COMPOSITE CONCRETE AND WOODEN PILING A UNIQUE FEATURE OF OREGON FEDERAL-AID BRIDGE

COMPILED FROM REPORTS SUBMITTED BY R. E. MERRICK OF DISTRICT 1 AND C. B. MCCULLOUGH, BRIDGE ENGINEER OF THE OREGON STATE HIGHWAY DEPARTMENT

COMPOSITE CONCRETE AND WOODEN PILING WAS A UNIQUE FEATURE IN THE CONSTRUCTION OF THE TRESTLE SECTION OF THE FEDERAL-AID BRIDGE ON UNITED STATES ROUTE 101, ACROSS THE SILETZ RIVER, NEAR TAFT, OREGON. THE STRUCTURE (F.A. PROJECT NO. 110-D) CONSISTS OF A 240-FOOT STEEL SWING-SPAN OVER THE MAIN CHANNEL, A SHORT APPROACH ON THE NORTH END, AND 414 FEET OF TRESTLE, WHICH CONNECTS THE SOUTH EXTREMITY WITH A 10-FOOT FILL EXTENDING FOR A DISTANCE OF HALF A MILE ACROSS AN OPEN TIDE-FLAT. (FIGURE 1 - TOP)

THE PLANS AND SPECIFICATIONS FOR THE APPROACH TRESTLE CALLED FOR THREE COMPOSITE PILES TO EACH BENT. THESE COMPOSITE PILES WERE TO BE CONSTRUCTED BY FIRST DRIVING A TIMBER PILE, AND FOLLOWING IT WITH A SECTION OF CONCRETE PILING, DRIVEN TO SUCH A DEPTH THAT THE ENTIRE TIMBER SECTION WAS SUBMERGED BENEATH THE LOW-WATER LINE. THE OBJECT OF THE CONCRETE-FOLLOWER SECTION WAS: (1) TO RESIST THE ATTACK OF THE TEREDO, WHICH BORES INTO WOODEN PILING IN THE ZONE BETWEEN THE GROUND OR FRESH-WATER LINE AND THE HIGH-TIDE LEVEL; AND (2) TO OVERCOME THE EFFECT OF ALTERNATE WETTING AND DRYING, CAUSED BY THE RISE AND FALL OF THE TIDE. SALT WATER IS THE NATURAL HABITAT FOR THIS WOOD-BORING MUSSEL, WHICH CAN NOT EXIST IN FRESH WATER. ABOVE THE HEIGHT SUBJECT TO THE RAVAGES OF THE TEREDO AND THE OXIDATION OF THE AIR, THE CHEAPER WOODEN TYPE OF CONSTRUCTION WAS USED. THE PLANS AT THIS LEVEL CALLED FOR A DECK OF WOODEN STRINGERS AND A PLANK FLOOR, ALL LAID UPON CONCRETE CAPS CAST UPON THE TOPS OF THE COMPOSITE PILING.

THE PRE-CAST CONCRETE PILES WERE DESIGNED WITH A TAPERED SHANK. (FIGURE 1 - BOTTOM) THE LOWER END OF THE PILE WAS ENLARGED TO FORM A BELL-SHAPED SECTION, IN WHICH WAS CONSTRUCTED A SOCKET 42 INCHES DEEP BY 14 INCHES IN DIAMETER, WHICH WAS FITTED OVER THE TOP OF THE PREVIOUSLY-DRIVEN TIMBER PILE. INTO THE OUTER END OF THE SOCKET WAS FIXED A CAST-STEEL DIE WITH A CUTTING EDGE. (FIGURE 2) PREPARATORY TO DRIVING THE CONCRETE PILE, THE TOP OF THE WOODEN PILE WAS TRIMMED SO AS TO BE ABOUT 1 INCH LARGER IN DIAMETER THAN THE DIE. AS THE DRIVING PROGRESSED, THE DIE CUT AWAY THE SURPLUS WOOD, AND A TIGHT FIT WAS OBTAINED BETWEEN THE WOOD AND CONCRETE SECTIONS OF THE COMPOSITE PILE.

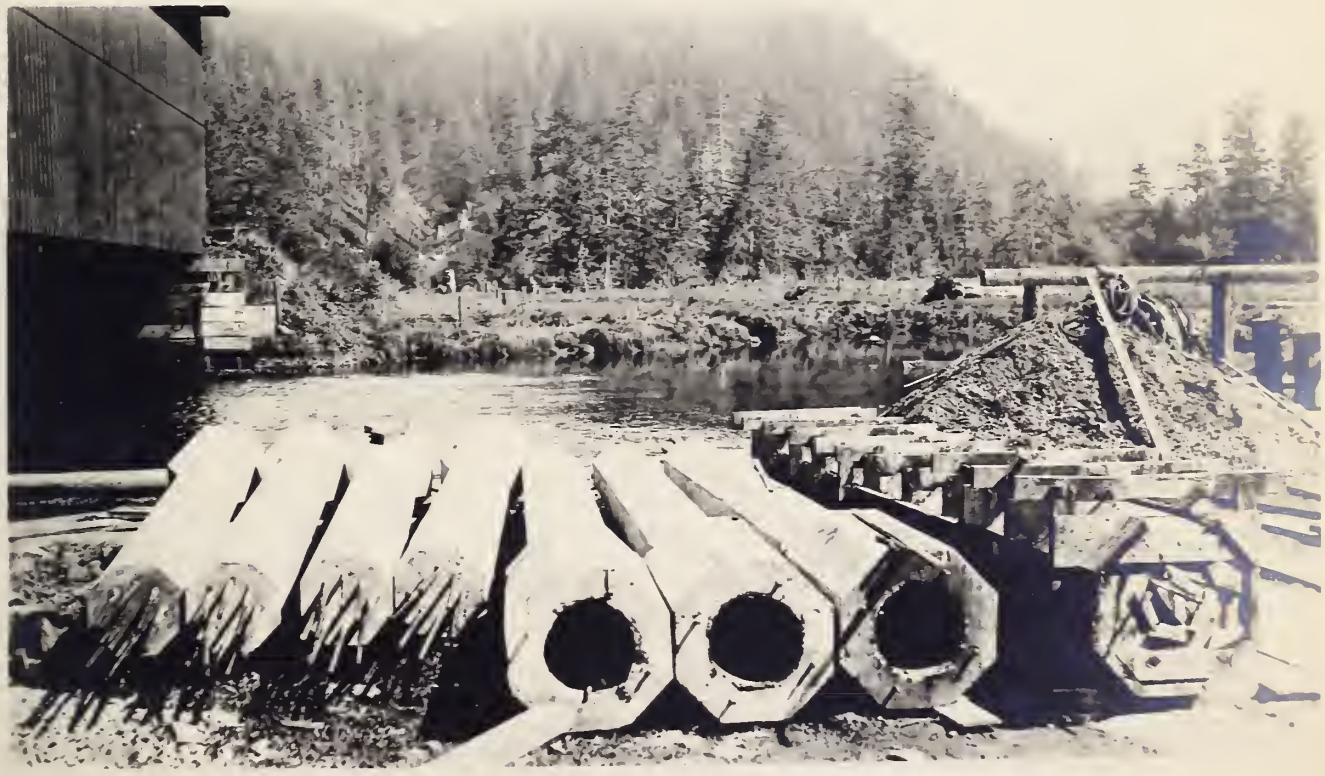

FIG. 1 (TOP). - GENERAL VIEW OF COMPOSITE-PILING TRESTLE ON OREGON FEDERAL-AID BRIDGE PROJECT 110-D

(BOTTOM). - UPPER AND LOWER ENDS OF COMPOSITE PILING

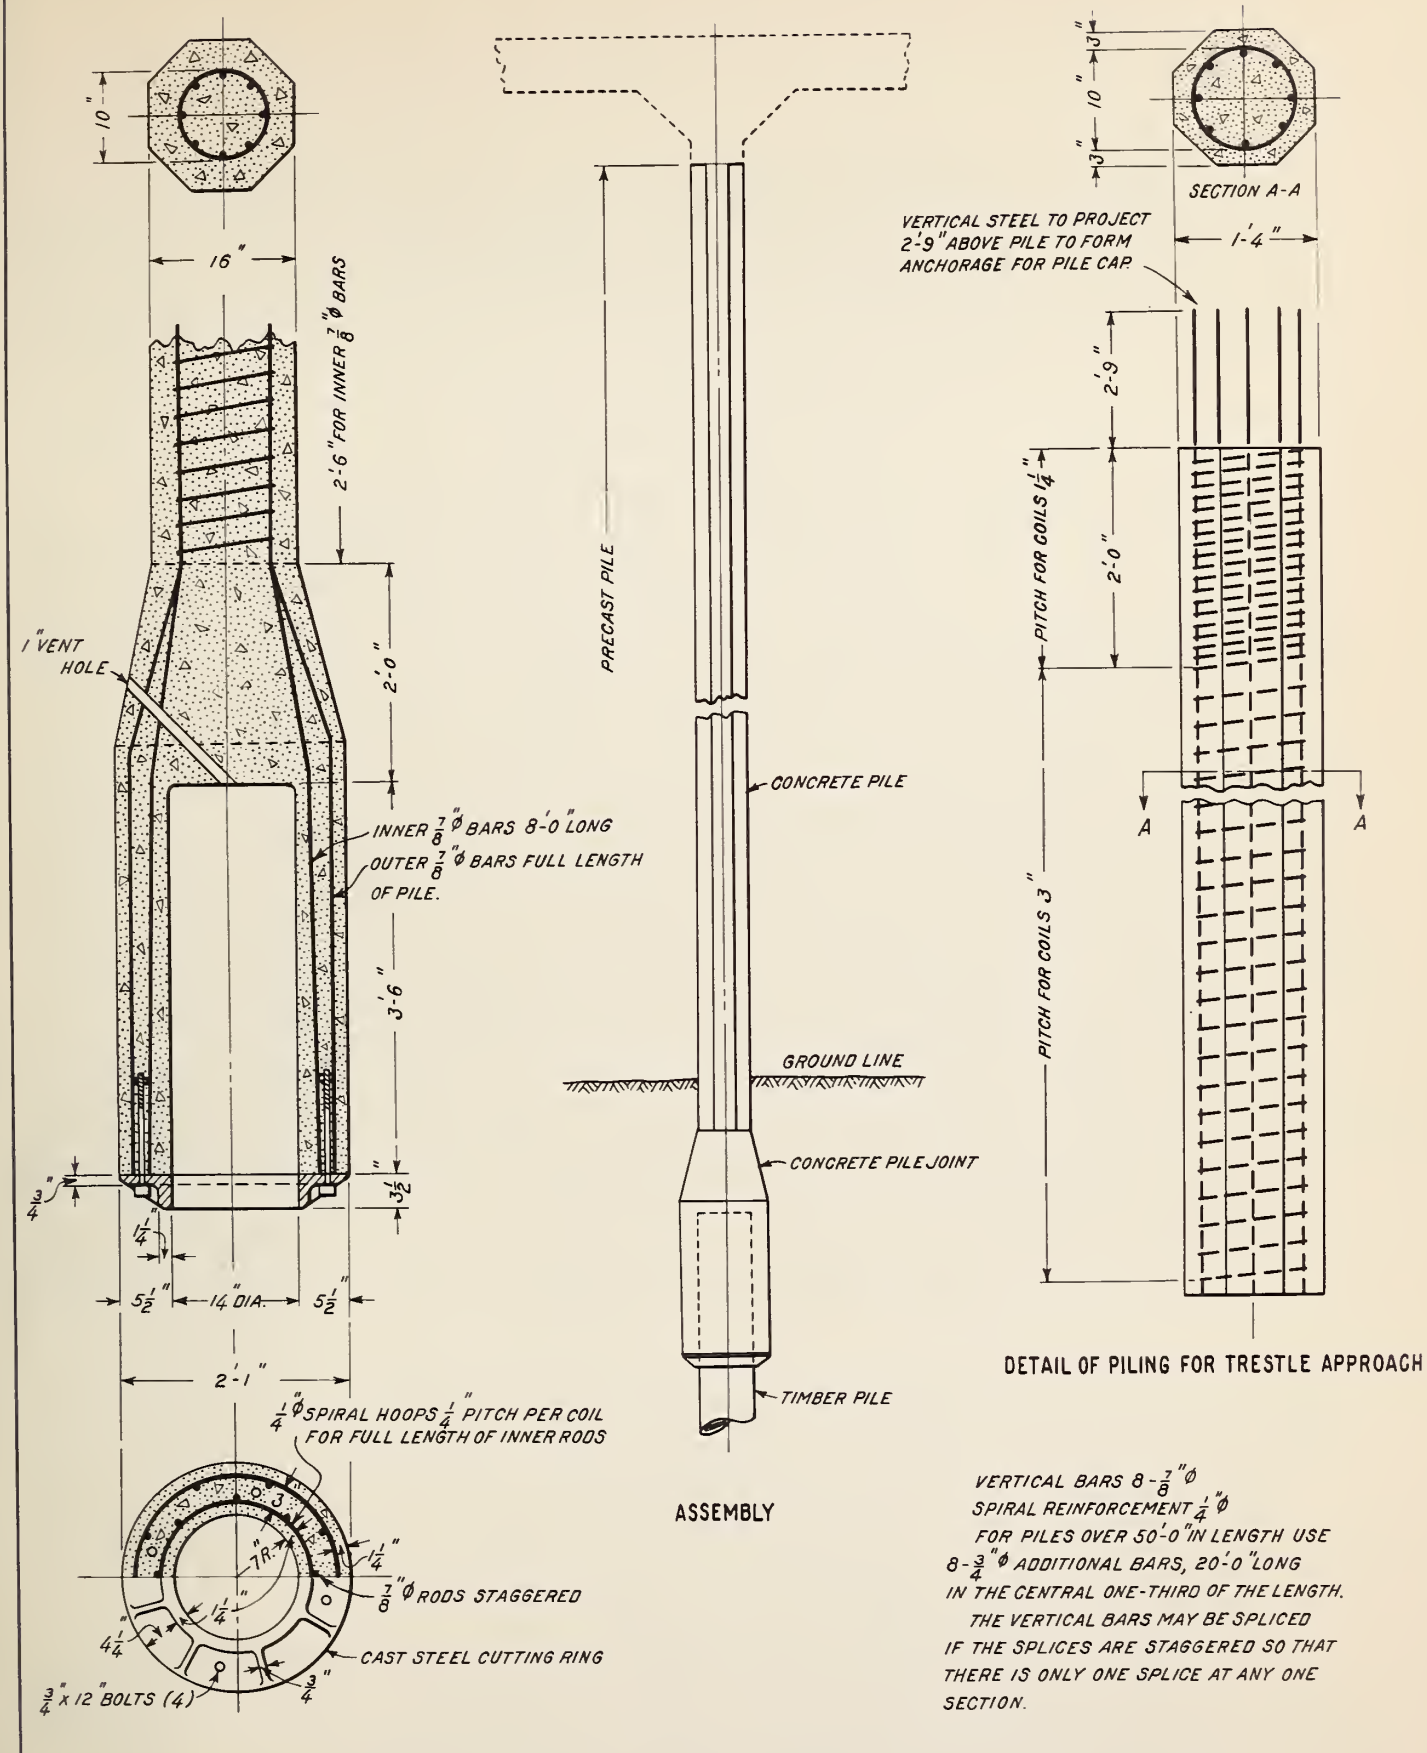

FIGURE 2 - DETAILS OF REINFORCED CONCRETE SECTION OF COMPOSITE PILING.

The concrete piles varied in length from 22 to 56 feet. On account of the proposed exposure to sea water, they were cured for more than the 60 days required by the specifications. The concrete in the piles developed a high strength - 1,839 pounds at the end of 7 days.

Method of Construction

The first step in the construction of the trestle was the driving of a series of test piles, to determine the character of the foundation. These were driven to a depth of 100 feet without reaching a solid footing through the silt, and sand and gravel deposit at the site of the bridge. After one or two days had elapsed, it was discovered that the test piles could be driven further with only a few blows of the hammer. This condition influenced the contractor to drive the timber piles, for the entire approach, several weeks in advance of the time when the concrete sections had become finally cured. This was intended to give the wooden stubs ample time to reach a condition of equilibrium with the surrounding soil. These wooden units, from 45 to 50 feet in length, were driven so that 6 or 8 feet projected above the surface of the ground. More than 60 days later, when the concrete sections were spliced to the wooden piles, it was discovered that the latter were held so tightly by the surrounding soil, that it was impracticable to drive them without resort to auxiliary equipment. It was even difficult, in some instances, to start the wooden stubs after jetting four holes around each one. It is believed that the difficulties and cost of construction could have been reduced considerably, if the timber stubs and concrete followers had been driven in one continuous operation.

The driver was constructed with a pendulum lead so that, when once set in position on a bent along the center line of the roadway, all the piles in the bent could be driven without changing its location. This method made it necessary to alter the batter of the piles as shown on the plans, so that their projected center lines would intersect at a common point - coinciding with the head-block of the driver. The contractor used a 7 x 10 American Hoist donkey-engine, which was slightly overloaded by the concrete piles, the maximum length of which was 56 feet. He recommends an 8-1/4 x 10 donkey-engine with a separate heavy head-block, and with the running line for handling the pile set not less than one foot in front of the main head-block for the hammer.

Developments During the Driving Operations

The first attempts at driving the concrete-pile sections were not very successful. A No. 1 Union steam hammer was tried first with unsatisfactory results. A 4,600-pound drop hammer was then resorted to with considerable increase in driving efficiency. For short piles, it is probable that the steam hammer would have proved superior, but the mass of the long composite piles was so large in proportion to the energy developed by the steam hammer, that satisfactory penetration could not be attained. A cast steel mushroom-shaped follower was interposed between the hammer and the pile head. The follower was recessed beneath to allow for the insertion of a cushion, consisting of two layers of 2-inch spruce separated by one inch of rubber. Holes were drilled in the flange of the follower to permit the passage of the reinforcing bars, which projected from the top of the pile.

The driving of the concrete sections was begun at the south end on a vertical pile. About twenty feet of penetration was obtained, and it was necessary to trim the badly-shattered top of the concrete pile. The next trial was made on one of the battered units which, after being driven about 15 feet, broke in the center, and the upper portion had to be withdrawn. The break was caused by lack of support at the mid-section. Following this experience, lateral timber braces were placed near the center of the pile, and no further difficulty of this kind was encountered. These braces prevented any undue kicking of the pile, especially of those on a batter.

In one instance a concrete pile was broken, during the driving, a short distance below the ground line. This was caused by excessive driving, after the point of the pile had penetrated a deep layer of intermingled logs and stumps. The break, which occurred about four feet above the bell-shaped socket, was of the typical conical, compression-failure type. The reinforcing steel was bent inward on all sides. Repairs were made by sinking a crib, and excavating the earth around the pile to permit the construction of an 18-inch reinforced concrete collar, from the bell to a point four feet above the top of the break. This experience indicates that, when hard driving is anticipated, it would be desirable to reduce the diameter of the bell-shaped pile-end. This could be accomplished by reducing the diameter of the top of the wooden pile, by cutting a shoulder around the complete circumference; and also by reducing the thickness of the walls of the socket, and adding more reinforcement. It would also be well to place a steel driving-ring four or five inches wide, around the top of the concrete pile.

The contractor states that the steel castings, used for the sockets in the bell-shaped ends, were excessive in cross section and weight. In his opinion a one-inch thickness would have been sufficient, and would have reduced the cost materially. As it was, the castings, which cost $18 apiece, were effective as a die for cutting the head of the wooden pile to the proper size. Whether this would be the case if the dimensions of the bell-shaped socket were reduced must be determined by further experiment. The 45-degree bevel on the cutting edge also resisted any sidewise movement and consequent splitting of oblique-grained piles, which might have occurred had the angle been flatter.

After the piles in the first bent were placed, the balance of the driving was less difficult. The greater difficulty, experienced in driving the initial piling, was probably caused by the weight of ten feet of new sand-fill under the bent, which may have compressed the subsoil. An effort to start the stub pile by direct driving was unsuccessful. Thereafter, four holes were jetted around each stub pile before driving was begun, and two jets were operated continuously while the concrete followers were being driven, except for the last few feet of penetration, when the jets were withdrawn. A crew of eight men drove an average of 2-1/2 and a maximum of 5 piles in one day.

The concrete piles were driven so that the bells, in the bents on the bank, were at least 6 feet below the low-water level. In the stream, where the water was more than 6 feet deep, the bells were driven in all cases below the ground line, thus giving added strength to the bents. The tops of the completely-driven concrete piles were considerably out of line, on account of the deflection caused by the heterogeneous nature of the foundation material. All variations in alignment were compensated by altering the dimensions of the concrete cap.

The erection of the steel span presented no unusual difficulties. It was fabricated on the rest pier in a direction parallel to the center line of the stream. A small framed bascule bridge, operated by a winch, permitted the construction crew to cross the channel on the north end. This temporary bascule bridge was raised, as occasion required, to provide a clear passageway for boats. Except for some painting and miscellaneous work, the structure was finished by December, 1926.

Advantages of Composite Piling

The principal advantage of the composite piling is the relative ease in handling. Where monolithic concrete piling is used, especially where the piles are of great length, there is considerable difficulty in handling them in the leads. In the Siletz River work, the use of monolithic piling would have necessitated a reconstruction of the equipment to obtain the proper batter. By utilizing a composite type, the relatively short timber stubs could be driven first and then followed by the concrete units. This made it unnecessary to handle the entire length of the pile at one operation.

Another advantage of the composite pile is the reduction in first cost. Concrete piling costs from 4 to 6 times as much per lineal foot as timber piling. Where the length involved is great enough to offset the additional cost of the socket joint, a considerable saving is made possible by the timber section.

The type of piling used on this project appears to be entirely practicable, and may be used wherever ordinary concrete or timber piling can be driven.

Disadvantages of Composite Piling

The principal disadvantages of the composite piling may be attributed to the jetting difficulties, the additional cost of the socket joint, and the amount of driving energy absorbed by the socket joint.

It is more difficult to jet a composite pile than either a concrete or timber pile alone, because of the presence of the bell-shaped joint. The widened section holds the jet at a distance from the side of the pile at the normal section, and makes it difficult to direct the stream of water under the toe, where it is most effective. One of the most efficient types of concrete pile contains, in the center, a pre-cast jetting pipe. It is obvious that this construction could not be used in a composite pile.

Apparently, the presence of so many joints, between the hammer and the tip of the pile, causes a loss of driving energy, which the steam hammer does not overcome.

General Observations

In general, it may be said that there is no difficulty inherent in the curing of the composite pile which does not apply to all concrete piling. With regard to handling, the concrete stubs were as easy to manipulate as concrete piling of the same length and weight. The seating of the concrete sections on the wooden stubs was, comparatively, a simple operation. In fact, toward the end of the job, it was found to be unnecessary to shape the top of the wooden stub; because the cutting edge of the socket shaped the timber to size without splitting or damage of any kind.

On this project, the reinforcing steel was carried above the top of the concrete pile to provide a suitable connection with the concrete caps. This made necessary a rather complicated follower-block to fit around the steel. The experience gained on this project indicates that it would be better practice to cast the concrete above the ends of the steel, with the intent of chipping the concrete after the driving is completed to expose sufficient steel for a proper joint. The jar of the follower-block causes the concrete to spall, in any event, and makes necessary considerable cutting and trimming. For this reason, it is believed that the additional expense, caused by the elimination of the follower-block, would be more than compensated by the savings in driving time.

All in all, the results obtained by the use of the composite piling were entirely satisfactory. The contractor probably lost money on the pile driving, and if so, a considerable portion of this loss may be attributed to the novelty of the method, and to the lost motion in getting properly equipped for the work. In the light of the final penetrations, it is possible that the piles were driven 4 or 5 feet deeper than was necessary. Although the results were satisfactory, the costs of driving the last few feet were excessive. Another factor, which prevented low driving costs, was the practice of driving the stubs some weeks prior to the concrete followers. This caused the stubs to set solidly, and resist further penetration. The primary reason for this procedure, however, was to avoid delaying the driver-crew while the timber piles were being cut off, and shaped to receive the bell-shaped socket. A further loss of time was experienced, because of the failure to cast the concrete followers in time to allow for their curing before the wooden stubs were driven. All of these delays, which increased the driving costs, could be eliminated in future work.

NOTES: (1) ROADS UNDER CONTROL OF STATE HIGHWAY DEPARTMENTS. DOES NOT INCLUDE ROADS UNDER COUNTY AND LOCAL CONTROL.
(2) ESTIMATED, AS STATE DOES NOT SEGREGATE MILEAGE OF EARTH IMPROVED, GRAVEL AND WATERBOUND MACADAM.

BUREAU EXHIBIT ON DISPLAY AT RENO, NEVADA

As a unit in the general exhibit of the Department, at the Transcontinental Highways Exposition, which is being held at Reno, Nevada, from June 25 to July 31; the Bureau has on display the material shown at the Sesquicentennial Exposition at Philadelphia, together with some booths from the convention of the American Road Builders' Association at Chicago.

The Transcontinental Highways Exposition is intended to celebrate the completion of United States Route 40 across Nevada. Although a considerable portion of the road is still unimproved, it is expected that the entire route will be completed at an early date, and it is now in condition for travel without serious difficulty.

In addition to the Bureau exhibit, the general Departmental display includes material furnished by other bureaus, whose work is confined largely to the western States; such as, the Forest Service, Biological Survey, Extension Service, Bureau of Animal Industry, and the Bureau of Plant Industry.

Mr. P. A. Kersey of this Bureau has been appointed by the Office of Exhibits as representative in general charge of the Department exhibit. Additional personnel, including several men from the western districts of this Bureau, will be assigned by the various bureaus to demonstrate the subject matter of the display.

W. H. LYNCH MADE DISTRICT ENGINEER OF DISTRICT 5

To fill the vacancy caused by the death of Mr. Wonders, Mr. W. H. Lynch, who has occupied the position of acting district engineer for some time, was appointed district engineer of District 5, effective June 7, 1927. Future correspondence to the Omaha district office should be addressed to Mr. Lynch, under his new title.

PRESENT STATUS OF UNITED STATES ROUTES 40, 41, 51, 61, AND 66

Contributed by F. W. Mills of the Division of Design

United States route 40-North is 65 per cent improved with gravel, and the higher types of surfacing. Another 21 per cent consists of graded and drained road, and the balance is unimproved. The route is surfaced continuously from Atlantic City, across New Jersey, Delaware, Maryland, Pennsylvania, West Virginia, Ohio, Indiana, Illinois, Missouri, practically to St. Marys, Kans., - a distance of 1,300 miles - with the exception of 4.23 miles of earth road in Pennsylvania. West of St. Marys, in Kansas, and through the western States of Colorado, Utah, Nevada, and California, the route is surfaced for 42 per cent of the 1,906-mile distance with gravel, or better. Of the remainder, 35 per cent is unsurfaced earth road, and 23 per cent is unimproved. The total length of the route, from Atlantic City to San Francisco, is 3,205 miles.

A detailed statement of the condition of the road, as determined by a Bureau survey, follows:

SUMMARY OF TYPES
UNITED STATES ROUTE 40-NORTH

	MILES	PER CENT
HARD SURFACE PAVEMENT, INCLUDING BRICK, CONCRETE, MACADAM, AND BITUMINOUS MACADAM	1,550.05	48.4
GRAVEL	539.20	16.8
EARTH, AND GRADED AND DRAINED ROADS	671.92	20.9
UNIMPROVED	444.17	13.9
TOTAL	3,205.34	100.0

United States route 41 is 85 per cent improved with gravel, and the higher types of surfacing. The remaining 15 per cent includes unsurfaced earth roads, unimproved sections, and bridges. With the exception of 3.4 miles of unimproved road in Indiana, between Boston and Hammond, along Lake George, there is a continuously surfaced road for a distance of 805 miles; beginning a short distance north of Powers, Mich., and extending through Wisconsin, Illinois, Indiana, and Kentucky, to Murfreesboro, Tenn.

In Michigan, Tennessee, Georgia, and Alabama, the surfaced sections total 77 per cent; the unsurfaced earth roads, 10 per cent; and the unimproved units aggregate 13 per cent. The total length of United States route 41 is 1,925 miles.

UNITED STATES ROUTE 51 IS 84 PER CENT SURFACED WITH SAND-CLAY, GRAVEL, AND THE HIGHER TYPES OF SURFACE. ANOTHER 9 PER CENT CONSISTS OF UNSURFACED EARTH ROAD, AND THE BALANCE IS UNIMPROVED. THERE IS NO CONSIDERABLE DISTANCE OF CONTINUOUSLY SURFACED ROAD ON THIS ROUTE, AND THERE ARE UNIMPROVED SECTIONS IN EVERY STATE EXCEPTING WISCONSIN, AND KENTUCKY. IN THE FORMER, THERE IS AN UNSURFACED SECTION 76 MILES IN LENGTH. THE SHORT CROSSING OF KENTUCKY, 40 MILES LONG, IS COMPLETELY SURFACED.

TOTAL MILES 1,472.11

Summary of Types
United States Route 51

	Miles	Per cent
Hard surface pavements, including brick, concrete, city pavement, bituminous concrete and macadam, and surface treated macadam	644.46	43.8
Gravel, shell, and sand-clay	591.51	40.2
Earth	131.46	8.9
Unimproved	104.68	7.1
Total	1,472.11	100.0

United States route 61 is 91 per cent surfaced with gravel, and the higher types of surface. The other 9 per cent consists of unsurfaced earth roads. There are no unimproved sections on this route. There is no extensive length of continuously surfaced road, since the earth sections are scattered through all the States, with the exception of Arkansas, and Tennessee; and in these States the distances are relatively short - 82 miles. The total length of the route is 1,850 miles.

TOTAL	1,850.4	100.0

UNITED STATES ROUTE 66 IS 50 PER CENT SURFACED WITH GRAVEL, AND THE HIGHER TYPES OF SURFACE. ANOTHER 24 PER CENT CONSISTS OF UNSURFACED EARTH ROAD, AND THE BALANCE IS UNIMPROVED. THERE IS A CONTINUOUS PAVEMENT FROM CHICAGO TO CUBA, MO., AND MUCH OF THE BALANCE OF THE ROUTE IN MISSOURI IS SIMILARLY IMPROVED. THE TOTAL LENGTH OF THE ROUTE IS 2,448 MILES.

REMARKS: THE ABOVE DATA IS REPORTED BY THE STATE HIGHWAY DEPARTMENTS OF THE RESPECTIVE STATES WITH BUT FEW EXCEPTIONS AS NOTED. THE FIGURES WHICH ARE CONSERVATIVE ESTIMATES AS A RULE, REPRESENT PRELIMINARY BUDGETS, EXCEPT THAT ROAD BOND PAYMENTS WHICH AMOUNT TO OVER $100,000,000 ARE EXCLUDED.
(1) SOME STATES INCLUDE RECONSTRUCTION OF ROAD COSTS IN MAINTENANCE EXPENSES AND WHEN SO REPORTED ARE SHOWN HERE SEPARATELY. IN OTHER STATES RECONSTRUCTION IS INCLUDED WITH CONSTRUCTION, THE ALLOCATION DEPENDING UPON THE POLICY OF THE STATE IN REGARD TO ROAD CONSTRUCTION. (2) WHERE NO ENTRY IS SHOWN, OVERHEAD IS INCLUDED IN CONSTRUCTION AND MAINTENANCE. IF LARGE MISCELLANEOUS EXPENSES ARE REPORTED SAME ARE NOTED. (3) INCLUDES 300 MILES OF ROAD OILING, $360,000. (4) REPRESENTS ROAD BUILDING THROUGH CITIES AND REFUNDS; OVERHEAD INCLUDED IN CONSTRUCTION AND MAINTENANCE. (5) INCLUDED IN ROAD CONSTRUCTION. (6) INCLUDES KENNEBEC BRIDGE, $2,090,740 (7) INCLUDES $464,000 FOR OTHER THAN OVERHEAD (8) STATE HIGHWAY MILEAGE THOROUGHLY MAINTAINED: EXCLUDES 6,000 MILES OF TOWN ROADS PARTLY MAINTAINED.
(9) INCLUDES $500,000 FOR PURCHASE OF RIGHT OF WAY. (10) EXCLUDES LOCAL ROAD MILEAGE FORMERLY REPORTED MAINTAINED BY STATE HIGHWAY DEPARTMENT. (11) INCLUDES $650,000 FOR MISCELLANEOUS EXPENSES.
(12) MISCELLANEOUS ONLY (13) INCLUDES $1,500,000 FOR PURCHASE OF RIGHT OF WAY. (14) ESTIMATE (BASED ON PREVIOUS YEAR'S DATA) MADE BY BUREAU OF PUBLIC ROADS (15) PARTIAL ESTIMATE BY BUREAU OF PUBLIC ROADS. (16) EXCLUDES $2,300,000 EXPENSES FOR HIGHWAY PATROL AND MOTOR VEHICLE REGISTRATION BUREAU. (17) INCLUDES $3,000,000 BOND ISSUE FOR WASHINGTON BRIDGE AT PROVIDENCE (18) IN ADDITION STATE MAINTAINS 12,200 MILES OF LOCAL SYSTEM. (19) ALL STATE HIGHWAY EXPENDITURES AND MILEAGE DATA ESTIMATED BY STATE HIGHWAY COMMISSIONER.

ANTIVENIN ADVOCATED AS A NORTH AMERICAN SNAKE-BITE SERUM

According to a circular recently received from the H. K. Mulford Company of Philadelphia, that company is prepared to furnish a serum, known as Antivenin, which is efficacious in treating the bites of North American venomous snakes.

The serum is distributed in 10-cubic-centimeter syringes, which are sterilized and ready for immediate use. Where medical aid is not available, it may be self-administered by injection made under the skin of the thigh or, preferably, of the side of the abdomen.

The syringe contains enough Antivenin to protect against the average amount of venom secreted at one time by North American serpents. Where there is reason to believe that the poison injected by the serpent was of unusually large quantity, or when the symptoms develop quickly and in severe form as, for instance, in children, it is advisable to give a second dose within a few hours if the first has not given the desired relief. In any case, the entire contents of the syringe should be injected at one dose, whether the patient is an adult or a child.

The Mulford Company's circular advocates the application of a ligature or tourniquet immediately above the wound, if the bite has been inflicted on a limb. It stated that there is no particular advantage in making an incision, or in applying permanganate of potash solution or crystals, or any other chemical agents commonly recommended for the purpose; that, in order to have an effect on venom, potassium permanganate solution must be used in concentrations that are injurious to the tissues.

Above everything else, the company advocates that the use of alcohol, or any stimulant, be avoided. These, by strengthening the circulation, tend to help the distribution of the venom throughout the body. Strychnine or caffeine, however, may be used if symptoms of weakness and giddiness develop.

After the preliminary ligature has been applied, the patient should proceed to the nearest place where Antivenin may be administered. There is often sufficient time to have the injection made by a doctor, since North American snake venoms are usually slow in acting. If the Antivenin can be obtained within 12 to 24 hours after the bite, the chances of its being effective are good. In the meantime, the tourniquet should be kept in place, but care should

be taken to release the pressure at intervals to prevent the setting in of gangrene. As soon, however, as the serum is injected the tourniquet should be released.

The list price of Antivenin is $7.50 a package, containing one syringe, and it is available through the branches and depots of the H. K. Mulford Company, and their principal distributors throughout the United States.

The Bureau has been advised by the Public Health Service that serum for the relief of snake bites is not distributed by that service, and there is apparently no other branch of the Government from which such a serum may be obtained. The head of the Hygienic Laboratory, Dr. McCoy, states that experimental treatments of rabbits and mice with Antivenin have indicated that this serum is efficacious in the treatment of animals. No experiments have been made upon human beings, but the head of the laboratory understands that physicians in Texas have used the Mulford serum with good effect. While Dr. McCoy does not wish to commit himself as to the efficacy of the serum for the treatment of human beings, he states that he would not hesitate to prescribe its use as it would probably do some good, and certainly could do no harm.

Before ordering the serum, it is suggested that district engineers consult local representatives of the Public Health Service, or local physicians designated for the treatment of injured Government employees. In case the serum is used, an immediate and complete report should be made to the headquarters office as to the effect of the treatment.

NEW RESEARCH PROJECT APPROVED

Title: A Statistical Analysis of Highway-Railroad Grade Crossing Accidents, in 1926, as reported by the Steam Railroads to the Interstate Commerce Commission.

Approved: May 28, 1927.

Leaders: A. B. Fletcher and W. G. Eliot, 3d.

Object: 1. To determine the relative frequency of grade-crossing accidents in rural and urban areas. The data may be used later in an attempt to establish the correct ratios which grade crossing accidents in the rural areas bear to the total of all the highway accidents in those areas.

2. To discover any other significant evidence as to causes and conditions of accidents which may be revealed in a mass analysis of the 5,890 accidents reported in 1926.

Procedure: The Bureau of Statistics of the Interstate Commerce Commission has on file a complete set of individual accident reports from all railroads under its jurisdiction. For those involving highway-railroad grade crossings the pertinent data will be transcribed and analyzed by means of tabulating machines.

Cooperation: None

Location: Washington, D. C.

Legal Authority: Bureau of Public Roads Appropriation Acts, 1927 and 1928.

Proposed Expenditure: About $1,000 (Salaries only of Mr. Eliot and two assistants. No travel required. This estimate includes no stationery or typewriting expense, nor tabulating machine cards, nor operating costs).

History: While the Interstate Commerce Commission has for some years published an analysis of grade-crossing accidents with respect to casualties and to details of railroad operation, there has been no complete analysis of these reports from the point of view of highway construction and traffic regulation.

JOHN MILTON GOODELL

John Milton Goodell, consulting engineer to the Bureau during the years 1918-1920, died, on June 21, at the French Hospital in New York City.

Mr. Goodell, who had been editor of the Engineering Record, from 1903 to 1912, retired from active business in the latter year. Subsequently, he spent much of his time in writing books and technical articles on sewage, water supply, and roads. He was the author of "Location Construction and Maintenance of Roads."

At the outbreak of the World War he served for a time with the Committee on Public Information, later being employed as acting chairman of the U. S. Highways Council, a body created to control the distribution of materials, transportation, and labor for road work.

As a consulting engineer for the Bureau, Mr. Goodell was closely associated with Mr. Logan Waller Page, then director of the Office of Public Roads and Rural Engineering. He was also a warm, personal friend of Mr. MacDonald.

One of Mr. Goodell's outstanding accomplishments, as consultant to the Bureau, was his work in connection with the organization of the American Association of State Highway Officials.

Mr. Goodell was born at Worcester, Mass., on August 3, 1867. He was graduated from the Worcester Polytechnic Institute, with the degree of B.S. in C.E., in 1888, and later spent the winter of 1888-89, in post-graduate studies, at the Zurich Polytechnic Institute in Switzerland.

He was affiliated with the American Society of Civil Engineers, and a member of the American Society of Mechanical Engineers, the American Water Works Association, the Boston Society of Civil Engineers, and the New England Water Works Association.
