GIFT OF  
GEORGE ARTHUR PLIMPTON  
OF NEW YORK

JANUARY 25, 1924

ELEMENTS  
OF  
GEOMETRY AND TRIGONOMETRY,

FROM THE WORKS OF

A. M. LEGENDRE.

REVISED AND ADAPTED TO THE COURSE OF MATHEMATICAL INSTRUCTION IN  
THE UNITED STATES,

BY CHARLES DAVIES, LL. D.,

AUTHOR OF ARITHMETIC, ALGEBRA, PRACTICAL MATHEMATICS FOR PRACTICAL MEN,  
ELEMENTS OF DESCRIPTIVE AND OF ANALYTICAL GEOMETRY, ELEMENTS  
OF DIFFERENTIAL AND INTEGRAL CALCULUS, AND SHADES,  
SHADOWS, AND PERSPECTIVE.

---

NEW-YORK:  
PUBLISHED BY A. S. BARNES & CO.,  
No. 51 JOHN-STREET.  
CINCINNATI: H. W. DERBY & CO.  
1854.

# DAVIES' COURSE OF MATHEMATICS

---

**Davies' First Lessons in Arithmetic—For Beginners.**

**Davies' Arithmetic—Designed for the use of Academies and Schools.**

**Key to Davies' Arithmetic.**

**Davies' University Arithmetic—Embracing the Science of Numbers and their numerous Applications.**

**Key to Davies' University Arithmetic.**

**Davies' Elementary Algebra—Being an introduction to the Science, and forming a connecting link between ARITHMETIC and ALGEBRA.**

**Key to Davies' Elementary Algebra.**

**Davies' Elements of Geometry and Trigonometry, with APPLICATIONS IN MENSURATION.—**This work embraces the elementary principles of Geometry and Trigonometry. The reasoning is plain and concise, but at the same time strictly rigorous.

**Davies' Practical Mathematics for Practical Men—Embracing the Principles of Drawing, Architecture, Mensuration, and Logarithms, with Applications to the Mechanic Arts.**

**Davies' Bourdon's Algebra—Including STURM'S THEOREM—**Being an abridgment of the Work of M. BOURDON, with the addition of practical examples.

**Davies' Legendre's Geometry and Trigonometry—**From the works of A. M. Legendre, with the addition of a Treatise on MENSURATION OF PLANES AND SOLIDS, and a Table of LOGARITHMS and LOGARITHMIC SINES.

**Davies' Surveying—**With a description and plates of the THEODOLITE, COMPASS, PLANE-TABLE, and LEVEL; also, Maps of the TOPOGRAPHICAL SIGNS adopted by the Engineer Department—an explanation of the method of surveying the Public Lands, Geodesic and Maritime Surveying, and an Elementary Treatise on NAVIGATION.

**Davies' Descriptive Geometry—**With its application to SPHERICAL PROJECTIONS.

**Davies' Shades, Shadows, and Linear Perspective.**

**Davies' Analytical Geometry—Embracing the EQUATIONS OF THE POINT AND STRAIGHT LINE—of the CONIC SECTIONS—of the LINE AND PLANE IN SPACE; also, the discussion of the GENERAL EQUATION of the second degree, and of SURFACES of the second order.**

**Davies' Differential and Integral Calculus.**

**Davies' Logic and Utility of Mathematics.**

---

ENTERED according to Act of Congress, in the year one thousand eight hundred and fifty-one, by CHARLES DAVIES, in the Clerk's Office of the District Court of the United States for the Southern District of New York.

---

The methods of demonstration, in several of the Books, have been entirely changed. By regarding the circle as the limit of the inscribed and circumscribed polygons, the demonstrations in Book V. have been much simplified; and the same principle is made the basis of several important demonstrations in Book VIII.

The subjects of Plane and Spherical Trigonometry have been treated in a manner quite different from that employed in the original work. In Plane Trigonometry, especially, important changes have been made. The separation of the part which relates to the computations of the sides and angles of triangles from that which is purely analytical, will, it is hoped, be found to be a decided improvement.

The application of Trigonometry to the measurement of Heights and Distances, embracing the use of the Table of Logarithms, and of Logarithmic Sines; and the application of Geometry to the mensuration of planes and solids, are useful exercises for the Student. Practical examples cannot fail to point out the generality and utility of abstract science.

FISHKILL LANDING, }

## INTRODUCTION.

1. SPACE extends indefinitely in every direction and contains all bodies.

2. EXTENSION is a limited portion of space, and has three dimensions, length, breadth, and thickness.

3. A SOLID, or BODY, is a limited portion of space supposed to be occupied by matter. The difference between the terms, *extension* and *solid*, is simply this: the former denotes a limited portion of space, viewed in the abstract, while the latter denotes such a portion occupied by matter.

The term, *Solid*, is generally used in Geometry, in preference to *Extension*, because the mind apprehends readily the forms and relations of tangible objects, while it often experiences much difficulty in dealing with the abstract notions derived from them. It is, however, important to observe, that *the geometrical properties of solids have no connection whatever with matter, and that the demonstrations which establish and make known those properties, are based on the attributes of extension only.*

4. A Solid being a limited portion of space, is necessarily divided from the indefinite space which surrounds it: that which so divides it, is called a *Surface*. Now, since that which bounds a solid is no part of the solid itself, it follows, that a surface has but two dimensions, length and breadth.

5. If we consider a limited portion of a surface, that which separates such portion from the other parts of the surface, is called a *Line*. This mark of division forms no part of the surfaces which it separates: hence, a line has length only, without breadth or thickness.

6. If we regard a limited portion of a line, that which separates such portion from the part, at either extremity, is called a *Point*. But this mark of division forms no part of the line itself: hence, a point has neither length, breadth, nor thickness, but place or position only.

7. Although we use the term *solid* to denote a given portion of space, the term *surface* to denote the boundary of a solid, the term *line* to denote the boundary of a surface, and the term *point* to designate the limit of a line, still, we may employ either of these terms, in an abstract sense, without any reference to the others.

Thus, we may contemplate a river, as a solid, without considering its boundaries; may look upon the surface and perceive that it has length and breadth without referring to its depth; or, we may regard the distance across without taking into account either its depth or length. So likewise, we may consider a point without any reference to the line which it limits.

In the definitions and reasonings of Geometry these terms are always used in an *abstract sense*; they are mere signs to the mind of the conceptions for which they stand.

8. ANGLE is a term which designates the portion of a surface included by two lines meeting at a common point;

and it also denotes a portion of space included by two or more planes.

9. **MAGNITUDE** is a general term employed to denote those quantities which arise from considering the dimensions of extension, and is equally applicable to lines, angles, surfaces, and solids. Geometry is conversant with four kinds of magnitude.

1. Lines; which have length without breadth or thickness.
2. Angles; bounded by straight lines, by curves, and by planes.
3. Surfaces; which have length and breadth without thickness: and
4. Solids; which have length, breadth, and thickness.

10. **FIGURE** is a term applied to a geometrical magnitude and expresses the idea of shape or form. It is that which is enclosed by one or more boundaries. Thus, "A triangle is a plane *figure* bounded by three straight lines."

11. A **PROPERTY** of a figure is a mark or attribute common to all figures of the same class.

12. The portions of extension which constitute the geometrical magnitudes, are indicated to the mind by certain marks called *lines*.

Thus, we say, the straight line  $AB$ , is the shortest distance between the two points  $A$  and  $B$ . The mark  $AB$ , on the paper, is not the geometrical line  $AB$ , but only the sign or representative of it—the geometrical line itself, having merely a mental existence.

We also say, that the triangle  $ACB$  is bounded by the three straight lines  $AB$ ,  $AC$ ,  $CB$ . Now, the triangle  $ACB$ , is but the sign, to the mind, of a portion of a plane. That which the eye sees is not the geometrical conception on which the mind acts and reasons: but is, as it were, the word or sign which stands for and expresses the abstract idea.

These considerations have induced me to represent the geometrical magnitudes by the fewest possible lines, and to reject altogether the method of shading the figures. It is the conception of extension, in the abstract, with which the mind should be made conversant, and too much pains cannot be taken to exclude the idea that we are dealing with material things.

# ELEMENTS OF GEOMETRY.

---

## BOOK I.

### DEFINITIONS.\*

1. **EXTENSION** has three dimensions, length, breadth, and thickness.

2. **GEOMETRY** is the science which has for its object :  
1st. The measurement of extension ; and 2dly. To discover, by means of such measurement, the properties and relations of geometrical magnitudes.

3. A **POINT** is that which has place, or position, but not magnitude.

4. A **LINE** is length, without breadth or thickness.

5. A **STRAIGHT LINE** is one which lies in the same direction between any two of its points.

6. A **BROKEN LINE** is one made up of straight lines, not lying in the same direction.

7. A **CURVE LINE** is one which changes its direction at every point.

The word *line* when used alone, will designate a straight line ; and the word *curve*, a curve line.

8. A **SURFACE** is that which has length and breadth without thickness.

---

\* See Davies' *Logic and Utility of Mathematics.* § 1.

9. A PLANE is a surface, such, that if any two of its points be joined by a straight line, such line will be wholly in the surface.

10. Every surface, which is not a plane surface, or composed of plane surfaces, is a *curved surface*.

11. A SOLID, or BODY is that which has length, breadth, and thickness: it therefore combines the three dimensions of extension.

12. A plane ANGLE is the portion of a plane included between two straight lines meeting at a common point. The two straight lines are called the *sides* of the angle, and the common point of intersection, the *vertex*.

Thus, the part of the plane included between  $AB$  and  $AC$  is called an *angle*:  $AB$  and  $AC$  are its *sides*, and  $A$  its *vertex*.

An angle is sometimes designated simply by a letter placed at the vertex, as, the angle  $A$ ; but generally, by three letters, as, the angle  $BAC$  or  $CAB$ ,—the letter at the vertex being always placed in the middle.

13. When a straight line meets another straight line, so as to make the adjacent angles equal to each other, each angle is called a *right angle*; and the first line is said to be *perpendicular* to the second.

14. An ACUTE ANGLE is an angle less than a right angle.

15. An OBTUSE ANGLE is an angle greater than a right angle.

16. Two straight lines are said to be *parallel*, when being situated in the same plane, they cannot meet, how far soever, either way, both of them be produced.

17. A PLANE FIGURE is a portion of a plane terminated on all sides by lines, either straight or curved.

18. A POLYGON, or *rectilinear figure*, is a portion of a plane terminated on all sides by straight lines.

The broken line that bounds a polygon is called its *perimeter*.

19. The polygon of three sides, the simplest of all, is called a *triangle*; that of four sides, a *quadrilateral*; that of five, a *pentagon*; that of six, a *hexagon*; that of seven, a *heptagon*; that of eight, an *octagon*; that of nine, an *nonagon*; that of ten, a *decagon*; and that of twelve, a *dodecagon*.

20. An *EQUILATERAL* polygon is one which has all its sides equal; an *equiangular* polygon, is one which has all its angles equal.

21. Two polygons are *equilateral*, or *mutually equilateral* when they have their sides equal each to each, and placed in the same order: that is to say, when following their bounding lines in the same direction, the first side of the one is equal to the first side of the other, the second to the second, the third to the third, and so on.

22. Two polygons are *equiangular*, or *mutually equiangular*, when every angle of the one is equal to a corresponding angle of the other, each to each.

23. Triangles are divided into classes with reference both to their sides and angles.

1. An *equilateral triangle* is one which has its three sides equal.

2. An *isosceles triangle* is one which has two of its sides equal.

3. A *scalene triangle* is one which has its three sides unequal.

4. An *acute-angled triangle* is one which has its three angles acute.

5. A *right-angled triangle* is one which has a right angle. The side opposite the right angle is called the *hypotenuse*, and the other two sides, the *base* and *perpendicular*.

6. An *obtuse-angled triangle* is one which has an obtuse angle.

24. There are three kinds of QUADRILATERALS:

1. The *trapezium*, which has no two of its sides parallel.

2. The *trapezoid*, which has only two of its sides parallel.

3. The *parallelogram*, which has its opposite sides parallel.

25. There are four varieties of PARALLELOGRAMS :

1. The *rhomboid*, which has no right angle.

2. The *rhombus*, or *lozenge*, which is an equilateral rhomboid.

3. The *rectangle*, which is an equiangular parallelogram.

4. The *square*, which is both equilateral and equiangular.

26. A *DIAGONAL* of a figure is a line which joins the vertices of two angles not adjacent.

27. A *base* of a plane figure is one of its sides on which it may be supposed to stand.

#### DEFINITIONS OF TERMS.

1. An *axiom* is a self-evident truth.
2. A *demonstration* is a train of logical arguments brought to a conclusion.
3. A *theorem* is a truth which becomes evident by means of a demonstration.
4. A *problem* is a question proposed, which requires a solution.
5. A *lemma* is a subsidiary truth, employed for the demonstration of a theorem, or the solution of a problem.

6. The common name, *proposition*, is applied indifferently, to theorems, problems, and lemmas.

7. A *corollary* is an obvious consequence, deduced from one or several propositions.

8. A *scholium* is a remark on one or several preceding propositions, which tends to point out their connection, their use, their restriction, or their extension.

9. A *hypothesis* is a supposition, made either in the enunciation of a proposition, or in the course of a demonstration.

10. A *postulate* grants the solution of a self-evident problem.

#### EXPLANATION OF SIGNS

1. The sign  $=$  is the sign of equality; thus, the expression  $A = B$ , signifies that  $A$  is equal to  $B$ .

2. To signify that  $A$  is smaller than  $B$ , the expression  $A < B$  is used.

3. To signify that  $A$  is greater than  $B$ , the expression  $A > B$  is used; the smaller quantity being always at the vertex of the angle.

4. The sign  $+$  is called *plus*; it indicates addition:

5. The sign  $-$  is called *minus*; it indicates subtraction:

Thus,  $A+B$ , represents the sum of the quantities  $A$  and  $B$ ;  $A-B$  represents their difference, or what remains after  $B$  is taken from  $A$ ; and  $A-B+C$ , or  $A+C-B$ , signifies that  $A$  and  $C$  are to be added together, and that  $B$  is to be subtracted from their sum.

6. The sign  $\times$  indicates multiplication: thus  $A \times B$  represents the product of  $A$  and  $B$ .

The expression  $A \times (B+C-D)$  represents the product of  $A$  by the quantity  $B+C-D$ . If  $A+D$  were to be multiplied by  $A-B+C$ , the product would be indicated thus;

$$(A+D) \times (A-B+C),$$

whatever is enclosed within the curved lines, being consid-

ered as a single quantity. The same thing may also be indicated by a bar: thus,

$$\overline{A+B+C} \times D,$$

denotes that the sum of  $A$ ,  $B$  and  $C$ , is to be multiplied by  $D$ .

7. A figure placed before a line, or quantity, serves as a multiplier to that line or quantity; thus  $3AB$  signifies that the line  $AB$  is taken three times;  $\frac{1}{2}A$  signifies the half of the angle  $A$ .

8. The square of the line  $AB$  is designated by  $\overline{AB}^2$ ; its cube by  $\overline{AB}^3$ . What is meant by the square and cube of a line, will be explained in its proper place.

9. The sign  $\sqrt{\quad}$  indicates a root to be extracted; thus  $\sqrt{2}$  means the square-root of 2;  $\sqrt{A \times B}$  means the square-root of the product of  $A$  and  $B$ .

#### AXIOMS.

1. Things which are equal to the same thing, are equal to one another.

2. If equals be added to equals, the wholes will be equal.

3. If equals be taken from equals, the remainders will be equal.

4. If equals be added to unequals, the wholes will be unequal.

5. If equals be taken from unequals, the remainders will be unequal.

6. Things which are doubles of equal things, are equal to each other.

7. Things which are halves of equal things, are equal to each other.

8. The whole is greater than any of its parts.

9. The whole is equal to the sum of all its parts.

10. All right angles are equal to each other.

11. From one point to another only one straight line can be drawn.

12. A straight line is the shortest distance between two points.

13. Through the same point, only one straight line can be drawn which shall be parallel to a given line.

14. Magnitudes, which being applied the one to the other, coincide throughout their whole extent, are equal.

#### POSTULATES.

1. Let it be granted, that a straight line may be drawn from one point to another point.

2. That a terminated straight line may be prolonged, in a straight line, to any length.

3. That if two straight lines are unequal, the length of the less may always be laid off on the greater.

4. That a given straight line may be bisected: that is, divided into two equal parts.

5. That a straight line may bisect a given angle.

6. That a perpendicular may be drawn to a given straight line, either from a point without the line, or at a point of a line.

7. That a straight line may be drawn, making with a given straight line, an angle equal to a given angle.

PROPOSITION I. THEOREM.

*If one straight line meet another straight line, the sum of the two adjacent angles will be equal to two right angles.*

Let the straight line  $DC$  meet the straight line  $AB$  at  $C$ ; then will the angle  $ACD$  plus the angle  $DCB$ , be equal to two right angles.

At the point  $C$  suppose  $CE$  to be drawn perpendicular to  $AB$ : then,  $ACE + ECB =$  two right angles (D. 13).\* But  $ECB$  is equal to  $ECD + DCB$  (A. 9): hence,  $ACE + ECD + DCB =$  two right angles. But  $ACE + ECD = AOD$  (A. 9): therefore,  $ACD + DCB =$  two right angles.

*Cor. 1.* If one of the angles  $ACD$  or  $DCB$ , is a right angle, the other will also be a right angle.

*Cor. 2.* If a straight line  $DE$  is perpendicular to another straight line  $AB$ ; then, reciprocally,  $AB$  will be perpendicular to  $DE$ .

For, since  $DE$  is perpendicular to  $AB$ , the angle  $ACD$  will be a right angle (D. 13). But since  $AC$  meets  $DE$  at the point  $C$ , making one angle  $ACD$  a right angle, the adjacent angle  $ACE$  will also be a right angle (C. 1). Therefore,  $AB$  is perpendicular to  $DE$  (D. 13).

*Cor. 3.* The sum of the successive angles  $BAC, CAD, DAE, EAF$ , formed on the same side of the line  $BF$ , is equal to two right angles; for, their sum is equal to that of the two adjacent angles  $BAC$  and  $CAF$ .

\* In the references, A. stands for Axiom—D. for Definition—B. for Book—P. for Proposition—C. for Corollary—S. for Scholium, and Prob. for Problem.

## PROPOSITION II. THEOREM.

*Two straight lines, which have two points common, coincide the one with the other, throughout their whole extent, and form one and the same straight line.*

Let  $A$  and  $B$  be the two common points of two straight lines.

In the first place, the two lines will coincide between the points  $A$  and  $B$ ; for, otherwise there would be two straight lines between  $A$  and  $B$ , which is impossible (A. 11).

Suppose, however, that in being prolonged, these lines begin to separate at some point, as  $C$ , the one becoming  $CD$ , the other,  $CE$ . At the point  $C$ , suppose  $CF$  to be drawn, making with  $AC$ , the right angle  $ACF$ .

Now, since  $ACD$  is a straight line, the angle  $FCD$  will be a right angle (P. I., c. 1): and since  $ACE$  is a straight line, the angle  $FCE$  will also be a right angle. Hence, the angle  $FCD$  is equal to the angle  $FCE$  (A. 10): that is, a whole is equal to one of its parts, which is impossible (A. 8): therefore the two straight lines which have two points,  $A$  and  $B$ , in common, cannot separate at any point, when prolonged; hence, they form one and the same straight line.\*

## PROPOSITION III. THEOREM.

*If, when a straight line meets two other straight lines at a common point, the sum of the two adjacent angles which it makes with them, is equal to two right angles, the two straight lines which are met, form one and the same straight line.*

Let the straight line  $CD$  meet the two lines  $AC$ ,  $CB$ , at their common point  $C$ , and let the sum of the two adjacent angles,  $DCA$ ,  $DCB$ , be equal to two right angles: then

---

\* See Note A. It is earnestly recommended to every pupil to read and understand this Note. Also, see Logic and Utility of Mathematics, § 262.

will  $CB$  be the prolongation of  $AC$ ; or,  $AC$  and  $CB$  will form one and the same straight line.

For, if  $OB$  is not the prolongation of  $AC$ , let  $CE$  be that prolongation. Then the line  $ACE$  being straight, the sum of the angles  $ACD$ ,  $DCE$ , will be equal to two right angles (P. 1). But by hypothesis, the sum of the angles  $ACD$ ,  $DCB$ , is also equal to two right angles: therefore (A. 1),

$ACD + DCE$  must be equal to  $ACD + DCB$ .

Taking away the angle  $ACD$  from each, there remains the angle  $DCE$  equal to the angle  $DCB$ : that is, a whole equal to a part, which is impossible (A. 8): therefore,  $AC$  and  $CB$  form one and the same straight line.

PROPOSITION IV. THEOREM.

*When two straight lines intersect each other, the opposite or vertical angles, which they form, are equal.*

Let  $AB$  and  $DE$  be two straight lines, intersecting each other at  $C$ ; then will the angle  $ECB$  be equal to the angle  $ACD$ , and the angle  $ACE$  to the angle  $DCB$ .

For, since the straight line  $DE$  is met by the straight line  $AC$ , the sum of the angles  $AOE$ ,  $ACD$ , is equal to two right angles (P. 1); and since the straight line  $AB$  is met by the straight line  $EC$ , the sum of the angles  $ACE$ , and  $ECB$ , is equal to two right angles: hence (A. 1),

$ACE + ACD$  is equal to  $ACE + ECB$ .

Take away from both, the common angle  $ACE$ , there remains (A. 3) the angle  $ACD$ , equal to its opposite or vertical angle  $ECB$ . In a similar manner it may be proved that  $ACE$  is equal to  $DCB$ .

*Scholium.* The four angles formed about a point by two straight lines, which intersect each other, are together equal

to four right angles. For, the sum of the two angles  $ACE$ ,  $ECB$ , is equal to two right angles (P. 1); and the sum of the other two,  $ACD$ ,  $DCB$ , is also equal to two right angles: therefore, the sum of the four, is equal to four right angles.

In general, if any number of straight lines  $CA$ ,  $CB$ ,  $CD$ , &c., meet in a common point  $C$ , the sum of all the successive angles,  $ACB$ ,  $BCD$ ,  $DCE$ ,  $ECF$ ,  $FCA$ , will be equal to four right angles. For, if four right angles were formed about the point  $C$ , by two lines perpendicular to each other, their sum would be equal to the sum of the successive angles  $ACB$ ,  $BCD$ ,  $DCE$ ,  $ECF$ ,  $FCA$ .

PROPOSITION V. THEOREM.

If two triangles have two sides and the included angle of the one, equal to two sides and the included angle of the other, each to each, the two triangles will be equal.

In the two triangles  $EDF$  and  $BAC$ , let the side  $ED$  be equal to the side  $BA$ , the side  $DF$  to the side  $AC$ , and the angle  $D$  to the angle  $A$ ; then will the triangle  $EDF$  be equal to the triangle  $BAC$ .

For, if these triangles be applied the one to the other, they will exactly coincide. Let the side  $ED$  be placed on the equal side  $BA$ ;

then, since the angle  $D$  is equal to the angle  $A$ , the side  $DF$  will take the direction  $AC$ . But  $DF$  is equal to  $AC$ ; therefore the point  $F$  will fall on  $C$ , and the third side  $EF$ , will coincide with the third side  $BC$  (A. 11): consequently, the triangle  $EDF$  is equal to the triangle  $BAC$  (A. 14).

*Cor.* When two triangles have these three things equal, viz., the side  $ED=BA$ , the side  $DF=AC$ , and the angle  $D=A$ , the remaining three are also respectively equal, viz., the side  $EF=BC$ , the angle  $E=B$ , and the angle  $F=C$ .

## PROPOSITION VI. THEOREM.

*If two triangles have two angles and the included side of the one, equal to two angles and the included side of the other, each to each, the two triangles will be equal.*

Let  $EDF$  and  $BAC$  be two triangles, having the angle  $E$  equal to the angle  $B$ , the angle  $F$  to the angle  $C$ , and the included side  $EF$  to the included side  $BC$ ; then will the triangle  $EDF$  be equal to the triangle  $BAC$ .

For, let the side  $EF$  be placed on its equal  $BC$ , the point  $E$  falling on  $B$ , and the point  $F$  on  $C$ . Then, since the angle  $E$  is equal to the angle  $B$ , the side  $ED$  will take the direction  $BA$ ; and hence, the point  $D$  will be found somewhere in the line  $BA$ . In like manner, since the angle  $F$  is equal to the angle  $C$ , the line  $FD$  will take the direction  $CA$ , and the point  $D$  will be found somewhere in the line  $CA$ . Hence, the point  $D$ , falling at the same time in the two straight lines  $BA$  and  $CA$ , must fall at their intersection  $A$ : hence, the two triangles  $EDF$ ,  $BAC$ , coincide with each other, and consequently, are equal (A. 14).

*Cor.* Whenever, in two triangles, these three things are equal, viz.: the angle  $E=B$ , the angle  $F=C$ , and the included side  $EF$  equal to the included side  $BC$ , it may be inferred that the remaining three are also respectively equal, viz.: the angle  $D=A$ , the side  $ED=BA$ , and the side  $DF=AC$ .

*Scholium.* Two triangles which being applied to each other, coincide in all their parts, are equal (A. 14). The like parts are those which coincide with each other; hence, they are also equal each to each. The converse of this proposition is also true; viz., *if two triangles have all the parts of the one equal to the parts of the other, each to each, the triangles will be equal*: for, when applied to each other, they will mutually coincide.

## PROPOSITION VII. THEOREM.

*The sum of any two sides of a triangle; is greater than the third side.*

Let  $ABC$  be a triangle: then will the sum of two of its sides, as  $AB$ ,  $BC$ , be greater than the third side  $AC$

For the straight line  $AC$  is the shortest distance between the points  $A$  and  $C$  (A. 12); hence,  $AB+BC$  is greater than  $AC$ .

*Cor.* If from both members of the inequality

$$AC < AB + BC$$

we take away either of the sides, as  $BC$ , we shall have (A. 5)

$$AC - BC < AB:$$

that is, *the difference between any two sides of a triangle is less than the third side.*

## PROPOSITION VIII. THEOREM.

*If from any point within a triangle, two straight lines be drawn to the extremities of either side, their sum will be less than that of the two remaining sides of the triangle.*

Let  $O$  be any point within the triangle  $BAC$ , and let the lines  $OB$ ,  $OC$ , be drawn to the extremities of either side, as  $BC$ ; then will

$$OB + OC < BA + AC.$$

Let  $BO$  be prolonged till it meets the side  $AC$  in  $D$ : then

$$OC < OD + DC \text{ (P. 7):}$$

add  $BO$  to each, and we have

$$BO + OC < BO + OD + DC \text{ (A. 4):}$$

or,  $BO + OC < BD + DC.$

But,  $BD < BA + AD:$

add  $DC$  to each, and we have

$$BD + DC < BA + AC.$$

But it has been shown that

$$BO + OC < BD + DC:$$

therefore, still more is

$$BO + OC < BA + AC.$$

PROPOSITION IX. THEOREM.

*If two triangles have two sides of the one equal to two sides of the other, each to each, and the included angles unequal, the third sides will be unequal; and the greater side will belong to the triangle which has the greater included angle.*

Let  $BAC$  and  $EDF$  be two triangles, having the side  $AB = DE$ ,  $AC = DF$ , and the angle  $A > D$ ; then will the side  $BC$  be greater than  $EF$ .

Make the angle  $CAG = D$ ; take  $AG = DE$ , and draw  $CG$ .

Then, the triangles  $GAC$  and  $EDF$  will be equal, since they have two sides and an included angle in each equal, each to each (P. 5); consequently,  $CG$  is equal to  $EF$  (P. 5, c).

There may be three cases in this proposition.

1st. When the point  $G$  falls without the triangle  $BAC$ .

2d. When it falls on the side  $BC$ ; and

3d. When it falls within the triangle.

*Case I.* In the triangles  $AGC$  and  $ABC$ , we have,

$$GI + IC > GC; \text{ and}$$

$$AI + IB > AB;$$

therefore

$$AG + BC > GC + AB.$$

Taking away  $AG$   
from the one side and

its equal  $AB$  from the other, and there will remain  $BC$

greater than  $GC$ . But we have found that  $GC$  is equal to  $EF$ ; therefore,  $BC$  will be greater than  $EF$ .

*Case II.* If the point  $G$  fall on the side  $BC$ , it is evident that  $GC$ , or its equal  $EF$ , will be shorter than  $BC$  (A. 8).

*Case III.* Lastly, if the point  $G$  fall within the triangle  $BAC$ , we shall have

$$AG + GC < AB + BC,$$

taking  $AG$  from the one, and its equal  $AB$  from the other, there will remain

$$GC < BC \text{ or } BC > EF.$$

*Cor.* Conversely: if two sides  $BA$ ,  $AC$ , of a triangle  $BAC$ , are equal to two sides  $ED$ ,  $DF$ , of a triangle  $EDF$ , each to each, while the third side  $BC$  of the first is greater than the third side  $EF$  of the second, then the angle  $BAC$  of the first triangle will be greater than the angle  $EDF$  of the second.

For, if not greater, the angle  $BAC$  must be equal to  $EDF$  or less than it. In the first case, the side  $BC$  would be equal to  $EF$  (p. 5, c), in the second,  $BC$  would be less than  $EF$ ; but either of these results contradicts the hypothesis: therefore,  $BAC$  is greater than  $EDF$ .

#### PROPOSITION X. THEOREM.

*If two triangles have the three sides of the one equal to the three sides of the other, each to each, the triangles are equal.*

Let  $EDF$  and  $BAC$  be two triangles, having the side  $ED=BA$ , the side  $EF=BC$ , and the side  $DF=AC$ ; then will the angle  $D=A$ , the angle  $E=B$ , and the angle  $F=C$ , and consequently the triangle  $EDF$  will be equal to the triangle  $BAC$ .

For, since the sides  $ED$ ,  $DF$ , are equal to  $BA$ ,  $AC$ , each to each, if the angle  $D$  were greater than  $A$ , it would follow, by the last proposition, that the side  $EF$  would be greater than  $BC$ ; and if the angle  $D$  were less than  $A$ , the side  $EF$  would be less than  $BC$ . But  $EF$  is equal to  $BC$ , by hypothesis; therefore, the angle  $D$  can neither be greater nor less than  $A$ ; therefore it must be equal to it. In the same manner it may be shown that the angle  $E$  is equal to  $B$ , and the angle  $F$  to  $C$ : hence, the two triangles are equal (p. 6, s).

*Scholium.* It may be observed, that when two triangles are equal to each other, the equal angles lie opposite the equal sides, and consequently, the equal sides opposite the equal angles: thus, the equal angles  $D$  and  $A$ , lie opposite the equal sides  $EF$  and  $BC$ .

PROPOSITION XI. THEOREM.

*In an isosceles triangle, the angles opposite the equal sides are equal.*

Let  $BAC$  be an isosceles triangle, having the side  $BA$  equal to the side  $AC$ ; then will the angle  $C$  be equal to the angle  $B$ .

For, join the vertex  $A$ , and the middle point  $D$ , of the base  $BC$ . Then, the triangles  $BAD$ ,  $DAC$ , will have all the sides of the one equal to those of the other, each to each. For,  $BA$  is equal to  $AC$ , by hypothesis,  $AD$  is common, and  $BD$  is equal to  $DC$  by construction: therefore, by the last proposition, the angle  $B$  is equal to the angle  $C$ .

Therefore, the angle  $B$  is equal to the angle  $C$ .

*Cor.* 1. An equilateral triangle is likewise equiangular, that is to say, has all its angles equal.

*Cor.* 2. The equality of the triangles  $BAD$ ,  $DAC$ , proves also that the angle  $BAD$ , is equal to  $DAC$ , and  $BDA$  to

$ADC$ ; hence, the latter two are right angles. *Therefore, the line drawn from the vertex of an isosceles triangle to the middle point of the base, divides the angle at the vertex into two equal parts, and is perpendicular to the base.*

*Scholium.* In a triangle which is not isosceles, any side may be assumed indifferently as the *base*; and the *vertex* is, in that case, the vertex of the opposite angle. In an isosceles triangle, however, that side is generally assumed as the base, which is not equal to either of the other two.

PROPOSITION XII. THEOREM.

*Conversely: If two angles of a triangle are equal, the sides opposite them are also equal, or, the triangle is isosceles.*

In the triangle  $BAC$ , let the angle  $B$  be equal to the angle  $ACB$ ; then will the side  $AC$  be equal to the side  $AB$ .

For, if these sides are not equal, suppose  $AB$  to be the greater. Then, take  $BD$  equal to  $AC$ , and draw  $CD$ . Now, in the two triangles  $BDC$ ,  $BAC$ , we have  $BD=AC$ , by construction; the angle  $B$  equal to the angle  $ACB$ , by hypothesis; and the side  $BC$  common: therefore, the two triangles,  $BDC$ ,  $BAC$ , have two sides and the included angle of the one, equal to two sides and the included angle of the other, each to each: hence they are equal (P. 5). But the part cannot be equal to the whole (A. 8); hence, there is no inequality between the sides  $BA$  and  $AC$ ; therefore, the triangle  $BAC$  is isosceles.

PROPOSITION XIII. THEOREM.

*The greater side of every triangle is opposite to the greater angle; and conversely, the greater angle is opposite to the greater side.*

*First,* In the triangle  $CAB$ , let the angle  $C$  be greater than the angle  $B$ ; then will the side  $AB$ , opposite  $C$ , be greater than  $AC$ , opposite  $B$ .

For, make the angle  $BCD=B$ . Then, in the triangle  $CDB$ , we shall have  $CD=BD$  (p. 12).

Now, the side  $AC < AD+DC$ ;

but  $AD+DC=AD+DB=AB$ :

therefore,  $AC < AB$ , or,  $AB > AC$ .

*Secondly.* Suppose the side  $AB > AC$ ; then will the angle  $C$ , opposite to  $AB$ , be greater than the angle  $B$ , opposite to  $AC$ .

For, if the angle  $C < B$ , it follows, from what has just been proved, that  $AB < AC$ ; which is contrary to the hypothesis. If the angle  $C=B$ , then the side  $AB=AC$  (p. 12); which is also contrary to the supposition. Therefore, when  $AB > AC$ , the angle  $C$  cannot be less than  $B$ , nor equal to it; therefore, the angle  $C$  must be greater than  $B$ .

PROPOSITION XIV. THEOREM.

*From a given point, without a straight line, only one perpendicular can be drawn to that line.*

Let  $A$  be the point, and  $DE$  the given line.

Let us suppose that we can draw two perpendiculars,  $AB, AC$ . Prolong either of them, as  $AB$ , till  $BF$  is equal to  $AB$ , and draw  $FC$ . Then the two triangles  $CAB, CBF$ , will be equal: for, the angles  $CBA$  and  $CBF$  are right angles, the side  $CB$  is common, and the side  $AB$  equal to

$BF$ , by construction; therefore, the two triangles are equal, and the angle  $ACB=BCF$  (p. 5, c). But the angle  $ACB$  is a right angle, by hypothesis; therefore,  $BCF$  must likewise be a right angle. Now, if the adjacent angles  $BCA, BCF$ , are together equal to two right angles,  $ACF$  must be a straight line (p. 3). Whence, it follows, that between the same two points,  $A$  and  $F$ , two straight lines can be drawn, which is impossible (A. 11): therefore, only one

perpendicular can be drawn from the same point to the same straight line.

*Cor.* At a given point  $C$ , in the line  $AB$ , it is also impossible to erect more than one perpendicular to that line. For, if  $CD$ ,  $CE$ , were both perpendicular to  $AB$ , the angles  $BCD$ ,  $BCE$ , would both be right angles; hence, they would be equal (A. 10), and a part would be equal to the whole, which is impossible.

PROPOSITION XV. THEOREM.

*If from a point without a straight line, a perpendicular be let fall on the line, and oblique lines be drawn to different points:*

- 1st. *The perpendicular will be shorter than any oblique line.*
- 2d. *Any two oblique lines which intersect the given line at points equally distant from the foot of the perpendicular, will be equal.*
- 3d. *Of two oblique lines which intersect the given line at points unequally distant from the perpendicular, the one which cuts off the greater distance will be the longer.*

Let  $A$  be the given point,  $DE$  the given line,  $AB$  the perpendicular, and  $AD$ ,  $AC$ ,  $AE$ , the oblique lines.

Prolong the perpendicular  $AB$  till  $BF$  is equal to  $AB$ , and draw  $FC$ ,  $FD$ .

*First.* The triangle  $BCF$ , is equal to the triangle  $CAB$ , for they have the right angle  $CBF = CBA$ , the side  $CB$  common, and the side  $BF = BA$ ; hence, the third sides,  $CF$  and  $CA$  are equal (P. 5, c). But  $ABF$ , being a straight line, is shorter than  $ACF$ , which is a broken line (A. 12); therefore,  $AB$ , the half of  $ABF$ , is shorter than  $AC$ , the half of  $ACF$ ; hence, the perpendicular is shorter than any oblique line.

*Secondly.* Let us suppose  $BC=BE$ ; then the triangle  $CAB$  will be equal to the triangle  $BAE$ ; for  $BC=BE$ , the side  $AB$  is common, and the angle  $CBA=ABE$ ; hence, the sides  $AC$  and  $AE$  are equal (p. 5, c): therefore, two oblique lines, which meet the given line at equal distances from the perpendicular, are equal.

*Thirdly.* Since the point  $C$  is within the triangle  $FDA$ , the sum of the sides  $FD, DA$ , is greater than the sum of the lines  $FC, CA$  (p. 8): therefore  $AD$ , the half of the broken line  $FDA$ , is greater than  $AC$ , the half of  $FCA$ : consequently, the oblique line which cuts off the greater distance, is the longer.

*Cor. 1.* The perpendicular measures the shortest distance of a point from a line.

*Cor. 2.* From the same point to the same straight line, only two equal straight lines can be drawn; for, if there could be more, we should have at least two equal oblique lines on the same side of the perpendicular, which is impossible.

PROPOSITION XVI. THEOREM.

*If at the middle point of a given straight line, a perpendicular to this line be drawn:*

- 1st. *Any point of the perpendicular will be equally distant from the extremities of the line:*
- 2d. *Any point, without the perpendicular, will be unequally distant from the extremities.*

Let  $AB$  be the given straight line,  $C$  its middle point, and  $ECF$  the perpendicular.

*First.* Let  $D$  be any point of the perpendicular, and draw  $DA$  and  $DB$ . Then, since  $AC=CB$ , the two oblique lines  $AD, DB$ , are equal (p. 15). So, likewise, are the two oblique lines,  $AE, EB$ , the two  $AF, FB$ , and so on. Therefore, any point in the perpendicular is equally distant from the extremities  $A$  and  $B$ .

*Secondly.* Let  $I$  be any point out of the perpendicular. If  $IA$  and  $IB$  be drawn, one of these lines will cut the perpendicular in some point as  $D$ ; from this point, drawing  $DB$ , we shall have  $DB=DA$ . But, the straight line  $IB$  is less than  $ID+DB$ , and

$$ID+DB=ID+DA=IA;$$

therefore,  $IB < IA$ ; consequently, any point out of the perpendicular, is unequally distant from the extremities  $A$  and  $B$ .

*Cor.* Conversely: if a straight line have two points  $E$  and  $F$ , each of which is equally distant from the extremities  $A$  and  $B$ , it will be perpendicular to  $AB$  at the middle point  $C$ .

PROPOSITION XVII. THEOREM.

*If two right-angled triangles have the hypotenuse and a side of the one equal to the hypotenuse and a side of the other, each to each, the triangles are equal.*

Let  $BAC$  and  $EDF$  be two right-angled triangles, having the hypotenuse  $AC=DF$ , and the side  $BA=ED$ : then will the triangle  $BAC$  be equal to the triangle  $EDF$ .

If the sides  $BC$  and  $EF$  are equal, the triangles are equal (p. 10). Now, suppose these two sides to be unequal, and  $BC$  to be the greater.

On  $BC$  take  $BG=EF$ , and draw  $AG$ . Then, in the two triangles  $BAG$ ,  $EDF$ , the angles  $B$  and  $E$  are equal, being right angles, the side  $BA=ED$  by hypothesis, and the side  $BG=EF$  by construction; consequently,  $AG=DF$  (p. 5, c). But by hypothesis  $AC=DF$ ; and therefore,  $AC=AG$  (A. 1). But the oblique line  $AC$  cannot be equal to  $AG$ , since  $BC$  is greater than  $BG$  (p. 15); consequently,  $BC$  and  $EF$  cannot be unequal, and hence, the triangles are equal (p. 10).

PROPOSITION XVIII. THEOREM.

*If two straight lines are perpendicular to a third line, they are parallel to each other.*

Let the two lines  $AC$ ,  $BD$ , be perpendicular to  $AB$ ; then will they be parallel.

For, if they could meet in a point  $O$ , on either side of  $AB$ , there would be two perpendiculars  $OA$ ,  $OB$ , let fall from the same point on the same straight line; which is impossible (p. 14).

PROPOSITION XIX. THEOREM.

*If two straight lines meet a third line, making the sum of the interior angles on the same side equal to two right angles, the two lines are parallel.*

Let the two lines  $KC$ ,  $HD$ , meet the line  $BA$ , making the angles  $BAC$ ,  $ABD$ , together equal to two right angles: then the lines  $KC$ ,  $HD$ , will be parallel.

From  $G$ , the middle point of  $BA$ , draw the straight line  $EGF$ , perpendicular to  $KC$ : then, it will also be perpendicular to  $HD$ . For, the sum  $BAC + ABD$  is equal to two right angles, by hypothesis; the sum  $ABD + ABE$  is likewise equal to two right angles (p. 1): taking away  $ABD$  from both, there will remain the angle  $BAC = ABE$ .

Again, the angles  $EGB$ ,  $AGF$ , are equal (p. 4); therefore, the triangles  $EGB$  and  $AGF$ , have each a side and two adjacent angles equal each to each; therefore the triangles are equal, and the angle  $GEB$  is equal to  $GFA$  (p. 6, c). But  $GEB$  is a right angle by construction; therefore,  $GFA$  is a right angle; hence, the two lines  $KC$ ,

$HD$ , are perpendicular to the same straight line, and are therefore parallel (P. 18).

*Scholium.* When two parallel straight lines  $AB$ ,  $CD$ , are met by a third line  $FE$ , the angles which are formed take particular names.

*Interior angles on the same side*, are those which lie within the parallels, and on the same side of the secant line; thus,  $HGB$ ,  $GHD$ , are interior angles on the same side; and so also are the angles  $HGA$ ,  $GHC$ .

*Alternate angles* lie within the parallels, and on different sides of the secant line, but not adjacent;  $AGH$ ,  $GHD$ , are alternate angles; and so also are the angles  $GHC$ ,  $BGH$ .

*Alternate exterior angles* lie without the parallels, and on different sides of the secant line, but not adjacent:  $EGB$ ,  $CHF$ , are alternate exterior angles; so also are the angles  $AGE$ ,  $FHD$ .

*Opposite exterior and interior angles* lie on the same side of the secant line, the one without and the other within the parallels, but not adjacent: thus,  $EGB$ ,  $GHD$ , are opposite exterior and interior angles; and so also, are the angles  $AGE$ ,  $GHC$ .

*Cor. 1.* If two straight lines meet a third line, making the alternate angles equal, the straight lines are parallel.

Let the straight line  $EF$  meet the two straight lines  $CD$ ,  $AB$ , making the alternate angles  $AGH$ ,  $GHD$ , equal to each other: then will  $AB$  and  $CD$  be parallel.

For, to each of the equal angles, add the angle  $HGB$ ; we shall then have

$$AGH + HGB = GHD + HGB.$$

But  $AGH + HGB$  is equal to two right angles (P. 1): hence,  $GHD + HGB$  is also equal to two right angles (A. 1): then  $AB$  and  $CD$  are parallel (P. 19.)

*Cor. 2.* If a straight line  $EF$ , meet two straight lines  $CD$ ,  $AB$ , making the exterior angle  $EGB$ , equal to the interior and opposite angle  $GHD$ , the two lines will be parallel. For, to each add the angle  $HGB$ : we shall then have,

$$EGB + HGB = GHD + HGB:$$

but  $EGB + HGB$  is equal to two right angles; hence,  $GHD + HGB$  is equal to two right angles; therefore,  $CD$ , and  $AB$ , are parallel (P. 19).

PROPOSITION XX. THEOREM.

*If a straight line meet two parallel straight lines, the sum of the interior angles on the same side will be equal to two right angles.*

Let the parallels  $AB$ ,  $CD$ , be met by the secant line  $FE$ : then will  $HGB + GHD$ , or  $HGA + GHC$ , be equal to two right angles.

For, if  $HGB + GHD$  be not equal to two right angles, let  $IGL$  be drawn, making the sum  $HGL + GHD$  equal to two right angles; then  $IL$  and  $CD$  will be parallel (P. 19); and hence, we shall have two lines  $GB$ ,

$GL$ , drawn through the same point  $G$  and parallel to  $CD$ , which is impossible (A. 13): hence,  $HGB + GHD$  is equal to two right angles. In the same manner it may be proved that  $HGA + GHC$  is equal to two right angles.

*Cor. 1.* If  $HGB$  is a right angle,  $GHD$  will be a right angle also: therefore, every straight line perpendicular to one of two parallels, is perpendicular to the other.

*Cor. 2.* If a straight line meet two parallel straight lines, the alternate angles will be equal.

Let  $AB$ ,  $CD$ , be two parallels, and  $FE$  the secant line.

The sum  $HGB + GHD$  is equal to two right angles. But the sum  $HGB + HGA$  is also equal to two right angles (P. 1). Taking from each the angle  $HGB$ , and there remains  $AGH = GHD$ . In the same manner we may prove that  $GHC = HGB$ .

*Cor. 3.* If a straight line meet two parallel lines, the opposite exterior and interior angles will be equal. For, the sum  $HGB + GHD$  is equal to two right angles. But the sum  $HGB + EGB$  is also equal to two right angles. Taking from each the angle  $HGB$ , and there remains  $GHD = EGB$ . In the same manner we may prove that  $GHC = AGE$ .

*Scholium.* We see that of the eight angles formed by a line cutting two parallel lines obliquely, the four acute angles are equal to each other, and so also are the four obtuse angles.

PROPOSITION XXI. THEOREM.

*If two straight lines meet a third line, making the sum of the interior angles on the same side less than two right angles, the two lines will meet if sufficiently produced.*

Let the two lines  $CD, IL$ , meet the line  $EF$ , making the sum of the interior angles  $HGL, GHD$ , less than two right angles: then will  $IL$  and  $CD$  meet if sufficiently produced.

For, if they do not meet they are parallel (D. 16). But they are not parallel, for if they were, the sum of the interior angles  $LGH, GHD$ , would be equal to two right angles (P. 20), whereas it is less by hypothesis: hence, the lines  $IL, CD$ , will meet if sufficiently produced.

*Cor.* It is evident that the two lines  $IL, CD$ , will meet on that side of  $EF$  on which the sum of the two angles  $HGL, GHD$ , is less than two right angles.

PROPOSITION XXII. THEOREM.

*Two straight lines which are parallel to a third line, are parallel to each other.*

Let  $CD$  and  $AB$  be parallel to the third line  $EF$ ; then are they parallel to each other.

Draw  $PQR$  perpendicular to  $EF$ , and cutting  $AB$ ,  $CD$ , in the points  $P$  and  $Q$ . Since  $AB$  is parallel to  $EF$ ,  $PR$  will be perpendicular to  $AB$  (p. 20, c. 1); and since  $CD$  is parallel to  $EF$ ,  $PR$  will for a like reason be perpendicular to  $CD$ . Hence,  $AB$  and  $CD$  are perpendicular to the same straight line; hence, they are parallel (p. 18).

PROPOSITION XXIII. THEOREM.

*Two parallels are everywhere equally distant.*

Let  $CD$  and  $AB$  be two parallel straight lines. Through any two points of  $AB$ , as  $F$  and  $E$ , suppose  $FH$  and  $EG$  to be drawn perpendicular to  $AB$ . These lines will also be perpendicular to  $CD$  (p. 20, c. 1); and we are now to show that they will be equal to each other.

If  $GF$  be drawn, the angles  $GFE$ ,  $FGH$ , considered in reference to the parallels  $AB$ ,  $CD$ , will be alternate angles, and therefore, equal to each other (p. 20, c. 2). Also, the straight lines  $FH$ ,  $EG$ , being perpendicular to the same straight line  $AB$ , are parallel (p. 18); and the angles  $EGF$ ,  $GFH$ , considered in reference to the parallels  $FH$ ,  $EG$ , will be alternate angles, and therefore equal. Hence, the two triangles  $EFG$ ,  $FGH$ , have a common side, and two adjacent angles in each equal; therefore, the triangles are equal (p. 6); consequently,  $FH$ , which measures the distance of the parallels  $AB$  and  $CD$  at the point  $F$ , is equal to  $EG$ , which measures the distance of the same parallels at the point  $E$ .

## PROPOSITION XXIV. THEOREM.

If two angles have their sides parallel and lying in the same direction, they will be equal.

Let  $BAC$  and  $DEF$  be the two angles, having  $AB$  parallel to  $ED$ , and  $AC$  to  $EF$ ; then will they be equal.

For, produce  $DE$ , if necessary, till it meets  $AC$  in  $G$ . Then, since  $EF$  is parallel to  $GC$ , the angle  $DEF$  is equal to  $DGC$  (p. 20, c. 3); and since  $DG$  is parallel to  $AB$ , the angle  $DGC$  is equal to  $BAC$ ; hence, the angle  $DEF$  is equal to  $BAC$  (A. 1).

*Scholium.* The restriction of this proposition to the case where the side  $EF$  lies in the same direction with  $AC$ , and  $ED$  in the same direction with  $AB$ , is necessary, because if  $FE$  were prolonged towards  $H$ , the angle  $DEH$  would have its sides parallel to those of the angle  $BAC$ , but would not be equal to it. In that case,  $DEH$  and  $BAC$  would be together equal to two right angles. For,  $DEH + DEF$  is equal to two right angles (p. 1); but  $DEF$  is equal to  $BAC$ : hence,  $DEH + BAC$  is equal to two right angles.

## PROPOSITION XXV. THEOREM.

In every triangle the sum of the three angles is equal to two right angles.

Let  $ABC$  be any triangle: then will the sum of the angles  $C + A + B$  be equal to two right angles.

For, prolong the side  $CA$  towards  $D$ , and at the point  $A$ , suppose  $AE$  to be drawn, parallel to  $BC$ . Then, since  $AE$ ,  $CB$ , are parallel, and  $CAD$  cuts them, the exterior angle  $DAE$

is equal to its interior opposite angle  $C$  (p. 20, c. 3). In like manner, since  $AE$ ,  $CB$ , are parallel, and  $AB$  cuts them,

the alternate angles  $B$  and  $BAE$ , are equal; hence, the three angles of the triangle  $BAC$  are equal to the three angles  $CAB$ ,  $BAE$ ,  $EAD$ , each to each; but the sum of these three angles is equal to two right angles (P. 1); consequently, the sum of the three angles of the triangle, is equal to two right angles (A. 1).

*Cor. 1.* Two angles of a triangle being given, or merely their sum, the third will be found by subtracting that sum from two right angles.

*Cor. 2.* If two angles of one triangle are respectively equal to two angles of another, the third angles will also be equal, and the two triangles will be mutually equiangular.

*Cor. 3.* In any triangle there can be but one right angle: for if there were two, the third angle must be nothing. Still less, can a triangle have more than one obtuse angle.

*Cor. 4.* In every right-angled triangle, the sum of the two acute angles is equal to one right angle.

*Cor. 5.* Since every equilateral triangle is also equiangular (P. 11, c. 1), each of its angles will be equal to the third part of two right angles; so, that, if the right angle is expressed by unity, each angle of an equilateral triangle will be expressed by  $\frac{2}{3}$ .

*Cor. 6.* In every triangle  $ABC$ , the exterior angle  $BAD$  is equal to the sum of the two interior opposite angles  $B$  and  $C$ . For,  $AE$  being parallel to  $BC$ , the part  $BAE$  is equal to the angle  $B$ , and the other part  $DAE$  is equal to the angle  $C$ .

PROPOSITION XXVI. THEOREM.

*The sum of all the interior angles of a polygon, is equal to twice as many right angles, less four, as the figure has sides.*

Let  $ABCDE$  be any polygon: then will the sum of its interior angles

$$A+B+C+D+E$$

be equal to twice as many right angles, less four, as the figure has sides.

From the vertex of any angle  $A$ , draw diagonals  $AC$ ,  $AD$ , to the vertices of the other angles. It is plain that the polygon will be divided into as many triangles, less two, as it has sides; for, these triangles may be considered as having the point  $A$  for a common vertex, and for bases, the several sides of the polygon, excepting the two sides which form the angle  $A$ . It is evident, also, that the sum of all the angles in these triangles does not differ from the sum of all the angles in the polygon: hence, the sum of all the angles of the polygon is equal to two right angles, taken as many times as there are triangles in the figure; that is, as many times as there are sides, less two. But this product is equal to twice as many right angles as the figure has sides, less four right angles.

*Cor. 1.* The sum of the interior angles in a quadrilateral is equal to two right angles multiplied by  $4-2$ , which amounts to four right angles: hence, if all the angles of a quadrilateral are equal, each of them will be a right angle. Hence, each of the angles of a rectangle, and of a square, is a right angle (D. 25).

*Cor. 2.* The sum of the interior angles of a pentagon is equal to two right angles multiplied by  $5-2$ , which amounts to six right angles: hence, when a pentagon is equiangular, each angle is equal to the fifth part of six right angles, or to  $\frac{2}{5}$  of one right angle.

*Cor. 3.* The sum of the interior angles of a hexagon is equal to  $2 \times (6-2)$ , or eight right angles; hence, in the equiangular hexagon, each angle is the sixth part of eight right angles, or  $\frac{4}{3}$  of one.

*Cor. 4.* In any equiangular polygon, any interior angle is equal to twice as many right angles, less four, as the figure has sides, divided by the number of angles.

*Scholium.* When this proposition is applied to polygons which have *re-entrant* angles, each re-entrant angle must be regarded as greater than two right angles. But to avoid all ambiguity, we shall henceforth limit our reasoning to polygons with *salient* angles, which are named *convex polygons*. Every *convex* polygon is such, that a straight line, drawn at pleasure, cannot meet the sides of the polygon in more than two points.

PROPOSITION XXVII. THEOREM.

*If the sides of any polygon be prolonged, in the same direction, the sum of the exterior angles will be equal to four right angles.*

Let the sides of the polygon *ABCDFG*, be prolonged, in the same direction; then will the sum of the exterior angles

$$a + b + c + d + f + g,$$

be equal to four right angles.

For, each interior angle, plus its exterior angle, as  $A + a$ , is equal to two right angles (P. 1). But there are as many exterior as interior angles, and as many of each as there are sides of the polygon: hence the sum of all the interior

and exterior angles, is equal to twice as many right angles as the polygon has sides. Again, the sum of all the interior angles is equal to twice as many right angles as the figure has sides, less four right angles (P. 26). Hence, the interior angles plus four right angles, is equal to twice as many right angles as the polygon has sides, and consequently, equal to the sum of the interior angles plus the sum of the exterior angles. Taking from each the sum of the interior angles, and there remains the sum of the exterior angles, equal to four right angles.

## PROPOSITION XXVIII THEOREM.

*In every parallelogram, the opposite sides and angles are equal each to each.*

Let  $ABCD$  be a parallelogram: then will  $AB=DC$ ,  $AD=BC$ , the angle  $A=C$ , and the angle  $ADC=ABC$ .

For, draw the diagonal  $BD$ , dividing the parallelogram into the two triangles,  $ABD$ ,  $DBC$ . Now, since  $AD$ ,  $BC$ , are parallel, the angle  $ADB=DBC$  (P. 20, c. 2); and since  $AB$ ,  $CD$ , are parallel, the angle  $ABD=BDC$ : and since the side  $DB$  is common, the two triangles are equal (P. 6); therefore, the side  $AB$ , opposite the angle  $ADB$ , is equal to the side  $DC$ , opposite the equal angle  $DBC$  (P. 10, s.), and the third sides  $AD$ ,  $BC$ , are equal: hence, the opposite sides of a parallelogram are equal.

Again, since the triangles are equal, the angle  $A$  is equal to the angle  $C$  (P. 10, s.) Also, the angle  $ADC$  composed of the two angles,  $ADB$ ,  $BDC$ , is equal to  $ABC$ , composed of the corresponding equal angles  $DBC$ ,  $ABD$  (A. 2): hence, the opposite angles of a parallelogram are equal.

*Cor. 1.* Two parallels  $AB$ ,  $CD$ , included between two other parallels  $AD$ ,  $BC$ , are equal; and the diagonal  $DB$  divides the parallelogram into two equal triangles.

*Cor. 2.* Two parallelograms which have two sides and the included angle in the one equal to two sides and the included angle in the other, each to each, are equal.

Let the parallelogram  $ABCD$ , have the sides  $AB$ ,  $AD$ , and the included angle  $BAD$  equal to the sides  $AB$ ,  $AD$ , and the included angle  $BAD$ , in the next figure; then will they be equal.

For, in each figure, draw the diagonal  $DB$ . By the last corollary, the diagonal divides each parallelogram into two equal triangles: but the triangle  $BAD$  in one parallelogram, is equal to the triangle  $BAD$  in the other (P. 5): hence, the parallelograms are equal (A. 6).

## PROPOSITION XXIX. THEOREM.

*If the opposite sides of a quadrilateral are equal, each to each, the equal sides are parallel, and the figure is a parallelogram.*

Let  $ABCD$  be a quadrilateral, having its opposite sides respectively equal, viz.:  $AB=DC$ , and  $AD=BC$ ; then will these sides be parallel, and the figure a parallelogram.

For, having drawn the diagonal  $BD$  the two triangles  $ABD$ ,  $BDC$ , have all the sides of the one equal to the corresponding sides of the other; therefore they are equal, and the angle  $ADB$ , opposite the side  $AB$ , is equal to  $DBC$ , opposite  $CD$  (P. 10, s.); therefore the side  $AD$  is parallel to  $BC$  (P. 19, c. 1) For a like reason  $AB$  is parallel to  $CD$ : therefore, the quadrilateral  $ABCD$  is a parallelogram.

## PROPOSITION XXX. THEOREM.

*If two opposite sides of a quadrilateral are equal and parallel, the other sides are equal and parallel, and the figure is a parallelogram.*

Let  $ABCD$  be a quadrilateral, having the sides  $AB$ ,  $CD$ , equal and parallel; then will the figure be a parallelogram.

For, draw the diagonal  $DB$ , dividing the quadrilateral into two triangles. Then, since  $AB$  is parallel to  $DC$ , the alternate angles  $ABD$ ,  $BDC$  are equal (P. 20, c. 2); moreover, the side  $DB$  is common, and the side  $AB=DC$ ; hence, the triangle  $ABD$  is equal to the triangle  $DBC$  (P. 5); therefore, the side  $AD$  is equal to  $BC$ , the angle  $ADB=DBC$ , and consequently  $AD$  is parallel to  $BC$  (P. 19, c. 1); hence, the figure  $ABCD$  is a parallelogram.

## PROPOSITION XXXI. THEOREM.

*The two diagonals of a parallelogram divide each other into equal parts, or mutually bisect each other.*

Let  $ADCB$  be a parallelogram,  $AC$  and  $DB$  its diagonals, intersecting at  $E$ ; then will  $AE=EC$ , and  $DE=EB$ .

Comparing the triangles  $AED$ ,  $BEC$ , we find the side  $AD=CB$  (p. 28), the angle  $ADB=CBE$ , and the angle  $DAE=ECB$  (p. 20, c. 2); hence, these triangles are equal (p. 6); consequently,  $AE$ , the side opposite the angle  $ADE$ , is equal to  $EC$ , opposite  $CBE$ , and  $DE$  opposite  $DAE$  is equal to  $EB$  opposite  $ECB$ .

*Scholium.* In the case of the rhombus, the sides  $AB$ ,  $BC$ , being equal, the triangles  $AEB$ ,  $EBC$ , have all the sides of the one equal to the corresponding sides of the other, and are therefore equal: whence, it follows, that the angles  $AEB$ ,  $BEC$ , are equal, and therefore, the two diagonals of a rhombus bisect each other at right angles.

## BOOK II.

### OF RATIOS AND PROPORTIONS.

#### DEFINITIONS.

1. PROPORTION is the relation which one magnitude bears to another magnitude of the same kind, with respect to its being greater or less.\*

2. RATIO is the measure of the proportion which one magnitude bears to another; and is the quotient which arises from dividing the second by the first. Thus, if  $A$  and  $B$  represent magnitudes of the same kind, the ratio of  $A$  to  $B$  is expressed by

$$\frac{B}{A};$$

$A$  and  $B$  are called the terms of the ratio; the first is called the *antecedent*, and the second, the *consequent*.

3. The ratio of magnitudes may be expressed by numbers, either exactly or approximatively; and in the latter case, the approximation may be brought nearer to the true ratio than any assignable difference.

Thus, of two magnitudes, one may be considered to be divided into some number of equal parts, each of the same kind as the whole, and regarding one of these parts as a unit of measure, the magnitude may be expressed by the number of units it contains. If the other magnitude contain an exact number of these units, it also may

---

\* See Davies' *Logic of Mathematics*: Proportion, § 267.

be expressed by the number of its units, and the two magnitudes are then said to be *commensurable*.

If the second magnitude do not contain the measuring unit an exact number of times, there may perhaps be a smaller unit which will be contained an exact number of times in each of the magnitudes. But if there is no unit of an *assignable* value, which is contained an exact number of times in each of the magnitudes, the magnitudes are said to be *incommensurable*.

It is plain, however, that if the unit of measure be repeated as many times as it is contained in the second magnitude, the result will differ from the second magnitude by a quantity less than the unit of measure, since the remainder is always less than the divisor. Now, since the unit of measure may be made as small as we please, it follows, that magnitudes may be represented by numbers to any degree of exactness, or they will differ from their numerical representatives by less than any assignable magnitude.

4. We will illustrate these principles by finding the ratio between the straight lines  $CD$  and  $AB$ , which we will suppose commensurable.

From the greater line  $AB$ , cut off a part equal to the less  $CD$ , as many times as possible; for example, twice, with the remainder  $BE$ .

From the line  $CD$ , cut off a part,  $CF$ , equal to the remainder  $BE$ , as many times as possible; once, for example, with the remainder  $DF$ .

From the first remainder  $BE$ , cut off a part equal to the second,  $DF$ , as many times as possible; once, for example, with the remainder  $BG$ .

From the second remainder  $DF$ , cut off a part equal to  $BG$ , the third remainder, as many times as possible.

Continue this process, till a remainder occurs, which is contained exactly, a certain number of times, in the preceding one.

Then, this last remainder will be the common measure of the proposed lines. Regarding this as unity, we shall

easily find the values of the preceding remainders; and at last, those of the two proposed lines, and hence, their ratio in numbers.

Suppose, for instance, we find  $GB$  to be contained exactly twice in  $FD$ ;  $BG$  will be the common measure of the two proposed lines. Put  $BG=1$ ; we shall then have,  $FD=2$ ; but  $EB$  contains  $FD$  once, plus  $GB$ ; therefore, we have  $EB=3$ :  $CD$  contains  $EB$  once, plus  $FD$ ; therefore, we have  $CD=5$ : and lastly,  $AB$  contains  $CD$  twice, plus  $EB$ ; therefore, we have  $AB=13$ ; hence, the ratio of the lines is that of 5 to 13. If the line  $CD$  were taken for unity, the line  $AB$  would be  $\frac{13}{5}$ ; if  $AB$  were taken for unity,  $CD$  would be  $\frac{5}{13}$ .

5. What has been shown, in respect to the straight lines,  $CD$  and  $AB$ , is equally true of any two magnitudes,  $A$  and  $B$ .

For, we may conceive  $A$  to be divided into a number  $M$  of units, each equal to  $A'$ : then  $A=M \times A'$ : let  $B$  be divided into a number  $N$  of equal units, each equal to  $A'$ ; then  $B=N \times A'$ ;  $M$  and  $N$  being integer numbers. Now the ratio of  $A$  to  $B$ , will be the same as the ratio of  $M \times A'$  to  $N \times A'$ ; that is, the same as the ratio of the numerical quantities  $M$  and  $N$ , since  $A'$  is a common unit.

6. If there be four magnitudes,  $A$ ,  $B$ ,  $C$ , and  $D$ , having such values that

$$\frac{B}{A} = \frac{D}{C},$$

then  $A$  is said to have the same ratio to  $B$ , that  $C$  has to  $D$ ; or, the ratio of  $A$  to  $B$  is said to be equal to the ratio of  $C$  to  $D$ . When four quantities have this relation to each other, they are said to be in *proportion*.

To indicate that the ratio of  $A$  to  $B$  is equal to the ratio of  $C$  to  $D$ , the quantities are usually written thus,

$$A : B :: C : D,$$

and read,  $A$  is to  $B$  as  $C$  is to  $D$ . The quantities which are compared together are called the *terms* of the proportion. The first and last terms are called the *two extremes*, and the second and third terms, the *two means*.

7. Of four proportional quantities, the last is said to be a *fourth proportional* to the other three, taken in order. The first and second terms, are called the *first couplet* of the proportion; and the third and fourth terms, the *second couplet*: the first and third terms are called the *antecedents*, and the second and fourth terms, the *consequents*.

8. Three quantities are in proportion, when the first has the same ratio to the second, that the second has to the third; and then the middle term is said to be a *mean proportional* between the other two.

9. Magnitudes are in proportion by *alternation*, or alternately, when antecedent is compared with antecedent, and consequent with consequent.

10. Magnitudes are in proportion by *inversion*, or *inversely*, when the consequents are taken as antecedents, and the antecedents as consequents.

11. Magnitudes are in proportion by *composition*, when the sum of the antecedent and consequent is compared either with antecedent or consequent.

12. Magnitudes are in proportion by *division*, when the difference of the antecedent and consequent is compared either with antecedent or consequent.

13. Equimultiples of two quantities are the products which arise from multiplying the quantities by the same number: thus,  $m \times A$ ,  $m \times B$ , are equimultiples of  $A$  and  $B$ , the common multiplier being  $m$ .

14. Two varying quantities,  $A$  and  $B$ , are said to be *reciprocally proportional*, or *inversely proportional*, when their values are so changed that one is increased as many times as the other is diminished. In such case, either of them is always equal to a constant quantity divided by the other, and their product is constant.

## PROPOSITION I. THEOREM.

*When four magnitudes are in proportion, the product of the two extremes is equal to the product of the two means.*

Let  $A, B, C, D$ , be any four magnitudes, and  $M, N, P, Q$ , their numerical representatives;

then, if  $M : N :: P : Q$ ,

we shall have  $M \times Q = N \times P$ .

For, since the magnitudes are in proportion, we have (D. 6),

$$\frac{N}{M} = \frac{Q}{P}; \text{ therefore,}$$

$$N = M \times \frac{Q}{P}; \text{ whence, } N \times P = M \times Q.$$

*Cor.* If there are three proportional quantities, the product of the extremes will be equal to the square of the mean (D. 8). For, if  $N = P$ , we have

$$M \times Q = N^2 \text{ or } P^2.$$

## PROPOSITION II. THEOREM.

*If the product of two magnitudes be equal to the product of two other magnitudes, two of them may be made the extremes and the other two the means of a proportion.*

If we have  $M \times Q = N \times P$ ; then will  $M : N :: P : Q$ .

For, if  $P$  have not to  $Q$ , the ratio which  $M$  has to  $N$ , let  $P$  have to  $Q'$ , (a number greater or less than  $Q$ ,) the same ratio which  $M$  has to  $N$ : that is, let

$$M : N :: P : Q';$$

then (P. 1),  $M \times Q' = N \times P$ ;

$$\text{hence, } Q' = \frac{N \times P}{M}; \text{ but, } Q = \frac{N \times P}{M};$$

Consequently,  $Q' = Q$ , and the supposition that it is either greater or less, is absurd; hence, the four magnitudes  $M, N, P, Q$ , are proportional.

## PROPOSITION III. THEOREM.

*If four magnitudes are in proportion, they will be in proportion when taken alternately.*

Let  $M, N, P, Q$ , be four quantities in proportion; so that  
 $M : N :: P : Q$ ; then will  $M : P :: N : Q$ .

For, since  $M : N :: P : Q$ : we have  $M \times Q = N \times P$ ;  
 therefore  $M$  and  $Q$  may be made the extremes, and  $N$  and  
 $P$  the means of a proportion (p. 2);

hence,  $M : P :: N : Q$ .

## PROPOSITION IV. THEOREM.

*If there be four proportional magnitudes, and four other proportional magnitudes, having the antecedents the same in both, the consequents will be proportional.*

Let  $M : N :: P : Q$ , giving  $M \times Q = N \times P$ ,  
 and  $M : R :: P : S$ , giving  $R \times P = M \times S$ ,  
 then will  $N : Q :: R : S$ .

For, multiplying the equations member by member,

$$M \times Q \times R \times P = M \times S \times N \times P;$$

cancelling  $M \times P$  in both members, we have,

$$Q \times R = S \times N: \text{ hence (p. 2),}$$

$$N : Q :: R : S.$$

*Cor.* If there be two sets of proportionals, in which the ratio of an antecedent and consequent of the one is equal to the ratio of an antecedent and consequent of the other, the remaining terms will be proportional.

For, if we had the two proportions,

$$M : P :: N : Q \text{ and } R : S :: T : V,$$

we shall also have

$$\frac{P}{M} = \frac{Q}{N} \text{ and } \frac{S}{R} = \frac{V}{T}$$

$$\text{Now, if } \frac{P}{M} = \frac{S}{R}, \text{ then } \frac{Q}{N} = \frac{V}{T},$$

and we shall have  $N : Q :: T : V$ .

PROPOSITION V. THEOREM.

*If four magnitudes are in proportion, they will be in proportion when taken inversely.*

If  $M : N :: P : Q$ , then will  $N : M :: Q : P$ .  
For, from the given proportion, we have

$$M \times Q = N \times P, \text{ or, } N \times P = M \times Q.$$

Now,  $N$  and  $P$  may be made the extremes, and  $M$  and  $Q$  the means of a proportion (P. 2): hence

$$N : M :: Q : P.$$

PROPOSITION VI. THEOREM.

*If four magnitudes are in proportion, they will be in proportion by composition or division.*

If we have  $M : N :: P : Q$ ,  
we shall also have  $M \pm N : M :: P \pm Q : P$ .

For, from the first proportion, we have

$$M \times Q = N \times P, \text{ or } N \times P = M \times Q.$$

Add each of the members of the last equation to, and subtract it from  $M \times P$ , and we shall have,

$$M \times P \pm N \times P = M \times P \pm M \times Q; \text{ or}$$

$$(M \pm N) \times P = (P \pm Q) \times M.$$

But  $M \pm N$  and  $P$ , may be considered the two extremes, and  $P \pm Q$  and  $M$ , the two means of a proportion (P. 2): hence,

$$(M \pm N) : P :: (P \pm Q) : M.$$

PROPOSITION VII. THEOREM.

*Equimultiples of any two magnitudes, have the same ratio as the magnitudes themselves,*

Let  $M$  and  $N$  be any two magnitudes, and  $m$  any number whatever; then will  $m \times M$ , and  $m \times N$ , be equal mul-

tiples of  $M$  and  $N$ : then  $m \times M$  will be to  $m \times N$ , in the ratio of  $M$  to  $N$ .

For,  $M \times N = N \times M$ :

multiplying each member by  $m$ , and we have

$$m \times M \times N = m \times N \times M: \text{ then (P. 2),}$$

$$m \times M : m \times N :: M : N.$$

PROPOSITION VIII. THEOREM.

*Of four proportional magnitudes, if there be taken any equimultiples of the two antecedents, and any equimultiples of the two consequents, such equimultiples will be proportional.*

Let  $M, N, P, Q$ , be four magnitudes in proportion; and let  $m$  and  $n$  be any numbers whatever, then will

$$m \times M : n \times N :: m \times P : n \times Q.$$

For, since  $M : N :: P : Q$ ,

we have

$$M \times Q = N \times P;$$

hence,

$$m \times M \times n \times Q = n \times N \times m \times P,$$

by multiplying both members of the equation by  $m \times n$ . But  $m \times M$  and  $n \times Q$ , may be regarded as the two extremes, and  $n \times N$  and  $m \times P$ , as the means of a proportion; hence,

$$m \times M : n \times N :: m \times P : n \times Q.$$

PROPOSITION IX. THEOREM.

*Of four proportional magnitudes, if the two consequents be either augmented or diminished by magnitudes which have the same ratio as the antecedents, the resulting magnitudes and the antecedents will be proportional.*

Let  $M : N :: P : Q$ ,

and let  $M : P :: m : n$ ;

then will  $M : P :: N \pm m : Q \pm n$ .

For, since  $M : N :: P : Q$ ,  $M \times Q = N \times P$ .

and since  $M : P :: m : n$ ,  $M \times n = P \times m$ ,

therefore,  $M \times Q \pm M \times n = N \times P \pm P \times m$ ,

or  $M \times (Q \pm n) = P \times (N \pm m)$ :

hence (P. 2),  $M : P :: N \pm m : Q \pm n$ .

PROPOSITION X. THEOREM.

*If any number of magnitudes are proportionals, any one antecedent will be to its consequent, as the sum of all the antecedents to the sum of the consequents.*

Let  $M : N :: P : Q :: R : S$ , &c.

Then since,

$M : N :: P : Q$ , we have  $M \times Q = N \times P$ ,  
 and,  $M : N :: R : S$ , we have  $M \times S = N \times R$ ,  
 add to each  $M \times N = M \times N$ ,  
 then,  $M \times N + M \times Q + M \times S = M \times N + N \times P + N \times R$ ,  
 or,  $M \times (N + Q + S) = N \times (M + P + R)$ ;  
 therefore (P. 2),  $M : N :: M + P + R : N + Q + S$ .

PROPOSITION XI. THEOREM.

*If two magnitudes be each increased or diminished by like parts of each, the resulting magnitudes will have the same ratio as the magnitudes themselves.*

Let  $M$  and  $N$  be any two magnitudes and  $\frac{M}{m}$  and  $\frac{N}{n}$  like parts of each.

We have  $M \times N = M \times N$   
 add to both, or subtr.  $\frac{M \times N}{m} = \frac{M \times N}{m}$ , member by member

and we have (A. 2),  $M \times N \pm \frac{M \times N}{m} = M \times N \pm \frac{M \times N}{m}$ ,

or,  $M \left( N \pm \frac{N}{m} \right) = N \left( M \pm \frac{M}{m} \right)$ ,

that is (P. 2),  $M : N :: M \pm \frac{M}{m} : N \pm \frac{N}{m}$ .

PROPOSITION XII. THEOREM.

*If four magnitudes are proportional, their squares or cubes will also be proportional.*

Let  $M : N : P : Q$ ,

Then will,  $M \times Q = N \times P$ .

By squaring both members,  $M^2 \times Q^2 = N^2 \times P^2$ ,

and by cubing both members,  $M^3 \times Q^3 = N^3 \times P^3$ ;

therefore,  $M^2 : N^2 :: P^2 : Q^2$ ,

and  $M^3 : N^3 :: P^3 : Q^3$ .

*Cor.* In a similar way it may be shown that like powers or roots of proportional magnitudes are proportionals.

PROPOSITION XIII. THEOREM.

*If there be two sets of proportional magnitudes, the products of the corresponding terms will be proportionals.*

Let  $M : N :: P : Q$ ,

and  $R : S :: T : V$ ,

then will  $M \times R : N \times S :: P \times T : Q \times V$ .

For, since  $M \times Q = N \times P$ ,

and  $R \times V = S \times T$ ,

we shall have  $M \times Q \times R \times V = N \times P \times S \times T$ ,

or,  $\overline{M \times R \times Q \times V} = \overline{N \times S \times P \times T}$ ;

therefore,  $\overline{M \times R} : \overline{N \times S} :: \overline{P \times T} : \overline{Q \times V}$ .

PROPOSITION XIV. THEOREM.

*If any number of magnitudes are continued proportionals; then, the ratio of the first to the third will be duplicate of the common ratio; and the ratio of the first to the fourth will be triplicate of the common ratio; and so on.*

For, let  $A$  be the first term, and  $m$  the common ratio: the proportional magnitudes will then be represented by

$$A, m^1 \times A, m^2 \times A, m^3 \times A, m^4 \times A, \&c.:$$

Now, the ratio of the first to any one of the following terms exactly corresponds with the enunciation.

# BOOK III.

## THE CIRCLE, AND THE MEASUREMENT OF ANGLES.

### DEFINITIONS.

1. The CIRCUMFERENCE OF A CIRCLE is a curve line, all the points of which are equally distant from a point within, called the *centre*.

The *circle* is the portion of the plane terminated by the circumference.

2. Every straight line, drawn from the centre to the circumference, is called a *radius*, or, *semidiameter*. Every line which passes through the centre, and is terminated, on both sides, by the circumference, is called a *diameter*.

From the definition of a circle, it follows, that all the radii are equal; that all the diameters are also equal, and each double the radius.

3. Any part of the circumference is called an *arc*. A straight line joining the extremities of an arc, and not passing through the centre, is called a *chord*, or *subtense* of the arc.\*

4. A SEGMENT is the part of a circle included between an arc and its chord.

5. A SECTOR is the part of the circle included between an arc, and the two radii drawn to the extremities of the arc.

---

\* In all cases, the same chord belongs to two arcs, and consequently, also to two segments: but the smaller one is always meant, unless the contrary is expressed.

6. A **STRAIGHT LINE** is said to be *inscribed in a circle*, when its extremities are in the circumference.

An *inscribed angle* is one which has its vertex in the circumference, and is included by two chords of the circle.

7. An *inscribed triangle* is one which has the vertices of its three angles in the circumference.

And generally, a *polygon* is said to be *inscribed in a circle*, when the vertices of all its angles are in the circumference. The circumference of the circle is then said to *circumscribe* the polygon.

8. A **SECANT** is a line which meets the circumference in two points, and lies partly within, and partly without the circle.

9. A **TANGENT** is a line which has but one point in common with the circumference.

The point where the tangent touches the circumference, is called the *point of contact*.

10. Two circumferences *touch* each other when they have but one point in common. The common point is called the *point of tangency*.

11. A polygon is *circumscribed about a circle*, when each of its sides is tangent to the circumference. In the same case, the circle is said to be *inscribed in the polygon*.

#### POSTULATE.

12. Let it be granted that the circumference of a circle may be described from any centre, and with any radius.

PROPOSITION I. THEOREM.

*Every diameter divides the circle and its circumference each into two equal parts.*

Let  $AEBF$  be a circle, and  $AB$  a diameter. Now, if the figure  $AEB$  be applied to  $AFB$ , their common base  $AB$  retaining its position, the curve line  $AEB$  must fall exactly on the curve line  $AFB$ , otherwise there would, in the one or the other, be points unequally distant from the centre, which is contrary to the definition of a circle. Hence, the diameter divides the circle and its circumference, each into two equal parts.

PROPOSITION II. THEOREM.

*Every chord is less than a diameter.*

Let  $AD$  be any chord. Draw the radii  $CA$ ,  $CD$ , to its extremities. We shall then have (B. I., P. 7)\*

$$AD < AC + CD,$$

but  $AC$  plus  $CD$  is equal to  $AB$ ; hence,  $AD < AB$ .

*Cor.* Hence, the greatest line which can be inscribed in a circle is a diameter.

PROPOSITION III. THEOREM.

*A straight line cannot meet the circumference of a circle in more than two points.*

For, if it could meet it in three, those three points would be equally distant from the centre; and there would be three equal straight lines drawn from the same point to the same straight line, which is impossible (B. I., P. 15, c. 2).

---

\* When reference is made from one Proposition to another, in the *same Book*, the number of the Proposition referred to is alone given; but when the Proposition is found in a different Book, the number of the Book is also given.

## PROPOSITION IV. THEOREM.

*In the same circle, or in equal circles, equal arcs are subtended by equal chords: and conversely, equal chords subtend equal arcs.*

Let  $C$  and  $O$  be the centres of two equal circles, and suppose the arc  $AMD$  equal to the arc  $ENG$ : then will the chord  $AD$  be equal to the chord  $EG$ .

For, since the diameters  $AB$ ,  $EF$ , are equal, the semi-circle  $AMDB$  may be applied to the semi-circle  $ENGF$ , and the curve line  $AMDB$  will coincide with the

curve line  $ENGF$ . But the part  $AMD$  is equal to the part  $ENG$ , by hypothesis; hence, the point  $D$  will fall on  $G$ ; therefore, the chord  $AD$  will coincide with  $EG$  (B. I., A. 11), and hence, is equal to it (B. I., A. 14).

*Conversely:* If the chord  $AD$  is equal to the chord  $EG$ , the subtended arcs  $AMD$ ,  $ENG$ , will also be equal.

For, drawing the radii  $CD$ ,  $OG$ , the triangles  $ACD$ ,  $EOG$ , will have their sides equal, each to each, namely,  $AC=EO$ ,  $CD=OG$ , and  $AD=EG$ ; hence, the triangles are themselves equal; and, consequently, the angle  $ACD$  is equal to  $EOG$  (B. I., P. 10.)

Now, place the semi-circle  $ADB$  on its equal  $EGF$ , so that the radius  $AC$  may fall on the equal radius  $EO$ . Then, since the angle  $ACD$  is equal to the angle  $EOG$ , the radius  $CD$  will fall on  $OG$ , and the sector  $AMDC$  will coincide with the sector  $ENGO$ , and the arc  $AMD$  with the arc  $ENG$ : therefore, the arc  $AMD$ , is equal to the arc  $ENG$  (B. I., A. 14).

## PROPOSITION V. THEOREM.

*In equal circles, or in the same circle, a greater arc is subtended by a greater chord: and conversely, the greater chord subtends the greater arc.*

Let  $O$  be the common centre of two equal circles: then, if the arc  $ADH$  is greater than the arc  $AD$ , the chord  $AH$  will be greater than the chord  $AD$ .

For, draw the radii  $CA$ ,  $CD$ ,  $CH$ , and the chords  $AD$ ,  $AH$ . Now, the two sides  $AC$ ,  $CH$ , of the triangle  $ACH$  are equal to the two sides  $AC$ ,  $CD$ , of the triangle  $ACD$ , and the angle  $ACH$ , is greater than  $ACD$ : hence, the third side  $AH$  is greater than the third side  $AD$  (B. I., P. 9); there fore the chord which subtends the greater arc is the greater.

*Conversely:* If the chord  $AH$  is greater than  $AD$ , the arc  $ADH$  will be greater than the arc  $AD$ .

For, if  $ADH$  were equal to  $AD$ , the chord  $AH$  would be equal to the chord  $AD$  (P. 4), which is contrary to the hypothesis: and if the arc  $ADH$  were less than  $AD$ , the chord  $AH$  would be less than  $AD$ , which is also contrary to the hypothesis. Then, since the arc  $ADH$ , subtended by the greater chord, cannot be equal to, nor less than  $AD$ , it must be greater.

*Scholium.* The arcs here treated of are each less than the semi-circumference. If they were greater, the reverse property would have place; for, as the arcs increase, the chords will diminish, and conversely.

PROPOSITION VI. THEOREM.

*The radius which is perpendicular to a chord, bisects the chord, and bisects also the subtended arc of the chord.*

Let  $AB$  be any chord, and  $CG$  a radius perpendicular to it: then will  $AD$  be equal to  $DB$ , and the arc  $AG$  to the arc  $GB$ .

For, draw the radii  $CA$ ,  $CB$ . Then the two right-angled triangles  $ADC$ ,  $CDB$ , will have  $AC$  equal to  $CB$ , and  $CD$  common; hence,  $AD$  is equal to  $DB$  (B. I., P. 17).

Again, since  $AD$ ,  $DB$ , are equal,  $CG$  is a perpendicular

erected from the middle of  $AB$ ; and since  $G$  is a point of this perpendicular, the chords  $AG$  and  $GB$  are equal (B. I., P. 16). But if the chord  $AG$  is equal to the chord  $GB$ , the arc  $AG$  is equal to the arc  $GB$  (P. 4); hence, the radius  $CG$ , at right angles to the chord  $AB$ , divides the arc subtended by that chord into two equal parts.

*Scholium.* The centre  $C$ , the middle point  $D$  of the chord  $AB$ , and the middle point  $G$  of the subtended arc, are three points of the same straight line perpendicular to the chord. But two points determine the position of a straight line (A. 11); hence, every straight line which passes through two of these points, will necessarily pass through the third, and be perpendicular to the chord.

It follows, also, that *the perpendicular raised at the middle point of a chord passes through the centre of the circle, and through the middle point of the subtended arc.*

For, the perpendicular to the chord, drawn from the centre of the circle, passes through the middle point of the chord, and only one perpendicular can be drawn from the same point to the same straight line (B. I., P. 14, c).

PROPOSITION VII. THEOREM.

*Through three given points, not in the same straight line, one circumference may always be made to pass, and but one.*

Let  $A$ ,  $B$ , and  $C$ , be the given points.

Join the points  $A$  and  $B$  by the straight line  $AB$ , and the points  $B$  and  $C$  by the straight line  $BC$ , and then bisect these lines by the perpendiculars  $DE$   $FG$ : we say first, that  $DE$  and  $FG$ , will intersect in some point  $O$ .

For, they intersect each other unless they are parallel (B. I., D. 16). Now, if they are

parallel, the line  $AB$  which is perpendicular to  $DE$ , is also perpendicular to  $FG$ , and the angle  $K$  is a right angle (B. I., P. 20, c. 1). But  $BK$ , the prolongation of  $AB$ , is a different line from  $BF$ , because the three points  $A, B, C$ , are not in the same straight line; hence, there would be two perpendiculars,  $BF, BK$ , let fall from the same point  $B$ , on the same straight line, which is impossible (B. I., P. 14); hence,  $DE, FG$ , are not parallel, and consequently, will intersect in some point  $O$ .

Moreover, since the point  $O$  lies in the perpendicular  $DE$ , it is equally distant from the two points,  $A$  and  $B$  (B. I., P. 16); and since the same point  $O$  lies in the perpendicular  $FG$ , it is also equally distant from the two points  $B$  and  $C$ : hence, the three distances  $OA, OB, OC$ , are equal; therefore, the circumference described from the centre  $O$ , with the radius  $OB$ , will pass through the three given points,  $A, B, C$ .

We have now shown that one circumference can always be made to pass through three given points, not in the same straight line: we say farther, that but one can be described through them.

For, if there were a second circumference passing through the three given points  $A, B, C$ , its centre could not be out of the line  $DE$ , for any point out of this line is unequally distant from  $A$  and  $B$  (B. I., P. 16); neither could it be out of the line  $FG$ , for a like reason; therefore, it would be in both the lines  $DE, FG$ . But two straight lines cannot cut each other in more than one point; hence, there is but one circumference which can pass through three given points.

*Cor.* Two circumferences cannot meet in more than two points; for, if they have three common points, there will be two circumferences passing through the same three points; which has been shown, by the proposition, to be impossible.

## PROPOSITION VIII. THEOREM.

*Two equal chords are equally distant from the centre; and of two unequal chords, the less is at the greater distance from the centre.*

Suppose the chord  $AB$  to be equal to the chord  $DE$ . From  $C$  the centre of the circle, draw  $CF$ , and  $CG$  respectively perpendicular to the chords: then will  $CF$  be equal to  $CG$ .

Draw the radii  $CA$ ,  $CD$ ; then in the right-angled triangles  $CAF$ ,  $D CG$ , the hypotenuses  $CA$ ,  $CD$ , are equal (D. 2); and the side  $AF$ , the half of  $AB$  (P. 6), is equal to the side  $DG$ , the half of  $DE$ : hence, the triangles are equal, and  $CF$  is equal to  $CG$  (B. I., P. 17); consequently, the two equal chords  $AB$ ,  $DE$ , are equally distant from the centre.

*Secondly.* Let the chord  $AH$  be greater than  $DE$ : then will  $DE$  be furthest from the centre  $C$ . Since the chord  $AH$  is greater than  $DE$  the arc  $AKH$  is greater than  $DME$  (P. 5). Cut off from the former, a part  $ANB$ , equal to  $DME$ ; draw the chord  $AB$ , and draw  $CF$  perpendicular to this chord, and  $CI$  perpendicular to  $AH$ . It is evident that  $CF$  is greater than  $CO$  (B. I., A. 8), and  $CO$  than  $CI$  (B. I., P. 15); therefore,  $CF$  is still greater than  $CI$ . But  $CF$  is equal to  $CG$ , because the chords  $AB$ ,  $DE$ , are equal: hence,  $CG$  is greater than  $CI$ ; therefore, of two unequal chords, the less is the farther from the centre of the circle.

## PROPOSITION IX. THEOREM.

*A straight line perpendicular to a radius, at its extremity, is tangent to the circumference.*

Let the line  $BD$  be perpendicular to the radius  $CA$  at its extremity  $A$ ; then will it be tangent to the circumference.

For, every oblique line  $CE$ , is longer than the perpendicular  $CA$  (B. I., P. 15); hence, the point  $E$  is without the circle; therefore, the line  $BD$  has no point but  $A$  in common with the circumference; consequently, the line  $BD$  is a tangent (D. 9).

*Cor. 1.* Conversely, if a straight line be tangent to a circle, it will be perpendicular to the radius drawn to the point of contact.

Let  $BAD$  be a tangent, and  $CA$  a radius drawn through the point of contact  $A$ : then will  $BD$  be perpendicular to  $CA$ . For, through the centre  $C$ , suppose any other line, as  $COE$ , to be drawn. Then, since  $BD$  is a tangent, the point  $E$  will lie without the circle, and consequently  $CE$  will be greater than the radius  $CO$  or  $CA$ ; therefore, the radius  $CA$ , measures the shortest distance from the centre  $C$ , to the tangent  $BD$ : hence, it is perpendicular to the tangent (B. I., P. 15, c. 1).

*Cor. 2.* At a given point of the circumference only one tangent can be drawn to the circle. For, let  $A$  be the given point,  $BD$  a tangent, and  $CA$  the radius drawn through the point of contact  $A$ . Now, if another tangent could be drawn, it would also be perpendicular to  $CA$  at the point  $A$ , by the last corollary: that is, we should have two lines perpendicular to  $CA$ , at the same point; which is impossible (B. I., P. 14, c).

PROPOSITION X. THEOREM.

*Two parallels intercept equal arcs of the circumference.*

There may be three cases.

*First.* When the two parallels are secants. Let  $AB$  and  $DE$  be two parallels: draw the radius  $CH$  perpendicular to the chord  $MP$ . It will, at the same time, be perpendicular to  $NQ$  (B. I., P. 20, c. 1); therefore, the point  $H$  will be at

once the middle of the arc  $MHP$ , and of the arc  $NHQ$  (P. 6); consequently, we shall have the arc  $MH=HP$ , and the arc  $NH=HQ$ ; and therefore

$$MH - NH = HP - HQ;$$

in other words,  $MN=PQ$ .

*Second.* When, of the two parallels  $AB, DE$ , one is a secant, and the other a tangent, draw the radius  $CH$  to the point of contact  $H$ ; it will be perpendicular to the tangent  $DE$  (P. 9, c. 1), and also to its parallel  $MP$  (B. I., P. 20, c. 1). But since  $CH$  is perpendicular to the chord  $MP$ , the point  $H$  must be the middle of the arc  $MHP$  (P. 6); therefore, the arcs  $MH, HP$ , included between the parallels  $AB, DE$ , are equal.

*Third.* If the two parallels  $DE, IL$ , are tangents, the one at  $H$ , the other at  $K$ , draw the parallel secant  $AB$ ; and, from what has just been shown, we shall have

$$MH=HP, MK=KP:$$

and hence, the whole arc  $HMK=HPK$ . It is further evident that each of these arcs is a semi-circumference.

*Cor.* Conversely: If the arc  $HM$  is equal to the arc  $HP$ , it is plain that the chord  $MP$  will be parallel to the tangent  $DE$ .

#### PROPOSITION XI. THEOREM.

*If two circumferences have one point common, out of the straight line which joins their centres, they will also have a second point in common; and the two points will be situated in a line perpendicular to the line joining the centres, and at equal distances from it.*

Let the two circumferences described about the centres  $C$  and  $D$  intersect each other at the point  $A$ ; draw  $AF$

perpendicular to  $CD$ , and prolong it till  $BF$  is equal to  $AF$ ; then will the circumferences also intersect each other at  $B$ .

For, since  $AF$  is equal to  $FB$ ,  $CF$  common and the angles at  $F$  right angles, the hypotenuses  $CB$  and  $CA$  are equal (B. I., P. 5): hence, the circumference described about the centre  $C$ , with the radius  $CA$ , will pass through  $B$ . In the same manner it may be shown, that the circumference described about the centre  $D$ , with the radius  $DA$ , will also pass through  $B$ .

*Cor.* If two circumferences intersect each other, they will intersect in two points, and the line which joins the centres will be perpendicular to the common chord at the middle point.

PROPOSITION XII. THEOREM.

*If the circumferences of two circles intersect each other, the distance between their centres will be less than the sum of their radii, and greater than the difference.*

Let two circumferences be described about the centres  $C$  and  $D$ , with the radii  $CA$  and  $DA$ : then, if these circumferences intersect each other, the triangle  $CAD$  can always be formed. Now, in this triangle,  $CAD$ ,

$$CD < CA + AD \text{ (B. I., P. 7),}$$

also,

$$CD > DA - AC \text{ (B. I., P. 7, C.)}$$

## PROPOSITION XIII. THEOREM.

*If the distance between the centres of two circles is equal to the sum of their radii, the circumferences will touch each other externally.*

Let  $C$  and  $D$  be the centres of two circles at a distance from each other equal to  $CA + AD$ .

The circles will evidently have the point  $A$  common, and they will have no other; because if they have two points common, the distance between their centres must be less than the sum of their radii, which is contrary to the supposition.

*Cor.* If the distance between the centres of two circles is greater than the sum of their radii, the two circumferences will be exterior the one to the other.

## PROPOSITION XIV. THEOREM.

*If the distance between the centres of two circles is equal to the difference of their radii, the two circumferences will touch each other internally.*

Let  $C$  and  $D$  be the centres of two circles at a distance from each other equal to  $AD - CA$ .

It is evident, as before, that the two circumferences will have the point  $A$  common: they can have no other; because if they had, the distance between the centres would be greater than  $AD - CA$  (P. 12); which is contrary to the supposition.

*Cor.* 1. Hence, if two circles touch each other, either externally or internally, their centres and the point of contact will be in the same straight line.

*Cor.* 2. If the distance between the centres of two

circles is less than the difference of their radii, one circle will be entirely within the other.

*Scholium* 1. All circles which have their centres on the right line  $AD$ , and which pass through the point  $A$ , are tangent to each other at the point  $A$ . For, they have only the point  $A$  common, and if through  $A$ ,  $AE$  be drawn perpendicular to  $AD$ , it will be a common tangent to all the circles.

*Scholium*. 2. Two circumferences must occupy with respect to each other, one of the five positions above indicated.

- 1st. They may intersect each other in two points :
- 2d. They may touch each other externally :
- 3d. They may be external, the one to the other :
- 4th. They may touch each other internally :
- 5th. The one may be entirely within the other.

PROPOSITION XV. THEOREM.

*In the same circle, or in equal circles, radii making equal angles at the centre, intercept equal arcs on the circumference. And conversely : If the arcs intercepted are equal, the angles contained by the radii are also equal.*

Let  $C$  and  $C$  be the centres of equal circles, and the angle  $ACB = DCE$ .

*First.* Since the angles  $ACB$ ,  $DCE$ , are equal, one of them may be placed upon the other. Let the angle  $ACB$  be placed on  $DCE$ . Then since their sides are equal,

the point  $A$  will evidently fall on  $D$ , and the point  $B$  on  $E$ . The arc  $AB$  will also fall on the arc  $DE$ ; for, if the arcs did not exactly coincide, there would, in the one or the other, be points unequally distant from the centre; which is impossible: hence, the arc  $AB$  is equal to  $DE$  (A. 14).

*Second.* If the arc  $AB = DE$ , the angle  $ACB$  is equal

to  $DCE$ . For, if these angles are not equal, suppose one of them, as  $ACB$ , to be the greater, and let  $ACI$  be taken equal to  $DCE$ . From what has just been shown, we shall then have  $AI = DE$ ; but, by hypothesis,  $AB$  is equal to  $DE$ ; hence,  $AI$  must be equal to  $AB$ , or a part equal to the whole, which is absurd (A. 8); hence, the angle  $ACB$  is equal to  $DCE$ .

PROPOSITION XVI. THEOREM.

*In the same circle, or in equal circles, if two angles at the centre have to each other the ratio of two whole numbers, the intercepted arcs will have to each other the same ratio: or, we shall have the angle to the angle, as the corresponding arc to the corresponding arc.*

Suppose, for example, that the angles  $ACB$ ,  $DCE$ , are to each other as 7 is to 4; or, what is the same thing, suppose that the angle  $M$ , which may serve as a common measure, is contained 7 times in the angle  $ACB$ , and 4

times in  $DCE$ . The seven partial angles  $ACm$ ,  $mCn$ ,  $nCp$ , &c., into which  $ACB$  is divided, are each equal to any of the four partial angles into which  $DCE$  is divided; and each of the partial arcs,  $Am$ ,  $mn$ ,  $np$ , &c., is equal to each of the partial arcs  $Dx$ ,  $xy$ , &c. (p. 15). Therefore, the whole arc  $AB$  will be to the whole arc  $DE$ , as 7 is to 4. But the same reasoning would evidently apply, if in place of 7 and 4 any numbers whatever were employed; hence, if the angles  $ACB$ ,  $DCE$ , are to each other as two whole numbers, they will also be to each other as the arcs  $AB$ ,  $DE$ .

*Cor.* Conversely: If the arcs  $AB$ ,  $DE$ , are to each other as two whole numbers, the angles  $ACB$ ,  $DCE$  will be to

each other as the same whole numbers, and we shall have

$$AB : DE :: ACB : DCE.$$

For, the partial arcs,  $Am$ ,  $mn$ , &c., and  $Dx$ ,  $xy$ , &c., being equal, the partial angles  $ACm$ ,  $mCn$ , &c., and  $DCx$ ,  $xCy$ , &c., will also be equal, and the entire arcs will be to each other as the entire angles.

PROPOSITION XVII. THEOREM.

*In the same circle, or in equal circles, any two angles at the centre are to each other as the intercepted arcs.*

Let  $ACB$  and  $ACD$  be two angles at the centres of equal circles: then will

$$ACB : ACD :: AB : AD.$$

For, if the angles are equal, the arcs will be equal (P. 15). If they are unequal, let the less be placed on the greater. Then, if the proposition is not true, the

angle  $ACB$  will be to the angle  $ACD$  as the arc  $AB$  is to an arc greater or less than  $AD$ . Suppose such arc to be greater, and let it be represented by  $AO$ ; we shall thus have,

$$\text{the angle } ACB : \text{angle } ACD :: \text{arc } AB : \text{arc } AO.$$

Next conceive the arc  $AB$  to be divided into equal parts, each of which is less than  $DO$ ; there will be at least one point of division between  $D$  and  $O$ ; let  $I$  be that point; and draw  $CI$ . Then the arcs  $AB$ ,  $AI$ , will be to each other as two whole numbers, and by the preceding theorem, we shall have,

$$\text{angle } ACB : \text{angle } ACI :: \text{arc } AB : \text{arc } AI.$$

Comparing the two proportions with each other, we see that the antecedents in each are the same: hence, the consequents are proportional (B. II., P. 4); and thus we find,

$$\text{the angle } ACD : \text{angle } ACI :: \text{arc } AO : \text{arc } AI.$$

But the arc  $AO$  is greater than the arc  $AI$ ; hence, if this proportion is true, the angle  $ACD$  must be greater than the

angle  $ACI$ : on the contrary, however, it is less; hence, the angle  $ACB$  cannot be to the angle  $ACD$  as the arc  $AB$  is to an arc greater than  $AD$ .

By a process of reasoning entirely similar, it may be shown that the fourth term of the proportion cannot be less than  $AD$ ; hence, it is  $AD$  itself; therefore, we have

$$\text{angle } ACB : \text{angle } ACD :: \text{arc } AB : \text{arc } AD.$$

*Scholium 1.* Since the angle at the centre of a circle, and the arc intercepted by its sides, have such a connection, that if the one be augmented or diminished, the other will be augmented or diminished in the same ratio, we are authorized to assume the one of these magnitudes as the measure of the other; and we shall henceforth assume the arc  $AB$  as the measure of the angle  $ACB$ . It is only necessary, in the comparison of angles with each other, that the arcs which serve to measure them, be described with equal radii.

*Scholium 2.* An angle less than a right angle will be measured by an arc less than a quarter of the circumference: a right angle, by a quarter of the circumference: and an obtuse angle by an arc greater than a quarter, and less than half the circumference.

*Scholium 3.* It appears most natural to measure a quantity by a quantity of the same species; and upon this principle it would be convenient to refer all angles to the right angle. This being made the unit of measure, an acute angle would be expressed by some number between 0 and 1; an obtuse angle by some number between 1 and 2. This mode of expressing angles would not, however, be the most convenient in practice. It has been found more simple to measure them by the arcs of a circle, on account of the facility with which arcs can be made to correspond to angles, and for various other reasons. At all events, if the measurement of angles by the arcs of a circle is in any degree indirect, it is still very easy to obtain the direct and absolute measure by this method; since, by comparing the fourth part of the circumference with the arc which serves as a measure of any angle, we find the ratio of a right angle to the given angle, which is the *absolute measure*.

*Scholium 4.* All that has been demonstrated in the last three propositions, concerning the comparison of angles with arcs, holds true equally, if applied to the comparison of sectors with arcs. For, sectors are not only equal when their angles are so, but are in all respects proportional to their angles; hence, *two sectors  $AOB, AOD$ , taken in the same circle, or in equal circles, are to each other as the arcs  $AB, AD$ , the bases of those sectors.* Hence, it is evident that the arcs of equal circles, which serve as a measure of corresponding angles, are proportional to their sectors.

PROPOSITION XVIII. THEOREM.

*Any inscribed angle is measured by half the arc included between its sides.*

Let  $BAD$  be an inscribed angle, and let us first suppose the centre of the circle to lie within the angle  $BAD$ . Draw the diameter  $ACE$ , and the radii  $CB, CD$ .

The angle  $BCE$ , being exterior to the triangle  $ABC$ , is equal to the sum of the two interior angles  $CAB, ABC$  (B. I., P. 25, c. 6): but the triangle  $BAC$  being isosceles, the angle  $CAB$  is equal to  $ABC$ ; hence, the angle  $BCE$  is double  $BAC$ . Since  $BCE$  is at the centre, it is measured by the arc  $BE$  (P. 17, s. 1); hence,  $BAC$  will be measured by the half of  $BE$ . For a like reason, the angle  $CAD$  will be measured by the half of  $ED$ ; hence,  $BAC + CAD$ , or  $BAD$  will be measured by half of  $BE + ED$ , or half of  $BED$ .

*Secondly.* Suppose the centre  $C$  to lie without the angle  $BAD$ . Then, drawing the diameter  $ACE$ , the angle  $BAE$  will be measured by the half of  $BE$ ; the angle  $DAE$  by the half of  $DE$ : hence, their difference,  $BAD$ , will be measured by the half of  $BE$  minus the half of  $ED$ , or by the half of  $BD$ . Hence, every inscribed angle is measured by half the arc included between its sides.

*Cor. 1.* All the angles  $BAC$ ,  $BDC$ ,  $BEC$ , inscribed in the same segment are equal; because they are each measured by half of the same arc  $BOC$ .

*Cor. 2.* Every angle  $BAD$ , inscribed in a semicircle is a right angle; because it is measured by half the semicircumference  $BOD$ , that is, by the fourth part of the whole circumference (P. 17, s. 2).

*Cor. 3.* Every angle  $BAC$ , inscribed in a segment greater than a semicircle, is an acute angle; for it is measured by half the arc  $BOC$ , less than a semicircumference (P. 17, s. 2).

And every angle  $BOC$ , inscribed in a segment less than a semicircle, is an obtuse angle; for it is measured by half the arc  $BAC$ , greater than a semicircumference.

*Cor. 4.* The opposite angles  $A$  and  $C$ , of an inscribed quadrilateral  $ABCD$ , are together equal to two right angles: for, the angle  $BAD$  is measured by half the arc  $BCD$ , the angle  $BCD$  is measured by half the arc  $BAD$ ; hence, the two angles  $BAD$ ,  $BCD$ , taken together, are measured by half the circumference; hence, their sum is equal to two right angles (P. 17, s. 2).

PROPOSITION XIX. THEOREM.

*The angle formed by two chords, which intersect each other, is measured by half the sum of the arcs included between its sides.*

Let  $AB$ ,  $CD$ , be two chords intersecting each other at  $E$ : then will the angle  $AEC$ , or  $DEB$ , be measured by half of  $AC+DB$ .

Draw  $AF$  parallel to  $DC$ : the arc  $DF$  will be equal to  $AC$  (p. 10), and the angle  $FAB$  equal to the angle  $DEB$  (B. I., p. 20, c. 3). But the angle  $FAB$  is measured by half the arc  $FDB$  (p. 18); therefore,  $DEB$  is measured by half of  $FDB$ ; that is, by half of  $DB+DF$ , or half of  $DB+AC$ .

To prove the same for the angle  $DEA$ , or its equal  $BEC$ . Draw the chord  $AC$ . Then, the angle  $DCA$  will be measured by half the arc  $DFA$ ; and the angle  $BAC$  by half the arc  $CB$  (p. 18). But the outward angle  $AED$ , of the triangle  $EAC$ , is equal to the sum of the angles  $A$  and  $C$  (B. I., p. 25, c. 6); hence, this angle is measured by one-half of  $BC$  plus one-half of  $AFD$ ; that is, by half the sum of the intercepted arcs. By drawing a chord  $BC$ , similar reasoning would apply to the angle  $AEC$  or  $DEB$ .

PROPOSITION XX. THEOREM.

*The angle formed by two secants, is measured by half the difference of the arcs included between its sides.*

Let  $AB, AC$ , be two secants: then will the angle  $BAC$  be measured by half the difference of the arcs  $BEC$  and  $DF$ .

Draw  $DE$  parallel to  $AC$ : the arc  $EC$  will be equal to  $DF$  (p. 10), and the angle  $BDE$  equal to the angle  $BAC$  (B. I., p. 20, c. 3). But  $BDE$  is measured by half the arc  $BE$  (p. 18); hence,  $BAC$  is also measured by half the arc  $BE$ ; that is, by half the difference of  $BEC$  and  $EC$ , and consequently, by half the difference of  $BEC$  and  $DF$ .

## PROPOSITION XXI. THEOREM.

*Any angle formed by a tangent and a chord passing through the point of contact, is measured by half the arc included between its sides.*

Let  $BE$  be a tangent, and  $AC$  a chord.

From  $A$ , the point of contact, draw the diameter  $AD$ . The angle  $BAD$  is a right angle (P. 9), and is measured by half the semicircumference  $AMD$  (P. 17, s. 2); the angle  $DAC$  is measured by the half of  $DC$ ; hence,  $BAD + DAC$ , or  $BAC$ , is measured by the half of  $AMD$  plus the half of  $DC$ , or by half the whole arc  $AMDC$ .

It may be shown, by taking the difference of the angles  $DAE$ ,  $DAC$ , that the angle  $CAE$  is measured by half the arc  $AC$ , included between its sides.

## PROBLEMS

## RELATING TO THE FIRST AND THIRD BOOKS

## PROBLEM I.

*To bisect a given straight line.*

Let  $AB$  be the given straight line.

From the points  $A$  and  $B$  as centres, with a radius greater than the half of  $AB$ , describe two arcs cutting each other in  $D$ ; the point  $D$  will be equally distant from  $A$  and  $B$ . Find, in like manner, above or beneath the line  $AB$ , a second point  $E$ , equally distant from the points  $A$  and  $B$ ; through the two points  $D$  and  $E$ , draw the line  $DE$ , and the point  $C$ , where this line meets  $AB$ , will be equally distant from  $A$  and  $B$ .

For, the two points  $D$  and  $E$ , being each equally distant from the extremities  $A$  and  $B$ , must both lie in the perpendicular raised at the middle point of  $AB$  (B. I., P. 16, c). But only one straight line can be drawn through two given points (A. 11); hence, the line  $DE$  must itself be that perpendicular, which divides  $AB$  into two equal parts.

PROBLEM II.

*At a given point, in a given straight line, to erect a perpendicular to that line.*

Let  $BC$  be the given line, and  $A$  the given point.

Take the points  $B$  and  $C$  at equal distances from  $A$ ; then from the points  $B$  and  $C$  as centres, with a radius greater than  $BA$ , describe two arcs intersecting each other at  $D$ ; draw  $AD$  and it will be the perpendicular required.

For, the point  $D$ , being equally distant from  $B$  and  $C$ , must be in the perpendicular raised at the middle of  $BC$  (B. I., P. 16); and since two points determine a line,  $AD$  is that perpendicular.

*Scholium.* The same construction serves for making a right angle  $BAD$ , at a given point  $A$ , on a given straight line  $BC$ .

PROBLEM III.

*From a given point, without a straight line, to let fall a perpendicular on that line.*

Let  $A$  be the point, and  $BD$  the given straight line.

From the point  $A$  as a centre, and with a radius sufficiently great, describe an arc cutting the line  $BD$  in two points  $B$  and  $D$ ; then mark a point  $E$ , equally distant from the points  $B$  and  $D$ , and draw  $AE$ : it will be the perpendicular required.

For, the two points  $A$  and  $E$  are each equally distant from the points  $B$  and  $D$ ; hence, the line  $AE$  is a perpendicular passing through the middle of  $BD$  (B. I., P. 16, c).

## PROBLEM IV.

*At a point in a given line, to construct an angle equal to a given angle.*

Let  $A$  be the given point,  $AB$  the given line, and  $IKL$ , the given angle.

From the vertex  $K$ , as a centre, with any radius,  $KI$ , describe the arc  $IL$ , terminating in the sides of the angle.

From the point  $A$  as a centre, with a distance  $AB$ , equal to  $KI$ , describe the indefinite arc  $BO$ ; then take a radius equal to the chord  $LI$ , with which, from the point  $B$  as a centre, describe an arc cutting the indefinite arc  $BO$ , in  $D$ ; draw  $AD$ ; and the angle  $BAD$  will be equal to the given angle  $K$ .

For, the two arcs  $BD$ ,  $LI$ , have equal radii, and equal chords; hence, they are equal (P. 4); therefore, the angles  $BAD$ ,  $IKL$ , measured by them, are also equal (P. 15).

## PROBLEM V.

*To bisect a given arc, or a given angle.*

*First.* Let it be required to divide the arc  $AEB$  into two equal parts. From the points  $A$  and  $B$ , as centres, with equal radii, describe two arcs cutting each other in  $D$ ; through the point  $D$  and the centre  $C$ , draw  $CD$ : it will bisect the arc  $AB$  in the point  $E$ .

For, the two points  $C$  and  $D$  are each equally distant from the extremities  $A$  and  $B$  of the chord  $AB$ ; hence, the line  $CD$  bisects the chord at right angles (B. I., P. 16, c); and consequently, it bisects the arc  $AEB$  in the point  $E$  (P. 6).

*Secondly.* Let it be required to divide the angle  $ACB$  into two equal parts. We begin by describing, from the vertex  $C$ , as a centre, the arc  $AEB$ ; which is then bisect-

ed as above. It is plain that the line  $CD$  will divide the angle  $ACB$  into two equal parts (P. 17, s. 1).

*Scholium.* By the same construction, each of the halves  $AE$ ,  $EB$ , may be divided into two equal parts; and thus, by successive subdivisions, a given angle, or a given arc, may be divided into four equal parts, into eight, into sixteen, and so on.

PROBLEM VI.

*Through a given point, to draw a line parallel to a given straight line.*

Let  $A$  be the given point, and  $BC$  the given line.

From the point  $A$  as a centre, with a radius  $AE$ , greater than the shortest distance from  $A$  to  $BC$ , describe the indefinite arc  $EO$ ; from the point  $E$  as a centre, with the same radius, describe the arc  $AF$ ; lay off  $ED = AF$ , and draw  $AD$ : this is the parallel required.

For, drawing  $AE$ , the angles  $AEF$ ,  $EAD$ , are equal (P. 15); therefore, the lines  $AD$ ,  $EF$ , are parallel (B. I., P. 19, c. 1).

PROBLEM VII.

*Two angles of a triangle being given, to find the third.*

Let  $A$  and  $B$  be the given angles.

Draw the indefinite line  $DEF$ ; at any point as  $E$ , make the angle  $DEC$  equal to the angle  $A$ , and the angle  $CEH$  equal to the other angle  $B$ : the remaining angle  $HEF$  will be the third angle required; because, these three angles are together equal to two right angles (B. I., P. 1, c. 3), and so are the three angles of a triangle (B. I., P. 25); consequently,  $HEF$  is equal to the third angle of the triangle.

## PROBLEM VIII.

*Two sides of a triangle, and the angle which they contain, being given, to construct the triangle.*

Let the lines  $B$  and  $C$  be equal to the given sides, and  $A$  the given angle.

Having drawn the indefinite line  $DF$ , make at the point  $D$ , the angle  $FDE$  equal to the given angle  $A$ ; then take  $DG=B$ ,  $DH=C$ , and draw  $GH$ :  $DGH$  will be the triangle required (B. I., P. 5).

## PROBLEM IX.

*A side and two angles of a triangle being given, to construct the triangle.*

The two angles will either be both adjacent to the given side, or one will be adjacent, and the other opposite: in the latter case find the third angle (PROB. 7), and the two adjacent angles will be known. Then draw the straight line  $DE$ , and make it equal to the given side: at the point  $D$ , make an angle  $EDF$ , equal to one of the adjacent angles, and at  $E$ , an angle  $DEG$  equal to the other; the two lines  $DF$ ,  $EG$ , will intersect each other in  $H$ ; and  $DEH$  will be the triangle required (B. I., P. 6).

## PROBLEM X.

*The three sides of a triangle being given, to construct the triangle.*

Let  $A$ ,  $B$ , and  $C$ , denote the three given sides.

Draw  $DE$ , and make it equal to the side  $A$ ; from the point  $D$  as a centre, with a radius equal to the second side  $B$ , describe an arc; from  $E$  as a centre, with a radius equal to the third side  $C$ ,

describe another arc intersecting the former in  $F$ ; draw  $DF$ ,  $EF$ ; and  $DEF$  will be the triangle required (B. I., P. 10).

*Scholium.* If one of the sides were greater than the sum of the other two, the arcs would not intersect each other, for no such triangle could exist (B. I., P. 7): but the solution will always be possible, when the sum of any two of the lines, is greater than the third.

PROBLEM XI.

*Two sides of a triangle, and the angle opposite one of them, being given, to construct the triangle.*

Let  $A$  and  $B$  be the given sides, and  $C$  the given angle. There are two cases.

*First.* When the angle  $C$  is a right angle, or when it is obtuse. Draw  $DF$  and make the angle  $FDE = C$ ; take  $DE = A$ : from the point  $E$  as a centre, with a radius equal to the given side  $B$ , describe an arc cutting  $DF$  in  $F$ ; draw  $EF$ ; then  $DEF$  will be the triangle required.

In this case, the side  $B$  must be greater than  $A$ ; for the angle  $C$  being a right angle, or an obtuse angle, is the greatest angle of the triangle (B. I., P. 25, c. 3), and the side opposite to it must, therefore, also be the greatest (B. I., P. 13).

*Secondly.* If the angle  $C$  is acute, and  $B$  greater than  $A$ , the same construction will again apply, and  $DEF$  will be the triangle required.

But if the angle  $C$  is acute, and the side  $B$  less than  $A$ , then the arc described from the centre  $E$ , with the radius  $EF = B$ , will cut the side  $DF$  in two points  $F$  and  $G$ , lying on the same side of  $D$ : hence, there will be two triangles  $DEF$ ,  $DEG$ , either of which will satisfy all the conditions of the problem.

*Scholium.* If the arc described with  $E$  as a centre, should be tangent to the line  $DG$ , the triangle would be right angled, and there would be but one solution. The problem will be impossible in all cases, when the side  $B$  is less than the perpendicular let fall from  $E$  on the line  $DF$ .

## PROBLEM XII.

*The adjacent sides of a parallelogram and their included angle being given, to construct the parallelogram.*

Let  $A$  and  $B$  be the given sides, and  $C$  the given angle.

Draw the line  $DH$ , and lay off  $DE$  equal to  $A$ : at the point  $D$ , make the angle  $EDF = C$ ; take  $DF = B$ ; describe two arcs, the one from  $F$  as a centre, with a radius  $FG = DE$ , the other from  $E$  as a centre, with a radius  $EG = DF$ ;

to the point  $G$ , where these arcs intersect each other, draw  $FG$ ,  $EG$ ;  $DEGF$  will be the parallelogram required.

For, the opposite sides are equal, by construction; hence, the figure is a parallelogram (B. I., P. 29); and it is formed with the given sides and the given angle.

*Cor.* If the given angle is a right angle, the figure will be a rectangle; if, in addition to this, the sides are equal, it will be a square.

## PROBLEM XIII.

*To find the centre of a given circle or arc.*

Take three points,  $A$ ,  $B$ ,  $C$ , anywhere in the circumference, or in the arc; draw  $AB$ ,  $BC$ , or suppose them to be drawn; bisect these two lines by the perpendiculars  $DE$ ,  $FG$  (PROB. 1): the point  $O$ , where these perpendiculars meet, will be the centre sought (P. 6, s).

*Scholium.* The same construction serves for making a circumference pass through three given points  $A, B, C$ ; and also for describing a circumference, which shall circumscribe a given triangle  $ABC$ .

PROBLEM XIV.

*Through a given point, to draw a tangent to a given circle.*

Let  $A$  be the given point, and  $C$  the centre of the given circle.

If the given point  $A$  lies in the circumference, draw the radius  $CA$ , and erect  $AD$  perpendicular to it:  $AD$  will be the tangent required (P. 9).

If the point  $A$  lies without the circle, join  $A$  and the centre, by the straight line  $CA$ : bisect  $CA$  in  $O$ ; from  $O$  as a centre, with the radius  $OC$ , describe a circumference intersecting the given circumference in  $B$ ; draw  $AB$ : this will be the tangent required.

For, drawing  $CB$ , the angle  $CBA$  being inscribed in a semicircle is a right angle (P. 18, c. 2); therefore,  $AB$  is a perpendicular at the extremity of the radius  $CB$ ; hence, it is a tangent (P. 9).

*Scholium 1.* When the point  $A$  lies without the circle, there will be two equal tangents,  $AB, AD$ , passing through the point  $A$ : for, there will be two right-angled triangles,  $CBA, CDA$ , having the hypotenuse  $CA$  common, and the side  $CB = CD$ ; hence, there will be two equal tangents,  $AB, AD$ . The angles  $CAD, CAB$ , are also equal (B. 1., P. 17).

*Scholium 2.* As there can be but one line bisecting the angle  $BAD$ , it follows, that the line which bisects the angle formed by two tangents, must pass through the centre of the circle.

## PROBLEM XV.

*To inscribe a circle in a given triangle.*

Let  $ABC$  be the given triangle.

Bisect the angles  $A$  and  $B$ , by the lines  $AO$  and  $BO$ , meeting in the point  $O$  (PROB. 5); from the point  $O$ , let fall the perpendiculars  $OD, OE, OF$  (PROB. 3), on the three sides of the triangle: these perpendiculars will all be equal.

For, by construction, we have the angle  $DAO = OAF$ , the right angle  $ADO = AFO$ ; hence, the third angle  $AOD$  is equal to the third  $AOF$  (B. I., P. 25, c. 2). Moreover, the side  $AO$  is common to the two triangles  $AOD, AOF$ ; and the angles adjacent to the equal side are equal: hence, the triangles themselves are equal (B. I., P. 6); and  $DO$  is equal to  $OF$ . In the same manner it may be shown that the two triangles  $BOD, BOE$ , are equal; therefore  $OD$  is equal to  $OE$ ; hence, the three perpendiculars  $OD, OE, OF$ , are all equal.

Now, if from the point  $O$  as a centre, with the radius  $OD$ , a circle be described, this circle will be inscribed in the triangle  $ABC$  (D. 11); for, the side  $AB$ , being perpendicular to the radius at its extremity, is a tangent (P. 9); and the same thing is true of the sides  $BC, AC$ .

*Scholium.* The three lines which bisect the three angles of a triangle meet in the same point.

## PROBLEM XVI.

*On a given straight line to describe a segment that shall contain a given angle; that is to say, a segment such, that any angle inscribed in it shall be equal to a given angle.*

Let  $AB$  be the given straight line, and  $C$  the given angle.

Produce  $AB$  towards  $D$ . At the point  $B$ , make the angle  $DBE=C$ ; draw  $BO$  perpendicular to  $BE$ , and at the middle point  $G$ , draw  $GO$  perpendicular to  $AB$ : from the point  $O$ , where these perpendiculars meet, as a centre, with the distance  $OB$ , describe a circumference: the required segment will be  $AMB$ .

For, since  $BF$  is perpendicular to the radius  $OB$  at its extremity, it is a tangent (P. 9), and the angle  $ABF$  is measured by half the arc  $AKB$  (P. 21). Also, the angle  $AMB$ , being an inscribed angle, is measured by half the arc  $AKB$  (P. 18): hence, we have  $AMB=ABF=EBD=C$ : hence, any angle inscribed in the segment  $AMB$  is equal to the given angle  $C$ .

*Scholium.* If the given angle were a right angle, the required segment would be a semicircle described on  $AB$  as a diameter.

PROBLEM XVII.

*Two angles being given, to find their common measure, if they have one, and by means of it, their ratio in numbers.*

Let  $CAD$  and  $EBF$  be the given angles. With  $A$  and  $B$  as centres, and with equal radii describe the arcs  $CD$ ,  $EF$ , to serve as measures for the angles.

Afterwards, proceed in the comparison of the arcs  $CD$ ,  $EF$ , in the same manner as in the comparison of two straight lines (B. II., D. 4); since an arc may be cut off from an arc of the same radius, as a straight

line from a straight line. We shall thus arrive at the common measure of the arcs  $CD$ ,  $EF$ , if they have one, and thereby at their ratio in numbers. This ratio will be the same as that of the given angles (P. 17); and if  $DO$  is the common measure of the arcs, the angle  $DAO$  will be that of the angles.

*Scholium.* According to this method, the absolute value of an angle may be found by comparing the arc which measures it, with a quarter circumference. For example, if a quarter circumference is to the arc  $CD$  as 3 to 1, then, the angle  $A$  will be  $\frac{1}{3}$  of one right angle, or  $\frac{1}{12}$  of four right angles.

It may also happen, that the arcs compared have no common measure; in which case, the numerical ratios of the angles will only be found approximately with more or less correctness, according as the operation is continued a greater or less number of times.

## BOOK IV.

### PROPORTIONS OF FIGURES—MEASUREMENT OF AREAS.

#### DEFINITIONS.

1. SIMILAR FIGURES are those which are mutually equiangular (B. I., D. 22), and have their sides about the equal angles, taken in the same order, proportional.

2. In figures which are mutually equiangular, the angles which are equal, each to each, are called *homologous* angles: and the sides which are like situated, in respect to the equal angles, are called *homologous* sides.

3. AREA, denotes the superficial contents of a figure. The area of a figure is expressed numerically by the number of times which the figure contains some other figure regarded as a unit of measure.

4. EQUIVALENT FIGURES are those which have equal areas. The term *equal*, when applied to quantity in general, denotes an equality of measures; but when applied to geometrical figures it denotes an equality in every respect; and such figures when applied the one to the other, coincide in all their parts (A. 14). The term *equivalent*, denotes an equality in one respect only; viz.: an equality between the measures of figures. The sign  $\simeq$ , denotes equivalency, and is read, *is equivalent to*.

5. Two sides of one figure are said to be *reciprocally proportional* to two sides of another, when one of the sides of the first is to one of the sides of the second, as the remaining side of the second is to the remaining side of the first.

6. SIMILAR ARCS, SECTORS, or, SEGMENTS, are those, which in different circles, correspond to equal angles at the centre.

Thus, if the angles  $A$  and  $O$  are equal, the arc  $BFC$  will be similar to  $DGE$ , the sector  $BAC$  to the sector  $DOE$ , and the segment  $BCF$ , to the segment  $DEG$ .

7. The ALTITUDE of a triangle is the perpendicular let fall from the vertex of an angle on the opposite side, or on that side produced: such side is then called a *base*.

8. The *altitude* of a parallelogram is the perpendicular distance between two opposite sides. These sides are called *bases*.

9. The *altitude* of a trapezoid is the perpendicular distance between its two parallel sides.

#### PROPOSITION I. THEOREM.

*Parallelograms which have equal bases and equal altitudes, are equivalent.*

Since the two parallelograms have equal bases, those bases may be placed the one on the other. Therefore, let  $AB$  be the common base of the two parallelograms  $ABCD$ ,  $ABEF$ , which have the same altitude: then will they be equivalent.

For, in the parallelogram  $ABCD$ , we have  
 $AB = DC$ , and  $AD = BC$  (B. I., P. 28);  
 and in the parallelogram  $ABEF$ ,  
 we have,

$$AB = EF, \text{ and } AF = BE:$$

hence,  $DC = EF$  (A. 1).

Now, if from the line  $DE$ , we take away  $DC$ , there will

remain  $CE$ ; and if from the same line we take away  $EF$ , there will remain  $DF$ ;

hence,  $CE = DF$  (A. 3);

therefore, the triangles  $ADF$  and  $BCE$  are mutually equilateral, and consequently, equal (B. I., P. 10).

But if from the quadrilateral  $ABED$ , we take away the triangle  $ADF$ , there will remain the parallelogram  $ABEF$ ; and if from the same quadrilateral, we take away the equal triangle  $BCE$ , there will remain the parallelogram  $ABCD$ . Hence, any two parallelograms, which have equal bases and equal altitudes, are equivalent.

*Scholium.* Since the rectangle and square are parallelograms (B. I., D. 25), it follows that either is equivalent to any parallelogram having an equal base and an equal altitude. And generally, whatever property is proved as belonging to a parallelogram, belongs equally to every variety of parallelogram.

PROPOSITION II. THEOREM.

*If a triangle and a parallelogram have equal bases and equal altitudes, the triangle will be equivalent to half the parallelogram.*

Place the base of the triangle on that of the parallelogram  $ABFD$ : then will they have a common base  $AB$ .

Now, since the triangle and the parallelogram have equal altitudes, the vertex  $C$ , of the triangle, will be in the upper base of the parallelogram, or in that base prolonged (B. I., P. 23). Through  $A$ , draw  $AE$  parallel to  $BC$ , forming the parallelogram  $ABCE$ .

Now, the parallelograms  $ABFD$ ,  $ABCE$ , are equivalent, having the same base and the same altitude (P. 1). But the triangle  $ABC$  is half the parallelogram  $BE$  (B. I., P. 28, c. 1): therefore, it is equivalent to half the parallelogram  $BD$  (A. 7).

*Cor.* All triangles which have equal bases and equal altitudes are equivalent, being halves of equivalent parallelograms.

## PROPOSITION III. THEOREM.

Two rectangles having equal altitudes are to each other as their bases.

Let  $ABCD$ ,  $AEFD$ , be two rectangles having the common altitude  $AD$ : they are to each other as their bases  $AB$ ,  $AE$ .

*First.* Suppose that the bases are commensurable, and are to each other, for example, as the numbers 7 and 4. If  $AB$  be divided into 7 equal parts,  $AE$  will contain 4 of those parts. At each point of division erect a perpendicular to the base; seven partial rectangles will thus be formed, all equal to each other, because they have equal bases and the same altitude (p. 1, s). The rectangle  $ABCD$  will contain seven partial rectangles, while  $AEFD$  will contain four: hence, the rectangle

$$ABCD : AEFD :: 7 : 4, \text{ or as } AB : AE.$$

The same reasoning may be applied to any other ratio equally with that of 7 to 4: hence, whatever be the ratio, we have, when its terms are commensurable,

$$ABCD : AEFD :: AB : AE.$$

*Second.* Suppose that the bases  $AB$ ,  $AE$ , are incommensurable: we shall still have

$$ABCD : AEFD :: AB : AE.$$

For, if the rectangles are not to each other in the ratio of  $AB$  to  $AE$ , they are to each other in a ratio greater or less: that is, the fourth term must be greater or less than  $AE$ . Suppose it to be greater, and that we have

$$ABCD : AEFD :: AB : AO.$$

Divide the line  $AB$  into equal parts, each less than  $EO$ . There will be at least one point  $I$  of division between  $E$  and  $O$ : from this point draw  $IK$  perpendicular to  $AI$ ,

forming the new rectangle  $AK$ : then, since the bases  $AB$ ,  $AI$ , are commensurable, we have,

$$ABCD : AIKD :: AB : AI.$$

But by hypothesis we have

$$ABCD : Aefd :: AB : AO.$$

In these two proportions the antecedents are equal; hence, the consequents are proportional (B. II., P. 4), that is,

$$AIKD : Aefd :: AI : AO.$$

But  $AO$  is greater than  $AI$ ; which requires that the rectangle  $Aefd$  be greater than  $AIKD$ : on the contrary, however, it is less (A. 8); hence, the proportion is not true; therefore  $ABCD$  cannot be to  $Aefd$ , as  $AB$  is to a line greater than  $AE$ .

In the same manner, it may be shown that the fourth term of the proportion cannot be less than  $AE$ ; therefore, being neither greater nor less, it is equal to  $AE$ . Hence, any two rectangles having equal altitudes, are to each other as their bases.

PROPOSITION IV. THEOREM.

*Any two rectangles are to each other as the products of their bases and altitudes.*

Let  $ABCD$ ,  $AEGF$ , be two rectangles; then will the rectangle,

$$ABCD : AEGF :: AB \times AD : AE \times AF.$$

Having placed the two rectangles, so that the angles at  $A$  are opposite, produce the sides  $GE$ ,  $CD$ , till they meet in  $H$ . Then, the two rectangles  $ABCD$ ,  $AEHD$ , having the same altitude

$AD$ , are to each other as their bases  $AB$ ,  $AE$ : in like manner the two rectangles  $AEHD$ ,  $AEGF$ , having the same altitude  $AE$ , are to each other as their bases  $AD$ ,  $AF$ . thus we have,

$$ABCD : AEHD :: AB : AE,$$

$$AEHD : AEGF :: AD : AF.$$

Multiplying the corresponding terms of these proportions together (B. II., P. 13), and omitting the factor  $AEHD$ , which is common to both the antecedent and consequent (B. II., P. 7), we have

$$ABCD : AEGF :: AB \times AD : AE \times AF.$$

*Scholium* 1. If we take a line of a given length, as one inch, one foot, one yard, &c., and regard it as the linear unit of measure, and find how many times this unit is contained in the base of any rectangle, and also, how many times it is contained in the altitude: then, the product of these two ratios may be assumed as the *measure* of the rectangle.

For example, if the base of the rectangle  $A$  contains ten units and its altitude three,

|   |   |   |   |   |   |   |   |   |    |
|---|---|---|---|---|---|---|---|---|----|
| A |   |   |   |   |   |   |   |   |    |
| 3 |   |   |   |   |   |   |   |   |    |
| 2 |   |   |   |   |   |   |   |   |    |
| 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |

the rectangle will be represented by the number  $10 \times 3 = 30$ ; a number which is entirely abstract, so long as we regard the numbers 10 and 3 as ratios.

But if we assume the square constructed on the linear unit, as the unit of surface, then, the product will give the number of superficial units in the surface; because, for one unit in height, there are as many superficial units as there are linear units in the base; for two units in height, twice as many; for three units in height, three times as many, &c.

In this case, the measurement which before was merely relative, becomes absolute: the number 30, for example, by which the rectangle was measured, now represents 30 superficial units, or 30 of those equal squares described on the unit of linear measure: this is called the *Area* of the rectangle.

*Scholium* 2. In geometry, the product of two lines frequently means the same thing as their *rectangle*, and this expression has passed into arithmetic, where it serves to designate the product of two unequal numbers. The term *square* is employed to designate the product of a number multiplied by itself.

The squares of the numbers 1, 2, 3, &c., are 1, 4, 9, &c. So likewise, the geometrical square constructed on a double line is evidently four times as great as the square on a single one; on a triple line it is nine times as great, &c.

PROPOSITION V. THEOREM.

*The area of a parallelogram is equal to the product of its base and altitude.*

Let  $ABCD$  be any parallelogram, and  $BE$  its altitude: then will its area be equal to  $AB \times BE$ . Draw  $BE$  perpendicular to  $AB$ , and complete the rectangle  $ABEF$ .

The parallelogram  $ABCD$  is equivalent to the rectangle  $ABEF$  (P. 1, s.); but this rectangle is measured by  $AB \times BE$  (P. 4, s. 1); therefore,  $AB \times BE$  is equal to the area of the parallelogram  $ABCD$ .

*Cor.* Parallelograms of equal bases are to each other as their altitudes; and parallelograms of equal altitudes are to each other as their bases. For, let  $C$  and  $D$  denote the altitudes of two parallelograms, and  $B$  the base of each: then,  $B \times C : B \times D :: C : D$  (B. II., P. 7).

If  $A$  and  $B$  are the bases, and  $C$  the altitude of each, we shall have,

$$A \times C : B \times C :: A : B:$$

and parallelograms, generally, are to each other as the products of their bases and altitudes.

PROPOSITION VI. THEOREM.

*The area of a triangle is equal to half the product of its base and altitude.*

Let  $BAC$  be a triangle, and  $AD$  perpendicular to the base: then will its area be equal to one-half of  $BC \times AD$ .

For, draw  $CE$  parallel to  $BA$ , and  $AE$  parallel to  $BC$ , completing the parallelogram  $BE$ . Then, the triangle  $ABC$  is half the parallelogram  $ABCE$ , which has the same base  $BC$ , and the same altitude  $AD$  (P. 2); but the area of the parallelogram is equal to  $BC \times AD$  (P. 5); hence, that of the triangle must be  $\frac{1}{2}BC \times AD$ , or  $BC \times \frac{1}{2}AD$ .

*Cor.* Two triangles of equal altitudes are to each other as their bases, and two triangles of equal bases are to each other as their altitudes. And triangles generally, are to each other, as the products of their bases and altitudes.

PROPOSITION VII. THEOREM.

*The area of a trapezoid is equal to the product of its altitude, by half the sum of its parallel bases.*

Let  $ABCD$  be a trapezoid,  $EF$  its altitude,  $AB$  and  $CD$  its parallel bases: then will its area be equal to  $EF \times \frac{1}{2}(AB + CD)$ .

Through  $I$ , the middle point of the side  $BC$ , draw  $KL$  parallel to the opposite side  $AD$ ; and produce  $DC$  till it meets  $KL$ .

In the triangles  $IBL$ ,  $ICK$ , we have the side  $IB = IC$ , by construction; the angle  $LIB = CIK$  (B. I., P. 4); and since  $CK$  and  $BL$  are parallel, the angle  $IBL = ICK$  (B. I., P. 20, c. 2); hence, the triangles are equal (B. I., P. 6); therefore, the trapezoid  $ABCD$  is equivalent to the parallelogram  $ALKD$ , and consequently, is measured by  $EF \times AL$  (P. 5).

But we have  $AL = DK$ ; and since the triangles  $IBL$  and  $KCI$  are equal, the side  $BL = CK$ : hence  $AB + CD = AL + DK = 2AL$ ; hence,  $AL$  is the half sum of the bases  $AB$ ,  $CD$ ; hence, the area of the trapezoid  $ABCD$ , is equal to the altitude  $EF$  multiplied by the half sum of the bases  $AB$ ,  $CD$ , a result which is expressed thus:

$$ABCD = EF \times \frac{AB + CD}{2}.$$

*Scholium.* If through  $I$ , the middle point of  $BC$ , the line  $IH$  be drawn parallel to the base  $AB$ , it will bisect  $AD$  at  $H$ . For, since the figure  $ALIH$  is a parallelogram, as also,  $HIKD$ , their opposite sides are parallel, and we have  $AH=IL$ , and  $DH=IK$ ; but since the triangles  $LBI$ ,  $IKC$ , are equal, we have  $IL=IK$ ; therefore,  $AH=HD$ .

But since the line  $HI=AL$ , it is also equal to  $\frac{AB+CD}{2}$ ; hence, the area of the trapezoid may also be expressed by  $EF \times HI$ ; consequently, *the area of a trapezoid is equal to its altitude multiplied by the line which connects the middle points of its inclined sides.*

PROPOSITION VIII. THEOREM.

*The square described on the sum of two lines is equivalent to the sum of the squares described on the lines, together with twice the rectangle contained by the lines.*

Let  $AB$ ,  $BC$ , be any two lines, and  $AC$  their sum; then

$$\overline{AC}^2 \text{ or } (AB+BC)^2 = \overline{AB}^2 + \overline{BC}^2 + 2AB \times BC.$$

On  $AC$  describe the square  $ACDE$ ; take  $AF=AB$ ; draw  $FG$  parallel to  $AC$ , and  $BH$  parallel to  $AE$ .

The square  $ACDE$  is made up of four parts; the first  $ABIF$  is the square described on  $AB$ , since we made  $AF=AB$ : the second  $IGDH$  is the square described on  $IG$ , or  $BC$ ; for, since we have  $AC=AE$  and  $AB=AF$ , the difference,  $AC-AB$  must be equal to the difference  $AE-AF$ , which gives  $BC=EF$ ; but  $IG$  is equal to  $BC$ , and  $DG$  to  $EF$ , because of the parallels; therefore,  $IGDH$  is equal to a square described on  $BC$ . Now, if these two squares be taken away from the large square, there will remain the two rectangles  $BCGI$ ,  $FIHE$ , each of which is measured by  $AB \times BC$ : hence, the square on the sum of two lines is equivalent to

the sum of the squares on the lines, together with twice the rectangle contained by the lines.

*Cor.* If the line  $AC$  were divided into two equal parts, the two rectangles  $FH$ ,  $BG$ , would become squares, and the square described on the whole line would be equivalent to four times the square described on half the line.

*Scholium.* This property is the same as the property demonstrated in algebra, in obtaining the square of a binomial; which is expressed thus:

$$(a+b)^2 = a^2 + 2ab + b^2.$$

PROPOSITION IX. THEOREM.

*The square described on the difference of two lines, is equivalent to the sum of the squares described on the lines, diminished by twice the rectangle contained by the lines.*

Let  $AB$ ,  $BC$ , be two lines, and  $AC$  their difference;

then,  $\overline{AC}^2$ , or  $(AB-BC)^2 = \overline{AB}^2 + \overline{BC}^2 - 2AB \times BC$ .

On  $AB$  describe the square  $ABIF$ ; take  $AE=AC$ ; through  $C$  draw  $CG$  parallel to  $BI$ , and through  $E$  draw  $EH$  parallel to  $AB$ , and prolong it to  $K$ , making  $EK=CB$ , and then complete the square  $KEFL$ .

Since  $KD=AB$ , and  $BC=KL$ , the two rectangles  $CI$ ,  $KG$ , are each measured by  $AB \times BC$ : the whole figure  $ABILKEA$ , is equivalent to  $\overline{AB}^2 + \overline{BC}^2$ ; take from each the two rectangles  $CI$ ,  $KG$ , and there will remain the square  $ACDE$ , equivalent to  $\overline{AB}^2 + \overline{BC}^2$  diminished by twice the rectangle of  $AB \times BC$ .

*Scholium.* This property is expressed by the algebraical formula,

$$(a-b)^2 = a^2 - 2ab + b^2.$$

PROPOSITION X. THEOREM.

The rectangle contained by the sum and the difference of two lines, is equivalent to the difference of their squares.

Let  $AB, BC$ , be two lines; then

$$(AB+BC) \times (AB-BC) = \overline{AB}^2 - \overline{BC}^2.$$

Upon  $AB$  and  $AC$ , describe the squares  $ABIF, ACDE$ ; prolong  $AB$  till  $BK$  is equal to  $BC$ ; and complete the rectangle  $AKLE$ , and prolong  $CD$  to  $G$ .

The base  $AK$  of the rectangle  $AL$  is the sum of the two lines  $AB, BC$ ; and its altitude  $AE$  is their difference; therefore, the rectangle  $AKLE$  is equivalent to

$$(AB+BC) \times (AB-BC).$$

Again,  $DHIG$  is equal to a square described on  $CB$ ; and since  $BH$  is equal to  $ED$ , and  $BK$  to  $EF$ , the rectangle  $BL$  is equal to the rectangle  $EG$ : hence, the rectangle  $AKLE$  is equivalent to  $ABHE$  plus  $EDGF$ , which is precisely the difference between the two squares  $AI$  and  $DI$  described on the lines  $AB, CB$ : hence, we have (A.1.),

$$(AB+BC) \times (AB-BC) = \overline{AB}^2 - \overline{BC}^2.$$

*Scholium.* This property is expressed by the algebraical formula,

$$(a+b) \times (a-b) = a^2 - b^2.$$

PROPOSITION XI. THEOREM.

The square described on the hypotenuse of a right-angled triangle is equivalent to the sum of the squares described on the other two sides.

Let  $BCA$  be a right-angled triangle, right-angled at  $A$ : then will the square described on the hypotenuse  $BC$  be equivalent to the sum of the squares described on the other two sides,  $BA, AC$ .

Having described a square on each of the three sides, let fall from  $A$ , on the hypotenuse, the perpendicular  $AD$ , and prolong it to  $E$ ; and draw the diagonals  $AF$ ,  $CH$ .

The angle  $ABF$  is made up of the angle  $ABC$ , together with the right angle  $CBF$ ; the angle  $CBH$  is made up of the same angle  $ABC$ , together with the right-angle  $ABH$ ; hence, the angle  $ABF$  is equal to  $HBC$  (A. 2). But we have  $AB=BH$ , being sides of the same square; and  $BF=BC$ , for the same reason: therefore, the triangles  $ABF$ ,  $HBC$ , have two sides and the included angle equal, each to each; therefore, they are themselves equal (B. I., p. 5).

But the triangle  $ABF$  is equivalent to half the rectangle  $BE$ , because they have the same base  $BF$ , and the same altitude  $BD$  (P. 2). The triangle  $HBC$ , in like manner is equivalent to half the square  $AH$ : for, the angles  $BAC$ ,  $BAL$ , being both right angles,  $AC$  and  $AL$  form one and the same straight line parallel to  $HB$  (B. I., p. 3); hence, the triangle and square have equal altitudes (B. I., p. 23); they also have the common base  $BH$ ; consequently, the triangle is half the square (P. 2).

The triangle  $ABF$  has already been proved equal to the triangle  $HBC$ ; hence, the rectangle  $BDEF$ , which is double the triangle  $ABF$ , must be equivalent to the square  $AH$ , which is double the equal triangle  $HBC$ . In the same manner it may be proved, that the rectangle  $EGCD$  is equivalent to the square  $AI$ . But the two rectangles  $FEDB$ ,  $EGCD$ , taken together, make up the square  $FGCB$ : therefore, the square  $FGCB$ , described on the hypotenuse, is equivalent to the sum of the squares  $BALH$ ,  $CIKA$ , described on the two other sides; that is,

$$\overline{BC}^2 = \overline{AB}^2 + \overline{AC}^2.$$

Cor. 1. Hence, the square of one of the sides of a right-

angled triangle is equivalent to the square of the hypotenuse diminished by the square of the other side; thus,

$$\overline{AB}^2 = \overline{BC}^2 - \overline{AC}^2.$$

*Cor. 2.* If from the vertex of the right angle, a perpendicular be let fall on the hypotenuse, the parts of the hypotenuse are called *segments*: we shall then have,

*The square of the hypotenuse is to the square of either side about the right angle, as the hypotenuse to the segment adjacent to that side.*

For, by reason of the common altitude  $BF$ , the square  $BG$  is to the rectangle  $BE$ , as  $BC$  to  $BD$  (P. 3): but the square  $BL$  is equivalent to the rectangle  $BE$ : hence

$$\overline{BC}^2 : \overline{BA}^2 :: BC : BD.$$

We may show, in like manner, that

$$\overline{BC}^2 : \overline{AC}^2 :: BC : DC.$$

*Cor. 3.* *The squares of the two sides containing the right angle, are to each other as the adjacent segments of the hypotenuse.*

For, the rectangles  $BDEF$ ,  $DCGE$ , having the same altitude, are to each other as their bases  $BD$ ,  $CD$  (P. 3). But these rectangles are equivalent to the squares  $AH$ ,  $AI$ ; therefore, we have

$$\overline{AB}^2 : \overline{AC}^2 :: BD : DC.$$

*Cor. 4.* *The square described on the diagonal of a square is equivalent to double the square described on a side.*

Let  $ABCD$  be a square described on  $AB$ , and  $EFGH$  a square described on the diagonal  $AC$ . The triangle  $ABC$  being right-angled and isosceles, we shall have

$$\overline{AC}^2 = \overline{AB}^2 + \overline{BC}^2 = 2\overline{AB}^2.$$

It is plain, that of the eight equal right-angled triangles which compose the square  $EG$ , four will lie without the square  $ABCD$ , and four within it: hence, *the square on the diagonal is equivalent to double the square on the side.*

Cor. 5. By the last corollary, we have

$$\overline{AC}^2 : \overline{AB}^2 :: 2 : 1;$$

hence, by extracting the square root (B. II., p. 12, c.),

$$AC : AB \sqrt{2} : 1:$$

that is, the diagonal of a square is to the side as the square root of two to one: consequently, the diagonal and side of a square are incommensurable.

PROPOSITION XII. THEOREM.

*In any triangle, the square of a side opposite an acute angle is equivalent to the sum of the squares of the base and the other side, diminished by twice the rectangle contained by the base and the distance from the vertex of the acute angle to the foot of the perpendicular let fall from the vertex of the opposite angle on the base, or on the base produced.*

Let  $ABC$  be a triangle,  $C$  one of the acute angles, and  $AD$  perpendicular to the base  $BC$ ; then will

$$\overline{AB}^2 = \overline{BC}^2 + \overline{AC}^2 - 2BC \times CD.$$

*First.* When the perpendicular falls within the triangle  $ABC$ , we have  $BD = BC - CD$ , and consequently,

$$\overline{BD}^2 = \overline{BC}^2 + \overline{CD}^2 - 2BC \times CD \text{ (P. 9).}$$

Adding  $\overline{AD}^2$  to each, and observing that the right-angled triangles  $ABD$ ,  $ADC$ ,

give  $\overline{AD}^2 + \overline{BD}^2 = \overline{AB}^2$ , and  $\overline{AD}^2 + \overline{CD}^2 = \overline{AC}^2$ ,

we have  $\overline{AB}^2 = \overline{BC}^2 + \overline{AC}^2 - 2BC \times CD$ .

*Secondly.* When the perpendicular  $AD$  falls without the triangle  $ABC$ , we have  $BD = CD - BC$ ; and consequently,

$$\overline{BD}^2 = \overline{CD}^2 + \overline{BC}^2 - 2CD \times BC \text{ (P. 9).}$$

Adding  $\overline{AD}^2$  to both, we find, as before,

$$\overline{AB}^2 = \overline{BC}^2 + \overline{AC}^2 - 2BC \times CD.$$

PROPOSITION XIII. THEOREM.

*In any obtuse-angled triangle, the square of the side opposite the obtuse angle is equivalent to the sum of the squares of the base and the other side, augmented by twice the rectangle contained by the base and the distance from the vertex of the obtuse angle to the foot of the perpendicular let fall from the vertex of the opposite angle on the base produced.*

Let  $ACB$  be a triangle,  $C$  the obtuse angle, and  $AD$  perpendicular to  $BC$  produced; then

$$\overline{AB}^2 = \overline{AC}^2 + \overline{BC}^2 + 2BC \times CD.$$

For, we have,  $BD = BC + CD$  ;  
consequently (P. 8),

$$\overline{BD}^2 = \overline{BC}^2 + \overline{CD}^2 + 2BC \times CD.$$

Adding  $\overline{AD}^2$  to both members, and reducing as in the last theorem, and we have

$$\overline{AB}^2 = \overline{BC}^2 + \overline{AC}^2 + 2BC \times CD.$$

*Scholium.* The right-angled triangle is the only one in which the sum of the squares described on two sides is equivalent to the square described on the third; for, if the angle contained by the two sides is acute, the sum of their squares is greater than the square of the opposite side; if obtuse, it is less.

PROPOSITION XIV. THEOREM.

*In any triangle, the sum of the squares described on two sides is equivalent to twice the square of half the third side, plus twice the square of the line drawn from the middle point of that side to the vertex of the opposite angle.*

Let  $ABC$  be any triangle, and  $AE$  a line drawn to the middle of the base  $BC$ ; then

$$\overline{AB}^2 + \overline{AC}^2 = 2\overline{BE}^2 + 2\overline{AE}^2.$$

For, on  $BC$ , let fall the perpendicular  $AD$ . Then,

$$\overline{AC}^2 = \overline{AE}^2 + \overline{EC}^2 - 2EC \times ED. \quad (\text{p. 12}).$$

And,

$$\overline{AB}^2 = \overline{AE}^2 + \overline{EB}^2 + 2EB \times ED \quad (\text{p. 13}).$$

Hence, by adding and observing that  $EB$  and  $EC$  are equal, we have

$$\overline{AB}^2 + \overline{AC}^2 = 2\overline{EB}^2 + 2\overline{AE}^2.$$

*Cor. 1.* In any quadrilateral, the sum of the squares of the four sides is equivalent to the sum of the squares of the two diagonals, plus four times the square of the line joining the middle points of the diagonals.

Let  $ABCD$  be a quadrilateral,  $AC$ ,  $BD$ , the diagonals, and  $EF$  a line joining their middle points  $E$  and  $F$ .

From the theorem, we have

$$\overline{CD}^2 + \overline{CB}^2 = 2\overline{BF}^2 + 2\overline{CF}^2,$$

$$\overline{AD}^2 + \overline{AB}^2 = 2\overline{BF}^2 + 2\overline{AF}^2;$$

and from the same theorem, by multiplying by 2,

$$2\overline{CF}^2 + 2\overline{AF}^2 = 4\overline{AE}^2 + 4\overline{EF}^2;$$

hence, by addition,

$$\overline{CD}^2 + \overline{CB}^2 + \overline{AD}^2 + \overline{AB}^2 = 4\overline{BF}^2 + 4\overline{AE}^2 + 4\overline{EF}^2;$$

whence (p. 8, c.),

$$\overline{CD}^2 + \overline{CB}^2 + \overline{AD}^2 + \overline{AB}^2 = \overline{BD}^2 + \overline{AC}^2 + 4\overline{EF}^2.$$

*Cor. 2.* In the case of the parallelogram the points  $E$  and  $F$  will coincide, and the sum of the squares described on the sides will be equivalent to the sum of the squares described on the diagonals.

PROPOSITION XV. THEOREM.

*If, in any triangle, a line be drawn parallel to the base, it will divide the two other sides proportionally.*

Let  $ABC$  be a triangle, and  $DE$  a straight line drawn parallel to the base  $BC$ ; then

$$AD : DB :: AE : EC.$$

Draw the lines  $BE$  and  $CD$ . Then, the triangles  $ADE$ ,  $BDE$ , having a common vertex,  $E$ , have the same altitude, and are to each other as their bases (P. 6, C.); hence we have

$$ADE : BDE :: AD : DB.$$

The triangles  $ADE$ ,  $DEC$ , with a common vertex  $D$ , also have the same altitude, and are to each other as their bases; hence,

$$ADE : DEC :: AE : EC.$$

But the triangles  $BDE$ ,  $DEC$ , are equivalent, having the same base  $DE$ , and their vertices  $B$  and  $C$  in a line parallel to the base: and therefore, we have (B. II., P. 4, C.)

$$AD : DB :: AE : EC.$$

*Cor. 1.* Hence, by composition, we have (B. II., P. 6),  
 $AD+DB : AD :: AE+EC : AE$ , or  $AB : AD :: AC : AE$ ;  
 and also,  $AB : BD :: AC : CE$ .

*Cor. 2.* If any number of parallels  $AC$ ,  $EF$ ,  $GH$ ,  $BD$ , be drawn between two straight lines  $AB$ ,  $CD$ , those straight lines will be cut proportionally, and we shall have

$$AE : CF :: EG : FH :: GB : HD.$$

For, let  $O$  be the point where  $AB$  and  $CD$  meet. In the triangle  $OEF$ , the line  $AC$  being drawn parallel to the base  $EF$ , we shall have

$$OE : AE :: OF : CF.$$

In the triangle  $OGH$ , we shall likewise have

$$OE : EG :: OF : FH.$$

And, by reason of the common antecedents  $OE, OF$  (B. II., P. 4), we have

$$AE : CF :: EG : FH.$$

It may be proved in the same manner, that

$$EG : FH :: GB : HD,$$

and so on; hence, the lines  $AB, CD$ , are cut proportionally by the parallels  $AC, EF, GH$ , &c.

PROPOSITION XVI. THEOREM.

*If two sides of a triangle are cut proportionally by a straight line, this straight line will be parallel to the third side.*

In the triangle  $BAC$ , let the line  $DE$  be drawn, cutting the sides  $BA$  and  $CA$  proportionally in the points  $D$  and  $E$ ; that is, so that

$$BD : DA :: CE : EA :$$

then will  $DE$  be parallel to  $BC$ .

Having drawn the lines  $BE$  and  $DC$ , we have (P. 6, c.),

$$BDE : DAE :: BD : DA,$$

$$DEC : DAE :: CE : EA :$$

but, by hypothesis,

$$BD : DA :: CE : EA :$$

hence (B. II., P. 4, c.),

$$BDE : DAE :: DEC : DAE,$$

and since  $BDE$  and  $DEC$  have the same ratio to  $DAE$ , they have the same area, and hence are equivalent (D. 4). They also have a common base  $DE$ ; hence, they have the same altitude (P. 6, c.); and consequently, their vertices  $B$  and  $C$  lie in a parallel to the base  $DE$  (B. I., P. 23): hence,  $DE$  is parallel to  $BC$ .

PROPOSITION XVII. THEOREM.

*The line which bisects the vertical angle of a triangle, divides the base into two segments, which are proportional to the adjacent sides.*

In the triangle  $ACB$ , let  $AD$  be drawn, bisecting the angle  $CAB$ ; then

$$BD : CD :: AB : AC.$$

Through the point  $C$  draw  $CE$  parallel to  $AD$ , and prolong it till it meets  $BA$  produced in  $E$ .

In the triangle  $BCE$ , the line  $AD$  is parallel to the base  $CE$ ; hence, we have the proportion (P. 15),

$$BD : DC :: BA : AE.$$

But the triangle  $ACE$  is isosceles: for, since  $AD$ ,  $CE$ , are parallel, we have the angle  $ACE = DAC$ , and the angle  $AEC = BAD$  (B. I., P. 20, c. 2, 3); but, by hypothesis,  $DAO = DAB$ ; hence, the angle  $ACE = AEC$ , and consequently,  $AE = AC$  (B. I., P. 12). In place of  $AE$  in the above proportion, substitute  $AC$ , and we shall have,

$$BD : DC :: AB : AC.$$

*Cor.* If the line  $AD$  bisects the exterior angle  $CAE$  of the triangle  $BAC$ , we shall have,

$$BD : DC : AB : AC.$$

For, through  $C$  draw  $CF$  parallel to  $AD$ .

Then, the angle  $CAD = ACF$ ,  
and, the angle  $EAD = AFC$ ;  
hence, (A. 1), the angle  $ACF = AFC$ ;  
consequently,  $AF$  is equal to  $AC$ .

But, since  $FC$  is parallel to the base  $AD$ ,

$$BD : DC : AB : AF;$$

hence,  $BD : DC : AB : AC.$

## PROPOSITION XVIII. THEOREM.

*Equiangular triangles have their homologous sides proportional, and are similar.*

Let  $BCA$  and  $CED$  be two equiangular triangles, having the angle  $BAC = CDE$ ,  $ABC = DCE$ , and  $ACB = DEC$ ; then, the homologous sides will be proportional, viz.:

$$BC : CE :: BA : CD :: AC : DE.$$

Place the homologous sides  $BC$ ,  $CE$  in the same straight line; and prolong the sides  $BA$ ,  $ED$ , till they meet in  $F$ .

Since  $BCE$  is a straight line, and the angle  $BCA$  equal to  $CED$ , it follows that  $AC$  is parallel to  $DE$  (B. I., P. 19, c. 2). In like manner, since the angle  $ABC$  is equal to  $DCE$ , the line  $AB$  is parallel to  $DC$ . Hence, the figure  $ACDF$  is a parallelogram, and has its opposite sides equal (B. I., P. 28).

In the triangle  $BEF$ , the line  $AC$  is parallel to the base  $FE$ ; hence, we have (P. 15.)

$$BC : CE :: BA : AF;$$

or putting  $CD$  in the place of its equal  $AF$ ,

$$BC : CE :: BA : CD.$$

In the same triangle  $BEF$ ,  $CD$  is parallel to  $BF$ ; and hence,

$$BC : CE :: FD : DE;$$

or putting  $AC$  in the place of its equal  $FD$ ,

$$BC : CE :: AC : DE.$$

And finally, since both these proportions have an antecedent and consequent common, we have (B. II., P. 4, c.),

$$BA : CD :: AC : DE.$$

Thus, the equiangular triangles  $CAB$ ,  $CED$ , have their homologous sides proportional. But two figures are similar when they have their angles equal, each to each, and their

homologous sides proportional (D. 1, 2); consequently, the two equiangular triangles  $BAC$ ,  $CED$ , are similar figures.

*Cor.* Two triangles which have two angles of the one equal to two angles of the other, are similar; for, the third angles are then equal, and the two triangles are equiangular (B. I., P. 25, c. 2.)

*Scholium.* Observe, that in similar triangles, the homologous sides in each are opposite to the equal angles; thus, the angle  $BCA$  being equal to  $CED$ , the side  $AB$  is homologous to  $DC$ ; in like manner  $AC$  and  $DE$  are homologous, because opposite to the equal angles  $ABC$ ,  $DCE$ .

PROPOSITION XIX. THEOREM.

*Conversely: Triangles, which have their sides proportional, are equiangular and similar.*

If, in the two triangles  $BAC$ ,  $EDF$ , we have,

$$BC : EF :: BA : ED :: AC : DF;$$

then will the triangles  $BAC$ ,  $EDF$ , have their angles equal, namely,

$$A=D, B=E, C=F.$$

At the point  $E$ , make the angle  $FEG=B$ , and at  $F$ , the angle  $EFG=C$ ; the third angle  $G$  will then be equal to the third angle  $A$  (B. I., P. 25, c. 2). Therefore, by the last theorem, we shall have

$$BC : EF :: AB : EG;$$

but, by hypothesis, we have

$$BC : EF :: AB : DE;$$

hence,  $EG=DE$ . By the same theorem, we shall also have

$$BC : EF :: AC : FG;$$

and by hypothesis, we have

$$BC : EF :: AC : DF;$$

hence,  $FG=DF$ . Hence, the triangles  $EGF$ ,  $FED$ , having

their three sides equal, each to each, are themselves equal (B. I., P. 10). But, by construction, the triangles  $EGF$  and  $ABC$  are equiangular: hence,  $DEF$  and  $ABC$  are also equiangular and similar (A. 1).

*Scholium 1.* By the last two propositions, it appears that triangles which are equiangular are similar: and conversely: if triangles have their sides proportional, they are equiangular, and consequently, similar.

The case is different with regard to figures of more than three sides: even in quadrilaterals, the proportion between the sides may be altered without changing the angles, or the angles may be changed without altering the proportion between the sides. Thus, in quadrilaterals, equality between the corresponding angles does not insure proportionality among the sides: and reciprocally: proportionality among the sides does not insure equality among the corresponding angles. It is evident, for example, that if in the quadrilateral  $ABCD$ , we draw  $EF$  parallel to  $BC$ , the angles of the quadrilateral  $A E F D$ , are made equal to those of  $ABCD$ ; though the proportion between their sides is different; and in like manner, without changing the four sides  $AB$ ,  $BC$ ,  $CD$ ,  $AD$ , we can change the angles by making the point  $B$  approach to  $D$ , or recede from it.

*Scholium 2.* The two preceding propositions, are in strictness but one, and these, together with that relating to the square of the hypotenuse, are the most important and fertile in results of any in geometry. They are almost sufficient of themselves for every application to subsequent reasoning, and for solving every problem. The reason is, that all figures may be divided into triangles, and any triangle into two right-angled triangles. Thus, the properties of triangles include, by implication, those of all figures.

PROPOSITION XX. THEOREM.

*Two triangles, which have an angle of the one equal to an angle of the other, and the sides containing those angles proportional, are similar.*

Let  $ABC, DEF$ , be two triangles, having the angle  $A$  equal to  $D$ ; then, if

$$AB : DE :: AC : DF,$$

the two triangles will be similar.

Make  $AG=DE$ , and draw  $GH$  parallel to  $BC$ . The angle  $AGH$  will be equal to the angle  $ABC$  (B. I., P. 20, c. 3); and the triangles  $AGH, ABC$ , will be equiangular: hence, we shall have,

$$AB : AG : AC : AH.$$

But, by hypothesis, we have,

$$AB : DE :: AC : DF;$$

and by construction,  $AG=DE$ : hence  $AH=DF$ . Therefore, the two triangles  $AGH, DEF$ , have two sides and the included angle of the one equal to two sides and the included angle of the other: hence, they are equal (B. I., P. 5); but the triangle  $AGH$  is similar to  $ABC$ : therefore,  $DEF$  is also similar to  $ABC$ .

PROPOSITION XXI. THEOREM.

*Two triangles, which have their sides, two and two, either parallel or perpendicular to each other, are similar.*

Let  $BAC, EDF$ , be two triangles, having their sides respectively parallel to each other; then will they be similar.

*First.* If the side  $BA$  is parallel to  $ED$ , and  $BC$  to  $EF$ , the angle  $ABC$  is equal to  $DEF$  (B. I., P. 24): if  $CA$  is parallel to  $FD$ , the angle  $BCA$  is equal to  $EFD$ , and also,  $BAC$  to  $EDF$ ; hence, the triangles  $CBA, FED$ , are equiangular; consequently they are similar (P. 18).

*Secondly.* If the side  $DE$  is perpendicular to  $BA$ , and the side  $FD$  to  $CA$ , the two angles  $I$  and  $H$  of the quadrilateral  $DHAI$  are right angles; and since all the four angles are together equal to four right angles (B. I., P. 26, c. 1), the remaining two  $IAH$ ,  $IDH$ , are together equal to two right angles. But the sum of the angles  $EDF$ ,  $IDH$ , is also equal to two right angles (B. I., P. 1): hence, the angle  $EDF$  is equal to  $IAH$ , or  $BAC$  (A. 3). In like manner, if the third side  $EF$  is perpendicular to the third side  $BC$ , it may be shown that the angle  $DFE$  is equal to  $C$ , and  $DEF$  to  $B$ : hence, the triangles  $ABC$ ,  $DEF$ , which have the sides of the one perpendicular to the corresponding sides of the other, are equiangular and similar (P. 18).

*Scholium.* In the case of the sides being parallel, the homologous sides are the parallel ones: in the case of their being perpendicular, the homologous sides are the perpendicular ones. Thus, in the latter case,  $DE$  is homologous with  $BA$ ,  $DF$  with  $AC$ , and  $EF$  with  $BC$ .

The case of the perpendicular sides may present a relative position of the two triangles different from that exhibited in the diagram. But we can always conceive a triangle  $FED$  to be constructed within the triangle  $ABC$ , and such that its sides shall be parallel to those of the triangle compared with  $BAC$ ; and then the demonstration given in the text will apply.

PROPOSITION XXII. THEOREM.

*In any triangle, if a line be drawn parallel to the base, all lines drawn from the vertex will divide the base and the parallel into proportional parts.*

Let  $BAC$  be a triangle,  $DE$  parallel to the base  $BC$ , and the other lines drawn as in the figure; then

$$DI : BF :: IK : FG :: KL : GH.$$

For, since  $DI$  is parallel to  $BF$ , the triangles  $IDA$  and  $FBA$  are equiangular; and we have

$$DI : BF :: AI : AF;$$

and, since  $IK$  is parallel to  $FG$ , we have, in like manner,

$$AI : AF :: IK : FG;$$

hence (B. II., P. 4, C.),  $DI : BF :: IK : FG$ .

In the same manner, we may prove that

$$IK : FG :: KL : GH;$$

and so with the other segments: hence, the line  $DE$  is divided at the points  $I, K, L$ , in the same proportion, as the base  $BC$  is divided, at the points  $F, G, H$ .

*Cor.* Therefore, if  $BC$  were divided into equal parts at the points  $F, G, H$ , the parallel  $DE$  would be divided also into equal parts at the points  $I, K, L$ .

PROPOSITION XXIII. THEOREM.

*In a right-angled triangle, if a perpendicular is drawn from the vertex of the right angle to the hypotenuse.*

- 1st. *The triangles on each side of the perpendicular are similar to the given triangle, and to each other:*
- 2d. *Either side about the right angle is a mean proportional between the hypotenuse and the adjacent segment:*
- 3d. *The perpendicular is a mean proportional between the segments of the hypotenuse.*

Let  $BAC$  be a right-angled triangle, and  $AD$  perpendicular to the hypotenuse  $BC$ .

*First.* The triangles  $BAD$  and  $BAC$  have the common angle  $B$ , the right angle  $BDA = BAC$ , and therefore, the third angle  $BAD$  of the one, equal to the third angle  $C$ , of the other (B. I., P. 25, C. 2):

hence, these two triangles are similar (P. 18). In the same

manner it may be shown that the triangles  $DAC$  and  $BAC$  are similar; hence, the three triangles are all equiangular and similar.

*Secondly.* The triangles  $BAD$ ,  $BAC$ , being similar, their homologous sides are proportional. But  $BD$  in the small triangle, and  $BA$  in the large one, are homologous sides, because they lie opposite the equal angles  $BAD$ ,  $BCA$  (P. 18, s.); the hypotenuse  $BA$  of the small triangle is homologous with the hypotenuse  $BC$  of the large triangle: hence, the proportion,

$$BD : BA :: BA : BC.$$

By the same reasoning we have

$$DC : AC :: AC : BC;$$

hence, each of the sides  $AB$ ,  $AC$ , is a mean proportional between the hypotenuse and the adjacent segment.

*Thirdly.* Since the triangles  $DBA$ ,  $DAC$ , are similar, we have, by comparing their homologous sides,

$$BD : AD :: AD : DC;$$

hence, the perpendicular  $AD$  is a mean proportional between the segments  $BD$ ,  $DC$ , of the hypotenuse.

*Scholium.* Since  $BD : AB :: AB : BC$ ,

we have (B. II., P. 1, c.),  $\overline{AB}^2 = BD \times BC$ .

For a like reason,  $\overline{AC}^2 = DC \times BC$ ;

therefore,  $\overline{AB}^2 + \overline{AC}^2 = BD \times BC + DC \times BC = (BD + DC) \times$

$$BC = BC \times BC = \overline{BC}^2;$$

that is, the square described on the hypotenuse  $BC$  is equivalent to the sum of the squares described on the two sides  $BA$ ,  $AC$ . Thus, we again arrive at this property of the right-angled triangle, and by a path very different from that which formerly conducted us to it: and thus it appears that, strictly speaking, this property is a consequence of the more general property, that the sides of equiangular triangles are proportional. Thus, the fundamental propositions of geometry are reduced, as it were, to this single one, that *equiangular triangles have their homologous sides proportional*.

It happens frequently, as in this instance, that by deducing consequences from one or more propositions, we are led back to some proposition already proved. In fact, the chief characteristic of geometrical theorems, and one indubitable proof of their certainty is, that, however we combine them together, provided that our reasoning be correct, the results we obtain always agree with each other. The case would be different, if any proposition were false or only approximately true: it would frequently happen that on combining the propositions together, the error would increase and become perceptible. Examples in which the conclusions do not agree with each other, are to be seen in all the demonstrations, in which the *reductio ad absurdum* is employed. In such demonstrations, if the hypothesis is untrue, a train of accurate reasoning leads to a manifest absurdity: that is, to a conclusion in contradiction to a principle previously established: and from this we conclude that the hypothesis is false.

*Cor.* If from the point *A*, in the circumference of a circle, two chords *BA*, *AC*, be drawn to the extremities of a diameter *BC*, the triangle *BAC* will be right-angled at *A* (B. III., P. 18, c. 2); hence, first, the perpendicular *AD* is a mean proportional between the two segments *BD*, *DC*, of the diameter, hence,

$$\overline{AD}^2 \simeq BD \times DC.$$

Furthermore, by the proposition, the chord *BA* is a mean proportional between the diameter *BC*, and the adjacent segment *BD*, that is,

$$\overline{BA}^2 \simeq BC \times BD, \text{ and } \overline{AC}^2 \simeq BC \times CD.$$

PROPOSITION XXIV. THEOREM.

*Two triangles having an angle in each equal, are to each other as the rectangles of the adjacent sides.*

Let *ABC*, *ADE*, be two triangles having the equal angles *A*, placed, the one on the other; then the triangle

$$ABC : ADE :: AB \times AC : AD \times AE.$$

Draw  $BE$ . Then, the triangles  $ABE$ ,  $ADE$ , having the common vertex  $E$ , and their bases in the same straight line, are to each other as their bases, (P. 6, C.) that is

$$BAE : DAE :: BA : DA.$$

In like manner, since  $B$  is a common vertex, the triangle

$$BAC : BAE :: AC : AE.$$

Multiply together the corresponding terms of these proportions, omitting the common factor  $BAE$ ; and we have (B. II., P. 13),

$$BAC : DAE : BA \times AC : AD \times AE.$$

Cor. If the two triangles are equivalent, we have,

$$BA \times AC = DA \times AE:$$

hence (B. II., P. 2),

$$BA : DA : AE : AC:$$

consequently,  $DC$  and  $BE$  are parallel (P. 16).

#### PROPOSITION XXV. THEOREM.

*Similar triangles are to each other as the squares described on their homologous sides.*

Let  $ABC$ ,  $DEF$ , be two similar triangles, having the angle  $A$  equal to  $D$ , and the angle  $B = E$ : then will the triangle  $BAC$  be to the triangle  $EDF$ , as a square described on any side of  $BAC$  to a square described on the homologous side of  $EDF$ .

First, by reason of the equal angles  $A$  and  $D$ , we have (P. 24),

$$BAC : DEF :: BA \times AC : DE \times DF.$$

Also, because the triangles are similar (P. 18),

$$BA : DE :: AC : DF,$$

And multiplying the terms of this proportion by the corresponding terms of the identical proportion,

$$AC : DF :: AC : DF,$$

there will result

$$BA \times AC : DE \times DF :: \overline{AC}^2 : \overline{DF}^2$$

Consequently (B. II., p. 4, c.),

$$BAC : EDF :: \overline{AC}^2 : \overline{DF}^2.$$

Therefore, the similar triangles  $BAC, EDF$ , are to each other as the squares described on their homologous sides  $AC, DF$ , or as the squares described on any other two homologous sides.

PROPOSITION XXVI. THEOREM.

*Two similar polygons may be divided into the same number of triangles, similar each to each, and similarly placed.*

Let  $AEDCB, FKIHG$ , be two similar polygons.

From the vertex of any angle  $A$ , in the polygon  $AEDCB$ , draw diagonals,  $AD, AC$ . From the vertex of the homologous angle  $F$ , in the other polygon, draw the diagonals  $FI, FH$ , to the vertices of the other angles.

The polygons being similar, the homologous angles,  $ABC, FGH$ , are equal, and the sides  $AB, BC$ , proportional to  $FG, GH$ , that is,

$$AB : FG :: BC : GH \text{ (D. 1).}$$

Wherefore, the triangles  $ABC, FGH$ , have an angle in each equal, and the adjacent sides proportional: hence, they are similar (p. 20); consequently, the angle  $BCA$  is equal to  $GHF$ . Taking away these equal angles from the equal angles  $BCD, GHI$ , and there remains  $ACD = FHI$ . But since the triangles  $ABC, FGH$ , are similar, we have

$$AC : FH :: BC : GH;$$

and since the polygons are similar,

$$BC : GH :: CD : HI;$$

hence,

$$AC : FH :: CD : HI.$$

The angle  $ACD$ , we already know, is equal to  $FHI$ ; hence, the triangles  $ACD$ ,  $FHI$ , are similar (p.20). In the same manner, it may be shown that all the remaining triangles are similar, whatever be the number of sides in the polygons proposed: therefore, two similar polygons may be divided into the same number of triangles, similar, and similarly placed.

*Scholium.* The converse of the proposition is equally true: *If two polygons are composed of the same number of triangles similar and similarly situated, the two polygons are similar.*

For, the similarity of the respective triangles will give the angles,

$$ABC = FGH, BOA = GHF, ACD = FHI:$$

hence,  $BCD = GHI$ , likewise,  $CDE = HIK$ , &c.

Moreover, we have,

$$AB : FG :: BC : GH :: CD : HI :: DE : IK, \&c.,$$

hence, the two polygons have their angles equal each to each, and their sides proportional; consequently, they are similar.

#### PROPOSITION XXVII. THEOREM.

*The perimeters of similar polygons are to each other as their homologous sides: and the polygons are to each other as the squares described on these sides.*

Let  $AEDCB$  and  $FKIHG$ , be two similar polygons: then

$$\text{per. } AEDCB : \text{per. } FKIHG :: AE : FK.$$

*First.* Since the figures are similar, we have

$$AB : FG :: BC : GH :: CD : HI, \&c.,$$

hence, the sum of the antecedents  $AB + BC +$

$CD$ , &c., which makes up the perimeter of the first polygon, is to the sum of the consequents  $FG+GH+HI$ , &c., which makes up the perimeter of the second polygon, as any one antecedent is to its consequent (B. II., P. 10); that is, as  $AB$  to  $FG$ , or as any other two homologous sides.

*Secondly.* Since the triangles  $ABC$ ,  $FGH$ , are similar, we have (P. 25),

$$ABC : FGH :: \overline{AC}^2 : \overline{FH}^2;$$

and from the similar triangles  $ACD$ ,  $FHI$ ,

$$ACD : FHI :: \overline{AC}^2 : \overline{FH}^2;$$

therefore, by reason of the common ratio,  $\overline{AC}^2$  to  $\overline{FH}^2$ , we have (B. II., P. 4, C.)

$$ABC : FGH :: ACD : FHI.$$

By the same reasoning, we should find

$$ACD : FHI :: ADE : FIK;$$

and so on, if there were more triangles. And from this series of equal ratios, we conclude that the sum of the antecedents  $ABC+ACD+ADE$ , which makes up the polygon  $AEDCB$ , is to the sum of the consequents  $FGH+FHI+FIK$ , which makes up the polygon  $FKIHG$ , as one antecedent  $ABC$ , is to its consequent  $FGH$  (B. II., P. 10), or as  $\overline{AB}^2$  is to  $\overline{FG}^2$  (P. 25); hence, *similar polygons are to each other as the squares described on their homologous sides.*

*Cor.* *If three similar figures are described on the three sides of a right-angled triangle, the figure on the hypotenuse is equivalent to the sum of the other two.*

Let  $A$ ,  $B$ ,  $C$ , denote three similar figures described on the hypotenuse and sides of a right-angled triangle, and  $a$ ,  $b$ ,  $c$ , the corresponding squares; then,

$$A : B : C :: a : b : c;$$

and,  $A : B+C :: a : b+c$  (B. II., P. 9):

but,  $a$  is equivalent to  $b+c$  (P. 11);

hence,  $A$  is equivalent  $B+C$ .

## PROPOSITION XXVIII. THEOREM.

*If two chords intersect each other in a circle, the segments are reciprocally proportional.*

Let the chords  $AB$  and  $CD$  intersect at  $O$ : then

$$AO : DO :: OC : OB.$$

Draw  $AC$  and  $BD$ . In the triangles  $AOC$ ,  $DOB$ , the angles at  $O$  are equal, being vertical angles (B. I., P. 4): the angle  $A$  is equal to the angle  $D$ , because both are inscribed in the same segment (B. III., P. 18, c. 1); for the same reason the angle  $C=B$ ; the triangles are therefore similar (P. 18), and the homologous sides give the proportion

$$AO : DO :: CO : OB.$$

*Cor.* Therefore,

$$AO \times OB = DO \times CO :$$

hence, the rectangle of the two segments of one chord is equivalent to the rectangle of the two segments of the other.

## PROPOSITION XXIX. THEOREM.

*If from a point without a circle, two secants be drawn terminating in the concave arc, the whole secants will be reciprocally proportional to their external segments.*

Let the secants  $OB$ ,  $OC$ , be drawn from the point  $O$ : then

$$OB : OC :: OD : OA.$$

For, drawing  $AC$ ,  $BD$ , the triangles  $AOC$ ,  $BOD$  have the angle  $O$  common; likewise the angle  $B=C$  (B. III., P. 18, c. 1); these triangles are therefore similar (P. 18), and their homologous sides give the proportion,

$$OB : OC :: OD : OA.$$

*Cor.* Hence, the rectangle

$$OB \times OA = OC \times OD.$$

*Scholium.* This proposition, it may be observed, bears a close analogy to the preceding, and differs from it only as the two chords  $AB, CD$ , instead of intersecting each other within, cut each other without the circle. The following proposition may be regarded as a particular case of the proposition just demonstrated.

PROPOSITION XXX. THEOREM.

*If from a point without a circle, a tangent and a secant be drawn, the tangent will be a mean proportional between the secant and its external segment.*

From the point  $O$ , let the tangent  $OA$ , and the secant  $OC$  be drawn, then

$$OC : OA :: OA : OD,$$

or,  $\overline{OA}^2 \simeq OC \times OD.$

For, drawing  $AD$  and  $AC$ , the triangles  $DAO, CAO$ , have the angle  $O$  common; also, the angle  $OAD$ , formed by a tangent and a chord, is measured by half the arc  $AD$  (B. III., P. 21); and the angle  $C$  has the same measure (B. III., P. 18); hence, the angle  $OAD = C$  (A. 1): therefore, the two triangles are similar, and we have the proportion

$$OC : OA :: OA : OD.$$

which gives  $\overline{OA}^2 \simeq OC \times OD.$

PROPOSITION XXXI. THEOREM.

*If either angle of a triangle is bisected by a line terminating in the opposite side, the rectangle of the sides about the bisected angle, is equivalent to the square of the bisecting line, together with the rectangle contained by the segments of the third side.*

In the triangle  $BAC$ , let  $AD$  bisect the angle  $A$ ; then

$$AB \times AC \simeq \overline{AD}^2 + BD \times DC.$$

Describe a circle through the three points  $A, B, C$  (B. III., PROB. 13, s.); prolong  $AD$  till it meets the circumference in  $E$ , and draw  $CE$ .

The triangle  $BAD$  is similar to the triangle  $EAC$ ; for, by hypothesis, the angle  $BAD = EAC$ ; also, the angle  $B = E$ , since they are both measured by half the arc  $AC$  (B. III., P. 18); hence, these triangles are similar, and the homologous sides give the proportion

$$BA : AE :: AD : AC;$$

hence,  $BA \times AC = AE \times AD$ ; but  $AE = AD + DE$ , and multiplying each of these equals by  $AD$ , we have

$$AE \times AD = \overline{AD}^2 + AD \times DE;$$

now (P. 28, c.),  $AD \times DE = BD \times DC$ ;

hence, finally,  $BA \times AC = \overline{AD}^2 + BD \times DC$ .

PROPOSITION XXXII. THEOREM.

*In any triangle, the rectangle contained by two sides is equivalent to the rectangle contained by the diameter of the circumscribed circle, and the perpendicular let fall on the third side.*

In the triangle  $BAC$ , let  $AD$  be drawn perpendicular to  $BC$ ; and let  $EC$  be the diameter of the circumscribed circle: then will

$$AB \times AC = AD \times CE.$$

For, drawing  $AE$ , the triangles  $DBA, CAE$ , are right-angled, the one at  $D$ , the other at  $A$ : also, the angle  $B = E$  (B. III., P. 18, c. 1); these triangles are therefore similar, and we have

$$AB : CE :: AD : AC;$$

and hence,  $AB \times AC = CE \times AD$ .

*Cor.* If these equal quantities be multiplied by  $BC$ , there will result

$$AB \times AC \times BC = CE \times AD \times BC;$$

now,  $AD \times BC$  is double the area of the triangle (P. 6); therefore, *the product of the three sides of a triangle is equal to its area multiplied by twice the diameter of the circumscribed circle.*

The product of three lines is sometimes represented by a *solid*, for a reason that will be seen hereafter. Its value is easily conceived, by supposing the lines to be reduced to numbers, and then multiplying these numbers together.

*Scholium.* It may also be demonstrated, that *the area of a triangle is equal to its perimeter multiplied by half the radius of the inscribed circle.*

For, the triangles  $AOB$ ,  $BOC$ ,  $AOC$ , which have a common vertex at  $O$ , have for their common altitude the radius of the inscribed circle; hence, the sum of these triangles will be equal to the sum of the bases  $AB$ ,  $BC$ ,  $AC$ , multiplied by half the radius  $OD$ ; hence, the area of the triangle  $ABC$  is equal to its perimeter multiplied by half the radius of the inscribed circle.

PROPOSITION XXXIII. THEOREM.

*In every quadrilateral inscribed in a circle, the rectangle of the two diagonals is equivalent to the sum of the rectangles of the opposite sides.*

Let  $ABCD$  be a quadrilateral inscribed in a circle, and  $AC$ ,  $BD$ , its diagonals: then we shall have

$$AC \times BD = AB \times CD + AD \times BC.$$

Take the arc  $CO = AD$ , and draw  $BO$ , meeting the diagonal  $AC$  in  $I$ .

The angle  $ABD = CBI$ , since the one has for its measure half of the arc  $AD$  (B. III., P. 18), and the other, half of  $CO$ , equal to  $AD$ ; the angle  $ADB = BCI$ , because they are subtended by

the same arc; hence, the triangle  $ABD$  is similar to the triangle  $IBC$ , and we have the proportion

$$AD : CI :: BD : BC;$$

and consequently,

$$AD \times BC = CI \times BD.$$

Again, the triangle  $ABI$  is similar to the triangle  $BDC$ ; for the arc  $AD$  being equal to  $CO$ , if  $OD$  be added to each of them, we shall have the arc  $AO = DC$ ; hence, the angle  $ABI$  is equal to  $DBC$ ; also, the angle  $BAI$  to  $BDC$ , because they stand on the same arc; hence, the triangles  $ABI$ ,  $BDC$ , are similar, and the homologous sides give the proportion

$$AB : BD :: AI : CD;$$

hence,

$$AB \times CD = AI \times BD.$$

Adding the two results obtained, and observing that

$$AI \times BD + CI \times BD = (AI + CI) \times BD = AC \times BD,$$

we shall have

$$AD \times BC + AB \times CD = AC \times BD.$$

## PROBLEMS

### RELATING TO THE FOURTH BOOK.

#### PROBLEM I.

To divide a given straight line into any number of equal parts, or into parts proportional to given lines.

*First.* Let it be proposed to divide the line  $AB$  into five equal parts. Through the extremity  $A$ , draw the indefinite straight line  $AG$ : take  $AC$  of any magnitude, and apply it five times upon  $AG$ ; join the last point of division  $G$ , and the extremity  $B$  of the given line, by the straight line  $GB$ ; then through  $C$ , draw  $CI$  parallel to  $GB$ :

$AI$  will be the fifth part of the line  $AB$ ; and by applying  $AI$  five times upon  $AB$ , the line  $AB$  will be divided into five equal parts.

For, since  $CI$  is parallel to  $GB$ , the sides  $AG$ ,  $AB$ , are cut proportionally in  $C$  and  $I$  (p. 15). But  $AC$  is the fifth part of  $AG$ , hence,  $AI$  is the fifth part of  $AB$ .

*Secondly.* Let it be proposed to divide the line  $AB$  into parts proportional to the given lines  $P$ ,  $Q$ ,  $R$ . Through  $A$ , draw the indefinite line  $AG$ ; make  $AC=P$ ,  $CD=Q$ ,  $DE=R$ ; join the

extremities  $E$  and  $B$ ; and through the points  $C$  and  $D$ , draw  $CI$ ,  $DF$ , parallel to  $EB$ ; the line  $AB$  will be divided into parts  $AI$ ,  $IF$ ,  $FB$ , proportional to the given lines  $P$ ,  $Q$ ,  $R$ .

For, by reason of the parallels  $CI$ ,  $DF$ ,  $EB$ , the parts  $AI$ ,  $IF$ ,  $FB$ , are proportional to the parts  $AC$ ,  $CD$ ,  $DE$  (p. 15, c. 2); and by construction, these are equal to the given lines  $P$ ,  $Q$ ,  $R$ .

PROBLEM II.

To find a fourth proportional to three given lines,  $A$ ,  $B$ ,  $C$ .

Draw the two indefinite lines  $DE$ ,  $DF$ , forming any angle with each other. Upon  $DE$  take  $DA=A$ , and  $DB=B$ ; upon  $DF$  take  $DC=C$ , draw  $AC$ ; and through

the point  $B$ , draw  $BX$  parallel to  $AC$ ; and  $DX$  will be the fourth proportional required. For, since  $BX$  is parallel to  $AC$ , we have the proportion (p. 15, c. 1),

$$DA : DB :: DC : DX;$$

now, the first three terms of this proportion are equal to the three given lines: consequently,  $DX$  is the fourth proportional required.

*Cor.* A third proportional to two given lines,  $A, B$ , may be found in the same manner, for it will be the same as a fourth proportional to the three lines,  $A, B, B$ .

## PROBLEM III.

To find a mean proportional between two given lines  $A$  and  $B$ .

Upon the indefinite line  $DF$ , take  $DE=A$ , and  $EF=B$ ; and upon the whole line  $DF$ , as a diameter, describe the semicircumference  $DGF$ ; at the point  $E$ , erect, upon the diameter, the perpendicular  $EG$  meeting the semicircumference in  $G$ ;  $EG$  will be the mean proportional required.

For, the perpendicular  $EG$ , let fall from a point in the circumference upon the diameter, is a mean proportional between the two segments of the diameter  $DE, EF$  (P. 23, c.); and these segments are equal to the given lines  $A$  and  $B$ .

## PROBLEM IV.

To divide a given line into two such parts, that the greater part shall be a mean proportional between the whole line and the other part.

Let  $AB$  be the given line.

At the extremity  $B$ , erect the perpendicular  $BC$ , equal to the half of  $AB$ ; from the point  $C$ , as a centre, with the radius  $CB$ , describe a semicircle; draw  $AC$  cutting the circumference in  $D$ ; and take  $AF=AD$ : then  $F$  will be the point of division, and we shall have,

$$AB : AF :: AF : FB.$$

For,  $AB$  being perpendicular to the radius at its extremity, is a tangent (B. III., P. 9); and if  $AC$  be prolonged

till it again meets the circumference, in  $E$ , we shall have (P. 30),

$$AE : AB :: AB : AD;$$

hence, by division,

$$AE - AB : AB :: AB - AD : AD.$$

But, since the radius is the half of  $AB$ , the diameter  $DE$  is equal to  $AB$ , and consequently,  $AE - AB = AD = AF$ ; also, because  $AF = AD$ , we have  $AB - AD = FB$ : hence,

$$AF : AB :: FB : AD, \text{ or } AF;$$

whence, by inversion,

$$AB : AF :: AF : FB.$$

*Scholium.* This sort of division of the line  $AB$ , viz., so that the whole line shall be to the greater part as the greater part is to the less, is called division in extreme and mean ratio. It may further be observed, that the secant  $AE$  is divided in extreme and mean ratio at the point  $D$ ; for, since  $AE = DE$ , we have,

$$AE : DE :: DE : AD.$$

PROBLEM V.

*Through a given point, in a given angle, to draw a line so that the segments comprehended between the point and the two sides of the angle, shall be equal.*

Let  $BCD$  be the given angle, and  $A$  the given point.

Through the point  $A$ , draw  $AE$  parallel to  $CD$ , make  $BE = CE$ , and through the points  $B$  and  $A$ , draw  $BAD$ ; this will be the line required.

For,  $AE$  being parallel to  $CD$ , we have,

$$BE : EC :: BA : AD;$$

but  $BE = EC$ ; therefore,  $BA = AD$ .

## PROBLEM VI.

To describe a square that shall be equivalent to a given parallelogram, or to a given triangle.

*First.* Let  $ABCD$  be the given parallelogram,  $AB$  its base, and  $DE$  its altitude: between  $AB$  and  $DE$  find a mean proportional  $XY$ ; then will the square described upon  $XY$  be equivalent to the parallelogram  $ABCD$ .

For, by construction,

$$AB : XY :: XY : DE;$$

therefore,

$$\overline{XY}^2 \simeq AB \times DE;$$

but  $AB \times DE$  is the measure of the parallelogram (P. 5), and  $\overline{XY}^2$  that of the square; consequently, they are equivalent.

*Secondly.* Let  $BAC$  be the given triangle,  $BC$  its base,  $AD$  its altitude: find a mean proportional between  $BC$  and the half of  $AD$ , and let  $XY$  be that mean; the square described upon  $XY$

will be equivalent to the triangle  $BAC$ .

For, since

$$BC : XY :: XY : \frac{1}{2}AD,$$

it follows, that

$$\overline{XY}^2 \simeq BC \times \frac{1}{2}AD;$$

hence, the square described upon  $XY$  is equivalent to the triangle  $BAC$ .

## PROBLEM VII.

Upon a given line, to describe a rectangle that shall be equivalent to a given rectangle.

Let  $AD$  be the line, and  $ABFC$  the given rectangle.

Find a fourth proportional to the three lines,  $AD$ ,  $AB$ ,  $AC$ , and let  $AX$  be that fourth proportional; a rectangle constructed with the sides  $AD$  and  $AX$  will be equivalent to the rectangle  $ABFC$ .

For, since

$$AD : AB :: AC : AX,$$

it follows, that  $AD \times AX \simeq AB \times AC$ ;

hence, the rectangle  $ADEX$  is equivalent to the rectangle  $ABFC$ .

PROBLEM VIII.

To find two lines whose ratio shall be the same as the ratio of two rectangles contained by given lines.

Let  $A \times B$ ,  $C \times D$ , be the rectangles contained by the given lines  $A$ ,  $B$ ,  $C$ , and  $D$ .

Find  $X$ , a fourth proportional to the three lines,  $B$ ,  $C$ ,  $D$ ; then will the two lines  $A$  and  $X$  have the same ratio to each other as the rectangles  $A \times B$  and  $C \times D$ .

For since,

$$B : C :: D : X,$$

it follows that  $C \times D \simeq B \times X$ ; hence,

$$A \times B : C \times D :: A \times B : B \times X :: A : X.$$

Cor. Hence, to obtain the ratio of the squares described upon the given lines  $A$  and  $C$ , find a third proportional  $X$ , to the lines  $A$  and  $C$ , so that

$$A : C :: C : X;$$

you will then have

$$A \times X \simeq C^2, \text{ or } A^2 \times X \simeq A \times C^2; \text{ hence,}$$

$$A^2 : C^2 :: A : X.$$

## PROBLEM IX.

To find a triangle that shall be equivalent to a given polygon.

Let  $AEDCB$  be the given polygon.

First. Draw the diagonal  $CE$  cutting off the triangle  $CDE$ ; through the point  $D$ , draw  $DF$  parallel to  $CE$ , meeting  $AE$  prolonged, in  $F$ ; draw  $CF$ : the polygon  $AEDCB$  is equivalent to the polygon  $AFCB$ , which has one side less than the given polygon.

For the triangles  $CDE$ ,  $CFE$ , have the base  $CE$  common, they have also equal altitudes, since their vertices  $D$  and  $F$ , are situated in a line  $DF$  parallel to the base: these triangles are therefore equivalent (p. 2, c.) Add to each of them the figure  $AECB$ , and there will result the polygon  $AEDCB$ , equivalent to the polygon  $AFCB$ .

The angle  $B$  may in like manner be cut off, by substituting for the triangle  $ABC$ , the equivalent triangle  $AGC$ , and thus the pentagon  $AEDCB$  will be changed into an equivalent triangle  $GCF$ .

The same process may be applied to every other figure; for, by successively diminishing the number of its sides, one being retrenched at each step of the process, the equivalent triangle will at last be found.

*Scholium.* We have already seen that every triangle may be changed into an equivalent square (PROB. 6); and thus a square may always be found equivalent to a given rectilinear figure, which operation is called *squaring* the rectilinear figure, or the *quadrature* of it.

The problem of the *quadrature of the circle* consists in finding a square equivalent to a circle whose diameter is given.

PROBLEM X.

To find the side of, a square which shall be equivalent to the sum or the difference of two given squares.

Let  $A$  and  $B$  be the sides of the given squares.

*First.* If it is required to find a square equivalent to the sum of these squares, draw the two indefinite lines,  $ED$ ,  $EF$ , at right angles to each other; take  $ED=A$ , and  $EG=B$ ; and draw  $DG$ : this will be the required side of the square.

For the triangle  $DEG$  being right-angled, the square described upon the hypotenuse  $DG$ , is equivalent to the sum of the squares upon  $ED$  and  $EG$  (P. 11).

*Secondly.* If it is required to find a square equivalent to the difference of the given squares, form, as before, the right angle  $FEH$ ; take  $GE$  equal to the shorter of the sides  $A$  and  $B$ ; from the point  $G$  as a centre, with a radius  $GH$ , equal to the other side, describe an arc cutting  $EH$  in  $H$ : the square described upon  $EH$  will be equivalent to the difference of the squares described upon the lines  $A$  and  $B$ .

For, the triangle  $GEH$  is right-angled, the hypotenuse  $GH=A$ , and the side  $GE=B$ ; hence, the square described upon  $EH$ , is equivalent to the difference of the squares  $A$  and  $B$  (P. 11, c. 1).

*Scholium.* A square may thus be found, equivalent to the sum of any number of squares; for a construction similar to that which reduces two of them to one, will reduce three of them to two, and these two to one, and so of others. It would be the same, if any of the squares were to be subtracted from the sum of the others.

## PROBLEM XI.

To find a square which shall be to a given square as one given line is to another given line.

Let  $AC$  be the given square, and  $M$  and  $N$  the given lines.

Upon the indefinite line  $EG$ , take  $EF = M$ , and  $FG = N$ ; upon  $EG$  as a diameter describe a semicircle, and at the point  $F$  erect the perpendicular  $FH$ .

From the point  $H$ , draw the chords  $HG$ ,  $HE$ , which produce indefinitely: upon the first, take  $HK$  equal to the side  $AB$  of the given square, and through the point  $K$  draw  $KI$  parallel to  $EG$ ;  $HI$  will be the side of the required square.

For, by reason of the parallels  $KI$ ,  $GE$ , we have

$$HI : HK :: HE : HG;$$

hence,  $\overline{HI}^2 : \overline{HK}^2 :: \overline{HE}^2 : \overline{HG}^2 :$

but in the right-angled triangle  $GHE$ , the square of  $HE$  is to the square of  $HG$  as the segment  $EF$  is to the segment  $FG$  (p. 11, c. 3), or as  $M$  is to  $N$ ; hence,

$$\overline{HI}^2 : \overline{HK}^2 :: M : N.$$

But  $HK = AB$ ; therefore, the square described upon  $HI$  is to the square described upon  $AB$  as  $M$  is to  $N$ .

## PROBLEM XII.

Upon a given line, to describe a polygon similar to a given polygon.

Let  $FG$  be the given line, and  $AEDCB$  the given polygon.

In the given polygon, draw the diagonals  $AC, AD$ ; at the point  $F$  make the angle  $GFH = BAC$ , and at the point  $G$ , the angle  $FGH = ABC$ ; the lines  $FH, GH$  will intersect each other in  $H$ , and the triangle  $FGH$  will be similar to  $ABC$  (P. 18). In the same manner upon  $FH$ , homologous to  $AC$ , describe the triangle  $FIH$  similar to  $ADC$ ; and upon  $FI$ , homologous to  $AD$ , describe the triangle  $FIK$  similar to  $ADE$ . The polygon  $FGHIK$  will be similar to  $ABCDE$ , as required.

For, these two polygons are composed of the same number of similar triangles, similarly placed (P. 26, s.)

PROBLEM XIII.

*Two similar figures being given, to describe a similar figure which shall be equivalent to their sum or difference.*

Let  $A$  and  $B$  be homologous sides of the given figures.

Find a square equivalent to the sum or difference of the squares described upon  $A$  and  $B$ ; let  $X$  be the side of that square; then will  $X$  be that side in the figure required, which is homologous to the

sides  $A$  and  $B$  in the given figures. Let the figure itself, then, be constructed on the side  $X$ , as in the last problem. This figure will be equivalent to the sum or difference of the figures described on  $A$  and  $B$  (P. 27, c.)

PROBLEM XIV.

*To describe a figure similar to a given figure, and bearing to it the given ratio of  $M$  to  $N$ .*

Let  $A$  be a side of the given figure,  $X$  the homologous side of the required figure.

Find the value of  $X$ , such, that its square shall be to the square of  $A$ , as  $M$  to  $N$  (PROB. 11). Then upon  $X$  describe a figure similar to the given figure (PROB. 12): this will be the figure required.

## PROBLEM XV.

To construct a figure similar to the figure  $P$ , and equivalent to the figure  $Q$ .

Find  $M$ , the side of a square equivalent to the figure  $P$ , and  $N$  the side of a square equivalent to the figure  $Q$  (PROB. 9, s.) Let  $X$  be a fourth proportional to the three given lines,  $M$ ,  $N$ ,  $AB$ ; upon the side  $X$ , homologous to  $AB$ , describe a figure similar to the figure  $P$ ; it will also be equivalent to the figure  $Q$ .

For, calling  $Y$  the figure described upon the side  $X$ , we have,

$$P : Y :: \overline{AB}^2 : X^2;$$

but by construction,

$$AB : X :: M : N, \text{ or, } \overline{AB}^2 : X^2 :: M^2 : N^2;$$

hence,  $P : Y :: M^2 : N^2$ .

But, by construction also,

$$M^2 \simeq P, \text{ and } N^2 \simeq Q.$$

therefore,  $P : Y :: P : Q$ ;

consequently,  $Y \simeq Q$ ; hence, the figure  $Y$  is similar to the figure  $P$ , and equivalent to the figure  $Q$ .

## PROBLEM XVI.

To construct a rectangle equivalent to a given square, and having the sum of its adjacent sides equal to a given line.

Let  $C$  be the square, and the line  $AB$  equal to the sum of the sides of the required rectangle.

Upon  $AB$  as a diameter, describe a semicircle; at  $A$ , draw  $AD$  perpendicular to  $AB$ , and make it equal to the side of the square  $C$ ;

then draw the line  $DE$  parallel to the diameter  $AB$ ; from the point  $E$ , where the parallel cuts the circumference, draw  $EF$  perpendicular to the diameter;  $AF$  and  $FB$  will be the sides of the required rectangle.

For, their sum is equal to  $AB$ ; and their rectangle  $AF \times FB$  is equivalent to the square of  $EF$ , or to the square of  $AD$ ; hence, this rectangle is equivalent to the given square  $C$ .

*Scholium.* The problem is impossible, if the distance  $AD$  exceeds the radius; that is, the side of the square  $C$  must not exceed half the line  $AB$ .

PROBLEM XVII.

To construct a rectangle that shall be equivalent to a given square, and the difference of whose adjacent sides shall be equal to a given line.

Let  $C$  denote the given square, and  $AB$  the difference of the sides of the rectangle.

Upon the given line  $AB$ , as a diameter, describe a circumference. At the extremity of the diameter, draw the tangent  $AD$ , and make it equal to the side of the square  $C$ ; through the point  $D$  and the centre  $O$  draw the secant  $DOF$ , intersecting the circumference in  $E$  and  $F$ ; then will  $DE$  and  $DF$  be the adjacent sides of the required rectangle.

For, the difference of these lines is equal to the diameter  $EF$  or  $AB$ ; and the rectangle  $DE, DF$  is equivalent to  $AD^2$  (p. 30); hence, the rectangle  $DF \times DE$ , is equivalent to the given square  $C$

## PROBLEM XVIII.

To find the common measure, between the side and diagonal of a square.

Let  $ABCG$  be any square, and  $AC$  its diagonal.

We first apply  $CB$  upon  $CA$ . For this purpose let the semicircle  $DBE$  be described, from the centre  $C$ , with the radius  $CB$ , and produce  $AC$  to  $E$ . It is evident that  $CB$  is contained once in  $AC$ , with the remainder  $AD$ . The result of the first operation is, therefore, a quotient 1, with the remainder  $AD$ .

This remainder must now be compared with  $BC$ , or its equal  $AB$ .

Since the angle  $ABC$  is a right angle,  $AB$  is a tangent, and since  $AE$  is a secant drawn from the same point, we have (p. 30),

$$AD : AB :: AB : AE.$$

Hence, in the second operation, where  $AD$  is compared with  $AB$ , the equal ratio of  $AB$  to  $AE$  may be taken instead: but  $AB$ , or its equal  $CD$ , is contained twice in  $AE$ , with the remainder  $AD$ ; the result of the second operation is therefore a quotient 2 with the remainder  $AD$ , and this must be again compared with  $AB$ .

Thus, the third operation consists in comparing again  $AD$  with  $AB$ , and may be reduced in the same manner to the comparison of  $AB$  or its equal  $CD$  with  $AE$ ; from which there will again be obtained a quotient 2, and the remainder  $AD$ .

Hence, it is evident that the process will never terminate, and consequently that no remainder is contained in its divisor an exact number of times; therefore, there is no common measure between the side and the diagonal of a square. This property has already been shown, since (p. 11, c. 5),

$$AB : AC :: 1 : \sqrt{2},$$

but it acquires a greater degree of clearness by the geometrical investigation.

# BOOK V.

## REGULAR POLYGONS—MEASUREMENT OF THE CIRCLE.

### DEFINITION.

A **REGULAR POLYGON** is one which is both equilateral and equiangular.

A regular polygon may have any number of sides. The equilateral triangle is one of three sides; the square, is one of four.

### PROPOSITION I. THEOREM.

*Regular polygons of the same number of sides are similar figures.*

Let  $ABCDEF$ ,  $abcdef$ , be two such polygons.

Then, either angle, as  $A$ , of the polygon  $ABCDEF$ , is equal to twice as many right angles less four, as the figure has sides, divided by the number of sides; and the same is true of either angle of the other polygon (B. I., P. 26, C. 4); hence (A. 1), the angles of the polygons are equal.

Again, since the polygons are regular, the sides  $AB$ ,  $BC$ ,  $CD$ , &c., are equal, and so likewise the sides  $ab$ ,  $bc$ ,  $cd$  ( $d$ .), &c.; hence

$$AB : ab :: BC : bc :: CD : cd, \&c.;$$

therefore, the two polygons have their angles equal, and their sides taken in the same order proportional; consequently, they are similar (B. IV., D. 1).

*Cor. 1.* The perimeters of two regular polygons of the same number of sides, are to each other as their homologous sides, and their surfaces are to each other as the squares of those sides (B. IV., P. 27).

*Cor. 2.* The angle of a regular polygon, like the angle of an equiangular polygon, is determined by the number of its sides (B. I., P. 26, C. 4).

PROPOSITION II. THEOREM.

*A regular polygon may be circumscribed by the circumference of a circle, and a circle may be inscribed within it.*

Let  $HGFE$ , &c., be any regular polygon.

Through the three points  $A, B, C$ , describe the circumference of a circle: the centre  $O$  will lie in the line  $OP$ , drawn perpendicular to  $BC$  at the middle point  $P$  (B. III., P. 6, s.) Then draw  $OB$  and  $OC$ .

If the quadrilateral  $OPCD$  be placed upon the quadrilateral  $OPBA$ , they will coincide; for, the side  $OP$  is common; the angle  $OPC = OPB$ , each being a right angle; hence, the side  $PC$  will apply to its equal  $PB$ , and the point  $C$  will fall on  $B$ : besides, the polygon being regular, the angle  $PCD = PBA$  (D.); hence,  $CD$  will take the direction  $BA$ ; and since  $CD = BA$ , the point  $D$  will fall on  $A$ , and the two quadrilaterals will coincide. Hence,  $OD$  is equal to  $AO$ ; and consequently, the circumference which passes through the three points  $A, B, C$ , will also pass through the point  $D$ . In the same manner it may be shown, that the circumference which passes through the three points  $B, C, D$ , will also pass through the point  $E$ ; and so of all the other vertices; hence, the circumference which passes through the points  $A, B, C$ , passes also through the vertices of all the angles of the polygon, consequently, the circumference of the circle circumscribes the polygon (B. III., D. 7).

Again, in reference to this circle, all the sides  $AB, BC, CD$ , &c., of the polygon, are equal chords; they are therefore equally distant from the centre (B. III., P. 8): hence, if from the point  $O$  as a centre, with the distance  $OP$ , a circumference be described, it will touch the side  $BC$ , and all the other sides of the polygon, each in its middle point, and the circle will be inscribed in the polygon (B. III., D. 11).

*Scholium.* The point  $O$ , the common centre of the inscribed and circumscribed circles, may also be regarded as the centre of the polygon; and the angle  $AOB$  is called *the angle at the centre*, being formed by two lines drawn from the centre to the extremities of the same side  $AB$ . The perpendicular  $OP$ , is called the *apothem* of the polygon.

*Cor.* 1. Since all the chords  $AB, BC, CD, \&c.$ , are equal, all the angles at the centre are likewise equal (B. III., P. 4); and therefore, the value of any angle will be found by dividing four right angles by the number of sides of the polygon.

*Cor.* 2. To inscribe a regular polygon of any number of sides in a given circle, we have only to divide the circumference into as many equal parts as the polygon has sides; for, when the arcs are equal, the chords  $AB, BC, CD, \&c.$ , are also equal (B. III., P. 4);

hence, likewise the triangles  $AOB, BOC, COD, \&c.$ , must be equal, because their sides are equal each to each (B. I., P. 10); therefore, by addition, all the angles  $ABC, BCD, CDE, \&c.$ , are equal (A. 2); hence, the figure  $ABCDEH$ , is a regular polygon.

PROPOSITION III. PROBLEM.

*To inscribe a square in a given circle.*

Draw two diameters  $AC, BD$ , intersecting each other at right angles; join their extremities  $A, B, C, D$ , the figure  $ABCD$  will be a square.

For, the angles  $AOB, BOC, \&c.$ , being equal, the chords  $AB, BC, \&c.$ , are also equal (B. III., P. 4): and the angles  $ABC, BCD, \&c.$ , being inscribed in semicircles, are right angles (B. III., P. 18, c. 2).

*Scholium.* Since the triangle  $BCO$  is right-angled and isosceles, we have (B. IV., P. 11, c. 5),  $BC : BO :: \sqrt{2} : 1$ , hence, *the side of the inscribed square is to the radius, as the square root of two, to unity.*

## PROPOSITION IV. THEOREM.

*If a regular hexagon be inscribed in a circle, its side will be equal to the radius.*

Let  $ABCDEF$ , be a regular hexagon, inscribed in a circle: then will its side  $AB$  be equal to the radius  $OA$ .

For, the angle  $AOB$  is equal to one-sixth of four right angles, (P. 2, c. 1), or one-third of two right angles: hence, the sum of the remaining angles  $OAB$ ,  $OBA$ , is equal to two-thirds of two right angles (B. I., P. 25). But the triangle  $AOB$  is isosceles, hence, the angles at the base are equal (B. I., P. 11): therefore each is one-third of two right angles: hence, the triangle  $AOB$  is equiangular: hence,  $AB = AO$  (B. I., P. 12).

## PROPOSITION V. PROBLEM.

*To inscribe in a given circle, a regular hexagon.*

Let  $O$  be the centre, and  $OB$  the radius of the given circle.

Beginning at any point, as  $B$ , apply the radius  $BO$ , six times as a chord to the circumference, and we shall form the regular hexagon  $BCDEFA$  (P. 4). Hence, to inscribe a regular hexagon in a given circle, the radius must be applied six times as a chord, to the circumference; which will bring us round to the point of beginning.

*Cor. 1* If the vertices of the alternate angles be joined

by the lines  $AC$ ,  $OE$ ,  $EA$ , there will be inscribed in the circle an equilateral triangle  $ACE$ , since each of its angles will be measured by one-sixth of four right angles, or one-third of two (B. I., P. 25, c. 5).

*Cor. 2.* If we draw the radii  $OA$ ,  $OC$ , the figure  $OCBA$  will be a rhombus: for, we have

$$OC = CB = BA = AO.$$

Hence, the sum of the squares of the diagonals is equivalent to the sum of the squares of the sides (B. IV., P. 14, c. 2):

that is,  $\overline{AC}^2 + \overline{OB}^2 = 4\overline{AB}^2 = 4\overline{OB}^2$ ;

and by taking away  $\overline{OB}^2$ , we have,

$$\overline{AC}^2 = 3\overline{OB}^2; \text{ hence,}$$

$$\overline{AC}^2 : \overline{OB}^2 : 3 : 1; \text{ or,}$$

$$AC : OB :: \sqrt{3} : 1:$$

hence, the side of the inscribed equilateral triangle is to the radius, as the square root of three, to unity.

PROPOSITION VI. PROBLEM.

*In a given circle to inscribe a regular decagon.*

Let  $O$  be the centre, and  $OA$  the radius of the given circle.

Divide the radius  $OA$  in extreme and mean ratio at the point  $M$  (B. IV., PROB. 4): Take  $OM$ , the greater segment, and lay it off from  $A$  to  $B$ ; the chord  $AB$  will be the side of the regular decagon, and by applying it ten times to the circumference, the decagon will be inscribed in the circle.

For, drawing  $MB$ , we have by construction,

$$AO : OM :: OM : AM;$$

or, since  $AB = OM$ ,

$$AO : AB :: AB : AM.$$

But since the triangles  $ABO$ ,  $AMB$ , have a common angle  $A$ , included between proportional sides, they are similar (B. IV., P. 20). Now the triangle  $BAO$  being isosceles,  $AMB$  must be isosceles also, and  $AB = BM$ ; but  $AB = OM$ ; hence, also  $MB = MO$ ; hence, the triangle  $BMO$  is isosceles.

Again, in the isosceles triangle  $BMO$ , the angle  $AMB$  being exterior, is double the interior angle  $O$  (B. I., P. 25, c. 6): but the angle  $AMB = MAB$ ; hence, the triangle  $OAB$  is such, that each of the angles  $OAB$  or  $OBA$ , at its base, is double the angle  $O$ , at its vertex; hence, the three angles of the triangle are together equal to five times the angle  $O$ , which consequently, is the fifth part of two right angles, or the tenth part of four; hence, the arc  $AB$  is the tenth part of the circumference, and the chord  $AB$  is the side of the regular decagon.

*Cor. 1.* By joining the vertices of the alternate angles of the decagon, a regular pentagon  $ACEGI$  will be inscribed.

*Cor. 2.* Any regular polygon being inscribed, if the arcs which the sides subtend be severally bisected, the chords of those semi-arcs will form a new regular polygon of double the number of sides: thus it is plain, that the square will enable us to inscribe, successively, regular polygons of 8, 16, 32, &c., sides. And in like manner, by means of the hexagon, regular polygons of 12, 24, 48, &c., sides may be inscribed; and by means of the decagon, polygons of 20, 40, 80, &c., sides.

*Cor. 3.* It is further evident, that any of the inscribed polygons will be less than the inscribed polygon of double the number of sides, since a part is less than the whole.

PROPOSITION VII. PROBLEM.

*A regular inscribed polygon being given, to circumscribe a similar polygon about the same circle.*

Let  $O$  be the centre of the circle, and  $CDEFAB$  regular inscribed polygon.

At  $T$ , the middle point of the arc  $AB$ , draw a tangent  $GH$ , and do the same at the middle point of each of the arcs  $BC$ ,  $CD$ , &c.; these tangents will be parallel to the chords  $AB$ ,  $BC$ ,  $CD$ , &c. (B. III., p. 10, c.); and will, by their intersections, form the regular circumscribed polygon  $GHIK$  &c., similar to the one inscribed.

For, since  $T$  is the middle point of the arc  $BTA$ , and  $N$  the middle point of the equal arc  $BNC$ , it follows, that  $BT=BN$ ; or that the vertex  $B$  of the inscribed polygon, is at the middle point of the arc  $NBT$ . Draw  $OH$ . The line  $OH$  will pass through the point  $B$ .

For, the right-angled triangles  $OTH$ ,  $NOH$ , having the common hypotenuse  $OH$ , and the side  $OT=ON$ , are equal (B. I., p. 17), and consequently the angle  $TOH=HON$ , wherefore the line  $OH$  passes through the middle point  $B$  of the arc  $TN$  (B. III., p. 15). In the same manner it may be shown that  $OI$  passes through  $C$ ; and similarly for the other vertices.

But since  $GH$  is parallel to  $AB$ , and  $HI$  to  $BC$ , the angle  $GHI=ABC$  (B. I., p. 24); in like manner,  $HIK=BCD$  and so for the other angles: hence, the angles of the circumscribed polygon are equal to those of the inscribed. And further, by reason of these same parallels, we have

$GH : AB :: OH : OB$ , and  $HI : BC :: OH : OB$ ;  
therefore,  $GH : AB :: HI : BC$ .

But  $AB=BC$ ,  
therefore  $GH=HI$ .

For a like reason,  
 $HI=IK$ , &c.; hence,  
the sides of the circum-  
scribed polygon are all  
equal; hence, this poly-  
gon is regular and simi-  
lar to the inscribed  
polygon.

*Cor. 1.* Reciprocal-  
ly: if the circumscribed polygon  $GHIK$  &c., be given, and  
the inscribed one  $ABC$  &c., be required, it will only be  
necessary to draw from the vertices of the angles  $G, H, I$ ,  
&c., of the given polygon, straight lines  $OG, OH$ , &c., meet-  
ing the circumference in the points  $A, B, C$ , &c.; then to  
join these points by the chords  $AB, BC$ , &c.; this will  
form the inscribed polygon. An easier solution of this  
problem would be, simply to join the points of contact  $T$ ,  
 $N, P$ , &c., by chords  $TN, NP$ , &c., which likewise would  
form an inscribed polygon similar to the circumscribed one

*Cor. 2.* Hence, we may circumscribe about a circle any  
regular polygon similar to an inscribed one, and con-  
versely.

*Cor. 3.* It is plain that  $NH+HT=HT+TG=HG$ , one  
of the equal sides of the polygon.

*Cor. 4.* If through  $B, A, F$ , &c., the middle points of  
the arcs  $NBT, TAS, SFR$ , &c., we draw tangent lines, we  
shall thus form a new regular circumscribed polygon having  
double the number of sides: and this process may be re-  
peated as often as we please. The new polygon will be  
regular, because it will be similar to a new inscribed poly-  
gon which may be formed (P. 6, c. 2) of double the number  
of sides of the first. It is plain, that each new circumscribed  
polygon will be less than the one from which it was derived,  
since a part is less than the whole.

PROPOSITION VIII. THEOREM.

*The area of a regular polygon is equal to its perimeter multiplied by half the radius of the inscribed circle.*

Let there be the regular polygon  $GHIK$ , and  $ON$ ,  $OT$ , radii of the inscribed circle drawn to the points of tangency: then will its area be equal to the perimeter multiplied by one-half of  $OT$ .

For, the triangle  $GOH$  is measured by  $GH \times \frac{1}{2} OT$ ; the triangle  $OHI$ , by  $HI \times \frac{1}{2} ON$ : but  $ON = OT$ ; hence, the two triangles taken together are measured by

$$(GH + HI) \times \frac{1}{2} OT.$$

And, by finding the measures of the other triangles, it will appear that the sum of them all, or the whole polygon, is measured by the sum of the bases  $GH$ ,  $HI$ , &c., or, the perimeter of the polygon, multiplied by one-half of  $OT$ ; that is, the area of the polygon is equal to its perimeter multiplied by half the radius of the inscribed circle.

PROPOSITION IX. THEOREM.

*The perimeters of regular polygons, having the same number of sides, are to each other as the radii of the circumscribed circles; and also, as the radii of the inscribed circles; and their areas are to each other as the squares of those radii.*

Let  $AB$  be the side of one polygon,  $O$  the centre, and consequently  $OA$  the radius of the circumscribed circle, and  $OD$ , perpendicular to  $AB$ , the radius of the inscribed circle. Let  $ab$ , be a side of the other polygon,  $o$  the centre,  $oa$  and  $od$ , the radii of the circumscribed and the inscribed circles.

Then, the perimeters of the two polygons are to each other as the sides  $AB$  and  $ab$  (B. IV., P. 27): but the angles  $A$  and  $a$  are equal, being

each half of the angle of the polygon; so also are the angles  $B$  and  $b$ ; hence, the triangles  $ABO$ ,  $abo$ , are similar, as are, likewise, the right-angled triangles  $ADO$ ,  $ado$ ; therefore,

$$AB : ab :: AO : ao :: DO : do ;$$

hence, the perimeters of the polygons are to each other as the radii  $AO$ ,  $ao$ , of the circumscribed circles, and also, as the radii  $DO$ ,  $do$ , of the inscribed circles.

The surfaces of these polygons are to each other as the squares of the homologous sides  $AB$ ,  $ab$  (B. IV., P. 27); they are therefore likewise to each other as the squares of  $AO$ ,  $ao$ , the radii of the circumscribed circles, or as the squares of  $OD$ ,  $od$ , the radii of the inscribed circles.

PROPOSITION X. THEOREM.

*Two regular polygons, of the same number of sides, can always be formed, the one circumscribed about a circle, the other inscribed in it, which shall differ from each other by less than any given surface.*

Let  $Q$  be the side of a square less than the given surface. Bisect  $AC$ , a fourth part of the circumference, and then bisect the half of this fourth, and proceed in this manner, always bisecting one of the arcs formed by the last bisection, until an arc is found whose chord  $AB$  is less than  $Q$ . As this arc will be an exact part of the circumference, if we apply the chords  $AB$ ,  $BC$ ,  $CD$ , &c., each equal to  $AB$ , the last will terminate at  $A$ , and there will be formed a regular polygon  $ABCDE$  &c., inscribed in the circle.

Next, describe about the circle a similar polygon  $abcde$  &c. (P. 7): the difference of these two polygons will be less than the square of  $Q$ .

For, from the points  $a$  and  $b$ , draw the lines  $aO$ ,  $bO$ , to the centre  $O$ : they will pass through the points  $A$  and  $B$  (P. 7). Draw also  $OK$  to the point of contact  $K$ : it will

bisect  $AB$  in  $I$ , and be perpendicular to it (B. III., P. 6, s.) Prolong  $AO$  to  $E$ , and draw  $BE$ .

Let  $p$  represent the circumscribed polygon, and  $P$  the inscribed polygon: then since the triangles  $aOb$ ,  $AOB$ , are like parts of  $p$  and  $P$ , we have (B. II., P. 11),

$$aOb : AOB :: p : P:$$

But the triangles being similar (B. IV., P. 25),

$$aOb : AOB :: \overline{Oa}^2 : \overline{OA}^2, \text{ or } \overline{OK}^2.$$

Hence,  $p : P :: \overline{Oa}^2 : \overline{OK}^2$ .

Again, since the triangles  $OaK$ ,  $EAB$  are similar, having their sides respectively parallel (B. IV., P. 21).

$$\overline{Oa}^2 : \overline{OK}^2 :: \overline{AE}^2 : \overline{EB}^2, \text{ hence}$$

$$p : P :: \overline{AE}^2 : \overline{EB}^2, \text{ or by division (B. II., P. 6),}$$

$$p : p - P :: \overline{AE}^2 : \overline{AE}^2 - \overline{EB}^2, \text{ or } \overline{AB}^2.$$

But  $p$  is less than the square described on the diameter  $AE$  (P. 7, C. 4); therefore,  $p - P$  is less than the square described on  $AB$ : that is, less than the given square on  $Q$ : hence, the difference between the circumscribed and inscribed polygons may, by increasing the number of sides, always be made less than any given surface.

PROPOSITION XI. PROBLEM.

*The surface of a regular inscribed polygon, and that of a similar circumscribed polygon, being given; to find the surfaces of the regular inscribed and circumscribed polygons having double the number of sides.*

Let  $AB$  be a side of the given inscribed polygon;  $EF$ , parallel to  $AB$ , a side of the circumscribed polygon, and  $O$  the centre of the circle. If the chord  $AM$  and the tangents  $AP$ ,  $BQ$ , be drawn,  $AM$  will be a side of an in-

scribed polygon, having twice the number of sides; and  $AP + PM = 2PM$  or  $PQ$ , will be a side of the similar circumscribed polygon (P. 7, c. 3).

Now, as the same construction will take place at each angle corresponding to  $ACM$ , it will be sufficient to consider  $ACM$  by itself; for the triangles connected with it are evidently connected to each other as the whole polygons of which they form part. Let  $P$ , then, be the surface of the inscribed

polygon whose side is  $AB$ ,  $p$ , that of the similar circumscribed polygon;  $P'$  the surface of the polygon whose side is  $AM$ ,  $p'$  that of the similar circumscribed polygon:  $P$  and  $p$  are given; we have to find  $P'$  and  $p'$ .

*First.* Now the triangles  $ACD$ ,  $ACM$ , having the common vertex  $A$ , are to each other as their bases  $CD$ ,  $CM$  (B. IV., P. 6, c.); they are likewise to each other as the polygons  $P$  and  $P'$ , of which they form part (B. II., P. 11): hence,

$$P : P' :: CD : CM.$$

Again, the triangles  $CAM$ ,  $CME$ , having the common vertex  $M$ , are to each other as their bases  $CA$ ,  $CE$ ; they are likewise to each other as the polygons  $P'$  and  $p$  of which they form part; hence,

$$P' : p :: CA : CE.$$

But since  $AD$  and  $ME$  are parallel, we have,

$$CD : CM :: CA : CE;$$

hence,  $P : P' :: P' : p$ ;

hence, the polygon  $P'$  is a mean proportional between the two given polygons  $P$  and  $p$ , and consequently,

$$P' = \sqrt{P \times p}.$$

*Secondly.* The altitude  $CM$  being common, the triangle  $CPM$  is to the triangle  $CPE$ , as  $PM$  is to  $PE$ ; but since  $CP$  bisects the angle  $MCE$ , we have (B. IV., P. 17),

$$PM : PE :: CM : CE :: CD : CA :: P : P';$$

hence,  $CPM : CPE :: P : P'$ ;

and consequently,

$$CPM : CPM + CPE, \text{ or } CME :: P : P + P';$$

and hence,  $2CPM$ , or  $CMPA : CME :: 2P : P + P'$ .

But  $CMPA$  is to  $CME$  as the polygons  $p'$  and  $p$ , of which they form part: hence,

$$p' : p :: 2P : P + P'.$$

Now as  $P'$  has been already determined; this new proportion will serve to determine  $p'$ , and give us

$$p' = \frac{2P \times p}{P + P'};$$

and thus by means of the polygons  $P$  and  $p$  it is easy to find the polygons  $P'$  and  $p'$ , which have double the number of sides.

PROPOSITION XII. PROBLEM.

*To find the approximate area of a circle whose radius is unity.*

Let the radius of the circle be 1; the side of the inscribed square will be  $\sqrt{2}$  (p. 3, s.); that of the circumscribed square will be equal to the diameter 2; hence, the surface of the inscribed square will be two, and that of the circumscribed square will be 4. Hence,  $P=2$ , and  $p=4$ ; by the last proposition we shall find the

inscribed octagon  $P' = \sqrt{8} = 2.8284271$ ,

circumscribed octagon  $p' = \frac{16}{2 + \sqrt{8}} = 3.3137085$ .

The inscribed and the circumscribed octagons being thus determined, we shall easily, by means of them, determine the polygons having twice the number of sides. We have only in this case to put  $P=2.8284271$ ,  $p=3.3137085$ ; we shall find

$$P' = \sqrt{P \times p} = 3.0614674,$$

$$p' = \frac{2P \times p}{P + P'} = 3.1825979.$$

These polygons of 16 sides will enable us to find the polygons of 32 sides; and the processes may be continued

until the difference between the inscribed and circumscribed polygons is less than any given surface (p. 10). Since the circle lies between the polygons, it will differ from either polygon by less than the polygons differ from each other: and hence, in so far as the figures which express the areas of the two polygons agree, they will be the true figures to express the area of the circle.

We have subjoined the computation of these polygons, carried on till they agree as far as the seventh place of decimals.

| NUMBER OF SIDES. | INSCRIBED POLYGONS. | CIRCUMSCRIBED POLYGONS. |
|------------------|---------------------|-------------------------|
| 4 . . .          | 2.0000000 . . .     | 4.0000000               |
| 8 . . .          | 2.8284271 . . .     | 3.3137085               |
| 16 . . .         | 3.0614674 . . .     | 3.1825979               |
| 32 . . .         | 3.1214451 . . .     | 3.1517249               |
| 64 . . .         | 3.1365485 . . .     | 3.1441184               |

| 512 . . .        | 3.1415138 . . .     | 3.1416321               |
| 1024 . . .       | 3.1415729 . . .     | 3.1416025               |
| 2048 . . .       | 3.1415877 . . .     | 3.1415951               |
| 4096 . . .       | 3.1415914 . . .     | 3.1415933               |
| 8192 . . .       | 3.1415923 . . .     | 3.1415928               |
| 16384 . . .      | 3.1415925 . . .     | 3.1415927               |
| 32768 . . .      | 3.1415926 . . .     | 3.1415926               |

The approximate area of the circle, we infer, therefore, is equal to 3.1415926. Some doubt may exist perhaps about the last decimal figure, owing to errors proceeding from the parts omitted; but the calculation has been carried on with an additional figure, that the final result here given might be absolutely correct even to the last decimal place. The number generally used, for computation, is 3.1416, a number very near the true area.

*Scholium* 1. Since the inscribed polygon has the same number of sides as the circumscribed polygon, and since the two polygons are regular, they will be similar (P. 1): and, therefore, when their areas approach to an equality with the circle, their perimeters will approach to an equality with the circumference.

*Scholium 2.* That magnitude to which a varying magnitude approaches continually, and which it cannot pass, is called a *limit*.

Having shown that the inscribed and circumscribed polygons may be made to differ from each other by less than any given surface (P. 10), and since each differs from the circle less than from the other polygon, it follows that the circle is the limit of all inscribed and circumscribed polygons, formed by continually doubling the number of sides, and that the circumference is the limit of their perimeters. Hence, no sensible error can arise in supposing that what is true of such a polygon is also true of its limit, the circle. Indeed, the circle is but a regular polygon of an infinite number of sides.

PROPOSITION XIII. THEOREM.

*The circumferences of circles are to each other as their radii, and the areas are to each other as the squares of their radii.*

Let us designate the circumference of the circle whose radius is  $CA$  by *circ. CA*; and its area, by *area CA*: it is then to be shown that

$$\begin{aligned} \text{circ. } CA &: \text{circ. } OB :: CA : OB, \text{ and that} \\ \text{area } CA &: \text{area } OB :: CA^2 : OB^2. \end{aligned}$$

Inscribe within the circles two regular polygons of the same number of sides. Then, whatever be the number of sides, their perimeters will be to each other as the radii  $CA$  and  $OB$  (P. 9). Now, if the arcs subtended by the sides

of the polygons be continually bisected, and corresponding polygons formed, the perimeter of each new polygon will approach the circumference of the circumscribed circle, and at the limit (P. 12, s. 2), we shall have

$$\text{circ. } CA : \text{circ. } OB :: CA : OB.$$

Again, the areas of the inscribed polygons are to each other as  $\overline{CA}^2$  to  $\overline{OB}^2$  (P. 9). But when the number of sides of the polygons is increased, as before, at the limit we shall have

$$\text{area } CA : \text{area } OB :: \overline{CA}^2 : \overline{OB}^2.$$

*Cor. 1.* It is plain that the limit of any portion of the perimeter of an inscribed regular polygon lying between the vertices of two angles, is the corresponding arc of the circumscribed circle. Thus, the limit of the portion of the perimeter intercepted between  $G$  and  $E$  is the arc  $GFE$ .

*Cor. 2.* If we multiply the antecedent and consequent of the second couplet of the first proportion by 2, and of the second by 4, we shall have

$$\begin{aligned} \text{circ. } CA : \text{circ. } OB &:: 2CA : 2OB; \\ \text{and } \text{area } CA : \text{area } OB &:: 4\overline{CA}^2 : 4\overline{OB}^2; \end{aligned}$$

that is, *the circumferences of circles are to each other as their diameters, and their areas are to each other as the squares of their diameters.*

PROPOSITION XIV. THEOREM.

*Similar arcs are to each other as their radii: and similar sectors are to each other as the squares of their radii.*

Let  $AB, DE$ , be similar arcs, and  $ACB, DOE$ , similar sectors: then

$$AB : DE :: CA : OD;$$

and  $ACB : DOE :: \overline{CA}^2 : \overline{OD}^2$ .

For, since the arcs are similar, the angle  $C$  is equal to the angle  $O$  (B. IV., D. 6). But we have (B. III., P. 17),

angle  $C$  : 4 right angles  $:: AB : \text{circ. } CA$ ,  
 and, angle  $O$  : 4 right angles  $:: DE : \text{circ. } OD$ ;  
 hence (B. II., P. 4, c.),

$$AB : DE :: \text{circ. } CA : \text{circ. } OD;$$

but these circumferences are as the radii  $AC, DO$  (P. 13); hence,

$$AB : DE :: CA : OD.$$

For a like reason, the sectors  $ACB, DOE$ , are to each other as the whole circles: which again are as the squares of their radii (P. 13); therefore,

$$\text{sect. } ACB : \text{sect. } DOE :: \overline{CA}^2 : \overline{OD}^2.$$

PROPOSITION XV. THEOREM.

*The area of a circle is equal to the product of half the radius by the circumference.*

Let  $ACDE$  be a circle whose centre is  $O$  and radius  $OA$ : then will

$$\text{area } OA = \frac{1}{2} OA \times \text{circ. } OA.$$

For, inscribe in the circle any regular polygon, and draw  $OF$  perpendicular to one of its sides. The area of

the polygon is equal to  $\frac{1}{2}OF$ , multiplied by the perimeter (P. 8). Now, let the arcs which are subtended by the sides of the polygon be bisected and new polygons formed as before: the limit of the perimeter is the circumference of the circle; the limit of the apothem is the radius  $OA$ , and the limit of the area of the polygon is the area of the circle (P. 12, s. 2). Passing to the limit, the expression for the area becomes

$$\text{area } OA = \frac{1}{2}OA \times \text{circ. } OA;$$

consequently, the area of a circle is equal to the product of half the radius by the circumference.

*Cor.* The area of a sector is equal to the arc of the sector multiplied by half the radius.

For, we have (B. III., P. 17, s. 4),

*sect. ACB : area CA :: AMB : circ. CA ;*

or, *sect. ACB : area CA :: AMB  $\times$   $\frac{1}{2}CA : \text{circ. } CA \times \frac{1}{2}CA$ .*

But, *circ. CA  $\times$   $\frac{1}{2}CA$*  is equal to the area *CA*; hence, *AMB  $\times$   $\frac{1}{2}CA$*  is equal to the area of the sector.

#### PROPOSITION XVI. THEOREM.

*The area of a circle is equal to the square of the radius multiplied by the ratio of the diameter to the circumference.*

Let the circumference of the circle whose diameter is unity be denoted by  $\pi$ : then, since the diameters of circles are to each other as their circumferences (P. 13, c. 2),  $\pi$  will denote the ratio of any diameter to its circumference. We shall then have

$$1 : \pi :: 2CA : \text{circ. } CA :$$

therefore,  $\text{circ. } CA = \pi \times 2CA$ .

Multiplying both members by  $\frac{1}{2}CA$ , we have

$$\frac{1}{2}CA \times \text{circ. } CA = \pi \times \overline{CA}^2,$$

or (P. 15)  $\text{area } CA = \pi \times \overline{CA}^2$ ,  
 that is, the area of a circle is equal  
 to  $\pi$  into the square of the radius.

*Scholium* 1. Let  $CA = R$ , and area  
 $CA = A$ : then,  $A = \pi R^2$ , making  
 $CA = 1$ ; we shall have

$$\text{area } CA = \pi.$$

But we have found the area of the circle whose radius is  
 1 to be 3.1415926 (P. 12): therefore, we have

$$\pi = 3.1415926.$$

In common calculations, we take  $\pi = 3.1416$ .

*Scholium* 2. The problem of the quadrature of the circle,  
 as it is called, consists in finding a square equivalent in  
 surface to a circle, the radius of which is known. Now it  
 has just been proved, that a circle is equivalent to the rect-  
 angle contained by its circumference and half its radius  
 (P. 15); and this rectangle may be changed into an equiv-  
 alent square, by finding a mean proportional between its  
 length and its breadth (B. IV., PROB. 3). To square the  
 circle, therefore, is to find the circumference when the  
 radius is given; and for effecting this, it is enough to  
 know the ratio of the diameter to the circumference.

Hitherto the ratio in question has never been determin-  
 ed except approximatively; but the approximation has  
 been carried so far, that a knowledge of the exact ratio  
 would afford no real advantage whatever beyond that of  
 the approximate ratio. Accordingly, this problem, which  
 engaged geometers so deeply, when their methods of  
 approximation were less perfect, is now degraded to the  
 rank of those idle questions, with which no one possessing  
 the slightest tincture of geometrical science, will occupy  
 any portion of his time.

*Archimedes* showed that the ratio of the diameter to the  
 circumference is included between  $3\frac{1}{7}$  and  $3\frac{1}{4}$ ; hence,  $3\frac{1}{2}$   
 or  $\frac{22}{7}$  affords at once a pretty accurate approximation to  
 the number above designated by  $\pi$ ; and the simplicity  
 of this first approximation has brought it into very general

use. *Metius*, for the same quantity, found the much more accurate value  $\frac{355}{113}$ . At last, the value of  $\pi$ , developed to a certain order of decimals, was found by other calculators to be 3.1415926535897932 &c.: and some have had patience enough to continue these decimals to the hundred and twenty-seventh, or even to the hundred and fortieth place. Such an approximation is practically equivalent to perfect accuracy: the root of an imperfect power is in no case more accurately known.

PROPOSITION XVII. THEOREM.

*If the circumferences of two circles intersect each other, the arc of the common chord in the less circle will be longer than the corresponding arc of the greater.\**

Let  $A$  and  $B$  be the centres of two circles,  $AC$ ,  $BC$ , their radii,  $C$  and  $D$  the points in which their circumferences intersect and  $CD$  their common chord: then will the arc  $DEC$  described with the radius  $BC$ , be longer than the arc  $DFC$  described with the greater radius  $AC$ .

Join the centres  $A$  and  $B$ , and prolong  $AB$  to  $E$ . Then, since  $AB$  bisects the chord  $CD$  at right angles (B. III., P. 11); it also bisects the arcs at the points  $F$  and  $E$  (B. III., P. 6). Draw  $CE$  and  $DE$  which will be equal to each other (B. III., P. 4); also  $CF$  and  $DF$ .

Bisect the arcs  $CE$ ,  $ED$ , and also the arcs  $CF$ ,  $FD$ , and draw chords subtending the new arcs: there will thus be inscribed in the two segments  $DEC$ ,  $DFC$ , portions of two polygons, having the same number of sides in each.

Now, since the point  $F$  is within the triangle  $DEC$ ,

\* The arc considered in this demonstration is the one which is less than a semicircle.

$EC$  plus  $ED$  is greater than  $CF$  plus  $FD$  (B. I., P. 8): hence, the half,  $CE$  is greater than the half,  $CF$ . If now, with  $C$  as a centre, and  $CE$  as a radius, we describe an arc  $EH$ , the chord  $CE$  being greater than  $CF$ , the arc  $CFH$  will be greater than the arc  $CF$  (B. III., P. 5). If we suppose the arc  $CKE$  to move with the chord  $CE$  then, when the chord  $CE$  becomes the chord  $CH$ , the arc  $CKE$  will pass through the points  $C$  and  $H$ , and will have with  $CFH$ , the common chord  $CH$ .

If, now, we bisect the arc which is equal to  $CKE$ , and also the arc  $CFH$ , we know from what has already been shown, that the chord of half the outer arc will be greater than the chord of half the inner arc  $CFH$ , much more will it be greater than the chord of  $CL$ , which is half the arc  $CF$ ; that is, the chord of the arc  $CK$ , one-half of  $CE$ , will always be greater than the chord of the arc  $CL$ , one-half of  $CF$ . Hence, the perimeter of that portion of the polygon inscribed in the segment  $CED$ , will be greater than the perimeter of the corresponding polygon inscribed in the segment  $CFD$ . If, then, we continue the operations indefinitely, the limit of the outer perimeter will be the arc  $CED$ , and of the inner, the arc  $CFD$ : hence, the arc  $CED$  is greater than the arc  $CFD$ .

*Cor.* If equal chords be taken in unequal circles, the arc of the chord in the greatest circle will be the shortest; for, the circles may always be placed as in the figure.

# BOOK VI.

## PLANES AND POLYEDRAL ANGLES.

### DEFINITIONS.

1. A straight line is *perpendicular to a plane*, when it is perpendicular to every straight line of the plane which passes through its foot: conversely, the plane is perpendicular to the line. The point at which the perpendicular meets the plane, is called the *foot* of the perpendicular.

2. A line is *parallel to a plane*, when it cannot meet that plane, to what distance soever both be produced. Conversely, the plane is parallel to the line.

3. Two *planes* are *parallel* to each other, when they cannot meet, to what distance soever both be produced.

4. The indefinite space included between two planes which intersect each other, is called a *diedral angle*: the planes are called the *faces* of the angle, and their line of common intersection, the *edge* of the angle.

A *diedral angle* is measured by the angle contained between two lines, one drawn in each face, and both perpendicular to the common intersection at the same point. This angle may be acute, obtuse, or a right angle. If it is a right angle, the two *faces* are perpendicular to each other.

5. A **POLYEDRAL** angle is the indefinite space included by several planes meeting at a common point. Each plane is called a *face*: the line in which any two faces intersect, is called an *edge*: and the common point of meeting of all the planes, is called the *vertex* of the polyedral angle.

Thus, the polyedral angle whose vertex is  $S$ , is bounded by the four faces,  $ASB$ ,  $BSC$ ,  $CSD$ ,  $DSA$ . Three planes, at least, are necessary to form a polyedral angle.

A polyedral angle bounded by three planes, is called a *triedral angle*.

POSTULATES.

1. Let it be granted, that from a given point of a plane, a line may be drawn perpendicular to that plane.
2. Let it be granted, that from a given point without a plane, a perpendicular may be let fall on the plane.

PROPOSITION I. THEOREM.

*A straight line cannot be partly in a plane, and partly out of it.*

For, by the definition of a plane (B. I., D. 9), when a straight line has two points common with it, the line lies wholly in the plane.

*Scholium.* To discover whether a surface is plane, apply a straight line in different ways to that surface, and ascertain if it coincides with the surface throughout its whole extent.

PROPOSITION II. THEOREM.

*Two straight lines which intersect each other, lie in the same plane, and determine its position.*

Let  $AB$ ,  $AC$ , be two straight lines which intersect each other in  $A$ ; a plane may be conceived in which the straight line  $AB$  is found; if this plane be turned round  $AB$ , until it pass through the point  $C$ , then the line  $AC$ , which has two of its points  $A$  and  $C$ , in this plane, lies wholly in it; hence, the position of the plane is determined by the single condition of containing the two straight lines  $AB$ ,  $AC$ .

*Cor. 1.* Any three points  $A$ ,  $B$ ,  $C$ , not in a straight line, determine the position of a plane. Hence, a triangle  $BAC$ , determines the position of a plane.

*Cor. 2.* Hence, also, two parallels  $AB$ ,  $CD$ , determine the position of a plane; for, drawing the secant  $EF$ , the plane of the two straight lines  $AE$ ,  $EF$ , is that of the parallels  $AB$ ,  $CD$ . But the lines  $AE$ ,  $EF$ , determine this plane; therefore, so do the parallels,  $AB$ ,  $CD$ .

PROPOSITION III. THEOREM.

*If two planes cut one another, their common section will be a straight line.*

Let the two planes  $AB$ ,  $CD$ , cut one another, and let  $E$  and  $F$  be two points of their common section. Draw the straight line  $EF$ . This line lies wholly in the plane  $AB$ , and also, wholly in the plane  $CD$  (B. I., D. 9): therefore, it is in both planes at once. But since a straight line and a point out of it cannot lie in two planes at the same time (P. II., c. 1),  $EF$  contains all the points common to both planes, and consequently, is their common intersection.

PROPOSITION IV. THEOREM.

*If a straight line be perpendicular to two straight lines at their point of intersection, it will be perpendicular to the plane of those lines.*

Let  $MN$  be the plane of the two lines  $BB$ ,  $CC$ , and let  $AP$  be perpendicular to each of them at their point of intersection  $P$ ; then will  $AP$  be perpendicular to every line of the plane passing through  $P$ , and consequently to the plane itself (D. 1).

For, through  $P$  draw in the plane  $MN$ , any straight line as  $PQ$ . Through any point of this line, as  $Q$ , draw  $BQC$ , so that  $BQ$  shall be equal to  $QC$  (B. IV., PROB. 5); draw  $AB, AQ, AC$ .

The base  $BC$  being divided into two equal parts at the point  $Q$ , the triangle  $BPC$  gives (B. IV., P. 14).

$$\overline{PC}^2 + \overline{PB}^2 = 2\overline{PQ}^2 + 2\overline{QC}^2.$$

The triangle  $BAC$  in like manner gives,

$$\overline{AC}^2 + \overline{AB}^2 = 2\overline{AQ}^2 + 2\overline{QC}^2.$$

Taking the first of these equals from the second, and observing that the triangles  $APC, APB$ , being right-angled at  $P$ , give

$$\overline{AC}^2 - \overline{PC}^2 = \overline{AP}^2, \text{ and } \overline{AB}^2 - \overline{PB}^2 = \overline{AP}^2,$$

we shall have,

$$\overline{AP}^2 + \overline{AP}^2 = 2\overline{AQ}^2 - 2\overline{PQ}^2.$$

Therefore, by taking the halves of both, we have

$$\overline{AP}^2 = \overline{AQ}^2 - \overline{PQ}^2, \text{ or } \overline{AQ}^2 = \overline{AP}^2 + \overline{PQ}^2;$$

hence, the triangle  $APQ$  is right-angled at  $P$ ; hence,  $AP$  is perpendicular to  $PQ$ .

*Scholium.* Thus, it is evident, not only that a straight line may be perpendicular to all the straight lines which pass through its foot, in a plane, but that it always must be so, whenever it is perpendicular to two straight lines drawn in the plane: hence, a line and plane may fulfil the conditions of the first definition.

*Cor. 1.* The perpendicular  $AP$  is shorter than any oblique line  $AQ$ ; therefore, it measures the shortest distance from the point  $A$  to the plane  $MN$ .

*Cor. 2.* At a given point  $P$ , on a plane, it is impossible to erect more than one perpendicular to the plane; for, if there could be two perpendiculars at the same point  $P$ , draw through these two perpendiculars a plane, whose section with the plane  $MN$  is  $PQ$ ; then these two perpen-

diculars would be both perpendicular to the line  $PQ$ , at the same point, which is impossible (B. I., P. 14, C.)

It is also impossible to let fall from a given point, out of a plane, two perpendiculars to that plane; for, if  $AP$ ,  $AQ$ , be two such perpendiculars, the triangle  $APQ$  will have two right angles  $APQ$ ,  $AQP$ , which is impossible (B. I., P. 25, C. 3).

PROPOSITION V. THEOREM.

*If, from a point without a plane, a perpendicular be drawn to the plane, and oblique lines be drawn to its different points:*

- 1st. *The oblique lines which meet the plane at points equally distant from the foot of the perpendicular, are equal:*
- 2d. *Of two oblique lines which meet the plane at unequal distances, the one passing through the remote point is the longer.*

Let  $AP$  be perpendicular to the plane  $MN$ ;  $AB$ ,  $AC$ ,  $AD$ , oblique lines intercepting the equal distances  $PB$ ,  $PC$ ,  $PD$ , and  $AE$  a line intercepting the larger distance  $PE$ : then will  $AB=AC=AD$ ; and  $AE$  will be greater than  $AD$ .

For, the angles  $APB$ ,  $APC$ ,  $APD$ , being right angles, and the distances  $PB$ ,  $PC$ ,  $PD$ , equal to each other, the triangles  $APB$ ,  $APC$ ,  $APD$ , have in each an equal angle contained by two equal sides: therefore they are equal (B. I., P. 5); hence, the hypotenuses, or the oblique lines  $AB$ ,  $AC$ ,  $AD$ , are equal to each other.

Again, since the distance  $PE$  is greater than  $PD$ , or its equal  $PB$ , the oblique line  $AE$  is greater than  $AB$ , or its equal  $AD$  (B. I., P. 15).

*Cor.* All the equal oblique lines,  $AB$ ,  $AC$ ,  $AD$ , &c., terminate in the circumference  $BCD$ , described from  $P$ , the foot of the perpendicular, as a centre; therefore, a point  $A$  being given out of a plane, the point  $P$  at which the per-

perpendicular let fall from  $A$  would meet that plane, may be found by marking upon that plane three points,  $B, C, D$ , equally distant from the point  $A$ , and then finding the centre of the circle which passes through these points; this centre will be  $P$ , the point sought.

*Scholium.* The angle  $ABP$  is called the *inclination of the oblique line  $AB$  to the plane  $MN$* ; which inclination is evidently equal with respect to all such lines  $AB, AC, AD$ , as make equal angles with the perpendicular; for, all the triangles  $ABP, ACP, ADP$ , &c., are equal to each other.

PROPOSITION VI. THEOREM.

*If from the foot of a perpendicular a line be drawn at right angles to any line of a plane, and the point of intersection be joined with any point of the perpendicular, this last line will be perpendicular to the line of the plane.*

Let  $AP$  be perpendicular to the plane  $NM$ , and  $PD$  perpendicular to  $BC$ ; join  $D$  with any point of the perpendicular, as  $A$ ; then will  $AD$  also be perpendicular to  $BC$ .

Take  $DB=DC$ , and draw  $PB, PC, AB, AC$ . Now, since  $DB$  is equal to  $DC$ , the oblique line  $PB$  is equal to  $PC$  (B. 1, P. 5): and since  $PB$  is equal to  $PC$ , the oblique line  $AB$  is equal to  $AC$  (P. 5); therefore, the line  $AD$  has two of its points  $A$  and  $D$  equally distant from the extremities  $B$  and  $C$ ; therefore,  $AD$  is a perpendicular to  $BC$ , at its middle point  $D$  (B. I., P. 16, c.)

*Cor.* It is evident, likewise, that  $BC$  is perpendicular to the plane of the triangle  $APD$ , since it is perpendicular to the two straight lines  $AD, PD$  of that plane (P. 4).

*Scholium 1.* The two lines  $AE, BC$ , afford an instance of two lines which are not parallel, and yet do not meet, because they are not situated in the same plane. The short-

est distance between these lines is the straight line  $PD$ , which is at once perpendicular to the line  $AP$  and to the line  $BC$ . The distance  $PD$  is the shortest distance between them: because, if we join any other two points, such as  $A$  and  $B$ , we shall have  $AB > AD$ ,  $AD > PD$ ; therefore, still more,  $AB > PD$ .

*Scholium 2.* The two lines  $AE$ ,  $CB$ , though not situated in the same plane, are conceived as forming a right angle with each other; because  $AE$  and the line drawn through any one of its points parallel to  $BC$ , would make with each other a right angle. In the same manner,  $AB$ ,  $PD$ , which represent any two straight lines not situated in the same plane, are supposed to form with each other the same angle, as would be formed by  $AB$  and a straight line drawn through any point of  $AB$ , parallel to  $PD$ .

PROPOSITION VII. THEOREM.

*If one of two parallel lines be perpendicular to a plane, the other will also be perpendicular to the same plane.*

Let  $ED$ ,  $AP$ , be two parallel lines; if  $AP$  is perpendicular to the plane  $NM$ , then will  $ED$  be also perpendicular to it.

For, through the parallels  $AP$ ,  $DE$ , pass a plane; its intersection with the plane  $MN$  will be  $PD$ ; in the plane  $MN$  draw  $BD$  perpendicular to  $PD$ , and then draw  $AD$ .

Now,  $BD$  is perpendicular to the plane  $APDE$  (p. 6, c.) therefore, the angle  $BDE$  is a right angle; but the angle  $EDP$  is also a right angle, since  $AP$  is perpendicular to  $PD$ , and  $DE$  parallel to  $AP$  (B. I., p. 20, c. 1); therefore, the line  $DE$  is perpendicular to the two straight lines  $DP$ ,  $DB$ ; consequently it is perpendicular to their plane  $MN$  (p. 4).

*Cor. 1.* Conversely : if the straight lines  $AP$ ,  $DE$ , are perpendicular to the same plane  $MN$ , they will be parallel. For, if they be not parallel, draw, through the point  $D$ , a line parallel to  $AP$ , this parallel will be perpendicular to the plane  $MN$ ; therefore, through the same point  $D$  more than one perpendicular will be erected to the same plane, which is impossible (P. 4, c. 2).

*Cor. 2.* Two lines  $A$  and  $B$ , parallel to a third  $C$ , are parallel to each other ; for, conceive a plane perpendicular to the line  $C$ ; the lines  $A$  and  $B$ , being parallel to  $C$ , are perpendicular to this plane ; therefore, by the preceding corollary, they are parallel to each other.

The three parallels are supposed not to be in the same plane ; otherwise the proposition would be already proved. (B. I., P. 22).

PROPOSITION VIII. THEOREM.

*If a straight line is parallel to a line of a plane, it is parallel to the plane.*

Let the straight line  $AB$  be parallel to the line  $CD$  of the plane  $NM$ ; then will it be parallel to the plane  $NM$ .

For, if the line  $AB$ , which lies in the plane  $ABDC$ , could meet the plane  $MN$ , it could only be in some point of the line  $CD$ , the common intersection of the two planes ; but the line  $AB$  cannot meet  $CD$ , since they are parallel (B. I., D. 16) : hence, it will not meet the plane  $MN$ ; therefore, it is parallel to that plane (D. 2).

PROPOSITION IX. THEOREM.

*Two planes which are perpendicular to the same straight line are parallel to each other.*

Let the planes  $MN$ ,  $PQ$ , be perpendicular to the line  $AB$ , then will they be parallel.

For, if they can meet any where, let  $O$  be one of their common points, and draw  $OA$ ,  $OB$ . Now, the line  $AB$ , which is perpendicular to the plane  $MN$ , is perpendicular to the straight line  $OA$ , drawn through its foot in that plane (D. 1); for

the same reason  $AB$  is perpendicular to  $BO$ ; therefore, there are two perpendiculars,  $OA$  and  $OB$ , let fall from the same point  $O$ , upon the same straight line, which is impossible (B. I., P. 14); therefore, the planes  $MN$ ,  $PQ$ , cannot meet each other; consequently, they are parallel.

PROPOSITION X. THEOREM.

*If a plane cut two parallel planes, the lines of intersection will be parallel.*

Let the parallel planes  $NM$ ,  $QP$ , be intersected by the plane  $EH$ ; then will the lines of intersection  $EF$ ,  $GH$ , be parallel.

For, if the lines  $EF$ ,  $GH$ , lying in the same plane, were not parallel, they would meet each other when prolonged; and then the planes  $MN$ ,  $PQ$ , in which those lines lie, would also meet; and hence, the planes would not be parallel, which is contrary to the hypothesis.

PROPOSITION XI. THEOREM.

*If two planes are parallel, a straight line which is perpendicular to one, is also perpendicular to the other.*

Let  $MN$ ,  $PQ$ , be two parallel planes, and let  $AB$  be perpendicular to the plane  $NM$ ; then will it also be perpendicular to  $QP$ .

For, draw any line  $BC$  in the plane  $PQ$ , and through the lines  $AB$  and  $BC$ , pass a plane  $ABC$ , intersecting the plane  $MN$  in  $AD$ ; the intersection  $AD$  is parallel to  $BC$  (P. 10). But the line  $AB$ , being perpendicular to the plane  $MN$ , is perpendicular to the straight line  $AD$  (D. 1); therefore, also, to its parallel  $BC$  (B. I., P. 20, c. 1); hence, the line  $AB$  being perpendicular to any line  $BC$ , drawn through its foot in the plane  $PQ$ , is perpendicular to that plane (D. 1).

PROPOSITION XII. THEOREM.

*All parallels included between two parallel planes are equal.*

Let  $MN, PQ$ , be two parallel planes, and  $HF, GE$ , two parallel lines: then will  $GE=HF$ .

For, through the parallels  $GE, HF$ , draw the plane  $EGHF$ , intersecting the parallel planes in  $EF$  and  $GH$ . The intersections  $EF, GH$ , are parallel to each other (P. 10); and since  $GE, HF$  are parallel, the figure  $EGHF$  is a parallelogram; consequently,  $EG=HF$  (B. I., P. 28).

*Cor.* Hence, it follows, that *two parallel planes are everywhere equidistant*. For, suppose  $EG$  to be perpendicular to the plane  $PQ$ ; then, the parallel  $FH$  is also perpendicular to it (P. 7), and the two parallels are likewise perpendicular to the plane  $MN$  (P. 11); and being parallel, they are equal, as shown by the proposition.

## PROPOSITION XIII. THEOREM.

If two angles, not situated in the same plane, have their sides parallel and lying in the same direction, these angles will be equal and their planes will be parallel.

Let the angles  $CAE$  and  $DBF$ , have the side  $AC$  parallel to  $BD$ , and lying in the same direction: also,  $AE$  parallel to  $BF$ , and lying in the same direction; then will the angles  $CAE$  and  $DBF$  be equal, and their planes parallel.

For, take  $AC$  and  $BD$  equal to each other, and also  $AE=BF$ ; and draw  $CE, DF, AB, CD, EF$ . Since  $AC$  is equal and parallel to  $BD$ , the figure  $ABDC$  is a parallelogram (B. I., P. 30); therefore,  $CD$  is equal and parallel to  $AB$ . For a similar reason,  $EF$  is equal and parallel to  $AB$ ; hence, also,  $CD$  is equal and parallel to  $EF$  (P. 7, c. 2); hence, the figure  $DFEC$

is a parallelogram, and the side  $CE$  is equal and parallel to  $DF$ ; therefore, the triangles  $CAE, DBF$ , have their corresponding sides equal; consequently, the angle  $CAE=DBF$ .

Again, the plane  $ACE$  is parallel to the plane  $BDF$ . For, if not, suppose a plane to be drawn through the point  $A$ , parallel to  $BDF$ . If this plane be different from  $ACE$ , it will meet the lines  $CD, EF$ , in points different from  $C$  and  $E$ , for instance in  $G$  and  $H$ ; then, the three lines  $BA, DG, FH$ , will be equal (P. 12), and each equal to  $AB$ : but the lines  $AB, CD, EF$ , are already known to be equal; hence,  $DC=DG$ , and  $HF=FE$ , which is absurd; hence, the plane  $ACE$  is parallel to  $BDF$ .

*Cor.* If two parallel planes  $MN, PQ$ , are met by two other planes  $CABD, EABF$ , the angles  $CAE, DBF$ , formed by the intersections of the parallel planes are equal; for, the intersection  $AC$  is parallel to  $BD$ , and  $AE$  to  $BF$  (P. 10); therefore, the angle  $CAE=DBF$ .

PROPOSITION XIV. THEOREM.

*If three straight lines, not situated in the same plane, are equal and parallel, the triangles formed by joining the extremities of these lines will be equal, and their planes parallel.*

Let  $AB, CD, EF$ , be three equal and parallel lines.

Since  $AB$  is equal and parallel to  $CD$ , the figure  $ABDC$  is a parallelogram; hence, the side  $AC$  is equal and parallel to  $BD$  (B. I., P. 30). For a like reason, the sides  $AE, BF$ , are equal and parallel, as also  $CE, DF$ ; hence, the two triangles  $ACE, BDF$ , have their sides equal, and are therefore equal (B. I., P. 10); and as their sides are parallel and lie in the same directions, their planes are parallel (P. 13).

PROPOSITION XV. THEOREM.

*If two straight lines be cut by three parallel planes, they will be divided proportionally.*

Suppose the line  $AB$  to meet the parallel planes  $MN, PQ, RS$ , at the points  $A, E, B$ ; and the line  $CD$  to meet the same planes at the points  $C, F, D$ : then

$$AE : EB :: CF : FD.$$

Draw  $AD$  meeting the plane  $PQ$  in  $G$ , and draw  $AC, EG, GF, BD$ . Since the parallel planes  $PQ, RS$ , are cut by the third plane  $BAD$ , the intersections  $BD$  and  $EG$  are parallel (P. 10): and we have  $AE : EB :: AG : GD$ . and the intersections  $AC, GF$ , being parallel,

$AG : GD :: CF : FD$ ;  
hence (B. II., P. 4, c.),  $AE : EB :: CF : FD$ .

## PROPOSITION XVI. THEOREM.

*If a line is perpendicular to a plane, every plane passed through the perpendicular, is also perpendicular to the plane.*

Let  $AP$  be perpendicular to the plane  $NM$ ; then will every plane passing through  $AP$  be perpendicular to  $NM$ .

Let  $BF$  be any plane passing through  $AP$ , and  $BC$  its intersection with the plane  $NM$ . In the plane  $NM$ , draw  $DP$  perpendicular to  $BP$ : then the line  $AP$ , being perpendicular to the plane  $NM$ , is perpendicular to each of the two straight lines  $BC$ ,  $DE$ . Now, since  $AP$  and  $DE$  are both perpendicular to the common intersection  $BC$ , the angle which they form will measure the angle between the planes (D. 4): but the angle  $APD$ , or  $APE$ , is a right angle: hence, the two planes are perpendicular to each other.

*Scholium.* When three straight lines, such as  $AP$ ,  $BP$ ,  $DP$ , are perpendicular to each other, any two may be regarded as determining a plane, and the three will determine three planes. Now, each line is perpendicular to the plane of the other two, and the three planes are perpendicular to each other.

## PROPOSITION XVII. THEOREM.

*If two planes are perpendicular to each other, a line drawn in one of them perpendicular to their common intersection, will be perpendicular to the other plane.*

Let the plane  $BA$  be perpendicular to  $NM$ ; then, if the line  $AP$  be perpendicular to the intersection  $BC$ , it will also be perpendicular to the plane  $NM$ .

For, in the plane  $NM$ , draw  $PD$  perpendicular to  $PB$ ; then, because the planes are perpendicular, the angle  $APD$  is a right angle (D. 4); therefore, the line

$AP$  is perpendicular to the two straight lines  $PB, PD$ , passing through its foot; therefore, it is perpendicular to their plane  $MN$  (P. 4).

*Cor.* If the plane  $BA$  is perpendicular to the plane  $MN$ , and if at a point  $P$  of the common intersection we erect a perpendicular to the plane  $MN$ , that perpendicular will be in the plane  $BA$ . For, let us suppose it will not, then, in the plane  $BA$  draw  $AP$  perpendicular to  $PB$ , the common intersection, and this  $AP$  at the same time, is perpendicular to the plane  $MN$ , by the theorem; therefore at the same point  $P$  there are two perpendiculars to the plane  $MN$ , one out of the plane  $BA$ , and one in it, which is impossible (P. 4, c. 2).

PROPOSITION XVIII. THEOREM.

*If two planes which cut each other are perpendicular to a third plane, their common intersection is also perpendicular to that plane.*

Let the planes  $BA, DA$ , be perpendicular to  $NM$ ; then will their intersection  $AP$  be perpendicular to  $NM$ .

For, at the point  $P$ , erect a perpendicular to the plane  $MN$ ; that perpendicular must be at once in the plane  $AB$  and in the plane  $AD$  (P, 17, c.); therefore, it is their common intersection  $AP$ .

PROPOSITION XIX. THEOREM.

*The sum of either two of the plane angles which include a trihedral angle, is greater than the third.*

The proposition requires demonstration only when the plane angle, which is compared with the sum of the two others, is greater than either of them. Therefore, suppose the trihedral angle  $S$  to be formed by the three plane angles  $ASB, ASC, BSC$ , and that the angle  $ASB$  is the greatest; we are to show that  $ASB < ASC + BSC$ .

In the plane  $ASB$  make the angle  $BSD=BSC$ , and draw the straight line  $ADB$  at pleasure; then make  $SC=SD$ , and draw  $AC, BC$ .

The two sides  $BS, SD$ , are equal to the two  $BS, SC$ , and the angle  $BSD=BSC$ ; therefore, the triangles  $BSD, BSC$ , are equal (B. I., P. 5); hence,  $BD=BC$ . But  $AB < AC+BC$ ; taking  $BD$  from the one side, and from the other its equal  $BC$ , there remains  $AD < AC$ . The two sides  $AS, SD$ , are equal to the two  $AS, SC$ ; the third side  $AD$  is less than the third side  $AC$ ; therefore, the angle  $ASD < ASC$  (B. I., P. 9, c.) Adding  $BSD=BSC$ , we have

$$ASD+BSD, \text{ or } ASB < ASC+BSC.$$

PROPOSITION XX. THEOREM.

*The sum of the plane angles which include any polyedral angle is less than four right angles.*

Let  $S$  be the vertex of a polyedral angle bounded by the faces  $BSC, CSD, DSE, ESA, ASB$ ; then will the sum of the plane angles about  $S$  be less than four right angles.

For, let the polyedral angle be cut by any plane  $AD$ , intersecting the edges in the points  $A, B, C, D, E$ , and the faces in the lines  $AB, BC, CD, DE, EA$ . From any point of this plane, as  $O$ , draw the straight lines  $OA, OB, OC, OD, OE$ .

We thus form two sets of triangles, one set having a common vertex  $S$ , the other having a common vertex  $O$ , and both having the common bases  $AB, BC, CD, DE, EA$ . Now, in the set which has the common vertex  $S$ , the sum of all the angles is equal to the sum of all the plane angles which comprise the polyedral angle whose vertex is  $S$ , together with the sum of all the angles at the bases: viz.:  $SAB, SBA, SBC$ , &c.; and the entire sum is equal to twice as many right angles as there are triangles. In the set whose

common vertex is  $O$ , the sum of all the angles is equal to the four right angles about  $O$ , together with the interior angles of the polygon, and this sum is equal to twice as many right angles as there are triangles. Since the number of triangles, in each set, is the same, it follows that these sums are equal. But in the triedral angle whose vertex is  $B$ ,  $ABS + SBC > ABC$  (p. 19), and the like may be shown at each of the other vertices,  $C, D, E, A$ : hence, the sum of the angles at the bases, in the triangles whose common vertex is  $S$ , is greater than the sum of the angles at the bases, in the set whose common vertex is  $O$ : therefore, the sum of the vertical angles about  $S$  is less than the sum of the angles about  $O$ : that is, less than four right angles.

*Scholium.* This demonstration is founded on the supposition that the polyedral angle is convex, or that the plane of no one face produced can ever meet the polyedral angle; if it were otherwise, the sum of the plane angles would no longer be limited, and might be of any magnitude.

PROPOSITION XXI. THEOREM.

*If two triedral angles are included by plane angles which are equal each to each, the planes of the equal angles are equally inclined to each other.*

Let  $S$  and  $T$  be the vertices of two triedral angles, and let the angle  $ASC = DTF$ , the angle  $ASB = DTE$ , and the angle  $BSC = ETF$ ; then will the inclination of the planes  $ASC, ASB$ , be equal to that of the planes  $DTF, DTE$ .

For, having taken  $SB$  at pleasure, draw  $BO$  perpendicular to the plane  $ASC$ ; from the point  $O$ , where the perpendicular meets the plane, draw  $OA, OC$ , perpendicular to  $SA, SC$ ; draw  $AB, BC$ . Next take

$TE = SB$ ; draw  $EP$  perpendicular to the plane  $DTF$ ; from the point  $P$  draw  $PD, PF$ , perpendicular respectively to  $TD, TF$ ; lastly, draw  $DE$  and  $EF$ .

The triangle  $SAB$ , is right-angled at  $A$ , and the triangle  $TDE$  at  $D$  (p. 6): and since the angle  $ASB = DTE$ , we have  $SBA = TED$ . Moreover, since  $SB = TE$ , the triangle  $SAB$  is equal to the triangle  $TDE$ ; therefore,  $SA = TD$ , and  $AB = DE$ .

In like manner, it may be shown, that  $SC = TF$ , and  $BC = EF$ . That proved, the quadrilateral  $ASCO$  is equal to the quadrilateral  $DTFP$ : for, place the angle  $ASC$  upon its equal  $DTF$ ; because  $SA = TD$ , and  $SC = TF$ , the point  $A$  will fall on  $D$ , and the point  $C$  on  $F$ ; and, at the same time,  $AO$ , which is perpendicular to  $SA$ , will fall on  $DP$ , which is perpendicular to  $TD$ , and, in like manner,  $OC$  on  $PF$ ; wherefore, the point  $O$  will fall on the point  $P$ , and hence,  $AO$  is equal to  $DP$ .

But the triangles  $AOB$ ,  $DPE$ , are right-angled at  $O$  and  $P$ ; the hypotenuse  $AB = DE$ , and the side  $AO = DP$ : hence, those triangles are equal (B. I., p. 17); and, consequently, the angle  $OAB = PDE$ . But the angle  $OAB$  measures the inclination of the two faces  $ASB$ ,  $ASC$ ; and the angle  $PDE$  measures that of the two faces  $DTE$ ,  $DTF$ ; hence, those two inclinations are equal to each other.

*Scholium 1.* It must, however, be observed, that the angle  $A$  of the right-angled triangle  $AOB$  is properly the inclination of the two planes  $ASB$ ,  $ASC$ , only when the perpendicular  $BO$  falls on the same side of  $SA$ , with  $SC$ ; for, if it fell on the other side, the angle of the two planes would be obtuse, and the obtuse angle together with the angle  $A$  of the triangle  $OAB$  would make two right angles. But in the same case, the angle of the two planes  $TDE$ ,  $TDF$ , would also be obtuse, and the obtuse angle together with the angle  $D$  of the triangle  $DPE$ , would make two right angles; and the angle  $A$  being thus always equal to the angle  $D$ , it would follow that the inclination of the two planes  $ASB$ ,  $ASC$ , must be equal to that of the two planes  $TDE$ ,  $TDF$ .

*Scholium 2.* If two triedral angles are included by three

plane angles, respectively equal to each other, and if, at the same time, the equal or homologous angles are *disposed in the same order*, the two triedral angles will coincide when applied the one to the other, and consequently, are equal (A. 14).

For, we have already seen that the quadrilateral  $SAOC$  may be placed upon its equal  $TDPF$ ; thus, placing  $SA$  upon  $TD$ ,  $SC$  falls upon  $TF$ , and the point  $O$  upon the point  $P$ . But because the triangles  $AOB$ ,  $DPE$ , are equal,  $OB$ , perpendicular to the plane  $ASC$ , is equal to  $PE$ , perpendicular to the plane  $TDF$ ; besides, these perpendiculars lie in the same direction; therefore, the point  $B$  will fall upon the point  $E$ , the line  $SB$  upon  $TE$ , and the two angles will wholly coincide.

*Scholium 3.* The equality of the triedral angles does not exist, unless the equal faces are *arranged in the same manner*. For, if they were *arranged in an inverse order*, or, what is the same, if the perpendiculars  $OB$ ,  $PE$ , instead of lying in the same direction with regard to the planes  $ASC$ ,  $TDF$ , lay in opposite directions, then it would be impossible to make these triedral angles coincide the one with the other. The theorem would not, however, on this account, be less true, viz.: that the faces containing the equal angles must be equally inclined to each other; so that the two triedral angles would be equal in all their constituent parts, without, however, admitting of superposition. This sort of equality, which is not absolute, or such as admits of superposition, ought to be distinguished by a particular name: we shall call it, *equality by symmetry*.

Thus, those two triedral angles, which are formed by faces respectively equal to each other, but disposed in an inverse order, will be called *triedral angles equal by symmetry*, or simply *symmetrical angles*.

# BOOK VII.

## POLYEDRONS.

### DEFINITIONS.

1. **POLYEDRON** is a name given to any solid bounded by polygons. The bounding polygons are called *faces* of the polyedron; and the straight line in which any two adjacent faces meet each other, is called an *edge* of the polyedron.

2. A **PRISM** is a polyedron in which two of the faces are equal polygons with their planes and homologous sides parallel, and all the other faces parallelograms.

3. The equal and parallel polygons are called *bases* of the prism—the one the lower, the other, the upper base—and the parallelograms taken together, make up the *lateral* or *convex surface* of the prism.

4. The **ALTITUDE** of a prism is the distance between its two bases, and is measured by a line drawn from a point in one base, perpendicular to the plane of the other.

5. A **right prism** is one whose edges, formed by the intersection of the lateral faces, are perpendicular to the planes of the bases. Each edge is then equal to the altitude of the prism. In every other case, the prism is *oblique*, and each edge is then greater than the altitude.

6. A TRIANGULAR PRISM is one whose bases are triangles: a *quadrangular prism* is one whose bases are quadrilaterals: a *pentangular prism* is one whose bases are pentagons: a *hexangular prism* is one whose bases are hexagons, &c. "

7. A PARALLELOPIPEDON is a prism whose bases are parallelograms.

8. A RECTANGULAR PARALLELOPIPEDON is one whose faces are all rectangles. When the faces are squares, it is called a *cube*, or *regular hexaedron*.

9. A PYRAMID is a solid bounded by a polygon, and by triangles meeting at a common point, called the *vertex*. The polygon is called the *base* of the pyramid, and the triangles, taken together, the *convex*, or *lateral* surface. The pyramid, like the prism, takes different names, according to the form of its base: thus, it may be triangular, quadrangular, pentangular, &c.

10. The ALTITUDE of a pyramid is the perpendicular let fall from the vertex on the plane of the base.

11. A RIGHT PYRAMID is one whose base is a regular polygon, and in which the perpendicular let fall from the vertex upon the base passes through the centre of the base. This perpendicular is then called the *axis* of the pyramid.

12. The SLANT HEIGHT of a right pyramid, is the perpendicular let fall from the vertex to either side of the polygon which forms the base.

13. If a pyramid is cut by a plane parallel to its base, forming a second base, the part lying between the bases, is called a *truncated pyramid*, or *frustum of a pyramid*.

14. The *altitude* of a frustum is the perpendicular distance between its bases: and the *slant height*, is that portion of the slant height of the pyramid intercepted between the bases of the frustum.

15. The *diagonal* of a polyedron is a line joining the vertices of any two of its angles, not in the same face.

16. *Similar polyedrons* are those whose polyedral angles are equal, each to each, and which are bounded by the same number of similar faces.

17. Parts which are like placed, in similar polyedrons, whether faces, edges, or angles, are called *homologous*.

18. A *regular polyedron* is one whose faces are equal and regular polygons, and whose polyedral angles are equal.

PROPOSITION I. THEOREM.

*The convex surface of a right prism is equal to the perimeter of either base multiplied by its altitude.*

Let  $ABCDE-K$  be a right prism: then will its convex surface be equal to

$$(AB+BC+CD+DE+EA)\times AF.$$

For, the convex surface is equal to the sum of all the rectangles  $AG$ ,  $BH$ ,  $CI$ ,  $DK$ ,  $EF$ , which compose it. Now, the altitudes  $AF$ ,  $BG$ ,  $CH$ , &c., of the rectangles, are equal to the altitude of the prism, and the area of each rectangle is equal to its base multiplied by its altitude (B. IV., P. 5). Hence, the sum of these rectangles, or the convex surface of the prism, is equal to

$$(AB+BC+CD+DE+EA)\times AF;$$

that is, to the perimeter of the base of the prism multiplied by the altitude.

*Cor.* If two right prisms have the same altitude, their convex surfaces are to each other as the perimeters of their bases.

PROPOSITION II. THEOREM.

*In every prism, the sections formed by parallel planes, are equal polygons.*

Let the prism  $AH$  be intersected by the parallel planes  $NP, SV$ ; then are the polygons  $NOPQR, STVXY$ , equal.

For, the sides  $ST, NO$ , are parallel, being the intersections of two parallel planes with a third plane  $ABGF$ ; these same sides,  $ST, NO$ , are included between the parallels  $NS, OT$ , which are edges of the prism: hence,  $NO$  is equal to  $ST$ . For like reasons, the sides  $OP, PQ, QR$ , &c., of the section  $NOPQR$ , are equal to the sides  $TV, VX, XY$ , &c., of the section  $STVXY$ , each to each; and since the equal sides are at the same time parallel, it follows that the angles  $NOP, OPQ$ , &c., of the first section, are equal to the angles  $STV, TVX$ , &c., of the second, each to each (B. VI., P. 13). Hence, the two sections  $NOPQR, STVXY$ , are equal polygons.

*Cor.* Every section of a prism, parallel to the bases, is equal to either base.

PROPOSITION III. THEOREM.

*If a pyramid be cut by a plane parallel to its base:*

- 1st. *The edges and the altitude will be divided proportionally:*
- 2d. *The section will be a polygon similar to the base.*

Let the pyramid  $S-ABCDE$ , of which  $SO$  is the altitude be cut by the plane  $abcde$ ; then will

$$Sa : SA :: So : SO,$$

and the same for the other edges; and the polygon  $abcde$ , will be similar to the base  $ABCDE$ .

*First.* Since the planes  $ABC$ ,  $abc$ , are parallel, their intersections  $AB$ ,  $ab$ , by the third plane  $SAB$ , are also parallel (B. VI., P. 10); hence, the triangles  $SAB$ ,  $Sab$ , are similar (B. IV., P. 21), and we have

$$SA : Sa :: SB : Sb;$$

for a like reason, we have

$$SB : Sb :: SC : Sc;$$

and so on. Hence, the edges  $SA$ ,  $SB$ ,  $SC$ , &c., are cut proportionally in  $a$ ,  $b$ ,  $c$ , &c.

The altitude  $SO$  is likewise cut in the same proportion, at the point  $o$ ; for  $BO$  and  $bo$  are parallel, therefore, we have

$$SO : So :: SB : Sb.$$

*Secondly.* Since  $ab$  is parallel to  $AB$ ,  $bc$  to  $BC$ ,  $cd$  to  $CD$ , &c., the angle  $abc$  is equal to  $ABC$ , the angle  $bcd$  to  $BCD$ , and so on (B. VI., P. 13). Also, by reason of the similar triangles  $SAB$ ,  $Sab$ , we have

$$AB : ab :: SB : Sb;$$

and by reason of the similar triangles  $SBC$ ,  $Sbc$ , we have

$$SB : Sb :: BC : bc;$$

hence,  $AB : ab :: BC : bc$ ;

we might likewise have

$$BC : bc :: CD : cd,$$

and so on. Hence, the polygons  $ABCDE$ ,  $abcde$  have their angles equal, each to each, and their sides, taken in the same order, proportional; hence, they are similar (B. IV., D. 1).

*Cor. 1.* Let  $S-ABCDE$ ,  $S-XYZ$ , be two pyramids, having a common vertex and their bases in the same plane; if these pyramids are cut by a plane parallel to the plane of their bases, the sections,  $abcde$ ,  $xyz$ , will be to each other as the bases  $ABCDE$ ,  $XYZ$ .

For, the polygons  $ABCDE$ ,  $abcde$ , being similar, their surfaces are as the squares of the homologous sides  $AB$ ,  $ab$ ; that is, B. IV., P. 27),

$$ABCDE : abcde :: \overline{AB}^2 : \overline{ab}^2.$$

but,  $AB : ab :: SA : Sa$ ;

hence,  $ABCDE : abcde :: \overline{SA}^2 : \overline{Sa}^2.$

For the same reason,

$$XYZ : xyz :: \overline{SX}^2 : \overline{Sx}^2.$$

But since  $abc$  and  $xyz$  are in one plane, we have likewise (B. VI., P. 15),

$$SA : Sa :: SX : Sx;$$

hence,  $ABCDE : abcde :: XYZ : xyz$ ;

therefore, the sections  $abcde$ ,  $xyz$ , are to each other as the bases  $ABCDE$ ,  $XYZ$ .

*Cor. 2.* If the bases  $ABCDE$ ,  $XYZ$ , are equivalent, any sections  $abcde$ ,  $xyz$ , made at equal distances from the bases, are also equivalent.

PROPOSITION IV. THEOREM.

*The convex surface of a right pyramid is equal to the perimeter of its base multiplied by half the slant height.*

Let  $S$  be the vertex,  $ABCDE$  the base, and  $SF$  the slant height of a right pyramid; then the convex surface is equal to  $\frac{1}{2}SF \times (AB + BC + CD + DE + EA)$ .

For, since the pyramid is right, the point  $O$ , in which the axis meets the base, is the centre of the polygon  $ABCDE$  (D. 11); hence, the lines  $OA$ ,  $OB$ ,  $OC$ , &c., drawn to the vertices of the base, are equal.

In the right-angled triangles  $SAO$ ,  $SBO$ , the bases and perpendiculars are equal: hence, the hypotenuses are equal: and it may be proved in the

same way, that all the edges of the right pyramid are

equal. The triangles, therefore, which form the convex surface of the prism are all equal to each other. But the area of either of these triangles, as  $ESA$ , is equal to its base  $EA$ , multiplied by half the perpendicular  $SF$ , which is the slant height of the pyramid: hence, the area of all the triangles, or the convex surface of the pyramid, is equal to the perimeter of the base multiplied by half the slant height.

*Cor.* The convex surface of the frustum of a right pyramid is equal to half the sum of the perimeters of its upper and lower bases multiplied by its slant height.

For, since the section  $abcde$  is similar to the base (P. 3), and since the base  $ABCDE$  is a regular polygon (D. 11), it follows that the sides  $ea$ ,  $ab$ ,  $bc$ ,  $cd$ , and  $de$ , are all equal to each other. Hence, the convex surface of the frustum  $ABCDE-d$  is composed of the equal trapezoids  $EAae$ ,  $ABba$ , &c., and the perpendicular distance between the parallel sides of either of these trapezoids is equal to  $Ff$ , the slant height of the frustum. But the area of either of the trapezoids, as  $A Eea$ , is equal to  $\frac{1}{2}(EA + ea) \times Ff$  (B. IV., P. 7): hence, the area of all of them, or the convex surface of the frustum, is equal to half the sum of the perimeters of the upper and lower bases multiplied by the slant height.

PROPOSITION V. THEOREM.

*If the three faces which include a triedral angle of a prism are equal to the three faces which include a triedral angle of a second prism, each to each, and are like placed, the two prisms are equal.*

Let  $B$  and  $b$  be the vertices of two triedral angles included by faces respectively equal to each other, and similarly placed; then will the prism  $ABCDE-K$  be equal to the prism  $abcde-k$ .

For, place the base  $abcde$  upon the equal base  $ABCDE$ ;

then, since the triedral angles at  $b$  and  $B$  are equal, the parallelogram  $bh$  will coincide with  $BH$ , and the parallelogram  $bf$  with  $BF$ . But the two upper bases being equal to their corresponding lower bases, are equal to each other, and consequently, will coincide: hence,  $hi$  will coincide with  $HI$ ,  $ik$  with  $IK$ ,  $kf$  with  $KF$ ; and therefore, the lateral faces of the prisms will coincide: hence, the two prisms coinciding throughout, are equal (A. 14).

*Cor.* Two right prisms, which have equal bases and equal altitudes, are equal. For, since the side  $AB$  is equal to  $ab$ , and the altitude  $BG$  to  $bg$ , the rectangle  $ABGF$  is equal to  $abgf$ ; so also, the rectangle  $BGHO$  is equal to  $bghc$ ; and thus the three faces, which include the triedral angle  $B$ , are equal to the three which include the triedral angle  $b$ , each to each. Hence, the two prisms are equal.

PROPOSITION VI. THEOREM.

*In every parallelepipedon, the opposite faces are equal and parallel.*

Let  $ABCD$  be a parallelepipedon, then will its opposite faces be equal and parallel.

For, the bases  $ABCD$ ,  $EFGH$ , are equal parallelograms, and have their planes parallel (D. 7). It remains only to show, that the same is true of any two opposite lateral faces, such as  $BCGF$ ,  $ADHE$ .

Now,  $BC$  is equal and parallel to  $AD$ , because the base  $ABCD$  is a parallelogram; and since the lateral faces are also parallelograms,  $BF$  is equal and parallel to  $AE$ , and the like may be shown for the sides  $FG$  and  $EH$ ,  $CG$  and

$DH$ ; hence, the angle  $CBF$  is equal to the angle  $DAE$ , and the planes  $DAE$ ,  $CBF$ , are parallel (B. VI., p. 13); and the parallelogram  $BCGF$ , is equal to the parallelogram  $ADHE$ . In the same way, it may be shown that the opposite parallelograms  $ABFE$ ,  $DCGH$ , are equal and parallel.

*Cor. 1.* Since the parallelepipedon is a solid bounded by six faces, of which any two lying opposite to each other, are equal and parallel, it follows that any face and the one opposite to it, may be assumed as the bases of the parallelepipedon.

*Cor. 2.* The diagonals of a parallelepipedon bisect each other. For, suppose two diagonals  $BH$ ,  $DF$ , to be drawn through opposite vertices. Draw also  $BD$ ,  $FH$ . Then, since  $BF$  is equal and parallel to  $DH$ , the figure  $BDHF$  is a parallelogram; hence, the diagonals  $BH$ ,  $DF$ , mutually bisect each other at  $E$  (B. I., p. 31). In like manner, it may be shown that the diagonal  $BH$  and any other diagonal bisect each other; hence, the four diagonals mutually bisect each other, in a common point. If the six faces are equal to each other, this point may be regarded as the centre of the parallelepipedon.

*Scholium.* If three straight lines  $AB$ ,  $AE$ ,  $AD$ , passing through the same point  $A$ , and making given angles with each other, are known, a parallelepipedon may be formed on these lines. For this purpose, conceive a plane to be passed through the extremity of each line, and parallel to the plane of the other two, that is, through the point  $B$  pass a plane parallel to  $DAE$ , through  $D$  a plane parallel to  $BAE$ , and through  $E$  a plane parallel to  $BAD$ . The mutual intersections of these planes will form the edges of the parallelepipedon required.

PROPOSITION VII. THEOREM.

If a plane be passed through the opposite diagonal edges of a parallelepipedon, it will divide the solid into two equivalent triangular prisms.

Let the parallelepipedon  $ABCD-H$  be divided by the plane  $BDHF$ , passing through the opposite edges  $BF$ ,  $DH$ : then will the triangular prism  $ABD-H$ , be equivalent to the triangular prism  $BCD-H$ .

For, through the vertices  $B$  and  $F$ , pass the planes  $Bcda$ ,  $Fghe$ , at right angles to the edge  $BF$ , the former cutting the three other edges of the parallelepipedon prolonged in the points  $c$ ,  $d$ ,  $a$ , the latter in the points  $g$ ,  $h$ ,  $e$ .

Now, the sections  $Bcda$ ,  $Fghe$ , are equal parallelograms. For, the cutting planes being perpendicular to the same straight line  $BF$ , are parallel (B. VI., P. 9): hence, the sections are equal (P. 2); and they are parallelograms because  $Ba$ ,  $cd$ , two opposite sides of the same section, are formed by the meeting of a plane  $aBcd$ , with two parallel planes  $ABFE$ ,  $DCGH$  (B. VI., P. 10). For a similar reason  $Bc$  and  $ad$  are parallel; hence, the figures are equal parallelograms.

For a like reason the figure  $aBFfe$  is a parallelogram; so also, are  $BcgF$ ,  $cghd$ ,  $adhe$ , the other lateral faces of the solid  $aBcd-h$ ; hence, that solid is a prism (D. 2), and that prism is right, since the edge  $BF$  is perpendicular to its bases.

But the right prism  $aBcd-h$  is divided by the plane  $BH$  into two equal right prisms  $aBd-h$ ,  $Bcd-h$ ; for, the bases  $aBd$ ,  $Bcd$ , are equal, being halves of the same parallelogram, and since the prisms have the common altitude  $BF$ , they are equal (P. 5, c.)

It is now to be proved that the oblique triangular prism  $ABD-H$  is equivalent to the right triangular prism  $aBd-h$ . Since these prisms have a common part  $ABD-h$ , it will only be necessary to prove that the remaining parts,

namely, the solids  $aBd-D$ ,  $eFh-H$ , are equivalent. Since  $ABFE$ ,  $aBF_e$ , are parallelograms, the sides  $AE$ ,  $ae$ , are each equal to  $BF$ ; hence, they are equal to each other; and taking away the common part  $Ae$ , there remains  $Aa = Ee$ . In the same manner it may be proved that  $Dd = Hh$ .

To bring about the superposition of the two solids,  $eFh-H$ ,  $aBd-D$ , let the base  $eFh$  be placed on the equal base  $aBd$ —the point  $e$  falling on  $a$ , the point  $h$  on  $d$ : the edges  $eE$ ,  $hH$ , will then coincide with  $aA$ ,  $dD$ , since all the edges are perpendicular to the same plane  $aBcd$ . Hence, the two solids will coincide exactly with each other; consequently, the oblique prism  $ABD-H$  is equivalent to the right prism  $aBd-h$ . In the same manner, it may be shown that the oblique prism  $BCD-H$  is equivalent to the right prism  $Bcd-h$ . But the two right prisms have been proved equal: hence, the two triangular prisms  $ABD-H$ ,  $BCD-H$ , being equivalent to equal right prisms, are equivalent to each other.

*Cor.* Every triangular prism  $ABD-H$  is half the parallelepipedon  $AG$ , having the same triedral angle  $A$ , and the same edges  $AB$ ,  $AD$ ,  $AE$ .

#### PROPOSITION VIII. THEOREM.

*If two parallelepipedons have a common lower base, and their upper bases in the same plane and between the same parallels, they are equivalent.*

Let the parallelepipedons  $AG$ ,  $AL$ , have the common base  $ABCD$ , and their upper bases  $EG$ ,  $IL$ , in the same plane, and between the same parallels  $EK$ ,  $HL$ ; then will they be equivalent.

There may be three cases, according as  $EI$  is greater than, equal to, or less than  $EF$ ; but the demonstration, for each case, is the same.

We will show, in the first place, that the triangular prisms  $AIE-H$ ,  $BKF-G$  are equal. Since  $EF$  and  $IK$  are

each equal to  $AB$  (B. I., p. 28), they are equal to each other. Add  $FI$  to each, and we have

$$EI = FK:$$

and since the angle  $AEF$  is equal to  $BFK$  (B. I., p. 20, c. 3); the triangle

$AEI$  is equal to the triangle  $BFK$  (B. I., p. 5). Again, since  $EI$  is equal to  $FK$ , and  $EH$  equal and parallel to  $FG$ , the parallelogram  $EM$  is equal to the parallelogram  $FL$  (B. I., p. 28, c. 2): also, the parallelogram  $AH$  is equal to the parallelogram  $CF$  (p. 6): hence, the three faces which include the polyedral angle at  $E$  are respectively equal to the three which include the polyedral angle at  $F$ , and being like placed, the triangular prism  $AIE-H$  is equal to the triangular prism  $BKF-G$  (p. 5).

But, if the triangular prism  $AIE-H$  be taken away from the solid  $AL$ , there will remain the parallelepipedon  $ABCD-M$ ; and if the equal triangular prism  $BKF-G$  be taken away from the same solid, there will remain the parallelepipedon  $ABCD-H$ ; hence, the two parallelepipedons  $ABCD-M$ ,  $ABCD-H$ , are equivalent.

PROPOSITION IX. THEOREM.

*Two parallelepipedons, having their lower bases equal, and equal altitudes, are equivalent.*

Let the parallelepipedons  $AG$ ,  $AL$ , have the common base  $ABCD$ , and equal altitudes; then will their upper bases,  $EFGH$ ,  $IKLM$ , be in the same plane; and the two parallelepipedons will be equivalent.

For, let the edges  $FE$ ,  $GH$ , be prolonged, as also,  $KL$  and  $IM$ , till, by their intersections, they form the parallelogram  $NO PQ$ , in the plane of the upper bases: this parallelogram will be equal to either of the bases  $IL$ ,  $EG$ . For, the upper bases  $IL$ ,  $EG$ , being each equal to the common base  $AC$ , are equal to each other. But  $OP$  which is equal to  $FG$ , is also equal to  $KL$ , and  $ON$  is

equal to  $KI$ , being between the same parallels: hence, the parallelogram  $NP$  is equal to  $IL$  or  $EG$  (B. I., P. 28, c. 2).

Now, if a third parallelepipedon be conceived, having for its lower base the parallelogram  $ABCD$ , and for its upper base  $NOPQ$ , this third parallelepipedon will be equivalent to the parallelepipedon  $AG$ , since they have the same lower base, and their upper bases lie in the same plane and between the same parallels,  $QG, NF$  (P. 8). For a like reason, this third parallelepipedon will also be equivalent to the parallelepipedon  $AL$ ; hence, the two parallelepipedons  $AG, AL$ , which have equal bases and equal altitudes, are equivalent.

PROPOSITION X. THEOREM.

*Any parallelepipedon may be changed into an equivalent rectangular parallelepipedon having an equal altitude and an equivalent base.*

Let  $ABCD-H$  be any parallelepipedon.

From the vertices  $A, B, C, D$ , draw  $AI, BK, CL, DM$ , perpendicular to the plane of the lower base, and equal to the altitude of  $AG$ : there will thus be formed the parallelepipedon  $AL$  equivalent to  $AG$  (P. 9), and having its lateral faces  $AK, BL$ , &c., rectangles. Now, if the base  $ABCD$

is a rectangle,  $AL$  will be a rectangular parallelepipedon

equivalent to  $AG$ , and consequently, the parallelepipedon required.

But if  $ABCD$  is not a rectangle, draw  $AO$  and  $BN$  perpendicular to  $DC$ , and  $OQ$  and  $NP$  perpendicular to the base; we shall then have, a rectangular parallelepipedon  $ABNO-Q$ : for, by construction, the bases  $ABNO$ , and  $IKPQ$ , are rectangles; so also, are the lateral faces, the edges  $AI$ ,  $OQ$ , &c., being perpendicular to the plane of the base; hence, the solid  $AP$  is a rectangular parallelepipedon. But the two parallelepipedons  $AP$ ,  $AL$ , may be conceived as having the same base  $ABKI$ , and the same altitude  $AO$ : hence, the parallelepipedon  $AG$ , which was at first changed into an equivalent parallelepipedon  $AL$ , is now changed into an equivalent rectangular parallelepipedon  $AP$ , having the same altitude  $AI$ , and a base  $ABNO$  equivalent to the base  $ABCD$ .

PROPOSITION XI. THEOREM.

*Two rectangular parallelepipedons, which have equal bases, are to each other as their altitudes.*

Let the parallelepipedons  $AG$ ,  $AL$ , have the common base  $BD$ , then will they be to each other as their altitudes  $AE$ ,  $AI$ .

*First.* Suppose the altitudes  $AE$ ,  $AI$ , to be to each other as two whole numbers, as 15 is to 8, for example. Divide  $AE$  into 15 equal parts, whereof  $AI$  will contain 8; and through  $x$ ,  $y$ ,  $z$ , &c., the points of division, pass planes parallel to the common base. These planes will divide the solid  $AG$  into 15 parallelepipedons, all equal to each other, because they have equal bases and equal altitudes—equal bases, since every section  $KLMI$ , parallel to the base  $ABCD$ , is equal to that base (P. 2), equal alti-

tudes, because the altitudes are the equal divisions,  $Ax$ ,  $xy$ ,  $yz$ , &c. But of those 15 equal parallelopipedons, 8 are contained in  $AL$ ; hence, the solid  $AG$  is to the solid  $AL$  as 15 is to 8, or generally, as the altitude  $AE$  is to the altitude  $AI$ .

*Second.* If the ratio of  $AE$  to  $AI$  cannot be expressed exactly in numbers, it may still be shown, that we shall have

$$\text{solid } AG : \text{solid } AL :: AE : AI.$$

For, if this proportion is not correct, suppose we have,

$$\text{sol. } AG : \text{sol. } AL :: AE : AO \text{ greater than } AI.$$

Divide  $AE$  into equal parts, such that each shall be less than  $OI$ ; there will be at least one point of division  $m$ , between  $O$  and  $I$ . Let  $P$  denote the parallelopipedon, whose base is  $ABCD$ , and altitude  $Am$ ; since the altitudes  $AE$ ,  $Am$ , are to each other as two whole numbers, we have

$$\text{sol. } AG : P :: AE : Am.$$

But by hypothesis, we have

$$\text{sol. } AG : \text{sol. } AL :: AE : AO;$$

therefore (B. II., P. 4),

$$\text{sol. } AL : P :: AO : Am.$$

But  $AO$  is greater than  $Am$ ; hence, if the proportion is correct, the solid  $AL$  must be greater than  $P$ . On the contrary, however, it is less: therefore,  $AO$  cannot be greater than  $AI$ . By the same mode of reasoning, it may be shown that the fourth term cannot be less than  $AI$ ; therefore, it is equal to  $AI$ : hence, rectangular parallelopipedons having equal bases, are to each other as their altitudes.

PROPOSITION XII. THEOREM.

*Two rectangular parallelopipedons, having equal altitudes, are to each other as their bases.*

Let the parallelopipedons  $AG$ ,  $AK$ , have the same altitude  $AE$ ; then will they be to each other as their bases  $AC$ ,  $AN$ .

For, having placed the two solids by the side of each other, as the figure represents, prolong the plane  $NKLO$  till it meets the plane  $DCGH$  in  $PQ$ ; we thus have a third parallelopipedon  $AQ$ , which may be compared with each of the parallelopipedons  $AG$ ,  $AK$ . The two solids  $AG$ ,  $AQ$ , having the same base  $ADHE$  are to each other as their altitudes  $AB$ ,  $AO$ : in like manner, the two solids  $AQ$ ,  $AK$ , having the same base  $AOLE$ , are to each other as their altitudes  $AD$ ,  $AM$ . Hence, we have

$$\begin{aligned} & \text{sol. } AG : \text{sol. } AQ :: AB : AO; \\ \text{also, } & \text{sol. } AQ : \text{sol. } AK :: AD : AM. \end{aligned}$$

Multiplying together the corresponding terms of these proportions, and omitting, in the result, the common multiplier  $\text{sol. } AQ$ ; we shall have

$$\text{sol. } AG : \text{sol. } AK :: AB \times AD : AO \times AM.$$

But  $AB \times AD$  represents the area of the base  $ABCD$ ; and  $AO \times AM$  represents the area of the base  $AMNO$ ; hence, two rectangular parallelopipedons having equal altitudes, are to each other as their bases.

## PROPOSITION XIII. THEOREM.

Any two rectangular parallelopipedons are to each other as the products of their bases by their altitudes; that is, as the products of their three dimensions.

Having placed the two solids  $AG$ ,  $AZ$ , so that their faces have the common angle  $BAE$ , produce the planes necessary for completing the third parallelopipedon  $AK$ , which will have an equal altitude with the parallelopipedon  $AG$ . By the last proposition, we have

$$\text{sol. } AG : \text{sol. } AK :: \\ ABCD : AMNO.$$

But the two parallelopipedons  $AK$ ,  $AZ$ , having the same base  $NA$ , are to each other as their altitudes  $AE$ ,  $AX$ ; hence, we have,

$$\text{sol. } AK : \text{sol. } AZ :: AE : AX.$$

Multiplying together the corresponding terms of these proportions, and omitting in the result the common multiplier  $\text{sol. } AK$ ; we shall have,

$$\text{sol. } AG : \text{sol. } AZ :: ABCD \times AE : AMNO \times AX.$$

Instead of the bases  $ABCD$  and  $AMNO$ , put  $AB \times AD$  and  $AO \times AM$ , and we shall have,

$$\text{sol. } AG : \text{sol. } AZ :: AB \times AD \times AE : AO \times AM \times AX:$$

hence, any two rectangular parallelopipedons are to each other, as the products of their three dimensions.

*Scholium* 1. The magnitude of a solid, its volume or extent, is called its *solidity*; and this word is exclusively employed to designate the measure of a solid: thus, we say the solidity of a rectangular parallelopipedon is equal to the product of its base by its altitude, or to the product of its three dimensions.

In order to comprehend the nature of this measurement, it is necessary to consider, that the number of linear units in one dimension of the base multiplied by the number of linear units in the other dimension of the base, will give the number of superficial units in the base of the parallel-pipedon (B. IV., P. 4, s.) For each unit in height, there are evidently, as many solid units as there are superficial units in the base. Therefore, the number of superficial units in the base multiplied by the number of linear units in the altitude, gives the number of solid units in the parallel-pipedon.

If then, we assume as the unit of measure, the cube whose edge is equal to the linear unit, the solidity will be expressed numerically, by the number of times which the solid contains its unit of measure.

*Scholium 2.* As the three dimensions of the cube are equal, if the edge is 1, the solidity is  $1 \times 1 \times 1 = 1$ ; if the edge is 2, the solidity is  $2 \times 2 \times 2 = 8$ ; if the edge is 3, the solidity is  $3 \times 3 \times 3 = 27$ ; and so on. Hence, if the edges of a series of cubes are to each other as the numbers 1, 2, 3, &c., the cubes themselves, or their solidities, are as the numbers 1, 8, 27, &c. Hence it is, that in arithmetic, the cube of a number is the name given to a product which results from three equal factors.

If it were proposed to find a cube double of a given cube, we should have, unity to the cube-root of 2, as the edge of the given cube to the edge of the required cube. Now, by a geometrical construction, it is easy to find the square root of 2; but the cube-root of it cannot be found, by the operations of elementary geometry, which are limited to the employment of the straight line and circle.

Owing to the difficulty of the solution, the problem of the *duplication of the cube* became celebrated among the ancient geometers, as well as that of the *trisection of an angle*, which is a problem nearly of the same species. The solutions of these problems have, however, long since been discovered; and though less simple than the constructions of elementary geometry, they are not, on that account, less rigorous or less satisfactory.

## PROPOSITION XIV. THEOREM.

*The solidity of a parallelepipedon, and generally of any prism, is equal to the product of its base by its altitude.*

*First.* Any parallelepipedon is equivalent to a rectangular parallelepipedon, having an equal altitude and an equivalent base (P. 10). But, the solidity of a rectangular parallelepipedon is equal to its base multiplied by its height; hence, the solidity of any parallelepipedon is equal to the product of its base by its altitude.

*Second.* Any triangular prism is half a parallelepipedon so constructed as to have an equal altitude and a double base (P. 7). But the solidity of the parallelepipedon is equal to its base multiplied by its altitude; hence, that of the triangular prism is also equal to the product of its base, which is half that of the parallelepipedon, multiplied into its altitude.

*Third.* Any prism may be divided into as many triangular prisms of the same altitude, as there are triangles formed by drawing diagonals from a common vertex in the polygon which constitutes its base. But the solidity of each triangular prism is equal to its base multiplied by its altitude; and since the altitudes are equal, it follows that the sum of all the triangular prisms must be equal to the sum of all the triangles which constitute their bases, multiplied by the common altitude.

Hence, the solidity of any polygonal prism, is equal to the product of its base by its altitude.

*Cor.* Since any two prisms are to each other as the products of their bases and altitudes, if the altitudes be equal, they will be to each other as their bases simply; hence, *two prisms of the same altitude are to each other as their bases.* For a like reason, *two prisms having equivalent bases are to each other as their altitudes.*

PROPOSITION XV. THEOREM.

*Two triangular pyramids, having equivalent bases and equal altitudes, are equivalent, or equal in solidity.*

Let  $S-ABC'$ ,  $S-abc$ , be two such pyramids; let their equivalent bases  $ABC$ ,  $abc$ , be situated in the same plane, and let  $AT$  be their common altitude: then will they be equivalent.

For, if these pyramids are not equivalent, let  $S-abc$  be the smaller; and suppose  $Aa$  to be the altitude of a prism which, having  $ABC$  for its base, is equal to their difference.

Divide the altitude  $AT$  into equal parts  $Ax$ ,  $xy$ ,  $yz$ , &c., each less than  $Aa$ , and let  $k$  denote one of those parts; through the points of division pass planes parallel to the planes of the bases; the corresponding sections formed by these planes in the two pyramids are respectively equivalent, namely,  $DEF$  to  $def$ ,  $GHI$  to  $ghi$ , &c. (p. 3, c. 2).

This being done, upon the triangles  $ABC$ ,  $DEF$ ,  $GHI$ , &c., taken as bases, construct exterior prisms having for edges the parts  $AD$ ,  $DG$ ,  $GK$ , &c., of the edge  $SA$ ; in like manner, on bases  $def$ ,  $ghi$ ,  $klm$ , &c., in the second pyramid, construct interior prisms, having for edges the correspond-

ing parts of  $Sa$ . It is plain, that the sum of all the exterior prisms of the pyramid  $S-ABC$  is greater than this pyramid; and also, that the sum of all the interior prisms of the pyramid  $S-abc$  is less than this pyramid. Hence, the difference, between the sum of all the exterior prisms of one pyramid, and the sum of all the interior prisms of the other, is greater than the difference between the two pyramids themselves.

Now, beginning with the bases, the second exterior prism  $EFD-G$ , is equivalent to the first interior prism  $efd-a$ , because they have the same altitude  $k$ , and their bases  $EFD$ ,  $efd$ , are equivalent; for a like reason, the third exterior prism  $HIG-K$ , and the second interior prism  $hig-d$  are equivalent; the fourth exterior and the third interior; and so on, to the last in each series. Hence, all the exterior prisms of the pyramid  $S-ABC$ , excepting the first prism  $BCA-D$ , have equivalent corresponding ones in the interior prisms of the pyramid  $S-abc$ : hence, the prism  $BCA-D$ , is the difference between the sum of all the exterior prisms of the pyramid  $S-ABC$ , and the sum of the interior prisms of the pyramid  $S-abc$ . But the difference between these two sets of prisms has already been proved to be greater than that between the two pyramids; which latter difference we supposed to be equal to the prism  $BCA-a$ : hence, the

prism  $BCA-D$ , should be greater than the prism  $BOA-a$ . But in reality it is less; for they have the same base  $ABC$ , and the altitude  $Ax$  of the first is less than the altitude  $Aa$  of the second. Hence, the supposed inequality between the two pyramids cannot exist; therefore, the two pyramids  $S-ABC$ ,  $S-abc$ , having equal altitudes and equivalent bases, are themselves equivalent.

PROPOSITION XVI. THEOREM.

*Every triangular prism may be divided into three equivalent triangular pyramids.*

Let  $ABC-DEF$  be a triangular prism; then may it be divided into three equivalent triangular pyramids.

Cut off the pyramid  $F-ABC$  from the prism, by the plane  $FAC$ ; there will remain the solid  $F-ACDE$ , which may be considered as a quadrangular pyramid, whose vertex is  $F$ , and whose base is the parallelogram  $ACDE$ . Draw the diagonal  $CE$ ; and pass the plane  $FCE$ , which will cut the quadrangular pyramid into two triangular pyramids  $F-ACE$ ,

$F-CDE$ . These two triangular pyramids have for their common altitude the perpendicular let fall from  $F$ , on the plane  $ACDE$ ; they have equal bases; for the triangles  $ACE$ ,  $CDE$ , are halves of the same parallelogram; hence, the two pyramids  $F-ACE$ ,  $F-CDE$ , are equivalent (p. 15). But the pyramid  $F-CDE$ , and the pyramid  $F-ABC$ , have equal bases  $ABC$ ,  $DEF$ ; they have also the same altitude, namely, the distance between the parallel planes  $ABC$ ,  $DEF$ ; hence, the two pyramids are equivalent. Now, the pyramid  $F-CDE$ , has already been proved equivalent to  $F-ACE$ ; hence, the three pyramids  $F-ABC$ ,  $F-CDE$ ,  $F-ACE$ , which compose the prism, are all equivalent.

*Cor. 1.* Every triangular pyramid is a third part of a

triangular prism, which has an equivalent base and an equal altitude.

*Cor. 2.* The solidity of a triangular pyramid is equal to a third part of the product of its base by its altitude.

PROPOSITION XVII. THEOREM.

*The solidity of every pyramid is equal to a third part of the product of its base by its altitude.*

Let  $SABCDE$  be a pyramid: then will its solidity be equal to one-third of the product of the base  $ABCDE$  by the altitude  $SO$ .

Pass the planes  $SEB$ ,  $SEC$ , through the vertex  $S$ , and the diagonals  $EB$ ,  $EC$ ; the polygonal pyramid  $SABCDE$  will then be divided into several triangular pyramids, all having the same altitude  $SO$ . But each of these pyramids is measured by the product of its base  $ABE$ ,  $BCE$ ,  $CDE$ , by a third part of its altitude  $SO$  (p. 16, c. 2); hence, the sum of these triangular pyramids, or the polygonal pyramid  $SABCDE$  is measured by the sum of the triangles  $ABE$ ,  $BCE$ ,  $CDE$ , or the polygon  $ABCDE$ , multiplied by one-third of  $SO$ ; hence, every pyramid is measured by a third part of the product of its base by its altitude.

*Cor. 1.* Every pyramid is the third part of a prism which has the same base and the same altitude.

*Cor. 2.* Two pyramids having the same altitude are to each other as their bases.

*Cor. 3.* Two pyramids having equivalent bases are to each other as their altitudes.

*Cor. 4.* Pyramids are to each other as the products of their bases by their altitudes.

*Scholium.* The solidity of any polyedral body may be computed, by dividing the body into pyramids; and this

division may be accomplished in various ways. One of the simplest is to pass all the planes of division through the vertex of the same polyedral angle; in that case, there will be formed as many pyramids as the polyedron has faces, less those faces which bound the polyedral angle whence the planes of division proceed.

PROPOSITION XVIII. THEOREM.

*The solidity of the frustum of a pyramid is equal to that of three pyramids having for their common altitude the altitude of the frustum, and for bases the lower base of the frustum, the upper base, and a mean proportional between the two bases.*

Let  $ABCDE-e$  be the frustum of a pyramid: then will its solidity be equal to that of three pyramids having the common altitude of the frustum, and for bases the polygons  $ABCDE$ ,  $abcde$ , and a mean proportional between them. Let  $T-FGH$  be a triangular pyramid having the same altitude, and an equivalent base with the pyramid  $S-ABCDE$ . These two pyramids are equivalent (P. 17, c. 3).

Now, if we regard their bases as situated in the same plane; the plane of the section  $abcd$ , will form in the triangular pyramid a section  $fgh$ , at the same distance above the common plane of the bases; and, therefore, the section  $fgh$  will be to the section  $abcde$ , as the base  $FGH$  is to the base  $ABCDE$  (P. 3, c. 1): and since the bases are equivalent, the sections will also be equivalent. Hence, the pyramids  $S-abcde$ ,  $T-fgh$  will be equivalent (P. 17, c. 3). If these be taken from the entire pyramids  $S-ABCDE$ ,  $T-FGH$ , the frustums  $ABCDE-e$ ,  $FGH-h$  which remain, will be equivalent: hence, if the proposition is true, in the single case of the frustum of a triangular pyramid, it is true in every other.

Let  $FGH-h$  be the frustum of a triangular pyramid. Through the three points,  $F, g, H$ , pass the plane  $FgH$ ; it cuts off from the frustum the triangular pyramid  $g-FGH$ . This pyramid has for its base the lower base  $FGH$  of the frustum; its altitude is equal to that of the frustum, because the vertex  $g$  lies in the plane of the upper base  $fgh$ .

This pyramid being cut off, there remains the quadrangular pyramid  $g-fhHF$ , whose vertex is  $g$ , and base  $fhHF$ . Pass the plane  $gfH$  through the three points  $f, g, H$ ; it divides the quadrangular pyramid into two triangular pyramids  $g-fFH, g-fhH$ . The latter has for its base the upper base  $fgh$  of the frustum; and for its altitude, the altitude of the frustum, because its vertex  $H$  lies in the lower base. Thus we already know two of the three pyramids which compose the frustum.

It remains to examine the third pyramid  $g-fFH$ . Now, if  $gK$  be drawn parallel to  $fF$ , and if we conceive a new pyramid  $K-fFH$ , having  $K$  for its vertex and  $fFH$  for its base, these two pyramids have the same base  $HfF$ ; they also have the same altitude, because their vertices  $g$  and  $K$  lie in the line  $gK$ , parallel to  $Ff$ , and consequently, parallel to the plane of the base: hence, these pyramids are equivalent (p. 17, c. 3). But the pyramid  $K-fFH$  may be regarded as having  $FKH$  for its base, and its vertex at  $f$ : its altitude is then the same as that of the frustum. We are now to show that the base  $FKH$  is a mean proportional between the bases  $FGH$  and  $fgh$ . The triangles  $FHK, fgh$ , have the angle  $F=f$ ; hence (B. IV., p. 24),

$$FHK : fgh :: FK \times FH : fg \times fh;$$

but because of the parallels,  $FK = fg$ ,

$$FHK : fgh :: FH : fh.$$

We have also,

$$FHG : FHK :: FG : FK, \text{ or } fg.$$

But the similar triangles  $FGH, fgh$ , give

hence,  $FG : fg :: FH : fh;$   
 $FGH : FHK :: FHK : fgh;$

that is, the base  $FHK$  is a mean proportional between the two bases  $FGH, fgh$ . Hence, the solidity of the frustum of a triangular pyramid is equal to that of three pyramids whose common altitude is that of the frustum, and whose bases are the lower base of the frustum, the upper base, and a mean proportional between the two bases.

PROPOSITION XIX. THEOREM.

*Similar triangular prisms are to each other as the cubes of their homologous edges.*

Let  $CBD-P, cbd-p,$  be two similar triangular prisms, and  $BC, bc,$  two homologous edges: then will the prism  $CBD-P$  be to the prism  $cbd-p,$  as  $\overline{BC}^3$  to  $\overline{bc}^3.$

For, since the prisms are similar, the homologous angles  $B$  and  $b$  are equal, and the faces which bound them are similar (D. 16). Hence, if these triedral angles be applied, the one to the other, the angles  $cbd$  will coincide with  $CBD,$  the edge  $ba$  with  $BA,$  and the prism  $cbd-p$  will take the position  $Bcd-p.$

From  $A$  draw  $AH$  perpendicular to the common base of the prisms: then will the plane  $BAH$  be perpendicular to the plane of the common base (B. VI., P. 16). Through  $a,$  in the plane  $BAH,$  draw  $ah$  perpendicular to  $BH:$  then will  $ah$  also be perpendicular to the base  $BDC$  (B. VI., P. 17); and  $AH, ah$  will be the altitudes of the two prisms.

Since the bases  $CBD, cbd,$  are similar, we have (B. IV., P. 25),

$$\text{base } CBD : \text{base } cbd :: \overline{CB}^2 : \overline{cb}^2.$$

Now, because of the similar triangles  $ABH, aBh,$  and of the similar parallelograms  $AC, ac,$  we have

$$AH : ah :: AB : ab :: CB : cb;$$

hence, multiplying together the corresponding terms, we have

$$\text{base } CBD \times AH : \text{base } cbd \times ah :: \overline{CB}^3 : \overline{cb}^3.$$

But the solidity of a prism is equal to the base multiplied by the altitude (P. 14); hence,

$$\text{prism } BCD-P : \text{prism } bcd-p :: \overline{BC}^3 : \overline{bc}^3,$$

or as the cubes of any other of their homologous edges.

*Cor.* Whatever be the bases of similar prisms, the prisms are to each other as the cubes of their homologous edges.

For, since the prisms are similar, their bases are similar polygons (D. 16); and these similar polygons may each be divided into the same number of similar triangles, similarly placed (B. IV., P. 26); therefore, each prism may be divided into the same number of triangular prisms, having their faces similar and like placed; hence, their polyedral angles are equal (B. VI., P. 21, s. 2); and consequently, the triangular prisms are similar (D. 16). But these triangular prisms are to each other as the cubes of their homologous edges, and being like parts of the polygonal prisms, their sums, that is, the polygonal prisms, are to each other as the cubes of their homologous edges.

PROPOSITION XX. THEOREM.

*Two similar pyramids are to each other as the cubes of their homologous edges.*

For, since the pyramids are similar, the homologous polyedral angles at the vertices are equal (D. 16). Hence, the polyedral angles at the vertices may be made to coincide, or the two pyramids may be so placed as to have the polyedral angle  $S$  common.

In that position the bases  $ABCDE$ ,  $abcde$ , are parallel; for, the homologous faces being similar, the angle  $Sab$  is equal to  $SAB$ , and  $Sbc$  to  $SBC$ ; hence, the plane  $ABC$ , is parallel to the plane  $abc$  (B. VI., P. 13). This being proved, let  $SO$  be drawn from the vertex  $S$ , perpendicular to the plane  $ABC$ , and let  $o$ , be the point where this perpendicular pierces the plane  $abc$ : from what has already been

shown, we have (P. 3),

$$SO : So :: SA : Sa :: AB : ab;$$

and consequently,

$$\frac{1}{3}SO : \frac{1}{3}So :: AB : ab.$$

But the bases  $ABCDE$ ,  $abcde$ , being similar figures, we have (B. IV., P. 27),

$$ABCDE : abcde :: \overline{AB}^2 : \overline{ab}^2;$$

multiply the corresponding terms of these two proportions, there results,

$$ABCDE \times \frac{1}{3}SO : abcde \times \frac{1}{3}So :: \overline{AB}^3 : \overline{ab}^3.$$

Now,  $ABCDE \times \frac{1}{3}SO$  measures the solidity of the pyramid  $S-ABCDE$ , and  $abcde \times \frac{1}{3}So$  measures that of the pyramid  $S-abcde$  (P. 17); hence, two similar pyramids are to each other as the cubes of their homologous edges.

GENERAL SCHOLIUMS.

1. The chief propositions of this Book relating to the solidity of polyedrons, may be expressed in algebraical terms, and so recapitulated in the briefest manner possible.

2. Let  $B$  represent the base of a *prism*;  $H$  its altitude: then,

$$\text{solidity of prism} = B \times H.$$

3. Let  $B$  represent the base of a *pyramid*;  $H$  its altitude: then,

$$\text{solidity of pyramid} = B \times \frac{1}{3}H.$$

4. Let  $H$  represent the altitude of the *frustum of a pyramid*, having the parallel bases  $A$  and  $B$ ;  $\sqrt{A \times B}$  is the mean proportional between those bases; then

$$\text{solidity of frustum} = \frac{1}{3}H(A + B + \sqrt{A \times B}).$$

5. In fine, let  $P$  and  $p$  represent the *solidities of two similar prisms or pyramids*;  $A$  and  $a$ , two homologous edges: then,

$$P : p :: A^3 : a^3.$$

# BOOK VIII.

## THE THREE ROUND BODIES.

### DEFINITIONS.

1. A **CYLINDER** is a solid which may be generated by the revolution of a rectangle  $ABCD$ , turning about the immovable side  $AB$ .

In this movement, the sides  $AD$ ,  $BC$ , continuing always perpendicular to  $AB$ , describe the equal circles  $DHP$ ,  $CGQ$ , which are called the *bases of the cylinder*; the side  $CD$ , describing, at the same time, the *convex surface*.

The immovable line  $AB$  is called the *axis of the cylinder*.

Every section  $MNKL$ , made in the cylinder, by a plane, at right angles to the axis, is a circle equal to either of the bases. For, whilst the rectangle  $ABCD$  turns about  $AB$ , the line  $KI$ , perpendicular to  $AB$ , describes a circle, equal to the base, and this circle is nothing else than the section made by a plane, perpendicular to the axis at the point  $I$ .

Every section  $QPHG$ , made by a plane passing through the axis, is a rectangle double the generating rectangle  $ABCD$ .

2. **SIMILAR CYLINDERS** are those whose axes are proportional to the radii of their bases: hence, they are generated by similar rectangles (B. IV., D. 1).

3. If, in the circle  $ABCDE$ , which forms the base of a cylinder, a polygon  $ABCDE$  be inscribed, and a right prism, constructed on this base, and equal in altitude to the cylinder; then, the prism is said to be *inscribed in the cylinder*, and the cylinder to be *circumscribed about the prism*.

The edges  $AF$ ,  $BG$ ,  $CH$ , &c., of the prism, being perpendicular to the plane of the base, are contained in the convex surface of the cylinder; hence, the prism and the cylinder touch one another along these edges.

4. In like manner, if  $ABCD$  is a polygon, circumscribed about the base of a cylinder, a right prism constructed on this base, and equal in altitude to the cylinder, is said to be *circumscribed about the cylinder*, and the cylinder to be *inscribed in the prism*.

Let  $M$ ,  $N$ , &c., be the points of contact in the sides  $AB$ ,  $BC$ , &c.; and through the points  $M$ ,  $N$ , &c., let  $MX$ ,  $NY$ , &c., be drawn perpendicular to the plane of the base: these perpendiculars will then lie both in the surface of the cylinder, and in that of the circumscribed prism; hence, they will be their lines of contact.

5. A CONE is a solid which may be generated by the revolution of a right-angled triangle  $SAB$ , turning about the immovable side  $SA$ .

In this movement, the side  $AB$  describes a circle  $BDCE$ , called the *base of the cone*; the hypotenuse  $SB$  describes the *convex surface of the cone*.

The point  $S$  is called the *vertex of the cone*,  $SA$  the *axis*, or the *altitude*, and  $SB$  the *slant height*.

Every section  $HKFI$ , made by a

plane, at right angles to the axis, is a circle. Every section  $EDS$ , made by a plane passing through the axis, is an isosceles triangle, double the generating triangle  $SAB$ .

6. If, from the cone  $S-CDB$ , the cone  $S-FKH$  be cut off by a plane parallel to the base, the remaining solid  $CFHB$  is called a *truncated cone*, or the *frustum of a cone*.

The frustum may be generated by the revolution of the trapezoid  $ABHG$ , turning about the side  $AG$ . The immovable line  $AG$  is called the *axis*, or *altitude of the frustum*, the circles  $BDC$ ,  $HFK$ , are its *bases*, and  $BH$  its *slant height*.

7. **SIMILAR CONES** are those whose axes are proportional to the radii of their bases: hence, they are generated by similar right-angled triangles (B. IV., D. 1).

8. If, in the circle  $ABCDE$ , which forms the base of a cone, any polygon  $ABCDE$  is inscribed, and from the vertices  $A, B, C, D, E$ , lines are drawn to  $S$ , the vertex of the cone, these lines may be regarded as the edges of a pyramid whose base is the polygon  $ABCDE$  and vertex  $S$ . The edges of this pyramid are in the convex surface of the cone, and the pyramid is said to be *inscribed* in the cone. The cone is also said to be *circumscribed* about the pyramid.

9. The **SPHERE** is a solid terminated by a curved surface, all the points of which are equally distant from a point within, called the *centre*.

The sphere may be generated by the revolution of a semicircle  $DAE$ , about its diameter  $DE$ : for, the surface described in this movement,

by the semicircumference  $DAE$ , will have all its points equally distant from its centre  $C$ .

10. Whilst the semicircle  $DAE$ , revolving round its diameter  $DE$ , describes the sphere, any circular sector, as  $DCF$ , or  $FCA$ , describes a solid, called a *spherical sector*.

11. The *radius of a sphere* is a straight line drawn from the centre to any point of the surface; the *diameter* or *axis* is a line passing through the centre, and terminated, on both sides, by the surface.

All the radii of a sphere are equal; all the diameters are equal, and each is double the radius.

12. It will be shown (P. 7,) that every section of a sphere, made by a plane, is a circle: this granted, a *great circle* is a section which passes through the centre; a *small circle*, is one which does not pass through the centre.

13. A *plane* is *tangent* to a sphere, when it has but one point in common with the surface.

14. A *zone* is the portion of the surface of the sphere included between two parallel circles, which form its *bases*. If the plane of one of these circles becomes tangent to the sphere, the zone will have only a single base.

15. A *spherical segment* is the portion of the solid sphere, included between two parallel circles which form its bases. If the plane of one of these circles becomes tangent to the sphere, the segment will have only a single base.

16. The *altitude of a zone*, or *of a segment*, is the distance between the planes of the two parallel circles, which form the bases of the zone or segment.

17. The Cylinder, the Cone, and the Sphere, are the *three round bodies* treated of in the Elements of Geometry.

## PROPOSITION I. THEOREM.

*The convex surface of a cylinder is equal to the circumference of its base multiplied by its altitude.*

Let  $CA$  be the radius of the base of a cylinder, and  $H$  its altitude; denote the circumference whose radius is  $CA$  by *circ. CA*: then will the convex surface of the cylinder be equal to *circ. CA*  $\times H$ .

Inscribe in the base of the cylinder any regular polygon,  $BDEFGA$ , and construct on this polygon a right prism having its altitude equal to  $H$ , the altitude of the cylinder: this prism will be inscribed in the cylinder. The convex surface of the prism is equal to the perimeter of the polygon, multiplied by the altitude  $H$  (B. VII., P. 1). Let now the arcs which are subtended by the sides of the polygon be continually bisected, and the number of sides of the polygon continually doubled: the limit of the perimeter of the polygon is *circ. CA* (B. 5, P. 12, s. 2), and the limit of the convex surface of the prism is the convex surface of the cylinder. But the convex surface of the prism is always equal to the perimeter of its base multiplied by  $H$ ; hence, *the convex surface of the cylinder is equal to the circumference of its base multiplied by its altitude.*

## PROPOSITION II. THEOREM.

*The solidity of a cylinder is equal to the product of its base by its altitude.*

Let  $CA$  be the radius of the base of the cylinder, and  $H$  the altitude. Let the circle whose radius is  $CA$  be denoted by *area CA*: then will the solidity of the cylinder be equal to *area CA*  $\times H$ .

For, inscribe in the base of the cylinder any regular polygon  $BDEFGA$ , and construct on this polygon a right prism having its altitude equal to  $H$ , the altitude of the cylinder: this prism will be inscribed in the cylinder. The solidity of this prism will be equal to the area of the polygon multiplied by the altitude  $H$  (B. VII., P. 14).

Let now the number of sides of the polygon be continually increased, as before described; the solidity of each new prism will still be equal to its base multiplied by its altitude: the limit of the polygon is the *area CA*, and the limit of the prisms, the circumscribed cylinder. But the solidity of each new prism is equal to the base multiplied by the altitude: therefore, *the solidity of the cylinder is equal to the product of its base by its altitude.*

*Cor.* 1. Cylinders of equal altitudes are to each other as their bases; and cylinders of equal bases are to each other as their altitudes.

*Cor.* 2. Similar cylinders are to each other as the cubes of their altitudes, or as the cubes of the radii of their bases. For, the bases are as the squares of their radii (B. V., P. 13); and the cylinders being similar, the radii of their bases are to each other as their altitudes (D. 2); hence, the bases are as the squares of the altitudes; therefore, the bases multiplied by the altitudes, or the cylinders themselves, are as the cubes of the altitudes.

*Scholium.* Let  $R$  denote the radius of a cylinder's base and  $H$  the altitude; then we shall have,

$$\begin{aligned} \text{surface of base} &= \pi \times R^2, \\ \text{convex surface} &= 2\pi \times R \times H, \\ \text{solidity} &= \pi \times R^2 \times H. \end{aligned}$$

## PROPOSITION III. THEOREM.

*The convex surface of a cone is equal to the circumference of its base, multiplied by half the slant height.*

Let the circle  $ABCD$  be the base of a cone,  $S$  the vertex,  $SO$  the altitude, and  $SA$  the slant height: then will the convex surface be equal to  $\text{circ. } OA \times \frac{1}{2}SA$ .

For, inscribe in the base of the cone any regular polygon  $ABCD$ , and on this polygon as a base conceive a right pyramid to be constructed, having  $S$  for its vertex: this pyramid will be inscribed in the cone.

From  $S$ , draw  $SG$  perpendicular to one of the sides of the polygon. The convex surface of the inscribed pyramid is equal to the perimeter of the polygon which forms its base, multiplied by half the slant height  $SG$  (B. VII., P. 4). Let now the number of sides of the inscribed polygon be continually increased, as before described: the limit of the perimeters of the polygons is  $\text{circ. } OA$ ; the limit of the slant height of the pyramids is the slant height of the cone, and the limit of their surfaces, is the convex surface of the circumscribed cone. But the convex surface of each new pyramid is equal to the perimeter of the base multiplied by half the slant height (B. VII., P. 4); hence, *the convex surface of the cone is equal to the circumference of its base multiplied by half its slant height.*

*Scholium.* Let  $L$  denote the slant height, and  $R$  the radius of the base: then,

$$\text{convex surface} = 2\pi \times R \times \frac{1}{2}L = \pi \times R \times L.$$

PROPOSITION IV. THEOREM.

*The convex surface of the frustum of a cone is equal to its slant height, multiplied by half the sum of the circumferences of its bases.*

Let  $BIA-DE$  be a frustum of a cone: then will,  
 convex surface =  $AD \times \frac{1}{2}(\text{circ. } OA + \text{circ. } CD)$

For, inscribe in the bases of the frustum two regular polygons of the same number of sides, and having their sides parallel, each to each. The lines joining the vertices of the corresponding angles may be regarded as the edges of the frustum of a right pyramid inscribed in the frustum of the cone. The convex surface of the frustum of the pyramid is equal to half the sum of the perimeters of its bases multiplied by the slant height  $fh$  (B. VII., P. 4, c.) Let the number of sides of the inscribed polygons be continually increased as before described: the limits of the perimeters of the polygons are *circ. OA* and *circ. CD*; the limit of the slant height is the slant height of the frustum, and the limit of the convex surface, the convex surface of the frustum; hence, *the convex surface of the frustum of a cone is equal to its slant height multiplied by half the sum of the circumferences of its bases.*

*Cor.* Through  $l$ , the middle point of  $AD$ , draw  $lKL$  parallel to  $AB$ , also  $li$ ,  $Dd$ , parallel to  $CO$ . Then, since  $Al$ ,  $lD$ , are equal,  $Ai$ ,  $id$ , are also equal (B. IV., P. 15, c. 2): hence,  $Kl$  is equal to  $\frac{1}{2}(OA + CD)$ . But since the circumferences of circles are to each other as their radii (B. V., P. 13),

$$\text{circ. } Kl = \frac{1}{2}(\text{circ. } OA + \text{circ. } CD);$$

therefore, *the convex surface of the frustum of a cone is equal to its slant height multiplied by the circumference of a section at equal distances from the two bases.*

*Scholium 1.* If from the middle point  $l$  and the two extremities  $A$  and  $D$ , of a line  $AD$ , lying wholly on one side of the line  $OC$ , the perpendiculars  $DC$ ,  $lk$ , and  $AO$ , be drawn, and then the line  $AD$  be revolved around  $OC$ , we shall have

surf. described by  $AD = AD \times \frac{1}{2}(\text{circ. } OA + \text{circ. } CD)$ ;  
that is,  $= AD \times \text{circ. } Kl$ .

For, it is evident that the surface described by  $AD$  is that of the frustum of a cone, having  $OA$  and  $CD$  for the radii of its bases.

*Scholium 2.* The measure found above applies equally to the case when the point  $D$  falls at  $C$ , and the surface becomes that of a cone; and to the case in which  $AD$  becomes parallel to  $OC$ , and the surface becomes that of a cylinder. In the first case,  $OD$  is nothing: in the second, it is equal to  $OA$ .

PROPOSITION V. THEOREM.

*The solidity of a cone is equal to its base multiplied by a third of its altitude.*

Let  $SO$  be the altitude of a cone,  $OA$  the radius of its base, and let the area of the base be designated by *area*  $OA$ ; then will,

$$\text{solidity} = \text{area } OA \times \frac{1}{3}SO.$$

Inscribe in the base of the cone any regular polygon  $ABDEF$ , and join the vertices  $A, B, C$ , &c., with the vertex  $S$  of the cone: then will there be inscribed in the cone a right pyramid having the same vertex as the cone, and having for its base the polygon  $ABDEF$ . The solidity of this pyramid will be equal to its base multiplied by one-third

of its altitude (B. VII., P. 17).

Let the arcs be bisected and the number of sides of the polygon be continually increased: the limit of the polygons will be the *area*  $OA$ , and the limit of the pyramids will be the cone whose vertex is  $S$ : hence, *the solidity of the cone is equal to its base multiplied by a third of its altitude.*

*Cor.* 1. A cone is the third of a cylinder having the same base and the same altitude; whence it follows,

1. That cones of equal altitudes are to each other as their bases;

2. That cones of equal bases are to each other as their altitudes;

3. That similar cones are as the cubes of the diameters of their bases, or as the cubes of their altitudes.

*Cor.* 2. The solidity of a cone is equivalent to the solidity of a pyramid having an equivalent base and the same altitude.

*Scholium.* Let  $R$  be the radius of a cone's base,  $H$  its altitude; then,

$$\text{solidity} = \frac{1}{3}\pi \times R^2 \times H.$$

PROPOSITION VI. THEOREM.

*The solidity of the frustum of a cone is equivalent to the sum of the solidities of three cones whose common altitude is the altitude of the frustum, and whose bases are, the lower base of the frustum, the upper base of the frustum, and a mean proportional between them.*

Let  $AEB-CD$  be the frustum of a cone, and  $OP$  its altitude; then will its solidity be equivalent to

$$\frac{1}{3}\pi \times OP \times (\overline{OB}^2 + \overline{PC}^2 + OB \times PC).$$

For, inscribe in the lower and upper bases two regular polygons having the same number of sides, and having their sides parallel, each to each. Join the vertices of the corresponding angles, and there

will then be inscribed in the frustum of the cone, the frustum of a regular pyramid. The solidity of the frustum of this pyramid will be equivalent to three pyramids having the common altitude of the frustum, and for bases, the lower base of the frustum, the upper base of the frustum, and a mean proportional between them (B. VII., P. 18).

Let the number of sides of the inscribed polygons be continually doubled by the methods before described: the limits of the polygons will be, *area OB* and *area PC*; and the limit of the frustums of the pyramids will be the frustum of the cone: the expression for the solidity will then become:

|                       |  |
|-----------------------|--|
| of the first pyramid, | $\frac{1}{3}OP \times \overline{OB}^2 \times \pi,$ |
| of the second         | $\frac{1}{3}OP \times \overline{PC}^2 \times \pi,$ |
| of the third          | $\frac{1}{3}OP \times OB \times PC \times \pi.$    |

hence, the solidity of the frustum of the cone is equivalent to

$$\frac{1}{3}\pi \times OP \times (\overline{OB}^2 + \overline{PC}^2 + OB \times PC).$$

PROPOSITION VII. THEOREM.

*Every section of a sphere, made by a plane, is a circle.*

Let *AMB* be any section made by a plane, in the sphere whose centre is *C*: then will it be a circle.

For, from the point *C*, draw *CO* perpendicular to the plane *AMB*; and different lines *CM*, *CM*, to different points of the curve *AMB*, which terminates the section.

The oblique lines *CM*, *CM*, *CA*, are equal, being radii of the sphere; hence, they pierce the plane *AMB* at equal distances from the perpendicular *CO* (B. VI., P. 5, c.); therefore, all the lines *OM*, *OM*, *OB*, are

equal; consequently, the section  $AMB$  is a circle, whose centre is  $O$ .

*Cor. 1.* If the section pass through the centre of the sphere, its radius will be the radius of the sphere; hence, all great circles are equal.

*Cor. 2.* Two great circles always bisect each other; for their common intersection, passing through the centre, is a diameter.

*Cor. 3.* Every great circle divides the sphere and its surface into two equal parts: for, if the two parts were separated and afterwards placed on the common base, with their convexities turned the same way, the two surfaces would exactly coincide, no point of the one being nearer the centre than any point of the other.

*Cor. 4.* The centre of a small circle, and that of the sphere, are in the same straight line, perpendicular to the plane of the small circle.

*Cor. 5.* The radius of any small circle is less than the radius of the sphere; and the further its centre is removed from the centre of the sphere, the less is its radius: for, the greater  $CO$  is, the less is the chord  $AB$ , the diameter of the small circle  $AMB$ .

*Cor. 6.* An arc of a great circle may always be made to pass through any two given points of the surface of the sphere: for, the two given points, and the centre of the sphere make three points, which determine the position of a plane. But if the two given points were at the extremities of a diameter, these two points and the centre would then lie in one straight line, and an infinite number of great circles might be made to pass through the two given points.

*Cor. 7.* *The distance between any two points on the surface of a sphere is less when measured on the arc of a great circle than when measured on the arc of a small circle.*

For, let  $A$  and  $B$  be any two points on the surface of a sphere, let  $ADB$  be the arc of a great circle, and  $AMB$

the arc of a small circle passing through them, and  $AB$  the common chord. Then, since the radius  $CA$  is greater than the radius  $OA$ , the arc  $ADB$  is less than the arc  $AMB$  (B. V., P. 17).

PROPOSITION VIII. THEOREM.

*Every plane perpendicular to a radius at its extremity is tangent to the sphere.*

Let  $FAG$  be a plane perpendicular to the radius  $OA$ , at its extremity  $A$ : then will it be tangent to the sphere.

For, assuming any other point  $M$  in this plane, draw  $OA$ ,  $OM$ : then the angle  $OAM$  is a right angle, and hence, the distance  $OM$  is greater than  $OA$ : therefore, the point  $M$  lies without the sphere; hence, the plane  $FAG$ , can have no point but  $A$  common to it and the surface of the sphere; consequently, it is a tangent plane (D. 13).

*Scholium.* In the same way it may be shown, that two spheres are tangent the one to the other, when the distance between their centres is equal to the sum or the difference of their radii; in which case, the centres and the point of contact lie in the same straight line.

PROPOSITION IX. LEMMA.

*If a regular semi-polygon be revolved about a line passing through the centre and the vertices of two opposite angles, the surface described by its perimeter will be equal to the axis multiplied by the circumference of the inscribed circle.*

Let the regular semi-polygon  $ABCDEF$ , be revolved about the line  $AF$  as an axis: then will the surface described by its perimeter be equal to  $AF$  multiplied by the circumference of the inscribed circle.

For, from  $E$  and  $D$ , the extremities of one of the equal sides, let fall the perpendiculars  $EH, DI$ , on the axis  $AF$ ; and from the centre  $O$ , draw  $ON$  perpendicular to the side  $DE$ :  $ON$  will be the radius of the inscribed circle (B. V., P. 2). Now, the surface described in the revolution, by any one side of the regular polygon, as  $DE$ , has been shown to be equal to  $DE \times \text{circ. } NM$  (P. 4, s. 1). But since the triangles  $EDK, ONM$ , are similar (B. IV., P. 21),

$ED : EK'$  or  $HI :: ON : NM :: \text{circ. } ON : \text{circ. } NM$ ;  
hence,  $ED \times \text{circ. } NM = HI \times \text{circ. } ON$ ;

and since the like may be shown for each of the other sides, it is plain that the surface described by the entire perimeter is equal to

$$(FH + HI + IP + PQ + QA) \times \text{circ. } ON = AF \times \text{circ. } ON.$$

*Cor.* The surface described by any portion of the perimeter, as  $EDC$ , is equal to the distance between the two perpendiculars let fall from its extremities on the axis, multiplied by the circumference of the inscribed circle.

For, the surface described by  $DE$  is equal to  $HI \times \text{circ. } ON$ , and the surface described by  $DC$  is equal to  $IP \times \text{circ. } ON$ : hence, the surface described by  $ED + DC$ , is equal to  $(HI + IP) \times \text{circ. } ON$ , or equal to  $HP \times \text{circ. } ON$ .

PROPOSITION X. THEOREM.

*The surface of a sphere is equal to the product of its diameter by the circumference of a great circle.*

Let  $ABCDE$  be a semicircle. Inscribe in it a regular semi-polygon, and from the centre  $O$  draw  $OF$  perpendicular to one of the sides.

Let the semicircle and the semi-polygon be revolved about the common axis  $AE$ : the semicircumference  $ABCDE$  will describe the surface of a sphere (D. 9); and the peri-

meter of the semi-polygon will describe a surface which has for its measure  $AE \times \text{circ. } OF$  (P. 9), and this will be true whatever be the number of sides of the semi-polygon.

If now, the arcs be continually bisected, the limit of the perimeters of the semi-polygons will be the semicircumference  $ABCDE$ ; the limit of the area described by the perimeter will be surface of the sphere, and the limit of the perpendicular  $OF$  will be the radius  $OE$ : hence, the surface of the sphere is equal to  $AE \times \text{circ. } OE$ .

*Cor. 1.* Since the area of a great circle is equal to the product of its circumference by half the radius, or one-fourth of the diameter (B. V., P. 15), it follows that *the surface of a sphere is equal to four of its great circles: that is, equal to  $4\pi \times OA^2$*  (B. V., P. 16).

*Cor. 2.* *The surface of a zone is equal to its altitude multiplied by the circumference of a great circle.*

For, the surface described by any portion of the perimeter of the inscribed polygon, as  $BC + CD$ , is equal to  $EH \times \text{circ. } OF$  (P. 9, c.): and when we pass to the limit, we have the surface of the zone equal to  $EH \times \text{circ. } OA$ .

*Cor. 3.* When the zone has but one base, as the zone described by the arc  $ABCD$ , its surface will still be equal to the altitude  $AE$  multiplied by the circumference of a great circle.

*Cor. 4.* Two zones, taken in the same sphere or in equal spheres, are to each other as their altitudes; and any zone is to the surface of the sphere as the altitude of the zone is to the diameter of the sphere.

PROPOSITION XI. LEMMA.

If a triangle and a rectangle, having the same base and the same altitude, turn together about the common base, the solid generated by the triangle is a third of the cylinder generated by the rectangle.

Let  $BAC$  be a triangle,  $BFEC$  a rectangle, having the common base  $BC$ , about which they are to be revolved.

On the axis, let fall the perpendicular  $AD$ : then, the cone generated by the triangle  $BAD$  is a third part of the cylinder generated by the rectangle  $BFAD$  (p. v., c. 1): also, the cone generated by the triangle  $DAC$  is a third

part of the cylinder generated by the rectangle  $DAEC$ : hence, the sum of the two cones, or the solid generated by  $BAC$ , is a third part of the sum of the cylinders generated by the two rectangles, or a third part of the cylinder generated by the rectangle  $BFEC$ .

If the perpendicular  $AD$  falls without the triangle; the solid generated by  $CBA$  is, in that case, the difference of the two cones generated by  $BAD$  and

$CAD$ ; but at the same time, the cylinder generated by  $BFEC$ , is the difference of the two cylinders generated by  $BFAD$  and  $CEAD$ . Hence, the solid, generated by the revolution of the triangle, is still a third part of the cylinder generated by the revolution of the rectangle having the same base and the same altitude.

*Scholium.* The circle of which  $AD$  is the radius, has for its measure  $\pi \times AD^2$ ; hence,  $\pi \times AD^2 \times BC$  measures the cylinder generated by  $BFEC$ , and  $\frac{1}{3} \pi \times AD^2 \times BC$  measures the solid generated by the triangle  $BAC$ .

## PROPOSITION XII. LEMMA.

If a triangle be revolved about any line drawn through its vertex in the same plane, the solid generated will have for its measure, the area of the triangle multiplied by two-thirds of the circumference traced by the middle point of the base.

Let  $CAB$  be a triangle,  $I$  the middle point of the base, and  $CD$  the line about which it is to be revolved: then will the solid generated be measured by

$$\text{area } CAB \times \frac{2}{3} \text{ circ. } IK.$$

Prolong the base  $AB$  till it meets the axis  $CD$  in  $D$ ; from the points  $A$  and  $B$ , draw  $AM$ ,  $BN$ , perpendicular to the axis, and draw  $CP$  perpendicular to  $DA$  produced.

The scholium to the last proposition gives the following measures:

$$\text{solid generated by } CAD = \frac{1}{3} \pi \times \overline{AM}^2 \times CD,$$

$$\text{solid generated by } CBD = \frac{1}{3} \pi \times \overline{BN}^2 \times CD:$$

hence, the difference of these solids, which is the solid generated by the triangle  $CAB$ , has for its measure

$$\frac{1}{3} \pi \times (\overline{AM}^2 - \overline{BN}^2) \times CD.$$

To this expression another form may be given. From  $I$ , the middle point of  $AB$ , draw  $IK$  perpendicular to  $CD$ ; and through  $B$ , draw  $BO$  parallel to  $CD$ . We shall then have (B. IV., P. 7, s.),

$$AM + BN = 2IK, \text{ and } AM - BN = AO;$$

$$\text{hence, } (AM + BN) \times (AM - BN) = \overline{AM}^2 - \overline{BN}^2 = 2IK \times AO :-$$

hence, the measure of the solid is also equal to

$$\frac{2}{3} \pi \times IK \times AO \times CD.$$

But  $CP$  being perpendicular to  $AB$  produced, the triangles  $AOB$  and  $CPD$  are similar; hence,

$$AO : CP :: AB : CD,$$

and,

$$AO \times CD = CP \times AB.$$

But  $CP \times AB$  is double the area of the triangle  $CAB$ ; therefore,

$$AO \times CD = 2CAB :$$

hence, the solid generated by the triangle  $CAB$  is measured by

$$\frac{4}{3}\pi \times CAB \times IK = CAB \times \frac{4}{3}\pi \times IK ;$$

and since  $2\pi \times IK = \text{circ. } IK$ , we have,

$$\text{solid} = CAB \times \frac{2}{3} \text{circ. } IK.$$

*Cor.* If the triangle is isosceles, the perpendicular  $CP$  will pass through  $I$ , the middle point of the base; and we shall have

$$CAB = AB \times \frac{1}{2} CI.$$

Substituting this value of

$CAB$  in the measure of the solid before found, viz.:

$$\text{solid} = CAB \times \frac{4}{3}\pi \times IK, \text{ gives,}$$

$$\text{solid} = \frac{2}{3}\pi \times AB \times IK \times CI.$$

But the triangles  $AOB$ ,  $CKI$ , are similar (B. IV., P. 21);

hence,  $AB : BO \text{ or } MN :: CI : IK$ ,

which gives,  $AB \times IK = MN \times CI$ .

Substituting for  $AB \times IK$ , we have,

$$\text{solid} = \frac{2}{3}\pi CI^2 \times MN :$$

that is, the solid generated by the revolution of an isosceles triangle about any line drawn through its vertex, is measured by two-thirds of  $\pi$  into the square of the perpendicular let fall on the base, into the distance between the two perpendiculars let fall from the extremities of the base on the axis.

*Scholium.* The demonstration appears to involve the supposition that  $AB$  prolonged will meet the axis: but the results are equally true if  $AB$  is parallel to the axis.

Thus, the cylinder generated by  $MNBA$  is measured by  $\pi \times \overline{AM}^2 \times MN$ : the cone generated by  $CAM$  is measured by  $\frac{1}{3}\pi \times \overline{AM}^2 \times CM$ ; and the cone generated by  $CBN$  is measured by  $\frac{1}{3}\pi \times \overline{AM}^2 \times CN$ .

Add the first two solids, and from the sum subtract the third: we shall then have

$$\begin{aligned} \text{solid by } CAB &= \pi \times \overline{AM}^2 \times (MN + \frac{1}{3}CM - \frac{1}{3}CN) \\ &= \pi \times \overline{AM}^2 \times (\frac{1}{3}MN + \frac{1}{3}CM - \frac{1}{3}CN + \frac{2}{3}MN); \end{aligned}$$

and since  $\frac{1}{3}MN + \frac{1}{3}CM = \frac{1}{3}CN$ , we have

$$\text{solid by } CAB = \pi \times \overline{AM}^2 \times \frac{2}{3}MN.$$

But  $AM = CP$  and  $MN = AB$ ; hence,

$$\text{solid by } CAB = AB \times CP \times \frac{2}{3}\pi \times CP = CAB \times \frac{2}{3} \text{circ. } CP.$$

But the circumference traced by  $P$  is equal to the circumference traced by the middle point of the base: hence, the result agrees with the general enunciation.

PROPOSITION XIII. LEMMA.

*If a regular semi-polygon be revolved about a line passing through its centre and the vertices of two opposite angles, the solid generated will be measured by two-thirds the area of the inscribed circle multiplied by the axis.*

Let  $GDBF$  be a regular semi-polygon and  $OI$  the radius of the inscribed circle: then, if this semi-polygon be revolved about  $GF$ , the solid generated will have for its measure,

$$\frac{2}{3} \text{area } OI \times GF.$$

For, since the polygon is regular, the triangles,  $OFA$ ,  $OAB$ ,  $OBC$ , &c., are isosceles and equal; then, all the perpendiculars let fall from  $O$  on their bases, will be equal to  $OI$ , the radius of the inscribed circle.

Now, we have the following measures for the solids generated by these triangles (P. 12, c.): viz.,

$$\begin{aligned} OFA \text{ is measured by } & \frac{2}{3}\pi \times \overline{OI}^2 \times FM, \\ OAB \text{ " " " } & \frac{2}{3}\pi \times \overline{OI}^2 \times MN, \\ OBC \text{ " " " } & \frac{2}{3}\pi \times \overline{OI}^2 \times ON, \text{ \&c.}; \end{aligned}$$

hence, the entire solid generated by the semi-polygon is measured by

$$\frac{2}{3}\pi \times \overline{OI}^2 (FM + MN + NO + OQ + QR + RG) :$$

that is, by  $\frac{2}{3}\pi \times \overline{OI}^2 \times GF.$

But,  $\pi \times \overline{OI}^2 = \text{area } OI$  (B. V., P. 16):

hence,  $\text{solidity} = \frac{2}{3} \text{area } OI \times GF.$

PROPOSITION XIV. THEOREM.

*The solidity of a sphere is equal to its surface multiplied by a third of its radius.*

Let  $O$  be the centre of a sphere and  $OA$  its radius: then its solidity is equal to its surface into one-third of  $OA$ .

For, inscribe in the semi-circle  $ABCDE$  a regular semi-polygon, having any number of sides, and let  $OI$  be the radius of the circle inscribed in the polygon.

If the semicircle and semi-polygon be revolved about  $EA$ , the semicircle will generate a sphere, and the semi-polygon a solid which has for its measure  $\frac{2}{3}\pi \overline{OI}^2 \times EA$  (P. 13); and this is true whatever be the number of sides of the semi-polygon. But if the number of sides of the polygon be continually doubled, the limit of the solids generated by the polygons will be the sphere; and when we pass to the limit the expression for the solidity will become  $\frac{2}{3}\pi \times \overline{OA}^2 \times EA$ , or by substituting  $2OA$  for  $EA$ , it becomes  $\frac{4}{3}\pi \times \overline{OA}^2 \times OA$ , which is also equal to  $4\pi \times \overline{OA}^2 \times \frac{1}{3}OA$ . But  $4\pi \times \overline{OA}^2$  is equal to the surface of the sphere (P. X., c. 1): hence, the solidity of a sphere is equal to its surface multiplied by a third of its radius.

*Scholium 1. The solidity of every spherical sector is equal to the zone which forms its base, multiplied by a third of the radius.*

For, the solid described by any portion of the regular polygon, as the isosceles triangle  $OAB$ , is measured by  $\frac{2}{3}\pi\overline{OI}^2 \times AF$  (P. 12, c.); and when we pass to the limit which is the spherical sector, the expression for this measure becomes  $\frac{2}{3}\pi \times \overline{AO}^2 \times AF$ , which is equal to  $2\pi \times AO \times AF \times \frac{1}{3}AO$ . But  $2\pi \times AO$  is the circumference of a great circle of the sphere (B. V., P. 16), which being multiplied by  $AF$  gives the surface of the zone which forms the base of the sector (P. X., c. 2); and the proof is equally applicable to the spherical sector described by the circular sector  $BOC$ : hence, *the solidity of the spherical sector is equal to the zone which forms its base, multiplied by a third of the radius.*

*Scholium 2.* Since the surface of a sphere whose radius is  $R$ , is expressed by  $4\pi \times R^2$  (P. X., c. 1), it follows that the surfaces of spheres are to each other as the squares of their radii; and since their solidities are as their surfaces multiplied by their radii, it follows that *the solidities of spheres are to each other as the cubes of their radii, or as the cubes of their diameters.*

*Scholium 3.* Let  $R$  be the radius of a sphere; its surface will be expressed by  $4\pi \times R^2$ , and its solidity by  $4\pi \times R^2 \times \frac{1}{3}R$ , or  $\frac{4}{3}\pi \times R^3$ . If the diameter be denoted by  $D$ , we shall have  $R = \frac{1}{2}D$ , and  $R^3 = \frac{1}{8}D^3$ : hence, the solidity of the sphere may be expressed by

$$\frac{4}{3}\pi \times \frac{1}{8}D^3 = \frac{1}{6}\pi \times D^3.$$

PROPOSITION XV. THEOREM.

*The surface of a sphere is to the whole surface of the circumscribed cylinder, including its bases, as 2 is to 3: and the solidities of these two bodies are to each other in the same ratio.*

Let  $MPNQ$  be a great circle of the sphere;  $ABCD$  the

circumscribed square; if the semicircle  $PMQ$  and the half square  $PADQ$  are at the same time made to revolve about the diameter  $PQ$ , the semicircle will generate the sphere, while the half square will generate the cylinder circumscribed about that sphere.

The altitude  $AD$  of the cylinder is equal to the diameter  $PQ$ ; the base of the cylinder is equal to a great circle, since its diameter  $AB$  is equal to  $MN$ ; hence, the convex surface of the cylinder is equal to the circumference of the great circle multiplied by its diameter (P. 1). This measure is the same as that of the surface of the sphere (P. 10); hence, *the surface of the sphere is equal to the convex surface of the circumscribed cylinder.*

But the surface of the sphere is equal to four great circles; hence, the convex surface of the cylinder is also equal to four great circles: and adding the two bases, each equal to a great circle, the total surface of the circumscribed cylinder is equal to six great circles; hence, the surface of the sphere is to the total surface of the circumscribed cylinder, as 4 is to 6, or as 2 is to 3; which is the first branch of the proposition.

In the next place, since the base of the circumscribed cylinder is equal to a great circle of the sphere, and its altitude to the diameter, the solidity of the cylinder is equal to a great circle multiplied by its diameter (P. 2). But the solidity of the sphere is equal to four great circles multiplied by a third of the radius (P. 14); in other terms, to one great circle multiplied by  $\frac{4}{3}$  of the radius, or by  $\frac{2}{3}$  of the diameter; hence, the sphere is to the circumscribed cylinder as 2 to 3, and consequently, the solidities of these two bodies are as their surfaces.

*Scholium* 1. Conceive a polyedron, all of whose faces touch the sphere; this polyedron may be considered as composed of pyramids, each pyramid having for its vertex the centre of the sphere, and for its base one of the poly-

edron's faces. Now, it is evident that all these pyramids have the radius of the sphere for their common altitude: so that the solidity of each pyramid will be equal to one face of the polyedron multiplied by a third of the radius: hence, the whole polyedron is equal to its surface multiplied by a third of the radius of the inscribed sphere.

It is therefore manifest, that the solidities of polyedrons circumscribed about the sphere, are to each other as their surfaces. Thus, the property, which we have shown to be true with regard to the circumscribed cylinder, is also true with regard to an infinite number of other solids.

We might likewise have observed, that the surfaces of polygons, circumscribed about a circle, are to each other as their perimeters.

PROPOSITION XVI. THEOREM.

*If a circular segment is revolved about a diameter exterior to it, the solid generated is measured by one-sixth of  $\pi$  into the square of the chord, into the distance between two perpendiculars let fall from the extremities of the arc on the axis.*

Let  $DMB$  be a circular segment, and  $AC$  the axis about which it is revolved.

On the axis, let fall the perpendiculars  $BE$ ,  $DF$ ; from the centre  $C$ , draw  $CI$  perpendicular to the chord  $BD$ ; also draw the radii  $CB$ ,  $CD$ .

The solid generated by the sector  $CDMB$  is measured by  $\frac{2}{3}\pi \times \overline{CB}^2 \times EF$  (P. 14, s. 1). The solid generated by the isosceles triangle  $CDB$  has for its measure  $\frac{2}{3}\pi \times \overline{CI}^2 \times EF$  (P. 12, c.); hence, the solid generated by the segment  $DMB$ , is measured by

$$\frac{2}{3}\pi \times EF \times (\overline{CB}^2 - \overline{CI}^2).$$

But in the right-angled triangle  $CBI$ , we have (B. IV. P. 8, c),

$$\overline{CB}^2 - \overline{CI}^2 = \overline{BI}^2 = \frac{1}{4} \overline{BD}^2:$$

hence, the solid generated by the segment  $DMB$ , has for its measure

$$\frac{2}{3}\pi \times EF \times \frac{1}{4} \overline{BD}^2 = \frac{1}{6}\pi \times \overline{BD}^2 \times EF.$$

*Scholium.* The solid generated by the segment  $BMD$  is to the sphere which has  $BD$  for a diameter,

as  $\frac{1}{6}\pi \times \overline{BD}^2 \times EF$  is to  $\frac{1}{6}\pi \times \overline{BD}^3$ , or as  $EF$  to  $BD$ .

PROPOSITION XVII. THEOREM.

*Every segment of a sphere is measured by half the sum of its bases multiplied by its altitude, plus the solidity of a sphere whose diameter is this same altitude.*

Let  $DMB$  be the arc of a circle, and  $DF$ ,  $BE$ , perpendiculars let fall on the radius  $CA$ : then, if the area  $FDMBE$  be revolved about the radius  $CA$  it will generate a spherical segment. It is required to find the measure of this segment.

The solid generated by the circular segment  $DMB$  is measured by (P. 16)

$$\frac{1}{6}\pi \times \overline{BD}^2 \times EF:$$

the frustum of the cone described by the trapezoid  $FDBE$  is measured by (P. 6)

$$\frac{1}{3}\pi \times EF \times (\overline{BE}^2 + \overline{DF}^2 + BE \times DF):$$

hence, the segment of the sphere, which is the sum of these two solids, is measured by

$$\frac{1}{6}\pi \times EF \times (2\overline{BE}^2 + 2\overline{DF}^2 + 2BE \times DF + \overline{BD}^2).$$

But by drawing  $BO$  parallel to  $EF$ , we have,

$$DO = DF - BE \text{ and } \overline{DO}^2 = \overline{DF}^2 - 2DF \times BE + \overline{BE}^2;$$

and,  $\overline{BD}^2 = \overline{BO}^2 + \overline{DO}^2 = \overline{EF}^2 + \overline{DF}^2 - 2DF \times BE + \overline{BE}^2$ .

Substituting this value for  $\overline{BD}^2$  in the expression for the solidity of the segment, we have,

$\frac{1}{6}\pi \times EF \times (2\overline{BE}^2 + 2\overline{DF}^2 + 2BE \times DF + \overline{EF}^2 + \overline{DF}^2 - 2DF \times BE + \overline{BE}^2)$ ,  
 equal to  $\frac{1}{6}\pi \times EF \times (3\overline{BE}^2 + 3\overline{DF}^2 + \overline{EF}^2)$ ;

an expression which may be written in two parts, viz.,

$$EF \times \left( \frac{\pi \times \overline{BE}^2 + \pi \times \overline{DF}^2}{2} \right) \text{ and } \frac{1}{6}\pi \times \overline{EF}^3;$$

and these parts correspond with the enunciation.

*Cor.* If the radius of either base is nothing, the segment becomes a spherical segment with a single base; hence, *any spherical segment, with a single base, is equivalent to half the cylinder having the same base and the same altitude, plus the sphere of which this altitude is the diameter.*

#### GENERAL SCHOLIUMS.

1. Let  $R$  be the radius of a cylinder's base,  $H$  its altitude: the solidity of the cylinder is

$$\pi \times R^2 \times H.$$

2. Let  $R$  be the radius of a cone's base,  $H$  its altitude: the solidity of the cone is

$$\pi \times R^2 \times \frac{1}{3}H = \frac{1}{3}\pi \times R^2 \times H.$$

3. Let  $A$  and  $B$  be the radii of the bases of a frustum of a cone,  $H$  its altitude: the solidity of the frustum is

$$\frac{1}{3}\pi \times H \times (A^2 + B^2 + A \times B).$$

4. Let  $R$  be the radius of a sphere; its solidity is

$$\frac{4}{3}\pi \times R^3.$$

5. Let  $R$  be the radius of a spherical sector,  $H$  the altitude of a zone, which forms its base: the solidity of the sector is

$$\frac{2}{3}\pi \times R^2 \times H.$$

6. Let  $P$  and  $Q$  be the two bases of a spherical segment,  $H$  its altitude: the solidity of the segment is

$$\frac{P+Q}{2} \times H + \frac{1}{6}\pi \times H^3.$$

7. If the spherical segment has but one base, its solidity is

$$\frac{1}{2}P \times H + \frac{1}{6}\pi \times H^3.$$

# BOOK IX.

## SPHERICAL GEOMETRY.

### DEFINITIONS.

1. A SPHERICAL TRIANGLE is a portion of the surface of a sphere, bounded by three arcs of great circles.

These arcs are named the *sides* of the triangle, and each is less than a semicircumference. The angles which the planes of the circles make with each other, are the angles of the triangle.

2. A spherical triangle takes the name of *right-angled*, *isosceles*, *equilateral*, in the same cases as a rectilinear triangle.

3. A SPHERICAL POLYGON is a portion of the surface of a sphere bounded by three or more arcs of great circles.

4. A LUNE is a portion of the surface of a sphere included between two semi-circles intersecting in a common diameter of the sphere.

5. A SPHERICAL WEDGE, or UNGULA, is that portion of a solid sphere, included between two planes passing through the centre, and the lune which forms its base.

6. A SPHERICAL PYRAMID is a portion of the solid sphere, included between three or more planes. The *base* of the pyramid is the spherical polygon intercepted by the same planes. These planes bound a polyedral angle, whose vertex is at the centre of the sphere.

7. The POLE OF A CIRCLE is a point on the surface of the sphere, equally distant from every point in the circumference.

## PROPOSITION I. THEOREM.

*In every spherical triangle, any side is less than the sum of the two other sides.*

Let  $O$  be the centre of the sphere, and  $ACB$  a spherical triangle: then will any side be less than the sum of the two other sides.

For, draw the radii  $OA, OB, OC$ . Conceive the planes  $AOB, AOC, COB$ , to be drawn; these planes bound a polyedral angle whose vertex is at the centre  $O$ ; and the plane angles  $AOB, AOC, COB$ , are measured by  $AB, AC, BC$ , the sides of the spherical triangle. But each of the three plane angles which bound a polyedral angle is less than the sum of the two other angles (B. VI., P. 19); hence, any side of a spherical triangle is less than the sum of the two other sides.

## PROPOSITION II. THEOREM.

*The sum of all the sides of any spherical polygon is less than the circumference of a great circle.*

Let  $ABCDE$  be any spherical polygon, and  $O$  the centre of the sphere.

Conceive  $O$  to be the vertex of a polyedral angle bounded by the plane angles  $AOB, BOC, COD$ , &c. Now, the sum of the plane angles which bound a polyedral angle is less than four right angles (B. VI., P. 20); hence, the sum of the sides of any spherical polygon is less than the circumference.

*Cor.* The sum of the three sides of any spherical triangle is less than the circumference; for, the triangle is a polygon of three sides.

PROPOSITION III. THEOREM.

The poles of a great circle of a sphere are the extremities of that diameter of the sphere which is perpendicular to the circle; and these extremities are also the poles of all small circles parallel to it.

Let  $ED$  be perpendicular to the great circle  $AMB$ ; then will  $E$  and  $D$  be its poles; and they will also be the poles of every parallel small circle  $FNG$ .

For,  $DC$  being perpendicular to the plane  $AMB$ , is perpendicular to all the straight lines  $CA, CM, CB$ , &c., drawn through its foot in this plane (B. VI., D. 1); hence, all the arcs  $DA, DM, DB$ , &c., are quarters of the circumference. So likewise are all the arcs  $EA, EM, EB$ , &c.; therefore, the points  $D$  and  $E$

are each equally distant from all the points of the circumference  $AMB$ ; hence, they are the poles of that circumference (D. 7).

Again, the radius  $DC$ , perpendicular to the plane  $AMB$ , is perpendicular to the parallel  $FNG$ ; hence, it passes through  $O$ , the centre of the circle  $FNG$  (B. VIII., P. 7, C. 4); hence, if the chords  $DF, DN, DG$ , be drawn, these oblique lines will cut off equal distances measured from  $O$ ; hence, they will be equal (B. VI., P. 5). But, the chords being equal, the arcs are equal; hence, the point  $D$  is the pole of the small circle  $FNG$ ; and for like reasons, the point  $E$  is the other pole.

*Cor.* If through the pole  $D$  and any point  $M$ , in the arc of a great circle  $AMB$ , an arc of another great circle  $MD$  be drawn, the arc  $MD$  is a quarter of the circumference, and is called a *quadrant*. This quadrant makes a right angle with the arc  $AM$ . For, the line  $DC$  being perpendicular to the plane  $AMC$ , every plane  $DME$ , passing through the line  $DC$  is

perpendicular to the plane  $AMC$  (B VI., P. 16); hence, the angle of these planes, or the angle  $AMD$  is a right angle.

*Cor. 2.* Conversely: If the distance of the point  $D$  from each of the points  $A$  and  $M$ , in the circumference of a great circle, is equal to a quadrant, the point  $D$  is the pole of the arc  $AM$ .

For, let  $C$  be the centre of the sphere, and draw the radii  $CD$ ,  $CA$ ,  $CM$ . Since the angles  $ACD$ ,  $MCD$ , are right angles, the line  $CD$  is perpendicular to the two straight lines  $CA$ ,  $CM$ ; hence, it is perpendicular to their plane (B. VI., P. 4): hence, the point  $D$  is the pole of the arc  $AM$ .

*Scholium.* The properties of these poles enable us to describe arcs of a circle on the surface of a sphere, with the same facility as on a plane surface. It is evident, for instance, that by turning the arc  $DF$ , or any other line extending to the same distance, round the point  $D$ , the extremity  $F$  will describe the small circle  $FNG$ ; and by turning the quadrant  $DFA$  round the point  $D$ , its extremity  $A$  will describe the arc of a great circle  $AMB$ .

#### PROPOSITION IV. THEOREM.

*The angle formed by two arcs of great circles, is equal to the angle formed by the tangents of these arcs at their point of intersection. The angle is measured by the arc of a great circle described from the vertex as a pole, and limited by the sides, produced if necessary.*

Let the angle  $BAC$  be formed by the two arcs  $AB$ ,  $AC$ ; then will it be equal to the angle  $FAG$  formed by the tangents  $AF$ ,  $AG$ , and be measured by the arc  $DE$  of a great circle, described about  $A$  as a pole.

For, the tangent  $AF$ , drawn in the plane of the arc  $AB$ , is perpendicular to the radius  $AO$ ; and the tangent  $AG$ , drawn in the plane of the arc  $AC$ , is perpendicular to the same radius  $AO$ . Hence, the angle  $FAG$  is equal to the angle contained by the planes  $ABDH$ ,  $ACEH$  (B. VI., D. 4); which is that of the arcs  $AB$ ,  $AC$ , and is called the angle  $BAC$ .

Again, if the arcs  $AD$  and  $AE$  are both quadrants, the lines  $OD$ ,  $OE$ , are perpendicular to  $OA$ , and the angle  $DOE$  is equal to the angle of the planes  $ABDH$ ,  $ACEH$ ; hence, the arc  $DE$  is the measure of the angle contained by these planes, or of the angle  $CAB$ .

*Cor.* 1. The angles of spherical triangles may be compared together, by means of the arcs of great circles described from their vertices as poles and included between their sides: hence, it is easy to make an angle of this kind equal to a given angle.

*Cor.* 2. Vertical angles, such as  $ACO$  and  $BCN$  are equal; for either of them is still the angle formed by the two planes  $ACB$ ,  $OCN$ .

It is further evident, that, when two arcs  $ACB$ ,  $OCN$ , intersect, the two adjacent angles  $ACO$ ,  $OCB$ , taken together, are equal to two right angles.

PROPOSITION V. THEOREM.

*If from the vertices of the three angles of a spherical triangle, as poles, arcs be described forming a spherical triangle; then, the vertices of the angles of this second triangle, will be respectively poles of the sides of the first.*

From the vertices  $A$ ,  $B$ ,  $C$ , as poles, let the arcs  $EF$ ,  $FD$ ,  $ED$ , be described, forming on the surface of the sphere,

the triangle  $DFE$ ; then will the vertices  $D$ ,  $E$ , and  $F$ , be respectively poles of the sides  $BC$ ,  $AC$ ,  $AB$ .

For, the point  $A$  being the pole of the arc  $EF$ , the distance  $AE$  is a quadrant; the point  $C$  being the pole of the arc  $DE$ , the distance  $CE$  is likewise a quadrant: hence, the point  $E$  is removed the length of a quadrant from each of the points  $A$  and  $C$ ; hence, it is the pole of the arc  $AC$  (P. 3, c. 2). It may be shown by similar reasoning, that  $D$  is the pole of the arc  $BC$ , and  $F$  that of the arc  $AB$ .

*Scholium.* Hence, the triangle  $ABC$  may be described by means of  $DEF$ , as  $DEF$  is described by means of  $ABC$ . Triangles so described, are called *polar triangles*, or *supplemental triangles*.

PROPOSITION VI. THEOREM.

*The same supposition continuing as in the last Proposition, each angle in one of the triangles, will be measured by a semicircumference, minus the side lying opposite to it in the other triangle.*

For, produce the sides  $AB$ ,  $AC$ , if necessary, till they meet  $EF$ , in  $G$  and  $H$ . The point  $A$  being the pole of the arc  $GH$ , the angle  $A$  is measured by that arc (P. 4). But, since  $E$  is the pole of  $AH$ , the arc  $EH$  is a quadrant; and since  $F$  is the pole of  $AG$ ,  $FG$  is a quadrant: hence,  $EH + GF$  is equal to a semicircumference. But,  $EH + GF = EF + GH$ ; hence the arc  $GH$ , which mea-

sures the angle  $A$ , is equal to a semicircumference *minus* the side  $EF$ . In like manner, the angle  $B$  is measured by  $\frac{1}{2} \text{circ.} - DF$ : the angle  $C$ , by  $\frac{1}{2} \text{circ.} - DE$ .

This property is reciprocal in the two triangles, since each of them is described in a similar manner by means of the other. Thus the angle  $D$ , for example, of the triangle  $EDF$ , is measured by the arc  $MI$ ; but  $MI + BC = MC + BI = \frac{1}{2} \text{circ.}$ ; hence, the arc  $MI$ , the measure of  $D$ , is equal to  $\frac{1}{2} \text{circ.} - BC$ : the angle  $E$  is measured by  $\frac{1}{2} \text{circ.} - AC$ , and the angle  $F$  by  $\frac{1}{2} \text{circ.} - AB$ .

*Scholium.* It must further be observed, that besides the triangle  $DEF$ , three others might be formed by the intersection of the three arcs  $DE$ ,  $EF$ ,  $DF$ . But the proposition is applicable only to the central triangle, which is distinguished from the other

three by the circumstance, that the two angles  $A$  and  $D$  lie on the same side of  $BC$ , the two  $B$  and  $E$  on the same side of  $AC$ , and the two  $C$  and  $F$  on the same side of  $AB$ .

PROPOSITION VII. THEOREM.

*If around the vertices of any two angles of a given spherical triangle, as poles, the circumferences of two circles be described which shall pass through the vertex of the third angle of the triangle: if then, through the other point in which these circumferences intersect and the vertices of the first two angles of the triangle, two arcs of great circles be drawn, the triangle thus formed will have all its parts equal to those of the given triangle, each to each.*

Let  $ABC$  be the given triangle,  $CED$ ,  $DFC$ , the arcs described about  $A$  and  $B$  as poles; then will the triangles  $ABC$ ,  $ADB$  have all their parts equal each to each.

For, by construction, the side  $AD = AC$ ,  $DB = BC$ , and  $AB$  is common; hence, these two triangles have their *sides* equal, each to each. We are now to show, that the *angles* opposite these equal sides are also equal, each to each.

If the centre of the sphere is at  $O$ , a triedral angle may be conceived as formed at  $O$  by the three plane angles  $AOB$ ,  $AOC$ ,  $BOC$ ; likewise another triedral angle may be conceived as formed by the three plane angles  $AOB$ ,  $AOD$ ,  $BOD$ . And, because the sides of the triangle  $ABC$  are equal to those of the triangle  $ADB$ , the plane angles forming the one of these triedral angles, are equal to the plane angles forming the other, each to each: hence, the planes are equally inclined to each other (B. VI., P. 21); and all the angles of the spherical triangle  $DAB$ , are respectively equal to those of the triangle  $CAB$ , namely,  $DAB=BAC$ ,  $DBA=ABC$ , and  $ADB=ACB$ ; consequently, the sides and the angles of the triangle  $ADB$ , are equal to the sides and the angles of the triangle  $ACB$ , each to each.

*Scholium.* The equality of these triangles is not, however, an *absolute equality*, or one of *superposition*: for, it would be impossible to apply them to each other, unless they were *isosceles*. The equality meant here is what we have already named an equality by *symmetry* (B. VI., 21, s. 3); therefore, we shall call the triangles  $ACB$ ,  $ADB$ , *symmetrical triangles*.

PROPOSITION VIII. THEOREM.

*Two triangles on the same sphere, or on equal spheres, are equal in all their parts, when two sides and the included angle of the one are equal to two sides and the included angle of the other, each to each.*

Let  $ABC$ ,  $EFG$ , be two triangles having the side  $AB=EF$ , the side  $AC=EG$ , and the angle  $BAC=FEG$ ; then will the two triangles be equal in all their parts.

For, the triangle  $EFG$  may be placed on the triangle  $ABC$ , or on

$ABD$  symmetrical with  $ABC$ , just as two rectilineal triangles are placed upon each other, when they have an equal angle included between equal sides. Hence, all the parts of the triangle  $EFG$  are equal to all the parts of the triangle  $ABC$ ; that is, besides the three parts equal by hypothesis, we have the side  $BC=FG$ , the angle  $ABC=EFG$ , and the angle  $ACB=EGF$ .

PROPOSITION IX. THEOREM.

*Two triangles on the same sphere or on equal spheres, are equal in all their parts, when two angles and the included side of the one are equal to two angles and the included side of the other, each to each.*

For, one of these triangles, or the triangle symmetrical with it, may be placed on the other, as is done in the corresponding case of rectilineal triangles (B. I., P. 6).

PROPOSITION X. THEOREM.

*If two triangles on the same sphere, or on equal spheres, have all their sides equal, each to each, their angles will likewise be equal, each to each, the equal angles lying opposite the equal sides.*

The truth of this proposition is evident from Prop. VII., where it was shown, that with three given sides  $AB$ ,  $AC$ ,  $BC$ , only two triangles  $ACB$ ,  $ABD$ , can be constructed, and that these triangles will have all their parts equal each to each. Hence, the two triangles, having all their sides respectively equal, must either be absolutely equal, or *symmetrically equal*; in either of which cases, their corresponding angles are equal, and lie opposite to equal sides.

## PROPOSITION XI. THEOREM.

*In every isosceles spherical triangle, the angles opposite the equal sides are equal; and conversely, if two angles of a spherical triangle are equal, the triangle is isosceles.*

*First.* Suppose the side  $AB=AC$ ; we shall have the angle  $B=C$ .

For, if the arc  $AD$  be drawn from the vertex  $A$  to the middle point  $D$  of the base, the two triangles  $ABD$ ,  $ACD$ , will have all the sides of the one respectively equal to the corresponding sides of the other, viz.,  $AD$  common,  $BD=DC$ , and  $AB=AC$ : hence, by the last proposition, their angles will be equal; therefore,  $B=C$ .

*Secondly.* Suppose the angle  $B=C$ ; we shall have the side  $AC=AB$ .

For, if not, let  $AB$  be the greater of the two; take  $BO=AC$ , and draw  $OC$ . Then, in the two triangles  $BOC$ ,  $BAC$ , the two sides  $BO$ ,  $BC$ , are equal to the two  $AC$ ,  $BC$ ; the angle  $OBC$ , contained by the first two is equal to  $ACB$  contained by the second two. Hence, the two triangles  $BOC$ ,  $ACB$ , have all their other parts equal (P. 8); hence, the angle  $OCB=ABC$ : but, by hypothesis, the angle  $ABC=ACB$ ; hence, we have  $OCB=ACB$ , which is absurd (A. 8); therefore, an absurdity follows if we suppose  $AB$  different from  $AC$ ; hence, the sides  $AB$ ,  $AC$ , opposite to the equal angles  $B$  and  $C$ , are equal.

*Scholium.* Since, the triangles  $BAD$ ,  $DAC$ , are equal in all their parts (P. 10), the angle  $BAD=DAC$ , and  $BDA=ADC$ : consequently,  $ADB$  and  $ADC$ , are right angles: hence, the arc drawn from the vertex of an isosceles spherical triangle to the middle of the base, is at right angles to the base and bisects the vertical angle.

PROPOSITION XII. THEOREM.

*In any spherical triangle, the greater side is opposite the greater angle; and conversely, the greater angle is opposite the greater side.*

Let the angle  $A$  be greater than the angle  $B$ , then will  $BC$  be greater than  $AC$ ; and conversely, if  $BC$  is greater than  $AC$ , then will the angle  $A$  be greater than  $B$ .

*First.* Suppose the angle  $A > B$ ; make the angle  $BAD = B$ ; then we shall have  $AD = DB$  (p. 11); but  $AD + DC$  is greater than  $AC$ ; hence, putting  $DB$  in place of  $AD$ , we shall have  $DB + DC > AC$ , or  $BC > AC$ .

*Secondly.* If we suppose  $BC > AC$ , the angle  $BAC$  will be greater than  $ABC$ . For, if  $BAC$  were equal to  $ABC$ , we should have  $BC = AC$ ; if  $BAC$  were less than  $ABC$ , we should then, as has just been shown, find  $BC < AC$ . Either of these conditions is contrary to the supposition: hence, the angle  $BAC$  is greater than  $ABC$ .

PROPOSITION XIII. THEOREM.

*If two triangles on the same sphere, or on equal spheres, are mutually equiangular, they are also mutually equilateral.*

Let  $A$  and  $B$  be the two given triangles;  $P$  and  $Q$  their polar triangles.

Since the angles are equal, each to each, in the triangles  $A$  and  $B$ , the sides are equal each to each, in their polar triangles  $P$  and  $Q$  (p. 6): but, since the triangles  $P$  and  $Q$  are mutually equilateral, they must also be mutually equiangular (p. 10); and lastly, the angles being equal, each to each, in the triangles  $P$  and  $Q$ , it follows that the sides are equal each to each, in their polar triangles  $A$  and  $B$ .

Hence, the mutually equiangular triangles  $A$  and  $B$  are at the same time, mutually equilateral.

*Scholium.* This proposition is not applicable to rectilinear triangles; in which equality among the angles indicates only proportionality among the sides. Nor is it difficult to account for the difference, in this respect, between spherical and rectilinear triangles. In the proposition now before us, as well as in the preceding ones, which treat of the comparison of triangles, it is expressly required that the arcs be traced on the same sphere, or on equal spheres. Now, similar arcs are to each other as their radii; hence, on equal spheres, two triangles cannot be similar without being equal. Therefore, it is not strange that equality among the angles should produce equality among the sides.

The case would be different, if the triangles were drawn upon unequal spheres; there, the angles being equal, the triangles would be similar, and the homologous sides would be to each other as the radii of their spheres.

PROPOSITION XIV. THEOREM.

*The sum of all the angles, in any spherical triangle, is less than six right angles and greater than two.*

For, in the first place, every angle of a spherical triangle is less than two right angles: hence, the sum of the three is less than six right angles.

Secondly, the measure of each angle of a spherical triangle is equal to the semicircumference *minus* the corresponding side of the polar triangle (P. 6); hence, the sum of the three, is measured by the three semicircumferences, *minus* the sum of the sides of the polar triangle. Now, this latter sum is less than a circumference (P. 2, C.); therefore, taking it away from three semicircumferences, the remainder is greater than one semicircumference, which is the measure of two right angles; hence, the sum of the three angles of a spherical triangle is greater than two right angles.

*Cor. 1.* The sum of the three angles of a spherical triangle is not constant, like that of the angles of a rectilinear triangle, but varies between two right angles and six, without ever reaching either of these limits. Two given angles therefore do not serve to determine the third.

*Cor. 2.* A spherical triangle may have two, or even three of its angles right angles; also two, or even three of its angles obtuse.

*Cor. 3.* If the triangle  $ABC$  is *bi-rectangular*, in other words, has two right angles  $B$  and  $C$ , the vertex  $A$  is the pole of the base  $BC$ ; and the sides  $AB, AC$ , are quadrants (P. 3, c. 2).

If the angle  $A$  is also a right angle, the triangle  $ABC$  is *tri-rectangular*; each of its angles is a right angle, and its sides are quadrants. Two tri-rectangular triangles make half a hemisphere, four make a hemisphere, and eight the entire surface of a sphere.

PROPOSITION XV. THEOREM.

*The surface of a lune is to the surface of the sphere, as the angle of the lune, to four right angles; or, as the arc which measures that angle, to the circumference.*

Let  $AMB$  be a lune, and  $NCM$  the angle included between its two great circles: then will its surface be to the surface of the sphere as the angle  $NCM$  to four right angles, or as the arc  $NM$  to the circumference of a great circle.

For, suppose the arc  $MN$  to be to the circumference  $MNPQ$ , as some one integer number to another, as 5 to 48, for example. Divide the circumference  $MNPQ$ , into 48 equal parts,  $MN$  will contain 5 of them; and if the pole  $A$  were joined with the several points of division, by as many quadrants, we should in the hemisphere  $AMNPQ$ , have 48 triangles, all equal, because all the corresponding parts are equal. The whole sphere

would contain 96 of these triangles, and the lune  $AMBNA$ , 10 of them; hence, the lune is to the sphere as 10 is to 96, or as 5 to 48; in other words, as the arc  $MN$  is to the circumference.

If the arc  $MN$  is not commensurable with the circumference, it may still be shown, that the lune is to the sphere as  $MN$  to the circumference (B. III., P. 17).

*Cor. 1.* Two lunes on the same or on equal spheres, are to each other as their respective angles.

*Cor. 2.* It was shown above, that the whole surface of the sphere is equal to eight tri-rectangular triangles (P. 14, c. 3); hence, if the area of one such triangle be represented by  $T$ , the surface of the whole sphere will be expressed by  $8T$ . This granted, if the right angle be assumed equal to 1, the surface of the lune whose angle is  $A$ , will be expressed by  $2A \times T$ . For,

$$4 : A :: 8T : 2A \times T,$$

in which expression,  $A$  represents such a part of unity, as the angle of the lune is of one right angle.

*Scholium.* The spherical ungula, bounded by the planes  $AMB$ ,  $ANB$ , is to the whole solid sphere, as the angle  $A$  is to four right angles. For, the lunes being equal, the spherical unguulas are also equal; hence, two spherical unguulas are to each other, as the angles formed by the planes which bound them.

PROPOSITION XVI. THEOREM.

*Two symmetrical spherical triangles are equivalent.*

Let  $ABC$ ,  $DEF$ , be two symmetrical triangles, that is to say, two triangles having their sides  $AB=DE$ ,  $AC=DF$ ,  $CB=EF$ , and yet incapable of superposition: we are to show that the surface  $ABC$  is equal to the surface  $DEF$ .

Let  $P$  be the pole of the small circle passing through the three points  $A$ ,  $B$ ,  $C$ ;\* from this point draw the equal

---

\* The circle which passes through the three points  $A$ ,  $B$ ,  $C$ , or which circumscribes the triangle  $ABC$ , can only be a small circle of the sphere; for if it were a great circle, the three sides,  $AB$ ,  $BC$ ,  $AC$ , would lie in one plane, and the triangle  $ABC$  would be reduced to one of its sides.

arcs  $PA, PB, PC$  (p. 3); at the point  $F$  make the angle  $DFQ = ACP$ , the arc  $FQ = CP$ ; and draw  $DQ, EQ$ .

The sides  $DF, FQ$ , are equal to the sides  $AC, CP$ ; the angle  $DFQ = ACP$ ; hence, the two triangles  $DFQ, ACP$ , are equal in all their parts (p. 8); consequently, the side  $DQ = AP$ , and the angle  $DQF = APC$ .

In the triangles  $DFE, ABC$ , the angles  $DFE, ACB$ , opposite to the equal sides  $DE, AB$ , are equal (p. 10). If the angles  $DFQ, ACP$ , which are equal by construction, be taken away from them, there will remain the angle  $QFE$ , equal to  $PCB$ . The sides  $QF, FE$ , are equal to the sides  $PC, CB$ ; hence, the two triangles  $FQE, CPB$ , are equal in all their parts (p. 8); hence, the side  $QE = PB$ , and the angle  $FQE = CPB$ .

Now, the triangles  $DFQ, ACP$ , which have their sides respectively equal, are at the same time isosceles, and capable of coinciding, when applied the one to the other. For, having placed  $AC$  on its equal  $DF$ , the equal sides will fall the one on the other, and thus the two triangles will exactly coincide: hence, they are equal; and the surface  $DQF = APC$ . For a like reason, the surface  $FQE = CPB$ , and the surface  $DQE = APB$ ; hence we have,

$$DQF + FQE - DQE = APC + CPB - APB,$$

or, 
$$DFE = ABC;$$

hence, the two symmetrical triangles  $ABC, DEF$ , are equal in surface.

*Scholium.* The poles  $P$  and  $Q$  might lie within triangles  $ABC, DEF$ : in which case it would be requisite to add the three triangles  $DQF, FQE, DQE$ , together, in order to make up the triangle  $DEF$ ; and in like manner, to add the three triangles  $APC, CPB, APB$ , together, in order to make up the triangle  $ABC$ : in all other respects, the demonstration and the result would be the same.

## PROPOSITION XVII. THEOREM.

If the circumferences of two great circles intersect each other on the surface of a hemisphere, the sum of the opposite triangles thus formed, is equivalent to the surface of a lune whose angle is equal to the angle formed by the circles.

Let the circumferences  $AOB$ ,  $COD$ , intersect on the surface of a hemisphere; then will the opposite triangles  $AOC$ ,  $BOD$ , be equivalent to the lune whose angle is  $BOD$ .

For, produce the arcs  $OB$ ,  $OD$ , on the other hemisphere, till they meet in  $N$ . Now, since  $AOB$  and  $OBN$  are semicircumferences, if we take away the common part  $OB$ , we shall have  $BN=AO$ . For a like reason, we have  $DN=CO$ , and  $BD=AO$ . Hence, the two triangles  $AOC$ ,  $BDN$ ,

have their three sides respectively equal: they are therefore symmetrical; hence, they are equal in surface (P. 16). But the sum of the triangles  $BDN$ ,  $BOD$ , is equivalent to the lune  $OBND$ , whose angle is  $BOD$ : hence,  $AOC+BOD$  is equivalent to the lune whose angle is  $BOD$ .

*Scholium.* It is likewise evident, that the two spherical pyramids, which have the triangles  $AOC$ ,  $BOD$ , for bases, are together equivalent to the spherical ungula whose angle is  $BOD$ .

## PROPOSITION XVIII. THEOREM.

The surface of a spherical triangle is equal to the excess of the sum of its three angles above two right angles, multiplied by the tri-rectangular triangle.

Let  $ABC$  be any spherical triangle: then will its surface be equal to

$$(A+B+C-2) \times T.$$

For, produce its sides till they meet the great circle  $DEFG$ , drawn at pleasure, without the triangle. By the last theorem, the two triangles  $ADE$ ,  $AGH$ , are together

equivalent to the lune whose angle is  $A$ , and which is measured by  $2A \times T$  (p. 15, c. 2). Hence, we have  $ADE + AGH = 2A \times T$ ; and, for a like reason,  $BGF + BID = 2B \times T$ , and  $CIH + CFE = 2C \times T$ . But the sum of these six triangles exceeds the hemisphere by

twice the triangle  $ABC$ , and the hemisphere is represented by  $4T$ : therefore, twice the triangle  $ABC$ , is equivalent to  $2A \times T + 2B \times T + 2C \times T - 4T$ ;

and, consequently,

$$ABC = (A + B + C - 2) \times T;$$

hence, every spherical triangle is measured by the sum of its three angles *minus* two right angles, multiplied by the tri-rectangular triangle.

*Scholium 1.* When we speak of the *spherical angles*, we regard the right angle as unity, and compare the sum of the three angles with this standard. Hence, however many right angles there may be in the sum of the three angles minus two right angles, just so many tri-rectangular triangles, will the proposed triangle contain. If the angles, for example, are each equal to  $\frac{1}{3}$  of a right angle, the sum of the three angles is equal to 4 right angles; and this sum, minus two right angles, is represented by  $4 - 2$ , or 2; therefore, the surface of the triangle is equal to two tri-rectangular triangles, or to the fourth part of the surface of the entire sphere.

*Scholium 2.* The same proportion which exists between the spherical triangle  $ABC$ , and the tri-rectangular triangle, exists also between the spherical pyramid which has  $ABC$  for its base, and the tri-rectangular pyramid. The triedral angle of the pyramid is to the triedral angle of the tri-rectangular pyramid, as the triangle  $ABC$  to the tri-rectangular triangle. From these relations, the following consequences are deduced.

*First.* Two triangular spherical pyramids are to each other as their bases: and since a polygonal pyramid may always be divided into a certain number of triangular pyramids, it follows that any two spherical pyramids are to each other, as the polygons which form their bases.

*Second.* The polyedral angles at the vertices of these pyramids, are also as their bases; hence, for comparing any two polyedral angles, we have merely to place their vertices at the centres of two equal spheres; the angles are to each other as the spherical polygons intercepted between their faces.

The vertical angle of the tri-rectangular pyramid is formed by three planes at right angles to each other: this angle, which may be called a *right polyedral angle*, will serve as a very natural unit of measure for all other polyedral angles. If, for example, the area of the triangle is  $\frac{3}{4}$  of the tri-rectangular triangle, the corresponding tri-edral angle is also  $\frac{3}{4}$  of the right polyedral angle.

PROPOSITION XIX. THEOREM.

*The surface of a spherical polygon is equal to the excess of the sum of all its angles, over two right angles taken as many times as there are sides in the polygon less two, multiplied by the tri-rectangular triangle.*

Let  $ABCDE$  be a spherical polygon.

From one of the vertices  $A$ , let diagonals  $AC$ ,  $AD$ , be drawn to the other vertices; the polygon  $ABCDE$  will be divided into as many triangles less two, as it has sides.

Now, the surface of each triangle is equal to the sum of all its angles less two right angles, into the tri-rectangular triangle. The sum of the angles of all the triangles is the same as that of all the angles of the polygon; hence, the surface of the polygon is equal to the sum of all its angles, diminished by twice as many right angles as it has sides less two, into the tri-rectangular triangle.

*Scholium.* Let  $s$  be the sum of all the angles of a spherical polygon,  $n$  the number of its sides, and  $T$  the tri-rectangular triangle; the right angle being taken as unity, the surface of the polygon will be equal to

$$(s - 2(n - 2)) \times T = (s - 2n + 4) \times T.$$

## APPENDIX.

### NOTE A.—PAGE 22.

A DEMONSTRATION is a train of logical arguments brought to a conclusion. The bases or premises of a demonstration, are definitions, axioms, propositions previously established, and hypotheses. The arguments are the links which connect the premises, logically, with the conclusion or ultimate truth to be proved.

In Geometry we employ two kinds of demonstration—the Direct, and the Indirect or the method involving the *Reductio ad absurdum*.

These are also called Positive and Negative Demonstrations. In the direct method, the premises are definitions, axioms, and previous propositions; and by a process of logical argumentation, the magnitudes of which something is to be proved, are shown to bear the mark by which that may always be inferred, or, in other words, are shown to fall under some definition, axiom, or proposition, previously laid down. The direct demonstration may be divided into two classes:

1st. Where the argument depends on superposition—that is, on the coincidence of magnitudes when applied the one to the other: and

2dly. Where it depends on addition and subtraction, or immediately on principles previously laid down.

The indirect method rests on a hypothesis. This hypothesis is combined in a process of logical argumentation, with definitions, axioms, and previous propositions, until a conclusion is obtained, which agrees or disagrees with some known truth. Now, if the conclusion so deduced, is excluded from the truths previously established, that is, if

it is opposed to any of them, then it follows that the hypothesis, leading to a result contradictory to such truth, must be false. In the indirect demonstration, therefore, the *conclusion* is compared with the truths known antecedently to the proposition in question; if it disagrees with any of them, the hypothesis is false.

We have examples of the first class of the direct demonstration in the reasoning which establishes Propositions V. and VI.—and of the second class in that which establishes Propositions I. and IV. We have also examples of the indirect method in the demonstrations of Propositions II. and III.

It is often supposed, though erroneously, that the indirect demonstration is less conclusive and satisfactory than the direct. This impression is simply the result of a want of proper analysis. For example: in the demonstration of Proposition II. we propose to prove “that two straight lines having two points in common coincide throughout their whole extent.” Now, it is evident that they either coincide or separate. If they separate, they must separate at some point, as *C*. But the *supposition* or *hypothesis* of their separating at this point, involves the conclusion, that a *part is equal to the whole*, which is contrary to Axiom 8, and therefore untrue: Hence, they do not separate, and *therefore*, they coincide. Similar remarks apply to all indirect demonstrations.

In both kinds of demonstrations the premises and conclusion agree: that is, they are both true or both false, the reasoning or argument in both being supposed strictly logical.

For a more full discussion of this subject, see Davies' *Logic of Mathematics*.

## THE REGULAR POLYEDRONS.

A REGULAR POLYEDRON is one whose faces are all equal regular polygons, and whose polyedral angles are all equal to each other.

1. The TETRAEDRON, or *regular pyramid*, is a solid bounded by four equal equilateral triangles.

2. The HEXAEDRON, or *Cube*, is a solid bounded by six equal squares.

3. The OCTAEDRON, is a solid bounded by eight equal equilateral triangles.

4. The DODECAEDRON, is a solid bounded by twelve equal and regular pentagons.

5. The ICOSAEDRON is a solid bounded by twenty equal equilateral triangles.

*First.* If the faces are equilateral triangles, polyedrons may be constructed bounded by such triangles and will have polyedral angles contained either by three, four or five of them: hence arise three regular polyedral bodies, viz: the *tetraedron*, the *octaedron*, and the *icosaedron*, and no others can be constructed with equilateral triangles. For, each angle of an equilateral triangle being equal to a third part of two right, six such angles about the vertex of a polyedral angle would be equal to four right angles, which is impossible (B. VI., P. 20,

*Secondly.* If the faces are squares, their angles may be arranged by threes: hence, results the *hexaedron*, or *cube*. Four angles of a square are equal to four right angles, and cannot form a polyedral angle.

*Thirdly.* In fine, if the faces are regular pentagons, their angles likewise may be arranged by threes: the regular *dodecaedron* will result.

We can proceed no farther: three angles of a regular hexagon are equal to four right angles; three of a heptagon are greater.

Hence, there can only be five regular polyedrons; three formed with equilateral triangles, one with squares, and one with pentagons.

#### CONSTRUCTION OF THE TETRAEDRON.

Let  $ABC$  be the equilateral triangle which is to form one face of the tetraedron. At the point  $O$ , the centre of this triangle, erect  $OS$  perpendicular to the plane  $ABC$ ; terminate this perpendicular in  $S$ , so that  $AS=AB$ ; draw  $SB, SC$ ; the pyramid  $S-ABC$  is the tetraedron required.

For, by reason of the equal distances  $OA, OB, OC$ , the oblique lines  $SA, SB, SC$ , cut off equal distances estimated from the foot of the perpendicular  $SO$ , and consequently are equal (B. VI., P. 5). One of them  $SA=AB$ ; hence, the four faces of the pyramid  $S-ABC$ , are triangles, equal to the given triangle  $ABC$ . The triedral angles of this pyramid are all equal, because each of them is bounded by three equal plane angles (B. VI., P. 21, s. 2); hence, this pyramid is a regular tetraedron.

#### CONSTRUCTION OF THE HEXAEDRON.

Let  $ABCD$  be a given square. On the base  $ABCD$ , construct a right prism whose altitude  $AE$  shall be equal to the side  $AB$ . The faces of this prism will evidently be equal squares; and its triedral angles all equal, each being formed with three equal faces: hence, this prism is a regular hexaedron or cube.

The following propositions can be easily proved.

1. Any regular polyedron may be divided into as many right pyramids as the polyedron has faces; the common vertex of these pyramids will be the centre of the poly-

dron; and at the same time, that of an inscribed and of a circumscribed sphere.

2. The solidity of a regular polyedron is equal to its surface multiplied by a third part of the radius of the inscribed sphere.

3. Two regular polyedrons of the same name, are two similar solids, and their homologous dimensions are proportional; hence, the radii of the inscribed or the circumscribed spheres are to each other as the edges of the polyedrons.

4. If a regular polyedron be inscribed in a sphere, the planes drawn from the centre, through the different edges, will divide the surface of the sphere into as many spherical polygons, all equal and similar, as the polyedron has faces.

## APPLICATION OF ALGEBRA

TO THE

### SOLUTION OF GEOMETRICAL PROBLEMS.

A PROBLEM is a question which requires a solution. A geometrical problem is one, in which certain parts of a geometrical figure are given or known, from which it is required to determine certain other parts.

When it is proposed to solve a geometrical problem by means of Algebra, the given parts are represented by the first letters of the alphabet, and the required parts by the final letters. The geometrical relations which subsist between the known and required parts furnish the equations of the problem. The solution of these equations, when so formed, gives the solution of the problem.

No general rule can be given for forming the equations. The equations must be independent of each other, and their number equal to that of the unknown quantities introduced (Alg., Art. 103). Experience, and a careful examination of all the conditions, whether explicit or implicit (Alg., Art. 94), will serve as guides in stating the questions; to which may be added the following general directions.

1st. Draw a figure which shall represent all the given parts, and all the required parts. Then draw such other lines as will enable us to establish the necessary relations between them. If an angle is given, it is generally best to let fall a perpendicular that shall lie opposite to it; and this perpendicular, if possible, should be drawn from the extremity of a given side.

2d. When two lines or quantities are connected in the same way with other parts of the figure or problem, it is in general, not best to use either of them separately; but to use their sum, their difference, their product, their quotient, or perhaps another line of the figure with which they are alike connected.

3d. When the area, or perimeter of a figure, is given, it is sometimes best to assume another figure similar to that proposed, having one of its sides equal to unity, or some other known quantity. A comparison of the two figures will often give a required part. We will add the following problems.\*

PROBLEM I.

*In a right-angled triangle BAC, having given the base BA, and the sum of the hypotenuse and perpendicular, it is required to find the hypotenuse and perpendicular.*

Put  $BA = c = 3$ ,  $BC = x$ ,  $AC = y$ , and the sum of the hypotenuse and perpendicular equal to  $s = 9$ .

Then,  $x + y = s = 9$ ,  
 and (B. IV., P. 11),  $x^2 = y^2 + c^2$ .  
 From 1st equ:  $x = s - y$ ,  
 and  $x^2 = s^2 - 2sy + y^2$ .  
 By subtracting,  $0 = s^2 - 2sy - c^2$ ,  
 or,  $2sy = s^2 - c^2$ ;

hence,  $y = \frac{s^2 - c^2}{2s} = 4 = AC$ .

Therefore,  $x + 4 = 9$ , or  $x = 5 = BC$ .

\* The following problems are selected from Hutton's Application of Algebra to Geometry; and the examples in Mensuration, from his treatise on that subject.

PROBLEM II.

*In a right-angled triangle, having given the hypotenuse, and the sum of the base and perpendicular, to find these two sides.*

Put  $BC = a = 5$ ,  $BA = x$ ,  $AC = y$ , and the sum of the base and perpendicular  $= s = 7$ .

Then,  $x + y = s = 7$ ,  
and  $x^2 + y^2 = a^2$ .

From first equation,  $x = s - y$ .

or,  $x^2 = s^2 - 2sy + y^2$ ;

Hence,  $y^2 = a^2 - s^2 + 2sy - y^2$ ,

or,  $2y^2 - 2sy = a^2 - s^2$ ;

or,  $y^2 - sy = \frac{a^2 - s^2}{2}$ .

By completing the square  $y^2 - sy + \frac{1}{4}s^2 = \frac{1}{4}a^2 - \frac{1}{4}s^2$ ,

or,  $y = \frac{1}{2}s \pm \sqrt{\frac{1}{4}a^2 - \frac{1}{4}s^2} = 4$  or  $3$ .

Hence,  $x = \frac{1}{2}s \mp \sqrt{\frac{1}{4}a^2 - \frac{1}{4}s^2} = 3$  or  $4$ .

PROBLEM III.

*In a rectangle, having given the diagonal and perimeter, to find the sides.*

Let  $ABCD$  be the proposed rectangle.  
Put  $AC = d = 10$ , the perimeter  $= 2a = 28$ ,  
or  $AB + BC = a = 14$ : also put  $AB = x$ ,  
and  $BC = y$ .

Then,  $x^2 + y^2 = d^2$ ,

and  $x + y = a$ .

From which equations we obtain,

$$y = \frac{1}{2}a \pm \sqrt{\frac{1}{4}d^2 - \frac{1}{4}a^2} = 8 \text{ or } 6,$$

and  $x = \frac{1}{2}a \mp \sqrt{\frac{1}{4}d^2 - \frac{1}{4}a^2} = 6 \text{ or } 8$ .

## PROBLEM IV.

*Having given the base and perpendicular of a triangle, to find the side of an inscribed square.*

Let  $ABC$  be the triangle, and  $HEFG$  the inscribed square. Put  $AB = b$ ,  $CD = a$ , and  $HE$  or  $GH = x$ : then  $CI = a - x$ .

We have by similar triangles

$$AB : CD :: GF : CI,$$

or,  $b : a :: x : a - x.$

Hence,  $ab - bx = ax,$

or,  $x = \frac{ab}{a + b}$  = the side of the inscribed square;

which, therefore, depends only on the base and altitude of the triangle.

## PROBLEM V.

*In an equilateral triangle, having given the lengths of the three perpendiculars drawn from a point within, on the three sides: to determine the sides of the triangle.*

Let  $ABC$  be an equilateral triangle:  $DG$ ,  $DE$  and  $DF$  the given perpendiculars let fall from  $D$  on the sides. Draw  $DA$ ,  $DB$ ,  $DC$ , to the vertices of the angles, and let fall the perpendicular  $CH$  on the base. Let  $DG = a$ ,  $DE = b$ , and  $DF = c$ : put

one of the equal sides  $AB = 2x$ ; hence,  $AH = x$ , and  $CH = \sqrt{AC^2 - AH^2} = \sqrt{4x^2 - x^2} = \sqrt{3x^2} = x\sqrt{3}.$

Now, since the area of a triangle is equal to half its base into the altitude, (B. IV., P. 6),

$$\frac{1}{2}AB \times CH = x \times x\sqrt{3} = x^2\sqrt{3} = \text{triangle } ACB,$$

$$\frac{1}{2}AB \times DG = x \times a = ax = \text{triangle } ADB,$$

$$\frac{1}{2}BC \times DE = x \times b = bx = \text{triangle } BCD,$$

$$\frac{1}{2}AC \times DF = x \times c = cx = \text{triangle } ACD.$$

But the last three triangles make up, and are consequently equal to, the first;

hence,  $x^2 \sqrt{3} = ax + bx + cx = x(a + b + c)$ ;

or,  $x \sqrt{3} = a + b + c$ ;

therefore,  $x = \frac{a + b + c}{\sqrt{3}}$ .

REMARK. Since the perpendicular  $CH$  is equal to  $x\sqrt{3}$ , it is consequently equal  $a + b + c$ : that is, the perpendicular let fall from either angle of an equilateral triangle on the opposite side, is equal to the sum of the three perpendiculars let fall from any point within the triangle on the sides respectively.

PROBLEM VI.—In a right-angled triangle, having given the base and the difference between the hypotenuse and perpendicular, to find the sides.

PROBLEM VII.—In a right-angled triangle, having given the hypotenuse, and the difference between the base and perpendicular, to determine the triangle.

PROBLEM VIII.—Having given the area of a rectangle inscribed in a given triangle; to determine the sides of the rectangle.

PROBLEM IX.—In a triangle, having given the ratio of the two sides, together with both the segments of the base made by a perpendicular from the vertical angle; to determine the triangle.

PROBLEM X.—In a triangle, having given the base, the sum of the two other sides, and the length of a line drawn from the vertical angle to the middle of the base; to find the sides of the triangle.

PROBLEM XI.—In a triangle, having given the two sides about the vertical angle, together with the line bisecting that angle and terminating in the base to find the base.

PROBLEM XII.—To determine a right-angled triangle, having given the lengths of two lines drawn from the acute angles to the middle of the opposite sides.

**PROBLEM XIII.**—To determine a right-angled triangle, having given the perimeter and the radius of the inscribed circle.

**PROBLEM XIV.**—To determine a triangle, having given the base, the perpendicular, and the ratio of the two sides.

**PROBLEM XV.**—To determine a right-angled triangle, having given the hypotenuse, and the side of the inscribed square.

**PROBLEM XVI.**—To determine the radii of three equal circles, described within and tangent to, a given circle, and also tangent to each other.

**PROBLEM XVII.**—In a right-angle triangle, having given the perimeter and the perpendicular let fall from the right angle on the hypotenuse, to determine the triangle.

**PROBLEM XVIII.**—To determine a right-angled triangle, having given the hypotenuse and the difference of two lines drawn from the two acute angles to the centre of the inscribed circle.

**PROBLEM XIX.**—To determine a triangle, having given the base, the perpendicular, and the difference of the two other sides.

**PROBLEM XX.**—To determine a triangle, having given the base, the perpendicular, and the rectangle of the two sides.

**PROBLEM XXI.**—To determine a triangle, having given the lengths of three lines drawn from the three angles to the middle of the opposite sides.

**PROBLEM XXII.**—In a triangle, having given the three sides, to find the radius of the inscribed circle.

**PROBLEM XXIII.**—To determine a right-angled triangle, having given the side of the inscribed square, and the radius of the inscribed circle.

**PROBLEM XXIV.**—To determine a right-angled triangle, having given the hypotenuse and radius of the inscribed circle.

**PROBLEM XXV.**—To determine a triangle, having given the base, the line bisecting the vertical angle, and the diameter of the circumscribing circle.

# PLANE TRIGONOMETRY.

---

## INTRODUCTION.

### OF LOGARITHMS.

1. *The logarithm of a number is the exponent of the power to which it is necessary to raise a fixed number, in order to produce the first number.*

This fixed number is called the *base* of the system, and may be any number except 1: in the common system, 10 is assumed as the base.

2. If we form those powers of 10, which are denoted by entire exponents, we shall have

$$\begin{aligned} 10^0 = 1 & \quad 10^1 = 10, & \quad 10^3 = 1000 \\ 10^2 = 100, & \quad 10^4 = 10000, & \text{ \&c., \&c.,} \end{aligned}$$

From the above table, it is plain, that 0, 1, 2, 3, 4, &c., are respectively the logarithms of 1, 10, 100, 1000, 10000, &c.; we also see, that the logarithm of any number between 1 and 10, is greater than 0 and less than 1: thus,

$$\log 2 = 0.301030.$$

The logarithm of any number greater than 10, and less than 100, is greater than 1 and less than 2: thus,

$$\log 50 = 1.698970.$$

The logarithm of any number greater than 100, and less than 1000, is greater than 2 and less than 3: thus,

$$\log 126 = 2.100371, \text{ \&c.}$$

If the above principles be extended to other numbers, it will appear, that the logarithm of any number, not an exact power of ten, is made up of two parts, *an entire and a decimal part*. The *entire part* is called the *characteristic of the logarithm*, and is always *one less* than the number of places of figures in the given number.

3. The principal use of logarithms, is to abridge numerical computations.

Let  $M$  denote any number, and let its logarithm be denoted by  $m$ ; also let  $N$  denote a second number whose logarithm is  $n$ ; then, from the definition, we shall have,

$$10^m = M \quad (1) \quad 10^n = N \quad (2).$$

Multiplying equations (1) and (2), member by member, we have,

$$10^{m+n} = M \times N \text{ or, } m+n = \log(M \times N); \text{ hence,}$$

*The sum of the logarithms of any two numbers is equal to the logarithm of their product.*

4. Dividing equation (1) by equation (2), member by member, we have,

$$10^{m-n} = \frac{M}{N} \text{ or, } m-n = \log \frac{M}{N}; \text{ hence,}$$

*The logarithm of the quotient of two numbers, is equal to the logarithm of the dividend diminished by the logarithm of the divisor.*

5. Since the logarithm of 10 is 1, *the logarithm of the product of any number by 10, will be greater by 1 than the logarithm of that number*; also, *the logarithm of the quotient of any number divided by 10, will be less by 1 than the logarithm of that number.*

Similarly, it may be shown that if any number be multiplied by one hundred, the logarithm of the product will be greater by 2 than the logarithm of that number; and if any number be divided by one hundred, the logarithm of the quotient will be less by 2 than the logarithm of that number, and so on.

## EXAMPLES.

|            |    |                  |
|------------|----|------------------|
| log 327    | is | 2.514548         |
| - log 32.7 | "  | 1.514548         |
| log 3.27   | "  | 0.514548         |
| log .327   | "  | $\bar{1}.514548$ |
| log .0327  | "  | $\bar{2}.514548$ |

From the above examples, we see, that in a number composed of an entire and decimal part, we may change the place of the decimal point without changing the decimal part of the logarithm; but *the characteristic is diminished by 1 for every place that the decimal point is removed to the left.*

In the logarithm of a decimal, the *characteristic* becomes negative, and is numerically 1 greater than the number of ciphers immediately after the decimal point. The negative sign extends only to the characteristic, and is written over it, as in the examples given above.

## TABLE OF LOGARITHMS.

6. A table of logarithms, is a table in which are written the logarithms of all numbers between 1 and some given number. The logarithms of all numbers between 1 and 10,000 are given in the annexed table. Since rules have been given for determining the characteristics of logarithms by simple inspection, it has not been deemed necessary to write them in the table, the decimal part only being given. The characteristic, however, is given for all numbers less than 100.

The left hand column of each page of the table, is the column of numbers, and is designated by the letter N; the logarithms of these numbers are placed opposite them on the same horizontal line. The last column on each page, headed D, shows the difference between the logarithms of two consecutive numbers. This difference is found by subtracting the logarithm under the column headed 4, from the one in the column headed 5 in the same horizontal line, and is nearly a mean of the differences of any two consecutive logarithms on this line.

*To find, from the table, the logarithm of any number.*

7. If the number is less than 100, look on the first page of the table, in the column of numbers under N, until the number is found: the number opposite is the logarithm sought: Thus,

$$\log 9 = 0.954243.$$

*When the number is greater than 100 and less than 10000.*

8. Find in the column of numbers, the first three figures of the given number. Then pass across the page along a horizontal line until you come into the column under the fourth figure of the given number: at this place, there are four figures of the required logarithm, to which, two figures taken from the column marked 0, are to be prefixed.

If the four figures already found stand opposite a row of six figures in the column marked 0, the two left hand figures of the six, are the two to be prefixed; but if they stand opposite a row of only four figures, you ascend the column till you find a row of six figures; the two left hand figures of this row are the two to be prefixed. If you prefix to the decimal part thus found, the characteristic, you will have the logarithm sought: Thus,

$$\begin{aligned}\log 8979 &= 3.953228 \\ \log .08979 &= \bar{2}.953228\end{aligned}$$

If, however, in passing back from the four figures found, to the 0 column, any dots be met with, the two figures to be prefixed must be taken from the horizontal line directly below: Thus,

$$\begin{aligned}\log 3098 &= 3.491081 \\ \log 30.98 &= 1.491081\end{aligned}$$

If the logarithm falls at a place where the dots occur, 0 must be written for each dot, and the two figures to be prefixed are, as before, taken from the line below: Thus,

$$\begin{aligned}\log 2188 &= 3.340047 \\ \log .2188 &= \bar{1}.340047\end{aligned}$$

*When the number exceeds 10,000.*

9. The characteristic is determined by the rules already given. To find the decimal part of the logarithm: place a decimal point after the fourth figure from the left hand, converting the given number into a whole number and decimal. Find the logarithm of the entire part by the rule just given, then take from the right hand column of the page, under D, the number on the same horizontal line with the logarithm, and multiply it by the decimal part; add the product thus obtained to the logarithm already found, and the sum will be the logarithm sought.

If, in multiplying the number taken from the column D, the decimal part of the product exceeds .5, let 1 be added to the entire part; if it is less than .5, the decimal part of the product is neglected.

#### EXAMPLE.

1. To find the logarithm of the number 672887.

The characteristic is 5.; placing a decimal point after the fourth figure from the left, we have 6728.87. The decimal part of the log 6728 is .827886, and the corresponding number in the column D is 65; then  $65 \times .87 = 56.55$ , and since the decimal part exceeds .5, we have 57 to be added to .827886, which gives .827943.

Hence,  $\log 672887 = 5.827943$

Similarly,  $\log .0672887 = \bar{2}.827943$

The last rule has been deduced under the supposition that the difference of the numbers is proportional to the difference of their logarithms, which is sufficiently exact within the narrow limits considered.

In the above example, 65 is the difference between the logarithm of 672900 and the logarithm of 672800, that is, it is the difference between the logarithms of two numbers which differ by 100.

We have then the proportion

$$100 : 87 :: 65 : 56.55,$$

hence, 56.55 is the number to be added to the logarithm before found.

*To find from the table the number corresponding to a given logarithm.*

10. Search in the columns of logarithms for the decimal part of the given logarithm: if it cannot be found in the table, take out the number corresponding to the next less logarithm and set it aside. Subtract this less logarithm from the given logarithm, and annex to the remainder as many zeros as may be necessary, and divide this result by the corresponding number taken from the column marked D, continuing the division as long as desirable: annex the quotient to the number set aside. Point off, from the left hand, as many integer figures as there are units in the characteristic of the given logarithm increased by 1; the result is the required number.

If the characteristic is negative, the number will be entirely decimal, and the number of zeros to be placed at the left of the number found from the table, will be equal to the number of units in the characteristic diminished by 1.

This rule, like its converse, is founded on the supposition that the difference of the logarithms is proportional to the difference of their numbers within narrow limits.

#### EXAMPLE.

1. Find the number corresponding to the logarithm 3.233568.

The decimal part of the given logarithm is .233568  
 The next less logarithm of the table is .233504,  
 and its corresponding number 1712.

Their difference is . . . . . 64

Tabular difference 253)6400000(25

Hence, the number sought 1712.25.

The number corresponding to the logarithm  $\bar{3}.233568$  is .00171225.

2. What is the number corresponding to the logarithm  $\bar{2}.785407$ ?  
*Ans.* .06101084.

3. What is the number corresponding to the logarithm  $\bar{1}.846741$ ?  
*Ans.* .702653.

## MULTIPLICATION BY LOGARITHMS.

11. When it is required to multiply numbers by means of their logarithms, we first find from the table the logarithms of the numbers to be multiplied; we next add these logarithms together, and their sum is the logarithm of the product of the numbers (Art. 3).

The term *sum* is to be understood in its algebraic sense; therefore, if any of the logarithms have negative characteristics, the difference between their sum and that of the positive characteristics, is to be taken; the sign of the remainder is that of the greater sum.

## EXAMPLES.

1. Multiply 23.14 by 5.062.

$$\log 23.14 = 1.364363$$

$$\log 5.062 = 0.704322$$

$$\text{Product, } 117.1347 \dots \underline{2.068685}$$

2. Multiply 3.902, 597.16, and 0.0314728 together.

$$\log 3.902 = 0.591287$$

$$\log 597.16 = 2.776091$$

$$\log 0.0314728 = \bar{2}.497936$$

$$\text{Product, } 73.3354 \dots \underline{1.865314}$$

Here, the  $\bar{2}$  cancels the + 2, and the 1 carried from the decimal part is set down.

3. Multiply 3.586, 2.1046, 0.8372, and 0.0294 together.

$$\log 3.586 = 0.554610$$

$$\log 2.1046 = 0.323170$$

$$\log 0.8372 = \bar{1}.922829$$

$$\log 0.0294 = \bar{2}.468347$$

$$\text{Product, } 0.1857615 \dots \underline{1.268956}$$

In this example the 2, carried from the decimal part, cancels  $\bar{2}$ , and there remains  $\bar{1}$  to be set down.

## DIVISION OF NUMBERS BY LOGARITHMS.

12. When it is required to divide numbers by means of their logarithms, we have only to recollect, that the subtraction of logarithms corresponds to the division of their numbers (Art. 4). Hence, if we find the logarithm of the dividend, and from it subtract the logarithm of the divisor, the remainder will be the logarithm of the quotient.

This additional caution may be added. The difference of the logarithms, as here used, means the *algebraic difference*; so that, if the logarithm of the divisor have a negative characteristic, its sign must be changed to positive, after diminishing it by the unit, if any, carried in the subtraction from the decimal part of the logarithm. Or, if the characteristic of the logarithm of the dividend is negative, it must be treated as a negative number.

## EXAMPLES.

1. To divide 24163 by 4567.

$$\begin{array}{r} \log 24163 = 4.383151 \\ \log 4567 = 3.659631 \\ \hline \text{Quotient, } 5.29078 \quad . \quad . \quad \underline{0.723520} \end{array}$$

2. To divide 0.06314 by .007241.

$$\begin{array}{r} \log 0.06314 = \bar{2}.800305 \\ \log 0.007241 = \bar{3}.859799 \\ \hline \text{Quotient, } 8.7198 \quad . \quad . \quad \underline{0.940506} \end{array}$$

Here, 1 carried from the decimal part to the  $\bar{3}$ , changes it to  $\bar{2}$ , which being taken from  $\bar{2}$ , leaves 0 for the characteristic.

3. To divide 37.149 by 523.76.

$$\begin{array}{r} \log 37.149 = 1.569947 \\ \log 523.76 = 2.719133 \\ \hline \text{Quotient, } 0.0709274 \quad . \quad \underline{2.850814} \end{array}$$

4. To divide 0.7438 by 12.9476.

$$\log 0.7438 = \bar{1}.871456$$

$$\log 12.9476 = 1.112189$$

$$\text{Quotient,} \quad 0.057447 \dots \underline{\underline{2.759267}}$$

Here, the 1 taken from  $\bar{1}$ , gives  $\bar{2}$  for a result, as set down.

#### ARITHMETICAL COMPLEMENT.

13. The *Arithmetical complement* of a logarithm is the number which remains after subtracting the logarithm from 10.

Thus,  $10 - 9.274687 = 0.725313$ .

Hence, 0.725313 is the arithmetical complement of 9.274687.

14. We will now show that, *the difference between two logarithms is truly found, by adding to the first logarithm the arithmetical complement of the logarithm to be subtracted, and then diminishing the sum by 10.*

Let  $a$  = the first logarithm,  
 $b$  = the logarithm to be subtracted,  
 and  $c = 10 - b$  = the arithmetical complement of  $b$ .

Now the difference between the two logarithms will be expressed by  $a - b$ .

But, from the equation  $c = 10 - b$ , we have

$$c - 10 = -b,$$

hence, if we place for  $-b$  its value, we shall have

$$a - b = a + c - 10,$$

which agrees with the enunciation.

When we wish the arithmetical complement of a logarithm, we may write it directly from the table, *by subtracting the left hand figure from 9, then proceeding to the right, subtract each figure from 9 till we reach the last figure, which must be taken from 10: this will be the same as taking the logarithm from 10.*

## EXAMPLES.

1. From 3.274107 take 2.104729.

| <i>By common method.</i> | <i>By arith. comp.</i>         |
|--------------------------|--------------------------------|
| 3.274107                 | 3.274107                       |
| 2.104729                 | its ar. comp. 7.895271         |
| Diff. <u>1.169378</u>    | Sum <u>1.169378</u> after sub- |

tracting 10.

Hence, to perform division by means of the arithmetical complement, we have the following

## RULE.

*To the logarithm of the dividend add the arithmetical complement of the logarithm of the divisor: the sum, after subtracting 10, will be the logarithm of the quotient.*

## EXAMPLES.

1. Divide 327.5 by 22.07.

|                            |                 |
|----------------------------|-----------------|
| log 327.5 . . . . .        | 2.515211        |
| log 22.07 ar. comp.        | <u>8.656198</u> |
| Quotient, 14.839 . . . . . | <u>1.171409</u> |

2. Divide 0.7438 by 12.9476.

|                              |                                    |
|------------------------------|------------------------------------|
| log 0.7438 . . . . .         | $\bar{1}.871456$                   |
| log 12.9476 ar. comp.        | <u>8.887811</u>                    |
| Quotient, 0.057447 . . . . . | <u><math>\bar{2}.759267</math></u> |

In this example, the sum of the characteristics is 8, from which, taking 10, the remainder is  $\bar{2}$ .

3. Divide 37.149 by 523.76.

|                               |                                    |
|-------------------------------|------------------------------------|
| log 37.149 . . . . .          | 1.569947                           |
| log 523.76 ar. comp.          | <u>7.280867</u>                    |
| Quotient, 0.0709273 . . . . . | <u><math>\bar{2}.850814</math></u> |

Divide 0.875 by 25.

Ans. 0.035.

FINDING THE POWERS AND ROOTS OF NUMBERS BY LOGARITHMS.

15. We have (Art. 3),

$$10^m = M.$$

Raising both members of this equation to the  $n$ th power, we have,

$$10^{m \times n} = M^n,$$

in which  $m \times n$  is the logarithm of  $M^n$  (Art. 1): hence,

*The logarithm of any power of a given number is equal to the logarithm of the number multiplied by the exponent of the power.*

16. Taking the same equation,

$$10^m = M,$$

and extracting the  $n$ th root of both members, we have

$$10^{\frac{m}{n}} = M^{\frac{1}{n}},$$

in which  $\frac{m}{n}$  is the logarithm of  $M^{\frac{1}{n}}$ : that is,

*The logarithm of the root of a given number is equal to the logarithm of the number divided by the index of the root.*

EXAMPLES.

1. What is the 5th power of 9?

$$\text{Log } 9 = 0.954243; 0.954243 \times 5 = 4.771215;$$

whole number answering to 4.771215 is 59049.

2. What is the 7th power of 8? *Ans.* 2097152.

3. What is the cube root of 4096?

$$\text{Log } 4096 = 3.612360; 3.612360 \div 3 = 1.204120;$$

number answering to 1.204120 is 16.

4. What is the 4th root of .00000081?

$$\text{Log } .00000081 = \bar{7}.908485;$$

But,

$$\bar{7}.908485 = \bar{8} + 1.908485;$$

and,

$$\bar{8} + 1.908485 \div 4 = \bar{2}.477121,$$

the number answering to which is .03, which is the root.

*When the characteristic of the logarithm is negative, and not divisible by the index of the root, add to it such a negative number as will make the sum exactly divisible by the index, and then prefix the same number to the first decimal figure of the logarithm.*

5. What is the 6th root of .0432? *Ans.* .592353 +.

6. What is the 7th root of .0004967? *Ans.* .3372969,

## GEOMETRICAL CONSTRUCTIONS.

17. Before explaining the method of constructing geometrical problems, we shall describe some of the simpler instruments and their uses.

## DIVIDERS.

18. The dividers is the most simple and useful of the instruments used for drawing. It consists of two legs  $ba$ ,  $bc$ , which may be easily turned around a joint at  $b$ .

One of the principal uses of this instrument is to lay off on a line, a distance equal to a given line.

For example, to lay off on  $CD$  a distance equal to  $AB$ .

For this purpose, place the forefinger on the joint of the dividers, and set one foot at  $A$ : then extend, with the thumb and other fingers, the other leg of the dividers, until its foot reaches the point  $B$ . Then raise the dividers, place one foot at  $C$ , and mark with the other the distance  $CE$ : this will evidently be equal to  $AB$ .

## RULER AND TRIANGLE.

19. A Ruler of convenient size, is about twenty inches in length, two inches wide, and a fifth of an inch in thick-

ness. It should be made of a hard material, perfectly straight and smooth.

The hypotenuse of the right-angled triangle, which is used in connection with it, should be about ten inches in length, and it is most convenient to have one of the sides considerably longer than the other. We can solve, with the ruler and triangle, the two following problems.

I. *To draw through a given point a line which shall be parallel to a given line.*

20. Let  $C$  be the given point, and  $AB$  the given line.

Place the hypotenuse of the triangle against the edge of the ruler, and then place the ruler and triangle on the paper, so that one of the sides of the triangle shall coincide exactly with  $AB$ : the triangle being below the line.

Then placing the thumb and fingers of the left hand firmly on the ruler, slide the triangle with the other hand along the ruler until the side which coincided with  $AB$  reaches the point  $C$ . Leaving the thumb of the left hand on the ruler, extend the fingers upon the triangle and hold it firmly, and with the right hand, mark with a pen or pencil, a line through  $C$ : this line will be parallel to  $AB$ .

II. *To draw through a given point a line which shall be perpendicular to a given line.*

21. Let  $AB$  be the given line, and  $D$  the given point.

Place the hypotenuse of the triangle against the edge of the ruler, as before. Then place the ruler and triangle so that one of the sides of the triangle shall coincide exactly with the line  $AB$ . Then slide the triangle along the ruler until the other side reaches the point  $D$ : draw through  $D$  a right line, and it will be perpendicular to  $AB$ .

## SCALE OF EQUAL PARTS.

22. A scale of equal parts is formed by dividing a line of a given length into equal portions.

If, for example, the line  $ab$  of a given length, say one inch, be divided into any number of equal parts, as 10, the scale thus formed, is called a scale of ten parts to the inch. The line  $ab$ , which is divided, is called the *unit of the scale*. This unit is laid off several times on the left of the divided line, and the points marked 1, 2, 3, &c.

The unit of scales of equal parts, is, in general, either an inch, or an exact part of an inch. If, for example,  $ab$ , the unit of the scale, were half an inch, the scale would be one of 10 parts to half an inch, or of 20 parts to the inch.

If it were required to take from the scale a line equal to two inches and six-tenths, place one foot of the dividers at 2 on the left, and extend the other to .6, which marks the sixth of the small divisions: the dividers will then embrace the required distance.

## DIAGONAL SCALE OF EQUAL PARTS.

23. This scale is thus constructed. Take  $ab$  for the unit of the scale, which may be one inch,  $\frac{1}{2}$ ,  $\frac{1}{4}$  or  $\frac{3}{4}$  of an inch, in length. On  $ab$  describe the square  $abcd$ . Divide the sides  $ab$  and  $dc$  each into ten equal parts. Draw  $af$  and the other nine parallels as in the figure.

Produce  $ba$  to the left, and lay off the unit of the scale any convenient number of times, and mark the points

1, 2, 3, &c. Then, divide the line  $ad$  into ten equal parts, and through the points of division draw parallels to  $ab$ , as in the figure.

Now, the small divisions of the line  $ab$  are each one-tenth (.1) of  $ab$ ; they are therefore .1 of  $ad$ , or .1 of  $ag$  or  $gh$ .

If we consider the triangle  $adf$ , we see that the base  $df$  is one-tenth of  $ad$ , the unit of the scale. Since the distance from  $a$  to the first horizontal line above  $ab$ , is one-tenth of the distance  $ad$ , it follows that the distance measured on that line between  $ad$  and  $af$  is one-tenth of  $df$ : but since one-tenth of a tenth is a hundredth, it follows that this distance is one hundredth (.01) of the unit of the scale. A like distance measured on the second line will be two hundredths (.02) of the unit of the scale; on the third, .03; on the fourth, .04, &c.

If it were required to take, in the dividers, the unit of the scale, and any number of tenths, place one foot of the dividers at 1, and extend the other to that figure between  $a$  and  $b$  which designates the tenths. If two or more units are required, the dividers must be placed on a point of division further to the left.

When units, tenths, and hundredths, are required, place one foot of the dividers where the vertical line through the point which designates the units, intersects the line which designates the hundredths: then, extend the dividers to that line between  $ad$  and  $bc$  which designates the tenths: the distance so determined will be the one required.

For example, to take off the distance 2.34, we place one foot of the dividers at  $l$ , and extend the other to  $e$ : and to take off the distance 2.58, we place one foot of the dividers at  $p$  and extend the other to  $q$ .

REMARK I. If a line is so long that the whole of it cannot be taken from the scale, it must be divided, and the parts of it taken from the scale in succession.

REMARK II. If a line be given upon the paper, its length can be found by taking it in the dividers and applying it to the scale.

## SEMICIRCULAR PROTRACTOR.

24. This instrument is used to lay down, or protract angles. It may also be used to measure angles included between lines already drawn upon paper.

It consists of a brass semicircle,  $ABO$ , divided to half degrees. The degrees are numbered from 0 to 180, both ways; that is, from  $A$  to  $B$  and from  $B$  to  $A$ . The divisions, in the figure, are made only to degrees. There is a small notch at the middle of the diameter  $AB$ , which indicates the centre of the protractor.

*To lay off an angle with a Protractor.*

25. Place the diameter  $AB$  on the line, so that the centre shall fall on the angular point. Then count the degrees contained in the given angle from  $A$  towards  $B$ , or from  $B$  towards  $A$ , and mark the extremity of the arc with a pin. Remove the protractor, and draw a line through the point so marked and the angular point: this line will make with the given line the required angle.

# PLANE TRIGONOMETRY.

## DEFINITIONS.

1. In every plane triangle there are six parts: three sides and three angles. These parts are so related to each other, that when one side and any two other parts are given, the remaining ones can be obtained, either by geometrical construction or by trigonometrical computation.

2. *Plane Trigonometry* explains the methods of computing the unknown parts of a plane triangle, when a sufficient number of the six parts is given.

3. For the purpose of trigonometrical calculation, the circumference of the circle is supposed to be divided into 360 equal parts, called degrees; each degree is supposed to be divided into 60 equal parts, called minutes; and each minute into 60 equal parts, called seconds.

Degrees, minutes, and seconds, are designated respectively, by the characters  $^{\circ}$   $'$   $''$ . For example, *ten degrees, eighteen minutes, and fourteen seconds*, would be written  $10^{\circ} 18' 14''$ .

4. If two lines be drawn through the centre of the circle, at right angles to each other, they will divide the circumference into four equal parts, of  $90^{\circ}$  each. Every right angle then, as  $EOA$ , is measured by an arc of  $90^{\circ}$ ; every acute angle, as  $BOA$ , by an arc less than  $90^{\circ}$ ; and every obtuse angle, as  $FOA$ , by an arc greater than  $90^{\circ}$ .

5. The *complement* of an arc is what remains after subtracting the arc from  $90^{\circ}$ . Thus, the arc  $EB$  is the complement of  $AB$ . The sum of an arc and its complement is equal to  $90^{\circ}$ .

6. The *supplement* of an arc is what remains after subtracting the arc from  $180^{\circ}$ . Thus,  $GF$  is the

supplement of the arc  $AEF$ . The sum of an arc and its supplement is equal to  $180^\circ$ .

7. The *sine* of an arc is the perpendicular let fall from one extremity of the arc on the diameter which passes through the other extremity. Thus,  $BD$  is the sine of the arc  $AB$ .

8. The *cosine* of an arc is the part of the diameter intercepted between the foot of the sine and the centre. Thus,  $OD$  is the cosine of the arc  $AB$ .

9. The *tangent* of an arc is the line which touches it at one extremity, and is limited by a line drawn through the other extremity and the centre of the circle. Thus,  $AC$  is the tangent of the arc  $AB$ .

10. The *secant* of an arc is the line drawn from the centre of the circle through one extremity of the arc, and limited by the tangent passing through the other extremity. Thus,  $OC$  is the secant of the arc  $AB$ .

11. The four lines,  $BD$ ,  $OD$ ,  $AC$ ,  $OC$ , depend for their values on the arc  $AB$  and the radius  $OA$ ; they are thus designated :

$\sin AB$  for  $BD$

$\cos AB$  for  $OD$

$\tan AB$  for  $AC$

$\sec AB$  for  $OC$

12. If  $ABE$  be equal to a quadrant, or  $90^\circ$ , then  $EB$  will be the complement of  $AB$ . Let the lines  $ET$  and  $IB$  be drawn perpendicular to  $OE$ . Then,

$ET$ , the tangent of  $EB$ , is called the cotangent of  $AB$ ;

$IB$ , the sine of  $EB$ , is equal to the cosine of  $AB$ ;

$OT$ , the secant of  $EB$ , is called the cosecant of  $AB$ .

In general, if  $A$  is any arc or angle, we have,

$$\cos A = \sin (90^\circ - A)$$

$$\cot A = \tan (90^\circ - A)$$

$$\operatorname{cosec} A = \sec (90^\circ - A)$$

13. If we take an arc,  $ABEF$ , greater than  $90^\circ$ , its sine will be  $FH$ ;  $OH$  will be its cosine;  $AQ$  its tangent, and  $OQ$  its secant. But  $FH$  is the sine of the arc  $GF$ , which is the supplement of  $AF$ , and  $OH$  is its cosine; hence, *the sine of an arc is equal to the sine of its supplement; and the cosine of an arc is equal to the cosine of its supplement.\**

Furthermore,  $AQ$  is the tangent of the arc  $AF$ , and  $OQ$  is its secant:  $GL$  is the tangent, and  $OL$  the secant of the supplemental arc  $GF$ . But since  $AQ$  is equal to  $GL$ , and  $OQ$  to  $OL$ , it follows that, *the tangent of an arc is equal to the tangent of its supplement; and the secant of an arc is equal to the secant of its supplement.\**

TABLE OF NATURAL SINES.

14. Let us suppose, that in a circle of a given radius, the lengths of the sine, cosine, tangent, and cotangent, have been calculated for every minute or second of the quadrant, and arranged in a table; such a table is called a table of sines and tangents. If the radius of the circle is 1, the table is called a table of natural sines. A table of natural sines, therefore, shows the values of the sines, cosines, tangents, and cotangents of all the arcs of a quadrant, which is divided to minutes or seconds.

If the sines, cosines, tangents, and secants are known for arcs less than  $90^\circ$ , those for arcs which are greater can be found from them. For if an arc is less than  $90^\circ$ , its supplement will be greater than  $90^\circ$ , and the numerical values of these lines are the same for an arc and its supplement. Thus, if we know the sine of  $20^\circ$ , we also know the sine of its supplement  $160^\circ$ ; for the two are equal to each other. The Table of Natural Sines is not given, as it is much easier to make the computations by the Table which we are about to explain.

\* These relations are between the numerical values of the trigonometrical lines; the algebraic signs, which they have in the different quadrants, are not considered.

## TABLE OF LOGARITHMIC SINES.

15. In this table are arranged the logarithms of the numerical values of the sines, cosines, tangents, and cotangents of all the arcs of a quadrant, calculated to a radius of 10,000,000,000. The logarithm of this radius is 10. In the first and last horizontal lines of each page, are written the degrees whose sines, cosines, &c., are expressed on the page. The vertical columns on the left and right, are columns of minutes.

## CASE I.

*To find, in the table, the logarithmic sine, cosine, tangent, or cotangent of any given arc or angle.*

16. If the angle is less than  $45^\circ$ , look for the degrees in the first horizontal line of the different pages: when the degrees are found, descend along the column of minutes, on the left of the page, till you reach the number showing the minutes: then pass along a horizontal line till you come into the column designated, sine, cosine, tangent, or cotangent, as the case may be: the number so indicated is the logarithm sought. Thus, on page 37, for  $19^\circ 55'$ , we find,

|                     |         |           |
|---------------------|---------|-----------|
| sine $19^\circ 55'$ | . . . . | 9.532312  |
| cos $19^\circ 55'$  | . . . . | 9.973215  |
| tan $19^\circ 55'$  | . . . . | 9.559097  |
| cot $19^\circ 55'$  | . . . . | 10.440903 |

17. If the angle is greater than  $45^\circ$ , search for the degrees along the bottom line of the different pages: when the number is found, ascend along the column of minutes on the right hand side of the page, till you reach the number expressing the minutes: then pass along a horizontal line into the column designated tang, cot, sine, or cosine, as the case may be: the number so pointed out is the logarithm required.

18. The column designated sine, at the top of the page, is designated by cosine at the bottom; the one designated tang, by cotang, and the one designated cotang, by tang.

The angle found by taking the degrees at the top of the page, and the minutes from the left hand vertical column, is the complement of the angle found by taking the degrees

at the bottom of the page, and the minutes from the right hand column on the same horizontal line with the first. Therefore, sine, at the top of the page, should correspond with cosine, at the bottom; cosine with sine, tang with cotang, and cotang with tang, as in the tables (Art. 12).

If the angle is greater than  $90^\circ$ , we have only to subtract it from  $180^\circ$ , and take the sine, cosine, tangent, or cotangent of the remainder.

The column of the table next to the column of sines, and on the right of it, is designated by the letter *D*. This column is calculated in the following manner.

Opening the table at any page, as 42, the sine of  $24^\circ$  is found to be 9.609313; that of  $24^\circ 01'$ , 9.609597: their difference is 284; this being divided by 60, the number of seconds in a minute, gives 4.73, which is entered in the column *D*.

Now, supposing the increase of the logarithmic sine to be proportional to the increase of the arc, and it is nearly so for  $60''$ , it follows, that 4.73 is the increase of the sine for  $1''$ . Similarly, if the arc were  $24^\circ 20'$ , the increase of the sine for  $1''$ , would be 4.65.

The same remarks are applicable in respect of the column *D*, after the column cosine, and of the column *D*, between the tangents and cotangents. The column *D*, between the columns tangents and cotangents, answers to both of these columns.

Now, if it were required to find the logarithmic sine of an arc expressed in degrees, minutes, and seconds, we have only to find the degrees and minutes as before; then, multiply the corresponding tabular difference by the seconds, and add the product to the number first found, for the sine of the given arc.

Thus, if we wish the sine of  $40^\circ 26' 28''$ .

|   |                   |           |
|---|-------------------|-----------|
| The sine $40^\circ 26'$                     | . . . . .         | 9.811952  |
| Tabular difference 2.47                     | . . . . .         |           |
| Number of seconds 28                        | . . . . .         |           |
| - Product,                                  | 69.16 to be added | 69.16     |
| Gives for the sine of $40^\circ 26' 28''$ . |                   | 9.812021. |

The decimal figures at the right are generally omitted in the last result; but when they exceed five-tenths, the figure on the left of the decimal point is increased by 1; the logarithm obtained is then exact, to within less than one unit of the right hand place.

The tangent of an arc, in which there are seconds, is found in a manner entirely similar. In regard to the cosine and cotangent, it must be remembered, that they increase while the arcs decrease, and decrease as the arcs are increased; consequently, the proportional numbers found for the seconds, must be subtracted, not added.

## EXAMPLES.

1. To find the cosine of
- $3^{\circ} 40' 40''$
- .

|                               |   |   |   |          |
|-------------------------------|---|---|---|----------|
| The cosine of $3^{\circ} 40'$ | . | . | . | 9.999110 |
|-------------------------------|---|---|---|----------|

|                        |   |   |   |  |
|------------------------|---|---|---|--|
| Tabular difference .13 | . | . | . |  |
|------------------------|---|---|---|--|

|                      |   |   |   |  |
|----------------------|---|---|---|--|
| Number of seconds 40 | . | . | . |  |
|----------------------|---|---|---|--|

|          |                       |      |
|----------|-----------------------|------|
| Product, | 5.20 to be subtracted | 5.20 |
|----------|-----------------------|------|

|  |           |
|--|-----------|
| Gives for the cosine of $3^{\circ} 40' 40''$ | 9.999105. |
|--|-----------|

2. Find the tangent of
- $37^{\circ} 28' 31''$
- .

*Ans.* 9.884592.

3. Find the cotangent of
- $87^{\circ} 57' 59''$
- .

*Ans.* 8.550356.

## CASE II.

*To find the degrees, minutes, and seconds answering to any given logarithmic sine, cosine, tangent, or cotangent.*

19. Search in the table, in the proper column, and if the number is found, the degrees will be shown either at the top or bottom of the page, and the minutes in the side column either at the left or right.

But, if the number cannot be found in the table, take from the table the degrees and minutes answering to the nearest less logarithm, the logarithm itself, and also the corresponding tabular difference. Subtract the logarithm taken from the table from the given logarithm, annex two

ciphers to the remainder, and then divide the remainder by the tabular difference: the quotient will be seconds, and is to be connected with the degrees and minutes before found: to be added for the sine and tangent, and subtracted for the cosine and cotangent.

EXAMPLES.

1. Find the arc answering to the sine 9.880054  
 Sine  $49^\circ 20'$ , next less in the table 9.879963  
 Tabular difference, 1.8191.00(50"'

Hence, the arc  $49^\circ 20' 50''$  corresponds to the given sine 9.880054.

2. Find the arc whose cotangent is 10.008688  
 cot  $44^\circ 26'$ , next less in the table 10.008591  
 Tabular difference, 4.2197.00(23"'

Hence,  $44^\circ 26' - 23'' = 44^\circ 25' 37''$  is the arc answering to the given cotangent 10.008688.

3. Find the arc answering to tangent 9.979110.  
 Ans.  $43^\circ 37' 21''$ .

4. Find the arc answering to cosine 9.944599.  
 Ans.  $28^\circ 19' 45''$ .

20. We shall now demonstrate the principal theorems of Plane Trigonometry.

THEOREM I.

*The sides of a plane triangle are proportional to the sines of their opposite angles.*

21. Let  $ABC$  be a triangle; then  
 $CB : CA :: \sin A : \sin B$ .

For, with  $A$  as a centre, and  $AD$  equal to the less side  $BC$ , as a radius, describe the arc  $DI$ : and with  $B$  as a centre and the equal radius  $BC$ , describe the arc  $CL$ , and draw  $DE$  and  $CF$  perpen-

dicular to  $AB$ : now  $DE$  is the sine of the angle  $A$ , and  $CF$  is the sine of  $B$ , to the same radius  $AD$  or  $BC$ . But by similar triangles,

$$AD : DE :: AC : CF.$$

But  $AD$  being equal to  $BC$ , we have

$$\begin{aligned} BC : \sin A &:: AC : \sin B, \text{ or} \\ BC : AC &:: \sin A : \sin B. \end{aligned}$$

By comparing the sides  $AB, AC$ , in a similar manner, we should find,

$$AB : AC :: \sin C : \sin B.$$

#### THEOREM II.

*In any triangle, the sum of the two sides containing either angle, is to their difference, as the tangent of half the sum of the two other angles, to the tangent of half their difference.*

22. Let  $ACB$  be a triangle: then will

$$AB + AC : AB - AC :: \tan \frac{1}{2}(C + B) : \tan \frac{1}{2}(C - B).$$

With  $A$  as a centre, and a radius  $AC$ , the less of the two given sides, let the semicircumference  $IFCE$  be described, meeting  $AB$  in  $I$ , and  $BA$  produced, in  $E$ . Then,  $BE$  will be the sum of the sides, and  $BI$  their difference. Draw  $CI$  and  $AF$ .

Since  $CAE$  is an exterior angle of the triangle  $ACB$ , it is equal to the sum of the interior angles  $C$  and  $B$  (Bk. I., Prop. XXV., Cor 6). But the angle  $CIE$  being at the circumference, is half the angle  $CAE$  at the centre (Bk. III., Prop. XVIII.); that is, half the sum of the angles  $C$  and  $B$ , or equal to  $\frac{1}{2}(C + B)$ .

The angle  $AFC = ACB$ , is also equal to  $ABC + BAF$ ; therefore,  $BAF = ACB - ABC$ .

But,  $ICF = \frac{1}{2}(BAF) = \frac{1}{2}(ACB - ABC)$ , or  $\frac{1}{2}(C - B)$ .

With  $I$  and  $C$  as centres, and the common radius  $IC$ , let the arcs  $CD$  and  $IG$  be described, and draw the lines  $CE$  and  $IH$  perpendicular to  $IC$ . The perpendicular  $CE$  will pass through  $E$ , the extremity of the diameter  $IE$ ,

since the right angle  $ICE$  must be inscribed in a semicircle.

But  $CE$  is the tangent of  $CIE = \frac{1}{2}(C+B)$ ; and  $IH$  is the tangent of  $ICB = \frac{1}{2}(C-B)$ , to the common radius  $CI$ .

But since the lines  $CE$  and  $IH$  are parallel, the triangles  $BHI$  and  $BCE$  are similar, and give the proportion,

$$BE : BI :: CE : IH, \text{ or}$$

by placing for  $BE$  and  $BI$ ,  $CE$  and  $IH$ , their values, we have

$$AB + AC : AB - AC :: \tan \frac{1}{2}(C+B) : \tan \frac{1}{2}(C-B).$$

THEOREM III.

*In any plane triangle, if a line is drawn from the vertical angle perpendicular to the base, dividing it into two segments: then, the whole base, or sum of the segments, is to the sum of the two other sides, as the difference of those sides to the difference of the segments.*

23. Let  $BAC$  be a triangle, and  $AD$  perpendicular to the base; then

$$BC : CA + AB :: CA - AB : CD - DB$$

For,  $\overline{AB}^2 = \overline{BD}^2 + \overline{AD}^2$   
(Bk. IV., Prop. XI.);

and  $\overline{AC}^2 = \overline{DC}^2 + \overline{AD}^2$   
by subtraction,  $\overline{AC}^2 - \overline{AB}^2 = \overline{CD}^2 - \overline{BD}^2$ .

But since the difference of the squares of two lines is equivalent to the rectangle contained by their sum and difference (Bk. IV., Prop. X.), we have,

$$\overline{AC}^2 - \overline{AB}^2 = (AC + AB).(AC - AB)$$

and  $\overline{CD}^2 - \overline{BD}^2 = (CD + DB).(CD - DB)$

therefore,  $(CD + DB).(CD - DB) = (AC + AB).(AC - AB)$

hence,  $CD + DB : AC + AB :: AC - AB : CD - DB$ .

## THEOREM IV.

*In any right-angled plane triangle, radius is to the tangent of either of the acute angles, as the side adjacent to the side opposite.*

24. Let  $CAB$  be the proposed triangle, and denote the radius by  $R$ : then

$$R : \tan C :: AC : AB.$$

For, with any radius as  $CD$  describe the arc  $DII$ , and draw the tangent  $DG$ .

From the similar triangles  $CDG$  and  $CAB$ , we have,

$$OD : DG :: CA : AB; \text{ hence,} \\ R : \tan C :: CA : AB.$$

By describing an arc with  $B$  as a centre, we could show in the same manner that,

$$R : \tan B :: AB : AC.$$

## THEOREM V.

*In every right-angled plane triangle, radius is to the cosine of either of the acute angles, as the hypotenuse to the side adjacent.*

25. Let  $ABC$  be a triangle, right-angled at  $B$ : then

$$R : \cos A :: AC : AB.$$

For, from the point  $A$  as a centre, with a radius  $AD=R$ , describe the arc  $DF$ , which will measure the angle  $A$ , and draw  $DE$  perpendicular to  $AB$ : then will  $AE$  be the cosine of  $A$ .

The triangles  $ADE$  and  $ACB$ , being similar, we have,

$$AD : AE :: AC : AB: \text{ that is,} \\ R : \cos A :: AC : AB.$$

REMARK. The relations between the sides and angles of plane triangles, demonstrated in these five theorems, are

sufficient to solve all the cases of Plane Trigonometry. Of the six parts which make up a plane triangle, three must be given, and at least one of these a side, before the others can be determined.

If the three angles only are given, it is plain, that an indefinite number of similar triangles may be constructed, the angles of which shall be respectively equal to the angles that are given, and therefore, the sides could not be determined.

Assuming, with this restriction, any three parts of a triangle as given, one of the four following cases will always be presented.

- I. When two angles and a side are given.
- II. When two sides and an opposite angle are given.
- III. When two sides and the included angle are given.
- IV. When the three sides are given.

#### CASE I.

*When two angles and a side are given.*

26. Add the given angles together, and subtract their sum from 180 degrees. The remaining parts of the triangle can then be found by Theorem I.

#### EXAMPLES.

1. In a plane triangle,  $ABC$ , there are given the angle  $A = 58^\circ 07'$ , the angle  $B = 22^\circ 37'$ , and the side  $AB = 408$  yards. Required the other parts.

#### GEOMETRICALLY.

27. Draw an indefinite straight line,  $AB$ , and from the scale of equal parts lay off  $AB$  equal to 408. Then, at  $A$ , lay off an angle equal to  $58^\circ 07'$ , and at  $B$  an angle equal to  $22^\circ 37'$ , and draw the lines  $AC$  and  $BC$ : then will  $ABC$  be the triangle required.

The angle  $C$  may be measured with the protractor (see page 270), and when so measured, will be found equal to

$99^\circ 16'$ . The sides  $AC$  and  $BC$  may be measured by referring them to the scale of equal parts (see page 268). We shall find  $AC=158.9$  and  $BC=351$  yards.

## TRIGONOMETRICALLY BY LOGARITHMS.

|                     |                      |  |
|---------------------|----------------------|--|
| To the angle . . .  | $A = 58^\circ 07'$   |  |
| Add the angle . . . | $B = 22^\circ 37'$   |  |
|                     | Their sum,           | $= 80^\circ 44'$   |
|                     | taken from . . .     | $180^\circ 00'$  |
|                     | leaves $C$ . . . . . | $99^\circ 16'$ , of which, as it exceeds $90^\circ$ , we use the supplement $80^\circ 44'$ . |

*To find the side BC.*

|    |          |                |                      |                              |
|----|----------|----------------|----------------------|------------------------------|
|    | $\sin C$ | $99^\circ 16'$ | ar. comp.            | $0.005705$                   |
| :  | $\sin A$ | $58^\circ 07'$ | . . . . .            | $9.928972$                   |
| :: | $AB$     | $408$          | . . . . .            | $2.610660$                   |
| :  | $BC$     | $351.024$      | (after rejecting 10) | <u><math>2.545337</math></u> |

**REMARK.** The logarithm of the fourth term of a proportion is obtained by adding the logarithm of the second term to that of the third, and subtracting from their sum the logarithm of the first term. But to subtract the first term is the same as to add its arithmetical complement and reject 10 from the sum (Int. Art. 13): hence, the arithmetical complement of the logarithm of the first term added to the logarithms of the second and third terms, minus ten, will give the logarithm of the fourth term.

*To find the side AC.*

|   |          |                |           |                              |
|---|----------|----------------|-----------|------------------------------|
|   | $\sin C$ | $99^\circ 16'$ | ar. comp. | $0.005705$                   |
| : | $\sin B$ | $22^\circ 37'$ | . . . . . | $9.584968$                   |
| : | $AB$     | $408$          | . . . . . | $2.610660$                   |
| : | $AC$     | $158.976$      | . . . . . | <u><math>2.201333</math></u> |

2. In a triangle  $ABC$ , there are given  $A = 38^\circ 25'$ ,  $B = 57^\circ 42'$ , and  $AB = 400$ : required the remaining parts.  
*Ans.*  $C = 83^\circ 53'$ ,  $BC = 249.974$ ,  $AC = 340.01$ .

CASE II.

When two sides and an opposite angle are given.

28. In a plane triangle,  $ABC$ , there are given  $AC = 216$ ,  $CB = 117$ , the angle  $A = 22^\circ 37'$ , to find the other parts.

GEOMETRICALLY.

29. Draw an indefinite right line  $ABB'$ : from any point, as  $A$ , draw  $AC$ , making  $BAC = 22^\circ 37'$ , and make  $AC = 216$ . With  $C$  as a centre, and a radius equal to 117, the other given side, describe the arc  $B'B$ ; draw  $B'C$  and  $BC$ : then will either of the triangles  $ABC$  or  $AB'C$ , answer all the conditions of the question.

TRIGONOMETRICALLY.

To find the angle  $B$ .

|    |           |                                |                      |           |
|----|-----------|--------------------------------|----------------------|-----------|
|    | $BC$      | 117                            | ar. comp.            | 7.931814  |
| :  | $AC$      | 216                            | . . . . .            | 2.334454  |
| :: | $\sin A$  | $22^\circ 37'$                 | . . . . .            | 9.584968  |
| :  | $\sin B'$ | $45^\circ 13' 55''$ , or $ABC$ | $134^\circ 46' 05''$ | 9.851236. |

The ambiguity in this, and similar examples, arises in consequence of the first proportion being true for either of the angles  $ABC$ , or  $AB'C$ , which are supplements of each other, and therefore, have the same sine (Art. 13). As long as the two triangles exist, the ambiguity will continue. But if the side  $CB$ , opposite the given angle, is greater than  $AC$ , the arc  $BB'$  will cut the line  $ABB'$ , on the same side of the point  $A$ , in but one point, and then there will be only one triangle answering the conditions.

If the side  $CB$  is equal to the perpendicular  $Cd$ , the arc  $BB'$  will be tangent to  $ABB'$ , and in this case also there will be but one triangle. When  $CB$  is less than the perpendicular  $Cd$ , the arc  $BB'$  will not intersect the base  $ABB'$ , and in that case, no triangle can be formed, or it will be impossible to fulfil the conditions of the problem.

2. Given two sides of a triangle 50 and 40 respectively, and the angle opposite the latter equal to  $32^\circ$ : required the remaining parts of the triangle.

*Ans.* If the angle opposite the side 50 is acute, it is equal to  $41^\circ 28' 59''$ ; the third angle is then equal to  $106^\circ 31' 01''$ , and the third side to 72.368. If the angle opposite the side 50 is obtuse, it is equal to  $138^\circ 31' 01''$ , the third angle to  $9^\circ 28' 59''$ , and the remaining side to 12.436.

## CASE III.

*When the two sides and their included angle are given.*

30. Let  $ABC$  be a triangle;  $AB$ ,  $BC$ , the given sides, and  $B$  the given angle.

Since  $B$  is known, we can find the sum of the two other angles for

$$A + C = 180^\circ - B, \text{ and,} \\ \frac{1}{2}(A + C) = \frac{1}{2}(180^\circ - B).$$

We next find half the difference of the angles  $A$  and  $C$  by Theorem II., viz.,

$BC + BA : BC - BA :: \tan \frac{1}{2}(A + C) : \tan \frac{1}{2}(A - C)$ ,  
in which we consider  $BC$  greater than  $BA$ , and therefore  $A$  is greater than  $C$ ; since the greater angle must be opposite the greater side.

Having found half the difference of  $A$  and  $C$ , by adding it to the half sum,  $\frac{1}{2}(A + C)$ , we obtain the greater angle, and by subtracting it from half the sum, we obtain the less. That is,

$$\frac{1}{2}(A + C) + \frac{1}{2}(A - C) = A, \text{ and} \\ \frac{1}{2}(A + C) - \frac{1}{2}(A - C) = C.$$

Having found the angles  $A$  and  $C$ , the third side  $AC$  may be found by the proportion,

$$\sin A : \sin B :: BC : AC.$$

EXAMPLES.

1. In the triangle  $ABC$ , let  $BC=540$ ,  $AB=450$ , and the included angle  $B=80^\circ$ : required the remaining parts

GEOMETRICALLY.

31. Draw an indefinite right line  $BC$ , and from any point, as  $B$ , lay off a distance  $BC=540$ . At  $B$  make the angle  $CBA=80^\circ$ : draw  $BA$ , and make the distance  $BA=450$ ; draw  $AC$ ; then will  $ABC$  be the required triangle.

TRIGONOMETRICALLY.

$BC+BA=540+450=990$ ; and  $BC-BA=540-450=90$ .

$A+C=180^\circ-B=180^\circ-80^\circ=100^\circ$ , and therefore,

$$\frac{1}{2}(A+C)=\frac{1}{2}(100^\circ)=50^\circ.$$

To find  $\frac{1}{2}(A-C)$ .

|    |                         |               |           |           |
|----|-------------------------|---------------|-----------|-----------|
|    | $BC+BA$                 | 990           | ar. comp. | 7.004365  |
| :  | $BC-BA$                 | 90            | . . . . . | 1.954243  |
| :: | $\tan \frac{1}{2}(A+C)$ | $50^\circ$    | . . . . . | 10.076187 |
| :  | $\tan \frac{1}{2}(A-C)$ | $6^\circ 11'$ | . . . . . | 9.034795. |

Hence,  $50^\circ+6^\circ 11'=56^\circ 11'=A$ ; and  $50^\circ-6^\circ 11'=43^\circ 49'=C$ .

To find the third side  $AC$ .

|    |          |                |           |           |
|----|----------|----------------|-----------|-----------|
|    | $\sin C$ | $43^\circ 49'$ | ar comp.  | 0.159672  |
| :  | $\sin B$ | $80^\circ$     | . . . . . | 9.993351  |
| :: | $AB$     | 450            | . . . . . | 2.653213  |
| :  | $AC$     | 640.082        | . . . . . | 2.806236. |

2. Given two sides of a plane triangle, 1686 and 960, and their included angle  $128^\circ 04'$ : required the other parts.

*Ans.* Angles,  $33^\circ 34' 39''$ ;  $18^\circ 21' 21''$ ; side 2400.

CASE IV.

32. Having given the three sides of a plane triangle, to find the angles.

Let fall a perpendicular from the angle opposite the greater side, dividing the given triangle into two right-angled triangles: then find the difference of the segments of the base by Theorem III. Half this difference being added to half the base, gives the greater segment; and, being subtracted from half the base, gives the less segment. Then, since the greater segment belongs to the right-angled triangle having the greater hypotenuse, we have two sides and the right angle of each of two right-angled triangles, to find the acute angles.

## EXAMPLES.

1. The sides of a plane triangle being given; viz.,  $BC=40$ ,  $AC=34$ , and  $AB=25$ : required the angles.

## GEOMETRICALLY.

33. With the three given lines as sides construct a triangle as in Prob. IX. Then measure the angles of the triangle either with the protractor or scale of chords.

## TRIGONOMETRICALLY.

$$BC : AC + AB :: AC - AB : CD - BD,$$

$$\text{That is, } 40 : 59 :: 9 : \frac{59 \times 9}{40} = 13.275.$$

$$\text{Then, } \frac{40 + 13.275}{2} = 26.6375 = CD,$$

$$\text{And, } \frac{40 - 13.275}{2} = 13.3625 = BD.$$

*In the triangle DAC, to find the angle DAC.*

|    |         |                       |           |
|----|---------|-----------------------|-----------|
| AC | 34      | ar. comp.             | 8.468521  |
| :  | DC      | 26.6375 . . . . .     | 1.425498  |
| :: | sin D   | 90° . . . . .         | 10.000000 |
| :  | sin DAC | 51° 34' 40" . . . . . | 9.894014. |

In the triangle  $BAD$ , to find the angle  $BAD$ .

|      |            |                     |           |
|------|------------|---------------------|-----------|
| $AB$ | 25         | ar. comp.           | 8.602060  |
| :    | $BD$       | 13.3625             | 1.125887  |
| ::   | $\sin D$   | $90^\circ$          | 10.000000 |
| :    | $\sin BAD$ | $32^\circ 18' 35''$ | 9.727947. |

Hence,  $90^\circ - DAC = 90^\circ - 51^\circ 34' 40'' = 38^\circ 25' 20'' = C$ ,

and,  $90^\circ - BAD = 90^\circ - 32^\circ 18' 35'' = 57^\circ 41' 25'' = B$ ,

and,  $BAD + DAC = 51^\circ 34' 40'' + 32^\circ 18' 35'' = 83^\circ 53' 15'' = A$ .

2. In a triangle, of which the sides are 4, 5, and 6, what are the angles?

*Ans.*  $41^\circ 24' 35''$ ;  $55^\circ 46' 16''$ ; and  $82^\circ 49' 09''$ .

SOLUTION OF RIGHT-ANGLED TRIANGLES.

34. The unknown parts of a right-angled triangle may be found by either of the four last cases; or, if two of the sides are given, by means of the property that the square of the hypotenuse is equivalent to the sum of the squares of the two other sides. Or the parts may be found by Theorems IV. and V.

EXAMPLES.

1. In a right-angled triangle  $BAC$ , there are given the hypotenuse  $BC = 250$ , and the base  $AC = 240$ : required the other parts.

*Ans.*  $B = 73^\circ 44' 23''$ ;  $C = 16^\circ 15' 37''$ ;  $AB = 70.0003$ .

2. In a right-angled triangle  $BAC$ , there are given  $AC = 384$ , and  $B = 53^\circ 08'$ : required the remaining parts.

*Ans.*  $AB = 287.96$ ;  $BC = 479.979$ ;  $C = 36^\circ 52'$ .

## APPLICATION TO HEIGHTS AND DISTANCES.

1. A **HORIZONTAL PLANE** is one which is parallel to the water level.

2. A plane which is perpendicular to a horizontal plane, is called a *vertical plane*.

3. All lines parallel to the water level, are called *horizontal lines*.

4. All lines which are perpendicular to a horizontal plane, are called *vertical lines*; and all lines which are inclined to it, are called *oblique lines*.

5. A **HORIZONTAL ANGLE** is one whose sides are horizontal.

6. A **VERTICAL ANGLE** is one, the plane of whose sides is vertical.

7. An angle of *elevation*, is a vertical angle having one of its sides horizontal, and the inclined side above the horizontal side.

8. An angle of *depression*, is a vertical angle having one of its sides horizontal, and the inclined side under the horizontal side.

I. *To determine the horizontal distance to a point which is inaccessible by reason of an intervening river.*

35. Let  $C$  be the point. Measure along the bank of the river a horizontal base line  $AB$ , and select the stations  $A$  and  $B$ , in such a manner that each can be seen from the other, and the point  $C$  from both of them. Then measure the horizontal angles  $CAB$  and  $CBA$  with an instrument adapted to that purpose.

Let us suppose that we have found  $AB = 600$  yards,  $CAB = 57^\circ 35'$ , and  $CBA = 64^\circ 51'$ .

The angle  $C = 180^\circ - (A + B) = 57^\circ 34'$ .

*To find the distance BC.*

|         |                |              |                 |
|---------|----------------|--------------|-----------------|
| sin $C$ | $57^\circ 34'$ | ar. comp.    | 0.073649        |
| :       | sin $A$        |              | 9.926431        |
| ::      | $AB$           | 600          | <u>2.778151</u> |
| :       | $BC$           | 600.11 yards | <u>2.778231</u> |

To find the distance  $AC$ .

|         |         |              |                 |
|---------|---------|--------------|-----------------|
| sin $O$ | 57° 34' | ar. comp.    | 0.073649        |
| :       | sin $B$ | 64° 51'      | 9.956744        |
| ::      | $AB$    | 600          | 2.778151        |
| :       | $AC$    | 643.94 yards | <u>2.808544</u> |

II. To determine the altitude of an inaccessible object above a given horizontal plane.

FIRST METHOD.

36. Suppose  $D$  to be the inaccessible object, and  $BC$  the horizontal plane from which the altitude is to be estimated: then, if we suppose  $DC$  to be a vertical line, it will represent the required altitude.

Measure any horizontal base line, as  $BA$ ; and at the extremities  $B$  and  $A$ , measure the horizontal angles  $CBA$  and  $CAB$ . Measure also the angle of elevation  $DBC$ .

Then in the triangle  $CBA$  there will be known, two angles and the side  $AB$ ; the side  $BC$  can therefore be determined. Having found  $BC$ , we shall have, in the right-angled triangle  $DBC$ , the base  $BC$  and the angle at the base, to find the perpendicular  $DC$ , which measures the altitude of the point  $D$  above the horizontal plane  $BC$ .

Let us suppose that we have found

$BA = 780$  yards, the horizontal angle  $CBA = 41^\circ 24'$ ; the horizontal angle  $CAB = 96^\circ 28'$ , and the angle of elevation  $DBC = 10^\circ 43'$ .

In the triangle  $BCA$ , to find the horizontal distance  $BC$ .  
The angle  $BCA = 180^\circ - (41^\circ 24' + 96^\circ 28') = 42^\circ 08' = C$ .

|         |         |           |                 |
|---------|---------|-----------|-----------------|
| sin $C$ | 42° 08' | ar. comp. | 0.173369        |
| :       | sin $A$ | 96° 28'   | 9.997228        |
| ::      | $AB$    | 780       | 2.892095        |
| :       | $BC$    | 1155.29   | <u>3.062692</u> |

*In the right-angled triangle DBC, to find DC.*

|                  | <i>R</i> | ar. comp. |                  |
|------------------|----------|-----------|------------------|
| : tan <i>DBC</i> | 10° 43'  | . . . . . | 9.277043         |
| :: • <i>BC</i>   | 1155.29  | . . . . . | <u>3.062692</u>  |
| : <i>DC</i>      | 218.64   | . . . . . | <u>2.339735.</u> |

REMARK I. It might, at first, appear, that the solution which we have given, requires that the points *B* and *A* should be in the same horizontal plane; but it is entirely independent of such a supposition.

For, the horizontal distance, which is represented by *BA*, is the same, whether the station *A* is on the same level with *B*, above it, or below it. The horizontal angles *CAB* and *CBA* are also the same, so long as the point *C* is in the vertical line *DC*. Therefore, if the horizontal line through *A* should cut the vertical line *DC*, at any point, as *E*, above or below *C*, *AB* would still be the horizontal distance between *B* and *A*, and *AE*, which is equal to *AC*, would be the horizontal distance between *A* and *C*.

If at *A*, we measure the angle of elevation of the point *D*, we shall know in the right-angled triangle *DAE*, the base *AE*, and the angle at the base; from which the perpendicular *DE* can be determined.

37. Let us suppose that we had measured the angle of elevation *DAE*, and found it equal to 20° 15'.

*First: In the triangle BAC, to find AC or its equal AE.*

|                |         |           |                  |
|----------------|---------|-----------|------------------|
| sin <i>C</i>   | 42° 08' | ar. comp. | 0.173369         |
| : sin <i>B</i> | 41° 24' | . . . . . | 9.820406         |
| :: <i>AB</i>   | 780     | . . . . . | <u>2.892095</u>  |
| : <i>AC</i>    | 768.9   | . . . . . | <u>2.885870.</u> |

*In the right-angled triangle DAE, to find DE.*

|                | <i>R</i> | ar. comp. |                  |
|----------------|----------|-----------|------------------|
| : tan <i>A</i> | 20° 15'  | . . . . . | 9.566932         |
| :: <i>AE</i>   | 768.9    | . . . . . | <u>2.885870</u>  |
| : <i>DE</i>    | 283.66   | . . . . . | <u>2.452802.</u> |

Now, since  $DC$  is less than  $DE$ , it follows that the station  $B$  is above the station  $A$ . That is,

$$DE - DC = 283.66 - 218.64 = 65.02 = EC,$$

which expresses the vertical distance that the station  $B$  is above the station  $A$ .

REMARK II. It should be remembered, that the vertical distance which is obtained by the calculation, is estimated from a horizontal line passing through the eye at the time of observation. Hence, the height of the instrument is to be added, in order to obtain the true result.

SECOND METHOD.

38. When the nature of the ground will admit of it, measure a base line  $AB$  in the direction of the object  $D$ . Then measure with the instrument the angles of elevation at  $A$  and  $B$ .

Then, since the exterior angle  $DBC$  is equal to the sum of the angles  $A$  and  $ADB$ , it follows that the angle

angle  $ADB$  is equal to the difference of the angles of elevation at  $A$  and  $B$ . Hence, we can find all the parts of the triangle  $ADB$ . Having found  $DB$ , and knowing the angle  $DBC$ , we can find the altitude  $DC$ .

This method supposes that the stations  $A$  and  $B$  are on the same horizontal plane; and therefore it can only be used when the line  $AB$  is nearly horizontal.

Let us suppose that we have measured the base line, and the two angles of elevation, and

$$\text{found } \begin{cases} AB = 975 \text{ yards,} \\ A = 15^\circ 36', \\ DBC = 27^\circ 29'; \end{cases}$$

required the altitude  $DC$ .

First:  $ADB = DBC - A = 27^\circ 29' - 15^\circ 36' = 11^\circ 53'$ .

*In the triangle ADB, to find BD.*

|    |          |                |           |                  |
|----|----------|----------------|-----------|------------------|
|    | $\sin D$ | $11^\circ 53'$ | ar. comp. | 0.686302         |
| :  | $\sin A$ | $15^\circ 36'$ | . . . . . | 9.429623         |
| :: | $AB$     | 975            | . . . . . | 2.989005         |
| :  | $DB$     | 1273.3         | . . . . . | <u>3.104930.</u> |

*In the triangle DBC, to find DC.*

|    |          |                |           |                  |
|----|----------|----------------|-----------|------------------|
|    | $R$      |                | ar. comp. | 0.000000         |
| :  | $\sin B$ | $27^\circ 29'$ | . . . . . | 9.664163         |
| :: | $DB$     | 1273.3         | . . . . . | 3.104930         |
| :  | $DC$     | 587.61         | . . . . . | <u>2.769093.</u> |

### III. To determine the perpendicular distance of an object below a given horizontal plane.

39. Suppose  $C$  to be directly over the given object, and  $A$  the point through which the horizontal plane is supposed to pass.

Measure a horizontal base line  $AB$ , and at the stations  $A$  and  $B$  conceive the two horizontal lines  $AC, BC$ , to be drawn. The

oblique lines from  $A$  and  $B$  to the object are the hypotenuses of two right-angled triangles, of which  $AC, BC$ , are the bases. The perpendiculars of these triangles are the distances from the horizontal lines  $AC, BC$ , to the object. If we turn the triangles about their bases  $AC, BC$ , until they become horizontal, the object, in the first case, will fall at  $C'$ , and in the second at  $C''$ .

Measure the horizontal angles  $CAB, CBA$ , and also the angles of depression  $C'AC, C''BC$ .

Let us suppose that we have

$$\text{found } \begin{cases} AB = 672 \text{ yards} \\ BAC = 72^\circ 29' \\ ABC = 39^\circ 20' \\ C'AC = 27^\circ 49' \\ C''BC = 19^\circ 10'. \end{cases}$$

First: in the triangle  $ABC$ ,  
the horizontal angle  $ACB = 180^\circ - (A + B) = 180^\circ - 111^\circ 49' = 68^\circ 11'$ .

To find the horizontal distance  $AC$ .

|    |         |         |           |           |
|----|---------|---------|-----------|-----------|
|    | sin $C$ | 68° 11' | ar. comp. | 0.032275  |
| :  | sin $B$ | 39° 20' |           | 9.801973  |
| :: | $AB$    | 672     |           | 2.827369  |
| :  | $AC$    | 458.79  |           | 2.661617. |

To find the horizontal distance  $BC$ .

|    |         |         |           |           |
|----|---------|---------|-----------|-----------|
|    | sin $C$ | 68° 11' | ar. comp. | 0.032275  |
| :  | sin $A$ | 72° 29' |           | 9.979380  |
| :: | $AB$    | 672     |           | 2.827369  |
| :  | $BC$    | 690.28  |           | 2.839024. |

In the triangle  $CAC'$ , to find  $CC'$ .

|    |            |         |           |          |
|----|------------|---------|-----------|----------|
|    |            |         | ar. comp. | 0.000000 |
| :  | tan $C'AC$ | 27° 49' |           | 9.722315 |
| :: | $AC$       | 458.79  |           | 2.661617 |
| :  | $CC'$      | 242.06  |           | 2.383932 |

In the triangle  $CBC''$ , to find  $CC''$ .

|    |             |         |           |           |
|----|-------------|---------|-----------|-----------|
|    |             |         | ar. comp. | 0.000000  |
| :  | tan $C''BC$ | 19° 10' |           | 9.541061  |
| :: | $BC$        | 690.28  |           | 2.839024  |
| :  | $CC''$      | 239.93  |           | 2.380085. |

Hence also,  $CC' - CC'' = 242.06 - 239.93 = 2.13$  yards,  
which is the height of the station  $A$  above station  $B$ .

## PROBLEMS.

1. Wanting to know the distance between two inaccessible objects, which lie in a direct level line from the bottom of a tower of 120 feet in height, the angles of depression are measured from the top of the tower, and are found to be, of the nearer  $57^\circ$ , of the more remote  $25^\circ 30'$ : required the distance between the objects.

*Ans.* 173.656 feet.

2. In order to find the distance between two trees,  $A$  and  $B$ , which could not be directly measured because of a pool which occupied the intermediate space, the distances of a third point  $C$  from each of them were measured, and also the included angle  $ACB$ : it was found that,

$$CB = 672 \text{ yards,}$$

$$CA = 588 \text{ yards,}$$

$$ACB = 55^\circ 40';$$

required the distance  $AB$ .

*Ans.* 592.967 yards.

3. Being on a horizontal plane, and wanting to ascertain the height of a tower, standing on the top of an inaccessible hill, there were measured, the angle of elevation of the top of the hill  $40^\circ$ , and of the top of the tower  $51^\circ$ ; then measuring in a direct line 180 feet farther from the hill, the angle of elevation of the top of the tower was  $33^\circ 45'$ ; required the height of the tower.

*Ans.* 83.998.

4. Wanting to know the horizontal distance between two inaccessible objects  $E$  and  $W$ , the following measurements were made.

$$\text{viz. } \begin{cases} AB = 536 \text{ yards} \\ \angle BAW = 40^\circ 16' \\ \angle WAE = 57^\circ 40' \\ \angle ABE = 42^\circ 22' \\ \angle EBW = 71^\circ 07'; \end{cases}$$

required the distance  $EW$ .

*Ans.* 939.527 yards.

5. Wanting to know the horizontal distance between two inaccessible objects *A* and *B*, and not finding any station from which both of them could be seen, two points *C* and *D*, were chosen at a distance from each other, equal to 200 yards; from the former of these points *A* could be seen, and from the latter *B*, and at each of the points *C* and *D* a staff was set up. From *C* a distance *CF* was measured, not in the direction *DC*, equal to 200 yards, and from *D* a distance *DE* equal to 200 yards, and the following angles taken,

$$\text{viz. } \begin{cases} AFC = 83^\circ 00', & BDE = 54^\circ 30', \\ ACD = 53^\circ 30', & BDC = 156^\circ 25', \\ ACF = 54^\circ 31', & BED = 88^\circ 30'. \end{cases}$$

*Ans.*  $AB = 345.467$  yards.

6. From a station *P* there can be seen three objects, *A*, *B* and *C*, whose distances from each other are known: viz.,  $AB = 800$ ,  $AC = 600$ , and  $BC = 400$  yards. Now, there are measured the horizontal angles.

$APC = 33^\circ 45'$  and  $BPC = 22^\circ 30'$ : it is required to find the three distances *PA*, *PC*, and *PB*.

$$\text{Ans. } \begin{cases} PA = 710.193 \text{ yards.} \\ PC = 1042.522 \\ PB = 934.291. \end{cases}$$

7. This problem is much used in maritime surveying, for the purpose of locating buoys and sounding boats. The trigonometrical solution is somewhat tedious, but it may be solved geometrically by the following easy construction.

Let  $A$ ,  $B$ , and  $C$  be the three fixed points on shore, and  $P$  the position of the boat from which the angles  $APC = 33^\circ 45'$ ,  $CPB = 22^\circ 30'$ , and  $APB = 56^\circ 15'$ , have been measured.

Subtract twice  $APC = 67^\circ 30'$  from  $180^\circ$ , and lay off at  $A$  and  $C$  two angles,  $CAO$ ,  $ACO$ , each equal to half the remainder  $= 56^\circ 15'$ . With the point  $O$ , thus determined, as a centre, and  $OA$  or  $OC$  as a radius, describe the circumference of a circle: then, any angle inscribed in the segment  $APC$ , will be equal to  $33^\circ 45'$ .

Subtract, in like manner, twice  $CPB = 45^\circ$ , from  $180^\circ$ , and lay off half the remainder  $= 67^\circ 30'$ , at  $B$  and  $C$ , determining the centre  $Q$  of a second circle, upon the circumference of which the point  $P$  will be found. The required point  $P$  will be at the intersection of these two circumferences. If the point  $P$  fall on the circumference described through the three points  $A$ ,  $B$ , and  $C$ , the two auxiliary circles will coincide, and the problem will be indeterminate.

# ANALYTICAL

## PLANE TRIGONOMETRY.

---

40. WE have seen (Art. 2) that Plane Trigonometry explains the methods of computing the unknown parts of a plane triangle, when a sufficient number of the six parts is given.

To aid us in these computations, certain lines were employed, called sines, cosines, tangents, cotangents, &c., and a certain connection and dependence were found to exist between each of these lines and the arc to which it belonged.

All these lines exist and may be computed for every conceivable arc, and each will experience a change of value where the arc passes from one stage of magnitude to another. Hence, they are called *functions* of the arc; a term which implies such a connection between two varying quantities, that the value of the one shall always change with that of the other.

In computing the parts of triangles, the terms, sine, cosine, tangent, &c., are, for the sake of brevity, applied to angles, but have in fact, reference to the *arcs* which measure the angles. The terms when applied to angles, without reference to the measuring arcs, designate mere ratios, as is shown in Art. 88.

41. In Plane Trigonometry, the numerical values of these functions were alone considered (Art. 13), and the arcs from which they were deduced were all less than 180 degrees. *Analytical Plane Trigonometry*, explains all the processes for computing the unknown parts of rectilinear triangles, and also, the nature and properties of the circular functions, together with the methods of deducing all the formulas which express relations between them.

42. Let  $C$  be the centre of a circle, and  $DA$ ,  $EB$ , two diameters at right angles to each other—dividing the circumference into four quadrants. Then,  $AB$  is called the first quadrant;  $BD$  the second quadrant;  $DE$  the third quadrant; and  $EA$  the fourth quadrant. All angles having their vertices at  $C$ , and to which we attribute the plus sign, are reckoned from the line  $CA$ , and in the direction from right to left. The arcs which measure these angles are estimated from  $A$  in the direction to  $B$ , to  $D$ , to  $E$ , and to  $A$ ; and so on.

43. The value of any one of the circular functions will undergo a change with the angle to which it belongs, and also, with the radius of the measuring arc. When all the functions which enter into the same formula are derived from the same circle, the radius of that circle may be regarded as unity, and represented by 1. The circular functions will then be expressed in terms of 1: that is, in terms of the radius. Formulas will be given for finding their values when the radius is changed from unity to any number denoted by  $R$  (Art. 87).

44. We have occasion to refer to but one circular function not already defined. It is called the *versed sine*.

The *versed sine* of an arc, is that part of the diameter intercepted between the point where the measuring arcs begin and the foot of the sine. It is designated, *ver-sin*.

45. The names which have been given of the circular functions (Art. 11) have no reference to the quadrants in which the measuring arcs may terminate; and hence, are equally applicable to all angles.

*First quadrant.*

If  $CA = 1$

$$PM = \sin a,$$

$$CM = \cos a,$$

$$AT = \tan a,$$

$$CT = \sec a,$$

$$AM = \text{ver-sin } a.$$

*Second quadrant.*

$$\begin{aligned} PM &= \sin a, \\ CM &= \cos a, \\ AT &= \tan a, \\ CT &= \sec a, \\ AM &= \text{ver-sin } a. \end{aligned}$$

*Third quadrant.*

$$\begin{aligned} PM &= \sin a, \\ CM &= \cos a, \\ AT &= \tan a, \\ CT &= \sec a, \\ AM &= \text{ver-sin } a. \end{aligned}$$

*Fourth quadrant.*

$$\begin{aligned} PM &= \sin a, \\ CM &= \cos a, \\ AT &= \tan a, \\ CT &= \sec a, \\ AM &= \text{ver-sin } a. \end{aligned}$$

46. We will now proceed to establish some of the important general relations between the circular functions.

Regarding the radius  $CP$  of the circle as unity, and denoting it by 1 (Art. 43); we have in the right-angled triangle  $CPM$ ,

$$\overline{PM}^2 + \overline{CM}^2 = R^2 = 1,$$

that is,  $\sin^2 a + \cos^2 a = 1$ ,\* . (1)

47. Since the triangles  $CPM$  and  $CTA$  are similar, we have,

$$\frac{AT}{CA} = \frac{PM}{CM},$$

that is,  $\tan a = \frac{\sin a}{\cos a}$ , . (2)

\* The symbols  $\sin^2 a$ ,  $\cos^2 a$ ,  $\tan^2 a$ , &c., signify the *square of the sine*, the *square of the cosine*, &c.

48. Substituting in equation (2),  $90 - a$  for  $a$ , we have,

$$\tan (90 - a) = \frac{\sin (90 - a)}{\cos (90 - a)},$$

that is (Art. 12),  $\cot a = \frac{\cos a}{\sin a} \dots \dots \dots (3)$

49. Multiplying equations (2) and (3), member by member, we have,

$$\tan a \times \cot a = 1. \dots \dots (4)$$

50. From the two similar triangles  $CPM$  and  $CTA$ , we have,

$$\frac{CT}{CA} = \frac{CP}{CM};$$

that is,  $\sec a = \frac{1}{\cos a} \dots \dots \dots (5)$

51. Substituting for  $a$ ,  $90 - a$ , we have,

$$\sec (90 - a) = \frac{1}{\cos (90 - a)},$$

that is,  $\operatorname{cosec} a = \frac{1}{\sin a} \dots \dots \dots (6)$

52. In the right-angle  $CTA$ , we have,

$$\overline{CT}^2 = \overline{CA}^2 + \overline{AT}^2;$$

that is,  $\sec^2 a = 1 + \tan^2 a. \dots \dots (7)$

53. Substituting  $(90 - a)$  for  $a$ , in equation (7) and recollecting that  $\sec (90 - a) = \operatorname{cosec} a$ , and  $\tan (90 - a) = \cot a$ , we have

$$\operatorname{cosec}^2 a = 1 + \cot^2 a. \dots \dots (8)$$

54. We have,  $AM$  equal to the versed sine of the arc  $AP$ ; hence,

$$\operatorname{ver-sin} a = 1 - \cos a. \dots (9)$$

55. These nine formulas being often referred to, we shall place them in a table.

They are used so frequently, that they should be committed to memory.

TABLE I.

|    |   |   |   |  |
|----|---|---|---|--|
| 1. | . | . | . | $\sin^2 a + \cos^2 a = R^2 = 1.$             |
| 2. | . | . | . | $\tan a = \frac{\sin a}{\cos a}.$            |
| 3. | . | . | . | $\cot a = \frac{\cos a}{\sin a}.$            |
| 4. | . | . | . | $\tan a \times \cot a = R^2 = 1.$            |
| 5. | . | . | . | $\sec a = \frac{1}{\cos a}.$                 |
| 6. | . | . | . | $\operatorname{cosec} a = \frac{1}{\sin a}.$ |
| 7. | . | . | . | $\sec^2 a = 1 + \tan^2 a.$                   |
| 8. | . | . | . | $\operatorname{cosec}^2 a = 1 + \cot^2 a.$   |
| 9. | . | . | . | $\operatorname{ver-sin} a = 1 - \cos a.$     |

56. We will now explain the principles which determine the *algebraic signs* of the trigonometrical functions. There are but two.

1st. All lines estimated from  $DA$ , *upwards*, are considered *positive*, or have the sign  $+$ : and all lines estimated from  $DA$ , in the opposite direction, that is, *downwards*, are considered *negative*, or have the sign  $-$ .

2d. All lines estimated from  $EB$  along  $CA$ , that is, *to the right*, are considered *positive*, or have the sign  $+$ : and all lines estimated from  $EB$  along  $CD$ , that is, in the *opposite direction*, are considered *negative*, or have the sign  $-$ .

57. Let us determine, from the above principles, the algebraic signs of the sines and cosines in the different quadrants.

*First quadrant.*

58. In the first quadrant,

$$PM = \sin a,$$

and  $Pm = CM = \cos a,$

are both positive, the former being above the line  $DA$ , and the latter being estimated from  $C$  to the right (Art. 56).

*Second quadrant.*

59. In the second quadrant,

$$PM = \sin a,$$

and  $Pm = CM = -\cos a:$

the sine is positive, being above the line  $DA$ , and the cosine negative being estimated to the left of  $BE$ .

*Third quadrant.*

60. In the third quadrant,

$$PM = -\sin a,$$

and  $Pm = CM = -\cos a:$

the sine is negative, falling below the line  $DA$ , and the cosine is negative, being estimated to the left of the centre  $C$ .

*Fourth quadrant.*

61. In the fourth quadrant,

$$PM = -\sin a,$$

and  $Pm = CM = \cos a:$

the sine is negative, falling below the line  $DA$ , and the cosine is positive, falling on the right of  $EB$ . Hence, we conclude, that

1st. *The sine is positive in the first and second quadrants, and negative in the third and fourth :*

2d. *The cosine is positive in the first and fourth quadrants, and negative in the second and third :*

In other words,

1st. *The sine of an angle less than  $180^\circ$  is positive ; and the sine of an angle greater than  $180^\circ$  and less than  $360^\circ$ , is negative :*

2d. *The cosine of an angle less than  $90^\circ$  is positive ; the cosine of an angle greater than  $90^\circ$ , and less than  $270^\circ$ , is negative ; and the cosine of an angle greater than  $270^\circ$ , and less than  $360^\circ$ , is positive.*

62. The algebraic signs of the sine and cosine being determined, the signs of all the other trigonometrical functions may be at once established by means of the formulas of Table I.

Thus, for example,

$$\tan a = \frac{\sin a}{\cos a}.$$

Now, if the algebraic signs of  $\sin a$  and  $\cos a$  are alike, the tangent is positive ; if they are unlike, it is negative. Hence, *the tangent is positive in the first and third quadrants, and negative in the second and fourth.*

The same is also true of the cotangent: for,

$$\cot a = \frac{\cos a}{\sin a}.$$

63. Again, since

$$\sec a = \frac{1}{\cos a},$$

*the sign of the secant is always the same as that of the cosine.* And since,

$$\operatorname{cosec} a = \frac{1}{\sin a},$$

*the sign of the cosecant is always the same as that of the sine.*

64. The versed sine is constantly positive. For, it is always found by subtracting the cosine from radius, and the remainder is a positive quantity, since the cosine can never exceed radius. When the cosine is negative, the versed sine becomes greater than radius.

65. Let  $q$  denote a quadrant: then the following table will show the algebraic signs of the trigonometrical lines in the different quadrants.

|           | <i>First q.</i> | <i>Second q.</i> | <i>Third q.</i> | <i>Fourth q.</i> |
|-----------|-----------------|------------------|-----------------|------------------|
| sine      | +               | +                | -               | -                |
| cosine    | +               | -                | -               | +                |
| tangent   | +               | -                | +               | -                |
| cotangent | +               | -                | +               | -                |

66. We have thus far supposed all angles to be estimated from the line  $CA$  from right to left, that is in the direction from  $A$  to  $B$ , to  $D$ , &c., and have also regarded such angles as positive. It is sometimes convenient to give different signs to the angles themselves.

If we suppose the angles to be estimated from  $CA$ , in the direction from left to right, that is, in the direction from  $A$  to  $E$ , to  $D$ , &c., we must treat the angles themselves as negative, and affect them with the sign  $-$ .

For a negative angle less than  $90^\circ$ , the sine will be negative, and the cosine positive: for one greater than  $90^\circ$  and less than  $180^\circ$ , the sine and cosine will both be negative. The algebraic sign of the sine always changes, when we change the sign of the arc, but the sign of the cosine remains the same. Hence, calling  $x$  the arc, we have in general,

$$\begin{aligned}\sin(-x) &= -\sin x, \\ \cos(-x) &= \cos x, \\ \tan(-x) &= -\tan x, \\ \cot(-x) &= -\cot x.\end{aligned}$$

67. We shall now examine the changes which take

place in the values of the trigonometrical lines, as the angle increases from 0 to  $360^\circ$ , and shall begin with the sine and cosine.

When the arc is zero, the sine is 0, and the cosine equal to  $R = 1$ . At  $90^\circ$  the sine becomes equal to  $R = 1$ , and the cosine becomes 0. At  $180^\circ$ , the sine becomes 0, and the cosine equal to  $-R = -1$ . At  $270^\circ$ , the sine becomes equal to  $-R = -1$ , and the cosine equal to 0. At  $360^\circ$ , the sine becomes equal to 0, and the cosine to  $R = 1$ . Hence,

*First quadrant.*

As the arc increases from 0 to  $90^\circ$ :

The sine increases from 0 to 1:

The cosine decreases from 1 to 0.

*Second quadrant.*

As the arc increases from  $90^\circ$  to  $180^\circ$ :

The sine decreases from 1 to 0:

The cosine increases, numerically, from 0 to  $-1$ .

*Third quadrant.*

As the arc increases from  $180^\circ$  to  $270^\circ$ :

The sine increases, numerically, from 0 to  $-1$ :

The cosine decreases, numerically, from  $-1$  to 0.

*Fourth quadrant.*

As the arc increases from  $270^\circ$  to  $360^\circ$ :

The sine decreases, numerically, from  $-1$  to 0:

The cosine increases from 0 to  $R = 1$ .

68. By a careful consideration of the preceding principles and by making the proper substitutions in the formulas already deduced, we may now form the following Table:

TABLE II.

|                                   |                                   |
|-----------------------------------|-----------------------------------|
| $\sin 0 = 0,$                     | $\sin (180^\circ + a) = -\sin a,$ |
| $\cos 0 = 1,$                     | $\cos (180^\circ + a) = -\cos a,$ |
| $\tan 0 = 0,$                     | $\tan (180^\circ + a) = \tan a,$  |
| $\cot 0 = \infty.$                | $\cot (180^\circ + a) = \cot a.$  |
| $\sin (90^\circ - a) = \cos a,$   | $\sin (270^\circ - a) = -\cos a,$ |
| $\cos (90^\circ - a) = \sin a,$   | $\cos (270^\circ - a) = -\sin a,$ |
| $\tan (90^\circ - a) = \cot a,$   | $\tan (270^\circ - a) = \cot a,$  |
| $\cot (90^\circ - a) = \tan a.$   | $\cot (270^\circ - a) = \tan a.$  |
| $\sin 90^\circ = 1,$              | $\sin 270^\circ = -1,$            |
| $\cos 90^\circ = 0,$              | $\cos 270^\circ = 0,$             |
| $\tan 90^\circ = \infty,$         | $\tan 270^\circ = -\infty,$       |
| $\cot 90^\circ = 0.$              | $\cot 270^\circ = 0.$             |
| $\sin (90^\circ + a) = \cos a,$   | $\sin (270^\circ + a) = -\cos a,$ |
| $\cos (90^\circ + a) = -\sin a,$  | $\cos (270^\circ + a) = \sin a,$  |
| $\tan (90^\circ + a) = -\cot a,$  | $\tan (270^\circ + a) = -\cot a,$ |
| $\cot (90^\circ + a) = -\tan a.$  | $\cot (270^\circ + a) = -\tan a.$ |
| $\sin (180^\circ - a) = \sin a,$  | $\sin (360^\circ - a) = -\sin a,$ |
| $\cos (180^\circ - a) = -\cos a,$ | $\cos (360^\circ - a) = \cos a,$  |
| $\tan (180^\circ - a) = -\tan a,$ | $\tan (360^\circ - a) = -\tan a,$ |
| $\cot (180^\circ - a) = -\cot a,$ | $\cot (360^\circ - a) = -\cot a.$ |
| $\sin 180^\circ = 0,$             | $\sin 360^\circ = 0,$             |
| $\cos 180^\circ = -1,$            | $\cos 360^\circ = 1,$             |
| $\tan 180^\circ = 0,$             | $\tan 360^\circ = 0,$             |
| $\cot 180^\circ = -\infty.$       | $\cot 360^\circ = \infty.$        |

69. The examinations thus far, have been limited to arcs which do not exceed  $360^\circ$ . It is easily shown, however, that the addition of  $360^\circ$  to any arc as  $x$ , will make no difference in its trigonometrical functions; for, such addition would terminate the arc at precisely the same point of the circumference. Hence, if  $C$  represent an entire circumference, or  $360^\circ$ , and  $n$  any whole number, we shall have,

$$\sin (C + x) = \sin x; \text{ or, } \sin (n \times C + x) = \sin x.$$

The same is also true of the other functions.

70. It will further appear, that whatever be the value of an arc denoted by  $x$ , the sine may be expressed by that of an arc less than  $180^\circ$ . For, in the first place, we may subtract  $360^\circ$  from the arc  $x$ , as often as  $360^\circ$  is contained in it: then denoting the remainder by  $y$ , we have,

$$\sin x = \sin y.$$

Then, if  $y$  is greater than  $180^\circ$ , make

$$y - 180^\circ = z,$$

and we shall have,

$$\sin y = -\sin z.$$

Thus, all the cases are reduced to that in which the arc whose functions we take, is less than  $180^\circ$ ; and since we also know that,

$$\sin(90^\circ + x) = \sin(90^\circ - x),$$

they are ultimately reducible to the case of arcs between  $0$  and  $90^\circ$ .

#### GENERAL FORMULAS.

71. To find the formula for the sine of the difference of two angles or arcs.

Let  $ACB$  be a triangle. From the vertex  $C$  let fall the perpendicular  $CD$ , on the base  $AB$ , produced.

Denote the exterior angle  $CBD$  by  $a$ , and the angle  $CAB$  by  $b$ .

Then,  $AB = AD - DB$ .

But (Art. 25),  $AD = AC \cos b$ , and  $BD = BC \cos CBD$ .

Hence,  $AB = AC \cos b - BC \cos a$ .

Dividing both members by  $AB$ , we have

$$1 = \frac{AC}{AB} \cos b - \frac{BC}{AB} \cos a.$$

But, since  $\sin a = \sin CBA$ , we have (Art. 21)

$$\frac{AC}{AB} = \frac{\sin a}{\sin C}, \quad \text{and} \quad \frac{BC}{AB} = \frac{\sin b}{\sin C};$$

hence, 
$$1 = \frac{\sin a}{\sin C} \cos b - \frac{\sin b}{\sin C} \cos a,$$

or, 
$$\sin C = \sin a \cos b - \sin b \cos a.$$

But the angle  $C$  is equal to the difference between the angles  $a$  and  $b$  (Geom. B. I., P. 25, C. 6): hence,

$$\sin (a - b) = \sin a \cos b - \cos a \sin b; \dots (a)$$

that is, *The sine of the difference of any two arcs or angles is equal to the sine of the first into the cosine of the second, minus the cosine of the first into the sine of the second.*

It is plain that the formula is equally true in whichever quadrant the vertex of the angle  $C$  be placed: hence, the formula is true for all values, of the arcs  $a$  and  $b$ .

72. *To find the formula for the sine of the sum of two angles or arcs.*

By formula (a)

$$\sin (a - b) = \sin a \cos b - \cos a \sin b,$$

substituting for  $b, -b$ , and recollecting (Art. 66) that,

$$\sin (-x) = -\sin x$$

and 
$$\cos (-x) = \cos x;$$

and also that  $a - (-b) = a + b$ ,

we shall have, after making the substitutions and combining the algebraic signs,

$$\sin (a + b) = \sin a \cos b + \cos a \sin b. \dots (b)$$

73. *To find the formula for the cosine of the sum of two angles or arcs.*

By formula (b) we have,

$$\sin (a + b) = \sin a \cos b + \cos a \sin b,$$

substitute for  $a, 90^\circ + a$ , and we have,

$$\sin [(90^\circ + a) + b] = \sin (90^\circ + a) \cos b + \cos (90^\circ + a) \sin b$$

But,  $\sin [90^\circ + (a + b)] = \cos (a + b)$  (Table II.) :

$$\sin (90^\circ + a) = \cos a,$$

and,  $\cos (90^\circ + a) = -\sin a$  ;

making the substitutions, we have,

$$\cos (a + b) = \cos a \cos b - \sin a \sin b. \quad \dots (c)$$

74. *To find the formula for the cosine of the difference between two angles or arcs.*

By formula (b) we have,

$$\sin (a + b) = \sin a \cos b + \cos a \sin b.$$

For  $a$  substitute  $90^\circ - a$ , and we have,

$$\sin [90^\circ - (a - b)] = \sin (90^\circ - a) \cos b + \cos (90^\circ - a) \sin b.$$

But,  $\sin [90^\circ - (a - b)] = \cos (a - b)$  (Table II.),

$$\sin (90^\circ - a) = \cos a,$$

$$\cos (90^\circ - a) = \sin a ;$$

making the substitutions, we have,

$$\cos (a - b) = \cos a \cos b + \sin a \sin b. \quad \dots (d)$$

75. *To find the formula for the tangent of the sum of two arcs.*

By Table I.,

$$\tan (a + b) = \frac{\sin (a + b)}{\cos (a + b)},$$

$$= \frac{\sin a \cos b + \cos a \sin b}{\cos a \cos b - \sin a \sin b}, \text{ by (b) and (c),}$$

dividing both numerator and denominator by  $\cos a \cos b$ ,

$$= \frac{\frac{\sin a \cos b}{\cos a \cos b} + \frac{\cos a \sin b}{\cos a \cos b}}{1 - \frac{\sin a \sin b}{\cos a \cos b}},$$

$$\tan (a + b) = \frac{\tan a + \tan b}{1 - \tan a \tan b}. \quad \dots (f)$$

76. To find the tangent of the difference of two arcs.

$$\tan (a - b) = \frac{\sin (a - b)}{\cos (a - b)}, \quad (\text{Table I}).$$

$$= \frac{\sin a \cos b - \cos a \sin b}{\cos a \cos b + \sin a \sin b}, \text{ by (a) and (d').}$$

Dividing both numerator and denominator by  $\cos a \cos a$ ,

$$\tan (a - b) = \frac{\tan a - \tan b}{1 + \tan a \tan b}. \quad \dots (g)$$

77. The student will find no difficulty in deducing the following formulas.

$$\cot (a + b) = \frac{\cot a \cot b - 1}{\cot a + \cot b}, \quad \dots (h)$$

$$\cot (a - b) = \frac{\cot a \cot b + 1}{\cot b - \cot a}. \quad \dots (i)$$

78. To find the sine of twice an arc, in functions of the arc and radius.

By formula (b)

$$\sin (a + b) = \sin a \cos b + \cos a \sin b.$$

Make  $a = b$ , and the formula becomes,

$$\sin 2a = 2 \sin a \cos a. \quad \dots (k)$$

If we substitute for  $a$ ,  $\frac{a}{2}$ , we have,

$$\sin a = 2 \sin \frac{1}{2}a \cos \frac{1}{2}a. \quad \dots (k 1)$$

79. To find the cosine of twice an arc in functions of the arc and radius.

By formula (c)

$$\cos (a + b) = \cos a \cos b - \sin a \sin b.$$

Make  $a = b$ , and we have,

$$\cos 2a = \cos^2 a - \sin^2 a. \quad \dots (l)$$

By Table I,  $\sin^2 a = 1 - \cos^2 a$ ; hence, by substitution,

$$\cos 2a = 2 \cos^2 a - 1. \quad \dots (l 1)$$

Again, since  $\cos^2 a = 1 - \sin^2 a$ , we also have,

$$\cos 2a = 1 - 2 \sin^2 a. \quad \dots (l 2)$$

80. To determine the tangent of twice or thrice a given arc in functions of the arc and radius.

By formula (f)

$$\tan(a + b) = \frac{\tan a + \tan b}{1 - \tan a \tan b}.$$

Make  $b = a$ , and we have,

$$\tan 2a = \frac{2 \tan a}{1 - \tan^2 a} \dots \dots (m)$$

Making  $b = 2a$ , we have,

$$\tan 3a = \frac{\tan a + \tan 2a}{1 - \tan a \tan 2a};$$

substituting the value of  $\tan 2a$ , and reducing, we have,

$$\tan 3a = \frac{3 \tan a - \tan^3 a}{1 - 3 \tan^2 a}; \dots \dots (m 1)$$

The student will readily find

$$\cot 2a = \frac{\cot a - \tan a}{2} \dots \dots (n)$$

81. To find the sine of half an arc in terms of the functions of the arc and radius.

By formula (l 2)

$$\cos 2a = 1 - 2 \sin^2 a.$$

For  $a$ , substitute  $\frac{1}{2}a$ , and we have,

$$\cos a = 1 - 2 \sin^2 \frac{1}{2}a;$$

hence,

$$2 \sin^2 \frac{1}{2}a = 1 - \cos a,$$

$$\sin \frac{1}{2}a = \sqrt{\frac{1 - \cos a}{2}} \dots \dots (o)$$

82. To find the cosine of half a given arc in terms of the functions of the arc and radius.

By formula (l 1)

$$\cos 2a = 2 \cos^2 a - 1.$$

For  $a$ , substitute  $\frac{1}{2}a$ , and we have,

$$\cos a = 2 \cos^2 \frac{1}{2}a - 1;$$

hence,

$$\cos \frac{1}{2}a = \sqrt{\frac{1 + \cos a}{2}} \dots \dots (p)$$

83. To find the tangent of half a given arc, in functions of the arc and radius.

Divide formula (o) by (p), and we have,

$$\tan \frac{1}{2}a = \sqrt{\frac{1 - \cos a}{1 + \cos a}}, \quad \dots (q)$$

Multiplying both terms of the second member by  $\sqrt{1 - \cos a}$ ,

and reducing 
$$\tan \frac{1}{2}a = \frac{1 - \cos a}{\sin a}, \quad \dots (q 1)$$

Multiplying both terms by the denominator  $\sqrt{1 + \cos a}$ ,

and reducing 
$$\tan \frac{1}{2}a = \frac{\sin a}{1 + \cos a}, \quad \dots (q 2)$$

#### GENERAL FORMULAS.

84. The formulas of Articles 71, 72, 73, 74, furnish a great number of consequences; among which it will be enough to mention those of most frequent use. By adding and subtracting we obtain the four which follow,

$$\sin (a + b) + \sin (a - b) = 2 \sin a \cos b, \quad \dots (r)$$

$$\sin (a + b) - \sin (a - b) = 2 \sin b \cos a, \quad \dots (s)$$

$$\cos (a + b) + \cos (a - b) = 2 \cos a \cos b, \quad \dots (t)$$

$$\cos (a - b) - \cos (a + b) = 2 \sin a \sin b, \quad \dots (u)$$

and which serve to change a product of several sines or cosines into *linear* sines or cosines, that is, into sines and cosines multiplied only by constant quantities.

85. If in these formulas we put  $a + b = p$ ,  $a - b = q$ , which gives  $a = \frac{p + q}{2}$ ,  $b = \frac{p - q}{2}$ , we shall find

$$\sin p + \sin q = 2 \sin \frac{1}{2}(p + q) \cos \frac{1}{2}(p - q), \quad \dots (v)$$

$$\sin p - \sin q = 2 \sin \frac{1}{2}(p - q) \cos \frac{1}{2}(p + q), \quad \dots (x)$$

$$\cos p + \cos q = 2 \cos \frac{1}{2}(p + q) \cos \frac{1}{2}(p - q), \quad \dots (y)$$

$$\cos q - \cos p = 2 \sin \frac{1}{2}(p + q) \sin \frac{1}{2}(p - q), \quad \dots (z)$$

If we make  $q = 0$ , we shall have,

$$\sin p = 2 \sin \frac{1}{2}p \cos \frac{1}{2}p, \dots (x 1)$$

$$1 + \cos p = 2 \cos^2 \frac{1}{2}p, \dots (y 1)$$

$$1 - \cos p = 2 \sin^2 \frac{1}{2}p, \dots (z 1)$$

86. From formulas (v), (x), (y), (z), and (k 1), we obtain;

$$\frac{\sin p + \sin q}{\sin p - \sin q} = \frac{\sin \frac{1}{2}(p + q) \cos \frac{1}{2}(p - q)}{\cos \frac{1}{2}(p + q) \sin \frac{1}{2}(p - q)} = \frac{\text{tang } \frac{1}{2}(p + q)}{\text{tang } \frac{1}{2}(p - q)}$$

$$\frac{\sin p + \sin q}{\cos p + \cos q} = \frac{\sin \frac{1}{2}(p + q)}{\cos \frac{1}{2}(p + q)} = \text{tang } \frac{1}{2}(p + q).$$

$$\frac{\sin p + \sin q}{\cos q - \cos p} = \frac{\cos \frac{1}{2}(p - q)}{\sin \frac{1}{2}(p - q)} = \text{cot } \frac{1}{2}(p - q).$$

$$\frac{\sin p - \sin q}{\cos p + \cos q} = \frac{\sin \frac{1}{2}(p - q)}{\cos \frac{1}{2}(p - q)} = \text{tang } \frac{1}{2}(p - q).$$

$$\frac{\sin p - \sin q}{\cos q - \cos p} = \frac{\cos \frac{1}{2}(p + q)}{\sin \frac{1}{2}(p + q)} = \text{cot } \frac{1}{2}(p + q).$$

$$\frac{\cos p + \cos q}{\cos q - \cos p} = \frac{\cos \frac{1}{2}(p + q) \cos \frac{1}{2}(p - q)}{\sin \frac{1}{2}(p + q) \sin \frac{1}{2}(p - q)} = \frac{\text{cot } \frac{1}{2}(p + q)}{\text{tang } \frac{1}{2}(p - q)}$$

$$\frac{\sin p + \sin q}{\sin(p + q)} = \frac{2 \sin \frac{1}{2}(p + q) \cos \frac{1}{2}(p - q)}{2 \sin \frac{1}{2}(p + q) \cos \frac{1}{2}(p + q)} = \frac{\cos \frac{1}{2}(p - q)}{\cos \frac{1}{2}(p + q)}$$

$$\frac{\sin p - \sin q}{\sin(p + q)} = \frac{2 \sin \frac{1}{2}(p - q) \cos \frac{1}{2}(p + q)}{2 \sin \frac{1}{2}(p + q) \cos \frac{1}{2}(p + q)} = \frac{\sin \frac{1}{2}(p - q)}{\sin \frac{1}{2}(p + q)}$$

These formulas are the algebraic enunciations of so many theorems. The first expresses that, *the sum of the sines of two arcs is to the difference of those sines, as the tangent of half the sum of the arcs is to the tangent of half their difference.*

HOMOGENEITY OF TERMS.

87. An expression is said to be homogeneous, when each of its terms contains the same number of literal factors. Thus,

$$\sin^2 a + \cos^2 a = R^2 \dots (1)$$

is homogeneous, since each term contains two literal factors.

If we suppose  $R = 1$ , we have,

$$\sin^2 a + \cos^2 a = 1. \quad \dots \quad (2)$$

This equation merely expresses the numerical relation between the values of  $\sin^2 a$ ,  $\cos^2 a$ , and unity. If we pass from the radius 1 to any other radius, as  $R$ , it becomes necessary to replace these abstract numbers by their corresponding literal factors. For this, we must observe, that the radius of a circle bears the same ratio to any one of the functions of an arc, (the sine for example,) as the radius of any other circle, to the corresponding function of a similar arc in that circle. For example,

$$1 : \sin a :: R : \sin a ;$$

hence,

$$\frac{\sin a}{1} = \frac{\sin a}{R},$$

in which the  $\sin a$ , in the first member, is calculated to the radius 1, and in the second, to the radius  $R$ .

If, now, we substitute this value of  $\sin a$  to radius 1, in equation (2), we have,

$$\frac{\sin a}{R} \times \frac{\sin a}{R} + \frac{\cos a}{R} \times \frac{\cos a}{R} = 1 ;$$

or,

$$\sin^2 a + \cos^2 a = R^2,$$

an expression which is homogeneous: and any expression may be made homogeneous in the same manner; or, it may be made so, *by simply multiplying each term by such a power of  $R$  as shall give the same number of linear factors in all the terms.*

88. Since the sine of an arc divided by the radius is equal to the sine of another arc containing an equal number of degrees divided by its radius, we may, if we please, define the sine of an arc to be the ratio of the radius to the perpendicular let fall from one extremity of the arc on a diameter passing through the other extremity. Giving similar definitions to the other functions of the arc, each will have a corresponding function in either angle of a triangle. For, if in a right angled triangle, we let

$A$  = right angle;  $B$  = angle at base;  $C$  = vertical angle;  
 $a$  = hypotenuse;  $c$  = base;  $b$  = perpendicular,  
 we may deduce all the functions of the angle without any  
 reference to the circle.

For, let us call, by definition,

$$\sin B = \frac{b}{a}, \quad \cos B = \frac{c}{a},$$

$$\tan B = \frac{b}{c}, \quad \cot B = \frac{c}{b},$$

$$\sec B = \frac{a}{c}, \quad \operatorname{cosec} B = \frac{a}{b}.$$

Each of these expressions, regarded as a ratio, is a mere abstract number. If we make the hypotenuse  $a = 1$ , the abstract numbers will then represent parts of a right-angled triangle, or the corresponding functions of a circle whose radius is unity.

*Formulas relating to Triangles.*

89. Let  $ACB$  be any triangle, and designate the sides by the letters  $a, b, c$ ; then (Art. 21),

$$\frac{\sin A}{\sin B} = \frac{a}{b}; \quad \frac{\sin A}{\sin C} = \frac{a}{c}; \quad \frac{\sin B}{\sin C} = \frac{b}{c}: \quad (1)$$

that is, *the sines of the angles are to each other as their opposite sides.*

90. We also have (Art. 22),

$$a + b : a - b :: \tan \frac{1}{2}(A + B) : \tan \frac{1}{2}(A - B):$$

that is, *the sum of any two sides is to their difference, as the tangent of half the sum of the opposite angles to the tangent of half their difference.*

91. In case of a right-angled triangle, in which the right angle is  $B$ , we have (Art. 24),

$$1 : \tan A :: c : a; \text{ hence, } a = c \tan A, \quad (2)$$

And again (Art. 25),

$$1 : \cos A :: b : c; \text{ hence, } c = b \cos A, \quad (3)$$

92. There is but one additional case, that in which the three sides are given to find an angle.

Let  $ACB$  be any triangle, and  $CD$  a perpendicular upon the base. Then, whether the perpendicular falls without or within the triangle, we shall have (B. IV., P. 12),

$$\overline{CB}^2 = \overline{AC}^2 + \overline{AB}^2 - 2AB \times AD.$$

But,  $AD = AC \cos A$ ;

and representing the sides by letters, and substituting for  $AD$ , its value, we have,

$$\cos A = \frac{b^2 + c^2 - a^2}{2bc}.$$

If we now substitute for  $\cos A$ , its value from formula (Art. 81), we shall have,

$$\begin{aligned} 2\sin^2 \frac{1}{2}A &= 1 - \frac{b^2 + c^2 - a^2}{2bc}, \\ &= \frac{2bc - (b^2 + c^2 - a^2)}{2bc}, \\ &= \frac{a^2 - b^2 - c^2 + 2bc}{2bc} = \frac{a^2 - (b - c)^2}{2bc}, \\ &= \frac{(a + b - c)(a + c - b)}{2bc}, \\ \sin \frac{1}{2}A &= \sqrt{\frac{(a + b - c)(a + c - b)}{4bc}}. \end{aligned}$$

If now, we make

$$\frac{1}{2}(a + b + c) = s, \text{ we have } a + b + c = 2s, \text{ and } a + b - c = 2s - 2c; \text{ also, } a + c - b = 2s - 2b: .$$

hence, 
$$\sin \frac{1}{2}A = \sqrt{\frac{(s - b)(s - c)}{bc}},$$

93. If we add 1 to each member of the equation above, in which we have the value of  $\cos A$ , we shall have,

$$1 + \cos A = \frac{2bc + b^2 + c^2 - a^2}{2bc} = \frac{(b + c)^2 - a^2}{2bc}$$

$$= \frac{(b + c + a)(b + c - a)}{2bc}; \text{ and,}$$

$$1 + \cos A = \frac{2s(s - a)}{bc}.$$

Substituting for  $1 + \cos A$ , its value (Art. 82), and reducing, we have,

$$\cos \frac{1}{2} A = \sqrt{\frac{s(s - a)}{bc}}.$$

94. If, now, we recollect that the tangent is equal to the sine divided by the cosine (Art. 47), we have,

$$\tan \frac{1}{2} A = \sqrt{\frac{(s - b)(s - c)}{s(s - a)}};$$

and observing that the same formula applies equally to either of the other angles we have,

$$\tan \frac{1}{2} B = \sqrt{\frac{(s - a)(s - c)}{s(s - b)}},$$

$$\tan \frac{1}{2} C = \sqrt{\frac{(s - a)(s - b)}{s(s - c)}}.$$

#### CONSTRUCTION OF TRIGONOMETRICAL TABLES.

95. If the radius of a circle is taken equal to 1, and the lengths of the lines representing the sines, cosines, tangents, cotangents, &c., for every minute of the quadrant be calculated, and written in a table, this would be a table of *natural* sines, cosines, &c.

96. If such a table were known, it would be easy to calculate a table of sines, &c., to any other radius; since, in different circles, the sines, cosines, &c., of arcs containing the same number of degrees, are to each other as their radii (Art. 87).

97. Let us glance for a moment at some of the methods of calculating a table of natural sines.

When the radius of a circle is 1, the semi-circumfer-

ence is known to be 3.14159265358979. This being divided successively, by 180 and 60, or at once by 10800, gives .0002908882086657, for the arc of 1 minute. Of so small an arc, the sine, chord, and arc, differ almost imperceptibly from each other; so that the first ten of the preceding figures, that is, .0002908882 may be regarded as expressing the sine of 1'; and, in fact, the sine given in the tables, which run to seven places of decimals is .0002909. By Art. 46, we have,

$$\cos = \sqrt{(1 - \sin^2)}.$$

This gives, in the present case,  $\cos 1' = .9999999577$ . Then we have (Art. 84),

$$\begin{aligned} 2 \cos 1' \times \sin 1' - \sin 0' &= \sin 2' = .0005817764, \\ 2 \cos 1' \times \sin 2' - \sin 1' &= \sin 3' = .0008726646, \\ 2 \cos 1' \times \sin 3' - \sin 2' &= \sin 4' = .0011635526, \\ 2 \cos 1' \times \sin 4' - \sin 3' &= \sin 5' = .0014544407, \\ 2 \cos 1' \times \sin 5' - \sin 4' &= \sin 6' = .0017453284, \\ \&c., &\quad \&c., &\quad \&c. \end{aligned}$$

Thus may the work be continued to any extent, the whole difficulty consisting in the multiplication of each successive result by the quantity  $2 \cos 1' = 1.9999999154$ .

Or, having found the sines of 1' and 2', we may determine new formulas applicable to further computation.

If we multiply together formulas (a) and (b) (Art. 71-72), and substitute for  $\cos^2 a$ ,  $1 - \sin^2 a$ , and for  $\cos^2 b$ ,  $1 - \sin^2 b$ , we shall obtain, after reducing,

$$\sin(a + b) \sin(a - b) = \sin^2 a - \sin^2 b;$$

and hence,  $\sin(a + b) \sin(a - b) = (\sin a + \sin b) (\sin a - \sin b)$

or,  $\sin(a - b) : \sin a - \sin b :: \sin a + \sin b : \sin(a + b)$ .

Applying this proportion, we have,

$$\begin{aligned} \sin 1' : \sin 2' - \sin 1' &:: \sin 2' + \sin 1' : \sin 3', \\ \sin 2' : \sin 3' - \sin 1' &:: \sin 3' + \sin 1' : \sin 4', \\ \sin 3' : \sin 4' - \sin 1' &:: \sin 4' + \sin 1' : \sin 5', \\ \sin 4' : \sin 5' - \sin 1' &:: \sin 5' + \sin 1' : \sin 6', \\ \&c., &\quad \&c., &\quad \&c. \end{aligned}$$

In like manner, the computer might proceed for the sines of degrees, &c., thus:

$$\begin{aligned} \sin 1^\circ & : \sin 2^\circ - \sin 1^\circ :: \sin 2^\circ + \sin 1^\circ : \sin 3^\circ, \\ \sin 2^\circ & : \sin 3^\circ - \sin 1^\circ :: \sin 3^\circ + \sin 1^\circ : \sin 4^\circ, \\ \sin 3^\circ & : \sin 4^\circ - \sin 1^\circ :: \sin 4^\circ + \sin 1^\circ : \sin 5^\circ, \\ & \qquad \qquad \qquad \&c., \qquad \qquad \qquad \&c., \qquad \qquad \qquad \&c. \end{aligned}$$

Having found the sines and cosines, the tangents, cotangents, secants, and cosecants, may be computed from them (Table I).

98. There are yet other methods of computation and verification, which it may be well to notice.

Let  $AP$  be an arc of  $60^\circ$ : then the chord  $AP$  is equal to the radius  $CA$  (B. V., P. 4): and the triangle  $CPA$  is equilateral. Hence,  $PM$  bisects  $CA$ , or  $\cos 60^\circ = \frac{1}{2}R$ , or equal to one-half, when  $R = 1$ .

But  $\cos 60^\circ = \sin 30^\circ$  (Art. 12):

hence,  $\sin 30^\circ = \frac{1}{2}$ ; and,

$$\cos 30^\circ = \sqrt{1 - \sin^2 30^\circ} = \frac{1}{2} \sqrt{3}.$$

Then, by formulas of Articles 81, and 82, we can find the sine and cosine of  $15^\circ$ ,  $7^\circ 30'$ ,  $3^\circ 45'$ , &c.

99. If the arc  $AP$  were  $45^\circ$ , the right-angled triangle  $CPM$  would be isosceles, and we should have  $CM = PM$ ; that is,

$$\sin 45^\circ = \cos 45^\circ.$$

Hence,  $\sin^2 a + \cos^2 a = 1$ ,

gives  $2 \sin^2 45^\circ = 1$ ;

or,  $\sin 45^\circ = \cos 45^\circ = \sqrt{\frac{1}{2}} = \frac{1}{2} \sqrt{2}$ .

Also,  $\tan 45^\circ = \frac{\sin 45^\circ}{\cos 45^\circ} = 1 = \cot 45^\circ$ .

Above  $45^\circ$ , the process of computation may be simplified by means of the formula for the tangent of the sum of two arcs (Art. 75).

$$\tan (45^\circ + b) = \frac{1 + \tan b}{1 - \tan b}.$$

100. If the trigonometrical lines themselves were used, it would be necessary, in the calculations, to perform the operations of multiplication and division. To avoid so tedious a method of calculation, we use the logarithms of the sines, cosines, &c.; so that the tables in common use show the values of the logarithms of the sines, cosines, tangents, cotangents, &c., for each degree and minute of the quadrant, calculated to a given radius. This radius is 10,000,000,000, and consequently, its logarithm is 10.

The logarithms of the secants and cosecants are not entered in the tables, being easily found from the cosines and sines. The secant of any arc is equal to the square of radius divided by the cosine, and the cosecant to the square of radius divided by the sine (Table I): hence, the logarithm of the former is found by subtracting the logarithm of the cosine from 20, and that of the latter, by subtracting the logarithm of the sine from 20

# SPHERICAL TRIGONOMETRY.

---

1. A SPHERICAL TRIANGLE is a portion of the surface of a sphere included by the arcs of three great circles (B. IX., D. 1). Hence, every spherical triangle has six parts; three sides and three angles.

2. SPHERICAL TRIGONOMETRY explains the processes of determining, by calculation, the unknown sides and angles of a spherical triangle, when any three of the six parts are given. For these processes, certain formulas are employed which express relations between the six parts of the triangle.

3. Any two parts of a spherical triangle are said to be of the *same species* when they are both less or both greater than  $90^\circ$ ; and they are of different species, when one is less and the other greater than  $90^\circ$ .

4. Let  $ABC$  be a spherical triangle, and  $P$  the centre of the sphere. The angles of the triangle are equal to the dihedral angles included between the planes which determine its sides; viz.: the angle  $A$  to the angle included by the planes  $PAB$  and  $PAC$ ; the angle  $B$  to the angle included by the planes  $PBC$  and  $PBA$ ; the angle  $C$  to the angle included by the planes  $PCB$  and  $PCA$  (B. IX., D. 1). If we regard the side  $PA$  as unity, the sides  $CB$ ,  $CA$ ,  $AB$ , of the spherical triangle will measure the angles  $CPB$ ,  $CPA$ ,  $APB$ , at the centre of the sphere. Denote these sides or angles, respectively, by  $a$ ,  $b$ , and  $c$ .

5. On  $PA$ , the intersection of two faces, assume any point, as  $M$ , and in the planes  $APB$ ,  $APC$ , draw  $MN$  and

$MO$ , both perpendicular to the common intersection  $PA$ : then,  $OMN$  will measure the angle between these planes (B. VI., D. 4), and hence, will be equal to the angle  $A$  of the triangle. Join  $O$  and  $N$  by the straight line  $ON$ .

In the triangles  $NPO$  and  $NMO$ , we have (Plane Trig., Art. 92).

$$\cos P = \cos a = \frac{\overline{PN}^2 + \overline{PO}^2 - \overline{NO}^2}{2PN \times PO}; \cos M = \cos A = \frac{\overline{MN}^2 + \overline{MO}^2 - \overline{NO}^2}{2MO \times MN}$$

and by reducing to entire terms,

$$2PN \times PO \times \cos a = \overline{PN}^2 + \overline{PO}^2 - \overline{NO}^2; 2MO \times MN \times \cos A = \overline{MN}^2 + \overline{MO}^2 - \overline{NO}^2$$

By subtracting the second equation from the first, we have,

$$2(PN \times PO \times \cos a - MO \times MN \cos A) = \overline{PN}^2 - \overline{MN}^2 + \overline{PO}^2 - \overline{MO}^2 = 2\overline{PM}^2$$

and by dividing both members by  $2PN \times PO$ , we have,

$$\cos a - \frac{MO}{PO} \times \frac{MN}{PN} \times \cos A = \frac{PM}{PN} \times \frac{PM}{PO}$$

But (Plane Trig., Art. 88), gives

$$\frac{MO}{PO} = \sin b, \frac{MN}{PN} = \sin c, \frac{PM}{PN} = \cos c, \frac{PM}{PO} = \cos b;$$

substituting these values, we have,

$$\cos a - \sin b \sin c \cos A = \cos b \cos c;$$

and by transposing,

$$\cos a = \cos b \cos c + \sin b \sin c \cos A.$$

A similar equation may be deduced for the cosine of either of the other sides: hence,

$$\left. \begin{aligned} \cos a &= \cos b \cos c + \sin b \sin c \cos A, \\ \cos b &= \cos a \cos c + \sin a \sin c \cos B, \\ \cos c &= \cos a \cos b + \sin a \sin b \cos C. \end{aligned} \right\} (1)$$

That is: *The cosine of either side of a spherical triangle is equal to the product of the cosines of the two other sides plus the product of their sines into the cosine of their included angle.*

The three equations (1) contain all the six parts of the spherical triangle. If three of the six quantities which

enter into these equations be given or known, the remaining three can be determined (Bourdon, Art. 103): hence, if three parts of a spherical triangle be known, the other three may be determined from them. These are the primary formulæ of Spherical Trigonometry. They require to be put under other forms to adapt them to logarithmic computation.

6. Let the angles of the spherical triangle, polar to  $ABC$ , be denoted respectively by  $A', B', C'$ , and the sides by  $a', b', c'$ . Then (B. IX., P. 6),

$$\begin{aligned} a' &= 180^\circ - A, & b' &= 180^\circ - B, & c' &= 180^\circ - C, \\ A' &= 180^\circ - a, & B' &= 180^\circ - b, & C' &= 180^\circ - c. \end{aligned}$$

Since equations (1) are equally applicable to the polar triangle, we have,

$$\cos a' = \cos b' \cos c' + \sin b' \sin c' \cos A':$$

substituting for  $a', b', c'$  and  $A'$ , their values from the polar triangle, we have,

$$-\cos A = \cos B \cos C - \sin B \sin C \cos a;$$

and changing the signs of the terms, we obtain,

$$\cos A = \sin B \sin C \cos a - \cos B \cos C.$$

Similar equations may be deduced from the second and third of equations (1); hence,

$$\left. \begin{aligned} \cos A &= \sin B \sin C \cos a - \cos B \cos C, \\ \cos B &= \sin A \sin C \cos b - \cos A \cos C, \\ \cos C &= \sin A \sin B \cos c - \cos A \cos B. \end{aligned} \right\} (2)$$

That is: *The cosine of either angle of a spherical triangle, is equal to the product of the sines of the two other angles into the cosine of their included side, minus the product of the cosines of those angles.*

7. The first and second of equations (1) give, after transposing the terms,

$$\begin{aligned} \cos a - \cos b \cos c &= \sin b \sin c \cos A, \\ \cos b - \cos a \cos c &= \sin a \sin c \cos B; \end{aligned}$$

by adding, we have,

$$\cos a + \cos b - \cos c (\cos a + \cos b) = \sin^2 c (\sin b \cos A + \sin a \cos B);$$

and by subtracting the second from the first,

$$\cos a - \cos b + \cos c (\cos a - \cos b) = \sin c (\sin b \cos A - \sin a \cos B);$$

these equations may be placed under the forms,

$$(1 - \cos c) (\cos a + \cos b) = \sin c (\sin b \cos A + \sin a \cos B),$$

$$(1 + \cos c) (\cos a - \cos b) = \sin c (\sin b \cos A - \sin a \cos B);$$

multiplying these equations, member by member, we obtain,

$$(1 - \cos^2 c) (\cos^2 a - \cos^2 b) = \sin^2 c (\sin^2 b \cos^2 A - \sin^2 a \cos^2 B):$$

substituting  $\sin^2 c$  for  $1 - \cos^2 c$ ,  $1 - \sin^2 A$  for  $\cos^2 A$ , and  $1 - \sin^2 B$  for  $\cos^2 B$ , and dividing by  $\sin^2 c$ , we have,

$$\cos^2 a - \cos^2 b = \sin^2 b - \sin^2 b \sin^2 A - \sin^2 a + \sin^2 a \sin^2 B:$$

then, since  $\cos^2 a - \cos^2 b = \sin^2 b - \sin^2 a$ , we have,

$$\sin^2 b \sin^2 A = \sin^2 a \sin^2 B;$$

and, by extracting the square root,

$$\sin b \sin A = \sin a \sin B.$$

By employing the first and third of equations (1) we shall find,

$$\sin c \sin A = \sin a \sin C;$$

and, by employing the second and third,

$$\sin b \sin C = \sin c \sin B; \text{ hence,}$$

$$\left. \begin{aligned} \frac{\sin A}{\sin B} &= \frac{\sin a}{\sin b}; \text{ or } \sin B : \sin A :: \sin b : \sin a, \\ \frac{\sin A}{\sin C} &= \frac{\sin a}{\sin c}; \text{ or } \sin C : \sin A :: \sin c : \sin a, \\ \frac{\sin C}{\sin B} &= \frac{\sin c}{\sin b}; \text{ or } \sin B : \sin C :: \sin b : \sin c. \end{aligned} \right\} (3)$$

That is: *In every spherical triangle, the sines of the angles are to each other as the sines of their opposite sides.*

8. Each of the formulas designated (1) involves the three sides of the triangle together with one of the angles. These formulas are used to determine the angles when the three sides are known. It is necessary, however, to put

them under another form to adapt them to logarithmic computation.

Taking the first equation, we have,

$$\cos A = \frac{\cos a - \cos b \cos c}{\sin b \sin c}.$$

Adding 1 to each member, we have,

$$1 + \cos A = \frac{\cos a + \sin b \sin c - \cos b \cos c}{\sin b \sin c}.$$

But,  $1 + \cos A = 2 \cos^2 \frac{1}{2} A$  (Plane Trig., Art. 85),  
and,  $\sin b \sin c - \cos b \cos c = -\cos (b + c)$  (Art. 73);

hence,  $2 \cos^2 \frac{1}{2} A = \frac{\cos a - \cos (b + c)}{\sin b \sin c}$

or,  $\cos^2 \frac{1}{2} A = \frac{\sin \frac{1}{2}(a + b + c) \sin \frac{1}{2}(b + c - a)}{\sin b \sin c}$  (Art. 85).

Putting  $s = a + b + c$ , we shall have,

$$\frac{1}{2}s = \frac{1}{2}(a + b + c) \text{ and } \frac{1}{2}s - a = \frac{1}{2}(b + c - a):$$

hence, 
$$\left. \begin{aligned} \cos \frac{1}{2} A &= \sqrt{\frac{\sin \frac{1}{2}(s) \sin (\frac{1}{2}s - a)}{\sin b \sin c}}, \\ \cos \frac{1}{2} B &= \sqrt{\frac{\sin \frac{1}{2}(s) \sin (\frac{1}{2}s - b)}{\sin a \sin c}}, \\ \cos \frac{1}{2} C &= \sqrt{\frac{\sin \frac{1}{2}(s) \sin (\frac{1}{2}s - c)}{\sin a \sin b}}, \end{aligned} \right\} (4)$$

9. Had we subtracted each member of the first equation in the last article, from 1, instead of adding, we should, by making similar reductions, have found,

$$\left. \begin{aligned} \sin \frac{1}{2} A &= \sqrt{\frac{\sin \frac{1}{2}(a + b - c) \sin \frac{1}{2}(a + c - b)}{\sin b \sin c}}, \\ \sin \frac{1}{2} B &= \sqrt{\frac{\sin \frac{1}{2}(a + b - c) \sin \frac{1}{2}(b + c - a)}{\sin a \sin c}}, \\ \sin \frac{1}{2} C &= \sqrt{\frac{\sin \frac{1}{2}(a + c - b) \sin \frac{1}{2}(b + c - a)}{\sin a \sin b}}, \end{aligned} \right\} (5)$$

Putting  $s = a + b + c$ , we shall have,

$$\frac{1}{2}s - a = \frac{1}{2}(b + c - a), \quad \frac{1}{2}s - b = \frac{1}{2}(a + c - b), \quad \text{and} \quad \frac{1}{2}s - c = \frac{1}{2}(a + b - c);$$

$$\text{hence, } \left. \begin{aligned} \sin \frac{1}{2}A &= \sqrt{\frac{\sin(\frac{1}{2}s - c) \sin(\frac{1}{2}s - b)}{\sin b \sin c}}, \\ \sin \frac{1}{2}B &= \sqrt{\frac{\sin(\frac{1}{2}s - c) \sin(\frac{1}{2}s - a)}{\sin a \sin c}}, \\ \sin \frac{1}{2}C &= \sqrt{\frac{\sin(\frac{1}{2}s - b) \sin(\frac{1}{2}s - a)}{\sin a \sin b}}, \end{aligned} \right\} (6)$$

10. From equations (4) and (6) we obtain,

$$\left. \begin{aligned} \tan \frac{1}{2}A &= \sqrt{\frac{\sin(\frac{1}{2}s - c) \sin(\frac{1}{2}s - b)}{\sin \frac{1}{2}(s) \sin(\frac{1}{2}s - a)}}, \\ \tan \frac{1}{2}B &= \sqrt{\frac{\sin(\frac{1}{2}s - c) \sin(\frac{1}{2}s - a)}{\sin \frac{1}{2}(s) \sin(\frac{1}{2}s - b)}}, \\ \tan \frac{1}{2}C &= \sqrt{\frac{\sin(\frac{1}{2}s - b) \sin(\frac{1}{2}s - a)}{\sin \frac{1}{2}(s) \sin(\frac{1}{2}s - c)}} \end{aligned} \right\} (7)$$

11 We may deduce the value of the side of a triangle in terms of the three angles by applying equations (5), to the polar triangle. Thus, if  $a', b', c', A', B', C'$ , represent the sides and angles of the polar triangle, we shall have (B. IX., P. 6),

$$\begin{aligned} A &= 180^\circ - a', \quad B = 180^\circ - b', \quad C = 180^\circ - c'; \\ a &= 180^\circ - A', \quad b = 180^\circ - B', \quad \text{and} \quad c = 180^\circ - C'; \end{aligned}$$

hence, omitting the ', since the equations are applicable to any triangle, we shall have,

$$\left. \begin{aligned} \cos \frac{1}{2}a &= \sqrt{\frac{\cos \frac{1}{2}(A + B - C) \cos \frac{1}{2}(A + C - B)}{\sin B \sin C}}, \\ \cos \frac{1}{2}b &= \sqrt{\frac{\cos \frac{1}{2}(A + B - C) \cos \frac{1}{2}(B + C - A)}{\sin A \sin C}}, \\ \cos \frac{1}{2}c &= \sqrt{\frac{\cos \frac{1}{2}(A + C - B) \cos \frac{1}{2}(B + C - A)}{\sin A \sin B}}, \end{aligned} \right\} (8)$$

Putting  $S = A + B + C$ , we shall have

$$\frac{1}{2}S - A = \frac{1}{2}(C + B - A), \quad \frac{1}{2}S - B = \frac{1}{2}(A + C - B),$$

and,  $\frac{1}{2}S - C = \frac{1}{2}(A + B - C);$

$$\left. \begin{aligned} \text{hence, } \cos \frac{1}{2}a &= \sqrt{\frac{\cos(\frac{1}{2}S - C) \cos(\frac{1}{2}S - B)}{\sin B \sin C}}, \\ \cos \frac{1}{2}b &= \sqrt{\frac{\cos(\frac{1}{2}S - C) \cos(\frac{1}{2}S - A)}{\sin A \sin C}}, \\ \cos \frac{1}{2}c &= \sqrt{\frac{\cos(\frac{1}{2}S - B) \cos(\frac{1}{2}S - A)}{\sin A \sin B}} \end{aligned} \right\} (9)$$

12. All the formulas necessary for the solution of spherical triangles, may be deduced from equations marked (1). If we substitute for  $\cos b$  in the third equation, its value taken from the second, and substitute for  $\cos^2 a$  its value  $1 - \sin^2 a$ , and then divide by the common factor,  $\sin a$ , we shall have,

$$\cos c \sin a = \sin c \cos a \cos B + \sin b \cos C.$$

But equations (3) give  $\sin b = \frac{\sin B \sin c}{\sin C};$

hence, by substitution,

$$\cos c \sin a = \sin c \cos a \cos B + \frac{\sin B \cos C \sin c}{\sin C}.$$

Dividing by  $\sin c$ , we have,

$$\frac{\cos c}{\sin c} \sin a = \cos a \cos B + \frac{\sin B \cos C}{\sin C}.$$

But,  $\frac{\cos}{\sin} = \cot$  (Art. 55).

Therefore,  $\cot c \sin a = \cos a \cos B + \cot C \sin B.$

Hence we may write the three symmetrical equations,

$$\left. \begin{aligned} \cot a \sin b &= \cos b \cos C + \cot A \sin C, \\ \cot b \sin c &= \cos c \cos A + \cot B \sin A, \\ \cot c \sin a &= \cos a \cos B + \cot C \sin B. \end{aligned} \right\} (10)$$

That is: *In every spherical triangle, the cotangent of one of the sides into the sine of a second side, is equal to the cosine of the second side into the cosine of the included angle, plus the cotangent of the angle opposite the first side into the sine of the included angle.*

## NAPIER'S ANALOGIES.

13. If from the first and third of equations (1),  $\cos c$  be eliminated, there will result, after a little reduction,

$$\cos A \sin c = \cos a \sin b - \cos C \sin a \cos b.$$

From the second and third of equations (1), we get,

$$\cos B \sin c = \cos b \sin a - \cos C \sin b \cos a.$$

Hence, by adding these two equations, and reducing, we shall have,

$$\sin c (\cos A + \cos B) = (1 - \cos C) \sin (a + b).$$

But since,  $\frac{\sin c}{\sin C} = \frac{\sin a}{\sin A} = \frac{\sin b}{\sin B}$ , we shall have,

$$\sin c (\sin A + \sin B) = \sin C (\sin a + \sin b),$$

and,  $\sin c (\sin A - \sin B) = \sin C (\sin a - \sin b)$ .

Dividing these two equations, successively, by the preceding, member by member, we shall have,

$$\frac{\sin A + \sin B}{\cos A + \cos B} = \frac{\sin C}{1 - \cos C} \times \frac{\sin a + \sin b}{\sin (a + b)}.$$

$$\frac{\sin A - \sin B}{\cos A + \cos B} = \frac{\sin C}{1 - \cos C} \times \frac{\sin a - \sin b}{\sin (a + b)};$$

reducing these by the formulas (Plane Trig., Arts. 85, 86), we have,

$$\text{tang } \frac{1}{2}(A + B) = \cot \frac{1}{2} C \times \frac{\cos \frac{1}{2}(a - b)}{\cos \frac{1}{2}(a + b)},$$

$$\text{tang } \frac{1}{2}(A - B) = \cot \frac{1}{2} C \times \frac{\sin \frac{1}{2}(a - b)}{\sin \frac{1}{2}(a + b)}.$$

Hence, two sides,  $a$  and  $b$ , with the included angle  $C$  being given, the two other angles  $A$  and  $B$  may be found by the proportions,

$$\cos \frac{1}{2}(a + b) : \cos \frac{1}{2}(a - b) :: \cot \frac{1}{2} C : \text{tang } \frac{1}{2}(A + B),$$

$$\sin \frac{1}{2}(a + b) : \sin \frac{1}{2}(a - b) :: \cot \frac{1}{2} C : \text{tang } \frac{1}{2}(A - B).$$

We may apply the same proportions to the triangle, polar to  $ABC$ , by putting

$180^\circ - A'$ ,  $180^\circ - B'$ ,  $180^\circ - a'$ ,  $180^\circ - b'$ ,  $180^\circ - c'$ , instead of  $a$ ,  $b$ ,  $A$ ,  $B$ ,  $C$ , respectively; and after reducing and omitting the accents, we shall have,

$$\begin{aligned} \cos \frac{1}{2}(A + B) : \cos \frac{1}{2}(A - B) &:: \operatorname{tang} \frac{1}{2}c : \operatorname{tang} \frac{1}{2}(a + b), \\ \sin \frac{1}{2}(A + B) : \sin \frac{1}{2}(A - B) &:: \operatorname{tang} \frac{1}{2}c : \operatorname{tang} \frac{1}{2}(a - b); \end{aligned}$$

by means of which, when a side  $c$  and the two adjacent angles  $A$  and  $B$  are given, we are enabled to find the two other sides  $a$  and  $b$ . These four proportions are known by the name of *Napier's Analogies*.

14. In the case in which there are given two sides and an angle opposite one of them, there will in general be two solutions corresponding to the two results in Case II., of rectilinear triangles. It is also plain, that this ambiguity will extend itself to the corresponding case of the polar triangle, that is, to the case in which there are given two angles and a side opposite one of them. In every case we shall avoid all false solutions by recollecting,

1st. *That every angle, and every side of a spherical triangle is less than  $180^\circ$ .*

2d. *That the greater angle lies opposite the greater side, and the least angle opposite the least side, and reciprocally.*

NAPIER'S CIRCULAR PARTS.

15. Besides the analogies of Napier already demonstrated, that Geometer invented rules for the solution of all the cases of right-angled spherical triangles.

In every right-angled spherical triangle  $BAC$ , there are six parts: three sides and three angles. If we omit the consideration of the right angle, which is always known, there are five remaining parts, two of which must be given before the others can be determined.

The *circular parts*, as they are called, are the two sides  $c$  and  $b$ , about the right angle, the complements of the oblique angles  $B$  and  $C$ , and the complement of the hypotenuse  $a$ . Hence, there are five circular parts. The right angle  $A$  not

being a circular part, is supposed not to separate the circular parts  $c$  and  $b$ , so that these parts are considered as lying adjacent to each other.

If any two parts of the triangle are given, their corresponding circular parts are also known, and these, together with a required part, will make three parts under consideration. Now, these three parts *will all lie together, or one of them will be separated from both of the others.* For example, if  $B$  and  $c$  were given, and  $a$  required, the three parts considered would lie together.

But, if  $B$  and  $C$  were given, and  $b$  required, the parts would not lie together; for  $B$  would be separated from comp.  $C$  by the part comp.  $a$ , and from  $b$  by the part  $c$ . In either case, comp.  $B$  is the *middle part*. Hence, when there are three of the circular parts under consideration, *the middle part is that one of them to which both of the others are adjacent, or from which both of them are separated.* In the former case, the parts are said to be *adjacent*, and in the latter case, the parts are said to be *opposite*.

This being premised, we are now to prove the following theorems for the solution of right-angled spherical triangles, which, it must be remembered, apply to the *circular parts*, as already defined.

- 1st. *Radius into the sine of the middle part is equal to the rectangle of the tangents of the adjacent parts.*
- 2d. *Radius into the sine of the middle part is equal to the rectangle of the cosines of the opposite parts.*

These theorems are proved by assuming each of the five circular parts, in succession, as the middle part, and by taking the extremes first opposite, and then adjacent. Having thus fixed the three parts which are to be consid-

ered, take that one of the general equations for oblique-angled triangles, that will contain the three corresponding parts of the triangle, together with the right angle; then make  $A = 90^\circ$ , and after making the reductions corresponding to this supposition, the resulting equation will prove the rule for that particular case.

For example, let comp.  $a$ , be the middle part and the extremes opposite. The equation to be applied in this case must contain  $a$ ,  $b$ ,  $c$ , and  $A$ . The first of equations (1) contains these four quantities:

$$\cos a = \cos b \cos c + \sin b \sin c \cos A.$$

If  $A = 90^\circ$   $\cos A = 0$ ;

hence,  $\cos a = \cos b \cos c$ ;

that is, radius, which is 1, into the sine of the middle part, (which is the complement of  $a$ ,) is equal to the rectangle of the cosines of the opposite parts.

Suppose, now, that the complement of  $a$  were the middle part and the other parts adjacent. The equation to be applied must contain the four quantities  $a$ ,  $B$ ,  $C$ , and  $A$ . It is the first of equations (2):

$$\cos A = \sin B \sin C \cos a - \cos B \cos C.$$

Making  $A = 90^\circ$ , we have,

$$\sin B \sin C \cos a = \cos B \cos C,$$

or,  $\cos a = \cot B \cot C$ ;

that is, radius, which is 1, into the sine of the middle part is equal to the rectangle of the tangent of the complement of  $B$ , into the tangent of the complement of  $C$ , that is, to the rectangle of the tangents of the adjacent circular parts.

Let us now take the comp.  $B$ , for the middle part and the extremes opposite. The two other parts under consideration will then be the perpendicular  $b$  and the comp. of the angle  $C$ . The equation to be applied must contain the four parts  $A$ ,  $B$ ,  $C$ , and  $b$ : it is the second of equations (2).

$$\cos B = \sin A \sin C \cos b - \cos A \cos C.$$

Making  $A = 90^\circ$ , we have,

$$\cos B = \sin C \cos b.$$

Let comp.  $B$  be still the middle part and the extremes adjacent. The equation to be applied must then contain the four parts  $a$ ,  $B$ ,  $c$ , and  $A$ . It is similar to equations (10);

$$\cot a \sin c = \cos c \cos B + \cot A \sin B.$$

But, if  $A = 90^\circ$ ,  $\cot A = 0$ ;

hence,  $\cot a \sin c = \cos c \cos B$ ;

or,  $\cos B = \cot a \operatorname{tang} c$ .

By pursuing the same method of demonstration when each circular part is made the middle part, and making the terms homogeneous, when we change the radius from 1 to  $R$  (Plane Trig., Art. 87), we obtain the five following equations, which embrace all the cases.

$$\left. \begin{aligned} R \cos a &= \cos b \cos c = \cot B \cot C, \\ R \cos B &= \cos b \sin C = \cot a \operatorname{tang} c, \\ R \cos C &= \cos c \sin B = \cot a \operatorname{tang} b, \\ R \sin b &= \sin a \sin B = \operatorname{tang} c \cot C, \\ R \sin c &= \sin a \sin C = \operatorname{tang} b \cot B. \end{aligned} \right\} (11)$$

We see from these equations that, *if the middle part is required we must begin the proportion with radius; and when one of the extremes is required we must begin the proportion with the other extreme.*

We also conclude, from the first of the equations, that when the hypotenuse is less than  $90^\circ$ , the sides  $b$  and  $c$  are of the same species, and also that the angles  $B$  and  $C$  are likewise of the same species. When  $a$  is greater than  $90^\circ$ , the sides  $b$  and  $c$  are of different species, and the same is true of the angles  $B$  and  $C$ . We also see from the last two equations that a side and its opposite angle are always of the same species.

These properties are proved by considering the algebraic signs which have been attributed to the trigonometrical functions, and by remembering that the two members of an equation must always have the same algebraic sign.

SOLUTION OF RIGHT-ANGLED SPHERICAL TRIANGLES BY LOGARITHMS.

16. It is to be observed, that when any part of a triangle becomes known by means of its sine only, there may be two values for this part, and consequently two triangles that will satisfy the question; because, the same sine which corresponds to an angle or an arc, corresponds likewise to its supplement. This will not take place, when the unknown quantity is determined by means of its cosine, its tangent, or cotangent. In all these cases, the sign will enable us to decide whether the part in question is less or greater than  $90^\circ$ ; the part is less than  $90^\circ$ , if its cosine, tangent, or cotangent, has the sign  $+$ ; it is greater if one of these quantities has the sign  $-$ .

In order to discover the species of the required part of the triangle, we shall annex the minus sign to the logarithms of all the elements whose cosines, tangents, or cotangents, are negative. Then, by recollecting that the product of the two extremes has the same sign as that of the means, we can at once determine the sign which is to be given to the required element, and then its species will be known.

It has already been observed, that the tables are calculated to the radius  $R$ , whose logarithm is 10 (Plane Trig., Art. 100); hence, all expressions involving the circular functions, must be made homogeneous, to adapt them to the logarithmic formulas.

EXAMPLES.

1. In the right-angled spherical triangle  $BAC$ , right-angled at  $A$ , there are given  $a = 64^\circ 40'$  and  $b = 42^\circ 12'$ : required the remaining parts.

First, to find the side  $c$ .

The hypotenuse  $a$  corresponds to the middle part, and the extremes are opposite: hence,

$$R \cos a = \cos b \cos c, \text{ or,}$$

|     |          |          |             |      |           |
|-----|----------|----------|-------------|------|-----------|
| cos | <i>b</i> | 42° 12'  | ar. comp.   | log. | 0.130296  |
| :   | <i>R</i> | .        | .           | .    | 10.000000 |
| ::  | cos      | <i>a</i> | 64° 40'     | .    | 9.631326  |
| :   | cos      | <i>c</i> | 54° 43' 07" | .    | 9.761622  |

To find the angle *B*.

The side *b* is the middle part and the extremes opposite: hence,

$$R \sin b = \cos (\text{comp. } a) \times \cos (\text{comp. } B) = \sin a \sin B.$$

|     |          |          |             |      |           |
|-----|----------|----------|-------------|------|-----------|
| sin | <i>a</i> | 64° 40'  | ar. comp.   | log. | 0.043911  |
| :   | sin      | <i>b</i> | 42° 12'     | .    | 9.827189  |
| ::  | <i>R</i> | .        | .           | .    | 10.000000 |
| :   | sin      | <i>B</i> | 48° 00' 14" | .    | 9.871100  |

To find the angle *C*.

The angle *C* is the middle part and the extremes adjacent: hence,

$$R \cos C = \cot a \text{ tang } b.$$

|          |      |          |             |      |          |
|----------|------|----------|-------------|------|----------|
| <i>R</i> | .    | .        | ar. comp.   | log. | 0.000000 |
| :        | cot  | <i>a</i> | 64° 40'     | .    | 9.675237 |
| ::       | tang | <i>b</i> | 42° 12'     | .    | 9.957485 |
| :        | cos  | <i>C</i> | 64° 34' 46" | .    | 9.632722 |

2. In a right-angled triangle *BAC*, there are given the hypotenuse *a* = 105° 34', and the angle *B* = 80° 40': required the remaining parts.

To find the angle *C*.

The hypotenuse is the middle part and the extremes adjacent: hence,

$$R \cos a = \cot B \cot C.$$

|     |          |          |              |      |             |
|-----|----------|----------|--------------|------|-------------|
| cot | <i>B</i> | 80° 40'  | ar. comp.    | log. | 0.784220 +  |
| :   | cos      | <i>a</i> | 105° 34'     | .    | 9.428717 -  |
| ::  | <i>R</i> | .        | .            | .    | 10.000000 + |
| :   | cot      | <i>C</i> | 148° 30' 54" | .    | 10.212937 - |

Since the cotangent of *C* is negative, the angle *C* is greater than 90°, and is the supplement of the arc which would correspond to the cotangent, if it were positive.

To find the side  $c$ .

The angle  $B$  corresponds to the middle part, and the extremes are adjacent: hence,

$$R \cos B = \cot a \tan c.$$

|         |                 |                      |      |          |   |
|---------|-----------------|----------------------|------|----------|---|
| cot $a$ | $105^\circ 34'$ | ar. comp.            | log. | 0.555053 | - |
| :       | $R$             | .                    | .    | .        | . |
| ::      | cos $B$         | $80^\circ 40'$       | .    | .        | . |
| :       | tang $c$        | $149^\circ 47' 36''$ | .    | .        | . |
|         |                 |                      |      | 9.209992 | + |
|         |                 |                      |      | 9.765045 | - |

To find the side  $b$ .

The side  $b$  is the middle part and the extremes are opposite: hence,

$$R \sin b = \sin a \sin B.$$

|     |         |                     |      |          |          |
|-----|---------|---------------------|------|----------|----------|
| $R$ | .       | ar. comp.           | log. | .        | 0.000000 |
| :   | sin $a$ | $105^\circ 34'$     | .    | .        | .        |
| ::  | sin $B$ | $80^\circ 40'$      | .    | .        | .        |
| :   | sin $b$ | $71^\circ 54' 33''$ | .    | .        | .        |
|     |         |                     |      | 9.994212 |          |
|     |         |                     |      | 9.977982 |          |

OF QUADRANTAL TRIANGLES.

17. A *quadrantal* spherical triangle is one which has one of its sides equal to  $90^\circ$ .

Let  $BAC$  be a quadrantal triangle of which the side  $a = 90^\circ$ . If we pass to the corresponding polar triangle, we shall have

$$A' = 180^\circ - a = 90^\circ, B' = 180^\circ - b,$$

$$C' = 180^\circ - c, a' = 180^\circ - A,$$

$$b' = 180^\circ - B, c' = 180^\circ - C;$$

from which we see, that the polar triangle will be right-angled at  $A'$ , and hence, every case may be referred to a right-angled triangle.

But we can solve the quadrantal triangle by means of the right-angled triangle in a manner still more simple.

Let the side  $BC$  of the quadrantal triangle  $BAC$ , be equal to  $90^\circ$ ; produce the side  $CA$  till  $CD$  is equal to  $90^\circ$ , and conceive the arc of a great circle to be drawn through  $B$  and  $D$ .

Then  $C$  will be the pole of the arc  $BD$ , and the angle  $C$  will be measured by  $BD$  (B. IX., p. 4), and the angles  $CBD$  and  $D$  will be right angles. Now before the remaining parts of the quadrantal triangle can be found, at least two parts must be given in addition to the side  $BC = 90^\circ$ ; in which case two parts of the right-angled triangle  $BDA$ , together with the right angle, become known. Hence, the conditions which enable us to determine one of these triangles, will enable us also to determine the other.

EXAMPLES.

1. In the quadrantal triangle  $BCA$ , there are given  $CB = 90^\circ$ , the angle  $C = 42^\circ 12'$ , and the angle  $A = 115^\circ 20'$ ; required the remaining parts.

Having produced  $CA$  to  $D$ , making  $CD = 90^\circ$ , and drawn the arc  $BD$ , there will then be given in the right-angled triangle  $BAD$ , the side  $a = C = 42^\circ 12'$ , and the angle  $BAD = 180^\circ - BAC = 180^\circ - 115^\circ 20' = 64^\circ 40'$ , to find the remaining parts.

To find the side  $d$ .

The side  $a$  is the middle part, and the extremes opposite: hence,

$$R \sin a = \sin A \sin d.$$

|     |     |         |             |      |                 |
|-----|-----|---------|-------------|------|-----------------|
| sin | A   | 64° 40' | ar. comp.   | log. | 0.043911        |
| :   | R   | .       | .           | .    | 10.000000       |
| ::  | sin | a       | 42° 12'     | .    | 9.827189        |
| :   | sin | d       | 48° 00' 14" | .    | <u>9.871100</u> |

To find the angle  $B$ .

The angle  $A$  corresponds to the middle part, and the extremes are opposite: hence,

$$R \cos A = \sin B \cos a.$$

|    |         |              |           |      |           |
|----|---------|--------------|-----------|------|-----------|
|    | cos $a$ | 42° 12'      | ar. comp. | log. | 0.130296  |
| :  | $R$     | .            | .         | .    | 10.000000 |
| :: | cos $A$ | 64° 40'      | .         | .    | 9.631326  |
| :  | sin $B$ | 35° 16' 53'' | .         | .    | 9.761622  |

To find the side  $b$ .

The side  $b$  is the middle part, and the extremes are adjacent: hence,

$$R \sin b = \cot A \tan a.$$

|    |          |              |           |      |          |
|----|----------|--------------|-----------|------|----------|
|    | $R$      | .            | ar. comp. | log. | 0.000000 |
| :  | cot $A$  | 64° 40'      | .         | .    | 9.675237 |
| :: | tang $a$ | 42° 12'      | .         | .    | 9.957485 |
| :  | sin $b$  | 25° 25' 14'' | .         | .    | 9.632722 |

Hence,  $CA = 90^\circ - b = 90^\circ - 25^\circ 25' 14'' = 64^\circ 34' 46''$   
 $CBA = 90^\circ - ABD = 90^\circ - 35^\circ 16' 53'' = 54^\circ 43' 07''$   
 $BA = d \quad \quad \quad = 48^\circ 00' 14''$

2. In the right-angled triangle  $BAC$ , right-angled at  $A$ , there are given  $a = 115^\circ 25'$ , and  $c = 60^\circ 59'$ : required the remaining parts.

$$\text{Ans. } \begin{cases} B = 148^\circ 58' 45'' \\ C = 75^\circ 30' 33'' \\ b = 152^\circ 13' 50'' \end{cases}$$

3. In the right-angled spherical triangle  $BAC$ , right-angled at  $A$ , there are given  $c = 116^\circ 30' 43''$ , and  $b = 29^\circ 41' 32''$ : required the remaining parts.

$$\text{Ans. } \begin{cases} C = 103^\circ 52' 46'' \\ B = 32^\circ 30' 22'' \\ a = 112^\circ 48' 58'' \end{cases}$$

4. In a quadrantal triangle, there are given the quadrantal side  $= 90^\circ$ , an adjacent side  $= 115^\circ 09'$ , and the included angle  $= 115^\circ 55'$ : required the remaining parts.

$$\text{Ans. } \begin{cases} \text{side,} & 113^\circ 18' 19'' \\ \text{angles,} & \begin{cases} 117^\circ 33' 52'' \\ 101^\circ 40' 07'' \end{cases} \end{cases}$$

SOLUTION OF OBLIQUE-ANGLED TRIANGLES BY LOGARITHMS.

18. There are six cases which occur in the solution of oblique-angled spherical triangles.

1. Having given two sides, and an angle opposite one of them.
2. Having given two angles, and a side opposite one of them.
3. Having given the three sides of a triangle, to find the angles.
4. Having given the three angles of a triangle, to find the sides.
5. Having given two sides and the included angle.
6. Having given two angles and the included side.

CASE I.

*Given two sides, and an angle opposite one of them, to find the remaining parts.*

19. For this case, we employ proportions (3);

$$\sin a : \sin b :: \sin A : \sin B.$$

*Ex. 1.* Given the side  $a = 44^\circ 13' 45''$ ,  $b = 84^\circ 14' 29''$ , and the angle  $A = 32^\circ 26' 07''$ ; required the remaining parts.

To find the angle  $B$ .

|     |     |                     |                          |           |                              |
|-----|-----|---------------------|--------------------------|-----------|------------------------------|
| sin | $a$ | $44^\circ 13' 45''$ | ar. comp.                | log.      | 0.156437                     |
| :   | sin | $b$                 | 84° 14' 29''             | . . . . . | 9.997803                     |
| ::  | sin | $A$                 | $32^\circ 26' 07''$      | . . . . . | 9.729445                     |
| :   | sin | $B$                 | $49^\circ 54' 38''$ , or | sin $B'$  | $130^\circ 5' 22''$ 9.883685 |

Since the sine of an arc is the same as the sine of its supplement, there are two angles corresponding to the logarithmic sine 9.883685, and these angles are supplements of each other. It does not follow, however, that both of them will satisfy all the other conditions of the question. If they do, there will be two triangles  $ACB'$ ,  $ACB$ ; if not, there will be but one.

To determine the circumstances under which this ambiguity arises, we will consider the 2d of equations (1)

$$\cos b = \cos a \cos c + \sin a \sin c \cos B,$$

from which we obtain,

$$\cos B = \frac{\cos b - \cos a \cos c}{\sin a \sin c}.$$

Now, if  $\cos b$  be greater than  $\cos a$ , we shall have,

$$\cos b > \cos a \cos c,$$

or, the sign of the second member of the equation will depend on that of  $\cos b$ . Hence,  $\cos B$  and  $\cos b$  will have the same sign, or  $B$  and  $b$  will be of the same species, and there will be but one triangle.

But when  $\cos b > \cos a$ , then  $\sin b < \sin a$ : hence,

*If the sine of the side opposite the required angle be less than the sine of the other given side, there will be but one triangle.*

If, however,  $\sin b > \sin a$ , the  $\cos b$  will be less than  $\cos a$ , and it is plain that such a value may then be given to  $c$ , as to render

$$\cos b < \cos a \cos c,$$

or, the sign of the second member may be made to depend on  $\cos c$ .

We can therefore give such values to  $c$  as to satisfy the two equations,

$$+ \cos B = \frac{\cos b - \cos a \cos c}{\sin a \sin c},$$

$$- \cos B = \frac{\cos b - \cos a \cos c}{\sin a \sin c}:$$

*hence, if the sine of the side opposite the required angle be greater than the sine of the other given side, there will be two triangles which will fulfil the given conditions.*

Let us, however, consider the triangle  $ACB$ , in which we are yet to find the base  $AB$  and the angle  $C$ . We can find these parts by dividing the triangle into two right-angled triangles. Draw the arc  $CD$  perpendicular to the base  $AB$ : then, in each of the triangles there will be given the hypotenuse and the angle at the base. And generally,

when it is proposed to solve an oblique-angled triangle by means of the right-angled triangle, we must so draw the perpendicular, that it shall pass through the extremity of a given side, and lie opposite to a given angle.

To find the angle  $C$ , in the triangle  $ACD$ .

|            |                     |           |      |           |
|------------|---------------------|-----------|------|-----------|
| cot $A$    | $32^\circ 26' 07''$ | ar. comp. | log. | 9.803105  |
| :          | $R$                 |           |      | 10.000000 |
| :: cos $b$ | $84^\circ 14' 29''$ |           |      | 9.001465  |
| :          | cot $ACD$           |           |      | 8.804570  |

To find the angle  $C$  in the triangle  $DCB$ .

|            |                     |           |      |           |
|------------|---------------------|-----------|------|-----------|
| cot $B$    | $49^\circ 54' 38''$ | ar. comp. | log. | 0.074810  |
| :          | $R$                 |           |      | 10.000000 |
| :: cos $a$ | $44^\circ 13' 45''$ |           |      | 9.855250  |
| :          | cot $DCB$           |           |      | 9.930060  |

Hence,  $ACB = 135^\circ 56' 44''$ .

To find the side  $AB$ .

|            |                     |           |      |          |
|------------|---------------------|-----------|------|----------|
| sin $A$    | $32^\circ 26' 07''$ | ar. comp. | log. | 0.270555 |
| :          | sin $C$             |           |      | 9.842198 |
| :: sin $a$ | $44^\circ 13' 45''$ |           |      | 9.843563 |
| :          | sin $c$             |           |      | 9.956316 |

The arc  $64^\circ 43' 48''$ , which corresponds to  $\sin c$  is not the value of the side  $AB$ : for the side  $AB$  must be greater than  $b$ , since it lies opposite to a greater angle. But  $b = 84^\circ 14' 29''$ : hence, the side  $AB$  must be the supplement of  $64^\circ 43' 48''$ , or,  $115^\circ 16' 12''$ .

*Ex.* 2. Given  $b = 91^\circ 03' 25''$ ,  $a = 40^\circ 36' 37''$ , and  $A = 35^\circ 57' 15''$ : required the remaining parts, when the obtuse angle  $B$  is taken.

$$\text{Ans. } \begin{cases} B = 115^\circ 35' 41'' \\ C = 58^\circ 30' 57'' \\ c = 70^\circ 58' 52'' \end{cases}$$

CASE II.

*Having given two angles and a side opposite one of them, to find the remaining parts.*

20. For this case, we employ the proportions (3).

$$\sin A : \sin B :: \sin a : \sin b.$$

*Ex. 1.* In a spherical triangle  $ABC$ , there are given the angle  $A = 50^\circ 12'$ ,  $B = 58^\circ 8'$ , and the side  $a = 62^\circ 42'$ ; to find the remaining parts.

To find the side  $b$ .

|          |                |  |           |                 |
|----------|----------------|--|-----------|-----------------|
| $\sin A$ | $50^\circ 12'$ | ar. comp.                                      | log.      | 0.114478        |
| :        | $\sin B$       | $58^\circ 08'$                                 | . . . . . | 9.929050        |
| ::       | $\sin a$       | $62^\circ 42'$                                 | . . . . . | 9.948715        |
| :        | $\sin b$       | $79^\circ 12' 10''$ , or, $100^\circ 47' 50''$ |           | <u>9.992243</u> |

We see here, as in the last example, that there are two angles corresponding to the 4th term of the proportion, and these angles are supplements of each other, since they have the same sine. It does not follow, however, that both of them will satisfy all the conditions of the question. If they do, there will be two triangles; if not there will be but one.

To determine when there are two triangles, and also when there is but one, let us consider the second of equations (2),

$$\cos B = \sin A \sin C \cos b - \cos A \cos C,$$

which gives, 
$$\cos b = \frac{\cos B + \cos A \cos C}{\sin A \sin C}.$$

Now, if  $\cos B$  be greater than  $\cos A$ , we shall have,

$$\cos B > \cos A \cos C,$$

and hence, the sign of the second member of the equation will depend on that of  $\cos B$ , and consequently  $\cos b$  and  $\cos B$  will have the same algebraic sign, or  $b$  and  $B$  will be of the same species. But when  $\cos B > \cos A$  the  $\sin B < \sin A$ : hence,

*If the sine of the angle opposite the required side be less*

than the sine of the other given angle, there will be but one solution.

If, however,  $\sin B > \sin A$ , the  $\cos B$  will be less than  $\cos A$ , and it is plain that such a value may then be given to  $\cos C$ , as to render

$$\cos B < \cos A \cos C,$$

or, the sign of the second member of the equation may be made to depend on  $\cos C$ . We can therefore give such values to  $C$  as to satisfy the two equations,

$$+ \cos b = \frac{\cos B + \cos A \cos C}{\sin A \sin C},$$

and 
$$- \cos b = \frac{\cos B + \cos A \cos C}{\sin A \sin C}.$$

Hence, if the sine of the angle opposite the required side be greater than the sine of the other given angle, there will be two solutions.

Let us first suppose the side  $b$  to be less than  $90^\circ$ , or, equal to  $79^\circ 12' 10''$ .

If, now, we let fall from the angle  $C$ , a perpendicular on the base  $BA$ , the triangle will be divided into two right-angled triangles, in each of which there will be two parts known besides the right angle.

Calculating the parts by Napier's rules, we find,

$$C = 130^\circ 54' 28''$$

$$c = 119^\circ 03' 26''$$

If we take the side  $b = 100^\circ 47' 50''$ , we shall find,

$$C = 156^\circ 15' 06''$$

$$c = 152^\circ 14' 18''$$

*Ex. 2.* In a spherical triangle  $ABC$ , there are given  $A = 103^\circ 59' 57''$ ,  $B = 46^\circ 18' 07''$ , and  $a = 42^\circ 08' 48''$ ; required the remaining parts.

There will be but one triangle, since  $\sin B < \sin A$ .

$$\text{Ans. } \begin{cases} b = 30^\circ \\ C = 36^\circ 07' 54'' \\ c = 24^\circ 03' 56'' \end{cases}$$

CASE III.

*Having given the three sides of a spherical triangle, to find the angles.*

21. For this case we use equations (4).

$$\cos \frac{1}{2}A = R\sqrt{\frac{\sin \frac{1}{2}s \sin (\frac{1}{2}s - a)}{\sin b \sin c}}$$

*Ex. 1.* In an oblique-angled spherical triangle, there are given  $a = 56^\circ 40'$ ,  $b = 83^\circ 13'$ , and  $c = 114^\circ 30'$ : required the angles.

$$\begin{aligned} \frac{1}{2}(a + b + c) &= \frac{1}{2}s = 127^\circ 11' 30'', \\ \frac{1}{2}(b + c - a) &= (\frac{1}{2}s - a) = 70^\circ 31' 30''. \end{aligned}$$

|                                   |                      |           |           |
|-----------------------------------|----------------------|-----------|-----------|
| log sin $\frac{1}{2}s$            | $127^\circ 11' 30''$ | . . .     | 9.901250  |
| log sin $(\frac{1}{2}s - a)$      | $70^\circ 31' 30''$  | . . .     | 9.974413  |
| - log sin $b$                     | $83^\circ 13'$       | ar. comp. | 0.003051  |
| - log sin $c$                     | $114^\circ 30'$      | ar. comp. | 0.040977  |
| Sum                               | . . . . .            | . . . . . | 19.919691 |
| Half sum = log cos $\frac{1}{2}A$ | $24^\circ 15' 39''$  | . . .     | 9.959845  |

Hence, angle  $A = 48^\circ 31' 18''$ .

The addition of twice the logarithm of radius, or 20, to the numerator of the quantity under the radical, just cancels the 20 which is to be subtracted on account of the arithmetical complements, so that the 20, in both cases, may be omitted.

Applying the same formulas to the angles  $B$  and  $C$ , we find,

$$\begin{aligned} B &= 62^\circ 55' 46'' \\ C &= 125^\circ 19' 02'' \end{aligned}$$

*Ex. 2.* In a spherical triangle there are given  $a = 40^\circ 18' 29''$ ,  $b = 67^\circ 14' 28''$ , and  $c = 89^\circ 47' 06''$ : required the three angles.

$$\text{Ans. } \left\{ \begin{aligned} A &= 34^\circ 22' 16'' \\ B &= 53^\circ 35' 16'' \\ C &= 119^\circ 13' 32'' \end{aligned} \right.$$

CASE IV.

Having given the three angles of a spherical triangle, to find the three sides.

22. For this case we employ equations (9).

$$\cos \frac{1}{2}a = R \sqrt{\frac{\cos (\frac{1}{2}S - B) \cos (\frac{1}{2}S - C)}{\sin B \sin C}}$$

Ex. 1. In a spherical triangle  $ABC$  there are given  $A = 48^\circ 30'$ ,  $B = 125^\circ 20'$ , and  $C = 62^\circ 54'$ ; required the sides.

|   |                         |           |           |
|---|-------------------------|-----------|-----------|
| $\frac{1}{2}(A + B + C) = \frac{1}{2}S =$ | $118^\circ 22'$         |           |           |
| $(\frac{1}{2}S - A)$                      | $. . . = 69^\circ 52'$  |           |           |
| $(\frac{1}{2}S - B)$                      | $. . . = - 6^\circ 58'$ |           |           |
| $(\frac{1}{2}S - C)$                      | $. . . = 55^\circ 28'$  |           |           |
| log cos $(\frac{1}{2}S - B)$              | $- 6^\circ 58'$         | . . .     | 9.996782  |
| log cos $(\frac{1}{2}S - C)$              | $55^\circ 28'$          | . . .     | 9.753495  |
| - log sin $B$                             | $125^\circ 20'$         | ar. comp. | 0.088415  |
| - log sin $C$                             | $62^\circ 54'$          | ar. comp. | 0.050506  |
| Sum . . . . .                             |                         |           | 19.889198 |
| Half sum = log cos $\frac{1}{2}a$         | $28^\circ 19' 48''$     | . . .     | 9.944599  |

Hence, side  $a = 56^\circ 39' 36''$ .

In a similar manner we find,

$$b = 114^\circ 29' 58''$$

$$c = 83^\circ 12' 06''$$

Ex. 2. In a spherical triangle  $ABC$ , there are given  $A = 109^\circ 55' 42''$ ,  $B = 116^\circ 38' 33''$ , and  $C = 120^\circ 43' 37''$ ; required the three sides.

$$\text{Ans. } \begin{cases} a = 98^\circ 21' 40'' \\ b = 109^\circ 50' 22'' \\ c = 115^\circ 13' 26'' \end{cases}$$

CASE V.

Having given in a spherical triangle, two sides and their included angle, to find the remaining parts.

23. For this case we employ the two first of Napier's Analogies.

$$\begin{aligned} \cos \frac{1}{2}(a + b) : \cos \frac{1}{2}(a - b) &:: \cot \frac{1}{2}C : \tan \frac{1}{2}(A + B), \\ \sin \frac{1}{2}(a + b) : \sin \frac{1}{2}(a - b) &:: \cot \frac{1}{2}C : \tan \frac{1}{2}(A - B). \end{aligned}$$

Having found the half sum and the half difference of the angles  $A$  and  $B$ , the angles themselves become known; for, the greater angle is equal to the half sum plus the half difference, and the lesser is equal to the half sum minus the half difference.

The greater angle is then to be placed opposite the greater side. The remaining side of the triangle can be found by Case II.

*Ex. 1.* In a spherical triangle  $ABC$ , there are given  $a = 68^\circ 46' 02''$ ,  $b = 37^\circ 10'$ , and  $C = 39^\circ 23'$ ; to find the remaining parts.

$$\frac{1}{2}(a + b) = 52^\circ 58' 1'', \quad \frac{1}{2}(a - b) = 15^\circ 48' 01'', \quad \frac{1}{2}C = 19^\circ 41' 30''.$$

|                             |                     |      |           |           |
|-----------------------------|---------------------|------|-----------|-----------|
| $\cos \frac{1}{2}(a + b)$   | $52^\circ 58' 01''$ | log. | ar. comp. | 0.220205  |
| : $\cos \frac{1}{2}(a - b)$ | $15^\circ 48' 01''$ | .    | .         | 9.983272  |
| :: $\cot \frac{1}{2}C$      | $19^\circ 41' 30''$ | .    | .         | 10.446253 |
| : $\tan \frac{1}{2}(A + B)$ | $77^\circ 22' 25''$ | .    | .         | 10.649730 |

|                             |                     |      |           |           |
|-----------------------------|---------------------|------|-----------|-----------|
| $\sin \frac{1}{2}(a + b)$   | $52^\circ 58' 01''$ | log. | ar. comp. | 0.097840  |
| : $\sin \frac{1}{2}(a - b)$ | $15^\circ 48' 01''$ | .    | .         | 9.435023  |
| :: $\cot \frac{1}{2}C$      | $19^\circ 41' 30''$ | .    | .         | 10.446253 |
| : $\tan \frac{1}{2}(A - B)$ | $43^\circ 37' 21''$ | .    | .         | 9.979116  |

Hence,  $A = 77^\circ 22' 25'' + 43^\circ 37' 21'' = 120^\circ 59' 47''$

$B = 77^\circ 22' 25'' - 43^\circ 37' 21'' = 33^\circ 45' 03''$

side  $c$  . . . . . =  $43^\circ 37' 37''$

*Ex. 2.* In a spherical triangle  $ABC$ , there are given  $b = 83^\circ 19' 42''$ ,  $c = 23^\circ 27' 46''$ ; the contained angle  $A = 20^\circ 39' 48''$ : to find the remaining parts.

$$\text{Ans. } \begin{cases} B = 156^\circ 30' 16'' \\ C = 9^\circ 11' 48'' \\ a = 61^\circ 32' 12'' \end{cases}$$

CASE VI.

*In a spherical triangle, having given two angles and the included side, to find the remaining parts.*

24. For this case, we employ the second of Napier's Analogies.

$$\cos \frac{1}{2}(A + B) : \cos \frac{1}{2}(A - B) :: \operatorname{tang} \frac{1}{2}c : \operatorname{tang} \frac{1}{2}(a + b),$$

$$\sin \frac{1}{2}(A + B) : \sin \frac{1}{2}(A - B) :: \operatorname{tang} \frac{1}{2}c : \operatorname{tang} \frac{1}{2}(a - b).$$

From which  $a$  and  $b$  are found as in the last case. The remaining angle can then be found by Case I.

*Ex. 1.* In a spherical triangle  $ABC$ , there are given  $A = 81^\circ 38' 20''$ ,  $B = 70^\circ 09' 38''$ ,  $c = 59^\circ 16' 23''$ : to find the remaining parts.

$$\frac{1}{2}(A+B)=75^\circ 53' 59'', \frac{1}{2}(A-B)=5^\circ 44' 21'', \frac{1}{2}c=29^\circ 38' 11''.$$

|                           |  |                     |           |                  |
|---------------------------|--|---------------------|-----------|------------------|
| $\cos \frac{1}{2}(A + B)$ | $75^\circ 53' 59''$                      | log.                | ar. comp. | 0.613287         |
| :                         | $\cos \frac{1}{2}(A - B)$                | $5^\circ 44' 21''$  | .         | 9.997818         |
| ::                        | $\operatorname{tang} \frac{1}{2}c$       | $29^\circ 38' 11''$ | .         | 9.755051         |
| :                         | $\operatorname{tang} \frac{1}{2}(a + b)$ | $66^\circ 42' 52''$ | .         | <u>10.366156</u> |

|                           |  |                     |           |                 |
|---------------------------|--|---------------------|-----------|-----------------|
| $\sin \frac{1}{2}(A + B)$ | $75^\circ 53' 59''$                      | log.                | ar. comp. | 0.013286        |
| :                         | $\sin \frac{1}{2}(A - B)$                | $5^\circ 14' 21''$  | .         | 9.000000        |
| ::                        | $\operatorname{tang} \frac{1}{2}c$       | $29^\circ 38' 11''$ | .         | <u>9.755051</u> |
| :                         | $\operatorname{tang} \frac{1}{2}(a - b)$ | $3^\circ 21' 25''$  | .         | <u>8.768337</u> |

Hence,  $a = 66^\circ 42' 52'' + 3^\circ 21' 25'' = 70^\circ 04' 17''$   
 $b = 66^\circ 42' 52'' - 3^\circ 21' 25'' = 63^\circ 21' 27''$   
 angle  $C = 64^\circ 46' 33''$

*Ex. 2.* In a spherical triangle  $ABC$ , there are given  $A = 34^\circ 15' 03''$ ,  $B = 42^\circ 15' 13''$ , and  $c = 76^\circ 35' 36''$ : to find the remaining parts.

$$\text{Ans. } \begin{cases} a = 40^\circ 00' 10'' \\ b = 50^\circ 10' 30'' \\ C = 121^\circ 36' 19'' \end{cases}$$

# MENSURATION OF SURFACES.

---

1. WE determine the area, or contents of a surface, by finding how many times the given surface contains some other surface which is assumed as the unit of measure. Thus, when we say that a square yard contains 9 square feet, we should understand that one square foot is taken for the unit of measure, and that this unit is contained 9 times in the square yard.

2. The most convenient unit of measure for a surface, is a square whose side is the linear unit in which the linear dimensions of the figure are estimated. Thus, if the linear dimensions are feet, it will be most convenient to express the area in square feet; if the linear dimensions are yards, it will be most convenient to express the area in square yards, &c.

3. We have already seen (B. IV., P. 4, s. 2), that the term, rectangle or product of two lines, designates the rectangle constructed on the lines as sides; and that the numerical value of this product expresses the number of times which the rectangle contains its unit of measure.

4. To find the area of a square, a rectangle, or a parallelogram.

*Multiply the base by the altitude, and the product will be the area* (B. IV., P. 5).

*Ex.* 1. To find the area of a parallelogram, the base being 12.25, and the altitude 8.5. *Ans.* 104.125.

2. What is the area of a square whose side is 204.3 feet? *Ans.* 41738.49 sq. ft.

3. What are the contents, in square yards, of a rectangle whose base is 66.3 feet, and altitude 33.3 feet?

*Ans.* 245.31.

4. To find the area of a rectangular board, whose length is  $12\frac{1}{2}$  feet, and breadth 9 inches. *Ans.*  $9\frac{3}{8}$  sq. ft.

5. To find the number of square yards of painting in a parallelogram, whose base is 37 feet, and altitude 5 feet 8 inches. *Ans.*  $21\frac{1}{2}$ .

5. To find the area of a triangle.

CASE I.

When the base and altitude are given.

*Multiply the base by the altitude, and take half the product.*

Or, *multiply one of these dimensions by half the other* (B. IV., P. 6).

*Ex.* 1. To find the area of a triangle, whose base is 625, and altitude 520 feet. *Ans.* 162500 sq. ft.

2. To find the number of square yards in a triangle, whose base is 40, and altitude 30 feet. *Ans.*  $66\frac{2}{3}$ .

3. To find the number of square yards in a triangle, whose base is 49, and altitude  $25\frac{1}{4}$  feet. *Ans.* 68.7361.

CASE II.

6. When two sides and their included angle are given.

*Add together the logarithms of the two sides and the logarithmic sine of their included angle; from this sum subtract the logarithm of the radius, which is 10, and the remainder will be the logarithm of double the area of the triangle. Find, from the table, the number answering to this logarithm, and divide it by 2; the quotient will be the required area.*

Let  $BAC$  be a triangle, in which there are given  $BA$ ,  $BC$ , and the included angle  $B$ .

From the vertex  $A$  draw  $AD$  perpendicular to the base  $BC$ , and represent the area of the triangle by  $Q$ . Then (Trig. Th. I),

$$R : \sin B :: BA : AD;$$

hence, 
$$AD = \frac{BA \times \sin B}{R}.$$

But, 
$$Q = \frac{BC \times AD}{2} \text{ (Art. 5):}$$

hence, by substituting for  $AD$  its value, we have,

$$Q = \frac{BC \times BA \times \sin B}{2R}, \text{ or, } 2Q = \frac{BC \times BA \times \sin B}{R}.$$

Taking the logarithms of both members, we have,

$$\log. 2Q = \log. BC + \log. BA + \log. \sin B - \log R;$$

the formula of the rule as enunciated.

*Ex. 1.* What is the area of a triangle whose sides are,  $BC = 125.81$ ,  $BA = 57.65$ , and the included angle  $B = 57^\circ 25'$ ?

$$\begin{array}{r} \text{Then, } \log. 2Q = \left\{ \begin{array}{lll} + \log. BC & 125.81 & 2.099715 \\ + \log. BA & 57.65 & 1.760799 \\ + \log. \sin B & 57^\circ 25' & 9.925626 \\ - \log. R & . & -10. \\ \hline \log. 2Q & . & 3.786140 \end{array} \right. \end{array}$$

and  $2Q = 6111.4$ , or  $Q = 3055.7$ , the required area.

2. What is the area of a triangle whose sides are 30 and 40, and their included angle  $28^\circ 57'$ ?

*Ans.* 290.427.

3. What is the number of square yards in a triangle of which the sides are 25 feet and 21.25 feet, and their included angle  $45^\circ$ ?

*Ans.* 20.8694.

CASE III.

7. When the three sides are known.

1. *Add the three sides together, and take half their sum.*
2. *From this half-sum subtract each side separately.*
3. *Multiply together the half-sum and each of the three remainders, and the product will be the square of the area of the triangle. Then, extract the square root of this product, for the required area.*

Or, *After having obtained the three remainders, add together the logarithm of the half-sum and the logarithms of the respective remainders, and divide their sum by 2: the quotient will be the logarithm of the area.*

Let  $ACB$  be a triangle: and denote the area by  $Q$ : then, by the last case, we have,

$$Q = \frac{1}{2}bc \times \sin A.$$

But, we have (Plane Trig., Art. 78),

$$\sin A = 2 \sin \frac{1}{2}A \cos \frac{1}{2}A;$$

hence,  $Q = bc \sin \frac{1}{2}A \cos \frac{1}{2}A.$

By substituting in this equation the values of  $\sin \frac{1}{2}A$ , and  $\cos \frac{1}{2}A$ , found in Arts. 92 and 93, Plane Trigonometry, we obtain,

$$Q = \sqrt{s(s-a)(s-b)(s-c)}.$$

*Ex. 1.* To find the area of a triangle whose three sides 20, 30, and 40.

|             |                    |                   |                  |
|-------------|--------------------|-------------------|------------------|
| 20          | 45                 | 45                | 45 half-sum.     |
| 30          | 20                 | 30                | 40               |
| 40          | <u>25</u> 1st rem. | <u>15</u> 2d rem. | <u>5</u> 3d rem. |
| <u>2)90</u> |                    |                   |                  |
| 45          |                    |                   | half-sum.        |

Then,  $45 \times 25 \times 15 \times 5 = 84375.$

The square root of which is 290.4737, the required area.

2. How many square yards of plastering are there in a triangle whose sides are 30, 40, and 50 feet? *Ans.*  $66\frac{3}{4}.$

8. To find the area of a trapezoid. -

*Add together the two parallel sides: then multiply their sum by the altitude of the trapezoid, and half the product will be the required area* (B. IV., P. 7).

*Ex. 1.* In a trapezoid the parallel sides are 750 and 1225, and the perpendicular distance between them is 1540; what is the area? *Ans.* 152075.

2. How many square feet are contained in a plank, whose length is 12 feet 6 inches, the breadth at the greater end 15 inches, and at the less end 11 inches?

*Ans.*  $13\frac{3}{4}$  sq. ft.

3. How many square yards are there in a trapezoid, whose parallel sides are 240 feet, 320 feet, and altitude 66 feet? *Ans.* 2053 $\frac{1}{2}.$

9. To find the area of a quadrilateral.

*Join two of the angles by a diagonal, dividing the quadrilateral into two triangles. Then, from each of the other angles let fall a perpendicular on the diagonal: then multiply the diagonal by half the sum of the two perpendiculars, and the product will be the area.*

*Ex. 1.* What is the area of the quadrilateral  $ABCD$ , the diagonal  $AC$  being 42, and the perpendiculars  $Dg$ ,  $Bb$ , equal to 18 and 16 feet?

*Ans.* 714.

2. How many square yards of paving are there in the quadrilateral whose diagonal is 65 feet, and the two perpendiculars let fall on it 28 and  $33\frac{1}{2}$  feet? *Ans.*  $222\frac{1}{2}$ .

10. To find the area of an irregular polygon.

*Draw diagonals dividing the proposed polygon into trapezoids and triangles. Then find the areas of these figures separately, and add them together for the contents of the whole polygon.*

*Ex. 1.* Let it be required to determine the contents of the polygon  $ABCDE$ , having five sides.

Let us suppose that we have measured the diagonals and perpendiculars, and found  $AC = 36.21$ ,  $EC = 39.11$ ,  $Bb = 4$ ,  $Dd = 7.26$ ,  $Aa = 4.18$ : required the area.

*Ans.* 296.1292.

11. To find the area of a long and irregular figure, bounded on one side by a right line.

1. *At the extremities of the right line measure the perpendicular breadths of the figure; then divide the line into any number of equal parts, and measure the breadth at each point of division.*
2. *Add together the intermediate breadths and half the sum of the extreme ones: then multiply this sum by one of the equal parts of the base line: the product will be the required area, very nearly.*

Let  $AEEa$  be an irregular figure, having for its base the right line  $AE$ . Divide  $AE$  into equal parts, and at the points of division  $A, B, C, D,$  and  $E$ , erect the perpendiculars  $Aa, Bb, Cc, Dd, Ee$ , to the base line  $AE$ , and designate them respectively by the letters  $a, b, c, d,$  and  $e$ .

Then, the area of the trapezoid  $ABba = \frac{a + b}{2} \times AB$ ,

the area of the trapezoid  $BCcb = \frac{b + c}{2} \times BC$ ,

the area of the trapezoid  $CDdc = \frac{c + d}{2} \times CD$ ,

and the area of the trapezoid  $DEed = \frac{d + e}{2} \times DE$ ;

hence, their sum, or the area of the whole figure, is equal to

$$\left( \frac{a + b}{2} + \frac{b + c}{2} + \frac{c + d}{2} + \frac{d + e}{2} \right) \times AB,$$

since  $AB, BC,$  &c., are equal to each other. But this sum is also equal to

$$\left( \frac{a}{2} + b + c + d + \frac{e}{2} \right) \times AB,$$

which corresponds with the enunciation of the rule.

*Ex. 1.* The breadths of an irregular figure at five equidistant places being 8.2, 7.4, 9.2, 10.2, and 8.6, and the length of the base 40: required the area.

|                           |                           |
|---------------------------|---------------------------|
| 8.2                       | 4)40                      |
| 8.6                       | 10 one of the equal parts |
| <u>2)16.8</u>             |                           |
| 8.4 mean of the extremes. |                           |
| 7.4                       | 35.2 sum.                 |
| 9.2                       | 10                        |
| <u>10.2</u>               | <u>35.2 = area.</u>       |
| 35.2 sum.                 |                           |

2. The length of an irregular figure being 84, and the breadths at six equidistant places 17.4, 20.6, 14.2, 16.5, 20.1, and 24.4; what is the area? *Ans.* 1550.64.

12. To find the area of a regular polygon.

*Multiply half the perimeter of the polygon by the apothem, or perpendicular let fall from the centre on one of the sides, and the product will be the area required (B. V., P. 8).*

REMARK I.—The following is the manner of determining the perpendicular when one side and the number of sides of the regular polygon are known :

First, divide 360 degrees by the number of sides of the polygon, and the quotient will be the angle at the centre; that is, the angle subtended by one of the equal sides. Divide this angle by 2, and half the angle at the centre will then be known.

Now, the line drawn from the centre to an angle of the polygon, the perpendicular let fall on one of the equal sides, and half this side, form a right-angled triangle, in which there are known the base, which is half the side of the polygon, and the angle at the vertex. Hence, the perpendicular can be determined.

*Ex. 1.* To find the area of a regular hexagon, whose sides are 20 feet each.

$$6)360^\circ$$

$$\underline{60^\circ} = ACB, \text{ the angle at the centre.}$$

$$\underline{30^\circ} = ACD, \text{ half the angle at centre.}$$

$$\text{Also, } CAD = 90^\circ - ACD = 60^\circ ;$$

$$\text{and, } AD = 10.$$

|       |             |   |                        |   |   |                 |
|-------|-------------|---|------------------------|---|---|-----------------|
| Then, | sin $ACD$   | . | $30^\circ$ , ar. comp. | . | . | 0.301030        |
|       | : sin $CAD$ |   | .                      |   |   | 9.937531        |
|       | :: $AD$     |   | .                      | . | . | <u>1.000000</u> |
|       | : $CD$      |   | .                      | . | . | <u>1.238561</u> |

Perimeter = 120, and half the perimeter = 60.

Then,  $60 \times 17.3205 = 1039.23$ , the area.

2. What is the area of an octagon whose side is 20?

*Ans.* 1931.36886.

REMARK II.—The area of a regular polygon of any number of sides is easily calculated by the above rule.

Let the areas of the regular polygons whose sides are unity, or 1, be calculated and arranged in the following

TABLE.

| NAMES.       | SIDES. | AREAS.    | NAMES.      | SIDES. | AREAS.     |
|--------------|--------|-----------|-------------|--------|------------|
| Triangle . . | 3 . .  | 0.4330127 | Octagon . . | 8 .    | 4.8284271  |
| Square . .   | 4 . .  | 1.0000000 | Nonagon . . | 9 .    | 6.1818242  |
| Pentagon . . | 5 . .  | 1.7204774 | Decagon . . | 10 .   | 7.6942088  |
| Hexagon . .  | 6 . .  | 2.5980762 | Undecagon . | 11 .   | 9.3656399  |
| Heptagon . . | 7 . .  | 3.6339124 | Dodecagon . | 12 .   | 11.1961524 |

Now, since the areas of similar polygons are to each other as the squares of their homologous sides (B. IV., P. 27), we have,

$$1^2 : \text{any side squared} :: \text{tabular area} : \text{area.}$$

Hence, to find the area of any regular polygon,

1. *Square the side of the polygon.*
2. *Then multiply that square by the tabular area set opposite the polygon of the same number of sides, and the product will be the required area.*

*Ex. 1.* What is the area of a regular hexagon whose side is 20?

$$20^2 = 400, \quad \text{tabular area} = 2.5980762.$$

Hence,  $2.5980762 \times 400 = 1039.2304800$ , as before.

2. To find the area of a pentagon whose side is 25.

*Ans.* 1075.298375.

3. To find the area of a decagon whose side is 20.

*Ans.* 3077.68352.

13. To find the circumference of a circle when the diameter is given, or the diameter when the circumference is given.

*Multiply the diameter by 3.1416, and the product will be the circumference; or, divide the circumference by 3.1416, and the quotient will be the diameter.*

It is shown (B. V., P. 16; s. 1), that the circumference of a circle whose diameter is 1, is 3.1415926, or 3.1416. But, since the circumferences of circles are to each other as their

radii or diameters, we have, by calling the diameter of the second circle  $d$ ,

$$1 : d :: 3.1416 : \text{circumference,}$$

hence,  $d \times 3.1416 = \text{circumference.}$

Hence, also, 
$$d = \frac{\text{circumference}}{3.1416}.$$

*Ex. 1.* What is the circumference of a circle whose diameter is 25? *Ans.* 78.54.

2. If the diameter of the earth is 7921 miles, what is the circumference? *Ans.* 24884.6136.

3. What is the diameter of a circle whose circumference is 11652.1904? *Ans.* 3709.

4. What is the diameter of a circle whose circumference is 6850? *Ans.* 2180.41.

14. To find the length of an arc of a circle containing any number of degrees.

*Multiply the number of degrees in the given arc by 0.0087266, and the product by the diameter of the circle.*

Since the circumference of a circle whose diameter is 1, is 3.1416, it follows, that if 3.1416 be divided by 360 degrees, the quotient will be the length of an arc of 1 degree: that is,  $\frac{3.1416}{360} = 0.0087266 = \text{arc of one degree to the diameter 1.}$  This being multiplied by the number of degrees in an arc, the product will be the length of that arc in the circle whose diameter is 1; and this product being then multiplied by the diameter, the product is the length of the arc for any diameter whatever.

REMARK.—When the arc contains degrees and minutes, reduce the minutes to the decimal of a degree, which is done by dividing them by 60.

*Ex. 1.* To find the length of an arc of 30 degrees, the diameter being 18 feet. *Ans.* 4.712364.

2. To find the length of an arc of  $12^\circ 10'$  or  $12\frac{1}{6}^\circ$ , the diameter being 20 feet. *Ans.* 2.123472.

3. What is the length of an arc of  $10^\circ 15'$ , or  $10\frac{1}{4}^\circ$ , in a circle whose diameter is 68? *Ans.* 6.082396.

15. To find the area of a circle.

1. *Multiply the circumference by half the radius* (B. V., P. 15).  
 Or, 2. *Multiply the square of the radius by 3.1416* (B. V., P. 16).

*Ex.* 1. To find the area of a circle whose diameter is 10, and circumference 31.416. *Ans.* 78.54.

2. Find the area of a circle whose diameter is 7, and circumference 21.9912. *Ans.* 38.4846.

3. How many square yards in a circle whose diameter is  $3\frac{1}{2}$  feet? *Ans.* 1.069016.

4. What is the area of a circle whose circumference is 12 feet? *Ans.* 11.4591.

16. To find the area of a sector of a circle.

1. *Multiply the arc of the sector by half the radius* (B. V., P. 15, c).

Or, 2. *Compute the area of the whole circle: then say, as 360 degrees is to the degrees in the arc of the sector, so is the area of the whole circle to the area of the sector.*

*Ex.* 1. To find the area of a circular sector whose arc contains 18 degrees, the diameter of the circle being 3 feet. *Ans.* 0.35343.

2. To find the area of a sector whose arc is 20 feet, the radius being 10. *Ans.* 100.

3. Required the area of a sector whose arc is  $147^{\circ} 29'$ , and radius 25 feet. *Ans.* 804.3986.

17. To find the area of a segment of a circle.

1. *Find the area of the sector having the same arc, by the last problem.*
2. *Find the area of the triangle formed by the chord of the segment and the two radii of the sector.*
3. *Then add these two together for the answer when the segment is greater than a semicircle, and subtract the triangle from the sector when it is less.*

*Ex.* 1. To find the area of the segment  $ACB$ , its chord  $AB$  being 12, and the radius  $EA$ , 10 feet.

|              |                |                 |
|--------------|----------------|-----------------|
| $EA$         | 10 ar. comp.   | 9.000000        |
| : $AD$       | 6              | . 0.778151      |
| :: $\sin D$  | $90^\circ$     | . 10.000000     |
| : $\sin AED$ | $36^\circ 52'$ | $= 36.87$       |
|              | <u>2</u>       | <u>9.778151</u> |

$\frac{73.74}{2} =$  the degrees in the arc  $ACB$ .

Then,  $0.0087266 \times 73.74 \times 20 = 12.87 =$  arc  $ABC$  nearly.

$$\frac{5}{64.35} = \text{area } EACB.$$

Again,  $\sqrt{EA^2 - AD^2} = \sqrt{100 - 36} = \sqrt{64} = 8 = ED$ .  
and,  $6 \times 8 = 48 =$  the area of the triangle  $EAB$ .

Hence, sect.  $EACB - EAB = 64.35 - 48 = 16.35 = ACB$ .

2. Find the area of the segment whose height is 18, the diameter of the circle being 50. *Ans.* 636.4834.

3. Required the area of the segment whose chord is 16, the diameter being 20. *Ans.* 44.764.

18. To find the area of a circular ring: that is, the area included between the circumferences of two circles which have a common centre.

*Take the difference between the areas of the two circles.*

*Or, subtract the square of the less radius from the square of the greater, and multiply the remainder by 3.1416.*

For the area of the larger is  $R^2 \pi$ ,  
and of the smaller  $r^2 \pi$ .

Their difference, or the area of the ring, is  $(R^2 - r^2)\pi$ .

*Ex.* 1. The diameters of two concentric circles being 10 and 6, required the area of the ring contained between their circumferences. *Ans.* 50.2656.

2. What is the area of the ring when the diameters of the circles are 10 and 20? *Ans.* 235.62.

# MENSURATION OF SOLIDS.

---

1. THE mensuration of solids is divided into two parts:

*First.* The mensuration of their surfaces; and,

*Second.* The mensuration of their solidities.

2. We have already seen, that the unit of measure for plane surfaces is a square whose side is the unit of length.

A curved line which is expressed by numbers is also referred to a unit of length, and its numerical value is the number of times which the line contains its unit. If then, we suppose the linear unit to be reduced to a right line, and a square constructed on this line, this square will be the unit of measure for curved surfaces.

3. The unit of solidity is a cube, the face of which is equal to the superficial unit in which the surface of the solid is estimated, and the edge is equal to the linear unit in which the linear dimensions of the solid are expressed (B. VII., P. 13, s. 1).

The following is a table of solid measures:

1728 cubic inches = 1 cubic foot.

27 cubic feet = 1 cubic yard.

4492 $\frac{1}{2}$  cubic feet = 1 cubic rod.

## OF POLYEDRONS, OR, SURFACES BOUNDED BY PLANES.

4. To find the surface of a right prism.

*Multiply the perimeter of the base by the altitude, and the product will be the convex surface* (B. VII., P. 1). *To this add the area of the two bases, when the entire surface is required.*

*Ex.* 1. To find the surface of a cube, the length of each side being 20 feet. *Ans.* 2400 sq. ft.

2. To find the whole surface of a triangular prism, whose base is an equilateral triangle, having each of its sides equal to 18 inches, and altitude 20 feet.

*Ans.* 91.949.

3. What must be paid for lining a rectangular cistern with lead, at 2d. a pound, the thickness of the lead being such as to require 7lbs. for each square foot of surface; the inner dimensions of the cistern being as follows, viz.: the length 3 feet 2 inches, the breadth 2 feet 8 inches, and the depth 2 feet 6 inches? *Ans. 2l. 3s. 10½d.*

5. To find the surface of a right pyramid.

*Multiply the perimeter of the base by half the slant height, and the product will be the convex surface (B. VII., P. 4): to this add the area of the base, when the entire surface is required.*

*Ex. 1.* To find the convex surface of a right triangular pyramid, the slant height being 20 feet, and each side of the base 3 feet. *Ans. 90 sq. ft.*

2. What is the entire surface of a right pyramid, whose slant height is 15 feet, and the base a pentagon, of which each side is 25 feet? *Ans. 2012.798.*

6. To find the convex surface of the frustum of a right pyramid.

*Multiply the half sum of the perimeters of the two bases by the slant height of the frustum, and the product will be the convex surface (B. VII., P. 4, C.)*

*Ex. 1.* How many square feet are there in the convex surface of the frustum of a square pyramid, whose slant height is 10 feet, each side of the lower base 3 feet 4 inches, and each side of the upper base 2 feet 2 inches? *Ans. 110 sq. ft.*

2. What is the convex surface of the frustum of an heptagonal pyramid whose slant height is 55 feet, each side of the lower base 8 feet, and each side of the upper base 4 feet? *Ans. 2310 sq. ft.*

7. To find the solidity of a prism.

1. *Find the area of the base.*

2. *Multiply the area of the base by the altitude, and the product will be the solidity of the prism (B. VII., P. XIV).*

*Ex. 1.* What are the solid contents of a cube whose side is 24 inches? *Ans. 13824*

2. How many cubic feet in a block of marble, of which the length is 3 feet 2 inches, breadth 2 feet 8 inches, and height or thickness 2 feet 6 inches? *Ans.*  $21\frac{1}{2}$ .

3. How many gallons of water, ale measure, will a cistern contain, whose dimensions are the same as in the last example? *Ans.*  $129\frac{1}{4}$ .

4. Required the solidity of a triangular prism, whose height is 10 feet, and the three sides of its triangular base 3, 4, and 5 feet. *Ans.* 60.

8. To find the solidity of a pyramid.

*Multiply the area of the base by one-third of the altitude, and the product will be the solidity* (B. VII., P. 17).

*Ex.* 1. Required the solidity of a square pyramid, each side of its base being 30, and the altitude 25.

*Ans.* 7500.

2. To find the solidity of a triangular pyramid, whose altitude is 30, and each side of the base 3 feet.

*Ans.* 38.9711.

3. To find the solidity of a triangular pyramid, its altitude being 14 feet 6 inches, and the three sides of its base 5, 6, and 7 feet.

*Ans.* 71.0352.

4. What is the solidity of a pentagonal pyramid, its altitude being 12 feet, and each side of its base 2 feet?

*Ans.* 27.5276.

5. What is the solidity of an hexagonal pyramid, whose altitude is 6.4 feet, and each side of its base 6 inches?

*Ans.* 1.38564.

9. To find the solidity of the frustum of a pyramid.

*Add together the areas of the two bases of the frustum, and a mean proportional between them, and then multiply the sum by one-third of the altitude* (B. VII., P. 18).

*Ex.* 1. To find the number of solid feet in a piece of timber, whose bases are squares, each side of the lower base being 15 inches, and each side of the upper base 6 inches, the altitude being 24 feet.

*Ans.* 19.5.

2. Required the solidity of a pentagonal frustum, whose altitude is 5 feet, each side of the lower base 18 inches, and each side of the upper base 6 inches.

*Ans.* 9.31925.

DEFINITIONS.

10. A WEDGE is a solid bounded by five planes: viz., a rectangle,  $ABCD$ , called the base of the wedge; two trapezoids  $ABHG$ ,  $DCHG$ , which are called the sides of the wedge, and which intersect each other in the edge  $GH$ ; and the two triangles  $GDA$ ,  $HCB$ , which are called the ends of the wedge.

When  $AB$ , the length of the base, is equal to  $GH$ , the trapezoids  $ABHG$ ,  $DCHG$ , become parallelograms, and the wedge is then one-half the parallelepipedon described on the base  $ABCD$ , and having the same altitude with the wedge.

The altitude of the wedge is the perpendicular let fall from any point of the line  $GH$ , on the base  $ABCD$ .

11. A RECTANGULAR PRISMOID is a solid resembling the frustum of a quadrangular pyramid. The upper and lower bases are rectangles, having their corresponding sides parallel, and the convex surface is made up of four trapezoids. The altitude of the prismoid is the perpendicular distance between its bases.

TO FIND THE SOLIDITY OF THE WEDGE.

Let  $L = AB$ , the length of the base,  $l = GH$ , the length of the edge,  $b = BC$ , the breadth of the base,  $h = PG$ , the altitude of the wedge.

Then,  $L - l = AB - GH = AM$ .

Suppose  $AB$ , the length of the base, to be equal to  $GH$ , the length of the edge, the solidity will then be equal to half the parallelepipedon,

having the same base and the same altitude (B. VII., P. 7). Hence, the solidity will be equal to  $\frac{1}{2}bhl$  (B. VII., P. 14).

If the length of the base is greater than that of the edge, let a section  $MNG$  be made parallel to the end  $BCH$ . The wedge will then be divided into the triangular prism  $BCH-G$ , and the quadrangular pyramid  $G-AMND$ .

Then, the solidity of the prism

$$= \frac{1}{2}bhl; \text{ the solidity of the pyramid} = \frac{1}{3}bh(L - l);$$

and their sum,

$$\frac{1}{2}bhl + \frac{1}{3}bh(L - l) = \frac{1}{6}bh3l + \frac{1}{6}bh2L - \frac{1}{6}bh2l = \frac{1}{6}bh(2L + l).$$

If the length of the base is less than the length of the edge, the solidity of the wedge will be equal to the difference between the prism and pyramid, and we shall have for the solidity of the wedge,

$$\frac{1}{2}bhl - \frac{1}{3}bh(l - L) = \frac{1}{6}bh3l - \frac{1}{6}bh2l + \frac{1}{6}bh2L = \frac{1}{6}bh(2L + l).$$

*Ex.* 1. If the base of a wedge is 40 by 20 feet, the edge 35 feet, and the altitude 10 feet, what is the solidity?

*Ans.* 3833.33.

2. The base of a wedge being 18 feet by 9, the edge 20 feet, and the altitude 6 feet, what is the solidity?

*Ans.* 504.

12. To find the solidity of a rectangular prismoid.

*Add together the areas of the two bases and four times the area of a parallel section at equal distances from the bases: then multiply the sum by one-sixth of the altitude.*

For, let  $L$  and  $B$  denote the length and breadth of the lower base,  $l$  and  $b$  the length and breadth of the upper base,  $M$  and  $m$  the length and breadth of the section equidistant from the bases, and  $h$  the altitude of the prismoid.

Through the diagonal edges  $L$

and  $l'$  let a plane be passed, and it will divide the prismoid into two wedges, having for bases, the bases of the prismoid, and for edges the lines  $L$  and  $l' = l$ .

The solidity of these wedges, and consequently, of the prismoid, is

$$\begin{aligned} \frac{1}{6} Bh(2L + l) + \frac{1}{6} bh(2l + L) &= \frac{1}{6} h(2BL + Bl + 2bl + bL) \\ &= \frac{1}{6} h(BL + Bl + bL + bl + BL + bl). \end{aligned}$$

But since  $M$  is equally distant from  $L$  and  $l$ , we have,

$$2M = L + l, \text{ and } 2m = B + b;$$

hence,  $4Mm = (L + l) \times (B + b) = BL + Bl + bL + bl$ .

Substituting  $4Mm$  for its value in the preceding equation, and we have for the solidity

$$\frac{1}{6} h(BL + bl + 4Mm).$$

REMARK.—This rule may be applied to any prismoid whatever. For, whatever be the form of the bases, there may be inscribed in each the same number of rectangles, and the number of these rectangles may be made so great that their sum in each base will differ from that base, by less than any assignable quantity. Now, if on these rectangles, rectangular prismoids be constructed, their sum will differ from the given prismoid by less than any assignable quantity. Hence, the rule is general.

*Ex.* 1. One of the bases of a rectangular prismoid is 25 feet by 20, the other 15 feet by 10, and the altitude 12 feet; required the solidity. *Ans.* 3700.

2. What is the solidity of a stick of hewn timber, whose ends are 30 inches by 27, and 24 inches by 18, its length being 24 feet? *Ans.* 102 ft.

#### OF THE MEASURES OF THE THREE ROUND BODIES.

##### 13. To find the surface of a cylinder.

*Multiply the circumference of the base by the altitude, and the product will be the convex surface (B. VIII., P. 1). To this add the areas of the two bases, when the entire surface is required.*

*Ex.* 1. What is the convex surface of a cylinder, the diameter of whose base is 20, and whose altitude is 50?

*Ans.* 3141.6.

2. Required the entire surface of a cylinder, whose altitude is 20 feet, and the diameter of its base 2 feet.

*Ans.* 131.9472.

14. To find the convex surface of a cone.

*Multiply the circumference of the base by half the slant height (B. VIII., P. 3): to which add the area of the base, when the entire surface is required.*

*Ex.* 1. Required the convex surface of a cone, whose slant height is 50 feet, and the diameter of its base  $8\frac{1}{2}$  feet?

*Ans.* 667.59.

2. Required the entire surface of a cone, whose slant height is 36, and the diameter of its base 18 feet.

*Ans.* 1272.348.

15. To find the surface of a frustum of a cone.

*Multiply the slant height of the frustum by half the sum of the circumferences of the two bases, for the convex surface (B. VIII., P. 4): to which add the areas of the two bases, when the entire surface is required.*

*Ex.* 1. To find the convex surface of the frustum of a cone, the slant height of the frustum being  $12\frac{1}{2}$  feet, and the circumferences of the bases 8.4 feet and 6 feet. *Ans.* 90.

2. To find the entire surface of the frustum of a cone, the slant height being 16 feet, and the radii of the bases 3 feet and 2 feet. *Ans.* 292.1688.

16. To find the solidity of a cylinder.

*Multiply the area of the base by the altitude (B. VIII., P. 2).*

*Ex.* 1. Required the solidity of a cylinder whose altitude is 12 feet, and the diameter of its base 15 feet.

*Ans.* 2120.58.

2. Required the solidity of a cylinder whose altitude is 20 feet, and the circumference of whose base is 5 feet 6 inches.

*Ans.* 48.144.

17. To find the solidity of a cone.

*Multiply the area of the base by the altitude, and take one-third of the product (B. VIII., P. 5).*

*Ex. 1.* Required the solidity of a cone whose altitude is 27 feet, and the diameter of the base 10 feet.

*Ans.* 706.86.

2. Required the solidity of a cone whose altitude is  $10\frac{1}{2}$  feet, and the circumference of its base 9 feet.

*Ans.* 22.56.

18. To find the solidity of a frustum of a cone.

*Add together the areas of the two bases and a mean proportional between them, and then multiply the sum by one-third of the altitude (B. VIII., P. 6).*

*Ex. 1.* To find the solidity of the frustum of a cone, the altitude being 18, the diameter of the lower base 8, and that of the upper base 4.

*Ans.* 527.7888.

2. What is the solidity of the frustum of a cone, the altitude being 25, the circumference of the lower base 20, and that of the upper base 10?

*Ans.* 464.216.

3. If a cask which is composed of two equal conic frustums joined together at their larger bases, have its bung diameter 28 inches, the head diameter 20 inches, and the length 40 inches, how many gallons of wine will it contain, there being 231 cubic inches in a gallon?

*Ans.* 79.0613.

19. To find the surface of a spherical zone.

*Multiply the altitude of the zone by the circumference of a great circle of the sphere, and the product will be the surface (B. VIII., P. 10, C. 2).*

*Ex. 1.* The diameter of a sphere being 42 inches, what is the convex surface of a zone whose altitude is 9 inches?

*Ans.* 1187.5248 sq. in.

2. If the diameter of a sphere is  $12\frac{1}{2}$  feet, what will be the surface of a zone whose altitude is 2 feet?

*Ans.* 78.54 sq. ft.

20. To find the solidity of a sphere.

1. *Multiply the surface by one-third of the radius* (B. VIII., P. 14).  
 Or, 2. *Cube the diameter and multiply the number thus found by  $\frac{1}{6}\pi$ : that is, by 0.5236* (B. VIII., P. 14, s. 3).

*Ex.* 1. What is the solidity of a sphere whose diameter is 12? *Ans.* 904.7808.

2. What is the solidity of the earth, if the mean diameter be taken equal to 7918.7 miles?

*Ans.* 259992792083.

21. To find the solidity of a spherical segment.

*Find the areas of the two bases, and multiply their sum by half the height of the segment; to this product add the solidity of a sphere whose diameter is equal to the height of the segment* (B. VIII., P. 17).

REMARK.—When the segment has but one base, the other is to be considered equal to 0 (B. VIII., D. 15).

*Ex.* 1. What is the solidity of a spherical segment, the diameter of the sphere being 40, and the distances from the centre to the bases, 16 and 10? *Ans.* 4297.7088.

2. What is the solidity of a spherical segment with one base, the diameter of the sphere being 8, and the altitude of the segment 2 feet? *Ans.* 41.888.

3. What is the solidity of a spherical segment with one base, the diameter of the sphere being 20, and the altitude of the segment 9 feet? *Ans.* 1781.2872.

22. To find the surface of a spherical triangle.

1. *Compute the surface of the sphere on which the triangle is formed, and divide it by 8; the quotient will be the surface of the tri-rectangular triangle.*

2. *Add the three angles together; from their sum subtract  $180^\circ$ , and divide the remainder by  $90^\circ$ : then multiply the tri-rectangular triangle by this quotient, and the product will be the surface of the triangle* (B. IX., P. 18).

*Ex.* 1. Required the surface of a triangle described on a sphere, whose diameter is 30 feet, the angles being  $140^\circ$ ,  $92^\circ$ , and  $68^\circ$ . *Ans.* 471.24 sq. ft.

2. Required the surface of a triangle described on a sphere of 20 feet diameter, the angles being  $120^\circ$  each.

*Ans.* 314.16 sq. ft.

23. To find the surface of a spherical polygon.

1. Find the tri-rectangular triangle as before.
2. From the sum of all the angles take the product of two right angles by the number of sides less two. Divide the remainder by  $90^\circ$ , and multiply the tri-rectangular triangle by the quotient: the product will be the surface of the polygon (B. IX., P. 19).

*Ex.* 1. What is the surface of a polygon of seven sides, described on a sphere whose diameter is 17 feet, the sum of the angles being  $1080^\circ$  ?

*Ans.* 226.98.

2. What is the surface of a regular polygon of eight sides, described on a sphere whose diameter is 30, each angle of the polygon being  $140^\circ$  ?

*Ans.* 157.08.

OF THE REGULAR POLYEDRONS.

24. In determining the solidities of the regular polyedrons, it becomes necessary to know, for each of them, the angle contained between any two of the adjacent faces. The determination of this angle involves the following property of a regular polygon, viz.:

*Half the diagonal which joins the extremities of two adjacent sides of a regular polygon, is equal to the side of the polygon multiplied by the cosine of the angle which is obtained by dividing  $360^\circ$  by twice the number of sides: the radius being equal to unity.*

For, let  $ABCDE$  be any regular polygon. Draw the diagonal  $AC$ , and from the centre  $F$ , draw  $FG$  perpendicular to  $AB$ . Draw also,  $AF$ ,  $FB$ ; the latter will be perpendicular to the diagonal  $AC$ , and will bisect it at  $H$  (B. III., P. 6, s.)

Let the number of sides of the polygon be designated by  $n$ : then,

$$AFB = \frac{360^\circ}{n}, \text{ and } AFG = CAB = \frac{360^\circ}{2n}.$$

But, in the right-angled triangle  $ABH$ , we have,

$$AH = AB \cos A = AB \cos \frac{360^\circ}{2n} \text{ (Trig., Th. 5).}$$

REMARK 1.—When the polygon in question is the equilateral triangle, the diagonal becomes a side, and consequently, half the diagonal becomes half a side of the triangle.

REMARK 2.—The perpendicular  $BH = AB \sin \frac{360^\circ}{2n}$

25. To determine the angle included between two adjacent faces of either of the regular polyhedrons, let us suppose a plane to be passed perpendicular to the axis of a polyedral angle, and through the vertices of the polyedral angles which lie adjacent. This plane will intersect the convex surface of the polyedron in a regular polygon; the number of sides of this polygon will be equal to the number of planes which meet at the vertex of either of the polyedral angles, and each side will be a diagonal of one of the equal faces of the polyedron.

Let  $D$  be the vertex of a polyedral angle,  $CD$  the intersection of two adjacent faces, and  $ABC$  the section made in the convex surface of the polyedron by a plane perpendicular to the axis through  $D$ .

Through  $AB$  let a plane be drawn perpendicular to  $CD$ , produced, if necessary, and suppose  $AE$ ,  $BE$ , to be the lines in which this plane intersects the adjacent faces. Then will  $AEB$  be the angle included between the adjacent faces, and  $FEB$  will be half that angle which we will represent by  $\frac{1}{2}A$ .

Then, if we represent by  $n$  the number of faces which meet at the vertex of the solid angle, and by  $m$  the number of sides of each face, we shall have, from what has already been shown,

$$BF = BC \cos \frac{360^\circ}{2n}, \text{ and } EB = BC \sin \frac{360^\circ}{2m}.$$

But,  $\frac{BF}{EB} = \sin FEB = \sin \frac{1}{2}A$ , to the radius of unity;

hence,

$$\sin \frac{1}{2}A = \frac{\cos \frac{360^\circ}{2n}}{\sin \frac{360^\circ}{2m}}.$$

This formula gives, for the dihedral angle formed by any two adjacent faces of the

|                       |              |
|-----------------------|--------------|
| Tetraedron . . . . .  | 70° 31' 42"  |
| Hexaedron . . . . .   | 90°          |
| Octaedron . . . . .   | 109° 28' 18" |
| Dodecaedron . . . . . | 116° 33' 54" |
| Icosaedron . . . . .  | 138° 11' 23" |

Having thus found the dihedral angle included between the adjacent faces, we can easily calculate the perpendicular let fall from the centre of the polyedron on one of its faces, when the faces themselves are known.

The following table shows the solidities and surfaces of the regular polyedrons, when the edges are equal to 1.

A TABLE OF REGULAR POLYEDRONS WHOSE EDGES ARE 1.

| NAMES.                | NO. OF FACES. | SURFACE.             | SOLIDITY. |
|-----------------------|---------------|----------------------|-----------|
| Tetraedron . . . . .  | 4 . . . . .   | 1.7320508 . . . . .  | 0.1178513 |
| Hexaedron . . . . .   | 6 . . . . .   | 6.0000000 . . . . .  | 1.0000000 |
| Octaedron . . . . .   | 8 . . . . .   | 3.4641016 . . . . .  | 0.4714045 |
| Dodecaedron . . . . . | 12 . . . . .  | 20.6457288 . . . . . | 7.6631189 |
| Icosaedron . . . . .  | 20 . . . . .  | 8.6602540 . . . . .  | 2.1816950 |

26. To find the solidity of a regular polyedron.

1. *Multiply the surface by one-third of the perpendicular let fall from the centre on one of the faces, and the product will be the solidity.*
- Or, 2. *Multiply the cube of one of the edges by the solidity of a similar polyedron, whose edge is 1.*

The first rule results from the division of the polyedron into as many equal pyramids as it has faces, having

their common vertex at the centre of the polyedron. The second is proved by considering that two regular polyedrons having the same number of faces may be divided into an equal number of similar pyramids, and that the sum of the pyramids which make up one of the polyedrons will be to the sum of the pyramids which make up the other polyedron, as a pyramid of the first sum to a pyramid of the second (B. II., P. 10); that is, as the cubes of their homologous edges (B. VII., P. 20); that is, as the cubes of the edges of the polyedron.

*Ex.* 1. What is the solidity of a tetraedron whose edge is 15? *Ans.* 397.75.

2. What is the solidity of a hexaedron whose edge is 12? *Ans.* 1728.

3. What is the solidity of a octaedron whose edge is 20? *Ans.* 3771.236.

4. What is the solidity of a dodecaedron whose edge is 25? *Ans.* 119736.2328.

5. What is the solidity of an icosaedron whose edge is 20? *Ans.* 17453.56.

A TABLE  
OF  
LOGARITHMIC  
SINES AND TANGENTS,  
FOR EVERY  
DEGREE AND MINUTE  
OF THE QUADRANT.

---

REMARK. The minutes in the left-hand column of each page, increasing downwards, belong to the degrees at the top; and those increasing upwards, in the right-hand column, belong to the degrees below.

| M. | Sine     | D.      | Cosine    | D.  | Tang.    | D.      | Cotang.   |    |
|----|----------|---------|-----------|-----|----------|---------|-----------|----|
