical Magazine* some original observations on the heat developed by chemical combination, and defended with considerable success his claim of priority against Andrews and Joule. He was a man of remarkable ability and astoundingly general scientific interest, and it is much to be regretted that circumstances kept him in a small country town, and that his professional duties prevented him from adding further to scientific knowledge. He continued mentally and bodily fresh to the very end, ever eager to hear of the latest scientific discoveries, and Birr feels distinctly the poorer for his loss.

A REUTER message from Christiania states that at Nesdal, north of Bergen, on Sunday, a mass of rock slipped into the Loenvand Lake. A wave of water twenty feet high, which resulted from the fall, swept the neighbourhood, carrying away houses, people, and cattle.

As supplementary to the paragraph on the recent fall of cliff at St. Margaret's Bay, near Dover (NATURE, January 12), it may be mentioned that the cliffs at St. Margaret's Bay, which rise from 150 to 300 feet, are formed of the Upper Chalk, comprising soft chalk and harder nodular bands, with scattered flints and occasional continuous seams of flint. These beds are surmounted by chalk, with many layers of flint nodules and some continuous bands of flint; and this portion of the chalk forms the mass of the cliffs at St. Margaret's Bay, the lower beds appearing at beach level and rising southwards. The general dip of the chalk is to the north-east, corresponding to some extent with the trend of the coast from East Wear Bay to Dover and St. Margaret's. Numerous falls of cliff have taken place along this coast for many centuries, the greatest losses having occurred above East Wear Bay in the great landslip of the Warren, where notable founders occurred in 1716 and again in 1886. Such slips along the sea-front may serve for a time to protect the cliffs from further waste, until the débris is removed by the breakers. Copious springs issue along the foot of the cliffs here and there, and a powerful spring issues at St. Margaret's Bay. These probably had no direct influence on the recent falls of cliff, but rather would the slips be due to the local feeders of the springs, to their erosive action along joints in the chalk, and to the effects of frost. It is quite possible, as has been suggested, that blasting operations at the Admiralty Harbour at Dover may have accelerated the falls of cliffs at points where they were weakened by natural agencies.

THE *Victorian Naturalist* brings us news of the death, on November 18, 1904, of Mr. J. G. Luehmann, Government botanist and curator of the National Herbarium at Melbourne, at the age of sixty-one. Mr. Luehmann went to Victoria in 1862, and in 1867, on the resignation of Mr. E. B. Heyne, secretary to the late Baron von Mueller, Mr. Luehmann was offered the position, which he accepted, and he remained connected with the botanical department until shortly before his death. For many years he made the preliminary identifications of specimens for Baron von Mueller, becoming an authority on the eucalypts and acacias. His great assistance was acknowledged by Baron von Mueller in the preface to the "Key to the System of Victorian Plants." In the early days of the Field Naturalists' Club of Victoria, before the institution of the *Victorian Naturalist*, he contributed papers on the eucalypts and acacias. In 1896, on the death of Baron von Mueller, he was appointed curator of the National Herbarium, and afterwards became Government botanist. During late years he contributed several descriptions of plants to the club's proceedings, in addition to an interesting paper—observations on pre-Linnean botanists—in which he directed attention to the many valuable botanical works in the herbarium library. He was one of the earliest Victorian fellows of the Linnean Society of London.

IN a paper in the *Lancet* (January 7) Mr. G. C. Chatterjee, working under the direction of Captain L. Rogers, I.M.S., announces that he has succeeded in cultivating trypanosomes from the Leishman-Donovan body or parasite, thus confirming Captain Rogers's previous work in this direction.

WE have received the first number of the new volume of the *Journal of Hygiene* (vol. v., No. 1), which continues to maintain its previous high standard. It contains papers on piroplasmosis by Mr. Bowhill and by Mr. Ross, cultivation of trypanosomata by Mr. Smedley, epidemiology of plague by Mr. Hankin, a leprosy-like disease in the rat by Mr. Dean, &c. An introductory memoir, with a portrait, gives an account of the work of the late Sir John Simon.

MM. SALOMONSEN AND DREYER have conducted some experiments on the effect of the radium emanations on certain Protozoa and on the blood. The material consisted of fifty milligrams of pure radium bromide covered with a sheet of mica. On Nassula the radium had little effect, even with an exposure of six days. Some amœbæ were killed in less than twelve hours, but others survived four days. *Trypanosoma Brucei* was killed in from two to three hours. On blood corpuscles the radium exerted a hæmolytic power.

H.R.H. PRINCESS CHRISTIAN and Mr. Chamberlain were present on Friday last at St. George's Hall, Liverpool, on the occasion of a meeting in connection with the Liverpool School of Tropical Medicine, at which a lecture was delivered by Major Ronald Ross, F.R.S., on "The Progress of Tropical Medicine." Major Ross, in the course of his address, alluded to the discoveries which had proved that yellow fever is conveyed solely by mosquitoes, to the work of Sir William MacGregor in the suppression of malaria in Lagos, and to the anti-malarial measures of the Suez Canal Company, which had resulted in a reduction of the annual rate of malarial fevers at Ismailia from two thousand to two hundred. He also alluded to the fact that the Liverpool School had sent out no less than fourteen expeditions to investigate tropical diseases in various parts of the world.

Naturen for December, 1904, contains some realistic, and perhaps rather ghastly, photographs of a python and its prey, taken from menagerie specimens. In the first of the series we have an unfortunate rabbit "fascinated" and about to be seized by a python, in the second the rodent in the coils of the serpent, and in the third the python commencing to devour the crushed carcase.

THE most important, or at all events the longest and most fully illustrated, paper in the second part of vol. ii. of the quarterly issue of *Smithsonian Miscellaneous Contributions* is one by Mr. C. Schuchert on Silurian and Devonian cystoid echinoderms and the genus Camarocrinus, in the course of which many new forms are described, and some valuable contributions made to the morphology of the group. Among the other contents of this issue, reference may be made to a list of west Indian birds by Mr. J. H. Riley.

THE issue of *Biologisches Centralblatt* for January 1 contains an article by Dr. E. Rádl on the hearing of insects, at the conclusion of which it is pointed out that this sense is much less developed in that group than in the higher vertebrates. The hearing of insects seems, in fact, to be a muscular rather than a nervous sense. The other articles include one by Mr. H. S. Skorikow on the plankton of the Neva, in the course of which several new forms are described, and one by Dr. O. Zacharias on the light-organs of *Ceratium tripos*.

ICHTHYOSAURS, or the extinct marine "fish-lizards" of the Mesozoic epoch, form the subject of an article by Prof. H. F. Osborn in the January number of the *Century Magazine*. After tracing the ichthyosaurian paddle into a limb of the type of that of the existing terrestrial tuatera lizard (Sphenodon) of New Zealand, which is regarded as nearly related to the ancestral stock of the group, the author proceeds to point out how much we know with regard to the nature of the soft-parts and the life-history of the fish-lizards. We are aware, for instance, that they had a dorsal and a caudal fin, a naked scaleless skin, and a spiral valve to the intestine, similar to that of sharks; while, from the inclusion of skeletons of fœtuses within the ribs of full-grown individuals, we also know that they produced living young. This viviparous condition is, of course, an adaptive modification, similar to that which occurs in the sea-snakes of to-day, rendered necessary by the pelagic habits of these reptiles. The similarity in bodily form existing between sharks, dolphins, and fish-lizards is referred to as another instance of such an adaptive modification. Excellent illustrations—one showing a female ichthyosaur and her progeny—accompany the paper. Apparently the author is unaware that the name Shastasaurus, proposed for a Triassic American ichthyosaur, has been changed, on account of pre-occupation, to Merriamia.

A PAPER upon Mendel's discoveries in heredity, read by Mr. C. C. Hurst before the Leicester Literary and Philosophical Society, gives a succinct account of Mendel's experiments, and the rules which he evolved therefrom; also it contains a list of the chief experiments with different plants and animals which have been carried out subsequently. The paper is published in the *Transactions* of the society, vol. viii. (June, 1904), and in the same part will be found a useful summary prepared by Mr. H. St. J. Donisthorpe of additions to British Coleoptera during the last ten years.

IN the *Comptes rendus*, vol. xxxv., No. 6, of the Imperial Society of Naturalists of St. Petersburg, lists of new plants for the Crimea are given by Mr. K. Golde and Mr. A. Younghé. Two of the most striking mentioned by Mr. Younghé are *Crambe juncea*, a Persian plant, which grows to the height of a man, and *Lythrum nanum*, a dwarf Siberian plant. Both botanists make a special reference to the freshwater plants, which include species so familiar to us as *Zannichellia pedicellata*, *Œnanthe Phellandrium*, and species of Potamogeton.

THE first appendix to the *Kew Bulletin* for 1905, enumerating the hardy shrubs, trees, and herbaceous plants of which seed is available, has been received.

IN our issue of January 12 (p. 255) we referred to the prominent part taken by M. Leon Teisserenc de Bort in the establishment of a Scandinavian station for the exploration of the upper air by means of kites and unmanned balloons. The first results of this important enterprise have been published in a work entitled "Travaux de la Station Franco-Scandinave de Sondages aériens à Hald, 1902–1903," a large quarto volume of 160 pages. The station is situated on an extensive open domain belonging to M. Krabbe, near Viborg, in Jutland, and is due to the exertions of MM. Hildebrandsson, Paulsen, and Mascart, the official meteorological representatives of Sweden (Upsala), Denmark, and France. The necessary subscriptions for carrying out the experiments have been chiefly contributed by private persons—in Sweden, by an anonymous donor, 28,000 francs; in Denmark, 245,000 francs (including a grant of 10,000 francs by the Danish Government); in France, 66,100 francs (of which M. Teisserenc de Bort contributed 50,000 francs, and a further loan of material from Trappes valued at about 12,000 francs). The Danish Government also lent two gunboats for kite experiments; the value of kite ascents from steamers at sea has been more than ever fully established by the results obtained, some of the kites reaching altitudes varying from 3000 to 5900 metres. The difficulty of reaching such heights is well known to persons who have undertaken similar experiments.

PROF. DR. C. UHLIG contributes some notes of a journey from Kilimandjaro to Mweru to Nos. 9 and 10 of the *Zeitschrift* of the Berlin Gesellschaft für Erdkunde. The paper is illustrated by a number of excellent photographs.

THE last issue of the *Mitteilungen aus den deutschen Schutzgebieten* is entirely devoted to the region of the Pacific. Dr. Born records some observations on the ethnography of the Oleaī Islands, Herr Senfft describes a visit to some of the West Caroline Islands, and there are abstracts of meteorological observations for 1903, and maps based on recent surveys.

THE last number of the *Deutsche geographische Blätter* contains reports of two lectures delivered to the Vereinigung für staatswissenschaftliche Fortbildung at its meeting at Bremen in November last. Dr. Tetens discussed the importance of Bremen as a centre of trade, and gave an exhaustive statistical account of its development and a comparison with other seaports; his paper is illustrated by nineteen sheets of diagrams, and should be of great value to students and teachers of commercial geography. Dr. W. Hochstetter lectured on the history of the North German Lloyd.

THE Royal Geographical Society has issued, as an extra publication, a paper on recent contributions to our knowledge of the floor of the North Atlantic Ocean, by Sir John Murray and Mr. R. E. Peake. The new material dealt with consists chiefly of soundings from the telegraph ships *Minia* and *Faraday*, but the chart accompanying the paper has been fully brought up to date, and new measurements of areas at different depths have been made. An interesting correspondence with the United States Hydrographic Office about the origin of the term "telegraphic plateau" appears in the introduction.

THE first place in the January number of the *Geographical Journal* is given to a striking address delivered to the International Congress of Arts and Sciences at St. Louis in September last by Dr. H. R. Mill. Dr. Mill's address is entitled "The Present Problems of Geography," by which the author means not "the whole penumbra of our ignorance, but those problems the solution of which at the present time is most urgent and appears most promising." Many of his conclusions concerning the scope and methods of geography are of profound significance. It seems specially appropriate that the address should immediately precede a paper on geography and education in the same number, in which the recent articles and correspondence in the newspapers are summarised and discussed. Dr. Mill puts his finger on many points which have formed real obstacles to the development of geographical teaching in schools and elsewhere.

A CORRESPONDENT of the *Physikalische Zeitschrift* inquires whether any experimental or other information exists regarding the heeling over of a ship on one side caused by the turning moment on the screw shaft.

PROF. R. W. WOOD describes in the *Physikalische Zeitscrift* a simple experiment for showing the pressure due to sound waves. The waves are made to converge to a focus by reflection, and close to this point is placed a small horizontal paddle wheel almost exactly like a Crookes's radiometer. If the sound waves converge to one side of the wheel it will spin rapidly in the corresponding direction.

From the Volta Bureau of Washington we have received two reprints, one dealing with the so-called "visible speech" alphabet introduced into England by Dr. Alexander Melville Bell in 1865–7, and the other being an essay, by Dr. William Thornton, on teaching the deaf and dumb to speak, published in 1793. The reprints are illustrated by portraits of Drs. Bell and Thornton, and a biographical notice also accompanies Dr. Thornton's paper.

We have received the report for 1903-4 of the Scientific Society of St. Paul (Brazil), and have been able to gather from it that the society was founded in June, 1903, the city already having a historical and geographical, a medical and an agricultural society. It numbered in April last fifty-six effective, four contributing, one corresponding member, and two "socios ouvintes," a total of sixty-three members, of whom twenty-eight were foundation members. The membership list now, however, shows thirteen corresponding members. There have been held two preliminary, one inaugural, fourteen ordinary, and four "economic" meetings, and from the account of these meetings the papers seem to have been interesting and varied. A desirable improvement would be the publication of the reports in one of the international languages.

The question as to whether the trioxide of nitrogen, N_2O_3, is capable of existence has frequently been discussed, but until recently has remained unanswered owing to the lack of experimental data. When the brown gas produced by the action of starch or of arsenious anhydride on nitric acid is passed through a freezing mixture, it condenses to a blue liquid, which does not solidify at $-90°$. But the determination of its vapour-density shows that the gas is completely dissociated, and Ramsay and Cundall showed in 1885 that no contraction takes place when the monoxide and dioxide are mixed. The blue solution might therefore be regarded merely as a solution of NO in N_2O_4. The actual existence of the trioxide has recently been demonstrated by Wittorff (*Zeit. anorg. Chem.*, vii., 209), who has investigated the freezing point of mixtures of different composition. A liquid having the empirical composition N_2O_3 solidifies to a blue crystalline solid, which melts at $-103°$ C., and is undoubtedly the pure trioxide. As the proportion of N_2O_4 is increased the freezing point at first falls to a eutectic temperature at $-112°$ C., and then rises to the freezing point of the peroxide. In this way, by accurate work at low temperatures, it has been possible to solve one of the long-debated problems of inorganic chemistry.

It has long been suspected that in solution the dichromates might perhaps be dissociated into neutral chromates and free chromic acid, thus,

$$K_2Cr_2O_7 \rightleftharpoons K_2CrO_4 + CrO_3.$$

Purely chemical methods have given but little information as to the nature of the dissolved salt. As the result of an ingenious application of physicochemical methods, the problem has recently been solved by Abegg and Cox, and these authors have been able actually to determine the proportion of free chromic acid in dichromate solutions of different concentrations. The method, which is described in the *Zeitschrift für physikalische Chemie* (vol. xlviii. p. 725), depends on saturating a solution of a dichromate with neutral and basic mercuric chromates, $HgCrO_4$ and $HgCrO_4.HgO$. In presence of these two salts the concentration of free chromic acid in the solution is maintained constant at 0·706 mol. per litre at 50° and 0·456 mol. at 25°, and any excess of chromic acid must be combined either as chromate or as dichromate. It is calculated that in the case of potassium dichromate complete dissociation occurs at a dilution of 1000 litres, whilst at 100 litres 99 per cent. of the salt is dissociated, at 10 litres 91 per cent., and at a dilution of 1 litre 62 per cent. Even in the strongest solutions, therefore, the greater part of the dichromate is dissociated into chromic acid and normal chromate.

Messrs. Whittaker and Co. will shortly publish a new book entitled "The Insulation of Electric Machines," by Mr. H. W. Turner and Mr. H. M. Hobart.

Messrs. George Bell and Sons have published parts i. and ii. of "Elementary Algebra," by Messrs. W. M. Baker and A. A. Bourne, in one volume at 4*s*. 6*d*. The book may be had with or without answers.

The twenty-fourth volume of the *Geographical Journal* has now been published. It contains the monthly numbers from July to December, 1904. As usual, the volume is richly illustrated by means of blocks and a profusion of well executed maps. The volume should be added to the library of every geographer and teacher of geography.

Messrs. Newton and Co.'s new supplementary list of lantern slides includes several sets which should prove very valuable to science teachers and lecturers. Among these instructive slides we notice photographs by Mr. W. M. Martin illustrating the embryology of a chicken; British birds and nests photographed by Mr. R. B. Lodge; photographs of insects and other small forms of animal life; photomicrographs of rock sections; and photographs of diseases of the bone, by Dr. C. T. Holland.

A revised and enlarged edition of Dr. Arthur Keith's "Human Embryology and Morphology" has been published by Mr. Edward Arnold. This edition differs from the last in several particulars. The chapters dealing with the early development of the human embryo and the formation of the placenta and membranes have been re-written. Much of the chapter dealing with the urogenital system has been amended, and numerous additions have been made in other sections of the book.

OUR ASTRONOMICAL COLUMN.

Observations of Comets 1904 *d* and 1904 *e*.—The results of several observations of comets 1904 *d* and 1904 *e*, respectively, are published in a supplement to the *Astronomische Nachrichten*, No. 3987.

The latter object was observed at Bamberg by Prof. Hartwig on January 1 and 2, and was seen as a circular patch about 2′ in diameter, having a nucleus which was not symmetrical. The magnitude of this comet has been variously estimated. In the above observation Prof. Hartwig recorded it as 11·0, but Prof. Nijland, observing at Utrecht on January 1, estimated it as 9·5, whilst Prof. Ambronn, observing at Göttingen on January 2, found it to be 10. The brightness at the time of discovery, as given by M. Borrelly, was equal to the tenth magnitude.

The following is an extract from the daily ephemeris of comet 1904 *d* published by Herr M. Ebell:—

12*h*. (*M.T. Berlin*).

1905	α (true) h. m. s.	δ (true) ° ′	log *r*	log Δ	Brightness
Jan. 20	17 57 38	+44 57	0·3253	0·3437	0·98
,, 24	18 13 1	+47 5	0·3299	0·3446	0·95
,, 28	18 29 11	+49 10	0·3346	0·3465	0·93
Feb. 1	18 46 10	+51 9	0·3394	0·3495	0·89
,, 5	19 3 58	+53 3	0·3443	0·3535	0·86

Brightness at time of discovery = 1.

EPHEMERIS FOR COMET TEMPEL, 1904 *c*.—In No. 3986 of the *Astronomische Nachrichten* M. J. Coniel gives a daily ephemeris for Tempel's second comet extending from January 3 to March 2, which is a continuation of the ephemeris published by him in No. 3971 of the same journal. Although the southern declination of the comet is decreasing, its R.A. is so near to that of the sun, and the object itself is so faint, that observations will be difficult, and only possible immediately after sunset.

The comet's position on January 21 will be

$$\text{R.A.} = 22\text{h. } 37\text{m. } 47\text{s., dec.} = -16° \ 19'.$$

SEASONAL DEVELOPMENT OF MARTIAN CANALS.—A further contribution of observed phenomena, in support of his theory concerning the causes which produce the seasonal development of the canals on Mars, is published by Mr. Lowell in the January number of *Popular Astronomy*. The particular canal therein discussed is Brontes, which is 2440 miles in length and connects along a great circle, in nearly a north and south direction, the two important points Linus Titanum and the Propontis.

From a study of ninety drawings made during the period January-July, 1903, six of which are reproduced on the plate accompanying the paper, it was seen that the visibility of the canal increased after the summer solstice in the northern hemisphere, and, further, on dividing the canal into five nearly equal sections from north to south, the section nearest the north polar cap became strengthened first, and the others followed in order of their north polar distance. This is plainly shown on the visibility "cartouches" given by Mr. Lowell, who considers the phenomena as a further proof of his theory that the visibility of a canal is due to vegetation, quickened by the water loosened at the melting of the polar snows and flowing towards the equator. The extension south of the equator is considered as a probable proof of intelligent artificial interference in the propulsion of the water.

VARIABLE STARS AND NEBULOUS AREAS IN SCORPIO.—An examination of thirty-three plates exposed on the large nebulous regions mentioned in previous *Circulars* has led Miss H. S. Leavitt to the discovery of 105 new variable stars in the constellation Scorpio.

The positions of these, for 1900, their greatest and least observed magnitudes, and their magnitude ranges are given in No. 90 of the Harvard College Observatory *Circulars*.
