**Second report on the experiments on the influence of soil, season, and manuring on the quality and growth of barley, 1923**, E. J. RUSSELL (*Jour. Inst. Brewing, 30 (1924), No. 9, pp. 818-837*).—The yields and quality of barley in these experiments were generally much higher in 1923 than in the previous year (*E. S. R., 50, p. 233*). The complete fertilizer increased the yields in all but two cases. Nitrogen was most effective and was followed by phosphate, while potassium fertilizers produced measurable effects only on the light soils.

The effects of fertilizer on the valuation were not very consistent, and the relation between the valuation and nitrogen content of the grain, when comparing barley from the different centers, was less marked than in 1922. The nitrogen content of the grain was usually depressed by phosphate and increased by nitrogen, while potash had but little influence. The moisture content of the grain was usually lower on the plats receiving nitrogen and phosphates than on plats not so treated, and about the same on plats receiving or omitting potash. Within limits of variation of about 17 per cent, changes in moisture content appeared to have less effect on valuation than changes in nitrogen content.

**Second report on the influence of soil, season, and manuring on the quality and growth of barley, as indicated by the malts made therefrom**, H. M. LANCASTER (*Jour. Inst. Brewing, 31 (1925), No. 3, pp. 104-114*).—Malting tests with the barleys discussed above tended to confirm the results of the previous year (*E. S. R., 51, p. 36*). Other things being equal, differences in

fertilizer treatment resulted in practically no difference in the market value of the barleys, as judged by their malts. Soil and season seemed to be predominant in determining both actual and market value.

**The effects of fertilizers on the yield and the ear characters of corn,** T. K. WOLFE (*Jour. Amer. Soc. Agron.*, 16 (1924), No. 8, pp. 551, 552).—The effects of certain fertilizers on the yield and ear characters of corn were studied in a rotation on Hagerstown silt loam at the Virginia Experiment Station.

As compared with the check, the fertilizers used increased the yield of corn very materially and, with one exception, made the ear characters more pronounced. In most instances the complete fertilizer gave nearly as good as or better results than the stable manure. In its effect on ear characters and yield the complete fertilizer surpassed acid phosphate, nitrogen and potassium in combination, and the check in the order named.

**Handling the soft-corn crop,** F. D. RICHEY (*U. S. Dept. Agr., Dept. Circ. 333* (1924), pp. 8, pls. 2, figs. 4).—The different ways by which soft corn can be used or preserved, as outlined in this circular, are based largely on experimental results at the Illinois, Iowa, Minnesota, and Nebraska Experiment Stations and the published experiences of farmers. The information is particularly applicable to conditions in the northern part of the Corn Belt and northward.

**Spacing experiments with Acala cotton in southern California,** H. G. MCKEEVER (*Jour. Agr. Research [U. S.]*, 28 (1924), No. 11, pp. 1081-1093, figs. 3).—Experiments with cotton under irrigation in the Coachella Valley of California, wherein plants were spaced about 2, 6, and 12 in. apart in the row, gave indications that reduced yields do not follow when plants are left as close as 2 in., and that increased yields sometimes may be obtained from plants spaced 2 in. apart, even under long-season, weevil-free conditions. Plants spaced at 6 in. seemed to produce as well as or better than plants spaced 12 in. apart. However, since 6-in. spacing is not convenient in field operations, practical alternatives are suggested providing for 2 plants together at 12 in. or omitting the chopping operation, except in thick stands, when some plants should be pulled out. The yields in the first picking were about the same for all spacings, while in the second picking the 2- and 6-in. spacings outyielded the 12-in. in the order given. The early crowding of closely spaced cotton, which may result in suppressing some of the lower fruiting branches as well as of the vegetative branches, is lessened by the plants spreading apart as they become larger.

**[Cotton investigations in South Carolina]** (*South Carolina Sta. Rpt. 1924*, pp. 15-25, 27, 28, 34, 35, 73, figs. 5).—These pages report experiments continuing and supplementing previous work (E. S. R., 50, p. 638; 51, p. 234). Although closely-spaced cotton was little earlier than wide-spaced during a very wet season at Florence, the earliest and best yields came from spacing as close as 9 or 12 in. At Clemson the closely-spaced cotton continued to give the highest yield and the earliest crop. The results obtained indicate that the earliest crop and the highest yields are apt to be obtained from a spacing giving from 15,000 to 20,000 plants per acre, at which rate an average of 5 to 6 mature bolls per stalk will yield a bale of cotton per acre. Acid-delinted seed again excelled in the seed treatment tests. Plats chopped as soon as a stand was obtained gave the best yields.

Fertilizer trials with cotton substantiated results recorded earlier. Side applications of sodium nitrate seemed most profitable, especially just after the cotton is chopped.

At Florence, Lightning Express, College No. 1, and strains of Webber 49 began fruiting ahead of other varieties and these together with certain Cleveland strains, Deltatype Webber, and Carolina Foster, put on squares most rapidly during June and early July. Although Trice, Delfos, Lightning Express, Acala, King, and Carolina Foster started fruiting first at Clemson, the most rapid square formation during the first month of the fruiting period was observed on Cleveland strains, Lightning Express, Carolina Foster, College No. 1, and Acala. Little difference was seen in the periods required for a fruit bud (square) to develop to a bloom, about 23 days being needed for all varieties in 1923 and a few days longer in 1924. However, varieties differed in the length of time from bloom to open boll, in the rapidity of the growth of the bolls during the early stages of development, and in the rate of hardening of bolls. Correlation was apparent between the rate of hardening of the bolls and the seasonal conditions. The leading varieties at the station, at Florence, and at the Coast Substation are indicated with their acre yields.

Certain seasonal factors seem to influence the periods required for a fruit bud or square to reach the bloom stage and for a boll to develop from bloom to maturity. A very definite correlation has existed between the length of day and the boll period. Abortion of early buds and squares, evidently connected in some way with the unusually rainy season, is also commented on.

Stripping squares at any time or in any amount has not produced a net gain in yield. Early topping seems to delay maturity and reduce the yield slightly. Topping later in the season had little effect on yield but the topped cotton seemed to open up earlier and better than untopped plants. April plantings have given best stands and yields at Florence. Fruiting studies at Clemson showed that the rate of blooming and the total number of blooms varied directly with the time of planting.

**Cotton variety experiments at the main station, 1912 to 1922, G. N. STROMAN** (*Texas Sta. Bul. 321 (1924), pp. 3-20, fig. 1*).—Varietal experiments with cotton carried on at the college station from 1912 to 1922, inclusive, are summarized. The relative rank of the leading varieties during the period 1919-1922 was Belton, Truitt, Acala, Lone Star, Rowden, Durango, Kasch, Mebane, and Bennett. These are considered standard varieties for this section of the State. Averaging production during the years 1917-1922 showed the order to be Acala, Lone Star, Rowden, Durango, Mebane, and Kasch. Lone Star, Mebane, and Rowden ranked in order during the years 1912-1922, inclusive. High yields seemed to be correlated with well distributed rainfall, especially during June, July, and August, while the total annual rainfall was apparently without effect on yields. No significant correlation was found between lint percentage and yield of lint per acre.

**The moisture relations of cotton, II, III, A. R. URQUHART and A. M. WILLIAMS** (*Brit. Cotton Indus. Research Assoc., Shirley Inst. Mem., 3 (1924), Nos. 17, pp. 197-206, figs. 4; 27, pp. 307-320, figs. 9*).—Further investigations (*E. S. R., 51, p. 235*) on this subject are reported on.

**II. The absorption and desorption of water by soda-boiled cotton at 25° C.**—By a method considered more reliable than that given previously for the accurate determination of the moisture content at all humidities, soda-boiled cotton was found to absorb 22.6 per cent of water from a saturated atmosphere. The studies indicated that the hysteresis of cotton does not extend to zero humidity, but that the curves meet at  $p/P=0.018$ , and that no tendency is apparent for the loop to close at the saturation value. An explanation of the phenomenon of hysteresis is offered which depends on a theory of the capillary structure of cotton not inconsistent with botanical views. The diameter of the smallest pores in cotton was found to be of the order of  $13 \times 10^{-8}$  cm.

III. *The effect of temperature on the absorption of water by soda-boiled cotton.*—Experiments concerned with the absorption of water by cotton at all humidities and at temperatures up to 110° gave results showing that when the relative humidity is constant at less than 80 per cent, an increase of temperature from 10 to 110° reduces the moisture content of the cotton. When, however, the relative humidity is constant at more than 80 per cent, a similar decrease in moisture content only occurs as the temperature rises from 10 to 50°, while from 60 to 110° the moisture content may actually increase with rise of temperature. The increase of moisture content under constant high humidities, which begins at about 60°, is apparently due to swelling of the material and the consequent exposure of new surface. Processes depending for their success on the swollen state of the cotton will consequently be facilitated above 60° at high humidities.

**The relation between the breaking strength of cotton yarns and the twist at the place of breaking,** W. ENGLISH (*Jour. Textile Inst.*, 15 (1924), No. 8, pp. T385-T400, figs. 6).—Combed and carded Egyptian cotton yarns were spun to 60s on the ring frame with twist constants 2, 3, and 4, at the Manchester College of Technology. Within the range of twist investigated the mean strengths of the yarns increased with the twist, as did also the frequency of the breaks occurring at places of maximum twist in a specimen, but this was lower for carded qualities than for combed qualities of similar twist.

**Kikuyu grass (*Pennisetum clandestinum*, Chiov.),** O. STAFF (*Agr. Jour. India*, 19 (1924), No. 4, pp. 415-425, figs. 12).—The history, merits, habits, and characteristics of kikuyu grass are set forth with a detailed botanical description.

**Field experiments [with oats],** R. A. BERRY and D. G. O'BRIEN (*Jour. Agr. Sci. [England]*, 14 (1924), No. 3, pp. 407-412, fig. 1).—Examination of the yields in single plat tests with oats at the experiment station at Kilmarnock, of the West of Scotland College of Agriculture, showed that the size of the experimental errors renders single plat trials practically useless for comparing the grain yields of two oats varieties. The probable error on single plat trials amounts to about 18 per cent of the grain yield for the old Scotch varieties of oats and to about 20 per cent for the new varieties. Adopting single plat trials, an error of 18 per cent means that in a comparison of the grain yield of two varieties, when the difference is not likely to exceed about 5 per cent, 214 centers with no duplication of plats at any center would be needed to try for conclusive results from one year's trials, and 53 centers when the two varieties differ in yield by 10 per cent.

**Growing orchard grass in south Missouri,** C. A. HELM (*Missouri Sta. Circ. 130* (1924), pp. 8, figs. 5).—Orchard grass is compared with timothy, its place in cropping systems is indicated, and practices are outlined for fall and spring seeding, harvesting for seed and hay, pasturing, and establishing orchard grass in permanent Ozark pastures.

**Experiments with potatoes, I, II** (*New York State Sta. Bul. 518* (1924), pp. 3-36).—These experiments are reported on in two parts.

I. *Dusting vs. spraying*, F. C. Stewart and P. J. Parrott (pp. 3-29).—In comparisons during the years 1920-1923, inclusive, of the efficiency of the Sanders' copper-lime dust and of liquid Bordeaux mixture for the control of the insect and fungus enemies of potato foliage the spray gave much the better results, as shown by the appearance of the foliage and by the yield of marketable tubers. Both early blight and late blight were controlled fairly well by dusting but considerably better by spraying. The dust proved almost valueless for

the control of tipburn or hopperburn (caused by leafhoppers), whereas the spray showed high efficiency. Nevertheless, the dust may be advisable under certain conditions, as where water is difficult to obtain and in small fields where hand machines are required.

II. *Row competition and "border effect,"* F. C. Stewart (pp. 30-36).—Row competition and border effect were studied in the three-row plats used in the dusting and spraying experiments in 1922 and 1923. In the wet season of 1922 the outside rows definitely outyielded the middle rows, while in the dry season of 1923 only an insignificant difference was found in favor of the middle rows. Furthermore, in 1922 the south outside rows outyielded the north outside rows, apparently because of the better illumination of the former. Weather conditions are held to have an important relation to row competition and border effect in potato plats.

**Sprays outrank dusts for potatoes** (*New York State Sta. Bul. 518, pop. ed. (1925), pp. 4*).—A popular edition of the above.

**Rice**, E. B. COPELAND (*London: Macmillan & Co., Ltd., 1924, pp. XIV+352, pls. 20*).—Based largely on the experience and observations of the author and recent investigations, this volume, world-wide in its scope, deals with the botany of rice; climatic, soil, cultural, and water requirements; diseases and pests; seed and varieties; the industry in the United States, Philippines, and other countries; and the uses of rice. A discussion of the commercial, economic, and social aspects of the crop concludes the work.

**Sugar beets in Louisiana**, A. F. KIDDER and C. E. COATES (*Louisiana Stas. Bul. 192 (1924), pp. 23*).—Varietal and date of planting tests during four years suggest the possibility of growing sugar beets commercially in Louisiana. Sugar beets containing from 13 to 14 per cent sucrose with a purity of 80 to 85 per cent were grown successfully without fertilizer on bluff soils and on cut-over pine lands near Baton Rouge. The yields indicate that from 10 to 15 tons per acre can be produced. The harvest season has varied from 7 to 12 weeks in length, beginning about May 1.

**The reference book of the sugar industry of the world** (*La. Planter, Ref. Book Sugar Indus. World, July, 1924, pp. 144, pls. 4, figs. 37*).—Similar in its scope to the earlier work (E. S. R., 49, p. 737), this second annual review of the sugar industry includes the following articles of interest to the agronomist:

The Sugar Crop in Java in 1923, by H. C. P. Geerligs (p. 43); Sugar in Central Brazil, by J. B. Silvado (pp. 44, 45); Mauritius and Its Sugar Industry, by H. A. Tempany (pp. 45-48); The Natal Sugar Industry, by D. M. Eadic (pp. 48-50); Sugar Cane Agriculture and Manufacture in Jamaica, by F. M. K. Jarrett (pp. 50, 51); Good Tilth and Drainage Essential to a Successful Cane Crop in Louisiana, by W. C. Stubbs (p. 70); Four-Year Rotation Experiments at the Sugar Experiment Station, Baton Rouge, La., by W. R. Dodson (pp. 70, 71); Abandoned Virgin Soils in Cuba, by J. R. Zell (pp. 71-75); The Beet Sugar Industry of Wisconsin, by S. G. Ruegg (pp. 84-86); Irrigation and Growth of Sugar Beets, by F. C. Jean (pp. 86-88); and Sugar Beet Harvest Problems, by F. Saunders (pp. 88, 89).

**Sweet potato studies in New Jersey**, L. G. SCHERMERHORN (*New Jersey Stas. Bul. 398 (1924), pp. 19, figs. 12*).—Results in investigations concerned with sweet potato fertilizers and factors influencing the shape of the sweet potato have been recorded earlier (E. S. R., 51, p. 342). The effects of different percentages of potash on the ratio of length: diameter are illustrated, and the preliminary results of hill selection are summarized briefly.

**Investigations with high-nicotine tobacco** (*New York State Sta. Rpt. 1924, p. 21*).—*Nicotiana rustica* of the 1923 crop had a much higher nicotine content

than that of 1922. Adaptation was probably a factor. Broadcast tobacco of this species again had less nicotine than cultivated plants. The nicotine content of varieties of *N. tabacum* grown in 1922 was much lower than *N. rustica*, but varied only from 1.1 to 1.64 per cent. Other phases of this work have been noted (E. S. R., 52, p. 138).

**Nicotiana rustica as a source of nicotine for insect control**, D. E. HALEY, F. D. GARDNER, and R. T. WHITNEY (*Science*, 60 (1924), No. 1555, pp. 365-366).—Analyses at Pennsylvania State College of plants of *N. rustica*, the nicotine content of which had been increased by selection, disclosed that plants topped during growth contained 2.75 per cent of nicotine, suckered plants 3.79, plants topped and suckered 4.4, and untreated plants 1.61 per cent. Results from both Lancaster and Clinton Counties were very similar as to the nicotine contents of the leaves and stalks of the topped and suckered plants. In every case the percentage of nicotine in a topped or suckered plant greatly exceeded that of an untreated plant, the results agreeing more or less with those of Oosthuizen (E. S. R., 49, p. 36).

Methods of extracting nicotine from tobacco are outlined briefly.

**Common vetch and its varieties**, R. MCKEE and H. A. SCHOTH (*U. S. Dept. Agr. Bul.* 1289 (1925), pp. 20, figs. 8).—*Vicia sativa* and its varieties are described and classified; adaptation, varietal variation, and relative winter hardiness are commented on; and summary accounts are given of experiments with the crop in cooperation with the Oregon Experiment Station.

Under average conditions seed of common vetch will diminish little in vitality in from 6 to 8 years, tests showing no difference between varieties in this respect. The percentage of hard seed is not high except in *V. sativa macrocarpa*. At Corvallis, Oreg., the hard seed content of this variety has ranged for various seasons from 60 to 99 per cent 3 months after harvest and diminished about 15 per cent during each subsequent year. Other Oregon vetch seed germinates promptly, and under favorable conditions over 90 per cent germinates in the first 3 days.

While vetch flowers are highly self-fertile, tripping may be slightly effective in aiding fertilization. Inclosing the flowers in tarlatan cages and paper bags seems to decrease to some extent the number of flowers setting pods. Insects that may trip the flowers are not essential to seed setting, although perhaps somewhat beneficial. Numerous species have been found working on *V. sativa* plants.

Spring seedings have given very poor yields, whereas fall seedings are generally productive. Early fall seedings are suggested for best results. The best rates of seeding for western Oregon and western Washington seem to be 80 lbs. of vetch when sown alone, and 60 lbs. of vetch and 40 lbs. of oats when used in combination. The usual winter injury will probably necessitate as heavy rates for the South Atlantic and Gulf Coast States. For California 60 lbs. of common vetch when sown alone, and 50 lbs. of vetch and 30 lbs. of oats or other small grain are recommended. Limited experiments indicate that drilling somewhat excels broadcasting. Depths of seeding between 1 and 4 in. did not affect yields. While rotation has been beneficial to seed yields of vetch, oats being one of the best crops for this purpose, at the same time continuous cropping to vetch has not decreased the yield. A decrease occurred in the vetch hay yields when rotated with oats and an increase when rotated with corn.

**New ways of determining the origin of seed** [trans. title], G. TRYTT (*Tidsskr. Norske Landbr.*, 31 (1924), No. 5, pp. 189-199, figs. 12).—Characteristic weed seed and the floral and mineral complex of the sample give indications of the source of seed. Fragments of horse nettle (*Solanum carolinense*)

with stellate hairs characterize *Poa* and *Agrostis*, and fragments with single hairs are found in *Phleum* and *Festuca* seed from the United States. Undetermined black excrements, such as are found in timothy, are said to be one of the characteristics of seed of American origin. Eolian sands may signify a central European source, while the samples from Norway, north Sweden, Finland, or Canada may contain the sharp alluvial or sea sand.

**A viability test for some tropical seeds, A. TOLENTINO** (*Philippine Agr.*, 13 (1924), No. 3, pp. 129-141).—Experiments at Los Baños, P. I., showed that potassium hydroxide, after the method of Lesage (*E. S. R.*, 25, p. 222), is a practical test reagent for the viability of the seeds of some tropical crops. The strength of solutions and time required to test viability for different crop seeds were as follows: Rice 0.2-0.3 N, 3 hours; corn 0.2 N, 3 hours; squash 0.4 N, 3 hours; brown mungo bean 0.025 N, 3 hours; and gray Lima bean 0.05 N, 0.5 hour. The test was not applicable to naturally colored seeds such as sitao (*Vigna sesquipedalis*), red mungo, McCall bean, red Lima bean, patola (*Luffa acutangula*), calamismis (*Psophocarpus tetragonolobus*), papaya, and sincamas (*Pachyrrhizus erosus*).

The embryo appeared to be chiefly responsible for the discoloration of the solution by dead seed, but never in the case of viable seed. Discoloration by the seed coat alone is insufficient to indicate dead seed. The most common color of the discolored potassium hydroxide solutions is either yellow or brown, and that of dead seeds is either amber or dark brown or a combination of both. Seeds with rigid, hard, and colorless seed coats require rather strong solutions. The number of seeds germinating after soaking in such solutions varied inversely with the strength of the solution when that strength exceeded the optimum, probably due to a lethal effect of the potassium hydroxide.

**Nitrogen content of weeds, E. G. CAMPBELL** (*Bot. Gaz.*, 78 (1924), No. 1, pp. 103-115, figs. 4).—Analysis of *Amaranthus retroflexus* and 25 other weed species collected at 3 stages of development and under various growth conditions showed that nitrate nitrogen (*E. S. R.*, 51, p. 39), prominent in plants of *A. retroflexus* and some other weeds during young and immature stages, completely disappears at full maturity, contrary to Woo's (*E. S. R.*, 43, p. 225) prediction. In all species grown under normal conditions, the highest percentage of nitrate is said to be found in the stage termed just before blooming. Nitrate was still present at early maturity, and at full maturity in *A. retroflexus* and *Atriplex patula* grown upon manure piles and heaps of decaying hog hair.

## HORTICULTURE

[**Horticultural investigations at the Alaska Stations**], C. C. GEORGESON (*Alaska Stas. Rpt. 1923*, pp. 14, 15, 16, 17, figs. 3).—In accordance with earlier reports (*E. S. R.*, 50, p. 539), brief notes are presented upon the behavior of various vegetable and fruit plants. The Petrowski turnip and the Yellow Transparent apple continued to show marked superiority for Alaskan conditions. While certain sour cherries produced fruit in 1923, the sweet varieties were failures, as were also pears and plums. Small fruits, namely, currants, gooseberries, and raspberries yielded well, and the Sitka hybrid strawberries (*E. S. R.*, 50, p. 140) gave satisfaction wherever tested, even in the interior of Alaska, where commercial varieties from the United States invariably winterkill. A large number of apple, gooseberry, currant, raspberry, and ornamental plants were propagated for distribution to the settlers. *Gladiolus* bloomed abundantly and was highly esteemed.

[**Horticultural investigations at the New York State Station**] (*New York State Sta. Rpt. 1924, pp. 46-50*).—This is the usual annual report (E. S. R., 50, p. 539) containing brief progress notes upon the work of the year ended June 30, 1924. Grape fertilizer studies at Fredonia and Urbana continue to show that nitrogen is the only form of fertilizer returning a profit to grape growers.

Observations extending over a 12-year period upon budded and grafted apple trees showed no differences between the two. A comparison between apples topworked on Northern Spy and grown on their own roots indicated that own-rooted trees are preferable. Rome Beauty trees propagated from productive and unproductive parents showed, at 12 years of age, no differences that could be attributed to ancestry. The fact that Baldwin trees procured from 40 locations in the United States are producing fruits identical in size, color, season, and quality leads to the conclusion that, if there are distinct strains of this variety, such have not originated because of environmental differences due to geographical location.

[**Horticultural investigations at the South Carolina Station**] (*South Carolina Sta. Rpt. 1924, pp. 53-56, 57-59, figs. 3*).—Cooperative experiments with peach fertilizers have indicated that on both sandy and clay soils nitrogen is the limiting factor to tree growth. Applications of phosphoric acid and potash up to 10 per cent did not result in greater growth than was attained without the materials. With newly set trees, 0.5 lb. of nitrate of soda gave better growth results than did larger amounts. Heavy applications of nitrogen were observed to delay the ripening of fruit.

On sandy river bottom soil of rather poor quality, the maximum yield of marketable tomatoes was obtained with 1 ton of mixed fertilizer rich in phosphoric acid and organic nitrogen. Muriate of potash was found to be significantly more beneficial for the tomato than was sulfate of potash.

Variety tests of tomatoes, apples, and northern grapes are reported.

[**Horticultural work at the Brandon, Man., Experimental Farm in 1923**], W. C. MCKILLICAN (*Canada Expt. Farms, Brandon (Man.) Farm Rpt. Supt. 1923, pp. 57-72*).—This report, composed principally of brief cultural and varietal notes on vegetables, reports the results of a test of the effect of pinching the leaders of staked tomato plants. No advantage was gained in earliness of fruiting where only one truss was allowed to fruit, while at the same time there was a heavy reduction in yield.

**Report on commercial insecticides and fungicides** (*Connecticut State Sta. Bul. 258 (1924), pp. 361-377*).—Like the preceding report (E. S. R., 49, p. 233) this paper is presented in two parts, the first of which comprises the text of the insecticide law of Connecticut and regulations for its enforcement, and the second part, by E. M. Bailey in collaboration with R. E. Andrew et al., contains the results of the examination of insecticides, fungicides, healthy and diseased tobacco plants, etc. In the case of the tobacco plants, the analyses of which were made for the benefit of the department of botany, diseased leaves were found to have in most cases a higher nitrogen and a lower carbohydrate content than healthy leaves. Allowing for the ash insoluble in acid, it is believed that diseased leaves are somewhat poorer in mineral constituents than are healthy leaves.

**Orchard soil management**, F. W. FAUROT (*Kans. State. Hort. Soc. Bien. Rpt., 37 (1922-23), pp. 56-60*).—Measurements of the increment of trunk growth in two apple orchards planted in 1919 and 1921 on rather poor soil at the Missouri Fruit Experiment Station, Mountain Grove, showed that cultural treatments have had very significant effects on growth. Those trees in the 1919 orchard receiving tillage, manure, sodium nitrate, and cover crops made

the greatest average annual gain, 1.91 in., as compared with 1.17 in. for the control trees where grass was cut but not gathered. In the 1921 orchard, where no fertilizers had been used, the best gain, 1.44 in. per year, was made by trees which were mulched with the grass cut in the interspaces. The check trees in this case made but 0.78 in. gain.

**A preliminary report on Jonathan breakdown,** P. M. DALY (*Sci. Agr.*, 5 (1925), No. 5, pp. 155-165, figs. 6).—Following the suggestion from practical growers that Jonathan breakdown is associated with the stage of maturity at which the fruit is harvested, in the fall of 1923 fruits were gathered twice a week, starting September 17 and ending October 27, from carefully selected trees located in five orchards in the Okanagan Valley, British Columbia. Approximately half of the fruit was stored at Summerland, and the rest, after preliminary holding at Kelowna, was forwarded to Ottawa and there placed in ordinary storage, ranging between 38 and 40° F.

In examinations made at Ottawa at approximately monthly intervals, it was found that of the 51 experimental trees involved, 38 bore fruit showing breakdown and 13 fruit absolutely free therefrom. Fruits picked prior to October 11 showed only one defective apple in 5,460 examined, indicating that the date of picking was a very important factor. Beyond October 11 an increasing percentage of breakdown was correlated with the advance of the picking season. That growing environments may have an important relation to breakdown in the Jonathan apple was shown in very significant differences in the amount of defective fruits from the several orchards. The fact that nonirrigated and irrigated trees bore fruit developing breakdown in almost equal quantities is deemed to indicate that soil moisture is not a contributory factor. Furthermore, soil fertility and the vigor of the trees could not be in any way associated with the trouble.

The author concludes that the results to date show that picking maturity is the main factor in the prevention of Jonathan breakdown, but warns that, because of seasonal fluctuations, no particular date for picking can be established, the stage of maturity being determined by actual examination of the fruit.

**How to prune the young cherry tree,** R. H. ROBERTS (*Wisconsin Sta. Bul.* 370 (1924), pp. 16, figs. 13).—In this well-illustrated bulletin there are presented concise, practical directions for pruning immature sour cherry trees, paying particular attention to the selection of the leader and the distribution of the principal scaffold limbs.

**The grafting of American grapes,** F. E. GLADWIN (*New York State Sta. Bul.* 520 (1924), pp. 3-18, pls. 6).—Following an earlier bulletin (E. S. R., 52, p. 443) outlining the results of grafting American grapes upon various stocks, the author herein discusses the methods and practices employed in grape grafting, pointing out the niceties of technique which are required to insure success. Failure in cleft grafting in the vineyard is thought due to several reasons, such as the use of incompatible varieties, unfavorable seasonal conditions, exclusion of air by wax or other similar material, and the presence of excessive moisture. The English whip-and-tongue graft was found especially satisfactory for bench grafting, using as stocks cuttings taken from one-year canes and as scions one bud pieces of the same diameter and of the desired variety.

Callusing was promoted by storing grafts in an upright position in wooden boxes lined with wet sawdust. Tests carried on for three years indicated that temperature is an important factor in callusing. In general, vinifera and southern United States varieties required more heat than did northern sorts.

The time required for callusing was found to vary with the seasons, indicating perhaps, an effect of stored foods. For example, in 1922 Iona, Campbell, Delaware, Worden, and Concord required 27 days, with a mean temperature of 76° F., while in 1923, 21 days at 70° were sufficient. In general conclusion, the author asserts that 50 per cent is a normal expectancy of survival in well-made and well-called grafts of Concord and Catawba.

**Cool storage of fruit: Report on experiments conducted during 1923 season, D. B. ADAM** (*Jour. Dept. Agr. Victoria, 22 (1924), No. 10, pp. 577-590*).—A further report upon studies in fruit storage (*E. S. R., 49, p. 437*).

Records taken on Kieffer pears stored at 32 and 34° F. showed 88 and 75 per cent, respectively, of sound fruit after eight months' storage. The relation of the stage of maturity at harvest to blackening of the skin of Kieffers was indicated by 8, 7, and 23 per cents of discoloration for fruits gathered February 16 and March 2 and 24, 1923, respectively.

In the case of Jonathan apples harvested March 22 and April 17 from the same trees, then inclosed in ordinary paper wrappers, and stored at 32 and 36°, scald was much severer at both temperatures on the early picked fruits. Similar results were secured with Stone Pippin apples harvested April 18 and May 2 and stored at 34°. While oiled wrappers materially reduced the amount of scald on various varieties of apples they had no consistent effect on the development of Jonathan spot. A study of the relation of time of picking to the development of internal breakdown in Stone Pippin apples indicated, contrary to the findings of Daly, noted on page 538, that relatively immature fruits were more susceptible to this type of injury. An examination of Rokewood apples held six months at 32 and 37° showed somewhat more internal browning at the lower temperature. In the case of bitter pit, early picked Anne Elizabeth apples developed more injury in storage than did later gathered fruits. Rokewood apples moderately affected with water core regained their normal character after a few weeks in storage.

Observations on the keeping quality of oranges grown in different localities showed some differences in connection with the source. Tissue wrapped oranges, although keeping little better than control fruits, were more attractive in outward appearance.

Apricots stored at 37 and 35° developed more blue mold but were higher flavored than those held at 32°. Of three plums, Wickson, President, and Fellenberg, the President was found to be the best keeper.

In studies of peaches, Elberta did not keep at all satisfactorily, quickly becoming mealy and losing its flavor. Catherine Ann peaches held their original condition much better at 32° than at higher degrees, and a small shipment of this variety was successfully transported to London markets.

In storage tests with Bartlett (William's Bon Chretien) pears, 32° proved a more satisfactory temperature than either 34 or 36°.

**Transportation of citrus fruit from Porto Rico, R. G. HILL and L. A. HAWKINS** (*U. S. Dept. Agr. Bul. 1290 (1924), pp. 20, figs. 8*).—Records taken on four experimental trips from Porto Rico to New York City showed the possibility of cooling down a cargo of fruit approximately 15 to 27° F. during the voyage when the outside air and water temperatures ranged about 80°. The value of refrigeration in inhibiting rot development was shown in a comparative test of ventilation and refrigeration, the respective percentages of rot in the case of well-grown and well-packed oranges being 3.7 and 1. The average percentage of rot in refrigerated oranges, including both cultivated and uncultivated material, was 1.7. For grapefruit the average was less than 1 per cent. The value of refrigeration was more marked in the case of a lot of oranges

shipped in two vessels, one refrigerated and the other simply ventilated. The refrigerated fruit arrived in New York with no appreciable decay, while the ventilated showed 22 per cent injury.

The placing between the layers of boxes of strips of wood, called dunnage, enabled the air to circulate in the interior of the load and greatly facilitated the cooling of the fruit. In a test of three methods of stowage: (1) Dunnage between each layer, (2) between every second layer, and (3) no dunnage, the average temperature of the middle layers was reduced 14, 11, and 10°, respectively, during the trip from San Juan to New York. The authors conclude, therefore, that the use of dunnage for every layer greatly promotes the efficiency of refrigeration, and in general conclusion state that well-grown, carefully packed, and carefully stowed citrus fruits may be safely carried in refrigerated vessels from San Juan to New York City.

**The coconut in Indo-China** [trans. title], GUILLAUME (*Bul. Écon. Indochine, n. ser.*, 27 (1924), No. 165, pp. 137-194, pls. 4, figs. 18).—A survey of the coconut-growing industry, discussing such details as distribution, botany, soils, cultural aspects, injurious insects, harvesting practices, and utilization, including manufacture of copra, oil, fibers, etc.

**The coconut industry in Portuguese India**, P. CORREIA AFONSO (*O Coqueiro: Produção, Indústrias, Comércio. Nova Goa, Portug. India: Dir. Serv. Agr., Florestais e Pecuários, 1924, pp. 172+II, pls. 25*).—This comprises general information concerning the extent and distribution of the industry and cultural and manufacturing practices.

**Almond varieties in the United States**, M. N. WOOD (*U. S. Dept. Agr. Bul. 1282 (1924), pp. 142, pls. 26, figs. 16*).—Confusion in the nomenclature of the almond having led to the presence of a large proportion of inferior and unadapted varieties in California orchards, the author conducted a careful study of the varieties, both those commercially grown and those little known in the United States, and herein presents carefully detailed technical descriptions of varieties, with a key based on the characteristics of the nuts. The information is further enhanced by accurate drawings of the nuts and photographs of the bark and of the leaves. Early attempts at almond production in the United States, the present distribution in California, and the importance of choosing the best varieties are briefly discussed.

**The book of gardens and gardening**, edited by R. T. TOWNSEND (*Garden City, N. Y.: Doubleday, Page & Co., 1924, pp. [6]+106, pl. 1, figs. 293*).—A symposium of illustrated articles relating to gardens, their arrangement, utilization, and management.

**Gardens: A note-book of plans and sketches**, J. C. N. FORESTIER, trans. by H. M. FOX (*New York and London: Charles Scribner's Sons, 1924, pp. X+237, illus.*).—An elaborate volume, probably of chief interest to the landscape gardener or architect, and consisting for the most part of copies of sketches of French and Spanish gardens with discussions of their principal features.

## FORESTRY

**Some factors affecting reproduction after logging in northern Idaho**, J. A. LARSEN (*Jour. Agr. Research [U. S.], 28 (1924), No. 11, pp. 1149-1157, figs. 5*).—Records taken on a broad river bench at an elevation of 2,300 ft. in the Priest River Valley, Idaho, indicated that the amount of forest cover has a very important bearing upon soil and air temperatures and humidity. Three neighboring stations, (1) within a virgin mixed forest, (2) under approximately one-third overhead shade, and (3) on a fully exposed site, were

utilized. Air and soil temperatures in the open averaged from 7 to 8° higher than in the virgin forest, and were accompanied by lower humidity and higher evaporation, factors militating against the establishment on such sites of western white pine and other moisture-loving species. Large openings in the forest, bringing about as they do a change in the physical condition of the site, were observed to affect materially the character of reproduction.

Studies of the effect of the nature of the surface soil on the germination of western white pine seed showed the best total germination on the bare mineral soil and on partly burned duff, with the highest first-season germination on the deep ash area. A second germination test, in which western larch, Engelmann spruce, and western white pine were included, showed the larch and spruce to be somewhat better adapted to duff seeding than was the western white pine. Duff, however, was found subject to greater temperature and moisture fluctuations than the bare soil, and hence, for seedlings such as spruce, hemlock, and cedar, characterized by short and tender roots, was an unfavorable medium. Records taken on slopes of different exposure indicated that in full insolation soil surface temperatures often rise to a point practically prohibiting the establishment of seedlings of western white pine, cedar, and hemlock, thus explaining the general scarcity of these species on such open sites. It is suggested that a method of cutting which would provide smaller openings and partial shade would produce better silvicultural results.

**A study of Douglas fir reproduction under various cutting methods, J. ROESER, JR. (*Jour. Agr. Research [U. S.]*, 28 (1924), No. 12, pp. 1233-1242, pl. 1, figs. 3).**—In testing the effects of four cutting treatments, namely, (1) clear, (2) none, (3) shelterwood, and (4) selection, upon reproduction in a typical Douglas fir forest located at the Fremont, Colo., Forest Experiment Station, it was found that the shelterwood system of cutting was decidedly the most favorable to reproduction, both in the number and in the size of the surviving seedlings. Reproduction counts in 1923, 10 years after cutting operations, showed 1,005, 1,237, 6,891, and 4,638 established seedlings per acre for the respective areas. As compared with earlier records, there was shown a steady gain for the clear-cut area and a steady loss for the virgin stand. Douglas fir was represented on the respective areas by 62, 57, 80.3, and 85 per cent of the total reproduction. The lack of soil moisture in the clear-cut and the uncut areas is believed to be the most limiting factor to Douglas fir reproduction. On the uncut area, in periods of drought the parent trees may easily become the seedlings' worst enemy.

On each of the three lumbered areas two methods of slash disposal, (1) scattering and (2) piling and burning, were compared in their relation to reproduction, leading to the conclusion that either method plays only a minor rôle, especially in the case of Douglas fir, the most important species. Humus, an obstacle to root penetration of seedlings, was found to be deepest in the open area, especially under the scattered slash.

The superiority of the shelterwood system of cutting was also shown in the comparative height of Douglas fir seedlings on the various areas. On the uncut area, the average height was 1.49 in., while on the shelterwood, clear-cut, and selection areas the average heights were, respectively, 3.53, 2.66, and 2.15 in. in the slash-scattered section and 3.12, 2.7, and 2.7 in. in the slash-burned sections. The figures are based on groups of from 40 to 341 seedlings of average ages varying from 5.4 to 6.05 years.

**Fall sowing and delayed germination of western white pine seed, W. G. WAHLENBERG (*Jour. Agr. Research [U. S.]*, 28 (1924), No. 11, pp. 1127-1131, figs. 4).**—Studies carried on at the Priest River Forest Experiment Station,

Idaho, and the Savenac nursery, Montana, have shown that fall sowing of western white pine seeds is much more satisfactory than spring sowing, the former resulting in prompt and satisfactory germination the succeeding spring, whereas spring sowing was generally unsatisfactory because of incomplete and delayed germination. Spring sowing usually resulted in uneven sized stands, which either required severe culling at the end of the second year or had to be left an extra year in order for the smaller plants to attain satisfactory size. Time of planting studies, in which sowings were made at frequent intervals from late August to November at the Savenac nursery, showed that the first two weeks in September is the most satisfactory period for planting western white pine seed at this location. Because of their early spring germination, thus affording opportunity for considerable development before the advent of hot summer weather, fall-sown beds did not require straw mulching or lath shading, operations both expensive and laborious.

**Growth on cut-over and virgin western yellow pine lands in central Idaho.** C. F. KORSTIAN (*Jour. Agr. Research [U. S.]*, 28 (1924), No. 11, pp. 1139-1148, pls. 3).—A study of mortality and increment on 16 sample plats representing both cut-over and virgin stands of western yellow pine, located in the Payette National Forest, Idaho, showed the cut-over areas to be in much the thriftier and more vigorous condition. Records taken over a 5-year period indicated that the cubic volume upon the cut-over areas had increased at the rate of 5.3 per cent per annum as compared with 0.6 per cent for the virgin stands, a difference believed to be due largely to the greater amount of bark-beetle injury, wind throw, mistletoe on Douglas firs, and suppression on the older stands, which consisted largely of ripe or very mature trees. The losses from death and decay thus practically nullified the annual increment. Observations on reproduction on several plats indicated the importance of sparing advance reproduction during logging, estimates indicating that otherwise as many as 20 years are often required to secure adequate restocking of poorer quality sites. The leaving of a few healthy seed trees still capable of making profitable growth further insures reproduction. Preferably such seed trees, except on wind-swept ridges, should be located singly, so that full advantage may be taken of light and satisfactory seed distribution assured.

**The rôle of fire in the California pine forests.** S. B. SHOW and E. I. KOTOK (*U. S. Dept. Agr. Bul. 1294 (1924)*, pp. 80, pls. 15).—An extended study of burned-over areas in the California pine forest region showed that, although fires in the virgin forest are rarely devastating, there is always a large amount of relatively inconspicuous and insidious injury, notably the killing of reproduction and the scarring of tree trunks, leading to their ultimate destruction. Furthermore, each succeeding fire apparently becomes more and more serious, until finally the scarred virgin forest becomes pure brush or chaparral, through the successive stages of a broken, patchy timber stand and brush fields containing isolated or small groups of trees.

An examination of fire-scarred trunks showed that fires have occurred in the California forests at approximate intervals of eight years for centuries, and undoubtedly have been a potent factor in determining the character of the forest. Inasmuch as highly inflammable pitch exudes from slight as well as severe wounds, light fires are considered potentially as serious to the welfare of the forest as are severe fires.

In respect to susceptibility to heat killing, western yellow and sugar pines were strikingly less susceptible than white fir or incense cedar, due to the inflammability of the white fir foliage and the low stature of the cedar. Quality of site was also a factor in heat injury, in that on the better sites the trees

were taller. Increment borings in crown-injured trees showed a growth reduction in direct relation to the extent of the injury. In correlating crown injury with height of fire-injured western yellow pine, it was evident that the degree of injury varied inversely with the total height of the trees. Concerning the relative susceptibility of species to crown injury, the western yellow and the sugar pines were found more resistant than Douglas fir or incense cedar. Insect and fungus injuries were found much more severe following burnings. Even the lightest of fires were found to have a disastrous effect on reproduction, especially on seedlings 2 in. or less in diameter. Observations on trees less than 4 in. in diameter showed the western yellow pine to be the most resistant to fire of four species, followed by sugar pine, white fir, and incense cedar. In general conclusion, the authors point out that every phase of the study indicates the incorrectness of the old conception that fire is beneficial to the California pine forests.

## DISEASES OF PLANTS

[Plant disease investigations at the New York State Station] (*New York State Sta. Rpt. 1924, pp. 29-34*).—Summary reports are given of various investigations of plant diseases in progress at the station, including those on isolation and roguing and mosaic of potatoes noted on page 548.

Seeding beans as late as June 15 is said to have resulted in plants less susceptible to bacterial wilt than earlier plantings. The removal of flowers and pods seemed to delay attacks of bacterial wilt, and it is believed that susceptibility is associated with translocation of nutrients within the plant.

The application of fungicides to soil is said to have controlled China aster diseases so far as they are due to fungi which occur near the surface of the soil. It did not, however, control those which attack the roots deep in the soil.

Summary accounts are given of investigations in cabbage seed bed diseases and Delphinium root rots (E. S. R., 52, p. 50), and cauliflower diseases on Long Island (E. S. R., 51, p. 152). More recent investigations of cauliflower diseases are said to indicate that black rot is generally present in the seed and is usually introduced in the field by means of the seed. Investigations are said to be in progress on methods of seed treatment adapted to Long Island conditions.

An account is given of the dying of fruit trees in the Hudson Valley, observations having been made on about 200 separate lots of trees. The disease is not confined to the Hudson Valley, and the preliminary results indicate that it is due to many causes not definitely mentioned.

In the study of apple diseases in the Hudson Valley, an attempt was made to control the Phoma or Brooks' fruit spot of apples by spraying and dusting. Owing to the absence of disease in the orchards under experiment, no definite results were obtained.

Spraying experiments for scab were carried on in two orchards, and in connection with these experiments the discharge of the ascospores of the fungus was studied and the periods of infection in the spring determined.

Notes are given on raspberry disease investigations, particular attention being paid to mosaic and wilt. Experimental plantings made in the spring of 1923 of mosaic-free stock are said to show considerable mosaic, and to make it doubtful whether the roguing method of control can be made successful. The success of roguing is thought to be connected with the control of the aphid which is responsible for its spread. Preliminary studies on the running out of black raspberries are said to indicate that probably the wilt due to *Verticillium albo-atrum* is an important factor.

**Plant diseases** (*South Carolina Sta. Rpt. 1924, pp. 48-51*).—As an outcome of a plant disease survey, it is reported that there were observed in South Carolina an *Ascochyta* canker of cotton, which was first reported in Arkansas (E. S. R., 47, p. 447), and another destructive cotton disease, the cause of which has not been definitely determined.

The nematode disease of wheat was found in the northwestern part of South Carolina in May, 1924.

Previous work of the station on cotton anthracnose has shown that infected seed become free from the fungus if kept in storage long enough (E. S. R., 36, p. 646). Subsequent studies were carried on in an effort to find means of hastening the death of the fungus, but the results thus far do not seem to be very promising in this respect.

A bacterial pod spot of peas is reported, in which the organism has been isolated and the disease reproduced. The organism is being studied preliminary to a detailed publication.

A disease of wild onions, which is said to be exterminating that plant in one of the counties in South Carolina, is reported. The fungus responsible for the disease is as yet undescribed.

**Plant pathology**, C. D. SHERBAKOFF (*Tennessee Sta. Rpt. 1923, p. 27*).—In a study of wheat deterioration attempts have been made to determine the varietal susceptibility and resistance to root rots, scab, and black chaff. Field tests are said to have shown a marked difference in the degree of susceptibility of different varieties to scab and possibly to black chaff.

A study of the fusaria causing wilt of economic plants in Tennessee has been continued, and information has been obtained on the morphology and physiology of the species of *Fusarium* occurring on tomatoes, potatoes, soy beans, and other plants. Studies of *F. moniliforme*, a common corn parasite, are said to indicate that this fungus, although occurring on corn seed, has little effect on the yield of corn, under conditions of the author's experiment.

[**Plant diseases, Mysore, 1922-23**], K. V. ANANTARAMAN (*Mysore Dept. Agr. Rpt., 1922-23, pp. 1, 2*).—In this report it is stated that areca nut koleroga, which is spreading, caused heavy losses during the year, being favored by rains, which did not, however, prevent an increase of the area sprayed to 1,200 acres as against 750 acres in 1921-22. Further studies on sandal spike proved beyond doubt that root connections constitute one means of spreading the disease. The hibernating stage of coffee black rot was found, and ragi smut and betel and grapevine mildew received attention.

[**Report of mycological section, Mysore**], H. V. KRISHNAYYA (*Mysore Dept. Agr. Rpt., 1922-23, pt. 1, p. 4*).—The facts above noted regarding koleroga, coffee black rot, ragi smut, and sandal spike are referred to, emphasizing the need and value of adding to the spray for koleroga a casein adhesive. The addition of this spreader to Bordeaux mixture has been found effective also against grapevine mildew.

**Report of work done in the mycological section during 1922-23** [Mysore], M. J. NARASIMHAN (*Mysore Dept. Agr. Rpt., 1922-23, pt. 2, pp. 13-15*).—Losses due to koleroga of areca nut were heavy where spraying had not yet been resorted to or where the work was hindered by continuous rain. Extension of work testing casein as an adhesive showed that 0.5 lb. to 25 gal. of spray mixture was efficient even in spite of the heavy rainfall of the Ghat areas.

A disease similar to koleroga was observed to cause the fall of all the leaves. A similar disease was observable on plants common around the garden, as *Bryophyllum calycinum*, *Colocasia antiquorum*, and wild fig.

Areca nut root disease (*Thielaviopsis* sp.) was brought into pure culture and inoculated into healthy trees, and the results of these experiments are awaited.

Coffee black rot was studied, and the hibernating stage was found. A number of wild plants are attacked by a disease apparently similar. Coffee die-back was severe. Lime applications had no good effect.

Smut on seeds of *Eleusine coracana* was apparently eliminated in one experiment by the use of copper sulfate, copper sulfate and lime, or formalin. Betel vine mildew has done no severe damage since the spraying of August, 1922.

Bordeaux mixture in December at 5-5-50 strength with casein was effective against grapevine mildew, as also against leaf rust (*Uredo vialae*) and fruit rust. Banana fruits and stems inoculated with *Thielaviopsis* sp. showed local discoloration and lack of development.

Root connections have been shown by exposure and photography to cause spike in sandal. Spiked sandal is often associated with spiked *Zizyphus*.

**A new method of obtaining mosaic "virus,"** J. JOHNSON and M. MULVANIA (*Science*, 60 (1924), No. 1540, p. 19).—The authors found by submitting the root system, or the end of a cut stem, to a pressure of about 100 lbs. the contents of the vascular bundles could be forced out of the plants and collected with capillary pipettes or medicine droppers. When a succulent mosaic plant with hydathodes was so treated it yielded considerable quantities of liquid water containing the infectious principle, though apparently the virus was not as concentrated as when secured from crushed tissue. A comparative microscopic study of the liquid exuded from healthy and diseased plants did not lead to any conclusive results as to the presence of an organism.

Virus obtained in this way is considered to approximate closely the virus obtained by sucking insects, and the method is considered useful for cross-inoculation studies.

**Aecial stages of the leaf rusts of rye, *Puccinia dispersa* Erikss. and Henn., and of barley, *P. anomala* Rostr., in the United States,** E. B. MAINS and H. S. JACKSON (*Jour. Agr. Research [U. S.]*, 28 (1924), No. 11, pp. 1119-1126, pl. 1).—The authors report that the leaf rust of rye is able to produce aecia on species of *Anchusa* in the United States. *A. officinalis* and *A. capensis* were found to be quite susceptible. *Nonnea rosea* was infected occasionally, with production of pycnia only. The other boraginaceous species tested remained uninfected. *A. capensis* was found naturally infected by the leaf rust of rye, and it is thought that it may become of some importance in the spread of the disease. The teliospores of the leaf rust of rye are said to be capable of overwintering in the United States, and may germinate the following spring.

The leaf rust of barley, *P. anomala*, was found to develop aecia on *Ornithogalum umbellatum*.

**Relative resistance of wheat to bunt in the Pacific Coast States,** W. H. TISDALE, J. H. MARTIN, ET AL. (*U. S. Dept. Agr. Bul.* 1299 (1925), pp. 30).—The results are given of studies at Davis, Calif., Moro, Oreg., and Pullman, Wash., of nearly all of the commercial varieties of wheat grown in the United States, as well as numerous foreign wheats and selections from other domestic varieties. Seed of the different varieties and strains was smutted by the spores of *Tilletia tritici* and planted in nurseries at the above stations during two seasons.

Nearly all the varieties of American wheats, all but one of the Australian wheats, and all of the Indian and South African wheats tested were found more or less susceptible to bunt. Of the four commercial classes of common wheat, the hard red winter wheats were found the most resistant, and the white wheats were as a class the most susceptible. The hard red spring and soft

red winter varieties were somewhat intermediate in susceptibility, but one of the soft red winter varieties proved highly resistant. The club wheats as a rule proved the most susceptible to bunt. Durum, Polish, and poulard wheats, as well as emmer and spelt, were in general somewhat more resistant than the common wheats, except hard red winter.

The varieties and strains proving to be immune or highly resistant are enumerated, and their probable value for further hybridization work and for commercial planting is indicated.

**The present status of the hot water treatment in Indiana,** C. T. GREGORY (*Ind. Acad. Sci. Proc.*, 38 (1922), pp. 315-318).—It has been shown that presoaking is one of the essential steps in the treatment of loose smut in wheat. Presoaking for 4 hours is sufficient, and 12 hours' soaking may cause germination. Not more than 1 bu. of dry wheat should be soaked in a 2-bu. burlap sack on account of swelling. Where large amounts of wheat are treated a device has been used, consisting of a heavy wire drum holding 5 bu. of soaked wheat, which revolves in a large tank of water heated by steam. A device enabling the operator to keep the wheat in the hot water without burning his hands consists of loops of heavy twine fastened by a slip noose to the mouth and one corner of the sack.

The time of treating and the temperature of the water have not undergone any change. Temperatures as high as 135° F. will not injure wheat, and it is known also that immersion at 130° for 15 minutes will not do any particular harm to the seed. It has been found that it is necessary only to surface dry the grain so that it will run through the drill without clogging.

Usually the stand of the treated wheat is rather thin, but the plants stool much more than the untreated wheat, so that the final number of heads produced is about the same in both cases. Generally the heads in the treated wheat are much more uniform in size and are usually somewhat larger than in the untreated. The treated wheat will usually ripen about a week later than the untreated wheat, but this is not objectionable. The hot water treatment as a means of ridding the wheat of cockle can not always be depended upon.

It has been demonstrated in Knox and Shelby Counties that a widespread use of treated seed will greatly reduce the dangers of the spread of smut. The best way to handle this problem is to establish smut-free areas or communities.

**Chemical eradication of the common barberry,** N. F. THOMPSON (*U. S. Dept. Agr., Dept. Circ. 332* (1924), pp. 4).—Suggestions are given for the destruction of the common barberry by the use of salt or kerosene. The advantages and disadvantages of each chemical are pointed out.

**Differences in the susceptibility of clover to powdery mildew,** E. B. MAINS (*Ind. Acad. Sci. Proc.*, 38 (1922), pp. 307-313, fig. 1).—The mildew of red clover (*Trifolium pratense*) is apparently specialized on that host, crimson (*T. incarnatum*), alsike (*T. hybridum*), and white (*T. repens*) not being infected. Considerable differences are shown among red clover varieties as to mildew susceptibility, American varieties being much more susceptible than European. Resistant individuals in various numbers are probably to be found in all varieties. Selection and breeding for resistance offer the best means for controlling the disease.

**Transmission of cowpea mosaic by the bean leaf-beetle,** C. E. SMITH (*Science*, 60 (1924), No. 1551, p. 268).—Preliminary experiments carried on during 1921 indicated that the bean leaf beetle (*Ceratoma trifurcata*) transmitted the cowpea mosaic. Subsequent investigations have confirmed this

previous conclusion, and it was established that insects which were fed for one day on diseased plants and then transferred to healthy plants transmitted the disease in practically every case.

The "mosaic disease" of the hop, E. S. SALMON (*Jour. Inst. Brewing*, 29 (1923), No. 11, pp. 882-889).—As part of the sixth report on the trial of new varieties of hops, an account is given of an outbreak of leaf mosaic at the research station, East Malling, with discussion of the question as to whether the new variety M45 is a carrier of the mosaic disease.

"The cause of 'mosaic' and 'nettlehead' diseases is probably to be attributed either to a virus or to an ultramicroscopical organism carried in the sap of the hop plant and transmitted from diseased to healthy plants by aphids. . . .

"With our present knowledge, therefore, it is clearly inadvisable to plant M45 in the immediate neighborhood of commercial varieties which are susceptible to the 'mosaic' disease. It is possible that it will prove safe to grow M45 with the Fuggles variety, since the latter, although subject to the 'nettlehead' disease, appears to be resistant to the 'mosaic' disease."

**Potato leaf roll in Indiana**, M. W. GARDNER and J. B. KENDRICK (*Indiana Sta. Bul.* 284 (1924), pp. 23, figs. 7).—This bulletin treats of the nature and behavior of potato leaf roll under Indiana conditions, and gives an account of investigations on the effect of disease on yield, its spread in the State in different seasons, and the relative susceptibility of various commercial varieties.

The authors report that under Indiana conditions it is practically impossible to recognize leaf roll plants in the late crop with any degree of certainty, but the presence of the disease is readily revealed by growing the second generation in the greenhouse. By testing in the greenhouse one eye each from tubers sent in from various counties, it was found that the disease was widespread and prevalent in the State, particularly in low-yielding stocks. In field plats in a number of regions of the State, the yield from rows planted with leaf roll tubers was from 22 to 66 per cent less than that from healthy tubers. In 1923 the infection was more extensive than in the previous year, and in 1922 the disease was more prevalent than in 1921.

Recent investigations showed that the disease decreased with increasing distance from the source of infection, although considerable infection occurred at a distance of 75 ft. Recently infected hills were found to produce tubers, some of which yielded leaf roll and some healthy plants in the greenhouse tests. The varieties Early Ohio and Irish Cobbler proved susceptible in field plats, but not as susceptible as the Rural New Yorker. The variety Bull Moose was also found to be very susceptible. While the use of leaf roll seed tubers was found to reduce the yield, it was found that as a rule this was not true of current season infection.

From the authors' investigations it is concluded that leaf roll can not be detected with certainty in the field and that current season infection does not decrease the yield, rendering it practically impossible to eliminate the disease from seed fields. As a means of practical control, the authors recommend the use of seed stocks grown in regions where the disease does not spread or where it may be eliminated by field inspection.

**Pythium rootlet rot of sweet potatoes**, L. L. HARTER (*Jour. Agr. Research* [U. S.], 29 (1924), No. 1, pp. 53-55, pl. 1).—A description is given of a *Pythium* rootlet rot of sweet potatoes which is said to occur quite commonly in hotbeds in various parts of the country. The disease is apparently due to species of *Pythium* of the *debaryanum* type. It apparently begins at the end of the small

rootlets and works progressively toward the main roots. All 21 varieties tested were found susceptible to the disease, but not to the same degree.

**Control of leafroll and mosaic in potatoes by isolating and roguing the seed plat,** F. C. STEWART (*New York State Sta. Bul. 522 (1924), pp. 3-14*).—The results are given of an experiment carried on at the station during five seasons in which an attempt was made to rogue the plats for leaf roll and mosaic. It was found difficult to rogue properly, and as a result there was in the fifth season 15.5 per cent of leaf roll in stock which was practically free from leaf roll at the beginning of the experiment.

An experiment on the control of mosaic by roguing was conducted at Malone, in the northern part of the State, during three seasons. It was begun with greenhouse-tested seed thought to be mosaic-free, yet the crop of 1923, when tested in the greenhouse, was 4.4 per cent mosaic.

As a result of these experiments, the author concludes that isolation and roguing of the seed plat can not be depended upon to control satisfactorily either mosaic or leaf roll, or even to prevent potatoes from running out with the latter disease under certain conditions. Nevertheless, the practice is recommended as a helpful one.

Experiments are said to show that the tuber-index method of testing tubers for mosaic in the greenhouse is an excellent one for obtaining mosaic-free seed with which to start a seed plat.

**Growing disease-free seed potatoes** (*New York State Sta. Bul. 522, pop. ed. (1925), pp. 4*).—A popular edition of the above.

**The sugar cane disease situation in 1923 and 1924,** C. W. EDGERTON, W. G. TAGGART, and E. C. TIMS (*Louisiana Stas. Bul. 191 (1924), pp. 3-44, figs. 8*).—According to the authors, the seasons of 1923 and 1924 were unfavorable to sugar cane growing in Louisiana, that of 1923 being exceptionally wet and 1924 extremely dry. Cane borer infestation was very heavy in 1923, and this was accompanied by severe infection of red rot. The three diseases which had a detrimental effect on the crop are said to be red rot (*Colletotrichum falcatum*), mosaic, and root rots, due to species of *Marasmius* and *Rhizoctonia*. The red rot is said to have decreased the sugar content of the juice in 1923, and materially hurt the germination of the buds. Mosaic has been found to decrease the vigor of the cane, and is considered responsible for considerable losses. The oldest infected districts, however, were not the ones showing the poorest crop conditions. Root rots aided by weather conditions were very important, the diseases appearing in practically every section in the State. Some varieties of cane have been found to be less subject to infection, and these are being propagated for general planting. The selection of healthy seed cane is advocated in order to free canes gradually from excessive root rot infection and to reduce loss from mosaic.

**Phytophthora rot of tomato, eggplant, and pepper,** J. B. KENDRICK (*Ind. Acad. Sci. Proc., 38 (1922), pp. 299-306, figs. 2*).—A *Phytophthora* rot of tomato, eggplant, and pepper fruits occurred in a field at Lafayette, Ind., in 1921, being repeatedly isolated also from diseased fruits. Successful inoculations were secured on eggplant and pepper with the fungus isolated from tomato, and subsequent reisolations from inoculated fruits were made. The symptoms on tomato resemble very closely tomato buckeye rot as described by Sherbakoff (*E. S. R., 38, p. 251*), and the fungus agrees morphologically with *P. terrestris*. Under field conditions, natural infection of immature, uninjured, green tomato fruits occurred.

**The control of tomato leaf-spot,** F. J. PRITCHARD and W. S. PORTE (*U. S. Dept. Agr. Bul. 1288 (1924), pp. 19, pls. 2, figs. 9*).—The results are given of experiments carried on for the control of tomato leaf spot due to *Septoria*

*lycopersici*. According to the authors, the use of Bordeaux mixture or other copper sprays has given effective control, but the profits from spraying are variable and not always sufficient to justify the expense. It is believed that a more effective and economical method of control lies in the use of modified field practices. It is claimed that leaf spot epidemics can be largely avoided by setting out large, stocky, well-hardened plants early in the spring. The fungus is said to overwinter in old tomato vines, and plowing them under in autumn will largely prevent the reappearance of the disease. The fungus, however, grows and produces spores on various weeds, grasses, and the remains of various crops, especially cornstalks, and these should be destroyed or covered with soil by plowing.

"Sleepy disease" of the tomato, W. F. BEWLEY (*Jour. Min. Agr. [Gt. Brit.]*, 30 (1923), No. 5, pp. 450-457, pl. 1).—The term "sleepy disease" as commonly used in Great Britain covers a number of separate diseases, the most important of which is Verticillium wilt. The other diseases under this general title include Fusarium wilt and a root rot caused by *Vermicularia varians*. These are discussed as related to temperature, soil, and control.

Fire blight, J. A. McCLINTOCK (*Tennessee Sta. Rpt. 1923, p. 25*).—In connection with investigations of fire blight, inoculations with pure cultures of the organism were made in varieties of pears, quinces, and apples of known or reported resistance to fire blight. From the data collected, it appears that seedlings of known resistant stocks, open fertilized in an orchard containing some susceptible varieties, showed a high degree of resistance, indicating that this factor is dominant.

Grape diseases, with special reference to black-rot and anthracnose, A. S. RHOADS (*Fla. State Plant Bd. Quart. Bul.*, 8 (1924), No. 4, pp. 102-112).—Brief accounts are given of black rot and anthracnose, which are known to occur on the Carman and other grapes in Florida, as regards history, symptoms, causal organisms (*Guignardia bidwellii* and *Sphaceloma ampelinum*, respectively), and control measures.

Ripe-rots of grapes and the copper acetates as non-staining sprays for late applications to control them, A. S. RHOADS (*Fla. State Plant Bd. Quart. Bul.*, 8 (1924), No. 4, pp. 97-102).—Owing to the prevalence of humid or rainy weather during the ripening period in Florida, grapes are subject to considerable damage from at least three widespread diseases, bitter rot (*Melanconium fuligineum*), white rot (*Coniothyrium diploidiella*), and anthracnose due to *Glomerella cingulata*. Bitter rot and white rot are the more important, since they often attack early the stem of the cluster, its branches, or the stalks of the berries. Bordeaux mixture spots the fruit. Burgundy mixture or cuprammonium sprays tend to cause burning. Insufficient trial has been made of a neutral mixture of copper and caustic soda.

"The copper acetates, on the other hand, form even less conspicuous deposits than the cuprammonium sprays and, for the equivalent amount of copper, are many times less injurious to the plant sprayed. They compare favorably with Bordeaux mixture as regards effectiveness. They present in addition the important practical advantages of not burning the foliage, freedom from nozzle trouble, and are very convenient as regards the making up of spray mixtures."

The merits are discussed of basic copper acetate (verdigris) and of neutral or normal copper acetate. The latter always requires the addition of gelatin to increase adhesiveness, and the former is improved by it.

"Despite the greatly increased cost of the copper acetates as compared to copper sulfate the basic copper acetate or verdigris is by no means prohibitive in price when its value for a final application on the ripening grapes is considered."

Department of citrus canker eradication.—Report on eradication work in cooperation with the Bureau of Plant Industry, U. S. D. A., for quarter ending June 30, 1924, [F. STIRLING] (*Fla. State Plant Bd. Quart. Bul.*, 8 (1924), No. 4, pp. 115, 116).—Accounts and tabulations previously noted (*E. S. R.*, 51, pp. 155, 156), as now brought up to the middle of 1924, show that citrus canker has been found in 22 Florida counties; grove trees infected since May, 1914, numbering 15,151; nursery trees infected, 342,260; properties, 510; and properties still classed as infected June 30, 1924, 9. No citrus canker outbreak has been noted since the one isolated case appearing in October, 1923.

Chestnut trees surviving blight, A. P. KELLEY (*Science*, 60 (1924), No. 1552, pp. 292, 293).—The results are given of studies of areas containing chestnut trees in which the second growth and seedlings have produced a greater amount of growth than that killed during the same year. Not only were saplings found that were recovering but older trees as well. Similar observations have been made elsewhere, and it is believed that the improved condition may not be due wholly to greater resistive powers but to a lessened supply of spores of *Endothia parasitica*. Some trees have also shown their ability to heal serious cankers.

Preliminary note concerning physiological specialization in *Fomes pinicola*, H. SCHMITZ (*Science*, 60 (1924), No. 1550, pp. 248, 249).—A report is given of results obtained from a physiological study of four cultures of *F. pinicola* obtained from four different hosts, namely, Douglas fir (*Pseudotsuga taxifolia*), white fir (*Abies grandis*), western hemlock (*Tsuga heterophylla*), and western white pine (*Pinus monticola*). The results obtained are said to show that these four strains differ very markedly in their characteristics of growth, rate of growth, extracellular enzyme activity, intracellular enzyme activity, effects produced in mixed cultures, growth on liquid media, and nitrogen relations.

Survey of blister rust infection on pines at Kittery Point, Maine, and the effect of *Ribes* eradication in controlling the disease, G. B. POSEY and E. R. FORD (*Jour. Agr. Research [U. S.]*, 28 (1924), No. 12, pp. 1253-1258, figs. 5).—According to the authors, there was in 1916 an outbreak of white pine blister rust in York County, Me., which was traced to a planting in 1897 of cultivated black currants from England. An investigation showed that cultivated black currants were mainly responsible for the spread of the infection to pines, the amount of infection being in proportion to the nearness of stands of white pine. The highest degree of infection was in the path of late summer and autumn storms. The rate of infection increased from 1900 to 1916, and it was most severe on the larger sized pine trees where the stand was understocked and among the dominant trees. The destruction of all *Ribes* in an area of six square miles prevented the occurrence of new pine infections and permitted the restocking of the area with disease-free pine seedlings.

South American leaf disease of Para rubber, R. D. RANDS (*U. S. Dept. Agr. Bul.* 1286 (1924), pp. 19, pls. 6, fig. 1).—An account is given of a leaf disease of Para rubber caused by *Dothidella ulei*, the information being based on recent observations and the published work of others, among them reports by Stahel and Bancroft (*E. S. R.*, 38, p. 153).

Spike disease of sandal, B. N. IYENGAR (*Mysore Dept. Agr. Rpt.*, 1922-23, pt. 2, pp. 10-12).—During the year, clear experimental evidence was obtained for the first time regarding root transmission of sandal spike disease. Of healthy seedlings five years old, having good root development and haustorial connections, one in each group was grafted with spike in July, 1921. Two months later the disease appeared in the grafted trees. One of the other trees

showed the disease in July, 1922, this whole tree a month later bursting out all over with spike, which by that time had appeared in two other trees. A detailed account by Coleman is noted below.

An elaborate series of experiments bearing upon formation rate showed that carbon dioxide absorption rate in spiked leaves is always less per unit area than in normal leaves. Of diseased trees, only one, treated the year before with potassium chloride, was still alive. Other supposed differences between sound and spiked trees are being tested out. Oils from both sound and spiked trees satisfy the requirements of the British Pharmacopoeia.

**The transmission of sandal spike**, L. C. COLEMAN (*Indian Forester*, 49 (1923), No. 1, pp. 6-9, pls. 3).—Since the publication of the author's 1917 bulletin (E. S. R., 38, p. 855), the staff of the Agricultural Department of India has been engaged in an investigation of spike in sandal. Of the information collected, the present account details chiefly some results regarding the natural spread of the disease.

Of numerous grafting experiments not one shows a case where a diseased scion established connection and grew without transmitting spike to the stock and finally killing the tree. Where no connection was formed, no spike appeared on the stock, however severely it was cut back.

It is considered as safe to conclude from the evidence obtained that the disease in nature is transmitted only through the roots or the portion above ground, that the haustoria do transmit the disease, and that there is no external cause for sandal spike disease.

It appears to the author unlikely, however, that the natural transmission of sandal spike takes place only through the haustoria. Much information on this point has appeared in regard to similar diseases in other parts of the world, insects often playing a part in such diseases, though not yet proved to carry spike disease.

**On some plant parasitic nemas and related forms**, G. STEINER (*Jour. Agr. Research* [U. S.], 28 (1924), No. 11, pp. 1059-1066, pls. 4).—Notes are given of *Cephalobus subelongatus* on green leaves of *Phlox drummondii*; the occurrence of *Heterodera radiculicola* on roots of the African sausage tree, *Kigelia pinnata*; on the chrysanthemum nema, *Aphelenchus ritzema-bosi*, and its occurrence in the United States; on the food habits of *Dorylaimus regius*; and the infestation of Zinnia roots by *Paratylenchus nanus*.

## ECONOMIC ZOOLOGY—ENTOMOLOGY

**Principles of animal biology**, A. F. SHULL (*New York and London: McGraw-Hill Book Co., Inc.*, 1924, 2. ed., [rev.], pp. XVIII+422, pls. 2, figs. 269).—This is a second edition of the work by Shull, with the collaboration of G. R. Larue and A. G. Ruthven. The several chapters deal with the subject as follows: Introduction (pp. 1-24), morphology of the cell (pp. 25-38), physiology of cells (pp. 39-61), cell division (pp. 62-76), the origin of the Metazoa (pp. 77-96), morphology of higher types (pp. 97-132), physiology of organs (pp. 133-153), reproduction (pp. 154-175), the breeding habits of animals (pp. 176-191), embryonic development (pp. 192-222), genetics (pp. 223-245), classification of animals (pp. 246-264), the animal and its environment (pp. 265-280), geographic distribution (pp. 281-301), fossil animals (pp. 302-332), and evolution (pp. 333-357). A glossary of 43 pages is included.

**The European hare (*Lepus europaeus pallas*) in North America**, J. SILVER (*Jour. Agr. Research* [U. S.], 28 (1924), No. 11, pp. 1133-1137, fig. 1).—The European hare was introduced and liberated first in 1888 at Jobstown, N. J., but more successfully at Millbrook, Dutchess Co., N. Y., in 1893 and

later. It now occurs from southern Vermont to central New Jersey, and eastward 20 or 30 miles into Connecticut and Massachusetts, and to a limited extent westward across the Hudson and Delaware Rivers into extreme eastern Pennsylvania. Complaints of serious injury to young fruit trees in the Hudson River Valley of New York led to field investigations by the U. S. D. A. Bureau of Biological Survey in 1916 and 1918. Questionnaires were issued in 1922, and the facts gathered have shown that the European hare is steadily increasing in numbers and gradually widening its range. Its only serious injury is to young orchard trees, which takes place during severe winter weather, when its natural food is not readily obtainable. A decided preference is shown for apple trees, although slight injury may be done to shade trees, ornamentals, shrubbery, small fruit bushes, etc. In addition to shooting, control measures include the use of woven-wire fences, individual tree protectors, repellent washes, and winter feeding. Poultry netting 30 in. high, of 1-in. mesh, encircling the tree is one of the best of the mechanical protectors.

**Revised encyclopedia of canaries** (*Louisville, Ky.: Audubon Pub. Co., 1924, pp. 89, figs. 26*).—Twelve varieties are described and illustrated in this work on the breeding of canaries for pleasure and profit.

**The kea or mountain-parrot**, J. G. MYERS (*New Zeal. Jour. Agr., 29 (1924), No. 1, pp. 25-35, fig. 1*).—An account of the sheep-killing parrot, *Nestor notabilis* Gould.

**Notes on the habits and life-history of the Indian glow-worm: An enemy of the African or Kalutara snail**, J. C. HUTSON and G. D. AUSTIN (*Ceylon Dept. Agr. Bul. 69 (1924), pp. 15, pl. 1*).—This is a report of studies of *Lamprophorus tenebrosus* Wlk., which first came under the special observation of the senior author in 1920.

**Agricultural entomology and parasitology**, G. GUÉNAUX (*Entomologie et Parasitologie Agricoles. Paris: J.-B. Baillière & Son, 1922, 4. ed., rev. and enl., pp. VIII+592, figs. 427*).—The several parts of this handbook deal with the subject as follows: I, Protozoa, particularly Sporozoa (pp. 5-10) and Flagellata (pp. 10-12); II, Vermes, including Platyhelminthes (pp. 13-38), Nematelminthes (pp. 39-72), and Annelida (pp. 72-77); III, Mollusca (pp. 78-84); IV, Arthropoda, including Insecta (pp. 85-533), Myriapoda (pp. 534-539), and Arachnida (pp. 539-574).

[Report of the New York State Station] **division of entomology** (*New York State Sta. Rpt. 1924, pp. 39-46*).—This is a brief statement on the entomological work of the year.

In an orchard at North Rose the fruit-tree leaf-roller is the most important insect pest met with. Its eggs commence to hatch normally during the prepink stage in the spraying schedule, but during some seasons larvae continue to emerge over a period of from four to six weeks. Oil sprays do not appear to be wholly dependable. A marked improvement in the condition of plats thoroughly sprayed with arsenicals, applications having been made at rather short intervals during the period when the eggs were hatching, was an important result of the experimental work. As a result, there was little or no injury by the caterpillars to the blossoms and fruit clusters, and the damage to the terminal growth was negligible. Extensive injuries by the codling moth in the Great Lakes region of the State led to investigations of the habits of the insect, which relate to initial and maximum oviposition of the first brood.

The pear psylla is effectively held in check by timely and thorough applications of spray mixtures, but the difficulty experienced by owners of large pear orchards in carrying out the spraying schedule led to investigations of its susceptibility to dust mixtures and their utility when employed to supplement

spraying operations. Work with the grape leafhopper indicates that proper spraying with nicotine sulfate is more certain and cheaper than treatment with nicotine dusts, but further work is necessary before definite conclusions can be drawn.

In control work with the striped cucumber beetle, the spray consisting of lead arsenate 5 lbs., Kayso 5 lbs., and water 100 gal. has given better results than dust mixtures, such as lead arsenate 1 lb. and gypsum 20 lbs., due principally to the fact that the injury of the ingredients to the plant was less. The use of nicotine dust against the striped cucumber beetle has not given satisfactory results, due chiefly to unfavorable weather conditions at the time of application. Unfavorable weather conditions are said to have led to injury of cauliflower, Brussels sprouts, and radish in the seed bed by corrosive sublimate treatment applied for the cabbage maggot. The effectiveness of tobacco dust of 200-mesh grade for control of thrips and aphids in the cauliflower seed bed is said to have been demonstrated.

In field studies, it was determined that the winged migrants of the green peach aphid are largely the progeny of colonies on the potato. Soap was found to be very satisfactory as a fall spray against the pear psylla in the Hudson River Valley.

**Insect pests** (*South Carolina Sta. Rpt. 1924, pp. 43-48*).—Brief notes are given on several new materials, including nicotine preparations and combinations of nicotine sulfate with calcium arsenate, as tested in the laboratory with a view to discovering substances of high toxicity in a search for control measures for the cotton boll weevil and the cotton aphid. A brief reference is made to the occurrence of the Mexican bean beetle in South Carolina and means for its control.

A type of injury to cotton plants, apparently new, which appeared during the summer, was found to be very largely caused by the cotton flea (*Psallus seriatus* Reut.). This injury was observed early in the season when certain growers were examining cotton for the first signs of boll weevil activity. The injury is characterized by the young terminal bud and terminal leaf withering, turning black, and dropping from the plant, as a result of which the squares fail to develop. Severe infestation resulted in the failure of the plant to fruit. The damage to cotton usually occurred in rather localized areas, although more or less injury sometimes occurred throughout large fields. The insect appears to be somewhat migratory in habit, feeding upon the more succulent plants of an infested field and migrating to other sections after the buds of the infested area had been killed or the plant growth retarded. The damage first appeared in the coastal section of the State and spread gradually northward and westward. The central and eastern portions of the State suffered the most severe damage, the injury being of little consequence west of Anderson.

**Entomology [studies at the Tennessee Station]**, S. MARCOVITCH (*Tennessee Sta. Rpt. 1923, pp. 24, 25*).—In studies of the strawberry root aphid, the relative length of daily light exposure rather than temperature is the most important factor in influencing the appearance of the sexes. A daily exposure of strawberry plants for 7.5 hours, beginning February 23, caused the sexes of strawberry root aphid to appear on May 7 and eggs to be deposited May 22, whereas normally the sexes do not make their appearance until November. By giving the cabbage aphid on curled dock and *Capitophorus hippophaes* on smartweed a short day exposure, fall migrants were made to appear during the latter part of May and early June, whereas normally they do not make their appearance until October. In life history studies of the woolly aphid, the author has found that the elm is its principal host in Tennessee, as first reported by Patch from Maine (E. S. R., 36, p. 755).

[Contributions on economic insects] (*Ztschr. Angew. Ent.*, 10 (1924), No. 1, pp. 270, pls. 2, figs. 27).—The papers here presented (E. S. R., 50, p. 255) relating to insects of economic importance include the following: Repression of the More Important Forest Insects by Palearctic Birds, by A. F. von Vietinghoff von Riesch (pp. 1–55); Mechanical Trap Control Experiments with *Meligethes aeneus* F., by H. Blunck (pp. 56–66); Tea Pests in Dutch East Indies and Their Control: The Tachinid *Chaetoxorista javana* B. & B. as an Efficient Parasite of the Limacodid Caterpillar *Setora (Miresa) nitens* Wlk., by R. Menzel (pp. 67–74); A Test of the Influence of Time of Sowing, Size of Grain, Stand, and Tillage on the Attack of Four Varieties of Oats by *Oscinis frit*, by R. Kleine (pp. 75–98); The Polyhedral Disease of the Nonne or Nun Moth and Its Cause, by J. Komárek and V. Breindl (pp. 99–162); The Spreading Power of Liquid Sprays and Its Measurability by a New Method (pp. 163–176), The Woolly Aphid and Its Host Plants (pp. 177–180), and *Tinea cloacella* Hw. and *Tinea granella* L. (pp. 181–188), all by F. Stellwaag; Spraying and Dusting with Arsenicals for the Control of the Codling Moth, by W. Speyer (pp. 189–210); and Notes on Plant Pathology in Holland, by L. Reh (pp. 211–216).

Among other short contributions are the following: On the Outbreak of Tipulids in Nun Moth Areas (pp. 217, 218) and *Hedobia pubescens* F., an Enemy of Loranthaceae (pp. 218–220), both by M. Dingler; Economic Entomology in Russia, by K. Escherich (pp. 220, 221); Nematodes and *Hylobius abietis* (pp. 225, 226); A Contribution to the Control of the Woolly Aphid, by H. W. Frickhinger\* (pp. 228, 229); A New Effective Insecticide for the Clothes Moth (Hexachlorethane C<sub>2</sub>Cl<sub>6</sub>), by M. Dingler (p. 231).

The insect fauna of Quelpart Island (Saishiu-to), H. OKAMOTO (*Chosen Govt. Gen. Agr. Expt. Sta. Bul.*, 1 (1924), No. 2, pp. [2]+IV+47–233, pls. 5).—This paper deals with a general survey of the insect fauna of Saishu (Quelpart) Island and of Chosen (Corea) and Japan, with those of adjacent and other parts of the world, and with their relations to agricultural crops and to human welfare.

Report by the entomologist, Mandalay, for the year ended 30th June, 1923, C. C. GHOSH (*Mandalay Ent. Rpt. 1923*, pp. 27).—This report deals with the occurrence of and work with the more important insects of the year.

Report of work done in the entomological section [Mysore], during the year ending 30th June, 1923, K. KUNHI KANNAN (*Mysore Dept. Agr. Rpt. 1922–23*, pt. 2, pp. 16–20).—Campaigning work against *Amsacta albistriga*, which resulted in the collection of 270,299 moths, is first reported upon, followed by an account of the occurrence of and work with the mango hoppers (*Idiocerus* spp.), control work with the rhinoceros beetle (*Oryctes rhinoceros*), the insecticidal property of metallic mercury, the coffee borer, sugar cane borer, etc.

Annual report of the Government entomologist [of Uganda], H. HARGREAVES (*Uganda Dept. Agr. Ann. Rpt.*, 1923, pp. 15–21).—This report deals with insects of economic importance in Uganda during 1923, particularly those attacking coffee and cotton.

Important foreign insect pests collected on imported nursery stock in 1923, E. R. SASSCER (*Jour. Econ. Ent.*, 17 (1924), No. 4, pp. 443, 444).—This is an abstract of a paper on the more important interceptions of insects on nursery stock in 1923.

Status of hydrocyanic acid gas treatment of nursery stock, J. J. DAVIS (*Jour. Econ. Ent.*, 17 (1924), No. 4, pp. 440–443).—The author summarizes the complaints from both nurserymen and orchardmen relative to the injury to

nursery trees when fumigated with hydrocyanic acid gas and the factors involved. The need of further experiments with the gas and additional materials and probable plans for such investigations are suggested.

**Effect of fumigation upon heating of grain caused by insects**, E. A. BACK and R. T. CORRON (*Jour. Agr. Research [U. S.]*, 28 (1924), No. 11, pp. 1103-1116, figs. 2).—In reviewing the literature on the subject, the authors point out that, while wheat with a moisture content of less than 14.5 per cent will remain in condition if given proper storage and kept free of insects, it may heat when the moisture content is as low as 12 per cent if insects are present. A study by the U. S. D. A. Bureau of Markets led to the conclusion that heating due to insect infestation occurred when the moisture content was as low as 11.3 to 12 per cent. The authors have known chick-peas in 240-lb. sacks to heat as a result of attack by *Bruchus quadrimaculatus*, the temperature rising as high as 103° F. when the normal temperature was 58°. Such heating has quite generally been thought to be due to fermentation started by the attraction of moisture to the feces of the insects. Others have considered it due to mechanical friction caused by the insects' feeding.

In the authors' investigations, the details of which are presented in tabular form, it was found that fumigation with either hydrocyanic acid gas or carbon disulfide of grain that had heated as a result of insect infestation brings about a fall in the temperature of the grain to normal. This has led the authors to conclude that, barring the possibility that bacteria, molds, or other agencies causing heat are killed by the fumigation with these insecticides, the activity of certain stored-product pests is directly responsible for the development of the heat in the grain. A list is given of 16 references to the literature cited.

**New insecticides for the Mexican bean beetle and other insects**, S. MARCOVITCH (*Tennessee Sta. Bul. 131 (1924)*, pp. 19, figs. 8).—Experiments conducted by the author have shown that many of the fluorine compounds are effective in destroying the adult Mexican bean beetles. Sodium fluosilicate, calcium fluosilicate, and cryolite have considerable insecticidal value when mixed with hydrated lime in the proper proportions. Sodium fluosilicate is a contact as well as a stomach poison. Due to its irritating effect, the beetle attempts to clean its feet in its mouth, and enough of the chemical is thus ingested to cause death. It is pointed out that sodium fluosilicate is cheaper than arsenicals, has the advantage of acting as a contact as well as a stomach poison, kills more rapidly, is less poisonous to people, and is effective against a variety of insects, such as chicken lice, roaches, tobacco hornworms, flea-beetles, and potato beetles. The density of sodium fluosilicate as obtained in the market is high, but work is being carried out with a view to remedying this defect. Cotton boll weevils were killed with sodium fluosilicate without lime in from 4 to 30 hours.

In experimental work, gases absorbed on charcoal gave good results as insecticides. Charcoal containing 0.01 per cent mustard gas with a little ether was dusted on plant, and bean beetles were killed in from 3 to 12 hours. Nitrobenzene on charcoal was also effective in destroying the beetles. These gasses killed boll weevils in from 6 hours to 5 days. When used as a dust, sodium fluosilicate mixed with nine parts by volume of hydrated lime gave excellent control against the Mexican bean beetle. When thus mixed, and properly used, sodium fluosilicate showed a net return as high as \$187.60 per acre at a time of the season when bean beetles were very abundant.

**Promising plant insecticides**, S. MARCOVITCH (*Science*, 61 (1925), No. 1566, p. 22).—This article deals with the work presented in the account above noted.

The minor pests of sugar-cane in Fiji, R. VEITCH (*Colon. Sugar Refining Co. [Sydney] Agr. Rpt. 7 (1923), pp. 30, pls. 7*).—This report deals with 17 pests of minor importance as enemies of sugar cane.

**Biological control of prickly-pear in Australia: Contributing efforts in North America**, J. C. HAMLIN (*Jour. Econ. Ent., 17 (1924), No. 4, pp. 447-460, pls. 2*).—An account by the officer in charge of the prickly pear investigations of the Australian Government.

**Observations on the clear-winged grasshopper (*Camnula pellucida* Scudder)**, J. R. PARKER (*Minnesota Sta. Bul. 214 (1924), pp. 5-44, figs. 6*).—This is an account of a widely distributed species which in Minnesota is largely confined to the northern half of the State, it being the grasshopper found most commonly in the Iron Range counties. The studies conducted included experiments with poison bran mash, investigations of the response to meteorological factors, and observations on its seasonal history and habits, the details being presented in large part in tabular and chart form.

Amyl acetate was found to be the most effective of several materials used as attractants in grasshopper baits, surpassing butyl and propyl acetate, lemons, and synthetic apple flavoring. All of the attractants except lemons gave better results when used in combination with molasses. It was found that salt not only added to the effectiveness of all attractants with which it was combined, but in some tests ranked very high when used alone. It is concluded that grasshopper baits for use in Minnesota should contain amyl acetate, molasses, and salt, in addition to the basic ingredients, bran, arsenic, and water.

The activities of *C. pellucida* are to a large extent controlled by temperature. The range of normal activity extends from approximately 68 to 104° F. Little movement is seen at air temperatures below 60° F., and several hours' exposure at 40° F. renders it completely dormant. Fatal temperatures for a 12-hour exposure are reached at 17.6° F. and for 10-minute exposures at 122 to 136° F. (several specimens surviving the latter temperature, however). When given a choice, *C. pellucida* prefers to rest on surfaces whose temperatures approximate 98 to 100° F. The surface of the ground frequently is much warmer than this, but the grasshopper can generally reach a temperature it prefers by simply climbing up weeds or grass to 2 in. above the ground, this sometimes making a difference of 39.6° F. Maximum feeding at poisoned bran mash occurs when the air temperature first reaches from 73 to 77° F.

"A comparison of tin pans and boards for containers of poisoned bran mash in conducting grasshopper bait tests showed that the surface of the boards was much warmer than the surface of the pans. This caused the grasshoppers to seek the boards for warmth during the cooler hours of the day and to avoid them during the hottest hours, thus introducing a serious experimental error. Continued high relative humidity is detrimental to *C. pellucida*, as it brings about conditions favorable for the development of grasshopper diseases.

"In Minnesota *C. pellucida* nymphs did not migrate, and no congregating of the adults in definite areas for egg laying was witnessed. This is in marked contrast to the habits of the same species in Montana and Utah, where migrations of the young nearly always take place, and the adults gather over a considerable area in a few places for mating and egg laying."

**A preliminary report on the parasitic enemies of the citricola scale [*Coccus pseudomagnoliarum* (Kuwana)], with descriptions of two new chalcicoid parasites**, H. COMPERE (*Bul. South. Calif. Acad. Sci., 23 (1924), No. 4, pp. 113-123, figs. 6*).—It is first pointed out that the so-called citricola scale has been found by Clausen (*E. S. R., 49, p. 355*) to be synonymous with *C. pseudomagnoliarum*. The scale is said to be preyed upon by at least four

species of primary parasites, which are the same species that attack the soft brown scale. While the latter is held in check almost entirely by these parasites, they lack effectiveness against the citricola scale, but, in the author's opinion, to the fact that it has but one generation, whereas the soft brown scale has several. The parasites mentioned are *Aphycus luteolus* Timb., *Coccophagus lecanii* (Fitch), *C. lunulatus* How., and *Microterys flavus* (How.). Shipments of parasitized citricola scale material by Clausen in Japan have resulted in the rearing of four primary parasites, namely, *Anicetus annulatus* Timb., *C. yoshidae* Nak., *Aphycus orientalis* n. sp., found in the débris of the shipping boxes, and *C. japonicus* n. sp., described from 25 females reared from the citricola scale and from specimens found dead in the débris of shipping boxes.

**Parasitism of scales—San José and oyster shell**, E. H. SIEGLER and H. BAKER (*Jour. Econ. Ent.*, 17 (1924), No. 4, pp. 497-499).—In determining the species of parasites present, infested twigs were collected from several regions and the following parasites reared: From San José scale, *Prospaltella perniciosi* Tow., *Aphelinus fuscipennis* How., *A. mytilaspidis* LeB., *Signiphora pulchra* Gir., *Perissopterus* sp., and *Ablerus clisiocampae* Ashm., and from oyster shell scale, *A. mytilaspidis*.

**The green peach aphid and its control**, W. B. GURNEY and W. LE G. BRERETON (*Agr. Gaz. N. S. Wales*, 35 (1924), No. 9, pp. 667, 668).—This is an account of *Myzus persicae* Sulz., which appeared in the Glen Innes district of New South Wales in 1910, being troublesome then and at intervals during succeeding years. It has also appeared in various districts where peaches are grown, including the Murrumbidgee irrigation area.

**The fight against the gipsy moth in New Jersey**, T. J. HEADLEE (*Jour. Econ. Ent.*, 17 (1924), No. 4, pp. 438-440).—This is a summary of the eradication work conducted against the gipsy moth in New Jersey, where the 500 square miles of the original area of infestation has now been reduced to about 250 square miles.

**Results of the fourth year's work against the gipsy moth in New Jersey**, H. B. WEISS ET AL. (*N. J. Dept. Agr. Circ.* 79 (1924), pp. 13, figs. 8).—This circular summarizes the results of gipsy moth work conducted in New Jersey during the fiscal year ended June 30, 1924 (E. S. R., 50, p. 257). Many of the data are presented in tabular and chart form.

**The larval stages and biology of the commoner species of Australian mosquitoes, with the biology of *Aedes pecuniosus* Edwards**, L. E. COOLING (*Aust. Dept. Health, Serv. Pub. (Trop. Div.) No. 8* (1924), pp. 40, figs. 16).—In this contribution the author deals with 11 forms of mosquitoes occurring in Australia.

**A synonymic list of the more important species of Culicidae of the Australian region**, L. E. COOLING (*Aust. Dept. Health, Serv. Pub. (Trop. Div.) No. 2* (1924), pp. 61).—This synonymic list includes a 21-page index of the genera and species.

**Malaria, with especial reference to Australia and its dependencies**, R. W. CILENTO (*Aust. Dept. Health, Serv. Pub. (Trop. Div.) No. 3* [1923], pp. 141, figs. 35).—This is a review of the status of knowledge of the disease, its transmission by mosquitoes, and means for control. In an appendix (pp. 97-141), Anopheline Mosquitoes of North Australia and the Tropical Dependencies of Australia are dealt with by L. E. Cooling.

**The importance of the flaxseed count in predicting the actual fly-free date**, C. J. DRAKE, F. A. FENTON, and F. D. BUTCHER (*Jour. Econ. Ent.*, 17 (1924), No. 4, pp. 480-486, figs. 3).—Through the daily collection of flaxseeds

and the dissection of the viable flaxseeds to determine the percentage of larvae, of pupae, and of parasitized larvae of the Hessian fly, the daily rate of transformation from the larva to the pupa and to the adult state, as well as the rate of approach of the fly-free date, was obtained.

"When this count yields very few pupae and only a small percentage of larvae in contrast to a large number of empty flaxseeds, it is proof that the actual fly-free date is at hand, and that the few remaining pupae will immediately issue as flies, lay their eggs, and perish before wheat drilled at this time will come up. Thus it is possible to predict the fly-free date so that farmers can begin drilling wheat six or seven days before the end of the egg-laying period of the fall brood of flies. The records of the Iowa observation stations for 1922 and 1923 are given in the form of a summary."

**Rearing flies for experimental purposes, with biological notes**, R. W. GLASER (*Jour. Econ. Ent.*, 17 (1924), No. 4, pp. 486-496, pls. 2).—During the course of studies of the transmission of microorganisms by insects, in which the house fly, stable fly, and horn fly were used, simple, inexpensive, and effective methods were developed for the rearing and handling of large numbers of flies. Special emphasis is placed on a type of breeding jar, on adult fly foods, on temperature, and on humidity.

**A bacterial disease of adult house flies**, R. W. GLASER (*Amer. Jour. Hyg.*, 4 (1924), No. 5, pp. 411-415, pl. 1).—In this contribution from the department of animal pathology of The Rockefeller Institute for Medical Research, at Princeton, N. J., the author describes a bacterial disease of adult house flies, the first thus far recorded. This disease is sporadic in its appearance and never assumes the form of an epidemic. About 50 per cent of the adult flies contract the disease when experimentally infected, the males being more susceptible than the females. A Staphylococcus, for which the name *S. muscae* is suggested, is found to be the inciting cause. Experimentally infected flies die in from 7 to 29 days, with a mean of 16+ days. The symptoms appear in from 2 to 5 days prior to death. The author presents his reasons for the assumption that but little may be expected from the disease from an economic standpoint.

**Plantain root beetle borer**, N. K. JARDINE (*Trop. Agr. [Ceylon]*, 62 (1924), No. 6, p. 372, pl. 1).—This is a brief summary of information on the banana root borer.

**Dusting and spraying to control grape root-worm**, F. Z. HARTZELL (*New York State Sta. Bul.* 519 (1924), pp. 3-29, pls. 2, figs. 2).—Experiments conducted by the author in 1921 and 1922 have failed to discover a dust that will control the grape rootworm or powdery mildew. Dusts made after Sanders' formula, composed of finely powdered monohydrated copper sulfate, hydrated lime, and calcium arsenate, do not have the physical characters to make them adhere to Concord grape foliage, with the result that wind and rain remove so much of the material that little gain is secured in rootworm control, and powdery mildew is not checked.

"The addition of nicotine to Sanders' dust does not increase its toxicity for the rootworm. Nurexo, while giving better control of rootworm than dust, was much less effective than Bordeaux and lead. However, it did check powdery mildew. Homemade Bordeaux mixture with arsenate of lead proved superior to dusts in every test both as regards the suppression of the rootworm and the control of powdery mildew. Sanders' dust, including the expense of application, costs slightly more per application than Bordeaux, lead, and soap. Dusting is about two and one-fourth times as rapid as spraying under vineyard conditions obtaining in Chautauqua County. As regards time-

liness of application, spraying has considerable advantage over dusting, owing to the wind velocities common to the Lake Erie Valley during the season when remedial measures are necessary."

It is strongly recommended that grape growers use homemade Bordeaux mixture (8-8-100) with either 3 lbs. of dry or 6 lbs. of paste arsenate of lead for the control of the grape rootworm and powdery mildew. The addition of 3 lbs. of resin fish oil soap to each 100 gal. of the mixture is advisable, since the cost is small and the increased spreading qualities add to the effectiveness of the spray.

**The effect of deficiency and excess in rainfall upon the hickory bark beetle (*Eccoptogaster quadrispinosus* Say),** M. W. BLACKMAN (*Jour. Econ. Ent.*, 17 (1924), No. 4, pp. 460-470, fig. 1).—This is a report of investigations conducted during the course of an outbreak of *E. quadrispinosus* in Syracuse, N. Y., which started in 1912. The author has found that, when the adults are active, continued rain kills many while feeding and establishing their burrows and also checks egg laying. Excess rainfall, humidity, and cloudiness kill the larvae because these conditions produce an excess of water in the plant tissues, and this is set free into the larval mines. Deficiency in rainfall has a beneficial effect upon both adults and larvae, and this may be put to practical use. If it is known that there has been a deficiency in rainfall extending over several years, an intelligent lookout can be made for the first signs of undue increase of dangerous forms, and these can be controlled before they reach epidemic proportions.

**Egg and first-stage larva of *Tarsostenus univittatus* (Rossi),** a beetle predacious on powder-post beetles, R. A. ST. GEORGE (*Jour. Agr. Research [U. S.]*, 29 (1924), No. 1, pp. 49-51, fig. 1).—This paper deals with a clerid beetle which is of considerable economic importance because of its predacious habits, both in the larval and adult stages. The eggs, which are placed in or near the entrance galleries of their host, hatch in about 10 days. Under normal conditions, the beetles pass the winter in the larval stage, although a few may pupate before early spring.

**The sweet potato weevil (*Cylas formicarius* (F.), var. *elegantulus* Summ.),** C. C. GOWDY (*Jamaica Dept. Agr., Ent. Circ.* 11 (1924), pp. 5).—This is a summary of information on the weevil in Jamaica.

**Results secured from late season applications of calcium arsenate dust for the control of the cotton boll weevil,** C. B. NICKELS (*Jour. Econ. Ent.*, 17 (1924), No. 4, pp. 477-480).—This is a report of experiments conducted in the Piedmont section of South Carolina during 1923. Serious injury by the boll weevil did not occur in the majority of fields until August 10 or later, damage by the pest being to late fruiting crops two weeks before migration or after the beginning of migration. The average increase in yield of seed cotton resulting from the use of calcium arsenate dust on comparable plats was 236 lbs. per acre. The average expense of using the calcium arsenate dust method was the cost of 29.27 lbs. of calcium arsenate and 3.6 hours of labor.

**Cotton boll weevil situation in Arizona,** M. E. BEMIS (*Calif. Cult.*, 63 (1924), No. 14, p. 336).—This is a statement of the present status of control work with the cotton boll weevil from Thurberia in Arizona.

[**Boll weevil investigations**] (*South Carolina Sta. Rpt.* 1924, pp. 6-15, 79, 80, figs. 3).—Following a brief discussion of the boll weevil problem, direct methods of weevil control are considered under the headings of biological and life history work at Florence, field tests with poisons, and laboratory and field studies with poisons at Clemson. A discussion of indirect methods of weevil control is included.

In hibernation work during the winter of 1923-24, 0.02 per cent of 21,617 weevils placed in hibernation on September 8 emerged. Of weevils placed in hibernation between October 1 and 15 0.19 per cent survived, between October 16 and 31 59 per cent survived, and between November 1 and 13 2.45 per cent survived. These data are considered to emphasize the importance of stalk destruction.

In work conducted cooperatively with the U. S. D. A. Bureau of Entomology, F. A. Fenton found that there was a maximum of four generations and a minimum of one generation at Florence during the season of 1924. The overwintered weevils laid a larger number of eggs than in any of the succeeding generations, and some of these overwintered weevils remained alive in the field until August. During the middle of the summer the life cycle was completed in about 28 days. So few weevils emerged from hibernation in the spring that emergence dates are not conclusive, although they show that in 1924 emergence was practically completed by the middle of June, and overwintered weevils commenced to oviposit about the same time. The late summer migration began on August 24, and large numbers were in flight on August 26 and 27, at which time cotton in the vicinity of Florence was beginning to open and square shedding was quite general on account of the dry weather. Punctured squares collected showed the weevil to be attacked by three important species of parasites and two less common species were also reared.

E. D. Kyzer succeeded in keeping the boll weevil completely under control until several weeks after general migration had begun through applying calcium arsenate dust as soon as infestation reached approximately 10 per cent. As a result of the control measures instituted at the station, some of the best varieties in the experimental plats produced more than 2,000 lbs. of seed cotton per acre.

The apple blossom weevil, H. W. MILES (*Univ. Bristol, Agr. and Hort. Research Sta. Ann. Rpt., 1923, pp. 58-61, pls. 3*).—This is a more complete account of *Anthonomus pomorum* L. than that previously noted (E. S. R., 50, p. 560). Control measures recommended include scraping the trunks of old orchard trees in February and applying an emulsion consisting of potash soft soap 0.5 per cent, paraffin 10 per cent, and soft water 89.5 per cent; spraying with lime sulfur 1-20 in the delayed dormant stage; banding from the middle of March to the end of April; collection of capped blossoms during the first fortnight of May; and banding from mid-June onward.

The solubility of arsenate of lead in the digestive fluids of the honey bee (*Apis mellifica*), H. M. TIETZ (*Jour. Econ. Ent., 17 (1924), No. 4, pp. 471-477*).—Using the honeybee as the insect and the solubility of arsenate of lead powder in water as the unit of solubility, the author has drawn the following conclusions:

“(1) The solubility of arsenate of lead does not seem to increase when the powder is acted upon by the fluids in the esophagus. (2) The digestive secretions of the honey stomach and the stomach render the poison at least one and one-quarter times as soluble. (3) The action of the intestinal juices is to throw at least three and three-quarters times as much of the powder in solution as would be dissolved by water alone.”

Morphology of the honeybee larva, J. A. NELSON (*Jour. Agr. Research [U. S.], 28 (1924), No. 12, pp. 1167-1214, pls. 8, figs. 5*).—This detailed account of studies of the morphology of the bee larva is in continuation of the author's studies of the development of the egg, previously noted (E. S. R., 34, p. 362). A list of 55 references to the literature cited is included.

Attacks of *Vespa communis* De Saussure on *Hypantiria cunea* Drury, M. T. SMULYAN (*Psyche, 31 (1924), No. 3-4, pp. 138, 139*).—The author reports

attacks of the fall webworm by *V. communis*, which were observed at Roycefield, N. J., in September, 1923. The wasps appeared in large numbers and persistently attacked caterpillars which had been collected for parasite study. They apparently made no attempt to carry off the caterpillars, merely piercing the integument with their mandibles and consuming the liquid and softer parts.

**Biological observations on Hemiteles areator Grav.** [trans. title], J. C. FAURE (*Compt. Rend. Soc. Biol. [Paris]*, 89 (1923), No. 37, pp. 1301, 1302).—The author here describes a new mode of suction observed in the suction of its host by *H. areator*, a parasite of *Apanteles glomeratus*.

**On the variability of the life cycle of a new ichneumonid parasite of the larvæ of *Neurotoma nemoralis*** [trans. title], A. PAILLOT (*Compt. Rend. Soc. Biol. [Paris]*, 89 (1923), No. 33, pp. 1045–1048).—The author reports upon the parasitism of *N. nemoralis*, which has invaded peach orchards in the valley of the Rhone, by *Limnerium crassifemur*, a parasite of microlepidopterous larvae, including *Pyrausta nubilalis*. It is pointed out that the change of host is accompanied by an important modification of the life cycle of the parasite.

**Eggs of *Ascaris lumbricoides* and low temperatures** [trans. title], C. R. BAKKER (*Tijdschr. Vergelijk. Geneesk.*, 10 (1924), No. 4, pp. 275–281).—Exposure of eggs of *A. lumbricoides* to a temperature of  $-15^{\circ}$  ( $5^{\circ}$  F.) had no influence upon their development, but none of the eggs could resist a temperature of  $-30^{\circ}$  or lower.

## FOODS—HUMAN NUTRITION

**Absorption and retention of hydrocyanic acid by fumigated food products, Part II**, E. L. GRIFFIN and E. A. BACK (*U. S. Dept. Agr. Bul. 1307* (1924), pp. 8).—The investigation previously noted (E. S. R., 49, p. 456) has been extended to dried fruits, candy and candy-making materials, cereals, meat, cheese, and dried milk. The fumigation with hydrocyanic acid was carried out by the pot method, using 1 oz. of sodium cyanide for each 100 cu. ft. of space and a time of exposure of about 18 hours. All of the products tested were fumigated without any protection from the gas, and also in the containers in which they were purchased—cloth sacks, wrapped cartons, tin foil, etc. The content of hydrocyanic acid in the products was determined by the method outlined in the previous publication on the day of fumigation and after storage at about 40 and 70° F. for periods of 1, 7, 30, and 90 days.

All of the dried fruits left unwrapped absorbed hydrocyanic acid. The penetration into the wrapped samples depended upon the nature of the wrapper. Newspaper and pasteboard afforded little protection and waxed paper almost complete protection. Most of the fruits which had absorbed hydrocyanic acid retained some of it even at the end of 3 months' storage. More was retained in cold storage than at room temperature. Dried black raspberries absorbed and retained more hydrocyanic acid than any of the other fruits.

Of the candies and candy-making materials, cocoa absorbed and retained the largest amount. Candies absorbed very little. Nut meats absorbed a large proportion of hydrocyanic acid and gave up most of it very readily, but the remaining amount, about 11 parts per million, was held very firmly.

The cereals absorbed considerable hydrocyanic acid, but gave it up readily. This was also true of meat, dried milk, and of soft, loosely wrapped cheese. The hard rind of American Swiss cheese furnished sufficient protection against absorption of the gas.

Attempts to remove the hydrocyanic acid from some of the products by boiling with water for 30 minutes were not entirely successful.

Supplemental data from the literature on the subject are reviewed and discussed.

**Methods of educating the public to the value of milk** (*U. S. Dept. Agr., Dairy Div., World's Dairy Cong. Proc., 1923, vol. 1, pp. 661-694*).—Papers presented at the congress under this general subject are as follows: Per Capita Milk Consumption from the Point of View of the Public Health Officer, by H. Emerson; Welfare Agencies as a Factor in Educating Consumers in the Use of Milk, by L. H. Gillett; The Work of the Canadian Department of Agriculture in Increasing the Consumption of Milk, by H. G. Campbell; The Health Demonstration and Nutrition, by W. H. Brown; Community Milk-for-health Campaigns as Conducted by the United States Department of Agriculture, by J. M. Hoover; and The Work of the Dairy Council, by M. D. Munn.

**Milk in the diet** (*U. S. Dept. Agr., Dairy Div., World's Dairy Cong. Proc., 1923, vol. 2, pp. 837-850*).—The program on this general subject at the World's Dairy Congress consisted of papers on Nutrition Work in Labrador, by M. R. Moseley, and Milk and Health, by C. Hedger.

**Milk in relation to child life and health**, B. DAVIES (*U. S. Dept. Agr., Dairy Div., World's Dairy Cong. Proc., 1923, vol. 1, pp. 555-562*).—This paper is essentially a plea, supported by data on infant mortality in England and Wales, for rigid laws concerning the bottling of milk. The beneficial effects of pasteurization are shown to be counteracted if the milk is not protected from contamination until used. The advantages in this respect of the use of dried milk are emphasized.

[**Nutrition activities in the public schools**] (*U. S. Dept. Agr., Dairy Div., World's Dairy Cong. Proc., 1923, vol. 1, pp. 114-128, 130-133*).—Included in the program of National Dairy Council day were the following papers: Health of Our School Children, by S. L. Jean; The Philadelphia Public Schools, by E. C. Broome; Demonstration of School Work, by L. Conwell; and Results of Dairy Council Work, by W. A. Wentworth.

**The use of evaporated, condensed, and dried milk in the dietary** (*U. S. Dept. Agr., Dairy Div., World's Dairy Cong. Proc., 1923, vol. 1, pp. 149-206, figs. 10*).—This symposium consisted of the following papers, the subject matter of some of which has been noted from other sources: The Use of Sweetened Condensed, Evaporated, and Powdered Milks for Feeding Infants in the Tropics, by W. E. Deeks (*E. S. R., 51, p. 556*); Observations on Milk Supply under Tropical and Subtropical Conditions, by C. P. Sherwin; Variations of the Vitamin A Content of Cow's Milk under Different Conditions of Feeding, by J. Golding (*E. S. R., 49, p. 780*); The Use of Milk in Bread, by R. M. Allen; The Use of Milk Powder in Baking, by C. A. Glabau; The Development of Dried Milk as a Food, by R. J. Blackham; and Vitamins in Preserved Milks, by C. Kennedy.

**The nutritional value of milk** (*U. S. Dept. Agr., Dairy Div., World's Dairy Cong. Proc., 1923, vol. 1, pp. 421-464, figs. 13*).—This symposium includes six papers.

*The nutritional value of milk*, E. V. McCollum, H. T. Parsons, and E. Kalmbach (pp. 421-437).—A general report, with selected data, is given of a demonstration on an extensive scale of the value of milk as a supplement to a qualitatively insufficient diet. In an institution containing 236 negro children all in a condition of malnutrition, 84 were selected for the investigation, which continued in the case of most of the children for 21 months. The children were paired as closely as possible according to weight, size, and general condition. All were continued on the institutional diet, which consisted essentially of a soup made from a fairly wide variety of foodstuffs, with bread ad libitum. One of each pair received in addition 1 qt. of milk daily.

Evidence that the diet had been insufficient quantitatively as well as qualitatively and was improved in the latter respect when the investigation was begun was afforded by the rapid gain in weight at first of the children in both groups. After about 6 weeks this ceased with the children receiving simply the institutional diet, but growth continued at more than normal rate with the children receiving milk. Several increased 50 per cent or more in weight during the first year. After 15 months, the children in the control group were also given a quart daily of reconstituted milk and showed the same response in gain of weight. It is stated that the children not receiving milk were apathetic and tractable, while those receiving milk showed greater restlessness and desire for activity.

An interesting point brought out in the study was the lack of scurvy in all children, although the diet before improvement had no fresh foodstuffs. It was found that the institution received regular donations of lemons from nearby fruit vendors and each child had been given a slice of lemon a day.

*Milk as a food*, L. B. Mendel (pp. 438-444).—This is a general discussion of the value of milk as a food from the standpoint of the quality of its proteins, its content of vitamins and calcium, and the use of milk as a carrier of acidophilic microorganisms (*Bacillus acidophilus*).

*The optimum amount of milk for children*, H. C. Sherman (pp. 445-447).—This paper consists essentially of a brief review of the study by Sherman and Hawley of calcium and phosphorous metabolism in childhood (E. S. R., 48, p. 463), which showed the optimal amount of milk for growing children to be about 1 qt. a day. From the long-continued investigation which is being conducted in the author's laboratory of the effect through successive generations of limited and ample amounts of milk, a further recommendation is made as follows:

"In view of such evidence, it seems a mistake to limit the recommendation of a quart of milk per day to the ages from infancy to puberty. Undoubtedly it would better be extended, probably to all ages. Certainly it seems to me the boy should have his quart of milk per day until he is a man full grown, and the girl should continue to take her quart of milk per day until as a woman she has weaned her last child."

*Blindness and other diseases in children arising in consequence of deficient nutrition (lack of fat-soluble A factor)*, C. E. Bloch (pp. 447-456).—Previously noted from another source (E. S. R., 51, p. 267).

*Milk in the Tropics*, R. J. Blackham (pp. 456-463).—Essentially noted from another source (E. S. R., 46, p. 879).

*Milk as a standard of nutrition*, C. Pirquet (pp. 463, 464).—A brief summary of the essential features of the author's nem system (E. S. R., 48, p. 462).

*The calcium metabolism of atrophic infants and its relationship to their fat metabolism*, E. M. HICKMANS (*Biochem. Jour.*, 18 (1924), No. 5, pp. 925-936, figs. 7).—Data are reported on the calcium and fat metabolism of 48 atrophic infants during 5-day periods on specified diets, preceded by 3 days on the same diets which included humanized, dried, condensed, and skim milk. In addition to the tabulated data, the results obtained are presented graphically to show for the same diets the relationship between the weight of dried feces and its content of calcium oxide, the intake and output of calcium oxide on the various diets, the weight of calcium oxide absorbed and the fat intake, and the weight of fat and calcium oxide absorbed and excreted.

The average absorption of calcium oxide for the 48 cases was 43 per cent, the amount varying with the different diets and with the proportion of fat to calcium. The best absorption took place when the amount of

calcium oxide was from 0.04 to 0.078 gm. for 1 gm. of fat in the milk and water mixture. With one sample of dried milk the absorption was good when calcium oxide ran as high as 0.12 gm., while a dried humanized milk powder gave a very low value.

The actual weight of calcium oxide absorbed varied from 0 to 1.7 gm., with an average of 0.43 gm. in 24 hours. The amount absorbed per kilogram of body weight varied from 0 to 0.33 gm., with an average of 0.12 gm. It is considered that to insure an absorption of 0.1 gm. of calcium oxide per kilogram of body weight the fat must be between 2 and 6 gm. per kilogram.

**Fasting and undernutrition, S. MORGULIS** (*New York: E. P. Dutton & Co. 1923, pp. XIII+407, pls. 6, figs. 9*).—In this volume on the biological and sociological aspects of inanition, physiological inanition as illustrated by hibernation is first discussed from its chemical, physiological, and morphological phenomena. Experimental inanition is then considered under the same groupings, with additional chapters on partial, chronic, and intermittent inanition. A final section deals with inanition and growth.

An extensive bibliography classified according to the topics discussed is appended.

**On the existence of a hitherto unknown dietary factor essential for reproduction, H. M. EVANS** (*U. S. Dept. Agr., Dairy Div., World's Dairy Cong. Proc., 1923, vol. 2, pp. 1027-1034*).—Essentially noted from another source (*E. S. R., 51, p. 167*).

**Investigation of barley, malt, and beer for vitamins B and C, A. HARDEN and S. S. ZILVA** (*Biochem. Jour., 18 (1924), No. 5, pp. 1129-1132*).—The authors have reinvestigated the antineuritic and antiscorbutic properties of barley, malt, and beer, using for the tests for vitamin B both pigeons and rats and for vitamin C guinea pigs and monkeys.

Pigeons fed on steeped grain, grain germinated for 5 days, and the germinated grain just before kilning gained in weight and were protected from polyneuritis, while pigeons fed on barley or malt did not gain in weight but were protected from polyneuritis. In the rat experiments, growth resulted when either barley or malt constituted from 10 to 50 per cent of a diet otherwise lacking in vitamin B. The evaporated extract of beer in amounts constituting from 5 to 25 per cent of the ration was without effect.

In the guinea pig experiments barley and malt were inactive as a source of vitamin C, but the steeped grain, the grain germinated for 5 days, and the germinated grain just before kilning were all active when fed ad libitum. Beers were tested for vitamin C on monkeys and were found to be inactive.

**The fate of bakers' yeast in the intestine of man and of the white rat, L. F. RETTGER, G. F. REDDISH, and J. G. McALPINE** (*Jour. Bact., 9 (1924), No. 4, pp. 327-337*).—In this investigation the fate of bakers' yeast in the intestinal tract of rats and human subjects was studied from the point of view of the viability of the yeast and possible changes in the intestinal bacteria brought about by its presence. In addition, the effect was studied of the introduction of yeast into mice, guinea pigs, and rabbits by subcutaneous, intravenous, and intraperitoneal injections. The rats were fed ground dog biscuit mixed up with melted butter to a smooth paste, and the human subjects ate their customary diet. The rats received from 0.2 to 3 gm. of yeast daily and the human subjects from 14 to 42 gm., or from 1 to 3 yeast cakes daily.

During the yeast feeding, viable cells were excreted, but in small numbers compared with the amount ingested. It is estimated that less than 1 per cent of the cells escape destruction within 24 hours. After the discontinuance of the yeast feeding both dead and living cells disappeared very rapidly.

The injection of bakers' yeast into mice, guinea pigs, and rabbits caused no injury nor was the temperature of the animals affected. The weight of the animals remained stationary or increased slightly during the period of observation following the injection.

**Newer clinical signs of early rickets, C. U. MOORE** (*Jour. Amer. Med. Assoc.*, 83 (1924), No. 19, pp. 1469-1473, figs. 8).—This and the four papers which follow constitute a symposium on rickets held at the annual meeting of the American Medical Association in Chicago, June, 1924.

In this paper the author discusses the more important skeletal signs of rickets, pointing out that rickets develops during the period of the most rapid growth of the portion of the body affected and consequently that during the first four months of life craniotabes or cranial rickets most frequently occurs, accompanied or followed by disturbances in the thorax indicated by rachitic changes in the chest and still later by rickets of the extremities. Descriptions are given of the evidence of these three forms of rickets.

**The underlying cause in the pathogenesis of rickets, L. FINDLAY** (*Jour. Amer. Med. Assoc.*, 83 (1924), No. 19, pp. 1473-1479, figs. 3).—In this discussion, which is based largely on the extensive investigations of the author and co-workers at the University of Glasgow, the conclusion is drawn that a diminished absorption of calcium from the intestines is the chief etiological factor in rickets. As to the cause of the diminished absorption, the possibility is suggested of a specific infection influencing the reaction of the intestinal contents in such a way as to render the calcium less soluble and less easily absorbed. In confirmation of this hypothesis, experiments are cited showing that in health all of the calcium of a given diet is rendered soluble within two hours, while in rickets only about 90 per cent becomes soluble during the same period.

**The organization of a special clinic for the treatment of rickets with the mercury vapor quartz lamp in an outpatient department, E. T. WYMAN and C. A. WEYMULLER** (*Jour. Amer. Med. Assoc.*, 83 (1924), No. 19, pp. 1479-1483, figs. 4).—At a special outpatient clinic in the Children's Hospital, Boston, 86 cases of acute rickets have been cured by ultraviolet radiation three times a week for a period of from 6 to 8 weeks. Six normal babies which received the same treatment showed no evidence of rickets and an improvement in general condition, while 6 others receiving both light and cod liver oil treatment showed even more marked improvement. In the experience of the authors, ultraviolet rays bring about a more complete cure of rickets than any other therapeutic agent alone.

**Rickets as influenced by the diet of the mother during pregnancy and lactation, A. F. HESS and M. WEINSTOCK** (*Jour. Amer. Med. Assoc.*, 83 (1924), No. 20, pp. 1558-1562).—The authors discuss the question of hereditary and congenital factors in rickets, and report studies on the influence of the diet of the mother on the subsequent development of rickets in her offspring.

The conclusion reported in a previous paper (E. S. R., 51, p. 267) that cod liver oil fed during pregnancy and lactation is incapable of preventing rickets in young rats after they have been placed upon ricket-producing diets has apparently been confirmed in the case of human subjects. Of 28 women who took 16 oz. or more of cod liver oil during the last 2 months of pregnancy, 15 had babies which developed rickets while being nursed.

A further series of experiments was carried out on female rats, the scheme being to feed an inadequate diet supplemented with antirachitic substances during one or more of the prepregnant, pregnant, and nursing periods and to note the presence or absence of rickets in the young, as well as their growth. The results obtained showed that it is not possible to prevent rickets by improving the diet of the mother during any or all of these periods.

"It must not, however, be assumed that the contrary holds true and that resistance can not be broken down by this means. It may be stated as a principle that resistance to rickets can be lessened by means of inadequacy of a mother's diet far more readily than a refractory condition can be brought about. The distinction between these two points of view should not be lost sight of in considering the relation of diet to rickets either in animals or in man. The fact that susceptibility to rickets may be induced by an inadequacy of the maternal diet does not warrant the conclusion which has at times been drawn that it is likewise possible to render the young resistant by fortifying nutrition during the prenatal period."

**Correlation of clinical, roentgenologic, and serologic evidences of rickets in breast-fed.** L. R. DEBUYS and L. VON MEYSENBUG (*Jour. Amer. Med. Assoc.*, 83 (1924), No. 20, pp. 1563, 1564).—A study of various clinical signs of infantile rickets is reported with the conclusion that serologic examination, while not always of practical application, is the most reliable method of determining the activity of the disease. Positive X-ray evidence is thought to be of decided value, and epiphyseal enlargement and costal beading the most dependable of the clinical symptoms.

**Further studies on the nervous paralysis of the polished rice disease.** G. KATO (*Japan Med. World*, 4 (1924), No. 9, pp. 233-237).—This paper reports further studies carried on by the various workers in the author's laboratory on the relation of H-ion concentration to the nerve paralysis in avian polyneuritis (*E. S. R.*, 46, p. 669).

Determinations by means of the subcutaneous electrode of the H-ion concentration of tissue fluids directly surrounding the sciatic nerve in fowls showed that in normal and in starved fowls the reaction is nearly neutral, but that in polyneuritic fowls the H-ion concentration is greatly increased. When rice bran extract is injected into the pectoral muscles or fed, the fluid is reduced to normal H-ion concentration and the nerves show recovery. It was also demonstrated that the rice bran extract acts directly upon the nerves of polyneuritic but not of normal fowls. Heated extracts no longer containing vitamin B have a similar action, although much slower and within definite limits of H-ion concentration (neutral or slightly alkaline).

It is concluded that the curative effect of heated extracts is due to the decrease in H-ion concentration of the nerves as the result of the alkalinity of the solution, while the curative effect of extracts of vitamin B is due to a special property of vitamin B of decreasing negative charges in paralyzed nerves.

**The relationship of phosphates to carbohydrate metabolism.—I, Time relationship of the changes in phosphate excretion caused by insulin and sugar.** S. S. SOKHEY and F. N. ALLAN (*Biochem. Jour.*, 18 (1924), No. 5, pp. 1170-1184, figs. 5).—Analyses are reported of the urine of normal and depancreatized dogs for phosphorus, total nitrogen, ammonia, and creatinine before, during, and after insulin hypoglycemia. To eliminate the effect of food, the animals were starved throughout the experiment.

The administration of insulin to the normal animals was followed immediately by a reduction in the excretion of organic phosphate in the urine, sometimes to a point at which it became too small to measure. After about 6 hours there was an increase in the phosphate excreted, often bringing the total amount excreted to from 25 to 35 per cent above the normal for the day. The nitrogen excretion was increased to an average of about 20 per cent above normal and occasionally to double the normal amount. The excretion of ammonia and the titratable acidity of the urine in general followed the same course as the phosphorus. There was no change in creatinine.

The ingestion of sugar by normal fasting animals brought about practically the same changes as did insulin, only more slowly. Insulin and glucose together brought about the same changes as when given separately.

In diabetic dogs the phosphate excretion was more than double the normal. The administration of insulin caused a decrease in the excretion at first, followed by an increase to the level for a normal dog. Clear-cut results were not obtained with sugar.

These experiments are thought to furnish clear evidence of an intimate relationship between the metabolism of carbohydrates and phosphoric acid. The increase in nitrogen excretion after insulin injections is considered due to the breaking down of the process in order to provide for the necessary sugar.

**The efficiency of various sugars and their derivatives in relieving the symptoms caused by insulin in mice,** P. T. HERRING, J. C. IRVINE, and J. J. R. MACLEOD (*Biochem. Jour.*, 18 (1924), No. 5, pp. 1023-1042).—This paper consists of a report by P. T. Herring of a comparison of the value of various sugars and their derivatives in the treatment of insulin convulsions in mice, a discussion by J. C. Irvine of the results obtained in terms of carbohydrate structure, and comments by J. J. R. Macleod.

Of the unsubstituted sugars, glucose and mannose were the most effective, with maltose next. Fructose was usually effective, but only temporarily. Galactose occasionally gave a temporary but never a permanent effect. Lactose and sucrose were inactive. Of the three substituted reducing sugars tested, tetraacetylfructose in a few instances relieved convulsions temporarily, while tetramethylglucose and trimethylglucose were inactive. Seven glucosidic compounds, two alcohols (mannitol and dulcitol), and one anhydro-sugar,  $\beta$ -glucosan, were inactive.

In the interpretation of these results from the standpoint of structure, it is concluded that for activity the presence of a reducing group and of certain asymmetric systems is essential. The reaction is thought to "take place in definite steps, the first of which involves the reducing group either alone or in conjunction with one other hydroxyl group. The remaining hydroxyl groups then react singly or in pairs according to their stereochemical position." In other words, it is not the sugar as a whole which reacts but definite sections of the molecule."

In the comments by Macleod, attention is called to the fact that the sugars which are most active in relieving hypoglycemic symptoms are those which are directly fermentable by yeasts.

## ANIMAL PRODUCTION

**Inspection of commercial feeding-stuffs,** H. R. KRAYBILL, T. O. SMITH, and J. T. SULLIVAN (*New Hampshire Sta. Bul.* 213 (1924), pp. 63).—This is the usual report of the inspection of feeding stuffs during 1924, consisting mainly of a list of the feeds with their guaranties and analyses and definitions of feeding materials (E. S. R., 51, p. 73).

[**Experiments in beef production at the South Carolina Station**] (*South Carolina Sta. Rpt.* 1924, pp. 64, 84).—Tests of rations for feeding calves and breeding stock were conducted during the year.

*Velvet beans and cottonseed meal for fattening calves.*—In continuing the study of the feeding value of velvet beans (E. S. R., 50, p. 672), whole velvet beans and cottonseed meal were compared as protein supplements to a ration of shelled corn, oats, and corn silage for fattening calves. The lot receiving the cottonseed meal made average daily gains of 2.19 lbs. at a calculated feed cost of \$8.90 per 100 lbs. of gain, while the lot receiving velvet beans made

average daily gains of 2.34 lbs., and the calculated feed cost was only \$7.78 per 100 lbs. of gain.

*Wintering beef cattle [at the Coast Substation]* (pp. 64, 84).—The costs of wintering aged cows, 2-year-old heifers, and yearling heifers from December 19 to March 7 on a ration of cottonseed meal and sorghum silage were determined as follows: \$13.85, \$9.68, and \$7.76, respectively. The average daily gains of the respective lots were 0.16, 0.60, and 0.57 lb.

**Effects of winter rations on pasture gains of beef calves and yearlings.** E. W. SHEETS and R. H. TUCKWILLER (*West Virginia Sta. Bul.* 186 (1924), pp. 34, figs. 13).—Another account of the experiments previously noted in U. S. Department of Agriculture Bulletins 870 and 1042 (E. S. R., 44, p. 176; 46, p. 765).

**Effect of winter rations on subsequent pasture gains of steers.** E. W. SHEETS (*Jour. Agr. Research [U. S.]*, 28 (1924), No. 12, pp. 1215-1232, pls. 9, figs. 12).—Another account of the experiments previously noted (E. S. R., 51, p. 772).

**Fattening western lambs, 1923-1924.** H. D. FOX (*Nebraska Sta. Bul.* 204 (1924), pp. 24).—Two experiments in comparing the feeding and management of fattening lambs were conducted, the first experiment being similar to the one previously noted (E. S. R., 50, p. 574).

Ten lots of 30 lambs each were fed in this test, which lasted 110 days. Lots 1 and 10 received a basal ration of shelled corn and alfalfa hay, the results with the two lots being averaged as lot 1. Changes and additions as follows were made to this ration for the other lots: Lot 2 received a small amount of oats during the first 8 weeks of the experiment; lots 3, 4, and 5 received additional supplements of 0.142, 0.237, and 0.342 lb. of linseed oil meal, respectively, per head daily; lot 6 received prairie hay in place of the alfalfa hay and 0.352 lb. of linseed oil meal per day; and lots 7, 8, and 9 received alfalfa molasses meal in the following average amounts per lamb daily: 0.186, 0.554, and 0.976 lb., respectively.

Six lots of 26 lambs each were fed in the second experiment, which lasted 60 days. Lots 1, 2, and 3 received rations of corn and alfalfa hay, while lots 4, 5, and 6 received, in addition, 0.22 lb. of linseed meal per head daily. The effects of different times of shearing were compared in this test, lots 1 and 4 not being sheared. Lots 2 and 5 were sheared 10 days after being started on feed, while lots 3 and 6 were sheared 2 weeks before marketing. The results of both experiments are summarized in the following table:

*Experiments in fattening western lambs*

Experiment	Lot	Average initial weight	Average daily gain	Feed consumed per 100 lbs. gain						Calculated profit per head	Dressing percentage
				Corn	Oats	Linseed oil meal	Alfalfa molasses meal	Prairie hay	Alfalfa hay		
		<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>		<i>Per ct.</i>
1	1	63.07	0.258	455	-----	-----	-----	-----	435	\$0.43	48.49
	2	62.93	.251	410	75	-----	-----	-----	408	.33	48.27
	3	63.50	.294	402	-----	48	-----	-----	377	.70	49.04
	4	62.87	.312	373	-----	76	-----	-----	354	.84	50.07
	5	62.67	.328	351	-----	104	-----	-----	318	.78	49.96
	6	62.80	.262	448	-----	135	-----	272	-----	-----	48.04
	7	62.97	.275	426	-----	-----	68	-----	360	.64	49.64
	8	63.00	.299	390	-----	-----	185	-----	281	.69	49.60
	9	63.00	.265	426	-----	-----	368	-----	159	.31	49.52
-----	1	71.69	.517	326	-----	-----	-----	-----	235	3.20	48.64
	2	70.73	.463	355	-----	-----	-----	-----	295	1.60	48.51
	3	70.92	.449	347	-----	-----	-----	-----	257	1.87	50.09
	4	72.31	.546	301	-----	40	-----	-----	224	3.19	48.84
	5	71.42	.551	308	-----	39	-----	-----	237	1.96	50.04
	6	71.96	.528	318	-----	41	-----	-----	215	2.09	52.49

The results showed that the larger amounts of oil meal produced greater gains and kept the lambs in better feeding condition. The alfalfa molasses meal added in small amounts reduced the costs of gain and the amount of alfalfa hay required, but the greatest profits were made with medium amounts of alfalfa meal. No advantage was shown for the oats or prairie hay feeding. As to the different times of shearing, it was found that the late shorn lambs produced from 0.9 to 0.98 lb. more wool of a better quality than early shorn lambs.

**The influence of individuality, age, and season upon the weights of fleeces produced by Angora goats under range conditions,** J. L. LUSH and J. M. JONES (*Texas Sta. Bul. 320 (1924), pp. 3-54, figs. 13*).—This bulletin reports the results of a study of the weights of the fleeces of Angora goats for two 12-months spring shearings, five 6-months fall shearings, and five 6-months spring shearings. The relations between the successive shearings of the same goats have been grouped according to breeding, age, and sex, and a series of 302 correlation tables have been constructed, the calculated coefficients being tabulated. There was much variability in the different correlations, but the averages showed some tendency toward uniformity in the fleece weights of individuals at succeeding shearings. Shearings at the same season of the year resembled each other more closely than spring and fall shearings. There was also a higher correlation between shearings separated by a shorter time interval than between shearings several years apart.

Angora fleeces are apparently influenced more by environmental conditions than are wool fleeces, as was found in Bulletin 311 (E. S. R., 51, p. 75). Age has a distinct effect on the first three shearings, the maximum fleece production being attained during the second year. Advancing age does not greatly reduce fleece production except in goats over 6 years. It is recommended that mohair producers cull their flocks on the basis of the individual fleece weights.

**[Feeding experiments with swine at the South Carolina Station]** (*South Carolina Sta. Rpt. 1924, pp. 61-64, figs. 3*).—The results of feeding experiments with swine in continuation of those previously noted (E. S. R., 50, p. 672) are briefly reported.

**Soy bean forage for hogs.**—In another year's study of the value of soy bean forage for hogs, 25 pigs were divided into two lots, one lot being placed on soy bean pasture with a 2 per cent corn ration for 71 days while the other lot received corn and tankage in dry lot. The average daily gains of the two lots were, respectively, 0.85 and 0.74 lb., the former lot requiring 128.26 lbs. of corn and 0.22 acre of soy bean forage per 100 lbs. of gain. The hogs in dry lot required 333.24 lbs. of corn and 53.71 lbs. of tankage per 100 lbs. of gain.

Following the grazing period both lots received corn and tankage in dry lot. The average daily gains during the entire period of the lot which was started on forage were 1.14 lbs. and the feed requirements 273.32 lbs. of corn, 23.75 lbs. of tankage, and 0.1 acre of soy bean forage per 100 lbs. of gain. The pigs fed in dry lot throughout made average daily gains of 0.94 lb., requiring 390.98 lbs. of corn and 56.14 lbs. of tankage per 100 lbs. of gain. At the close of the grazing period, three hogs shipped to Beltsville, Md., killed soft, while of others shipped after 55 to 84 days finishing on corn and tankage half killed soft and half hard.

**Hogging down forage crops [at the Pee Dee Substation].**—In a comparative test of dry lot feeding of corn and tankage with hogging down peanuts, peanuts and sweet potatoes, and peanuts plus a 2 per cent corn ration, it was found that the most rapid gains were made on the last-named feed, while the cheapest gains were made on sweet potatoes and peanuts.

*Protein supplements for hogs.*—In comparisons of animal and protein supplements for hogs, mixtures of soy bean meal and fish meal, equal parts, when fed with corn, gave the most satisfactory results in rate and economy of gain. Peanut feed and fish meal were second, and in all cases where soy bean meal or peanut meal were used as the sole protein supplements the gains were more rapid and more economical than when tankage or fish meal furnished the only source of protein.

*Alfalfa and horses, R. S. HUDSON (Michigan Sta. Circ. 65 (1924), pp. 7, fig. 1).*—The preliminary results of experiments in comparing rations of corn and alfalfa hay with corn, oats, and timothy hay for work horses are reported. During the first 13 weeks of the experiment, which was conducted in the winter, one horse of each of nine teams received each of the rations. The horses receiving corn and alfalfa hay worked 472 days and gained a total of 740 lbs. at a calculated feed cost per day of 29.7 cts. The other horses receiving the contrasting ration worked a total of 430 days, lost a total of 30 lbs., and the calculated daily feed cost was 34.1 cts.

During the second period of like length, conducted in the spring of the year, the rations were reversed, but again the alfalfa ration proved superior in maintaining weight and the feed cost was less.

[*Poultry investigations at the Dominion experimental farms*], F. C. ELFORD (*Canada Expt. Farms, Poultry Div. Rpt. 1923, pp. 10-31, figs. 4*).—The following investigations have been conducted during the year 1923, many being continuations from the previous report (E. S. R., 50, p. 777):

*Chick feeds and feeding.*—In a comparison of different drinks for baby chicks, 5 lots were selected, each of which received one of the following drinks: Sour skim milk, sweet skim milk, sweet whole milk, sour whole milk, and water. The lowest mortality, 4 per cent, was recorded in the pens receiving sweet whole milk and water, and the highest, 13 per cent, in the pen receiving sweet skim milk. The greatest gains in weight, however, were made in the latter pen and the least in the pen receiving water.

The results of several experiments dealing with the addition of foods containing vitamins, such as canned tomatoes, yeast, and green feeds and curds to the ration of baby chicks showed practically no advantages for the additions of these feeds. In certain cases advantages were shown in the rate of gain of chicks on one of the foods, but such an advantage was usually counterbalanced by a greater mortality. The addition of yeast or canned tomatoes to a ration of dry or boiled rice did not produce normal growth in baby chicks in a 3-weeks' experiment, nor did the addition of raw liver, cod liver oil, or egg yolk to this basal ration produce growth at all comparable to that made on a standard ration.

*Capons vs. Roasters.*—In comparing the rates of fattening and economy of gains of capons and cockerels, 25 Barred Rock cockerels were caponized, of which 3 died soon after the operation. The gains of the other 22 capons were compared with 22 similar cockerels during a test period lasting from July 8 to December 13. In this period the capons gained an average of 5 lbs. 5 oz., and roasters made average gains of 5 lbs. 1 oz. The capons consumed an average of 18 lbs. 5 oz. of scratch grain, 11 lbs. 9 oz. of mash, and 4.8 gal. of milk, while the roasters consumed an average of 19 lbs. 2 oz. of scratch grain, 10 lbs. 3 oz. of mash, and 6.3 gal. of milk. The conclusion from the experiment is that the value of caponizing lies chiefly in the production of meat of superior quality, rather than in any greater efficiency of growth or fattening.

*Feeding for winter egg production.*—In a comparison of a commercial mash and a home mixed mash consisting of equal parts of bran, shorts, oat chop,

and corn meal, with 20 per cent beef meal, for egg production, it was found that the two lots laid exactly the same numbers of eggs. The fertility of the eggs laid by the birds receiving home mixed mash was 87.4 per cent, of which 35.6 per cent hatched, which was somewhat better than the fertility of the eggs produced by hens receiving the commercial mash, which was 58.8 per cent, of which 28.6 per cent hatched.

In comparing various sources of animal protein for egg production, 3 pens of birds were fed alike except that beef scrap, tankage, or fish meal was added to the mash in amounts of 20 per cent. The total numbers of eggs laid and their estimated cost per dozen were in the different lots, respectively, beef scrap 1,374 eggs and 12.5 cts., tankage 1,167 eggs and 12.4 cts., and fish meal 1,257 eggs and 13.6 cts. Fertility and hatchability differed somewhat on the rations, 71.4, 91, and 72.3 per cent of the eggs being fertile on the beef scrap, tankage, and fish meal rations, respectively. The hatching percentages of the fertile eggs were 34.4, 41.5, and 38.8. As in the earlier experiments, tankage was found to be an uneconomical substitute for beef scrap.

In another experiment, milk was compared with beef scrap as a source of animal protein, 1 pen of hens receiving milk but no beef scrap, whereas another pen received water, with 20 per cent beef scrap added to the mash, as well as beef scrap available in a self-feeder at all times. The former lot laid 1,045 eggs at an estimated cost of 14.7 cents per dozen, while the latter lot laid 1,201 eggs at an estimated cost of 15 cents per dozen. Of the eggs produced on the milk ration, 92.4 per cent were fertile, of which 45.2 per cent hatched, while on the beef scrap ration only 72.5 per cent of the eggs were fertile, of which only 18 per cent hatched. The beef scrap thus gave a higher production and greater profit, but the milk produced better hatching eggs at a slightly lower cost.

In a test comparing the egg production and hatching ability of eggs laid by hens receiving various green feeds or substitutes, 5 pens were selected and furnished with similar feeds with the following exceptions: Pen 1 mangels once a day; pen 2 sprouted oats once a day; pen 3 red clover leaves chopped and fed dry once daily; pen 4 mangels, sprouted oats, and clover; and pen 5 no green feed but 1.5 oz. Epsom salts per pen daily in the drinking water. The total eggs laid by the pens in numerical order were, respectively, as follows: 1,285, 1,403, 1,438, 1,393, and 1,414. The estimated costs per dozen eggs were 15.4, 12.1, 13.8, 13.7, and 13.1 cts. Practically 90 per cent or above of the eggs were fertile in all lots, though only 32 per cent of the fertile eggs hatched in the mangel-fed lot as compared with 50.8 per cent in the clover pen. It is thus concluded that clover gave the best results both in production and hatchability, with Epsom salts a close second.

In another test dealing with the addition of animal protein, a pen of pullets receiving both buttermilk and water to drink produced 1,535 eggs at an estimated cost of 12.9 cts. per dozen. Of these eggs, 75.3 per cent were fertile, of which 38 per cent hatched. A similar pen of pullets receiving only water to drink laid 1,139 eggs at an estimated cost of 15.9 cts. per dozen. Of these eggs, 94.1 per cent were fertile, of which 54.4 per cent hatched. It is, therefore, stated that milk has given the best results for production and profit, but better hatching resulted when no milk was given.

*Duck feeding experiments.*—The gains made by two lots of 45 ducklings each hatched early in June were compared, the one lot being furnished with green feed while the other received none. A similar comparison was made with two lots of 25 ducklings each hatched late in June. The ducks receiving green feed

made slightly better gains in both experiments, but contradictory results were obtained in the previous year. It is concluded that where access to small runs containing some green material is afforded, it is not necessary to feed additional green feed in the rations of green ducks.

*Preserving and storing eggs.*—In a study of the effect of various factors on the keeping qualities of eggs in storage, it was found that new-laid eggs were not in as good condition as determined by candling after storing for 6 months when they were treated by a commercial process as when they were untreated. Such decisive results were not obtained with commercial eggs, however, there being 11 per cent more extras but also more seconds and cracks among the processed eggs.

In a comparison of different types of cases, no superiority was shown in the use of a type of nonventilated case over the use of the usual common egg case. Of the eggs which were washed before storage, 63 per cent were graded as extras as compared with 53 per cent of clean eggs in another experiment. A comparison of the use of clean fillers with dirty fillers in the egg cases showed that eggs packed for storage in clean fillers and flats graded 3 per cent better than those packed in dirty fillers. The storage of eggs with the small end down produced over twice as many extras as when they were stored with the small end up. The comparisons for table use of processed and nonprocessed storage eggs were decidedly in favor of the processed eggs.

**Comparative influences of various protein feeds on laying hens, R. M. SHERWOOD** (*Texas Sta. Bul. 317 (1924), pp. 5-24*).—The results are reported of five experiments in which varying amounts of animal proteins have been replaced by cottonseed meal in the rations of laying hens.

*Comparative value of meat scrap, tankage, and cottonseed meal for laying hens.*—Eight pens of 19 Single Comb White Leghorn pullets each were used in this experiment which lasted from January 6 to August 31, 1920. The mash fed to these birds consisted as a basis of 125 parts of wheat bran, 75 parts of wheat shorts, and 100 parts of milo meal. The protein supplements to the basal mash in the different lots consisted of 100 parts of meat scrap, 83 parts of tankage, 85 parts of meat scrap and 20 parts of cottonseed meal, 71 parts of tankage and 20 parts of cottonseed meal, 70 parts of meat scrap and 40 parts of cottonseed meal, 58 parts of tankage and 40 parts of cottonseed meal, 55 parts of meat scrap and 60 parts of cottonseed meal, and 46 parts of tankage and 60 parts of cottonseed meal. The mash eaten per hen varied from 16.4 lbs. for the lot receiving the maximum amount of cottonseed meal with tankage to 22.2 lbs. for the lot receiving meat scrap only. The egg production varied from an average of 8.4 doz. per hen by the lot receiving 40 parts of cottonseed meal and 58 parts of tankage to 10.7 doz. by the lot receiving meat scrap only. Tankage gave as satisfactory results as meat scrap, but the animal proteins without cottonseed meal were not uniformly better than when cottonseed meal replaced part of the animal protein.

*Comparison of fish meal and tankage with cottonseed meal for laying hens.*—Four pens of 40 White Leghorn pullets were used in this test which was started November 2, 1920, and ended October 1, 1921. The animal protein used consisted of fish meal during the first 94 days and tankage during the succeeding 240 days. A mash of wheat bran, gray wheat shorts, and milo meal, 1:1:2, served as a basic feed, with protein supplements of 1 part of fish meal or tankage in one pen. In the other pens 15, 30, and 50 per cent of this protein was replaced by 19 lbs. of cottonseed meal for each 15 lbs. of the replaced animal protein, respectively. The feed consumption of all the pens was quite uniform, and the maximum difference in average egg production was only 0.9 doz.

*Comparison of tankage with cottonseed meal for laying hens.*—In this test, which continued from November 1, 1921, to September 21, 1922, three lots of 40 White Leghorn pullets each were fed. One lot received tankage in the ration, while the others had one-half or all of the tankage replaced by double the amount of cottonseed meal. The pen receiving only the cottonseed meal as a protein supplement laid an average of 12 doz. eggs per bird as compared with 10.6 and 10 doz., respectively, by the lots receiving the tankage only and the combination of protein supplements. The mortality in the cottonseed meal pen was highest, 5 hens dying as compared with 2 in the tankage pen. The feed cost for the eggs produced was lowest in the cottonseed meal pen.

*Comparison of meat scrap with cottonseed meal for laying hens.*—This experiment was similar to the preceding except that meat scrap was used in place of tankage, and the test was conducted from October 1, 1922, to August 31, 1923. The average egg production was 12.3 doz. by the meat scrap pen, 10.9 doz. by the cottonseed meal pen, and 10.8 doz. by the lot receiving the combined proteins.

*Value of meat scrap, cottonseed meal, and alfalfa meal for laying hens.*—This experiment differed from the preceding experiments in that the birds were confined in concrete yards without access to range. The time of the experiment was from October 1, 1922, to May 21, 1923. Four lots of birds were used. Two of the lots (1 and 3) received additions of 60 parts of meat scrap to a mash of wheat bran, gray wheat shorts, and white corn meal, 125:75:75, while the other two lots (2 and 4) had 120 parts of cottonseed meal added to the mash. Lots 3 and 4 also received additions of 25 parts of alfalfa meal to the ration. The mortality was as follows: Lot 1, 7; lot 2, 7; lot 3, 1 (killed because of canker); and lot 4, 3 (two with broken eggs in the oviduct). The pens not receiving the alfalfa meal were largely unhealthy, showing throat lesions and a nasal discharge. The average egg production per bird in the lots 1, 2, 3, and 4 were 7.3, 6, 8.5, and 8.1 doz., respectively.

After the first three months of the experiment, the pens receiving cottonseed meal laid practically as well as those receiving meat scrap. The hatching percentages of the eggs during a part of the experiment were determined as follows: Pen 1, 52; pen 2, 72; pen 3, 65; and pen 4, 66 per cent.

*New chick feeding facts*, E. B. HART, H. STEENBOCK, J. G. HALPIN, and O. N. JOHNSON (*Wisconsin Sta. Bul.* 371 (1924), pp. 24, figs. 16).—A popular account of the practical application of the results of the more recent chick feeding experiments, dealing especially with the importance and sources of vitamins and minerals in the ration.

*Egg production, monthly costs, and receipts on New Jersey poultry farms*, W. H. ALLEN (*New Jersey Stas., Hints to Poultrymen*, 13 (1925), No. 4, pp. 4).—A summary of the monthly records of production, costs, and returns from 30 poultry farms in the State keeping over 500 birds each. The records are for the season November, 1923, to October, 1924.

*Fifth western Washington egg laying contest*, MR. and MRS. G. R. SHOUP (*Western Washington Sta. Bimo. Bul.*, 12 (1925), No. 5, pp. 115-124).—An account of the fifth western Washington egg-laying contest conducted during 1923-24, with comparisons with earlier contests.

## DAIRY FARMING—DAIRYING

*Proceedings of the World's Dairy Congress* (U. S. Dept. Agr., Dairy Div., *World's Dairy Cong. Proc.*, 1923, vols. 1, pp. X+743, figs. 31; 2, pp. VI+745-1599, figs. 55).—The following papers and various discussions in addition to those noted elsewhere were presented at the World's Dairy Congress, previously

discussed editorially (E. S. R., 49, p. 601): Address of Welcome, by C. E. Hughes (pp. 2, 3); Response to Address of Welcome [trans. title], by J. Maenhaut (pp. 4, 5); Welcome on Behalf of the Department of Agriculture, by H. C. Wallace (pp. 6-8); Presidential Address, by H. E. Van Norman (pp. 8-14); Dairy Products' Place in Improvement of Human Health, by H. C. Hoover (pp. 14-17); The International Dairy Federation [trans. title], by C. Porcher (pp. 41-45); The Dairy Cattle Associations and Their Work, by F. O. Lowden (pp. 65-69); The Relations Between the Manufacturer and the Producer, by B. H. Rawl (pp. 69-77); Address by the President of the United States, C. Coolidge (p. 108); Address of Welcome, by J. H. Moore (pp. 109, 110); Programs and Methods, by R. W. Balderston (pp. 112-114); Quality Control Work of the Dairy Council, by C. I. Cohee, jr. (pp. 128-130); Self-government in Industry, by G. Pinchot (pp. 135-138); The Relation of the Dairy Industry to Child Welfare, by Mrs. I. C. Wood (pp. 139-143); Production and Marketing of Dairy Products in England, by E. W. Langford (pp. 143-146); The Meat Packer as a Distributer of Dairy Products, by L. D. H. Weld (pp. 223-234); The Organization of United Dairies (Ltd.), by J. H. Maggs (pp. 235-242); Dairy and Factory Management, by A. Peter (pp. 242-245); The International Dairy Institute [trans. title], by A. C. Bovy (pp. 245-252); The Dairy Industry in Norway, by R. **Relative utilization of energy in milk production and body increase of dairy cows**, J. A. FRIES, W. W. BRAMAN, and D. C. COCHRANE (*U. S. Dept. Agr. Bul. 1281 (1924), pp. 36, fig. 1*).—This bulletin reports the results of a metabolism experiment with dairy cows conducted cooperatively by the Institute of Animal Nutrition of Pennsylvania State College and the U. S. Department of Agriculture. Three mature cows were used for the tests. The animals received the same ration of grain and alfalfa hay throughout the experiment, the ration being calculated to maintain milk production and produce an increase in live weight as lactation advanced. Two of the cows were fed during three periods, while the results on the third animal are only for two periods. Each period was divided into a preliminary portion and a digestion experiment of at least 9 days' duration. The animals were also placed in the respiration calorimeter for 48 hours during the last 10 days of each period. The usual analyses of feed, excreta, and milk were made during the digestion periods, as well as determinations of the gas and heat metabolism while in the respiration calorimeter. The amount of methane lost and the heat of fermentation were found to affect markedly the efficiency of digestion of the energy in the dry matter of the ration. The manner of considering the milk as body gain or by ignoring it also had a distinct effect on the digestibility of the ration.

The results indicated that milk production takes place by a more direct method than through the transformation of body tissue, since there was a 22.32 per cent greater utilization of the net energy of the feed for milk production than for body increase. The computed heat production of the cows was from 2 to 3 per cent higher than that measured by the calorimeter, indicating that the measured heat production is slightly less than that actually produced. There was an increase of about 2 per cent in the heat production of animals during the last stages of gestation as compared with similar nonpregnant cows. The excess energy required for standing over lying was similar in amount to that found in earlier experiments with steers.

A special container devised by the senior author for collecting the excreta from the cow in the respiration chamber is described.

[Experiments with dairy cattle at the South Carolina Station] (*South Carolina Sta. Rpt. 1924, pp. 67, 68, 70, 71*).—The results of various experiments with dairy cattle are reported.

**Preliminary milking for two-day tests**.—In tests of the influence of leaving milk in the udder on the butterfat yield during the succeeding two days, it was found in the 12 trials that in 9 there was an increase in the butterfat yield, in 10 an increase in the butterfat percentage, and in 7 an increase in the milk yield.

**Comparative value of corn and sorghum silage**.—The results of the comparative study of corn and sorghum silage were much as in the previous year

(E. S. R., 50, p. 679). It required 165 lbs. of corn silage or 181 lbs. of sorghum silage to produce 100 lbs. of milk. The corn silage, however, cost 1.78 times as much to produce.

*Calves feeding.*—The results of a comparative test of hand-feeding and self-feeding grain to calves are reported. The experiment lasted nine weeks, during which one lot of calves was hand-fed twice daily a ration of 100 parts corn meal, 100 parts ground oats, 100 parts wheat bran, 50 parts linseed meal, and 3.5 parts salt, while the other lot had access in separate compartments of a self-feeder to shelled corn, wheat bran, linseed meal, whole oats, corn meal, ground oats, velvet bean meal, bone meal, salt, and ground limestone. The self-fed calves showed a preference for whole corn and oats as compared with the ground grains. The average gains in weight of the two lots were similar, being 143 lbs. for the self-fed lot and 137 lbs. for the hand-fed animals. The hand-fed group, however, gained 5.48 in. in height as compared with 3.32 in. by the self-fed group. It is pointed out that the gain in bony growth was more desirable for animals of this age than the fattening tendency of the self-fed calves. The calculated costs per pound of gain were 12.4 cts. for the self-fed group and 10.4 cts. for the hand-fed group.

*Effect of feeding cabbage and potatoes on flavor and odor of milk, C. J. BABCOCK (U. S. Dept. Agr. Bul. 1297 (1924), pp. 12, figs. 4).*—Six Holstein and 10 Jersey cows were divided into four groups for the study of the effect of the feeding of cabbage and potatoes on the flavor of the milk produced, as was done with turnips and other succulent feeds in earlier investigations (E. S. R., 50, p. 377). The results of the opinions of the judges of the flavor and odor of the milk produced while on these feeds were as follows:

*Classification of samples of milk produced by cows receiving cabbage and potatoes*

Kind of feed	Flavor				Odor			
	Normal	Very slightly off	Slightly off	Off	Normal	Very slightly off	Slightly off	Off
Basal ration (check for cabbage).....	<i>Per ct.</i> 94.2	<i>Per ct.</i> 4.6	<i>Per ct.</i> 1.2	<i>Per ct.</i> 0	<i>Per ct.</i> 93.8	<i>Per ct.</i> 4.60	<i>Per ct.</i> 1.60	<i>Per ct.</i> 0
15 lbs. of cabbage 1 hour before milking.....	34.0	28.0	22.9	15.1	30.3	31.70	26.20	11.8
30 lbs. of cabbage 1 hour before milking.....	19.6	21.2	25.7	33.5	16.8	22.60	28.50	32.1
30 lbs. of cabbage immediately after milking.....	76.2	13.6	8.5	1.7	79.0	9.65	9.65	1.7
Basal ration (check for potatoes).....	96.0	3.6	.4	0	96.9	2.20	.90	0
15 lbs. of potatoes 1 hour before milking.....	87.7	8.6	3.7	0	87.7	7.40	4.90	0
30 lbs. of potatoes 1 hour before milking.....	88.7	7.9	3.4	0	88.2	7.30	4.50	0
30 lbs. of potatoes immediately after milking.....	96.4	3.6	0	0	97.0	2.40	.60	0

The results showed that the feeding of cabbage before milking produced abnormal flavors and odors in the milk, which were increased by increasing the amount of cabbage fed. The flavors were also more pronounced in the cream than in the milk. Aeration was found to reduce the objectionable flavors and odors in the milk. Potatoes consumed one hour before milking had a slight tendency to produce objectionable flavors and odors, but the extent was not increased with an increase in the amount of potatoes consumed. Both potatoes and cabbage could be fed after milking without the development of serious objectionable flavors and odors.

**Raising the dairy calf when whole milk is sold**, C. H. ECKELS and T. W. GULLICKSON (*Minnesota Sta. Bul.* 215 (1924), pp. 3-30, figs. 13).—This bulletin reports the results of experiments in raising calves with minimum amounts of whole and skim milk and with powdered skim milk, malted milk, and powdered and semisolid buttermilk. The part dealing with the desiccated milk products has been previously noted (E S. R., 49, p. 473; 51 p. 778.)

Eighteen calves divided into five groups were used in the study of the minimum whole and skim milk requirements. Three of the groups received whole milk until weaning at from 50 to 72 days of age. Group 4 received part skim milk after 40 days, while group 5 received only skim milk after 4 weeks of age. The calves of groups 1, 2, and 5 were grade Holsteins, while group 3 consisted of purebred Jerseys and group 4 of grade Guernseys. All calves had access to grain and alfalfa hay, the former being limited to 5 lbs. per head daily. When whole milk only was fed, the Holstein calves required from 432 to 879 lbs., while the jerseys required 572 lbs. each. With skim milk the Holsteins required from 161 to 178 lbs. of whole milk and 378 lbs. of skim milk, while the Guernsey required from 360 to 506 lbs. of whole milk and from 72 to 103 lbs. of skim milk.

The gains in weight and height of the calves were compared with the normal to 180 days of age. It was found that the calves were somewhat below normal in weight for some time after weaning, but this was no more evident for those weaned at 50 days than in other groups. Height was less affected by the feeding than was weight. It is stated that these calves will attain normal growth by 2 years of age.

**The bacterial flora of milking machines**, A. H. ROBERTSON (*New York State Sta. Tech. Bul.* 105 (1924), pp. 3-52).—The results are reported of a study of the morphology, motility, spore formation, chromogenesis, Gram stain gelatin liquefaction, nitrate reduction, fermentation of dextrose, lactose, and saccharose, and litmus milk reactions of 721 cultures isolated from various parts of milking machines used in 42 dairies. The cultures have been tabulated according to the genera, with characteristics of each, and described by the numerical system recommended by the Society of American Bacteriologists.

There appeared to be some relation between the care given the milking machines and the flora found. In general the group of white Gram-positive micrococci was the most common when the machines received relatively good care by cleaning with brine hypochlorite solutions. Gram-negative rods of *Streptococcus lactis* types were more prevalent when conditions were less sanitary. Alkali-forming rods were found in connection with tubes cleaned by submerging them in cold water or weak sterilizing solutions. Various other forms were also found, including yeasts and molds. The types found were no more harmful than those on other dairy utensils, but under poor conditions the quantities gaining access to the milk from the milking machine may be greater.

**Filtration and clarification of milk**, A. C. DAHLBERG and J. C. MARQUARDT (*New York State Sta. Tech. Bul.* 104 (1924), pp. 3-27 pls. 4 fig. 1).—The effect of clarification and filtration on the various qualities of the milk has been investigated by comparing portions of the same milk after filtration or clarification with the original raw milk. The filters used in this study were the Burrell-Simplex No. 8, the Ladd filter No. 7, and the Creamery Package No. 6. Clarification was done with the De Laval clarifiers Nos. 95 and 120. The results of the laboratory findings were verified in commercial milk plants.

Both clarification and filtration removed the visible sediment, but by microscopic examination it was found that filtration did not remove all invisible particles (less than 0.02 to 0.05 mm. in diameter), though they were apparently

removed by clarification. Neither method of removing the sediment affected the composition, flavor, acidity, nor keeping quality of the milk. Clarification at a high temperature tended to decrease the size of the cream layer, due to a reduction in the size of the fat globules, while filtration had no effect. The optimum temperature for clarification was 40° F. Bacterial studies of the milk showed that clarification broke up the large clumps of bacteria, while filtration had no effect. Clarification reduced the cell content of the milk 67.3 per cent, while filtration had no influence in this respect.

**Successful cream whipping**, J. C. HENING (*New York State Sta. Circ. 77* (1924), pp. 4, fig. 1).—Directions for whipping cream.

**Ice cream formulas and standardization**, H. P. DAVIS, P. A. DOWNS, and B. MASUROVSKY (*Nebraska Sta. Bul. 203* (1924), pp. 3-23).—This consists mainly of a presentation of formulas for various kinds of ice cream, including a classification of ice creams and directions for standardizing mixes.

## VETERINARY MEDICINE

**Lang's German-English dictionary of terms used in medicine and the allied sciences**, edited and rev. by M. K. MEYERS (*Philadelphia: P. Blakiston's Son & Co., 1924, 3. ed., enl., pp. VII+613*).—The third edition of this glossary of German medical terms is said to contain approximately 53,000 definitions, including over 4,000 new terms.

**Animal diseases in southern Brazil** [trans. title], F. SCHMIDT (*Berlin. Tierärztl. Wchnschr., 40* (1924), No. 39, pp. 532-534).—A brief account of the occurrence of the more important infectious diseases of domestic animals in southern Brazil.

**Annual report on the occurrence of infectious diseases of animals in Germany** [trans. title] (*Jahresber. Verbr. Tierseuch. Deut. Reiche, 32* (1920-1921), pp. IV+56+56).—This continuation of the reports previously noted (E. S. R., 50, p. 182) covers the years 1920 and 1921.

**A new clinical method for blood typing**, O. M. GRUHZIT and L. T. CLARK (*Jour. Lab. and Clin. Med., 10* (1924), No. 1, pp. 66-68, figs. 2).—The authors describe a simple test which may be completed in 5 to 10 minutes.

**Specific dressings.—A study of local immunity** [trans. title], A. BESBEDKA (*Ann. Inst. Pasteur, 38* (1924), No. 7, pp. 565-580).—Essentially noted from another source (E. S. R., 50, p. 78).

**The relation of the melitensis-abortus group of organisms to human health**, A. C. EVANS (*U. S. Dept. Agr., Dairy Div., World's Dairy Cong. Proc., 1923, vol. 1, pp. 562-568*).—In this paper the author deals with the present status of knowledge of this group of pathogenic organisms. The account is based upon investigations by the author, previously noted (E. S. R., 39, p. 289; 49, p. 380; 50, p. 183; 51, p. 283), and of others. The author concludes that, if there were no other reason for milk pasteurization, it would appear to be folly to drink raw milk containing the *abortus* organism. Recent accounts of investigations by Keefer (E. S. R., 50, p. 684), Auricchio (E. S. R., 51, p. 81), and Burnet (E. S. R., 51, p. 181) have been noted.

**On the serological differentiation of B. abortus and B. melitensis** [trans. title], H. FUTAMURA (*Jour. Japan. Soc. Vet. Sci., 3* (1924), No. 2, pp. 127-147).—In attempts to differentiate between *Bacterium abortus* and *B. melitensis*, the only point of differentiation appeared to be the agglutination with heated antigen. On heating the antigen to from 60 to 100° C. for an hour, *B. abortus* was agglutinated more powerfully than *B. melitensis*.

**A study of the agglutination test for bovine infectious abortion**, F. P. MATHEWS (*Jour. Infect. Diseases, 35* (1924), No. 5, pp. 498-501).—In the study

reported an antigen was prepared by growing three different cultures of *Bacillus abortus* on agar for 48 hours and washing off the growth with phenolized salt solution. This antigen was diluted to correspond with a turbidity of 3 in the McFarland nephelometer, a definite amount of this dilution was further diluted with an equal amount of phenolized salt solution, and a portion of the second dilution was treated in the same manner. The 3 antigens thus prepared were tested with the sera of 170 cows from 9 herds, the test being made at the end of 18- and 42-hour incubations, respectively.

The results obtained were divided into three groups, the first comprising the sera from 82 animals, all of which gave negative results with antigen 1, 53 negative with antigen 2, and 21 negative with antigen 3; the second the sera of 8 animals reacting alike at the 18-hour reading and giving a titer of 1 to 25 with antigen 1, 1 to 50 with antigen 2, and 1 to 100 with antigen 3; and the third the sera of the 80 remaining animals, all of which gave higher reactions than the other groups. The titers in groups 2 and 3 showed that a definite ratio exists between the amount of serum and the number of organisms in the antigen when the titer of the serum is reached, and that as the turbidity decreases the agglutinability increases.

The results obtained at the forty-second hour reading were inconstant with antigens 2 and 3, and are thought to indicate that after 18 hours the reaction becomes nonspecific.

Tests with antigens varying in H-ion concentration between pH 6 and 8 indicated no variation in agglutinability with a change in H-ion concentration.

In the particular herds studied the average titer of positively reacting sera was higher in herds in which the abortions had persisted for some time than in those in which the disease was of shorter duration.

**Studies on a non-virulent living culture of *Bact. abortus* towards protective vaccination of cattle against bovine infectious abortion (Bang's abortion disease), I. F. HUDDLESON (*Michigan Sta. Tech. Bul. 65 (1924)*, pp. 3-36).**—The avirulent strain of *B. abortus* used in previous immunization experiments conducted on guinea pigs (*E. S. R.*, 52, p. 481) has been tested similarly on cattle, including 23 animals in an experimental herd and 118 in five other herds.

The general procedure was to administer subcutaneously 10 cc. of a bacterin prepared from the avirulent strain by sterilization with phenol and to follow this after a week's interval by the same dose of a living culture. The blood of each animal was examined by the complement fixation and agglutination tests before and after the inoculation. Similar tests were also made with the milk, and the milk fetuses and fetal membranes were examined bacteriologically and the results confirmed by guinea pig inoculation. Routine clinical examinations were made throughout. In the experimental herd the animals, when treated, were grouped according to their previous histories of abortion and blood reaction.

Six pregnant heifers, which had no history of abortion and gave negative blood tests, were exposed to natural infection after the inoculation. All gave birth to normal calves, and *B. abortus* was not recovered from the uterus nor milk of a single animal. Antibodies for *B. abortus* were absent or slight at the time of parturition but increased rapidly after the injection, declining slowly again after about 60 days. In all but one case, the antibody content of the milk was low. The blood sera of the calves were negative before and after nursing.

Four pregnant heifers which had previously shown a positive blood reaction to one or both tests were subjected to artificial infection after inoculation. Three calved normally, the fourth being accidentally killed.

In a group of 10 cows having a history of abortion or a positive blood test at the time of treatment, 3 showed no evidence of the disease after treatment, nor was *B. abortus* found in the uterus or the milk. Of the remaining 7, 2 of which had aborted previously, 5 were pregnant at the time of vaccination and the other 2 became so later. Of the entire number, 5 aborted, and *B. abortus* was recovered from either the milk or the uterus of all. Two cows which had never given a positive blood reaction nor aborted were injected intravenously with living vaccine. Both were slaughtered before calving and showed no evidence of *B. abortus* in any of the organs tested, including the fetuses. As a check on these results, 2 heifers were given intravenous injections of a virulent strain of *B. abortus*, and this was later recovered in the uterus and fetus.

The effect of the treatment of herd cattle with killed and living avirulent cultures is shown by the breeding efficiency after treatment, which varied from 78.6 per cent to 100 per cent. In the controls receiving no treatment, the breeding efficiency ranged from 0 to 86.6 per cent.

The data are thought to indicate that the culture studied has lost its virulence for cattle as well as for guinea pigs, and that some degree of immunity follows its inoculation. Attention is called, however, to the fact that not all abortions are due to *B. abortus*. "It is certainly evident that all breeding troubles will not be solved alone by giving the animal protection against *B. abortus* infection. If the vaccine proves to be of value in the fight against this one disease of the genital organs, then its application, together with the necessary clinical treatment for other diseases of the reproductive organs, should reduce the abortion rate and breeding trouble in cattle to a small percentage. The use of this nonvirulent culture of *B. abortus* is still in the experimental stage as regards its virulence and value as an immunizing agent. Further, it is not certain that the correct dosage or route of injection is being used. It will require many years of work and entail much expense before all uncertain factors are made clear."

**Investigations upon flagellate infections**, R. P. STRONG (*Amer. Jour. Trop. Med.*, 4 (1924), No. 4, pp. 345-374, pls. 6).—In the course of the author's investigations, a flagellate parasite was discovered in three species of *Euphorbia* in Central and South America, in which it produces flagellosis. The coreid bug *Chariesterus cuspidatus* was found to transmit the infection from the plant to a species of lizard. Extensive experiments upon animals demonstrated that the flagellate as it occurs in the plant and also in the intestinal tract of the insect is not pathogenic for vertebrates. However, after it has passed through the insect to the lizard it acquires pathogenic properties and may give rise to a form of tropical ulceration in the skin.

**Experimental treatment of "mal de caderas" with Bayer 205** [trans. title], R. DIOS (*Compt. Rend. Soc. Biol. [Paris]*, 91 (1924), No. 31, pp. 1032, 1033).—The author's experiments, together with those of others, have led him to conclude that Bayer 205 is useful in combating mal de caderas in the north of Brazil.

**Report of experimental work to determine whether avian tuberculosis is transmitted through the eggs of tuberculous fowls**, C. P. FITCH, R. E. LUBBEHUSEN, and R. N. DIKMANS (*Jour. Amer. Vet. Med. Assoc.*, 66 (1924), No. 1, pp. 43-53).—The authors' investigations, details of which are presented in tabular form, have led to the conclusion that the egg is of no considerable significance in the transmission of avian tuberculosis. Of 62 hens used, only 43 laid, indicating that as high as 30 per cent of tuberculous hens in all stages of the disease may not produce eggs. Of 876 eggs examined, 367 by culture

and 509 by inoculation, the germ of tuberculosis was found in the composite of 9 eggs, but this does not imply that all of the 9 eggs contained tubercular bacteria, since they came from 2 different hens and only an occasional egg from these hens actually contained the germ.

"It would be safe to conclude from these results that less than 1 per cent of eggs from tuberculous fowls actually contain living tubercle bacteria. It has been shown, however, that chicks may be hatched from artificially infected eggs, and it is possible that a naturally infected egg might hatch and the chick itself be actually tuberculous. The possibility of this actually occurring under field conditions and, further, that it would result in the active spread of disease is quite remote."

The shells of 209 eggs coming from known tuberculous birds were carefully washed in sterile saline, the saline centrifuged, and the sediment injected intraperitoneally into poultry with a view to determining whether the disease is disseminated through their becoming soiled with feces containing the bacillus. The results obtained were negative in all cases.

**Diseases of dairy cattle** (*U. S. Dept. Agr., Dairy Div., World's Dairy Cong. Proc., 1923, vol. 2, pp. 1453-1528, fig. 1*).—Addresses presented before the congress include: Protozoan Diseases of Dairy Cattle, by A. Theiler (pp. 1453-1460); Diseases of the Digestive System of Cattle, by D. H. Udall (pp. 1461-1467); Bovine Mastitis, by F. S. Jones (pp. 1468-1473); Mastitis, by J. N. Frost (pp. 1473-1481); Bovine Tuberculosis Control, by V. A. Moore (pp. 1482-1488); Investigations on the Pathology of Streptococic Mastitis and on the Transmission of Mastitis through Milking Machines, by O. E. Stenström (pp. 1489-1493); Osteomalacia and Its Occurrence in Cattle in Norway, by P. Tuff (pp. 1494-1501); Control of Foot-and-mouth Disease in Europe<sup>1</sup> [trans. title], by R. von Ostertag (pp. 1501-1512); Sterility in Dairy Cattle, by W. L. Boyd (pp. 1512-1519); and The Present Status of Our Knowledge of Abortion Disease, by C. P. Fitch (pp. 1519-1528).

**International trade in dairy cattle**, J. R. MOHLER (*U. S. Dept. Agr., Dairy Div., World's Dairy Cong. Proc., 1923, vol. 1, pp. 26-33*).—Regulations governing the importation and exportation of livestock, formulated with a view to preventing the dissemination of parasitic and microbial diseases, are discussed.

**The piroplasms found in bovines.**—I, **The Theilerias** [trans. title], E. BRUMPT (*Ann. Parasitol. Humaine et Compar., 2 (1924), No. 4, pp. 340-353, figs. 3*).—In this first paper, on Theileria, the species *T. annulata*, *T. dispar*, and *T. mutans* are dealt with. A bibliography of 20 titles is included.

**Experiments with anti-hog cholera serum and hog cholera virus**, E. W. PORTER (*Vet. Alumni Quart. [Ohio State Univ.], 12 (1924), No. 2, pp. 38-41*).—To throw some light on post-vaccination troubles in hog cholera immunization work, a study was made of the effect of using (1) large doses of serum and (2) virus which had been held at high temperature.

In the first test three litters of pigs of the same age were treated with the same amount of virus, 2 cc., and amounts of serum varying from 5 to 40 cc. One litter, which was kept under farm conditions in cholera-free territory, was tested for immunity about 6 months later and one which had been kept in a laboratory about 8 months later. In both cases the immunity remained absolute. The third litter, which had been sold and was fed on city garbage, was not tested, but remained healthy. It is concluded that large amounts of serum can be given without decreasing the immunity secured.

To test the effect of heat, samples of carbolized and uncarbolized virus were held at temperatures of 50, 70, and 99.5° F. and tested for virulence on the

<sup>1</sup> Also in *Berlin. Tierärztl. Wchnschr.*, 40 (1924), No. 36, pp. 481-484.

eighth and fifty-seventh days. In the tests with virus held for 8 days, all of the pigs developed symptoms within 7 days, the time of death showing little variation. In the lot injected with virus which had been held for 57 days there was a slightly slower reaction, but with little difference as a result of the different temperatures used. At the end of this time both carbolized and uncarbolized virus appeared to be badly contaminated.

**Investigations of the extensive outbreak of Borna disease of the horse in Hesse** [trans. title], W. ZWICK and O. SEIFRIED (*Berlin. Tierärztl. Wchnschr.*, 40 (1924), No. 35, pp. 465-471, figs. 7).—The authors report upon investigations of an outbreak of this disease in Oberhessen, where it has not previously been known to occur so extensively. A list of 34 references to the literature is included.

**The frog as the second intermediate host of a trematode parasite of the duck and hen** [trans. title], W. NÖLLER and C. WAGNER (*Berlin. Tierärztl. Wchnschr.*, 39 (1923), No. 44, pp. 463, 464).—The authors find that the frog is a host of the cercaria of *Hypoderaeum conoideum* (Bloch)=*Echinostomum conoideum* (Bloch) Kowalewski (1898), a parasite of the duck and hen. Encapsulation takes place in the kidneys of the tadpole and the young frog, and the parasite is later consumed with the frog host by the fowl. A list is given of six references to the literature.

**Development of the liver fluke up to cercaria in *Limnaea stagnalis*** [trans. title], W. NÖLLER and K. SPREHN (*Berlin. Tierärztl. Wchnschr.*, 40 (1924), No. 29, pp. 369, 370).—The authors' investigations show that the miracidia of the liver fluke (*Fasciola hepatica* L.) may penetrate young snails of *L. stagnalis* Schnkn. and pass their development to the cercarial stage.

**The influence of diet upon the liver injury produced by carbon tetrachloride**, N. C. DAVIS (*Jour. Med. Research*, 44 (1924), No. 5, pp. 601-614, pls. 2).—Experiments conducted by the International Health Board of the Rockefeller Foundation upon dogs are reported which show conclusively that factors of diet exert an enormous influence upon the toxicity of carbon tetrachloride.

"Mixed diets and high protein diets, which may be considered normal for dogs, are more or less protective. High carbohydrate diets afford very striking protection against liver injury. Starvation, on the other hand, is harmful. 'All-fat' diets preceding carbon tetrachloride administration are conducive to a maximal injury of liver parenchyma."

## RURAL ENGINEERING

**Hydrodynamics**, H. LAMB (*Cambridge: Univ. Press, 1924, 5. ed., pp. XVI+687, figs. 86*).—This is the fifth edition of this book, the first edition of which was published in 1879. It contains chapters on the equations of motion, integration of the equations in special cases, irrotational motion, motion of a liquid in two dimensions, irrotational motion of a liquid—problems in three dimensions, on the motion of solids through a liquid—dynamical theory, vortex motion, tidal waves, surface waves, waves of expansion, viscosity, and rotating masses of liquid.

**Semi-circular weirs calibrated at Purdue University**, F. W. GREVE (*Engin. News-Rec.*, 93 (1924), No. 5, pp. 182, 183, figs. 2).—The results of tests of semi-circular weirs of six different sizes of opening are presented and discussed, and the equation representing the flow from such a weir opening is deduced.

**Farm drainage methods (survey and design), 1908-1922**, H. B. ROE (*Minnesota Sta. Bul. 216* (1924), pp. 5-71, figs. 22).—A large amount of routine

engineering information is contained in this bulletin on methods of survey and design of farm drainage systems, which is based on experience at the station from 1908 to 1922, inclusive.

**Farm drainage methods (construction), 1908-1922**, H. B. ROE (*Minnesota Sta. Bul.* 217 (1924), pp. 5-44, figs. 51).—A large amount of routine information on the construction of farm drainage systems is presented, which is based on experience at the station during the period 1908-1922.

**The deterioration and preservative treatment of timber**, A. S. DAWSON (*Engin. Jour. [Canada]*, 7 (1924), No. 8, pp. 558-563, fig. 1).—This is an economic discussion of the subject in which data are presented on deterioration in structural timbers and the economic value of preservative treatment. Records of results from the treatment of timber are tabulated.

**Relation of temperature and pressure to the absorption and penetration of zinc chloride solution into wood**, J. D. MACLEAN (*Amer. Wood Preservers' Assoc. Proc.*, 20 (1924), pp. 44-71, figs. 8).—Studies conducted by the U. S. D. A. Forest Products Laboratory are reported which showed that high solution temperatures are very effective in improving the absorption and penetration of zinc chloride in wood. There is a limit above which the temperature-pressure combination should not go if collapse is to be avoided. This limit is apparently higher for large pieces than for small ones, and higher for some species than others.

It is believed that the use of high temperatures in the zinc chloride treatment will not only result in better treatment but will bring about considerable saving in cost of operation, by shortening the time of treatment or by eliminating steaming.

**Crushed brick makes good concrete block** (*Concrete [Detroit]*, 25 (1924), No. 3, pp. 91, 92).—The results of experiments are briefly reported which showed that crushed brick aggregate, while a little harsher to work than a mixture of screenings and torpedo sand, is as easy to work as a straight torpedo mixture, and for a given amount of cement and a given fineness modulus of the aggregate will produce concrete of about the same strength as when ordinary aggregates are used.

**Popular mechanics concrete handbook No. 1** (*Chicago: Popular Mechanics Press*, [1923], pp. [3]+88, figs. 138).—The use of concrete in the manufacture of small useful articles around the farmhouse and garden is briefly described.

**Public Roads, [December, 1924]** (*U. S. Dept. Agr., Public Roads*, 5 (1924), No. 10, pp. 24, figs. 27).—This number of this periodical contains the status of Federal-aid highway construction as of November 30, 1924, together with the following articles: *Accurate Accelerometers Developed by the Bureau of Public Roads*, by L. W. Teller (see below); *Highway Traffic in California*, by L. I. Hewes; *The Economical Use of Wheel Scrapers*, by J. L. Harrison; and *North Carolina Investigating Pressure on Pipe Culverts*.

**Accurate accelerometers developed by the Bureau of Public Roads**, L. W. TELLER (*U. S. Dept. Agr., Public Roads*, 5 (1924), No. 10, pp. 1-9, figs. 15).—Accelerometers developed in connection with the well known studies of impact of trucks on pavement are described, and data from their calibration are tabulated.

**Laboratory strength-tests of motor-truck wheels**, T. W. GREENE (*Jour. Soc. Automotive Engin.*, 15 (1924), No. 2, pp. 150-155, 174, figs. 13).—Laboratory tests conducted at the U. S. Bureau of Standards with two each of standard wood, cast steel, I-beam type, steel disk, aluminum, and rubber cushion motor truck wheels are reported.

In radial compression all of the wheels were sufficiently strong to withstand any load to which they might be subjected in service. With reference to the

specific strength and resiliency developed in both the radial compression and side thrust tests, the results indicated that the wood wheel is probably the best adapted for motor-truck service. Although the other wheels developed considerably higher ultimate strengths, particularly the cast steel and the special steel disk wheel, the proportional limit of the wood wheel was only about 20 per cent less than that of any of the other wheels. The specific strength was higher for the wood wheel than for the others except the aluminum wheel. This was also true of the elastic resiliency and the elastic resiliency per pound of weight.

**California air-cleaner tests, 1924 series,** A. H. HOFFMAN (*Jour. Soc. Automotive Engin.*, 15 (1924), No. 2, pp. 140-148, figs. 8).—In a contribution from the California Experiment Station, the results of a continuation of the tests of tractor engine air cleaners begun in 1922 (E. S. R., 49, p. 688) are reported.

In the 1924 work road tests of air cleaners were conducted, efforts being made to find out how much dust an engine would draw in if the cleaner and connections were removed, and to catch and weigh the dust the air cleaner being tested failed to catch. The absolute air cleaner used in connection with the air cleaners being tested is described, and standard dusts for testing purposes, including fuller's earth, are discussed. Road tests are treated generally and specifically and compared with laboratory tests, and the 32 air cleaners submitted for testing are described. Tabular data of the test results are included.

It was found that every air cleaner built can be made to test 100 per cent efficient if a shrewd choice is made of the dust to be fed into it. The particles must be large enough so that they can not pass the filter, and must be heavy enough so that inertia or gravity will leave them behind when the air going toward the carburetor swings around the turn.

**Specific heats of lubricating oils,** E. H. LESLIE and J. C. GENIESSE (*Indus. and Engin. Chem.*, 16 (1924), No. 6, pp. 582, 583, fig. 1).—In studies conducted at the University of Michigan the specific heats of six typical lubricating oils were measured over a range of temperatures of from 37.78 to 143.33° C. (100 to 290° F.). An increase of from 35 to 40 per cent in specific heats was found. It is considered obvious that a change as large as this must be taken into account in engineering work. The variation of specific heats with temperature is not the same for all oils, and it is suggested that further study may disclose some connection between the temperature rate of change of specific heats and the properties of an oil as a lubricant.

**A discussion of creep in power belting,** R. F. JONES (*Cement and Engin. News*, 36 (1924), No. 9, pp. 21, 22, 24, figs. 3).—This is an analysis of the effect of creep on the application of the fundamental belting formula.

**Plow bolts** (*U. S. Dept. Com., Off. Sec., Elimination of Waste Ser.*, pp. 9, figs. 4).—This circular presents the report of a general conference of the farm equipment manufacturing industry and a simplified list of plow bolts proposed on that occasion by the National Association of Farm Equipment Manufacturers.

**Principles of electric motors and control,** G. FOX (*New York and London: McGraw-Hill Book Co., Inc.*, 1924, pp. XIV+499, figs. 298).—Information on the principles, performance, characteristics, and practical construction of electric motors and controllers is presented.

**Hatching chicks electrically,** H. E. BELL (*Jour. Elect.*, 53 (1924), No. 3, pp. 85-88, figs. 7).—In a contribution from the Oregon Agricultural College data on the operation of an electrically equipped incubating plant on the

Pacific coast having a capacity of 80,000 eggs are presented. The plant consists of a wooden building 44 ft. by 150 ft., which contains 131 incubators with a capacity of 612 eggs each. Double walls packed with sawdust for heat insulation are used, and the floor is covered with dirt and a layer of sawdust and shavings to reduce heat radiation. The building is heated by the incubators alone, and the temperature varies from 60 to 70° F. Each incubator is heated by 10 elements which are placed at the top of the incubator and spaced 7 in. apart, with 6 in. from the end elements to the end of the compartment.

Tests showed that the power in each individual machine was on for very short intervals of time only. The current in no machine remained on for more than a minute to a minute and a half, with the exception of the time necessary to reheat the eggs after cooling or turning, during which period the current remained on for an hour at a time. The power consumption was found to drop off on the fourteenth day due to the fact that the growth of the germ at this period begins to use the latent heat stored within the egg. The energy used during the first day was found to be relatively high on account of the initial heating of both the incubator chamber and the eggs. The daily consumption then remained constant at 4 kw. hours per day until the fourteenth day. From this time on until the chick was hatched, the consumption gradually fell off and dropped as low as 1 kw. hour per day with a room temperature of 65°.

Tests to determine the voltage regulation and the number of interruptions to service showed that the power went off on an average of once in every three days, but only once a season for a long enough period to require the starting of an emergency plant. The voltage had about the same characteristics from day to day, with a maximum of 122 volts and a minimum of 114 volts.

A third test showed that the temperature of the room affected the consumption of power materially. If the temperature of the incubator room was high, the amount of power used by the machines in operation was lowered. The three factors governing the proper maximum temperature for the room are considered to be the most satisfactory temperature for cooling the eggs, the temperature under which it is possible for men to work comfortably, and the temperature adapting itself to most efficient ventilation. Since the eggs must be cooled down to 98° several times during incubation, it has been found that the room temperature should not go above 95° in order to secure economy of time in the egg-cooling process, and an average of from 85 to 90° has been found to be the best.

Ventilation is said to be the most important factor. Experiments showed that when the temperature of the incubator room was raised to 85 or 90°, the ventilation in the type of incubator manufactured to-day becomes inefficient. It is stated that another feature of electric incubation upon which experimental study could be advantageously undertaken is that of the most desirable capacity of the heating elements.

**Building the dairy barn**, N. S. FISH (*Wisconsin Sta. Bul. 369 (1924)*, pp. 31, figs. 27).—Practical information on the construction of dairy barns, with special reference to the requirements of Wisconsin conditions, is presented, together with a number of working drawings.

**Sewerage systems for farm homes**, N. S. FISH, E. G. HASTINGS, and F. R. KING (*Wis. Agr. Col. Ext. Circ. 173 (1924)*, pp. 19, figs. 15).—Practical information on the planning and construction of sewerage systems for farm homes, with special reference to conditions in Wisconsin, is presented.

## RURAL ECONOMICS AND SOCIOLOGY

A study of farm organization in central Kansas, W. E. GRIMES, J. A. HODGES, R. D. NICHOLS, and J. W. TAPP (*U. S. Dept. Agr. Bul. 1296 (1925)*, pp. 75, figs. 31).—An intensive study of the organization and operation of 25 farms in McPherson County for the years 1920 to 1922, inclusive, was conducted cooperatively by the Bureau of Agricultural Economics, U. S. D. A., and the Kansas Experiment Station.

The average area of the farms included in 1922 was 295 acres, 245 of which were in crops and 42 in pasture. Wheat was the major crop, with corn the second, followed in rank by oats and alfalfa. Livestock raising was a minor part of the business. The labor and materials used in the several operations involved in the production of specific crops and of cattle, hogs, poultry, and work horses, and also the man and horse labor given to manure hauling, maintenance of machinery and real estate, hauling feed, garden work, preparing seed for seeding, and other miscellaneous duties, are set forth. The seasonal labor and tasks that may be interfered with or not by rain are classified, and suggestions are made as to the management of the labor program. The principles governing the choice of farm enterprises are discussed, and their application is illustrated by a suggested reorganization of a selected farm, representative in size and type of many McPherson County farms, and yielding approximately \$500 more in return for the farm resources. Under this plan the wheat acreage is reduced slightly, while that of feed crops is increased, adding alfalfa and Sudan grass. The numbers of milch cows, hogs, and chickens are increased, but the number of work horses is decreased. It is assumed that no radical changes would have taken place in wheat prices, yet an increased production of butterfat per cow and of eggs is counted upon.

**Farm organization and cost of production on cotton farms in Anderson County, S. C., in 1922**, W. C. JENSEN (*South Carolina Sta. Bul. 221 (1924)*, pp. 101, figs. 18; *abs. in South Carolina Sta. Rpt. 1924*, pp. 39-42).—The survey reported upon here was planned with the purpose of determining the facts and principles involved in the organization and management of, and farming practices on, cotton farms in the Piedmont region of South Carolina. It included 333 farms and was conducted cooperatively by the Bureau of Agricultural Economics, U. S. D. A., and the station for the year 1922. The economic, social, and physical conditions of the region are described.

On the farms studied 52 per cent of the crop acreage was in cotton. Out of an average total of 68.2 acres, 17.8 were in corn, 8.8 in small grains, 3 in first crop hay, and 6 in second crop hay, principally cowpeas after grain. An average of 2 milch cows, 2 hogs, and 57 chickens were found per farm.

There were selected 120 farms of the entire number for the computation of costs of cotton, corn, oats, cowpea hay, and wheat and the cost of keeping mules. The more important factors that determine the yield and hence affect costs and profits were mule and man labor for cultivation, fertilizers, and damage by the boll weevil. Yields of less than 200 lbs. of cotton per acre cost about 7 cts. more a pound than higher ones. Man and mule labor costs were correlated to a considerable extent with the acre cost of cotton, but on a pound and total production basis heavy applications of these factors usually paid. The average yield of corn on the 120 farms was 16.5 bu., the average cost of production per bushel being \$1.45.

Analyzing the farm business as a unit, it was found that an average farm income of \$378 was obtained by the operators of the 333 farms included in the study. The owners made a higher farm income than the tenants. The average

labor income was —\$392, that for the tenants being \$227, while for the owners it averaged —\$502. The distribution of farm area to various purposes, the distribution of labor on entire farms, and the amount and kinds of fertilizer used are discussed, as are also the form of tenure, the amount of indebtedness, and the landlord's profits. The color and education of operators are considered to be important determining factors affecting farm income, being fixed ones, over which the operator has no control. Over tenure and size of business, however, he has more or less control, while others, such as yield, percentage of crop land in cotton, and efficiency in the use of work stock, are shown to be subject to human control in a given season. The relative profits of certain crops that may be grown subsidiary to cotton are briefly set forth, and certain broad economic and social applications are made of the results obtained by the study.

**Organization and management of typical West Virginia farms, A. J. DADISMAN** (*West Virginia Sta. Bul. 187 (1924), pp. 75, figs. 26*).—Surveys were made in 1914 in four regions of the State which were deemed representative of typical conditions, taking 544 complete farm management records. Studies based on data taken in two of the regions have been noted (*E. S. R., 35, p. 90; 43, p. 92*). In this one the distribution of capital, number and value of farm animals, crop acreage and yields, and farm receipts, expenses, and earnings are shown for general farms operated by owners and by tenants and livestock, dairy, and truck farms, including the farms surveyed in the four sections. From 201 farms in Brooke County 22, and from 74 in Preston County 20, farms surveyed in the summer of 1914 were selected for a 5-year study. The changes in the farm business on these farms from 1913 to 1917, inclusive, with the 5-year averages, are tabulated, illustrated, and discussed.

About 25 records were obtained by personal visits to farmers during the summers of 1915 and 1923 with respect to the total cost of producing corn, oats, wheat, buckwheat, and potatoes for the previous years in Preston and Brooke Counties. These are shown, and the distribution of man and horse labor on these crops in Preston County is presented graphically. The publication is concluded with a discussion of the relative importance of certain factors in farm organization.

**Landlords of Nebraska farms, J. O. RANKIN** (*Nebraska Sta. Bul. 202 (1924), pp. 38, figs. 4*).—A survey previously noted (*E. S. R., 49, p. 189*) supplied the data discussed here. Information was secured with reference to 654 landlords, 495 of whom owned full tenant farms, while 159 owned only the rented portions of the part-owner farms. Nearly half of these landlords owned two or more farms apiece.

A comparison is made between returns from the 1900 census with those from this survey. A marked contrast is noted between the number of one-farm owners in 1920 in the region surveyed and in the United States as a whole in 1900 as revealed by the census. In the latter case 80 per cent owned only one farm apiece.

Practically one-half of this discussion deals with the business relations of landlords and their tenants, setting forth terms of leases, what each contributes; the percentage of the personal property furnished by landlords and tenants; the compensation, supervision of farms, and work done by landlords; and the landlord's share, giving particularly his share of the corn, wheat, oats, and barley, and alfalfa and other hay crops.

**Economic studies of dairy farming in New York.—II, Grade A milk with and without cash crops, E. G. MISNER** (*New York Cornell Sta. Bul. 433 (1924), pp. 147, figs. 19*).—This bulletin continues work previously noted

(E. S. R., 50, p. 89). The history of the production of grade A milk in New York State is set forth, and a detailed report is made covering 135 farms, 84 of which were in Chenango County, in the vicinity of Oxford and Brisben, and delivered milk to the plants of a single company in these two villages. These farms comprised the group without cash crops. The remaining 51 farms were in the vicinity of Homer, Cortland County, and Tully, Onondaga County, delivering milk to incorporated dairies in the villages named. These farms comprised the group with cash crops.

Of the 84 Oxford operators 66 were owners, 13 were share tenants, and 3 were cash tenants, while of the second group 38 were owners and 10 were share tenants. The common method of leasing is under a half-and-half share agreement, with the landlords usually furnishing more than half the cattle. The average value of the 135 operators' time was \$956 for 12 months. The following table summarizes some of the data presented:

*Cost of milk production on New York farms, 1921-22*

Item	Oxford	Tully and Homer
Number of farms.....	84	51
Average size.....acres.....	194	168
Average crop area.....do.....	64	75
Average total capital.....	\$13,040	\$19,204
Average value per acre.....	46	81
Total receipts.....	4,161	7,018
Current operating expenses.....	2,828	3,997
Expense for new buildings.....	66	508
Expense for livestock purchased.....	316	488
Farm income.....	951	2,025
Labor income.....	299	1,065
Net cost of production of 100 lbs. of milk.....	2.59	2.79
Net cost per pound of butterfat.....	.72	.80
Average loss per cow.....	9.04	10.73
Decrease in market value per cow.....	26.43	23.02
Loss per 100 lbs. of milk produced.....	.17	.18
Return per hour after all charges except for labor were made.....	.20	.24

The cost of raising heifers, the question of fall or spring freshening, and the several combinations of enterprises with dairying are discussed to bring out their advantages and disadvantages. Of the Tully and Homer farms those adding cows entirely by purchase were larger. They obtained 827 lbs. more milk per cow at the same cost per 100 lbs. and had a labor income of \$1,108 more per farm than those farms that added cows exclusively by raising. Of the Oxford farms, 14 replaced cows entirely by purchase, and their average labor income was \$247, while 44 replaced entirely by raising and had an average labor income of \$430. On the 135 grade A farms there were only five flocks of 200 fowls at the end of the year. The leading cash crops on the Tully and Homer farms were potatoes, cabbage, hay, and factory peas.

The variations in the size of the business, rates of production, kinds and amounts of fertilizer used, the distribution of labor, and cropping systems and rotations are brought out, and the averages for the two groups of farms are tabulated and compared. Finally, the important business factors for four of the most successful farms with cash crops are given, and copies of the record forms that were used for the survey are appended.

The cost of producing milk and some factors influencing the cost, E. G. MISNER (*U. S. Dept. Agr., Dairy Div., World's Dairy Cong. Proc., 1923, vol. 2, pp. 1097-1111*).—Data showing the feed and labor cost of milk production are summarized from long continuous records in reports and bulletins of the ex-

periment stations. An analysis is made also to show the features of the organization of the dairy enterprise or methods of feeding and handling which influence cost. These are taken to be the size of the business, the size and age of the cow, the time of freshening, feeding practices, and the value of offspring. A bibliography of 25 titles on the subject of milk production costs is included.

**Work of children on truck and small-fruit farms in southern New Jersey** (*U. S. Dept. Labor, Children's Bur. Pub. 132 (1924), pp. V+58, pls. 3*).—The study upon which this report is made was conducted in Cumberland, Gloucester, and Burlington Counties in southern New Jersey. Detailed information as to the nature and extent of work on truck farms was obtained for every child under 16 years of age who had worked in the fields at least 12 days during the year previous to September, 1921. General information was secured from school authorities and other local officials, and an inquiry was made into the methods of recruiting migratory labor in Philadelphia.

In the 243 local families interviewed there were 445 children who had worked on truck farms during the preceding year, 345 of whom lived on farms and 100 of whom came from nearby settlements. The workers ranged in age from 5 to 15 years, 76 per cent of the group being under 14, and 20 per cent younger than 10 years of age. They were found to have done general farm work, planting and transplanting, and harvesting. Of the total number reporting hours worked in the field, 22.8 per cent spent 6 hours and less than 8 hours on a typical day, 16.4 per cent were found in each of the groups of less than 4 hours and 4 hours and less than 6, while 15.1 per cent spent 10 hours and less than 11 in the field. Half of the working children had received wages. Of 69 children from 12 to 15 years of age who reported their earnings, almost half had made 15 cts. an hour or more, 6 of them having received 25 cts. or more. A large majority of the 377 working children whose school records showed that they had been absent during the school year preceding the survey had lost from several days to four months on account of farm work.

More than half of the children working on the truck and fruit farms of the areas included in the survey were included in the families of migratory workers. Of their number 79 per cent were under 14 years of age, and 21 per cent were under 10. The work of children in these migratory families was less varied than that of the local workers, and the city children worked on the whole longer hours than the local workers. Although all except 14 of the 186 children who could tell the exact amount earned on the day preceding the agent's visit were 10 years of age or over, 81 per cent had earned less than 15 cts. an hour and 46 per cent less than 10 cts. School records obtained from 294 children indicated that three-fourths of them had been present less than 80 per cent, and a little over one-fourth had attended a little less than 60 per cent of the school term. The schools attended by the children were in session from 181 to 194 days.

Attendance and scholarship records were obtained for 1,298 children in Philadelphia who had left school in the spring of 1921 because their families had moved to the country, and these data are set forth and discussed in detail. The houses for these migratory workers are also described.

**The function of the local bank in financing the farmer**, E. B. HARSHAW (*U. S. Dept. Agr., Dairy Div., World's Dairy Cong. Proc., 1923, vol. 1, pp. 207-223*).—A discussion of marketing programs for cooperative organizations in the United States and of the legislation providing long-time, intermediate, and short-time credit to farmers.

**Economic and social factors in price conciliation in the milk industry**, C. L. KING (*U. S. Dept. Agr., Dairy Div., World's Dairy Cong. Proc., 1923,*

vol. 2, pp. 869-875).—Fourteen forces that bring about a demand for the machinery of price conciliation and arbitration in the milk industry are analyzed, being grouped according as they may be advantages of collective bargaining to producers, milk buyers and distributors, or the consumer.

**Development and present status of farmers' cooperative business organizations**, R. H. ELSWORTH (*U. S. Dept. Agr. Bul. 1302 (1924), pp. 76, figs. 37*).—The data, classified and tabulated, comprising the major portion of this report were obtained by survey in 1922 and by subsequent follow-up work until in March, 1924, information had been gathered with reference to 10,160 active cooperative buying and selling organizations. The first survey study in a series of which this is the third was made in 1915 and has been noted (E. S. R., 37, p. 888). Data obtained in a second study in 1919 are briefly summarized and incorporated in two tables in this publication. The latest returns are presented graphically and summarized for years and periods of years, in some cases beginning with 1900, in 95 tables pertaining to the associations in the United States and in leading States; organization characteristics and membership; amount of business; date of organization; collective purchasing; grain marketing associations; creameries, 1922 and 1923; fruit and vegetable associations; associations handling livestock; cotton, rice, tobacco, and wool associations; agricultural consumer cooperation; associations "out of business"; and specific associations.

**Cooperation as a factor in stabilizing the market for agricultural products**, S. I. MILLER, JR. (*U. S. Dept. Agr., Dairy Div., World's Dairy Cong. Proc., 1923, vol. 1, pp. 252-256*).—Cooperation is held first to standardize the quality of the product and develop brands and good will throughout the marketing world; second, to standardize quantity; third, to create a better spread of the product upon the existing market; and fourth, to develop and expand the market for the product coming within the cooperative endeavor.

**Status of trade associations in the dairy industry from the standpoint of economics**, R. E. LITTLE (*U. S. Dept. Agr., Dairy Div., World's Dairy Cong. Proc., 1923, vol. 1, pp. 256-265*).—The history of the guild movement is briefly outlined. The trade association of to-day is defined, and its activities are outlined as including industrial and commercial research, market expansion, legislative activities, the study of transportation problems, credit and insurance protective work, the prevention of trade abuses, simplification and standardization, publicity, the initiation of policies of employee relations, and mediation in Government relations. Trade associations complement the corporations, and while they do not manufacture nor do they distribute or sell, their aim is to facilities these and other commercial or governmental processes. A brief bibliography is appended.

**Marketing dairy products: Creameries and cooperative cream shipping stations in North Dakota**, A. H. BENTON (*North Dakota Sta. Bul. 182 (1924), pp. 40, figs. 19*).—Records are said to show that at least 145 local creameries have been established in North Dakota. Thirty-eight were in operation in 1923, all but 4 of these being engaged in the manufacture of butter. The bulk of the cream in North Dakota is purchased by centralizer creameries, of which there are 14 located in the State. Between 25 and 30 others shipped cream to their plants in neighboring States. In 1923 there were 1,235 cream stations, 1,209 of which were operated by centralizer creameries and independent cream buyers and 26 by cooperative cream shipping associations. One-third of these have been very successful. The average value of equipment of the cooperative stations was \$452, and the average operating expense \$1,822. The

successful ones handled an average of 76,527 lbs. of butterfat and had an average of 105 members. Legal and business forms are suggested for use in the organization and operation of these stations.

**The cooperative marketing movement**, A. SAPIRO (*U. S. Dept. Agr., Dairy Div., World's Dairy Cong. Proc., 1923, vol. 1, pp. 100-107*).—A discussion is given of the so-called commodity plan of cooperative marketing as applied to the marketing of milk in the United States. The proper aim of milk market organization is held to be to develop and stabilize the market for milk and milk products and to use the legitimate dealer to his own profit in the process.

**Cooperative marketing of milk** (*U. S. Dept. Agr., Dairy Div., World's Dairy Cong. Proc., 1923, vol. 1, pp. 83-86, 695-743*).—The following papers were presented at a session of the congress devoted to this subject: Cooperative Dairying, by R. M. Owen; Work of the National Farmers' Union in Connection with Milk Organization in England, by E. W. Langford; Review of Progress in Fluid-milk Marketing in the United States, by C. W. Holman; Types of Collective Bargaining Organizations, by R. Pattee; The Dairymen's League, by J. D. Miller; Milk Collection, Treatment, and Distribution in the Industrial Cooperative Movement of England, by A. Park; The Cooperative Milk Plant in the Small City, by L. B. Cook; Cooperation as Applied to the Dairy Industry in England, by F. D. Acland; and Cooperative Milk Distribution, by H. Hartke. A paper entitled Cooperative Marketing of Milk, by J. D. Miller (pp. 83-86), was given in a session on the development of dairying in the United States.

**Cooperative marketing of manufactured products** (*U. S. Dept. Agr., Dairy Div., World's Dairy Cong. Proc., 1923, vol. 2, pp. 889-945, fig. 1*).—The papers read at this session of the World's Dairy Congress are concerned with the particular problems of marketing dairy products in certain regions. Among them are Danish Cooperative Dairy Organizations and Their Works, by S. Sørensen; A Central Cooperative Organization for the Marketing of Butter, by J. Brandt; The Cooperative Marketing of Butter on the Pacific Coast, by C. L. Mitchell; Building a Cheese Industry in New Territory, by V. D. Chappell; Cooperative Manufacturing and Marketing of Dairy Products, by J. A. Scollard; Systems of Dairy Farming in Scotland and the Development of Cooperative Organization in Dairying, by J. Drysdale; The Methods That Have Been Used by the Cooperative Marketing Association in Holland, and the Results That Have Been Obtained, by R. M. Veeman; Cooperative Creameries in Ireland; Cooperative Creameries in the Mississippi Valley, by O. A. Storvick; and Cooperative Marketing of Cheese by Producers: Its Difficulties and Advantages, by T. Macklin.

**Fundamental aspects of dairy marketing**, L. D. H. WELD (*U. S. Dept. Agr., Dairy Div., World's Dairy Cong. Proc., 1923, vol. 1, pp. 77-82*).—Marketing functions and the system by which they are performed by middlemen are briefly outlined, and the particular problems in the marketing of butter, milk, and cheese are noted. It is pointed out that butter is marketed on a very narrow margin of cost, while milk distribution and to a lesser degree that of cheese are relatively very expensive.

**The cooperative advertising of dairy products**, P. F. O'KEEFE (*U. S. Dept. Agr., Dairy Div., World's Dairy Cong. Proc., 1923, vol. 2, pp. 945-949*).—Numerous instances of the economic effectiveness of cooperative advertising by producers of agricultural products in the United States are cited.

**The marketing and distribution of American-grown Bermuda onions**, W. M. STEVENS (*U. S. Dept. Agr. Bul. 1283 (1925), pp. 56, figs. 14*).—The principal onion-growing regions of the United States are defined, methods of distribution are described, and important factors which affect Bermuda onion

prices are pointed out. They are said to be characterized by wide fluctuation, both within each season and as between one season and another. A remarkably close correlation is shown to exist between the quantity of old onions in storage February 1 and the opening price. The size of the new crop exerts only a moderate influence on the price level at which the new crop will sell. The rate of shipments, however, affects the price during the season considerably. Most of the factors affecting prices are said to be beyond the control of the individual grower and can be met only by organized united effort. Recommended United States grades for Bermuda onions are given.

**The market for American agricultural products in the United Kingdom,** G. B. L. ARNER (*Jour. Farm Econ.*, 6 (1924), No. 3, pp. 283-294).—This is a discussion of changes in economic conditions affecting demand in the United Kingdom, changes in the condition of supply in the United States, and the competition of other countries, and of the way in which these factors apply in the cases of commodities such as cotton, wheat and flour, pork products, tobacco, and minor ones. It is held to be reasonable to expect that in the future the United Kingdom will continue to import from the United States cotton in decreased volume, tobacco in constant or perhaps increasing volume, pork products as long as the price remains low and in reduced quantities at higher prices, wheat and flour in small quantities varying with the degree of competition from Canada and Argentina, feedstuffs in considerable quantities only in years of crop shortage in competing countries, fresh fruits in fairly constant but relatively small quantities, dried fruits in fair volume depending on the price and the future growth of competition, and glucose and perhaps other specialized grain products in the same volume as in the past with little competition.

**International trade in dairy products: Significant trends of supply, demand, and price,** H. C. TAYLOR (*U. S. Dept. Agr., Dairy Div., World's Dairy Cong. Proc.*, 1923, vol. 1, pp. 55-62).—Sources of surplus dairy products are said to have shifted from the countries of the Northern to those of the Southern Hemisphere, and as a result of this shift the seasonal trend of butter imports into Great Britain is such as to tend toward a uniform supply throughout the year. From the point of view of the United States, this recent far-reaching change in seasonal supply and price serves to concentrate attention upon the possibility that mutually advantageous seasonal trade in fresh butter may eventually replace, to some degree, the system of seasonal storage that is developing here. The dairy interests of Denmark, Russia, Germany, New Zealand, Canada, and the Netherlands are touched upon briefly.

**Some aspects of the international trade in dairy produce,** J. A. RUDDICK (*U. S. Dept. Agr., Dairy Div., World's Dairy Cong. Proc.*, 1923, vol. 1, pp. 20-26).—This paper is confined largely to an analysis of the imports of butter and cheese into the United Kingdom, the principal international market for dairy products. A rapid increase in exports from New Zealand since about 1883 and a remarkable development in exports from the Southern Hemisphere in general since 1903 are pointed out. Certain tropical and subtropical regions are thought to offer a possibility for future expansion of dairying, the establishment of the creamery industry on the Fiji Islands being noted in this connection. It is considered unlikely that the industry will expand to any great extent in those countries where it has been extensively developed. The importance of the Baltic States in the future is emphasized.

**Monthly Supplement to Crops and Markets, [December, 1924]** (*U. S. Dept. Agr., Crops and Markets*, 1 (1924), Sup. 12, pp. 393-448, figs. 6).—Statistics representing estimates of the harvested acreage, production, yield, value,

and price of important crops for the years 1922 to 1924, inclusive, are tabulated by States. Statistics of truck crops for shipment and for canning or manufacture are tabulated for 1921-1924. The usual estimated farm prices of important products are shown for November 15, 1924, with comparisons, and monthly average farm prices of specific commodities are given. A review of the price situation is presented with tabulated index numbers of farm prices and wholesale prices of nonagricultural commodities through a period of years. The percentage of the corn crop maturing is set forth graphically and statistically, with a brief discussion.

**Crops and Markets, [December, 1924]** (*U. S. Dept. Agr., Crops and Markets, 2 (1924), Nos. 23, pp. 353-368; 24, pp. 369-384; 25, pp. 385-400, fig. 1; 26, pp. 401-416*).—Current weekly abstracts of market reports and reviews of the market situation through the month are presented, with reference to important agricultural commodities, and detailed data are tabulated. Brief notes are also given covering the condition of foreign crops and the foreign market situation.

**Corn and hog correlations, S. WRIGHT** (*U. S. Dept. Agr. Bul. 1300 (1925), pp. 60, figs. 30*).—The present study was made in order to discover what relations existed during a period of normal conditions from 1871 to 1915 between pork production and prices and the corn situation. The factors considered with respect to corn are acreage and yield per acre and the average farm price. With respect to hogs the slaughter at large markets, the average weight, the pork production, the average market price, and the farm price have been found. In all but the last of these items the data from the eastern and from the western pack have been considered separately. All the possible correlations among these variables have been calculated. In an attempt to find the system of causal relations that would account for the observed correlations, path coefficients have been calculated for each path of influence in this system, from which the expected value of each of the 510 correlations has been found (pp. 45-50). A series of formulas is given for predicting the fluctuations of each variable, with discussions of limitations. The following conclusions are reached:

The dominating features of the hog situation are certain effects of the corn crop and price and an innate tendency to fall into a cycle of successive overproduction and underproduction, two years from one extreme to the other. The amount of breeding at a given time is determined largely by the profits from hog raising during the preceding year, which depends on the ratio between the price the packers pay for the hogs and the price of corn during the period in which they were raised and finished. The peak effect on breeding occurs from half a year to a year after the hog-corn price ratio has reached its peak and begun to decline. Breeding, however, does not reach its low point until some time after the hog-corn price ratio has begun to rise. The interactions among the corn and hog prices and hog breeding, around which the whole hog situation centers, are given in detail. The summer live weight is for various reasons a remarkably close indicator of the amount of breeding for the period from the preceding through the following fall. It shows higher correlations on the whole with other hog variables than any other variable dealt with, although the least affected by corn prices. Winter live weight, on the contrary, is determined largely by the preceding corn crop and only secondarily by the amount of breeding during the preceding year.

Seasonal slaughter is determined in part by the amount of breeding during at least three years preceding and in part by a tendency toward concentration in the summer season, in which prices are high, at the expense of the winter,

whenever the corn supply permits. The corn crop has its maximum effect on slaughter in the following summer. Pork production depends very much more on the fluctuations in slaughter than on the relatively small percentage fluctuations in weight. The eastern pack runs parallel to the western in most respects: The influence of corn crop and prices is considerably less. Western hog prices, on the other hand, are even more closely correlated with the eastern than with the western pack, probably owing to their influence on eastern shipments. The farm price of hogs is very closely correlated with the packers' price but seems to lag behind several months.

**Agriculture and dairying in the world's economic equilibrium**, B. M. ANDERSON, JR. (*U. S. Dept. Agr., Dairy Div., World's Dairy Cong. Proc., 1923, vol. 1, pp. 34-41*).—While the loss of European markets for food and raw materials at the same time that producing capacity was unimpaired adversely affected American agriculture through the wheat surplus, the author believes that American dairy interests are very largely emancipated from dependence on the international market. There appears to be ample opportunity for further consumption at home, although labor is the limiting factor. Certain difficulties in determining the comparative importance of dairying and other branches of agriculture are pointed out

The collection and distribution of milk and dairy products statistics by the International Institute of Agriculture at Rome, C. LONGOBARDI (*U. S. Dept. Agr., Dairy Div., World's Dairy Cong. Proc., 1923, vol. 1, pp. 45-55*).—The plans and efforts of the International Institute of Agriculture in organizing statistics of milk and dairy production are briefly described, with notes as to the available statistical material in certain countries. It is held necessary for every country to possess annual figures for the number of milch cows, and desirable to concentrate chiefly on efforts to secure the establishment of annual statistics of milk production in the different countries.

## AGRICULTURAL EDUCATION

**Research and education in agriculture, including dairying, in the United States**, A. C. TRUE (*U. S. Dept. Agr., Dairy Div., World's Dairy Cong. Proc., 1923, vol. 1, pp. 86-100*).—This is a brief presentation of the general system of agricultural education and research in the United States, particularly in its application to dairying, and discusses agencies for research, higher education, extension work, and secondary education.

**Instruction in dairying in educational institutions** (*U. S. Dept. Agr., Dairy Div., World's Dairy Cong. Proc., 1923, vol. 1, pp. 587-593, 603-659*).—Among the papers read before this session of the congress were The Education of Farmers and Dairymen in Switzerland [trans. title], by A. Peter; Vocational Instruction in Dairying in Secondary Schools, by J. R. Dice; Methods of Teaching Dairying to College Students, by H. H. Dean; Collegiate Instruction in Dairying, by W. A. Stocking; Graduate Instruction in Dairy Husbandry, by C. H. Eckles; The Status of Dairy Education in England and Wales, by V. E. Wilkins; Dairy Instruction in Austria, by W. Winkler; Dairy Instruction in Norway, by K. Støren; Instruction in Dairy Science in the Agricultural College at Wageningen, by B. van der Burg; Dairy Instruction in Sweden, by L. F. Rosengren; The Dairy Industry of Denmark: Education as the True Foundation, by N. K. Jensen; Dairy Instruction in the Netherlands, by K. H. M. van der Zande; Cheese-making Instruction in Italy [trans. title], by G. Fascetti; and Short-course Instruction in the Manufacture of Dairy Products, by E. H. Farrington.

**Extension methods in dairy education** (*U. S. Dept. Agr., Dairy Div., World's Dairy Cong. Proc., 1923, vol. 1, pp. 343-352, 366-381, 400-419*).—Among the papers read at this session of the World's Dairy Congress are Agricultural Extension Methods and Activities, by A. A. Borland; Methods Adopted in England and Wales to Convey Dairy Education and the Principles of Cooperation to the Farmer, by J. F. Blackshaw; The Work of a County Dairy Instructress in England and Wales, by D. G. Saker; and Dairy Instruction Given by the Cooperative Dairy Organizations in the Netherlands, by J. A. Geluk. The proceedings of an informal conference on extension methods are included.

**Motion pictures and dairy education**, R. W. BALDERSTON (*U. S. Dept. Agr., Dairy Div., World's Dairy Cong. Proc., 1923, vol. 1, pp. 537-541*).—The organizations providing them and some of the films available dealing with dairying and dairy education are briefly noted.

**An extension program in crop production to reenforce range livestock, dairying, and human nutrition for the Western States**, W. A. LLOYD (*U. S. Dept. Agr., Dept. Circ. 335 (1924), pp. 16*).—Reports of the committees on range livestock, dairying, human nutrition, and farm crops are incorporated into the report of the coordinating committee appointed to go over the material presented at the Western States extension conference, held at Tucson, Ariz., November 3-8, 1924.

**Agricultural education in Cornwall**, W. BORLASE (*Jour. Min. Agr. [Gt. Brit.], 31 (1924), No. 5, pp. 442-452*).—This account covers briefly evening classes in agriculture, other educational activities, and technical instruction in dairying, horticulture, and poultry management.

**Day courses in agriculture for countrywomen**, E. H. PRATT (*Jour. Min. Agr. [Gt. Brit.], 31 (1924), No. 8, pp. 757-763*).—A syllabus in use in a series of day classes for farmers' daughters conducted in Derbyshire, England, is reproduced.

**The teaching plan and the organization of subject matter in the agricultural schools under the direction of the chamber of agriculture for the Rhine Province** [trans. title] (*Veröffentl. Landw. Kammer Rheinprov., No. 2 (1924), pp. 53*).—A new schedule of courses in agriculture and horticulture and an outline of the subject matter to be presented are given here.

**Outlines of course of instruction in agricultural nature study for the rural schools of California**, O. J. KERN (*California Sta. [Pamphlet], rev., 1924, pp. 100, figs. 60*).—This is a revised edition of a teaching outline previously noted (*E. S. R., 49, p. 195*).

**Junior project work in agriculture**, H. E. GAYMAN (*Jour. Rural Ed., 4 (1924), No. 3, pp. 97-105*).—The program of junior agricultural project work in Pennsylvania is set forth in detail.

**The health of rural school children**, A. D. MUELLER (*Jour. Rural Ed., 4 (1924), No. 3, pp. 106-113*).—Several instances of rural health services in various sections of the United States are described.

**The field of research in the economics of the home**, H. KNEELAND (*Jour. Home Econ., 17 (1925), No. 1, pp. 15-19*).—The truly economic problems of the home are thought to include the utilization of wealth in the home, as well as the production and distribution of it there. The author holds it to be essential that students analyze data with reference to family expenditures to determine causal relationships and formulate generalizations from them, thereby, perhaps, discovering to what extent family expenditures are influenced by advertising and salesmanship on the part of the producer seeking profits and to what extent by traditional standards of consumption. Evaluation of possible methods of providing the population with the essential housekeeping services

is deemed necessary. Other specific problems center about the economic relationships within the family; the part of the home maker in the control of family income, expenditures, and property; and the relative needs of various members of the family in the way of food, clothing, and other items.

**Agricultural mechanics**, R. H. SMITH (*Philadelphia and London: J. B. Lippincott Co., 1925, pp. VII+357, figs. 366*).—This book presents a course of instruction in farm mechanics intended to prepare the average farmer to make his own minor necessary repairs. The material is organized to be presented by the project method, the exercises including the construction of devices for use in the farm shop, the dairy, the poultry house, and other departments of the farm.

**Economic geography**, R. H. WHITBECK and V. C. FINCH (*New York and London: McGraw-Hill Book Co., Inc., 1924, pp. X+558, figs. 331*).—This book emphasizes especially the economic adjustment of peoples to their geographic environment. It is divided into two parts. Chapters 1 to 18, inclusive, treat of the United States and Canada, since these two countries are subject to similar geographical influences. The second part of the book, including chapters 19 to 36, deals with foreign countries.

### MISCELLANEOUS

**Report of the Alaska Agricultural Experiment Stations, 1923**, C. C. GEORGESON (*Alaska Stas. Rpt. 1923, pp. [2]+37, figs. 24*).—This contains the organization list and a report of the several lines of work carried on during the fiscal year ended June 30, 1923. Meteorological data and accounts of the extensive tests with field and garden crops are abstracted elsewhere in this issue.

**Thirty-second Annual Report of [Minnesota Station, 1924]**, W. C. COFFEY (*Minnesota Sta. Rpt. 1924, pt. 1, pp. 38*).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1924, and a report by the director dealing with changes in staff, publications, and the classification of the station projects.

**Forty-third Annual Report of the New York State Agricultural Experiment Station, [1924]**, R. W. THATCHER (*New York State Sta. Rpt. 1924, pp. 56*).—This contains the organization list, a review of the work and publications of the station, and a financial statement for the fiscal year ended June 30, 1924. The experimental work reported is for the most part abstracted elsewhere in this issue.

**Thirty-seventh Annual Report of the South Carolina Experiment Station, [1924]**, H. W. BARRE (*South Carolina Sta. Rpt. 1924, pp. 95, figs. 30*).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1924, and a report of the work and publications of the station during the year. The experimental features reported are for the most part abstracted elsewhere in this issue.

**Thirty-sixth Annual Report of [Tennessee Station], 1923**, C. A. MOOERS ET AL. (*Tennessee Sta. Rpt. 1923, pp. 31, fig. 1*).—This contains the organization list, a report of the director and heads of departments, and a financial statement for the fiscal year ended June 30, 1923. The experimental work is for the most part abstracted elsewhere in this issue.

**Bi-monthly Bulletin [of Western Washington Station, January, 1925]** (*Western Washington Sta. Bimo. Bul., 12 (1925), No. 5, pp. 97-124, figs. 7*).—In addition to articles abstracted elsewhere in this issue, this number contains brief articles entitled Cow Pox, by J. W. Kalkus; Pruning Ornamental Plants, by H. D. Locklin; and Spraying Trees and Bushes, by A. Frank.

## NOTES

---

**California University and Station.**—A range of 10 greenhouses each 30 by 80 ft. is under construction. These houses will be divided among 11 departments of the College of Agriculture with the larger amount of space allotted to pomology, plant nutrition, landscape gardening, and genetics. When completed the present conservatory will be torn down, the entire equipment of the college then being on the agricultural campus. Funds for the work were supplied in part by the State and in part by private subscriptions in Oakland, Berkeley, and San Francisco. Ultimately a series of five head houses will be added.

A stationary spray plant is to be installed on the university farm, the orchards being piped with mains connected with the stationary pumping plant. This system will permit of quick spraying at critical times for pest control, even though the land is too wet to be crossed by a spray rig.

**Indiana Station.**—Edward G. Proulx, State chemist and seed commissioner, died March 31 after an illness of over two years. He was born in Hatfield, Mass., December 3, 1880, graduating from Massachusetts Agricultural College in 1903, and receiving the M. S. degree from Purdue University in 1909. He served in the Massachusetts Station as assistant chemist from 1903 until 1907 and subsequently at Purdue, becoming State chemist in 1917 and State seed commissioner in 1921. He was president of the Association of Official Seed Analysts of North America in 1924.

**Kansas College.**—The short course in beef cattle herdsmanship referred to in the January issue (*E. S. R.*, 52, p. 99) was the fourth to be offered by the college, the first having been given in 1921. The college was in no way responsible for the erroneous implications in the note as originally printed.

**Massachusetts College and Station.**—A series of radio talks on poultry husbandry was followed by applications from 738 radio listeners for the supplements on poultry raising issued by the college in connection with the course, and the questions sent out were answered regularly by 150 persons. It is stated that some of the best replies were received from students in the Perkins Institute for the Blind.

Harlan N. Worthley, investigator in entomology in the station, resigned March 1 to accept a position as extension entomologist in the Pennsylvania College.

**Cornell University.**—The legislature has constituted the school of home economics of the College of Agriculture as the New York State College of Home Economics, coordinate with the other colleges of the university and administered in a way comparable with the New York State College of Agriculture and the New York State Veterinary College. The new college will, however, continue to utilize the same officers of administration for extension work, library facilities, and bookkeeping as the College of Agriculture.

The College of Home Economics has a staff of 7 professors, 11 assistant professors, 6 instructors, 2 assistants, 5 administrative officers, 8 administrative extension officers, and 2 junior extension specialists, together with a clerical staff and a student enrollment of 554. A research laboratory in human nutrition has recently been established.

**New York State Station.**—The 1925 Legislature made the following appropriations for the station: Personal services \$190,050, maintenance and opera-

tion \$55,175, special items \$35,300, and new construction \$3 500, making a total of \$284,025. Among the special items is a provision for \$1,500 for investigations relating to canning crops. Three new positions have been created, one in entomology, one in plant pathology, and one in vegetable gardening. Appointments to these positions will be made July 1, when the measure goes into effect, and the three appointees will make their headquarters at Geneva. A farm of about 60 acres will be leased in the vicinity of the station, where investigations will be made under field conditions.

Dr. U. P. Hedrick, horticulturist, has been made a member of the advisory board of the Russian Reconstruction Farms, Inc., described as "a philanthropic and humanitarian organization to prevent future famines by educating Russian peasants in modern American farming methods."

**Ohio State University.**—The new agricultural engineering building has been named Ives Hall in honor of the late F. W. Ives, whose death in July, 1924, has been noted (E. S. R., 51, p. 300). The building will cost \$127,000, and two wings will be erected subsequently at an additional cost of \$73,000. It is expected that machinery valued at approximately \$100,000 will be lent by the different implement companies.

**Utah Station.**—The legislature has appropriated funds for establishing two new experimental farms, one to be located in San Juan County and the other in Uintah County. These farms will be for the purpose of carrying on experimental work in the growing of alfalfa seed.

**Necrology.**—Dr. Charles D. Woods, director of the Maine Experiment Station from 1896 to 1920, died at West Newton, Mass., on March 30.

Doctor Woods was a native of Maine, being born at Brooks September 11, 1856. He was graduated at Wesleyan University in 1880 and served as assistant in chemistry there until 1883. After a period of five years as teacher in science at Wilbraham Academy in Massachusetts, he became chemist and vice director of the Connecticut Storrs Station, holding this position until his appointment in 1896 as professor of agriculture in the University of Maine and director of the Maine Station. In 1921 he became consultant in agriculture for the War Department, and since 1922 he had been director of information in the Massachusetts Department of Agriculture.

Doctor Woods made notable contributions to the subjects of acquisition of atmospheric nitrogen by plants, the effect of fertilizers on the composition of corn, methods of field sampling of crops for analysis, and the improvement of the bomb calorimeter. He was also one of the pioneer station workers in human nutrition, serving as an expert of the U. S. Department of Agriculture from 1894 to 1908. This work included cooperative investigations of wheat flour and various other foods, dietary studies, food analyses, digestion experiments, and the like, and he was the author of numerous publications dealing with these matters.

For many years he was a leading figure in the Association of American Agricultural Colleges and Experiment Stations, serving in various capacities but notably as a member of the committee on experiment station organization and policy from its creation in 1905 until his retirement from station work in 1920. He was intensely interested in the promotion of research, and he labored earnestly and consistently to raise the standards and ideals and strengthen the status of the stations as research institutions. He conceived the function of the station director to be fundamentally that of providing conditions congenial to effective research, and he endeavored to realize this ideal for his own staff of workers so far as possible. Under his leadership the Maine Station made marked progress despite restricted resources and other handicaps, and by its success his own career can perhaps be most adequately evaluated.

# EXPERIMENT STATION RECORD

VOL. 52

MAY, 1925

No. 7

The conference on the Purnell Act, held at St. Louis April 20 and 21, was a remarkable gathering, well conceived, enthusiastic, and fruitful. It brought together, at a time when plans were being made and policies initiated, most of the people immediately interested in the administration of the new act, for a period of counsel and conference. It helped to clear the way for constructive and effective action when the act goes into operation July 1, and it reduced to a minimum the lost motion and uncertainty and any working at cross-purposes which might have attended a beginning without the benefit of such a meeting of minds.

Although the Purnell Act, like its predecessors, provides for the appropriation of funds to each State as an independent unit, the idea of experiment station solidarity has become so firmly established with the passing of the years as to lead almost instinctively to group conference and action. This means that the stations, despite the absence of organic connection, are no longer isolated institutions but units in a great country-wide system of research, with many things in common and in which, without sacrifice of individuality or autonomy, the interests of the group as a whole receive large consideration.

The St. Louis conference was arranged by the Association of Land-Grant Colleges as a special meeting of presidents and station directors. Its purpose was to consider not only the opportunities under the new act for enlarging the scope of investigation at the stations but also the obligations which it imposes and the means of meeting these in the most effective way. Attendance was obviously voluntary, and it is most gratifying that, although the meeting was injected into the midst of a busy college year, every State was represented. For the 48 stations, 43 directors and 3 vice directors were present, as well as 22 college presidents. The Federal Department of Agriculture was represented by its Secretary, the Chief of the Office of Experiment Stations, and officers of several bureaus immediately concerned. Interest in the sessions was keen and participation in the discussions abundant and informative.

In a comprehensive review of the situation, the Secretary of Agriculture spoke of the gathering as a "time for counsel and for mutual understanding, a close working together for common ends." He pointed out that the Purnell Act affords an exceptional opportunity for service, as it is the "strongest testimony of confidence in the power of organized agricultural research that this or any other government has ever expressed," but that it carries with it grave responsibilities in which both the stations and the department will share, and in which the need for close cooperation and coordination of effort has become outstanding.

Secretary Jardine went on to set forth the objects of the legislation, outlining ideals for investigation under it, and suggesting specific lines in which the field of inquiry might be profitably enlarged. The point was made clear that the act is designed to give further aid to a going concern, that it is "for the more complete endowment and maintenance of agricultural experiment stations now established," each with an existing organization, administrative machinery, and in large measure the buildings, land, and other basic facilities for research. This would imply that, as President Pearson of the executive committee and several others indicated, the new appropriations ought not to add materially to the general overhead expenses of the stations, but that they will be almost wholly available, as the act prescribes, for "paying the necessary expenses of conducting investigations or making experiments . . . and for printing and disseminating the results of said research."

Another fundamental principle laid down by the Secretary was that the fund should be used primarily for investigations of substantial character. The act "is a fact-finding, fact-interpreting measure. Tested methods of research should be applied to investigations which will yield the most useful results. Every effort should be made to avoid a type of superficial investigation which now has been outgrown. Problems of fundamental importance should be attacked by adequate methods and with full knowledge of other investigations in order to avoid wasteful duplication. In other words, what is most needed is thoroughly constructive work. The new fund is not for the exploitation of what is known or for speculation based on personal opinion or inadequate data, but it is for sound investigation in the best sense, calling for men and women with breadth and penetration of vision and of demonstrated ability in the research field."

As regards subject matter, considerable emphasis was naturally laid on agricultural economics, home economics, and rural sociology. The large prominence which was accorded these questions was to have been expected under the circumstances. Unlike the Hatch and

Adams Acts, the Purnell Act makes specific provision for studies of the distribution and marketing of agricultural products and for "such economic and sociological investigations as have for their purpose the development and improvement of the rural home," thus making possible the bringing to bear of attack by organized research on a wide range of comparatively new but very important problems. To a considerable extent the passage of the act was undoubtedly facilitated by the special need which was being felt for a comprehensive and unbiased study of these questions. Secretary Jardine visualized this situation, showing that as a result of the growing complexity of modern economic life and the abnormal conditions since the war, there have arisen a multitude of economic and social problems with which the stations have not been adequately prepared to cope, but for whose services there has been insistent demand. "The Purnell Act is the Government's answer to this appeal for help. Building on the splendid foundation that already has been laid, the act greatly broadens the research work of the stations. While some of the work performed with these funds may lie in fields already occupied, it is believed that the framers of the law intended that for the present at least large emphasis should be placed on the economic and social problems of agriculture."

This view was corroborated by President Pearson as having been brought out in the later hearings before Congress on the bill. He also referred to the acceptance of the measure in many quarters as in this sense emergency legislation of the most constructive type. Director Thatcher, speaking for the President's Agricultural Conference, emphasized the great need felt by that body for unbiased fact-finding agencies, basing their conclusions on comprehensive investigation as a constructive factor in the relief of agriculture. Likewise, President Butterfield conceived the act to provide for three main lines of inquiry—the food supply for man and animals, the provision of an efficient and permanent agriculture, and the study of the rural home and rural life with a view to maintenance of living standards that will keep farm people out of a potential peasant class.

As regards home economics, Secretary Jardine drew attention to the fact that the legislation for the first time gives ample authority for carrying on investigational work in this field. The problems of the home include some of the most vital factors in the development of a permanent and satisfactory rural life, and, as he stated, "if farm management studies have contributed to economy and efficiency in the operation of the farm, similar studies in home management should give equal returns in lightening the burdens of the farm woman and give added opportunity for the care and training of children, for social and community work, and for the organization

of a more satisfactory home life. . . . Money invested in these problems may not yield as immediate returns in the farm income as studies on the feeding of pigs, but it may easily mean immensely more in the development of a sound and enduring agricultural civilization on which to found a prosperous and progressive nation. Taken as a whole, the home economics field should receive every possible encouragement, and wherever leadership is available serious investigational work should be undertaken."

Notwithstanding the interest manifested in these newer subjects of inquiry, it was pointed out by a number of speakers that the stations are by no means confined to them. Secretary Jardine predicted that the meeting would undoubtedly "spend the major portion of its time in the discussion of economic problems, on the one hand, and those of the home and rural life, on the other—problems that have not received adequate consideration in the past. Still," he declared, "it must not be forgotten that production problems are, after all, fundamental, and that every possible reduction in the cost of production, every handicap to production removed or controlled, every improvement in the production of a variety or a breed, is a permanent contribution not only to agriculture but to national progress and development as well."

This view was further supplemented by the Chief of the Office of Experiment Stations, who pointed out that "any investigations or experiments appropriate to the Hatch Act will be appropriate under the new act, and it is likely that it will be desired to use the latter to some extent in strengthening lines of work in which the stations are now engaged. Comparatively small additions to the funds now available for some well-established projects may hasten conclusions or possibly mark the difference between comparative failure and definite success. Wise administration of the Purnell Act will therefore call for consideration of the claims of existing projects, along with those of new undertakings."

The theme of cooperation and coordination in the developments under the new act was stressed at the meeting as never before in the history of the stations. Dean Dodson of Louisiana pointed out, for example, that the phrase "the establishment and maintenance of a permanent and efficient agricultural industry," which is one of the leading objects of the act, applies not to the States separately but to the Nation as a whole. Independently planned and overlapping investigations, in his view, would not be in the interest of economy or efficiency, and a broad, patriotic viewpoint must be maintained. Full realization was expressed of the fact that many types of investigation must be left to individuals, and that in the past some of the

largest contributions have come in this way, but at the same time it was felt that the conduct of the stations' inquiries to so large an extent on an independent basis has prevented the most effective attack, and has deprived individual workers of knowledge of what others were doing which would have been helpful in hastening a solution of their problems. None the less, there have been notable examples of successful cooperation which have helped to demonstrate the feasibility of joint effort, and these give confidence in the practicability of a considerable extension in that direction.

The interest of the Federal Government in cooperation was set forth by Secretary Jardine, and its desire to join hands with the stations in the study of national or regional problems was made very clear. It was frankly admitted that a lack of such coordination in the past has resulted in considerable duplication and has stood in the way of the highest efficiency in the investigation of many broad questions. As he expressed it, "cooperation is good for research people as well as for farmers. Waste and needless duplication are just as reprehensible in research as in the handling of farm products, and the Department of Agriculture and the experiment stations should set farmers an example in the elimination of wasteful methods."

"It is a reasonable expectation," he went on to say, "that the Purnell Act will lead to a considerable enlargement of the cooperative relations between stations and with the various bureaus of the department. This seems important at the present juncture. It is in line with the idea of organizing investigation around problems instead of around a single station department. Very many of the problems we now face are too large for individual States acting separately. They are regional or even national, and there is danger of viewing them too narrowly. An experiment station working single-handed can rarely expect to reach conclusive and comprehensive results in such broad subjects. It is important for both the institution and the investigator in many cases to detach themselves sufficiently from the local aspects of a question to view it impartially in its relation to the underlying problem and to what others are doing about it."

Especially encouraging and effective was the spirit of cooperation in which the conference abounded and its numerous practical manifestations. There was a widespread determination to make the new funds count for the utmost possible in research and, to that end, to take counsel on problems of both national and regional character as to how they could best be approached and studied. An important outcome was the selection from a large number of projects submitted of six comprehensive problems of national scope in which the stations and the Department of Agriculture might cooperate. These included

the distribution and marketing of farm products, the problem of surpluses of farm products, the vitamin content of foods in relation to human nutrition, rural home management studies, rural social organizations and agencies essential to a permanent and efficient agriculture, and factors influencing the production and quality of meats. It will be noted that the first two of these problems lie specifically in the field of agricultural economics, the third and fourth in home economics, the fifth in rural sociology, and the sixth in a branch of production.

Each of these topics is recognized as a very broad one, including many aspects and phases which will give opportunity for approach from various points of view and with specialized methods of study. These larger problems can not be studied as units, and rarely can all phases of them be carried on at the same time. But an advantage will be in having the work so coordinated that it may be more definitely directed toward determined ends, and within this range the field may be more adequately covered.

Special committees of experts were provided to handle these several problems. These committees have since been selected by the executive committee of the Association of Land-Grant Colleges, acting under authority granted by the conference and on the basis of nominations received from the various stations. They will concern themselves with the respective problems to which they relate and not with the broader fields, and it will be their duty to convene at an early date for the purposes of study, determining what is necessarily involved and what it is most important to take up at the outset, and thus blocking out the field and the course of procedure. Some of the stations have already indicated the problems in which they wish to cooperate, and the particular aspects of the investigation they would be in best position to carry on. The way will be open for others to express their readiness, and in certain prominent cases institutions or investigators will doubtless be invited to take part or to exercise leadership in particular features. This preliminary work of the committees will help to bring the investigation of individual stations down to a specific and limited scope suited to the setting up of projects. Another part of the plan will contemplate the review of the programs on these problems by the joint committee of the association on projects and correlation of research, consisting of representatives from the stations and the department.

It is hoped to get these cooperative undertakings into operation at an early date, even though they may possibly need modification as time goes on. The fact was stressed at St. Louis of the expectation which these increased funds would arouse, and the necessity of getting work organized and in full swing as promptly as circumstances permit. Obviously investigation can not be hurried, but the prepara-

tions for it can be given the right of way and the actual inauguration of operations thus be speeded up.

One advantage of coordination and unified action should be an increased concentration of the attack on a limited number of specific features, in place of the broad diffusion over the whole field likely to occur under independent and unrelated action. Another advantage from analysis of the field and the work by a committee of specialists is likely to be a weighing of the relative importance at the present time of various aspects of large problems, the determination of things which should take precedence, and the discovery of gaps in the range of investigation which need to be provided for.

Another feature of the conference was the holding of sectional meetings made up of representatives from typical regions. Such conferences were held by the northeastern group of stations, the Corn Belt group, the cotton States, and the intermountain and western group. These sections discussed problems of common interest which it was thought would lend themselves to helpful cooperation, frequently adopting two or three such problems as a beginning. Officers were selected to carry forward the plans thus provided for.

The conference was also helpful in drawing attention to various administrative problems confronting the stations as the act goes into operation. The shortage of trained personnel in the newer lines of research was referred to as restricting developments in some cases, but also as a condition which should be overcome at the earliest opportunity. The funds available under the act are also limited for the ensuing year, and obviously should not be spread over too many directions. Research programs should, however, take cognizance of the contemplated increases under the provisions of the act and prepare for development.

With the enlargement of the stations' activities and the broadening relationships, the direction of an experiment station will become increasingly important. As Secretary Jardine stated, "it will require not only special qualifications, but will call for time to study the lines in which research is most needed, for the effective organizing of these efforts, and for securing and sustaining men and women of the right type for productive research. This important function of administration ought not to be made incidental to other lines of activity, and especially in the large institutions it will be necessary to provide specifically for it. Manifestly the proper organization and manning of this research branch, the maintenance of contacts within and without the individual institutions, and the efficient direction of a program of research employing from \$100,000 to a quarter of a million annually, calls for high qualifications and a large measure of freedom from other engrossing duties."

Timely counsel along the same line was also given by the Chief of the Office of Experiment Stations. As he expressed it, "the administration of the stations will form a highly important feature in determining the success of the new act. The idea that research does not call for capable administrative attention is not borne out by the experience of the past twenty-five years. This is particularly the case when special ends are in view, and when the staffs are made up of people of varying ability in the field of research and having other duties."

In his opinion, the whole administrative situation has now changed. It will no longer suffice for directorship to be casual; "it will need to be aggressive, sympathetic, and discriminating. With the contemplated expansion of the field may well go a thorough survey of the work in hand, with a view to the possible redirection of some of the types of work long in progress. The size of the personnel will grow, and the new members will need to be selected and started on their work with care. These things will call more than ever for an officer of experience in research, with time to study the work and the field of the station, to counsel with and promote the efforts of his staff, and to maintain the necessary contacts within the college and outside of it."

Doctor Allen went on to stress the need of promoting by all feasible means, along with the strengthening of administration, the conditions of work which make for steady and substantial progress in investigation. Not only adequate facilities but freedom of time, relief from excessive pressure from teaching or extension work, and the provision of effective assistance and the necessary collaboration of other groups of workers are among the special needs if full efficiency is to be forthcoming.

Next to the inauguration of the American system of experiment stations, the passage of the Purnell Act is the most momentous step in the progress of agricultural investigation in any country. The wisdom of counsel at this time is beyond question. The history back of experiment station work will lead to large expectations. Fortunately, scientific results are not the only product which has come out of the past. The experience gained in organization, administration, the building up and direction of personnel, and the maintenance of close contacts with science on the one hand and with practice and the business of agriculture on the other, will be a source of strength in this period of expansion. The readiness to counsel, to receive suggestion, to accept leadership, as exemplified in the St. Louis conference and subsequent developments, is evidence of a spirit which has developed to a point hardly to be found in a similar group in any other country or any other branch of science.

## RECENT WORK IN AGRICULTURAL SCIENCE

### AGRICULTURAL CHEMISTRY—AGROTECHNY

**Chemical encyclopaedia**, C. T. KINGZETT (*New York: D. Van Nostrand Co., 1924, 3 ed., pp. X+606*).—This is a revised and enlarged edition of the volume previously known as *The Popular Chemical Dictionary* (E. S. R., 47, p. 801).

**Chemical dictionary**, H. REMY (*Chemisches Wörterbuch. Leipzig: B. G. Teubner, 1924, pp. VIII+416, figs. 15*).—This dictionary of chemical terms is one of a series of technical dictionaries entitled *Teubners Kleine Fachwörterbücher*.

**Colloid chemistry**, J. ALEXANDER (*New York: D. Van Nostrand Co., 1924, 2. ed., rev. and enl., pp. VIII+208, pls. 3, figs. 6*).—This is a revised and enlarged edition of the volume previously noted (E. S. R., 41, p. 310).

**Fifth report on colloid chemistry and its general and industrial applications**, F. G. DONNAN ET AL. (*Brit. Assoc. Adv. Sci., Rpt. Colloid Chem. [etc.], 5 (1923), pp. [3]+130*).—This final report of the series previously noted (E. S. R., 49, p. 308) contains the following papers: *The Measurement of Surface Tensions*, by A. Ferguson; *Report on Collagen and Gelatin*, by H. R. Procter and J. A. Wilson; *Colloid Phenomena in Bacteriology*, by E. K. Rideal; *Industrial Applications of Wetting Power*, by W. H. Nuttall; *Colloids in Relation to the Manufacture of Inks*, by C. A. Mitchell; and *The Manufacture of Artificial Silk in Relation to Colloid Chemistry*, by E. Wheeler. Subject and author indexes to the five reports are appended.

**Starches**, W. A. NIVLING (*New York: Barr-Erhardt Press, Inc., 1924, pp. VII+82, figs. 25*).—This is a brief discussion of the physical properties of solutions of the natural or unmodified starches as related to testing for fluidity and to their use in sizing textile fibers. Illustrations of apparatus and photographs showing the penetration of sizing in yarn are included.

**The polysaccharides**, H. PRINGSHEIM (*Die Polysaccharide. Berlin: Julius Springer, 1923, 2. ed., rev., pp. V+234*).—In this revision of the volume previously noted (E. S. R., 45, p. 310) a discussion of the literature on the subject through 1922 is included, with footnote references.

**Modern cereal chemistry**, D. W. KENT-JONES (*Liverpool: Northern Pub. Co., Ltd., 1924, p. IX+324, figs. 23*).—The first two chapters of this textbook for cereal chemists and millers deal with the general composition of wheat flour and the differences in wheat varieties and with the vitamin content of wheat and flour. These are followed by chapters on colloidal chemistry and H-ion concentration which serve as an introduction to a discussion, based upon recent literature, of the colloidal chemistry of flours and the baking process. The remaining chapters deal with the composition of mill products, bleaching and flour improvers, conditioning, moisture in wheat and flour, and analysis of flour. A foreword by W. Jago and an appendix containing the approved and tentative methods of analysis of the American Association of Cereal Chemists are included.

Some nitrogenous constituents of the juice of the alfalfa plant.—I, The amide and amino acid nitrogen, H. B. VICKERY (*Jour. Biol. Chem.*, 60 (1924), No. 3, pp. 647-655).—This paper reports a continuation of the investigation of the constituents of the alfalfa plant, previous reports of which by Osborne et al. have been noted (*E. S. R.*, 48, p. 201). The present study was limited to the distribution of amide and amino acid nitrogen in the filtrate obtained when the juice expressed from the fresh ground alfalfa plant was treated with 53 per cent of its weight of alcohol to precipitate proteins and other organic matter.

A system of fractionation was employed by means of which various groups of nitrogenous constituents were separated. The first precipitant used was normal lead acetate, which precipitated 10.7 per cent of the total nitrogen, 15.2 per cent of the amino nitrogen, and 14.2 per cent of the organic solids of the alfalfa filtrate. The filtrate from the first precipitation was treated with mercuric acetate, sodium carbonate, and alcohol, which precipitated amino acids and certain basic substances. The basic substances were removed by decomposing the precipitate with hydrogen sulfide and reprecipitating with phosphotungstic acid, and the amino acids and amides were removed from the filtrate of the phosphotungstic acid precipitate by fractional recrystallization. The phosphotungstic acid precipitate was decomposed into purine, arginine, and lysine fractions by precipitation with silver sulfate and the silver sulfate with barium hydroxide. The filtrate from the second precipitate with mercuric acetate, etc., was precipitated with mercuric chloride.

There were finally identified in the various fractions asparagine to the extent of 1.82 per cent of the organic solids or 5.82 per cent of the total nitrogen of the filtrate, simple  $\alpha$ -amino acids to the extent of 13.6 per cent of the total nitrogen, less than 0.2 per cent of tyrosine, and a small amount of polypeptides.

Some nitrogenous constituents of the juice of the alfalfa plant.—II, The basic nitrogen, H. B. VICKERY (*Jour. Biol. Chem.*, 61 (1924), No. 1, pp. 117-127).—The precipitate and filtrate from the Newberg reagent in the scheme of fractionation of alfalfa juice noted above have been examined for basic substances with the following results, calculated in grams per liter of concentrated alfalfa filtrate representing the juice of approximately 6,460 gm. of the fresh plant: Arginine 0.522 gm., lysine 0.073, stachydrine 3.768, choline 0.249, chloride of a purine 0.048, and a base yielding a picrate of melting point 298° C. 0.290 gm.

It is pointed out that since the above substances have been isolated from the unhydrolyzed filtrate they must occur free or as salts in the juice of the alfalfa plant.

A contribution to the chemistry of grape pigments.—II, Concerning the anthocyanins in Clinton grapes, R. J. ANDERSON and F. P. NABENHAUER (*Jour. Biol. Chem.*, 61 (1924), No. 1, pp. 97-107).—The studies previously noted (*E. S. R.*, 50, p. 410) have been extended to the Clinton grape, a cultivated variety of *Vitis riparia* crossed with *V. labrusca*.

The pigment occurring in Clinton grapes was found to be identical with the anthocyanins isolated from the Norton and Concord grapes. The anthocyanadin chloride prepared as in the previous study was found to consist largely of a monomethyl ether of delphinidin but to contain some of the corresponding dimethyl ether.

The lipochromes of etiolated wheat seedlings, K. H. COWARD (*Biochem. Jour.*, 18 (1924), No. 5, pp. 1123-1126).—Wheat seeds in which no traces of lipochromes could be found were germinated and grown in the dark for 17

days, and the etiolated shoots tested for lipochromes. Carotin and four xanthophylls known to be present in green leaves were identified in the shoots.

**Recent work on insulin**, C. H. BEST (*Endocrinology*, 8 (1924), No. 5, pp. 617-629, figs. 2).—The author reviews briefly recent work on the preparation of insulin, methods of testing, yield and distribution, and the insulin-like material in plants. Preliminary experiments are also reported on the effects of varying doses of insulin on dogs. These show an irregularity in results, a large dose not invariably producing a greater effect than a small dose. It is considered probable that insulin may be stored to some extent in the body.

A list of 35 references to the literature is appended.

**The influence of insulin on the glucose-fermenting action of *Bacillus coli***, G. MCGUIRE and K. G. FALK (*Jour. Biol. Chem.*, 60 (1924), No. 3, pp. 489, 490).—The presence of insulin was found to have no influence upon the fermentation of glucose by *B. coli*.

**The fermentation of pentoses by *Bacillus granulobacter pectinovorum***, W. H. PETERSON, E. B. FRED, and E. G. SCHMIDT (*Jour. Biol. Chem.*, 60 (1924), No. 3, pp. 627-631).—Data are reported on the total fermentation products obtained from xylose, arabinose, and glucose by the action of *B. granulobacter pectinovorum*.

The rate of fermentation was somewhat slower for the pentoses than for glucose, but practically all the sugar was destroyed in 72 hours and the same products were formed. The amount of volatile acids was slightly greater and of solvents slightly smaller in the fermentation products of the pentoses than of glucose.

**The formation of l-leucic acid in the acetone-butyl alcohol fermentation**, E. G. SCHMIDT, W. H. PETERSON, and E. B. FRED (*Jour. Biol. Chem.*, 61 (1924), No. 1, pp. 163-175).—"A nonvolatile acid produced by *Bacillus granulobacter pectinovorum* from corn mash has been isolated, and shown to be l-leucic acid ( $\alpha$ -hydroxyisocaproic acid). The acid is orthorhombic in crystallization, and the acute angle measures  $72^\circ (\pm 3^\circ)$ . It has a melting point of  $75-77^\circ$  C. and a specific rotation of  $-9.23$ .

"The acid yields a calcium salt corresponding to the formula  $(C_6H_{11}O_3)_2Ca$ . The zinc, carbon, hydrogen, and oxygen content of the zinc salt corresponds to that required for the salt,  $(C_6H_{11}O_3)_2Zn$ . The zinc salt crystallizes with 7 to 7.5 per cent of water ( $1\frac{1}{2} H_2O$ )."

**The production of organic compounds of sulphur in bacterial cultures, with special reference to glutathione**, J. W. MCLEOD and J. GORDON (*Biochem. Jour.*, 18 (1924), No. 5, pp. 937-940).—On applying the nitroprusside test for glutathione to 24- to 48-hour cultures of various bacteria, positive reactions were obtained with all of the anaerobes and facultative anaerobes but not with the aerobes tested. That this reaction was due not to the production of glutathione by the bacteria but to the reduction of the residual oxidized glutathione present in the medium is thought to be proved by the negative results obtained when the medium has been freed from substances reacting with nitroprusside, and by positive results in media not containing bacteria but subjected to prolonged reduction by aluminum mercury couples.

It is concluded that bacteria do not produce glutathione, but that certain bacteria which are capable of reducing glutathione utilize it when growing under anaerobic conditions to obtain oxygen necessary for their metabolism.

**Comparative study of *Lactobacillus acidophilus* and *Lactobacillus bulgaricus***, W. L. KULP and L. F. RETTGER (*Jour. Bact.*, 9 (1924), No. 4, pp. 357-394, pl. 1).—In this comparative study of *L. acidophilus* and *L. bulgaricus* a

tryptic digest of casein or milk powder (Klim) was used as the nitrogenous base for the media employed.

In morphological and cultural characteristics the two species proved very similar, the chief differences being in their fermentative action on maltose, sucrose, and levulose. All strains of *L. acidophilus* and only two of *L. bulgaricus* fermented lactose, all strains of *L. acidophilus* and only one of *L. bulgaricus* reacted with sucrose to form acid, and all strains of *L. acidophilus* but two fermented both heated and unheated levulose, while *L. bulgaricus* fermented only the heated levulose. The other chief point of difference is in the habitat. *L. acidophilus* lives and develops in the intestines of man and animals, while *L. bulgaricus* is unable to do so.

"The differences noted between these two types constitute evidence enough for classifying them as separate species. However, because of the various close relationships, it is suggested that these two types be placed in one and the same species of which *L. acidophilus* is the central type and *L. bulgaricus* a variant."

**A note on the gravimetric microchemical technique, L. DIENES** (*Jour. Biol. Chem.*, 61 (1924), No. 1, pp. 73-76, fig. 1).—The author recommends in microgravimetric determinations the separation of the precipitate by centrifugation instead of by filtration. A special precipitation tube with conical bottom is described and illustrated, with methods for its use. The materials are introduced into the tube by means of a mounted pipette graduated in 0.01 cc., and the washing liquid is introduced by means of a capillary tube in such a way as to stir up the precipitate.

**The buffer mechanism for the calcium concentration and the determination of calcium buffer values, I. N. KUGELMASS** (*Jour. Biol. Chem.*, 60 (1924), No. 2, pp. 237-256, figs. 2.)—This is a theoretical discussion of the regulation of calcium ion concentration by carbonate and phosphate buffers, with derivations of equations for determining the buffer values of different solutions in terms of calcium concentration.

**The determination of nitrogen in connection with the wet combustion method for carbon, A. K. ANDERSON and H. S. SCHUTTE** (*Jour. Biol. Chem.*, 61 (1924), No. 1, pp. 57-61).—The wet combustion method of Rogers and Rogers, as modified by Gortner (*E. S. R.*, 36, p. 512), has been found to be suitable for the determination of both carbon and nitrogen, the latter by making alkaline the residue from the digestion with chromic acid and distilling the ammonia as in the usual Kjeldahl process. If chlorides are present, it is necessary to aerate the sample for about 30 minutes in the presence of hot sulfuric acid before adding the potassium dichromate.

**The determination of ammonia in soil, N. BENGTSSON** (*Soil Sci.*, 18 (1924), No. 4, pp. 255-278).—Various direct methods of determining ammonia in soils have been tested on eight different soils, the criterion of accuracy being the quantitative recovery of added ammonia, as well as the ammonia originally present in the soil.

With none of the methods tried, which included those of Boussingault, Baragiola and Schuppli, Potter and Snyder (*E. S. R.*, 33, p. 411), Matthews (*E. S. R.*, 43, p. 211), and Gibbs, Neidig, and Batchelor (*E. S. R.*, 50, p. 203), was there a quantitative recovery of added ammonia.

Experiments with different extracting agents showed that in general it is impossible to bring all of the ammonia into solution by one extraction. Of the various reagents tested, potassium chloride proved most effective. In the case of surface soils, the successive extraction with fresh solutions of 4 per cent potassium chloride resulted in the quantitative removal of the ammonia,

but with heavy clay subsoils taken from a depth of from 25 to 35 cm., the successive extraction process was unsatisfactory.

On the basis of these results, the method recommended for the determination of ammonia in surface soils consists in the successive extraction at room temperature of 25 gm. of soil with 4 per cent potassium chloride solution, using at the most 7 100-cc. portions for mineral soils and 10 50-cc. portions for peat soils. The combined filtrates are distilled with magnesium oxide, and the liberated ammonia is caught in  $N/10$   $H_2SO_4$ . After the distillation is finished the distillate is boiled to remove  $CO_2$ , cooled, and titrated with  $N/10$   $NaOH$ , with methyl red as indicator. Blank determinations should be made with the reagents alone.

**Methods of studying the strength of soil acids**, J. W. TIDMORE and F. W. PARKER (*Soil Sci.*, 18 (1924), No. 4, pp. 331-338, fig. 1).—This study was confined to a comparison of three methods of measuring the intensity factor in soil acidity—H-ion concentration by the electrometric method, sugar inversion, and the Truog avidity method (E. S. R., 35, p. 503). Twenty-five soils, representing 15 soil types, were used in the comparison, and in all cases the amounts of the soils were varied according to their lime requirement so that all would contain the same amount of acid.

The results of the three methods showed good correlation, as indicated by the calculated coefficients of correlation, which are as follows: Truog avidity and sugar inversion methods,  $0.899 \pm 0.025$ ; Truog avidity method and H-ion concentration,  $0.789 \pm 0.050$ ; and sugar inversion method and H-ion concentration,  $0.817 \pm 0.045$ . This is considered to indicate, as pointed out in a previous paper by Parker and Bryan (E. S. R., 49, p. 722), that the H-ion concentration of the soil solution is largely determined by the acidity of the acid silicates of the soil.

A study was also made of the effect of the presence of different amounts of soils in the solid phase on the rate of inversion of sugar when the H-ion concentration and conductivity of the solutions were the same. With increasing amounts of the solid phase the rate of hydrolysis was increased. This is explained as follows:

"There is a higher concentration of H-ions at the surface and in the interior of the gel-like aggregates of soil colloids than in the free soil solution. This difference in the H-ion concentration is readily explained by Donnan's theory of membrane equilibria. The colloids of a mineral acid soil are complex hydrogen aluminum silicates. On hydrolysis these silicates give diffusible H-ions and nondiffusible silicate ions. According to Donnan's theory the presence of the nondiffusible ion causes an unequal distribution of the diffusible ions. In an acid soil suspension there would be a higher concentration of H-ions at the surface of the soil particles than in the free soil solution."

**A modification of the molybdic method for the determination of inorganic phosphorus in serum**, S. R. BENEDICT and R. C. THEIS (*Jour. Biol. Chem.*, 61 (1924), No. 1, pp. 63-66).—Slight changes in the Briggs modification (E. S. R., 48, p. 111) of the Bell-Doisy method of determining inorganic phosphorus are described, by means of which the color produced is said to be about three times as intense as that obtained by the Briggs procedure.

**Method of estimating minute quantities of iodine in biological material**, F. C. KELLY and A. D. HUSBAND (*Biochem. Jour.*, 18 (1924), No. 5, pp. 951-956).—The authors discuss briefly the advantages and disadvantages of several methods of determining iodine when occurring in small amounts in biological material, and describe in considerable detail the Kendall method (E. S. R., 44, p. 113) which, with slight modifications, they have adopted as the most satis-

factory. This method is considered to have an absolute limit of accuracy of 0.0001 gm. per hundred. The minimum amount of N/200 sodium thiosulfate with which a change of color could be observed was 0.05 cc., equivalent to 0.0000317 gm. of iodine.

**Observations on a micro method for the determination of silicon and on the content of this element in certain organs** [trans. title], G. BERTRAND (*Bul. Soc. Chem. Biol.*, 6 (1924), No. 7, pp. 656-658).—Attention is called to one or two sources of error in the micro method of determining silicon described by Isaacs (*E. S. R.*, 51, p. 612). It has been found that the color does not reach its maximum intensity for some time, the interval depending on the thickness of the tubes, the external temperature, etc. It has also been found that at the same concentration a blue color is developed in the presence of phosphoric acid after a much longer period. In the presence of large amounts of  $P_2O_5$  it is considered probable that the color would develop as quickly as with small amounts of silicon. This is thought to account for the high figures reported by Isaacs for the content of silicon in the brain.

**Further studies on the determination of calcium, magnesium, and phosphorus in animal substances**, L. DIENES (*Jour. Biol. Chem.*, 61 (1924), No. 1, pp. 77-90).—Slight modifications in the author's microgravimetric method of determining calcium, magnesium, and phosphorus in animal substances (*E. S. R.*, 43, p. 204) are described.

**The identification of glycerol by a bacterial method**, A. CASTELLANI and F. E. TAYLOR (*Jour. Trop. Med. and Hyg.* [London], 27 (1924), No. 20, pp. 271-273, figs. 3).—The mycological-bacterial method for the identification of carbohydrates previously described (*E. S. R.*, 49, p. 112) has been extended to the identification of glycerol. Mycological formulas for its identification are appended.

**The chemical examination of various peat materials by means of food stuff analyses**, A. P. DACHNOWSKI (*Jour. Agr. Research* [U. S.], 29 (1924), No. 2, pp. 69-83).—In studies conducted by the Bureau of Plant Industry, U. S. D. A., the results obtained with 20 different kinds of peat indicated the feasibility of the application of foodstuff analyses for the determination of qualitative differences in sedimentary, fibrous, and woody peat materials. These data pointed to contrasts between peat materials in regard to their nitrogenous substances, lignin, cellulose, and other carbohydrates, waxes, resins, and similar plant products. Their value was found to be necessarily limited, since it was only possible to utilize analyses of the same character as those used for crops and feeding stuffs. However, they illustrated the fact that a close connection exists between the botanical and chemical composition of the main groups of peat.

By the application of this method it becomes possible to correlate variations in the chief groups of organic compounds with structural differences in the profile of peat deposits, to follow the progress of decomposition in drained surface peat soils, and to determine the degree of chemical alteration taking place in the several layers of peat below the water level.

The analyses showed the wide differences in agricultural value of the several kinds of peat, on the basis of the ratio of nonnitrogenous to nitrogenous materials, and the limited usefulness of various kinds of raw peat as a source of food for livestock or for soil microorganisms.

**A system of blood analysis.—Supplement V, The improvements in the quality and method of preparing the uric acid reagent**, O. FOLIN and H. TRIMBLE (*Jour. Biol. Chem.*, 60 (1924), No. 2, pp. 473-479, fig. 1).—In this supplement to the system of blood analysis of Folin and Wu (*E. S. R.*, 47, p. 410), a simple method is described for preparing the uric acid reagent almost

entirely free from molybdenum. The process depends upon the fact that the molybdenum is precipitated as sulfide by hydrogen sulfide in the presence of phosphoric acid. Certain improvements are also reported in the ordinary process for making the uric acid reagent from normal sodium tungstate, sodium paratungstate, and ordinary phosphotungstic acid.

**Estimation of sugar in the blood**, E. G. B. CALVERT (*Biochem. Jour.*, 18 (1924), No. 5, pp. 839-844, fig. 1).—This paper consists of a refutation of the criticism of Stanford and Wheatley (*E. S. R.*, 51, p. 507) in regard to the author's previously described method of estimating the sugar content of the blood (*E. S. R.*, 49, p. 408), and a detailed description of this method, modified by the substitution for the platinum capsule of a special pipette for collecting measured amounts of blood.

**An apparatus for the exact analysis of air in metabolism investigations with respiratory exchange chambers**, T. M. CARPENTER (*Jour. Metabolic Research*, 4 (1923), No. 1-2, pp. 1-25, fig. 1).—A gas analysis apparatus, based upon the Haldane principle, has been devised for use with the large respiration chamber for animals described by Benedict et al. (*E. S. R.*, 44, p. 68). The apparatus is described and illustrated, with directions for its manipulation and data showing its accuracy. "It has a capacity of 40.04 cc., and readings can be made to 0.001 per cent. Samples of gases containing as much as 1.7 per cent of carbon dioxide and from 78.4 to 79.6 per cent of nitrogen can be analyzed with this apparatus. Analyses of outdoor air have given  $0.030 \pm 0.003$  per cent for carbon dioxide and  $20.940 \pm 0.003$  per cent for oxygen."

**Sugar machinery**, A. J. WALLIS-TAYLER (*London: William Rider and Son, Ltd.*, 1924, pp. XVI+410, pl. 1, figs. 162).—This is a descriptive treatise devoted to the machinery and processes used in the manufacture of cane and beet sugar. It contains chapters on the sugar cane; complete cane sugar factories; the extraction of the juice from the raw material; modern types of cane mills; safety devices for cane mills, etc.; motive power for cane mills, etc.; the treatment of the juice prior to concentration; concentration under atmospheric pressure; concentration in vacuo; extracting the molasses from the sugar; tests; beet sugar; the manufacture of beet sugar; treatment of the juice; evaporation and concentration; sugar refining; and the distillation of rum. Appendixes are included on sugar packeting machinery, useful tables, bibliography, etc.

**The manufacture of vanillin**, P. MAY (*Perfumery and Essential Oil Rec.*, 15 (1924), No. 11, pp. 351-358).—A review of the literature on the manufacture of vanillin from the first artificial production 50 years ago to the present time.

## METEOROLOGY

**Solar and terrestrial radiation**, A. ÅNGSTRÖM (*Quart. Jour. Roy. Met. Soc.* [London], 50 (1924), No. 210, pp. 121-126, pls. 2).—This article is of interest especially from the standpoint of the methods and apparatus employed to measure the total radiation income and to evaluate the factors affecting it, to determine the relation to sunshine and cloudiness, and to interpret the data obtained.

"A treatment of the registration at Stockholm gives the result that the total radiation-income  $Q_s$  during the day may be expressed by the formula:

$$Q_s = Q_0(0.25 + 0.75 \cdot S),$$

where  $Q_0$  is the radiation-income which corresponds to a perfectly clear day, and  $S$  is the time of sunshine expressed in the greatest possible time of sunshine as unit. . . .

"As the radiation-income from perfectly overcast skies is a function of the mass of precipitated water in the atmosphere, the registrations give a means to evaluate the 'capacity' of the cloud layer. . . . The radiation during clear and half-clear days has a minimum in the afternoon hours (between noon and 4 p. m.). . . . Radiation during days with overcast or nearly overcast skies has a maximum in the afternoon hours (between noon and 4 p. m.). These results are explained by the influence of convection, which gives rise to a creation of cumulus clouds during clear or almost clear days but causes breaches in the uniform cloud layer of the overcast skies. A close relation is found to exist between the evaporation and the radiation-income during the day. As the evaporation depends in high degree upon the vertical convection, and the convection in its turn upon the heating of the ground through radiation, this result is a natural one.

"From the previous summary the great importance of continuous registrations of the radiation must be clear. The proposal seems therefore justified that a recording actinometric station ought to be erected in every country."

**General and physiological features of the vegetation of the more arid portions of southern Africa, with notes on the climatic environment,** W. A. CANNON (*Carnegie Inst. Wash. Pub. 354 (1924), pp. VIII+159, pls. 31, figs. 13*).—This publication gives a somewhat detailed account of the climate of the southern part of Africa, especially with reference to the amount and distribution of rainfall in its relation to distribution and growth of plants, the plant studies dealing particularly with "(1) the perennial flora of the more arid regions, (2) the climatic environment, (3) plant habits and plant habits, (4) comparative structure of leaves, and (5) the transpiring power of leaves."

Comparing climatic conditions and vegetation of this region with that of other similar regions, it is observed that like conditions of rainfall are not necessarily associated with plant growth of the same character and distribution. "The leading features of the climatic environment of plants of arid regions can be said to lie in the temperature and its variation, in the intensity of light, and in the amount and seasonal distribution of the rainfall, together with certain other related factors, including the frequently low relative humidity. A change in one of these, particularly in the amount or the season of the rains, very profoundly modifies the rest, with consequent serious alteration in the environic complex as a whole.

"Thus, when the rainfall is in the cool season only, when the temperature is low, the humidity high, and the light values low, the aridity of the drought period is accentuated by the fact of high temperatures, low relative humidity, and high light values. When, on the other hand, the rainy period coincides with the warm season, the period of drought is not so markedly arid, for the reason that the temperature at the time is relatively low, with correspondingly high relative humidity and relatively low light intensity. Accordingly, it is not difficult to understand why, in regions of winter rainfall, the perennials should have pronounced xerophytic characteristics, even if the amount of rain be considerable.

"In regions with equal precipitation, but occurring the one in the cool and the other in the warm season, it appears to be the rule that the former is the more arid. In certain arid and semiarid regions of the world both types of rainfall occur. In such event, if the rains of summer and of winter are fairly large, as in southern Arizona, the vegetation is correspondingly abundant, but in case the periodic rains are uncertain, both as to amount and season, the arid conditions may be intense. The latter obtains in central Australia and in a portion of South Africa, especially in the Karroos."

The climatic conditions of southern Africa are discussed with reference to latitude, topography, proximity to the ocean, and relation to regions of permanent low atmospheric pressure. "There is a gradual increase [in temperature] on any parallel of latitude from the west to the east and along the west coast from the north to the south and along the east coast from the south to the north." In general the climate is mild temperate. In the interior the summers are hot and the winters cool, with heavy frosts and snows in the mountains. A marked feature of the rainfall is its periodicity. On the east the rains occur mainly in summer, on the west mainly in winter. In general the total rainfall increases from the west to the east and to a less marked and constant extent from the south to the north.

The effective rainfall, 0.15 in. or more, is relatively high. "In the Karroos, for example, it ranges between 86 and 92 per cent. Even at Laingsburg, where the annual precipitation is extremely low, it is about 89 per cent effective. About 52 per cent of the rainfall at this place is in summer." Where the rainfall is relatively large the noneffective rainfall is relatively small.

There is evidently a "close relation between the character of the vegetation, including often the local distribution, and the general facts as to the amount and seasonal distribution of the rainfall. And an important feature of the environmental complex is the fact of often long yearly periods of drought, which may be associated with seasons of high temperature, in which event the aridity is particularly intense."

**Climatological data for the United States by sections, [November-December, 1924]** (*U. S. Dept. Agr., Weather Bur. Climat. Data, 11 (1924), Nos. 11, pp. [187], pls. 4, fig. 1; 12, pp. [194], pls. 5, fig. 1*).—These numbers contain brief summaries and detailed tabular statements of climatological data for each State for November and December, 1924.

**Meteorological observations at the Massachusetts Agricultural Experiment Station, J. E. OSTRANDER and J. BOWER, JR.** (*Massachusetts Sta. Met. Buls. 433-434 (1925), pp. 4 each*).—Summaries are given of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during January and February, 1925. The data are briefly discussed in general notes on the weather of each month.

## SOILS—FERTILIZERS

**Soil survey of the San Simon area, Arizona, E. J. CARPENTER and W. S. BRANSFORD** (*U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1921, pp. III+583-622, pls. 3, fig. 1, map 1*).—This survey, made in cooperation with the University of Arizona, deals with the soils of an area of 286,720 acres lying in the northeastern part of Cochise County in the extreme southeastern part of Arizona. The greater part of the area is smooth enough for irrigation with but little leveling, and drainage is well established except in local areas.

The soils differ widely in origin, color, physical properties, lime content, drainage, and crop adaptation. They are grouped as old valley filling soils, recent alluvial, and miscellaneous materials. Including rough stony land and riverwash, 20 soil types of 10 series are mapped, of which the Cavot and Mohave gravelly sandy loams cover 39.5 and 16.1 per cent of the area, respectively. Analyses of soils for alkali showed that the areas within injurious alkali accumulations are small, being confined largely to the recent alluvial soils along San Simon Creek and to some of the more poorly drained old valley filling soils.

**Soil survey of the Victorville area, California, A. E. KOCHER and S. W. COSBY** (*U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1921, pp. III+623-*

672, pls. 4, figs. 2, map 1).—This survey, made in cooperation with the California Experiment Station, deals with the soils of an area of 226,560 acres lying along the southern margin of the Mohave Desert in the southwestern part of San Bernardino County in southern California. With the exception of the mountain foot slopes along the south side and a few scattering buttes and low rocky ridges, the area in general is smooth. The area is a structural basin which has been filled in to a depth of several hundred feet.

The soils, which are formed mainly of granitic material, range in color from grayish brown to red. Including rough broken land, rough stony land, riverwash, and dunesand, 20 soil types of 7 series are mapped, of which the Hesperia loamy sand, Adelanto sandy loam, Hesperia sand, and Adelanto sand cover 16.6, 15.9, 12.1, and 11.8 per cent of the area, respectively. It is stated that a large portion of the area is adapted to irrigation. Alkali determinations are said to have rarely indicated the presence of more than a trace of salts.

**Soil survey of Alcorn County, Mississippi, E. M. JONES and E. P. LOWE** (*U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1921, pp. III+673-705, pls. 2, fig. 1, map 1*).—This survey, made in cooperation with the Mississippi Geological Survey, deals with the soils of an area of 254,720 acres lying in the Coastal Plain in the northeastern corner of Mississippi. The surface ranges from gently rolling to hilly and rough, and drainage is well established in most places.

Including chalk, 26 soil types of 17 series are mapped, of which the Pheba silt loam, Ruston fine sandy loam, Collins silt loam, and Ruston stony fine sandy loam cover 26.7, 17.7, 11.6, and 10.2 per cent of the area, respectively.

**Investigation of the nature of the soils of the Biesbosch in South Holland** [trans. title], J. G. MASCHHAUPT and D. J. HISSINK (*Dept. Binnenland. Zaken en Landb. [Netherlands], Verslag. Landbouwk. Onderzoek. Rijkslandbouwproefsta., No. 29 (1924), pp. 110-136, figs. 5*).—Physical and chemical studies of samples of soil taken from the Biesbosch in South Holland are reported, and the results are discussed and compared with polder samples.

These soils are evidently well supplied, especially in the top strata, with total nitrogen, phosphoric acid, lime, and organic matter, and have a slightly alkaline reaction. It is thought that after drainage they should possess a greater immediate cultural value than the polder soils.

A brief description of the analytical methods of study used is presented.

**[Investigation of the Dollard soils of the Province of Groningen]**, J. G. MASCHHAUPT (*Bijdr. Kennis Prov. Groningen, n. ser., 1923, No. 2, pp. [4]+76, pls. 4, figs. 2*).—Studies of the soils of the Dollards of Groningen to determine the agricultural value of these diked-in soils are reported. Soil borings were made at about 70 different locations, and the samples obtained were studied in the laboratory. A large amount of comparative data is presented and discussed.

**The natural and chemical changes which alluvial soils undergo after diking** [trans. title], D. J. HISSINK (*Dept. Binnenland. Zaken en Landb. [Netherlands], Verslag. Landbouwk. Onderzoek. Rijkslandbouwproefsta., No. 29 (1924), pp. 170-184*).—Studies of the physical and chemical properties of the alluvial soils of the Netherlands and of the natural and chemical changes which they undergo after reclamation by diking are reported.

The results show that these soils possess a large percentage of pore space which varies with the clay content, and they are naturally very pervious. When reclaimed and drained oxidation processes are rapid, resulting in the formation of carbon dioxide, and consequently calcium carbonate, which flocculates the soda clay and forms also calcareous clay. The physical condition of these soils is improved and the porosity increased.

**Calculation of the coefficient of permeability of clay from the hydrodynamic pressure phenomena** [trans. title], K. v. TERZAGHI (*Sitzber. Akad. Wiss. Wien, Math. Naturw. Kl.*, 132 (1923), IIa, No. 3-4, pp. 125-138, figs. 4; *abs. in Sci. Abs., Sect. A—Phys.*, 27 (1924), No. 322, pp. 853, 854).—Studies are reported in which it was found that in clay with a porosity number less than 2 and a coefficient of permeability greater than 0.06 cm. per year, there was no appreciable variation from the law of Darcy.

In an investigation to determine the coefficient of permeability of loam and of clay in the viscous-plastic and in the semisolid form, the direct method of measurement failed because the coefficient of permeability of the soils in this form was very small as compared with a coefficient of 0.06 cm. per year. A method was therefore developed to avoid the errors of the direct method, which consisted in the observation of the time change of the pressure phenomena in clay. The hydrodynamic pressure phenomena is considered to be the delay which is caused in clay in the pressure due to the resistance to the outflow of squeezed out water. It is stated that the permeability coefficient can be calculated from the time variation of the equalization of pressure as long as all other important factors are known.

With the help of diagrams, the case of a block of loam or clay of height  $h$  contained in a vessel which will prevent spreading is considered. As the pressure is increased the porosity number and the coefficient of permeability decrease, and a definite amount of water is squeezed out of the clay. The unit of volume is taken as a prism of unit sectional area. The length of the prism in the direction of the pressure is variable, the reduced thickness of the layer is the thickness which the layer would have if the porosity number were 0, and the coefficient of permeability denotes the velocity of flow of the water through a layer of clay of the real thickness when the difference of pressure height is 1 cm. The differential equation for the flow is exactly the same as that for the nonstationary propagation of heat in an isotropic medium. The solution of the equation is given, and the results for special cases are plotted. It is concluded that Darcy's law holds for the flow of water through loam in a semisolid form.

**Heat of wetting as a new means of estimating the colloidal material in soils**, G. J. BOUYOUKOS (*Science*, 60 (1924), No. 1553, p. 320).—In a brief contribution from the Michigan Experiment Station the conclusion is drawn that the heat of wetting presents probably the best means for estimating the colloidal content of soils as well as their state of activation. It has been found that the heat of wetting of soils is due mainly, if not entirely, to their colloids, as noncolloidal material even in a very fine state of division does not produce heat of wetting.

According to this method the colloidal content of soils may range from 0 to 80 per cent of their weight, and the average soil is found to contain a far larger amount of colloids than is commonly believed. It has been further found that the reactivity of material may not depend entirely upon the size of its particles but also upon the state of its activation. The procedure of the method consists of determining the heat of wetting of a soil, then extracting a certain amount of colloids from it and determining their heat of wetting, from which data the colloidal content is readily calculated.

**The effect of drying upon the acidity of soil samples**, C. O. ROST and E. A. FIEGER (*Science*, 60 (1924), No. 1552, p. 297).—Further studies conducted at the Minnesota Experiment Station on the effect of drying upon the H-ion concentration of about 200 samples of soils in both moist and air-dry condition (E. S. R., 50, p. 718) are summarized.

Samples from one field showed marked changes upon being allowed to become air-dry, those from two fields changed somewhat less but still appreciably, and those from the remaining two only slightly. Generally the H-ion concentration increased, but in a few instances it decreased. Where sufficient lime or marl had been added to make the soil alkaline, some samples showed no change in H-ion concentration, some an increase, and others a decrease upon air-drying.

A group of 92 glacial soils, partly acid and partly alkaline, were found after air-drying to be decidedly more acid than before, the alkaline soils, however, showing the more marked change. A group of loessial soils which were on the whole more acid than the glacial soils showed less change.

Oven-drying increased the H-ion concentration more than air-drying. Samples moistened after air-drying became more acid than the original moist samples and usually more acid than the air-dried samples. Moist samples kept in glass air-tight containers generally became more acid on standing. Air-dried samples showed a more acid reaction than moist ones freshly taken from the field.

**A bibliography relating to soil alkalies**, compiled by F. V. KING, G. ERVIN, and O. L. EVANS (*U. S. Dept. Agr. Bul. 1314 (1925), pp. 40*).—This bibliography was compiled under the direction of S. H. McCrory, with special reference to the deleterious action of soil alkalies and various other chemical agents on cement and concrete. It contains sections on soil alkalinity, alkali soil salts, sea water, other injurious agents, waterproofing of concrete, and alkali-resistant concrete.

**Soil temperature determinations from April to October, 1924** [trans. title], J. HUDIG (*Landbouwk. Tijdschr. (Utrecht)*, 36 (1924), No. 434, pp. 420-424).—Soil temperature determinations taken from April to October at depths of 50, 75, and 100 cm. (19.7, 29.5, and 39.4 in.) in Dutch soils are briefly presented and discussed. These show naturally that the temperatures decreased with depth, and all of them increased quite uniformly as the temperature of the air increased. However, the difference between the temperatures at different depths was much less marked at the end than at the beginning of the period.

**The principles of summer-fallow tillage**, M. A. MCCALL and H. M. WANSER (*Washington Col. Sta. Bul. 183 (1924), pp. 6-77, figs. 5*).—The results of studies on the subject conducted in cooperation with the U. S. Department of Agriculture are summarized.

It is concluded that the summer fallow system is necessary in eastern Washington dry farming because of the seasonal distribution and amount of precipitation, the purpose being to conserve moisture and to accumulate nitrate nitrogen. Climatic conditions divide the fallow period into distinct subperiods, emphasizing either absorption or retention. The existence of a soil mulch during the fall and winter period of precipitation inhibits moisture absorption by the soil to a degree which is proportional to the depth of the mulch. A soil mulch during the summer period of intensive evaporation retains moisture already in the soil.

Early spring plowing was found to give the largest accumulation of nitrates, intermediate spring and fall plowing being from 10 to 15 per cent less efficient. Disking was less efficient than plowing in promoting nitrification.

There was a significant positive correlation between soil moisture and accumulated nitrate nitrogen and yield of straw and grain. There was a more significant correlation between grain yield and soil moisture content than between grain yield and nitrate nitrogen accumulations. Moisture conservation is therefore considered to be the most important function of the summer fallow

under the experimental conditions, although a proper balance between nitrate accumulations and soil moisture is necessary for best results. Fallow prepared during the intermediate spring was found most nearly to meet this requirement. There was a significant positive correlation between grain quality and accumulated nitrate nitrogen.

**Chemical factors in denitrification**, G. J. FOWLER and Y. N. KOTWAL (*Jour. Indian Inst. Sci.*, 7 (1924), No. 2, pp. 29-37, pl. 1).—Experiments to determine whether losses of nitrogen from stored nitrogenous materials through chemical causes occur under conditions comparable with those encountered in practice are reported. The general conclusion is drawn that the evolution and consequent losses of gaseous nitrogen, taking place in nature or in the operations of agriculture and sewage purification due to purely chemical causes, are negligible as far as the reactions investigated are concerned. The losses of nitrogen due to biochemical changes were found to occur in a great variety of ways.

**Determination of fertilizer requirements of soils**, E. A. MITSCHERLICH (*Die Bestimmung des Düngerbedürfnisses des Bodens. Berlin: Paul Parey, 1924, pp. 99, figs. 7*).—The details of different methods of determining the fertilizer requirements of soils are described, and the relation between these and the chemical composition and reaction of soils is brought out.

Special attention is drawn to the utility of pot and field fertilizer experiments in determining available fertility as well as fertility requirements of soils, and the proper interpretation of these is discussed.

**Report of field experiments with fertilizers in Sweden in the years 1922 and 1923** [trans. title], H. VON FEILITZEN (*Meddel. Centralanst. Försöksv. Jordbruksområdet [Sweden]*, Nos. 259 (1924), pp. 415, figs. 12; 272, pp. 471, figs. 15).—A large amount of data from field experiments with fertilizers in Sweden during the years 1922 and 1923 is summarized, together with other general data in connection with this work, which was begun in 1900.

**Fertilizer suggestions for crops under Pennsylvania conditions**, F. D. GARDNER and A. L. PATRICK (*Penn. State Col. Ext. Circ. 102 (1924), pp. 8*).—Practical suggestions on the use of fertilizers for crops in Pennsylvania are presented.

**The influence of phosphate, biphosphate, carbonate, silicate, and sulfate of calcium, sodium, and potassium on plant growth in acid mineral soils**, K. MIYAKE, I. TAMACHI, and J. KONNO (*Soil Sci.*, 18 (1924), No. 4, pp. 279-309, figs. 14).—Studies conducted at the Hokkaido Imperial University, Sapporo, Japan, are reported on the behavior of the phosphate, biphosphate, carbonate, silicate, and sulfate of calcium, sodium, and potassium on acid soils in connection with plant growth.

The acidity of the soils was reduced by the addition of carbonate, phosphate, biphosphate, and silicate of calcium, sodium, and potassium in the order mentioned, while sulfate did not make any reduction. The H-ion concentration of the soil solution also was reduced by the addition of these salts, but the order of the reduction did not coincide with that observed in the case of the acidity.

The amount of aluminum dissolved out in the solution of potassium chloride from the soils after the addition of these salts agreed well with that of the acidity. The acidity seems then to be due to the amount of aluminum in the solution. In their power to make soluble aluminum into insoluble, the salts ranked in their order, carbonate, phosphate, biphosphate, and silicate. Sulfate not only lacked this power but increased the amount of soluble aluminum. This order coincided with that of the reduction of acidity by the salts.

The growth of barley was affected by the addition of the salts. A favorable effect was produced by phosphate, biphosphate, carbonate, and silicate in the order mentioned, while the unfavorable effect was caused by sulfate. This order seemed to agree with that of the salts in converting soluble aluminum into insoluble, except that phosphate and carbonate were interchanged. Hence the aluminum abundantly present in acid soils seemed to be a very important factor causing inferior plant growth.

The superior effect of phosphate upon plant growth seemed to be due to the great deficiency of phosphoric acid in this kind of soil. Though the H-ion concentration of the soil solution also was reduced by the addition of the salts, it did not show any relation to the plant growth.

These results are taken to indicate that the inferior quality of the acid soil as a medium for plant growth is due in some measure at least to the presence of soluble aluminum, which is decidedly toxic, and to the deficiency of phosphoric acid. Hence the chemicals which supply phosphoric acid and cause the elimination of soluble aluminum seem to be the best agents for improving acid soils.

**Nitrification of stable manure in cultivated soils** [trans. title], C. BARTHEL and N. BENGTSSON (*Meddel. Centralanst. Försöksv. Jordbruksområdet [Sweden]*, No. 269 (1924), pp. 13).—Studies on the influence of newly slaked lime, added in amounts corresponding to those used in practice, on the nitrification of barnyard manure are reported.

The results showed that lime used in normal quantities had no influence in this respect. It is concluded that lime added to the soil either in the form of calcium carbonate or as newly slaked lime and in amounts used in practice has no noteworthy effect on the nitrification of barnyard manure, and that the time of liming does not alter the results.

**Influence of koufri, marog, and tafla on the physical properties of soil** [trans. title], V. M. MOSSÉRI (*Bul. Inst. Égypte*, 5 (1922-23), pp. 85-113).—Studies are reported which showed that koufri, marog, and tafla, which are rich in salts of calcium, magnesium, or potassium, except potassium carbonate, decrease the air capacity and increase the moisture-holding capacity, capillarity, and permeability of heavy Egyptian delta soils, but slightly decrease the two last named in lighter alluvial soils.

Materials containing salts of sodium, especially sodium carbonate, acted in much the same manner on the capacity for air and moisture, but decreased the permeability and capillarity of both soils considerably. However, when sodium sulfate formed the major part of the salts the permeability of the heavy soils was increased. A high content of calcium sulfate or of this salt mixed with calcium chloride notably increased the permeability of both soils.

**The availability of nitrogen in peat**, C. B. LIPMAN and M. E. WANK (*Soil Sci.*, 18 (1924), No. 4, pp. 311-316, figs. 2).—Studies conducted at the University of California on the value of peat as a source of nitrogen when applied to a soil which had always responded to nitrogenous fertilizers are reported.

The results showed that peat untreated or treated with acid and with acid plus steam under pressure is of practically no value as a source of available nitrogen when results from particular experiments carried on for this purpose are properly studied.

**Nitrate facts and figures, 1924**, compiled by A. F. B. JAMES (*London: C. Mathieson & Sons, 1924, pp. 15*).—A statistical review of the nitrate industry from the British viewpoint, for the year 1924 in particular as compared with previous years, is presented. The feature of the year under review is said to be the steady improvement in the statistical position of the commodity. Special reference is made to the Chilean nitrate industry.

**Ammonium nitrate as an explosive**, R. M. COOK (*Chem. and Metall. Engin.*, 31 (1924), No. 6, pp. 231-233, fig. 1).—Experiments are reported which are considered to offer striking confirmation of the impression that organic or carbonaceous materials even in small percentages have a marked effect on the sensitiveness of ammonium nitrate toward detonation.

**Test of phosphatic fertilizers** [trans. title], C. BRIOUX and A. TARDY (*Ann. Sci. Agron. Franç. et Étrang.*, 41 (1924), No. 5, pp. 312-319, fig. 1).—Comparative tests of basic slag, superphosphate, dicalcium phosphate, and a Tunisian phosphate ground colloiddally fine showed that on grain crops such as oats the so-called colloidal phosphate had little beneficial influence, while on root crops such as potatoes it gave practically as good results as superphosphate.

**Origin of phosphorite and the degree of its pulverization as principal factors in its assimilation by vegetation** [trans. title], A. LEBEDIANTZEV (*Ann. Sci. Agron. Franç. et Étrang.*, 41 (1924), No. 5, pp. 330-338, fig. 1).—Studies with five different sorts of Russian phosphorites are reported which showed that these vary in value, depending largely upon whether or not they can best be used in powdered raw form or in the manufacture of superphosphate. The fineness of the powder in the first use is of decisive importance, and the particles should not exceed 0.05 mm. The availability of the phosphoric acid of four of the five sorts tested was strongly influenced by the degree of pulverization.

**Reciprocal action of ground phosphorite and soils not having an acid reaction** [trans. title], A. N. LEBEDIANTZEV (*Ann. Sci. Agron. Franç. et Étrang.*, 41 (1924), No. 5, pp. 320-329).—Studies of the activity of ground phosphorite in fallow and cropped soils are reported.

The results indicated the great importance of the biological activity of soil in modifying the availability of phosphorite. In the majority of cases the action of phosphorite added directly previous to planting was more pronounced than that of phosphorite added to fallowed and subsequently cropped soil.

The results are taken further to indicate that the phosphoric acid of phosphorite becomes available in soils much more easily than has hitherto been thought, but that it may again be rendered insoluble by chemical and biological action. Phosphorite was also found to be quite sensitive to the action of the desiccation, reacting more markedly to this influence than basic slag or superphosphate. Since desiccation apparently exercises its main influence on organic compounds in soils and has little influence on mineral compounds, it is thought that the greater part of the phosphoric acid of phosphorite passes into organic combination.

The results in general are taken to indicate that the phosphoric acid of phosphorite is inherently much more mobile under soil conditions than that of superphosphate or basic slag.

**Agricultural liming materials** (*Md. Univ. Quart. No. 109* (1924), pp. 24, figs. 2).—Actual and guaranteed analyses of 104 samples of various forms of agricultural lime products collected for inspection in Maryland during the year ended November 1, 1924, are presented and discussed, together with general information on the quarrying and manufacture of liming materials.

**Report on commercial fertilizers, 1924**, E. M. BAILEY (*Connecticut State Sta. Bul. 261* (1924), pp. 3-100).—Guaranties and the results of actual analyses of 592 samples of fertilizers and fertilizer materials collected for inspection in Connecticut during 1924 are summarized. The essential features of the State fertilizer law and the fertilizer registrations for 1924 are also included.

**Commercial fertilizers, 1924**, J. M. BARTLETT (*Maine Sta. Off. Insp. 113* (1924), pp. 37-68).—Guaranties and actual analyses of 392 samples of fertilizers

and fertilizer materials collected for inspection in Maine during 1924 are presented.

**Commercial fertilizers**, J. L. HILLS, C. H. JONES, and G. F. ANDERSON (*Vermont Sta. Bul.* 240 (1924), pp. 3-24).—Guaranties and actual analyses of 382 samples of fertilizers and fertilizer materials representing 180 brands collected for inspection in Vermont during 1924 are summarized and discussed.

## AGRICULTURAL BOTANY

**Can the hydrogen ion concentration of living protoplasm be determined?** G. W. SCARTH (*Science*, 60 (1924), No. 1558, pp. 431, 432).—The author claims that the various determinations that have been made of H-ion concentration in organisms are applicable in the case of plants only to the cell sap, and in the case of animals usually to the body fluids bathing the exterior of the cells. Based on a study of the ameba *Pelomyxa palustris*, which was filled with algae, diatoms, etc., he believes that the H-ion concentration of a vacuole can be no criterion of that of the protoplasm that surrounds it.

**Iron supply in a nutrient medium**, H. S. REED and A. R. C. HAAS (*Bot. Gaz.*, 77 (1924), No. 3, pp. 290-299).—In the course of an investigation on the growth of citrus trees and their absorption of materials from nutrient solutions, numerous cases of chlorosis appeared despite the fact that special attention was given to the supply of iron salts. Not all these cases of chlorosis could be correlated with insufficient iron, and they often appeared to be connected with nutritional disturbances due to the absence of other nutrient ions. Studies were undertaken to determine some of the conditions which affect the amount of soluble iron salts in nutrient solutions, the problem being considered as one of importance for the intelligent use of such solutions.

It is stated that the iron of ferric tartrate soon becomes converted into insoluble compounds when added to nutrient solutions, the change being more rapid in solutions of higher pH. The introduction of carbon dioxide lowers the pH of slightly acid, neutral, or alkaline solutions, but does not increase the solubility of iron compounds which they contain. The addition of certain organic compounds to an alkaline nutrient solution increases the amount of soluble iron in the solution. This fact may be of significance in maintaining an adequate supply of soluble iron in solutions for the growth of plants.

**Biochemical aspects of fermentation**, A. SLATOR (*Jour. Inst. Brewing*, 29 (1923), No. 10, pp. 814-818).—Chemical action due to microorganisms usually occurs chiefly during the growth and development of such organisms, giving a typical S-shaped curve of an autocatalytic reaction. To understand this curve it is necessary to know the factors determining and influencing both the growth and the fermentative activity of the yeast. In certain parts of this curve so many factors are changing simultaneously as to complicate its analysis. In the present paper a short account of these factors is given.

**Chemical aspects of germination**, J. L. BAKER and H. F. E. HULTON (*Jour. Inst. Brewing*, 29 (1923), No. 10, pp. 824-833).—This outline of the chemical aspects of germination deals mainly with previous work by others and admittedly includes only a few of the more salient features of the subject.

**Temperature coefficient of absorption in seeds of corn**, C. A. and S. P. SHULL (*Bot. Gaz.*, 77 (1924), No. 3, pp. 262-279, fig. 1).—A study of the influence of wide temperature differences on the rate of water absorption by seeds of corn has given results agreeing completely with those of a similar study of *Xanthium* seeds and pea cotyledons made previously (*E. S. R.*, 44, p. 728). The same type of formula and the methods of mathematical analysis used with other seeds were found to apply with great exactness to the data obtained

with corn. The rate of absorption at 50° C. is somewhat more than eight times as fast as at 5°, whereas the chemical theory of absorption would call for a rate 32 times as great. From mathematical considerations, the velocity of intake at any given moment must be considered as approximately an inverse exponential function of any amount of water previously absorbed. Attention is called to cases of irregular absorption rates, indicating that many substances have specific absorption behavior. A rate law with wide applicability is not to be expected. The importance of semipermeability with reference to the intake of water from solutions of various kinds is pointed out.

**The rate of growth of green and albino maize seedlings, J. H. KEMPTON** (*Jour. Agr. Research [U. S.]*, 29 (1924), No. 6, pp. 311, 312, fig. 1).—In connection with observed differences in plants as to their response to temperature and solar radiation, a comparison was made of the elongation rate of albino seedlings with that of normal green ones. Little difference was observed in the size of the seedlings until they had produced three leaves, after which the green plants forged ahead and the albinos declined.

The growth curves were remarkably alike, both kinds of plants showing almost identical response to light and temperature. The author considers it remarkable that sister maize plants differing so greatly in a major physiological characteristic should have such similar growth rates. Such behavior is believed to show that the response of the plant to air temperature and radiation is controlled by inherent factors not associated with the production of chlorophyll and photosynthesis.

**Influence of time of seeding of cereals on their vegetative rhythm** [trans. title], G. MARTINET (*Ann. Agr. Suisse*, 24 (1923), No. 1, pp. 1-7).—Facts adduced in connection with the reactions of a number of wheats, and of this and other cereals in elevated regions, are said to show these to possess great power of adaptation in difficult situations endangering reproduction.

**Growth of plants in artificial light.—II, Intensities of continuous light required for blooming, E. HENDRICKS and R. B. HARVEY** (*Bot. Gaz.*, 77 (1924), No. 3, pp. 330-334, fig. 1).—Of a number of plants grown in the rooms described in a previous paper by Harvey (*E. S. R.*, 51, p. 25) and subjected to continuous artificial illumination, some showed growth and blooming throughout a wide range of intensities, others through a limited range only. A speeding up of the blooming of Easter lilies was correlated with an increase in the carbohydrate content of the leaves when grown in continuous artificial light.

**Studies on the effects of air temperature and relative humidity on the transpiration of *Pinus strobus*, E. J. DOLE** (*Vermont Sta. Bul.* 238 (1924), pp. 3-39, pls. 2, figs. 11).—The results are given of studies on the effects of air temperature and relative humidity on the transpiration phenomena in the white pine, comparisons being made with transpiration in an uncontrolled environment, with plants deprived of their normal period of rest, and as influenced by soil conditions.

The author's results show that environment influences the hourly fluctuation in transpiration, and the previous environmental condition influences the rate of transpiration when grown under control conditions. Within the limits of the experiment the author found that the amount of available soil water had an important bearing on the transpiration, and that soil conditions, as well as atmospheric conditions, must be controlled. It is claimed that absolute transpirational losses can not be correlated either with relative humidity or with temperature, nor can they be correlated with the combined effect of these two factors as expressed in terms of vapor pressure. The products of actual losses and vapor pressure, it is said, may be correlated with temperature, which implies that temperature has an additional influence on the phenomenon

other than its influence in determining the value of vapor pressure. In an unchanging environment the phenomena of transpiration and evaporation were found to be closely parallel.

A bibliography of literature on transpiration is given.

**Comparative studies on respiration.—XXI, Acid formation and decreased production of CO<sub>2</sub> due to ethyl alcohol, M. IRWIN and M. WEINSTEIN** (*Amer. Jour. Bot.*, 9 (1922), No. 6, pp. 277-282, figs. 2).—Ethyl alcohol decreases the production of carbon dioxide by radish seedlings, and at the same time brings about the formation of organic acids.

**Comparative studies on respiration.—XXII, The effect of lactic acid on the respiration of wheat, E. P. SMITH** (*Amer. Jour. Bot.*, 9 (1922), No. 6, pp. 307-310, figs. 2).—In high dilutions, as 0.0025 M, lactic acid first accelerates and then depresses the rate of production of carbon dioxide by wheat seedlings. As the concentration of the acid increases, the preliminary rise in rate becomes less marked, until a concentration is reached at which the rate begins to fall. Even if the rate has been rapidly reduced to 25 per cent of the normal by 2 M lactic acid, recovery is possible and appears to be complete. The observed effects are due not merely to osmotic pressure or to acidity, but to some specific action of the lactic acid.

Since there is no permanent increase in the rate of production of carbon dioxide, as would be expected on the hypothesis that lactic acid is a stage in the metabolism of wheat, it is concluded that lactic acid is not, in this case, an important intermediate substance.

**Comparative studies on respiration.—XXIII, The effect of adrenalin on the production of carbon dioxide by animals and by plants, D. M. HUTCHINSON** (*Amer. Jour. Physiol.*, 62 (1922), No. 2, pp. 192-196, figs. 2).—The action of adrenaline on the production of carbon dioxide as measured by the apparatus previously described by Osterhout (*E. S. R.*, 41, p. 524) shows that adrenaline gives similar effects on the respiration of frog's muscle and on that of radish seedlings. The stronger solutions (0.002 to 0.003 per cent) cause a depression. This is followed by a return to normal, probably due to the oxidation of the adrenaline. Weaker solutions produce a rhythmic effect, the carbon dioxide production rate alternately and repeatedly falling and rising.

**Assimilation-respiration balance as related to length of day reactions of soy beans, F. M. EATON** (*Bot. Gaz.*, 77 (1924), No. 3, pp. 311-321, figs. 4).—The somewhat preliminary experiments here recorded were planned to ascertain whether the daily balance between assimilation and respiration might not prove to be a controlling influence determining plant development as to its vegetative or reproductive form.

The time of flowering of Peking soy beans given high, low, and uncontrolled nightly temperatures was affected to an extent comparable with the differences brought about by varying the length of day. It was found that respiration proceeded almost twice as rapidly under hot night conditions as under cold night conditions. Depriving soy beans of carbon dioxide for a part of the day did not affect the time of blooming. Not all short-day plants gave the same reactions to varied nightly temperatures. Elongation of maize during the night was found to be nearly proportional to the temperature.

**Effect of ethylene upon respiration of lemons, F. E. DENNY** (*Bot. Gaz.*, 77 (1924), No. 3, pp. 322-329, figs. 2).—In experimentation started by the laboratory of fruit and vegetable chemistry, Bureau of Chemistry, U. S. D. A., to determine the gaseous constituent of the sweat room atmosphere effective in coloring lemons, it was found that ethylene was very effective, 1:1,000,000 turning green but mature lemons yellow in from 6 to 10 days. These experi-

ments also showed high ethylene concentrations (80 per cent), high temperatures (92° F.), low temperatures (45° F.), and lack of oxygen to prevent or greatly check the coloring action. Conditions suitable for the life processes of the fruit favored the color change. Coloring with ethylene or gas from kerosene stoves caused loss of the buttons (calyx, receptacle, and part of the peduncle), with enlargement and gelatinization of the absciss-layer cells. It is supposed that secondary growth had set up here at least, producing a condition in lemons analogous to the extrusion of tissue on stems of plants mentioned by Doubt (E. S. R., 37, p. 726). These facts indicated that ethylene in some manner stimulated the growth or the life processes of the cells of the fruit, probably increasing respiration. The results of the measurements of the carbon dioxide output of ethylene-treated lemons as compared with those receiving no ethylene are here recorded.

Ethylene in air at concentrations of 1:1,000, 1:10,000, 1:100,000, and 1:1,000,000 increased the respiration of green lemons. The effect appeared to be greatest at the intermediate concentrations. The increase in carbon dioxide output ranged from about 100 per cent to about 250 per cent, followed by a decrease on discontinuance of the ethylene applications. Yellowing of the ethylene-treated fruit became apparent about the third or fourth day, the full yellow color developing in from 6 to 10 days, and untreated fruit remaining green.

**The development and nutrition of yeast, [I], II, A. TAIT and L. FLETCHER** (*Jour. Inst. Brewing*, 28 (1922), No. 8, pp. 597-621, figs. 2; 29 (1923), No. 7, pp. 509-537, figs. 7).—Besides particulars having more technical bearings which are brought out by this investigation, the authors point out in the first paper the comparative insufficiency of asparagine as a nitrogen source, the influence of acidity on yeast growth, the importance of pH in brewing, the inadequacy of ammonium salts as food for *Saccharomyces cerevisiae*, the relationship between the fermentative power and nitrogen content of yeast under certain conditions, and a distinct relationship between the initial nitrogen content of worts and the amount of yeast produced, at least at the lower nitrogen concentrations.

In the second paper they state that there is practically no difference in the relative values of the nitrogenous constituents of malt rootlets and malt worts as yeast food. Worts or artificial nutrient solutions when aerated by standing for 48 hours at room temperature contain sufficient oxygen for the normal reproduction of yeast. Continuous aeration does not influence the rate of reproduction under the conditions herein laid down. Carbon dioxide should not be used to displace the air above fermenting solutions since this gas retards distinctly yeast multiplication. At a concentration of about 0.7 per cent alcohol with the carbonic acid retained in solution, there is a marked retardation in the rate of yeast reproduction. Except in the very early stages, the alcohol formation and the yeast multiplication rate do not follow the same exponential law. Owing to the variation in weight of cells during fermentation general conclusions can not be deduced from the weights of final crops. Preferable methods are the determination of the nitrogen coefficient or direct counting, the latter of which is the more reliable.

**Origin of prairies in Illinois, J. WOODARD** (*Bot. Gaz.*, 77 (1924), No. 3, pp. 241-261).—The prairies of Illinois are shown to be near the eastern edge of an eastern extension of the prairie province of the United States and Canada (which is outlined). They are said to lie really in a region having a woodland climate, the reasons for which fact are presented in connection with the apparent geological and later vegetal history of the region.

**Age and area: A review of J. C. Willis' theory of the origin of species, H. DE VRIES** (*Jour. Heredity*, 14 (1923), No. 4, pp. 165-170).—A review is given of Willis' theory of the origin of species as embodied in the book previously noted (E. S. R., 51, p. 821).

## GENETICS

[**Plant breeding activities at the Dahlem Station**], HÖSTERMANN (*Ber. Höher. Gart. Lehranst. Berlin-Dahlem*, 1922-1923, pp. 32-38).—Selfing tests with the Berner Rosenapfel and Baumann Renette apples and the Liegel Winterbutterbirne pear showed these varieties to be nonautogamous. Gooseberries, on the other hand, lent themselves readily to self-fertilization. *Juglans cordiformis* was successfully crossed with *J. regia* in an attempt to develop hardy, productive types of hybrids. No evidence was obtained in garden pea hybridization to show that the male parent exerts an immediate influence on the first generation. Crosses between *Papaver somniferum* and *P. orientale* showed that the color and productivity of the latter species is dominant in the F<sub>1</sub> generation. Work with the garden stock, *Matthiola annua*, indicated that the first seeds to germinate carry a higher proportion of double flowered plants than do the later seeds.

**Triploidy in the tomato**, J. W. LESLEY and M. C. MANN (*Science*, 61 (1925), No. 1573, p. 208).—A cytological examination of root tip cells of an abnormal, unfruitful plant appearing in a Dwarf Aristocrat population showed 36 chromosomes, as compared with 24 for typical, normal plants. Both in the greenhouse and the field flowers of the abnormal plant were found to contain a considerable proportion of sterile pollen. While the pollen grains of the abnormal plant were similar in average size to those of normal plants, the variability was much greater. Progeny raised from the variant included some plants containing an extra number of chromosomes.

**A dominant lethal chlorophyll mutation in maize**, J. H. KEMPTON (*Jour. Agr. Research* [U. S.], 29 (1924), No. 6, pp. 307-309).—The author gives an account of the elimination of a dominant mutation that appeared in studies of maize. In a population of 50 plants of an F<sub>1</sub> between two varieties of maize there appeared a single plant, one half of which was normal green in color, the other half being yellow. The plant as a whole was a perfect example of a sectorial chimera. Pollen taken from the two halves of the plant in question was applied to normal green plants, and the cross having the green side of the chimera as the male parent gave only green seedlings in F<sub>1</sub> and F<sub>2</sub> progeny, while the cross having as a male parent the yellow side of the chimera gave equal numbers of yellow and green plants in the F<sub>1</sub>. The green plants gave only green in the F<sub>2</sub> generation and the yellow plants died in the field. It is concluded that the yellow character represents a dominant mutation that is lethal under field culture.

**An hereditary intra-uterine developmental deficiency in the dominant white mouse**, S. B. DE ABERLE (*Abs. in Anat. Rec.*, 27 (1924), No. 4, pp. 177, 178).—The occurrence of an intrauterine anemia in fetuses over 16 days of gestation is noted in dominant white mice from the Stanford Medical School. The anemia causes death in the young within 5 days after birth. In crosses with recessive white mice, this abnormality has been found due to a recessive Mendelian factor not carried by recessive whites.

**A sterile hybrid of spelt and rye** [trans. title], L. BLARINGHEM (*Compt. Rend. Acad. Sci. [Paris]*, 175 (1922), No. 16, pp. 635-637).—A crossing, accomplished in 1921, between *Triticum spelta* and *Secale cereale* is noted, with an

account of certain characters of the resulting hybrid progeny, as xenia, vigor, structure, and florescence.

**Some natural violet hybrids of North America, E. BRAINERD** (*Vermont Sta. Bul. 239 (1924), pp. 3-205, figs. 90*).—In continuation of a study of the species of North American violets (E. S. R., 47, p. 526), the author describes 82 hybrids that were found growing naturally. The hybrids are considered to have originated through the natural crossing of 30 species. The probable origin of each hybrid, its distribution, and leading characteristics are described.

In an introduction by G. P. Burns, it is stated that while the new forms arising from the natural hybrids may show, in general, a separation in accordance with Mendelian principles, an example of pure segregation of characters was not found. The hybrids always showed to a greater or less extent a blending of the characters of the parents.

**The shape and weight of eggs in relation to the sex of chicks in the domestic fowl, M. A. JULL and J. P. QUINN** (*Jour. Agr. Research [U. S.], 29 (1924), No. 4, pp. 195-201*).—This is a report of a statistical study conducted in the Bureau of Animal Industry, U. S. D. A., dealing with the relation of the length, breadth, and weight of eggs to the sex of the chicks at hatching. The results are based on length and breadth measurements of 990 eggs of 24 Barred Plymouth Rock pullets and weights of 418 eggs of Barred Plymouth Rock females mated with Rhode Island Red males and 226 eggs of Rhode Island Red females mated with Rhode Island Red males.

The results were uniformly negative, the following table showing the similarity of the measurements and weights of the eggs developing into males and females:

*Constants of eggs hatching into males and females*

	Mean length	Mean length-breadth index	Mean weight Rock×Red hatched	Mean weight Rock×Red died in shell	Total mean weight Rock×Red	Mean weight Red×Red hatched	Mean weight all eggs
	<i>Mm.</i>		<i>Gm.</i>	<i>Gm.</i>	<i>Gm.</i>	<i>Gm.</i>	<i>Gm.</i>
Males.....	55.31±0.06	75.17±0.09	58.64±0.19	57.56±0.44	58.49±0.17	58.06±0.26	58.24±0.14

**Studies on the sex-ratio and related phenomena.—III, Note on the influence of size of litter, A. S. PARKES** (*Ann. Appl. Biol., 10 (1923), No. 2, pp. 287-292, fig. 1*).—The author reports a study of the effect of size of litter on the sex ratio in swine.

Based on 982 litters, comprising 7,932 individuals, recorded in volume 67 of the National Duroc-Jersey Record, the numbers of males per 100 females in the litters of from 4 to 12 pigs, were, respectively, 131, 135, 105, 112, 99, 101, 105, 125, and 107. The works of other investigators along similar lines are reviewed.

The preceding study of this series has been noted (E. S. R., 51, p. 634).

**Studies on the sex-ratio and related phenomena.—IV, The frequencies of sex combinations in pig litters, A. S. PARKES** (*Biometrika, 15 (1923), No. 3-4, pp. 373-381, fig. 1*).—A statistical study of the sex ratios in different sized litters of pigs has been made, using the 2,020 litters recorded in volume 67 of the National Duroc-Jersey Record as the basis for the study.

The tabulated material showed that there were 50 per cent or slightly more males in litters of 2, 3, 4, 12, 13, and 14, but less than 50 per cent males in the

litter sizes of 5 to 11, inclusive. The data have been studied by various statistical methods, and among the conclusions derived are the following: "The analyses here given show that in pigs the mean sex combinations have a greater than probable frequency, while the litters approaching to unisexuality have a less than probable frequency, a finding very hard to interpret."

**Studies on the sex-ratio and related phenomena.**—V, **The sex-ratio in mice, and its variation**, A. S. PARKES (*Brit. Jour. Expt. Biol.*, 1 (1924), No. 3, pp. 323-334, figs. 2).—The results of a study of the sex ratios among mice are reported for the stocks raised by the author at University College, London.

The sex ratio of the 1,031 mice born was 118 males to 100 females. The breeding of the young was carefully controlled so that the mother did not become pregnant during lactation. Season was found to have some effect on the sex ratio, as young born from March to June consisted of slightly less than 50 per cent males while there were 56.5 per cent males among those born from July to October. Small litters (1 to 4) had a low sex ratio of 45.5 per cent males, while among large litters (9 to 12) there were 55.6 per cent males. The first litters of females averaged 55.4 per cent males, while subsequent litters averaged 60 per cent.

The author has endeavored to explain the deviation from equality in the sex ratio on the basis of the chromosome theory of sex determination and sexual selective prenatal mortality.

**An undescribed constituent of semen**, P. A. FISH (*Abs. in Soc. Expt. Biol. and Med. Proc.*, 21 (1924), No. 8, pp. 566, 567).—The presence of many very minute particles, probably of a fatty nature, in semen of various animals and man has been observed with the dark field microscope at the New York State Veterinary College. Spermatomicrons is suggested as the name for these particles. In fresh specimens the spermatomicrons are apparently embedded in a gelatinous matrix which becomes liquified with age, at which time the particles exhibit Brownian movement. Wide variations in the numbers of the spermatomicrons in the semen of the different classes of animals, and even in different individuals of the same class, have been observed. Similar particles called galatomicrons have been observed in the milk of various species of animals, but have not been found in other secretions of the body such as saliva, urine, and bile.

**The effect of pregnancy upon postpubertal ovogenesis**, E. ALLEN and B. ATCHESON (*Abs. in Anat. Rec.*, 27 (1924), No. 4, p. 178).—By making serial sections of the ovaries of mice killed at daily intervals during pregnancy, it was found at the University of Missouri that pregnancy greatly inhibits the occurrence of mitosis in the germinal epithelium (first stage of postpubertal ovogenesis), but did not prevent its occurrence more frequently at the seventh, fourteenth, and twenty-first days of pregnancy than at other times.

**Selective elimination of ova in the adult ovary**, E. ALLEN, W. B. KOUNTZ, and B. F. FRANCIS (*Abs. in Anat. Rec.*, 27 (1924), No. 4, pp. 178, 179).—Ovaries of sows have been found to contain an average of 45 visible follicles smaller than 3 mm. in diameter two weeks before ovulation, but the average number ovulated is only 6.5, indicating an elimination of 85 per cent. The 6.5 follicles attaining maturity are considered the metabolic equivalent of the 45 smaller ones. The presence of the large numbers of follicles from 10 to 14 days before oestrus insures a proper secretion of the follicular hormone over a considerable portion of the oestrous cycle. It is suggested that prenatal mortality may be considered as a continuation of preovulation mortality.

**Polynuclear ova and polyovular follicles in the opossum**, C. HARTMAN (*Abs. in Anat. Rec.*, 27 (1924), No. 4, p. 182).—The relatively common occurrence of ova having more than one germinal vesicle due to fusion of the germ

cells and the occurrence of polyovular follicles have been observed in 200 opossum ovaries examined at the University of Texas. The polynuclear ova are doomed to die, while the polyovular follicles become atresic and thus have no relation to fertility.

**Correlations of external signs and vaginal changes with the ovarian cycle in swine,** F. F. MCKENZIE (*Abs. in Anat. Rec.*, 27 (1924), No. 4, pp. 185, 186).—The external characteristics and vaginal changes during the oestrous cycle in swine are briefly described and correlated with ovarian changes. Large follicles were present during oestrus, but the follicles had ruptured two days after oestrus and innumerable follicles less than 1 mm. in diameter were present in the ovary. Ten days after oestrus from 41 to 42 follicles of an average diameter of 3.8 mm. were observed, while at 12 days after oestrus 22 to 23 follicles of an average diameter of 4.4 mm. and at 15 days after oestrus 17 follicles having an average diameter of 5.6 mm. were present. Thus, as the size of the follicles increases their number seems to decrease.

**An inhibition in ovulation by the intraperitoneal injection of anterior hypophyseal substance in the domestic fowl,** A. T. WALKER (*Abs. in Anat. Rec.*, 27 (1924), No. 4, p. 190).—Intraperitoneal injections into laying hens of extracts of the fresh anterior lobe of the hypophysis have been found, at the University of California, to immediately stop laying for from 1 to 4 weeks after the injections were discontinued. On post-mortem examination it was found that the ovaries were smaller than normal and that no large ova were present. All except the smaller follicles were undergoing atresia, and the yolk mass was being replaced by lutein tissue.

**The corpus luteum of the oestrous cycle in the ox ovary.**—Preliminary report, G. W. McNUTT (*Abs. in Anat. Rec.*, 27 (1924), No. 4, p. 211).—Ovulation in cows in which copulation was not permitted has been found, in studies at the Iowa State College, to occur in from 30 to 65 hours after the onset of heat. The follicle shrinks from a diameter of from 16 to 19 mm. to one of from 6 to 7 mm. with ovulation. Lutein cells are formed from both granulosa and theca interna. Vascularization starts immediately after ovulation and is practically complete in 9 days. There appears to be no relation between the size of the follicles which rupture and the size of the corpora lutea which develop in successive oestrous periods.

**The cyclic changes of the tubular part of the genitalia of ox during the oestrous cycle.**—Second paper, H. S. MURPHEY (*Abs. in Anat. Rec.*, 27 (1924), No. 4, pp. 213, 214).—Brief notes on the histological changes in the vagina, uterus, and tubes of the cow during the oestrous cycle are given, as observed at the Iowa State College.

**Studies of the oestral flow of the pig,** B. A. ZUPP (*Abs. in Anat. Rec.*, 27 (1924), No. 4, pp. 224, 225).—Brief notes are given on the nature of the secretions of the genital organs of the sow during oestrus, as observed at the Iowa State College.

**A method of determining the prenatal mortality in a given pregnancy of a mouse without affecting its subsequent reproduction,** E. C. MACDOWELL ET AL. (*Anat. Rec.*, 27 (1924), No. 5, pp. 329-336).—A description is given of a simple operation for making counts of the corpora lutea in the ovaries of pregnant mice a few days before parturition, for a determination of prenatal mortality. The count is made by carefully drawing the ovary out through an incision in the abdominal wall, the corpora lutea readily being recognized at this stage of pregnancy.

The results with females, many of which were operated on in this way for several successive litters, indicated that the operation had no influence on the number of young born alive or on the size of subsequent litters. In 136

operations 33.9 per cent of the ova that came to maturity were not represented by living young.

**The effect of light doses of alcohol upon the estrus cycle, and on the number of corpora lutea and prenatal mortality in the mouse,** E. C. MACDOWELL (*Abs. in Soc. Expt. Biol. and Med. Proc.*, 21 (1924), No. 8, pp. 480-485).—In a study at the Carnegie Institution laboratory at Cold Spring Harbor, L. I., it was found that the daily treatment of mice with alcohol for 45 minutes did not affect the age of the opening of the vagina, the age of the occurrence of the first oestrus, the length of the oestrous cycle, the number of corpora lutea per ovulation, prenatal or natal mortality, or number of living young per litter. The corpora lutea counts in these mice were made by the method described in the above paper. The average corpora lutea counts per pregnancy were 9.95 for treated females and 9.9 for controls. Equal numbers of living young were born per litter by control and treated females, 5.79.

**Deficiency effects in guinea-pigs,** A. W. MEYER (*Abs. in Anat. Rec.*, 27 (1924), No. 4, pp. 211, 212).—Observations extending over nearly a decade at the Stanford Medical School indicate a lowered birth rate in guinea pigs from November to March. The occurrence of a bronchopneumonic infection in two different years caused considerable losses in the stocks, but the addition of tomato juice to the ration of weakened animals showing motor disability improved their vigor and appetite and made them more resistant to epidemics. It is suggested that the lowered vitality of the guinea pigs during the winter season may account for the reduced fecundity.

## FIELD CROPS

**Growth of corn and sunflowers in relation to climatic conditions,** W. F. HANNA (*Bot. Gaz.*, 78 (1924), No. 2, pp. 200-214, figs. 4).—In an investigation in the department of field husbandry, University of Alberta, early seedings of Mammoth Russian sunflowers germinated and appeared above ground sooner than early seedings of Northwestern Dent corn, while late seedings of both plants required about the same time. The corn was retarded more than the sunflowers by the low soil temperatures obtaining early in the season. A temperature of 29° F. in the spring of 1920 injured the corn but did not affect the sunflowers, and in 1921 a temperature of 24° killed the corn and slightly injured the sunflowers.

The growth of both corn and sunflowers showed closer correlation with temperature than with any other single climatic factor. The fact that corn gave the best correlation with temperature when remainder indices derived from temperatures above 10° C. (40° F.) were employed, while sunflowers gave the best correlation with temperatures above 0°, appeared to indicate a greater capacity in sunflowers than corn for growth at low temperatures. Physiological temperature efficiency indices derived from Lehenbauer's observations on the growth of maize seedlings (*E. S. R.*, 32, p. 334) showed no relation to the growth of sunflowers, but gave a distinct correlation with the growth of corn. While insufficient soil moisture in 1921 was undoubtedly responsible for the low yields of sunflowers in that year, corn showed no reduction in yield due to this cause.

Consideration of the climatic data, growth measurements, and yields for 1920 and 1921 indicated that corn promises to give better yields of fodder than sunflowers in areas with a comparatively long growing season, high temperatures, and limited soil moisture. Sunflowers should be well suited to sections where moisture is more abundant, with low temperatures at the begin-

ning and end of the growing season, and where there is danger from spring and fall frosts.

**Fall seeding of spring crops** [trans. title], N. I. PUSHKAREV (*Izv. Opytn. Dona i Sev. Kavkaza (Jour. Agr. Research Don and North Caucasus) No. 3 (1923), pp. 19-40, fig. 1*).—Varieties of crops normally sown in the spring were planted in September, October, and November at Rostov, which is located in a region bordering on the zone of continuous vegetation. Corn, beans, flax, poppies, and mustard did not live through the winter, and so few individuals of oats, millet, soy beans, peas, and sugar beets survived that their yields were insignificant. However, Sudan grass and hemp passed the winter in such numbers and with such vigor that hemp gave normal yields. Sorghum, cowpeas, and lentils produced thin stands and only average yields.

Late fall seeding seemed conducive to better stands, and plants passing through the winter successfully were characterized by a greater vigor than spring sown plants. Fall seeded spring wheat and sunflowers made 23 and 51 per cent, respectively, more grain and seed than the same varieties spring sown, and the sunflowers produced 44 per cent more oil per unit area. Fall sown *Abutilon avicennae* made greatly enhanced yields of stalks and seed.

**Irrigated pastures**, D. HANSEN (*Montana Sta. Bul. 166 (1924), pp. 2-12, fig. 1*).—Based on experiments made in cooperation with the U. S. Department of Agriculture at the Huntley Substation during 10 years, methods are recommended for establishing and maintaining irrigated pastures in southern Montana. The carrying capacity tests with dairy cattle reported are reviewed on p. 678.

Good stands were obtained by spring seeding mixtures alone, with a nurse crop of wheat cut for grain or for hay, and by late summer seeding in wheat stubble. However, the spring seeded plats were better established and in better condition for grazing during the season after seeding and produced more when harvested for hay. Late summer seeding resulted in good stands but with light growth during the next season and is recommended mainly if spring seeding fails. While seeding with a nurse crop gave good stands, its success depends largely upon favorable weather and requires that the grain be removed immediately after harvest in order to irrigate the grasses.

**The Rieti Experiment Station for Cereals** [trans. title], MAYLIN (*Ann. Sci. Agron. Franç. et Etrang., 41 (1924), No. 5, pp. 339-351, pls. 3*).—The activities and productions of the experimental station for cereal culture at Rieti, Italy, under the direction of N. Strampelli, are detailed, with a descriptive list of 33 varieties of wheat developed at this station.

**Corn in Connecticut**, D. F. JONES, W. L. SLATE, JR., and B. A. BROWN (*Connecticut State Sta. Bul. 259 (1924), pp. 381-470, figs. 67; also Connecticut Storrs Sta. Bul. 124 (1924), pp. 309-396, figs. 66*).—Nearly 150 varieties and strains of flint and dent corn were grown in comparison at Mount Carmel and at Storrs for various periods between 1914 and 1922, in a joint project between the Connecticut State and Storrs Stations. The varieties are described with notes on their origin, and according to their apparent adaptation certain varieties are suggested for five arbitrary districts in the State.

The highest yielding flints at both places included Mammoth White, Rhode Island White, and Sanford White; Bacon and Purdy Gold Nugget; Burwell Yellow, Frost Yellow, Skilton Yellow, and Zwick Yellow; Behan, Keeler, and Mosher strains of Longfellow; Bissel Yellow Dutton, U. S. No. 193, and Pied Flint. Among the most productive dents were Beardsley, Lanterman, and Vinehill strains of Leaming; Century, Dowd, Early Michigan, Herr White Cap, Lakeside, Luce Favorite, Northern White, Silver King, Sutton, Tryon,

and Webber Dent. Silage varieties of merit embraced Beardsley Leaming, Fureka, Funk 90-Day, Klondyke, Lakeside, Mastodon, and Northern White Dent.

On the average, dent varieties required a longer growing season than flints and yielded more grain and stover. When dent and flint varieties maturing in the same length of time were compared, the dents seemed somewhat more efficient as grain producers, but they did not always ripen as satisfactorily as the flints. In some seasons the highest yielding flint varieties surpassed the highest yielding dents at both places. No difference in the yield of yellow and white dent or flint varieties was observed.

**What is the relation between the moisture content and viability of seed corn when subjected to low temperatures?** W. SCOTT (*Iowa Acad. Sci. Proc.*, 30 (1923), pp. 254-262).—An experiment wherein corn with a high germination and various moisture contents was subjected to  $-12^{\circ}$  C. ( $10.4^{\circ}$ F.) for from 12- to 72-hour periods gave indications that the percentage of germination decreases as the moisture content rises above 30 per cent where a constant temperature of  $-12^{\circ}$  is maintained longer than 12 hours. Practically no germination took place when the moisture content of the frozen corn had been much above 35 per cent. Seeds showing no injury under such conditions probably owed their power of resistance to impermeable or partly impermeable seed coats.

**Cotton experiments, 1924**, R. R. CHILDS (*Ga. Agr. Col. Circ. 104* (1925), pp. [4]).—Strains of College No. 1, Cleveland, and Express produced the highest acre yields and value in the 1924 variety tests. Fairly close spacing made the highest yields in spite of extremely dry weather. While bolls were slightly smaller in unthinned rows and in 7-in. spacings, no appreciable difference was found in length or percentage of lint in the different spacings. In all spacings, two plants per hill gave higher yields than one plant. Acid-delinted seed germinated earlier and produced a better stand than untreated seed in 1924.

**Cotton in Australia**, R. HARDING (*London and New York: Longmans Green & Co., 1924. pp. XVIII+270. figs. 64*).—The possibilities and the limitations of Australia as a cotton growing country are set forth in this volume, which includes an historical account, describes present and potential production and climatic, soil, and agricultural conditions in the regions best suited to the crop, and outlines seed control and cultural methods. Notes on cotton diseases, a summary of the life history of cotton in Egypt, and rainfall data are appended.

**Studies of gambo hemp** [trans. title], W. A. HORST (*Faserforschung*, 4 (1924), No. 2, pp. 61-124, pls. 8, figs. 9).—The botanical relations and nomenclature of *Hibiscus cannabinus* are discussed, with accounts of investigations of the microscopic, physical, chemical, and textile characteristics of its fiber, known as gambo hemp or bimli hemp, in comparison with jute and similar fibers. The culture requirements of *H. cannabinus* are outlined, and a note on *Crotalaria usaramoensis* and its fiber, said to be very similar to sunn fiber, is appended.

The fiber of *H. cannabinus* is similar to jute and can be used for textile purposes. The flowers are largely dependent upon self-fertilization. The fiber length is somewhat greater than that of genuine jute, and the fiber cells are generally somewhat longer, broader, and thicker walled than jute cells and differ therefrom in the ends. Fiber of *H. cannabinus* is somewhat less lignified than jute fiber but is similar in its content of water, ash, and cellulose. The weight of the bark, which consisted of from 30 to 50 per cent of fiber, constituted about one-third of the weight of the stalk in one of the varieties. The fiber content of the stalks is greater than that of hemp stalks.

**Results of experiments with oats in New York**, H. H. LOVE and W. T. CRAIG (*New York Cornell Sta. Bul.* 436 (1925), pp. 24, figs. 8).—Experiments with oats conducted in cooperation with the U. S. Department of Agriculture since 1914 are summarized. Earlier work has been noted (E. S. R., 31, p. 434).

Comparative tests with numerous oats varieties during several years showed that the selected strains are superior to the commercial varieties now on the market. The behavior of individual selections from National oats indicated the possibilities of gain through selection. The tabulations show State Selection 133-46, Cornelian, and National Selection 127-9 to be outstanding.

According to the averages early oats yield less than medium or late oats. Side oats are not considered good oats for the State; they are outyielded by the spreading panicle type and neither fill nor tiller well. Weight per bushel was not indicative of the value of a variety, whereas the percentage of kernel appears to be an important character. The fact that Cornelian had a very high percentage of kernel in addition to its yielding power makes it a very desirable variety of oats. With well prepared land and well cleaned seed, a seeding rate of 2.5 bu. per acre seemed adequate.

**Variation in vigor of sprouts from quarters of single tubers**, J. BUSHNELL (*Bot. Gaz.*, 78 (1924), No. 2, pp. 233-236, fig. 1).—Early Ohio potatoes from cold storage were quartered along the longitudinal axis and planted under uniform conditions at the Minnesota Experiment Station. A marked variation was seen in the time of appearance above the soil of the sprouts from the four pieces of the same tuber. There was an equally striking variation in the vigor of sprouts, the more vigorous sprouts generally being first to appear. The vigor of the sprout was directly correlated with its position on the seed piece. All of the small plants were attached at the tip or near the edge of the seed pieces, while the larger plants arose from more centrally located buds. Plants arising near the edge or at the tip apparently were unable to draw upon the reserve foods of the tuber as successfully as sprouts more favorably located. The stronger sprouts consistently produced the larger plants.

**Depression of check-row yields by adjoining high yielding plot rows in potatoes**, G. W. MUSGRAVE (*Jour. Amer. Soc. Agron.*, 16 (1924), No. 10, pp. 633-635).—In a size-of-seed experiment with potatoes carried on by the New Jersey Experiment Stations, single row test plots were alternated with check plots. Although the depression of the check yield by the adjoining high yielding plot rows was slight, it suggested that competition existed in the cases cited. This was indicated by the high negative correlation coefficient,  $-0.6526 \pm 0.1914$ , as found by comparing the respective check yields with the average of the adjoining plot yields.

**Synonyms of varieties of potatoes with a list of the distinct varieties tested at the potato testing station, Ormskirk, from 1915-1924**, R. N. SALAMAN (*Jour. Natl. Inst. Agr. Bot.*, No. 2 (1924), pp. 39-53).—These pages include a list of about 480 distinct varieties of potatoes with wart immunity indicated, and a list of about 780 synonyms (E. S. R., 46, p. 730), each with its particular variety designated.

**Report of the potato synonym committee on the potatoes sent for immunity trials to the potato testing station, Ormskirk, Lancashire, 1923**, R. N. SALAMAN ET AL. (*Jour. Natl. Inst. Agr. Bot.*, No. 2 (1924), pp. 29-38).—The results of examinations of 307 varieties are reported, with comment on the presence of wart disease.

**Observations on the time of blooming of rice flowers**, J. W. JONES (*Jour. Amer. Soc. Agron.*, 16 (1924), No. 10, pp. 665-670).—Observations made on a number of early and late short grain and late long grain varieties of rice at the Biggs (Calif.) Rice Field Station (E. S. R., 49, p. 433) disclosed that over

three-fourths of the rice flowers studied bloomed between 12 m. and 2 p. m., and that more flowers bloomed between 2 and 4 p. m. than between 10 a. m. and 12 m. Varietal differences appeared to have some influence on the time of blooming, fewer flowers of Shinriki blooming before 12 m. and more after 2 p. m. than was the case with Omachi and Wataribune. Many more flowers of the long grain varieties, C. I. Nos. 1241 and 1258, bloomed between 10 a. m. and 12 m. than of the short grain varieties. The maximum period of blooming of rice flowers in California appears to be later in the day than in other countries for which such data are available.

**The soy bean: Its history, culture, and uses,** F. BOTTARI (*La Soja: Nella Storia, Nell' Agricoltura e Nelle Applicazioni Alimentari ed Industriali*. Turin: S. Lattes & Co., 1923, pp. [5]+243, pl. 1, figs. 30).—This volume treats of the origin and history of soy beans, methods and extent of production in different countries, uses for food and feedstuffs, and industrial applications of the crop.

**Environmental factors affecting the protein and the oil content of soybeans and the iodine number of soybean oil,** R. W. STARK (*Jour. Amer. Soc. Agron.*, 16 (1924), No. 10, pp. 636-645).—Investigation of the composition of soy beans grown in rotations variously fertilized on the Carthage, Raleigh, Sparta, and Odin soil fertility fields of the Illinois Experiment Station showed some correlation apparent between the yield of beans and their composition, an increase in yield frequently being coincident with an increase in protein content and a decrease in the oil.

Applications of limestone and organic matter were found to increase the percentage of protein and decrease the percentage of oil in a marked degree, and these tendencies were further pronounced by additional applications of rock phosphate. Potassium applied in addition to rock phosphate, limestone, and residues resulted in a decreased percentage of protein and an increase in that of oil. The acre yield of oil was increased by applications of organic matter, and limestone in addition to organic matter caused a large increase in oil production, while phosphorus and potassium apparently had little effect upon the acre yield of oil.

Analyses of four varieties of soy beans from different sections of Illinois, considered with the data from the plats, showed that such variations as were observed in this investigation were apparently not due to geographical position or climatic condition, but may probably be attributed chiefly to differences in soil fertility and soil reaction. Greater differences in composition may be found within the variety than exists normally between different varieties. From the evidence in these experiments soy beans seem to tend toward a uniform protein content when the conditions favor large protein production. A fairly close correlation is to be seen between the protein and the oil content of different lots of the same variety of soy beans. Conditions producing an increased percentage of protein result in a decreased oil content, and vice versa.

Wide differences were noted in the average iodine number characteristic of the different varieties. Within the varieties considerable variation was found, but it was not consistent enough to indicate that location or soil treatment was responsible.

**Report on the sugar-cane experiments for the season between 1921-1923,** J. R. BOVELL and J. P. D'ALBUQUERQUE (*Barbados Dept. Agr., Rpt. Sugar-Cane Expts., 1921-1923, pp. 65*).—The details of varietal and fertilizer trials with sugar cane in Barbados along the same general lines as recorded previously (E. S. R., 49, p. 133) are discussed and tabulated for the season indicated, together with rainfall data and comment on the prevalence of the root borer (*Diaprepes abbreviatus* L.) and the brown hardback (*Phytalus smithi* Arrow).

**The relation of moisture and available nitrogen to the yield and protein content of wheat, R. E. NEIDIG and R. S. SNYDER** (*Soil Sci.*, 18 (1924), No. 3, pp. 173-179).—To correlate definitely the effect of different percentages of moisture on the protein content and yield of wheat both with and without an excess of available nitrogen (E. S. R., 47, p. 636), Palouse Bluestem wheat was planted at the Idaho Experiment Station in pots on soil with different fixed and alternating moisture contents, and receiving sodium nitrate at planting or in cumulative additions.

The results of this work indicated that a high moisture content in soil with enough available nitrogen for the maximum growth and development of the wheat plant results in high yielding wheat with a high percentage of protein. A low moisture content in soil containing excessive available nitrogen results in a lower wheat yield but a higher protein content. A high or optimum moisture content in a soil having considerable nitrogen available for the plant in the early periods of growth, but not enough during the fruiting and ripening periods for maximum growth, results in a high yield of wheat with a low protein content. A low moisture content in a soil having enough nitrogen available to the plant during the early growth stages, but not enough for the fruiting and ripening periods, results in a low yield of wheat, the percentage of protein varying according to the degree to which the wheat is shriveled from moisture deficiency. An example of the effect of moisture on the yield and protein content of wheat grown under field conditions is shown by a comparison of several years' data from a rotation experiment in progress at the station.

**Varietal experiments with hard red winter wheats in the dry areas of the western United States, J. A. CLARK and J. H. MARTIN** (*U. S. Dept. Agr. Bul.* 1276 (1925), pp. 48, figs. 3).—Yields and other important agronomic data are presented in detail and summarized for about 110 varieties and strains of winter wheat grown cooperatively in plats in Idaho, Kansas, Montana, North Dakota, Oregon, South Dakota, Texas, Utah, Washington, and Wyoming. Milling and baking tests were made with samples of the more important varieties. The hard red winter wheats consistently outyielded the other classes of winter wheat.

Kharkof, the standard for comparison, was found to be equal or slightly superior to Turkey, the leading variety of hard red winter wheat, in yield, winter hardiness, and other agronomic characters, and in milling and baking quality. Several strains of these or other hard red winter wheats seemed to have certain advantages over Kharkof and Turkey, although most of the sorts tested were not superior to them. In general, Kanred was the most productive hard red winter wheat for the Great Plains area. Other high yielding wheats include Alberta Red, Argentine, Beloglina, Blackhull, Karmont, Montana No. 36, Nebraska No. 60, and Turkey (C. I. No. 1571). Few strains or varieties were found to be distinctly earlier and taller than Kharkof. Blackhull exceeds most of the other varieties in these characters, which appears to give it a decided advantage in some sections. In winter hardiness Minturki, and in stem rust resistance Kanred, have surpassed most of the other varieties of hard red winter wheat. As determined from the crude protein content, yield of straight flour, and volume of loaf, Beloglina, Kanred, and Minturki have distinct advantages over Kharkof and other hard red winter wheats for milling and baking.

**Report of trials of Yeoman II wheat, 1922-23, W. H. PARKER** (*Jour. Natl. Inst. Agr. Bot.*, No. 2 (1924), pp. 4-8).—Comparisons at 10 centers in England showed Yeoman II wheat, produced by R. H. Biffen, practically to equal Selected Yeoman in yields.

**Report on the quality of a new form of wheat, compared with Selected Yeoman and older forms of English wheat,** A. E. HUMPHRIES and R. HUTCHINSON (*Jour. Natl. Inst. Agr. Bot.*, No. 2 (1924), pp. 9-18, pl. 1).—In milling and baking tests Yeoman II and Selected Yeoman wheat grown at the 10 centers mentioned above surpassed in baking quality ordinary English varieties grown in the same areas. Earlier baking tests showed Yeoman II to excel ordinary Yeoman in baking quality and to approximate closely the strength of Red Fife and No. 1 Northern Manitoba.

**Report on the quality of Red Fife wheat grown successively in England for twenty-one years,** A. E. HUMPHRIES and R. HUTCHINSON (*Jour. Natl. Inst. Agr. Bot.*, No. 2 (1924), pp. 3-16, pl. 1).—Milling and baking tests showed that Red Fife wheat after continuous production for 21 years in England retained its characteristics even when sown in 11 differing environments in Great Britain. Although it is said that flour from ordinary English wheat can not be subjected successfully to extended baking processes, the Red Fife behaved as well as No. 1 Northern Manitoba in this respect. Even when the wheat contained from 18 to 21 per cent of moisture after harvest, its quality was not substantially affected. Differences in gluten content did not seem to be correlated with the differences in loaf volume. Red Fife almost invariably yields insufficient gas in panary fermentation unless some form of yeast food is used.

**Ten years' grain and seed testing in Montana,** C. MCKEE and W. O. WHITCOMB (*Montana Sta. Bul.* 167 (1924), pp. 18, figs. 6).—The activities of the Montana Grain Inspection Laboratory during the period 1913-1922 are reviewed, with comment on its work during the year ended June 30, 1923. Tabulations show the average germination and purity of 2,783 samples of field crops seed, 1,167 of vegetable seed, and 851 samples of flower seed received; the hard seeds in legumes; the percentages of 1,710 wheat samples graded into the several classes and grades and the reasons for low grades; the test weights and dockage content of the several wheat grades; and the composition of mixed wheat as graded. Montana seed tests are compared with those from other laboratories.

**Agricultural seed inspection,** A. S. LUTMAN (*Vermont Sta. Bul.* 241 (1924), pp. 3-7).—Tabulations show the purity, guaranty, percentage of germination, and number of weed seed per pound for 91 samples of agricultural seed taken from local dealers in the State during April and May, 1924.

**Seed testing investigations and miscellaneous work** (*Ireland Dept. Agr. and Tech. Instr.*, *Ann. Gen. Rpt.*, 22 (1921-22), pp. 48-50).—About 50, 33, and 25 per cent, respectively, of the hard seeds of red clover, white clover, and alsike clover germinated during the first 2 years with the usual laboratory methods. During the succeeding years germination continued at a very low rate, not ceasing even at the end of the tenth year. With all three clovers the total germination was greater in soil than in the germinators. The addition of basic slag to the soil had no effect in hastening the germination of hard seeds.

At the end of 10 days the germination of cereals at a constant temperature was found to be practically the same as that at alternating temperature. Mangel seed seemed to germinate rather poorer when tested in soil than in sterilized silver sand, the usual laboratory method. Where sand is used the germination is practically complete at the end of 2 weeks, the normal time for the test. In tests of samples of inferior perennial rye grass and Italian rye grass, the best results were obtained at 20° C. (68° F.), and 14 days sufficed for the completion of the test.

Results in longevity studies showed that although the total period in which some of the seeds in each case remain viable did not differ widely for high

and low initial germinations, yet the loss of vitality was generally more rapid when the initial germination was low.

**Official Seed Testing Station for England and Wales—sixth annual report, [1923],** C. B. SAUNDERS (*Jour. Natl. Inst. Agr. Bot., No. 2 (1924), pp. 20-28, fig. 1*).—The average purity and germination are tabulated for 21,678 samples of agricultural seed received during the year ended July 31, 1923.

**Morphological differences of the seeds of some species of Carophyllaceae [found in Russian clover seed]** [trans. title], K. V. KAMENSKIÏ (*Zap. Semenovedeniū (Ann. Essais Semences, Jardin Bot. Petrograd), 4 (1923), No. 5, pp. 3-13*).—*Silene dichotoma*, *S. inflata*, and *Lychnis (Melandrium) alba* are the species of Carophyllaceae seen most frequently in samples of clover seed in Russia, while *S. noctiflora* appears rather seldom. *S. inflata* is seen oftenest in clover from southern and middle Russia as well as from the northern section of European Russia. While *L. alba* is found almost everywhere, it is seldom seen in clover from the northern governments. *S. dichotoma* is found principally in clover from the southern governments, for which it may be considered as indicative. *S. noctiflora* appears infrequently in clover from southern Russia. Agronomic data and characteristic differences of these seeds are given in a German résumé.

**The jointed cactus, S. SCHONLAND** (*Union So. Africa Dept. Agr. Jour., 9 (1924), No. 3, pp. 216-225, figs. 3*).—The distribution in the Cape Province, adaptation, and dissemination of the jointed cactus (*Opuntia aurantiaca*), a weed pest menacing certain areas in the Cape Province of South Africa, are discussed with comment on eradication methods.

**Cuscuta in Iowa, G. L. WITROCK** (*Iowa Acad. Sci. Proc., 30 (1923), pp. 351-354, fig. 1*).—This account of the occurrence and distribution of *Cuscuta* (dodder) in Iowa discloses the presence of 11 species in the State.

## HORTICULTURE

[**Horticultural investigations at the Canadian experimental stations and farms**] (*Canada Expt. Farms, Rpts. Supts. 1923, Agassiz (B. C.) Farm, pp. 19-27; Cap Rouge (Que.) Sta., pp. 16-32, 33, 34, fig. 1; Charlottetown (P. E. I.) Sta., pp. 16-20, 20-22; Fredericton (N. B.) Sta., pp. 28-37; Invermere (B. C.) Sta., pp. 7, 10-12; Kapuskasing (Ont.) Sta., pp. 31-40; Lennoxville (Que.) Sta., pp. 23-33, figs. 3; Lethbridge (Alta.) Sta., pp. 28, 29, 30, 31; Morden (Man.) Sta., pp. 15-25, 27-31, figs. 2; Nappan (N. S.) Sta., pp. 23-27, 28, 30, 31; Scott (Sask.) Sta., pp. 28-34, 36-40, figs. 4; Sidney (B. C.) Sta., pp. 9-20, 21-29, figs. 2; Ste. Anne de la Pocatière (Que.) Sta., pp. 16-21; Indian Head (Sask.) Farm Rpts. Supt. 1921-1922, pp. 20-24, 26-30; 1923, pp. 19-23; La Ferme (Que.) Sta. Rpt. Supt. 1922-1923, pp. 46-53*).—In each of the above pamphlets there is included a report upon horticultural activities by W. H. Hicks, G. A. Langelier, J. A. Clark, C. F. Bailey, R. G. Newton, S. Ballantyne, J. A. McClary, W. H. Fairfield, W. R. Leslie, W. W. Baird, M. J. Tinline, E. M. Straight, J. A. Ste. Marie, N. D. MacKenzie, and P. Fortier, respectively, which for the most part consisted of cultural and varietal tests of fruits, vegetables, and ornamental plants.

Attempts at the Sidney Station to stimulate sweet pea germination by immersing seed for 20 minutes in concentrated sulfuric acid yielded negative results, the acid treated seed germinating less than the untreated.

**Memorial of the hundredth anniversary of the founding of the Dahlem Experimental Station** (*Denkschrift zum 100 Jährigen Bestehen der Höheren Gemüsebaues. Berlin: Paul Parey, 1924, pp. XIX+1065, figs. 263*).—This com-Trowitzsch & Son, 1924, pp. 240, pls. 2, figs. 62).—This is a record of the his-

tory, personnel, activities and achievements, and present equipment of this institution, located near Berlin.

**Red as a protective color in vegetation**, R. B. HARVEY (*Jour. Forestry*, 23 (1925), No. 2, pp. 179, 180).—A brief article in which the author points out that the red color found in the fruiting and vegetative parts of plants has a distinct protective value, such portions tending to become less heated in direct sunlight than green, brown, gray, or black surfaces.

**Handbook of vegetable gardening**, J. BECKER (*Handbuch des Gesamten Gemüßebaues*. Berlin: Paul Parey, 1924, pp. XIX+1065, figs. 263).—This comprehensive manual is practically a monograph on vegetable growing, containing as it does information on general culture, forcing, storage, seed production, vegetable breeding, and technical descriptions of nearly all cultivated aromatic, medicinal, and kitchen garden plants, arranged according to their botanical relationships. In addition considerable data on the chemical composition of vegetables are included.

**Field notes on carrots**, L. L. MORSE (*San Francisco: C. C. Morse & Co.*, 1924, 2. ed., rev. [and enl.], pp. 24, figs. 16).—Beginning with comments on the carrot seed-producing industry in California, the author presents brief technical descriptions of the principal carrot varieties of the United States.

**Premature seeding of celery**, C. C. STARRING (*Montana Sta. Bul.* 168 (1924), pp. 16, fig. 1).—A presentation of material the greater part of which has been noted from another source (E. S. R., 51, p. 143).

**A new method for blanching celery**, R. B. HARVEY (*Minn. Hort.*, 53 (1925), No. 2, pp. 41-43, figs. 2).—Preliminary observations upon the use of ethylene gas as a medium for blanching celery indicated that a very satisfactory product may be obtained with six days' exposure, thus materially reducing the usual time required to blanch celery without in any way reducing the quality.

**Greenhouse tomatoes**, J. H. BEATTIE (*U. S. Dept. Agr., Farmers' Bul.* 1431 (1924), pp. II+25, figs. 7).—In addition to presenting general information on various phases of glasshouse tomato production, data are included on the comparative yields of English and American tomato varieties in the Arlington Experiment Farm glasshouses. In general, the large fruited American types were more productive than the English sorts.

**Fruit statistics of Canada, 1920-23** (*Canada Bur. Statis., Fruit Statis.*, 1920-1923, pp. 20).—This brief statement comprises statistical data on production and prices of the various tree and small fruits grown in Canada.

**Orchard management**, J. H. GOURLEY (*New York and London: Harper & Bros.*, 1925, pp. VIII+247, pls. 7, figs. 13).—A comprehensive discussion of the various phases of fruit production.

**Top-working fruit and nut trees by the Biederman bark graft method**, A. F. KINNISON (*Ariz. Agr. Col. Ext. Circ.* 49 (1924), pp. 23, figs. 16).—This contains practical information.

**Cranberry picking studies**, H. J. FRANKLIN (*Cape Cod Cranberry Growers' Assoc. Ann. Apt.*, 36 (1923-24), p. 8).—Investigations conducted at the State-Experimental Bog, East Wareham, Mass., in the fall of 1922 showed that the method of harvesting in which cranberries are scooped from a flooded bog greatly impairs the keeping quality of the fruit. Fruits gathered in the late afternoon kept better, other things being equal, than those gathered in the heat of midday.

**Some results of recent experiments in pruning raspberries**, S. JOHNSTON (*Mich. State Hort. Soc. Ann. Rpt.*, 53 (1923), pp. 12-15).—Studies conducted at the South Haven, Mich., substation on red and black raspberries indicated the importance of paying increased attention to the number and vigor of canes left after pruning and the number of buds carried on such canes.

In the case of the black raspberry the best results, where size of the berry as well as total yield was considered, were obtained with plants pruned to four canes, with laterals cut back to an average length of four buds. A definite correlation was observed between cane diameter and yields, the largest canes being associated with the largest yields and the largest-sized berries.

In the case of red raspberries, where the canes were pruned back to various heights the yield increased with the height of the cane. However, it was noticed that the size of the berries decreased rapidly above the thirty-fifth bud, and that the long canes bend too easily with the load of ripening fruits. The diameter of the canes was found to be equally as important an index to value in the red as in the black raspberry.

**Manual of American grape-growing**, U. P. HEDRICK (*New York: Macmillan Co., 1924, rev. ed., pp. XIII+458, pls. 32, figs. 54*).—In presenting this new and revised edition (E. S. R., 41, p. 446), the author states that material changes have been made in those sections relating to grape products and to grape varieties, some varieties being discarded in favor of more recent introductions.

**Results of two years' work in pruning and training Illinois grapes**, A. C. VOGELE (*Ill. State Hort. Soc. Trans., 58 (1924), pp. 123-127*).—A study of the relation of the number of buds left subsequent to pruning to the yield of fruit showed, in general, that the larger number of buds up to the maximum observed in the study (from 56 to 65) was correlated with increased production. In the instance of low-producing vines, the number of buds left per vine was, apparently, of less significance than in the case of high producers. The most fruitful type of cane was that which at the third node was approximately from 10 to 15 times as long as the diameter of the cane. Canes less than 0.65 cm. in diameter were invariably poor producers and weakly vegetative. Canes of 0.65 to 0.85 cm. in diameter were the most fruitful, while those from 0.85 to 1.00 cm. inclined to be less fruitful, and large, thick canes whose diameters exceeded 1.00 cm. were invariably poor producers, possessing long internodes, fewer leaves, and low carbohydrate supply. It was found that the small bud close to the base of each cane was invariably dormant or produced a fruitless cane. In fact, only a few clusters of fruit were produced from this basal bud in observations on approximately 950 canes.

**An investigation into some physical and chemical changes occurring in grapes during ripening**, P. R. v. D. R. COPEMAN (*Union So. Africa Dept. Agr. Sci. Bul. 30 (1924), pp. 38, figs. 29*).—Working at the Government Wine Farm, Groot Constantia, South Africa, with four varieties of grapes, an attempt was made to establish simple physical and chemical standards by which grapes may be judged suitable for picking for export. The author found that, if the changes in the weight of berries were taken into consideration, the total yield of sugar from a given number of berries reached a limiting value at a stage when the grapes could be considered ripe. Density and degrees Balling of the juice showed irregular increases. Sucrose content increased steadily throughout the entire period. Acidity showed a gradual continuous decrease during the entire storage period, but was not in direct inverse proportion to the increase in glucose. A tendency was observed for the proportion of acid to glucose to arrive at a limiting value of 0.2. The H-ion concentration of the juice increased gradually.

**Problems of the viticultural industry**, A. V. LYON (*Aust. Inst. Sci. and Indus. Bul. 28 (1924), pp. 84, figs. 17*).—A discussion of grape growing in the irrigated lands of the Murray Valley, Victoria, laying stress on pruning, training, irrigation, fertilization, and control of fungus and insect enemies.

**The California raisin industry: A study in geographic interpretation**, C. C. COLBY (*Ann. Assoc. Amer. Geogr., 14 (1924), No. 2, pp. 49-108, figs. 13*).—

Conditions favoring the growing of raisin grapes are found to exist nearly to perfection in the middle section of the San Joaquin Valley, where low humidity and rainfall are combined with an abundant supply of pure irrigation water, drawn from rivers rising in the upper reaches of the Sierra Nevada Mountains and so located that water may be distributed largely by gravity flow. The weather in September and October is usually characterized by clear, bright days and low humidity, conditions favoring the production of high-grade raisins. As a result of the favorable environment, the production of satisfactory crops has been regular and has contributed to the building of a permanent and stable industry, reflected in comfortable homes and in a vigorous, intelligent population.

The author discusses in a general way the early history of grape growing in California, pointing out the many obstacles, such as unfavorable irrigation laws, improper marketing practices, insect and fungus pests, etc., which have been overcome. Success in marketing came with the organization in 1913 of a cooperative association, which, through the introduction of improved drying and packing practices and the stimulation of consumption through nationwide advertising, has been the vital factor in keeping the raisin industry in a prosperous condition despite economic readjustments in the postwar period and a greatly increased production.

**Smyrna fig culture**, C. G. SAVAGE (*Jour. Dept. Agr. So. Aust.*, 28 (1924), No. 5, pp. 404-421, figs. 8).—A general article, paying particular attention to the subject of pollination through the agency of the Blastophaga insect.

**Fertilizer studies with the olive** [trans. title], J. BONNET (*Prog. Agr. et Vitic. (Éd. l'Est-Centre)*, 45 (1924), No. 49, pp. 544-546).—In tests conducted at La Fare and Ledenon, France, complete fertilizer plats returned yields per tree of 19.4 and 29.8 lbs., respectively, increases of 14.7 and 15.3 lbs. above the average of the control trees.

**Report of an investigation of coffee**, S. C. PRESCOTT (*New York: Joint Coffee Trade Publicity Com.*, 1924, pp. 84, figs. 5).—Herein are reported the results of a comprehensive study of coffee, considering such points as chemical and physiological properties, roasting of coffee, preparation of beverage coffee, etc.

**Pecan growing**, H. P. STUCKEY and E. J. KYLE (*New York: Macmillan Co.*, 1925, pp. XIII+233, pls. 12, figs. 33).—A comprehensive discussion of pecan production, taking into consideration the history and development of the industry, propagation, general culture, harvesting and marketing, control of insect and fungus pests, botany, varieties, etc.

**The pecan in Texas**, J. H. BURKETT (*Texas Dept. Agr. Bul.* 77 (1924), pp. 177, pls. 20, figs. 71).—A revision of a previously noted bulletin (E. S. R., 48, p. 738).

**Rhododendrons for amateurs**, E. H. M. COX (*London: Country Life, Ltd.; New York: Charles Scribner's Sons*, 1924, pp. XVI+112, pls. 15, fig. 1).—Information of a popular nature is presented on the culture of the rhododendron, paying special attention to the selection of desirable species and varieties.

**Shrubs for amateurs**, W. J. BEAN (*London: Country Life, Ltd.; New York: Charles Scribner's Sons*, 1924, pp. VIII+117, pls. 15).—A small handbook devoted to the cultivation, transplanting, arrangement, pruning, propagation, selection, and characteristics of various plant materials.

**The week-end gardener**, F. H. FARTHING (*London: Grant Richards, Ltd.*, 1924, [3. ed.], pp. 455, pls. 16, figs. 380).—A guide for the amateur gardener, with material arranged according to the activities of the various months.

**The little garden for little money**, K. L. BREWSTER (*Boston: Atlantic Monthly Press*, 1924, pp. [9]+109, pls. 8, figs. 4).—A popular account dealing

chiefly with the choice of proper plant material for various situations about the home.

**Planning and planting for the home beautiful**, C. B. FARGO (*New York: Author, 1925, pp. 222, pls. 3*).—Information of a general nature relative to desirable varieties and species of ornamental plants and the care is presented.

## FORESTRY

**Some ecological effects of shading coniferous nursery stock**, C. F. KORSTIAN (*Ecology, 6 (1925), No. 1, pp. 48-51, fig. 1*).—Studies carried on at the Cottonwood Nursery, Utah, by the U. S. D. A. Forest Service showed that the degree of insolation received by young conifers has a direct effect upon the structure of the leaves and, incidentally, on the physiological activities of the entire plant. Analysis of the leaf sap of shaded and openly exposed 3-year-old Douglas fir seedlings showed that shading has a decided effect in lowering the sap density. The leaves of the shaded plants had a less compact structure, thinner epidermis and cuticle, more spongy tissue, closer lying cells, and less deeply depressed stomata than those of the fully insolated plants.

In respect to the optimum amount of shade, Englemann spruce and Douglas fir thrived best under half shade, while lodgepole pine and western yellow pine were grown successfully without any shade. The beneficial effects of shading are deemed to lie in the reduction of soil evaporation and plant transpiration, increased humidity, and lower temperature. Too much shade, however, was found to prolong growth into late autumn and to cause seedlings to become weak and slender and undesirable for transplanting. As a practical deduction, it is recommended that seedlings destined for planting in the open be exposed to full sunlight during their last year in the nursery and, reciprocally, that stock for shaded sites be shaded in the nursery.

**The Rainbow forest plantations: Guide to experimental plots and report of progress, 1924**, H. W. HICOCK (*Connecticut State Sta. Bul. 262 (1924), pp. 103-135, pls. 9*).—Of a large number of forest species and combinations of species tested on a comparatively infertile, sandy soil located in the towns of Windsor and East Granby, three species, namely, the red, white, and Scotch pines, were found by far the most satisfactory. The hardwoods, in no measure as satisfactory as conifers, contained only three promising species, red oak, black locust, and chestnut, all of which suffered to such an extent from animal, insect, and fungus pests as to be considered almost complete failures. The red and the white pines were found to make about equal growth, but, since the white pine is very subject to injury from the weevil, the red is deemed the better of the two species. Scotch pine made a rapid growth but was somewhat inclined to develop crooked boles, and hence final judgment on the species is withheld until the trees have reached a marketable age. Seeding proved unsatisfactory; in fact, regeneration by this practice was abandoned early in favor of planting stock. A map of the area is included.

**Forest planting in the intermountain region**, C. F. KORSTIAN and F. S. BAKER (*U. S. Dept. Agr. Bul. 1264 (1925), pp. 57, pls. 7, figs. 7*).—Based on experience gained in reforestation operations, the authors discuss the various phases of the problem of planting in a region characterized by limited rainfall and great temperature fluctuations. Under such conditions direct seeding proved a failure. Among the various points considered in the paper are the collecting and handling of seed, nursery practices, choice of field sites for the various species considered, best age of planting stock, rates and time of planting, planting practices, survival expectancies, various factors concerned in limiting survival, costs of planting, the general outlook for planting on the area discussed in the bulletin, etc.

**The growth, returns, and uses of planted cottonwood in Iowa,** G. B. MACDONALD (*Iowa Sta. Bul.* 223 (1924), pp. 167-201, figs. 13).—Because of its extremely rapid growth and ability to thrive on soils subject to overflow and, therefore, unfit for general agricultural purposes, the cottonwood (*Populus deltoides*) has become increasingly valuable in Iowa.

That diameter increment is extremely rapid under favorable growing conditions was shown in measurements taken in a 12-year-old plantation established on the station grounds. The trees averaged 6.66 in. in diameter, equivalent to an average annual increment of 0.55 in. Trees planted in single rows made much more rapid diameter gain than did those of the same age in plantations. Height records taken in several plantations showed remarkably rapid development, especially in young trees located on fertile bottom lands. As with other trees, a moderate amount of crowding was apparently necessary for the development of tall, straight stems.

Records taken in various parts of the State showed that, with reasonable care and protection, cottonwood plantations are capable of producing in 35 years a yield of 30,000 bd. ft. per acre in addition to considerable fuel material. Cottonwood has also proved of great value to Iowa farmers in the production of posts which, when properly creosoted, last many years. The lumber, valuable in the construction of barns, sheds, and other rough buildings, is capable of long endurance when properly protected from the weather.

**Aspen in the central Rocky Mountain region,** F. S. BAKER (*U. S. Dept. Agr. Bul.* 1291 (1925), pp. 47, pls. 10, figs. 3).—A comprehensive discussion, taking into consideration the distribution of the species, botany of the tree, variability in response to environments, climatic requirements, soil and moisture needs, tolerance to adverse light conditions, susceptibility to disease, insect and other animal pests, reproduction, species associations, rate of growth, yield on different quality sites, properties and uses of the wood, systems of silvicultural management, etc. Volume tables are appended.

**The growing season of western yellow pine,** G. A. PEARSON (*Jour. Agr. Research* [U. S.], 29 (1924), No. 4, pp. 203, 204, figs. 2).—Dendograph records taken in 1923 at the Southwestern Forest Experiment Station, Flagstaff, Ariz., upon two western yellow pine trees, 5.4 and 15.8 in. in diameter, showed approximate accretion periods of 117 days for the smaller tree and 88 days for the larger tree. Growth in the smaller tree embraced the period May 16 to September 10 and in the larger tree June 1 to August 27. The maximum development for the smaller tree occurred during the first days of June. In both trees diameter enlargement continued longer than shoot development, which on the basis of 14 years' observations was found to practically cease in the western yellow pine by July 1.

**The caoutchouc in Indo-China** [trans. title], L. CARTON (*Bul. Écon. Indochine, n. ser.*, 27 (1924), No. 167, pp. 349-456, pls. 4, figs. 21).—A general discussion relating to the early history of rubber production in Indo-China, the rubber-supplying species, introduction of *Hevea brasiliensis*, methods of culture of Hevea, collection and manufacture of latex, the improvement of Hevea by tree selection, etc.

**Report on the forest administration of the Central Provinces for the year 1922-23,** H. A. FARRINGTON (*Cent. Provs. [India] Forest Admin. Rpt.*, 1922-23, pt. 1, pp. [7]+34; [pt. 2], pp. LXI).—Like that of the preceding year (E. S. R., 51, p. 146), this report is presented in two pamphlets, the first of which deals with general information concerning forest policies, alterations in area, construction activities, forest protection, silvicultural practices, exploitation, etc., and the second contains tabulated statistical data.

## DISEASES OF PLANTS

**Report of the International Conference of Phytopathology and Economic Entomology, Holland, 1923**, edited by T. A. C. SCHOEVERS (*Wageningen: H. Veenman & Sons, [1923], pp. 290+IV, pls. 18, figs. 11*).—A brief general account of this conference has been noted (*E. S. R.*, 49, p. 398). The papers and other data presented included the following:

General Remarks on Potato Diseases of the Curl Type, by H. M. Quanjer (pp. 23–28); Some Peculiar Pathological Conditions in the Leaves of Potatoes Affected with Mosaic Disease, by K. M. Smith (p. 30); Oospores of *Phytophthora infestans*, by H. L. G. de Bruyn (pp. 30, 31); Verticillium Wilt, by J. H. H. van der Meer (pp. 31, 32); Stipple Streak Disease of Potato (p. 32), and The Fusarium Disease of Cereals, both by D. Atanasoff (pp. 32, 33); Resistance of Several Strains of White Flowering Flax to *Melampsora lini*, by J. C. Dorst (p. 33); The Mycoplasma Stage of *P. infestans* [trans. title], by J. Eriksson (pp. 33, 34); Premature Tuber Formation in Early Potato Varieties, by S. J. Wellensiek (pp. 34, 35); Insect Transmission of "Curl" Diseases of Potato, by D. L. Elze (p. 35); International Cooperation in Combating Plant Diseases and Insect Pests, by L. O. Howard (pp. 36–38); Potato Leaf Roll Influenced by the Origin of the Tubers, by E. Gram (pp. 38, 39); The Visibility of Symptoms of Potato Mosaic [trans. title], by V. Ducomet (pp. 39–43); The Valuation of Seed Potatoes from the Standpoint of Plant Protection [trans. title], by G. Köck (pp. 43–48); The Proposed Separation of Phytopathology into Practical Botany and Practical Zoo-(Entomo-)logy [trans. title], by L. Reh (pp. 48–51); How Do We Receive and Keep Phytopathological Information? by E. Gram (pp. 51–53); International Phytopathology, by C. L. Shear (pp. 53–58); "Internal Rust Spot" Disease of the Potato Tuber, by S. G. Paine (pp. 74–78); The Supposed Relation of Potato Skin Spot to Corky Scab, by W. A. Millard and S. Burr (pp. 78, 79); Anatomical and Microchemical Alterations in Potato Phloem [trans. title], by Von Brehmer (pp. 79–85); Organization and Methods of the Phytopathological Service of Holland, by N. van Poeteren (pp. 86–96); International Plant Disease Legislation as Viewed by a Scientific Officer of an Importing Country, by H. T. Güssow (pp. 96–107); Remarks on Plant Disease Legislation in Canada, by A. Gibson (pp. 107–110); Mistakes and Misuse in Connection with Protective Media [trans. title], by J. Bernátsky (pp. 126–131); Proposals for an Acceptable Evaluation of Plant Protective Media [trans. title], by E. Riehm (pp. 131–135); Diseases of Crops on Alkaline and Sour Soils, by J. Hudig (pp. 136–141); The Potato-selection Farm at Oostwold, by J. O. Botjes (pp. 142–147); Transmission of Leaf Roll of Potatoes in N. Wales During 1921, by I. Whitehead (pp. 147–149); Modern Methods of Combating Bulb Diseases, by E. van Slogteren (pp. 150–162); The Central Bureau for Fungus Cultures (pp. 165–171) and Studies on *Nectria coccinea* and *N. galligena* [trans. title] (pp. 171–173), both by J. Westerdijk; On the Resistance of the Potato Tuber Against Phytophthora, by M. P. Löhnis (pp. 174–179); The Biology of *Vermicularia varians* [trans. title], by D. Cavadas (pp. 181–183); Some Facts Regarding the Erysiphaceae [trans. title], by E. Foex (pp. 184–190); Protozoa in Plants [trans. title], by J. Franchini (pp. 191–195); A New Fungus Enemy of Dwellings, *Phellinus cryptarum* [trans. title], by L. Mangin (pp. 196–199); On the Development of Wheat Rusts in Relation to Climatic Conditions, by J. Beauverie (pp. 201–203); Root Rot of Peas in the United States (pp. 203, 204), and Mycorrhizal Fungi in the Roots of Legumes (pp. 204, 205), both by F. R. Jones; European Phytopathologic Collaboration, by J. Eriksson (pp. 205–214); Plant Protection and Instruction [trans. title], by O. Appel (pp.

226-231); The Effects of Partial Sterilization of the Soil, by E. J. Russell (pp. 233-238); Historical Résumé of the Development of Phytopathology in Russia [trans. title] (pp. 238-243), and The Classification of Pathological Phenomena in Plants [trans. title], both by A. de Jacewski (pp. 244-251); Methods for the Estimation of Injury Due to Cryptogamic Parasites [trans. title], by A. Naoumov (pp. 251-257); The Estimation of Injury Caused by Parasitic Fungi to Forest Species [trans. title] (pp. 258-262), Annular Rot of Oak Produced by *Vuilleminia comedens* [trans. title] (pp. 263, 264), and *Hydnum septentrionale*, a Parasite of [Forest] Trees [trans. title], all by E. Vanine (pp. 264-267); The Recent Threatening Development of *Tilletia secalis* in Russia [trans. title], by A. de Jacewski (pp. 267-272); Methods of Combating Cereal Rust by Means of High Temperatures [trans. title], by A. Schitkova (pp. 272-275); Experiments Employing Soda as a Fungicide Against Erysiphaceae [trans. title], by A. Patkaniane (pp. 275, 276); Influence of Meteorological Conditions on the Development of Cereal Rust [trans. title], by L. Roussakov (pp. 277-280); and Fungus Diseases of Hungarian Medicinal Plants [trans. title], by G. von Moesz (pp. 280-283).

**Cooperative dusting and spraying experiments in 1921** (*Crop Protect. Digest*, 1 (1922), No. 2, pp. 30).—In addition to a general account by C. R. Orton (pp. 1-6), the following reports are presented.

*Results on apples and peaches in Connecticut*, W. E. Britton, M. P. Zappe, and E. M. Stoddard (pp. 7-13).—Descriptive and tabular details are presented of the work as regards materials, methods, and results in different orchards.

*Dusting for the control of sucking insects in New York*, P. J. Parrott (pp. 13-15).—Brief accounts are given of experiments on apple, currant, potato, and cabbage.

*Report on disease control in Pennsylvania*, R. C. Walton (pp. 15-21).—In all the tests where lime-sulfur spray was used in comparison with dust materials superior control of apple scab upon both fruit and foliage was given. The data upon apple rust are meager, though lime sulfur appears to be more effective here also. Lime sulfur surpassed dust for control of frog-eye upon apple foliage, especially in cases of heavy infection. Fruit spot was effectively controlled in only one orchard, where infection was relatively slight. As regards sooty blotch, little difference was observed between various materials used. In the tests with dust mixtures for the control of leaf scab, sulfur, lead arsenate, and lime (80-10-10) and sulfur, lead arsenate, and nicotine (90-10-2) were the most effective, and copper dust (Niagara Potato Dust) was least effective. Practically no differences were noted in the efficiency of sulfur and lead arsenate (90-10) and sulfur, dry lime sulfur, and lead arsenate (75-15-10). Soluble sulfur showed practically as good fungicidal properties as commercial lime sulfur, but is not recommended as a summer spray because of severe foliage burning. The dusting materials considerably reduced the diseases (and defoliation), but did not control them effectively.

*Report on insect control in Pennsylvania*, S. W. Frost (pp. 21-23).—Data are given for curculio, codling moth, red bug, aphid, and leaf roller, both early and late.

*Results in disease control in West Virginia*, N. J. Giddings and A. Berg (pp. 23-26).—The data, as given by orchards or counties, show nothing in favor of the sulfur-dry lime-sulfur-arsenate mixture. In several orchards the copper-lime mixture and the sulfur mixture containing copper caused some injury to the fruit and foliage, which may have been primarily due to the small lumps of copper occurring in the mixture.

*Results of dusting and spraying in Ontario*, W. A. Ross (pp. 26-28).—In all parts of Ontario where apple scab was bad, dust mixtures gave deficient con-

trol, though good results were obtained where scab infection was comparatively slight. The failure of dusting was undoubtedly due to the fact that dust mixtures did not afford protection over a sufficiently long period. The weak point with dust lies in the fact that it washes off too easily.

*General recommendations for future work* (pp. 29, 30).—In all experiments on dusting and spraying it is deemed of the greatest importance that the machines used give adequate pressure and dispersal of the materials. Sprayers giving a pressure of less than 200 lbs. are considered of little use. The present state of perfection of dusting machines is not found to be generally satisfactory.

**The relation of cucurbit mosaic to wild catnip**, J. H. MUNCIE (*Abs. in Iowa Acad. Sci. Proc.*, 29 (1922), p. 346).—"Preliminary experiments by the writer show that cucurbit mosaic can be transmitted to *Nepeta cataria* by the insertion of crushed mosaic leaf tissue of mosaic gourd into the stems of catnip. Typical mosaic symptoms appeared on the tips of the leaves of the catnip in about three weeks, and after six weeks practically every leaf showed the mosaic. Mosaic of catnip has not been observed in the field by the writer, but with the ease of obtaining infection and chances of insect inoculation, this perennial host may be a source of early infection to cucumbers in the field."

**Effect of hardness of water on the fungicidal value of mercuric chloride solutions**, J. C. GILMAN (*Abs. in Iowa Acad. Sci. Proc.*, 29 (1922), p. 347).—A comparison of the fungicidal value of mercuric chloride solutions made up in tap water with those made up in distilled water showed the tap water solutions to be much less effective in killing the sclerotia of *Rhizoctonia solani* on potato tubers.

**The health of seed** [trans. title], DOIJER (*Dept. Binnenland. Zaken en Landb. [Netherlands], Verslag. Landbouwk. Onderzoek. Rijkslandbouwproefsta., No. 28 (1923), pp. 148-158*).—This is an account of seed infection percentages and accompanying germinability under varied conditions in case of several economic plants.

**Studies of insect transmission and cross-inoculation of mosaic on the Solanaceae, Cucurbitaceae, and Leguminosae**, O. H. ELMER (*Iowa Acad. Sci. Proc.*, 29 (1922), pp. 311, 312).—Recent experimentation, tending to show that mosaic disease is not so limited in its host range as it was formerly thought to be, is confirmed by this brief note. "These data are of interest, in addition to the fact that the disease was transmitted by the mealy bugs, in that the infection was from Cucurbitaceae to Leguminosae and gives added proof that mosaic can be transmitted to plants belonging to other families and orders."

**Rust infection of leaves in Petri dishes**, G. P. CLINTON and F. A. MCCORMICK (*Connecticut State Sta. Bul.* 260 (1924), pp. 475-501, pls. 2).—A description is given of a method adopted by the authors for studying infection of leaves by rusts. Leaves used in inoculation experiments were placed in Petri dishes, and for most hosts in the experiments they remained in a living condition long enough to permit the development of the fungi. The method is considered to be as successful as that in which living plants are used and has the advantage of greater simplicity and of occupying much less space.

Altogether 13 different genera of rusts were used as follows: *Caeoma*, *Coleosporium*, *Cronartium*, *Gymnoconia*, *Gymnosporangium*, *Kuehneola*, *Melampsora*, *Melampsoridium*, *Melampsoropsis*, *Phragmidium*, *Puccinia*, *Pucciniastrum*, and *Uromyces*. Successful inoculations produced one or more infections with all these genera except the first. Forty-five species were used, and successful inoculations were secured with all but 17. Most inoculations were made with the I and II stages, but no new relationships between supposedly distinct species were found. Several new hosts, however, were secured

through inoculations, and a few old hosts are reported for the first time as having been experimentally demonstrated.

Details of inoculations and infections are given.

**Stripe rust (*Puccinia glumarum*) of cereals and grasses in the United States**, H. B. HUMPHREY, C. W. HUNGERFORD, and A. G. JOHNSON (*Jour. Agr. Research* [U. S.], 29 (1924), No. 5, pp. 209-227, pl. 1, figs. 5).—An account is given of the occurrence of stripe rust in the United States. This rust was first recognized as occurring in the United States in 1915 (E. S. R., 33, p. 744). It is now known to occur from British Columbia to Mexico and eastward to 103° W. longitude, and it has been found in all of the Pacific and Intermountain States except Nevada and New Mexico. In addition to attacking wheat, barley, rye, spelt, and emmer, *P. glumarum* is known to occur in nature on 34 wild grasses common to the United States. An aecial host for *P. glumarum* has not yet been discovered.

Certain varieties of wheat are apparently more subject to glume and kernel infection than others, and all susceptible varieties show general leaf infection. On most hosts the fungus is confined to the leaves and culms. Where it occurs on the kernels and glumes of certain varieties of wheat there is much shrinkage, and apparently the viability of the grain is reduced. The severity and spread of stripe rust in any locality devoted to winter wheat is said to depend on the fall weather conditions favorable to seedling infection, successful hibernation of mycelium, and spring weather conditions favorable to germination of urediniospores. In the Pacific Coast States the fungus has been found capable of surviving the winter by means of living mycelium or viable urediniospores. Varietal resistance studies have shown that several varieties of wheat are highly resistant to stripe rust.

**Infection of barley by *Ustilago nuda* through seed inoculation**, W. H. TISDALE and V. F. TAPKE (*Jour. Agr. Research* [U. S.], 29 (1924), No. 6, pp. 263-284, pls. 9).—This paper gives an account of recent studies which indicate that previous investigators have been confused regarding the infection of barley by *U. nuda*, at least to a certain extent, and that the fungus infects the seedlings and causes severe injury when heavily infected.

The fact that surface disinfectants have been found to control loose smut in certain varieties of barleys led the authors to carry on experiments with different varieties of barley, in some of which the hulls were removed and others not, after which they were heavily inoculated with smut spores. One variety, Nakano Wase, remained resistant throughout all the experiments. Seedlings from dehulled-inoculated seed of practically all varieties were severely injured, and in many cases they failed to emerge, while seedlings from hulled-inoculated seed were not noticeably injured. A microscopic study of seedlings revealed infection of the coleoptile and first leaves of the plumule of barley seedlings by *U. nuda*. Both susceptible and resistant varieties were infected.

**Root-rots of wheat**, A. W. HENRY (*Minnesota Sta. Tech. Bul.* 22 (1924), pp. 3-71, pls. 12, figs. 2).—An investigation of root rots of wheat was made, not only to get a survey of the fungi which cause root rots but also to determine their pathogenicity through inoculation experiments. The studies in the greenhouse demonstrated that the important pathogenes of wheat roots belong to the genera *Fusarium* and *Helminthosporium*. Some species of these genera, however, were nonpathogenic or only feebly attacked the host plants. Strains of other fungi penetrated the roots or caused deformities of them, but it was not considered that they would be destructive in the field. Among the species of *Fusarium*, *F. graminearum* (*Gibberella saubinetii*) was the most virulent pathogene of those studied. Strains of *F. moniliforme* and two species belong-

ing to the *Elegans* section, though less destructive, were also decidedly parasitic on wheat roots. In addition to wheat, *F. moniliforme* was found to attack barley, rye, oats, and corn.

Of the fungi of black pointed seeds studied, *H. sativum* was the most common cause of black point as shown by inoculation studies. However, two other species of *Helminthosporium*, as well as *Stemphylium parasiticum*, were capable of causing black point. In general, *H. sativum* was found the most common and the most destructive of the species of *Helminthosporium*, although at least three others were isolated from wheat. One of these is described as *H. pedicellatum* n. sp.

Temperature and other relations of the different fungi are discussed at considerable length, and the effect of disinfecting soil on the development of root rot is described.

A bibliography of 89 references is given.

**Botrytis rot of the Globe artichoke**, G. K. K. LINK, G. B. RAMSEY, and A. A. BAILEY (*Jour. Agr. Research [U. S.]*, 29 (1924), No. 2, pp. 85-92, pl. 1).—A description is given of *Botrytis* rot of artichokes, which is said to occur seriously in shipments of Globe artichoke buds from California. A study of the organism showed that it was apparently of the *B. cinerea* type and was identical with those obtained from other vegetables. The disease is said to be of little importance in the artichoke fields but occasions considerable loss in shipments. The temperature and moisture relations of the fungus have been studied, and it is found to have a wide temperature range, although moisture appeared to be the principal limiting factor for infection. Control measures include field sanitation and possibly protective spraying or dusting, and also careful handling to avoid wounds in harvesting and packing. Low humidity and temperatures of about 5° C. (41° F.) in transit are recommended.

**Celery diseases in Florida**, A. C. FOSTER and G. F. WEBER (*Florida Sta. Bul.* 173 (1924), pp. 21-77, figs. 34).—A description is given of various diseases to which celery is subject in Florida, together with suggestions for their control.

**The influence of broken pericarp on the germination and yield of corn**, M. T. MEYERS (*Jour. Amer. Soc. Agron.*, 16 (1924), No. 8, pp. 540-550).—Laboratory experiments with seed corn of six strains from northern, southern, and central Ohio indicated that the disease readings on the germinator were no more discriminating than careful examination of the ears before testing. Seed corn is ordinarily exposed under handling to many sorts of disease spores, which lead to serious injury following the moist conditions on the germinator. This is greatly increased by broken seed coats.

Field experiments gave no significant increase for disease-free ears, selected on the basis of disease readings on the germinator from carefully selected seed corn, over the most diseased-appearing ears, or over ears taken from the lot without reference to diseased appearance on the germinator.

Under field conditions, reduced stands were obtained from seeds with broken seed coats, the stands being reduced by unfavorable conditions, in some cases as much as 30 per cent, and seedling vigor being decidedly lessened by the same conditions. An unbroken seed coat proved to be complete protection against infection with spores of the same kind.

**The nodal infection of corn by *Diplodia zeae***, L. W. DURRELL (*Abs. in Iowa Acad. Sci. Proc.*, 29 (1922), pp. 346, 347).—Corn dry-rot (*D. zeae*) was very prevalent in Iowa during 1921, particularly in the central portion of the State. The disease originates in the material left in the field, spores of the organism being blown to the young corn plants and germinating under conditions of extreme moisture and high temperature. Infection may occur on the

roots, stems, or ears, though the most common points of attack are the nodes. There is no consistent evidence of a migration of the disease from the soil to the ears or higher parts of the plant. All observations and experiments emphasize the fact that *D. zeae* infects locally at any point where blown spores lodge, and that moisture and temperature are essential.

**Malformations of cotton plants in Haiti: A new disease named smalling or stenosis, causing abnormal growth and sterility.** O. F. COOK (*Jour. Heredity*, 14 (1923), No. 7, pp. 323-335, figs. 6).—A cotton plant disease apparently new to north-central Haiti, causing abnormal growth and sterility and designated locally as smalling or stenosis, is described. A similar distortion of cotton was previously reported by the author for points in China in 1920 (*E. S. R.*, 43, p. 446). The disease in Haiti has been observed to affect several varieties, the Haitian cotton, however, appearing at least mainly immune.

The two disorders (Chinese and Haitian) show very similar results in altering the appearance and behavior of the plants, and are considered as belonging undoubtedly to the group of so-called mosaic diseases, which in some cases are caused by leafhoppers. Symptoms differ greatly in degree and general effect with different plants.

The upland type of cotton in Haiti showed a more general distortion and buckling of the leaves, with less tendency to discoloration and rolling under of the leaf margins, which were the special symptoms with upland cotton in China. Other comparisons are made. The disease is not contagious but is, apparently, carried. No recovery is noted, the growth continuing in abnormal fashion.

Haitian cotton, at least relatively immune, is described as not related to the Sea Island type, but as probably descended from material brought from the East Indies during the period of the French occupation. It belongs to *Gossypium purpurascens*. The type is usually called Bourbon cotton, and is here briefly described.

**Onion smut in Indiana.** C. T. GREGORY (*Ind. Acad. Sci. Proc.*, 38 (1922), pp. 318-320).—A survey of the important onion-growing regions of Indiana in 1922 showed smut disease to occur abundantly in Lake County, around Munster, and in one locality near Rensselaer in Jasper County. The losses caused are of two types, due directly to the destruction of the plants or indirectly to the production of oversized onions which are often discarded, not being salable as sets. It has been proved that the formaldehyde drip method of treatment will control the onion smut where onions are sown at the rate of 5 to 7 lbs. per acre. In Lake County, however, where the seed is sown at the rate of 60 lbs. per acre, the control is never 100 per cent, but it has been sufficiently effective to secure its adoption by the majority of growers. It is believed that spring plowing loosens the soil so that the formaldehyde penetrates too deeply for proper or sufficient disinfection. Rainfall is important, probably diluting the disinfectant or preventing uniform penetration. The usual dilution employed is 1 pint of 40 per cent formaldehyde in 16 gal. of water, to be used at the rate of 200 gal. per acre. The treated onions had about 5 per cent of smut, the untreated parts showing about 50 per cent. Increases in yields of 100 bu. per acre were obtained. At Munster dilutions as low as 1 pint in 10, 12, or even 14 gal. of water gave control of the smut in 1922, without causing seedling injury.

**Bacterial pustule of soybean.** F. A. WOLF (*Jour. Agr. Research [U. S.]*, 29 (1924), No. 2, pp. 57-68, pls. 3, figs. 4).—A description is given of bacterial pustule of soy beans, together with accounts of the relation of this disease to

other soy bean leaf spots of bacterial origin, studies on the etiology of the disease, and on the morphology and physiology of the causal organism.

This disease, which is prevalent in North Carolina and also known to occur in Texas, Louisiana, South Carolina, Virginia, and Kansas, is said to be quite distinct from bacterial blight and from bacterial diseases of the soy bean which have been described from the Orient. The disease is apparently confined to the foliage and is caused by the organism described by Hedges as *Bacterium phaseoli sojense* (E. S. R., 48, p. 48). The author of the present paper reports his inability to find any morphological or physiological characters by which this organism can be differentiated from *B. phaseoli*.

**A study of bacterial pustule of soybean, and a comparison of *Bact. phaseoli sojense* Hedges with *Bact. phaseoli* EFS., F. HEDGES** (*Jour. Agr. Research* [U. S.], 29 (1924), No. 5, pp. 229-251, pls. 7).—In a previous publication the author gave a brief account of a pustule disease of soy bean, and attention was called to the similarity of the causal organism *B. phaseoli sojense* with *B. phaseoli*, the cause of bean blight (E. S. R., 48, p. 48).

In the present paper an account is given of further studies as to the identity of the two organisms, and their morphological and physiological characters are contrasted. They are said to differ in some of their cultural characters as well as to reactions when used to inoculate soy beans and species of *Phaseolus*. The organism from soy beans is said not to produce pustules on *Phaseolus*. *B. phaseoli* is only weakly pathogenic to soy beans, and in none of the experiments does it form pustules such as are characteristic of the soy bean disease.

**Apple storage investigations, H. H. PLAGGE and T. J. MANEY** (*Iowa Sta. Bul.* 222 (1924), pp. 64, figs. 16).—In continuation of investigations on apple storage (E. S. R., 43, p. 38) the authors give accounts of studies on the development and control of Jonathan spot, soft scald, apple scald, and internal breakdown in storage as influenced by orchard and storage conditions.

**I. Jonathan spot and soft scald** (pp. 2, 5-36).—Storage temperatures were found to influence the development of Jonathan spot, the proportion of spotting increasing with temperatures above 32° F. It also increased with relative humidity. Variation in size of fruit was found to have little effect on the development of spotting, and varying soil treatments did not control it. No relation was found to exist between temperature, rainfall, and sunshine during the growing period and the occurrence of Jonathan spot in storage.

The time of placing in storage, in relation to picking, and the kind of storage were found to be important factors. Immediate placing of fruit in cold storage is said to be better than delayed cold storage or ordinary storage. A constant air movement or wrapping fruit in oiled papers did not control Jonathan spot. This type of spotting is said to have been more severe during the latter part of the cold storage season and increased according to the time the fruit had been in storage. It is stated that Jonathan apples should not be held in storage longer than the first of January.

With reference to soft scald of Jonathan apples, maturity of the fruit when placed in storage and time of storing were found to be important factors. Delaying storage after picking or storing immature fruit resulted in increased scalding. Aeration and ventilation together reduced scalding, but aeration alone did not. Oiled wrappers did not control scald. Internal breakdown was not found to be a factor in the storage of Iowa Jonathan apples.

**II. Apple scald and internal breakdown** (pp. 37-64).—The authors have given an account of the amount of scald developing on Grimes apples grown under each of the four types of soil culture practiced at the station orchard at Council Bluffs, Iowa. No wide differences in the amount of scald were observed that could be attributed to soil treatment, although there was a slight

decrease in scald on apples from the blue grass plats, and this was attributed to the earlier maturity of the fruit. In the experiments maturity was found to be an important factor in scald development, Grimes apples picked in an immature condition having scalded badly. Delayed storage decreased the amount of scald on mature fruit, but the decrease was not always in proportion to the amount of delay. Aeration did not control apple scald. Oiled wrappers were found more effective as a scald preventive than aeration, and apples in an immature condition responded best to this treatment. Apples were said to have scalded worse when placed in wax or tin-foil wraps than in common paper wraps or unwrapped. Artificial scald, produced by ethyl acetate and acetaldehyde, was delayed or entirely prevented by wrapping apples in oiled wraps.

Experiments with Grimes apples are said to have shown that the occurrence of breakdown increased with late picking, as well as with delayed storing. Late picking with immediate storage was found comparable to early picking with late storage in the amount of breakdown. Wrapping fruit in oiled wraps and aerating the storage room were not effective in reducing internal breakdown, and differences in the rate of cooling between unwrapped, oiled paper wrapped, and common paper wrapped apples were slight and probably of no commercial significance. The effect of wrapping on temperature of apples was investigated and differences noted.

**Freezing injury of apples**, H. C. DIEHL and R. C. WRIGHT (*Jour. Agr. Research* [U. S.], 29 (1924), No. 3, pp. 99-127, pls. 5, figs. 12).—The investigations reported deal with determinations of the freezing points of many of the important commercially grown varieties of apples, with a study of undercooling and its relation to injury, and a determination of the effect of freezing on the bruising of the fruit, visual injury, keeping quality in storage, etc.

The freezing point of different apples varied somewhat, the average of all the varieties, both eastern and western grown, being 28.5° F., with a maximum of 29.4° and a minimum of 27.8°. Cooling apples below their freezing points without the formation of ice in the tissues did not cause any visual injury or softening of the fruit. By undercooling isolated apples it was possible at times to carry them at 7 or 8° below their freezing point without ice formation, provided the fruit was left undisturbed. The bruising of apples while they are hard frozen resulted in a much more serious injury than a similar pressure on unfrozen fruit. As a consequence the authors suggest that handling of frozen apples will usually result in more or less severe bruising injury. Bruises made on apples before they are frozen do not become more serious as to depth when the fruit is frozen, nor do they change materially in appearance. No significant differences were observed in the depth of bruises on hard-frozen fruit when subjected to different thawing temperatures.

The point to which the internal temperature of an apple must be reduced before visual injury occurs was found to vary widely with the time of exposure to the temperature, with the variety, and with the individual apple. Wrapping fruit served to hinder the loss of heat from fruit under freezing conditions, and thereby delayed the formation of ice in the fruit tissues. Repeated freezing and thawing of apples caused a progressive increase in the freezing injury, though not so great an increase as a prolonged continuous exposure. The temperature at which apples are ordinarily thawed are said to have only a slight effect upon the subsequent condition of the fruit. There was found to be a distinct weakening in the keeping quality of the apples when they had been frozen, even when there was no visual evidence that freezing had occurred.

**Oiled paper and other oiled materials in the control of scald on barrel apples**, C. BROOKS and J. S. COOLEY (*Jour. Agr. Research [U. S.]*, 29 (1924), No. 3, pp. 129-135).—In continuation of previous investigations on the control of apple scald through the use of oiled wrappers (E. S. R., 50, p. 841), a report is given of experiments in which various materials were tested for the control of scald in barrel apples. Oiled barrels and oiled liners reduced scald on the outside apples but had little effect upon the package as a whole. Oiled straw, shredded oiled paper, and layers of oiled wrappers gave practically as good scald control as wrapping the apples in oiled paper. The success of these various treatments is believed to depend on the thoroughness with which the oiled material is distributed in the package. Shredded oiled paper is considered to furnish the most promising method of scald control for apples in barrels.

**Diseases of stone fruits on the market**, D. H. ROSE (*U. S. Dept. Agr., Farmers' Bul. 1435 (1924)*, pp. II+17, figs. 7).—A description is given of a number of diseases of stone fruits, particular attention being given to the market phases of the problem, but field phases are treated when reference to them helps to explain the conditions which may arise during the marketing process.

**Studies on banana anthracnose**, R. A. TORO (*Jour. Dept. Agr. Porto Rico*, 6 (1922), No. 4, pp. 23, pls. 5).—Banana anthracnose (*Gloeosporium musarum*), said to have been originally described from Australia, first reported in the United States in 1892, and probably first introduced into Porto Rico some time before it was reported in 1918, is important, so far as this island is concerned, chiefly or only in connection with shipping and marketing, as this condition affects returns in both northern and southern markets.

Even when inoculated from the same culture the spores show great differences in size from different varieties. The behavior of different forms in a culture medium furnished a more definite clue for separation between them. Spores throw out one or two germ tubes, which usually remain single celled. Appressoria form in contact with the glass slides.

Other hosts which may be attacked are cowpea, mango, avocado, and guava. Tomato gave doubtful results.

The mycelium contains a substance which dissolves the parenchyma tissue of mature bananas, but does not affect unripe bananas or epidermal cells of mature or immature fruit.

Susceptibility or resistance does not depend on the tannin content of the peel. Possibly mechanical injury is followed by a change in the chemical composition, developing sugar in the peel. Dryness and coolness, which are essential to measures intended to lower injury, require methods securing adequate aeration.

**Observations on diseases of coffee and trees used for shade** [trans. title], F. D. KERN and H. H. WHETZEL (*Rev. Agr. Puerto Rico*, 13 (1924), No. 1, pp. 7-11, figs. 2).—The most important disease observed in coffee trees was a root rot supposedly due to at least one fungus and associated, usually, with one resembling *Rosellinia* sp. in the crown or roots. The gradual introduction and growing of resistant trees is regarded as a practical measure. A suspected disease of guava, used for shade in coffee plantations, may be due solely to a borer.

**Progress report on big bud and reversion of black currants**, A. H. LEES (*Univ. Bristol, Agr. and Hort. Research Sta. Ann. Rpt., 1923*, pp. 69-72).—The author points out that general conclusions as to this work, previously noted (E. S. R., 49, p. 649; 51, p. 52), can not yet be drawn further than to state that, as regards reversion, the number of new infections has decreased each year,

and there is no evidence that reverted bushes act as sources of infection. As regards big bud, a vigorous removal of big buds in the winter considerably reduces the infection the following year, even with bad cases, and mildly attacked bushes show no appreciable reduction of crop.

**The structure of reverted black currants**, W. F. F. RIDLER (*Univ. Bristol, Agr. and Hort. Research Sta. Ann. Rpt., 1923, pp. 73, 74*).—The work of Lees (E. S. R., 49, p. 649), describing a method for the purpose of identifying cases of black current reversion, has been followed up to ascertain whether there be differences between reverted and normal plants that can be reliably or decisively correlated with presence or absence of the disease. For this purpose a large number of normal and reverted plants were examined in considerable detail, sections being cut from every part of the plants, which were grown at Long Ashton, and included Edina, Seabrook Black, Boskoop Giant, and Baldwin.

“Briefly, the main differences showing to a greater or lesser extent all through the plant are a reduction in the amount of wood and a consequent increase in medullary ray tissue, coupled with a tendency to produce more gum in the reverted plant than in the normal.”

**A leaf and corm disease of gladioli caused by *Bacterium marginatum***, L. McCULLOCH (*Jour. Agr. Research [U. S.], 29 (1924), No. 4, pp. 159–177, pls. 5, fig. 1*).—A detailed account is given of investigations on the bacterial disease of gladiolus due to *B. marginatum*, a preliminary account of which has been noted (E. S. R., 45, p. 752). This disease has been under observation for a number of years and has been found in the District of Columbia, Michigan, Ohio, Pennsylvania, Maryland, Virginia, Florida, California, and Indiana. The leaf injuries vary from minute, reddish spots to large, brownish areas occurring abundantly on the lower part of the leaves. Infected corms are more or less disfigured by circular, shallow depressions. These are usually brown in color, horny or brittle in texture, and exude a gummy substance. Isolations of the organism have been made from the different parts of the plant, and its pathogenicity established by inoculation experiments.

There is said to be evidence that the organism remains alive in the soil in which diseased plants have been grown. Crop rotation should be practiced. Control measures have not been sufficiently developed to warrant recommendation, but considerable success has resulted from treating the corms with corrosive sublimate or formalin solutions.

**The depth distribution of the root-knot nematode, *Heterodera radicola*, in Florida soils**, G. H. GODFREY (*Jour. Agr. Research [U. S.], 29 (1924), No. 2, pp. 93–98, figs. 5*).—The results are given of a study designed to determine the relative root-knot nematode content of certain soils at different depths and at different seasons. Samples of soils at desired depths were taken and placed in flower pots in which tomato seedlings were planted. The occurrence of the nematodes was based on an estimate of the relative number of knots produced on the tomato roots. It was found that the nematodes are often very numerous to a depth greater than that ordinarily reached by plows, and considerable variation from one spot to another and from one month to another was found in the depths of the regions of maximum infestation. A number of factors are believed to influence the distribution, among them the depth penetration of infested roots, the relation of the time of taking soil samples to a period of heavy rainfall, the height of the water table, and the type of the soil and the subsoil. The influence of these factors may be so great as to overcome any seasonal change, such as would occur between one month and the next. During the winter months a considerable reduction in the total root-knot nematode content of the soil is said to be evident.

## ECONOMIC ZOOLOGY—ENTOMOLOGY

**Herons of the United States**, T. G. PEARSON (*Natl. Assoc. Audubon Soc.* *Bul.* 5 (1924), pp. 38, pls. 4, figs. 12).—This is a semipopular account of the herons in this country, there being 17 species and subspecies of the family Ardeidae in the United States.

**Some insecticidal properties of the fatty acid series**, E. H. SIEGLER and C. H. POPENOE (*Jour. Agr. Research [U. S.]*, 29 (1924), No. 5, pp. 259-261).—The authors show that, contrary to existing theories, the fatty acid radicals of soaps rather than the alkaline constituents are responsible for their insecticidal value, the fatty acids freed through hydrolysis of soaps in dilute solution providing the toxic principle. Experiments so far conducted indicate that the toxicity of the fatty acids increases with the molecular weight, at least to a certain point not yet definitely determined. The peak of toxicity in the fatty acid series appears to lie near capric acid. Capric acid killed more than 99 per cent of the apple aphid at a dilution of 1 to 1,200, lauric acid killed 92 per cent at the same dilution, and myristic acid 78 per cent. Paralysis is complete and practically immediate when aphids are subjected to toxic strengths of the fatty acids. In tests on the black chrysanthemum aphid (*Anuraphis sanborni* Gill.) the mortality caused by nicotine sulfate was indicated by the large percentage of dead aphids which dropped from the sprayed plants, while with the fatty acids the dead insects remained attached by their inserted beaks, affording no gauge of toxicity until the actual counts were made.

The fatty acids showed unusual wetting and spreading powers when applied in the emulsion form to either insects or foliage, wetting readily such insects as the polished black aphids, the squash bug, and hairy caterpillars. Leaves having a waxy covering, such as nasturtium and cabbage, were found to be easily and evenly coated. The physiological action of the fatty acids on the insect organism is as yet undetermined. Experiments so far conducted indicate that the toxicity of the fatty acids increases with the molecular weight, at least to a certain point not yet definitely determined. No variation in toxicity is experienced under varying summer temperatures and humidity, thus differing from the action of nicotine. No injury to chrysanthemum plants was shown by dilutions fatal to the black chrysanthemum aphid, but the foliage of nasturtium is injured by the dilutions required to kill the bean aphid.

Tests toward the practical application of the insecticidal properties as shown by preliminary work with the long-chain fatty acids resulted in the selection of a product commercially known as "double distilled coconut fatty acids" as the most promising. Difficulties in the preparation of a stock solution and the retention of the insoluble acids in a stable emulsion have been met by the addition of an equal amount of benzol gasoline to the commercial fatty acids, afterwards using powdered glue as a colloidal stabilizer. When used in tests in the proportions of 1 part of the coconut fatty acids to from 800 to 1,200 parts of water, a mortality rate of from 94 to 98 per cent of the apple aphid was obtained, equivalent to the rate obtained with commercial 40 per cent nicotine sulfate in parallel tests at the same dilutions.

"The spreading power of the emulsion is excellent, toxicity high, and cost of material extremely low. Prepared by this formula, coconut fatty acids have compared favorably in efficiency, pound for pound, in the experiments so far conducted, with commercial nicotine preparations at less than one-fourth the cost per gallon of spray mixture."

**Oil sprays: Their preparation and use for insect control, A. L. MELANDER, A. SPULER, and E. L. GREEN** (*Washington Col. Sta. Bul. 184 (1924), pp. 31*).—This is a summary of information on oil sprays based upon work conducted in continuation of that previously noted (*E. S. R., 51, pp. 157, 158*).

The so-called neutral type of lubricating oil gave the best results in experiments with dormant sprays in 1924. Heavier oils apparently lack penetration, and lighter oils do not have sufficient body. Used crank case oil is not dependable because of its uncertain composition. Some proprietary oils have not been efficient, and others vary in composition from year to year. The authors consider cresoap, made from potash fish-oil soap and cresylic acid, to be the best emulsifier for miscible oil. A miscible oil which requires no boiling, pumping, or complicated equipment in its preparation is composed of lubricating oil and cresoap, 90 and 10 per cent by weight or 91 and 9 per cent by volume, respectively. It can not freeze, does not spoil on standing, and in field tests has given better results than any other oil spray, its increased efficiency more than making up for its greater cost. Caseinate spreader and glue are considered the best nonsoap emulsifiers for emulsion stocks. It was found that kerosene can be emulsified more easily with cresoap or caseinate than with boiling soap. Emulsion stocks should not be made to contain more than 75 per cent of lubricating oil or 67 per cent of kerosene, or a reversed emulsion will result which will not mix with water.

If a spray emulsion breaks, the watery portion may be too weak to be effective and the oily scum is injurious if sprayed on trees. It is pointed out that soap emulsions should be used where the water is soft or alkaline, and non-soap emulsions where the water is hard. The dormant sprays of lubricating oil should be applied when buds begin to swell in early spring. Sprays for scale insects should contain 4 per cent of actual oil, and for leaf roller 8 per cent, a 2 per cent oil spray being too weak for the San José scale under Washington conditions. As a summer spray, 1 per cent of oil is useful for red spiders and for crawlers of scale, but is not strong enough for old scale or aphids. Summer sprays containing more than 1 per cent of oil may cause spray burn if used in very hot weather or on delicate plants. A trouble chart for oil sprays is included.

Work with lubricating oil emulsions by Yothers et al. in Florida (*E. S. R., 39, p. 160; 43, p. 157; 50, p. 239*); Quaintance (*E. S. R., 47, p. 453*), Ackerman (*E. S. R., 49, p. 354*), and Isely (*E. S. R., 51, p. 552*) in Arkansas; Flint (*E. S. R., 49, p. 355*) and Carver and Compton (*E. S. R., 51, p. 361*) in Illinois; Davis in Indiana (*E. S. R., 51, p. 361*); Haseman and Sullivan (*E. S. R., 49, p. 253*) and Burroughs (*E. S. R., 50, pp. 51, 657*) in Missouri; Newcomer in Washington (*E. S. R., 50, p. 844*); Weigel and Broadbent (*E. S. R., 52, p. 61*); and Sullivan and McBride (*p. 658*) has been noted.

**Making oil sprays, A. L. MELANDER** (*Wash. State Col. Ext. Bul. 129 (1925), pp. 10*).—This is a summary of the bulletin noted above.

**Loss of nicotine from nicotine dusts during storage, C. C. McDONNELL and H. D. YOUNG** (*U. S. Dept. Agr. Bul. 1312 (1925), pp. 15, figs. 13*).—The results of investigations conducted by the Bureau of Chemistry are here presented, in large part in tabular and chart form.

The rate of loss of nicotine from nicotine sulfate dusts prepared with kaolin, kieselguhr, talcum, plaster of Paris, calcium hydroxide, and calcium carbonate took place in the order named. Dusts made with free nicotine solution lose their nicotine much more rapidly than those made with nicotine sulfate. Air-tight metal or glass containers only should be used for packing the dusts. A rapid loss of nicotine from plaster of Paris-nicotine sulfate dusts is thought to

have been due to the presence of calcium carbonate as an impurity in the plaster of Paris. Nicotine sulfate solutions became concentrated to about 45.5 per cent nicotine, owing to evaporation, when they were exposed to the air at room temperature, but with little or no loss of nicotine. Under the same conditions solutions of free nicotine lost, in addition to water, from 10 to 17 per cent of the nicotine originally present, and reached a concentration of 89 per cent nicotine, which remained unchanged under the conditions of the test.

**The preparation from tobacco of a solution for spraying,** O. M. SHEDD and A. J. OLNEY (*Jour. Econ. Ent.*, 17 (1924), No. 6, pp. 650-656).—This is a contribution from the Kentucky Experiment Station, in which the authors state that common tobacco trash is the only grade of Kentucky tobacco, other than stems and stalks, that can be used profitably at present prices for making a spray solution. It has a wide variation in nicotine content, ranging in 79 samples of white Burley and dark tobacco from 0.26 to 4.50 per cent in the air-dry trash. Infusions made from 26 samples of trash, using such quantities of cold water as would give from 0.05 to 0.07 per cent of nicotine in the solution, as computed from analyses of the samples, were about equally effective in exterminating aphids. Lower concentrations were not as satisfactory.

Blackleaf 40 solution diluted to contain 3.5 per cent of nicotine did not injure tomato plants. Higher concentrations caused injury, which was partly preventable by soap.

**Lead arsenate, lime sulfur, and tobacco dust as a triple spray mixture,** L. R. STREETER (*Jour. Econ. Ent.*, 17 (1924), No. 6, pp. 656-658).—This is a brief report of work at the New York State Experiment Station conducted in connection with the investigation previously noted (E. S. R., 52, p. 501).

**[Economic insects and their control in Pennsylvania]** (*Penn. Dept. Agr. Buls.* 383 (1924), pp. 10, figs. 3; 386, pp. 7, figs. 7; 390, pp. 19, figs. 6, insert, pp. 2, fig. 1).—These practical summaries of information deal, respectively, with P D B (Paradichlorobenzene) and Other Controls for the Peach Tree Borer, by T. L. Guyton and J. R. Stear; The Round-headed Apple Tree Borer, by T. L. Guyton and J. N. Knull; and The Japanese Beetle in Pennsylvania, by C. H. Hadley.

**New termites and hitherto unknown castes from the Canal Zone, Panama,** T. E. SNYDER (*Jour. Agr. Research [U. S.]*, 29 (1924), No. 4, pp. 179-193, pls. 2, figs. 9).—While in the Canal Zone in February, 1924, two types of soldiers of similar form, belonging to the new subgenus *Uniformitermes* of the genus *Nasutitermes* Banks, were collected by the author. New species were found in two rare American genera, namely, *Cylindrotermes* and *Armitermes* (*Rhynchotermes*). In addition to biological notes, descriptions are given of seven new species. A list of the 36 termites, representing 15 genera, known to occur in the Canal Zone and near-by Panama is included.

**The comparative resistance of woods to the attack of the termite, *Cryptotermes brevis* Walker,** G. N. WOLCOTT (*Porto Rico Dept. Agr. and Labor Sta. Bul.* 33 (1924), pp. 15).—It is pointed out that of 13 species of termites at present known in Porto Rico, only 2 are sufficiently common to be of economic importance. *Nasutitermes morio* Latr., which builds large, rounded, dark-brown nests on the ground, on trees or posts, or in buildings, is controlled by destroying the main nest. This is accomplished by breaking open the top, or the main tunnels, of the nest and placing therein about a tablespoonful of a stomach poison, such as Paris green, arsenate of lead, or calomel.

The other common termite, *C. brevis* Wlk., which destroys furniture and the woodwork of houses, is a much more serious pest, since it builds no external

nest, and usually the only indication of its presence is the excrement, consisting of minute pellets, which appears beneath infested wood. So far as observed, it attacks only seasoned wood and usually that protected from rainfall. In tests conducted, extending over nearly a year, the details of which are presented in tabular form, it was found that mahogany and cypress are the two woods most desirable for use in resisting the attacks of termites.

"Mahogany is not entirely resistant, but cypress, at least in these experiments, has proved absolutely so, and appears to be almost as safe from termite attack as creosoted wood. Maga, cobana, ortegón, ausubo, mangrove, and black walnut also prove to be desirable woods, while, quite surprisingly, California redwood is not as resistant as genuine white pine, or as yellow cedar. Cedro is far down the list, and eucalyptus, despite its odor, is one of the woods preferred by termites. Sitka spruce is preferred to almost any other wood and is consequently the least desirable wood that can be used for construction in Porto Rico. . . . While creosoting any wood makes it unattractive to the termites, it does not protect it from attack on any of its uncovered surfaces."

A list is given of 50 woods tentatively arranged in order of their resistance.

**Tree cricket injury to prunes**, M. A. YOTHERS (*Jour. Econ. Ent.*, 17 (1924), No. 6, pp. 661, 662, pl. 1).—This is a brief account of injury by *Oecanthus* spp., which when about two-thirds grown begin feeding on half-grown prunes, gnawing holes on the surface and often deep down into the fruit. During the past few years they have become one of the most important insect enemies of the prune in southern Idaho.

**Studies in the control and biology of capsids on apple trees** [trans. title], S. ROSTRUP and M. THOMSEN (*Tidsskr. Planteavl.*, 29 (1923), No. 3, pp. 395-461, figs. 11).—This is a report of experiments in Denmark, in which a spray containing 0.1 per cent of nicotine with 1 per cent of soap was used with a view to determining the most suitable time for application. The experiments of 1919 are said to confirm the conclusion reached in the three preceding years, that the second spraying, just prior to blossoming, is most efficacious against the capsids, the first being too early and the third practically neutral. An account of the biology of *Plesiocoris rugicollis*, the main cause of the injury, and *Lygus pabulinus* is included and reference is made to several other species of importance.

**Calcium cyanide dust for control of the grape leaf hopper**, H. J. QUAYLE (*Jour. Econ. Ent.*, 17 (1924), No. 6, p. 668).—This is a brief report of experimental work at the Citrus Experiment Station, Riverside, Calif., in 1923 and 1924, with the overwintering grape leafhoppers. The author finds that when calcium cyanide dust is blown into the vine the leafhoppers are quickly overcome and fall to the ground. If there are no cyanide particles on the ground the hoppers will recover, but if there is a slight deposit of the cyanide on the ground sufficient gas will be given off to prevent their recovery.

**Causes of fluctuation in numbers of beet leafhoppers (*Eutettix tenella* Baker) in a natural breeding area of the San Joaquin Valley in California**, H. H. P. SEVERIN (*Jour. Econ. Ent.*, 17 (1924), No. 6, pp. 639-645).—The author reports that the primary cause for the enormous reduction in numbers of the spring brood of beet leafhoppers during 1923 was the early drying of the pasture vegetation during March, instead of April and May as in previous years from 1919 to 1922. Secondary factors which reduce the number of leafhoppers in a natural breeding ground are natural enemies, spring and summer migrations, fungus diseases, and rainfall.

**The effects of oil spray on apple aphids**, K. C. SULLIVAN and O. C. McBRIDE (*Jour. Econ. Ent.*, 17 (1924), No. 6, pp. 658-660).—Experiments conducted with the apple-grain aphid in Missouri indicate that neither lime sulfur

nor lubricating oil emulsions can be recommended for complete control of apple aphids.

**A bacterial disease of silkworms**, R. W. GLASER (*Jour. Bact.*, 9 (1924), No. 4, pp. 339-355, figs. 4).—In this contribution from the department of animal pathology of The Rockefeller Institute for Medical Research, at Princeton, N. J., an account is given of a bacterial disease which appeared and rapidly assumed epidemic proportions among the author's silkworm cultures. The external appearance of diseased living and dead worms is described, and an account of the histo-pathology of the disease is given. A bacillus was isolated from the feces, blood, and various tissues of diseased living and dead worms, which has been demonstrated to be the causative agent. The investigations show that dying and dead worms infect the food of normal silkworms by means of the feces and body fluids. Some evidence is advanced to show that the disease-producing bacillus is not transmitted from generation to generation through the egg. The possible relation of this disease to the flacherie-like affections of silkworms is mentioned, and its distinctness from pébrine, muscardine, and the polyhedral disease, also termed "jaundice," "gelbsucht," or "grasserie," is emphasized.

**The greenhouse leaf-tyer**, *Phlyctaenia rubigalis* (Guenée), C. A. WEIGEL, B. M. BROADBENT, A. BUSCK, and C. HEINRICH (*Jour. Agr. Research [U. S.]*, 29 (1924), No. 3, pp. 137-158, pls. 2, figs. 3).—This is a report of studies of the life history and habits of and control measures for one of the more important enemies of chrysanthemum, cineraria, snapdragon, rose, violet, and many other ornamental and greenhouse plants. In several instances its attack has resulted in complete destruction of the plants. The species, which is of American origin, having been described by Guenée in 1854, has frequently been mistaken for the closely related European species *P. ferrugalis* Hübn.

Nine distinct generations were reared during 1921, indicating that there may be a definite overlapping of generations throughout the year under greenhouse conditions. The destruction of plants is due to the feeding of the larvae, which later increase the injury by tying themselves up in the foliage prior to pupation, thus causing further disfigurement and consequent decrease in commercial value. The pupae are well protected by the formation of the pupal case within tied leaves lined with a rather tough silken cocoon. The adults are nocturnal in habit. A systematic description of the adult and immature stages is by Busck and Heinrich.

Spiders and ants are important enemies, and single records have been made of parasitism by *Synetaeris* sp., *Apanteles glomeratus* L., and *Phorocera parva* Bigot. Control experiments indicate that the adults may be successfully held in check by fumigation for an hour, twice, with an interval of 7 days, with hydrocyanic acid gas at the rate of 1 oz. of sodium cyanide per 1,000 cu. ft. of air space, or by dusting with a 5 per cent nicotine sulfate dust. The eggs were found to be impervious to contact insecticides, the larvae succumbed to the effects of arsenical poisons when applied either in the dry or liquid form, and the pupae were virtually immune from all artificial control measures, except hand picking, because of their protection and resistance. A list of 13 references to the literature cited is included.

**Dosing the root borer with paradichlorobenzine**, C. J. McINTOSH (*Better Fruit*, 19 (1924), No. 3, pp. 5, 6, fig. 1).—The author reports that under Oregon conditions this chemical must be applied during late August or early September. Experimental work with spring treatment is under way.

**A supposedly beneficial insect discovered to be a citrus pest**, A. J. BASINGER (*Jour. Econ. Ent.*, 17 (1924), No. 6, pp. 637-639).—This is a contribution from the Citrus Experiment Station at Riverside, Calif., in which the

larva of the moth *Holcocera iceryaella* Ril., formerly recorded as a scale predator and a scavenger, is reported to be also a secondary feeder on oranges, causing damage similar to that of *Tortrix citrana* Fer.

**The azalea leaf miner (Lepid.: Tineidae), F. M. TRIMBLE** (*Ent. News*, 35 (1924), No. 8, pp. 275-279, pl. 1).—This is a brief account of *Gracillaria azaleella* Brants, which is the cause of the loss of leaves on azaleas in greenhouses. The pest is a native of Japan and was imported into this country on azaleas from Belgium and the Netherlands, where it had been received from Japan on young plants, having been first observed by E. P. Felt in New York in 1911. It has since been found in greenhouses throughout Pennsylvania and has been reported many times from other Northern States and Canada. Cyanide fumigation, followed later by alternate night fumigations with nicotine sulfate, is said to control the pest.

**Notes on Japanese Lepidoptera and their larvae, VI, VII, A. E. WILEMAN** (*Philippine Jour. Sci.*, 19 (1921), No. 2, pp. 209-231, pls. 2; 25 (1924), No. 1, pp. 75-109, pls. 2).—These contributions are in continuation of the work previously noted (E. S. R., 40, p. 456).

**The Bombyliidae of the Ethiopian region, M. BEZZI** (*London: Brit. Mus. (Nat. Hist.)*, 1924, pp. VIII+390, figs. 46).—This is a monographic account, based upon material in the British Museum (Natural History). Three hundred twelve forms, representing 30 genera, are dealt with. Tables for the separation of, and an index to, the genera and species are included.

**Combating the olive fly in Corfu** [trans. title], J. SORDINAS (*Redia*, 15 (1924), No. 1-2, pp. 97-103; *abs. in Rev. Appl. Ent.*, 12 (1924), Ser. A, No. 5, pp. 190, 191).—A successful campaign against the olive fly (*Dacus oleae*) in Greece led to the application of the same measures in Corfu in 1921, namely, the application of a modified De Cillis spray containing 900 parts by weight of water to 100 parts of molasses and 3 parts of sodium arsenite. Four applications were made to olive trees throughout the island, at the end of June, July, and August, and from mid-September to early October, with another in the low-lying districts, especially on the coast, where the flies of the third generation may do great damage and even destroy the entire crop.

The work resulted in the preservation of the entire crop and, incidentally, in the destruction of the common flies, mosquitoes, wasps and hornets, and *Lasioptera berlesiana*, another dipterous enemy of olives. The destruction of mosquitoes led to the total absence of malaria in 1921. Bees did not touch molasses containing sodium arsenite. It is reported that in neighboring small islands that were not treated, or incompletely so, between 20 and 100 per cent of the olive crop was lost.

**The bee-louse, Braula coeca, in the United States, E. F. PHILLIPS** (*U. S. Dept. Agr., Dept. Circ.* 334 (1925), pp. 12).—This summary of information includes a review of the literature in connection with a list of 39 references on *B. coeca*, a minute wingless dipteran which has been introduced into this country from Europe and is known to occur in Carroll County, Md., a small area in south-central Pennsylvania, and at Mankato, Minn. It infests honeybees only, being usually found on worker bees, rarely more than one to a bee, though under some circumstances it may collect in larger numbers on the queen bees. It is not known to damage colonies, and no serious harm is anticipated from its establishment in this country.

**The blueberry leaf-beetle and some of its relatives, H. C. FALL and W. C. Woods** (*Maine Sta. Bul.* 319 (1924), pp. 81-140, pl. 1, figs. 2).—In the first part of this bulletin (pp. 81-91), Fall presents a systematic account of the New England species of *Galerucella*. A key for their separation is followed by

notes on 16 species, of which 5, namely, *G. kalmiae* on laurel, *G. vaccinii* on blueberry, *G. spiraeae* on meadowsweet, *G. alni* on alder, and *G. perplexa* on willow are described as new.

In the second part (pp. 92-140), Woods deals with the economics and biology of 15 species of the genus *Galerucella*, of which all but 4 have been known to occur in Maine. The biology and control of the blueberry leaf-beetle (*G. vaccinii* Fall) (pp. 93-105), the gray willow leaf-beetle (pp. 105-112), the brown willow leaf-beetle (pp. 112-115), the brown alder leaf-beetle (pp. 115-122), the meadowsweet leaf-beetle (*G. spiraeae* Fall) (pp. 122-127), and the laurel leaf-beetle (*G. kalmiae* Fall) (pp. 127-133) are considered at length, and brief notes are given on the other species, including the cherry leaf-beetle (*G. cavicollis* LeC.), the azalea leaf-beetle, the pond-lily leaf-beetle (*G. nymphaeae* L.), the elm leaf-beetle (*G. xanthomelaena (luteola)*), the smooth goldenrod leaf-beetle, *G. americana* Fab. and *G. conferta* LeC., the boneset leaf-beetle, and the ragweed leaf-beetle.

**Longevity and fecundity of *Bruchus quadrimaculatus* Fab. as influenced by different foods**, A. O. LARSON and C. K. FISHER (*Jour. Agr. Research [U. S.]*, 29 (1924), No. 6, pp. 297-305).—The authors find that the weevil *Mylabris quadrimaculatus*, officially known as the four-spotted bean-weevil, in its normal condition in the warehouse lives a shorter time without food than when it has access to water or sweetened water. The difference in the average length of life of the weevils receiving no food and those receiving water varied from less than 3 days with the lone males to 11 with the lone females. Access to water lengthened the lives of the pairs about 10 days, and sugar water lengthened their lives from 13 to 27 days as an average for different groups of weevils. Access to water increased the average number of eggs laid by about 30 per cent, and access to sugar water about 50 per cent.

"Food reduced the number of eggs laid during the first few days of oviposition, but lengthened the time over which eggs were laid. Viable eggs were laid over twice as great a period of time by weevils receiving sugar water as by those without food. Frequent mating, such as occurs normally under storage conditions, reduced the length of life of both males and females. Females which mated only once during the first few hours after emergence deposited large numbers of fertile eggs. Virgins deposited only small numbers of infertile eggs and in no case produced fertile eggs."

**Fumigation against grain weevils with various volatile organic compounds**, I. E. NEIFERT, F. C. COOK, R. C. ROARK, W. H. TONKIN, E. A. BACK, and R. T. COTTON (*U. S. Dept. Agr. Bul. 1313 (1925)*, pp. 40, fig. 1).—This is a report of investigations conducted cooperatively by the Bureaus of Chemistry and Entomology, in which the action of 100 organic compounds was tested on several species of weevils under conditions permitting a control of the factors of concentration, time, and humidity, and with observations of the temperature.

Thirty compounds which were more toxic to the rice weevil than carbon disulfide include 2 of 8 bromides tested, 3 of 15 chlorides, the only iodide tested, 1 alcohol of 8 alcohols and phenols, 3 of 4 aldehydes, 2 of 4 ketones, both of the chlorine-substituted ketones tested, 1 of 2 chlorohydrins, 5 of 9 esters, 4 of 12 sulfur compounds, 1 nitrile of 5 nitriles and isonitriles, both of the nitrites tested, 2 of 8 amines, and pyridine. The relative toxicity of the different classes of compounds can not be given because the low volatility of several of those tested gave only very low vapor concentrations.

"As a class, the hydrocarbons showed the lowest insecticidal efficiency, not one of the 8 tested equaling carbon disulfide in fumigating power. The most effective fumigant in the glass-jar tests was epichlorohydrin, which killed the

rice weevil at a concentration of 0.09 per cent, equivalent to 8.23 lb. per 1,000 cu. ft. It was, however, an unsatisfactory fumigant in the presence of grain. There is no constant relationship between the boiling points and the lethal concentrations of the compounds killing 100 per cent of the rice weevils after exposure for 24 hours."

Ethyl formate and ethyl acetate were the only promising fumigants for grain in box cars, the acetate costing only about one-third as much as the formate. It was found that a pure grade of ethyl acetate leaves practically no odor in the fumigated grain or in the bran or shorts made from the grain, and none in the flour or in the bread baked from the flour. Under practical fumigating conditions the insecticidal efficiency of ethyl acetate is increased by the addition of carbon tetrachloride. Next to carbon disulfide, the most effective fumigant for weevils in wheat in grain cars under practical fumigating conditions is a mixture of about 40 volumes of ethyl acetate and about 60 volumes of carbon tetrachloride, which is noninflammable at ordinary temperatures. The proper dosage of this mixture for fumigating box cars is about 45 lbs. per 1,000 cu. ft. It is pointed out that both the ethyl acetate and carbon tetrachloride must be tested to be sure that they are from odoriferous constituents of low volatility before they are used in fumigating grain.

The work includes a list of 26 references to the literature cited.

**Ethyl acetate-carbon tetrachloride mixture**, E. A. BACK and R. T. COTTON (*Jour. Econ. Ent.*, 17 (1924), No. 6, p. 663).—This relates to the investigations noted above.

**Application of the Röntgen tube to detection of boring insects**, N. YAGHI (*Jour. Econ. Ent.*, 17 (1924), No. 6, pp. 662, 663).—This is a contribution by an entomologist of the Government Agricultural Experiment Station at Tokyo, Japan, in which it is stated that he has used the Roentgen tube for the detection of boring insects in their food substances with success.

**Another lead boring beetle**, W. J. CHAMBERLIN (*Jour. Econ. Ent.*, 17 (1924), No. 6, pp. 660, 661, fig. 1).—The author presents notes on a species of *Callidium* occurring in Oregon.

**Studies of the parasites of the alfalfa weevil in Europe**, T. R. CHAMBERLIN (*Jour. Econ. Ent.*, 17 (1924), No. 6, pp. 623-632).—This is a brief account of a study of the parasites of the alfalfa weevil made by the author in Europe between August, 1921, and August, 1923. Fourteen primary parasites were encountered, the habits and distribution of which are briefly considered. It is concluded that most of the more important forms can withstand a climate similar to that of Utah, and that it is advisable to attempt the colonization of the more promising.

**The brown vegetable weevil (*Listroderes (Desiantha) nociva*)**, T. McCARTHY (*Agr. Gaz. N. S. Wales*, 35 (1924), No. 8, pp. 573-580, figs. 2).—This is a report of studies of the pest in Australia, recent accounts of which in the United States by Bynum (*E. S. R.*, 49, p. 761), Harned (*E. S. R.*, 48, p. 852), and Chittenden (*E. S. R.*, 50, p. 57) have been noted.

**Injuries to peppers in California by *Anthonomus eugenii* Cano**, R. E. CAMPBELL (*Jour. Econ. Ent.*, 17 (1924), No. 6, pp. 645-647).—The pepper weevil was found in November, 1923, to be present in several pepper fields in southern California, this being the first record of its occurrence in that State. It was most abundant during November and December, when practically all of the late peppers in infested fields were destroyed. The injury to the pods resulted in decay, which usually started in the seed cluster, and in small peppers the growth was checked and the pods distorted.

**An enemy of the olive in Japan, *Hylobius perforatus* Roel.** (*Col., Curculionidae*) [trans. title], R. POUTIERS (*Bul. Soc. Ent. France*, No. 3

(1924), pp. 47, 48; abs. in *Internatl. Rev. Sci. and Pract. Agr.* [Rome], n. ser., 2 (1924), No. 2, p. 473).—The larva of the curculionid *H. perforatus* excavates galleries of increasing size, at times completely encircling the young olive branches, which wither and die.

**Report of the Maryland State Beekeepers' Association** (*Md. Agr. Soc., Farm Bur. Fed., Rpt.*, 8 (1923), pp. 318-346).—Included in this report is an account of Beekeeping in the Northwest, by E. F. Phillips (pp. 322-330); of Commercial Beekeeping, by J. I. Hambleton (pp. 330-337); of Comb Honey Production, by N. W. James (pp. 337-340); and a discussion on How Shall We Market Our Honey in Maryland? by G. Harrison, jr. (pp. 340-346).

**The presence of the Argentine ant in Valencia** [trans. title], R. FONT DE MORA (*Bol. R. Soc. Españ. Hist. Nat.*, 23 (1923), No. 2, pp. 77, 78; abs. in *Internatl. Rev. Sci. and Pract. Agr.* [Rome], n. ser., 1 (1923), No. 3, p. 780).—This pest is said to have appeared in the neighborhood of Valencia, Spain, and already to have become very common in the orange grooves, where it increases the injury caused by at least four coccids. It is not infrequently found in the gardens and nurseries.

**New chalcidids from France** [trans. title], R. GARCÍA MERCET (*Bol. R. Soc. Españ. Hist. Nat.*, 22 (1922), No. 9, pp. 396-402, figs. 4; abs. in *Internatl. Rev. Sci. and Pract. Agr.* [Rome], n. ser., 1 (1923), No. 3, pp. 782, 783).—Descriptions are given of *Tetrastichodes platanellus* n. sp., a parasite of the microlepidopteran *Lithocolletis platani*, and *Coccidencyrtus poutiersi* n. sp., parasitic on *Howardia zamiae*, in France.

**Polyscelis modestus Gahan, a minor parasite of the Hessian fly, P. R. MYERS** (*Jour. Agr. Research* [U. S.], 29 (1924), No. 6, pp. 289-295, figs. 2).—This is a report of observations of a parasite of the Hessian fly, first collected near Hanover, Pa., in 1915, and later reared from material collected in five additional localities in north-central Maryland and southeastern and south-central Pennsylvania. The species, which was described by Gahan in 1922 as new (*E. S. R.*, 48, p. 59), is of minor importance, not having been recovered since 1918. It attacks and destroys both the larvae and the pupae of the Hessian fly, as also the larvae and probably the eggs and pupae of its own species. It is occasionally hyperparasitic, probably on *Platygaster vernalis* (Myers). Females reproducing parthenogenetically are arrhenotokous. Before consumption by the parasite, the internal contents of the Hessian fly larvae undergo a process of liquefaction. This is thought to be caused by the injection of a secretion by the primary parasitic larva.

**Adirus trimaculatus Say, a rose pest, A. B. CHAMPLAIN** (*Jour. Econ. Ent.* 17 (1924), No. 6, pp. 648-650).—The author finds *A. trimaculatus*, a sawfly of the family Cephidae known as a borer in blackberry canes in the larval stage, to cause similar injury to rose stems in Pennsylvania.

## FOODS—HUMAN NUTRITION

**The digestibility of tepary beans, H. J. DEUEL** (*Jour. Agr. Research* [U. S.], 29 (1924), No. 4, pp. 205-208).—Following the usual methods employed in the extensive series of digestion experiments conducted at the Office of Home Economics, U. S. D. A. (*E. S. R.*, 51, p. 60), a study was made of the digestibility of tepary beans (*Phaseolus acutifolius*) for purposes of comparison with other legumes such as navy and kidney beans.

The beans were prepared by soaking overnight and cooking for an hour under 15 lbs. pressure and were eaten with a basal diet of bread, butter, fruit, and sugar. The beans supplied on an average 40 gm. of protein and 99 gm. of carbohydrate per man per day. The average results obtained

with the five subjects were as follows: Digestibility of the entire ration—protein 80.3, fat 93.2, carbohydrate 97.8, and ash 74.6 per cent; estimated digestibility of the tepary bean—protein 75.9 and carbohydrate 98 per cent. These values correspond closely to those reported by Wait (E. S. R., 19, p. 163) for the protein of navy and red kidney beans (78 per cent) and by Mendel and Fine (E. S. R., 26, p. 564) for the protein of navy bean (77.9), and are somewhat higher than the value (96 per cent) reported by Wait for navy bean carbohydrate.

A list of 31 references to the literature is appended.

**Vitamin A content of fresh eggs**, J. C. MURPHY and D. B. JONES (*Jour. Agr. Research [U. S.]*, 29 (1924), No. 5, pp. 253-257, figs. 4).—In this contribution from the Bureau of Chemistry, U. S. D. A., data are reported on the content of vitamin A in fresh eggs laid during the summer months by hens which had access to plenty of fresh green food.

The experiments were conducted on young rats, using both preventive and curative tests. In the former 0.75 gm. daily of egg proved adequate for normal growth and 0.5 gm. for growth at somewhat less than the optimal amount. In the curative experiments the rats were fed a vitamin A-free basal diet until the development of ophthalmia and were then fed the egg in different amounts. With 0.5 gm. there was prompt cure of ophthalmia and restoration of growth. With 0.25 gm., the time required for the cure of ophthalmia was somewhat longer and the rats made slightly poorer growth. With 0.1 gm., the growth recovery approximated that with 0.25 gm., but this amount proved insufficient to cure ophthalmia in some cases. The amounts of egg yolk corresponding to 0.75, 0.5, and 0.25 gm. of whole egg are calculated to be about 0.26, 0.17, and 0.088 gm., respectively. Attention is called to the fact that the amount required for growth approximates closely the 0.25 gm. reported by Hess to be the protective dose for rickets (E. S. R., 50, p. 165). It is further calculated that a little more than 0.05 gm. of the oil of egg yolk would be required for promoting growth and 0.025 gm. for curing ophthalmia. This is thought to indicate that egg oil has a vitamin A potency of between 2 and 4 per cent of that of the most potent cod liver oil.

**The effect of long-continued storage at low temperature on the vitamin-A content of eggs**, D. B. JONES, J. C. MURPHY, and O. MOELLER (*Amer. Jour. Physiol.*, 71 (1925), No. 2, pp. 265-273, figs. 2).—In this study the vitamin A content of eggs which had been stored in a frozen condition for 9 years was compared with that of fresh eggs as noted in the above paper.

No difference could be detected between the fresh and storage eggs except in the smallest amount fed, 0.1 gm. In this amount the fresh eggs appeared to be slightly more potent than the storage. The differences were, however, so slight as to be of little significance. It is concluded that no appreciable deterioration in the vitamin A content of eggs takes place on prolonged storage in a frozen condition.

**Hydrogen ion concentration in the human duodenum**, H. V. HUME, W. DENIS, D. N. SILVERMAN, and E. L. IRWIN (*Jour. Biol. Chem.*, 60 (1924), No. 3, pp. 633-645, fig. 1).—This paper reports electrometric determinations of the H-ion concentration of the human duodenum at frequent intervals before, during, and after the ingestion of considerable amounts of milk, cream, eggs, and crackers, respectively. The determinations were made by inserting a specially modified Hildebrand electrode in a duodenal fistula.

The minimum, maximum, and average pH values obtained in the four experiments were as follows: Milk 6.59, 7.33, and 6.91; cream 6.66, 7.91, and 7.17; egg whites 5.90, 7.65, and 6.95; and starch 6.19, 8.23, and 7.07, respec-

tively. These results are thought to indicate that the reaction of the duodenum is not affected by the type of food ingested.

Interesting observations were also made on the time of appearance of fragments of food in the liquid exuding from the fistulous opening. The approximate time of appearance of the different foods was starch 19 minutes, cream 31, egg white 37, and milk 41 minutes, respectively.

**Animal calorimetry.**—[XXV], **The relative specific dynamic action of various proteins**, D. RAPPORT (*Jour. Biol. Chem.*, 60 (1924), No. 3, pp. 497-511, fig. 1).—In this continuation of the series of studies on animal calorimetry by Lusk and his coworkers (*E. S. R.*, 51, p. 558), the specific dynamic action of beef, gelatin, casein, gliadin, codfish, and chicken was determined by the usual methods. These materials were selected on account of the extreme differences in their content of glycine and alanine, amino acids considered of special significance in specific dynamic action.

When given to dogs in portions each of which contained 6 gm. of nitrogen, these proteins showed practically the same specific dynamic action, although gelatin contains about 26 per cent of glycine and 9 per cent of alanine and casein approximately no glycine and 1.5 per cent of alanine.

The specific dynamic action of a mixture of gelatin and cystine was also determined in order to see whether there might be an increase in the heat produced from the formation of glutathione. No such effect was noted.

These results indicate that the specific dynamic action of proteins of varied amino acid content is not proportional to their content of glycine and alanine.

**Animal calorimetry.**—[XXVI], **The interrelations between certain amino acids and proteins with reference to their specific dynamic action**, R. WEISS and D. RAPPORT (*Jour. Biol. Chem.*, 60 (1924), No. 3, pp. 513-544, figs. 6).—In an attempt to explain the results reported in the previous paper the specific dynamic action was determined of various proteins alone and combined with glycine or alanine, and with other proteins.

Casein and glycine together showed no greater specific dynamic action than casein alone. Similarly, gelatin and glycine in an amount equal to the glycine content of gelatin had no greater specific dynamic action than gelatin alone. With glycine and a smaller amount of gelatin and with the same amount of gelatin and a larger amount of glycine there was a summation of effect. The specific dynamic action of alanine with casein or gelatin was no greater than that of the proteins alone.

With increasing quantities of beef there was an increase in the specific dynamic action proportional to the amount of protein metabolized. Meat and casein together were equivalent in specific dynamic action to the sum of both separately. Glycine and alanine together had a greater effect than either alone, but with glycine, alanine, and gelatin the effect was practically the same as with gelatin alone.

Evidence was also obtained that the absence of summation was not due to delay in intestinal absorption, and that the reactions which neutralize the effect of amino acids when combined with protein may occur in the blood or in the tissues outside of the gastrointestinal tract. It is concluded that other factors than the direct influence of the amino acids glycine and alanine contribute to or modify the specific dynamic action of protein. The possibility is suggested that gelatin and casein yield certain amino acids or polypeptides which react with glycine to neutralize its specific dynamic effect.

**Fat excretion.**—II, **The quantitative relations of the fecal lipoids**, W. M. SPERRY and W. R. BLOOR (*Jour. Biol. Chem.*, 60 (1924), No. 2, pp. 261-287).—In continuation of the investigation previously noted (*E. S. R.*, 48, p. 161), the

lipoid material of the feces of cats and dogs on diets furnishing known amounts of various fats and on sham diets equivalent to fasting has been analyzed for unsaponifiable matter and nonvolatile, volatile, total, solid, and liquid fatty acids with a view to determining the origin of fecal fat and its relation to fat metabolism.

The data obtained are thought to indicate that the fecal fat does not come directly from unabsorbed fatty material in the food. As evidence in support of this, it is shown that in many cases almost as much fatty material appears in the feces on a fat-free as on a fat-rich diet, that there is a considerable amount of fat in the feces during fasting, and that the fecal fat is different in composition from the food fat. That the fat of the diet has some influence on the fat of the feces, however, is shown by a higher proportion of solid fatty acids excreted on diets high in solid acids and a similar increase in the excretion of liquid fatty acids on diets containing large amounts of liquid fatty acids. The influence of food in general is shown by the greater lipoid excretion on fat-free diets than during fasting.

The most probable origin of fecal fat is thought to be in the blood. Evidence in support of this is the similarity in the lipoids of the blood and feces with regard to the ratios of solid to liquid fatty acids and the melting points of the nonvolatile fatty acids. Two possible explanations of this are advanced: (1) That the lipoid of the feces may be a true excretion of waste material from lipoid metabolism and (2) that it may be a leakage of usable fat due to fat excess. Indirect evidence is given in support of both of these.

**Catabolism of odd in comparison with even carbon fatty acids in man,** H. LUNDIN (*Jour. Metabolic Research*, 4 (1923), No. 1-2, pp. 151-176, figs. 3).—This and the following paper are contributions from the Physiatrie Institute at Morristown, N. J. In the investigation reported in this paper the author served as subject in an elaborate study of the metabolism of the odd carbon fat intarvin.

An adequate protein, low carbohydrate, and high fat diet was first used until acetone bodies appeared in the urine (about 7 days), when for 100 gm. of the natural fat the same amount of intarvin was substituted. This resulted in 4 days in a decrease in the acetone bodies from 3.3 to 1.5 gm. On returning to the natural fat the acetone bodies increased to 4.7 gm., and on increasing the carbohydrate from 20 to 70 gm. they again disappeared. During the intarvin period the fat absorbed was from 80 to 85 per cent as compared with 95 per cent for the natural fat.

In addition to total acetone bodies, determinations were made of  $\beta$ -hydroxybutyric acid, volatile acids, total organic acid, and individual organic acids. The data thus obtained showed that in the abnormal catabolism of a low carbohydrate-high fat diet when the fat is natural (an even number of carbon atoms),  $\beta$ -hydroxybutyric and acetoacetic acid are formed but no lactic nor pyruvic acid, while on the odd fat diet lactic or pyruvic acid or both are formed, with no  $\beta$ -hydroxybutyric and acetoacetic acid. These results are in accord with the Knoop theory of  $\beta$ -oxidation, and indicate moreover that the acidosis resulting from an improper balance of fat and carbohydrate in normal subjects does not disappear on the substitution of intarvin, but is simply of another kind. This shows that odd-carbon fats, as well as even, require carbohydrate for their complete utilization.

**Clinical observations with odd-carbon-atom fat (intarvin),** F. S. MODERN (*Jour. Metabolic Research*, 4 (1923), No. 1-2, pp. 177-188).—The conclusions drawn in the metabolic study noted above were substantiated by the clinical results obtained in the use of intarvin in several cases of diabetes. As has been generally reported, extreme difficulty was experienced in taking the

intarvin. Nausea and marked constipation were present in every case and gastrointestinal disturbances in several.

In general the portion of intarvin absorbed appeared to be utilized like natural fat, but from 15 to 25 per cent of the fat was excreted unchanged. A nitrogen-sparing action similar to that of ordinary fat was noted.

Three case reports are given in detail, two of diabetic subjects in whose diet intarvin was substituted for part of the natural fat in connection with insulin treatment, and one of a nondiabetic subject in whom ketosis was induced as in the subject of the previous study and intarvin then substituted for the natural fat.

Practically the only difference between the effect of intarvin and natural fat was the absence of ketosis on the former. The subjective symptoms accompanying ketosis were not relieved, nor was acidosis, as determined by plasma bicarbonate volume, lessened. The intarvin had essentially the same insulin requirement as natural fat.

It is concluded that "for the above reasons an odd-carbon fat is of no possible value in practical diabetic treatment. On account of the interesting theoretical and experimental opportunities opened up, however, it is a valuable contribution to the subject of diabetes and metabolism."

**The clinical assaying of insulin and the insulin requirement, R. M. WILDER** (*Endocrinology*, 8 (1924), No. 5, pp. 630-638).—In this discussion of the clinical method of assaying insulin by determining its glucose equivalent in diabetic patients of known history, various factors altering the glucose equivalent of insulin are discussed. High protein and high carbohydrate diets, acute diseases in complication, and various infections tend to increase the demand for insulin and starvation to lower it. "The fact that consistent values for the glucose equivalent of insulin have been obtained under standard conditions with patients of different ages and weights is evidence for the assumption that the action of insulin is directly on glucose, and that a definite chemical interaction occurs between insulin and glucose."

**The isolation of a hypoglycemia-producing principle from vegetables and the nature of the action of vegetable extracts on the blood sugar of normal rabbits, H. E. DUBIN and H. B. CORBITT** (*Jour. Metabolic Research*, 4 (1923), No. 1-2, pp. 89-104).—Evidence is presented that cabbage, celery, lettuce, and spinach contain both hyperglycemia- and hypoglycemia-producing substances, and that red beets and carrots contain the former but not the latter. By a method of fractionation with alcohol, followed by dinitrosalicylic or picric acid, the hypoglycemic substance is precipitated and the hyperglycemic left in the filtrate. From the precipitate the active substance may be obtained as a hydrochloride by decomposing with hydrochloric acid and alcohol and precipitating with ether. The yield is about 0.01 gm. per kilogram of the original substance. The purified substance is said to give positive nitrogen, sulfur, Molisch, and biuret tests and negative Millon and phosphorus tests. When injected into the blood it gives results similar to those produced by insulin. The delayed or prolonged action of glucokin of Collip (*E. S. R.*, 51, p. 66) is considered to be due to the presence of the hyperglycemic substance.

It is suggested that some relationship may exist between insulin and vitamin B, as shown by the similarity in method of preparation and certain properties.

**The uric acid problem.—An experimental study on animals and man, including gouty subjects, O. FOLIN, H. BERGLUND, and C. DERICK** (*Jour. Biol. Chem.*, 60 (1924), No. 2, pp. 361-471).—In this extensive investigation of uric acid metabolism the fate of uric acid injected intravenously into various animals was determined by analyses of the blood, urine, and tissues. In the experiments on human subjects, both normal and gouty, uric acid in the form

of lithium urate was injected intravenously, and subsequent analyses were made of the blood and urine.

The general conclusion drawn from the investigation is that uric acid, when injected into the blood stream, is partly taken up by the kidneys and partly destroyed in the blood stream. Differences in different animals and in man are due chiefly to the varying permeability of the kidneys to uric acid. In animals (dogs, cats, rabbits, and goats) the kidneys appear to be very permeable to uric acid and take up a large proportion of it almost immediately. In the dog, with the exception of the Dalmatian hound, the destruction of the uric acid in the circulating blood is extremely rapid at first, about 70 per cent of the amount injected being destroyed in the first 10 minutes and the rest in the next 2 hours. As the destruction in the blood proceeds the portion temporarily stored in the kidney goes back into the blood. In herbivorous animals such as goats and rabbits the destruction of uric acid is only about one-tenth as rapid as in the dog. The blood in all cases loses its power to destroy uric acid when removed from the living animal.

In man the intravenous injection of about 20 mg. per kilogram of uric acid in the form of lithium urate is followed by an increase in the uric acid content of the blood and eventually by the excretion of from 30 to 90 per cent of the amount injected. The high level of uric acid in human blood is thought to indicate a lack of responsiveness of the kidney. High protein diets tend to increase the permeability of the kidneys and thus lower the level of the circulating uric acid and at the same time produce a large excretion of endogenous uric acid.

In gouty subjects the lack of permeability of the kidneys is increased. This has suggested a new point of view for the dietetic treatment of persons with a tendency to gout. "It has long been recognized that such persons should abstain from food which is rich in purines, and it has also been thought advisable to reduce the endogenous production of uric acid by a sparing use of every kind of protein material. But our findings seem to indicate that the best dietetic method for reducing the circulating uric acid should be a purine-free diet containing enough protein to yield 15 to 20 gm. of nitrogen in the urine. The dietetic literature bearing on gout has probably greatly exaggerated the importance of abstaining from all food which contains any purine materials. A small amount of purine products should be of very little consequence provided that the diet is distinctly high in protein."

The experimental findings are thought to furnish proof that the muscles of gouty subjects contain no more uric acid than those of normal subjects, and that only cartilage and connective tissues are permeable to uric acid.

**Uric acid excretion**, A. E. KOEHLER (*Jour. Biol. Chem.*, 60 (1924), No. 3, pp. 721-736).—A more limited study than the above is reported of the effects of the intravenous injection of uric acid in the form of lithium urate on its content in the blood and urine of normal subjects, patients with renal insufficiency, and patients with other diseases.

With normal subjects, only about one-half of the injected uric acid was recoverable in the urine, thus pointing to a rapid destruction in the blood. In the case of renal insufficiency, there was a slight retention of uric acid in the blood. The results obtained with patients not having renal disturbances were similar to those obtained with the normal subjects except that the percentage recovery was somewhat lower and individual variations somewhat greater.

**The photoactivity of substances curative of rickets and the photolysis of the oxy-products of ultraviolet radiation**, I. N. KUGELMASS and I. MCQUARRIE (*Science*, 60 (1924), No. 1551, pp. 272-274).—The experiments reported

in this paper were planned to determine if possible the relationship between radiant energy and the various substances curative for rickets.

Substances known to be curative and noncurative for rickets were tested for the emission of ultraviolet radiation in the natural state, after having been made alkaline with 10 per cent potassium hydroxide and oxidized by treating with a current of pure oxygen, and after having been reduced with ammonium ferrotartrate. The method consisted in placing the substances to be tested in beakers covered with specially prepared photographic plate holders, containing in one case quartz and in the other glass screens covered with ultraviolet sensitive films. The whole apparatus was placed within a double light-proof container and allowed to stand for 24 hours, after which the plates were developed in a suitable medium.

Substances curative for rickets upon oxidization blackened the sensitive film through quartz but not through glass screens. The same substances untreated produced the same effect, though not to so marked an extent. The noncurative substances and the reduced substances, both curative and noncurative, did not blacken the sensitive film through either quartz or glass.

It is concluded that the curative substances upon oxidization give off ultraviolet rays similar to those emitted by the quartz mercury vapor lamp.

"The experiments recorded may be applicable to physiologic phenomena in general. Not only do they suggest the mechanism common to all rickets-healing processes and imply a method to measure the therapeutic potency of the curative agents, but they also disclose the fact that solar energy exerts a hitherto neglected function in the physiology of higher organisms as well as in plants."

**The photo-activity of substances curative of rickets—a remarkable discovery** (*Jour. Amer. Med. Assoc.*, 83 (1924), No. 15, pp. 1169-1171).—An editorial discussion of the above paper and a previous paper by Park et al. (*E. S. R.*, 50, p. 262).

## ANIMAL PRODUCTION

**Seasonal changes in organ weights and their relation to meteorological conditions**, W. H. BROWN, L. PEARCE, and C. M. VAN ALLEN (*Soc. Expt. Biol. and Med. Proc.*, 21 (1924), No. 7, pp. 373-375).—In a study of the variations between the ratio of the weights of various organs and the body weights in rabbits, conducted at the Rockefeller Institute for Medical Research, two groups of rabbits were killed each month. The results of a study of the relationship of this ratio to environmental conditions indicated that "all the organs examined were found to undergo rhythmic changes in weight per unit of net body weight which conformed in general to the progression of the seasons."

The changes in the weights of the heart and kidneys amounted to about 20 per cent, while the liver exceeded 40 per cent, and the endocrine glands, thymus, spleen, and lymph nodes in some cases amounted to from 50 to 100 per cent. The changes in the weights of the majority of the organs appeared to be related to the actual amount of sunshine which occurred at the different seasons, but others appeared to be more closely related to temperature or humidity.

**The effect of acute scurvy on the subsequent nutrition and growth of guinea pigs**, W. E. ANDERSON and A. H. SMITH (*Jour. Biol. Chem.*, 61 (1924), No. 1, pp. 181-191, figs. 4).—In a study at the laboratory of physiological chemistry at Yale University of the subsequent effect of acute scurvy on nutrition and growth, 9 pairs of guinea pigs were used. All the pigs were supplied with a diet lacking only in vitamin C and consisting largely of soy bean gruel

flour and maysoya. In addition 20 gm. of fresh raw cabbage were fed daily to one of the guinea pigs of each pair (control), while the other (experimental) animal received an equivalent amount of cooked dried cabbage. The amount of feed furnished daily to the control animals was limited by the amount consumed by the experimental animals on the preceding day. Scurvy, as indicated by sensitiveness of the wrists, developed in the experimental animals in from 10 to 18 days. Three days after the development of the scorbutic symptoms 20 gm. of fresh raw cabbage replaced the dried cabbage in the ration.

The results of the experiment, which in 5 cases lasted from 51 to 61 days and in 4 cases extended over a period of from 103 to 110 days, indicated that the food intake decreased with the onset of scurvy, which was also accompanied by a decrease in the growth rate as compared with the controls, though equal amounts of feed were consumed. After the feeding of raw cabbage to the experimental animals was begun, the consumption by these animals of the soy bean ration was from 1.8 to 26.6 per cent greater than that of the controls, and a rate of growth equal to the controls was resumed.

It is thus concluded that scorbutic animals suffer a decrease in body weight greater than that simply due to inanition. As indicated by the conditions of the animals, growth rate, and X-ray pictures, the curative measures used removed the pathological evidences of acute scurvy, though greater amounts of food were consumed per unit of gain than by the controls, indicating that normal recovery was not entirely complete.

**Phosphorus in the live stock industry**, A. THEILER, H. H. GREEN, and P. J. DU TOIT (*Union So. Africa Dept. Agr. Jour.*, 8 (1924), No. 5, pp. 460-504, figs. 29).—The results of experiments conducted by the Department of Agriculture, Union of South Africa, which indicate that phosphorus is a limiting factor in the growth of young stock, the milk production of cows, the rate of gains made by fattening steers, and the economy of feed utilization by the various types of animals, are given. The low phosphorus content of the soil accounts for a very low phosphorus content of the range plants and the frequent occurrence of osteophagia in range cattle. Bone meal feeding is recommended. Pot experiments with range vegetation indicate that the phosphorus deficiency of the soil and lack of rainfall are the two main factors limiting the carrying capacity of the ranges.

**Grassland and the grazing animal**, R. G. STAPLEDON, T. W. FAGAN, and R. D. WILLIAMS (*Welsh Plant Breeding Sta., Aberystwyth, [Bul.], Ser. H, No. 3 (1920-1923)*, pp. 159-168).—This is mainly a discussion of various methods of handling pastures, dealing with the advisability of pasturing aftermath, the injuries from overstocking, desirability of rotating pastures, etc.

**Feed inspection report, 1923**, J. O. HALVERSON and L. M. NIXON (*N. C. Dept. Agr. Bul.*, 1924, June, pp. 79).—In addition to the usual report (E. S. R., 50, p. 169) of the guaranteed and found contents of protein, fat, and fiber in the samples of feeding stuffs officially analyzed during 1923, two papers are presented.

**Onion milk investigation**, S. Combs and J. O. Halverson.—Three cows received onion tops in amounts of from 2 to 2.5 lbs. daily, and the milk was tested for onion flavor with and without the feeding of "Mrs. Lea's Milk and Butter Purifier" to the cows. When this substance was not fed an onion taste was evident in 32 of the 33 samples taken, but only in 43 of 106 samples collected from the cows when they were receiving the milk and butter purifier. The ingredients of the purifier were found to consist of common salt, charcoal, sodium bicarbonate, Epsom salts, and sugar.

*The calcium requirement of animals in relation to the calcium content of feeds*, J. O. Halverson and L. M. Nixon.—The calcium needs of livestock and the calcium contents of feeds are briefly discussed.

**Commercial feeding stuffs**, J. L. HILLS, C. H. JONES, and G. F. ANDERSON (*Vermont Sta. Bul. 242 (1924)*, pp. 3-32).—The usual report of the official inspection of feeding stuffs during the spring of 1924 (E. S. R., 52, p. 167).

**Waters suitable for live stock**.—**Analyses and experiences in New South Wales**, A. A. RAMSAY (*Agr. Gaz. N. S. Wales, 35 (1924), No. 5, pp. 339-342*).—The following conclusions as to the suitability of water for livestock were based on analyses of samples of water sent to the New South Wales Department of Agriculture:

"(1) Horses will thrive on water containing 400 grains common salt and 550 grains total solids per gallon, and provided they are not worked may be sustained on water containing up to 638 grains salt and 950 grains total solids. Water containing as much as 798 grains salt and 1,022 grains total solids has been used for a period of three months without ill effects.

"(2) Cattle will thrive on water containing 800 grains common salt and 1,000 grains total solids, but when the concentration reaches 970 grains salt and 1,300 grains total solids they are injuriously affected.

"(3) Sheep will thrive on water containing 800 grains common salt and 1,000 grains total solids, and will do well even up to 1,197 grains salt and 1,350 grains total solids. When the concentration reaches 1,277 grains common salt and 1,868 grains total solids the sheep are injuriously affected."

**Beef cattle investigations on the farm—Kansas Experiment Station, 1923-24**, C. W. McCAMPBELL (*Cattleman, 11 (1924), No. 1, pp. 59-65*).—The results of comparative tests of adding varying amounts of cottonseed meal to a basal ration of corn, alfalfa, and cane silage for baby beef and of different methods of feeding beef calves are reported from the Kansas Experiment Station. The experiments dealing with the addition of different amounts of cottonseed meal to the ration were conducted with 4 lots averaging about 415 lbs. per steer. The basal ration fed to all lots and without additions to lot 1 consisted of a full feed of cane silage and corn plus 2 lbs. of alfalfa hay per head daily. Lots 2 and 3 received additional supplements of 1 and 2 lbs., respectively, of cottonseed meal per head daily, while lot 4 received 1 lb. of linseed oil meal.

The average daily gains made during the 165-day test by the 4 lots in their respective order were 1.88, 2.12, 2.10, and 2.10 lbs. The check lot receiving only the basal ration required 476 lbs. of corn, 107 lbs. of alfalfa hay, and 574 lbs. of silage per 100 lbs. of gain. The lot receiving additions of 1 lb. of cottonseed meal per head daily required 422 lbs. of corn, 94 lbs. of alfalfa, 509 lbs. of silage, and 42 lbs. of cottonseed meal per 100 lbs. of gain. With the supplement of 2 lbs. of cottonseed meal per head daily, 413 lbs. of corn, 95 lbs. of alfalfa, 514 lbs. of silage, and 80 lbs. of cottonseed meal were required per 100 lbs. of gain. The feed requirements per 100 lbs. of gain of the lot receiving linseed meal were 430 lbs. of corn, 95 lbs. of alfalfa, 514 lbs. of silage, and 43 lbs. of linseed meal. The estimated values of the calves per 100 lbs. at the conclusion of the test as an indication of their finish were \$8, \$8.25, \$8.35, and \$8.50, respectively. It was concluded that the addition of 1 lb. of cottonseed meal or linseed meal to the basal ration increased the rate of gain, finish, and profits as compared with the control lot.

In comparing various methods of wintering calves, it was found that full feeding calves on corn, cottonseed meal, alfalfa hay, and silage from weaning time in the fall until late spring or early summer was more profitable than

roughing the calves through the winter on corn silage, with limited amounts of alfalfa hay or cottonseed cake, followed by subsequent full feeding in dry lot or on pasture and marketing in the fall. In regard to the two latter methods of feeding, calves on pasture were found to require less feed per unit of gain and sold for a better price and thus at a greater profit than calves roughed through the winter and finished in dry lot.

**Beef-cattle production in the range area**, V. V. PARR (*U. S. Dept. Agr., Farmers' Bul. 1395 (1925), pp. 11+44, figs. 20*).—This deals with the methods of management, feeding, and breeding of beef cattle in the range area, which is considered as that portion of the United States west of the one-hundredth meridian.

**Dual-purpose cattle merits demonstrated in Minnesota**, R. E. HODGSON (*Breeder's Gaz., 86 (1924), No. 14, p. 307, fig. 1*).—This consists of a brief report of the milk records made by a herd of milking Shorthorns established at the Southeast Demonstration Farm and Substation near Waseca, Minn., in 1913.

The average annual production per cow from 1919 to 1923 varied from 6,169 to 6,938, lbs. of milk. The fat yields ranged from 210 to 268 lbs. per year.

The results of an experiment in feeding steers from this herd averaging 555 lbs. at 13 months of age are reported during a 180-day feeding test. The average daily gains made were 2.42 lbs., with a feed requirement per 100 lbs. of gain as follows: 292.4 lbs. of ground corn, 119.4 lbs. of ground oats, 28.9 lbs. of linseed meal, 800 lbs. of corn silage, and 194.8 lbs. of alfalfa hay. The author believes that it is thus demonstrated that cows yielding a satisfactory milk production may also produce calves making good beef.

**Lamb-raising trials, season 1923**, E. A. ELLIOTT (*Agr. Gaz. N. S. Wales, 35 (1924), No. 5, pp. 331-335*).—Another year's results are reported of the experiments conducted at the Cowra and Bathurst Experiment Farms, New South Wales, previously noted (*E. S. R., 50, p. 271*). In the 1923 experiments at Cowra, lots of 120 Border Leicester×Merino and Lincoln×Merino ewes each were mated with 2 Dorset Horn and 2 Ryeland rams, respectively. The Dorset rams produced 98 and the Ryeland rams 115 lambs that were marked. There were 94 ewes in each of two lots similarly mated at the Bathurst farm. Eighty-six lambs were marked from the 2 Dorset Horn rams, while only 70 offspring of the Ryeland rams were marked. In the experiments at both farms, it was found that the lambs from the Dorset crosses were taller and more leggy, while the Ryeland cross lambs were more compact and solid and therefore more attractive.

**Lamb feeding experiments at the Irrigation Branch Experiment Station**, H. HACKEDORN, R. P. BEAN, and J. SOTOLA (*Washington Col. Sta. Bul. 185 (1924), pp. 42, figs. 4*).—The combined results of three years' experiments (1922-1924) in fattening lambs are reported, the first two years' results having been noted (*E. S. R., 48, p. 269; 51, p. 172*). As in the earlier experiments, the first and third cuttings of alfalfa hay proved superior to the second cutting, while well-cured sweet clover compared favorably with alfalfa hay. The feeding of corn silage proved advantageous in the three years' trials as compared with the use of hay as the sole roughage.

**Sheep shearing**, J. H. KRUGER (*Union So. Africa Dept. Agr. Jour., 9 (1924), No. 1, pp. 10-30, figs. 17*).—This includes a discussion of the methods of shearing sheep, including directions for baling the fleece and other related information.

**Methods of investigating the physical properties of wool** (trans. title), E. TÄNZER (*Deut. Landw. Tierzucht, 28 (1924), No. 25, pp. 353-358*).—This is mainly a discussion of the results of various investigations of the relations

of fineness of wool fibers to their strength, stretching qualities, and other physical properties.

[Hog feeding experiments by the Canadian Department of Agriculture], G. B. ROTHWELL (*Canada Expt. Farms, Anim. Husb. Div. Interim Rpt., 1922, pp. 43-63, figs. 10*).—In one experiment skim milk was found superior to buttermilk or water as a supplement to the ration of sows while suckling pigs. In another experiment fattening pigs made greater gains on pasture than others confined in a piggery, but the former lot averaged 50.7 lbs. at the start as compared with 35.7 lbs by the second lot. The more economical gains were made by the confined pigs. The addition of a mineral mixture to the ration of fattening pigs slightly increased the rate of gain, but also increased the feed consumption per unit of gain. The addition of molasses to the ration increased the gains, but also increased the costs of gain. Molasses-fed hogs showed more gloss to the hair and higher finish.

In a comparison of 25-lb. Berkshire and Yorkshire pigs on self-feeders, the pigs of the former breed made greater daily gains but required slightly larger amounts of feed, therefore the Yorkshires produced the more economical gains. In a comparison of the rate and economy of gains made by Berkshires, Yorkshires, and crossbred Berkshire-Yorkshire pigs, it was found that the latter pigs gained more rapidly than either of the purebred lots and consumed less feed than the Berkshires. The Yorkshires made the slowest but the most economical gains. In experiments with the crossbreds, oat flour substituted for ground oats in the ration produced more rapid gains, but the costs of gain were greater. Both Berkshires and crossbreds were inferior to Yorkshires for the production of Wiltshire sides, the former particularly because of lack of length and uniformity of fleshing, while the latter lacked uniformity in length.

The results of several comparisons of hullless oats and ground oats when fed with shorts, middlings, flax, and tankage were somewhat contradictory as to the superiority of each.

A comparison of self-feeding and hand-feeding of hogs indicated that gains were made more rapidly but less economically with a self-feeder. The quality of the carcass from a bacon standpoint was not so good as that produced by hand-feeding. One lot of 4 sows receiving an average ration of 7 lbs. of grain and 1 lb. of beet pulp farrowed an average of 9 pigs averaging 2.83 lbs. each at birth, while another lot of 5 sows receiving daily rations of 5 lbs. of grain and 5 lbs. of pulp mangels farrowed an average of 12 pigs per sow, having birth weights averaging 2.91 lbs. each. One lot of pigs having access to water at all times made greater and more economical gains than another lot receiving the same ration (grain mixture) and buttermilk.

In a study of the desirability of Berkshire and Yorkshire carcasses for bacon production, it was found that Yorkshires more closely met the requirements of the packers. A select Berkshire carcass was a little heavier than desired and not quite so long as the Yorkshire. A heavy Berkshire carcass was too thick and heavy.

“Pineapple bran” mixture versus barley and tankage for hogs, L. A. HENKE (*Hawaii Univ. Quart. Bul., 3 (1924), No. 1, pp. 27-32*).—In hog feeding experiments at the University of Hawaii, the gains made by pigs averaging 71 lbs. while fattening on barley and tankage in separate self-feeders were compared with the gains made when self-fed a mixture of pineapple bran, wheat middlings, coconut meal, and tankage, 5:3:1:1. The fattening period, which lasted from November 10 to January 26, was divided into four sub-periods, and the rations were reversed for each lot during each successive sub-

period. The results showed that while fattening on the pineapple bran mixture average daily gains of 0.98 lb. per pig were made, as compared with 1.06 lbs. on the barley and tankage ration. Per pound of gain, 4.53 lbs. of concentrates were consumed on the former ration as compared with 5.19 lbs. on the latter. The calculated costs of feed per pound of gain on the two rations were 9.27 and 10.59 cts., respectively. Additional minerals were available to both lots. It is stated that the pigs receiving the barley and tankage ration appeared the more thrifty.

The same pigs used in these experiments received free access to a number of feeds provided in separate self-feeders from the time of weaning on October 1 until the beginning of the experiment on November 10. The rations as balanced by them consisted of the following proportions of the different feeds: Wheat middlings 26 per cent, cracked corn 28, rolled oats 7, tankage 17, rolled barley 16, and pineapple bran 6 per cent.

**Pig breeders' annual, 1923** (*London: Natl. Pig Breeders' Assoc., 1923, pp. 67+I, II, figs. 17*).—This is the usual pig breeders' annual for 1923 (E. S. R., 48, p. 171) containing the following articles dealing mainly with the practical application in swine production of the results of scientific investigations: Some Digressions upon Breeding, by H. G. Robinson; Differences in Quality of Pig Foods, by W. M. Tod; The Vital Importance of Developing the Pig Industry, by L. C. Paget; Vomiting in Pigs, by H. Leeney; Notes on Feeding Stuffs for Pigs, by C. Crowther; Dry Feeding of Pigs, by W. A. Stewart; The Position of the Pig Industry, by J. Long; and The Improvement of Live Stock, by F. N. Webb, as well as other information and statistics of interest to the swine producer.

**Pig breeders' annual, 1924** (*London: Natl. Pig Breeders' Assoc., 1924, pp. 17-134, figs. 34*).—The following articles are included in the pig breeders' annual for 1924: Records of Production and Their Use in Breeding, by H. R. Davidson; Animal Nutrition, by E. T. Halnan; Genetics and the Pig Breeder, by F. A. E. Crew; The Future Possibilities of Breed Society Work, by H. G. Robinson; The Pedigree versus the "Scrub" Pig for the Butcher; "Wiltshire" Bacon, by R. P. Redman; The Use of Separated Milk for Pig Feeding, by W. M. Tod; Rickets in Pigs, by H. Leeney; Bacon-pigs: The Midland Curers' Requirements, by A. E. Marsh; On Protein and Proteins as Affecting Pig Feeding, by F. W. Jackson; The Common Diseases of Swine, by G. H. Conn; Some Defects of the Open Air System, by C. F. Chance; The Home Slaughtering and Marketing of Pigs, by V. C. Fishwick and V. R. S. Vickers; Simple Facts Relating to Pig Rations and Feeding, by V. C. Fishwick; The Value of Pedigree Stock for Commercial Purposes, by H. Henshaw; Sexual Abnormalities in Pigs, by J. R. Baker; and Bacon Factories in England and Scotland.

**The economy and effect of corn in the winter feeding of horses**, G. B. ROTHWELL (*Canada Expt. Farms, Anim. Husb. Div. Interim Rpt., 1922, pp. 39, 40*).—Fourteen work horses were used in comparing a ration of oats and bran, 13:2, fed with timothy and alsike hay, with a ration of oats, corn, and bran, 5:8:2, fed with similar hay. The experiment lasted 12 weeks, the 2 horses of each team always being on different rations. The results showed that the horses gained on both rations, but the one including corn was less expensive, though the gains were slightly less.

**The police dog**, D. BROCKWELL (*New York: G. Howard Watt, 1924, pp. 190, pls. 10, figs. 16*).—The origin, characteristics, breeding, care, diseases, training, and uses of police dogs are in turn discussed. An introduction is included by G. G. Anderson and illustrations by R. W. Tauskey.

**The effect of feeding thyroid on the plumage of the fowl**, L. J. COLE and D. H. REID (*Jour. Agr. Research [U. S.]*, 29 (1924), No. 6, pp. 285-287, pl. 1).—The results are briefly reported of a study of the effect of thyroid feeding on the characteristics of new feathers produced by Brown Leghorn cockerels, which was conducted at the Wisconsin Experiment Station from February 9 to May 2, 1923.

One lot of 4 birds received every other day at first and later daily 400 mg. of desiccated thyroid containing 0.8 mg. of iodine. Other birds received a like amount of iodine either dissolved in alcohol or in the form of potassium iodide, while others not treated were used as controls. Feathers were pulled from the cape and wing bow on February 20 and later from the saddle and sickle of each bird, and the new developing feathers carefully watched. The replacement of the feathers was apparently more rapid in the birds receiving the thyroid, and these feathers were strikingly modified. There was much variability, but it was evident that a reduction in the red pigment occurred which tended toward stippling if any red were present. The broad rounded ends of these feathers and lack of barbs also resembled female feathers. The replaced feathers of the control birds showed no such change. The action of the thyroid was supposed to be due to a direct action on the metabolism of the feather germ.

**Investigation of body form and egg production** [trans. title], WEINMÜLLER (*Deut. Landw. Tierzucht*, 28 (1924), No. 23, pp. 327-330, figs. 8).—The relation between body measurements and annual egg production per kilogram of live weight of the fowls of several breeds has been studied at the Technical High School at Munich. It was found that certain of the body characters, as determined by correlation coefficients, were fairly good indicators of productive capacity, but that none were as good as actual egg records.

**Egg weight in relation to production.—Part II, The nature and causes of changes in egg weight in relation to annual production in pullets**, M. A. JULL (*Poultry Sci.*, 3 (1924), No. 5, pp. 153-167, 170-172, figs. 2).—This is the second study in the series previously noted (*E. S. R.*, 51, p. 674), and consists of a statistical treatment of the weights of the eggs, age in days at commencing laying, maximum body weight, and annual egg production of 40 Barred Plymouth Rock pullets. Coefficients of correlation were calculated between the averages for the different determinations, and Path's coefficients were calculated between the different factors and egg weight. The author summarizes the paper dealing with the effect of the various factors on egg weight as follows:

"Age in days that pullets commence laying and rate of production seem to be due primarily to genetic factors. Since the earlier that laying commences the greater is the production, the total production for the pullet year is due to the hereditary constitution of the individual. Also, since the earlier that laying commences the lower is the mean weight of the total production, it would appear that the size of egg laid is also due to the hereditary constitution of the individual. On the other hand, mean egg weight is more probably due primarily to physiological factors, since it has been shown that antecedent production affects rate of increase both in egg weight and body weight."

**Culling for efficient egg production**, W. H. RICE (*Id. Univ. [Agr.] Ext. Bul.* 35 (1924), pp. 20, figs. 11).—Popular directions for culling poultry for egg production are given.

**The effect of cod liver oil in various amounts and forms on the growth of young chickens**, L. C. DUNN (*Jour. Biol. Chem.*, 61 (1924), No. 1, pp. 129-136, fig. 1).—This is a more detailed report of the second experiment pre-

viously noted from Connecticut Storrs Station Bulletin 116 (E. S. R., 51, p. 378).

**Experiments in incubation**, W. C. RUGG and W. O. PEDERICK (*Jour. Dept. Agr. Victoria*, 22 (1924), No. 8, pp. 511, 512).—In a study of the methods of incubating hen's eggs artificially at the Werrabee State Research Farm, it was found that the hatch was slightly increased by placing a moisture tray in the incubator. The hatch was only about one-half as good when the eggs were turned on the fifth and fourteenth days only, i. e., at the time of testing for fertility.

**The present outlook for the poultryman**, G. W. HERVEY and C. S. PLATT (*New Jersey Stat. Hints to Poultrymen*, 13 (1925), No. 5, pp. 4, figs. 3).—A popular discussion of the relation of feed prices to egg production, with comparisons for the preceding years.

**Muskrat farming**, [J. L. EDWARDS] (*Utica, N. Y.: Fur Farms Pub. Co.*, 1924, pp. 56, figs. 13).—This consists of a popular discussion of muskrat farming, including directions for the trapping of wild breeding stock.

## DAIRY FARMING—DAIRYING

**Report of the proceedings of the forty-third annual convention of the Connecticut Dairymen's Association, held at Unity Hall, Hartford, Conn., January 23-24, 1924** (*Conn. Dairymen's Assoc. Rpt. Proc.*, 43 (1924), pp. 138).—In addition to the routine proceedings of this association, the following papers were presented: Milk Advertising in Connecticut, by D. Buckley; Feeding Cows on Official Test, by E. J. Perry; Clean Milk, Its Relation to Profitable Dairying, by R. C. Fisher; Summer Feeding and Forage Crops, by H. E. Cook; The Mating of Sexually Sound Animals as the First Principle in Successful Reproduction, by W. L. Williams; Better Bulls for Connecticut, by A. R. Merrill; The Importance of the Human Equation in Dairying, by H. E. Cook; The Future Outlook in Dairying, by E. J. Perry; An Outline for the Control of Sterility and Abortion, by W. L. Williams; The Feeding of Calves, by A. R. Merrill; and The Quest for the Fountain of Health, by M. E. Dallinger.

**On the protein requirement of milk production**, J. A. FRIES, W. W. BRAMAN, and M. KRISS (*Jour. Dairy Sci.*, 7 (1924), No. 1, pp. 11-23).—This is a more detailed account of an investigation conducted from February 28 to May 1, 1919, at the Pennsylvania Institute of Animal Nutrition than was previously noted (E. S. R., 52, p. 274). The study deals with the minimum protein requirements of dairy cattle for milk production. Two mature Jersey cows were used as the experimental animals. The rations fed were made up of alfalfa hay, corn meal, linseed oil meal, peanut meal, oat straw, and cornstarch, which were mixed in proper proportions to supply the specified amounts of protein, the total of which in each ration was derived 35 per cent from the alfalfa hay, 25 per cent from corn meal, 20 per cent from linseed oil meal, and 20 per cent from peanut meal.

The experiment was divided into five test periods of 7 days each, with transition periods of from 2 to 5 days. After allowing 0.5 lb. of digestible true protein per 1,000 lbs. of live weight for maintenance, the following amounts of digestible true protein in relation to the protein in the milk produced in the preceding period were fed in the respective periods for one cow 1.6, 1.3, 1.027, 1.28, and 1.869 times the milk protein and for the other cow 1.6, 1.3, 1.028, 0.966, and 2.054.

The results of the experiments are tabulated in detail, showing the daily nitrogen balances, live weights of the cows, milk and fat production, and the percentages synthesized of the total nitrogen and that available for milk pro-

duction, as well as other related data. The milk production in the different periods was apparently very little affected by changes in the amount of protein supplied, indicating "that the milk-producing cow adheres to her natural rate of milk production with remarkable persistence in spite of extensive change in the nitrogen intake." The decrease in the nitrogen intake was almost entirely made up in those periods of low intake by a decreased amount of nitrogen in the excreta.

The authors state that it appears from the experiment that the smallest amount of crude protein, fed, i. e., 1.11 and 1.17 times the milk protein, was the most satisfactory for economical production, as there was no significant change in the live weights of the animals and the efficiency of the protein utilization was high, 85.5 and 97.3 per cent. It is of interest to note that the coefficient of digestibility of the nitrogen was apparently decreased as the consumption of nitrogen decreased, and again increased with increases in the nitrogen consumption. This is due to metabolic protein being more nearly a body constant than a variable related directly to the feed.

**Feeding cocoa meal to dairy cows,** H. B. ELLENBERGER and J. A. NEWLANDER (*Vermont Sta. Bul. 243 (1924), pp. 3-20, figs. 2*).—The results of five experiments in which cocoa meal was fed to dairy cows are reported. Six cows were fed in each of the first two experiments by the double reversal method, the comparative rations consisting of a grain mixture containing 18.2 per cent of protein and a similar ration of equal protein content containing 10 per cent of cocoa meal. The feeding periods were 4 weeks in duration, with intervening transition periods of 1 week. In the third experiment the same basal ration was similarly compared with one containing 20 per cent of cocoa meal, using 8 cows for the trial.

The results of the three experiments showed that there was a reduction in milk yield varying from 5 per cent with the 10 per cent cocoa meal ration to 13 per cent for the 20 per cent cocoa meal ration. The decrease in milk flow was accompanied by an increase in the solids content of the milk, amounting to 15.41 per cent in the fat when the grain consisted of 20 per cent of cocoa meal.

To study the effect of temporary feeds of cocoa meal on the butterfat yields in the 2-day advanced registry tests, 28 cows were divided into four groups, one of which received a basal ration, while the others received 2, 4, and 6 feeds, respectively, of 20 per cent cocoa meal in the grain mixture. The milk yields decreased, and the fat percentages increased for 2 days subsequent to the cocoa feeding. Similar results were obtained in another trial in which only 1 and 2 feeds of the cocoa meal were given.

To test the effect of cocoa meal on the condition of the animal, a small Jersey heifer was fed without bad effects for 24 weeks on a ration containing as much as 40 per cent of cocoa meal. The milk tested 6.69 per cent butterfat during the last 3 weeks of the trial.

**Optimum root crop ration as shown by feeding experiments with dairy cows** [trans. title], N. HANSSON (*Meddel. Centralanst. Försöksv. Jordbruksområdet [Sweden], No. 268 (1924), pp. 34, figs. 3*).—In studying the replacement values of oats and roots for milk production, four rations were used for comparison: 5.4 kg. of ground oats, 3.6 of ground oats and 15 of roots, 1.8 of ground oats and 30 of roots, and 45 kg. of roots. In the replacement it was calculated that 1.2 kg. of oats could be replaced by 1.1 kg. of dry matter in the roots.

The results of the experiment indicated that as the amount of roots in the ration was increased, especially above 30 kg., the efficiency of utilization decreased. When medium sized root rations were exchanged for oats, one food

unit of oats (1.2 kg.) and 1.1 kg. of dry matter in the roots were practically equal in nutritive value. Decreases in milk production and losses in live weight accompanied the feeding of from 40 to 45 kg. of roots to the animals daily.

The bulletin is abstracted in English.

[Carrying capacity of irrigated pastures], D. HANSEN (*Montana Sta. Bul.* 166 (1924), pp. 12-26, figs. 3).—The author reports the results of studies of the carrying capacity of various pastures with dairy cattle, conducted from 1918 to 1923. Data accumulated during the first four years' work have been previously noted (*E. S. R.*, 49, p. 875). In the test from 1921 to 1923 the carrying capacity of the pastures was increased an average of 14 per cent by top-dressing each year with 10 loads of manure per acre.

Studies in the growth and nutrition of dairy calves.—IX, X, A. C. McCANDLISH (*Jour. Dairy Sci.*, 7 (1924), Nos. 1, pp. 94-106, figs. 4; 2, pp. 160-162).—This continues the series (*E. S. R.*, 51, p. 378).

IX. *The addition of tomatoes to a milk ration.*—Two calves were used in studying the factors responsible for the deficiency of milk as the sole diet. One calf, which was fed milk alone, died at 180 days of age. The other calf was fed whole milk only until the end of 7 months, after which it received 1 lb. 3 oz. of canned tomatoes daily in addition. The tomatoes were replaced by alfalfa hay at the end of 12 months, and the calf was slaughtered at 15 months of age. The calf dying at 180 days was below normal in weight and measurements, while the other calf had a tendency to be above normal in live weight, but the body measurements were not increasing at a normal rate until alfalfa hay was fed. The latter calf chewed the pen during the fifth month of the experiment and became stiff in the joints in the seventh month. These conditions were temporarily relieved by the tomato juice, and the eyes, which had previously become watery and dull, became normal. Within 2 months, however, the calf again returned to its former condition, but by the addition of alfalfa hay to the ration the calf was put in good shape.

The results of this and preceding studies of this series indicate that milk is not satisfactory as the sole feed of calves for any considerable time. The animals could not consume enough milk to provide for their requirements of digestible nutrients. The necessity of supplying additional dry matter, bulk, and minerals in the milk ration is pointed out.

X. *Self-feeding a grain mixture to young calves.*—In continuing the experiments on the use of self-feeders for raising dairy calves (*E. S. R.*, 51, p. 378), four calves averaging 16 days of age were started on whole milk hand-fed during two monthly periods, followed by the gradual substitution of skim milk for the whole milk during the third, fourth, and fifth months, with skim milk only furnished during the sixth month. The grain mixture of cracked corn, ground oats, wheat bran, and old process linseed oil meal (5:2:2:1) was kept before the calves at all times, as well as alfalfa hay and salt. An average of 1,062 lbs. of whole milk, 1,153 lbs. of skim milk, 214 lbs. of alfalfa hay, and 604 lbs. of the grain mixture were consumed per calf during the six-month period.

The average weight at the start of the test was 59 lbs. and at the end of the trial 346 lbs., or a gain of 491 per cent. Gains in height, depth, and width of 37, 56, and 77 per cent, respectively, were also made. The gains were all better than those made by the normally fed heifers in study 3 of this series (*E. S. R.*, 47, p. 781), and the calculated costs of the self-fed mixture were also lower.

A note on the similarities between the curves of growth and of regeneration, S. BRODY (*Jour. Gen. Physiol.*, 6 (1924), No. 6, pp. 629-633, fig. 1).—

It is shown that the curves of growth in the dairy cow and regeneration in the tail of the tadpole follow the same general course and can be represented by the same exponential equation. Both curves have the common peculiarity of a slow rate in the early stages of growth or regeneration. The conditions responsible for the lag in the early rate of growth are discussed.

**The change of form with age in the dairy cow,** S. BRODY and A. C. RAGSDALE (*Missouri Sta. Research Bul. 67 (1924), pp. 3-48, figs. 40*).—The changes in form of the dairy cow during growth are shown by photographs, graphs, and by superimposing outlines of animals of one age upon those of another. The work is based on 21 linear measurements taken at monthly intervals during the first 60 months of extra-uterine life. The data are based on Jerseys, Holsteins, and Ayrshires.

**Interpretation of dairy pedigrees,** J. W. GOWEN (*Maine Sta. Bul. 318 (1924), pp. 53-80, figs. 5*).—A popular account of what may be observed from pedigrees, based mainly on the statistical analyses of milk records previously noted from various sources.

**The effect of the sugar content in the manufacture of commercial ice cream,** W. H. E. REID (*Missouri Sta. Research Bul. 69 (1924), pp. 3-15, figs. 5*).—An investigation of the various properties of ice cream made with sugar contents varying from 8 to 16 per cent has indicated that the higher contents of this ingredient reduce the hardness, time required for melting, and score of the finished product, and also the overrun when above 12 per cent. Increases in the percentage of sugar caused relative increases in the density of the mix, the time required for freezing, and the weight of the ice cream. The hardness was determined by finding how far a needle with a definite force would penetrate a brick, while standing up qualities were tested in a temperature of 86° F.

## VETERINARY MEDICINE

**Normal immunity reactions of the cow and the calf with reference to antibody transmission in the colostrum,** J. B. NELSON (*Missouri Sta. Research Bul. 68 (1924), pp. 3-30*).—Following an extensive review of the literature on antibody transmission in the colostrum of the cow, a series of experiments is reported in which an attempt was made to determine the cause of the increased resistance of the suckled calf to *Bacillus coli* invasion.

In the first, two cows were immunized with horse blood cells late in the gestation period, and at parturition the blood of the calf and of the dam and the colostrum were tested for the presence of hemolytic amboceptor. The blood of the calf and the colostrum were also tested at varying periods thereafter. The blood and colostrum of one of the cows showed a higher titer of anti-horse hemolysin than that of the other, but in both cases the titer of the colostrum was as high as that of the blood. No hemolysins were present in the blood of the calf until after nursing. The maximum concentration of antibodies occurred 24 hours after nursing and was followed by a gradual decline. The concentration of antibodies in the colostrum declined most rapidly during the first 24 hours and then more slowly, until at the end of 2 weeks it had practically disappeared.

A study was next made of the bacteriolytic action of normal blood serum of the cow for *B. coli*, followed by a similar study of the blood of the calf before nursing and after receiving colostrum or milk. The fresh normal blood serum of the cow inhibited to a marked extent the growth of *B. coli* but not of *Staphylococcus aureus* or *B. subtilis*. The inhibition was accompanied by lysis of the bacilli after preliminary agglutination. Serum from which complement

had been removed by heating, deterioration, or specific fixation did not inhibit the growth of *B. coli*. The blood serum of the calf before nursing showed slight inhibiting action toward *B. coli*. A small amount of complement was present in the serum and this was almost completely removed by the addition of *B. coli*. After nursing the complement titer was markedly increased, and this was accompanied by increased bacteriolytic action toward *B. coli*. Similar changes took place when milk was fed instead of colostrum, indicating that the increased bacteriolytic action of calf serum is not due to transmission of antibodies through the colostrum.

Finally a study was made of the agglutinating action toward *B. coli* of the serum of the cow and the calf and of colostrum. Agglutinins were found to be present regularly in the blood serum of the cow and in even larger amounts in the colostrum. No agglutinins could be demonstrated in the blood serum of the calf before suckling nor after being fed ordinary milk, but appeared shortly after the ingestion of colostrum, indicating direct absorption.

It is concluded that the newborn calf possesses some degree of protection against invasion by *B. coli* through the bacteriolytic action of its blood serum, and that this protection is increased to a marked extent by the agglutinins which are passively transmitted to the serum by means of colostrum.

**Tissue resistance and the cause of permanent acquired immunity, S. NUKADA and T. MATSUZAKI** (*Jour. Expt. Med.*, 40 (1924), No. 5, pp. 661-669).—In an attempt to explain the nature of the permanent immunity acquired after a single attack of certain infectious diseases such as smallpox, typhoid fever, etc., experiments were conducted on the freshly isolated hearts of rabbits. The first test consisted in comparing the resistance of the hearts of typhoid-immune rabbits with that of normal controls against the toxic products of typhoid bacilli as determined by the length of time the hearts continued to beat after perfusion with liquids containing the toxic products. The second series of experiments was similar to the first except that instead of normal controls animals immunized with bacteria other than typhoid bacilli were used.

In both cases, the resistance of the hearts of typhoid-immune rabbits was greater than that of the controls. Attempts to demonstrate the presence of antitoxin in the fluid from the heart tissue of the immunized animals gave negative results.

These experiments are thought to demonstrate "that permanent acquired immunity, at least in typhoid, instead of being due principally to antibodies, is caused by a lasting specific increase of resisting power acquired by the tissue cells against the toxic products of bacteria. This theory seems to hold good with other infectious diseases in which one attack conveys permanent immunity."

**The effect of intravenous injection of mercurochrome on the kidneys, J. H. HILL and C. Y. BIDGOOD** (*Bul. Johns Hopkins Hosp.*, 35 (1924), No. 406, pp. 409-411, pl. 1).—The investigations conducted show that intravenous mercurochrome causes a mild reaction in the kidney which is directly proportional to the dose given. "There is no actual destruction of tubular epithelium from doses as high as 7.5 mg. per kilogram of body weight, but with 10 mg. per kilogram there is definite renal damage, so that it would be unwise to use so large a dose clinically. Repeated injections do not cause any added damage and can be given, as in these animals [rabbits], as often as twice a week with safety, provided a dose of 5 mg. per kilogram of body weight be not exceeded. The slight damage is not irreparable, and at the end of two months the kidneys show no evidence of any previous lesion."

**On the nature of the heat-labile substance ("V") required for the growth of the bacillus of Pfeiffer, T. ТИЖОРТА** (*Jour. Expt. Med.*, 40 (1924),

No. 5, pp. 671-678).—Evidence along two different lines is presented, indicating that the heat-labile, growth-promoting factor V for the cultivation of Pfeiffer's bacillus (E. S. R., 46, p. 78) is not identical with the antineuritic vitamin B.

As determined by growth experiments with Pfeiffer's bacillus, the blood of pigeons and hens which had developed symptoms of polyneuritis as the result of continued feeding on diets deficient in vitamin B was found to contain as much of the V factor as normally fed controls. The second line of evidence that the two factors are not identical was the difference in thermostability. The growth-promoting substance V was destroyed at 105° C., while vitamin B-containing food did not lose its property of preventing polyneuritis after being autoclaved for 1 hour at 115°.

**A filterable virus infection of rabbits.**—I-II, C. H. ANDREWS and C. P. MILLER (*Jour. Expt. Med.*, 40 (1924), No. 6, pp. 773-796, pls. 2, figs. 2).—The authors report that in two, and possibly four, of six transmission series of rabbits inoculated with the blood of apparently normal rabbits a virus was recovered having the same properties as that recovered from series originally inoculated with material from rheumatic fever patients. The virus is thought to be a parasite of the domestic rabbit, but up to the present time the natural course of the infection in that animal is unknown.

**Infectious abortion (fifth report)**, G. C. WHITE, L. F. RETTGER, and J. G. MCALPINE (*Connecticut Storrs Sta. Bul.* 123 (1924), pp. 281-303, figs. 2).—In the first part (pp. 281-288) of this fifth report (E. S. R., 49, p. 784), the authors deal with investigations of the gestation period of cows. They find the average length of the gestation period of 640 calvings of uninfected animals to be 280 or 281 days. Only 2.87 per cent of the gestations of non-reacting cows terminated before the two-hundred-and-sixty-sixth day. It is said that in frequency distribution a sharp division line occurs on the two-hundred-and-sixty-sixth day, and gestations terminating prior to it may properly be looked upon as abortions due, with relatively few exceptions, to *Bacterium abortus*. Many of the permanently reacting cows were found to be able to carry calves to full time, but over a period of years 26.23 per cent of the calvings terminate before the two-hundred-and-sixty-sixth day. A much higher percentage of reactors than this abort during the gestation in which they first become infected, and only a few reacting cows escape abortion entirely if their career extends over any considerable time. The average length of gestation of 629 reacting cows was 266.9 days, as compared with 279.2 for the 671 nonreacting cows. The authors conclude from these studies that only about 1 in 10 of premature calvings may be attributed to causes other than *B. abortus*. Abortions may occur at any time during the gestation period, but with greatest frequency between the two-hundred-and-twentieth and two-hundred-and-sixty-fifth days.

In the second part (pp. 288-295), which relates to retained afterbirth, the authors report finding that retention apparently occurs as frequently with non-reacting cows as with reactors, which should eliminate *B. abortus* as the chief factor.

Part 3 (p. 295) relates to calf scours, infectious mammitis, and calf pneumonia. These affections have been infrequently met with in the herds badly infected with *B. abortus*, indicating that they occur independent of the *B. abortus* disease.

In part 4 (pp. 295-300) the history is given of the daughters of reacting and nonreacting dams. The conclusion reached is that calves are not permanently infected in utero, nor during early calthood, and, regardless of whether or not the dam is infected, all of the calves run the same hazards and share the same fortunes when they start their reproduction career.

In part 5 (pp. 300, 301), which consists of a brief history of purchased cows, it is stated that 29.1 per cent of the purchased cows reacted, revealing the widespread occurrence of the disease. Forty-nine of the 118 originally nonreacting purchased cows became infected after purchase, and 57.7 per cent of these aborted, showing that mature or nearly mature cows as well as heifers are extremely susceptible to *B. abortus* infection when they are introduced into herds that are badly infected.

**The actual state of our experimental knowledge of foot-and-mouth disease** [trans. title], M. H. VALLÉE (*Ann. Méd. Vét.*, 69 (1924), Nos. 6, pp. 241-251; 8-9, pp. 337-348; *abs. in Vet. Rec.*, 4 (1924), No. 45, pp. 951, 952).—In his investigations of the virus of foot-and-mouth disease, the author obtained it from the blood of infected cattle in the preruleptive stage of the disease, and not, as formerly, from the lymph of unruptured vesicles. This can be preserved in an undeteriorated state for months in a refrigerator at 0 to 2° C. The investigations have led him to conclude that two strains of virus exist, and these he terms O and A. The period of incubation is found to be longer for the O than for the A strain, and the duration of the period of immunity at least twice as long for the former as for the latter. An extended discussion is given of immunity work.

**The specific microorganism of foot-and-mouth disease**, C. M. HARING (*Jour. Amer. Vet. Med. Assoc.*, 65 (1924), No. 6, pp. 768-773).—This is a discussion of the addresses presented by P. Frosch and H. Dahmen at Utrecht on June 16, 1924, at a meeting under the auspices of the Netherlands Ministry of Agriculture attended by the author, in which the discovery of the causative organism of foot-and-mouth disease was reported (*E. S. R.*, 52, p. 179).

**The California foot-and-mouth disease outbreak**, J. R. MOHLER (*Jour. Amer. Vet. Med. Assoc.*, 65 (1924), No. 6, pp. 760-767).—This is a discussion of the outbreak of foot-and-mouth disease in California and the eradication work conducted, which was presented as an address at the annual meeting of the American Veterinary Medical Association, at Des Moines, Iowa, in August, 1924.

**Production of immunity in mice by inhalation of pneumococci**, E. G. STILLMAN (*Jour. Expt. Med.*, 40 (1924), No. 4, pp. 567-574, fig. 1).—Experiments are reported which indicate that normal mice may be immunized against virulent pneumococci by repeated inhalation of the live organisms.

In 449 mice exposed to from 1 to 10 inhalations of pneumococcus cultures, there were 29 deaths, the greatest number, 10, occurring after the second inhalation. There were no deaths after the first and tenth inhalations. Repeated inhalations of killed organisms resulted in only a slight degree of immunity.

**Personal experiences with the cultivation of tubercle bacilli and the use of the guinea pig as a diagnostic test animal for tuberculosis**, H. J. CORPER (*Jour. Lab. and Clin. Med.*, 9 (1924), No. 11, pp. 766-776).—This is a summary of the results obtained in a long-continued study of methods of cultivating human and bovine tubercle bacilli and of using guinea pigs as the diagnostic reagent. The chief recommendations resulting from this study are as follows:

The preferred method of isolating tubercle bacilli from tissues and contaminating materials is the Petroff sodium hydroxide method combined with seeding on gentian violet egg medium, to which glycerol is added for human but not for bovine bacilli. After artificial cultivation for over a year the strains are continued on glycerol agar or, in special cases, on glycerol broth. Tubercle bacilli should not be left longer than a month in the incubator or ice box without transfer to a fresh medium.

In guinea pig inoculation, the method of choice is considered to be the subcutaneous injection of the suspected material, properly prepared by pre-

liminary sodium hydroxide treatment and neutralization. The subcutaneous method is preferred to the intracutaneous on account of the greater danger of ulceration and contamination in the latter. The disadvantage of intravenous, intracardiac, and intraperitoneal inoculation is considered to be the necessity for complete examination of the animal before there are visible external signs of the disease. The use of extraneous agents such as Roentgen ray exposure, injection of radioactive substances, etc., is considered not to hasten the development of tuberculosis and is not to be recommended.

**Calmette's protective inoculation against tuberculosis**, A. K. K[RAUSE] (*Amer. Rev. Tuberc.*, 10 (1924), No. 2, pp. 219-225).—This is a review and an editorial discussion on recent work of Calmette and his associates on immunization against tuberculosis with bile-treated bacilli (*E. S. R.*, 52, p. 282).

**On the iodized swine erysipelas vaccine** [trans. title], S. FUJIMURA (*Jour. Japan. Soc. Vet. Sci.*, 3 (1924), No. 1, pp. 17-36).—The author reports satisfactory results in the immunization of swine against swine erysipelas with an iodized vaccine, prepared by treating a suspension of 24- to 48-hour agar and broth cultures in salt solution with Lugol's solution (iodine 1, potassium iodide 2, and distilled water 200 parts) in the proportion of 1:5 and allowing it to stand at room temperature for 1 hour, with frequent shaking. The suspension, which is cloudy at first, is allowed to stand for some time or until the supernatant liquid has become clear, when it is ready for use.

After preliminary immunizing experiments with small laboratory animals, the vaccine was injected subcutaneously into 8 pigs, 4 of which received a single dose of 5 cc. and the rest two doses of the same amount. After 15 days the vaccinated animals and 2 controls were injected with 10 cc. of a 48-hour serum broth culture of the organism. The vaccinated animals receiving the double dose and 2 receiving the single dose of vaccine showed no reaction. The other 2 which had been vaccinated showed a slight rise in temperature and a few red patches, while the control animals developed typical symptoms of the disease but recovered.

Agglutination tests carried out on the vaccinated animals before and after vaccination showed an appreciable production of agglutinins.

It is stated that in a district in which swine erysipelas had been prevalent vaccination has been practiced with satisfactory results on over 1,600 animals. The amount of vaccine used was in the proportion of 1 cc. to 10 kg. of body weight. The duration of the immunity conferred by this vaccination has not yet been determined. The vaccine is said to retain its potency under suitable conditions for about a month.

**The common parasites of hogs**, K. W. STODER (*Iowa Agr. Col. Ext. Bul.* 119 (1924), pp. 12, figs. 3).—This is a practical summary of information on the subject.

**The question of the human and pig Ascaris**, F. K. PAYNE, J. E. ACKERT, and E. HARTMAN (*Amer. Jour. Hyg.*, 5 (1925), No. 1, pp. 90-101).—This is a contribution from the Kansas Experiment Station, based upon work commenced in Trinidad in 1921 and later continued in Kansas and Virginia. The investigations include (1) experimental feedings of embryonated eggs of human *Ascaris* to pigs and of pig *Ascaris* eggs to primates and (2) studies on the incidence of human and pig ascarids in Trinidad.

“Repeated feedings of infective human *Ascaris* eggs were made to five young pigs, all of which suffered respiratory disturbances and other systemic disorders. Subsequent post-mortem examinations showed no ascarids in the digestive tract of any of the pigs. Severe cases of ‘thumps’ occurred in all of the pigs fed eggs of the human *Ascaris*. This appears to be the first record of thumps caused by the administration of human *Ascaris* eggs to pigs. Infec-

tive pig *Ascaris* eggs were taken by one monkey and by two human subjects. Fecal examinations made throughout periods of several months after the initial administration of eggs failed to show the presence of any *Ascaris* eggs. The incidence of *Ascaris* in north, central, and southern Trinidad, British West Indies, varied from 20 to 70 per cent for the human *Ascaris* and from 3.5 to 10.8 per cent for the pig *Ascaris*. In the vicinity of Arouca, one of the principal swine raising regions, the incidence of human *Ascaris* was 64.3 per cent, as compared with 10.8 per cent for the pig *Ascaris*. The experimental results indicate that embryonated eggs of the human *Ascaris* will not produce mature ascarids in pigs, that infective eggs of the pig *Ascaris* will not produce mature ascarids in the adult primates (monkey and man), and that there is thus a physiological difference between the human and the pig *Ascaris*."

A list of 13 references to the literature is included.

**The blood, urine, and tissue juices in azoturia.—A preliminary report,** C. E. HAYDEN and M. TUBANGUI (*Cornell Vet.*, 11 (1921), No. 2, pp. 81-84).—This is a preliminary report of investigations conducted at the New York State Veterinary College at Cornell University. While the data obtained are too limited to establish definite facts, the extractives in the blood seem to be no greater or even less in quantity than those of normal blood. "The quantity of sugar, total nonprotein nitrogen, and preformed creatinine of expressed muscle juice seems to be excessive. This points to retention of these extractives in the tissues rather than an overloading of the blood. The results from urine examinations are not in accord with the expressed idea of a high urea content. The samples analyzed so far do not indicate any marked nephritis."

**The blood, urine, and tissue juices in azoturia.—A second report,** C. E. HAYDEN (*Cornell Vet.*, 14 (1924), No. 2, pp. 158-165).—The author finds that in the blood of the horse in azoturia there appears to be a moderate average increase in some of the extractives, notably that of the total nonprotein nitrogen and sugar, though this is not true in all cases. Increases in individual cases tend to raise the average, but those cases showing the greatest individual increase are not always the worst cases in so far as clinical symptoms go. There is not enough increase in the extractives in either average or individual readings to justify the claims that the blood is loaded with extractives or that there is uremic poisoning to the extent that it might be the cause of the disease. The quantity of sugar found in average or individual cases so far also does not justify the claim that azoturia might be due to disturbed carbohydrate metabolism. Urine findings so far still do not indicate a nephritis of enough severity to be the cause of azoturia or of an uremia which might be severe enough to cause the disease. The report, however, is not considered as final.

**Pyotherapy in the purulent nasopharyngeal affection, so-called contagious pleuropneumonia (grip) in the horse** [trans. title], E. BEMELMANS (*Bul. Soc. Cent. Méd. Vét.*, 100 (1924), No. 20, pp. 458-465).—Excellent results are reported in the treatment of equine contagious pleuropneumonia with an autogenous vaccine prepared from nasal secretions by shaking about 4 cc. of the nasal discharge with 30 cc. of a 0.5 per cent phenol solution, heating the mixture to a temperature of 62° C. for 30 minutes, and allowing it to settle. The treatment consisted in the subcutaneous injection in the neck of from 3 to 5 cc. of the clear supernatant liquid, followed by gentle massage at the site of inoculation. Improvement in condition was noted within 24 hours. Occasionally a second injection is considered advisable.

**An outbreak of goose septicemia, with notes on the commercial fattening of geese,** F. R. BEAUDETTE (*Jour. Amer. Vet. Med. Assoc.*, 66 (1924), No. 2, pp. 145-150).—This is a contribution from the New Jersey Experiment Stations, in which the author reports upon an outbreak of goose septicemia, due to

*Pasteurella avium*, that occurred in one of the largest goose-fattening plants in northern New Jersey. The geese had been purchased mainly in Illinois and Missouri, being shipped in carload lots of from 1,500 to 1,800 geese. The outbreak was brought under control through isolation and the application of sanitary measures.

## RURAL ENGINEERING

**The artesian-water supply of the Dakota sandstone in North Dakota, with special reference to the Edgeley quadrangle, O. E. MEINZER and H. A. HARD** (*U. S. Geol. Survey, Water-Supply Paper 520-E (1925), pp. II+73-95, pls. 2, figs. 2*).—In cooperation with the North Dakota Geological Survey, the results of a questionnaire survey of the status of about 230 artesian wells in the area are presented and discussed.

**The San Juan Canyon, southeastern Utah: A geographic and hydrographic reconnaissance, H. D. MISER** (*U. S. Geol. Survey, Water-Supply Paper 538 (1924), pp. V+80, pls. 22, figs. 3*).—The results of a survey of the geography, geology, and surface conditions of the San Juan Canyon in southeastern Utah are presented.

**A discussion of certain Colorado River problems, G. E. P. SMITH** (*Arizona Sta. Bul. 100 (1925), pp. 143-175, fig. 1*).—This is a progress report supplementing Bulletin 95 of the station (*E. S. R., 47, p. 187*).

**Surface water supply of Pacific slope basins in Washington and upper Columbia River basin, 1921** (*U. S. Geol. Survey, Water-Supply Paper 532 (1924), pp. VI+222, pls. 2*).—This report, prepared in cooperation with the States of Washington, Montana, and Idaho, presents the results of measurements of flow made on streams in the Pacific slope basins in Washington and the upper Columbia River basin during the year ended September 30, 1921.

**Base exchange in ground water by silicates as illustrated in Montana, B. C. RENICK** (*U. S. Geol. Survey, Water-Supply Paper 520-D (1924), pp. II+53-72, pls. 3, fig. 1*).—Studies of ground water in an area of Lance and Fort Union formations in east-central Montana in the Great Plains province are summarized.

The results showed that near the surface the water is relatively high in calcium and magnesium, which, with increasing depth, are exchanged for sodium and perhaps potassium, the result being a natural softening. The minerals of the leverrierite group, which are plentiful though disseminated in these formations, and are believed to be derived from the decomposition in place of the glassy constituents of rock fragments, are considered to be the principal agents in effecting this exchange of bases, although the exchange may be aided by such minerals as kaolinite, feldspar, and mica. This exchange of bases is accomplished at a depth of 125 ft. or less. There is no tendency for the water to acquire more dissolved material with increasing depth. The amount of total dissolved solids is therefore determined relatively near the surface.

**Effects of storage on artificially polluted waters, R. C. FREDERICK** (*Analyst, 49 (1924), No. 575, pp. 63-73*).—Studies into the chemical changes which occur in excretally polluted water in storage are reported. The findings were coordinated with the results of analyses of nearly 1,000 samples of water from every type of source throughout the British Isles.

Studies to determine comparatively the changes taking place in water polluted with urine, with an equal quantity of feces, and with the same weight of a mixture of equal parts of urine and feces showed that the chemical changes in samples take place comparatively slowly, and that quite different results are obtained according to the nature of the pollution. The analytical results showed that if pollution of the water is very recent, the evidence in

the samples will be more pronounced if the analysis is actually delayed for a considerable period.

It was further found that in the case of a very recent pollution, particularly urinary, the free ammonia obtained by distillation is not infrequently evolved in a large number of fractions, each of which after the first few contains about the same amount as that immediately preceding. In samples in which the pollution is more remote, the free ammonia is completely evolved in a small number of fractions which show progressively a distinct fall in amount.

Recent pollution is indicated by distinct evidence of free ammonia. It was found that, of waters considered fit for potable purposes, none contained free ammonia in excess of 0.003, albuminoid ammonia in excess of 0.008, or nitrites in excess of 0.0001 part per 100,000, after excluding samples which could have derived these substances from other than excretal sources. It is concluded that these are the limits which, if exceeded and a nonexcretal origin can be excluded, provide definite evidence of excretal pollution. It is also concluded that the nitrates should not exceed 0.05 part per 100,000.

It is pointed out that it is not necessary to exceed all these figures to cause suspicion. A distinct excess of any one is sufficient, although the occurrence of only a single abnormality is said to be uncommon. Attention is drawn to the fact that, in the polluted waters considered, the limit for free ammonia was not exceeded in 32 per cent of the cases, for albuminoid ammonia in 16, and for nitrites in 14 per cent.

It was further found that exposure of samples of water to light resulted in an enormous increase in the albuminoid ammonia content due to the growth of algae, but for all practical purposes there was no effect on the rate of production and the amount of free ammonia and nitrites. This is considered proof that there is a fallacious increment to and not a decrement from the indications of pollution on storage in light as is commonly supposed.

The presence of 0.1 part per 100,000 of copper sulfate in samples stored in the dark very greatly restrained the production of free ammonia and entirely inhibited its oxidation into nitrites and nitrates, thus preventing to a great extent the creation of evidence of original pollution. Chlorination to the extent of 3 parts per 1,000,000 of samples stored in the dark completely prevented, for all practical purposes, the production of free ammonia, nitrites, and nitrates, and even one-fourth of this amount of chlorination was only slightly less effective.

**Size and depth of sand for filters** (*Engin. and Contract., Water Works, 62 (1924), No. 4, pp. 827, 828*).—The results of tests conducted by C. M. Daily on the size and depth of sand in seven water filters are briefly reported.

It was found that good water may be obtained with a 12-in. bed of sand by sacrificing the length of run through the use of fine sand. No sand finer than 0.38 mm. is considered to be desirable in a filter bed, and sand coarser than 1 mm. did not appear to be of any value. It is considered doubtful if any advantage is secured by having a greater depth than 24 in. of sand in a filter. Sand 24 in. deep composed of four layers, including (1) a 2-in. depth graded from 0.38 to 0.49 mm., (2) a 6-in. depth graded from 0.49 to 0.62 mm., (3) a 10-in. depth graded from 0.62 to 0.82 mm., and (4) a 6-in. depth graded from 0.82 to 1 mm., was found to give satisfactory results.

It was further found that where sand grains become coated with calcium deposits smaller sized grains should be used, and that the rate of filtration may influence the character of the effluent for any grading of sand. The effluent after washing was first clear, then became turbid, and after a period of from 30 to 45 minutes, running at one-fourth rate, became clear and remained so even after raising the rate until the tests were concluded. The best effluent was produced after 3 hours in service. It was found that the

agar count in the effluent may not vary as the turbidity varies, but that it roughly follows the same changes.

**Revenue report on the irrigation works of the Ajmer-Merwara District for the year 1922-23**, E. C. GIBSON ET AL. (*Ajmer-Merwara Irrig. Works Rev. Rpt., 1922-23, pp. 21, pls. 2*).—The text of this report is given.

**Public Roads, [January, 1925]** (*U. S. Dept. Agr., Public Roads, 5 (1925), No. 11, pp. 26, figs. 14*).—This number of this periodical contains the status of Federal-aid highway construction as of December 31, 1924, together with the following articles:

The Supporting Value of Soil as Influenced by the Bearing Area, by A. T. Goldbeck and M. J. Bussard (see below); Highway Research Board Proceedings, by J. L. Harrison; Recent Conclusions in Highway Research, by A. T. Goldbeck; Comparisons of the Strength of Concrete in Tension and Compression, by N. M. Finkbiner (see below); Highway Income from the Motor Vehicle, by H. R. Trumbower; and Highway Transportation Courses, Their Place and Content, by C. L. Raper.

**Comparisons of the strength of concrete in tension and compression**, N. M. FINKBINER (*U. S. Dept. Agr., Public Roads, 5 (1925), No. 11, p. 14*).—Studies conducted by the Oregon State Highway Commission are briefly reported, indicating that under general field conditions in Oregon the compressive strength of concrete in pounds per square inch divided by 10 will give approximately the strength of the concrete in tension at the age of 28 days.

**The supporting value of soil as influenced by the bearing area**, A. T. GOLDBECK and M. J. BUSSARD (*U. S. Dept. Agr., Public Roads, 5 (1925), No. 11, pp. 1-4, 8, figs. 9*).—Studies are reported which showed that when a given unit of load is applied to a soil over various areas, the depth of penetration is directly proportional to the square root of the area over which the load is applied. The general form of the relation expressed mathematically is

$\frac{p}{P} = \sqrt{\frac{a}{A}}$ , in which  $p$  and  $P$  are the penetrations resulting from the application of a constant unit load to areas  $a$  and  $A$ .

The above relation was established experimentally, and was also developed mathematically on the assumption that for any particular soil the areas under pressure at different depths are confined within lines of like inclination extending from the boundaries of the bearing areas.

**The viscosity of oils at high temperatures**, A. R. FORTSCH and R. E. WILSON (*Indus. and Engin. Chem., 16 (1924), No. 8, pp. 789-792, figs. 3*).—Due to the lack of data on the viscosity of oils at temperatures above 212° F., data and curves covering viscosity determinations on a wide variety of oils from Midcontinent and similar crudes up to a temperature of 495° are presented. The curves are discussed, and a method of interpolation is outlined by which it should be possible to obtain to within a few per cent the viscosity of practically any oil derived from Midcontinent or other intermediate base crude at any temperature up to 550°, given a single reliable determination of its viscosity at ordinary temperatures.

**Does the  $zn/p$  function fit the facts?** A. E. BECKER (*Indus. and Engin. Chem., 16 (1924), No. 8, pp. 856, 857, figs. 3*).—Data are presented which are taken to indicate that the theories which have been advanced in regard to the  $zn/p$  relation in the lubrication of bearings fail to fit the facts. This relation is that, for a given bearing and a given oil, changes in the coefficient of friction are determined largely by the modulus  $zn/p$ , in which  $z$  is the viscosity of the oil at the temperature of the oil film,  $n$  represents the revolutions per minute, and  $p$  is the nominal pressure on the bearing in pounds per square inch.

**Industrial electricity**, W. H. TIMBIE (*New York: John Wiley & Sons, Inc.; London: Chapman & Hall, Ltd., 1924, pp. XIII+735, figs. 469*).—This is one of the Wiley Technical Series, and its purpose is to explain how direct current electricity is generated, transmitted, and used, and to afford an adequate foundation for further study in the application of alternating current electricity to modern practice. It contains chapters on power and power transmission; Ohm's law; distributing systems; electric power; electrical properties of wire; methods of measuring resistance; magnets and magnetism; electromagnets; the magnetic circuit; generators; motors; armature winding and commutation; further applications; inductance; dielectrics, insulators, and condensers; electrochemistry; electrical measuring instruments; and vacuum tubes and gaseous conduction.

**Some research features of the application of electricity to agriculture**, R. W. TRULLINGER (*Agr. Engin., 5 (1924), Nos. 8, pp. 180-185; 9, pp. 203-208*).—A preliminary analysis is given of some of the more important research features involved in the application of electricity to agricultural processes along the lines discussed editorially (*E. S. R., 51, p. 301*).

**Artificial haymaking** (*Impl. and Mach. Rev., 50 (1924), No. 594, pp. 654, 655, fig. 1; also in Engineering [London], 118 (1924), No. 3068, pp. 554, 555, figs. 2*).—A brief account is given of studies conducted by the Institute of Agricultural Engineering Research of Oxford University, England, on the artificial drying and curing of hay. Investigations on the consolidation of the stack, porosity of the material in relation to penetrability, design of the chamber around which the stack is built, and the design of the fan resulted in the development of a central chamber that permits of equal penetration of the air in the stack.

It has been found that the requirements of proper drying are met best by using a cone-shaped structure in a circular stack. The slope of the side of the structure is based on turbulence, consolidation of the crop, and the porosity at different levels. A special air preheating arrangement is used in which the air is drawn by a fan over several hot spots or spiral heat conductors heated by paraffin fires under pressure. This air passes out of the heating chamber through a duct into the central chamber in the stack, from whence it passes uniformly to all parts of the mass. It has been found advisable to restrict the size of the stacks to from 10 to 25 tons, and to build them regularly to avoid uneven distribution of the air. The hay is stacked immediately after cutting, and blowing with preheated air is started as soon as the stack is completely made. It has been found that under ordinary circumstances a stack containing excess moisture will gradually heat until a temperature of 120° F. is reached. Fermentation then sets in and causes a rapid rise to about 150°, which is sufficient to kill many of the bacteria responsible for the heating. At such a stage, however, there is danger of another rapid rise due to ordinary chemical oxidation. In the drying process there is no need for the stack to rise above 100°, and fermentation is completely arrested.

The hay made by this process has been of a green appearance and has a pleasant smell and good taste. On the other hand, hay made in the ordinary way has some of its chemical constituents destroyed by the sun and prolonged exposure. Nutritive elements of the artificially cured hay are also said to be preserved to a greater extent. It is noted that the artificial method of curing is also being extended to corn drying.

**Heat loss through wall constructions**, A. KOLFLAATH (*Jour. Amer. Soc. Heating and Ventilating Engin., 30 (1924), Nos. 9, pp. 627-643, figs. 7; 10, pp. 661-668, figs. 4*).—Experiments conducted at the Norway Institute of Technology on the principles governing the loss of heat through the walls of 27 different test houses built in an open field are reported. The houses had inside

dimensions of 6.6 by 6.6 by 7.5 ft. The data obtained are analyzed primarily for the purpose of indicating their application in the determination of heat transmission coefficients of different types of wall construction.

**Tests on the hydraulics and pneumatics of house plumbing, H. E. BABBITT** (*Ill. Univ., Engin. Expt. Sta. Bul. 143 (1924), pp. 80, figs. 31*).—Studies to obtain information concerning the positive and negative pressures found in soil stacks, waste pipes, traps, and vent pipes, and also concerning the limitations of rates of discharge and the capacities of waste pipes and soil stacks are reported. Various diameters, lengths, and arrangements of pipes, traps, and vents were tested.

The maximum change of level of the water in a trap resulting from the application of pressure was found to be approximately the same for all diameters of traps, provided they are sufficiently large to render the effect of friction in retarding the movement of water negligible. The minimum diameter of trap to satisfy this condition seemed to be about 1 in. This is taken to indicate that for practical purposes in plumbing design the change of level of the water in traps will be the same under the same application of pressure, regardless of the depth of water in the trap.

The withdrawal of water from a trap was found not to weaken its resistance to the passage of air, provided the volume of water remaining in the trap was sufficient to fill the connection between the two legs and to form a vertical column of a height equal to the depth of seal in that leg of the trap in which the water rises. The resistance of a trap to the passage of air through it was found to vary directly with the depth of the seal. It is concluded that for safety in plumbing design it should be assumed that a water closet, other than the automatic valve type, may discharge at the rate of 50 gal. per minute for 7 seconds.

With unvented traps the pressure was found to vary as the five-halves power of the rate of discharge down the soil stack. With vented traps the pressure varied as some constant power of the rate of discharge, depending upon the type and capacity of the vent, and varying between about one-third for very complete venting and five-halves for no vent. The positive pressure in unvented traps was found to vary as the five-halves power of the height of fall of the water to the point of observation. Neither positive nor negative pressures were produced above the point of entrance of water to the soil stack. The negative pressure was found to be dependent both upon the vertical distance the water falls to the point where the negative pressure is measured and upon the vertical fall below this point. The greatest positive pressure is greater than the greatest negative pressure anywhere in a soil stack.

The maximum rate at which water will flow down a 4-in. soil stack without creating uncontrollable pressures in a plumbing system was found to be high, and a 2-in. pipe is considered to be unsuitable for use as a stack. The rates at which one horizontal waste pipe of the same diameter as the soil stack will discharge water into a soil stack through a sanitary T without backing up in the waste pipe were found to be for a 2-in. soil stack 25 gal. per minute for 7 seconds, for a 3-in. soil stack 50 gal., and for a 4-in. soil stack 100 gal.

The submergence of the house drain resulted in a material increase in the pressures created in a plumbing system. Since the use of a house trap, either vented or unvented, at the end of the house drain increases the pressures throughout the plumbing system, it is concluded that such a trap should not be used. Closures of the top of the soil stack or of vent pipes were found to result in such increases of pressure as to endanger the seals in trap.

**House painting, A. H. SABIN** (*New York: John Wiley & Sons, Inc.; London: Chapman & Hall, Ltd., 1924, 3. ed., rev. and enl., pp. XV+160*).—This is a practical treatise on house painting, glazing, paper hanging, and whitewashing.

## RURAL ECONOMICS AND SOCIOLOGY

**Farming partnerships in Tuscany as exhibited in some medieval documents** [trans. title], A. CASABIANCA (*Atti R. Accad. Georg. [Florence]*, 5. ser., 20 (1923), No. 2-4, pp. 19-28).—These notes describe some of the earliest farming partnership contracts and references to the system found in the medieval literature of Italy, certain of them dating back to the sixth century. The earliest actual authentic document of such a contract is said to bear the date of August 17, 1224.

**More profit for the wheat farmers of central Kansas**, J. W. TAPP and W. E. GRIMES (*U. S. Dept. Agr., Farmers' Bul. 1440* (1924), pp. II+14, figs. 11).—This is based upon data which have been noted (*E. S. R.*, 52, p. 588).

**Costs, profits, and practices of the sweet potato industry in New Jersey, 1922**, A. G. WALLER and H. B. WEISS (*N. J. Dept. Agr. Circ. 70* (1923), pp. 55, figs. 17).—Survey data collected in the field covering the year 1922 are incorporated in these pages, together with information as taken from official reports and other sources. New Jersey is found to rank second in the number of cars of sweet potatoes shipped, and with a production of less than 5 per cent of the total crop to ship to market from 15 to 20 per cent of the total car lot shipments.

The cost of producing sweet potatoes in New Jersey in 1922 was \$167.78 per acre or 94.9 cts. per bushel, the cost of growing plants amounting to \$18.57 per acre, preparing the seed beds \$13.27, planting and caring for the crop \$34.04, and labor and materials up to the point of harvesting \$91.60. Harvesting, including storage, containers, labor, and insurance, cost \$64.96, and interest on land or land rental was estimated at \$8.87. Man labor was the largest single item of expense, representing 43.7 per cent of the total cost. Next in order were fertilizer 10.4, containers 10.4, horse labor 9.9, land rental 5.3, and manure 4.2 per cent. An average of over 21 days of man labor per acre were required to raise the crop. Of the total production 34.3 per cent was produced at a cost of 80 cts. or less per bushel, 7.8 per cent at \$1.41 or over, and the bulk of the crop within the range of 81 to 140 cts. per bushel. The farms producing 100 bu. or less had an average cost of \$1.56 per bushel, while those producing 251 bu. and over per acre had an average cost of 66 cts. per bushel. The average yield per acre in 1922 was 176.7 bu., in comparison with the 10-year average of 129.

New Jersey has storage facilities for over 375,000 bu. of sweet potatoes, or a capacity for at least 10 or 15 per cent of the total crop. Over a period of years it has been found slightly profitable to store; during the 5-year period, 1918-1922, it was more profitable.

**The cost of raising swine under existing conditions in the College of Agriculture**, D. B. PEÑA (*Philippine Agr.*, 12 (1924), No. 10, pp. 469-479, fig. 1).—An experiment begun August 11, 1920, and ended December 1, 1921, at the College of Agriculture of the University of the Philippines was intended to determine the profits of hog raising under conditions existing at the college and to discover the relation of the proportion of Berkshire blood to the rapidity of growth of pigs. Not including pigs that died, 73 pigs, 9 sows, and 11 litters were used in this study. The growth data are briefly discussed.

The economic phase was carried out by recording the labor, feed, and disinfectants used, the depreciation on equipment, the rent of land and sows, and depreciation on the sows. The sum of these items was subtracted from the sum of the revenue derived from the sale of products to show the net return. The gross income from the 73 pigs, 23 of which were sold for breeding and 50 for meat, was ₱2,161.23. The total expenses were ₱1,772.77, making a net income of ₱388.46, which is calculated as 30.5 per cent of the average invest-

ment for the period of  $1\frac{1}{3}$  years, or 22.9 per cent per annum. Conditions are considered to have been more favorable in this experiment than at normal times. Under existing conditions at the college, the project was profitable when the retail price of pork was ₧1.20 a kilogram. After deducting all costs of operation, the managerial income of the operator was ₧291.65 per annum.

**The depreciation of the currency and its effects on agricultural credit in Germany,** W. VON ALTROCK (*Internatl. Rev. Agr. Econ.* [Rome], n. ser., 2 (1924), No. 2, pp. 163-193).—The credit system of the *Landschaften* in Germany made it impossible for these institutions to take into account the changed conditions in money values of the postwar period, and their method of obtaining capital by issuing mortgage bonds met with difficulties. The nominal value of their capital in relation to the fall in the mark was increased by raising the estimated values of buildings and other assets. The *Landschaft* bonds and other mortgage bonds are said to be no longer adapted to the needs of the period, and a substitute has been found for them in certificates of the sale of rye and bonds on a basis of rye values.

A rye bond bank making loans on mortgage securities was founded as a limited liability company by the society for the settlement of new lands at Berlin. Another banking enterprise was founded in November, 1922, on a somewhat similar basis, mainly to encourage land improvement. Its object is particularly the financing of large land improvement schemes. In the spring of 1923 the Central *Landschaft* for the Prussian States decided to grant rye loans and to issue rye bonds. Various other enterprises are noted, including the activities of cooperative and other organizations providing personal credit.

**The higher finance of agricultural co-operation in India,** H. CALVERT (*Internatl. Rev. Agr. Econ.* [Rome], n. ser., 2 (1924), No. 2, pp. 231-239).—Numerous devices were resorted to in order to meet the demand for an outside financing agency for cooperative societies in India. Central provincial banks, banking unions, and certain intermediary institutions are described in this paper.

**The organization and development of cooperative fire insurance companies in New York,** R. W. BARTLETT (*New York Cornell Sta. Bul.* 435 (1924), pp. 36, figs. 7).—The costs and some of the factors contributing to the success of these companies are set forth on the basis of data compiled since 1910 as obtained from State insurance reports.

On January 1, 1923, there were 166 cooperative fire insurance companies in New York State operating in 58 counties. They were of two general types, 135 assessment and 31 advance premium companies. It is estimated that of the total insurance on insurable farm property in the State approximately 90 per cent was written by cooperative companies. Of the total insurance of cooperative companies, 72 per cent was written by assessment companies in 1923 and 60 per cent by county assessment companies. The latter are said to be probably the most satisfactory type, since their losses and expenses are somewhat lower. Losses were found to have been greater in counties where low land values prevail than in those of high land values. The success of cooperative fire insurance companies is largely due to the fact that they have given reliable insurance at reasonable cost.

**Tax revision in Kansas,** E. ENGLUND (*Kansas Sta. Bul.* 234 (1924), pp. 3-95, figs. 8).—Data have been compiled from the Federal census and other official sources, and some information from an earlier investigation (E. S. R., 52, p. 294) is used in support of a statement of the principal reasons why tax revision is needed in Kansas. A program involving changes in the valuation of property for taxation and the institution of a State personal income tax and a tax on mineral and oil lands and on gasoline is outlined.

**Wheat forecasts in the Punjab, H. K. TREVASKIS** (*Agr. Jour. India, 19 (1924), No. 3, pp. 232-250*).—Crop statistics are said to have been collected originally in the Punjab for land revenue purposes, and an inevitable tendency toward underestimating the outturn was involved. The development of wheat export and the increased anxiety on the part of the Government to secure an adequate supply of food for the population have given rise to a demand for statistics free from bias. A method of gathering and checking village estimates for outturn, consumption, and stocks in hand is presented.

**The statistical measurement of the elasticity of demand for beef, H. SCHULTZ** (*Jour. Farm Econ., 6 (1924), No. 3, pp. 254-278, figs. 8*).—The problem dealt with in these pages is that of determining the effect of a tariff on the price paid by the consumer, on consumption, and on imports and profits in the cattle industry. Statistical data were found to be available with respect to the total quantity of beef slaughtered under Federal inspection in the United States and the prices at Chicago of native beef cattle per 100 lbs. live weight. The period covered by these statistics includes 73 months from January, 1907, to January, 1913. The method of trend ratios was used in eliminating disturbing factors influencing the price of beef, deriving the demand curve from the ratios of the data to their respective trends. When the production ratios and price ratios are plotted they exhibit a fair inverse correlation, although the effect of an increase in production upon prices is found to be not immediate. The tendency, however, is for prices to decline as production increases.

The elasticity of the domestic demand is derived and found to be about  $-4.5$ . Its margin of error is indicated, and some possible objections, both to the data and the method, are anticipated and discussed. The data which are necessary for the derivation of the coefficients of the domestic and foreign supply are said to be lacking. It is held that the effect of the tariff on beef is an example of a case where the demand is elastic and the tax is levied on the elastic supply, and that the increase in price due to the tariff is not so great as it would have been had our demand been inelastic, but not so small as it might have been had the foreign (taxed) supply been less elastic than the domestic (untaxed) supply. The quantitative answer to the problem set is deemed still unanswerable until further statistical data are available.

**The determination of hog prices at public markets, E. N. WENTWORTH and T. U. ELLINGER** (*Jour. Farm Econ., 6 (1924), No. 3, pp. 279-282*).—This study is based upon prices of hogs and pork products as exhibited in data published by the U. S. Department of Agriculture, comprising the items of the monthly receipts of hogs at Chicago, the monthly average prices of medium weight hogs at Chicago, and monthly price quotations at eastern points on fresh pork loins, breakfast bacon, smoked hams, picnic shoulders, and lard. The quotations cover the period of 46 months from January 1, 1920, to October 31, 1923.

The relationships between six of the variables mentioned have been correlated in all combinations of two. The relative size of these coefficients indicates that prices on live hogs are more closely correlated with prices on cured pork products and lard than with loin prices. This fact suggests that live prices are, therefore, more definitely determined by them than by loin quotations. The multiple correlation between live prices and the combined six other variables has been calculated. Four conclusions are drawn as follows:

(1) If receipts were constant and provision prices were constant, hog prices would display no appreciable variation. (2) Current hog quotations do, to a remarkably high extent, reflect the number of animals marketed by the producers as well as the prices which the consuming public is willing, at that particular time, to pay for the finished products in the volume available for

sale. (3) The six factors included in this analysis account for practically all variations in the average monthly hog prices, and other suspected causes of fluctuations either neutralize each other or are insignificant. (4) For the period covered by the study, it appears that the cause of price variations in live hogs originated outside of the marketing system and in the field of production or consumption.

**Interim report on meat, poultry, and eggs, MARQUESS OF LINLITHGOW ET AL.** (*London: Min. Agr. and Fisheries, 1923, pp. 185, figs. 7*).—This is another one of the reports of the departmental committee on distribution and prices of agricultural produce in the same series previously noted (*E. S. R., 50, p. 690*). The oral evidence obtained in the course of the investigation consisted largely of details of private and in many cases of competitive businesses. Furthermore, questionnaires were furnished to meat retailers throughout Great Britain, of which between 700 and 800 were returned complete. Information with reference to meat is presented in sections on statistics of live-stock and meat, methods of marketing stock and of distribution of fresh meat and bacon, costs of marketing livestock, slaughterhouses and slaughtering charges, costs of distribution of meat and bacon, the price structure, meat markets and depots, insurance against condemnation of meat, cooperation of producers, and the imported meat trade and empire supplies. That with respect to poultry and eggs is covered in sections on production and consumption, methods and costs of marketing and distribution, preparation for market, packages, and cooperation of producers.

**Cold-storage holdings to October, 1924** (*U. S. Dept. Agr., Statis. Bul. 4 (1925), pp. 32*).—The statistics in this bulletin, prepared by the Bureau of Agricultural Economics, are presented in revision of earlier information (*E. S. R., 49, p. 892*).

**Crops and Markets, [January, 1925]** (*U. S. Dept. Agr., Crops and Markets, 3 (1925), Nos. 1, pp. 16; 2, pp. 17-32; 3, pp. 33-48, fig. 1; 4, pp. 49-64; 5, pp. 65-80*).—Statistics are tabulated from current weekly market reports covering important classes of agricultural products and specific commodities, and brief special articles are given, reviewing their situation in the market. Foreign crops and markets notes are also presented.

**Agriculture and American business, J. H. BARNES** (In *The Genius of American Business. Garden City, N. Y.: Doubleday, Page & Co., 1924, pp. 42-51*).—This chapter from a book of collected addresses puts forth the conviction that agriculture in the United States is in a secure position, and emphasizes the need for expansion of railroad facilities as one means of preserving it.

**Agriculture and foreign relations, J. H. BARNES** (In *The Genius of American Business. Garden City, N. Y.: Doubleday, Page & Co., 1924, pp. 52-61*).—Another chapter from the book noted above discusses the interest of the American farmer in the restoration of buying power in Europe, reviewing the position of Germany, France, Great Britain, and Italy as the chief customers for the products of American agriculture.

**European economic conditions which affect the markets for agricultural products, H. B. SMITH** (*U. S. Dept. Com., Bur. Foreign and Dom. Com., Trade Inform. Bul. 235 (1924), pp. II+62*).—Questions relating to the purchasing power, productive ability, labor conditions, social and financial stability, and industrial and agricultural activity in the principal countries of Europe are covered in this bulletin. One of the facts of prime significance brought out is that, according to the best estimates available, industrial activity in Europe is on a level only 60 or 70 per cent as high as before the war. The economic situation of individual countries is set forth in some detail. It is held that most of Europe has been and is financing its trade through measures which are

neither sound nor constructive, and which place a limit upon the extent to which they can be made effective in the future.

**The future of wheat export from the United States**, A. E. TAYLOR (*Kans. State Bd. Agr. [Quart.] Rpt., 43 (1924), No. 169, pp. 35-51*).—The author discusses the position on the world market of wheat exported from the United States. It is declared that expansion of production is to be expected in Canada, Argentina, and Australia, as well as in Russia. A number of price fixing and marketing schemes are discussed. The Coulter plan providing for extension to wheat growers of already existing governmental credit facilities with specified application of the credits to diversified farming and particularly the purchase of animals is favored as sound and constructive. Farmers were advised to restrict operations in 1923-24 to the domestic basis, and it is held that they should not be told that experiences and precedents in cooperative marketing warrant the expectation that such collective organization would raise the price of wheat sold in the export market.

**Permanent agriculture, population restriction, and national progress**, E. M. EAST (In *Mankind at the Crossroads. New York and London: Charles Scribner's Sons, 1923, pp. 146-198, figs. 4*).—This chapter from the author's book on population and the food supply comprises a brief sketch of the agricultural situation in the United States in its relation to population problems, which brings together data from several official and other sources with regard to the limitations upon natural resources, as well as a discussion of problems of agronomy bearing upon the future food resources of the United States and the world and the probable development of the agricultural industry.

**The agricultural regions of North Dakota**, R. E. WILLARD (*North Dakota Sta. Bul. 183 (1924), pp. 5-168, figs. 64*).—The material presented here has been assembled from a number of official sources, and constitutes a survey of the physical and climatic features of the State, the principal regions for the production of particular crops, yields, relative damage to crops, the agricultural belts of the State, and crop production trends. A synopsis of North Dakota agriculture is given by counties.

**Rural social survey of Hudson, Orange, and Jesup consolidated school districts, Black Hawk and Buchanan Counties, Iowa**, G. H. VON TUNGELN and H. L. EELLS (*Iowa Sta. Bul. 224 (1924), pp. 201-251, figs. 18*).—The report is made of a detailed survey of 385 farm homes and farm families, which was conducted by means of personal interviews during the year 1920-21. Information is presented showing the nationality and marital condition of the population, the size of families, and the economic, social, educational, and religious conditions which prevail in these regions among both tenants and owners. In general, about 75 per cent of the young people declared their intentions of remaining on the farm, and from 55 per cent in Jesup to 94 per cent in Orange district of the tenants who did not own land showed that they expected to become farm owners. The appendix compares the results of an earlier survey of the Orange district (E. S. R., 40, p. 593) with those of the year 1920-21.

**Monthly Supplement to Crops and Markets, [January, 1925]** (*U. S. Dept. Agr., Crops and Markets, 2 (1925), Sup. 1, pp. 32, figs. 3*).—The results of the December 1 pig survey, tabulated data showing the utilization of the corn crops of 1923 and 1924, and a survey of the world flaxseed production, together with reviews of the 1924 produce season and the production of certified seed potatoes and statistics of American cotton consumption, 1924, with comparisons, are featured in this issue. The usual estimated farm prices of important products and statistics of the livestock and meat situation and of fruit and vegetable shipments and prices are presented.

**Horses, mules, and motor vehicles** (*U. S. Dept. Agr., Statis. Bul. 5* (1925), pp. 95).—Statistics for the year ended March 31, 1924, with comparisons, compiled in the Bureau of Agricultural Economics from commercial and official sources, are presented in 104 tables showing the numbers, receipts, shipments, exports and imports, costs of raising and prices of horses and mules, and the production, uses, costs, and other items with respect to motor vehicles.

**Agriculture [in Algeria in 1923]** [trans. title], T. STEEG ([*Gouv. Gén. Algérie*] *Exposé Situation Gén. Algérie, 1923*, pp. 501-507, 525-528, 558-562, 585-705).—The annual report with reference to the encouragement of agricultural interests by the Government of Algeria is submitted, continuing the series previously noted (*E. S. R.*, 50, p. 193).

## AGRICULTURAL EDUCATION

**Report of the committee on agricultural education and research in Scotland**, A. H. B. CONSTABLE ET AL. (*Edinburgh: Govt., 1924*, pp. 54; *abs. in Scot. Jour. Agr.*, 7 (1924), No. 4, pp. 401-404).—This committee report gives a short summary of the development of agricultural education in Scotland from 1790 onward, and traces the rise of teaching centers at Aberdeen, Edinburgh, and Glasgow, respectively.

The growth in expenditure at these three collegiate centers is noted, the gradual increase in the proportion of State to local contribution being specially brought out. The existing organization of the colleges and their methods of working are described, the extension work in the counties is noted in some detail, and the general results of the whole system are reviewed. The relations between the universities and the colleges are considered in view of a suggestion made to the committee that all the higher scientific teaching should be left to the universities. Suggestions are made for modifying the curricula at the colleges and for encouraging a certain amount of specialization at each center in relation to the prevailing types of agriculture in the respective areas. Evidence pointed to the fact that the governing boards of the colleges have grown too big, and the committee proposes reconstruction of these bodies.

A section of the report is devoted to a discussion of the problem of rural education, which, in the opinion of the committee, is the most difficult of those reported upon. It is recommended that an experiment be made in establishing one or two residential schools offering short courses to farmers' sons along the lines of the inexpensive schools in Denmark, Norway, and Sweden. Special training in women's work on the farm is also recommended, and the value of the work of women's rural institutes in this connection is recognized.

The 30 specific recommendations of the committee are drawn up with regard to agricultural education, research, and veterinary colleges. With regard to research, it is deemed important to encourage further investigation in animal diseases and plant breeding. It is declared that Rowett Research Institute should be provided with an experimental and demonstration farm, and that a research institute should be established in connection with the National Dairy School at Kilmarnock. The systematic recording and analysis of data necessary for agricultural cost studies should be resumed and extended, and provision should be made for special research in plant pests and diseases. It is recommended that careful consideration should be given to the suggestion for a limited tax on agricultural land as one means for raising special funds for agricultural research.

[Seventh and eighth reports with reference to the work of the Federal Board for Vocational Education in agriculture and home economics] (*Fed. Bd. Vocat. Ed. Ann. Rpts.*, 7 (1923), pp. 37-54, 67-88, pl. 1, figs. 6; 8 (1924), pp. 54-66, 80-89, pls. 3, figs. 7).—Portions of these annual reports set forth part-time and other teaching of vocational agriculture, as well as research, service activities, and cooperative teacher training work in 1923 and 1924.

**Orchard improvement instruction in Herefordshire**, A. J. MANNING (*Jour. Min. Agr. [Gt. Brit.]*, 31 (1924), No. 4, pp. 355-360, pl. 1).—In 1912 annual competitions were planned for five years as a part of a scheme for orchard improvement. After the Armistice was signed, the further development of horticultural education in the county was provided for by the organization of systematic training of classes of about six men in pruning and grafting. Classroom lessons in fruit growing have been given in connection with the winter courses in agriculture for young farmers.

**Students' competitions at agricultural shows**, A. GREGG (*Jour. Min. Agr. [Gt. Brit.]*, 31 (1924), No. 4, pp. 349-354).—Student competitions at agricultural and at fat stock shows in Cornwall are described, and the score cards used are exhibited.

**Manual in agriculture: Growing things** (*Pierre, S. Dak.: Dept. Pub. Instr.*, 1924, pp. 176, figs. 135).—Teaching material and suggestions are presented for use in the schools of South Dakota in connection with the State course of study.

**Crop production and soil management**, J. F. COX (*New York: John Wiley & Sons, Inc.; London: Chapman & Hall, Ltd.*, 1925, pp. XXX+516, figs. 225).—A handbook for students of crop production and soil management problems in vocational schools or colleges or for practical farmers is presented. Part 1 includes chapters dealing with farm operations, while part 2 covers the growing of specific crops.

**Studies in horticulture**, J. W. LLOYD, edited by E. DAVENPORT (*Chicago: Rand McNally & Co.*, 1924, pp. VIII+421, figs. 192).—This is designed for use as a text and guide in high schools giving two or more years of instruction in agriculture, one of which is devoted to horticulture. It covers the two branches of the subject, namely, fruit culture and vegetable gardening, selecting for treatment a few kinds of fruits and vegetables considered most important in the groups to which they belong. Chapters are included covering briefly the preservation and the selling of vegetables. Suggested home projects and a list of references constitute two appendixes.

**Lessons for pig club members**, R. B. MILLIN (*Mont. Agr. Col. Ext. [Pub.] No. 68* (1924), pp. 46, figs. 19).—Eighteen elementary lessons in pig production and care are suggested.

**Poultry raising for club members**, D. H. HALL and J. H. NEELY (*Clemson Agr. Col. S. C., Ext. Bul. 65* (1924), pp. 43, figs. 14).—This has been prepared for the guidance of boys and girls engaged in the second-year activities of the boys' and girls' poultry clubs of South Carolina.

**Boys' and girls' club work: Clothing handbook** (*Maine Agr. Col. Ext. Bul. 149* (1924), pp. 36, figs. 37).—This gives concise information on the processes involved in garment making, the selection and care of clothing, and the recognition of textiles.

**Essentials of sewing**, R. C. COOK (*Peoria, Ill.: Manual Arts Press*, 1924, pp. 238, figs. 162).—This textbook is designed as an aid to teachers and to assist students in solving the problems of garment making in school and at home.

**The country theatre**, H. A. SECKERSON (*Conn. Agr. Col. Ext. Bul. 80* (1924), pp. 16, figs. 3).—The growth of the little country theater movement in Connecticut is set forth. Books on dramatics and plays adapted to amateur production are suggested.

## NOTES

---

**California University and Station.**—The last legislature appropriated \$135,000 for the construction of two units of a plant to house the activities of the divisions of agricultural engineering and irrigation investigations and practice.

Twenty-three acres of land recently acquired in Berkeley for the use of the College of Agriculture are being placed in condition. Five acres adjoin the campus and the remainder are about a mile distant.

A cold storage unit has been installed in the truck crops laboratory at Davis, making available much needed facilities for this division.

The technical series of station publications has been superseded by a serial entitled *Hilgardia, a Journal of Agricultural Science*, the first number appearing in May. This journal will contain the same type of articles that formerly appeared in the technical series, and is dedicated to Dr. E. W. Hilgard, the first director of the station.

J. W. Gilmore, head of the division of agronomy, has been granted a six months' leave of absence, beginning July 1, to enable him to make an agricultural survey of the Dominican Republic.

Dr. Jacob Traum, associate professor of veterinary science, was granted leave of absence from April 15 to July 1, as one of a corps of three investigators working under the auspices of the U. S. Department of Agriculture, on a study in Europe of foot-and-mouth disease.

**Georgia College.**—The week of April 6 was observed as girls' club enrollment week, the membership campaign being conducted by the home demonstration agents. In 1924 the membership was 8,402 and the value of products \$362,827.65, of which \$250,502.97 was from canning clubs and the remainder from the dairy, poultry, millinery, and sewing clubs. As a direct result of the club work in the State, 656 girls are now attending high school and 146 are in college, while 760 have bank accounts.

**Illinois University.**—The new horse barn, constructed of hollow tile and concrete with steel framework, is nearing completion.

Three new dairy barns, two for cattle and one for calves, and four silos have recently been finished. Vitrified tile has been used for all these buildings. The cattle barns are each 118 by 40 ft. and accommodate 50 and 54 head of cattle, respectively. The calf barn contains 4 bull pens, 8 group calf pens, 12 individual calf stalls, and 15 individual cow stalls.

**Kansas College and Station.**—In accordance with recent legislation, the University of Kansas, the Kansas State Agricultural College, and the three State teachers' colleges on July 1 pass under the control of a nonsalaried board of regents of nine members, appointed by the governor. The first board comprises 3 members for 1-year terms, 2 for 2 years, 2 for 3 years, and 2 for 4 years, and their successors will regularly be appointed for 4-year terms.

Dr. F. D. Farrell, acting president since March 2, has been appointed president, effective May 5. The degree of doctor of agriculture was conferred

on President Farrell April 15 by the University of Nebraska. The occasion was the commencement exercises of the school of agriculture, at which he delivered the principal address on Law in Agriculture.

N. E. Olson, associate professor of dairy husbandry in charge of dairy manufactures in the college and station, has resigned to enter commercial work, effective June 1.

A conference of branch experiment station workers was held at Manhattan April 13 and 14.

Feeding trials with dairy cattle recently completed show that there is no particular difference in efficiency between corn chop and ground sorgo seed for milk production when fed with a liberal ration of alfalfa hay, grain, and silage, although the ground sorgo seed ration consistently produced somewhat more butterfat than the corn chop ration. Ground kafir was about 97 per cent as efficient as corn chop for milk and butterfat production when fed in a liberal ration of alfalfa hay, grain, and silage. Alfalfa hay was more efficient than sweet clover hay for milk production.

**Louisiana University.**—Press reports state that Oscar B. Turner, instructor in agronomy, was found murdered in the agronomy building June 7. He had been at the university since 1923 and was 55 years of age. No indication of his assailant has thus far been obtained.

**Maryland University and Station.**—Director H. J. Patterson has also been appointed dean of the College of Agriculture.

**Michigan College and Station.**—The name of the college was changed to Michigan State College of Agriculture and Applied Science by an act of the 1925 legislature. The change of name became effective May 13, the seventieth anniversary of the passage of the act establishing the college and of the acquisition of the present college estate, as well as of the sixty-eighth anniversary of the opening of the college. The year 1925 also marks the fortieth anniversary of the inauguration of a course in engineering, the thirtieth anniversary of the establishment of a course in home economics and of the passage of the law establishing a state-wide system of farmers' institutes, and the tenth anniversary of the acceptance of the Smith-Lever Extension Act by the State legislature. During the week of May 11 a series of conferences was held commemorating these dates and calling attention to some of the forward-looking programs of the various divisions of the college.

A total of \$4,063,000 from State sources will be available for maintenance and building work during the next biennium. This amount provides for a \$600,000 chemistry building and a \$250,000 armory, and \$438,000 for permanent improvements. Aside from the mill tax, which returns \$2,000,000 for current maintenance, an additional \$700,000 was appropriated for extension and research. This gives the institution the largest amount of money ever at its disposal.

L. H. Cooledge, research associate in bacteriology since 1912, died May 12, at the age of 37 years. He was a native of South Dakota, graduating from the South Dakota College in 1911 and receiving the M. A. degree from the University of Missouri in 1912. Among his contributions to science was the development of the colorimetric hydrogen-ion method of determining the keeping qualities of dairy products. He was also among the first to study the occurrence of *Bacterium abortum* in the milk of the cow, and he has made numerous contributions on that subject.

**Minnesota Station.**—Arnold H. Johnson, Ph. D., instructor in agricultural biochemistry, has been appointed assistant chemist in the Montana Station

vice Dr. Paul F. Sharp, who has accepted a position as professor of dairy chemistry in Cornell University.

**New Jersey College and Stations.**—The State appropriations for the work of the agricultural college and stations show liberal increases in a number of items for the fiscal year 1925-26. An appropriation is made for the development of roads and grounds, \$200,000 is allowed for a new physics building, and a small grant is made for the establishment of a chair in journalism. There is also a special appropriation for remodeling the administration building.

Alvah Peterson, Ph. D., associate professor of entomology and associate entomologist, resigned May 1 to accept a position with the U. S. Department of Agriculture, for the present at the Japanese Beetle Laboratory at Riverton. C. C. Hamilton, associate entomologist at the Maryland Station, was appointed assistant entomologist on the same date.

**Cornell University.**—The General Education Board has granted the department of rural education of the College of Agriculture \$10,000 a year for five years. Dr. Clyde B. Moore, associate professor of principles of education at the University of Pittsburgh, has been given an appointment in the department under the provisions of the fund.

A child-training department has been organized in the new College of Home Economics under a grant from the Laura Spellman Rockefeller fund. Dr. Nellie Perkins has been appointed head of this department.

Dr. Burt G. Wilder, emeritus professor of neurology and vertebrate zoology, died January 20 at Chestnut Hill, Mass., in his eighty-fourth year. Doctor Wilder was associated with the university from 1868 until his retirement in 1910. During this long period he trained an unusual number of students in physiology, zoology, and related subjects and, at the completion of his first quarter century of service, some of them prepared and published in his honor a volume of original contributions to science. He was also a pioneer in investigating various zoological problems and had published many papers.

Dr. J. R. Schramm, professor of botany, has resigned to become editor of *Biological Abstracts* and has been succeeded by Dr. L. W. Petrie of Syracuse University.

Dr. Emil F. Guba, assistant extension professor of plant pathology, has accepted an appointment as assistant research professor of botany.

**New York State Station.**—The appointments are noted of Ralph H. Shriner, Ph. D., a graduate student at the University of Illinois, as associate in research (biochemistry), beginning July 1, to fill the vacancy caused by the resignation of Dr. Fred P. Nabenhauer; Carl S. Pederson, a graduate student at the University of Wisconsin, assistant in research (bacteriology), beginning July 1, this being a new position created at the last session of the legislature; and F. L. Gambrell, a graduate student at Ohio State University, assistant in research (entomology), beginning May 1, filling the vacancy caused by the transfer of F. G. Munding to the entomological work of the Hudson River Valley, previously noted. Rodney Cecil of the U. S. D. A. Bureau of Entomology has been assigned to conduct investigations on the Mexican bean beetle in cooperation with the division of entomology of the station.

**North Carolina College and Station.**—James McDowell has been appointed in charge of research in the textile school. It is planned to make a study of cotton fibers from various parts of the State and elsewhere as to their affinity for bleaching, dyeing, and mercerization, as well as tests of yarns and cloth and of starches, the discovery of new uses for the cotton fiber, the problem of waste as related to imperfect fiber and other factors, and numerous other manufacturing problems.

Press reports announce that Dean and Director B. W. Kilgore has resigned after 30 years' service.

**Ohio State University and Station.**—The resignation of President W. O. Thompson, effective November 5 when he becomes 70 years of age, has been accepted. He has been appointed president emeritus at his present salary.

The board of control of the station and the trustees of the university have approved an understanding whereby a substation will be established at the College of Agriculture. Members of the college faculty may be appointed to the station staff in the usual way. Such part of their salary as may be agreed upon will be paid by the station, as well as all expenses for the research work done at the college, and the station will be responsible for their work. Under this arrangement the station has appointed Dr. J. I. Falconer head of its newly established department of rural economics.

According to a note in *Science*, Augusto Bonazzi, for many years in charge of soil biological investigations, has accepted the directorship of the Chaparra Sugar Cane Experiment Station in San Manuel, Oriente, Cuba. M. A. Bachtell has been appointed associate in the department of farm management, which has charge of operations on the three district and nine county experiment farms of the State.

**Pennsylvania College and Station.**—Miss Emma Francis, assistant professor of agriculture and biological chemistry since 1921, died March 4 at the age of 49 years.

The resignations are noted of L. M. Black, P. A. Frost, and N. E. Phillips, assistant professors, respectively, of poultry husbandry, zoology, and entomological extension, and W. A. Kuntz, instructor in botany. George H. Rea has been appointed assistant professor of apicultural extension.

**Rhode Island Station.**—Basil E. Gilbert, Ph. D., has been appointed chemist.

**Texas Station.**—J. J. Hunt, wool and mohair specialist in the division of range animal husbandry, resigned March 31 to engage in commercial work, and was succeeded May 1 by Frank Grayson, a practical wool and mohair grader of many years' experience in Rhode Island.

**Utah College and Station.**—Dr. George R. Hill, jr., has resigned as professor of botany and plant pathology and dean of the school of agriculture to become director of the department of agricultural research of a Utah smelting and refining company.

**Wisconsin University and Station.**—President E. A. Birge is to retire at the end of the present academic year and will be succeeded by Glenn Frank, editor of the *Century Magazine*.

A bronze tablet, known as the Henry Tablet, has been recently set in a huge boulder at the entrance to the College of Agriculture grounds. The tablet bears the following inscription:

The Henry Quadrangle—In Recognition of the Pioneer Services of Dean William Arnon Henry to the Science and Practice of Agriculture in this University, The State, and The Nation from 1880 to 1907—This Approach to The College of Agriculture Has Been Designated by the Regents The Henry Quadrangle.

# EXPERIMENT STATION RECORD

VOL. 52

JUNE, 1925

No. 8

---

That science and religion have the common aim of uplifting humanity through the education and development of the individual was aptly illustrated by a meeting to consider agricultural missions, held in this city some months ago as a part of the program of the great Interdenominational Foreign Missions Convention. The first speaker at this meeting was the head of a commission which, in 1920 and 1921, made a first-hand study of education in Africa under the auspices of the Phelps-Stokes Fund and the foreign mission societies of North America and Europe, and in his address he struck the keynote of the session by calling attention to the necessity of improving the economic and living conditions of backward peoples along with or even as a foundation for their religious education. He was followed by several missionaries, who spoke of the extensive work in agricultural education already being carried on at mission stations in various far-away lands, and by representatives of the Federal Department of Agriculture, who discussed a number of specific aspects of this movement, which, despite its comparatively recent origin, is becoming an increasingly important factor in the improvement of the world's agriculture, as well as in the economic and social betterment of the peoples immediately benefited.

The practical applications of agriculture and Christian ethics seem to be nowhere more harmonious than when the two are taught and demonstrated side by side in the mission stations. In most of the foreign mission fields agriculture is usually the principal occupation of the masses, and yet it is more often true than not that their food supply and living conditions are wholly inadequate. In much of Central and South America, for example, the necessity arises of arousing submerged and subjugated races to an interest in raising their standard of living through encouraging the possession of land and training small farmers in improved methods.

Field investigations in representative farming communities of north and central China have shown that from 75 to 95 per cent of the population is engaged in agriculture on a whole-time basis, per-

haps the larger number working as tenants. In the north over 80 per cent of the population realize a yearly income estimated at less than \$150 per family of five persons, which amount is the minimum for subsistence for such a family. The farmer is said to exist mainly by sparing himself all unnecessary exertion from December to March, cutting down drastically on food consumption until spring when work begins again in the fields, and he must labor in an emaciated condition for several weeks before a new supply of food can be obtained. Mission workers, faced with such conditions among the people they desire to serve, find that they must bring about an improvement in their economic welfare, principally by giving attention to the upbuilding of their agriculture and simple industries.

Under the tribal organization of the natives of central Africa, it is the women who sow and care for and harvest the food crops and select and prepare the food; hence, it is the agricultural education of this group that would most directly affect the welfare of the family. Among certain pastoral tribes, however, the men are interested in livestock and take pride in caring for it. With recent developments arising out of British efforts to expand cotton production in central Africa, the men are practically compelled to cultivate a given acreage of cotton as a direct means of paying their taxes or as a money crop. The provision of agricultural instruction by the missions has been of marked assistance to these people. Indeed, the report of the commission already referred to declares that "the services of the missionaries equal and in some respects surpass those of all other groups in the quality of their influence on the African people. . . . The school systems are almost exclusively the result of missionary efforts. . . . They usually represent the ideals of education prevailing in the home country . . . though . . . they are gradually adapting education to the needs of the people." The commission further holds that the best experience in Africa points to the conclusion that, while the education of religious workers and teachers is evidently the first responsibility of secondary schools maintained by the missions, the training of agricultural and industrial leaders is their second duty, and preparation for medicine, theology, engineering, or law their third.

The famine recurrences and dire poverty in India, which is first of all an agricultural country, are well known and, together with the influence of the caste system, give rise to some of the most urgent problems which the missions there must cope with. The instance is cited of the experience of Mr. Sam Higginbottom, an American evangelist now widely known as a pioneer in the agricultural missions field, who upon arrival at his station some years ago was

placed in charge of the leper hospital. In an attempt to secure better living conditions for the patients and keep them from dwelling upon their misfortune, he started them at farm work so that they might provide part of their food and be able to use their Government dole for other purchases. In order to prepare himself for better leadership he returned to the United States for a two-year study of agriculture at the Ohio State University. The ultimate outcome of his effort was the purchase by his board of 275 acres of land and the establishment of the Allahabad Agricultural Institute, now one of the leading specialized agricultural missionary institutions engaged in training teachers and in experimentation.

As a recognized and formally organized phase of foreign missionary endeavor, the agricultural work is a rather recent development and must still be regarded as in the formative period. To be sure, as early as 1876, Dr. W. S. Clark, one of the first presidents of the Massachusetts Agricultural College, established in Japan the Imperial Agricultural College at Sapporo, lecturing on Christian ethics from the Bible in the same classroom where he taught agriculture, but the purpose of his mission and that of his colleagues was primarily educational and not that of evangelization. One of the first men with training in agriculture to go into the foreign field as a missionary seems to have been a Cornell graduate, William C. Bell, although he did not establish a school until 1914. Probably the first of the mission schools to be organized specifically for teaching agriculture was the Thessalonica Agricultural and Industrial Institute, founded in 1903. Agricultural mission work in India was instituted about 1906 by Mr. J. B. Knight, a graduate of the Massachusetts College. In general, however, mission boards have only of late been realizing the importance and opportunity of improving the condition of the natives in this fundamental way.

Since 1912, when Mr. Higginbottom completed his special training and returned to the field to demonstrate the value of his experiment, attention has been definitely directed to the special training of the agricultural missionary and the importance of including an agriculturist on mission staffs. In 1920 the International Association of Agricultural Missions was founded at Amherst, Mass., by a group of returned missionaries who had been in convention at Des Moines, Iowa, in 1919, in order to promote the interests of Christian agricultural work in all lands and expressly to call this field to the attention of the mission boards. The first student conference of the association was held at the Massachusetts Agricultural College, April 8-10, 1921. Among those present was Mr. Higginbottom, who, in emphasizing the demand for trained workers, declared that 99 per cent of the agricultural departments in mission

stations in India had failed because of the tendency to place in charge a theologian who was unfitted by training or inclination for the work.

Within the last few months, an important international project for the scientific improvement of the important food crops of China has been inaugurated by the University of Nanking and Cornell University, with the aid of the International Education Board. Under this plan Dr. H. H. Love of the department of plant breeding in the New York State College of Agriculture left Ithaca in March for China, to devote his sabbatic leave of six months to organizing the work, and beginning in February, 1926, Dr. C. H. Myers of the same department will carry it on for a similar period. It is expected that this procedure will be followed for from five to ten years until a trained staff has been developed at Nanking to take over the work completely.

This program is part of a large scheme for the prevention of famines in China, in which the University of Nanking is doing important work, and it looks to a permanent increase of the food supply by developing better strains of the various food crops. It is expected that as much plant improvement work as the facilities and time will permit will be carried on from the beginning. A general study of the principal food crops in several provinces to determine the best foundation stocks is contemplated.

Under the conditions prevailing, the formal organization of research under missionary auspices can hardly hope for immediate attention in any comprehensive way, and in most institutions provision for it has been more or less incidental and subordinate to that for instruction and demonstration. At the same time, much of the work undertaken is necessarily experimental and consequently contributes to a distinct increase in knowledge. One of the lessons earliest impressed upon the mission workers was the unwisdom of attempting to transplant without sufficient adaptation the farm practice with which they had been familiar. To an exceptional degree, modifications to meet local conditions have been imperative to avoid disaster. This has made essential a study of the situation as it exists, an actual testing out of proposed innovations, and in many cases an enlightened combination of the old and the new. Thus, the task of educating the native peoples has not been entirely one-sided, and the outcome has shown some general as well as many local advantages.

In 1923 a conference was held in Washington, D. C., between representatives of the Federal Department of Agriculture, the Indian Office of the Interior Department, and various missionary boards and agencies. The primary purpose of this conference was to stimulate suggestions as to how agricultural mission schools might encourage investigation of local practices and native products

and the adaptation of improved methods to local conditions, as well as how best to train research workers among native students or staff members. Attention was directed to the work carried on by the Canton Christian College in the way of research for some years with respect to varieties, methods of culture, soil requirements, and means of propagating the lychee, a native fruit similar to the peach, and also with respect to the butter-producing capacity of the water buffalo, the preservation of foods, and improved sericulture. The College of Agriculture and Forestry at Nanking University was also referred to as having rendered valuable service in spreading the practical gospel of reforestation and in making possible actual plantings of considerable size, as well as in numerous lines of agricultural work.

One of the topics of discussion at this conference was the development of exchange relations between institutions such as these and the Department of Agriculture in the introduction of seeds and plants and other ways of mutual helpfulness. That considerable direct service to agricultural science may be derived from such contacts is illustrated by the fact that nearly 500 shipments of seeds and other plant material have been received by the Department from foreign missionaries within the past five years. As earlier instances may be cited the history of the Washington Navel orange, introduced into the United States in 1870 by a missionary at Bahia, Brazil, and the efforts of Dr. W. P. Brooks, for twelve years head of the agricultural college at Sapporo, Japan, in connection with the introduction of the soy bean and other economic plants. Mention should also be made of the valuable assistance which has often been afforded agricultural explorers from this country in remote and unfamiliar regions by mission workers.

At the time of the Washington conference, agriculture was reported to be definitely a part of the teaching program in about 235 mission stations. Of these, 135 were located in Africa, 40 each in China and India, 5 each in Ceylon and Turkey, 4 in South America, and 1 each in Australia, Burma, France, Siam, and the Philippine Islands. Naturally, great variations in scope, in equipment, in background, and in accomplishments exist in the different institutions. In many the agricultural instruction is of the simplest kind, the object being mainly the improvement of the economic status of the people of the region. Others are quite elaborate in organization and equipment, and not a few provide instruction of advanced high school or collegiate grade.

In the more pretentious mission schools, and in some of the more elementary type as well, the operation of large farms by improved

methods is an important feature of the work. Thus, in South America alone, mention may be made of the 3,800-acre farm of the Bunster Agricultural Institute, El Verjel, near Angol, Chile, under Methodist auspices, where students are given practical employment for half a day; the 600-acre property of the Presbyterians at the agricultural high school at Lavras, Minas Geraes, Brazil, in charge of an American who has been engaged in organizing and directing the work since 1907; an English evangelical mission school at Urco, near Calca, Peru; and a tract of land given to the Methodist Board some years ago in Argentina.

As would be expected, demonstration and extension work seems to be quite generally carried on to the full extent that facilities will permit. At the Pinyinana Agricultural School, an American Baptist mission in Burma, where two agriculturally trained men are employed, agricultural extension work, short courses, and conferences are actively conducted. The Salvation Army is interested in a number of farm settlements in India. Gwalior Mission Farm is a Presbyterian settlement for Christian farmers, who are taught improved methods on their own farms.

It is perhaps in Africa that the teaching of practical agriculture has been most extensively developed at the mission stations. Mariannahill Institute, founded 40 years ago by a Trappist monk for native boys and girls in the Province of Natal, is an important center, well known for its intensive industries and agricultural activities. Among these are numerous projects for community betterment, the organization of elementary agricultural instruction, and the preparation of several standard textbooks on agriculture for native schools. At Amanzimtoti Institute, founded in 1848 by the American Zulu Mission, a specialist in agriculture is employed and the erection of an agricultural building is under consideration.

In west-central Africa, Currie Institute under the Canadian and American Congregational Churches renders a unique service, including classroom instruction in agriculture and training on the land in cattle raising, dairying, and the use of farm machinery. Rice and wheat are being extensively cultivated in the lowlands at Kamundongo Station, as well as a mission orange grove.

Extensive and successful farming operations are in progress in the lower Kongo region at the Kisantu Jesuit School, the Kisantu School for Girls under the direction of the Sisters of Notre Dame, and the Tshumbiri Station of the American Baptist Mission Society, while the Disciples of Christ Kongo Mission is preparing to expand its work in agricultural education in the Equatorial district. In Liberia the Lutheran Mission Board has under way considerable agricultural work in the Muhlenberg Mission Boys' School in gardening, cattle raising, and coffee growing. The Kpolopepe School,

75 miles in the interior, offers instruction of elementary grade, with considerable practice work in gardening, the production of bananas and pineapples, and the growing of palm oil trees, and the Bethel Station School gives instruction in four elementary grades with much training in farm work.

Agricultural mission work in the Near East is represented at the International College at Smyrna and the Thessalonica Agricultural and Industrial Institute at Saloniki, already referred to. The latter school, which has now been in operation for nearly a quarter of a century, has aroused considerable interest among the natives in farming by what it has accomplished on what was formerly a barren waste, as well as by the better cattle and other farm animals that have been introduced.

The foregoing summary makes no pretence of completeness, but is intended merely to indicate some typical missionary enterprises. The assembling of comprehensive information for the project as a whole does not seem to have been attempted as yet, and the task obviously presents many difficulties. Not the least of these is the fact that the work is in progress under so many auspices and scattered over so wide a range of comparatively remote territory. There are, however, increasing manifestations of group solidarity, as is shown by the conferences already organized, and in time the community of interest and purpose will doubtless lead to a better acquaintance and closer contacts.

Meanwhile the movement holds much of interest from many viewpoints. It represents pioneer work, a breaking of new ground in a field which fires the imagination. If limited by meager resources to a fraction of the population with whom it is surrounded, it may none the less set in motion a desire for agricultural improvement which may ultimately be carried forward by governmental or other agencies and lead to far-reaching consequences.

Even in its immediate and present-day aspects, the agricultural missionary movement has much of significance and value. It has been largely sponsored and financed in this country, some of its earliest leaders and a large proportion of its active workers have been trained in our colleges of agriculture, and many of its institutions are actively cooperating with agricultural agencies here. These elements alone would give it a direct appeal. For these and many other reasons there will be general good will and genuine interest in the practical attempts being made by the agricultural missionaries to raise the standards of the world's agriculture through the introduction and dissemination of better methods among native peoples and to elevate the living conditions of these peoples by bringing to their doors the best of modern knowledge and experience.

## RECENT WORK IN AGRICULTURAL SCIENCE

### AGRICULTURAL CHEMISTRY—AGROTECHNY

Proceedings of the thirty-ninth annual convention of the Association of Official Agricultural Chemists, 1923 (*Jour. Assoc. Off. Agr. Chem.*, 7 (1924), Nos. 3, pp. 175-304, pls. 3; 4, pp. 305-443, fig. 1; 8 (1924), Nos. 1, pp. 83, figs. 3; 2, pp. 85-214, figs. 3).—This is the complete report of the convention held at Washington, D. C., November 19-21, 1923 (E. S. R., 50, p. 196). Abstracts of some of the papers presented are given elsewhere in this section. A paper by Pine has been previously noted (E. S. R., 51, p. 713).

**Spinacin, a new protein from spinach leaves**, A. C. CHIBNALL (*Jour. Biol. Chem.*, 61 (1924), No. 2, pp. 303-308).—With the use of the new method of extracting vacuole and cytoplasmic material from leaf cells (E. S. R., 51, p. 309), the author has isolated from the cytoplasm of spinach leaves a new protein, spinacin, which appears to be present in the cytoplasm as an anion at an H-ion concentration only slightly lower than that of its isoelectric point, which lies between pH 4 and 4.6. The new protein is insoluble in water and salt solution, soluble in excess of either acid or alkali, and is said to contain 16.25 per cent of nitrogen and to be free from carbohydrate.

On analysis by the Van Slyke method the protein, after hydrolysis with 20 per cent hydrochloric acid for 30 hours, showed the following distribution of nitrogen: Amide nitrogen 6.93 per cent, humin nitrogen in acid 0.76, humin nitrogen in lime 1.46, humin nitrogen in amyl alcohol 0.25, cystine 1.27, arginine 13.80, histidine 3.89, lysine 9.63, amino nitrogen in filtrate 58.09, and nonamino nitrogen in filtrate 2.58 per cent.

**Note on the basic amino acids yielded by casein**, C. S. LEAVENWORTH (*Jour. Biol. Chem.*, 61 (1924), No. 2, pp. 315, 316).—The examination of the filtrate from the lysine picrate in the determination of the basic amino acids in the products of hydrolysis of casein showed the presence of only 3.14 gm. of basic nitrogen, equal to only 1.1 per cent of the total nitrogen of the casein. Since a part of this nitrogen must be ascribed to arginine and histidine whose silver salts are slightly soluble, it is concluded that casein contains no appreciable amounts of any hitherto unrecognized base and that the lysine obtained as picrate represents practically all of the lysine of the casein. This amounted to 5.77 per cent of the casein.

**Studies with phytosterols, I-V** (*New York State Sta. Tech. Bul.* 108 (1924), pp. 3-40, fig. 1).—The five papers included in this publication are: The Phytosterols of the Endosperm of Corn, by R. J. Anderson (E. S. R., 52, p. 110); and The Phytosterols of Wheat Endosperm, The Separation of Unsaturated from Saturated Sterols, Reduction of Sitosterol—Preparation of Dihydro-sitosterol or Sitostanol, and Sitosterol, all by R. J. Anderson and F. P. Nabenhauer (and noted below).

**The phytosterols of wheat endosperm**, R. J. ANDERSON and F. P. NABENHAUER (*Jour. Amer. Chem. Soc.*, 46 (1924), No. 7, pp. 1717-1721).—A study

similar to that previously reported for corn endosperm (E. S. R., 52, p. 110) has been made of the phytosterols of wheat endosperm and incidentally of wheat bran, with the following results:

"Wheat endosperm contains at least two different sterols, namely, ordinary sitosterol,  $C_{27}H_{48}OH$ , and dihydrositosterol,  $C_{27}H_{47}OH$ , melting point  $144-145^{\circ}$  [C.];  $[\alpha]_{D}^{20} +25.82^{\circ}$ . The dihydrositosterol from wheat bran appears to be identical with the saturated sterol that occurs in corn endosperm. The substance exists throughout the wheat endosperm but the bran is particularly rich in this sterol."

**The separation of unsaturated from saturated sterols**, R. J. ANDERSON and F. P. NABENHAUER (*Jour. Amer. Chem. Soc.*, 46 (1924), No. 8, pp. 1957-1960).—A method is described for the separation of unsaturated sterols from the saturated dihydrositosterol by a modification of the Liebermann-Burchard reaction, essentially as follows:

On treating a chloroform or carbon tetrachloride solution of the mixture of sterols with acetic anhydride and concentrated sulfuric acid, the unsaturated sterol combines with the sulfuric acid to form a stable soluble compound of bluish or purplish-green color which can be removed by the addition of a few drops of water. A saturated sterol is obtained by evaporating the solvent and saponifying and crystallizing the residue from alcohol.

**Reduction of sitosterol.—Preparation of dihydrositosterol or sitostanol**, R. J. ANDERSON and F. P. NABENHAUER (*Jour. Amer. Chem. Soc.*, 46 (1924), No. 8, pp. 1953-1956).—In connection with the isolation of saturated sterols from the endosperm of corn and wheat noted above, the authors have subjected the unsaturated levorotatory sitosterol to reduction with hydrogen in ethereal solution in the presence of platinum black.

The dextrorotatory dihydrositosterol or sitostanol,  $C_{27}H_{47}OH$ , thus formed appeared to be identical with the dihydrositosterol isolated from corn and wheat endosperm, as shown by the following characteristics: Melting point between  $141$  and  $142^{\circ}$  C., specific dextrorotation in chloroform solution  $+24.16^{\circ}$ , Liebermann-Burchard reaction negative, and Whitby reactions atypical. The substances crystallized in large colorless hexagonal plates containing one molecule of water of crystallization, and the acetyl derivative in large hexagonal plates free from water of crystallization and melting between  $138$  and  $139^{\circ}$ .

**Sitosterol**, R. J. ANDERSON and F. P. NABENHAUER (*Jour. Amer. Chem. Soc.*, 46 (1924), No. 9, pp. 2113-2118, fig. 1).—Preparations of sitosterol obtained from corn gluten, as previously described (E. S. R., 52, p. 110), and from wheat bran and crude corn oil were purified by fractional precipitation of the dibromo-compound from its solution in ether and glacial acetic acid. The purified sitosterol was found to have a higher melting point and higher levorotation than preparations purified by ordinary recrystallization.

It is concluded that "the phytosterol occurring in corn and wheat consists of a mixture of sitosterol and dihydrositosterol. The two compounds occur throughout the grain but the germ contains mostly sitosterol, while the endosperm is richer in dihydrositosterol, and the latter is present in even larger amounts in the bran."

**The concentration of vitamin B**, P. A. LEVENE and B. J. C. VAN DER HOEVEN (*Jour. Biol. Chem.*, 61 (1924), No. 2, pp. 429-443, figs. 2).—The principle upon which the authors' attempts at concentrating vitamin B were based was the gradual removal of inert material from the Osborne and Wakeman yeast fraction (E. S. R., 42, p. 314).

With Lloyd's reagent the optimal adsorption of the vitamin took place at pH 4, while the optimal extraction from the adsorbed material was at pH 9. By this means a fraction was obtained which was from two to three times as active as the original material. The use of kaolin as adsorbent gave unsatisfactory results. With silica gel better results were obtained than with any other adsorbent. The optimal H-ion concentration for adsorption was at pH 5, while for the subsequent extraction a considerable portion was extracted by acids at pH 3 and a still larger fraction by subsequent extraction with alkalis at pH 9.

Using barium hydroxide as a precipitating agent, as noted in a preliminary report (E. S. R., 51, p. 609), a precipitate was obtained which was eight times as active as the original fraction. By adsorbing on silica gel the solution containing the active material obtained by the barium process and subsequently extracting it at pH 9, material was obtained which was from 200 to 400 times as potent as dried yeast, but this activity was obtained only with a considerable loss of the original material. A better method consisted in suspending the original barium precipitate in water and passing a stream of carbon dioxide through it. Under these conditions most of the potent material remained in the precipitate, while the inert material passed into solution. The precipitate, freed from barium, was active in amounts furnishing about 0.00017 gm. of nitrogen per day, and is to be used as a starting point for further concentration of the vitamin.

The various steps in the procedure as outlined are given in diagrammatic form, with estimates of the activity of the various fractions.

**The antiscorbutic fraction of lemon juice, II**, S. S. ZILVA (*Biochem. Jour.*, 18 (1924), No. 3-4, pp. 632-637).—The author has continued his attempts to isolate vitamin C from lemon juice, and reports that by submitting to further fractionation the active residue obtained in the previous study (E. S. R., 51, p. 503), he has obtained preparations containing only from 0.03 to 0.07 per cent of solids without loss of antiscorbutic activity.

The purest fraction was obtained by first decitrating the lemon juice by a modified method, which is essentially as follows: The juice is treated with an excess of chalk and allowed to remain for from 30 to 60 minutes to deposit salts, after which it is filtered and the filtrate concentrated in vacuo 50° C. to about one-fifth of the original volume. To this is gradually added a volume of alcohol equal to about one-half the original volume of the juice, the inactive precipitate is filtered off and washed with a little alcohol, and the filtrate and washings are distilled in vacuo at 50° to remove the alcohol. The final residue is made up to the original volume.

The decitrated juice as thus prepared is fermented as previously described, concentrated to a small volume, and treated with several volumes of absolute alcohol. The inactive precipitate formed is filtered off and the excess alcohol removed from the active filtrate as before. To the filtrate is added basic lead acetate until no further precipitate is obtained. This is quickly centrifuged, the residue dissolved in acetic acid, magnesium sulfate added to precipitate the lead, and the solution treated with two volumes of absolute alcohol and filtered. The filtrate is finally distilled in vacuo at 50° to remove alcohol and acetic acid and the preparation diluted to the volume of the original juice.

This preparation contained from 0.03 to 0.05 per cent of total solids. An equivalent of 10 cc. yielded only 0.2 cc.  $N/50$   $NH_3$  by the Kjeldahl method and an equivalent of 100 cc. in two determinations 0.000137 gm. and 0.0000909 gm. of phosphorus. It reduced ammoniacal silver nitrate in the cold and decolorized potassium permanganate. Daily doses of 1.5, 3, and 5 cc. protected guinea pigs from scurvy for 54 days.

**The reducing properties of antiscorbutic preparations**, S. J. B. CONNELL and S. S. ZILVA (*Biochem. Jour.*, 18 (1924), No. 3-4, pp. 638-640).—To determine whether the ability to reduce ammoniacal silver nitrate and decolorize potassium permanganate is an inherent property of the antiscorbutic vitamin, decitrated lemon juice was inactivated by heating in a boiling water bath in an atmosphere of carbon dioxide for 3 hours and in air for 1 and 3 hours, respectively, and also by the action of alkalis as previously described (E. S. R., 49, p. 806). The resulting preparations were tested for the percentage of silver-reducing and permanganate-reducing substances destroyed.

The various treatments had but little effect upon the permanganate-reducing property but a considerable but variable effect on the silver-reducing substance. It is concluded that a part at least, if not all, of the reducing material is chemically independent of the antiscorbutic vitamin.

It is also noted that a repetition of the Bezssonoff test for antiscorbutic vitamin, using the improved reagent (E. S. R., 51, p. 714), gave negative results. "The reaction is therefore useless for the purpose of establishing the presence of the antiscorbutic factor."

**The differential dialysis of the antiscorbutic factor, II**, S. J. B. CONNELL and S. S. ZILVA (*Biochem. Jour.*, 18 (1924), No. 3-4, pp. 641-646, fig. 1).—An extension of previous experiments on the diffusibility of active preparations of vitamin C (E. S. R., 46, p. 11) is reported.

The diffusion of the vitamin as present in decitrated lemon juice was found to take place at a different rate from that of the sugar and nitrogenous substances present. The fact that neither the sugar nor the vitamin diffused through an 87 per cent membrane, while the 88.5 per cent membrane allowed the slow passage of the former but not the latter, is thought to indicate that the dimensions of the vitamin molecule are not far different from those of hexoses.

The vitamin present in swede juice diffused through membrane of the same permeability as when present in lemon juice.

**Apparatus with rotating anode for rapid electrolytic analysis** [trans. title], L. BERTIAUX (*Ann. Chim. Analyt.*, 2. ser., 6 (1924), No. 9, pp. 257-264, figs. 3).—In the apparatus described and illustrated, the anode and cathode both consist of perforated platinum-iridium cylinders, the larger fixed one serving as the cathode within which the smaller anode revolves, thus keeping the electrolyte in motion. The shape of the electrodes affords a large contact surface.

**The analysis of phosphate rock**, G. E. F. LUNDELL and J. I. HOFFMAN (*Jour. Assoc. Off. Agr. Chem.*, 8 (1924), No. 2, pp. 184-206).—This paper, which should be consulted in the original, is based upon the study of existing methods and the development of new methods for analyzing phosphate rock in connection with the analysis of the Bureau of Standards standard sample of phosphate rock. A general discussion of methods for the various determinations is first given, followed by the details of the methods finally adopted as most satisfactory. These include methods for the determination of moisture, phosphoric acid, "soluble iron and alumina," and calcium.

**A rapid method for the determination of lead and arsenic in lead arsenate**, C. C. HEDGES and W. A. STONE (*Jour. Assoc. Off. Agr. Chem.*, 7 (1924), No. 4, pp. 321, 322).—The method described combines the tentative sulfate method of determining lead with the Official potassium iodide method of determining arsenic. The lead is determined in the dissolved sample direct, without evaporation, and the arsenic in the filtrate and washings.

**A quick method for determining water-soluble arsenic in lead arsenate and zinc arsenite**, R. C. ROARK (*Jour. Assoc. Off. Agr. Chem.*, 7 (1924), No. 4, pp. 322-327).—Existing methods for determining water-soluble arsenic in lead arsenate and zinc arsenite are reviewed, and a method is described which requires only 5 minutes for the extraction of the arsenic instead of the 24 hours required in the Official method. The technique of the method is as follows:

"Add 2 gm. of dry (or 4 gm. of paste) lead arsenate or 1 gm. of zinc arsenite to 100 cc. of cold water in a 400-cc. beaker, heat to boiling, and continue the boiling 5 minutes. Transfer to a 1-liter volumetric flask, make to volume, shake thoroughly, filter through a dry filter, transfer 250 cc. of the clear filtrate to an Erlenmeyer flask, add 3 cc. of concentrated sulfuric acid, and evaporate on a hot plate. When the volume reaches about 100 cc., add 1 gm. of potassium iodide and continue the boiling until the volume is about 40 cc. Cool, dilute to about 200 cc., and remove the excess iodine with  $N/20$  sodium thiosulfate, avoiding the use of starch solution at this point. Neutralize with sodium bicarbonate, add 4-5 gm. in excess, and titrate with standard iodine solution to a permanent blue color, using starch solution as indicator. From the number of cubic centimeters of iodine solution used calculate the percentage of water-soluble arsenic in the sample."

**The determination of iodine in food, drink, and excreta**, J. F. McCLENDON (*Jour. Biol. Chem.*, 60 (1924), No. 2, pp. 289-299, figs. 2).—Methods of determining iodine in water and organic materials are described in considerable detail.

In the case of water it is often necessary to use at least 100 liters for the determination. This is made alkaline with sodium carbonate, bicarbonate, or hydroxide and evaporated in a large receptacle such as a large dish pan. The dry residue is powdered and placed in a silica or nickel boat, which is then inserted in a long silica combustion tube bent at right angles and leading into a Pyrex tube containing sodium hydroxide. The other end of the combustion tube is provided with a special water-cooled stopper containing a glass tube, through which a stream of oxygen is passed over the sample while it is being heated to dull redness. The ash, together with the evaporated residue from the sodium hydroxide and the rinsings, is extracted with a measured amount of water. A 7.5-cc. aliquot of the filtered extract is neutralized with concentrated hydrochloric acid, made up to a volume of 10 cc., and placed in a separatory funnel with 1 drop of concentrated hydrochloric acid and 1 cc. of purified carbon tetrachloride. If a pink color denoting the presence of iodates appears on shaking, 1 drop of  $N/10$  arsenious acid is added, followed after 20 minutes by 1 drop of nitrosyl sulfuric acid. The separatory funnel is shaken vigorously for 2 minutes, after which the carbon tetrachloride is run into a glass-stoppered bottle, centrifuged, and transferred to a microcolorimeter where the amount of dissolved iodine is determined by comparison with a standard solution.

The method for organic materials is the same with the exception of the first ashing process, which is carried out with special precautions, which are described in detail.

It is said to be possible with this method to detect 0.001 mg. of iodine in 1 cc. of carbon tetrachloride and to make a roughly quantitative determination of it in a microcolorimeter.

**An improved method for the separation of unsaponifiable matter from fats and oils**, R. H. KEER and D. G. SOBBER (*Jour. Assoc. Off. Agr. Chem.*, 8 (1924), No. 2, pp. 90, 91).—The method described, the technique of which is given in detail, employs the reverse process of that usually used in the separation of unsaponifiable matter, i. e., after saponification, instead of extracting

the unsaponifiable matter from an aqueous solution of the soap with an immiscible solvent, the soap is mixed with the solvent and extracted from this solution with water. The method is recommended as "a rapid, simple, and convenient method for the determination of unsaponifiable matter in fats and oils."

**Determination of fat in cacao products**, L. FELDSTEIN (*Jour. Assoc. Off. Agr. Chem.*, 8 (1924), No. 1, p. 75).—To overcome the difficulties in extracting fat from cacao powder due to the clogging of the pores of the filter paper, the author recommends a method of extraction consisting essentially in first digesting the powder on the steam bath with 1:1 hydrochloric acid and then extracting the fat in a Röhrig tube with washed ether, followed by petroleum ether, inverting the tube from 20 to 25 times after adding each solvent, and letting it stand for 30 minutes. The extraction is repeated twice with smaller portions of the solvents, and the combined extracts are evaporated slowly on a steam bath and the fat dried in a boiling water oven to constant weight, dissolved in petroleum ether, and again dried to constant weight.

**Analyses of noodles of known composition and estimation of their egg solids content**, R. BUCHANAN (*Jour. Assoc. Off. Agr. Chem.*, 7 (1924), No. 4, pp. 407-424).—Analyses are reported of a large number of samples of noodles prepared under known conditions from semolina, flour, and a mixture of the two, using whole eggs and egg yolk, dried or frozen and alone or in varying proportions. The determinations included moisture, lipoids, and lipid  $P_2O_5$  by the Rask-Phelps and the Hertwig methods (*E. S. R.*, 51, p. 205), water-soluble nitrogen, and water-soluble protein nitrogen precipitable by 40 per cent alcohol.

The data reported show that with the same egg content the composition of the noodles varies but little whether made from semolina or flour or a mixture of both. The most satisfactory methods for determining egg solids were found to be lipoids, lipid  $P_2O_5$ , total nitrogen, and water-soluble protein nitrogen precipitable by 40 per cent alcohol. The ratios between certain of these substances as proposed by Hertwig distinguished easily whole egg from yolk noodles. The recovery of the lipid  $P_2O_5$  of the ingredients ranged from 81.3 to 104.5 per cent by the Rask-Phelps method and from 80.1 to 105.5 per cent by the Hertwig method. Low results were attributed to decomposition of the lipid  $P_2O_5$  during the time between manufacture and analysis of the noodles.

Losses occurring in samples stored in sealed Mason jars were similar to those occurring in samples stored in paper boxes. It is emphasized that these losses must be taken into consideration in estimating the egg-solids content of noodles which have been stored for some time.

A list of 45 references to the literature is appended.

**The lead number of maple products**, C. A. CLEMENS (*Jour. Assoc. Off. Agr. Chem.*, 7 (1924), No. 4, pp. 350-353).—A comparison of the sulfate method with the chromate, molybdate, and phosphate methods for determining the lead number in maple products is reported.

The molybdate method proved unsatisfactory on account of difficulty in filtering. This was also true of the phosphate method. The presence of potassium acetate interfered with accurate determinations by the sulfate method. The chromate method is recommended as most satisfactory, particularly as not requiring alcohol and, therefore, being more economical.

**The lead number of vanilla extracts**, C. A. CLEMENS (*Jour. Assoc. Off. Agr. Chem.*, 8 (1924), No. 1, pp. 79-82).—A comparison similar to the above was made of the chromate and sulfate methods for the determination of lead in

the lead number of vanilla extract, together with a comparison of the Official and the Wichmann (E. S. R., 45, p. 718) methods of preparing the solutions.

The Wichmann method was found to give an increase in the lead number of about 50 per cent over the values as determined by the Official method, regardless of whether the lead number was determined by sulfate or chromate. The chromate method gave results agreeing closely with the sulfate method and, as in the case of maple products, is recommended as being accurate, rapid, and economical.

The detection of methyl alcohol in the presence of ethyl alcohol [trans. title], A. KLING and A. LASSIEUR (*Ann. Chim. Analyt.*, 2. ser., 6 (1924), No. 10, pp. 302-305).—The method described is based upon the Denigès test for the detection of methyl alcohol by oxidation with potassium permanganate, and the action of the formaldehyde thus formed on Schiff's reagent. With the technique employed the limit of sensitiveness is about 1 per cent of methyl alcohol.

## METEOROLOGY

Report of the chief of the Weather Bureau, 1923-24 (*U. S. Dept. Agr., Weather Bur. Rpt. 1924*, pp. III+271, pls. 7).—This report gives a summary account of the work of the Weather Bureau during the year ended June 30, 1924, and reviews the general weather conditions of the year 1923, with the usual detailed tabulations of meteorological data.

Classification of civilian employees and the program of increased governmental efficiency and economy as they affect the work of the bureau are briefly commented upon. Work briefly noted, having a direct and special bearing on agriculture, included the weekly reports on weather and crop conditions which were resumed during the year, the fruit frost service particularly on the Pacific coast, the beekeepers' service, aid in combating the Mediterranean flour moth in mills, protection of bananas in transit, forest fire weather warnings, and preparation of a revision of the temperature section of the Atlas of American Agriculture. "The publication of the weekly Corn and Wheat Region Bulletin at Chicago, the Cotton Region Bulletin at New Orleans, the weekly weather and crop summaries at the several section centers, and the daily Cotton and Corn and Wheat Region Bulletins at a number of points in the principal agricultural districts, as well as weekly Cattle Region Bulletins for the western grazing section, was continued as in previous years. . . .

"The outstanding features of the weather during the year [1923] were the unusual warmth of January and the last two months; the excessive accumulation of snow and the severe cold over Northeastern States, particularly in New England, during the first three months of the year; the heavy rains during May, September, and October over Oklahoma and portions of adjacent States; and the persistent and large deficiency of rain and snow in California and adjacent areas."

The weather of 1924, A. J. HENRY (*U. S. Mo. Weather Rev.*, 52 (1924), No. 12, p. 588, pls. 2).—Tables show temperature and precipitation departures for the United States for each month and for the year as a whole. The geographic distribution of annual temperature and precipitation departures is charted.

The annual temperature for the country was 0.6° F. below normal. This was "due to the low temperature of the last month of the year and of the last 10 days in that month. Had the computation ended with December 20 the final result would have been a positive departure of at least a whole degree Fahrenheit. . . . In general the spring was cool and wet east of the Rocky

Mountains, the summer was close to the normal, and the autumn on the whole was warm, relatively high temperature continuing well into December." The precipitation departure for the year was  $-3.7$  in. "Notwithstanding the wet weather in Atlantic Coast States in April, May, and September, the year as a whole for the entire area was a dry one. The greatest deficit in rain was felt from the Rocky Mountains to the Pacific, also in a somewhat less degree in the Plains and Gulf States."

**The year 1816—the causes of abnormalities**, W. I. MILHAM (*U. S. Mo. Weather Rev.*, 52 (1924), No. 12, pp. 563-570).—Possible reasons advanced for the unusual meteorological conditions which prevailed in 1816, "the year without a summer," are the violent volcanic eruption of Tambora in 1815 and a sun spot maximum in 1816. Among the possible causes of abnormality of any month or year are "volcanic eruptions, changes in the activity or condition of the sun (sun spots, solar constant), changes in the surface temperatures of the oceans, changes in the composition of the atmosphere (ozone, carbon dioxide), and accidental causes."

**Monthly Weather Review, [November-December, 1924]** (*U. S. Mo. Weather Rev.*, 52 (1924), Nos. 11, pp. 521-561, pls. 17, figs. 12; 12, pp. 563-611, pls. 19, figs. 15).—In addition to detailed summaries of meteorological and climatological data and weather conditions for November and December, 1924, and notes, abstracts, and reviews, these numbers contain the following contributions:

No. 11.—An Analysis of a Retrograde Depression in the Eastern United States of America (illus.), by J. Bjerknes and M. A. Giblett; Variation in Solar Radiation Intensities Measured at the Surface of the Earth (illus.), by H. H. Kimball (see p. 716); Forty Years' Study of Snow Crystals (illus.), by W. A. Bentley; Note on Certain Cloud Forms Observed at Tucson, Ariz., August 18, 1924, by A. E. Douglass; Meetings of the Meteorological Section of the International Geodetic and Geophysical Union, Second General Assembly, Madrid, Spain, October 1-8, 1924, by H. H. Kimball; An Approach to Runoff Expectancy (illus.), by S. L. Moyer; Comparison of Rain-gage Can and the Horton Snow-board Measurements of Snowfall at Grand Forks, N. Dak. (illus.), by A. W. Cook; and Twilight Phenomena on Mont Blanc, by E. Bauer, A. Danjon, and J. Langevin, trans. by B. M. Varney.

No. 12.—The Year 1816—the Causes of Abnormalities, by W. I. Milham (see above); A New Classification of Typhoons of the Far East (illus.), by C. Chu; Dorno on the Technique of the Measurement of Solar Radiation in Restricted Spectral Regions (illus.), by H. H. Kimball; The Probabilities of 0.10 Inch, or More, of Rainfall at Springfield, Ill. (illus.), by W. F. Feldwisch; Hourly Rainfall at Los Angeles, Calif. (illus.), by G. M. French; Diurnal Variations of Precipitation at Honolulu, Hawaii (illus.), by E. H. Loveridge; The Glaze Storm of December 17, 1924, in Illinois (illus.), by C. J. Root; Sleet and Ice Storm at Corpus Christi, Tex., December 19-21 and 25, 1924, by J. P. McAuliffe; The Squall Cloud in a Thunderstorm: A Direct Observation of Its Motion, by D. L. Webster; Temperature of Deep Water, by W. J. Humphreys; The Weather of 1924 (illus.), by A. J. Henry (see p. 714); and Tropical Disturbances during the Hurricane Season of 1924 (illus.), by W. P. Day.

**Periodicities, solar and meteorological**, C. CHREE (*Quart. Jour. Roy. Met. Soc. [London]*, 50 (1924), No. 210, pp. 87-97, fig. 1; *abs. in Sci. Abs., Sect. A—Phys.*, 27 (1924), No. 323, pp. 956, 957; *U. S. Mo. Weather Rev.*, 52 (1924), No. 11, p. 542).—From the study here reported, the author concludes that there is a decided relation between magnetic phenomena and sun spot frequency,

but that this "does not necessarily imply that sun spots themselves are immediately responsible for what happens on the earth. They may be only a symptom of increased solar activity, resulting in increased ionization in the earth's atmosphere."

**Variation in solar radiation intensities measured at the surface of the earth**, H. H. KIMBALL (*U. S. Mo. Weather Rev.*, 52 (1924), No. 11, pp. 527-529, fig. 1).—This article summarizes observations on duration and character of solar radiation intensity at various stations in different parts of the world over the period 1882-1923, with citations of the sources of the data. The main features of a free-hand curve drawn from the data are great depressions following the volcanic eruptions of Krakatao in 1883; Mont Pelée, Santa Maria, and Colima in 1902; and Katmai in 1912.

**The dustfall of February 13, 1923**, A. N. WINCHELL and E. R. MILLER (*Jour. Agr. Research [U. S.]*, 29 (1924), No. 9, pp. 443-450, figs. 2).—This paper deals with the third of four dustfalls known to have occurred in this country within the past six years. Descriptions of two of these dustfalls have previously been noted (*E. S. R.*, 40, p. 616; 47, p. 510). "The physical, chemical, mineral, and vegetable composition of the dustfall of February 13, 1923, is discussed in connection with that of other dustfalls of this country and abroad, and tabular analyses are presented. . . ."

"The close similarity of composition of atmospheric dust to loess, and the divergence of such dust from other types of soils, suggest very strongly that the two are identical. . . . The fine size of the loess components indicates that they had been carried long distances by the wind, rather than obtained by deflation in the vicinity of deposit.

"The presence of viable spores of plant disease in association with atmospheric dust which has been transported hundreds and even thousands of miles indicates that such diseases may be rapidly spread over longer distances than plant pathologists have hitherto considered possible."

**[Meteorological observations at the New Jersey Experiment Stations]** (*New Jersey Stas. Rpt. 1923*, pp. 116, 117).—Maximum, minimum, and mean monthly temperatures and daily, monthly, and annual precipitation as compared with the normals are given for the year ended June 30, 1923.

**Climatological data for Wyoming**, F. E. HEPNER (*Wyoming Sta. Bul. 139* (1924), pp. 63-160, pls. 2, figs. 11).—This is a revision of Bulletin 100 (*E. S. R.*, 29, p. 812) summarizing observations at Laramie, Wyo., during the 30 years 1891 to 1920 and also at 37 weather bureau stations at other places having records for 10 years or more and fairly representative of meteorological conditions in the State.

Laramie is situated at an elevation of over 7,000 ft. on the eastern edge of a large, nearly level plateau surrounded on three sides by high elevations, which accentuate the prevailing cool, dry conditions and shorten the day from sunrise to sunset about 20 minutes.

The mean annual temperature for the period was 40.7°. The highest temperature recorded at Laramie during the 30 years was 92° F., the lowest -42°. "Only six times in the 30 years has the temperature reached 90°. The sky is nearly always clear and the humidity is low; hence, though the days may be warm, or even hot, the nights are always cool. In other words, the daily range of temperature is great. Another noticeable effect is the great difference in temperature between the sunshine and shade. The winters, while cold, are not excessively so, and, owing to the low humidity, the temperature seldom becomes disagreeable."

The mean annual pressure corrected for temperature but not reduced to sea level was 23.04 in.

The annual precipitation for the 30 years was 10.72 in. "More than 60 per cent of the precipitation comes during the season April 1 to September 1, or what might be called the growing season. The last 10-year period shows an increase of precipitation over the two previous decades but not enough to warrant the assumption that the climate is changing." The mean annual relative humidity was 63.5 per cent. The average number of clear days per year was 188. The prevailing direction of the wind was southwest.

A map prepared by the U. S. Weather Bureau shows the distribution of the average annual rainfall of the State, which varies from 4.48 in. at Hyattville in Big Horn County to 20.61 in. at Alta, Lincoln County.

## SOILS—FERTILIZERS

**Agrological studies, soil classification, and physical analysis of soils** [trans. title], L. A. R. DA SILVA (*Bol. Min. Agr. [Portugal]*, 5 (1922), No. 1-6, pp. [4]+127, figs. 4).—This is the second revised and enlarged edition of this contribution, which deals with the mechanical, physical, and chemical properties of soils and their classification on these bases. Reference is made to methods of studying these properties, particularly those which are intended to evaluate some of the dynamic factors of soils, such as tenacity, adhesion, etc. Tabular data are included, for instance, on the adhesion of soil to iron and wooden surfaces. Other data are included which should be of interest in a study of soil dynamics.

**Chemical analysis of soil** [trans. title], J. VALMARI (*Acta Forest. Fennica*, 20 (1921-22), pp. 1-67).—The results of chemical analyses of a large number of soil samples are presented and discussed and correlated with types of vegetation growing thereon, special reference being made to the influence of the different plant and chemical factors involved on the availability of soil nutrients and soil reaction.

**The sampling of soils**, J. O. VEATCH (*Michigan Sta. Quart. Bul.*, 7 (1925), No. 3, pp. 96-98, fig. 1).—Brief information is given on the proper sampling of soils, it being stated that the various layers of the soil profile must be considered in determining the value of the soil.

**Soil survey of Choctaw County, Alabama**, H. C. SMITH ET AL. (*U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils*, 1921, pp. III+975-1009, fig. 1, map 1).—This survey, made in cooperation with the Alabama Department of Agriculture and Industries, deals with the soils of an area of 583,680 acres in southwestern Alabama. The county is said to present a wide diversity of topographic features, soil characteristics, and drainage conditions. Physiographically, it consists of the remnants of a southward to southeastward sloping plain so thoroughly dissected that little or none of the original surface is left intact. With the exception of the first and second bottoms every part is well drained, and on the whole the drainage is excessive.

The soils are dominantly light colored, the surface soils being chiefly gray, yellowish gray, and light brown. Most of the soils are deficient in organic matter. Including meadow, 22 soil types of 15 series are mapped, of which the Ruston fine sandy loam, Guin soils, Susquehanna fine sandy loam, and Susquehanna clay cover 15.7, 11.1, 10.7, and 10 per cent of the area, respectively.

**Soil survey of Andrew County, Missouri**, A. T. SWEET and H. V. JORDAN (*U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils*, 1921, pp. III+817-850, pls. 4, fig. 1, map 1).—This survey, made in cooperation with the Missouri

Experiment Station, deals with the soils of an area of 278,400 acres included in the Corn Belt region in northwestern Missouri. The greater part of the county is upland, which is nearly level to gently rolling in the northeastern part, undulating to moderately hilly in the central part, and quite hilly in the southwestern part. The uplands are nearly all well drained, and erosion is active over much of the region.

The soils of the county are of loessial, glacial, and alluvial origin, and are predominantly dark in color. They have the texture of silt loams or loams. Including riverwash, 21 soil types of 13 series are mapped, of which the Marshall and Wabash silt loams, Shelby loam, and Grundy silt loam cover 31.3, 15.1, 13, and 11.9 per cent of the area, respectively.

**Soil survey of Antelope County, Nebraska,** F. A. HAYES ET AL. (*U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1921, pp. III+757-816, fig. 1, map 1*).—This survey, made in cooperation with the University of Nebraska, deals with the soils of an area of 552,960 acres lying within the loess hill region of northeastern Nebraska. The topography ranges from almost flat through rolling and steeply rolling to hilly and extremely dissected. The alluvial lands have a generally flat topography. Ample drainage is afforded for most of the country by the Elkhorn River, creeks, and intermittent drainage ways. Surface drainage is not well established in the sandy upland belt throughout the southwestern and north-central parts, but the internal drainage is thorough.

Including dunesand and riverwash, 32 soil types of 14 series are mapped, of which the Valentine sand and loamy sand and Marshall silt loam cover 22.8, 18, and 16.7 per cent of the area, respectively.

**Soil survey of Deuel County, Nebraska,** L. A. WOLFANGER ET AL. (*U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1921, pp. III+707-755, fig. 1, map 1*).—This survey, made in cooperation with the University of Nebraska, deals with the soils of an area of 280,960 acres lying in the Great Plains province in western Nebraska. The topography of the county varies from flat on the high table-land and the alluvial valley land to rough and rolling in the slope lands and dunelike in the sandy areas. Drainage is fairly well established except in depressions on the upland and in parts of the flood plains.

The soils are of residual, wind laid, alluvial, and miscellaneous origin. Including dunesand, 28 soil types of 14 series are mapped, of which the Rosebud and Dawes silt loams cover 37.4 and 13.4 per cent of the area, respectively.

**Soil survey of Perkins County, Nebraska,** L. A. WOLFANGER ET AL. (*U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1921, pp. III+883-928, fig. 1, map 1*).—This survey, made in cooperation with the University of Nebraska, deals with the soils of an area of 567,040 acres lying in the Great Plains region in southwestern Nebraska. The surface is in general nearly flat, but has minor relief features. The county is without well-established drainage. Surface and internal drainage are said to be generally sufficient, however.

Including dunesand, 29 soil types of 10 series are mapped, of which the Dawes and Rosebud loams and dunesand cover 32.2, 17.8, and 14.6 per cent of the area, respectively.

**The cultivated soils of the east coast of Sumatra and their fertility** [trans. title], F. C. VAN HEURN (*Proefschr., Tech. Hoogeschool, Delft, 1922, pp. XIV+110, pls. 23*).—This is a survey of the cultivated soils of the east coast of Sumatra. It deals with their physical, mechanical, and chemical characteristics, fertility requirements, and crop adaptations. The prevailing soil types are the upland red soils, the lowland gray-white sandy clay soils, and the so-called tertiary soils. The first two are the most important agriculturally, and are distinguished primarily by their color and elevation.

A summary is given of data relating to the cultivated vegetation of these soils, with special reference to their fertility characteristics. The relation of the fertility of these soils to their volcanic origin, their mineralogical, physical, and chemical composition, and their structure and ground water level is also discussed at some length.

**Studies in the soil salt system: A special device for the continuous percolation of solutions through cylindrical masses of soil,** R. V. ALLISON (*New Jersey Stat. Rpt. 1923, pp. 231-234, fig. 1*).—This device is illustrated and briefly described.

**Tank experiments on soil moisture,** D. W. PITTMAN (*Utah Sta. Bul. 192 (1925), p. 25*).—Experiments with alfalfa, corn, wheat, and sugar beets are said to have indicated a maximum yield of all these crops when the soil was maintained at a moisture content of from 20 to 25 per cent of saturation. The greatest efficiency in the use of water closely approximates the point of maximum yield.

[**Leaching of heavy clay soils**], M. D. THOMAS (*Utah Sta. Bul. 192 (1925), p. 27*).—It has been found that when the salt concentration of heavy clay soils is materially decreased in part of the soil column, the percolate becomes alkaline and the soil column becomes extremely impermeable to water.

**Percentage of water freezable in soils,** A. M. WINTERMYER (*U. S. Dept. Agr., Public Roads, 5 (1925), No. 12, pp. 5-8, figs. 2*).—Experiments are reported which showed that when water contained in a soil is frozen, such freezing very seldom involves all of the water of the soil. When frozen in a dilatometer the water content can be divided into three volumes determined by the temperature at which they are frozen. The first volume, which is frozen at 0° C., is classified as free water; the second, which freezes at from -4° to -78°, is classified as capillary or adsorbed water; and the third, classified as combined water, is so intimately associated with the soil that it can not be frozen at temperatures below -78°. Different soils varied widely in the percentages of their contained water which fall into these three classes.

Studies of the properties of the soil which affect the percentage of the contained water that may be frozen showed that as a rule the condition of the moisture and the temperature at which it will be frozen depend upon the physical, chemical, and mineralogical composition of the soil. Soluble salts, organic matter, and colloidal material present will remove a certain percentage of the moisture from the free state and prevent its freezing.

The mechanical analysis does not indicate the freezing percentage since it merely shows the size of the soil particles, and the unfrozen water is an index not only of the size of the particles but of other properties as well.

**Plowing and cultural tests [at the Utah Station],** A. F. BRACKEN (*Utah Sta. Bul. 192 (1925), p. 21*).—It has been found that either fall plowing or plowing done in early spring to a depth of 8 in., followed by enough tillage to keep weed growth down and prepare a good seed bed, is sufficient. Deep plowing, very frequent tillage of fallow, double plowing, and disking preceding plowing are said to be unnecessary.

A test of the time of spring plowing indicates that all spring plowing should be done within a period of two weeks after the season for plowing starts, and that the land which can not be turned in this period should be fall plowed.

**Seeding of winter wheat with furrow drill and ordinary drill,** A. F. BRACKEN (*Utah Sta. Bul. 192 (1925), p. 23*).—In these tests nitrate accumulation has been directly correlated with the moisture content. Any tillage which tends to conserve moisture, such as fall or early spring plowing followed by normal summer cultivation, is said also to stimulate nitrate formation. Barn-

yard manure added to plats receiving normal tillage stimulates nitrate accumulation.

[Soil microbiological studies at the New Jersey Stations] (*New Jersey Stas. Rpt. 1923, p. 35*).—It is stated that studies on the influence of partial sterilization of soil have shown that this process almost completely destroys the protozoa and fungi and greatly reduces the bacteria, while the Actinomycetes are least affected. The soil organic matter is modified and made more available for the activities of microorganisms, and the partially sterilized soil becomes a better medium for the development of bacteria and certain specific fungi. The Actinomycetes develop only to a limited extent in partially sterilized soil unless a great deal of organic matter is present.

Studies of the thermochemical relationships of the oxidation of sulfur by *Thiobacillus thiooxidans* have shown that about 32 parts of sulfur are oxidized for every unit of carbon assimilated from the carbon dioxide of the atmosphere. However, when conditions are unfavorable for growth, the sulfur-carbon ratio is greatly increased. In studies of the influence of various salts on the growth and respiration of *T. thiooxidans*, nitrates and peptones were found to have an injurious effect on both activities, while sulfates had not. Small amounts of organic substances like dextrose or soil extract may even exert a stimulating effect.

Numbers of microorganisms, nitrifying and carbon-dioxide producing capacity, and soil fertility, S. A. WAKSMAN and R. L. STARKEY (*New Jersey Stas. Rpt. 1923, pp. 230, 231*).—The results of studies of the number of microorganisms and the nitrifying capacity of soils from three different plats are correlated, with crop yields therefrom, to illustrate the work along this line in progress at the station (*E. S. R., 51, p. 624*).

Soil bacteriological studies [trans. title], M. DÜGGEL (*Landw. Jahrb. Schweiz, 38 (1924), No. 2, pp. 203-251*).—A summary is given of the results of a large number of studies begun in 1908 on the activities of soil organisms, particularly nitrogen-fixing organisms, in certain Swiss soils under different methods of fertility treatment.

The results showed that soils fertilized with potash and phosphoric acid, but not with nitrogen, contained a much greater number of nonsymbiotic nitrogen-fixing organisms of aerobic types, such as *Azotobacter chroococcum*, and of anaerobic types, such as *Bacillus amylobacter*, than soils fertilized with sodium nitrate. The latter soils contained the greater number of denitrifying organisms.

Plowing these soils and treating them with liquid cow manure or stable manure increased the numbers of *A. chroococcum*, but plowing seemed to be somewhat injurious to the *B. amylobacter*.

A marked decrease in bacterial numbers in these soils was noted during the period from April to July. This was found to be due not only to a decrease in the amount of available moisture and easily assimilable organic matter, but also to the rapid multiplication of soil protozoa, which was favored by the higher soil temperatures. In fact, the destruction of bacteria by protozoa during this period is considered to be the greatest cause of their rapid decrease in numbers.

Study of anaerobiosis in arable soil [trans. title], S. WINOGRADSKY (*Compt. Rend. Acad. Sci. [Paris], 179 (1924), No. 18, pp. 861-863*).—Studies are briefly reported with *Azotobacter chroococcum* and *Bacillus amylobacter* to show that the activity of these two nitrogen-fixing organisms of aerobic and anaerobic nature, respectively, may be governed by the moisture content of the soil. By use of a suitable nutritive material it was found that when the moisture con-

tent was below a certain point the *A. chroococcum* predominated, but when it exceeded this point and anaerobic conditions prevailed the *B. amylobacter* predominated.

**Behavior of bacteria, especially soil bacteria, toward carbon disulfide and the influence of treating soils with carbon disulfide on plant growth** [trans. title], A. MAASSEN and H. BEHN (*Arch. Biol. Reichsanst. Land u. Forstw.*, 12 (1924), No. 5, pp. 285-338, fig. 1).—Studies are reported on the influence of carbon disulfide on soil bacteria and on the influence of soil treatment with carbon disulfide on plant growth.

Liquid carbon disulfide was found to reduce markedly the number of bacteria in soils, being the most destructive to the nitrifying bacteria and the least to the denitrifying and putrefactive bacteria. It was as destructive to soil bacteria when dissolved in water as when in vapor form. The vapor form was more destructive to *Azotobacter* than water half saturated with carbon disulfide, but less so than fully saturated water.

Further experiments showed that the treatment of ordinary soils in the field with carbon disulfide generally favored plant growth. This favorable influence was usually also observed in pot experiments. However, soil which had shown increases in yield due to such treatment in the field did not so react when potted. No increase in crop yield resulted from the treatment of sterilized soil with carbon disulfide. There was usually a residual effect of carbon disulfide treatment in field soils, which was noticeable in the second crop, but no such residual effect was observed in pots.

The favorable action of carbon disulfide on the yield of crops and its residual effect were considerably weakened by the addition of organic nitrogenous material, such as bone meal, manure, or moor soil. This was especially true with manure when added some time before the carbon disulfide treatment, and is taken to indicate that the favorable influence of carbon disulfide is not due to an increase in the availability of nitrogenous organic matter.

The yields of crops in soils well supplied with soluble plant nutrients were usually increased by carbon disulfide treatment, although this effect was not observed in sterilized soils aside from a small increase in yield in sterilized but fertilized sand. This is taken to indicate that carbon disulfide exercises a growth-promoting action on crops. However, it is concluded that the favorable residual effect of this substance can not be explained in this manner, but may be due to chemical or biological changes produced. It is also considered possible that the favorable influence of treatment with carbon disulfide is due to partial sterilization of the soil, whereby injurious organisms are killed and organisms tending to increase the supply of available plant nutrients are permitted to multiply in greatly increased numbers.

**The continuous growing of wheat and rye, 1922**, J. G. LIPMAN and A. W. BLAIR (*New Jersey Stas. Rpt. 1923*, pp. 222-224).—A continuation of studies begun in 1909 (E. S. R., 51, p. 622) indicated that symbiotic nitrogen fixation is more important in maintaining the nitrogen supply of the soil than fixation through the free-living organisms of the soil.

**The continuous growing of corn with a legume and nonlegume green manure crop, 1922**, J. G. LIPMAN and A. W. BLAIR (*New Jersey Stas. Rpt. 1923*, pp. 224-226).—A continuation of studies to compare a legume and a nonlegume green manure crop and to determine the influence of small applications of manure as a means of introducing organisms in the soil (E. S. R., 51, p. 622) emphasized the value of the legume green manure as a means of furnishing organic matter for the crop and for soil improvement.

**The effect in pot culture of green manure in different stages of growth and decomposition, on the subsequent crop**, B. L. HARTWELL and F. R.

PEMBER (*Jour. Amer. Soc. Agron.*, 16 (1924), No. 11, pp. 750-753).—The results of studies on the subject at the Rhode Island Experiment Station are briefly reported.

It was found that oats planted at a given time affected the following crops the most favorably if they were turned under when young and subjected to decomposition, whereas their influence was the least advantageous or the most objectionable when they were turned under at the approach of maturity and allowed no opportunity to decompose before the following crop was planted. It was further found that the variation in the effect of green manure, depending on its stage of growth and decomposition, was prevented by the prodigal use of fertilizer during the growth of lettuce.

**Action of stable manure on potatoes when applied in different ways** [trans. title], D. MEYER (*Deut. Landw. Presse*, 51 (1924), No. 4, pp. 29, 30).—Experiments with potatoes and grain on loess loam soil to determine the influence of time and manner of application of stable manure on its effectiveness as a fertilizer are briefly reported.

The results showed that stable manure placed in the furrows gave better results in the spring than manure plowed under. Also manure spread on plowed ground gave better results in the fall than manure plowed under. The residual action on grain crops of manure applied in the furrows was also greater than that of manure plowed under.

**The use of nitrogen in muck fertilization**, P. M. HARMER (*Michigan Sta. Quart. Bul.*, 7 (1925), No. 3, pp. 92-96, fig. 1).—Experiments are briefly reported indicating that the value of nitrogen in a fertilizer mixture for muck depends upon the type of muck—that is, whether low or high in lime—and upon the crops to be grown. It is stated that in general the nitrogen content of low-lime muck is from one-half to two-thirds that of high-lime muck.

**The influence of varying ratios of phosphoric acid and potash on the yield and on the nitrogen and phosphoric acid content of the crop with different nitrogenous materials**, J. G. LIPMAN and A. W. BLAIR (*New Jersey Stas. Rpt.* 1923, pp. 213-222).—Studies on the influence of the phosphoric acid-potash ratio on the availability of nitrogen in sodium nitrate, dried blood, ammonium sulfate, and a combination of these three materials, in a silt loam soil, using barley and sorghum as indicators, are reported.

Nitrogen fertilization distinctly increased the yield of barley grain and straw, sodium nitrate giving the highest yields and highest nitrogen recovery and ammonium sulfate the lowest. Increasing the amount of phosphoric acid from one to two gave increased yields of grain and straw in most cases, but a further increase to three did not materially increase the yields. Varying the amount of phosphoric acid and potash had practically no effect on the percentage of nitrogen and phosphoric acid in the grain and straw.

Some increase in the yield of sorghum was produced by nitrogen fertilization, but increasing the amounts of phosphoric acid and potash fertilization did not consistently increase the yields. A change in the ratio of phosphoric acid and potash did not materially change the percentage of nitrogen and phosphoric acid.

**Action of urea as a nitrogenous fertilizer, its influence on soil reaction** [trans. title], C. BRÉUX (*Compt. Rend. Acad. Agr. France*, 10 (1924), No. 31, pp. 898-905; also in *Compt. Rend. Acad. Sci. [Paris]*, 179 (1924), No. 18, pp. 915-917).—Laboratory studies on the rapidity of the transformation of urea in soil and on its influence on soil reaction, and pot and field experiments to compare urea with sodium nitrate as a nitrogenous fertilizer, are reported.

The pot and field experiments showed that the urea gave as good as, and in

some cases better results than, sodium nitrate. Its manner of action was similar to that of ammonium salts, such as the chloride and sulfate. It was further found that urea added to soil imparted an alkaline reaction at first as it was transformed into ammonium carbonate, but as it was nitrified it gradually developed an acid reaction.

**Fertilizer experiments with nitrogen on meadow** [trans. title], A. ALVES and O. NOLTE (*Mitt. Deut. Landw. Gesell.*, 39 (1924), No. 43, pp. 764-769).—The results of a number of comparative fertilizer experiments with ammonium sulfate and lime nitrogen on meadow are reported and discussed.

The results showed that in general nitrogen fertilization markedly increased the hay yields. The greatest yields were obtained in 21 cases with ammonium sulfate and in 8 cases with lime nitrogen, while in 10 cases there was little difference in the action of the two nitrogenous fertilizers. Owing to the caustic action of lime nitrogen, the best results were obtained by applying it in the fall. Timely rainfall was found to be an important factor in reducing such caustic action. It was found that applications of from 200 to 300 kg. per hectare (178 to 267 lbs. per acre) of ammonium sulfate or of a corresponding amount of lime nitrogen, accompanied by sufficient rainfall, resulted in generally profitable increases in meadow crops.

**Effectiveness and profit of nitrogen fertilization of different crops** [trans. title], O. NOLTE and R. LEONHARDS (*Mitt. Deut. Landw. Gesell.*, 39 (1924), No. 38, pp. 675-683).—The results of a large number of fertilizer experiments with different forms of nitrogen on winter rye, oats, beets, potatoes, and winter grain are briefly summarized. A striking feature of the results is the fact that in all the experiments, with the exception of that with beets, the greatest relative returns were obtained from the largest applications of nitrogen. This is taken to indicate the danger that where insufficient nitrogen is used it may be unprofitable.

**Fertilizer experiments with Rhenania phosphate in comparison with other phosphoric acid fertilizers** [trans. title], A. GEHRING and E. POMMER (*Deut. Landw. Presse*, 50 (1923), Nos. 45, p. 376; 46-47, p. 386).—Six fertilizer experiments to compare Rhenania phosphate with superphosphate, Thomas meal, and a so-called colloidal phosphate on barley, potatoes, oats, and rye are reported. In the majority of cases the Rhenania phosphate did not give as good results as Thomas meal, especially on nonacid soils.

**The chemico-physical influences of quicklime and calcium carbonates on mineral soils**, E. RAMANN (*Soil Sci.*, 18 (1924), No. 5, pp. 387-400).—This is a very technical account of studies on the chemico-physical influences of quicklime and calcium carbonates on mineral soils.

**The influence of sodium chloride upon alfalfa grown in solution cultures**, S. LOMANITZ (*Soil Sci.*, 18 (1924), No. 5, pp. 353-369, figs. 2).—Studies conducted at the New Jersey Experiment Stations in which a greater range of sodium chloride concentrations than usual was covered and the subject studied more in detail are reported. Alfalfa was grown for 77 days in solutions with amounts of sodium chloride varying from 0 to 0.6 atmosphere osmotic pressure.

An increase in yield was observed in five out of the six cultures containing sodium chloride, the greatest relative increase occurring in the tops. The curve for water absorption followed the direction of the curves for yields of tops and for those of whole plants. Not much variation was noticed in the values for water requirement when whole plant yields were considered. More pronounced differences were found when the values for water requirements of tops were compared. There was an indication that the ratio of root growth to that of tops was greater where the total yield was low than where it was high.

The variations in the nitrogen percentages of the whole plants were not of an order to indicate with certainty any definite relationship between this datum and any of the others studied. The roots from the sodium chloride cultures showed a larger nitrogen percentage than those from the check cultures. The chlorine intake of the plants varied directly with the amount of sodium chloride supplied. This applied to the roots as well as the tops, the roots, however, containing a much smaller percentage.

**Inspection of commercial fertilizers for 1924**, H. R. KRAYBILL, T. O. SMITH, and S. R. SHIMER (*New Hampshire Sta. Bul. 214* (1924), pp. 19).—Guaranties and actual analyses of 115 samples of fertilizers and fertilizer materials collected for inspection in New Hampshire during 1924 are presented.

**Analyses of fertilizers, spring season (supplement), 1924** (*N. C. Dept. Agr. Bul., 1924, Aug., Sup., pp. 16*).—Guaranties, actual analyses, and relative valuations of 287 samples of fertilizer and fertilizer materials collected for inspection in North Carolina during the spring season of 1924 are presented.

**Fertilizer report, August 1 to December 31, 1922**, J. W. KELLOGG (*Penn. Dept. Agr. Bul. 377* (1923), pp. 55).—Guaranties, actual analyses, and valuations of 644 samples of fertilizers and fertilizer materials, representing 427 brands collected for inspection in Pennsylvania from August 1 to December 31, 1922, are presented.

**How is one protected against fraud in the purchase of commercial fertilizers?** [trans. title] H. NEUBAUER (*Veröffentl. Landw. Kammer Rheinprov., No. 3* (1924), pp. V+41).—Practical information on the selection and purchase of commercial fertilizers for specific purposes and on how to profit by the results of official inspections is presented for the use of German farmers.

## AGRICULTURAL BOTANY

**An apparatus used in a study of carbon dioxide evolution from soil supporting plant growth**, R. L. STARKEY and J. W. SHIVE (*New Jersey Stat. Rpt. 1923, pp. 241-243, fig. 1*).—A description is given of an apparatus devised by the authors that is said to have proved quite satisfactory for the study of carbon dioxide evolution from soil supporting plant growth.

**Influence of soil moisture on the relation between fertilizer treatment and the growth of potatoes**, W. H. MARTIN and J. W. SHIVE (*New Jersey Stat. Rpt. 1923, pp. 237-240*).—A report is given of experiments conducted with potatoes to determine their water requirement, transpiration, dry weight of tops, and yields when grown with five different percentages of moisture and two rates of fertilizer applications. In every case but one the dry weight of the tops and water loss by transpiration increased with each increase of soil moisture content, and the high fertilizer series required less water to form a gram of dry weight than the low fertilizer series. The highest yields were from the series of cultures with medium moisture content rather than from the highest. The authors point out the importance of considering the relationship of differences of soil moisture to the effect of fertilizers in conducting experiments with fertilizers.

**Notes on the influence of sodium chloride on the growth of alfalfa in solution cultures**, S. LOMANITZ (*New Jersey Stat. Rpt. 1923, pp. 243-246*).—The results are given of a series of culture experiments with alfalfa grown in Totttingham's solution modified in different series by the addition of sodium chloride and by the elimination of amounts of other salts so that the osmotic concentration of the solutions was retained at the same rates. A considerable increase was noted in the yields of all series receiving sodium chloride except one, and the difference here is considered to be due probably to some other

cause than the addition of salt. The greatest relative increase was in the roots. The nitrogen content of the plants did not differ materially in the different series. Chlorine in the plants increased uniformly with the increased supplies in the solutions. The author found, as had other investigators, that the pH values of the discarded solution showed a gradual approach to neutrality as the period of growth advanced.

**Ferric glycerophosphate and soluble ferric phosphate as sources of iron for soybean plants in solution cultures**, R. P. MARSH (*New Jersey Stat. Rpt. 1923, pp. 247-252, pl. 1, fig. 1*).—A brief account is given of a study of the influence of small amounts of iron in the forms of ferric glycerophosphate and soluble ferric phosphate upon the growth and appearance of soy bean plants in seven nutrient solutions containing varying partial concentrations of ammonium sulfate.

The data show, with one exception, that the yields of plants grown in cultures receiving ferric glycerophosphate were more than double those receiving the soluble ferric phosphate, and all plants receiving the latter suffered from iron toxicity while those grown in solutions receiving the same concentration of ferric glycerophosphate produced excellent plants. From the author's experiments it appears that ferric glycerophosphate is a form of iron that can be used effectively in culture solutions in which the H-ion concentration is maintained at a relatively high level, and that ferric phosphate may not be used without danger of iron injury except in much lower concentrations than were used.

Both series of plants showed a marked decrease in yield with an increase in the amounts of ammonium sulfate supplied to the solutions. The author claims that by the selection of the proper type of culture solution and the procedure which he followed it is possible to maintain a solution in contact with the roots of vigorously growing plants during their entire growth period without any marked alteration in its pH value from the initial concentration.

**Iron solubility tests in culture solutions at different pH values**, R. P. MARSH (*New Jersey Stat. Rpt. 1923, pp. 252-255*).—Tottingham and Rankin having shown that the reaction of a culture solution had a marked effect on the solution of iron compounds (E. S. R., 52, p. 123), an experiment was undertaken to determine the solubility of ferric glycerophosphate, soluble ferric phosphate, ferric tartrate, and ferrous sulfate in culture solutions.

The solutions after being adjusted for their pH values received the iron compounds, after which they were allowed to stand in the greenhouse for three days, when the precipitates were collected and analyzed for their iron content. Differences in solubility were observed for the several iron compounds, the solubility being influenced by the type and pH value of the culture solutions. The data presented are considered to suggest in a general way that ferric glycerophosphate could be used to advantage as a source of iron for plants in culture solutions in which the H-ion concentration is maintained at a high level during contact with the plant roots without much danger of iron toxicity, which is quite likely to occur in plants grown in a culture solution of this type when soluble ferric phosphate or ferrous sulfate is used as a source of iron, particularly in culture solutions with pH values approaching the neutral point. It is believed that in solutions of this type ferric tartrate should prove more effective as a source of iron than any of the other compounds considered.

**The influence of soluble aluminum salts on the growth of wheat seedlings in Shive's  $R_2C_2$  solution**, R. M. BARNETTE (*New Jersey Stat. Rpt. 1923, pp. 255-258*).—The results are given of a study of the influence of aluminum

nitrate, sulfate, and chloride on the growth of wheat seedlings in a culture solution. The seedlings were grown in the solution for a period of three weeks under the influence of varying concentrations of the aluminum salts.

In general, the plants behaved quite similarly under the influence of the different salts used. With a single exception, considering averages alone, 0.1 mg. of aluminum per liter of the culture solution, and all concentrations above this, caused a decrease in the dry weight of all parts of the plant. The increasing concentrations of aluminum added to the culture solutions as soluble salts caused slight but progressive increases in the H-ion concentrations of these solutions due to the hydrolysis of the aluminum salts. It is claimed that under the conditions of the experiment the aluminum ion was distinctly toxic to the growth of wheat at concentration of 0.5 mg. per liter of the culture solution and at all higher concentrations. It is considered significant that the aluminum ion exerts a distinctly toxic action on plant growth, and that little, if any, of the deleterious effect observed can be attributed to the increased H-ion concentration due to the hydrolysis of the aluminum salts.

**Notes on the stimulating influence of seed treatment upon the subsequent growth of the plants,** D. SILBERT (*New Jersey Stas. Rpt. 1923, pp. 259-262*).—A preliminary report is given of studies on the stimulating influence of seed treatments on the subsequent growth of plants from treated seed. The experiments were conducted with soy beans, Canada field peas, and buckwheat; the stimulants used were the compounds ordinarily used as seed disinfectants, copper sulfate, sodium hypochlorite, mercuric chloride, and formalin. Seed of each kind were soaked for 15 minutes in a definite quantity of solution and afterwards placed on filter paper to remove the film of moisture on the outside. They were then planted in earthenware pots and the plants grown to maturity and the dry weights determined.

From the data presented it is clearly indicated that the dry weight of soy beans was increased in all the treatments except those where mercuric chloride was used at concentrations of 0.05 and 0.15 per cent. The increase in average yields from the seeds treated with formalin and those treated with sodium hypochlorite was not so pronounced as that from seeds treated with copper sulfate. The stimulation resulting from seed treatment was maintained throughout the entire growth period of the plants. Canada field peas in general did not show any increased yields resulting from the seed treatment. With buckwheat the dry weight of the tops was greatest from treated seeds, although the difference in top yield was not particularly pronounced. The yield of seed was consistently superior for the treated seed.

No attempt was made to determine the limits either in concentration of the disinfectants used or the time of seed treatment within which no injurious effects would be observed.

**The vitality of buried seeds,** W. L. Goss (*Jour. Agr. Research [U. S.], 29 (1924), No. 7, pp. 349-362, pls. 2*).—In continuation of studies on a series of buried seeds (*E. S. R., 17, p. 556*), a further report is given of the behavior of the seeds of 107 species of plants buried in 1902 and tested at various intervals since that date. In 1923, after having been buried for 20 years, seeds of 51 species grew. Most of them were seeds of common weeds, and it is believed that the seeds of most weeds, when plowed under, will not perish during the period of any normal crop rotation.

**Peru as a center of domestication: Tracing the origin of civilization through the domesticated plants,** O. F. COOK (*Jour. Heredity, 16 (1925), Nos. 2, pp. 32-46, figs. 10; 3, pp. 94-110, figs. 11*).—This general article, relating to the various plants utilized by the early Peruvian people, contains references to the origin and dissemination of many horticultural plants.

## GENETICS

**Chromosomal chimeras in the Jimson weed**, A. F. BLAKESLEE and J BELLING (*Science*, 60 (1924), No. 1540, pp. 19, 20).—From a study of a number of aberrant forms of *Datura stramonium*, the authors believe that the evidence already obtained is sufficient to indicate that chromosomal aberrations may be an important cause in the production of bud sports.

**Studies of oogenesis in mammals based on investigations with rats and mice** [trans. title], J. KREMER (*Arch. Mikros. Anat. u. Entwickl. Mech.*, 102 (1924), No. 1-3, pp. 337-358, figs. 14).—The results of cytological studies of ovarian and tubal eggs of rats and mice are reported from the Anatomical Institute at Bonn. The modern theory of chromosome behavior is mainly verified.

**Natural crossings in oats at Akron, Colorado**, T. R. STANTON and F. A. COFFMAN (*Jour. Amer. Soc. Agron.*, 16 (1924), No. 10, pp. 646-659).—In an experiment at the Akron (Colo.) Field Station, of the U. S. Department of Agriculture, four varieties of black and four of white oats grown in adjacent head rows crossed naturally to the extent of at least 0.36 per cent of the  $F_1$  progeny of the white oats. The extent of natural crossing seemed to vary in the different varieties and also in different head selections within varieties. The authors suggest that in oats natural crossing may account for some of the variability observed in supposedly pure line varieties, as well as for the frequent occurrence of widely aberrant forms in certain varieties.

**Genetic relations of five factor pairs for virescent seedlings in maize**, M. DEMEREC (*New York Cornell Sta. Mem.* 84 (1924), pp. 3-38).—A group of corn seedling characters with retarded chlorophyll development is termed "virescent." In the early stage the seedlings are more or less devoid of chlorophyll, which develops later so that the mature plants are normally green. Environment influences appreciably the development of chlorophyll in virescent seedlings, high temperature having a stimulating effect.

Five genetically different virescent types symbolized by  $V_1v_1$ ,  $V_2v_2$ ,  $V_3v_3$ ,  $V_4v_4$ ,  $V_5v_5$  were found in the material used in these investigations. Intercrosses showed that none of these is an allelomorph of a mature plant character called fine-striped  $F f$ , which appears as virescent in the seedling stage. The type  $V_1v_1$  belongs to the  $C-Sb-Wx$  linkage group, and the type  $V_4v_4$  is found linked with  $Lg lg$  and  $B b$ , the order of the genes being  $C-Sb-Wx-V_1$  and  $Lg-B-V_4$ , respectively. In each of 14 other linkage tests made between different virescents and other factor pairs, the factors tested were found independent in inheritance. A slight indication of linkage was noticed between  $V_4v_4$  and  $D d$ .

**The inheritance of brown aleurone in maize**, P. KVAKAN (*New York Cornell Sta. Mem.* 83 (1924), pp. 22).—Brown aleurone in corn was found to be inherited as a simple dominant, being due to a single factor,  $Bn bn$ , which is linked with the factor pairs  $Gl gl$ , glossy seedlings;  $V_2v_2$ , virescent seedlings; and  $Ra ra$ , ramosa ears. Microscopic, chemical, and genetic studies gave indications that brown aleurone and "pale yellow endosperm" are identical. The pigment of the latter occurs in the aleurone but not in the endosperm. Some differences between the brown or pale yellow pigment of the aleurone, and the common or strong yellow pigment of the endosperm, are discussed.

**Inheritance of xantha seedlings in maize**, H. TRAJKOVICH (*New York Cornell Sta. Mem.* 82 (1924), pp. 3-13).—Xantha,  $Xn xn$ , is a chlorophyll character observed in corn seedlings, although under favorable conditions a few plants can be grown to maturity. Xantha seedlings are yellow and have the normal amount of xanthophyll and about 10.7 per cent of the normal amount of chlorophyll. Xantha seedling is determined by a factor or factors

distinct from those controlling virescent and yellow (luteus) seedlings. Xantha seedling seems to be determined by duplicate genes, and possibly one pair of these was present in a homozygous recessive condition in the virescent family used in intercrosses. One of the genes for xantha seedling did not appear to be closely linked with either the gene for virescent seedling or that for endosperm color. A positive correlation was noted between the size of the plastids and the amount of chlorophyll of various seedling types.

**Studies on the inheritance of earliness in wheat**, V. H. FLORELL (*Jour. Agr. Research [U. S.]*, 29 (1924), No. 7, pp. 333-347, figs. 5).—Sunset, an early Australian wheat, and Marquis hard spring wheat, a midseason to late variety when grown in California, and  $F_1$ ,  $F_2$ , and  $F_3$  generations of reciprocal hybrids between them were studied in California in endeavors to determine the inheritance of earliness in wheat. The index of earliness used was the date of appearance of the tip of the first spike on the plant.

No data were secured on the  $F_1$  generation. The  $F_2$  population fell into a large early and a small late group in the proportion of 3.07 to 0.93, indicating one allelomorph pair of factors, with possibly a number of minor modifying factors. The recessive late group of  $F_2$  remaining late in  $F_3$  and the fact that over one-half of the  $F_3$  population apparently was homozygous for earliness tended to confirm the presence of only one pair of factors for earliness as contrasted with lateness. Assuming that pure-line rows pass through the heading stage in the same time as pure-line parent varieties, this period may possibly be used to determine progeny rows homozygous for earliness in  $F_3$  and subsequent hybrid generations.

The use of a time-temperature efficiency unit as a method of analysis suggested that while consideration of the time-temperature relation apparently permits a somewhat more accurate analysis of the genetic factors involved in the inheritance of earliness than time alone, more information is evidently needed concerning the response of the wheat plant to temperature and other factors which influence growth.

**An experiment in breeding apples, II**, R. WELLINGTON (*New York State Sta. Tech. Bul.* 106 (1924), pp. 5-149).—This presentation of data on the fruit and tree characteristics of apple seedlings resulting from 48  $F_1$  generation crosses, 13  $F_1$  generation selfs, 1 Baldwin self (?), and 4 crosses between  $F_1$  generation seedlings is a further contribution (*E. S. R.*, 27, p. 843) upon long continued apple breeding investigations.

The probable gametic composition of the varieties used as parents is discussed in connection with an evaluation of the varieties as breeding material. Emphasizing the difficulty of analyzing Mendelian segregation in the apple, a fruit heterozygous for most characters and usually of unknown ancestry, the author states that certain varieties, at least, possess attributes which are sufficiently constant in inheritance to form a basis for predicting breeding results. For example, crosses involving McIntosh may be expected to yield a large proportion of strong, vigorous seedlings. Lack of resistance to certain diseases may be inherited, as shown in the frequent susceptibility of Yellow Transparent seedlings to blight. Red skin color was found to be usually dominant over yellow. Bloom on the fruit and greasy, oily quality of skins were apparently recessive characters, appearing only infrequently. Many characters, such as fruit size and shape, flesh texture and color, and flavor and quality, seemed dependent upon a number of gametes, preventing any definite deductions. Since some acid-fruited parents yielded only acid-fruited seedlings, the author deems it likely that acidity may be a homozygous character in certain varieties. It was a noteworthy fact that crosses involving certain varieties such as Mc-

Intosh, Northern Spy, Yellow Newtown, Delicious, and Yellow Transparent yielded many good quality seedlings, while other crosses involving varieties such as Boiken, Canada Baldwin, and Montgomery were conspicuous for the lack of quality in their progeny. Certain varieties dominated a cross so strongly that many times it was possible to indicate at least one parent by simple examination of the fruit. Of the many varieties utilized in the study, the McIntosh is considered to have been by far the best parent.

**A correlation between color of grape leaves at time of foliation and fruit color, F. E. GLADWIN** (*New York State Sta. Tech. Bul. 107 (1924)*, pp. 3-8).—Repeated observations on the expanding leaves of a large number of grape varieties showed marked differences in the color of the under surfaces of the first leaves, the colors ranging from pale white, yellow, or creamy, light pink to deep pink and in a few cases crimson and orange. An attempt to correlate these colors with the species' origin failed to yield positive results. However, it was found that white under surfaces were almost invariably correlated with white fruit, or, in other words, the absence of red pigment in the leaves was found to be correlated with the absence of red pigment in the fruit. All efforts to correlate red and black fruits with pinkness of leaves proved inconclusive. In general conclusion, the author points out that the established correlation should be useful in assisting the plant breeder to rogue all white-fruited seedlings from the nursery row and also in assisting the nurseryman in keeping his stocks pure.

**Correlation studies on winter fecundity, F. A. HAYS, R. SANBORN, and L. L. JAMES** (*Massachusetts Sta. Bul. 220 (1924)*, pp. 43-53).—The authors have calculated the coefficients for expressing the correlation between various factors and the winter egg production of 959 Rhode Island Red pullets hatched in weekly broods from March 25 to June 3, 1923. The correlation coefficients were as follows: Hatching date and weight at 150 days (for the entire flock)  $-0.3293 \pm 0.0194$ , hatching date and weight at first egg  $-0.3807 \pm 0.0201$ , hatching date and age at first egg  $-0.1487 \pm 0.0228$ , hatching date and winter production (for the entire flock)  $-0.2920 \pm 0.0218$ , hatching date and winter production (for the genetically early maturing birds alone)  $-0.4790 \pm 0.0254$ , age at first egg and winter production (for the entire flock)  $-0.6061 \pm 0.0151$ , age at first egg and winter production (first three hatches only)  $-0.6413 \pm 0.0320$ , weight at 150 days and winter production (for the entire flock)  $+0.2758 \pm 0.0220$ , weight at 150 days and winter production (for the hatches of April 15 and 22 only)  $+0.2475 \pm 0.0545$ , weight at first egg and winter production (for the entire flock)  $-0.1894 \pm 0.0231$ , weight at first egg and winter production (for the first eight hatches only)  $-0.2963 \pm 0.0269$ , average daily gain, 150 days old to age at first egg, and winter production (for the entire flock)  $+0.2899 \pm 0.0220$ , average daily gain, 150 days old to age at first egg, and winter production (for the genetically early maturing group alone)  $+0.2055 \pm 0.0318$ , weight at 150 days and age at first egg  $-0.2135 \pm 0.0221$ , weight at first egg and age at first egg  $+0.4604 \pm 0.0185$ , and average daily gain and number of days, from 150 days old to age at first egg  $-0.4145 \pm 0.0196$ .

**A genetic linkage between size and color factors in the tomato, E. W. LINDSTROM** (*Science, 60 (1924), No. 1547, pp. 182, 183*).—It is claimed that from studies of a large number of crosses involving various sizes and colors of fruit, a definite linkage between these two types of genetic factors was established. Color in tomato fruits is considered to be mainly determined by two different pairs of genes. One pair, *Rr*, controls the red and yellow flesh color, the former being dominant. The other pair, *Yy*, determines skin color, *Y* producing a yellow pigment in the cell walls of the epidermis of the

fruit, and  $y$  giving a colorless condition in these cells which is recessive in inheritance. Size of fruit in tomatoes is considered best interpreted by the multiple factor hypothesis.

Reciprocal crosses involving these two pairs of color genes and different sizes of fruit are said to indicate that the color factor pair  $Yy$  is closely linked with genetic factors for weight of fruit. It is also noted that red and yellow flesh color, dependent on genes  $R$  and  $r$ , seem to be independent of weight.

**Contribution to the comparative physiology of spermatozoa, II, III** [trans. title], E. GELLHORN (*Pflüger's Arch. Physiol.*, 193 (1922), No. 5-6, pp. 555-594, figs. 26).—In continuing this series of studies,<sup>1</sup> two papers are presented.

II. *Further studies on the action of salts.*—The relative effects of the chlorides of various salts and various compounds of sodium on the motility, duration of life, and morphological changes in the spermatozoa of *Rana temporaria*, *R. esculenta*, and guinea pigs have been determined.

III. *Further studies on the action of salts with special reference to mixtures of electrolytes.*—In these investigations it was conclusively demonstrated that in mixtures of electrolytes the toxicity of one tended to neutralize the toxicity of the other toward the activity of spermatozoa of the animals used in the above paper.

**Physiological investigations of spermatozoa and ova** [trans. title], E. GELLHORN (*Arch. Mikros. Anat. u. Entwickl. Mech.*, 101 (1924), No. 1-3, pp. 437-443, fig. 1).—This is a discussion of the various physicochemical influences affecting the vitality, morphology, and physiology of spermatozoa and ova, based on studies similar to those noted above and with like results.

**Investigations of the reciprocal influence of the ovaries and uterus** [trans. title], S. TAKAKUSU (*Arch. Mikros. Anat. u. Entwickl. Mech.*, 102 (1924), No. 1-3, pp. 1-50, figs. 34).—In this study, which was conducted at the Kaiser Wilhelm Institute for Biology, the effect of the removal of the uterus of rats on the histological changes in the ovaries and the effect of ovariectomy on the uterus were investigated. The removal of the uterus was found to be almost immediately followed by ovarian changes in which the development of follicles stopped, those present became atresic, and large amounts of lutein tissue developed in the ovary. Some corpora lutea were also present and a few cystic follicles.

Prolonged injections of uterine extracts into hysterectomized females seemed to influence the production of large amounts of fat throughout the ovary. Experiments dealing with the effects of the uterus of one animal on the ovaries of another attached to it further indicated that the secretions of the uterus have a direct effect on the regulation of the normal activity of the ovary. Ovariectomy also was found to reduce the size of the uterus, thus indicating the production of secretions by the ovary which control the function of the uterus.

**The follicular hormone of the hen ovary**, E. ALLEN, J. W. WHITSETT, J. W. HARDY, and F. L. KNEIBERT (*Abs. in Soc. Expt. Biol. and Med. Proc.*, 21 (1924), No. 8, pp. 500-503).—In testing the action of the follicular hormone of the hen's ovary extracts of small (less than 15 mm. in diameter), medium (15 to 35 mm.), and large (over 35 mm.) follicles were injected into spayed rats for three consecutive doses of 1 cc. at 3- to 4-hour intervals. The occurrence of oestrus in the spayed rats was determined by vaginal smears.

<sup>1</sup> Pflüger's Arch. Physiol., 185 (1920), No. 4-6, pp. 262-280.

Oestrum was noticed in all of the four experiments in which extracts of the small follicles were used and in three of the four in which the extracts of the medium-sized follicles were used, but extracts of full-sized follicles, eggs from the oviduct, fresh eggs (yolks and whites separately), and 5-, 10-, and 14-day embryos with their membranes all gave negative results.

These experiments furnish evidence of the nonspecificity of the follicular hormone in birds and mammals.

**Microbic virulence and host susceptibility in paratyphoid-enteritidis infection of white mice.—IV, The effect of selective breeding on host resistance,** L. T. WEBSTER (*Jour. Expt. Med.*, 39 (1924), No. 6, pp. 879-886, figs. 5).—In continuing this series of studies (E. S. R., 50, p. 478), it was found that only 42 per cent of the offspring of mice which have survived a lethal dose of mouse typhoid bacilli succumbed to a lethal dose of these bacilli as compared with 72 per cent of the controls. In the second generation from the resistant mice only 15 per cent succumbed as compared with 70 per cent of the controls. A repetition of this experiment gave similar results. Only mice showing no mouse typhoid bacilli in the blood or feces or specific agglutins were used for breeding, thus eliminating the chance of the development of immunity by the young in utero or from the mother's milk. In two experiments offspring of the disease-resistant mice were also found to be more resistant to doses of bichloride of mercury.

"The experiments reported in this paper were performed under conditions which reduced the possibility of specific acquired immunity to a minimum, and indicate, therefore, that in mice host resistance contains important hereditary factors both specific and nonspecific in nature, and that the degree of this resistance in a given population may be enhanced by selective breeding."

## FIELD CROPS

**The rôle of statistics in agronomic experimentation,** H. H. LOVE (*Sci. Agr.*, 5 (1924), No. 3, pp. 84-92).—A discussion of the use of statistical methods in interpreting the results and the planning of agronomic experiments.

**Relation of seed size to the yield of small grain crops,** T. A. KIESSELBACH (*Jour. Amer. Soc. Agron.*, 16 (1924), No. 10, pp. 670-682, fig. 1).—A summary of all available published field data dealing with the grain yields from seed grades of small grain crops is presented, together with the results of similar work at the Nebraska Experiment Station. See also an earlier note (E. S. R., 38, p. 732).

In the Nebraska experiments wherein hand selected large and small seed representing extreme grades of winter wheat, spring wheat, and oats were compared, small seed yielded 18 per cent less than large when spaced to permit maximum individual plant development, 10 per cent less when equal numbers of seed were sown per acre at an optimum rate for the large seed, and 5 per cent less when equal weights of seed were sown per acre at an optimum rate for the large seed. Unselected seed yielded 4 per cent less than the large when equal numbers were sown per acre, and 1 per cent less when equal weights of seed were sown. Comparison of fanning-mill grades of winter wheat during 17 years showed the heaviest one-fourth to yield 0.3 per cent more, and the lightest one-fourth 2 per cent less than the unselected seed. During 18 years, the heaviest one-fourth of Kherson oats yielded 0.9 per cent more, and the lightest one-fourth yielded 0.7 per cent less than the original unselected seed.

In general, the work at the Nebraska Station seemed to indicate that there will be no material or practical gain in the grain yield, under farm conditions, from the practice of grading seed of small grains which is reasonably free from trash and inert matter.

**Some green manures and cover plants**, T. H. HOLLAND (*Ceylon Dept. Agr. Leaflet 30 (1924), pp. 6, pls. 7*).—Based on experience at the Peradeniya Experiment Station, information is given concerning the value for green manure and as cover crops of *Erythrina lithosperma*, *Gliricidia maculata*, *Albizzia moluccana*, *Leucaena glauca*, *Adhatoda vasica*, *Tephrosia candida*, *T. hookeriana*, *T. purpurea*, *Crotalaria striata*, *C. usaramoensis*, *C. incana*, *Indigofera arrecta*, *I. hirsuta*, *I. endecaphylla*, *Sesbania aculeata*, *Cassia hirsuta*, *Clitoria cajanifolia*, *Centrosema plumieri*, *C. pubescens*, *Vigna oligosperma*, *Desmodium triflorum*, *Pueraria javanica*, and *Mikania scandens*.

**The grasses of Pennsylvania**, E. M. GRESS (*Penn. Dept. Agr. Bul. 384 (1924), pp. 245, figs. 235*).—This manual includes descriptions, illustrations, and the known distribution in Pennsylvania for about 250 species and varieties of grasses. In addition to appropriate keys, the work includes discussion of the genetic relationships, classification and characteristics, gross anatomy, uses, and distribution of grasses.

**Legume inoculant work** (*New Jersey Stas. Rpt. 1923, pp. 141, 142*).—Of nine varieties of soy beans tested, Haberlandt nodulated to a limited extent, Virginia intermediately, and Mammoth Yellow profusely, the difference being attributed to the composition of the internal juices of plants serving as a food and energy source for the organism. The influence of mineral fertilizers on nodulation of soy beans has been described (*E. S. R., 52, p. 340*) by Perkins. The closer the moisture content of the substratum approached 100 per cent of the water-holding capacity, the greater was the nodulation and the plant growth.

Bacterial counts should evidently be run in connection with hothouse trials to determine the number of viable organisms present and their ability to produce nodules upon the specific host. Tests with diluted cultures demonstrated that a minimum number of bacteria is required to give maximum nodulation, and that this minimum varies widely with the moisture content of the substratum and the presence of energy-giving carbohydrates. The minimum found necessary to give nodulation in the absence of carbohydrates was about 50 bacterial cells per seed.

**[Field crops experiments in New Jersey]**, J. G. LIPMAN, L. G. SCHERMERHORN, and G. W. MUSGRAVE (*New Jersey Stas. Rpt. 1923, pp. 17, 18, 34, 95-100, 153-165, pl. 1, fig. 1*).—Variety trials with oats, corn, wheat, barley, rye, buckwheat, timothy, millets, and soy beans; breeding work with corn and potatoes; seed tests with potatoes; studies of the effect of fertilizers (*E. S. R., 51, p. 342*) on the yield and shape of sweet potatoes; and trials of kudzu, red clover, and sweet clover are reported on as heretofore (*E. S. R., 51, p. 636*). Plats treated with sulfur generally produced potatoes yielding somewhat lower but usually freer from scab than those on unsulfured plats.

**[Agronomic experiments in Utah]**, A. F. BRACKEN, G. STEWART, D. W. PITTMAN, A. L. WILSON, and L. M. WINSOR (*Utah Sta. Bul. 192 (1925), pp. 21, 22, 23, 25, 26, 28-30, 40, 53*).—Varietal trials with winter and spring wheat, winter barley, silage corn, potatoes and sweet potatoes, and breeding work with wheat and potatoes are commented on briefly. Alfalfa and rye were the forage crops best adapted to dry land.

Alternate cropping, wheat after fallow, has proved safest under all conditions, the next best method being two crops of wheat followed by a fallow

season. When wheat was plowed under at different stages of growth each successive stage showed decreases in the yields of the following wheat crop. Wheat after peas similarly turned under showed increases in yield up to the bloom stage of the peas. Cultivating wheat grown in rows generally decreased yields. Seeding experiments indicate sowing not less than 5 pk. of good clean winter wheat not later than October 1. Significant differences were not shown between irrigated and dry land seed.

Irrigating the seed bed before planting grain has largely increased total yields as compared with planting under natural conditions and irrigating as usual. Several crops of alfalfa were obtained by early irrigation alone, whereas only one crop was harvested without early water. Fall irrigation has prevented the appearance of burned spots during the following season. Irrigating before planting brought up sugar beets successfully from ground lacking enough moisture. Thinning beets to 12 in. apart, with irrigation soon after thinning, seems to be a desirable practice.

**Report of the Dominion cerealist for the year 1923**, L. H. NEWMAN (*Canada Expt. Farms, Cereal Div. Rpt. 1923, pp. 20, fig. 1*).—Yields and agronomic data are reported from variety trials in 1923 and during various periods with spring wheat, oats and barley for grain and hay, spring rye, field peas, field beans, and flax and hemp for seed.

**Characteristics of clover and alfalfa seed from southern France** [trans. title], L. FRANÇOIS (*Ann. Sci. Agron. Franç. et Étrang., 41 (1924), No. 4, pp. 272-282*).—A résumé of the recorded appearances in France of *Trifolium supinum*, an Italian legume, considered with the results of a survey in south-eastern France led the author to conclude that French-grown clover never includes seeds of *T. supinum* among its natural impurities. The presence of seed of *Coronilla scorpioides*, *Helminthia echioides*, *Centaurea solstitialis*, and *Rubus* sp. in clover and alfalfa seed is held indicative of a southern France origin. While *T. stellatum*, *T. angustifolium*, *Bonjeania recta*, *Bromus rubens*, *B. madritensis*, and *Hedypnois polymorpha* may also be indicative, they are not essential to designate a southern France clover or alfalfa if the sample includes among its impurities some seed of *Coronilla scorpioides*, or in its absence, considerable amounts of seed of *Helminthia echioides* and of *Centaurea solstitialis*.

**Home-grown vs. foreign red clover seed**, L. E. THATCHER (*Ohio Sta. Mo. Bul., 9 (1924), No. 11-12, pp. 187-191, fig. 1*).—Source-of-seed tests with red clover at the station showed seed from Michigan, Germany, and Chile to be most productive in both first and second cuttings. Clover from Italian seed gave the lowest hay yield, was badly affected by anthracnose, and had a considerable weed content. These and previous results and experiments elsewhere (E. S. R., 50, pp. 435, 829) with somewhat similar climatic conditions show that clover seed produced in Ohio, Indiana, Illinois, Michigan, and Wisconsin may be grouped in so far as hardiness and yield are concerned. Red clover seed from this territory should be given first choice for Ohio farms.

**Jala maize**, J. H. KEMPTON (*Jour. Heredity, 15 (1924), No. 8, pp. 337-344, figs. 6*).—A type of corn cultivated at Jala, about 60 miles southeast of Tepic, Mexico, is characterized by plants averaging 20 ft. in height, ears about 20 in. long and 9 in. in circumference, comparatively heavy kernels ranging from 700 to 1,000 in number, and leaves, tassels, and diameter of the stalks in proportion to the height. The size of this type of corn was shown to be neither the result of a favorable environment nor the result of a doubling in chromosome number. The author thinks that for tropical countries with a long growing season there are possibilities inherent in this variety justifying the careful attention of breeders.

**Cotton culture in Argentina** [trans. title], N. E. WINTERS (*Min. Agr. [Argentina], Secc. Propaganda e Informes Circ. 320 (1924), pp. 24*).—A practical discussion of the environmental and cultural requirements of the crop with notes on varieties, insect pests, and production costs.

**I, Report of three years' cotton improvement work. II, Observations on the behavior of cotton plants, especially during acclimatization**, J. B. GRIFFING (*Univ. Nanking, Agr. and Forestry Ser., 1 (1923), No. 6, pp. 45, pls. 6, figs. 3*).—The progress of work with cotton by the University of Nanking involving the acclimatization of American varieties and the improvement of Chinese cotton is reported on, with comment on extension activities, improved implements, cotton insects, and the future of this work in China.

Sample measurements with American varieties, including Trice, Acala, Miller, and College No. 1, have demonstrated the efficacy of roguing and selection in overcoming the degenerative tendencies resulting from change of environment. As judged by lint length, size of seed, and lint index, the quality of the crop at the end of three years' work seemed superior to that of the first year. Fixing of type in superior progenies appeared to be shown by the low coefficient of variability of the above characters in selected progenies. Breaking up of variety type into diverse forms was noted in all imported stocks, even in such pure strains as College No. 1. A strong positive correlation existed between lint index and size of seed, with a moderate negative correlation between percentage and size of seed, whereas no correlation existed between lint length and size of seed.

**Inoculation increases yield and quality of peas for canning**, A. L. WHILING, E. B. FRED, and J. W. STEVENS (*Wisconsin Sta. Bul. 372 (1925), pp. 23, figs 19*).—Inoculated canning peas were compared with uninoculated peas on a field scale in most of the pea-growing sections of Wisconsin.

On soils without pea bacteria, inoculated plants through their darker green color and increased height showed greater vigor than uninoculated plants. Bacteria persisting since a previous crop of peas did not suffice to exert the maximum effect, inoculation generally being followed by an increased yield of shelled peas and more vigorous vines with increased protein content. Inoculation seemed quite beneficial in the presence of low temperatures and excess rainfall. Increased percentages of the smaller sizes of peas and improved quality, as shown in tenderness and taste, also followed inoculation. Where some soil inoculation already existed the cultures had little effect in increasing the protein content of the green peas, this effect being much more pronounced when no nodules were present on the uninoculated part of the field.

**The influence of plot size and replication on experimental error in field trials with potatoes**, K. C. WESTOVER (*West Virginia Sta. Bul. 189 (1924), pp. 32, figs. 11*).—Experiments were made in 1922 and 1923 to determine the size of single-row potato plats and the number of replications needed to reduce experimental error to practical limits.

In field experiments under West Virginia conditions with the Carman No. 3 potato planted 10 to 12 in. apart in rows spaced 3.5 ft. apart, reliable results probably may be expected from the use of a 40-ft. single-row plat replicated 4 times. Under existing conditions, the increased accuracy which might be had by using a single-row potato plat more than 40 ft. long would not offset the added inconveniences. Only plantings of native strains gave significant differences in standard deviation between the 10- and the 20-ft. plats. Strains from other sources (Minnesota and Canada) required greater plat lengths to obtain significant differences. As in similar work with other crops, these studies indicate that there are limits in plat size and in number of replications beyond which no practical reduction in experimental error occurs.

**Sorghum** [trans. title], L. A. ZHDANOV (*Izv. Opytn. Dona i Sev. Kavkaza (Jour. Agr. Research Don and North Caucasus) No. 3 (1923), pp. 70-83*).—Rather extensive trials at the Rostov Experiment Station showed sorghum to be a highly productive grain and forage crop for the arid southeastern regions of Russia, surpassing corn in reliability. The best crops were produced by early varieties.

**The influence of lime on the yield and nitrogen content of soy beans, 1922**, J. G. LIPMAN and A. W. BLAIR (*New Jersey Stat. Rpt. 1923, pp. 227-229*).—Varieties of soy beans grown on both limed and unlimed plats during the tenth year of this experiment (E. S. R., 51, p. 639) produced respective average yields of 21.2 bu. of beans with 1,856 lbs. of dry stalks per acre and 3 bu. with 334 lbs. The average acre recovery of nitrogen was 92.8 lbs. per acre from the limed and 14.8 lbs. from the unlimed plats. The original nitrogen content of the soil in the limed plats has been practically maintained, whereas the unlimed plats suffered a considerable loss.

**Sugar beet fertilization**, O. B. PRICE (*Michigan Sta. Quart. Bul., 7 (1925), No. 3, pp. 87-89, fig. 1*).—Fertilizer trials with sugar beets showed the use of phosphoric acid to give the largest increases in yields, results from potash being more variable, and those from nitrogen carriers depending largely on climatic conditions. Injury due to drilling ammonium sulfate with the seed is illustrated. See also a previous note (E. S. R., 51, p. 38).

**The inoculation of sugar beets** [trans. title], A. NĚMEC (*Ann. Sci. Agron. Franç. et Étrang., 41 (1924), No. 4, pp. 254-259*).—Experiments cited showed substantial increases in the yield of sugar beets to follow inoculation with suitable microorganisms.

**Studies on fertility of sugar-cane flowers** (*Queensland Agr. Jour., 22 (1924), No. 3, pp. 248-255, figs. 5*).—Observations by W. Cottrell-Dormer and McWalters at the South Johnstone Sugar Experiment Station were concerned with hybridization, ripening of fertile spikelets in the arrows, and seed development and germination, and with the insects attacking the arrows. The fact that many of the spikelets sinking in ether proved fertile gave an index to the possible germination of the seed in an arrow.

**Deterioration of Uba sugar cane between cutting and milling** [trans. title], L. F. DE FROBERVILLE (*Rev. Agr. Maurice, Nos. 13 (1924), pp. 11-18; 14, pp. 74-84*).—Experiments in Natal showed a daily loss of weight in stripped cane. Regardless of whether cut or whole, erect or recumbent, sheltered or not, burned cane lost more weight than stripped cane.

The percentage loss of sucrose was lower in the burned cane than in the stripped cane during the first three days, but increased after the fourth day. The purity of sheltered cane, either stripped or burned, declined less than that exposed to the air, although the glucose increased to a greater extent under shelter. The decline in purity seemed less in the basal portions of the cane than in the middle or tops, whatever the length of the section, indicating that deterioration started where the sucrose was least and invert sugar present in the greatest proportion. The greatest amount of sucrose was apparently in that part of the cane where the weight per running foot of cane was heaviest. For the same weight per running foot, the sucrose content appeared greater in burned cane than in stripped cane.

[**Experimental work with sugar cane in Queensland, 1923**], H. T. EASTERBY (*Queensland Bur. Sugar Expt. Stat. Ann. Rpt., 23 (1923), pp. 1-46, 52-58*).—Besides reporting the progress in 1923 of experiments with sugar cane along the same general lines as noted earlier (E. S. R., 49, p. 828), these pages describe work with bud variations and sports in sugar cane at the South Johnstone Experiment Station and irrigation tests at Home Hill State Farm.

**The culture of sugar crops in arid regions** [trans. title], N. I. PUSHKAREV (*Izv. Opytn. Dona i Sev. Kavkaza (Jour. Agr. Research Don and North Caucasus) No. 2 (1923)*), pp. 87-123).—Field and laboratory experiments with corn, sorgo, and sugar beets grown as sugar plants were carried on at Rostov during the period 1919-1922. Removal of corn ears and sorgo heads in the milk stage increased sugar production in the plants and resulted in a better quality of juice. Sorgo was considered much superior to corn both for sugar and forage. Sugar beets surpassed both corn and sorgo in sugar production, and are thought to be well suited to culture in the rather arid districts of southern Russia if proper methods are followed and economic obstacles overcome.

**Growing sweet clover**, G. H. CUTLER and G. F. H. BUCKLEY (*Alberta Univ. Col. Agr. Bul. 2 (1923)*), pp. 24, figs. 5).—Practices considered suitable for the production and utilization of sweet clover in Alberta are outlined.

Experiments at the University of Alberta indicated that when a nurse crop is not used sweet clover, if well started, can be cut for hay or pastured during the season of planting without materially reducing profitable production the next season. When the crop was cut closely at intervals to simulate pasturing by stock the yield data showed that sweet clover can produce a large amount of pasturage during the season after planting or during the second year. Sweet clover was not as promising for silage as for pasture.

**Fertilizer experiments with tobacco, 1919-20-1922-23** [trans. title], A. N. J. BEETS (*Proefstat. Vorstenland. Tabak [Dutch East Indies], Meded. 50 (1924)*), pp. III+66).—Fertilizer experiments carried on with tobacco in the Dutch East Indies during the above period showed the value of lime on heavy soils. The use of dessa earth or stable manure favorably influenced acre yields and length and quality of leaves, but these materials are considered potential sources of infection of the soil with *Phytophthora nicotianae*, the cause of lanas disease. Application of ammonium sulfate without manure to tobacco on light soils gave results but little better than those obtained on unfertilized soils. In a dry year differences in length of leaves were not apparent, whether the plants received sodium nitrate or ammonium sulfate. Ureum gave variable results in comparison with ammonium sulfate on light soils. Favorable results followed the application of tobacco seed cake and peanut cake. Bat dung contained so little nitrogen as to be impracticable.

**Root development in wheat**, R. D. LEES (*Agr. Gaz. N. S. Wales, 35 (1924)*), No. 9, pp. 609-612).—When different amounts of superphosphate were applied to wheat at the Wagga Experiment Farm, the superphosphate appeared to increase the depth of root penetration, a plat receiving a dressing of 1 cwt. per acre producing the greatest root development and highest hay yields. While no outstanding differences were noted in the root development of a number of varieties studied, early seeding led to greater root penetration than late seeding.

**Report of the experimental work, State testing mill, crop season of 1922**, C. H. BAILEY (*Minn. Dept. Agr. Bul. 34 (1924)*), pp. 29, figs. 7).—Sixty-one lots of northwestern-grown hard spring wheat were tested during the crop season of 1922. This crop differed markedly from that preceding (E. S. R., 49, p. 831), the kernels being much plumper and heavier, but lower in crude protein and hence in gluten. In general, the spring wheat grown in the western portion of the spring-wheat area was more glutinous than that from the eastern portion.

When groups of samples of straight grade flour were compared, a definite tendency was observed in the direction of larger loaves of bread as the crude protein content increased. Yield of flour increased fairly regularly with in-

creasing weight per bushel. Gains in milling were experienced in grinding average 1922-crop wheat, due to its dry condition.

Ash content of flour was not invariably a criterion of the degree of refinement, particularly when wheats abnormally high or low in ash were milled and when washed and unwashed wheats were compared. Moisture content of the straight grade flour was observed to vary at different seasons, the highest percentages in 1922 and 1923 being encountered in the late spring and late fall. Samples of No. 3 Dark Northern Spring and No. 3 Northern Spring wheat, degraded because of foreign material other than dockage, could generally be cleaned enough before milling so that the resulting flour would be refined and of normal quality. Milling and baking tests with Kota wheat from two points in North Dakota were considered inconclusive.

Results of seed tests for the year ending June 30, 1924, M. G. EASTMAN (*New Hampshire Sta. Bul. 215 (1924), pp. 18*).—The percentage of germination and purity are tabulated for 248 official samples of agricultural seed tested during the year ended June 30, 1924.

Proceedings of the sixteenth annual meeting of the Association of Official Seed Analysts of North America (*Assoc. Off. Seed Anal. North Amer. Proc., 16 [1923], pp. 78, figs. 45*).—A report of the activities of the association during 1923 is given, with the following papers presented at the sixteenth annual meeting at Cincinnati, December 27–30, 1923:

Seventy-five Years of Agricultural Progress, by F. W. Taylor; A Special Form of Delayed Germination in Wheat, by A. M. Lute; Dormancy of Newly Threshed Grain, and Correlation of Laboratory and Field Germination Tests, both by W. O. Whitcomb; The Germination of Vegetable Seeds Sold in Virginia during the Spring Months of 1923, by G. T. French; Observed Variations of Duplicate Germination Tests, by F. S. Holmes; Report on Study of Origin of Alfalfa and Red Clover, by F. H. Hillman; Relation of the Seed Analyst to Uniform Weed Legislation, by A. C. Wilson; The Germination of Cotton Seed, by E. H. Toole (*E. S. R., 52, p. 34*); Studies on Lettuce Seed Germination, by E. F. Hopkins; The Germination of Lettuce Seed, by W. E. Davis; and Study of Influence of Heat and Cold on Germination of Hard Seeds in Alfalfa and Sweet Clover, by J. G. Rodriguez.

Weeds of cranberry bogs, C. S. BECKWITH and J. G. FISKE (*New Jersey Stas. Circ. 171 (1925), pp. 22, figs. 23*).—The more common types of weeds infesting cranberry bogs, which are described with the most effective methods for their control, include cut-grass (*Carex bullata*), reed grass (*Calamovilfa brevipilis*), wool grass (*Scirpus cyperinus*), redroot (*Lachnanthes tinctoria*), double-seeded millet (*Amphicarpon purshii*), green brier (*Smilax* sp.), swamp blackberry (*Rubus hispida*), bracken (*Anchistea virginica*), cinnamon fern (*Osmunda cinnamomea*), and royal fern (*O. regalis*). Weed control in bogs has resulted in increased yields of cranberries.

## HORTICULTURE

[Horticultural investigations at the New Jersey Stations] (*New Jersey Stas. Rpt. 1923, pp. 75–95, 101–116, pls. 2, fig. 1*).—In cultural studies with the carnation no differences were found whether the space below the top 4 in. of soil was filled with sand or cinders or simply left an open space. C. H. Connors, working with pure line carnations, reports that apparently fixed white and scarlet types have bred true to the sixth and fourth generations, respectively. In sexual status (*E. S. R., 51, p. 647*), the carnation was found exceedingly variable, ranging from completely staminate to completely pistil-

late plants. Among the 1,200 and odd seedlings grown in the summer of 1923 there were found several very promising individuals. Soil acidity studies with the hydrangea are again reviewed (E. S. R., 52, p. 143). Peach breeding projects were actively pursued, particular attention being paid to crosses between important commercial varieties and some of the station seedlings. Studies of fruit setting in the J. H. Hale variety gave further evidence of male sterility.

Studies conducted by M. A. Blake upon the rate of growth of nursery peach trees showed that at times the Elberta shoots elongate at a rate of more than 1 in. per day. In the case of one station seedling an average height growth of 1.41 in. daily was noted during the period from June 3 to 12. Observations on the roots of peach stocks used in a hardiness test showed marked differences in relation to parentage. The Muir seedlings, for example, were especially vigorous, and had heavy, much-branched root systems. Phenological data upon fruits and ornamentals are presented in tabular form.

Tomato fertilizer studies, reported by L. G. Schermerhorn, show that over a period of three years the highest yield was obtained upon the plat fertilized at the rate of 800 lbs. of acid phosphate, 200 lbs. of potassium chloride, and 100 lbs. of sodium nitrate per acre. In the case of the Bonny Best variety, subjected to 22 fertilizer treatments, the highest yields, based on three years' investigations, were secured from the use of a 6-4-6 mixture. Early Knight cantaloupes started under glass were not only more productive than those sown directly in the field, but were decidedly earlier in ripening, completing their fruiting season the same day that the first fruits were harvested from the field-grown plants. In comparing several fertilizers for cantaloupes, including manure, the maximum yields were obtained on that area where, following the turning under of a crop of rye, there was broadcasted, per acre, 150 lbs. of potassium chloride and 45 lbs. of acid phosphate, supplemented with 250 lbs. of tankage applied in the furrows, and 100 lbs. of sodium nitrate and 100 lbs. of fish meal used as a side dressing. The results of fertilizer studies on 4- and 5-year-old asparagus plantations at New Brunswick are presented in tabular form. A list of vegetable varieties suited to New Jersey is given.

Pomological investigations, reported by A. J. Farley, include the results of a study of the rate of growth of apple fruits of five varieties. It was found that the maximum growth occurred during a brief period succeeding petal fall, and the lowest growth rate during the three weeks preceding maturity. No correlation was noted between the rate of growth and the total weekly rainfall, and no distinct reaction in the rate of growth was observed in response to weekly variations in temperature.

In strawberry investigations preliminary records indicated that in matted row culture, plants spaced 6 and 8 in. apart are more productive than those spaced 3 in. or those allowed to establish themselves naturally. Increased yield is believed to be due to increased size rather than number of fruits.

Considerable time was devoted to further testing of the so-called dry-mix spraying mixture (E. S. R., 49, p. 349). The addition of lime to concentrated lime sulfur used at the recommended strength for summer spraying of apples had no effect whatsoever on spray injury to either fruit or foliage. So far as could be observed, calcium caseinate exerted no influence on the fungus or insect controlling qualities of lime sulfur and lead arsenate summer sprays. Blooming data for peaches, apples, plums, cherries, and pears are presented in tabular form.

[Horticultural investigations at the Utah Station], A. L. WILSON and T. H. ABELL (*Utah Sta. Bul.* 192 (1925), pp. 38-40, 41, 45-47, 48-51).—Onion

variety tests carried on at the Davis County Experimental Farm showed the Valencia type to be significantly the best yielding of the many varieties and strains tried. Attempts to develop a wilt resistant watermelon by crossing with the citron proved unsuccessful, for from 11 original crosses not a single edible melon was obtained in the  $F_2$  generation. Irrigation studies with peas showed in 1923 a distinct advantage in withholding the initial application of water until the plants actually began to show some injury. However, in 1924 exactly the opposite results were secured, indicating that climatic variations play an important rôle. Of 15 cucumber varieties, the Vaughan and the Perfected Davis Perfect proved most satisfactory. Records taken on onions kept in common storage showed the Australian Brown, Valencia, Yellow Globe Danvers, and the Southport Globe to be the best keepers.

Of four methods of planting canning peas, (1) single row, (2) double row, (3) strip, and (4) solid field, tested in an attempt to develop a method which would allow spray rigs to pass without injury to the vines, the fourth method resulted in yields 17.3 per cent above any of the others. Strain tests with the Stone and Greater Baltimore tomatoes showed striking differences in fruit types in stocks obtained from various sources. Crosses between Stone and Earliana yielded seedlings which in nearly all characters resembled the Earliana parent.

**Growing and handling asparagus crowns, H. A. JONES and W. W. ROBBINS** (*California Sta. Bul. 381 (1924), pp. 3-34, figs. 15*).—This is a combination of careful observations on the development of the young asparagus plant and general cultural information suitable for the practical grower.

The number of seeds to an asparagus berry was found to range from one to eight, with the greatest frequencies at five and six. The fact that asparagus seeds contain a large supply of reserve foods, hemicellulose and fat, enables the germinating plantlet to survive even though deeply planted. Optimum temperature for germination was from 77 to 86° F., and though seeds survived long immersion in water, germination did not result in absence of abundant oxygen. Asparagus seeds absorbed water much more rapidly at temperatures favoring germination than at lower levels. Observations on the first seven shoots developing on young plants showed a gradual increase in length and diameter from the first to the seventh, which was the first to bear blossoms. Male plants bloomed approximately two weeks earlier than did females. The latter, however, were, as a rule, taller and often characterized by fewer shoots. Crowns subjected to desiccation by storage for 53 days in a dry room were slow to develop shoots.

**Pollen studies with the pear and the apple** [trans. title], F. KOBEL (*Deut. Obst u. Gemüsebau Ztg., 71 (1925), Nos. 9, pp. 98-101; 11, pp. 134, 135*).—Studies conducted at the Experimental Station at Wädenswil, Switzerland, upon the pollen of 21 pear and 20 apple varieties showed important varietal peculiarities. The viability of pear pollen ranged from 4 per cent for Pastorenbirne to 78 per cent for Vereins-Dechantsbirne, and of apple pollen from 7 per cent for Gravenstein to 98 per cent for Sauergrauech.

Comparing three sugar solutions, namely, 2.5, 10, and 20 per cent, as pollen growing media, it was found that the maximum germinations were quite evenly distributed in the 10 and 20 per cent groups. One pear variety, Fondante Thriot, gave its highest germination in the 2.5 per cent solution. Contrary to the results obtained by Florin (*E. S. R., 46, p. 39*), the germination differences between the three sugar strengths were for the most part inconsiderable. It is deemed likely that the results were affected by the introduction into each culture of a piece of the pistil of the same variety.

Because of the great variability in the length of the pollen tubes, the author believes that the percentage of viability is probably not a direct measure of fruitfulness. In general, it was found that long, vigorous tubes were associated with uniform, well-filled pollen grains, and that the more uniform the pollen, the greater its viability. Lack of uniformity and low viability of pollen was usually associated with short, thick, and unsymmetrical tubes having the appearance of not being able to traverse the long distance from the stigma to the ovary.

A positive correlation was noted between viability of pollen and the length of the tubes, e. g., apples and pears with 60 per cent germination or above usually developed excellent tubes, while varieties with 30 per cent or less usually produced imperfect tubes. The Bartlett (Williams Christbirne) and the Angoulême (Herzogin von Angoulême) pears and the Jonathan apple were found to be among the good pollen producers, while the Baldwin and Gravenstein apples are listed among the inferior pollen bearers. Unexpectedly, the perry types of pears were usually poor pollen bearers, while cider apples were usually good bearers. It is believed that many of the perry pears produce their fruit parthenocarpically.

Cross-pollination studies with apples confirmed the results of pollen studies, namely, the pollen parents of good pollen-producing qualities tended to produce much higher sets of fruit than did poor pollen bearing parents.

**Commercial fertilizers for grapes**, N. L. PARTRIDGE (*Michigan Sta. Quart. Bul.*, 7 (1925), No. 3, pp. 98-100).—Working in two Van Buren County Concord vineyards, one located on a naturally fertile loam and the other on a sandy soil of low fertility, the author found that applications of nitrogen-bearing fertilizers were distinctly beneficial to grapes on the poorer soil, but of little value to those on the fertile area. The addition of phosphoric acid, potassium, or both materials in combination to nitrogen did not show any benefit, indicating that nitrogen is the only element likely to prove profitable in vineyards. A comparison of nitrate of soda and ammonium sulfate showed little difference between the two materials.

**Concerning the development and present status of grape improvement studies in Prussia** [trans. title], J. WORTMANN (*Veröffentl. Preuss. Hauptlandw. Kammer*, No. 7 (1924), pp. 26).—This pamphlet contains a general review of grape breeding and propagation activities, especially as relates to the utilization of American grape species in combating phylloxera.

**The biology of the olive** [trans. title], J. M. PRIEGO (*Bol. Agr. Téc. y Econ. [Spain]*, 15 (1923), No. 175, pp. 655-665, figs. 9).—A discussion of botanical relationships and habits of flowering, fruiting, and vegetative development, pointing out in conclusion the extraordinary longevity of the olive tree.

**Report of the Cranberry Substation [New Jersey]**, C. S. BECKWITH (*New Jersey Stas. Rpt.* 1923, pp. 299-305).—This is a further report (E. S. R., 51, p. 645) upon the fertility and acidity studies with cranberry soils. Yield records taken on Savannah soils which had received nitrogen in the form of nitrate of soda and dried blood for four consecutive years showed in every case that nitrate of soda had been more effective than dried blood used in equivalent amounts. Acid phosphate was apparently superior to rock phosphate, but since a combination of the two was even more effective than either one, no definite conclusions are drawn. In a quantitative test with mixed fertilizer, consisting of 75 lbs. of nitrate of soda, 75 lbs. of dried blood, 300 lbs. of rock phosphate, and 50 lbs. of sulfate of potash, 800 lbs. per acre was again the most satisfactory quantity. On muck soils rock phosphate supplemented with acid phosphate proved beneficial in increasing yields. On the other hand, on

new muck soils fertilizers of any nature apparently exerted a deleterious effect.

Records covering five years of soil acidity studies, both on the Savannah and the muck soil types, continued in general to show that lime, either in the form of high calcium or magnesium limestone, increases yields.

**Outdoor flowering annuals**, P. KACHE and C. SCHNEIDER (*Einjahrsblumen*. Berlin: Gartenschönheit, 1924, pp. 171, pls. 12, figs. 116).—Illustrated in part in color, this handbook is devoted to the description, planting, culture, and utilization of outdoor flowering annuals.

**The culture of perennials**, D. M-P. CLOUD (*New York: Dodd, Mead & Co., 1925, pp. XIII+271, pls. 16*).—A presentation of popular information concerning the planting and care of perennial flower gardens, and the propagation and utilization of perennial plants.

**Iris for the beginner**, edited by R. S. SURTEVANT (*Amer. Iris Soc. [Bul.] 10 (1924), pp. 59, figs. 23*).—This pamphlet contains several brief articles relating to the botany of the iris, its culture and hybridization, and the production of new varieties from seed.

**How to grow roses**, R. PYLE (*West Grove, Pa.: Conard-Pyle Co., 1925, 16. ed., rev., pp. 189, pls. 16, figs. 111*).—This illustrated handbook on the rose is a revised edition of the work previously noted (*E. S. R., 50, p. 645*).

**Roses in the garden**, C. H. CONNORS (*New Jersey Stas. Circ. 172 (1924), pp. 27, figs. 14*).—Abundantly illustrated, this pamphlet contains general information on rose growing, types and varieties, soils and soil preparation, culture, pruning, protection from various pests and from winter cold, etc.

**The book of water gardening**, P. BISSET (*New York: A. T. De La Mare Co., Inc., 1924, 2. ed., rev., pp. 205, pls. 3, figs. 126*).—This elaborately illustrated book, containing general information concerning the arrangement and culture of aquatic and moisture-loving plants, pays especial attention to the water lilies.

**Garden improvement**, T. G. W. HENSLOW (*London: Dean & Son, Ltd.; New York: Brentano's, 1924, pp. XXII+368, pls. 160, figs. 16*).—This is a general treatise on gardening, discussing such matters as equipment, planning, and planting; plant materials and their utilization; protection from insects, etc.

**The horticultural exhibitor: A guide to success**, A. J. MACSELF (*London: Thornton Butterworth, Ltd., 1924, pp. 222, pls. 8, figs. 26*).—Information is presented concerning the choice of plant materials for exhibition purposes, methods of culture and display, etc.

## FORESTRY

**Hemlock: Its place in the silviculture of the southern New England forest**, P. H. MERRILL and R. C. HAWLEY (*Yale Univ. School Forestry Bul. 12 (1924), pp. 68, pls. 6, figs. 2*).—A report upon studies begun in 1923 to determine the rate of growth and the principal silvicultural requirements of the hemlock, a comparatively neglected species in southern New England. Evidence was obtained to indicate that hemlock is a constant element of the climax forest on the upper soils of southern New England and contiguous areas, its frequent absence being due to its extreme susceptibility to fire injury in the seedling stages, and also to its inability to sprout from the stump. Because of an unusual tolerance to shade, hemlock is deemed an excellent tree for understory growth in hardwood forests. Furthermore, the wood has considerable value as lumber, railroad ties, poles, charcoal, and fuel.

Log rules and volume and yield tables computed from actual measurements showed that, in general, hemlock occupies an intermediary position between the oak and the white pine, estimates indicating that hemlock stands will

produce on rotations under 60 years 50 per cent, and over 60 years 60 per cent of the yield of white pine. In the region considered in this study, hemlock reproduces naturally, whereas white pine must be introduced artificially and maintained against hardwood competition. Since hemlock liberated from a hardwood cover was found to grow almost 2.5 times as rapidly as before releasing, it is suggested that mixed stands may be gradually converted to pure hemlock by repeated thinnings of the hardwoods. In order to insure regeneration following clear cutting operations, a few hemlocks should be left as seed trees, fires excluded, and grazing allowed for the purpose of suppressing hardwoods.

In the form of an appendix there are presented the data and methods used in the computation of the various tables, those for taper values being prepared under the supervision of C. E. Behre, of the recently established Northeastern Forest Experiment Station. Height measurements of seedling hemlocks ranging from 1 to 10 years in age were, respectively, 0.1, 0.2, 0.3, 0.6, 0.8, 1.25, 1.8, 2.7, 3.9, and 5.2 ft.

**Cultivation of forest plantations, A. K. CHITTENDEN** (*Michigan Sta. Quart. Bul.*, 7 (1925), No. 3, pp. 112, 113).—Norway spruce planted in a carefully prepared and manured soil, tilled four times each year succeeding planting, showed at the end of the fourth season 59 per cent greater height growth than did similar trees planted in a heavy June grass sod.

**Growth of Eucalyptus in California plantations, W. METCALF** (*California Sta. Bul.* 380 (1924), pp. 61, figs. 28).—Of the many species of Eucalyptus introduced into California, only four, namely, the blue, gray, red, and sugar gums, have been used to any extent in establishing plantations. Records taken in 67 widely distributed groves of blue gum showed that this species is capable of making very rapid growth on favorable sites, figures for an 8-year-old plantation on a very fertile and moist silt loam in Alameda County showing a mean annual growth increment of 8.17 cords per acre. The average of the 67 groves was 3.02 cords per acre. Red and gray gums yielded an average of approximately 1 cord per acre per year, but were found more resistant to drought than the blue gum and more durable as posts set in moist soil. The sugar gum, very drought resistant but easily injured by frost, made an average annual growth of 1.22 cords per acre based on 17 groves. Various less important species are discussed, and notes are given on the utilization of the Eucalyptus wood, the chief uses being as fuel, charcoal, and in the manufacture of small turned articles. Appended are data on the methods employed in taking the field measurements, in classifying sites, and in the establishment of Eucalyptus plantations from seed.

**Key to the eucalypts of Western Australia, S. L. KESSELL and C. A. GARDNER** (*West. Aust. Forests Dept. Bul.* 34 (1924), pp. 128, figs. 38).—This pamphlet, containing descriptive and botanical notes concerning all the arborescent species of Eucalyptus known to be indigenous to Western Australia, constitutes a key to the genus.

**Some New Zealand woods, G. A. GARRATT** (*New Zeal. State Forest Serv. Prof. Paper 1* (1924), pp. 56).—A presentation of data obtained as a result of a macroscopic and microscopic study of the secondary wood of 10 gymnosperms and 18 dicotyledons, with keys to the identification of the latter.

**Turpentine studies in Greece** [trans. title], A. OEKONOMOPULOS (*Centbl. Gesam. Forstw.*, 48 (1922), No. 3-6, pp. 85-109, figs. 9).—An extended article dealing with the results of investigations of the various methods of tapping technique.

**Report of the Royal Commission on Pulpwood, Canada, J. PICARD ET AL.** (*Ottawa: Govt., 1924, pp. 292, figs. 12*).—Herein are presented the results of an inquiry upon the pulp wood resources of Canada, especially in relation to the advisability of restricting exports.

**The hundred and second report of the commissioners of His Majesty's woods, forests, and land revenues, N. BUXTON and G. G. L. GOWER** (*[Gt. Brit.] Commrs. Woods, Forests, and Land Rev. Rpt., 102 (1924) pp. 50*).—The usual annual statement (E. S. R., 50, p. 544), consisting for the most part of tabulated statistics concerning finances, accessions, leases, etc.

**[Annual report of the New Zealand State Forest Service, 1924], L. M. ELLIS ET AL.** (*New Zeal. State Forest Serv. Rpt. 1924, pp. 29, pls. 3, figs. 10*).—The usual annual statement (E. S. R., 50, p. 545).

## DISEASES OF PLANTS

**Report of the department of plant pathology, W. H. MARTIN ET AL.** (*New Jersey Stas. Rpt. 1923, pp. 341-414, pls. 3*).—A list is given of the more important plant diseases observed during the year, followed by progress reports on some of the major investigations that were carried on during the period covered by the report.

*Spindle tuber, a disease of potatoes, W. H. Martin* (pp. 345-347).—In the fall of 1921 the author's attention was called to a condition shown by late-planted Irish Cobbler potatoes grown for seed purposes, the vines being smaller and more upright and many of the tubers being elongated. At digging time normal tubers and elongated ones were selected and stored for planting in the spring of 1922. After planting under identical conditions the sprouts from the elongated tubers were spindling, of unusual color, and less vigorous. The yields of tubers from the round potatoes were about double those from the elongated ones, the striking difference being a large increase in yield of first-class tubers and the reduced numbers of seconds and culls from the round tubers. This disease is said to be confined in New Jersey to this one variety, and the author suggests the rejection from the seed plats of all plants producing long tubers.

*The use of sulfur for the control of potato scab—1922 results, W. H. Martin* (pp. 348-355).—The results are given of cooperative experiments with inoculated and uninoculated sulfur for the control of potato scab. Inoculated sulfur is said to have given the greatest percentage of clean tubers, and on light soils applications of 300 lbs. of inoculated sulfur per acre gave as satisfactory control as applications of 600 lbs. The pH reaction of the soil was reduced about as much by the smaller treatment as by the larger one. In tests of fertilizer ingredients on scab development ammonium sulfate was found to reduce and nitrate of soda to increase the amount of scab. Disinfecting the seed tubers is recommended, whether planted on clean or infected soil, although applications of sulfur will reduce the severity of attack regardless of condition of seed or soil.

*Potato spraying and dusting tests in 1922, W. H. Martin* (pp. 356-364).—Experiments with Bordeaux mixture and dust applications for the control of foliage diseases of potatoes are said to indicate the superiority of Bordeaux mixture over dust treatments and that homemade Bordeaux mixture prepared with stone lime was better than any of the commercial preparations or where hydrated lime was used. The results were especially marked where late blight was present.

*Peach wilt, C. M. Haenseler* (pp. 364-366).—A wilt of peach twigs is described, and in his studies the author isolated a form of *Verticillium* from

wilted twigs that was morphologically identical with *V. albo-atrum*. Attempts to reproduce the disease by inoculating with the organism gave negative results. The presence of the organism in the wilted twigs is believed to be associated with winter injury.

*Pea root rot investigation*, C. M. Haenseler (pp. 366-375).—Pea root rot is said to be widely spread in New Jersey. *Rhizoctonia solani*, two species of *Fusarium*, and a sterile fungus were isolated from diseased roots, and the disease was produced under greenhouse conditions. The species of *Fusarium* and the sterile fungus produced symptoms indistinguishable from those shown by diseased field grown plants. The author claims that the *Rhizoctonia* is least parasitic at soil moistures most favorable for the growth of the pea, while the sterile fungus is least parasitic in extremely dry soils or at a moisture content favorable for pea growth. The *Rhizoctonia* was found to attack peas at any time, but the plants were most susceptible during the germination period.

*Tomato disease investigations*, R. F. Poole (pp. 376-386).—Spraying and dusting experiments for the control of *Septoria lycopersici* and *Macrosporium solani*, as well as some other diseases, are reported. The most efficient control followed five sprayings with Bordeaux mixture to which fish oil soap was added. Copper lime dusts gave slightly increased yields, but the yields were not comparable with those obtained with Bordeaux mixture. Experiments with fertilizers are said to indicate that leaf spot can not be economically controlled by limiting the application of fertilizers. Streak, filiform, and mosaic diseases of tomatoes are reported as serious in some places in the greenhouse culture of this crop. Heavy applications of Bordeaux mixture did not control streak, nor did soil conditions appear to be a limiting factor in its occurrence.

*Some results obtained in the investigation of the control [of diseases] of sweet potatoes*, R. F. Poole (pp. 387-404).—Comparisons were made of inoculated and uninoculated sulfur, and studies were carried on on variety resistance to scurf of sweet potatoes due to *Monilochaetes infuscans*. Sulfur at all the rates used reduced scurf, inoculated sulfur proving best in most of the experiments. In some cases a red pigmentation of the roots was observed following the use of uninoculated sulfur. Considerable variation in susceptibility to scurf was shown by the varieties tested. For the control of sweet potato pox sulfur again reduced the percentage of disease present. The residual effect of lime applied in 1921 resulted in an increase of pox, while sulfur applied at the same time reduced pox infection and increased yield.

Stem rot or wilt caused by *Fusarium batatatis* and *F. hyperoxysporum* is said to be serious in the State, and the most satisfactory measures for control appear to be the development of resistant varieties. Some observations are reported on the relation of stem rot infected roots to the production of diseased sprouts.

*Corn root and ear rot studies*, W. D. Moore (pp. 404-407).—According to the author, the testing of seed corn will reduce the amount of disease, but will not give complete control, due probably to heavy soil infestation. Alkaline soils were found to favor root rot, and flinty types of corn appeared to be more resistant than other varieties tested.

*Spraying tests for the control of apple blotch*, G. W. Fant (pp. 408, 409).—Spraying with lime sulfur reduced but did not entirely control blotch. The author recommends that where blotch appears late in the season accessory sprays in addition to the regular schedule may prove valuable. It is believed that accessory sprays may be discarded in orchards that have been regularly sprayed for several seasons, as twig cankers as a source of infection would be eliminated.

*Seed potato disinfection studies*, E. S. Clark (pp. 410-414).—Hot and cold formaldehyde, mercuric chloride, and some of the new mercuric compounds were tested for the control of Rhizoctonia, the effect on the sclerotia being noted. Corrosive sublimate 1-1,000 gave good control, but the 1-240 formaldehyde solution did not destroy the sclerotia. Prolonging the time of treatment did not appreciably increase control. Heating to 120° F. increased the efficiency of the treatments, although again formaldehyde was less satisfactory than corrosive sublimate. Semesan and Kalimat were tested, and neither proved as efficient as corrosive sublimate solution in destroying the sclerotia.

**Plant pathology**, B. L. RICHARDS (*Utah Sta. Bul. 192 (1925)*, pp. 58-61).—A report is given of the investigations of mosaic and leaf roll diseases of potatoes. The symptomology of the two diseases was determined for the principal potato varieties known commercially in the State. It was found that the degree of isolation generally recommended is entirely inadequate under Utah conditions, and that only with a sufficient degree of isolation are the roguing and selection methods effective. In connection with this investigation spindle tuber was found generally distributed in the State.

Some attention was paid to diseases of canning crops, particularly peas and tomatoes. With peas four fungi were found responsible for the root rot, but *Aphanomyces* sp. was the most important one. The black leaf of the pea has been found generally distributed in North Cache and Morgan Counties, and studies on the life history of the causal organism, methods of dissemination, relation of the parasite to climate, and control measures are being carried on. With tomato diseases particular attention was paid to the Fusarium wilt, which is said to be rapidly becoming a limiting factor in tomato production in the State. Tests of varieties resistant to disease were carried on, and the variety Norton was found to exhibit a high degree of earliness. It is believed that this variety could be substituted for the ones commonly grown in Utah for canning purposes. The nature, cause, and means of control of western yellow blight, and also of mosaic, are being investigated.

As a result of a plant disease survey the author reports the occurrence of *Cytospora* of poplars, dry rot or *Phoma* rot of sugar beets, chlorosis of various perennial plants, and a number of diseases of the raspberry and strawberry which are said to be peculiar to the intermountain region. The occurrence of the nematode and crown wart of alfalfa is reported for the first time, and crown wart is said to be rather generally distributed in certain alfalfa-growing districts of the State.

Dry rot, seedling sickness, and late blight or *Phoma* rot of sugar beets are under investigation. The *Phoma* rot or late blight has been found to be closely correlated with drought occurring late in June and July.

**Plant parasitic diseases in the Valley of Bareges** [trans. title], J. DUFRENOY (*Assoc. Franç. Avanc. Sci. Confs., Compt. Rend., 46 (1922)*, pp. 371-375).—Within the very limited area here indicated a considerable number of disease fungi were noted, the generic coefficient (genera÷species) being rather low, namely, 32 per cent for the whole mycological flora of the area in question.

**Fungus diseases of cultivated plants in Egypt and their control** [trans. title], K. SNELL (*Angew. Bot., 5 (1923), No. 3*, pp. 121-131).—Brief accounts are given regarding disease incidence and control measures in case of cotton, clover, wheat, and miscellaneous plants of lesser importance economically.

**Congress of Plant Pathology, Strassburg, 1923** (*Congrès de Pathologie Végétale, Strasbourg, 1923*. [Paris]: *Min. Hyg., Assist. [etc.]*, 1923, pp. 74).—In addition to addresses in recognition of the work of Pasteur and various general topics by H. d'Andlau, P. A. Dangeard, C. L. Shear, J. Magrou, and P. Vuillemin, the following contributions on plant pathology were presented:

A Review of Studies at the Botanical Institute at Bern on the Biology of Parasitic Fungi, by E. Fischer; The Central Bureau of Fungus Cultures at Baarn, Netherlands, and An Account of Cultures Made by the Bureau, both by Bolle; Action at a Distance by Phytopathogenic Fungi, by C. Picado; The Formation of Chlamydo-spores in Oak Oidium, by L. Petri; Overwintering Among the Erysiphaceae, by E. Foex; Diseases and Animal Parasites of Chrysanthemum Cuttings, by J. Chiffot; a communication on grape downy mildew (*Plasmopara viticola*) and its control, by J. Capus; The Modification of Leaf-Surface Conditions by Copper Sprays, by M. Gard; The Comparative Anticryptogamic Values of Copper as Compared with Those of Lime Sulfur Sprays, by C. Chabrolin; The Value of Copper Salts in Viticulture, by P. Gervais; Esca, by P. Marsais, dealing with a grapevine rapid wilt (known in the Peloponnesus under the name ischa, following which the author proposes the name esca); and Agricultural Intelligence and Phytopathology, by J. Chaptal.

**A new chapter in plant pathology, linking that science with animal pathology** [trans. title], [H.] QUANJER (*Rev. Path. Vég. et Ent. Agr.*, 10 (1923), No. 1, pp. 22-40).—The author claims that phytopathology may contribute in a certain measure to medical and veterinary science.

**Notes on the biology of rusts and smuts** [trans. title], L. BLARINGHEM (*Rev. Path. Vég. et Ent. Agr.*, 10 (1923), No. 2, pp. 172-182).—The present report deals with phases and facts generally analogous to those previously set forth (*E. S. R.*, 33, p. 145), the main present subject being variability in mallow rust (*Puccinia malvacearum*) on green and on variegated plants of *Lavatera arborea*.

**The toxicity of copper** [trans. title], C. CHABROLIN (*Rev. Path. Vég. et Ent. Agr.*, 10 (1923), No. 2, pp. 132-137).—Discussion is given regarding the propositions recently upheld by the Villedieus regarding the alleged nontoxicity, as employed, of copper to pathogenic fungi.

**A miniature copper carbonate duster**, A. H. HOFFMAN (*Jour. Amer. Soc. Agron.*, 16 (1924), No. 8, pp. 482, 483, fig. 1).—For the purpose of applying effectively copper-carbonate dust to seed in experimental parcels without danger to health, a revolving box mixer is made by furnishing two diagonally opposite corners with wire nails as journals, one of these being bent to form a crank to turn the box so as to mix thoroughly the dust with the seed.

**Color indicators for blight disinfectants**, H. A. CARDINELL (*Science*, 60 (1924), No. 1559, p. 455).—In order to secure a better covering of exposed tissues after cutting out blighted areas, the author recommends the addition of fuchsin red to the Reimer-Day mercury and glycerin solution. This adds a pronounced color to the solution and permits the operator to detect any small untreated surface and to tell at a glance whether all the cut tissues in the tree have been treated. Field observations have not indicated any diminution in the effectiveness of the material, and the treatment, because of the greater thoroughness, is more effective.

**A mycorrhizal fungus in the roots of legumes and some other plants**, F. R. JONES (*Jour. Agr. Research [U. S.]*, 29 (1924), No. 9, pp. 459-470, pls. 2, figs. 3).—The author reports having found during a study of the fungus parasites of the roots of peas and other legumes that the roots of nearly all the common leguminous crops are extensively invaded by a characteristic fungus which has previously been known in a considerable number of plants as a mycorrhizal fungus. This is said to be so abundant that it is considered unlikely that many plants, such as alfalfa, clover, peas, etc., ever reach maturity without their roots being more or less invaded. The fungus is found only in the

primary cortex, and it exists as a coarse, nonseptate mycelium, and though it passes through the outer cells when entering the root, it is chiefly intercellular in the deeper parts, advancing in long strands toward the growing end. New roots of perennial plants, such as clover and alfalfa, contain but little of the fungus, but by midsummer the rootlets become invaded almost to their tips. In a single plot experiment clover, alfalfa, and sweet peas were found to grow more vigorously in soil in which the fungus had been killed by formaldehyde, but it is not considered certain that the absence of this parasite is the only factor which was responsible for the benefit. In addition to a large number of leguminous plants the fungus has been found in the roots of plants representing a number of other families.

**A cereal collar disease** [trans. title], [E.] MIÈGE (*Rev. Path. Vég. et Ent. Agr.*, 10 (1923), No. 1, pp. 53, 54).—At Mazagan, in 1921, the author for the first time observed a cereal stem base break affecting about 10 per cent of the plants, the same trouble causing, in 1922, serious injury at points named. From the brief studies effected to date of this account, it does not appear to be a case of foot or stalk disease usually ascribed to an *Ophiobolus* or to a *Leptosphaeria*, neither of these fungi being present.

**Observations on *Sclerotium oryzae* in Cochin China** [trans. title], F. VINCENS (*Rev. Path. Vég. et Ent. Agr.*, 10 (1923), No. 2, pp. 112-131, figs. 7).—One of the more common of the parasites of rice in Cochin China is *S. oryzae*, observed by the author as causing injury there as early as 1919. A study is outlined of this organism and its relationships. An account is given in this connection, with descriptions, of *Beauveria oryzae* n. sp. forms  $\alpha$  and  $\beta$ , of *Acremonium fuliginosum* n. sp., and of *Fusarium oryzae*  $\alpha$  and  $\beta$ .

***Fusarium* attack on wheat** [trans. title], L. DOYER (*Angew. Bot.*, 5 (1923), No. 3, pp. 160-164).—Facts and comments offered herein refer primarily and largely to matter contained in statements by Atanasoff, some of which have been noted (E. S. R., 44, p. 243).

**Smut control test**, A. F. BRACKEN (*Utah Sta. Bul.* 192 (1925), p. 23).—A comparative test of the efficiency of formalin, copper sulfate, and copper carbonate dusting treatment in smut control of wheat is said to show that copper carbonate prevented smut, and, in addition, it increased the yield over the two wet treatments.

***Alternaria* leafspot and brownrot of cauliflower**, J. L. WEIMER (*Jour. Agr. Research [U. S.]*, 29 (1924), No. 9, pp. 421-441, pls. 4, figs. 3).—The results are given of a study of a leaf spot of cauliflower caused by *A. brassicae*. In addition to attacking the leaves the fungus causes a brown rot of the curd of cauliflower. The cultural relations of the organism were determined, and suggestions are made for the control of the disease. In the case of cauliflower heads it is suggested that field infection should be prevented by thorough spraying with Bordeaux mixture 4-4-50, and in shipment to keep the temperature as low as possible, 7° C. (44.6° F.) or lower.

**The control of damping off of cotton seedlings by the use of Uspulun**, H. R. ROSEN (*Science*, 60 (1924), No. 1556, p. 384).—In an attempt to protect cotton seedlings from damping-off in some cotton breeding work the author watered several rows with a solution of Uspulun as recommended, about a gallon of the solution being applied to each square foot of soil. No further damping-off occurred in the treated rows, though untreated ones were badly infected. A microscopic examination of diseased plants is said to have shown that most, if not all, of the damping-off was due to *Rhizoctonia*.

**Three new diseases of the hop**, E. S. SALMON and H. WORMALD (*Jour. Min. Agr. [Gt. Brit.]*, 30 (1923) No. 5, pp. 430-435, pls. 2; abs. in *Jour. Inst. Brewing*,

29 (1923), No. 9, pp. 783, 784).—In this article three fungus diseases of the hop, new to Great Britain, are described. The first, downy mildew (*Pseudoperonospora humuli*), is an introduction from Japan or from America. The second, leaf spot, causes a spotting of the hop leaf, but so far as observed no serious injury. The fungus indicted is called *Cercospora* n. sp. The third, for which the name hop drop has been proposed, is associated with the presence of a minute fungus (*Macrosporium* sp.) which attacks the stalk of the cone, eating it through and causing it to fall to the ground. These are discussed as to history.

Potato diseases, G. R. HILL (*Utah Sta. Bul.* 192 (1925), pp. 34, 35).—A brief report is given of physiological studies conducted to determine whether seed potatoes produced at high elevations in the State were better than those grown in the larger, warmer valleys. The results of five years' work are said to indicate that in general normal plants showing no indication of disease differ in their behavior when grown at the different elevations, but the controlling factors varied so widely that the results were not the same for each year.

Potato leaf roll [Loire] [trans. title], C. PERRET (*Assoc. Franç. Avanc. Sci. Conf., Compt. Rend.,* 46 (1922), pp. 884–889, figs. 3).—Experimental infection at the Merle Experiment Station during 1921 and 1922 proved successful regarding the transmissibility of potato leaf roll. Plans for amelioration of conditions in regions showing leaf roll are based upon selection, and such plans are outlined as applicable to fields, regions, and stations.

The Rhizoctonia disease of the potato, B. F. DANA (*Washington Col. Sta. Pop. Bul.* 131 (1925), pp. 5–30, figs. 6).—A popular account is given of the Rhizoctonia disease of potatoes, together with the results of experiments for its control by the treating of the seed tubers. The author recommends the selection of tubers visibly free from the parasite and their treatment by dipping them in water and keeping them moist from 12 to 24 hours, after which they are treated with a solution of corrosive sublimate 4 oz. to 30 gal. of water for 1.5 hours. When treating large lots of seed the author recommends for each 4 bu. of seed treated the addition of 0.5 oz. of corrosive sublimate after each lot is removed. Hot solutions of formaldehyde or corrosive sublimate are said to be more rapid in their action and to permit of greatly shortened time of treatment.

Pear leaf blister (*Taphrina bullata*, Tul.), H. R. BRITON-JONES (*Univ. Bristol, Agr. and Hort. Research Sta. Ann. Rpt.,* 1923, pp. 89, 90, fig. 1).—This infrequent disease, which is described, was common on different pear varieties during the summer of 1923. It may, it is thought, be controlled by spraying with summer strength lime sulfur (treatment for scab, employing 1 gal. of the concentrated solution to 29 gal. of water). Differences in severity with different varieties are indicated.

The purple leaf blotch of strawberry, H. R. BRITON-JONES (*Univ. Bristol, Agr. and Hort. Research Sta. Ann. Rpt.,* 1923, p. 88).—Strawberry purple leaf blotch has been found to be due to attack by an aphid (*Myzus fragariella*), the crinkled surface and split edges being due to the growth of the unpunctured areas. Spraying does not readily reach the aphids within the close folds of very young leaves.

Red plant in strawberries and its correlation with "cauliflower disease," E. BALLARD and G. S. PEREN (*Jour. Pomol. and Hort. Sci.,* 3 (1923), No. 3, pp. 142–147, pls. 5; also in *Univ. Bristol, Agr. and Hort. Research Sta. Ann. Rpt.,* 1923, pp. 83–87, pls. 4).—Recognized by growers for a number of years, strawberry red plant became, in 1922 and later, more familiar and

enormously extended as regards area, seriously threatening the industry in certain districts. The symptoms are detailed, as are also those of the cauliflower (nematode) disease (*Aphelenchus fragariae*). The correlation studies show a constant overlapping of the symptoms of these troubles, and a consideration of all the factors leads to the conclusion that the two conditions are two aspects of one and the same disease. Apparently, the disease may pass from the parent plant along the stolon to the young plant. Much work of a comparative nature remains to be done. None of the 50 strains yet examined have displayed complete immunity.

**Grape mildew control [in France]** [trans. title], A. CADORET (*Assoc. Franç. Avanc. Sci. Confs., Compt. Rend.*, 46 (1922), pp. 869-872).—The author is convinced, as the result of early and more recent investigation, that north of a line running from Bordeaux to Briançon (about 45° N. latitude) copper sulfate sprays which are sufficient in dry years may be wholly ineffective in years of high precipitation. In 1910, 1915, 1916, and 1920, 12 sprayings in each year were not entirely protective. In such years only the blue vines (visibly covered with copper sulfate and lime) are able to resist fungus attack.

Plans regarding treatment are outlined for this region, also for the more southern parts of France, as well as for Algeria and Tunis.

**Geranium stemrot caused by *Pythium complexens* n. sp.**, H. BRAUN (*Jour. Agr. Research [U. S.]*, 29 (1924), No. 8, pp. 399-419, pls. 5, figs. 3).—The author reports the isolation from blackened geranium stems in 1919 of *P. debaryanum* and three other fungi belonging to the same genus. The present paper gives an account of one of these isolations, which differed very markedly in morphological and cultural characters from *P. debaryanum*. The disease consists of a progressive basal blackening accompanied by pectinization and soft rot of pith and cortex. Infection stops at a sharp line of demarcation from 20 to 40 mm. from the base within from six to eight days after inoculation. Stoppage of the infection is said to be due to a host resistance reaction manifested by the formation of a cork cambium completely across and within the stem. This reaction is considered specific for this particular host and organism, and was not found in the case of three other species of *Pythium*, nor in the case of cuttings of other species. A technical description of the organism is given. The significance of the *Pythium* type of sporangial germination is discussed.

**Schizophyllum commune on Japanese chestnut** [trans. title], BIERS (*Rev. Path. Vég. et Ent. Agr.*, 10 (1923), No. 2, pp. 151-153).—An importation of Japanese chestnut was placed under conditions favoring fungus development, and soon after showed the presence of *S. commune*. This fungus can evidently be transported for long distances in a viable condition, and it is recalled that Putterill has previously (*E. S. R.*, 48, p. 247) confirmed its capability as a dangerous parasite.

**Armillaria (Armillariella) mellea and walnut rot** [trans. title], GARD (*Rev. Path. Vég. et Ent. Agr.*, 10 (1923), No. 1, pp. 55-62, pls. 4).—The honey fungus (*Armillaria mellea*) rot has been studied locally in black walnut (*Juglans nigra*), and it is stated that the injury ceases its advance on proper application to the infected area of iron sulfate, potassium permanganate, or formol. The tree does not die in such cases unless the fungus has encircled the crown or has involved all of the roots.

## ECONOMIC ZOOLOGY—ENTOMOLOGY

**Spread of the European starling in North America**, M. T. COOKE (*U. S. Dept. Agr., Dept. Circ. 336* (1925), pp. 8, fig. 1).—This is an account of the

introduction and spread of the European starling in this country. Since its introduction at New York City in 1890, which led to its permanent establishment, the starling had spread until on December 15, 1924, its range extended from central Maine to central Ohio and Michigan and from southern Canada to Georgia and Florida, throughout much of which territory, however, it is still of only local occurrence. In the region contiguous to New York City it has become one of the most abundant birds. Thus far it has not been found to be as seriously destructive to crops in the United States as it is reported to be in some parts of the Old World.

**Report of the department of biology for the year ending June 30, 1923, T. C. NELSON** (*New Jersey Stat. Rpt. 1923, pp. 195-209, pl. 1, figs. 2*).—This report deals with studies of the oyster and of marine borers. Marked fluctuations were found to occur in the H-ion concentration of the water of shallow estuaries tributary to Barnegat Bay, fluctuations as great as pH 0.52 being observed between dawn and later in the day.

The first phase of the investigation of the food of the oyster was completed, a final summary by G. W. Martin being presented. The actual attachment of oyster larvae was observed and is here described for the first time. They were found to describe circular movements before coming finally to rest. The larva holds on with the foot, while attachment is effected through the pouring out of cementing fluid from the byssus gland in the base of the foot, distribution of the fluid being aided by the extended border of the mantle. Important practical bearings of the observation are discussed.

The larvae of marine borers were found to congregate about the bases of piling, thus substantiating the laboratory findings of C. H. Harrington that shipworm larvae are attracted by wood extracts. Examination of piling drawn from the bridge at Barnegat Pier showed a high degree of protection afforded by good creosoting, untreated piling having been practically destroyed through the activities of *Bankia* and *Teredo*.

**Personality of insects, R. DIXON and B. EDDY** (*New York: Charles W. Clark Co., 1924, pp. [12]+XI+247, pls. 33*).—This is a popular account of insect bionomics.

**Report of the department of entomology [of the New Jersey Stations], T. J. HEADLEE ET AL.** (*New Jersey Stat. Rpt. 1923, pp. 37-42, 265-337, pls. 3, figs. 4*).—The investigation of Milltown ball clay No. 9 was continued (E. S. R., 51, p. 658) with a view to determining how its preventive action against insect infestation of beans takes place. A careful observation of its action upon bean weevil larvae has shown that they are unable to grapple the bean surface because of the slipping of fine particles of dust which the claws and frequently the anal sucker seize upon. It is concluded that the efficiency of dusts as agents in preventing the infestation of the bean seed by bean larvae is correlated with the size of the particles composing them and the ease with which one particle moves upon another.

The codling moth investigations were continued at Glassboro. As relates to the value of the three usual sprays, the experience of two years seems to indicate: "(1) That when fighting very heavy and intensive infestations of codling moth it is essential that the coating of fruit and foliage be maintained during the periods when the larvae of the first brood and the larvae of the second brood are hatching and trying to enter the apples, (2) that this coating can be maintained almost or quite without accessory spraying if an adequate spreader and sticker is incorporated into the spraying mixture, and (3) that the cost of this operation is sufficiently small to justify its employment where codling moth infestation conditions demand drastic measures."

The details of work on types of materials and methods of application, conducted in four orchards with codling moth and curculio, and in two with aphids, are presented in tabular form. A discussion of the New Jersey dry mix, a detailed account of which, by Farley, has been given in Bulletin 379 (E. S. R., 49, p. 349), follows. It is pointed out that the combination of elemental sulfur, hydrated lime, and powdered lead arsenate apparently gives a very satisfactory control of both the disease and insects attacking the peach. Tests of dusts composed of these three materials indicate that, while dust materials can be applied to apple without serious burning, the control of apple insects, such as codling moth and curculio, was only about half as good as that obtained by water-suspended materials, due to the failure of the dusts to stick to the fruit and foliage. The observations indicate that there is little danger of burning with the combination of elemental sulfur, hydrated lime, and powdered lead arsenate applied as a water suspension, and that the activity of the arsenate of lead is in no way interfered with. The author is firmly convinced that film coatings are necessary for the control of codling moth when it is very abundant, although spot coatings are reasonably adequate when it is comparatively scarce.

In discussing the relation of time of application to seasonal development of the apple tree, it is pointed out that the application of spray No. 1 depends entirely upon the development of the apple tree and is not affected by the development of the codling moth, because the lead arsenate which is in the calices of the young apples is inclosed by the closing of the calyx and seems to remain in position throughout the time that the codling moth larvae of both broods are trying to enter the fruit. The time of application of spray No. 2 is determined by the gathering of 100 specimens of uninjured codling moth larvae early in the spring and observing when moths have emerged from 50 per cent of the living pupae, at which time the maximum emergence of moths has taken place and spraying should be commenced. The time of application of spray No. 3, which also depends upon the development of the moth itself, is determined by the collection of 100 healthy larvae from bands placed on from 5 to 10 trees distributed throughout the orchard and observing when about 30 per cent of the living pupae have given up moths, at which time spraying for the second brood should be begun.

A continuation of work with the pear psylla indicates that the dormant treatment has a long-continued influence on the abundance of the psylla, reducing the overwintering brood to such an extent that it lays only one-third as many eggs as would otherwise have been the case. The effect of the preblossom treatment is also marked. No conclusions could be drawn from psylla treatments made after the preblossom treatment because they were not correct as to time.

In a search for a sticker for lead hydrogen arsenate, a laboratory study of the sticking power of casein (Kayso form), high gluten wheat flour, and powdered sweet skim milk led to the conclusion that the optimum amount of gluten was not far from 3 per cent. The results indicate distinctly that with Kayso, flour, or milk more than twice as much of the lead is retained on the foliage as that when they are absent from the mixture. Of the three, it seemed that the flour was slightly the best. The addition of Kayso and powdered skim milk to the lead arsenate tends to reduce the water-soluble arsenic, and the addition of flour does not increase it.

A report of the Cranberry Substation is presented by C. S. Beckwith (pp. 299-307), part of which is noted on page 740. In continuing the work with the cranberry girdler, a plat 20 ft. square was flooded, resulting in 53 girdlers floating during the first 12 hours and none during the second 12 hours, at the

end of which time 60 per cent of those floating were dead. Girdlers which were submerged in a cheesecloth bag for 24 hours were all dead at the end of that time. The 24-hour reflow in August reduced the cranberry girdler infestation from 95 to 100 per cent on each of five bogs under observation, being 99 per cent or better on four of them.

In control work with wireworms it was found that the only corn seeds not eaten were those treated with corrosive sublimate or carbolic acid. The worms were not injured when treated with corrosive sublimate, but apparently they were killed by the gases given off by the carbolic acid. Bee investigations, including the relation of honeybees to fruit growing, the causes of certain bee diseases of obscure etiology, and the breeding of bees resistant to foulbrood and of high producing strains are reported upon by R. Hutson (pp. 313-323).

The mosquito campaign, conducted in continuation of that of previous years and reported upon at some length, includes discussions of the drainage of the salt marshes, the prevalence of mosquitoes on the wing, correlation of mosquito commission work, and of educational and administrative work, by W. M. Walden. A report upon the relation between atmospheric conditions and the behavior of mosquitoes, by Rudolfs (E. S. R., 50, p. 757), has been noted.

Work with the peach borer (E. S. R., 51, p. 457), blackberry psyllid (E. S. R., 49, p. 353), and pepper maggot (E. S. R., 49, p. 356), and with nicotine dust (E. S. R., 50, p. 254) is briefly summarized.

Entomology [studies at the Utah Station], I. M. HAWLEY (*Utah Sta. Bul.* 192 (1925), pp. 42-44).—In control work with the fruit-tree leaf-roller 44 different dormant oil spray treatments were applied to prevent hatching of the eggs. There was apparently a wide variation in effectiveness, although in some cases 96 per cent control was obtained. Two applications were made, one before the buds burst, the other when the first leaves were out. In 1924 the early spray gave the better control, whereas in 1923 the later spray gave the better results. This is explained by a difference in the season, the eggs hatching much earlier in 1924. Arsenate of lead was used with poor success against the caterpillars.

In control work with the blister mite 25 fall and spring applications of commercial oil and sulfur compounds were used against the overwintering mites. Some sulfur compounds, such as lime sulfur, dry lime sulfur, and soluble sulfur, applied either in the fall or spring, gave a control running in some cases as high as 99 per cent. Some oils gave fair control, but with others there were as many scars on the leaves as in the checks.

The life history of the sugar-beet root-maggot has been worked out. It passes the winter as a larva in beet fields, the fly appearing in the spring about thinning time and depositing its eggs in the ground near the young beets. The larvae upon hatching out feed on the roots of the beets and often cut off the tip, in which case the beet dies. Early irrigation of the beets is thought to keep the maggots feeding above the tip, thus preventing its being cut off.

Four separate treatments of paradichlorobenzene were applied for the peach borer, three in the fall at intervals of two weeks and one the following April. Control was nearly 100 per cent effective in all cases, the spring and fall applications being equally so. Thirty-six combinations of insecticides were used against four species of ants that are common in peach orchards and gardens as well as in grain fields. Calcium cyanide was most effective when driven into the nests with a dusting machine. Carbon disulfide gave good control in some cases, and a bait of sodium fluoride, sugar, and cornstarch was effective against some species. Nicodust used against the pea aphid on sweet peas and the currant and cabbage aphids gave good control.

An annotated list of the species of injurious insects and their parasites recorded from Italy up to the close of 1911, I, II [trans. title], G. LEONARDI (*Ann. R. Scuola Super. Agr. Portici*, 2. ser., 17 (1922), [Art. 4], pp. 147; 18 (1923), [Art. 5], pp. 80).—The first part of this work consists of a bibliography; the second part lists the Collembola, Orthoptera, Isoptera, Dermaptera, Corrodentia, Thysanoptera, and Hemiptera.

The control of truck crop pests by dusting, E. N. CORY (*Md. Agr. Soc., Farm Bur. Fed., Rpt.*, 8 (1923), pp. 378-381).—The author points out that tests at the Maryland Experiment Station have shown nicotine dusts to be effective against the garden fleahopper, the bean aphid, and, with certain limitations, against the asparagus beetle.

On the succession of insects living in the bark and wood of dying, dead, and decaying hickory, M. W. BLACKMAN and H. H. STAGE (*N. Y. State Col. Forestry, Syracuse Univ., Tech. Pub.* 17 (1924), pp. 3-269, figs. 53).—This is a contribution from the department of forest entomology of Syracuse University. A bibliography of 22 pages is included.

Problems and methods in forest entomology, I. TRAGARDH (*Jour. Forestry*, 22 (1924), No. 6, pp. 64-78).—This is an address given at Stockholm in June, 1923, in which the problems met with and some of the methods employed are considered. A discussion of the paper by F. C. Craighead follows (pp. 79-81).

The termites, E. HEGH (*Les Termites. Brussels: Industrielle & Financière*, 1922, pp. 756, pl. 1, figs. 460).—This account of the termites deals with their geographical distribution, classification, biology, economic importance, etc. A bibliography of 33 pages is appended.

The grape leafhoppers of bluegrass Kentucky, H. H. JEWETT (*Kentucky Sta. Bul.* 254 (1924), pp. 87-130).—This is a report of biological studies of leafhoppers found infesting the grape at the station from 1920 to 1922, including *Erythroneura comes vitis*, *E. comes comes*, *E. comes octonotata*, and *E. vulnerata*. *E. tricineta* was observed only occasionally. Observations of the sycamore leafhopper *Erythroneura* sp., which is closely related to the grape-infesting leafhoppers, are included. Much of the data is presented in tabular form. No reference is made to the literature, but a partial bibliography, consisting of 54 titles, is appended. A key to the Nearctic forms of *Erythroneura*, by McAtee, has been noted (*E. S. R.*, 44, p. 352.)

Sprays to be effective must be applied when the insect is in the nymphal stage and when the nymphs become numerous on the vines, from the middle of July to the first of August. The nymphs are sensitive to nicotine sprays and may be killed by a solution of nicotine sulfate at a dilution of 1 part to 1,400 parts of water. A dilution of 1 pint of nicotine sulfate to 200 gal. of water is nearly as effective as the stronger solution and may be applied with good results when the nymphs are not too far developed. The 1 to 1,400 solution killed from 97 to 100 per cent and the 1 to 1,600 solution 96.5 to 100 per cent of the nymphs of various sizes.

The citrus aphid, *Aphis spiraeicola* Patch, W. W. YOTHERS and F. R. COLE (*Citrus Indus.*, 5 (1924), No. 10, pp. 6-8, 18, 19, fig. 1).—In the introduction to this account, it is pointed out that experiments by A. C. Baker and the authors have shown that the aphid on *Spiraea* (*A. spiraeicola*) reproduces abundantly on citrus trees and also that the citrus aphid reproduces normally on *Spiraea*, several transfer tests having been made with identically the same results. *A. spiraeicola* has been reported from some 12 States extending from Maine, Virginia, and Alabama to Colorado and California. Its primary food plants appear to be *Spiraea cantoniensis* and *S. vanhouttei*, and in the northern

regions it is upon these plants that the eggs are deposited in the fall. In Florida the aphid has been found most abundant on the King, Temple, Satsuma, and Tangerine oranges, the sweet orange being next in preference, while grapefruit is not very severely injured. It is also found on loquats, sand pears growing near citrus trees, and on wild plum. In the laboratory it bred successfully on nightshade, Jerusalem oak, milkweed, dogfennel, cudweed, lettuce, and peppers. The total number of living young produced by the average female varies from 8 to 61. There are five stages from birth to maturity.

No less than eight species of predacious enemies have been observed to feed upon the aphid, but they were not very effective in holding it in control during the year. A fungus disease is said to have been an important factor in the reduction of numbers of aphids on citrus trees in the infested area during the summer. A spray of nicotine sulfate 1-800 with soap at the rate of 2 lbs. to 50 gal. of water is said to kill all the aphids hit. Oil emulsions, which cost much less than the nicotine sulfate spray, were found to be equally effective. Dust composed of 3 per cent nicotine or 7.5 lbs. of nicotine sulfate to 92.5 lbs. of hydrated lime is perhaps the most effective remedy for control of the pest, but is extremely expensive. Dusts consisting of 2 per cent nicotine, 40 per cent sulfur, and 58 per cent inert ingredients, also gave good results. It is pointed out, however, that practically all the spraying and dusting of the pest has been of little or no value in reducing its numbers, due to its rapid increase. In the control of this pest it is of primary importance that the control measure be applied before the infestation becomes general.

A note on the influence of climate on this pest, by Baker, accompanied by climatographs, is included.

**Some field observations on the new aphid, K. E. BRADON (*Citrus Indus.*, 5 (1924), No. 9, pp. 9, 24).**—The author reports that damage to many citrus trees, particularly trees 10 years old or younger, has been such that no growth could form during the spring. Practically all the fruit dropped, and the little that remained was warty and deformed. Older trees as a rule did not suffer so greatly, but many lost considerable fruit and growth, and the fruit was at first very rough and unsightly in appearance. Later in the season the fruit was growing out of this condition and promised to be normal when mature. It is pointed out that grapefruit trees appear to have been nearly immune from attack, although isolated cases of infestation were observed. While the orange trees that were severely injured in the spring as a rule made good recovery during the summer, the recovery was not complete and the great loss of early fruit was not made up by a June bloom. In sections of the State visited by the author there was little or no late bloom, and many and various attempts to force a late bloom by applications of nitrate of soda, heavy amounts of regular fertilizer mixtures, extra cultivation, etc., were made with practically no success. The author concludes that the sprays and dusts that were applied did not pay in actual results for the material and labor involved. It is also pointed out that the aphids will live only on very tender growth, and that long before it has reached its full development they will leave in search of younger growth or perish for lack of food.

**The new citrus aphid, J. R. WATSON and A. H. BEYER (*Citrus Indus.*, 5 (1924), No. 11, pp. 30, 31, fig. 1).**—This is an abstract of discussions of the new citrus aphid, including work previously noted (E. S. R., 51, p. 660).

**Life history of the new citrus Aphid, A. H. BEYER (*Fla. Ent.*, 8 (1924), No. 1, pp. 8-13).**—The author first reports upon generation studies, carried on in the field at Lakeland, Fla., from May 2 to June 20, of the citrus aphid since identified by Baker as *A. spiraeicola* Patch as noted below. The longevity of

the females ranged from 3 to 21 days. The reproduction period varied, during the time of the studies, from 2 to 11 days, with an average of 5 young per day. The total number of young produced varied from 8 to 61. Control measures are also considered.

**Controlling the citrus aphid (*Aphis spiraeicola* Patch), J. R. WATSON and A. H. BEYER** (*Florida Sta. Bul.* 174 (1925), pp. 79-96, figs. 9).—This is a practical summary of information on the citrus aphid, which has risen to a place of great economic importance in Florida. Earlier accounts of this aphid, which first appeared and caused serious injury in the southwestern part of the citrus belt in the spring of 1924, are noted above.

It is pointed out that this aphid, the native host of which appears to be members of the genus *Spiraea*, was described by Patch as *A. spiraeicola*, and is closely related to *A. pomi*. It can not live on mature citrus foliage or twigs, and many aphids born on the hardening foliage develop wings and fly away. On *spiraea* its behavior is quite different, since it can feed on the mature leaves and does not require new growth. In addition to feeding on *spiraea* through the winter, when there is no new growth on the citrus, it has been observed to oviposit thereon. In Florida it has also been observed to oviposit on *Pyrus delutaefolia* and the Japanese flowering quince, both of which are rare in the State. It is concluded that in many sections, particularly in the northern part of the citrus belt, it is *spiraea* that enables the aphid to live over the winter, when there is no new growth on the citrus trees. The danger to citrus communities from this source leads the author to recommend strongly the destruction of *spiraea* throughout the citrus belt. While it has been observed on a number of other host plants, these appear to be of a secondary nature and probably of minor importance.

The spread of this aphid in Florida is said to take place almost entirely by means of flight. The average length of the five stages varies from 20 to 64 hours. The first three nymphal stages are approximately of equal length, but the fourth stage is longer. During the late spring and summer the total average length of the nymphal life, from birth to maturity, was 4 days, and in December 6.5 days. The life of the females was found to range from 3 to 47 days, the reproductive period varying from 2 to 24 days. The maximum number of young produced by a single female is 64 and the minimum 8. The percentage of winged individuals produced during the experiments conducted ranged from 45 to 69. Until late in the fall no males were observed, the females reproducing parthenogenetically and bringing forth living young. This type of reproduction also continued all winter, but as cold weather came on, about December 1, some males were produced and eggs laid on some plants, but not on citrus.

Mention is made of a number of predacious insect enemies, an egg parasite, and at least one fungus parasite (*Entomophthora* sp.). It is pointed out that in control work it is important to delay the general infestation of a grove as long as possible, and for this purpose spot dusting is recommended. This consists in the inspection of the grove once or twice a week for any infested trees or parts of trees and the application, when an infestation appears, of a 3 per cent nicotine sulfate lime dust. Calcium cyanide has also been used extensively in the State for spot dusting with apparently good results. On very young trees infested twigs may be dipped in a contact insecticide. Where a heavy infestation of purple scale develops in the curled leaves, pruning is the most satisfactory method of dealing with it.

When infestation becomes quite general, the application of a 3 per cent nicotine sulfate lime dust, or a spray, which is more economical, should be made.

The early application of oil emulsion may be advisable. It is pointed out that in many cases it is possible to combine the control of the citrus aphid with that of other pests and greatly reduce the cost of control measures. In the case of oranges of the mandarin type the addition of 1 part nicotine sulfate to 800 parts of Bordeaux will render the solution very effective against the aphids and not lessen its fungicidal action. For the control of rust mites and red spiders an application of 1 pint of nicotine sulfate to each 100 gal. of lime-sulfur solution is recommended. If it is desired to control rust mites as well as aphids, a combination dust can be secured by adding from 10 to 15 per cent of sulfur in the nicotine sulfate lime dust.

The importance of keeping the grove dormant during the fall by cultivating as little as possible after the rainy season is pointed out. Such groves were exceptionally free from aphids by the first of February, and the infestation developed slowly during the succeeding weeks. The growing of truck crops near the citrus trees during the winter was observed to be of value through furnishing parasites and predators to attack the citrus aphid.

Mention is made of three species of ants associated with the aphid, the most abundant of which is a species of *Campanotus*.

**The grape phylloxera and viticulture** [trans. title], O. SCHNEIDER-ORELLI (*Neujahrsbl. Naturf. Gesell. Zürich, No. 125 (1923), pp. 15, pls. 4, figs. 4*).—This is a discussion of the subject as applied to European conditions.

**The European corn borer**, L. L. HUBER and C. R. NEISWANDER (*Ohio Sta. Mo. Bul., 9 (1924), No. 11-12, pp. 192-197, figs. 3*).—This is a progress report on the European corn borer (*E. S. R., 51, p. 255*), which appeared in Ohio in 1921 and has spread rapidly in the State, its spread in 1924 having been more extensive than the total spread during the three preceding years. The average infestation in 1923 rose to between 1 and 2 per cent, with a maximum of 17 per cent. It increased in 1924 to an average infestation of 15 per cent and a maximum of 46 per cent. In a large field of dent corn which had an infestation of about 43 per cent, several hundred ears taken from infested stalks when compared with an equal number of ears from uninfested stalks showed a difference in weight of about 2 per cent. In 1923 the infested stalks showed an average of slightly more than one borer to the stalk, while in 1924 there was an average of two borers each.

**Report of progress of the orange Tortrix investigation**, A. J. BASINGER (*Citrus Leaves, 1924, No. 9, pp. 1-3, figs. 6*).—This is a report of studies, conducted in 1923, of the life history of *T. citrana* Fern., known as a pest of oranges in California for nearly 40 years.

The eggs are deposited in flat patches, the egg mass varying from a few to several hundred, with an average of about 30, being placed on either the upper or lower surface of the leaves. They hatch in from 8 to 10 days during the spring and summer, and the young larvae seek the tender growth at the tips of twigs, where they web together two or three of the leaves, or make a nest in a curled leaf, feeding on the tender leaves or fruit hanging near by. From 40 to 50 days, or longer if there be a scarcity of food or cold weather, is required for completion of the larval period. Pupation takes place within the nest occupied by the larvae, 10 to 14 days being passed in this stage. While the number of generations each year has not been definitely determined, at least four are indicated.

The species is known to occur in southern California from San Diego to San Louis Obispo Counties, but most commonly in Los Angeles and Orange Counties, the section from Pasadena to Pomona being the center of greatest infestation in Los Angeles County and from Fullerton to Tustin in Orange County. The im-

portance of this pest consists largely in the damage caused by the larvae to oranges while the fruit is still on the tree, but occasionally a larva accidentally gets into a packed box of fruit and continues to feed and grow there, and is responsible for some damaged fruit. In feeding on an orange the larva eats into the skin, often boring a hole through it and a short distance into the flesh. If a Tortrix-injured orange gets by the sorting table it may decay and cause an appreciable amount of loss in that way. Some fruits are also destroyed at blossoming time by the larvae nibbling at the ovaries in the blossoms. Periodic outbreaks of the greatest severity are occasionally noted. The amount of fruit actually lost varies from a negligible percentage to as much as 20 or 25 per cent of the crop.

The author has reared six primary parasites from *T. citrana*, particularly *Apanteles aristotelidae* Vier, and *Hormius basalis* Prov., the former being by far the most important and responsible for 75 per cent of the total parasitism. The natural control has risen gradually from about 10 per cent during the winter to from 75 to 90 per cent in the various districts at the present time.

*Platynota tinctana* Wlk., another orange worm of less importance, is also under observation.

**Australian fruit crop endangered by fruit fly**, M. BLAKE (*Calif. Citrogr.*, 10 (1924), No. 1, p. 31, fig. 1).—Attention is called to the appearance of the Mediterranean fruit-fly in the Mildura fruit-growing area, one of the most important in Australia.

**Winter trapping of the fruit-fly, *Ceratitis capitata* (Weid.)**, L. J. NEWMAN (*Jour. Dept. Agr. West. Aust.*, 2. ser., 1 (1924), No. 2, pp. 177-181, figs. 7).—Studies of the life history of the Mediterranean fruit-fly have shown the occurrence of an active winter generation which carries the fly into the oranges and loquats, thus bridging the living connection between the autumn and early summer.

Experimental search for baits that could be used in traps at any season of the year, especially during the wet season, have been under way for several years. Kerosene, which had previously been discovered to exercise a peculiar attraction for *C. capitata* males, was the most effective of those tested, but there was a great preponderance (90-95 per cent) of males. Further investigations led to the discovery that pollard (bran) mixed with water has a most remarkable attraction for the female fruit-fly. Twelve 10-oz. lever-lid tin trays containing the bait placed in six orange trees in a suburban garden on May 8, and the bait renewed every seven days up to September 3, resulted in the capture of no less than 6,500 flies, 86 per cent being egg-laden females. The pest is said to have been practically wiped out by means of the lure, and from September 3 to the first week in January no flies were captured. In order to preserve the pollard solution from fermentation, and so becoming less attractive to the fly, powdered borax was added. The formula recommended by the author for use in traps consists of pollard 4 lbs., molasses (optional) 4 oz., arsenate of lead (optional) 5 oz., powdered borax 8 oz., and water to make 4 gal.

**The Mexican bean beetle, *Epilachna corrupta* Muls.**, A. E. MILLER (*Ohio Sta. Mo. Bul.*, 9 (1924), No. 11-12, pp. 197-204, figs. 3).—This is a report of studies of the Mexican bean beetle, which was first discovered in Ohio in August, 1923 (E. S. R., 51, p. 256). It now occurs in all of northern Ohio with the exception of the northwestern counties, as it does in parts of Indiana, Pennsylvania, and West Virginia, and in additional areas in States already known to be infested. In southern Ohio many growers have suffered total loss of both Lima and green beans.

The last of the three generations appears to be of little importance. The beetles first appeared on June 3, the peak of emergence occurring between June

15 and 19 and of oviposition between June 18 and 22, the latter continuing for 35 days. The eggs hatch in about 7 days, the larvae pupate 18 or 19 days later, and in 7 days the adults emerge. Oviposition by the first generation begins about 10 days after emergence. Development in the second generation is in general the same as that in the first.

Several insecticides were used in control work with similar results, all having been found to burn pole Lima beans to some extent, so that care must be taken not to exceed the amounts recommended, namely, (1) calcium arsenate 1 part, dusting sulfur 1 part, and hydrated lime 4 parts, (2) Niagara Aladust 100 per cent, (3) magnesium arsenate 1 part and hydrated lime 5 parts, and (4) arsenate of lead 1 part and hydrated lime 9 parts, the first three applied at the rate of 15 lbs. and the fourth at the rate of 18 lbs. per acre.

The Cicadellidae of the vicinity of Ithaca, New York, with special reference to the structure of the gonapophyses, J. L. BUYS (*New York Cornell Sta. Mem.* 80 (1924), pp. 3-115, figs. 183).—This is a synopsis of the leafhoppers of the Ithaca region.

The mint flea-beetle, *Longitarsus menthae* new species MS, L. G. GENTNER (*Michigan Sta. Quart. Bul.*, 7 (1925), No. 3, pp. 109, 110, figs. 2).—A small brownish-yellow flea-beetle appeared during the summer of 1924 and caused serious injury to mint grown in southern Michigan. The investigations which followed have shown the pest to represent a species not hitherto known.

The larvae feed on the rootlets and mine in the main roots and lower parts of the stems during June, either badly stunting the plants or killing them outright. Injured plants take on a reddish purple tinge which is quite conspicuous at times. The adult beetles, first appearing during the latter half of July, feed upon the mint leaves, badly riddling them and causing them to turn brown and later to drop off. After feeding for three or four weeks the beetles begin to oviposit near the surface of the soil, continuing to do so until they die or until severe cold weather sets in. When the mint sod is plowed under after the first freeze in the fall the eggs become covered and receive protection during the winter months.

In order to prevent migration of adult beetles into new mint, it is thought that the dusting of a strip around the edge of the field with an arsenical dust, such as calcium arsenate 1 part to 20 parts of finely powdered raw gypsum, will be effective.

The parsley weevil (*Listronotus latiusculus* Boh.), a potential pest, F. H. CHITTENDEN (*Bul. Brooklyn Ent. Soc.*, 19 (1924), No. 3, pp. 84-86, fig. 1).—This weevil is a source of injury to the carrot through its attack principally on the upper part of the head, though in small carrots the injury may extend well down to the roots. In the larger roots the larvae sometimes bore down to a depth of a full inch, occasionally toward the center, but usually around the outer surface. Practically all carrots that are attacked by this species are ruined for market. Only one larva has been observed in a single carrot, but it is considered possible that two or three might occasionally be found in case of unusual abundance of the weevil. One grower at Astoria, Long Island, reported having lost 50 per cent of his carrot crop in 1922, and the pest had reappeared in July of the following year. The presence of this pest has also been reported from Mineola, L. I., Valley Stream, Nassau Co., N. Y., Washington, D. C., and Urbana, Ill.

Possibility of the transmission of American foulbrood of bees by caterpillars of the bee moth [trans. title], F. VINCENS (*Compt. Rend. Acad. Sci. [Paris]*, 179 (1924), No. 12, pp. 574-577).—The author's observations have led him to conclude that the caterpillars of the bee moth may consume the desic-

cated cadavers of bee larvae killed by *Bacillus larvae* White without danger to themselves, that the spores of *B. larvae* are recovered in large numbers from and live in the dejecta of caterpillars that have consumed contaminated comb, and that the bee moth caterpillars migrate from one hive to another and can transport living germs of foulbrood from a hive depopulated by this disease to a healthy colony.

**Treatment for red-spider**, E. I. McDANIEL (*Michigan Sta. Quart. Bul.*, 7 (1925), No. 3, p. 108).—The author finds that the greenhouse red spider can be successfully combated by applications on each of three days in succession of the standard strength of lemon oil. The torpid periods, first observed by Vinal (E. S. R., 39, p. 65), during which times it is highly resistant to insecticides, last for only a day.

**Apple blister-mite and its control**, L. CHILDS (*Oregon Sta. Circ.* 59 (1925), pp. 8, figs. 4).—*Eriophyes pyri*, officially known as the pear-leaf blister-mite, has suddenly appeared and become widespread in apple orchards of the Pacific Northwest during the past two or three years. It has become a source of serious damage to both fruit and leaves in sections of British Columbia, the Yakima and Wenatchee districts, Spokane, and eastern and southern Oregon, as well as in the Hood River Valley. It appears to be a biological variety of the pear-leaf blister-mite, with which it is morphologically identical, since the author has found pear trees in an orchard near practically defoliated apple trees to be free from attack. On the other hand, observations were made in uninfested apple orchards in 1924 where pear trees could be found rather generally attacked.

The possibility of there being a native host plant from which the mite may have spread into the apple orchards of the different sections is suggested. Rather wide observations during the summer point to the possibility that the snowberry (*Symphoricarpos racemosus*) may be the native host involved, since it harbors a very similar if not identical mite, and apple trees near infested snowberries were always found attacked.

The first infestation observed on apples occurred in 1920 in an isolated upper valley orchard in which no pear trees were present. By 1923 their damage was so great as to cause almost complete defoliation in August, the fruit being severely russeted and of little value. The mites not only attack the young developing leaves but burrow into the flowers and stems. While they do not work long upon the young apples, they do so long enough to cause much damage, the injury appearing later in the summer as a severe russet. Often the apple is misshapen, and where generally infested it cracks open. Blister-mite infested apples seldom have more than a "C grade" or "cooker" value and are often worthless.

Control work was conducted with lime sulfur and with oil at different strengths, applied at different periods of bud development, as well as with oil combined with lime sulfur and with Bordeaux mixture. The mode of killing the mites was found to be quite different with the lime sulfur and oil, killing with the lime sulfur, which does not penetrate the bud scales, being delayed, while with oil, which penetrates the bud scales, it is immediate. The author is of the opinion that sulfur fumes being thrown off, especially on sunny days, prove to be very toxic to the young mites, causing their death, or that the young mites in leaving the buds come in contact with small particles of spray material scattered about on the unfolding bud.

In the spring of 1924, with the buds just beginning to swell, lime sulfur used at the rate of 1 to 25 permitted 7.77 per cent damage to the fruit, at 1 to 15 3.19 per cent, and at 1 to 10 1.69 per cent. In the two tests last mentioned the

injuries were merely a trace, but unsprayed trees developed 51 per cent injury. Where oil is used for the blister mite, spraying should be delayed until the buds begin to crack a little, observations indicating that a good miscible oil spray of not less than 5 per cent strength should be used.

"The results in the year's work are outstanding in favor of lime sulfur, due to the fact that the spray can be put on effectively over such a long period of time during the spring. In all orchards where the blister-mite is the outstanding pest and present in serious numbers, lime sulfur should be used at the rate of 1 to 10 or, if scale is present, 1 to 8. In orchards where the mite has not reached serious proportions and there are present such other pests as leaf roller and the brown aphid, an oil application of 8 to 100 is recommended. This must be applied only after the buds begin to crack slightly and preferably during warm, sunny weather."

Work with this mite by Parrot et al., in New York State, where it has been a serious enemy of the apple, has been noted (E. S. R., 20, p. 856), as has a short account by Quaintance (E. S. R., 35, p. 263).

**The bionomics of the sarcoptic mange parasite of the buffalo, with some observations concerning the relative power of resistance to adverse conditions of the different stages of the acarus and of its egg, T. M. TIMONEY** (*Agr. Research Inst., Pusa, Bul. 15 $\frac{1}{4}$  (1924), pp. 180-200, pls. 4*).—This is a reprint from the Proceedings of the Fifth Entomological Meeting held at Pusa, previously noted (E. S. R., 52, p. 154).

The author has found 17 or 18 to be the average number of eggs laid by an ovigerous female under experimental conditions, and 10 days to be the maximum duration of life of an egg-laying female. From 6 to 8 days was found to be the period between hatching and the attainment of adolescence.

"The ovigerous and pubescent females can withstand a longer separation from their host than can the other stages. The power of resistance to insulation is weakest in the male and small larvae. The nymph and large larvae occupy an intermediate position. The influence of sunshine in prolonging and the action of cold in curtailing the resisting powers of the acari were convincingly demonstrated. An exposure of 20 minutes to the action of a solution of 10 per cent creosote in olive oil, warmed to 31° C. (87.8° F.), killed all males, nymphs, larvae, and the majority of ovigerous and pubescent females. Tested by this acaricidal agent, the powers of resistance of the different stages corroborate the finding in regard to their resistance to more insulation. The incubative period is 1 to 2 days at summer temperature, and 2 to 3 days in winter. No egg separated for 5 days from the host hatched in the incubator (25-27°); and after 7 days at room temperature (10-13°) no egg hatched when subsequently placed in the host's body. Contact with 11 per cent creosote in olive oil for 30 minutes kills all eggs. Only a few survive an exposure of 20 minutes."

**The "blinding filaria" of Guatemala (*Onchocerca caecutiens* Brumpt, 1919), F. FÜLLEBORN** (*Jour. Amer. Med. Assoc., 83 (1924), No. 16, pp. 1269, 1270*).—The author discusses the transmission of *O. caecutiens*, which causes fibroma-like nodules on the scalp and is associated with certain chronic troubles of the eye (keratitis, etc.) in natives on the Pacific slopes of the volcanic ranges of Guatemala, in a narrow strip of country at an altitude between 600 and 2,000 meters (1,968 to 6,560 ft.). In some places 97 per cent of the population are affected. It is suggested that the nematode is transmitted by arthropods.

**Rat-bite disease in the United States with report of a case, G. C. SHATTUCK and M. THEILER** (*Amer. Jour. Trop. Med., 4 (1924), No. 5, pp. 453-460*,

fig. 1).—The authors report that, so far as they are able to determine, the case here reported is the first for the United States in which the presence of *Spirochaeta morsus-muris* has been demonstrated.

### FOODS—HUMAN NUTRITION

On the constancy of the basal metabolism, G. LUSK and E. F. DuBois (*Jour. Physiol.*, 59 (1924), No. 2-3, pp. 213-216).—Basal metabolism data on 11 female dogs used in the extensive series of studies on animal calorimetry previously noted (*E. S. R.*, 52, p. 665) are summarized and discussed.

The average basal heat production amounted to 772 calories per square meter of body surface per day, with an accuracy of  $\pm 15$  per cent. In one dog upon which many basal metabolism experiments were conducted, the variation in basal metabolism during 17 experiments in two successive years was only  $\pm 2.9$  per cent. In general the basal metabolism of the dog was higher when returned from the country in the fall than after having been in the laboratory all winter.

The reported data on the basal metabolism of men include 12 different observations conducted on the junior author over a period of 11 years and 3 for the senior author in 1910, 1913, and 1924. In the former the minimum, maximum, and average results were 34.8, 40.6, and 37.7 calories per square meter of body surface per hour, the average variation being  $\pm 7.6$  per cent. In the latter the values for the 3 determinations were 42.8, 41.4, and 32.7. The authors are inclined to attribute the much lower value in the final determination to lack of exercise and indoor confinement corresponding to cage life in the dog.

A study of the effect of temperature on protein intake, W. DENIS and P. BOGSTROM (*Jour. Biol. Chem.*, 61 (1924), No. 1, pp. 109-116, figs. 2).—An opportunity to compare the protein consumption of inhabitants of the semi-tropical portions of the United States with the general average for the whole country was afforded by data collected during a period of three years on the 24-hour excretion of total urinary nitrogen and creatinine by medical students at Tulane University, New Orleans. The material was obtained during the month of April, 1922, average temperature 22.94° C. (73.3° F.); April, 1923, temperature 21°; July, 1923, temperature 26.77°; and in February and March, 1924, temperature 13.05°. Reliable data were obtained on 233 men and 9 women, most of whom were between 18 and 22 years of age.

The average, maximum, and minimum figures obtained on the women subjects were urinary nitrogen 7.72, 10.62, and 4.05 gm.; creatinine coefficient 7.37, 8.5, and 5.97; and body weight 55.5, 65.91, and 45 kg., respectively.

For the male subjects, the average urinary nitrogen was 10.63 gm., or 11.07 gm. per 70 kg. man equivalent, and the creatinine coefficient 8.93, or 9.3 per 70 kg. On the assumption that 10 per cent of food protein is lost in the feces, the total average protein intake of the group was 73.8 gm. as compared with 121 gm. as the average protein intake for the United States according to Pearl, and 150 gm. according to the Atwater standard. By season, the lowest average of urinary nitrogen was 9.43 gm. in the summer and the highest 11.18 gm. in the cold weather in the spring of 1924, thus pointing to a seasonal influence. On grouping the subjects according to the places of residence, those coming from the Northern States showed an average excretion of about 2 gm. more than those coming from the Southern States.

“The results obtained furnish evidence in favor of the view that increase of temperature is accompanied by a decrease in protein intake, and that, apart

from the variations due to seasonal changes, the inhabitants of the semitropical portions of this country probably consume an amount of protein considerably below the quantity reported as the average intake for the Nation."

The biological value for maintenance and growth of the proteins of whole wheat, eggs, and pork, H. H. MITCHELL and G. G. CARMAN (*Jour. Biol. Chem.*, 60 (1924), No. 3, pp. 613-620, fig. 1).—Using the methods previously described (E. S. R., 51, p. 407), the authors have determined the biological values of the proteins of eggs, pork, and wheat.

A litter of 9 rats, weighing from 70 to 80 gm. each, was divided into two groups, the first group of 5 receiving the different rations in the order of protein-free, wheat, egg, pork, and protein-free, and the other group protein-free, egg, pork, wheat, and protein-free. The feeding periods were of 10 days' duration, the feces and urine of the last 7 days being used.

When fed at an 8 per cent level of intake, the average biological values found were eggs 93, pork 74, and wheat 67. The net protein values of the three foods, as calculated from average determinations of the crude protein content and the percentage losses in digestion and metabolism, were 12.5, 14.6, and 7.6 per cent, respectively.

Considerable and consistent individual differences were noted among the individual rats in the utilization of the dietary nitrogen, but the order in which the different foods were tested had no appreciable effect on the results obtained.

**Biological food tests.—VII, The vitamin A and B content of fresh and dehydrated pumpkin,** A. F. MORGAN and L. D. FRANCIS (*Amer. Jour. Physiol.*, 69 (1924), No. 1, pp. 67-77, figs. 2).—Using methods employed in previous papers of the series (E. S. R., 51, p. 666), the authors have investigated fresh and commercially dehydrated pumpkin for their content of vitamins A and B. Mice were used for the experiments on the vitamin B content of both fresh and dehydrated pumpkin, and rats for the vitamin A and vitamin B content of the dehydrated pumpkin.

As the sole source of vitamin B, the minimum amount of pumpkin flour for the normal growth of mice was from 0.5 to 0.6 gm., and for rats 1 gm. daily was necessary to restore normal growth after decline on a vitamin B-deficient diet. Of fresh pumpkin, an amount furnishing 0.4 gm. of solids daily was required for the normal growth of mice. As judged by the experiments with mice, pumpkin is considered to have a vitamin B potency of one-fifth to one-sixth in the dehydrated form, and one-fourth in the fresh form, of dry brewery yeast. As judged by the rat experiments, the potency of the dehydrated pumpkin is from one-third to one-fourth that of dry brewery yeast.

As a source of vitamin A for young rats suffering from a deficiency in this vitamin, 2 gm. daily was required, while 1 gm. was sufficient in protective experiments.

**Antirachitic properties imparted to inert fluids by ultraviolet irradiation,** A. F. HESS and M. WEINSTOCK (*Jour. Amer. Med. Assoc.*, 83 (1924), No. 23, pp. 1845, 1846).—It is reported briefly that cottonseed oil and linseed oil, irradiated in thin layers for an hour at a distance of 1 ft. from a quartz mercury vapor lamp, acquired antirachitic properties for rats, as shown by protective tests. The irradiated oils differed but little in iodine number from the corresponding untreated oils, but had a slightly higher total acidity. It is of interest that the oils on irradiation frequently acquired a somewhat fishy odor similar to that of cod liver oil.

Liquid petrolatum irradiated in a similar manner, water containing small amounts of radium bromide, linseed oil containing a minimal amount of radium, and ozonated water were all without protective properties.

**Antirachitic properties imparted to inert fluids and to green vegetables by ultra-violet irradiation**, A. F. HESS and M. WEINSTOCK (*Jour. Biol. Chem.*, 62 (1924), No. 2, pp. 301-313).—In addition to the materials noted above as capable of being rendered antirachitic by irradiation, wheat grown in the light and irradiated during growth and irradiated lettuce leaves were found to have antirachitic properties, while wheat grown in the dark and non-irradiated lettuce leaves were without effect. With cream, milk, gelatin, and human serum irregular results were obtained.

**The influence of light in relation to diet on the formation of teeth**, M. MELLANBY (*Brit. Dental Jour.*, 45 (1924), No. 9, pp. 545-552, figs. 3).—In continuation of the author's studies on the influence of diet on teeth formation (E. S. R., 41, p. 858), 5 puppies in the same litter were fed a basal diet consisting of from 250 to 300 cc. of separated milk, 5 gm. of yeast, from 10 to 20 gm. of lean meat, from 1 to 4 gm. of common salt, and from 3 to 5 cc. of orange juice. Two of the puppies received in addition from 30 to 50 gm. of oatmeal and 10 cc. of olive oil, 2 others from 45 to 100 gm. of oatmeal and 10 cc. of olive oil, and the remaining puppy from 45 to 100 gm. of oatmeal and 10 cc. of cod liver oil. The animals were all kept in the dark, but one of the first and one of the second groups received ultraviolet radiations daily. After a period of 5 months the animals were killed and their teeth photographed and examined.

The most perfect teeth were those of the fifth dog, the worst with respect to calcification and dentine the one on the second diet without light treatment, and only slightly better the other dog on the same diet with light treatment. Of the two in the first group, the one receiving light treatment had decidedly the better teeth.

**The effect of diet on the development and extension of caries in the teeth of children**, M. MELLANBY, C. L. PATTISON, and J. W. PROUD (*Brit. Med. Jour.*, No. 3322 (1924), pp. 354, 355).—The effect of diets similar in essential constituents to the above on the development of dental caries in children was tested on three groups of children of the same age. One group of 9 received a diet which included cod liver oil, milk, and eggs, but no oatmeal; a second group of 10 a diet including oatmeal, very little egg, less milk, and no cod liver oil; and a third group of 13 children was chosen from patients on ordinary hospital diet which was intermediate between the other two with respect to its power to aid calcification. The effect of these diets on general health and on the condition of the mouth and teeth was watched, and an examination was made at the end of the experiment, which lasted about 8 months, of the carious teeth which had been extracted.

While no difference could be noted in the general health of the children in the three groups, there was a marked difference in the extent of the spread of caries. On the first diet the average number of teeth per child in which caries had spread was 1.4, on the second 5.1, and on the third 2.9. The diet giving the best results was rich both in calcium and vitamin A and contained comparatively little cereal.

**The relation of calcium and phosphorus in the diet to the absorption of these elements from the intestine**, W. J. ORR, L. E. HOLT, JR., L. WILKINS, and F. H. BOONE (*Amer. Jour. Diseases Children*, 28 (1924), No. 5, pp. 574-581).—Metabolism studies, using the procedure previously described (E. S. R., 50, p. 669), were conducted on two subjects, a child with incipient rickets and another who had recovered from a mild nutritional disturbance. The calcium and phosphorus intake and output of these children were determined on a normal diet, a high calcium diet, and a high phosphorus diet, with suitable

intervals between the three periods of study. Determinations were also made of the calcium and phosphorus of the blood serum.

The results obtained showed that excessive amounts of calcium in the diet tend to increase the total absorption and retention of calcium and to decrease the retention of phosphorus. Following an excessive intake of phosphorus, the actual amount of phosphorus retained is not increased and may be somewhat diminished, although its concentration in the blood serum is definitely increased. This is accompanied by a marked decrease in the amount of calcium retained, an increase in the calcium of the feces, a decrease in the calcium in the urine, and in one case a decrease in the concentration of calcium in the serum.

In discussing these results, it is concluded that "the retention of one element in the intestine by an excessive amount of the other in the diet is best explained by the formation of insoluble phosphates of calcium which can not be absorbed."

The effect of heat treatment of milk feedings on the mineral metabolism of infants, A. L. DANIELS and G. STEARNS (*Jour. Biol. Chem.*, 61 (1924), No. 1, pp. 225-240, figs. 2).—The results previously obtained in the comparative study of the growth of young rats on milk pasteurized by the hold method and milk heated quickly to boiling (*E. S. R.*, 44, p. 860) have been confirmed in the case of a number of apparently well babies, whose weight remained stationary during a considerable period on pasteurized milk feedings but who gained promptly when the milk was changed to quickly-boiled milk. It is noted, however, that changes in the method of heating the milk did not result in growth stimulation in all of the babies under observation.

A further comparison was made of the relative value of the two methods of heating milk by conducting metabolism experiments on normal boy babies from 3 to 7 months of age. The pasteurized milk mixtures were prepared by heating milk in the feeding bottles at 145° F. for 30 minutes and the boiled milk by bringing it quickly to the boiling temperature three times in an aluminum pan over a gas flame, the whole process requiring about 8 minutes. Data are reported on the metabolism of nitrogen, calcium, and phosphorus in 6 subjects, 3 on one period of each form of milk and 3 on two alternating periods of each.

In all cases there was an appreciable increase in the retention of CaO and P<sub>2</sub>O<sub>5</sub> on the boiled milk, and in all but two cases this was accompanied by increased nitrogen retention. The excretion of calcium in the feces was greater on the pasteurized than on the boiled milk. The urinary calcium did not run parallel with the fecal. In the case of the phosphorus the amount excreted by the urine was higher and more consistent on the pasteurized milk than was that of the feces. The fecal nitrogen was not consistently greater during the pasteurized milk period, but the urinary nitrogen was higher. "It is probable that a baby fed pasteurized milk over a long period of time is receiving too little calcium for his growth needs."

Studies on carbohydrate metabolism.—I, Variations in the nature of the blood sugar, L. B. WINTER and W. SMITH (*Roy. Soc. [London], Proc., Ser. B*, 97 (1924), No. B 680, pp. 20-40, figs. 3).—In the investigation reported in this paper a comparison was made of the nature of the sugar in normal and diabetic blood as determined by the ratio of the observed optical rotation (*P*) to that calculated from the reducing power of the carbohydrate on the basis that glucose is the only reducing substance present, this factor being referred to as *C*.

As shown in a previous investigation (*E. S. R.*, 49, p. 715), the ratio *P:C* is low in normal blood. In diabetic blood the ratio was found to be abnormally

high. On subjecting equal quantities of sugar solution from diabetic blood to mild and strong hydrolysis, respectively, a large increase in the value of  $P$  and no change in  $C$  occurred following mild hydrolysis, while after strong hydrolysis the values of  $P$  and  $C$  corresponded to  $\alpha$ - and  $\beta$ - glucose in equilibrium. This is thought to indicate that "there is in diabetic blood a mixture of sugars, some of which are of considerable complexity. These may be changed as a result of mild hydrolysis to simpler and more strongly dextro-rotatory substances which are devoid of reducing action. The value of  $C$  was accordingly not increased with this treatment."

When normal blood sugar was subjected to mild hydrolysis the value of  $P$  did not rise above that of  $C$ . This was also true with the blood sugar of diabetic patients following insulin treatment, thus suggesting that the first change in the blood sugar due to insulin is the removal or breaking down of abnormal complex constituents. An examination of the blood sugar of rabbits following injection of adrenalin and thyroid extract alone gave results similar to those obtained with diabetic blood. The injection of thyroid and adrenalin together caused an increase in the total blood sugar but no change from the normal.

The blood sugar of normal rabbits after insulin injections gave positive values for  $P$  but no results for  $C$ . After prolonged hydrolysis only the faintest traces of reducing sugars were present. These results are thought to point to the presence of a very resistant type of carbohydrate. The blood sugar of a rabbit killed after recovery from insulin convulsions gave a small but appreciable value for  $C$ .

In discussing these results the apparently paradoxical effects of insulin on normal and diabetic blood are explained somewhat as follows: A normal dose of insulin given to a diabetic enables him to form a complex sugar of the nature of glycogen, which, on account of the need of the tissues for a reactive sugar, is broken down immediately. The presence of this reactive sugar in the blood is shown by the alteration in the ratio  $P:C$ . In the normal animal in which the pancreas is functioning the insulin converts all of the normal utilizable sugar into a stable form which is resistant to hydrolysis by acids. The lack of a reactive form of sugar is considered to prevent not only the normal metabolism of carbohydrate but also that of fat.

**Studies on carbohydrate metabolism, II, III, H. B. HUTCHINSON, W. SMITH, and L. B. WINTER** (*Biochem. Jour.*, 17 (1923), No. 6, pp. 683-692, 764-767, fig. 1).—In continuation of the investigation noted above, two papers are presented.

II. *On the preparation of an antidiabetic hormone from yeast*, I (pp. 683-692).—The results are reported of various attempts to obtain glucokinase from yeast by the method for the preparation of insulin devised by Collip and modified by Dudley (*E. S. R.*, 49, p. 803).

In the first series of experiments fresh bakers' yeast was used as the foundation material. The extract obtained caused less local irritation than insulin when injected into rabbits. Much larger amounts were required than of insulin to lower the blood sugar to the same level, but the action was considerably prolonged. Modifications of the process were found to produce no appreciable difference in the activity of the product obtained from a given sample of yeast, but different samples of yeast appeared to contain widely differing amounts of the substance. The presence or absence of phosphates alone affected the yield from any given variety of yeast.

The authors are of the opinion that by the selection of suitable yeasts a genuine antidiabetic hormone can be obtained, but that only in the case of an originally active yeast is it possible to increase the glucokinase formation.

III. *On the formation of an antidiabetic hormone by the action of a bacillus (preliminary communication)* (pp. 764-767).—From a culture of yeast containing a small amount of glucokinin, as tested in the above study, a pure culture of a coliform bacillus was obtained which, on cultivation in peptone water containing 1 per cent glucose and 1 per cent  $\text{Na}_2\text{HPO}_4$  or  $\text{NaH}_2\text{PO}_4$  and subsequent extraction, also yielded an insulin-like substance. The active substance resembled that obtained from yeast in that the same delayed action was obtained on injection in rabbits. The organism, which has not as yet been identified, produces acid and gas from glucose or lactose in 12 hours and does not liquefy gelatin.

Some effects of insulin on the carbohydrate and phosphorus metabolism of normal individuals, N. R. BLATHERWICK, M. BELL, and E. HILL (*Jour. Biol. Chem.*, 61 (1924), No. 1, pp. 241-259, figs. 3).—The recent literature on the connection between carbohydrate and phosphorus metabolism is reviewed, and additional evidence is presented in support of the theory that a compound of hexose with phosphoric acid is an intermediate product in carbohydrate metabolism.

The evidence was obtained along two lines. Determinations were made of the changes in the sugar and inorganic phosphorus of the blood and urine resulting from the ingestion of glucose following the injection of insulin, and from the injection of increasing amounts of insulin in connection with a standard diet.

The injection of insulin in normal subjects before the ingestion of glucose causes a marked decrease in the inorganic phosphorus of the blood plasma at the time of hypoglycemia. This was accompanied by a decrease in the excretion of phosphorus in the urine. When insulin was injected in increasing amounts in connection with a uniform basal diet there was an increase in the excretion of phosphorus for one or two days, accompanied by an increased elimination of nitrogen. With continued administration of insulin the excretion of both phosphorus and nitrogen decreased until values lower than normal were obtained. Insulin tended to cause a decrease in the excretion of phosphorus during the day and an increase during the night. "It may be assumed that these effects are produced by inorganic phosphorus being withdrawn from the blood to form the hexose phosphate combination in the other tissues, and when the effects of the insulin have been spent this compound breaks up, thus releasing phosphate into the blood and thence into the urine."

Methods of including intarvin and glyceryl margarate in the diabetic diet, M. S. REYNOLDS and A. L. MARLATT (*Jour. Home Econ.*, 16 (1924), No. 12, pp. 692-700).—This contribution from the home economics department of the University of Wisconsin reports a study of various methods of combining intarvin or glyceryl margarate with food materials suitable for diabetic patients to obtain palatable products. The preparations tested included bran cakes, cooked combinations with tomatoes or other vegetables, salads, frozen desserts, and highly seasoned sauces.

The most palatable products proved to be those in which tomatoes were used and various vegetable salads. "Two general rules may perhaps be laid down for introducing intarvin and glyceryl margarate into a palatable diet: (1) Whenever possible they should be used unmelted. (2) When used in hot foods they should be added immediately after the food is removed from fire, and the material should be served at once without reheating."

## ANIMAL PRODUCTION

Report of analyses of samples of feeding stuffs collected in New York State from July 1 to December 31, 1923, inclusive (*N. Y. State Dept*

*Farms and Markets, Agr. Bul. 167 (1924), pp. 138*).—This consists of the guaranties and analyses for protein, fat, and fiber of the samples of feeding stuffs collected in New York State from July 1 to December 31, 1923.

**Report of the departmental committee on the Fertilizers and Feeding Stuff Act, 1906, LORD CLINTON ET AL.** (*London: [Min. Agr. and Fisheries], 1924, pp. 63, pls. 2*).—This consists of the report of the committee appointed by the Minister of Agriculture and Fisheries to investigate the operations of the Fertilizers and Feeding Stuff Act of 1906, with suggestions for improvement.

**Beef cattle feeding experiments, H. HACKEDORN, J. SOTOLA, and R. P. BEAN** (*Washington Col. Sta. Bul. 186 (1924), pp. 4-26, figs. 6*).—This bulletin reports the results of three experiments in which the feeding value of corn and sunflower silage for steers was studied.

*A study of the comparative feeding value of sunflower silage and corn silage in rations of steers.*—In this experiment, which was conducted at the main station during the winter of 1921-22, corn and sunflower silage were compared for fattening 2-year-old steers. Two lots were fed for 75 days on 2 lbs. of cottonseed meal per head daily, and in addition lot 1 received a mixture of corn silage and chopped alfalfa hay (3:1), while lot 2 received sunflower silage and chopped alfalfa hay mixed at the rate of 3.5:1. The corn silage was slightly immature, due to early cutting on account of frost, but the Mammoth Russian sunflowers had well-developed seeds at the time of cutting. The average daily gains of the two lots were 1.2 lbs. and they were considered equally well finished. The sunflower lot consumed about 455 lbs. more silage per 100 lbs. of gain than the corn silage group, but less digestible nutrients were consumed by this lot. The efficiency of sunflower silage was calculated as 88 per cent that of corn silage on a pound basis.

*A study of various proportions of silage to feed with hay and small quantities of grain [for long yearling steers].*—This and the succeeding experiment were conducted at the Irrigation Substation during the winter of 1923-24. Three lots of 30 long yearling steers each were used in this experiment. All lots received 4 lbs. of cracked wheat daily per head and a full feed of alfalfa hay and corn silage. The proportions of the hay and silage fed in the different lots were 1:1 in lot 1, 1:2 in lot 2, and 1:3 in lot 3. The average daily gains of the three lots during the 60-day feeding period were, respectively, 1.75, 2, and 2.11 lbs. The feeds required per 100 lbs. of gain were 223 lbs. of cracked wheat, 882 lbs. of hay, and 888 lbs. of silage; 200 lbs. of cracked wheat, 605 lbs. of alfalfa hay, and 1,221 lbs. of silage; and 189 lbs. of cracked wheat, 489 lbs. of hay, and 1,578 lbs. of silage in the three lots, respectively. The rations containing the larger amounts of silage produced the cheaper gains and required less digestible nutrients per unit of gain, though all three rations were satisfactory.

*A comparison of a hay-silage ration with one of hay for calves receiving shelled corn as the concentrate.*—In this experiment a ration of shelled corn and alfalfa hay was compared with one of shelled corn, alfalfa hay, and corn silage for fattening calves. The average daily gains made during the 63-day test were nearly equal, being 2.08 lbs. on the former and 2.11 lbs. on the latter ration. There was little difference in the finish, but the group receiving silage had a glossier coat and shed sooner. Approximately 2.5 lbs. of silage replaced 1 lb. of hay. The silage ration as consumed supplied per day about 0.5 lb. less digestible nutrients than the hay ration.

The chemical composition and the digestibility of the feeds as obtained from other sources are also given.

**Rations for fattening cattle, W. E. CARROLL** (*Utah Sta. Bul. 192 (1925), p. 32*).—In a two years' study of the most efficient amount of grain to feed with

alfalfa hay for fattening cattle the gains of lots receiving alfalfa hay only and with 3, 5, 8, and 12 lbs. of grain per day, respectively, were compared.

When the rations included 3 lbs. of grain, each pound replaced 6.1 lbs. of hay, while gradual decreases in the amount of hay replaced per pound of grain occurred as more grain was added to the ration. Each pound of grain above 5 lbs. per day replaced only 2.1 lbs. of alfalfa hay when 8 lbs. of grain was fed.

In another test of rations consisting of alfalfa hay as a basis cattle receiving 9.4 lbs. of chopped barley gained 1.93 lbs. per head daily, and when corn silage was added to a ration of alfalfa hay and 4.8 lbs. of chopped barley the gain was 1.9 lbs. When wet beet pulp replaced the corn silage the average daily gain was 2.21 lbs. It was estimated that a ton of beet pulp replaced 1,100 lbs. of silage, 64 lbs. of chopped barley, and 150 lbs. of hay.

**Kemp fibres in the Merino sheep**, J. E. DUERDEN (*Union So. Africa Dept. Agr. Jour.*, 9 (1924), No. 2, pp. 167-170, figs. 3).—It is shown that kemp is the remnant of fibers of an outer coat on lambs at birth. The microscopical characteristics of kemp are described.

**The 1925 wool clip**, G. A. BROWN (*Michigan Sta. Quart. Bul.*, 7 (1925), No. 3, pp. 79-81, fig. 1).—A popular discussion of the effect of various factors, including the care of the sheep, feeding, shearing, and tying of the fleece, on the quality of the wool produced. A diagram of a wool box is included.

**Report on pig-feeding trials carried out at the County Council Farm, Hutton, 1920-1923**, J. J. GREEN and R. RICHARDSON (*Lancaster Co. Council Ed. Com., Agr. Dept., Farmers' Bul. 39* (1924), pp. 28).—The results of experiments conducted from October, 1920, to December, 1923, are briefly given. In determining the feed requirements per unit of gain the following succulent feeds have been considered as equal to 1 lb. of concentrates: 12 lbs. of whey, 8 lbs. of swedes or mangels, and 4 lbs. of potatoes.

*The value of fish meal as a feeding stuff for pigs* (pp. 6, 7).—In comparing the value of fish meal and corn meal for fattening pigs, twelve 14-weeks-old pigs averaging 58 lbs. were selected. The ration of one-half of the pigs consisted of 4 parts of sharps and 4 parts of corn meal, with from 1 to 1½ gal. of whey per day. The ration of the other half was similar except that 1 part of fish meal replaced 1 part of corn meal. The pigs receiving no fish meal developed lameness without exception, the first pig being affected at the end of 12 weeks. The average daily gains of the two lots up to this time were 0.9 and 0.83 lb., respectively, for the lots receiving fish meal and no fish meal. It became necessary to kill three of the pigs in the no-fish-meal lot, but by adding fish meal to the ration of the other three pigs the lameness gradually disappeared, probably due to the mineral content of the feed. Not only did the addition of fish meal produce more rapid gains and prevent lameness but the lot receiving this feed required 0.35 lb. less feed to produce 1 lb. of gain than the other lot.

*The value of fish meal and of oatmeal in pig feeding* (pp. 8-11).—Three lots of six pigs each averaging about 40 lbs. in weight were selected for this experiment. The ration fed to lot 1 consisted of 3 parts of sharps, 3 parts of palm kernel cake meal, 4 parts of corn, and 1 to 1½ gal. of whey per pig daily. This ration was modified for lot 2 by the substitution of 1 part of fish meal for 1 part of corn, and it was further modified for lot 3 to consist of 3 parts of sharps, ½ part of corn, 1½ parts of barley meal, and 2 parts of oatmeal, with the same amount of whey as the other lots received. The average daily gains made by the different lots during the first three months of this feeding experiment were 0.85, 0.76, and 0.78 lb., respectively, 3.61, 3.88, and 3.73 lbs. of meal being required to produce 1 lb. of gain by the respective lots. During this time 2 pigs in lot 1 became lame, and 1 from lot 3 developed rheumatism. Lots 2

and 3 were continued for a second three months' period, lot 2 making average daily gains of 1.44 lbs. as compared with 1.24 lbs. by lot 3. The respective feed requirements per pound of gain were 4.37 and 4.60 lbs. The fish meal was discontinued six weeks prior to the end of this experiment, and the amount of oatmeal was increased in the other lot. There was practically no difference in the carcasses and dressing percentages of the two lots, but the flavor of the cooked bacon from lot 3 was found to be better.

*Does fish meal taint pork or bacon?* (pp. 12-14).—In testing the possibility of fish meal flavoring pork products, five pigs were fattened on a ration consisting of one-eighth fish meal. One animal received the same ration up until the time of slaughter, while the fish meal was discontinued at 1, 2, 4, and 6 weeks, respectively, prior to the slaughtering of the other animals. No fishy flavor could be detected in the pork or the lard, but such flavor was detected in the bacon of those receiving fish meal up to one and two weeks before slaughter. A distinctly unpleasant flavor was observed in the bacon of the pig receiving fish meal until slaughtering occurred.

*The value of whey for pig feeding* (pp. 15-18).—In this experiment three rations were compared for fattening 10-weeks-old pigs averaging about 50 lbs. at the beginning of the test—lot 1, 6 parts of sharps, 4 parts of corn, and  $\frac{1}{2}$  to 1 gal. of water per pig per day; lot 2 the same as lot 1, except for the substitution of an equal amount of whey for the water; lot 3 the same as lot 1, except for the substitution of 1 part of fish meal for 1 part of corn. During the first 20 weeks the average daily gains of the three lots were 0.55, 0.84, and 0.81 lb., respectively. It was found necessary to add a mineral mixture to lot 1 as the pigs developed lameness at the end of 10 weeks. The fish meal was discontinued from the ration of lot 3 at the end of the 20 weeks, and the three lots were continued for a determination of the further gains. Lots 1 and 3 receiving the same ration made average gains per pig per day of 1.5 and 1.4 lbs., while lot 2 made gains of 1.6 lbs. per day. During the first six months of the experiment the whey-fed pigs appeared more thrifty and gained better, but later the pigs receiving meal only recovered a large part of this advantage.

*The value of palm kernel cake meal for pig feeding* (pp. 19, 20).—In this experiment 4 parts of sharps were compared with 4 parts of palm kernel cake meal in a ration consisting, in addition, of corn meal 3 parts and fish meal 1 part, with 1 to  $1\frac{1}{2}$  gal. of whey per pig daily.

The experiment lasted from January 11 to the end of July. The two lots of pigs, averaging 83 and 84 lbs. per head, made average daily gains of 1.32 lbs. and 1.42 lbs. on the sharps and palm kernel cake meal rations, respectively. The feed requirements to produce 1 lb. of gain were 4.97 and 4.76 lbs.

The author concludes that palm kernel cake meal has proved a satisfactory substitute for sharps and is more economical.

*Wet v. dry feeding of pigs* (pp. 21-23).—In an 18 weeks' experiment using two lots of 140-lb. pigs, one lot received a mixture of concentrates steeped in whey, while another lot received the same mixture in self-feeders, with an equal amount of whey fed separately. Average daily gains of 1.62 and 1.61 lbs. per head were made by the two methods of feeding. Slightly more feed, however, was required per pound of gain by the self-fed lot, i. e., 4.49 lbs. as compared with 4.37 lbs.

Since the feeding in the above experiment was done inside, a further test was conducted outdoors with pigs weighing about 50 lbs. During the  $5\frac{1}{2}$  months of the outdoor test the average daily gains of the self-fed lot exceeded those receiving the wet feed by from 0.1 to 0.36 lb. per day, but when the pigs were moved inside for a period of two weeks the reverse was true. The self-fed lot consumed more feed, but required 0.31 lb. less feed to produce 1 lb. of gain.

*Outdoor v. indoor pig keeping* (pp. 24-27).—Two lots of similar pigs averaging about 145 lbs. in weight were used for comparing inside v. outside methods of fattening. Each lot gained an average of 1.64 lbs. per day during the nine weeks, though the indoor-fed lot required 7.6 lbs. of feed per pound of gain as compared with 8.23 lbs. by the outdoor-fed lot.

In a second experiment the pigs selected were about 12 weeks old, averaging 52 and 51 lbs., respectively, in the two lots. During the first two months, June and July, the average daily gain made by the outdoor lot was 1.02 lbs., as compared with 0.9 lb. by the indoor lot, while during August and September the gains of the respective lots were 1.14 and 1.22 lbs. and during October and November 1.22 and 1.39 lbs. Due to weather conditions the outdoor lot was transferred to a piggery during two weeks in December, when the gains of the outdoor and indoor lots, respectively, were 1.63 and 1.57 lbs. The outdoor lot required 0.53 lb. more feed to produce 1 lb. of gain than the lot fed indoors. It is concluded to be more profitable to fatten pigs indoors during the autumn and early winter.

*Relation of weight of pigs to food consumed and rate of gain* (p. 28).—From the records of three years' experiments a table has been computed to show the average feed consumption, daily gain, and feed required to produce 1 lb. of gain in pigs of varying weights.

*Hog rations*, W. E. CARROLL (*Utah Sta. Bul.* 192 (1925), p. 31).—In comparing various rations for fattening swine in a 56-day test, the average daily gains and feed requirements per 100 lbs. of gain were as follows: Lot 1 1.55 lbs., requiring 22 lbs. tankage and 414 lbs. rolled barley; lot 2 1.42 lbs., requiring 33 lbs. tankage and 411 lbs. shelled corn; lot 3 1.18 lbs., requiring 124 lbs. bran, 251 lbs. shorts, and 634 lbs. buttermilk; and lot 4 1.23 lbs., requiring 422 lbs. rolled barley and 8 lbs. of alfalfa hay.

In another test, in which purebred Tamworths were fed for 82 days having access to alfalfa hay in racks, the efficiency of various methods of feeding barley was studied. Whole barley was 19 per cent less efficient than chopped barley and 22 per cent less efficient than rolled barley, while rolled barley was about 2.5 per cent more efficient than chopped barley.

*Self-feeders for hogs: Their construction and directions for self-feeding*, G. BOHSTEDT and W. L. ROBISON (*Ohio Sta. Mo. Bul.*, 9 (1924), No. 11-12, pp. 210-221, figs. 6).—This is a discussion of the construction of self-feeders and directions for their use in winter and summer feeding, including suggested mixtures for self-feeding pigs of various ages.

*Swine production*, E. Z. RUSSELL (*U. S. Dept. Agr., Farmers' Bul.* 1437 (1925), pp. II+30, figs. 18).—This discusses the hog raising industry in the United States and points out the general principles to be observed in the care, management, breeding, and feeding of swine. It supersedes *Farmers' Bulletin* 874 (E. S. R., 38, p. 169).

*Textbook of swine production*, F. DETTWEILER and K. MÜLLER (*Lehrbuch der Schweinezucht*. Berlin: Paul Parey, 1924, pp. XV+918, figs. 381).—This book discusses the various phases of swine production in much detail. Chapters are included on anatomy and physiology, selection and judging, origin of the domesticated swine races, the European breeds of the present day, breeding, feeding, management, slaughtering, and State and private agencies for the improvement of swine. An extensive discussion of swine diseases is given by W. Pfeiler in a chapter of 350 pages.

*Feeding work horses*, M. W. HARPER (*New York Cornell Sta. Bul.* 437 (1925), pp. 3-59).—This bulletin reports the results of comparisons of various rations for feeding work horses, which were in progress from November 9,

1910, to September 9, 1918. In conducting the tests the teams were divided so that one horse received one ration while the other horse received the contrasting ration for a test period, and in most of the tests a second period followed in which the rations were reversed. A recuperation period followed each test period, during which both horses of a team received a grain ration of half corn and half oats.

Records were kept of the feed consumption, monthly weights, hours of labor, condition and spirit of the animals, residual effect, and economy of the rations. The greater part of the work consisted of a comparison of oats and corn when fed with timothy hay. The grains were fed ground, whole, singly, and in combinations. All animals received a warm bran mash on Saturday nights. The main results of the experiments are summarized in the following table, which shows the kind and amount of grain and hay consumed per 1,000 lbs. live weight and the average gain or loss in live weight and the number of animals in poor condition during each experiment:

*Comparison of oats and corn for work horses*

Ex- peri- ment	Grain ration	Length of test period	Average gain	Average daily ration per 1,000 pounds live weight		Animals in the experiment	
				Grain	Timothy hay	Num- ber	Num- ber in poor condi- tion
		<i>Mos.</i>	<i>Pounds</i>	<i>Pounds</i>	<i>Pounds</i>		
1	{ Whole oats.....	6	-38.3	12.0	14.5	6	4
	{ Ground oats and corn meal 1:1.....	6	+22.5	11.6	13.8	6	1
2	{ Whole oats and shelled corn 1:1.....	7	-38.4	12.1	14.8	5	3
	{ Ground oats and corn meal 1:1.....	7	+25.8	12.0	15.4	5	1
3	{ Ground oats.....	6	-15.6	12.7	15.4	5	2
	{ Ground oats and corn meal 1:1.....	6	+17.4	12.7	15.3	5	1
4	{ Corn meal and wheat bran 9:1.....	6	-5.0	11.9	14.1	5	1
	{ Ground oats and corn meal 1:1.....	6	+16.0	11.0	13.4	5	1
	{ Ground oats.....	3	+2.5	11.7	14.4	6	0
5	{ Whole oats and shelled corn 1:1.....	3	-12.5	12.3	14.9	6	2
	{ Hominy, wheat feed, and oil meal 4:4:1.....	4-6	+23.0	12.5	14.6	10	1
6	{ Hominy and ground oats 1:1.....	4-6	+19.0	12.5	15.2	10	0
	{ Ground oats and hominy 1:1.....	6	+33.7	12.6	14.3	8	0
7	{ Ground oats and corn meal 1:1.....	6	+18.7	12.5	14.2	8	1
	{ Whole oats.....	6	-17.2	12.9	14.3	9	4
8	{ Whole oats and shelled corn 1:1.....	6	-18.9	12.5	13.7	9	4
	{ Ground oats and hominy 1:1.....	3	+12.1	12.8	12.8	12	1
9	{ Ground oats and corn meal 1:1.....	3	+9.2	13.1	13.2	12	2
	{ Whole oats.....	3	+2.7	12.8	12.8	11	2
10	{ Ground oats.....	3	+9.5	12.6	12.7	11	1
	{ Whole oats and hominy 1:1.....	6	+19.5	12.7	13.1	10	0
11	{ Ground oats and hominy 1:1.....	6	+40.5	12.5	12.9	10	0

The effects of the different rations were discussed with reference to health, spirit, and appetite of the animals. There was some irregularity among different horses, due to individuality and amount and kind of work, but it generally followed that "when the work was light or irregular in amount, oats, either whole or ground, gave good results, but when the work was severe and regular, continuing day after day, the addition of hominy or corn meal to the ration gave much better results."

Three other experiments are also reported in this bulletin in which the general methods of feeding were similar to those employed in the comparisons of oats and corn. In one of these experiments the usual ration of 15 or 18 lbs. of grain (ground oats and corn meal) and 16 or 18 lbs. of timothy hay was re-

placed by one containing two-thirds the amount of grain in the first test and three-fourths the amount of grain in the second test, with a sufficient increase in the hay to supply the same amount of total digestible nutrients. These tests were conducted by the reversal method, the first one being 112 days in duration and the second 100 days. In both tests the regular ration was found superior to the one containing less grain in its ability to maintain weight, spirit, endurance, and physical condition in the horses. High relative prices of grain as compared with hay, however, might make a reduction in the proportion of the grain in the ration desirable.

In another experiment consisting of three test periods of 52, 77, and 105 days in duration, long timothy hay was compared with timothy hay cut in about 0.5 in. lengths and fed with the grain. The horses receiving chopped hay consumed 0.3 lb. less hay and 0.3 lb. more grain per 1,000 lbs. of live weight than the other group. Chopped hay produced somewhat greater gains in body weight, and the general conditions of the horses seemed to be slightly superior.

In an experiment of 29 days' duration, alfalfa hay was compared with timothy hay and it was found that the horses receiving alfalfa hay required 0.6 lb. less grain and 0.6 lb. less hay per 1,000 lbs. of live weight, though they excelled their team mates in gains in weight, spirit, endurance, and in physical condition.

**Alfalfa and horses**, R. S. HUDSON (*Michigan Sta. Quart. Bul.*, 7 (1925), No. 3, pp. 75-79, fig. 1).—The results of the comparative feeding trials with rations of oats, corn, and timothy, and corn and alfalfa, in continuation of those previously reported (*E. S. R.*, 52, p. 570), are given. These trials carried the animals through the summer and fall. The results were very similar to those reported for the winter and spring, corn and alfalfa proving equal or slightly superior in maintaining weight, while the cost was less. The combined results of the four periods are summarized.

**The biology of the fowl**, E. EVANS (*Burnley, Eng.: John Dixon, Ltd.*, 1923, pp. 160, figs. 18).—The anatomy and physiology of the fowl are briefly discussed in relation to practical feeding, management, and breeding of poultry.

**On the length and variability of the bones of the White Leghorn fowl**, M. SCHNEIDER and L. C. DUNN (*Anat. Rec.*, 27 (1924), No. 5, pp. 229-239).—The usual biometrical constants have been calculated for the length and width of the cranium and the length of the humerus, ulna, femur, and tibia from the right side of 350 adult Single Comb White Leghorn females and 46 adult males which have not been closely inbred.

It was found that the variability was similar to that in other animals for like measurements and much less than for body weights in birds. The correlations between the different measurements as determined for the females were very high, ranging from  $0.562 \pm 0.049$  to  $0.943 \pm 0.004$ .

The constants obtained from this study are to be used in future investigations of the effect of inbreeding on the body size of White Leghorns at the Connecticut Storrs Experiment Station.

**Postnatal growth of the body, systems, and organs of the Single-Comb White Leghorn chicken**, H. B. LATIMER (*Jour. Agr. Research [U. S.]*, 29 (1924), No. 8, pp. 363-397, figs. 31).—This paper reports the results of an investigation at the Minnesota Experiment Station of the rate of postnatal growth of Single Comb White Leghorns from hatching to about 300 days of age, based on periodical live weights and the measurements and weights of various parts of the body and organs of over 100 birds killed at various ages.

The data obtained from the autopsies included weights of the dead animal, head, feathers, skin, comb and wattles, digestive tube full and empty, gizzard,

stomach, esophagus, crop and intestines, yolk sac, liver, pancreas, trachea and lungs, heart, thyroids, thymus, spleen, suprarenals, hypophysis, kidneys, ovaries and oviducts, testes, ligamentous skeleton, skeletal muscles, brain, spinal cord, and eyeballs, and measurements of the body length (tip of bill to anus), height (back to toe), left leg length (tip of toe to greater trochanter), left wing (tip of wing to proximal end of humerus), length of head, and dorsoventral and transverse diameter of the thorax.

The data are presented in the form of smoothed curves of both sexes, showing the relation of the different sizes of the body and organs to age and to body weight. The curve of growth in the chicken shows three phases, i. e., (1) a period of slow growth that includes a brief postnatal decrease, (2) a period of rapid growth, and (3) a period of slow growth. A similar type of growth was also found for the muscles, ligamentous skeleton, digestive tract, lungs, heart, kidneys, suprarenals, and integument. Sex differences were shown very soon after the beginning of the rapid growth period. The author has pointed out the peculiarities of the different curves.

**Poultry [experiments at the Utah Station],** B. ALDER (*Utah Sta. Bul.* 192 (1925), pp. 61, 62).—Progress reports on several experiments with poultry are given.

*Breeding for egg production.*—In endeavoring to produce a strain of fowls that will be heavy layers over a period of three years, a few outstanding individuals have been developed. One hen has produced 1,054 eggs, while others have produced over 600 eggs in three years.

*A study of incubation problems.*—In studying the time of hatching of birds with relation to their production it was found that April-hatched pullets gave slightly better results over a three-year period than pullets hatched in March, May, or June.

*Poultry feeding.*—The importance of protein feeds in addition to grain and mill by-products for egg production has been demonstrated, as well as the value of skim milk.

In other experiments, home-grown and home-mixed feeds have proved superior to corn and other imported and ready-mixed commercial feeds.

**Rearing early chicks,** C. G. CABD (*Michigan Sta. Quart. Bul.*, 7 (1925), No. 3, pp. 81-83).—A popular account of the nutritional requirements of chicks raised in confinement, with special reference to the need of direct sunlight and vitamins.

**The culling and feeding of poultry,** B. F. KAUPP (*N. C. Dept. Agr. Bul.*, 1924, Aug., pp. 40, figs. 23).—Popular directions are given for culling, feeding, and managing poultry, with special reference to the results of experiments conducted at the North Carolina Experiment Station.

## DAIRY FARMING—DAIRYING

**The intrauterine development of the bovine fetus in relation to milk yield in Guernsey cattle,** J. W. Gowen (*Jour. Dairy Sci.*, 7 (1924), No. 4, pp. 311-317).—This consists of a study of the effect of pregnancy on milk yields, based on the records reported in volume 31 of the Advanced Registry of the American Guernsey Cattle Club. Correlation coefficients between the 365-day milk yield and the duration of pregnancy, as determined by classifying the cows according to age in 6-months groups, varied from  $-0.021 \pm 0.059$  for cows of from 1.5 to 2 years of age to  $-0.275 \pm 0.022$  for cows of from 4 to 5 years of age and averaged  $-0.173$  for cows of all ages, thus indicating a reduction in the milk yield as a result of carrying a fetus. The butterfat content of the milk was apparently not influenced by pregnancy.

Further studies indicated that the cows having a greater productive capacity are more frequently not bred during lactation, or are bred at a much later stage in lactation than are cows having a lower productive capacity. By making allowance for this condition, the partial correlations determined between the length of time the calf is carried and the milk yield of the mother were for the second, third, and fourth months of lactation for cows from 3 to 3.5 years of age  $-0.151 \pm 0.028$ ,  $-0.112 \pm 0.028$ , and  $-0.099 \pm 0.028$ , and for cows from 3.5 to 4 years of age  $-0.183 \pm 0.031$ ,  $0.167 \pm 0.031$ , and  $-0.145 \pm 0.031$ , respectively. These constants thus indicate that even when the effect of the selection of cows of different productive capacities for early breeding is accounted for, there remains a significant correlation between the length of time the calf is carried and the milk yield of the mother.

Equations were also calculated for predicting the yearly milk yield, based on the monthly milk yield and pregnancy. The effect on the yearly milk yield of carrying a calf 9 months during lactation was found to reduce the yield from 342 to 628 lbs., which is equivalent to from 125 to 200 therms of energy.

**The production of cow's milk having antirachitic properties** [trans. title], LESNÉ and VAGLIANO (*Compt. Rend. Acad. Sci. [Paris]*, 179 (1924), No. 11 pp. 539-541).—Antirachitic properties were demonstrated for the milk and butter produced by a cow receiving 500 gm. of cod liver oil daily. Rickets occurred in young rats receiving butter from another cow, but this condition was cured when butter was supplied from the cow receiving the cod liver oil. The milk of this cow also tended to cure rickets in an infant.

**Contribution to investigations of milk** [trans. title], R. SCHMITT (*Milchw. Zentbl.*, 53 (1924), No. 1, pp. 1-5).—The specific gravity of the serum of milk was found in nearly all samples examined to decrease slightly when the milk coagulated.

**Pasteurization of milk**, G. L. A. RUEHLE (*Michigan Sta. Quart. Bul.*, 7 (1925), No. 3, p. 114).—A brief description of the process, with reference to the resulting changes.

**Fat droplets in pasteurized cream** [trans. title], O. RAHN and W. MOHR (*Milchw. Forsch.*, 1 (1924), No. 5-6, pp. 363-373, figs. 5).—Cream pasteurized by the flash method was found to churn when going through a pump. A microscopic examination of cream pasteurized by the flash method at the dairy institute at Kiel showed that in this cream the fat droplets were much larger than in raw cream or in cream pasteurized by the holding process. Pasteurization at the high temperature was found to injure the butter-making qualities, as the yield was reduced and the amount of fat lost in the butter-milk was increased. Cream pasteurized by the holding process had practically the same characteristics as raw cream. The physical properties of the butter were not altered through pasteurization by either method.

**Methods of dairy manufacture**, G. WILSTER (*Utah Sta. Bul.* 192 (1925), pp. 35, 36).—Two experiments were conducted in dairy manufacturing.

**Effect of clarification on quality of cheese**.—In a study of the quality of cheese as determined by the average scores of several judges, cheese made from clarified milk had a slightly higher score both at 1 and 3 months of age, the difference being 0.38 at the former and 0.87 at the latter age.

**Manufacture of butter from sweet cream**.—In butter-making experiments higher scoring butter has been produced at the station from a good quality of sweet cream which has been pasteurized and ripened to a low acidity than has been made by 197 other creameries located in several of the Western States. It was demonstrated that butter of excellent quality can be made by pasteurizing sweet cream, holding it at churning temperature, which should be

from 2 to 4° F. lower than for churning ripened cream, followed by churning the cream in a hand churn for from 40 to 50 minutes with a little more vigorous agitation than when churning ripened cream at a higher temperature.

**The water content of butter** [trans. title], O. RAHN (*Milchw. Forsch.*, 1 (1924), No. 5-6, pp. 294-315).—The effect of the season, temperature and duration of the churning, acidity of the cream, pasteurization, size of the fat globules and butter kernels, melting point of the fat, and the washing, working, and salting of the butter on the water content of the butter has been reviewed from the works of several investigators. It is concluded that the water content is independent of the fat content of the cream, but the following factors tend to increase the water content of the butter: Full churn, short churning period, soft fat, long working, high acidity of the cream, long washing period especially with warm water, and large fat globules. The water content is also dependent on the kind of butterfat, churning temperature, pasteurization of the cream, and salt.

**The air content of butter** [trans. title], O. RAHN and W. MOHR (*Milchw. Forsch.*, 1 (1924), No. 3-4, pp. 213-221, fig. 1).—Determinations of the air in butter by melting the sample in water in an air-tight container and collecting the air set free in a vacuum tube above have been made of 290 samples of butter at the Dairying Institute at Kiel.

The average air content was 4.2 cc. per 100 gm. of butter, the variations being 0.97 to 8.38 cc. in the different samples. Individual dairies tended to produce butter having a rather uniform air content. The season of the year also affected the amount of air present, it being high from June to October. Various conditions of manufacture and the characteristics of individual milks also had some influence.

**The air content of margarine** [trans. title], O. RAHN and W. MOHR (*Milchw. Forsch.*, 1 (1924), No. 5-6, pp. 360-362).—Determinations of the air content of margarine by the method used for butter (see above) have indicated much variability in the samples, but the air content of margarine is in general considerably higher than that of butter. Some of the air may be removed by prolonged working, which does not injure margarine as it does butter.

**The relation between yeasts and moulds and the keeping quality of butter**, D. B. SHUTT (*Jour. Dairy Sci.*, 7 (1924), No. 4, pp. 357-360).—Based on the changes in flavor and the mold and yeast counts of 21 samples of butter at the Manitoba Agricultural College, it was shown that the samples containing the lower counts tended to decrease less in flavor during the six months' storage at 10° F. than samples nearly free from yeasts and molds.

**Farm ice cream making**, P. S. LUCAS (*Michigan Sta. Quart. Bul.*, 7 (1925), No. 3, pp. 105, 106).—Directions for making ice cream on the farm and formulas for three types.

**Measuring quality in ice cream**, R. C. FISHER and H. F. JUDKINS (*Jour. Dairy Sci.*, 7 (1924), No. 1, pp. 31-39).—Essentially noted (E. S. R., 51, p. 79).

**Dry milk** [trans. title], K. LENDRICH (*Milchw. Forsch.*, 1 (1924), No. 5-6, pp. 251-293).—The results of studies of the biological, physical, and chemical properties of raw, evaporated, and dried milk are given from the Hygienic Institute at Hamburg. The properties of the remade milk were much the same as raw milk, except that the acidity was considerably reduced by the condensation and drying process. The influence of storage, atmospheric moisture, and homogenization on the composition of the dried milk was also studied.

**Sodium hypochlorite.**—IV, The phenol coefficient and relative disinfecting power of sodium hypochlorite, H. F. ZOLLER and S. M. EATON (*Jour. Dairy Sci.*, 7 (1924), No. 4, pp. 318-329).—Several organisms were used in determining the phenol coefficient of the disinfecting powers of sodium hypochlorite at the research department of the Nizer laboratories. The coefficients determined for sodium hypochlorite with the different organisms were as follows: Typhoid 233.3, tubercle bacilli 42.8, alkaligines 100, anthracis 160, *Bacterium neapolitanum (coli)* 200, gonococcus 280, and proteus 330. The H-ion concentration of the disinfectant apparently had no influence on the disinfecting properties at the concentrations used. Sodium hypochlorite was slightly superior to mercuric chloride when *B. neapolitanum* was used.

## VETERINARY MEDICINE

**Report on the Civil Veterinary Department (including the Insein Veterinary School), Burma, for the year ended the 31st March, 1924,** A. BLAKE (*Burma Civ. Vet. Dept. Rpt.*, 1924, pp. [6]+31, pl. 1).—This report (E. S. R., 50, p. 77) includes an account of the occurrence of and control work with contagious diseases of livestock.

[Annual reports of the chief veterinary research officer of Kenya Colony for the years 1922 and 1923], J. WALKER and W. KEARNEY (*Kenya Colony Dept. Agr. Ann. Rpts. 1922, pp. 67-103; 1923, pp. 43-62*).—An extended report is given on the occurrence of diseases of livestock and the control work conducted.

**Handbook of pharmacology including materia medica,** B. N. GHOSH (*Calcutta: Hilton & Co.*, 1923, pp. XII+396).—This handbook, which is designed for students of pharmacology, contains a brief section on materia medica, followed by a longer section on pharmacology in which the drugs discussed are classified chiefly on the basis of the organs on which they have their main effect.

**Critical tests of miscellaneous anthelmintics,** M. C. HALL and J. E. SHILLINGER (*Jour. Agr. Research [U. S.]*, 29 (1924), No. 7, pp. 313-332).—This is a report of critical tests of a number of drugs, consisting in their administration in definite known doses to animals, with subsequent collection for a suitable length of time of all worms passed and the post-mortem examination of the animals with the collection of all worms then present.

The work has shown that a mixture of carbon tetrachloride 3 parts, by volume, and chenopodium 1 part, at the rate of 0.3 cc. per kilogram, accompanied by 0.125 to 0.5 grain arecoline hydrobromide will maintain the rather high efficiency of 90 per cent against ascarids, but is considerably less efficacious against hookworms as compared with its constituents without the arecoline hydrobromide, removing only 46 per cent, and it fails entirely to remove tapeworms. The arecoline hydrobromide appears to diminish the efficacy of the other drugs against hookworms, possibly by its very rapid purgative action, purgation commonly occurring in from half an hour to an hour, and, so far as can be judged from two cases, the efficacy of the arecoline hydrobromide against tapeworms suffers a diminution from the presence of the two other drugs.

“Benzyl phenol proved only slightly anthelmintic for hookworms, removing only about 5 per cent of the hookworms present. Ethylene dichloride proved only slightly effective against hookworms when given at a dose rate equivalent to the therapeutic dose rate for carbon tetrachloride. Ferrous sulfate in large doses showed very little efficacy against whipworms, and is evidently not de-

pendably effective in single doses for removing these worms. Chenopodium intramuscularly failed to remove whipworms from two infested dogs. Intravenously it removed only one whipworm from each of two infested dogs, showing that the drug has some anthelmintic action when thus given, as Lambert had found, but also showing a lack of dependable action even in dangerous doses. Novarsenobenzol subcutaneously failed to remove any whipworms from the one dog on which the drug was thus tested. Intravenously in single dose to one dog and in two doses to another it failed to remove any whipworms. Tartar emetic in single dose intravenously to three dogs failed to remove any whipworms. A proprietary remedy for tapeworm in dogs removed only 9 per cent of the tapeworms present.

"Magnesium sulfate simultaneously administered with lethal doses of chenopodium to dogs protected them from the toxic effects of the chenopodium, three out of four animals surviving the dose. Hall has shown that castor oil or calomel will protect dogs against the toxic effects of lethal doses of such drugs as chenopodium and male fern, from which it appears that the protective action of magnesium sulfate is due not only to its salt action but also to its purely purgative action. Our experiments also show that magnesium sulfate simultaneously administered with therapeutic doses of chenopodium does not diminish the efficacy of the chenopodium against ascarids, and suggest that the same is true as regards effect on hookworms. The writers have previously shown that the magnesium sulfate simultaneously administered with carbon tetrachloride does not diminish the efficacy of this drug against hookworms.

"Carbon tetrachloride, given with magnesium sulfate, will remove hookworms and nodular worms from monkeys, but the exact efficacy is unknown. Carbon tetrachloride given to sheep in doses of 10 cc., followed immediately by 128 gm. of magnesium sulfate, shows 100 per cent efficacy against stomach worms, nodular worms, and small trichostrongyles. Previous evidence from other experiments indicates that it is also 100 per cent effective against hookworms. When thus administered with magnesium sulfate there is a marked increase in efficacy against tapeworms, this treatment removing 33 per cent of these worms instead of being almost entirely ineffective. . . .

"Arsenic in the 30-grain dose ordinarily recommended for worms in horses apparently failed entirely to remove any stomach worms, palisade worms, or cylicostomes from a horse. Copper sulfate (8 gm.) in solution apparently failed entirely to remove any stomach worms, palisade worms, or cylicostomes from a horse. Novarsenobenzol intravenously for 4 days for a total amount of 14.4 gm. failed to kill strongyles (*Strongylus vulgaris*) in a verminous aneurism in a horse."

A list of 43 references to the literature cited is included.

**The wandering of certain nematode larvae in the body of their hosts,** [F.] FÜLLEBORN (*Jour. Parasitol.*, 11 (1924), No. 2, pp. 98, 99).—This is an abstract of an address delivered by the author in Baltimore in November, 1923, an earlier account of which work has been noted (*E. S. R.*, 48, p. 680).

The author's investigations, now in progress, indicate that with *Oxyuris* (*Enterobius*) *vermicularis* there is no migration in the liver and lungs, and that *Enterobius* can, perhaps, reproduce in the intestine of its host in the same way as does *Rhabditis hominis*.

**Chemical changes in the blood and their clinical significance,** V. C. MYERS (*Physiol. Rev.*, 4 (1924), No. 2, pp. 274-328).—Included in this account is a bibliography of 11 pages.

**Anaerobic infections in animals,** S. H. GAIGER (*Vet. Rec.*, 4 (1924), Nos. 47, pp. 986-989; 48, pp. 1003-1014).—This account, by the director of the Animal

Diseases Research Association Laboratory, deals with the *Bacillus chauvoei*, *Vibrio septique* (Pasteur, 1877), *B. welchii* (Migula, 1900), *B. oedematiens* (Weinberg and Séguin, 1915), *B. histolyticus* (Weinberg and Séguin, 1915), *B. sporogenes* (Metchnikoff, 1908), and *B. botulinus* (Van Ermengem, 1896). The paper includes a list of 54 references to the literature.

**Anaplasmosis in Chile** [trans. title], J. DESCAZEUX (*Bul. Soc. Path. Exot.*, 17 (1924), No. 8, pp. 639-642).—The author reports that anaplasmosis is the cause of a large number of deaths among cattle in Chile in the vicinity of Traiguén, the symptoms observed being those of acute anemia with a predominance of nervous manifestations. The parasite found in the red corpuscles resembles *Anaplasma argentinum*. The incubation period was found through inoculation to be from 25 to 30 days. The animals recover after 8 to 10 days, but are never really fit for work. Sheep are very susceptible to anaplasmosis in Chile.

**Rats as possible carriers of foot-and-mouth disease**, J. M. BEATTIE and D. PEDEN (*Jour. Path. and Bact.*, 27 (1924), No. 4, pp. 415-424, figs. 4).—This is a detailed report of the experimental transmission of this disease to rats and of the examination of wild rats, a brief account of which has been previously noted (*E. S. R.*, 51, p. 83).

**Experiments on active immunization against foot-and-mouth disease** [trans. title], O. WALDMANN and K. TRAUTWEIN (*Arch. Wiss. u. Prakt. Tierheilk.*, 50 (1923), No. 3, pp. 229-236).—Data are reported on the immunization of cattle against foot-and-mouth disease by the subcutaneous injection of virulent guinea pig blood.

Of 30 cattle tested for susceptibility to foot-and-mouth disease, 13 were selected as highly susceptible, and were injected subcutaneously with from 1 to 27 cc., or intravenously with 15 cc., of virulent guinea pig blood and tested for immunity in from 15 to 21 days by intracutaneous or intravenous injections of virulent swine lymph. Of the 30 animals, only two, the ones injected with 1 cc. of virulent blood, showed any signs of reaction. In these two there was a slight rise in temperature accompanied by local reaction. This was attributed to the small dose employed. Similar experiments were conducted on calves and swine but with less favorable results.

**Foot-and-mouth disease** (*Vet. Rec.*, 5 (1925), No. 1, pp. 3, 4).—This is a comparison of the slaughter and isolation methods of combating foot-and-mouth disease, prepared by the Ministry of Agriculture, England.

**Tick biting experiments in bovine and cervine piroplasmiasis**, H. C. CLARK and J. ZETEK (*Amer. Jour. Trop. Med.*, 5 (1925), No. 1, pp. 17-26).—A survey of the disease among domestic and wild animals made in the lower part of the basin of the Chagres River in Panama, in 1917, led to the discovery of piroplasmiasis in the native cattle of the basin and in the white-tailed deer (*Odocoileus chiriquensis* Allen). Of 10 deer killed, 4 were found to contain piroplasms with the characteristics of those occurring in cattle. Of 42 white-tailed deer killed by a hunting club, only one gave evidence of serious illness. This animal, extremely emaciated and most heavily infested with ticks, was found to be suffering from a verminous broncho-pneumonia and liver fluke disease and had an associated acute attack of piroplasmiasis. The vast majority of the ticks removed from this deer proved to be *Margaropus annulatus australis*, but there were also a large number of *Amblyomma cajennense* present. Nearly all the deer were in prime physical condition, yet the majority revealed piroplasms in some of the capillary blood cells of brain films, and in a few cases long searches revealed them in blood films of the peripheral circulation.

In one instance in tick transmission experiments the progeny of ticks removed from the sick deer were capable of producing a mild attack of piroplasmosis in a half-breed, nonimmune calf. The ticks in question were *M. annulatus australis*. In another instance a mild attack of piroplasmosis was produced in a brocket deer (*Maxama sartorii reperticia* Goldm.) through attachment to the animal in a massive manner by the progeny of *M. annulatus australis* taken from prime beef cattle at the time these animals were slaughtered in Panama City.

It is thought probable that cervine and bovine Piroplasma are identical. If not, then *M. annulatus australis* is capable of being a carrier agent for two types of Piroplasma. The practical value of these experiments is the indication that the deer makes an important reservoir for cattle piroplasmosis.

**Bayer 205 (Naganol) and the treatment of trypanosomiasis in animals** [trans. title], R. VAN SACEGHEM (*Compt. Rend. Soc. Biol. [Paris]*, 91 (1924), No. 37, pp. 1452-1454).—The author finds this therapeutic agent to be more active in its effect on *Trypanosoma congolense* than it is on *T. vivax*. For use against infections of *T. vivax* it is not as effective as tartar emetic, and against *T. congolense* it does not appear to be more effective than emetic-atoxyl.

**Establishing a tuberculosis-free dairy herd**, S. E. B. (*Jour. Min. Agr. [Gt. Brit.]*, 31 (1924), No. 2, pp. 138-149).—This is a discussion of the subject as applied to conditions in Great Britain.

**Infectious abortion investigations**, H. F. LIENHARDT, C. H. KITSELMAN, and C. E. SAWYER (*Kansas Sta. Tech. Bul.* 14 (1925), pp. 4-23, fig. 1).—The investigations reported covered a period of five years ended June 30, 1924.

Bacterial examination of vaginal discharges, afterbirths, aborted fetuses, and milk from 119 cows which had aborted gave the following results: *Bacterium abortus* 21, *B. abortus* plus other organisms 20, pathogenic organisms other than *B. abortus* 59, and no organisms 19. These results confirm those of an earlier progress report (E. S. R., 49, p. 477) indicating that *B. abortus* is not the sole cause of abortion disease. In the isolation of the organism from infected material, the most satisfactory medium proved to be 2 per cent glucose, 2 per cent glycerin agar, pH 7.2, with 10 per cent horse serum in sealed jars with 10 per cent CO<sub>2</sub> gas.

An attempt was made to produce experimental lesions in two heifers by intraperitoneal injections of large doses of the organism grown in pure culture. After 30 days the animals were killed and autopsied. No changes of a pathological nature could be detected in either animal, but from one the organism was isolated in pure culture. In both of the animals there was a decided rise in the number of agglutinins in the blood serum.

An examination of 20 strains of *B. abortus* showed no differences in either morphology or sugar reactions in all but three of the strains. These were found to be members of a colon subgroup. In cross agglutination tests, the identity of the 17 strains and the nonidentity of the others were also established.

Attempts at immunity production were made in a small experimental herd of 12 cows. This was divided into four groups, three of which were vaccinated, bred, and then fed *B. abortus*-contaminated feed and water. The groups were treated as follows: (1) Three animals were injected subcutaneously at weekly intervals with 3 doses of physiological saline suspension of *B. abortus* heated for one-half hour at 60° C., (2) 3 were injected in the same manner with a suspension of *B. abortus* killed by 1 per cent formalin, and (3) 4 were injected subcutaneously with 5 doses of living organisms suspended in physiological salt solution. In the first group all of

the animals gave positive agglutination tests immediately after the third injection, and the tests remained positive for about 7 weeks. Two of the 3 animals aborted. In the second group the response to the agglutination test was similar to the first group and 1 cow aborted. In the third group the agglutination tests were more strongly positive and continued positive for a longer time than in the other two groups. There was one abortion in this group. Both of the unvaccinated controls calved normally.

The number of animals used in the immunization tests is considered too small to warrant drawing final conclusions, but it is considered significant that the abortions all occurred among the vaccinated animals.

**Vaccination against bovine infectious abortion** [trans. title], W. ZWICK (*Berlin. Tierärztl. Wchnschr.*, 40 (1924), No. 48, pp. 673-676).—The literature on attempts at immunization against *Bacterium abortus* infection by the use of killed and living cultures of the virulent organism is reviewed, and the results are reported of immunization experiments conducted on five herds.

All of the pregnant animals were tested serologically and those giving positive reactions were given two subcutaneous injections at intervals of from 10 to 14 days of a suspension of live organisms in physiological salt solution. The negatively reacting pregnant animals were similarly treated with killed cultures, and the nonpregnant animals received the same treatment as the positively reacting pregnant ones.

Of 23 positively reacting pregnant animals, 3 aborted, and of 30 negatively reacting animals treated with killed cultures, 6 aborted. Three negatively reacting pregnant animals were vaccinated in the second month of pregnancy with living cultures and all calved normally. A fourth which was vaccinated 2 and 14 days after conception also calved normally. It is concluded that the use of living cultures early in pregnancy is a safe procedure.

**Actinobacillosis in Australian cattle**, S. DODD (*Agr. Gaz. N. S. Wales*, 35 (1924), No. 11, pp. 807-812).—A brief report of investigations of this disease, which has been under the author's observation in abattoirs near Sydney for some years.

**Blackleg and gas gangrene in cattle** [trans. title], E. LECLAINCHE and H. VALLÉE (*Compt. Rend. Acad. Sci. [Paris]*, 178 (1924), No. 25, pp. 2024-2027; also in *Rev. Gén. Méd. Vét.*, 33 (1924), No. 391, pp. 357-361).—A brief résumé is given of studies conducted by the authors, with the collaboration of Glover and Pincemin, on blackleg and allied diseases of cattle.

In the experience of the authors *Bacterium chauvoei* isolated from gas gangrene is characterized by being nonpathogenic for horses, virulent for calves and guinea pigs, incapable of producing in the peritoneal cavity of guinea pigs long forms of unequal dimensions, and incapable of agglutination in concentrations of less than 1:50 with a septic antivibrion serum which agglutinates in 1:1,000 with cultures of *Bacillus septicus*. An authentic culture of *B. septicus* is avirulent for cattle by subcutaneous inoculation and highly pathogenic for the horse and guinea pig. In the guinea pig the cultures are long and of unequal length. This organism is not agglutinable in dilutions above 1:50 with serum which agglutinates *B. chauvoei* in dilutions above 1:20,000. Immunity reactions with these two species are quite specific.

In addition to these two organisms there may be isolated other types morphologically and biologically identical and capable of provoking symptoms of gas gangrene quite analogous to but not identical with blackleg. Finally, there are types resembling in some degrees *B. chauvoei* and in others *B. septicus*. The presence of so many organisms is thought to justify the use of attenuated polyvalent vaccines in place of toxins and aggressins.

**Preparasitic stages in the life history of the cattle hookworm (*Busotomum phlebotomum*),** B. SCHWARTZ (*Jour. Agr. Research [U. S.]*, 29 (1924), No. 9, pp. 451-458, figs. 4).—This is a report of studies of a hookworm which is believed by Dawson (E. S. R., 18, p. 877) to be the cause of that condition of cattle commonly known as "salt sick." It is pointed out that, with the exception of a study of Conradi and Barnett (E. S. R., 20, p. 382), none has been made of the life history of this parasite.

The author finds that, under laboratory conditions, at a temperature of from 70 to 80° F., the eggs of *B. phlebotomum* hatch in about 96 hours. "The first-stage larvae are found in lethargus 24 hours after hatching and 24 hours later the second lethargus is in progress. After a second lethargus, which lasts at least 24 hours, third-stage larvae emerge, the complete cycle of development up to this stage requiring a minimum of 7 days. In liquid cultures both cuticles are usually retained by the larvae, whereas in solid cultures the first cuticle is cast off. Observations on the loss of the first skin by infective larvae from liquid cultures indicate that contact with some solid object is necessary for exsheathing, and that in a liquid medium this process does not ordinarily take place.

"Infective larvae are only moderately active at room temperature, but may be readily stimulated to activity by mechanical factors. These larvae appear more resistant to an unfavorable environment than do preinfective larvae. Infective larvae are positively thermotropic and orient themselves in such a way that the cephalic extremity becomes directed to the source of heat, toward which the larvae swim rapidly. . . . The infective larvae succumb to desiccation, but can maintain their vitality under conditions which afford a slight amount of moisture. The infective larvae are positively phototropic, collecting in the lightest portion of the culture medium. They also crawl up the walls of culture bottles, but whether the latter is to be interpreted as a negative geotropism or is due to the positive phototropism of the larvae is not certain.

"Under experimental conditions the larvae show no tendency to penetrate the skin. Attempts made by various writers to correlate the behavior of various strongyle larvae with their skin-penetrating habits appear to be untenable from the data presented in this paper and from data obtained by others."

\*A list is given of 15 references to the literature cited.

**Experimental investigations on immunization against swine erysipelas, with special regard to susceptibility** [trans. title], W. SCHMIDT (*Arch. Wiss. u. Prakt. Tierheilk.*, 50 (1924), No. 4, pp. 341-350).—The chief point brought out in this experimental study of the immunization of mice against swine erysipelas by the simultaneous method is the necessity of a proper balance between serum and virus so that there shall be sufficient virus to stimulate the production of antibodies but not to exceed the protective power of the serum. The more sensitive the subject the longer is the time required for antibody formation. The immunity can be prolonged in most cases by a second injection of a less virulent culture after the establishment of immunity by means of the simultaneous treatment.

In the practical application of these results to the immunization of swine, the second injection is recommended unconditionally for animals which are sensitive to this disease, while for more resistant races the single simultaneous injection is considered sufficient.

**A contribution to the knowledge of hyphomycosis destruens**, J. WITKAMP (*Bijdrage tot de Kennis van de Hyphomycosis Destruens. Proefschr., Veeartsenijk. Hoogesch. Utrecht*, 1924, pp. 139, pls. 16).—This is a general

review of the knowledge of hyphomycosis of horses, also known as hyphomycosis destruens equi, leeches, and bursattee, with references to the literature and a report of investigations conducted by the author. A bibliography of five pages is included.

**Leptospiral jaundice in dogs (yellows)**, C. C. OKELL, T. DALLING, and L. P. PUGH (*Vet. Jour.*, 81 (1925), No. 595, pp. 3-35, figs. 3).—Clinical and pathological observations and experimental work have led to the conclusion that the commonly occurring enzootic jaundice of dogs is due to infection with *Leptospira icterohaemorrhagiae*, which, in Great Britain, is normally carried by a considerable percentage of rats.

[**A vitamin deficiency disease of poultry in California**], J. DRYDEN (*Country Gent.*, 89 (1924), No. 48, p. 32).—This article refers to a disease which closely resembles roup, investigated by J. R. Beach (*E. S. R.*, 50, p. 871), and found to be a nutritional disease due to the lack of vitamin A.

**The bacteriological study of fowl typhoid and allied infections with special reference to three epidemics**, J. W. EDINGTON (*Jour. Path. and Bact.*, 27 (1924), No. 4, pp. 427-437).—In connection with a study of the organisms isolated from three epidemics of white diarrhea in chickens, pure cultures of the organisms responsible for fowl typhoid and allied diseases were examined as to morphology, cultural characteristics, fermentation reactions, and agglutination and complement fixation tests, particular attention being paid in the serological tests to a possible differentiation between *Bacillus gallinarum* and *B. pullorum*. The results obtained are summarized and compared with those reported by Hadley et al. (*E. S. R.*, 40, p. 685) and other investigators.

The classification adopted as the result of this study differs slightly from that of Hadley, and is as follows: (a) Fowl cholera, due to *B. avisepcticus*; (b) fowl typhoid group, due to *B. gallinarum* and *B. pullorum*; (c) infections due to *B. rettgeri*; and (d) infections due to *B. pfaffi*. No difference could be detected in the agglutination and complement fixation tests between *B. pullorum* and *B. gallinarum*.

A study of the organisms isolated in the three epidemics showed them to be identical and to belong to the pullorum group.

**European fowl pest found in poultry in the United States**, J. R. MOHLER (*Vet. Med.*, 20 (1925), No. 2, pp. 57, 58).—This is a brief summary of information on this disease, which has been found to occur in New York City, Jersey City, and Philadelphia.

**The outbreak of the European fowl pest**, B. F. KAUPP (*Vet. Med.*, 20 (1925), No. 2, pp. 63, 64).—A brief account of this disease, which was discovered, about the middle of December, 1924, in the vicinity of New York City.

**The new poultry disease**, H. J. STAFSETH (*Michigan Sta. Quart. Bul.*, 7 (1925), No. 3, pp. 83-85).—This is a discussion of the symptoms, lesions, diagnosis, and prevention of a poultry disease similar to or identical with European fowl plague, which was found in the poultry markets in Detroit in January, 1925.

[**The use of calcium cyanide in the**] **killing of condemned chickens**, C. W. WINCHELL (*Rural New Yorker*, 84 (1925), No. 4830, p. 76).—In the course of control work with European fowl pest, the destruction of some 25,000 or 30,000 birds was successfully accomplished by the Jersey City Board of Health through the use of calcium cyanide. The method is said to be very simple, 1 lb. of calcium cyanide being used for about 2,000 fowls. The fowls destroyed were in the regulation live poultry cars, in shipping crates, in a box car, or in a large covered automobile truck. Where the birds were in exposed places calcium cyanide dust was blown on them from the windward side, and where

they were in a box car or inclosed truck 1 lb. of calcium cyanide flake was sprinkled on the floor for each 2,000 birds. Fowls died within one or two minutes, almost without struggling.

## RURAL ENGINEERING

**Ground water in Santa Clara Valley, California, W. O. CLARK** (*U. S. Geol. Survey, Water-Supply Paper 519 (1924), pp. VII+209, pls. 19, fig. 20*).—This report, prepared in cooperation with the Department of Engineering of the State of California, deals with the ground water of an area of 380,000 acres extending southeastward from San Francisco. It has been found that the ground water of Santa Clara Valley is on the whole satisfactory for both domestic use and irrigation. A few wells have water that is not considered good for domestic use or is said to be injurious to plants. The largest group of such wells is in a small area with meager water supply. All the wells of this locality are of small yield, and many of them can be pumped dry with an ordinary windmill.

**Surface water supply of North Atlantic slope drainage basins, 1922** (*U. S. Geol. Survey, Water-Supply Paper 541 (1925), pp. VI+258, pls. 2*).—This report, prepared in cooperation with the States of Maine, New Hampshire, Vermont, Massachusetts, New York, and New Jersey, presents the results of measurements of flow made on streams of the North Atlantic slope drainage basins during the year ended September 30, 1922.

**[Irrigation experiments at the Utah Station], D. W. PITTMAN and G. STEWART** (*Utah Sta. Bul. 192 (1925), p. 24*).—It is stated that in the course of irrigation experiments it has been definitely established that the heavier the irrigation treatment the more rapid is the exhaustion of the soil.

**Pumping for drainage in the San Joaquin Valley, California, W. W. WEIR** (*California Sta. Bul. 382 (1925), pp. 3-38, figs. 18*).—This bulletin reports an attempt to gather together and correlate some of the important data on pumping for the drainage of irrigated lands in the San Joaquin Valley, Calif.

It is stated that the cost of drainage by this method compares favorably with that of any other method yet tried, although the cost of operation is more. It has been found that more effective drainage may be accomplished by pumping than by tile or open drains because of the flexibility of the pumping system and the greater depth to which it is economically feasible to lower the water table. The pumped water is readily available for irrigation and compensates in part for the cost of drainage by this method.

**Public Roads, [February, 1925]** (*U. S. Dept. Agr., Public Roads, 5 (1925), No. 12, pp. 22, figs. 19*).—This number of this periodical contains the status of Federal-aid highway construction as of January 31, 1925, and a list of the 48 States and Hawaii showing their apportionment of Federal-aid funds for the fiscal year 1926, together with the following articles:

Impressions of English Highway Practice, by A. B. Fletcher; Percentage of Water Freezable in Soils, by A. W. Wintermyer (see p. 719); A Study of Motor Vehicle Accidents in Montana, Oregon, and Washington, by A. C. Rose; Crushed Stone Tests and Their Relation to the Service of the Finished Pavement, by A. T. Goldbeck; and Reinforced Concrete Pavement Survey, by C. A. Hogentogler.

**Rural highway mileage, income, and expenditures, 1921 and 1922, A. P. ANDERSON** (*U. S. Dept. Agr. Bul. 1279 (1925), pp. 88*).—A large amount of data on the subject is tabulated. These data show that on January 1, 1922, the rural public roads of the 48 States had a total length of 2,941,294 miles

and involved a disbursement of \$1,036,587,772 during the year 1921. Of the total road mileage, 387,760 miles had been improved with some form of surfacing when the year 1922 began.

Of the individual States, Indiana at the beginning of 1922 had the largest mileage of surfaced roads, a total of 39,857 miles, of which 30,801 miles were gravel. California led the States in the mileage of concrete roads, with 2,613 miles, followed by Illinois with 1,534 miles. Ohio was first in the mileage of brick roads and Florida second, while Oregon was first in mileage in bituminous concrete, followed closely by New Jersey. During the year 1921 a total of 41,171.7 miles of road were improved with some form of surfacing, and 34,456.3 miles were thus improved during 1922.

**Highway transportation costs**, T. R. AGG and H. S. CARTER (*Iowa Engin. Expt. Sta. Bul. 69 (1924), pp. 32, figs. 6*).—This publication presents a discussion of highway transportation costs, which is an outgrowth of a rather prolonged study of the various factors affecting vehicle operating cost, such as rolling resistance and the relation between road types, fuel consumption, and general operating costs of vehicles, and which has been carried out for the most part by the Engineering Experiment Station of Iowa State College in cooperation with the U. S. D. A. Bureau of Public Roads. The discussion of the economic principles involved in providing highway transportation at the minimum cost is intended to show the nature of the problems involved, and concerns itself with both vehicle and highway costs.

**United States Government specification for lubricants and liquid fuels and methods for testing** (*U. S. Dept. Int., Bur. Mines Tech. Paper 323A (1924), pp. VII+89, figs. 21*).—The text of these specifications is presented in detail.

**Tetralin**, F. NATHAN (*Fuel, 3 (1924), No. 10, pp. 346-349*).—Data on the history, manufacture, and use of tetralin for fuel in internal-combustion engines are presented. Tetralin is a colorless, stable hydrocarbon, and is considered to be a liquid fuel of considerable value. Owing to its high boiling point it can not be used undiluted as a motor fuel, but it has been found very suitable for that purpose when mixed with gasoline, benzol, or alcohol.

Comprehensive tests conducted at the Berlin Technical High School have shown the most satisfactory results with a mixture of equal parts of tetralin and ordinary gasoline, these being approximately equal to those obtained with benzol. Tetralitbenzol is a mixture of benzol, alcohol, and tetralin, and is called "Reichskraftstoff" in Germany. This fuel has a calorific value of 8,350 calories. It produces no carbon deposit and has, on the other hand, been found capable of thoroughly dissolving such deposits, which are removed in a few days by the escaping gas.

Tests conducted in England at the Government Fuel Research Station showed that mixtures of tetralin and gasoline containing less than 50 per cent of tetralin are apparently quite suitable for use in ordinary 4-cylinder automotive engines without any special adjustments. In every case it was found that mixtures of tetralin and gasoline are not so good as gasoline alone, either in flexibility of running, maximum power obtained, or thermal efficiency, but the inferiority is not sufficiently marked to preclude the use of tetralin, especially if it is slightly cheaper than gasoline. There were indications that a higher compression ratio may be used with mixtures of tetralin and gasoline than with gasoline alone. When the mixture of gasoline and tetralin contained more than 50 per cent of tetralin, the engine could be operated, but was much less flexible and the power and efficiency were decreased considerably. It was found in general that as the proportion of tetralin in the fuel increases the faults associated with incomplete combustion also increase.

**Wind power for farm electric plants**, F. J. PANCRATZ (*Mech. Engin. [New York]*, 46 (1924), No. 11, pp. 675-682, figs. 10).—A rather technical discussion is presented on test data on a 15-ft. wheel, losses due to air drag, the best size of wheel for farm electric light plants, and a combination plant for generating electric power and pumping.

The data as a whole indicate that the characteristics of a windmill are not favorable for large units. A 20-ft wheel is about the largest size that can be used and give satisfactory results for generating electric power. The smaller sizes of wheel are considered to offer a cheap and reliable means of supplying the average farmer or isolated places with the necessary electric power and water, and the first cost, cost of operating, and depreciation are said to compare very favorably with those of gasoline lighting plants.

**Ploughing without turning the furrow, in Austria**, H. KALLBRUNNER (*Internatl. Rev. Sci. and Pract. Agr. [Rome]*, n. ser., 1 (1923), No. 3, pp. 587-594, pl. 1).—The method in vogue in Austria of plowing without turning the furrow is described and illustrated, and some of the advantages claimed for this process are enumerated. The method is based on the principle that it is necessary to avoid the making of clods, which are extremely difficult to break up. The best implement for this operation is said to be an ordinary plow from which the moldboard for turning the furrow has been removed. As a rule, an attempt is made to break up the soil to as great a depth as possible. In the spring before seeding cultivators alone are used, and no attempt is made to break up the subsoil completely.

The use of wide, light harrows is also recommended. Practical experiments have shown that by breaking up the soil twice in this manner instead of once has resulted in a saving of labor of from 30 to 40 per cent.

**Motorized soil cultivation**, B. SIEVERS (*Motorische Bodenbearbeitung. Neudamm, Germany: J. Neumann, 1924, pp. 99+[3]*).—This treatise deals with the practical phases of the subject, with particular reference to the requirements of German agriculture. It contains a discussion of the scientific bases of soil cultivation, and describes different cultivation methods. Reasons for the selection of different motorized plowing systems are enumerated, and the practical features of motorized cultivation are outlined in some detail.

**A study of threshing losses from different types of harvester-threshers and headers and threshers on the Nephi-Levan ridge**, A. F. BRACKEN (*Utah Sta. Bul. 192 (1925), p. 23*).—Tests of threshing losses from about 12 harvester-threshers showed that the losses varied from about 4 lbs. to nearly 20 lbs. per acre for the harvester-threshers. This is considered to be a surprisingly low loss. In most cases the loss from the headers equaled that from the combines, and in addition the stationary gave a loss of about 1.75 per cent.

**Drying by means of air and steam**, E. HAUSBRAND, trans. by A. C. WRIGHT (*London: Scott, Greenwood & Son, 1924, 3. rev. Eng. ed., pp. VIII+77, pls. 2, figs. 7*).—This book, translated from the German, presents mathematical formulas and tabular data for calculating the dimension of apparatus, for drying wet material by means of air, and for determining the consumption of air and heat in such drying apparatus. Chapters are included on calculation of the maximum weight of saturated aqueous vapor which can be contained in 1 kg. of air at different pressures and temperatures; calculation of the necessary weight and volume of air and of the least expenditure of heat for drying apparatus with heated air at atmospheric pressure; drying apparatus in which in the drying chamber a pressure higher or lower than that of the atmosphere is artificially maintained; drying by means of superheated steam without air; and heating surface, velocity of the air current, dimensions of the

drying room, surface of the drying material, and losses of heat. An appendix of metric conversion diagrams is also included.

**Studies on the biology of sewage disposal**, M. HOTCHKISS (*Jour. Bact.*, 9 (1924), No. 5, pp. 437-461, figs. 7).—Two contributions from the New Jersey Experiment Stations and the New Jersey State Department of Health are presented.

*A survey of the bacteriological flora of a sewage treatment plant.*—By the use of the dilution method employing different media, the bacterial population in a sewage disposal plant was divided into arbitrary groups according to the physiological activities produced. These were organisms (1) reducing nitrate to nitrogen gas, (2) splitting protein with the production of hydrogen sulfide, (3) liquefying coagulated egg albumin, (4) reducing inorganic sulfates to hydrogen sulfide, (5) oxidizing ammonium salts to nitrites, (6) oxidizing nitrites to nitrates, and (7) oxidizing thiosulfite to sulfate. No attempt was made to isolate and observe individual bacterial types.

The largest number of bacteria per cubic centimeter was found in the digestive chamber of the Imhoff tank. This was true whether organisms of a reducing or of an oxidizing type were considered. The effluent from the sprinkling filter, except at the time of slough, contained the fewest bacteria per cubic centimeter.

Of the groups considered, the organisms most important numerically throughout the plant were the nitrate reducers, the hydrogen sulfide producers, and the albumin digesters. Nitrifying and sulfur oxidizing bacteria occurred throughout the plant and were consistently found even in the digestion chamber of the Imhoff tank. The material from the digestion chamber, however, contained no nitrites or nitrates. The number of nitrifying organisms increased in the filter bed, although they never became numerically predominant, and higher percentages of nitrifiers were found in liquid which had trickled through the lower levels of the bed than in that collected near the surface.

There was a drop in the numbers of hydrogen sulfide producing organisms as the sewage passed through the plant. This was the most striking change in the bacterial flora which could be demonstrated. It is stated that in general in a sewage plant handling stale sewage in a quantity at about its capacity, the proteolytic and reducing organisms overbalance the oxidizing organisms. However, the results are taken to indicate that by careful operation of a plant a satisfactory effluent can nevertheless be obtained.

*A sprinkling filter bed and its bacteriological population.*—These studies showed that the film about the stones of a sprinkling filter bed contains bacteria able to accomplish the same physiological activities as those which occur in an Imhoff tank. The stones are seeded by the effluent from the Imhoff tank which is sprayed over their surface. Conditions in the bed affect the types of bacteria with the result that the proteolytic bacteria decrease as the stones of the lower level of the bed are reached, while the oxidizing bacteria increase. This increase in oxidizing bacteria confirms the chemical analyses which show a higher nitrate production in the lowest level of the filter bed. Since many bacteria are able to effect denitrification, these types of bacteria may also be demonstrated readily in the sprinkling filter film.

**Investigation of farm sewage disposal systems**, R. H. DRIFTMIER (*Agr. Engin.*, 5 (1924), No. 10, pp. 232, 233).—In a contribution from the Kansas State Agricultural College an outline is presented of the research features involved in a fundamental study of the disposal of farm sewage. It is considered advisable when entering in a broad, general way into a study of farm sewage disposal to begin with an analysis and classification of conditions on the basis

that purification of sewage is primarily a biological phenomenon, regardless of the type of system employed. It is stated that since the biological conditions for an absolutely purifying sewage disposal system are not known, the problem logically resolves itself into a joint one for the agricultural engineer and the biologist. This would result in studying biological decomposition and purification entirely separately from the septic tank, in order to establish the exact conditions which must later be met by the engineer in the design of the tank.

An extensive bibliography on the subject is included.

## RURAL ECONOMICS AND SOCIOLOGY

**Report of investigational work in agricultural economics, A. G. WALLER** (*New Jersey Stas. Rpt. 1923, pp. 166-191, pls. 11*).—Investigational work in the cost of producing farm products and the best farm practices carried on by New Jersey Stations for the year ended June 30, 1923, is reported upon.

**Poultry investigations.**—The cost of producing 8,893 capons on 66 farms in Burlington County, N. J., is summarized. The gross sales per farm amounted to \$544.62 and the gross cost to \$240.68.

**Potato investigations.**—A preliminary statement of the production, costs, and profits of potatoes in New Jersey, and of the competition from other principal potato-producing areas is given here, following an investigation made in September, 1922. Census returns and unpublished data furnished by the U. S. Department of Agriculture are tabulated and briefly discussed. Correlations between the production of potatoes from 1899 to 1921, inclusive, and that of peaches, apples, sweet potatoes, and rice, and between the production and farm prices of potatoes with farm prices lagging one year, as well as the deviation from the 5-year average, 1909-1914, in production and farm prices of potatoes December 1, are presented graphically.

**Rye investigations.**—The margin of profit for buyers of rye and the course of prices paid the farmers in New Jersey during each year 1909 to 1922 were determined in considering the question of whether growers should do their own threshing and baling rather than selling the sheaf according to the present practice. The second alternative was held to be probably more advisable.

**Fruit investigation.**—The development of orchards by sections of the State, the production per capita, and the total crop, prices, and prospects for production of apples and peaches are shown graphically on the basis of census statistics for periods of years.

**The relative economy of ox labour in South African farming, E. PARISH** (*So. African Jour. Sci., 20 (1923), No. 2, pp. 316-322, fig. 1*).—From information obtained incidentally in the investigation of the cost of production of corn, it is concluded that horse and mule labor in South Africa is generally from 40 to 50 per cent more costly than ox labor. It is held that the price of land very largely determines the cost of ox labor. A progressive increase in the value of the land is observable in South Africa, and the cost of ox labor is also rising, proportionately less rapidly, however, than is the value of the land. It may be expected that when land has increased to more than one and a half times its present value the ox will begin to lose his relative superiority to the horse and will tend to be supplanted. It is assumed that this displacement will not be completed in the present generation.

**The formation of small holdings in Sweden, W. I. PETTERSSON** (*Internatl. Rev. Agr. Econ. [Rome], n. ser., 2 (1924), No. 2, pp. 215-230*).—This article

briefly describes the history of the subdivision of land in Sweden and the measures adopted to facilitate it. The problem is said to be growing constantly more complicated because of a diversity of opinion among the different political parties. The number of persons who apply under the system for loans for the purchase of property is said to be increasing yearly.

**A study of the onion industry in Pleasant Valley, Iowa,** A. T. ERWIN and W. L. HARTER (*Iowa Sta. Bul.* 225 (1925), pp. 257-286, figs. 16).—Herein are presented the results of an economic study of onion production on a small area in Scott County, where, under intensive methods, there are annually produced on 500 acres an approximate yield of 200,000 bu. of onions. Tenancy is comparatively rare, 90 per cent of the growers being owners, and the average size of the holdings being 10 acres. Approximately 85 per cent of the acreage is grown from seed, almost exclusively locally grown. Records showed that 220 hours of hand and 62 hours of horse labor are required per acre, and of the manual labor 50 per cent is used in August in harvesting and marketing the crop. Onions are marketed immediately after harvest, the bulk of the crop being shipped to the Cotton Belt States.

Cost of production data, consisting largely of estimates, were obtained from men who had been growing onions at least 5 years. It was determined that with a yield of 400 bu. per acre the cost was approximately 45 cts. a bushel. On the farms studied the costs varied from as low as \$91 per acre on one farm to as high as \$235 on another on which 12 acres were grown on land not previously freed from weeds. The labor incomes realized ranged from \$62 in the case of one man cultivating 1 acre to \$2,436 earned by another on 22 acres.

**Cost of producing strawberries,** A. L. WILSON (*Utah Sta. Bul.* 192 (1925), p. 40).—The costs at which two crops of strawberries of the Marshall variety, which was planted in 1922, were harvested from a tract of 0.38 acre on the Davis County Experimental Farm are briefly tabulated.

**How to keep a cash account on a farm,** V. B. HART (*Ithaca: N. Y. State Col. Agr., Cornell Univ.* [1924], pp. 33).—Simple directions and blank forms for keeping a record of receipts and expenses are provided.

**Agricultural wages in Switzerland** [trans. title], E. LAUR and H. NATER (*Sec. Paysans Suisses Pubs., Nos. 31* (1908), pp. IV+135; 40 (1911), pp. VII+113; 70 (1923), pp. 111).—The first of two inquiries reported here was instituted in 1906. It was concerned with the salaries paid in that year to domestics and rural day laborers, as well as wages paid in the various decades of the nineteenth century. It also inquired into the dearth of laborers, their standard of living, hiring agencies, and other matters. The second was carried on in 1921 and is very similar in plan, covering the wages paid all classes of workers by cantons and by kinds of work and comparing wages before and after the war.

**Assessment and equalization of farm and city real estate in Kansas,** E. ENGLUND (*Kansas Sta. Bul.* 232 (1924), pp. 3-70, figs. 5).—A statement in the abstract of this publication (*E. S. R.*, 52, p. 294) should be corrected to state that a greater equality is found among townships than among other assessing units or among individual properties.

**Facts and figures regarding cooperative livestock shipping in Ohio,** B. A. WALLACE (*Ohio Sta. Mo. Bul.*, 9 (1924), No. 11-12, pp. 204-209).—A short summary analysis of answers from shipping associations in the State to a questionnaire (*E. S. R.*, 51, p. 893) is given. A wide divergence in the weights and prices at which livestock is marketed in different counties is noted. The total expense of marketing each 200 lbs. of hogs sold in 1922 ranged from

\$1.01 to \$1.63, averaging \$1.29. The net return to the farmer varied from \$18.07 to \$19.97, averaging \$18.61.

**Crops and Markets, [February, 1925]** (*U. S. Dept. Agr., Crops and Markets, 3 (1925), Nos. 6, pp. 81-96; 7, pp. 97-112, fig. 1; 8, pp. 113-128; 9, pp. 129-144*).—Statistics and summary reports are given from weekly current market reports, relating to important classes of agricultural products and specific commodities, and brief special articles are given reviewing their position in the market. Foreign crops and markets notes are presented.

**Monthly Supplement to Crops and Markets, [February, 1925]** (*U. S. Dept. Agr., Crops and Markets, 2 (1925), Sup. 2, pp. 33-72, figs. 3*).—This supplement is devoted largely to livestock reports, including tabulations showing the estimated number and value of principal classes, January 1, 1925, with comparisons, and reports covering two milch cow surveys made June 1 and December 1, 1924. Statistics of the birth rate of horses and mules, the estimated wool production of the United States, 1919-1924, and corn and hog ratios, 1910-1924, together with a western livestock and range report, are given. Truck crop production and the imports of forage plant seeds are tabulated. The usual estimated farm prices of important products and statistics of cold storage holdings, the livestock and meat situation, average prevailing farm wage rates, and fruit and vegetable shipments and prices are presented, together with a review of the general price situation.

**The price situation in agriculture in the years 1920-21 to 1922-23, inclusive** [trans. title], FENSCH (*Deut. Landw. Rat Veröffentl. 1 (1923), pp. 22*).—A compilation of price data is presented here in tabulations of index numbers of wholesale prices, cost of living, and the prices of farm products, including grain, sugar beets, hay and straw, meat, and milk, as well as of supplies such as fertilizers, seeds, tools, machinery, fuel, and feeds, for the three years. Comparisons are made of monthly averages and of the purchasing price of the dollar. Phenomenal and irregular increases, especially in the last of the three years, in the prices of supplies are exhibited. It is pointed out that under such price conditions the orderly organization and conduct of the farm business has been impossible in Germany.

**The agrarian phase of the Mexican Revolution of 1910-1920**, H. PHIPPS (*Polit. Sci. Quart., 39 (1924), No. 1, pp. 1-18*).—This article describes Mexican history since the early part of the nineteenth century as consisting largely of a struggle between the proletariat and the privileged classes. Three principal revolutions are said to have taken place—the first banished the Spaniards, the second gave increased importance to the landed aristocracy and brought about the gradual disintegration of the Indian communal system of landholding, while the third was characterized by a more definite demand on the part of the Indians for agrarian reform, mainly in the way of the restoration of village lands.

**A short history of English agriculture and rural life**, C. J. HALL (*London: A. & C. Black, Ltd., 1924, pp. VIII+152, pls. 8, figs. 20*).—This is a popular account beginning with farming and rural life in England before the twelfth century, and describing the manorial system, the black death and its effects, the introduction of sheep raising, rural life in the Tudor period, agricultural reformers and the revolution in the eighteenth and early nineteenth centuries, and the prosperity and the difficulties of later years, especially those attendant upon the World War.

**Every-day life on an old Highland farm, 1769-1782**, I. F. GRANT (*London and New York: Longmans, Green & Co., 1924, pp. XI+277, pls. 6*).—The entries made in an old farm account book (*E. S. R., 51, p. 192*) by one William

Mackintosh of Balnespick, a leaseholder of a farm in the upper valley of the River Spey in northern Scotland, are interpreted here to show the life and farming methods followed in a particular district in the Scottish Highlands at a period just between two important agricultural revolutions. Other writings are extensively cited in supplementing the farm notes. The chapters include an introduction, the psychological atmosphere, the general appearance and conditions of the countryside, farming at Dunachton in the eighteenth century, Balnespick's financial position, Balnespick and his contemporaries, the subtenants, and the relations between Balnespick and his tenants. Appendixes reproduce pages from the old book and charts showing the distribution of Balnespick's subtenants and their relations with him.

**Where farming pays, and why**, W. MEAKIN (*London: Agr. Gaz. and Mod. Farming, 1923, pp. 64*).—This is a description of the prosperity surrounding the agricultural industry in Denmark, which is largely attributed to cooperation.

**An investigation with reference to agricultural associations in Switzerland** [trans. title], E. LAUR and H. NATER (*Sec. Paysans Suisses Pubs., No. 68 (1923), pp. 93*).—Information obtained during the winter of 1919–20 by means of a questionnaire is published here, setting forth the numbers of associations and their main purposes.

**Agricultural co-operation in Bulgaria**, P. N. ORECHKOFF (*Internatl. Rev. Agr. Econ. [Rome], n. ser., 2 (1924), No. 2, pp. 240–260*).—The organization of the first cooperative societies in Bulgaria is said to have taken place in 1898. Data with reference to membership and financial condition are presented, together with descriptive notes and the text of measures favoring cooperation.

**Report on the working of the co-operative societies in the Punjab for the year ending 31st July, 1923**, H. CALVERT (*Punjab Coop. Socs. Rpt., 1923, pp. [9]+60+CVII*).—This annual report succeeds one previously noted (*E. S. R., 50, p. 795*).

**Some geographical factors affecting agriculture in South Africa**, J. H. WELLINGTON (*So. African Geogr. Jour., 6 (1923), Dec., pp. 41–66, figs. 12*).—This article is presented in sections dealing with general factors controlling agricultural production, structural and surface features of South Africa, climatic controls, agricultural value of the precipitation, soils of the Union, irrigation, and some important crops.

It is held that the physical conditions of the western part of the plateau region are such that this part of the Union of South Africa can not become an agricultural region, but that considerable areas may be cultivated if local irrigation can be profitably practiced. Certain portions of the eastern plateau region are adapted to the growing of corn, while sorghums appear to be the most dependable crop in other parts. The climatic and topographical advantages of the northern Transvaal have scarcely been exploited. The low veld regions of the Transvaal and Natal show a high potentiality for the production of cotton in the interior and sugar cane along the coastal strip. On the whole, the geographical conditions of South Africa are more favorable for stock farming than for agriculture.

**Conference on the sociological implications of present-day agricultural movements** (*Amer. Sociol. Soc. Pubs., 18 (1924), pp. 183–198*).—Papers read at the conference under the leadership of C. C. Taylor, which was a part of the proceedings of the eighteenth annual meeting of the American Sociological Society at Washington, D. C., in December, 1923, are published as follows:

*Some sociological implications of the farm bureau movement*, E. C. Lindeman (pp. 183–189).—It is assumed that the sociological implications of any form of human organization are the possible, probable, and actual interactions

of dependent variables, and that from this point of view the farm bureau can prosecute its specialized economic program successfully only so long as it recognizes the individual personalities of its members. It is thought that an organization whose functions are preponderantly economic can not permanently refrain from engaging in social or political activities. The farm bureau movement can not survive without using its influence and power on behalf of specialized organizations, seeking to develop the school, the home, the church, recreation, and similar social interests.

*The sociological implications of the co-operative marketing movement*, B. F. Brown (pp. 190-193).—This analysis indicates that the cooperative marketing movement arose from a desire to improve rural conditions and from the recognition on the part of farmers of the fact that the strong position of big business is largely due to unification. Certain forces which are likely to militate against its successful operation are pointed out as lack of experience in cooperation and the opposition of such agencies as country buyers, warehousemen, and other so-called middlemen, who have a strong economic motive for the position they take. Cooperative marketing is said to have stirred the farmers of the South to constructive and broad thinking and to have widened their outlook considerably. The slow but steady increase in tenancy is said to be giving relatively greater importance to group activity.

*Agrarian political movements with special reference to the Nonpartisan League*, J. M. Gillette (pp. 194-198).—The influence of the Nonpartisan League is compared with that of earlier movements, such as the Farmers' Alliance and the Populist movement, and found to be of minor importance. It is said to have stimulated the growth of progressivism and the third party movement and to have left its impress upon the laws of North Dakota.

**The cost of living among colored farm families of selected localities of Kentucky, Tennessee, and Texas**, E. L. KIRKPATRICK and J. T. SANDERS (*U. S. Dept. Agr., Bur. Agr. Econ., 1925, pp. 13*).—Partial results of a study based upon schedules taken in the field for the year ended January 1, 1920, are presented in this preliminary mimeographed report. Averages are given for the size of the family and the household, ages of the members of the family, and the expenditures and goods used.

The majority of colored families in these regions were using from \$300 to \$899 worth of goods per year. Roughly about two-fifths of the family living was furnished by the farm without direct purchase, regardless of the average total value of the family living. Comparisons are made between colored owner, tenant, and cropper families. From the standpoint of the proportion of the total expenditures going for various purposes, tenant families appear to live about as well as owner families and somewhat better than do cropper families.

For many of the items reported upon the corresponding averages for white families of the localities studied are given by way of comparison.

**The welfare of children in cotton-growing areas of Texas** (*U. S. Dept. Labor, Children's Bur. Pub. 134 (1924), pp. V+83, pls. 6*).—This study was made in two cotton-growing counties of Texas, namely, Hill County, located in the north-central part of the State and chosen as typical of the black lands of the central prairie region, and Rusk County, near the Louisiana border, chosen as fairly representative of cotton-growing regions in east Texas. Information was secured through school attendance records and a house-to-house canvass in regard to all children between the ages of 2 and 16 years on September 30, 1920, living in families resident on farms in 13 school districts in Hill County and 12 in Rusk County for at least six months of the year previous to that date. A total of 1,121 families with 3,131 children were interviewed.

Four months or more had been devoted to picking cotton by 11 per cent of the white children of Hill County, while only 16 white and negro children in Rusk County had picked cotton four months or more. The average day's work for 153 children ranging in age from 3 to 15 years was slightly under 100 lbs. of cotton each. The majority of the children 14 and 15 years of age had averaged 150 lbs. or more a day, about three-fifths of those 12 and 13 years old had averaged over 100 lbs., and practically the same proportion of the 10- and 11-year-old boys and girls had picked on an average more than 75 lbs. Other kinds of labor, including hoeing and chopping cotton; plowing, harrowing, and planting; cultivating; picking corn, peanuts, dry peas, and other crops; other field work; and chores and housework, were reported by a large proportion of the children.

Of the 398 children between 6 and 16 years of age who had not been to school at all during the year of the study, 74 (27 white and 47 negro children) were of the compulsory school age. The 34 negro children of compulsory school age in the Hill County study who had been absent the entire year constituted 45 per cent of the negro children in their districts who were of compulsory school age. The negro children 6 to 15 years of age not attending school in Rusk County were only 4 per cent of those who were of compulsory school age. For white children in Hill County the average number of days' attendance was 76.7, for white children in Rusk County 78.9, and for negro children in Rusk 82.1. It was found that 58 per cent of the white children included in the survey in Hill County and 68 per cent of those in Rusk were retarded, while in each county an even larger proportion of the negro children had failed to make normal progress in school.

The living conditions, the work of the mothers, the diet, the literacy of parents and periodicals taken, and community life and social activities of these families were also investigated. Special attention was given to the conditions surrounding the children in migratory laborers' families.

In addition to educational measures, some public supervision of houses and sanitation is deemed desirable. The welfare of children in migratory laborers' families is said to deserve special consideration, particularly as regards their education and housing.

**International yearbook of agricultural statistics for 1923** (*Inst. Internatl. Agr. [Rome], Ann. Internatl. Statis. Agr. (Internatl. Yearbook Agr. Statis.), 1923, pp. XCV+471*).—The series previously noted (E. S. R., 50, p. 393) is continued, this edition being published in both French and English.

**Livestock and animal products statistics, 1923**, F. J. HORNING (*Canada Bur. Statis., Livestock and Anim. Prod. Statis., 1923, pp. 101, figs. 8*).—This annual report succeeds that for the earlier year previously noted (E. S. R., 52, p. 95).

**Agricultural statistics, 1923**, R. J. THOMPSON (*[Gt. Brit.] Min. Agr. and Fisheries, Agr. Statis., 58 (1923), Nos. 1, pp. 48; 2, pp. 49-92; 3, pp. 93-137*).—These annual official reports present statistics in continuation of those previously noted (E. S. R., 49, p. 895.)

**[Agricultural statistics for Denmark]** (*Statis. Aarbog Danmark, 29 (1924), pp. 36-76*).—Statistics in these pages of the annual report present current information as previously noted (E. S. R., 49, p. 895).

**[Agricultural statistics for Norway]** (*Statis. Årbok Kongeriket Norge, 43 (1923), pp. 43-66*).—Current data in these pages supplement those presented earlier (E. S. R., 50, p. 795).

**[Agricultural statistics for Sweden, 1924]** (*Statis. Årsbok Sverige, 11 (1924), pp. 64-82*).—Statistics for the later year are continued as previously noted (E. S. R., 50, p. 693).

**Statistical report on agricultural production in Greece for 1921** [trans. title] (*Statis. Ann. Rend. Agr. Grèce, 1921, pp. 66*).—This annual report presents tabulated data, showing the area cultivated, the production of fruits, and the number of livestock found by departments.

**The statistics of agriculture, industries, and commerce, 1922**, K. HIRATA ([*Japan*] *Dept. Agr. and Com., Statis. Agr., Indus., and Com., 1922, pp. [3]+7+200*).—Statistics of production and trade in Japan are given, continuing the series previously noted (E. S. R., 49, p. 895).

## AGRICULTURAL EDUCATION

**The agricultural high school in Ontario**, G. McMILLAN (*Toronto: Univ. Toronto Press, 1924, pp. 129, figs. 32*).—Analyzing the replies to questionnaires submitted to students in secondary schools and to teachers, the conclusion is drawn that special schools of agriculture are not well adapted to the needs of rural Ontario at the present but that vocational departments in the existing secondary schools offer a solution of one of the Province's most pressing requirements. A course of study and curriculum are suggested. Chapters are devoted to the topics of method, accommodation and equipment, teachers' qualifications, administration and supervision, and financial support.

**Courses of study at the Imperial Forestry Institute during the first year, October, 1924–September, 1925** (*Aust. Forestry Jour., 7 (1924), No. 12, p. 328*).—This program shows the distribution of studies throughout the year.

**Preparation of rural teachers in high schools**, M. CARNEY (*U. S. Bur. Ed., Rural School Leaflet 33 (1924), pp. 27*).—It is attempted to show what is being done throughout the United States, tracing first the origin and early history of the movement for preparing rural teachers in public high schools, describing its present status, presenting selected type studies, and setting forth the characteristic features and contributions of the various State systems.

**Elementary agriculture in rural schools from sixth to eighth grades**, E. H. SHINN (*Jour. Rural Ed., 4 (1924), No. 2, pp. 59–69*).—This paper discusses briefly the aims and objectives in teaching agriculture to rural pupils and the ways and means of achieving these objectives, and then presents information gathered from about 160 replies to a questionnaire sent to supervisors of rural schools, presidents of State normal schools, State supervisors of agricultural education, and heads of teacher-training divisions in land-grant colleges. Inquiries were made with reference to the State legislation which has functioned to procure for rural schools the type of education especially adapted to rural needs; the attitude of State departments of education as exhibited in policies, rulings, or encouragements which have assisted in developing rural education; the extent to which teacher-training institutions are attempting to train teachers of agriculture for rural schools; instances of effectiveness in teaching agriculture; the extent to which such teaching has helped to vitalize other school subjects of the rural school program; particular problems and difficulties; and improvements or solutions.

The author's recommendations are in favor of some agricultural instruction for the sixth, seventh, and eighth grades, although it is held that the course of study should not exclude general and cultural subjects. Opportunity should be offered to the older boys for carrying on an agricultural project. Teacher-training institutions, State departments of education, and land-grant colleges should give more attention and encouragement to the preparation of rural teachers, and closer cooperation between teachers and the numerous other agents, particularly extension workers, is urged.

**Teaching home relationships**, L. O. JACOBSON (*Vocat. Ed. Mag.*, 3 (1925), No. 1, pp. 27-29).—This article describes a short unit course given to a junior class in high school, in the course of which a score card was devised for judging a home on atmosphere, physical surroundings, management of the income and time, health, training and education of children, and support of community activities.

**Some practical uses of auditoriums in the rural schools of Montgomery County, Ala.**, L. ALLEN (*U. S. Bur. Ed., Rural School Leaflet 34* (1924), pp. 10).—The author suggests a general program coordinating school and community activities, and cites specifically a few of the programs that have been given in the rural schools of this county, including a May Day celebration and others.

**Southern field crops**, J. F. DUGGAR (*New York: Macmillan Co., 1925, rev. ed., pp. X+444, figs. 163*).—The author presents a revision of the textbook noted earlier (*E. S. R.*, 25, p. 297).

**A study of weeds**, G. E. RITCHEY (*Univ. Nanking, Agr. and Forestry Ser.*, 1 (1922), No. 5, pp. [2]+25, pls. 5, fig. 1).—A general discussion of weeds and their economic importance is presented for school use in China. Suggestions are made to teachers, and attention is given to the correlation of this with other subjects.

**Animal husbandry for schools**, M. W. HARPER (*New York: Macmillan Co., 1924, new and rev. ed., pp. IX+615, pl. 1, figs. 241*).—This is a revised edition of a high school and college textbook previously noted (*E. S. R.*, 29, p. 598).

**4-H sheep manual**, A. E. DARLOW and P. H. LOWERY (*Okla. Agr. Col. Ext. Circ. 198* [1924], pp. [8]).—Sheep club rules are drawn up and instructions are given for the care and exhibiting of sheep by club members.

**Vegetable and animal products of commercial importance**, A. ASTRUC and S. CHADEFaux (*Les Marchandises d'Origine Végétale et Animale. Paris: J. B. Baillièrre & Sons, 1924, pp. 444, figs. 118*).—This is a textbook describing food products, dyeing and tanning materials, perfumes, resins and vegetable secretions, drugs, textiles, and miscellaneous vegetable and animal products.

**The education of the consumer**, H. HARAP (*New York: Macmillan Co., 1924, pp. XXII+360*).—The effort is made to analyze into their elements food, clothing, and fuel consumption; housing; household materials requirements; and household skills in order to determine some of the actual needs of economic life. Quantitative data describing actual living conditions are brought together from direct surveys, experiments by industrial organizations and private and public investigational agencies, and trade and Government publications. This material is taken as a guide to wise educational objectives and as basic curriculum material. Present habits are compared with various standards of efficient practice.

**Red Cross course in food selection** (*Washington, D. C.: Amer. Red Cross, 1922, pp. 99*).—The course outlined in these 15 lessons is designed to give a knowledge of foods and food groups, as well as of the factors to be considered in selecting an adequate diet.

**Sewing manual**, J. F. EDDY (*Ala. Polytech. Inst. Ext. Circ. 76* (1924), pp. 46, figs. 47).—This is planned to be used as a reference book, particularly in home demonstration extension work.

**Rush work** (*Rural Indus. Bur. [London] Leaflet 16* [1925], pp. 27, figs. 19).—Information as to the preparation of rush materials and suggestions with regard to their adaptation to handicrafts and rural industries are given.

**Agricultural economics laboratory manual**, G. W. FORSTER (*Raleigh: N. C. State Col. Agr., 1924, pp. 47*).—A number of exercises in the graphic presenta-

tion of data illustrating some of the outstanding problems in agricultural economics are drawn up here, with considerable emphasis on the construction of index numbers.

**Principles of economics**, R. T. BUE (*New York: Alfred A. Knopf, 1924, pp. VII+508, figs. 22*).—Two of the 23 chapters in this textbook deal with land as a productive agent and income from land, respectively, the subject matter included following largely T. N. Carver.

**The school and country life**, S. B. MCCREADY (*Boston and London: D. C. Heath & Co., 1924, pp. IX+307, pls. 27, figs. 96*).—This is practically the same as the reader previously noted (E. S. R., 43, p. 195).

**A list of books for a teacher's professional library**, compiled by E. A. WRIGHT (*U. S. Bur. Ed., Teachers' Leaflet 17 (1924), pp. IV+15*).—This is a classified list of 100 titles of books regarded as useful to the majority of teachers. All are in English and, in most cases, are restricted to conditions existing in the United States. A few titles are to be found under the heads of rural schools and the teaching of agriculture and home economics.

**Suggestions for local leaders for junior agricultural clubs**, J. W. WHITEHOUSE (*Ky. Agr. Col. Ext. Circ. 177 (1925), pp. 24, figs. 5*).—Suggestions are offered as to club programs and projects and other activities. A number of games, songs, and yells for community recreation hours are given.

**Organization and programs for boys' and girls' clubs**, M. L. HALL (*Purdue Agr. Ext. Bul. 131 (1925), pp. 20, figs. 9*).—These suggestions apply to club meetings, types of programs, and methods of procedure.

**Plans for conducting boys' and girls' 4-H club work in Missouri**, T. T. MARTIN (*Missouri Agr. Col. Ext. Proj. Announc. 21 (1925), pp. 48, figs. 5*).—State and county organization of club work, ways of securing literature and supplies for club organization and projects, and suggestions with reference to programs and projects are outlined.

**Small school gardens** [trans. title] (*Min. Agr. [Argentina], Secc. Propaganda e Informes Circ. 333 (1924), pp. 98, figs. 58*).—This is a manual suggesting a procedure in introducing and developing school gardens in rural schools in Argentina.

## MISCELLANEOUS

**Elements of physical biology**, A. J. LOTKA (*Baltimore: Williams & Wilkins Co., 1925, pp. XXX+460, figs. 72*).—This treatise is subdivided into sections of general principles, kinetics, statics, and dynamics. Among the chapters may be noted those on evolution conceived as a redistribution, analysis of the growth function, the water, carbon dioxide, nitrogen, and phosphorus cycles, and the energy transformers of nature. A series of synoptic charts of physical biology is appended.

**Useful plants and animals of China**, P. KLAUTKE (*Nutzpflanzen und Nutztiere Chinas. Hanover: Hahnsche Buchhandl., 1922, pp. 160, figs. 37*).—The author of this account, instructor in biology in the Tung Chi Medical and Technical School for Chinese in Woosung, deals in the first portion with plant geographical features, field crops, fruit culture, important plant products, and Chinese gardens and flower culture, and in the second with animal breeding, silk culture, a general review of animal life in China, and certain selected forms, concluding with a short bibliography.

**Forty-fourth Annual Report of the New Jersey State Agricultural Experiment Station and the Thirty-sixth Annual Report of the New Jersey Agricultural College Experiment Station for the year ending June 30, 1923**, J. G. LIPMAN ET AL. (*New Jersey Stat. Rpt. 1923, pp. XXVIII+414, pls.*

24, figs. 9).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1923, a report of the director on the work and publications of the year, and departmental reports, the experimental features of which, not previously reported, are for the most part abstracted elsewhere in this issue.

**Biennial Report of the Utah Agricultural Experiment Station for the years 1923 and 1924**, W. PETERSON ET AL. (*Utah Sta. Bul.* 192 (1925), pp. 64, fig. 1).—This contains the organization list and a report on the work and publications of the station during the biennium ended June 30, 1924. The experimental work reported is for the most part abstracted elsewhere in this issue.

[**Reports of the director, Dominion Experimental Farms, 1923 and 1924**], E. S. ARCHIBALD (*Canada Expt. Farms, Rpts. Dir.*, 1923, pp. 82; 1924, pp. 90).—These reports, covering the fiscal years ended March 31, 1923, and March 31, 1924, respectively, include the organization lists and reports of the Central Experimental Farm and the branch farms. Field crop and livestock notes for 1922 and 1923 and a summary of meteorological observations at Ottawa for the fiscal years covered are also given.

**The Quarterly Bulletin [of the Michigan Station]**, edited by R. S. SHAW and E. B. HILL (*Michigan Sta. Quart. Bul.*, 7 (1925), No. 3, pp. 73-118, figs. 12).—In addition to articles abstracted elsewhere in this issue, this number contains the following: Spring Fertilization of Fall Seeded Grains, by G. M. Grantham; Soil Survey Work in Michigan, by M. M. McCool; Oat Variety Tests in St. Clair County, by D. F. Rainey; Fiber Flax Production in Michigan, by C. R. Megee; A Coloring Matter for Glymol, by P. S. Lucas; and Twenty Years of Legume Inoculation, by R. M. Snyder.

**Monthly Bulletin of the Ohio Agricultural Experiment Station** (*Ohio Sta. Mo. Bul.*, 9 (1924), No. 11-12, pp. 185-223, figs. 14).—Five articles abstracted elsewhere in this issue are included.

**Directory of field activities of the Bureau of Plant Industry** (*U. S. Dept. Agr., Misc. Circ.* 30 (1924), pp. II+62, pl. 1).—A directory of the field work of the bureau, arranged by States, is given.

## NOTES

---

**Purdue University.**—A tract of 360 acres of improved land in Washington, Newton County, has been transferred to the university under the will of the late Mrs. Ellen Victoria Ross Knaele. The land is subject to a life interest of her husband, but the income is to be used for the education of needy young men and women in the university.

Dr. J. C. Arthur, professor emeritus of botany, gave two lectures in April before the Pennsylvania College and the Graduate School of the U. S. Department of Agriculture, on Botany and Botanists in the Eighties, and The Rusts and Their Habits.

**Ohio State University.**—Dr. Thomas G. Phillips, professor of agricultural chemistry, has been appointed professor of agricultural chemistry and chemist in the New Hampshire University and Station.

**Wisconsin Station.**—Some surprising results are reported in experiments in the application of ultraviolet light for increased poultry production and greater hatchability of eggs, which are being carried on by the departments of agricultural chemistry and poultry. In recent trials a lot of 12 hens which were exposed to ultraviolet light for only 10 minutes daily during the month of February produced 140 per cent more eggs than a check lot which did not receive the light bath. The eggs from the hens receiving the ultraviolet light treatment were also very much higher in hatchability, over 60 per cent producing live chicks, while the average of three other lots not receiving the treatment was 28 per cent. The influence of the ultraviolet ray in stimulating the growth of the chick was as pronounced as the effect on egg production.

Work by the department of soils indicates that the use of fertilizers in the hill has a protective influence against the freezing of young corn plants. The fertilizer apparently increases the osmotic pressure of the sap in the corn plant, which in turn lowers the freezing temperature of the plant from 1.5 to 3° F. In some cases this may be sufficient to prevent plants from being frozen by late spring frosts. It is pointed out that the greatest benefit from this use of fertilizers will occur on peat and muck soils and on poor sandy soils.

Thirty-five field experiments in 14 counties on the inoculation of clover, peas, and beans are being conducted by the department of agricultural bacteriology. Special interest is being manifested in the clover inoculation trials, and reports from some of the county agents indicate that inoculation has been helpful in establishing stands of clover in sandy and extremely acid sections and on new lands where this crop had previously failed.

**Northeastern Forest Experiment Station.**—The work of this station is to be expanded during the coming year to include investigations of insect pests and diseases in cooperation with the U. S. D. A. Bureaus of Entomology and Plant Industry and other agencies. The investigations of insect pests are being financed in part by contributions from several individuals for a study of the white pine weevil, \$2,500 having been made available for two years

for the purpose. Studies will also be conducted of the larch sawfly and other forest insects. The plant disease work will deal especially with chestnut blight in an attempt to locate and propagate blight resistant trees, and will also take up white pine blister rust and the decay of logging slash.

**High Altitude Studies in Utah.**—The Brigham Young University of Provo, Utah, has had turned over to it a tract of 53 acres of land in the Wasatch National Forest, at an elevation of about 7,000 ft. The land will be used for experimental work in connection with the Alpine Summer School, which is carried on each summer for six weeks on Mount Trinpenagos, where the university erected dormitories, dining halls, and similar buildings two years ago.

**Albanian-American School of Agriculture and the Mechanic Arts.**—Funds are being raised in the United States for the establishment of a school of agriculture and mechanic arts in Albania. The Albanian Government has set aside a tract of 3,000 acres near Durazzo as a site for the institution. A technical school for the training of experts in agriculture, the natural sciences, and the industries is contemplated. C. Telford Erickson of New York City has been appointed president, and Dean E. E. Jones of Northwestern University a member of the board of trustees.

**New Research Institute in India.**—A research institute for the improvement of crops, especially cotton, was formally opened at Indore, Central India, November 24, 1924. A site of 300 acres has been leased by the Indore Durbar for 99 years at a nominal rental, and a grant of about \$75,000 has been made for capital expenditure by the Indian Central Cotton Committee. An annual grant of about \$45,000 has been provided for current expenses by the same committee and seven of the Central India States. The director of the institute will act as agricultural adviser of these States. Other features of the work in addition to research will be the development of a comprehensive library on crop production and the training of graduate students. Albert Howard, formerly Imperial economic botanist at the Agricultural Research Institute at Pusa, has been appointed director, and Mrs. Howard physiological botanist.

**Agricultural Education in Australia.**—The Waite Agricultural Institute has been established recently by the University of Adelaide to carry on research in agriculture. Its creation was made possible through a gift of the late Peter Waite, as pastoralist of South Australia, who left £100,000 to the university for agricultural research. This amount the Government of South Australia has supplemented by an appropriation of £5,000 per annum. The institute has been located at Glen Osmond, 3.5 miles from Adelaide, on a tract of 300 acres of good agricultural land. With the funds available, it is proposed to conduct investigations in agronomy, agricultural chemistry, plant pathology, and plant genetics.

The Government of Western Australia has authorized the establishment of an agricultural college, and an estate in the Avon Valley, one of the richest agricultural regions of the State, has been purchased for the purpose.

**Proposed Graduate School of Agriculture at Harvard University.**—A report of a committee appointed by the board of overseers at Harvard University to study the Bussey Institution recommends that the university establish a graduate department of agriculture. The committee estimates that an endowment of \$12,000,000 would be required to carry out this plan in an adequate way. This sum would provide \$150,000 per annum for 15 new professorships, a like sum for the maintenance of libraries and laboratories, and \$24,000 per annum for fellowships. The remainder of the endowment would be available for new laboratories, greenhouses, animal houses, and dormitory accommodations for the 400 students which the committee estimates would desire enrollment.

No action on this report has thus far been made public.

**World's Forestry Congress.**—The International Institute of Agriculture and the Italian Government have arranged a committee to organize a World's Forestry Congress to meet in Rome early in May, 1926. The headquarters of this committee are at the institute and its membership consists of Arrigo Serpieri, director of the Royal Higher Institute of Agriculture and Forestry at Florence, as president; Anders Fjelstad, delegate of Norway at the International Institute of Agriculture, and Dr. Alessandro Stella, director general of forests and State lands at the Italian Ministry of National Economy, as vice presidents; Ariberto Merendi, chief inspector of forests at the Ministry of National Economy, as secretary; together with Deoclecio de Campos, Gian Francesco Guerrazzi, and Asher Hobson, delegates, respectively, to the institute from Brazil, Italian Somaliland, and the United States.

An exhibition of forest products and the machinery used in their conversion will be held in connection with the International Fair at Milan. This will enable visitors to examine the different products of the wood-manufacturing industries and the wood-working machinery of the various countries.

Excursions to typical forest lands in Italy, and possibly in other countries, will be arranged to follow the sessions of the congress.

**New Journals.**—*Resumptio Genetica* is being published at The Hague under the editorship of Dr. J. P. Lotsy and H. N. Kooiman as an abstract journal of the current literature on genetics. The initial number contains a list of the literature and abstracts of selected articles published in 1923. Ultimately it is hoped to issue the journal monthly. The literature from 1900 to 1923 is being reviewed by subjects and issued under the title of *Bibliographia Genetica*, of which one volume of 480 pages has been printed and another is in press, with eight others in preparation.

*The Journal of the Department of Agriculture of Western Australia*, which was discontinued in 1909, has resumed publication as a quarterly. The initial number in the new series was issued in April, 1924, and contained an account of the organization and activities of the department of agriculture and a large number of short articles on various agricultural topics.

*Agricultura* is being published at Santiago de las Vegas, Cuba, as the official organ of the National Association of Agricultural Teachers. The initial number contains several short articles by the staff of the agricultural experiment station at Santiago de las Vegas, announcements, news notes, etc.

The Ministry of Agriculture of Argentina has discontinued its *Boletín del Ministerio de Agricultura* and is now issuing serially only the *Boletín Mensual de Estadística Agrícola*. Other information is to be disseminated in the form of separate bulletins.

A new series known as *Indian Medical Research Memoirs*, supplementing the *Indian Journal of Medical Research*, is being published by the Indian Research Fund Association. The initial number is devoted to a Report of the Ankylostomiasis Inquiry in Madras, by K. S. Mhaskar.

*C. R. E. A. Bulletin* is being published by the Committee on the Relation of Electricity to Agriculture. The initial number contains numerous brief notes, including one by the editor, E. A. White, on the committee's investigational program.

*Abstracts of Canning Technology* is being published as a quarterly by the National Cannery Association. The initial number contains abstracts or title references to 436 articles published in 1922, together with a list of the publications abstracted.

*Journal of Oil and Fat Industries* is being published by the American Oil Chemists' Society as a quarterly. The initial number is devoted mainly to the proceedings of the fifteenth annual convention.

**Necrology.**—Mark A. Carleton, with the U. S. Department of Agriculture from 1894 to 1918, and cerealist from 1900 to 1918, died recently in Peru, where he had gone some months previously in the service of a cotton growers' association, located at Piura. Mr. Carleton was born at Jerusalem, Ohio, March 7, 1866, graduating from the Kansas College in 1887 and receiving the M. S. degree there in 1893. While in the service of this Department, he served as explorer in Russia and Siberia, bringing back a number of durum wheats of much value. He was the author of *The Small Grains*, published in 1916.

G. M. Murgoci, chief of the agrogeological section of the Geological Institute of Rumania and professor in the Polytechnic School of Bucharest, died March 5 at the age of 53 years. He was president of the International Commission on Soil Mapping and director of the International Pedological Charts of Europe.

Professor August von Wassermann, eminent for his studies of immunity and related problems, died in Berlin, March 6, at the age of 60 years.

**Miscellaneous.**—*Science* announces that an anonymous friend of plant physiology has provided a temporary endowment to aid the newly organized American Society of Plant Pathologists. The principal given is approximately \$20,000, and the income, which is assured for three years beginning July 1, 1925, is to be used in aid of any enterprise the society may foster.

A recent note in *Nature* states that the foundation stone of the Cotton Technical Research Laboratory for India was laid December 3, 1924, by the Viceroy of India. At the same time he opened an experimental spinning mill, the equipment for which had been presented by Lancashire manufacturers. A. J. Turner, professor of textiles in the College of Technology, Manchester, has been appointed director of the laboratory.

The first agricultural college in Burma was opened at Mandalay December 22, 1924. A farm of 600 acres and facilities for a four-year course for 84 students have been provided. Special attention is to be given to the selection of better varieties of rice, beans, cotton, and sugar cane, the study of plant diseases, silk culture, and the building up of a pedigreed herd of pure Burma cattle.

The Ministry of Agriculture of France is establishing an Agronomic Research Institute at Clermont-Ferrand. Laboratories will be provided for plant studies from the standpoint of agricultural botany, genetics, pathology, entomology, etc. M. Crépin has been appointed director of the institute.

The retirement is noted of Dr. C. F. Juritz, chief of the division of chemistry of the Department of Agriculture of the Union of South Africa, terminating a prolific service, mostly under pioneer conditions, of about 35 years.

Dr. Robert L. Pendleton, director of agriculture in Gwalior State, India, has been appointed professor of soil technology at the University of the Philippines and in charge of the work in soils in the department of agronomy.

The retirement under a new pension law is reported of John R. Bovell, director of agriculture, Barbados, and in the service of the department since 1883.

## RECENT WORK IN AGRICULTURAL SCIENCE

---

### AGRICULTURAL CHEMISTRY—AGROTECHNY

**Observations on the mechanism of the reaction between formaldehyde and serum proteins**, R. R. HENLEY (*Jour. Agr. Research [U. S.]*, 29 (1924), No. 10, pp. 471-482, figs. 2).—In this investigation of the changes which take place in the proteins of formalized serums, the effect of formaldehyde on the precipitation limits of pure globulins and albumins was first determined.

It was found that in the presence of 0.18 per cent formaldehyde pure native pseudoglobulins behaved as if they were converted into euglobulins and pure native albumins into pseudoglobulins. With larger amounts of formaldehyde euglobulins were produced from albumins. The reactions resulting in these changes are thought to be of the second order. Determinations of the titratable acidity showed a primary increase in acidity related but not proportional to the amount of formaldehyde. This was followed by a general decline. The pH values determined at the same intervals showed a steady decrease.

In discussing these results and the results of other investigations along the same line, the mechanism of the changes taking place in the proteins of formalized serum is suggested to be as follows: In the first stage of the reaction, which is accompanied by increased acidity, the formaldehyde may attack certain basic groups of the protein molecule, as a result of which the protein molecule becomes acid. The second stage of reaction, in which there is a decrease in titratable acidity, is attributed to the reaction between the acid protein molecules formed in the first stage of the reaction and the enol group,  $-C(OH)=N-$ , or similar linkages. "This explanation of the mechanism of the changes which take place in the proteins of formalized serum is offered simply as a suggestion and with the full realization that the results presented herein are not sufficient to warrant at the present time a final conclusion."

A list of 16 references to the literature is appended.

**Total ash determination in spices**, A. L. MEHRING (*Jour. Agr. Research [U. S.]*; 29 (1924), No. 11, pp. 569-574).—This contribution from the Bureau of Animal Industry, U. S. D. A., consists chiefly of a compilation of data from the literature and from hitherto unpublished determinations made by J. B. Martin and by the author on the total ash of various spices. In the case of 31 of the more common spices, the data presented consist of weighted averages for from 14 to 841 samples each as determined by from 2 to 23 analysts. Data averaged from a few determinations on each variety are also given on the ash content of 12 other spices used in powdered form and on the composition of the ash of 9 spices. A classified bibliography of 111 titles is appended.

**A protein from the leaves of the alfalfa plant**, A. C. CHIBNALL and L. S. NOLAN (*Jour. Biol. Chem.*, 62 (1924), No. 1, pp. 173-178).—The authors have obtained from fresh alfalfa leaves by the method previously described for the preparation of spinacin from spinach leaves (*E. S. R.*, 52, p. 708) a protein resembling spinacin in its chemical and physical properties, particularly its sensitiveness to the presence of salts when in weak acid solution. The Van Slyke analysis of the protein after hydrolysis with 20 per cent HCl for 27 hours gave the following results: Amide N 5.51 per cent, humin N in acid 1.22, humin N in lime 1.46, humin N in amyl alcohol 0.04, cystine N 0.84, arginine N 15.32, histidine N 3.09, lysine N 9.97, amino N in filtrate 58.56, and non-amino N in filtrate 3.19 per cent.

**A protein from the leaves of Zea mays**, A. C. CHIBNALL and L. S. NOLAN (*Jour. Biol. Chem.*, 62 (1924), No. 1, pp. 179-181).—A protein similar to that obtained from the cytoplasm of alfalfa and spinach leaves has been obtained from the cytoplasm of the leaves of silage corn. The Van Slyke analysis of the protein after hydrolysis with 20 per cent HCl for 28 hours gave the following results: Amide N 7.44 per cent, humin N in acid 1.91, humin N in lime 2.47, humin N in amyl alcohol 0.19, cystine N 0.77, arginine N 14.69, histidine N 4.70, lysine N 8.78, amino N 55.81, and non-amino N 2.04 per cent.

**The tryptophane and cystine content of various proteins**, D. B. JONES, C. E. F. GERSDORFF, and O. MOELLER (*Jour. Biol. Chem.*, 62 (1924), No. 1, pp. 183-195).—A large number of proteins, including those isolated by the authors in their extensive series of protein investigations and others specially prepared for the present study, were analyzed colorimetrically for their cystine content by the method of Folin and Looney (*E. S. R.*, 47, p. 504) and for tryptophan by the method of May and Rose (*E. S. R.*, 48, p. 312). In the latter determination, the calculations were made on the basis that the casein used as a standard contained 2.2 per cent of tryptophan. The results are reported in tabular form, and a tabular comparison is included of the cystine content of certain proteins as determined by the colorimetric and the Van Slyke methods. In a large number of cases the results obtained by the two methods agreed fairly closely.

Of particular interest in the data reported are the high percentages of tryptophan and cystine in the proteins of wheat bran. The tryptophan content of the albumin of wheat bran (4.76 per cent) is said to be the highest yet reported for any plant protein. This protein also contained a high percentage of cystine, 3.29 per cent. The globulin of wheat bran contained 2.85 per cent of tryptophan and 1.52 per cent of cystine. Since albumin and globulin in approximately equal proportions make up about half of the proteins of wheat bran (*E. S. R.*, 50, p. 711), the nutritive value of wheat bran assumes an added importance.

The globulin of the almond was found to contain much less tryptophan and cystine, 1.37 and 0.85 per cent, respectively, than the corresponding proteins of Brazil nuts 2.59 and 1.84, the English walnut 2.84 and 2.18 and coconut 1.25 and 1.54 per cent, respectively. This is in agreement with the results of feeding experiments reported by Morgan, Newbecker, and Bridge for almond proteins (*E. S. R.*, 50, p. 857), Osborne and Mendel for the excelsin of Brazil nuts (*E. S. R.*, 33, p. 262), Mignon for the globulin of English walnuts (*E. S. R.*, 50, p. 462), and Johns, Finks, and Paul for the coconut globulin (*E. S. R.*, 41, p. 262).

Other points brought out in the discussion of the data are the high tryptophan content of the proteins of the oil seeds, the higher content of both trypto-

phan and cystine in  $\alpha$ - than  $\beta$ -globulins, and the high content of cystine in lactalbumin (4.25 and 3.91 per cent in two determinations).

A list of 49 references to the literature is appended.

**A method for the fractional analysis of incomplete protein hydrolysates,** H. WASTENEYS and H. BORSOOK (*Jour. Biol. Chem.*, 62 (1924), No. 1, pp. 1-14, fig. 1).—"Briefly, the method involves the precipitation of the protein by trichloroacetic acid, of the metaprotein by careful adjustment of the reaction, of the proteoses by  $\text{Na}_2\text{SO}_4$  at 33° C., of the peptones by tannic acid under definitely fixed conditions; and the determination of the residual amino acids and simple peptides by a slight modification of the alcohol precipitation methods of Folin and Denis and Van Slyke and Meyer. No new principle is introduced, but quantitative results with these reagents were found to be obtainable only under rigidly fixed conditions. The metaprotein fraction is determined on a separate aliquot of the original solution. For the assay of the other five fractions 100 cc. are required, containing not less than 200 mg. of nitrogen. The amount of each fraction is estimated by the nitrogen content, obtained by difference before and after filtration."

**A note on Dakin's method as applied to edestin,** T. B. OSBORNE, C. S. LEAVENWORTH, and L. S. NOLAN (*Jour. Biol. Chem.*, 61 (1924), No. 2, pp. 309-313).—A slight modification in the technique of the original Dakin butyl alcohol method of extracting the monamino acids from the products of protein hydrolysis is described, and its application to the analysis of edestin discussed. The modification consists in dropping the solution of the amino acids at room temperature into a tall jar containing a large amount of butyl alcohol and keeping the mixture agitated by stirring with an electric stirrer. The process is generally repeated and the butyl alcohol evaporated in vacuo in portions of about 1,500 cc.

Using the modified method on edestin, no oxyglutaminic acid was obtained. In view of unpublished experiments showing that satisfactory growth can be obtained on edestin as the sole source of protein, it is concluded that oxyglutaminic acid is not essential for adequate nutrition. From the proline fraction a crystalline substance was obtained which was identified as a diketopiperazine. It is pointed out that on account of the presence of this substance the Van Slyke method can not be used to estimate the proline from the imino nitrogen soluble in alcohol unless the diketopiperazines are hydrolyzed or the proline is esterified as recommended by Dakin.

**The optical properties of some amino acids,** G. L. KEENAN (*Jour. Biol. Chem.*, 62 (1924), No. 1, pp. 163-172, figs. 11).—With the use of the immersion method described by Wherry (E. S. R., 39, p. 415), the author has determined the optical properties of alanine, aspartic acid, cystine, glutamic acid, synthetic glycocoll, leucine, phenylalanine, serine, tryptophan, tyrosine, and valine. The data reported include crystal habit, refractive indices, characters shown in parallel and convergent polarized light with crossed Nicols, and diagnostic characters. Photomicrographs of the acids are also given.

**A contribution to the chemistry of grape pigments.—III, Concerning the anthocyanins in Seibel grapes,** R. J. ANDERSON (*Jour. Biol. Chem.*, 61 (1924), No. 3, pp. 685-694).—In continuation of the studies previously noted (E. S. R., 52, p. 610), a similar examination was made of the anthocyan occurring in the dark blue Seibel grape. As determined by the composition of the anthocyanin chloride and the anthocyanidin chloride, the anthocyan was identified as oenin, the glucoside derived from *Vitis vinifera*, thus showing that in this cross between the American varieties *V. aestivalis* and *V. rupestris* and the European variety *V. vinifera* the pigment of the European grape is inherited by the hybrid.

**Insulin from the cod fish.**—The direct application of picric acid to the islet tissue, H. W. DUDLEY (*Biochem. Jour.*, 18 (1924), No. 3-4, pp. 665-668).—A convenient method is described for collecting and preserving the islet tissue of the pancreas of cod for the preparation of insulin. The method consists in removing the tissue from freshly cut fish and dropping it immediately into saturated aqueous picric acid. The material, which can be kept without refrigeration, is worked up by pouring off the picric acid solution into a convenient receptacle, cutting up the tissue with scissors, grinding it in a mortar with sand, and returning it to the picric acid. After standing for a day, the material is filtered and the picric acid solution discarded. The tissue is then ground repeatedly in a mortar with small amounts of a 75 per cent aqueous solution of acetone (150 cc. of the acetone being used for 9.6 gm. of the moist tissue), centrifuged, and the picrate converted into a soluble hydrochloride by the method previously described (*E. S. R.*, 51, p. 502).

It is stated that a yield of 13.12 rabbit units per gram of tissue was obtained by this method from the islet tissue of the cod, although collected from fish which had been caught at varying intervals up to 24 hours before the extraction. It is estimated that the islet tissue of the cod contains, weight for weight, about 10 times as much insulin as mammalian pancreas.

**Studies on pentose metabolism.**—I, A colorimetric method for the estimation of furfural, G. E. YOUNGBURG and G. W. PUCHER (*Jour. Biol. Chem.*, 61 (1924), No. 3, pp. 741-746).—The method described is based upon the reaction between furfural and aniline in the presence of acetic acid. The technique is essentially as follows:

From 1 to 5 cc. of the distillate or reaction mixture to be tested, diluted if necessary so that 2 cc. contains between 0.01 and 0.05 mg. of furfural, is pipetted into a tube calibrated at 10, 15, and 20 cc., and to this as well as to two similar tubes are added from 1 to 2 drops of a 0.5 per cent alcoholic solution of phenolphthalein. Into one tube containing only the phenolphthalein is pipetted 1 cc. of a standard solution containing 0.02 mg. of furfural in toluene-saturated water, and to the other 1 cc. of a similar standard containing 0.05 mg. To each of the tubes is then added, drop by drop from a capillary pipette, 50 per cent sodium hydroxide until a permanent pink color is obtained, after which exactly 0.5 cc. of aniline and 4 cc. of acetic acid are added. The contents of each tube are diluted to 10 cc. with distilled water, thoroughly mixed, and the tubes are allowed to stand in diffused light or in the dark for 15 minutes, after which they are compared in a colorimeter with the standards.

Data are given showing that the new method gives results in close agreement with those obtained by the Official gravimetric phloroglucinol method and slightly lower than those obtained with the Pervier and Gortner electrometric method (*E. S. R.*, 51, p. 12).

**Fat-soluble vitamins.**—XX, A modified technique for the determination of vitamin A, H. STENBOCK, M. T. NELSON, and A. BLACK (*Jour. Biol. Chem.*, 62 (1924), No. 1, pp. 275-286, pl. 1, figs. 4).—The evidence advanced in a previous paper of the series (*E. S. R.*, 50, p. 363) that the growth-promoting properties of what has been known as the fat-soluble vitamin are really due to both the antiophthalmic vitamin (vitamin A) and the antirachitic vitamin is thought to necessitate a revision of methods of determining vitamin A which have used growth as the criterion for the quantitative occurrence of this vitamin.

By irradiating the experimental animals, failure to grow as the result of lack of antirachitic vitamin is avoided, and the continued growth or failure to grow after a certain period is a measure of the presence or absence of

vitamin A. Data are reported in tables and charts illustrating the use of the modified method. In determining the vitamin A content of millet seed and of alfalfa, the former was found to contain considerable quantities of vitamin A but to be deficient in antirachitic vitamin. Alfalfa cured in the dark was found to be rich in vitamin A, but when cured in the sun to be deficient in vitamin A but to contain the antirachitic factor.

**Vitamin studies: The water-soluble growth-promoting factors.—I, The quantitative determination of the growth-promoting factor for bacteria** [trans. title], H. DAVIDSOHN (*Biochem. Ztschr.*, 150 (1924), No. 3-4, pp. 304-336, figs. 3).—This paper consists of an extensive review of the literature on the water-soluble vitamins, the report of a study of various methods of determining quantitatively the growth-promoting substance for bacteria, with the development of a new method for this determination, and a theoretical discussion of the possible use that can be made of this method.

An examination of various bacteria led to the selection of *Bacillus coli* as best suited for the purpose. The method finally adopted consisted essentially in measuring the growth induced in this organism by the degree of turbidity produced in a given suspension under specified conditions. The standard fixed for comparative determinations was the amount of the substance to be tested which would give, after four hours' incubation at 37° C. with a given amount of *B. coli*, double the turbidity produced by the control without the added substance.

A list of 34 references to the literature is appended.

**A critical study of the Jendrassik reaction for water-soluble B**, V. E. LEVINE (*Jour. Biol. Chem.*, 62 (1924), No. 1, pp. 157-161).—The ferric ferri-cyanide reaction considered by Jendrassik to be specific for vitamin B (E. S. R., 50, p. 506) is reported to be positive for nearly all phenols and also for certain nonphenolic compounds. Negative results were obtained with phenols following reaction with alkali, as was shown by Jendrassik to be the case with preparations containing vitamin B. Negative results were also obtained with certain organic acids, aldehydes, ketones, and carbohydrates.

It is concluded that the test is not specific for vitamin B, but that it suggests the possibility that the vitamin B molecule may contain one or more phenolic groups.

**Cod-liver oil and its by-products**, A. D. HOLMES (*Jour. Amer. Pharm. Assoc.*, 13 (1924), No. 12, pp. 1112-1115, fig. 1).—A general description is given of modern methods of manufacturing medicinal cod liver oil and its by-products, with special emphasis on the variations in the vitamin content of the oil, depending upon whether it is rendered from fresh livers or prepared by the rotting process or by renovating nonedible oils.

**The chemistry of synthetic sweetening compounds**, G. M. DYSON (*Chem. Age [London]*, 11 (1924), No. 286, pp. 572-574).—This is a review of present theories concerning the correlation of the sweetness of certain synthetic organic compounds, such as saccharin, with their structure. The method of manufacturing saccharin is also outlined.

**Merck's catalogue of reagents**, E. MERCK (*Merck's Reagenzien-Verzeichnis. Darmstadt: L. C. Wittich, 1924, 5. ed., pp. [6]+656*).—This volume, of which this is the fifth edition, contains an extensive list of chemical reagents and reactions classified under the authors' names, with brief descriptions of the preparation and use of the reagents and of the technique and significance of the reactions and references to the original literature. At the end of the volume the reagents and reactions described are arranged according to subjects, with cross references to the authors.

**A systematic handbook of volumetric analysis**, F. SUTTON, rev. by W. L. SUTTON and A. E. JOHNSON (*Philadelphia: P. Blackiston's Son & Co., 1924, 11. ed., rev. and enl., pp. XII+629, figs. 120*).—In the preparation of the eleventh edition of this well-known volume every section has been thoroughly revised, and the section on gas analysis has been entirely rewritten by H. Hollings and J. S. G. Thomas.\* The International Atomic Weights for 1923 have been used throughout and all factors recalculated where necessary.

**A method for the quantitative determination of ammonium salts** [trans. title], S. LOVGREN (*Ztschr. Analyt. Chem., 64 (1924), No. 12, pp. 457-470*).—The author recommends for the determination of ammonium salts direct titration with sodium hydroxide in the presence of alcohol, with thymolphthalein as indicator. To obtain accurate results, the concentration of alcohol at the end of the experiment must be at least 50 per cent and the total volume not more than 10 cc. The method is considered applicable to the determination of small as well as large amounts of ammonium salts of either strong or weak acids. The strength of the base must correspond to that of the salt being titrated.

**An iodometric method for the determination of sodium in small amounts of serum**, B. KRAMER and I. GITTLEMAN (*Jour. Biol. Chem., 62 (1924), No. 2, pp. 353-360*).—On account of the unsatisfactory results reported by some investigators in the use of the gravimetric method of determining sodium described by Kramer and Tisdall (*E. S. R., 45, p. 716*), the authors have further modified the procedure by determining the antimony in the precipitate by iodometric titration. The various steps in the procedure are outlined as follows: "First, the precipitation of the sodium as the pyroantimonate compound; second, the separation of the supernatant fluid from the precipitate by centrifuging, followed by either siphoning or careful aspiration of all the supernatant fluid; third, the solution of the precipitate by means of an excess of concentrated hydrochloric acid or the acidification of the supernatant fluid with resolution of the precipitate that forms; fourth, the reduction of antimony ion with a simultaneous oxidation of the iodide ion of hydriodic acid to free iodine; and lastly, the reduction of free iodine to iodide ion by sodium thiosulfate with the formation of sodium iodide and sodium tetrathionate."

The chemical reactions involved are discussed, and data are reported on various analyses, indicating the degree of accuracy of the method. The maximum error is considered to be  $\pm 2$  per cent.

**The graphic determination of carbon dioxide output and the respiratory quotient with the differential spirometer** [trans. title], E. HELMREICH and R. WAGNER (*Biochem. Ztschr., 149 (1924), No. 5-6, pp. 560-565, figs. 3*).—A further discussion of the apparatus previously noted (*E. S. R., 51, p. 806*).

**On the determination of sugar in small amounts of blood**, M. GILBERT and J. C. BOCK (*Jour. Biol. Chem., 62 (1924), No. 2, pp. 361-369, fig. 1*).—In the method described the samples of blood are collected in specially prepared capillary tubes and weighed on a torsion balance. The contents of the tubes are then aspirated into water in precipitation tubes of special design, and the determination is made by a modification of the Folin-Wu method adapted to small amounts of blood.

**The nature of the sugar in normal urine.—I, A comparison of the glucose equivalent of various sugars in different methods for the determination of glucose**, I. GREENWALD, J. SAMET, and J. GROSS (*Jour. Biol. Chem., 62 (1924), No. 2, pp. 397-399*).—The data obtained in a comparison of various methods of determining the glucose equivalent of 1 mg. of various pure sugars are reported in the accompanying table. Attention is called to the fact that the amounts of sugar were so chosen as to bring the depth of color

or the amount of titrated material within the prescribed range, and that, since the glucose equivalent in general varies with the concentration of the sugar, the values obtained are only approximately correct and are not applicable to all concentrations.

*Comparison of the reducing action of various sugars with that of glucose*

Sugar	Glucose equivalents of 1 mg. of sugar					
	Methods					
	Folin-Wu	Shaffer-Hartmann	MacLean	Benedict and Osterberg		Sumner
				Na <sub>2</sub> CO <sub>3</sub>	NaOH	
Mg.	Mg.	Mg.	Mg.	Mg.	Mg.	
Xylose.....	0.94	0.96	0.83	1.09	1.28	1.14
Arabinose.....	.80	.80	.80	1.02	1.17	1.17
Fructose.....	.91	.90	.94	.96	1.08	1.00
Galactose.....	.75	.80	.77	.95	1.04	.95
Mannose.....	.58	.81	.93	1.08	.86	.76
Maltose.....	.40	.42	.46	.82	.77	.70
Lactose.....	.45	.53	.51	.78	.74	.70
Glucosamine.....	.92	.90	.95	.98	.54	.34

The Benedict and Osterberg sodium carbonate, MacLean, Folin-Wu, Shaffer-Hartmann, and Benedict-Osterberg sodium hydroxide methods have all been noted (E. S. R., 39, p. 112; 41, p. 505; 42 p. 712; 45, p. 111; 46, p. 417).

**Analytical methods and observations on the organic phosphorus of the urine,** G. E. YOUNGBURG and G. W. PUCHER (*Jour. Biol. Chem.*, 62 (1924), No. 1, pp. 31-44, fig. 1).—The authors, with the technical assistance of H. A. Day, have examined various methods of determining the organic phosphorus of the urine by the removal of inorganic phosphates by precipitation and the subsequent estimation of the organic phosphorus in the filtrate.

Of the various precipitants magnesium mixture was selected as the most satisfactory, and for the subsequent determination of the organic phosphorus a modification of the colorimetric method of Bell and Doisy (E. S. R., 44, p. 613). The filtrate is digested with sulfuric and nitric acids in a Pyrex test tube (200 by 25 mm. and graduated at 25 cc.), with copper sulfate added to hasten the decomposition and to serve as indicator in the subsequent neutralization with ammonia. To obtain the same degree of acidity in the unknown and standard solutions the cooled mixture is diluted, neutralized with phosphorus-free ammonia water, and reacidified. The rest of the procedure is the same as the original Bell-Doisy method, except that the mixture is kept throughout the experiment in the same tube and finally made up to 25 cc. and compared in the colorimeter.

The method is admitted to give low results on account of the loss of phosphorus in the digestion with acids. Efforts to overcome this loss have thus far been unsuccessful. The losses of phosphorus in urine on standing for two days were found to be within the limits of experimental error.

Data are reported on the organic phosphorus excretion of 12 medical students (males) for 24 hours in 2-hour periods. The amounts excreted by the same subject fluctuated considerably, variations of over 100 per cent being obtained in successive 2-hour periods. The minimum, maximum, and average figures obtained were 0.089, 0.187, and 0.131 mg. per kilogram in 24 hours.

## METEOROLOGY

**Climatic laws**, S. S. VISHER (*New York: John Wiley & Sons, Inc.; London: Chapman & Hall, Ltd., 1924, pp. 96, figs. 9; rev. in Amer. Jour. Sci., 5. ser., 9 (1925), No. 1, pp. 78, 79*).—This book gives 90 generalizations as to the geographic distribution and variation of temperature, wind, moisture, and miscellaneous phenomena.

**The laws of winds and moisture**, S. S. VISHER (*Ann. Assoc. Amer. Geogr., 13 (1923), No. 4, pp. 169–207*).—The laws concisely formulated, with references to the literature, relate to kinds, direction, velocity, and steadiness of winds; sources of moisture; rate of evaporation; distribution of moisture; relative humidity; condensation; and precipitation with reference to kind, place distribution, diurnal and seasonal distribution, and annual variability.

**Effects of tropical cyclones upon the weather of mid-latitudes**, S. S. VISHER (*Geogr. Rev., 15 (1925), No. 1, pp. 106–114*).—This article presents evidence and arguments to support the hypothesis “that tropical disturbances, particularly tropical cyclonic disturbances, give rise to many of the irregular weather changes of the rest of the world.” It is stated that “the effects of tropical cyclones upon the weather of mid-latitudes are both direct and indirect. The direct effects are partly the same as those produced within the Tropics and are partly different. Among those that are the same, mention may be made of the changes in air pressure, wind direction and velocity, cloudiness, humidity, and precipitation.” The indirect effects “are of three main types, those due to disturbances in the normal planetary circulation, those due to disturbances in the so-called permanent ‘centers of action,’ and those due to the influence of the tropical storms themselves upon other cyclones in middle latitudes.”

**[Fluctuations in solar radiation and their relation to weather]** (*Smithson. Misc. Collect., 76 (1924), No. 10, pp. 22–30, figs. 4; abs. in Jour. Franklin Inst., 198 (1924), No. 6, pp. 848–850*).—Observations at Mount Wilson, Calif. (later at Mount Harqua Hala, Ariz.), and at Calama, Chile (later at Mount Montezuma), of the same character as those already noted (E. S. R., 50, p. 509), are reviewed. “The two stations join in indicating the march of the solar heat up and down, and within the past year the fluctuations have ranged over about 4 per cent. During the years 1914 to 1921, the results had run generally at a level of about 1.95 calories per square centimeter per minute. Beginning in 1921, a notable downward march began, and by September, 1922, the monthly mean values were ranging at about 1.91. This lower level continued, with minor fluctuations, for a number of months, and the lowest values were reached in February and March, 1922. After that there was a gradual increase, until in September and early October, 1923, the values had come to an average level of about 1.93. Still more recently, there has begun a slump, so that at latest advices, up to February 1, 1924, the solar heat outside the atmosphere is running at approximately 1.92 calories.”

It is explained that there is no simple relation between fluctuations in solar radiation and rise or fall of temperature. “Consequently the study of the dependence of weather on solar radiation must be very long continued and thorough before it will be possible to hazard predictions based upon the variation of the sun, or even to know for certain that the variations of the sun are of importance for our forecasters.”

**Atmospheric electric currents, normal and abnormal, and their relation to the growth of plants**, V. H. BLACKMAN (*Quart. Jour. Roy. Met. Soc. [London], 50 (1924), No. 211, pp. 197–207, figs. 2*).—Reviewing the work of others and summarizing the results of field, pot, and laboratory experiments of

his own at Rothamsted, the Harper Adams Agricultural College, and Lincluden, Scotland, extending over several years, the author concludes in brief "that although no indubitable evidence has been obtained as to the favorable effect of the normal atmospheric current, yet the converging evidence now available from the laboratory, from pot cultures, and from the field can leave no doubt as to the favorable effect on the growth of plants which larger electrical discharges are able to produce," and he expresses the opinion "that in the biological effects of atmospheric electric currents we have a field of exploration of importance to both pure and applied science."

**Influence of meteorological factors on tree growth.—I, Influence on the trunk circumference of a fir tree** [trans. title], H. NAKASHIMA (*Jour. Col. Agr., Hokkaido Imp. Univ.*, 12 (1924), No. 2, pp. 69-263, pls. 14, figs. 3).—Observations with a Friedrich "growth autograph" (Zuwachsautograph) on a representative 50-year-old fir (*Abies mayriana*) growing on a deep, well-drained loam soil are recorded and discussed in detail. The growth measurements extended over a period from November 15, 1913, to December 31, 1918, and were accompanied by observations on soil and air temperature, precipitation, evaporation, humidity, cloudiness, sunshine, and wind.

The results showed two causes of change in trunk circumference, namely, growth, and swelling or contraction of the water-carrying tissue. A close relation with meteorological conditions was evident. Four periods are differentiated, vegetative, spring transition, fall transition, and rest. During the rest period, temperature was the controlling factor, in the vegetative period, precipitation. In the transition periods, the ratio of transpiration to absorption was the determining factor.

The relation between air temperature and circumference during the rest period is expressed as follows:

$$y = 0.66359 - 0.086265(2 - x) - 0.2$$

The relation between rainfall and trunk circumference during the vegetative period is represented by the following equation:

$$y = 0.055 - 0.02785(x + 0.5) - 0.41797$$

**Some aspects of the use of the annual rings of trees in climatic study**, A. E. DOUGLASS (*Smithsn. Inst. Ann. Rpt.*, 1922, pp. 223-239).—This article is reprinted from a source already noted (*E. S. R.*, 47, p. 510).

**The temperature region map**, A. E. PARKINS (*Abs. in Ann. Assoc. Amer. Geogr.*, 13 (1923), No. 4, pp. 214, 215).—This is an abstract of a paper presented at the Ann Arbor meeting of the Association of American Geographers, in which was briefly reviewed the development of the idea of temperature regions and a comparison made of various temperature region maps, the merits of a map proposed by the author being explained.

**Rainfall map of Sweden** [trans. title], A. WALLEN (*Meddel. Statens Met. Hydrog. Anst.*, Bd. 2, No. 3; *rev. in Nature* [London], 114, (1924), No. 2868, p. 588).—The map shows annual and monthly rainfall based on data from widely distributed stations for 1881 to 1920, with a summary of the data used and a discussion of the cartographic methods employed.

**[Heaviest rainfall ever recorded on the Island of Guam]** (*Guam Recorder*, 1 (1924), No. 8, p. 5).—A typhoon passing to the south of Guam on October 1, 1924, was accompanied by a rainfall on the island of 19 in. in 15

hours, 28.25 in. in 30 hours, and 33.09 in. in 48 hours. This is the heaviest rainfall recorded for the island and resulted in floods which did much damage.

### SOILS—FERTILIZERS

The moisture equivalent as influenced by the amount of soil used in its determination, F. J. VEIHMEYER, O. W. ISRAELSEN, and J. P. CONRAD (*California Sta. Tech. Paper 16 (1924), pp. 64, pls. 2, figs. 10*).—Studies of the influence of the amount of soil used in the determination of the moisture equivalent in five different soils are reported.

The results showed that the amount of soil used materially influences the moisture equivalent, the smaller the sample the larger the percentage of water retained. The difference was greater with small samples than with large ones. Some clay soils were found to become impermeable to water during centrifuging when the amount of soil placed in the centrifuge cup was increased, and these soils reabsorbed the supernatant water when the centrifugal force was relieved.

The moisture content was found to increase from the inner to the outer surface of a 60-gm. block of soil, but the rate of increase was lower than that resulting from reducing the size of sample from 60 to 5 gm. The amount of water retained within blocks of soil much larger than 60 gm. probably increases from the inner to the outer surface if the soil is centrifuged long enough to establish equilibrium. The apparent specific gravity of a 60-gm. block of soil was found to be significantly greater than that of a 10-gm. block, and decreased continuously as the size of sample was decreased from 60 to 10 gm. The apparent specific gravity within a 60-gm. sample increased significantly from the inner surface outward to a point about 6 mm. within the sample, beyond which it remained substantially constant to the outer surface.

The placing of weights on the inner surface of 5-, 10-, 20-, or 30-gm. samples decreased the amount of water retained by the soil. Subjecting the moist soil to centrifugal force until the moisture was in equilibrium with this force resulted in the establishment of an equipotential region throughout the block of soil. In general, it was found that the average pore space does not limit the amount of water retained by the soil block, and it is considered probable that the outer layer of the fine-textured soils is saturated, or nearly so.

When precision is desired, it is considered necessary to measure the sample by weight rather than by the measuring cup. The variation in moisture equivalent with samples of different sizes was found to be influenced by the degree of compactness as well as by the depth of the sample in the centrifuge cup. The results as a whole are taken to indicate that further standardization of the moisture equivalent method is necessary if comparable results are to be obtained.

The reservoir capacity of soil [at the Irrigation Substation], C. C. WRIGHT (*Washington Col. Sta. Bul. 187 (1924), pp. 101, 102*).—Studies of the reservoir capacity of six plats of the substation soil at depths of from 1 to 6 ft. showed that the water-holding capacity and rate of water penetration of the soil in the six plats was very uniform. This soil was found to hold as much as 3.5 in. of water per foot when saturated in the field and 2.5 in. per foot under conditions of equilibrium after being thoroughly irrigated, thus indicating that the upper soil blanket of 6 ft. will hold 15 in. of water before any loss by deep percolation takes place. It was further found that this soil must contain 0.5 in. per foot in order to have any water available for crops. Irrigation of from 2 to 3 in. every 20 days was required to keep this soil restocked with water during the irrigation season where there were no crop demands upon it.

**Thermal diffusivity and conductivity of some soil materials**, L. R. INGERSOLL and O. A. KOEPP (*Phys. Rev.*, 2. ser., 24 (1924), No. 1, pp. 92, 93).—The results of thermal diffusivity determinations of quartz sand, sandy clay, calcareous earth, and packed snow are briefly reported. The method used is based on the principle of linear heat flow in a slab whose faces are suddenly chilled. The material was packed in a narrow sheet copper box having broad faces, with a resistance thermometer in the center. After standing at room temperature for two days it was placed in stirred ice water and the time required for the temperature to fall half way to zero was noted, thus allowing direct calculation of the diffusivity. It is noted that where comparison of the values found with existing data is possible, the agreement is satisfactory.

The results showed that sandy clay gave the highest result of the earthy materials and the calcareous earth and quartz sand the lowest. The densely packed snow gave the highest result of all the materials.

**The chemistry and physics of clays and other ceramic materials**, A. B. SEARLE (*New York: Van Nostrand Co.*, 1924, pp. XIII+695, figs. 52).—This book, while prepared primarily from the ceramic standpoint, contains a large amount of information relating to the chemistry and physics of clays which should be of value in a study of soils and soil dynamics.

**The electrical charge on a clay colloid as influenced by hydrogen-ion concentration and by different salts**, W. C. DAYHUFF and D. R. HOAGLAND (*Soil Sci.*, 18 (1924), No. 5, pp. 401-408).—In a contribution from the University of California the results of measurements made of the cataphoretic charge on a clay colloid as influenced by varying H-ion concentrations and by varying salts are reported.

It was found that the colloid remained negatively charged within the entire range of H-ion concentrations used, namely, from pH 2.1 to pH 12.7. The predominant factors determining the stability of the suspension were the nature and the concentration of the cations present in the medium. It is suggested that an alkaline reaction may sometimes cause deflocculation primarily because of the lessened solubility of di- and trivalent cations rather than because of the direct effect of the OH-ion concentration.

**A study of the tolerance of plants to acid conditions as determined by the hydrogen ion concentration**, L. W. TARR (*Delaware Sta. Bul.* 139 (1925), pp. 15, 16).—It is stated that preliminary experiments conducted with a sand, clay loam, and a muck soil showed that soils differ materially in their resistance to change in reaction. The addition of small amounts of acid or alkali to the sand produced appreciable changes in reaction, whereas the muck resisted an appreciable change in reaction even upon the addition of relatively large amounts of acid or alkali. This is taken to indicate that the buffer action of the sand is slight, while that of the muck is considerable. The clay also exhibited considerable buffering effect. It is thought that the organic matter in some soils is undoubtedly a considerable factor in offering resistance to a change in reaction, and in others is due to colloidal iron, alumina, and silica. An effort is being made to correlate the buffer action observed with the colloidal materials of soils.

**Soil acidity in relation to soil type groups, in Nacogdoches County, Texas**, B. H. HENDRICKSON (*Soil Sci.*, 18 (1924), No. 5, pp. 383-385, fig. 1).—In a contribution from the U. S. D. A. Bureau of Soils the results of over 200 acidity tests of various soil types occurring in Nacogdoches County, Texas, are briefly summarized. Acidity tests were made of virgin soils only and according to natural soil horizons.

It was found that the reactions of the first horizons are quite similar for the various soil groups. This condition apparently reflects the common character,

namely, the surface organic layer. Below this horizon the several groups vary one from the other in textural and structural character, and as regards aeration and internal drainage. Correspondingly the soil reaction curves for the separate groups diverge for increasing depths below the surface. Increasing acidity is invariably associated with finer textures, poorer aeration, and poorer internal drainage conditions.

Causes of variations in reaction within the soil type were found to be almost entirely traceable to discernible physical variations within the type. It further appeared that the acidity relationship depends more upon the internal drainage than upon the regional drainage. It is also considered apparent that under climatic conditions tending to produce soils well leached of calcium carbonates, it is entirely possible to estimate the mean acidity content of well-developed, well-weathered types, and to show fairly consistent differences between the acidity contents of diverse types of this character.

**The vertical movement of alkali under irrigation in heavy clay soils,** F. T. SHUTT and J. M. MACOUN (*Roy. Soc. Canada, Proc. and Trans., 3. ser., 17 (1923), Sect. III, pp. 71-74*).—A continuation of previous studies is reported (*E. S. R., 49, p. 513*). It is noted that the experimental plats have received three irrigations each season for the past eight years, and that no surface indications of alkali have been evident.

The chemical data indicate that the saline content of the first 18 in. has remained practically unchanged. It is concluded that an area of heavy clay underlaid by a heavily impregnated subsoil may be safely irrigated for a number of years, provided the irrigation is judicious and that at the outset the surface soil to a depth of 18 in. is free, or practically free, from alkali.

**The "alkali" content of soils as related to crop growth,** F. T. SHUTT and J. M. MACOUN (*Roy. Soc. Canada, Proc. and Trans., 3. ser., 17 (1923), Sect. III, pp. 75-78*).—A continuation of studies begun in 1917 (*E. S. R., 49, p. 513*) is presented covering the results obtained in the season of 1922.

It is concluded that the results of this investigation from the beginning point to 0.35 per cent of sodium sulfate, when present in the chief root feeding zone, as being the limit of tolerance for wheat. Fairly good crops of wheat have been raised on soil containing a higher saline content, but almost invariably distinct signs of distress have been evident when the amount passed 0.5 per cent. The presence of magnesium sulfate in addition complicates the question, but it is considered evident that when the alkali content approaches 1 per cent in the first 6 in. of soil the limit of tolerance for good vigorous growth has been passed.

**Alkali studies.—I, Tolerance of wheat for alkali in Idaho soil,** R. E. NEIDIG and H. P. MAGNUSON (*Soil Sci., 18 (1924), No. 6, pp. 449-467, figs. 3*).—Studies conducted at the Idaho Experiment Station on the tolerance of wheat for alkali in silt loam soil are reported.

The results with the first crop showed that wheat was not affected by sodium carbonate until 0.1 per cent recoverable salt was found in the soil. At 0.2 per cent concentration there was evident toxicity, and 0.3 per cent recoverable salt always resulted in a total crop failure. Sodium chloride when present alone in the soil was not harmful to the growth of wheat until 0.2 per cent recoverable salt concentration was reached. A concentration of 0.25 per cent showed a decided toxicity.

Recoveries of 0.75 per cent sodium sulfate failed to show any detrimental effect on crop yield. The tolerance for this concentration of sodium sulfate was materially decreased by the presence of 0.07 per cent of sodium chloride. In the presence of the same amount of sodium sulfate, sodium carbonate

showed no effect until its own maximum tolerance limit of approximately 0.1 per cent was reached. In combinations of sodium carbonate and sodium chloride, small recoveries of either salt had an influence on crop yield only when the other salt concentration approached its maximum tolerance.

The results with the second crop showed that any toxic effect of the salts on plant growth was so effectively overshadowed by the stimulation of all treatments except the very highest carbonates that no measurement of toxicity could be made. However, where more crops were grown on the same soil this stimulation was overcome, and characteristic toxicities again became apparent.

**The alkali soils in Hungary and their reclamation**, A. A. J. DE 'SIGMOND (*Rev. in Soil Sci.*, 18 (1924), No. 5, pp. 379-381).—This is a short review of a monograph by the author on the subject.

**On the nature of burn-outs**, F. T. SHUTT and J. M. MACOUN (*Roy. Soc. Canada, Proc. and Trans.*, 3. ser., 17 (1923), Sect. III, pp. 79-82, fig. 1).—A continuation of previous work on the subject is noted (E. S. R., 48, p. 423).

The results of previous work are confirmed and the fact established that a burn-out is an area from which the surface soil has been removed. The subsoil is what is exposed at the bottom of a burn-out. On first breaking up these burn-outs, it has been noted that the crops are lighter on the site of the burn-outs than on the adjacent unaffected land. Cultivation for a few years brings about a uniformity of crop growth on such tracts, proving that the subsoils of the semiarid areas are fairly rich in plant nutrients and can be brought into a state of productiveness by tillage.

**[Soil bacteriological studies at the Idaho Station]** (*Idaho Sta. Bul.* 135 (1925), pp. 21-25).—Studies of the occurrence of *Azotobacter* in 106 samples of timbered soils of northern Idaho in which nitrification did not proceed normally indicated the presence of the organism in but 24 samples. The soils were divided into five classes, ranging from virgin timber to those cultivated for many years, and no correlation was evident between cultivation and the presence of the organism. Virgin timber soils contained the organism in a slightly greater number of cases than the cultivated soils.

Tests of 60 samples of this soil as to their ability to support the nitrogen-fixing organism showed that all supported it for a considerable period of time, and all but 14 still contained it after from 15 to 18 months.

Determinations of the H-ion concentration of each of the 106 samples by the electrometric method showed the majority of these soils to be neutral or basic, while the more common acidity tests showed all of these soils to be acid, in spite of the fact that they did not respond to applications of lime.

Tests of the influence of the leaves, needles, and bark from ash, maple, cedar, larch, white pine, yellow pine, and white and red fir on nitrogen fixation showed that in general the needles were more toxic than the sawdust from the same tree. Cedar was the most toxic, followed by the pines. These results are taken to indicate that the tree products which litter the soil are toxic to the nitrogen-fixing organism.

A study of the effect of various amounts of combinations of the carbonate, chloride, and sulfate of sodium on ammonia formation from blood, nitrate formation from ammonium sulfate, and on the growth and yield of wheat (see above) in a neutral silt loam soil showed a gradual decrease in total water-soluble salt as time progressed after their application. Sodium carbonate stimulated the ammonification of blood and the nitrification of ammonium sulfate during the period of growth of the first and second crops. Sodium chloride was toxic toward ammonification and slightly toxic toward nitrification during the first period, and slightly toxic to both processes during the second

period. Sodium sulfate was toxic toward ammonification and had little or no effect on nitrification during the first period, and was slightly toxic to both processes during the second period. The two salt combinations were toxic toward ammonification in every case in the first period, and generally stimulated nitrification. During the second period the toxicity to ammonification decreased and nitrification increased. All of the three salt combinations reduced ammonia formation during the first period, and the majority increased nitrification. These results were emphasized during the second period.

Studies on the effect of surface tension of the nutritive medium on the growth of nitrogen-fixing bacteria are also briefly reported. Soaps prepared from castor oil, palmitic acid, olive oil, and coconut oil were used as a means of depressing the surface tension of the nutritive medium. Only one case of benefit from reduced surface tension was observed.

[Soil studies at the Washington Station] (*Washington Col. Sta. Bul. 187 (1924)*, pp. 74-79).—Studies by F. J. Sievers and H. F. Holtz on the maintenance of organic matter in eastern Washington soil showed that the return of organic residues to the soil has an immediate and pronounced influence on soil fertility, depending not only upon the kind of residue but more upon its nitrogen content. When the nitrogen content of the residue applied is very low crop yields are decreased because of a lack of available nitrogen, and when the nitrogen content is very high the yields are also frequently decreased because of the luxuriant vegetative growth resulting from excessive tillering.

Fertility investigations of Washington soils by Sievers and Holtz indicated that on all soils, except the mucks and sandy loams, there is very little relation between soil acidity and lime deficiency. Where legumes have failed to make proper development on many of these soils, due apparently to soil acidity, it has been found with practically no exception that the soil can be brought into an ideal condition for the growing of such legumes by the application of a phosphate fertilizer.

Studies on the effect of soil composition on the composition of the plant grown thereon showed that any practice that provides a supply of available nitrogen during a season of normal precipitation will have a pronounced effect on crop yields, whether this practice is early summer fallow tillage, the use of an intertilled crop like corn or potatoes, nitrogen fertilization, or the growth of a legume crop. Where the precipitation is abnormally low, wheat yields are no longer influenced by practices that affect the available nitrogen supply only.

It is reported by Sievers, Holtz, and H. P. Singleton that all irrigated soils in eastern Washington are well supplied in their virgin state with the mineral nutritive elements but are very deficient in nitrogen. This deficiency is so pronounced that successful crop production is impossible unless provision is made for a nitrogen supply either through fertilizers or legumes.

[Sulfur and soil organic matter studies at the Washington Station], J. R. NELLER (*Washington Col. Sta. Bul. 187 (1924)*, pp. 37, 38).—It is reported that experiments on the effect of sulfur oxidation upon the rate of oxidation of soil organic matter have shown that comparatively large quantities of sulfur may be oxidized in the soils of eastern Washington without any marked retardation of organic oxidation (*E. S. R.*, 51, p. 122).

Percolation studies with fine sandy loam soil showed that the addition of large quantities of sulfur caused an increase in the water-soluble potassium and calcium. An increased yield of legumes following the use of sulfur or gypsum as a fertilizer frequently resulted in an increased percentage of total protein. When large quantities of sulfur were used, the percentage of

phosphorus and potassium also increased and the percentage of calcium decreased. Top-dressing of soils previously treated with sulfur resulted in marked increases in the yield of some of the greenhouse crops.

A continuation of straw humification experiments (E. S. R., 51, p. 118) has shown that this process proceeds at a considerably faster rate when sodium nitrate or ammonium sulfate and calcium carbonate are added to the straw. Greenhouse tests have shown that merely keeping the straw moist for a few weeks previous to incorporation with the soil serves to decrease considerably the depressing effect of the straw upon the growth of wheat. This is taken to indicate that some toxic substance may be formed in the initial stages of straw decay which is later oxidized to a harmless or perhaps beneficial compound.

[Soil studies at the Irrigation Substation], H. P. SINGLETON (*Washington Col. Sta. Bul. 187 (1924), pp. 96, 97*).—It is reported that two years' results indicate that the cultivation of corn, except to control weeds, does not pay on the sandy loam soil of the Yakima Valley.

An experiment on the rate of decomposition of and nitrate production in sweet clover sod just plowed and alfalfa sod just plowed showed that the former had a 102 per cent greater rate of decomposition and a 95 per cent greater nitrogen accumulation than the latter.

Soil organic matter maintenance [at the Adams Substation], H. M. WANSER and I. M. INGHAM (*Washington Col. Sta. Bul. 187 (1924), pp. 86, 87*).—It is stated that where barnyard manure was applied to winter wheat a slight increase in yield resulted, while all other applications of organic residues or fertilizers slightly depressed the yield. When a high carbon or a low nitrogen residue was applied there was a proportionately greater depression in straw yield than where a low carbon or a high nitrogen residue was applied.

The problem of soil organic matter and nitrogen in dry-land agriculture, J. S. JONES and W. W. YATES (*Jour. Amer. Soc. Agron., 16 (1924), No. 11, pp. 721-731*).—Studies conducted at the Oregon Experiment Station on the maintenance of organic matter and nitrogen in soils subjected to dry-land cultivation are briefly reported.

It has been found that corn and potatoes in rotation with the small grains leave the soil enriched with organic matter. Fallow crops, rye, and field peas turned under have thus far not all increased the organic matter content of the soil over that in plats alternately cropped to winter wheat and summer fallowed. The most substantial enrichment has occurred in those plats on which corn is also included in the rotations. Field peas turned under have been found to enrich the soil with nitrogen substantially. Nitrogen has thus far been maintained on plats that have grown field peas continuously with the crops removed, but the organic matter content is lower than in plats alternately cropped with winter wheat and summer fallowed.

Soil conditions which promote nitrogen fixation, N. E. WINTERS (*Jour. Amer. Soc. Agron., 16 (1924), No. 11, pp. 701-716*).—Studies conducted at Cornell University on soil conditions which promote nitrogen fixation are reported.

The results showed that in Volusia soil, with a high lime requirement, and in Dunkirk soil, with a low lime requirement, 1 ton of limestone per acre promoted nitrogen fixation about as much as any heavier application. There was practically no difference between the effects on the nitrogen-fixing bacteria of equivalent amounts of calcium as limestone and as burnt lime. Dolomitic limestone gave better results than pure calcium limestone. Rapid nitrogen fixation in the soil was at first accompanied by a decrease in nitrates. Gypsum gave

no significant results in its effect on nitrogen fixation. Two tons of calcium carbonate promoted nitrogen fixation as much as 8 tons of calcium silicate.

It was found that soils may respond to the use of mineral nutrients for field crops and yet contain enough soluble minerals to supply the requirements of the nitrogen-fixing organisms. Under the conditions of the experiment, 100-lb. applications of sodium nitrate or its equivalent in ammonium sulphate or calcium nitrate stimulated nitrogen fixation, but heavy applications depressed it. These results are taken to indicate that the judicious use of nitrogenous fertilizers does not interfere with nitrogen fixation.

With the soils used, inoculation was unnecessary when conditions were made favorable for nitrogen fixation. Small quantities of aluminum chloride depressed nitrogen fixation, but iron chloride stimulated it. The quality of the organic matter added was found to be as important as the quantity, horse manure being the most valuable of any of the materials used. Composting organic materials before adding them to the soil was found to hasten nitrogen fixation during the first six weeks after application.

**Nitrate studies on Purdue rotation field No. 6**, I. L. BALDWIN, W. J. NICHTER, and R. O. LINDSEY (*Ind. Acad. Sci. Proc.*, 39 (1923), pp. 269-280, figs. 2).—Studies are reported which showed that, in the order named, the following rotations are effective in producing a high nitrifying power of the soil: (1) Corn, wheat, clover, and timothy, (2) corn, oats, wheat, clover, and timothy, (3) corn and wheat, and (4) corn, oats, and wheat. Soil continuously cropped to either wheat or corn showed a lower nitrifying power than soil cropped to any of the above rotations. The present crop was found to have more influence on nitrification than previous crops.

**Soil improvement**, [E.] J. RUSSELL (*Jour. Min. Agr. [Gt. Brit.]*, 31 (1924), No. 2, pp. 120-127, pl. 1, figs. 3).—In a contribution from the Rothamsted Experimental Station a brief summary is presented, indicating the status of soil improvement investigations at the station.

**Soil management and fertilization**, M. NELSON and W. H. SACHS (*Ark. Agr. Col. Ext. Circ.* 149 (1923), pp. 30, figs. 8).—Practical information on the management and maintenance of the productivity of Arkansas soils is presented.

**Coniferous timber soil studies** (*Idaho Sta. Bul.* 135 (1925), pp. 14, 15).—Studies on the effect of fertilizers with and without lime on coniferous timber soils are said to have shown that nitrate is the only fertilizer that materially increases crop yields. Applications of well-rotted manure did not show increased yields in any way comparable with the nitrate additions, and lime did not seem to be of material benefit. Little indication of ammonifying or nitrifying action by bacteria was evident in this soil. A resinous-like body was successfully isolated from this soil, which retarded the growth of wheat seedlings.

**Mathematical expression of the influence of the fertilizing elements contained in or added to the soil** [trans. title], H. LAGATU (*Assoc. Franç. Avanc. Sci. Confs., Compt. Rend.*, 46 (1922), pp. 859-866).—A brief mathematical analysis of the subject is presented.

**Fertilizer instruction**, D. N. PRJANISCHNIKOW (PRIANISHNIKOV), trans. by M. VON WRANGEL (*Die Düngerlehre. Berlin: Paul Parey, 1923, 5 ed., pp. XII+450 figs. 84*).—This is the fifth edition of this book.

**The leaching of fertilizers from soils**, A. W. R. JOACHIM (*Trop. Agr. [Ceylon]*, 63 (1924), No. 5, pp. 277-282).—In a contribution from the Department of Agriculture of Ceylon a summary of data is presented on the leaching of fertilizers from soils, special attention being drawn to the ease with which nitrates are lost by leaching, and to the fact that of all the soluble chemical

fertilizers phosphoric acid applied in the form of superphosphate is the least likely to be lost in this manner.

**Fertilizer spreaders** [trans. title], LEONHARDS (*Ztschr. Pflanzenernähr. u. Düngung*, 3 (1924), No. 2, *Wirtschaft.-Prakt.*, pp. 461-464).—The author summarizes work by himself and others on the comparative value of broadcast and row fertilization of crops, especially grains, by machines. The conclusion is drawn that for German conditions row fertilization by machines has no advantage over broadcast fertilization for grains, and is practically out of the question for root and other wide-row crops.

**Industrial nitrogen**, P. H. S. KEMPTON (*London: Isaac Pitman & Sons, Ltd.*, 1922, pp. XII+104, figs. 19).—This is one of the Pitman Technical Primer series, edited by R. E. Neale. It deals with the principles and methods of nitrogen fixation and the industrial applications of nitrogen products in the manufacture of explosives, fertilizers, dyes, etc. It contains chapters on free and combined nitrogen and its sources, natural and artificial fixation of nitrogen, electrical fixation processes, catalytic fixation processes, fixation by combustion and explosion, industrial products of nitrogen fixation, explosives, fertilizers, dyes, other industrial nitrogen products, national nitrogen product developments, and imperial developments. A bibliography is included.

**Possible potash production from Minnesota shale**, H. A. SCHMITT (*Econ. Geol.*, 19 (1924), No. 1, pp. 72-83, figs. 2).—Studies conducted at the University of Minnesota are reported which showed that the Decorah shale in Minnesota is extensive and contains from 6 to 8 per cent of potash. The potash is in two states of combination, about 60 per cent being more easily available than the remainder. It was possible to obtain much potash from this shale by heat treatment with sodium salts equivalent in amount to the potash and with a slight excess of calcium carbonate. It could be rendered soluble and volatilized in part from bricks where salt and calcium carbonate were added to the raw shale.

This shale is said to be favorably situated for use with sand if a by-product from the potash extraction is suitable for sand-lime brick. It is also situated near some limestone which may be suitable for Portland cement. It has been tried without preliminary heat treatment with considerable promise of success as a fertilizer for peat soils deficient in potash.

**Final report of the special committee of the Association of Official Agricultural Chemists on the availability of phosphoric acid in basic slag phosphates**, H. D. HASKINS, J. A. BIZZELL, W. B. ELLETT, B. L. HARTWELL, and C. B. WILLIAMS (*Jour. Assoc. Off. Agr. Chem.*, 7 (1924), No. 3, pp. 218-252, pls. 3).—The results of studies on the availability of the phosphoric acid in basic slag phosphates conducted by the Hawaii, Illinois, Massachusetts, New Jersey, New York, North Carolina, North Dakota, Pennsylvania, Rhode Island, and Texas Experiment Stations are summarized, and data are presented on the reliability of the Wagner method of analysis for measuring the availability of the phosphoric acid in this class of products.

The results established the fact that four such slags contained their phosphoric acid in forms freely available to the crops grown, and compared favorably both in yield of crop and phosphoric acid recovered with results obtained with acid phosphate. In addition, the availability figures established by the vegetation pot work compared favorably with the available phosphoric acid as measured by the Wagner method for Thomas basic slag phosphate and the official neutral ammonium citrate method for acid phosphate or superphosphates.

**Effect of iron and aluminum salts on the phosphorus recovery from soils and quartz sand treated with Tennessee rock or double acid phos-**

phate, M. I. WOLKOFF (*Soil Sci.*, 18 (1924), No. 6, pp. 469-478, fig. 1).—Studies conducted at the University of Illinois on the effect of adding ferric and aluminum chlorides in modifying the phosphorus recovery from some soils and sand treated with phosphatic fertilizers are reported.

The results showed that the addition of ferric chloride to three different soils caused a decrease in phosphorus recovery when phosphorus was applied to the soil in the form of either Tennessee rock phosphate or double acid phosphate. Aluminum chloride applied to the same soils showed no depressive effect on the phosphorus recovery, but, on the contrary, in two out of three cases the phosphorus recovery was slightly increased. When either calcium carbonate, ferric chloride, or aluminum chloride was applied to fine silica flour (passing a 200-mesh sieve) treated with rock phosphate, the phosphorus recovery was not significantly affected. The application of a mixture of calcium carbonate and ferric chloride, of ferric chloride and aluminum chloride, or of calcium carbonate, ferric chloride, and aluminum chloride caused some decrease in the phosphorus recovery. The influence of applying a mixture of calcium carbonate and aluminum chloride was much smaller.

It is suggested that double salts of phosphates may be formed, which in some cases may be less soluble than the corresponding single salts. Ferric aluminum phosphate may be somewhat more insoluble than either ferric phosphate or aluminum phosphate. Structural formulas harmonizing with this hypothesis are suggested.

Repeated extractions with fresh nitric acid showed that the phosphorus from soil treated with iron goes into solution. Practically the same amount of phosphorus was extracted in five consecutive extractions whether the initial treatment was iron chloride or aluminum chloride.

**Synthetic calcium silicates as a source of agricultural lime.**—I, A comparison of the influence of synthetic calcium silicates with other forms of lime as affecting plant growth, R. M. BARNETTE (*Soil Sci.*, 18 (1924), No. 6, pp. 479-491).—Studies conducted at the New Jersey Experiment Stations are reported. The growth of several plants was studied in controlled pot experiments and also in field experiments to determine the influence of equivalent applications of lime in various forms on several acid soils. The studies were made with particular reference to calcium silicates as possible carriers of lime.

As a whole, the artificial calcium silicates were as effective as the common forms of lime in overcoming the unproductive condition of so-called acid soils when applied on an equivalent calcium oxide basis. The greatest deviation from this generalization occurred in the exceptional increase in the growth of barley on soils treated with dicalcium silicate. It is thought that the greater barley yields obtained with this silicate might possibly be due to the greater absorption of the silicon, resulting in a heavier and healthier plant.

The percentage of nitrogen in soy bean, barley, and buckwheat plants varied with the soil, the higher percentages being found under the more unfavorable conditions of the untreated or so-called acid soils. Treatments of limestone, calcium hydrate, and dicalcium silicate gave crops of closely comparable nitrogen content. The greatly enhanced growth on the limed soils always netted a greater recovery of nitrogen.

**The rôle and importance of lime in agriculture** [trans. title], M. LENGLEN (*Chim. et Indus.* [Paris], 10 (1923), No. 6, pp. 1015-1025; 11 (1924), No. 1, pp. 17-39).—This is a rather extensive review of data from various sources on the action of lime in soil, with special reference to its influence on the physical and chemical characteristics of the soil and on the growth and yield of crops.

**Making limestone more available for farmers**, G. ROBERTS (*Ky. Agr. Col. Ext. Circ. 174* (1924), pp. 17, figs. 5).—Practical information on the burning of limestone is presented, together with plans and specifications for building and burning a limekiln and plans and specifications for a lime shed.

**Some questions in the oxidation of elementary sulfur** [trans. title], A. RIPPEL (*Centbl. Bakt. [etc.]*, 2. Abt., 62 (1924), No. 13-16, pp. 290-295).—Studies are briefly reported, the results of which are taken to indicate that the oxidation of elementary sulfur in soil is almost exclusively of a biological nature. Apparently an entire series of aerobic microorganisms participate which are not generally thought of as sulfur bacteria, and most aerobic organisms are thought to possess such power under certain favorable conditions.

**Fertilization with gas house waste** [trans. title], D. M. KÜTZING (*Wasser u. Gas*, 13 (1923), No. 33-34, pp. 796, 797).—The results of six different experiments on the fertilizing value of the waste water from gas houses on meadow and beet crops, when applied as a top-dressing or incorporated in the soil, are briefly summarized.

The use of waste water as a top-dressing injured vegetation, due to the caustic action of the free ammonia and the toxic action of other constituents. Such injury was small during rainy weather or where the gas water was diluted. The injury disappeared after some weeks and was more than compensated for by the increased plant development due to the action of the nitrogen content of the gas water. The increase depended upon the extent of the previous injury and the volatility of the ammonia.

When incorporated in the soil gas water gave results approximating those given by ammonium sulfate, the best results being obtained when the gas water was applied during damp, cool weather. Measures used for the prevention of nitrogen losses from concentrated liquid manure were profitably applied to gas water.

**Commercial fertilizers** (*Kans. State Bd. Agr. [Quart.] Rpt.*, 43 (1924), No. 170, pp. 43).—Information about commercial fertilizers in Kansas is presented, together with rules and regulations concerning their registration and sale and lists of dealers and of fertilizers registered July 1, 1924. In addition, guaranties and the results of actual analyses of 60 samples of fertilizers and fertilizer materials collected for inspection in the State during the fall of 1923 and spring of 1924 are presented.

**Changes in the composition and cost of fertilizers in New York from 1914 to 1924**, L. L. VAN SLYKE (*New York State Sta. Bul.* 525 (1924), pp. 3-19).—This general review of conditions relating to commercial fertilizers before, during, and after the war indicates that normal conditions are gradually returning in respect to the kinds of materials offered for sale, the composition of fertilizer mixtures, and the cost of plant nutrient constituents. One outstanding fact is that mixed commercial fertilizers contain, at the present time, a larger average percentage of plant nutrients than ever before.

## AGRICULTURAL BOTANY

**The physiology of photosynthesis**, J. C. BOSE (*London, New York, and Calcutta: Longmans, Green & Co.*, 1924, pp. XX+287, figs. 60).—This record of quantitative research regarding various phases of photosynthesis involves the relative numerical efficiency of light waves of varying length and energy and the effects of temperature change or of carbon dioxide variation on the activity of photosynthesis. The experiments have been carried out by means of a variety of sensitive apparatus especially designed for the different objects in view, including the use of automatic recorders.

The various chapters deal, respectively, with methods; the evolution of pure oxygen under light; determination of rate of evolution of equal volumes of oxygen; the automatic record of the rate of evolution of oxygen; photosynthesis under increasing intensity of light; relation between the quality of light and the amount of photosynthesis; the physiological factor in photosynthesis; change in photosynthetic activity under stimulus, anaesthetics, and poisons; effect of infinitesimal traces of chemical substances on photosynthesis; the electric response to light; phenomenon of photosynthetic induction; effect of intermittent light on photosynthesis; the automatic radiograph; the electric photometer; relation between CO<sub>2</sub> supply and photosynthesis; photosynthetic evolution of oxygen in the complete absence of carbon dioxide; effect of variation of temperature on photosynthesis; the tonic factor in photosynthesis; the daily variation in photosynthetic activity; determination of the photosynthetic efficiency of light of different colors; determination of the energy of the different rays in the solar spectrum; determination of photosynthetic efficiency of the spectral rays; determination of the increase of weight due to photosynthesis; simultaneous determination of carbohydrate-formation by two independent methods; efficiency of the photosynthetic organ in storage of solar energy; the physiological scale and the law of photosynthesis for the different factors; and photosynthesis under simultaneous variation of different factors, with, finally, a general review presenting salient features.

**Effect of infinitesimal traces of chemical substances on photosynthesis.** J. C. BOSE (*Nature* [London], 112 (1923), No. 2803, pp. 95, 96, fig. 1).—The possibility of ultrameasurable traces of chemical substances affecting assimilation is considered as capable of being effectively investigated through the very sensitive process of carbon assimilation by water plants. The usual method of counting oxygen bubbles given out by such plants under illumination is, however, regarded as untrustworthy for purposes of exact quantitative determination, owing to the spontaneous variation in the size and frequency of the bubbles. This difficulty has now, it is claimed, been completely overcome by a new automatic device showing the normal rate of photosynthesis, as well as its induced variations, and described in full in the work noted above.

Application of a nitric acid solution 1:100,000,000,000 induced no change in photosynthesis by the aquatic plant *Hydrilla verticillata*, but 1:10,000,000,000 increased the rate by 100 per cent, and 1:2,000,000,000 "caused a further increase of nearly 200 per cent." This, however, was the climax. The enhanced activity underwent a slight decline at dilutions of from 1:1,000,000,000 to 1:100,000,000, though the activity was still 100 per cent greater than the normal. There was an abrupt depression of activity at lower dilutions than 1:1,000,000.

Other facts cited include the effects at low concentrations of certain other substances on carbon assimilation. Among these is formaldehyde, which, according to Baeyer's theory, is one of the first products from which carbohydrates are formed by polymerization. An objection to this theory has been that formaldehyde is extremely poisonous to plants, but the present author found that formaldehyde at 1:1,000,000,000 increased photosynthesis by 85 per cent, though in higher concentrations it produced its normal poisonous effect. Since the intermediate stages of transformation of formaldehyde to carbohydrate are likely to be rapid, no accumulation of formaldehyde to a poisonous degree would be likely to occur. Thus the difficulty in accepting Baeyer's theory may be removed.

**Nutrient and toxic effects of certain ions on citrus and walnut trees, with especial reference to the concentration and P<sub>H</sub> of the medium.** H. S.

REED and A. R. C. HAAS (*California Sta. Tech. Paper 17 (1924)*, pp. 75, pls. 2, figs. 29).—The authors give the results of an investigation on the effects of certain factors on the growth and composition of walnut and citrus trees, the work having an important bearing on orchard practices in semiarid regions. Seedlings were grown in water and sand cultures which received balanced nutrient solutions to which there were added varying proportions of a number of compounds.

Walnut seedlings were found to absorb sulfate in increased amounts when the concentration of that ion in the culture solution was increased, although absorption did not run parallel with concentration.

Concentrations of nitrate as high as 1,600 parts per million, furnished as sodium nitrate, had no detrimental effect on the growth of walnut seedlings, and higher concentrations had a retarding influence only on the growth of the tops.

Walnut and orange seedlings absorbed chlorine readily, and their growth was characteristically affected by amounts which were harmless in the case of other anions. Young orange trees grown in soil cultures were seriously injured by the application of irrigation water containing 880 parts per million of chlorine (1,500 parts per million of sodium chloride).

A concentration of 1,000 parts per million of sodium bicarbonate was found to restrict the growth of walnut roots and often prevented the development of the epicotyls.

The injurious effect of high concentrations of potassium ions were not evident until after a considerable time had passed. Walnut seedlings in culture solutions containing 1,700 parts per million of potassium made good growth for a time, but eventually the foliage turned yellow and the roots ceased to grow. Young orange trees in sand cultures exhibited a somewhat similar character when they received solutions containing 500 parts per million of potassium. The leaves ultimately present a characteristic mottled appearance.

From the authors' experiments it is concluded that sodium is not severely toxic unless the concentration is fairly high.

Walnut seedlings made thrifty growth in solutions of calcium chloride but were very restricted in their growth in equimolecular solutions of sodium chloride. Strong concentrations of chlorine as calcium chloride were somewhat less toxic to rough lemon seedlings than equivalent concentrations as sodium chloride. Where calcium was furnished in subminimal amounts the roots of the young orange trees died and the foliage was chlorotic. The ash of the trunk and main roots of citrus trees was found richer in calcium than that from other parts of the tree, though in some cases the older leaves were very rich in that element. Data were secured which indicate that the absorption of calcium and potassium presents a sort of antithesis in the function of the citrus tree. If one element is high in the ash, the other will be low. The roots of walnut seedlings were extremely sensitive and quickly injured in calcium-free solutions.

Culture solutions which were on the alkaline side of the neutral point were not detrimental to the growth of rough lemon seedlings; in fact, they made more growth at pH 8 than at pH 6 or lower. Citrus and walnut seedlings grown at pH values of 7 or higher contained as much chlorine in the ash of their tops as those grown at lower pH values. The pH values of the sap expressed from walnut seedlings were quite uniform regardless of the reaction of the solution in which they were grown.

A concentration of 1,500 parts per million of sodium sulfate caused no apparent injury to walnut seedlings, but at a concentration of from 3,000 to 6,000 parts per million the growth of the seedlings was progressively retarded. Increasing concentrations of sodium nitrate had a somewhat similar effect.

A low concentration of magnesium on orange trees was mainly evident in a peculiar type of chlorosis along the midribs of the leaves. Aside from this, no profound physiological disturbances were observed.

The authors claim that, while it is difficult to anticipate the effects of a given concentration of an ion in the culture solution upon the amount of that ion found in the plant, in a general way the percentage found in the plant reflects the concentration in the culture solution.

The effects of sodium chloride on trees growing in soils under controlled conditions are said to throw some light upon certain conditions often seen in the field. The restricted growth of roots and shoots and the premature abscission of leaves agreed with analyses which showed an increased chlorine content of those members.

**A study of the June drop of fruits in Delaware, L. R. DETJEN** (*Delaware Sta. Bul. 139 (1925), pp. 19-21*).—A report is given of a large amount of material studied for the development of the embryo as affected by various climatic and other conditions. Some of the drop of fruits was attributed to frost injury or lack of fertilization, which resulted in the failure of the embryo to develop. The data collected on the physiological drop of fruits are said to indicate that rain and heavy dew cause the abscission of fruits more readily than dry weather conditions. Fruits fell more readily when trees were jarred in the morning hours than in the late afternoon, probably because of the greater turgidity of cells. Wind was not a direct factor in causing physiological drop, nor were daily differences in temperature considered responsible for it. Studies of the fluctuation in soil temperature, evaporation of water, and atmospheric moisture are believed to indicate that these are not direct factors in the dropping of fruits.

**Some orchard conditions affected by arsenicals, marls, and other factors, W. P. HEADDEN** (*Colorado Sta. Bul. 294 (1924), pp. 3-31, figs. 10*).—Attention is called to the dying of orchard trees in parts of Colorado and elsewhere that is considered due to soil conditions. Several explanations are offered as to the immediate causes, and remedial suggestions are given.

In some cases the death of the trees is attributed to the corrosive effect of arsenicals used for controlling insect pests. The substitution of lead arsenate for the older arsenicals has done away with this form of injury, but the prolonged and heavy use of lead arsenate is considered to become injurious through the action of sodium compounds in the soil making the arsenic soluble and capable of absorption by the tree roots. Another factor which is detrimental to orchards is said to be the accumulation of injurious quantities of nitrates in the soil. Marl soils are also considered unfavorable.

The author suggests the avoidance of the causes of injury as far as possible and the growing and plowing under of cover crops in orchards.

**[Report of] division of bacteriology, S. C. VANDECAVEYE** (*Washington Col. Sta. Bul. 187 (1924), p. 35*).—Among investigations in progress, the author carried on a study of the value of certain stains for isolating legume bacteria. Most of the organisms associated with legume bacteria were easily eliminated, but *Bacterium radiobacter* appeared more resistant. Pure cultures of the organism, however, were killed in less time in a less concentrated solution than pure cultures of the legume bacteria, and this is believed to indicate that *B. radiobacter* can be eliminated from the legume bacteria.

## GENETICS

**Genetics and eugenics, W. E. CASTLE** (*Cambridge: Harvard Univ. Press; London: Humphrey Milford, 1924, [3. ed., rev. and enl.], pp. VIII+134, pls. 60,*

*figs. 41*).—This is a revised and enlarged edition of the book previously noted (E. S. R., 47, p. 67). The first portion of the new book deals with the biological basis of genetics, thus giving a better introduction to the essential facts relating to the material basis of heredity and the cytological evidence. Three other new chapters are included dealing with the principles of plant breeding, the principles of livestock improvement, and the relation of Mendelism to mutation and evolution. The newer developments in genetics have necessitated rewriting certain of the other chapters, especially those connected with linkage and crossing-over. The translation of Mendel's paper has been omitted.

**The founders of the art of plant breeding**, F. C. WERKENTHIN (*Iowa Acad. Sci. Proc.*, 29 (1922), pp. 291-310).—This posthumous paper is published with an introduction by L. H. Pammel.

**Plant breeding in the subtropical, semi-arid regions of Arizona** [trans. title], J. C. T. UPHOF (*Ztschr. Pflanzenzücht.*, 10 (1924), No. 1, pp. 9-23, *figs. 5*).—The methods and results in breeding work carried on by the Arizona Experiment Station with alfalfa, wheat, sweet corn, tepary beans, and sorghum are reviewed.

**A preliminary statement of the results of Mr. Houwink's experiments concerning the origin of some domestic animals.**—Part V, Conclusion, J. P. LOTSY and K. KUIPER (*Genetica [The Hague]*, 6 (1924), No. 2-3, pp. 221-277, *pls. 8*).—This is the concluding paper of this series (E. S. R., 51, p. 228), in which further accounts are given of various crosses between species of the genus Gallus.

It was found that the individuals called bankantam, which are the birds which Houwink thought to be pure *bankiva*, were usually dominant in most characteristics in the crosses. The crossbred individuals were in most cases more or less fertile. It is suggested, however, that the appearance of the duckwing pattern in some of the F<sub>2</sub>s of the *bankantam* x *G. sonnerati* must be from *sonnerati* birds, in which the silver factor (S) responsible for this pattern is inhibited by another factor called I.

In conclusion, the authors believe that their evidence indicates that *G. bankiva* is not the sole ancestor of our domestic poultry. The introduction of the silver factor from the *sonnerati* and the introduction of a factor for black from *G. varius* are offered as evidence, and it is believed that all known wild species of fowls have taken some part in the formation of our domestic poultry.

In a discussion as to the lack of the influence of the species other than *bankiva*, it is noted that this species is found in nature in a greater number of localities, thus indicating a greater adaptability and hardiness and suggesting the part which natural selection may have played.

**An introduction to cytology with special reference to the cotton plant**, H. J. DENHAM (*Brit. Cotton Indus. Research Assoc., Shirley Inst. Mem.*, 3 (1924), No. 19, pp. 217-226, *figs. 2*).—The meaning and purpose of cytology are explained under the topics of cell structure, cell division, chromosome number, and the cytology of the cotton plant. An ample glossary is appended.

**The cytology of the cotton plant, I, II**, H. J. DENHAM (*Brit. Cotton Indus. Research Assoc., Shirley Inst. Mem.*, 3 (1924), Nos. 20, pp. 227-248, *pls. 8; 21, pp. 249-252, pl. 1*).—Research carried out at Shirley Institute on the cytology of the cotton plant is reported on in the following papers:

**I. Microspore formation in Sea Island cotton.**—The cytology of pollen formation in Sea Island cotton (*Gossypium barbadense*) is briefly described, with special reference to the reduction division of the pollen mother cell and chromo-

some number. The reduction division takes place along normal telosynaptic lines, and on the whole agrees with the process as described by Cannon<sup>1</sup> in hybrid cotton plants. Of particular interest are the perinuclear zone, which seems to be largely concerned with spindle formation in both homotype and heterotype divisions, but not in the premeiotic or somatic divisions; the manner in which the chromosomes are brought to the center of the nucleus in diakinesis; and the method of tetrad division by furrowing. The chromosome number is 26, with two chromosomes distinctly larger than the others. Thread ring structures described in parallel material have not been found in well-fixed buds, but ring figures of a similar appearance occur in cells which show distortion by the fixative.

II. *Chromosome numbers of Old and New World cottons.*—Counts of the chromosome numbers in 32 varieties of cotton, including American, Sea Island, Egyptian, Indian, and Chinese types, and American grown in India showed these numbers to fall into groups of 26 and of 13 chromosomes. The cottons of the New World and Egypt were characterized by 26 chromosomes and those of Asia by 13. This may, perhaps, explain the impossibility of crossing American or Egyptian cottons with Indian types, and is thought to suggest a possible solution of the difficulty with the help of cytology.

The reduction division in some wheat species [trans. title], W. DE MOL (*Genetica [The Hague]*, 6 (1924), No. 4, pp. 289-336, figs. 57).—A study of the reduction division in a number of species of wheat showed the pollen mother cells in the young anthers to lie close together and in the later stages to form a ring, when seen in transverse sections. The first division stage, a contraction of the chromatic substance in the nucleus, is followed by the leptoneuma stage, synapsis, zygonema, a third contraction stage, strepsinema and diakinesis.

After diakinesis a fourth contraction was observed. The wall of the nucleus then disappears, and soon afterwards the gemini are seen in the cytoplasm. The multipolar spindle is then formed, and is followed by a bipolar spindle. In the bipolar spindle the bivalent chromosomes are scattered through the whole of the spindle figure, but in the later stages they are so arranged that they form the equatorial plate. Both this stage and the anaphase are favorable to the counting of the number of chromosomes. The anaphase and telophase of the first division take place in the usual way.

In the next stage, the interkinesis, the chromatic substance clings to the wall of the nucleus. After interkinesis another (fifth) contraction similar to the one following diakinesis was observed. The chromatic substance is scattered over the bipolar spindle, as described in the case of the heterotype division. In the metaphase of the homotype division, the number of chromosomes could not be determined. The anaphase, telophase, and the formation of the pollen tetrads are said to proceed normally. In the tetrads as well as in young pollen grains a radiation of the cytoplasm could be seen around the nucleus.

The cultivated species of wheat may be grouped as follows according to their chromosome numbers: *Triticum monococcum* with 7 chromosomes; *T. dicoccum*, *T. turgidum*, *T. durum*, and *T. polonicum* with 14 chromosomes; and *T. vulgare*, *T. compactum*, and *T. spelta* with 21 chromosomes. This division is held to correspond roughly to that based on different degrees of sterility, on serological behavior, and on susceptibility to certain diseases.

Investigations on the genetics of geographical variation, I [trans. title], R. GOLDSCHMIDT, J. SEILER, and H. POPPELBAUM (*Arch. Mikros. Anat. u.*

<sup>1</sup> Cannon, W. A. Studies in Plant Hybrids: The Spermatogenesis of Hybrid Cotton. *Bul. Torrey Bot. Club*, 30 (1903), pp. 133-172.

*Entwickl. Mech.*, 101 (1924), No. 1-3, pp. 92-337, figs. [162]).—This is the first paper of a series dealing with the inheritance of variations in the caterpillars of strains of gipsy moths found in different sections of the world. A statistical study has been made of the inheritance of various characters in crosses between 12 strains of the genus *Lymantria* native to Europe, Japan, and Massachusetts. Certain of the experimental work was done in each of the places mentioned.

**Mottling of soybeans**, C. M. WOODWORTH and L. J. COLE (*Jour. Heredity*, 15 (1924), No. 8, pp. 349-354, figs. 2).—The authors discuss their experience with mottling in soy beans and conjectural causes of its occurrence.

**Study of some correlations in the peanut** [trans. title], G. NEVANO (*Staz. Sper. Agr. Ital.*, 57 (1924), No. 1-3, pp. 17-32).—In studies with a type of peanut cultivated in the Provinces of Naples and Salerno the author found the coefficient of correlation between the weight of dry pods and their total number to be  $0.874 \pm 0.007$ ; between the weight of dry pods and their average unit weight,  $0.384 \pm 0.026$ ; between weight of dry pods and number of peas to the pod,  $0.218 \pm 0.029$ ; between weight of dry pods and of plants with pods attached at the time of lifting,  $0.794 \pm 0.011$ ; and between weight of dry pods and of plants without pods at time of lifting,  $0.610 \pm 0.019$ . The best method of improving the peanut is concluded to be that of selecting plants bearing the most seed pods without considering their weight or size and number of peas.

**The Pratt family: A record of human inbreeding for eight generations**, F. B. HANSON (*Jour. Heredity*, 15 (1924), No. 5, pp. 207-210, fig. 1).—An account is given of eight generations of a pedigree of a girl from a well-known family of St. Louis, Mo. The existence of considerable inbreeding in this pedigree is noted, with a discussion of the probable amounts of inbreeding that would be found in ordinary populations if sufficient numbers of the ancestors were known.

**Some varieties of white rabbits**, W. E. CASTLE (*Jour. Heredity*, 15 (1924), No. 5, pp. 211-219, figs. 9).—The genetic factors involved in the production of albino, Himalayan albino, yellow chinchilla (white with gray eyes), Vienna, Dutch, spotted English, and French silver rabbits are briefly reviewed, with reference to other color factors.

**Inheritance studies and crop breeding**, E. F. GAINES (*Washington Col. Sta. Bul.* 187 (1924), pp. 54, 55).—In crosses between varieties of club and common wheat occurred longer clubs than the average of the club parent and common types shorter than the common parent, variations breeding true in later generations. Horny endosperm was inherited as a single Mendelian unit in 20 different crosses. Yellow berry was inherited independently of true horny or starchiness and was controlled by two factors in certain crosses and three in others. Immunity from bunt in Hussar and a strain of White Odessa was dominant in inheritance, whereas the resistance of other wheats tested during recent years behaved as a recessive, multiple factors always being necessary to explain the results.

In crosses between Red Rustproof and hull-less, as well as common oat varieties, time of ripening, glume color, red lemma color, hull-lessness, awning of the secondary oat, rachis length, and resistance to covered smut segregated in  $F_2$  in response to the combined reaction of triple allelomorphs in each case. Black glume color was inherited as a simple dominant. Since certain wild oats have 7 chromosomes, others 14, and the cultivated oats of these experiments 21, it is suggested that the three factors producing a single effect may have a phylogenetic significance in many cases.

**On human albinism** [trans. title], H. ZIMMERMANN (*Arch. Rassen u. Gesell. Biol.*, 15 (1923), No. 2, pp. 113-136, figs. 6).—Several pedigrees are given which

include individuals showing complete or partial albinism. Total albinism was found to be inherited as a simple Mendelian recessive character, while the mode of inheritance of partial albinism was not so clear.

**Studies on the physiology of reproduction.—I, The flocculation of sperm suspensions in relation to surface charge, A. WALTON** (*Brit. Jour. Expt. Biol.*, 2 (1924), No. 1, pp. 13–20, fig. 1).—In physiological studies of the activity of spermatozoa of *Echinus esculentus* and *E. miliaris* at the Animal Breeding Research Department, Edinburgh, and the laboratory of the Marine Biological Association, Plymouth, the effect of solutions having pH values varying from 1 to 10 on the velocity of the movements and flocculation of the sperms was determined.

The velocity of the sperms was observed microscopically in a specially constructed glass cell through which an electric current was passed, and the rate of movement toward the cathode was estimated in microns per second by the use of a stop watch. Although several factors interfered with the detailed results, it was found that in extremely acid solutions pH 1 to 2, the charge of the sperms was positive, but as the pH increased the charge fell to 0 at about pH 3, with a negative charge increasing as the pH increased to from 7 to 8, followed by a fall in more alkaline solutions.

In the flocculation study series of solutions having pH values ranging from 1 to 10 were prepared in test tubes from m cane sugar, sea water, and egg water. Both microscopic and macroscopic determinations of the flocculation were made after slowly shaking the tubes on a rotary shaker. Agglutination was most intense at pH 3, while the sperms were completely dispersed from pH 5.2 to 8.5. The activity increased with H-ion concentration within this range, but the sperms became agglutinated at about pH 8.8. When flocculation occurred in acid solutions, the heads of the sperms were found to adhere, while in agglutination due to alkaline solutions the tails fused parallel and became twisted with the movement of the heads.

The author states that sea water decreases the stability of the suspension, with a greater decrease occurring in egg water. It is noted that a close relation apparently exists between the effect of the H-ion concentration on the velocity and its effect on the agglutination. In general the study indicates that agglutinating substances are those which are expected to reduce the charge of sperms or alternatively increase the velocity of collision.

**Fertility in mice, A. S. PARKES** (*Brit. Jour. Expt. Biol.*, 2 (1924), No. 1, pp. 21–31, figs. 2).—The average size of litters in 1,795 mice born under the author's observation was 6.72, with a standard deviation of 2.5. Of these, 52.1 per cent were born in litters of 6, 7, or 8.

In investigating the effect of various factors on litter size, it was found in 13 pregnant females, killed and dissected, that the total number from each cornu of the uterus was practically the same, though the equal distribution was not always followed in each individual. The average size of litters born during the different months of the years varied from a minimum in March of 5.0 to a maximum of 7.6 in July. When grouped according to 3-month periods the litter sizes were January to March 6.03, April to June 6.40, July to September 7.12, and October to December 6.45. The first litters of females averaged 6.2, the second litters 7.6, and the third litters 6.3, with 6.2 as the average size of litters after the third. The average size of litters in which the pregnancy was initiated immediately after parturition and thus carried during lactation was 6.4. Polygynous matings likewise had little effect on litter size, the average being 6.5.

In discussing the results, the author notes that 9.8 per cent of the ova produced (determined by the corpora lutea counts) by the females dissected were not accounted for as fetuses. It is suggested that the increased litter size in the summer months may be due to a temperature relation, since albino mice kept under unheated conditions did not breed during the winter. When a constant temperature was maintained, however, they bred throughout the winter with very little change in the normal litter size.

**The functional ability of transplanted ovaries in rats** [trans. title], B. P. WIESNER (*Arch. Mikros. Anat. u. Entwickl. Mech.*, 99 (1923), No. 1, pp. 140-149, pl. 1).—The author has made transplantations of ovaries into the uterus of female rats and young have been successfully produced at the Academy of Science at Vienna. In three cases colored young were produced from matings of albino males with albino females having ovaries transplanted from colored individuals. No evidence was found of any influence of the foster mother on the development or color of the young, but the number of young produced by mothers having transplanted ovaries was much reduced. There were also found to be decreased numbers of follicles in transplanted ovaries, and smaller numbers of ova were matured.

## FIELD CROPS

**Some misapplications and limitations in using Student's method to interpret field experiments**, S. C. SALMON (*Jour. Amer. Soc. Agron.*, 16 (1924), No. 11, pp. 717-721).—Attention is called to some limitations in the use of Student's method which must be considered if errors and misapplications are to be avoided.

**Handbook of breeding of agricultural plants**, C. FRUWIRTH (*Handbuch der Landwirtschaftlichen Pflanzenzüchtung*. Berlin: Paul Parey, 1924, vol. 3, 5 ed., rev., pp. XVI+245, figs. 46).—A further revision of the volume (E. S. R., 47, p. 823) dealing with the breeding of potatoes, Jerusalem artichokes, flax, hemp, tobacco, hops, buckwheat, and legumes.

**Experiments with cereals at the Akron (Colo.) Field Station in the 15-year period, 1908 to 1922, inclusive**, F. A. COFFMAN (*U. S. Dept. Agr. Bul.* 1287 (1925), pp. 63, figs. 29).—Varietal and seeding experiments with cereals, supplementing those noted earlier (E. S. R., 36, p. 33), are reviewed with descriptions of the soil, climate, and crops of the Akron district and discussion of the choice of crops and recommended types of farming. Meteorological data are included.

Varieties appearing to be best adapted and recommended for this district include Kanred and Turkey winter wheat; Peliss, Arnautka, Akrona, and Converse (Red Russian) spring wheat; Coast and Smyrna barley; Kherson, Albion, and Colburt oats; Red Turghai proso; Manchu Brown kaoliang and selections of Dawn kafir; and Akron White, Fulton Yellow, Minnesota No. 13, and White Cap corn. Early seeding is generally advised, with acre rates of from 3 to 5 pk. for winter and spring wheat, 4 pk. for oats and for barley, and from 15 to 20 lbs. for proso. Spring rye, winter and spring emmer, spelt, flax, buckwheat, and most of the grain sorghums are considered of doubtful value in this district.

**Crop rotation and cultural methods at the Akron (Colorado) Field Station in the 15-year period from 1909 to 1923, inclusive**, J. F. BRANDON (*U. S. Dept. Agr. Bul.* 1304 (1925), pp. 23, figs. 9).—The annual and average yields of winter and spring wheat, oats, barley, and corn in different crop sequences and under different cultural methods during the period indicated are reported on, with descriptions of environmental and climatic conditions in the

vicinity of the station and meteorological observations. The merits of the crops mentioned, kafir, milo, Sudan grass, alfalfa, sweet clover, brome grass, winter rye, and potatoes, are related, and methods are outlined for handling fallow, green manures, and crops on prairie sod, and for the control of soil blowing.

Winter wheat is one of the best adapted and generally most profitable crops for the region and responds the best to cultural methods. Its acre yield on fallow has averaged 19.1 bu., on disked corn land 13.5 bu., and on land continuously cropped to wheat and deep fall plowed 10.5 bu. Although it does not respond as well to fallow, spring wheat after either corn or small grain averages about the same as winter wheat. Barley, oats for grain and hay, and corn and sorghums for forage and silage are also valuable crops.

Spring plowing small grain stubble had an advantage over fall plowing during a series of years. Subsoiling, deep tilling, green manures, and sod crops were either unprofitable or were followed by reduced yields.

According to the data cited, the most stable type of agriculture for this region will be diversification, depending mainly on livestock and emphasizing the cash grain crops less. Corn in rotation with small grain would be especially valuable in such systems. More extensive grain production would be based upon winter wheat and a liberal use of fallow.

**Drill calibration and its relation to stand and yield of small grains,** H. W. HULBERT (*Jour. Amer. Soc. Agron.*, 17 (1925), No. 2, p. 92).—Seeding rates varying from 4 to 12 pk., depending upon the size of seed of the variety, were required to place equal numbers of seeds of different varieties of peas on a unit area at the Idaho Experiment Station. The number of seed delivered to a unit area with different varieties of wheat and oats also varied considerably, while less variation occurred in barley varieties. See also an earlier note (*E. S. R.*, 50, p. 230).

High or low speeds had little effect upon the amount of seed delivered, although a slight decrease was seen at the higher rates of speed. The amount of seed delivered was not affected by the amount of seed in the hopper. The size of seed of the different varieties must be considered carefully if accurate results are to be obtained in variety tests with field peas. The lesser variation in the size of the seed of small grain varieties would probably minimize the importance of such consideration.

**[Field crops experiments in Idaho, 1924]** (*Idaho Sta. Bul.* 135 (1925), pp. 17-19, 33, 44, 49-53).—Agronomic investigations (*E. S. R.*, 51, p. 829) at the station and substations included variety tests with winter and spring wheat, oats, barley, grasses, potatoes, field peas, vetch, red clover, and miscellaneous legumes; nursery trials with cereals; seeding tests with winter and spring wheat, oats, sunflowers, and potatoes; and studies of weed control.

Idaho-grown red clover was superior to other domestic and to exotic strains. Sweet clover was desirable as a drought resistant pasture crop for nonirrigated conditions and made ample hay yields. Sunflowers were a poor crop to precede fall-sown wheat, probably because they remove much plant food and moisture from the soil. Seeding flax in combination with wheat gave unsatisfactory results.

Cultivation seemed to be the cheapest and most effective means of eradicating wild morning-glory. Carbon disulfide properly applied will eradicate this weed, but the treatment is too expensive except for small areas.

Experiments with potato varieties demonstrated that yields can be consistently maintained by introducing new seed. May plantings produced the highest yields, but the tubers from June plantings were smoother and truer

to type. Seasonal conditions did not favor production of tubers true to type in the Palouse and other nonirrigated sections where certified seed potatoes are grown. Yield rose at the High Altitude Substation as the size of seed was increased up to the half potato, or 4-oz. seed piece.

Winter wheat on summer fallow at the High Altitude Substation produced twice as much grain as after wheat on late fall plowed land. Wheat stubbled in yielded less than half that on late fall plowed land planted the same date. Fallow receiving the better cultivation responded with increased wheat yields.

[**Field crops experiments in Washington**], O. E. BARBEE, E. G. SCHAFER, O. M. MORRIS, H. M. WANSEER, C. E. HILL, H. P. SINGLETON, and C. C. WRIGHT (*Washington Col. Sta. Bul. 187 (1924)*, pp. 52, 53, 55, 56, 64, 82-86, 88-92, 94-96, 98, 99, 100, 102-104).—Supplementing previous work (E. S. R., 51, p. 136), these pages report varietal trials with winter and spring wheat, oats, barley, rye, corn, soy beans, field peas, Lima beans, millet, sorgo, grain sorghums, alfalfa, and miscellaneous forage crops; breeding work with potatoes; seeding and cultural trials; and rotations carried on at the station or substations. The merits of certain important varieties are pointed out.

Yields of wheat following corn and sunflowers differed very little on rich soils, whereas on less fertile hill slopes the wheat yield after sunflowers was markedly reduced. More sunflower seed per acre was obtained from plants 12 in. apart in 36-in. rows than from thicker or thinner spacings. In the 2-year rotation of wheat and peas, winter wheat slightly outyielded spring wheat. In 2-year rotations winter wheat following corn, peas, and summer fallow produced 28.6, 34.7, and 42.9 bu., respectively. Similar differences in winter wheat yields occurred when the rotation was extended to 3 years and spring wheat included.

No consistent differences in type of material produced was found in the crop from various forms of seed tubers. Abnormal forms seem to result from growing conditions, and, as seed, have slight influence over the shape of tubers in the following crop.

According to preliminary studies at the Adams Substation of factors responsible for periodicity of growth of the wheat plant, delay in seeding, the nearest approach to a delay of season possible without controlled conditions, may produce a shift in the relative fruiting dates of different varieties. The optimum of light and temperature varied for different varieties, and delayed seeding shifted the growth period of the plant into an equilibrium of conditions appearing more favorable for some varieties and less favorable for others. Under semicontrolled greenhouse conditions one variety fruited in nearly the same number of days with a daily light exposure of any interval between 4 and 24 hours. Some relationship seemed to exist between the fruiting characteristics and possibilities of a variety and the climatic conditions under which it was developed. Because of its use of and need for moisture, Hybrid 128 could not be considered as drought resistant as Turkey wheat.

Contrary to results in similar experiments at Lind, Wash., and Moro, Oreg., (E. S. R., 49, p. 828), winter wheat yields at Waterville on fall plowed land have equaled or exceeded those on spring plowing. Fall plowing enough land so that the balance may be completed early in the spring is recommended as a practice saving labor and equipment and conserving soil moisture. Shallow cultivation during spring and summer of the fallow year followed by plowing in October after the rains, the land being left rough until spring seeding, has given best results with spring wheat.

Cutting experiments at the Irrigation Substation showed that alfalfa allowed to become fairly mature will produce larger yields than when cut immature,

even though an extra cutting is obtained. Cultivating corn, except to control weeds, does not seem to pay on the sandy loam soil of the Yakima Valley. The methods and current yields in a duty-of-water experiment with alfalfa and in a study of late fall irrigation of alfalfa and corn are set forth.

[Agronomic] work done under the economic botanist for the year **1922-23**, W. BURNS (*Bombay Dept. Agr. Ann. Rpt., 1922-23, pp. 151-159*).—Several of the canal weeds were found to have peculiar organs which enable the weeds to pass through dry seasons buried in mud. Such organs seem to be formed only when the drying is gradual. *Potamogeton perfoliatus*, the worst canal weed, grew better on silt substratum than on gravel. A constant level in the canal favored weed growth more than did a fluctuating discharge.

Studies on the life history of *Cyperus rotundus* (E. S. R., 50, p. 238) showed that although seeds are not the principal means of reproduction and only a small percentage succeed in developing into plants, the total seed production in infested fields is so great that seed formation must be prevented by cultivation. Experiments with the tubers gave indications that a combination of plowing and exposure in the hot weather with a cover of rubbish or a smother crop will rid a field of the pest, especially when followed by continued cultivation.

Injection of a solution of sodium arsenite into the stem quickly killed lantana. Analysis of the roots and branch tips showed that the poison had penetrated throughout the plant.

Pearl millet (bajri) was found to be in a very hybrid condition. Progeny of plants selected for apparent drought resistance could be grouped as to plants entirely hairless, those with hairs only at the base of the leaves, and those hairy all over the sheath, base, and leaves. Correlation studies showed that the hairless are generally larger plants with a lower death rate and higher yield, and that as hairiness increases size and yield decrease and the death rate increases. However, certain individuals characterized by both hairiness and high yields were seen.

The improvement of grazing areas (E. S. R., 51, p. 34), work with pure lines of safflower, seeding tests with pearl millet, and varietal and storage trials with potatoes are described briefly.

Simple contrivances for studying root development in agricultural crops, T. S. VENKATRAMAN (*Agr. Jour. India, 19 (1924), No. 5, pp. 509-514, pls. 4*).—Devices for observing the relative depths and plan of root development of agricultural crops, particularly sugar cane, are described and illustrated.

Seed of root crops produced in **1923** and its market during the winter of **1923-24** [trans. title], J. C. LUNDEN (*Tidsskr. Planteavl, 30 (1924), No. 5, pp. 770-790*).—Statistics are presented showing the production of seed of various root crops and its distribution in Denmark, and comparing the quality and quantity produced with those of previous years. The domestic and foreign trade in the seed during the winter of 1923-24 is discussed, and tabular data are given showing its extent.

The grasses and fodder plants of New South Wales, E. BREAKWELL (*Sydney: N. S. Wales Dept. Agr., 1923, pp. VII+370, figs. 183*).—This volume presents practical information on the characteristics, adaptation, distribution, cultural requirements, and uses of native and exotic grasses, alfalfa, sorghum, clover, sweet clover, crowfoot, vetch, saltbush, native fodder trees and shrubs, and miscellaneous fodder plants. Simple keys to the economic plants have been included. Pasture and meadow management, seeds, plant succession, and weeds are discussed in some detail.

Botanical characteristics and green manure value of **60** new legumes [trans. title], A. A. M. N. KEUCHENIUS (*Dept. Landb., Nijv. en Handel [Dutch*

*East Indies*], *Meded. Proefsta. Thee, No. 90 (1924), pp. 44, pls. 14*).—The botanical characteristics, origin, nomenclature, and green manure value of 60 leguminous plants are discussed, with tabulated agronomic notes showing field behavior, adaptation, and pests.

**Experiments with growing hard-coated leguminous seeds in soil** [trans. title], H. WITTE (*Svenska Mosskulturför. Tidskr., 38 (1924), No. 5-6, pp. 360-371*).—Hard-coated seeds of red clover, alsike clover, alfalfa, and bird's-foot trefoil were sown in the spring of 1922 in six specially prepared plats each of clay, sandy, and peaty soil. The original seed also was tested in an ordinary germinator and examined at different times. It was found that after about 12 days the red clover contained about 20.5, alsike clover 37.5, bird's-foot trefoil 47.7, and alfalfa 25.2 per cent of unsprouted or hard seeds. After about one year in the germinator the figures were, respectively, 15, 33.5, 38.7, and 0.3 per cent, and after nearly 19 months 13.1, 32.5, 38.6, and 0 per cent. The hard seeds of alfalfa had practically all sprouted at the end of 4 months.

In the open soil only a small percentage of the hard seeds of red clover, alsike clover, and bird's-foot trefoil grew the first year; but of the alfalfa seeds 37.9 per cent germinated. The second growing season 65.4 per cent of the red clover, 58.3 of the alsike clover, and 61.9 per cent of the bird's-foot trefoil seeds grew as compared, respectively, with 71.5, 65.4, and 68 per cent, the total number sprouted up to and including the growing season of 1924.

The average seed growth of all the crops amounted to 54.2 per cent on clay soil, 67.2 on sandy soil, and 72.8 per cent on peaty soil. With the exception of alfalfa, a larger percentage of hard seeds, as compared with the growth in the germinator, grew in the open soil. In general, the hard-coated seeds did not produce very thrifty and winter-resistant plants.

**New American Meibomias**, S. F. BLAKE (*Bot. Gaz., 78 (1924), No. 3, pp. 271-288, pl. 1*).—A dozen new species of Meibomia (*Desmodium*) from Mexico and Central and South America are described.

**Alfalfa for Vermont**, E. VAN ALSTINE (*Vt. Agr. Col. Ext. Circ. 32 (1924), pp. 20, figs. 4*).—Practical suggestions for growing alfalfa in Vermont.

**Altaswede red clover**, G. H. CUTLER and G. F. H. BUCKLEY (*Alberta Univ., Col. Agr. Bul. 4 (1923), pp. 19, figs. 6*).—Altaswede, a selected strain of late Swedish red clover developed in the department of field husbandry of the University of Alberta, is said to behave as a perennial and to possess an extensive root system, a high degree of winter hardiness, and fair drought resistance. Production in the year of planting is not high, due to the peculiar low-spreading growth. In the second and succeeding years the growth of Altaswede is distinctly tall and thick, with a heavy yield of forage. The late development of the variety, as shown by its blooming habit, makes it especially well suited to Alberta conditions. Cooperative trials indicate that Altaswede is suitable for all except the driest nonirrigated sections of the Province.

Nearly 8 bu. of seed per acre has been produced by this clover. Its seed resemble those of other red clover except being somewhat smaller and presenting a golden yellow appearance when viewed in bulk. About 60 per cent of the seed are pure yellow in color and the balance light purple and yellowish purple. Rather limited germination tests indicate that the seed of Altaswede may not develop hard impervious coats and that scarifying may not be necessary.

Cultural and field practices are suggested for growing Altaswede for forage and seed.

**"Hard seeds" and broken seedlings in red clover**, A. NELSON (*Bot. Soc. Edinb. Trans. and Proc., 29 (1923-24), pt. 1, pp. 66-68*).—Although the percent-

age of hard seed was reduced when abrasive machinery was used on large, well-developed red clover seed, the increased number of broken seedlings left the declarable germinating percentage as low as or lower than before treatment. This adverse condition did not obtain with a smaller type of seed.

**White clover (*Trifolium repens* L.),** A. G. ERITH (*London: Duckworth & Co., 1924, pp. 10+150, figs. 81*).—This monograph on white clover, similar in design to that of Percival on the wheat plant (*E. S. R., 46, p. 837*), deals in its successive chapters with the seed, germination and the seedling, the root system, the stem, the leaves, the inflorescence, the flower, the development of the flower, classification, teratology, and varieties and their agricultural value. A bibliography of 125 titles is appended.

**Check-row planting of maize,** H. G. MUNDY (*Rhodesia Agr. Jour., 21 (1924), No. 5, pp. 543-549*).—Experiments at the Salisbury, Rhodesia, Experiment Station, supported by the experience of experiment stations in the United States, appear to show that although checkrowing may be advisable for better weed control, it does not in itself result in yields heavier than those normally obtainable from drilled corn. Number of plants per acre appears to be the deciding factor, and reduced yield may follow when the stand exceeds or falls short of the optimum as indicated by rainfall, soil fertility, and variety.

**Cotton growing in Salvador,** F. CHOUSSY (*Cultivo del Algodón en El Salvador. San Salvador: Dir. Gen. Agr., 1924, pp. 104, figs. 35*).—With particular application to Salvador, this publication discusses the environmental and cultural needs of cotton, preparation and marketing of the fiber, and governmental regulations concerning the crop.

**Oats: Their varieties and characteristics,** H. HUNTER (*London: Ernest Benn, Ltd., 1924, pp. 131, pls. 4, fig. 1*).—This practical handbook, introduced by R. H. Biffen, discusses the origin, botanical characters, and species of oats, and describes and classifies the species of *Avena* and the varieties pertaining thereto. In a chapter on the chemical composition of oat grain, the suitability of cultivated varieties to different soil and climatic conditions is pointed out. Discussion of seed selection and the production of pure seed concludes the volume.

**Variations in varieties of canning peas,** F. H. HALL (*New York State Sta. Bul. 526 (1924), pp. 3-20*).—Plat tests were made with strains of each of 11 well-known varieties of canning peas and with 8 other promising varieties. The characteristics of each variety and strain are set forth with tabulations showing the total yields, the total and graded yields of peas, the grade percentage, the estimated returns per acre, the crop weight, the number and relationships of vines, pods, and peas, and the classified weights of refuse from the several strains.

The variations found between crops of the same variety of canning peas, grown under uniform conditions but from seed from different seed growers, extend to practically every character that canners consider when selecting varieties. In many cases factors of prime importance to canner or grower have varied as widely or more between strains as between varieties of similar general character.

Horal, Late Alaska, Allan Canner, and Badger of the new varieties showed much promise for New York conditions. Lincoln and Richard Seddon proved of splendid quality, and further trials were suggested.

**Canning peas** (*New York State Sta. Bul. 526, pop. ed. (1925), pp. 3*).—A popular edition of the above.

**Anatomy, embryology, and ecology of *Arachis hypogea*,** E. L. REED (*Bot. Gaz., 78 (1924), No. 3, pp. 289-310, pls. 2, figs. 11*).—Field, greenhouse, and laboratory studies were concerned with the anatomy, embryology, and ecology of the peanut.

Although the peanut (*A. hypogea*) is a native of Brazil, its wild ancestor is not known, and while a member of the Leguminosae, it has not been definitely placed as to its affinities. It grows well and fruits abundantly in hot, relatively dry climates, although the leaves are typically mesophytic with a few xerophytic characters. It is a low annual which, by a lengthening of the internode just below the ovary, pushes its pod below the surface of the soil where the seeds are ripened. Its root system is of the taproot type with root hairs of two kinds, normal root tip hairs, and rosettes at the base of the lateral roots. The hairs are so scantily developed in field-grown plants that their influence as absorptive organs is negligible.

The seed is a straight embryo, and consists of two large cotyledons, a short hypocotyl, and a plumule composed of a terminal and two lateral buds. The mature embryo sac has eight nuclei and numerous starch grains. The antipodals soon disappear. The endosperm nucleus forms numerous free nuclei, which later form a single layer of cells lining the sac. The fertilized egg produces a massive proembryo, which early differentiates into the embryo region and the suspensor. The gynophore has typical stem structure. There is a large pith, about 13 vascular bundles, both fascicular and interfascicular cambium, and a cortex. It responds to positive geotropism.

[Fourth and fifth annual reports] of the Nebraska Potato Improvement Association, edited by H. O. WERNER and W. MORROW (*Nebr. Potato Impr. Assoc. Ann. Rpts.*, 4 (1922), pp. 146, figs. 7; 5 (1923), pp. 183, figs. 13).—Papers presented at the fourth annual meeting of the association at Alliance in December, 1922, included Factors Affecting Freight Rates on Potatoes, by T. Brown; Marketing the Western Nebraska Potato Crop, by O. D. Miller; Report of Colorado [Potato] Experiment Station, by W. C. Edmundson; The Management of Western Nebraska Soil, by W. W. Burr; Seed Potato Certification in Minnesota, by A. G. Tolaas; and Seed Potato Certification in Nebraska in 1922 and Plans for 1923, by H. O. Werner.

Among the papers presented at the fifth annual meeting at Chadron in December, 1923, were the following: Nebraska Certified Seed Potatoes in Louisiana, by G. L. Tiebout; Potato Diseases, by R. W. Goss; and Preventing Tuber Injury for Control of Dry Rot, The Present and Future of Seed Potato Certification, and Significant Experimental Results on Potato Culture, all by H. O. Werner.

Rice, T. F. MAIN (*Bombay Dept. Agr. Ann. Rpt.*, 1922-23, pp. 105, 106).—In connection with breeding work with rice in Sind, K. I. Thadani observed that about 2 per cent of the flowers of most of the rice varieties never opened, and that a certain percentage of the open flowers gave worthless kernels. Total sterility from these two causes occasionally rose as high as 32 per cent of the grain in the panicle. Observations in 1922-23 showed rice fertilization to take place between 7.30 a. m. and 12.30 p. m., with the maximum activity from 10.30 a. m. to 11.30 a. m. The temperature corresponding to these periods ranged from 86° to 99° F.

Rice in Egypt [trans. title], J. ANHOURY (*Bul. Union Agr. Egypte*, 22 (1924), No. 155, pp. 91-107).—The production of the crop in Egypt is discussed from historical, cultural, irrigation, and economic viewpoints, with comment on the merits of varieties.

Different varieties of rye as nurse crops in seeding meadows [trans. title], H. WITTE (*Svenska Mosskulturför. Tidskr.*, 38 (1924), No. 5-6, pp. 382-385).—In six varieties of rye used as nurse crops for a clover and grass mixture sown for hay production the stiffness of the straw was in direct proportion to the yields of hay produced, and it is concluded that the choice of

varieties for this purpose is important. The average yield of hay after Stålråg and Stormråg, stiff-strawed varieties, was at the rate of 5,935 lbs., and after Wasaråg and Gråråg, weak-strawed varieties, at the rate of 4,418 lbs. per acre.

**The injurious after-effects of sorghum**, J. F. BREAZEALE (*Jour. Amer. Soc. Agron.*, 16 (1924), No. 11, pp. 689-700, fig. 1).—When kafir and corn were grown in competition, little evidence was obtained to show that the kafir plants are more vigorous feeders than corn. Experiments wherein wheat was grown in tap water, alone and with additions of stubble of corn, sorghum, and cowpeas, respectively, during and after decomposition of the stubble and in solutions of decomposed stubble, gave results indicating that the injurious after-effect of sorghum is due to the presence of a toxic body formed during the decomposition of the stubble. This toxic body seems to be soon volatilized or decomposed. During the decomposition of the stubble, and while the toxic body is still in the soil, the flora generating carbon dioxide is largely killed off. With the cessation of the evolution of carbon dioxide, a new equilibrium appears to be established in the soil, in which the sodium zeolite exists in excess over the calcium salt. This causes a deflocculation of the soil.

See also an earlier note by Sewell (*E. S. R.*, 49, p. 332).

**The sugar beet industry**, W. F. GEDDES (*Sci. Agr.*, 5 (1924), No. 4, pp. 101-112 figs. 4).—In a brief review of the sugar beet industry in the United States and Canada, which outlines the process of sugar extraction and summarizes sugar beet experiments carried on by the Manitoba Agricultural College, the author does not consider that the experimental results so far obtained would warrant the establishment of a sugar beet factory in Manitoba with the large capital expenditure involved.

**Sugar beets in Minnesota**, F. W. MCGINNIS (*Minn. Univ. Agr. Ext. Spec. Bul.* 90 (1924), pp. 12, figs. 7).—Practical information is given concerning the production of sugar beets in the State.

**Tests with sugar beets**, E. E. DOWN (*Michigan Sta. Circ.* 66 (1925), pp. 8, figs. 2).—Tabulated results of comparative tests of sugar beet seed (*E. S. R.*, 51, p. 38) from American and European sources, made in cooperation with the U. S. Department of Agriculture, show acre yields of beets and recoverable sugar, sugar percentages, and purity coefficients.

**Observations on seed production in beets during the first year** [trans. title], MUNERATI (*Compt. Rend. Acad. Sci. [Paris]*, 179 (1924), No. 13, pp. 604-606; also in *Com. Cent. Fabric. Sucre France, Circ. Heb.*, 36 (1924), No. 1857, pp. 507-509).—In a discussion of the phenomenon of premature seed production in sugar beets (*E. S. R.*, 50, p. 832), the author reports that when ordinary types of beets were subjected to intense nocturnal illumination, a number of individuals with from 8 to 10 leaves showed a tendency toward seed production about 1 month after planting. From 25 to 30 per cent were in full bloom 60 days after planting, and after 120 days, ripe and perfect glomerules were harvested. Under analogous conditions of continuous illumination, hemp continued to grow more than 6 months without differentiating, whereas under normal field conditions hemp from the same seed showed differences from the third month, and had the normal ratio of males to females.

**The effect of increased applications of sodium nitrate on the quality of sugar beets** [trans. title], J. URBAN and J. SOUČEK (*Ztschr. Zuckerindus. Čechoslovak. Repub.*, 48 (1924), No. 48, pp. 449-456).—The results of 66 similar cooperative fertilizer experiments with sugar beets carried on in Czechoslovakia under different soil and climatic conditions were studied to determine the influence of sodium nitrate on the sugar content and nitrogen content of

the root. Thrice replicated plats of equal areas received applications of sodium nitrate equivalent to 0, 100, 200, 300, and 450 kg. per hectare (0, 89, 178, 267, and 400.5 lbs. per acre). As general averages the respective yields of beets per hectare amounted to 32,000, 33,800, 35,400, 36,900, and 37,400 kg.; sugar content, 19.22, 19.16, 19.2, 19.08, and 19.02 per cent; yields of sugar per hectare 6,150, 6,470, 6,790, 7,040, and 7,120 kg.; purity of juice 90.4, 90.4, 90.2, 90.2, and 90.1; and nitrogen content of root 0.15, 0.153, 0.157, 0.162, and 0.165 per cent.

The average results are not held applicable to all the soils. On certain soils, about 58 per cent of the tests, sodium nitrate apparently reduced the sugar content about 0.75 per cent, whereas in 23 per cent of the fields an average increase of about 0.83 per cent was observed. In the remainder of the plats, the quality was similar to that of untreated beets. Where the beet yields on the plats receiving no nitrate were themselves heavy, the nitrate applications reduced the sugar content and the purity of juice and increased the nitrogen content. On poor fields the nitrate favorably affected both yields and quality.

**"Light and air" in cane cultivation**, A. H. ROSENFELD (*Sugar* [*New York*], 26 (1924), No. 12, pp. 588-591.)—Recent advocacy by several others of extremely wide spacing of sugar cane led the author to review experimental results throughout the sugar-producing regions of the world, and to conclude that sugar cane should be planted as closely as is consistent with proper cultivation with modern implements. This optimum row width appears to be 5 ft. for the thicker types of cane, such as the Cheribon, Lahaina, B. 208, H. 109, B. H. 10 (12), and S. C. 12/4, and from 5.5 to 6 ft. for rather luxuriantly stooling canes, such as the POJ Java seedlings and the East Indian types.

**The nature and practical measurement of frost resistance in winter wheat**, R. NEWTON (*Alberta Univ., Col. Agr. Research Bul. 1* (1924), pp. 53, figs. 5).—Continued study was made of the factors determining frost resistance in winter wheat and of methods for measuring this quality which may have practical application in breeding and selecting hardy varieties. Part of this work has been noted earlier (*E. S. R.*, 51, p. 237).

Preliminary results by a method based on the composition of the fresh tissue and its press juice indicate a wide variation in the distribution of nitrogen between cell colloids and aplastic forms. It appears probable that hardy varieties accumulate during the hardening process more protein in the form of cell colloids. The possible utility of the "gold number" as a measure of the quality of cell colloids is pointed out.

The ratio of amino nitrogen to total nitrogen increased in all varieties in the late fall, indicating an association of protein splitting with the later stages of the hardening process. Some correlation was found between the sugar content of hardened leaves and hardiness. The value of sugar as a protection against the precipitation of proteins by freezing was demonstrated by the use of press juice from greenhouse leaves. Precipitation was largely inhibited by the addition of 8 per cent of dextrose, and completely so by 8 per cent of sucrose. The rate of sugar loss from the leaves in late fall was found to be somewhat greater in nonhardy varieties. A more profound and stable dormancy in the hardy varieties, characterized by a slower rate of respiration, is suggested as a possible explanation.

**Baking qualities of Mesopotamian wheat** (*Bul. Imp. Inst. [London]*, 22 (1924), No. 3, pp. 284-292).—Milling and baking tests were made by J. Kirkland on a number of local and introduced varieties of durum and vulgare wheat grown at Bagdad. The flours from these wheats varied in their behavior in bread making, being comparable to the flours from Indian wheats showing similar variations. In the United Kingdom these wheats would be used for

mixing with more valuable Manitoba or Australian wheats. While all the samples listed probably would be suitable for this purpose, continuation of cultivation trials is suggested in order to determine the varieties attaining the best quality after acclimatization.

**Growing registered seed in Alberta**, G. H. CUTLER and J. R. FRYER (*Alberta Univ., Col. Agr. Bul. 3 (1923), pp. 32, figs. 8*).—Designed to present all available information concerning the growing of registered seed, this publication discusses the status of registered seed production in Alberta and elsewhere in Canada, and the practices involved in growing, harvesting, storing, marketing, and exhibiting registered seed.

**Inspection of agricultural seeds**, E. G. PROULX ET AL. (*Indiana Sta. Bul. 285 (1925), pp. 63, fig. 1*).—The purity, germination percentage, and hard seed and weed seed content are tabulated for 727 official samples of agricultural seed analyzed during 1924.

## HORTICULTURE

[**Horticultural investigations at the Delaware Station**], L. R. DETJEN (*Delaware Sta. Bul. 139 (1925), pp. 21, 22*).—Fertilizer studies with the apple again indicated (E. S. R., 51, p. 140) that nitrogen is the limiting factor in production on Delaware soils. However, nitrogen combined with either phosphoric acid or potash, or both, gave the largest and best quality yields. A qualitative study of nitrogen for the peach showed no difference in favor of any particular source.

Cabbage breeding investigations continued to show the difficulty of maintaining pure lines because of the frequent occurrence of self-incompatibility. In one strain, for example, known as the zinnia rosette, one of four selected plants failed to produce a single viable seed. The spindle or pointed type was found to breed quite true to type.

[**Horticultural investigations at the Idaho Station**] (*Idaho Sta. Bul. 135 (1925), pp. 31, 32, 33, 34, 35*).—The considerable extent to which the Ben Davis apple has been utilized in breeding studies is indicated in a tabulated statement of the parentage of seedlings fruiting in 1922 and 1923. Apple fertilizer studies conducted in the Moscow, Coeur d'Alene, and Lewiston districts failed to show any material advantage from the use of fertilizers. The value of adding spreaders to arsenate of lead apple sprays was indicated by an 8 per cent better control where such spreaders were used. Little difference was found between various commercial spreaders.

Studies in vegetable seed production again indicated the potential possibility of developing this industry in Idaho. A study of 12 strains of New York head lettuce showed only slight variation in germination, shape, and trueness to type. Lettuce yields were increased by the liberal application of phosphoric acid and potash. Of the many tomato varieties tested in an attempt to discover one better adapted to northern Idaho than the Earliana, the Puget Sound Special, Atlantic Prize, June Pink, Dwarf Ponderosa, King of Earliest, and Moore Early showed considerable merit. The Dwarf Champion and Puget Sound Special, together with certain station selections, apparently possessed some resistance to western tomato blight.

**Protecting South Carolina from plant diseases and crop pests**, J. A. BERLY (*South Carolina Sta. Circ. 32 (1924), pp. 3-32, figs. 22*).—In connection with a statement of the activities of the State Crop Pest Commission in preventing the entrance and dissemination of various insect and fungus pests, the sale of inferior insecticides and fungicides, etc., various pests, both those

already present and those whose entrance from other localities is deemed possible, are described and illustrated.

[**Horticultural investigations at the Washington Station**] (*Washington Col. Sta. Bul. 187 (1924)*, pp. 38, 39, 61-64, 106, 107).—Repeated chemical examinations by J. L. St. John of stored Jonathan apples showed that total and reducing sugars increase, while the alcohol-insoluble acid hydrolyzable material continues to decrease during storage as during growth. Attempts to use chemical examinations as a means of determining the stage of maturity of apples showed no progressive variations in ash, acid, total or reducing sugars, or in H-ion concentrations. The protein showed a tendency to decrease, and the alcohol-insoluble acid hydrolyzable material showed a progressive decrease as the time of picking approached.

Work by O. M. Morris indicated that, under average orchard conditions, alfalfa cover crops are undesirable in young apple orchards. Among summer planted cover crops, spring vetch, hairy vetch, and biennial sweet clover proved to be equally capable of germinating and establishing themselves in soils irrigated once every three or four weeks. Red clover, field peas, and alsike clover seemed unable to make a quick and satisfactory start under such conditions.

Work carried on at Wenatchee by Morris and W. A. Luce indicated a definite relation between vegetative growth and the color of the fruit. Apparently it was possible with cover crops to stimulate soil fertility beyond the point of best quality production in apples.

Morris, F. L. Overley, and H. J. Jensen, working at the Irrigation Substation at Prosser, found that apple trees standing in dry ground had a higher leaf temperature than trees well supplied with water. Furthermore, such differences were manifested several days before any external evidence, such as checked growth of rapid-growing twigs, was visible.

Observations by Morris, Luce, and T. R. Hall upon untreated and treated pruning wounds indicated the advisability of painting large wounds with waterproof paints. Thick lead paints and water glass gave good results, while creosote and coal-tar paints, though preserving the wood, killed the young cambium layer.

Grape pruning studies by Morris and Hall indicated that short spurs do not give as good results, either in quality or quantity of grapes, as do medium length spurs. Vines pruned to a short-spur system produced more shoots from the old secondary winter buds than were produced under other systems.

An attempt by Overley to discover a method of determining the maturity of Jonathan apples during storage showed that the hardness of the fruit is the most directly measurable character.

Cranberry investigations, conducted by D. J. Crowley, showed that serious frost injury results from a temperature of 32° F. during blossoming time, and that 28° will injure berries when nearly mature. About 5 per cent of ripe cranberries freeze at a temperature of 25°. The Howe variety was found to be the most resistant to low temperature.

**Growing tomatoes for the canning factory**, H. D. BROWN (*Indiana Sta. Bul. 288 (1924)*, pp. 27, figs. 19).—A general discussion, taking into consideration such details as extent and distribution of tomato growing in the State, plant production under protection and in the open, the value of selected seed, superiority of home-grown plants, field setting, culture, control of diseases and insect pests, etc.

**Asexual propagation as an aid to the breeding of rootstocks**, W. S. MALLOCH (*Jour. Agr. Research [U. S.]*, 29 (1924), No. 10, pp. 515-521, pl 1).—Herein are presented in tabular form, with discussion, the results of an in-

vestigation conducted at the University of California in 1923 upon root and vegetative development in hardwood cuttings of divers species obtained from California and Connecticut, planted outdoors in February, and lifted for examination in May of the same year. While many varieties of apple and pear (*Pyrus malus* and *P. communis*) callused, none of the cuttings of these two species formed roots. Certain European plums, such as Clyman, Peach, Pond, and Sultan, and the Japanese plum varieties Satsuma and Combination, formed roots. Roots were recorded on one or two obscure forms of peach, but in general peach varieties failed to show root formation. Among the *Prunus* species to root quite readily were *P. besseyi*, *P. pumila*, *P. cerasifera*, *P. munsoniana*, and *P. spinosa*, and some of the hybrids involving one of them. The author points out that the environmental conditions surrounding the tests were not ideal for the rooting of cuttings, and hence that even better results might be anticipated under more favorable conditions.

**Some factors influencing root development, R. G. HATTON, N. H. GRUBB, and J. AMOS (*East Malling [Kent] Research Sta. Ann. Rpt. 1923, pp. 110-119, pls. 8*).**—A study of the development of comparable roots of a clonal apple rootstock variety worked with Bramley Seedling and Stirling Castle apple scions showed a positive quantitative effect of the scion on the root, the average weight of the Bramley tree roots being approximately double that of the Stirling Castle roots. No qualitative effects were noted.

In the case of Lord Derby and Tyler Kernel apples worked on three clonal rootstocks it was found that Lord Derby trees actually developed a measurably larger proportion of fibrous roots on all three stocks. The tendency of the Lord Derby variety to influence the proportion of fibrous roots was further shown in an examination of four varieties worked on two clonal rootstocks. However, since the highest percentage of fibrous roots on one stock was lower than the lowest percentage on the other, the authors point out that scion influence is subordinate to the general character of the roots. Marked varietal differences were noted in respect to the proportion of root weight to total weight of the tree. The scion apparently had little influence upon the location of the side roots, although in the Grenadier variety a striking exception was observed, more than half the roots originating from the top area of the main root.

Observations upon the effect of top pruning on root development accorded, in general, with the results obtained by Chandler (*E. S. R.*, 49, p. 637), namely, that severe top pruning reduces root growth. Using as material clonal apple trees from which all side roots had been removed the authors found that unpruned trees made much greater root and much less top growth than did pruned trees. Trees top pruned in July also made less growth than control trees.

In comparing five preplanting root treatments, namely (1) control, (2) removal of fibrous roots only, (3) removal of coarse roots only, (4) removal of all side roots, and (5) exposure of roots to drying, it was found that, in general, the young trees had to practically renew afresh their root development subsequent to transplanting. The retention of fibrous roots was of less importance than coarse roots. However, in many instances the old fibrous roots enlarged into coarse roots. Very satisfactory root formation was secured in lot 4, from which all side roots had been removed. In respect to the effect of root pruning on top development, the removal of fibrous roots had much less inhibiting effect than the removal of coarse roots or all side roots. Root pruning had less effect than top pruning in reducing new root and vegetative development.

Trees planted in doubly tilled soils did not grow measurably different from those under which the subsoil was rammed in order to create an artificial

hardpan. The ramming of soil about the roots had no significant effect. However, in the case of Bramley Seedling trees on a clonal rootstock, depth of planting affected the location of root development. In the case of deeply planted trees there was a noticeable tendency for the principal root development to be shifted upward, although in no case did the scion itself send forth roots. Only those trees planted on the surface and mounded up showed inferior top growth. Working with other rootstocks, evidence was obtained to indicate that the variety of rootstock affected the results of depth of planting studies. In a dry season shallow-planted trees suffered more from drought and recovered quicker following rains than did deeply planted trees. A tendency was noted for shallow planting to increase fruit-bud formation. Deep planting did not prevent the enlargement of the union, and moderately deep-planting apparently favored better anchorage of the tree.

**A test to determine whether environment has produced different strains of Baldwin.** G. H. HOWE (*Amer. Soc. Hort. Sci. Proc.*, 21 (1924), pp. 62, 63).—A study at the New York State station of 84 Baldwin apple trees obtained from 40 locations in 15 States failed to show a single variation of sufficient significance to lead to the conclusion that there are different strains of this widely distributed apple variety.

**Pollination and the sterility problem.** J. H. GOUBLEY (*Ohio State Hort. Soc. Proc.*, 57 (1924), pp. 18–23).—Apple pollination studies conducted by the Ohio Experiment Station in 1923 are briefly reported in connection with a general discussion of the pollination problem.

Stayman Winesap blossoms pollinated with Wealthy, Grimes, Delicious, Baldwin, Jonathan, Ensee, Rome, Yellow Transparent, York Imperial, and Stayman Winesap gave respective sets of fruit of 0.6, 17.6, 5.6, 0, 11.1, 20.1, 43.3, 51.6, 60.6, and 0. The inferior value of Stayman Winesap as a pollen parent was shown in a test conducted at Chardon, wherein three pairs of trees each including a Stayman Winesap were inclosed in tents each containing a hive of bees. The three partners, Baldwin, Jonathan, and Yellow Bellflower, set 4.9, 1.5, and 0.16 per cent, respectively. In hand pollinations at Chardon, the Stayman Winesap pollinated with Grimes and McIntosh gave 17.9 and 19.3 per cent sets, respectively, while the reciprocal crosses yielded 1.1 and 0.9 per cent.

**Pollination of the sweet cherry.** W. P. TUFTS and G. L. PHILP (*California Sta. Bul.* 385 (1925), pp. 3–28, figs. 11).—Pollination investigations conducted in various cherry-producing sections of California during the years 1916–1924 showed all sweet cherry varieties studied to be practically sterile and in some instances intersterile. The highest percentage of set, 3.5, obtained in self-pollination tests was in the case of Bing in 1917. Seven varieties tested for only one or two years set no fruit. However, all varieties tested over a period of years yielded some fruit in some year.

The blooming periods of varieties determined incidental to cross-pollination investigations showed that certain varieties are completely past their period of effective blossoming before others begin to bloom. Fortunately, the blooming periods of the Black Tartarian and the Black Republican varieties, found to be valuable pollinizers, usually sufficiently overlapped those of the late-blooming varieties to allow adequate cross-pollination. Determinations of pollen production in 18 varieties revealed only one shy pollen producer, namely, Centennial. Tests in 12 per cent cane sugar solution showed satisfactory pollen germination for most varieties. Observations indicated that the presence or absence of bright, warm weather just preceding and during the blossoming period materially affected the viability of the pollen.

The results of extended cross-pollination tests, which are set forth in tabular form, led the authors to suggest compatible and incompatible varietal combinations. Napoleon, Lambert, and Bing were found to be intersterile, which was also true of Advance and Rockport and of Early Purple and Rockport. Unfortunately, it was found that in certain varieties there exist outwardly similar strains which when used as pollinizers for the same variety give widely divergent results. For example, in the Vaca Valley, the authors found five kinds of Black Tartarian which gave sets on a single Napoleon tree ranging from 3 to 40 per cent.

The importance of insects as pollinizers in cherry orchards was indicated in four tests wherein emasculated and unprotected cherry blossoms, apparently unvisited by bees or other insects, yielded sets of fruit ranging from 0.02 to 0.5 per cent.

In practical conclusion, the authors point out the necessity of planting compatible varieties, so arranged as to allow easy cross-pollination and at the same time to facilitate orchard management operations. It is recommended that, in varieties existing in the form of two or more similar strains differing in pollinating capacities, the valuable strains be isolated and propagated. It is advised that the unsatisfactory pollination often occurring in solid blocks of cherries may be remedied by grafting in each tree a branch of a compatible variety. In extreme cases temporary relief may be obtained by placing flowering branches of a compatible variety in jars of water distributed throughout the orchard.

**The nectarine as a future commercial fruit in New York State, R. WELLINGTON** (*Amer. Soc. Hort. Sci. Proc.*, 21 (1924), pp. 60-62).—Unprotected seeds saved from nectarine trees growing in a mixed peach and nectarine orchard on the New York State Station grounds gave rise in only one instance, namely, that of the Quetta variety, to a peach. Based on the supposition that the fuzz or tomentum of the peach is a dominant character, the results are deemed to indicate that the nectarines in the orchard are largely self-fertilized. The origin at the station of a promising nectarine designated as Hunter is again briefly discussed (*E. S. R.*, 49, p. 338). That the nectarine has not become a popular fruit in the United States is believed to be due to the fact that the Americans have usually grown European varieties without attempting to develop varieties adapted to our soils and climate.

**Raspberry investigations, N. H. GRUBB** (*East Malling [Kent] Research Sta. Ann. Rpt. 1923*, pp. 128-130).—Similarly to an earlier report (*E. S. R.*, 48, p. 737), the author discusses briefly the results of varietal and cultural tests with the raspberry. A variety hitherto known as Baumforth Seedling B is now deemed to be Northumberland Fillbasket, and one known as Fillbasket A is probably Fastolf. Of 10 varieties which have fruited at the East Malling Station for more than one year, Pyne Royal, for the fourth consecutive season, led in production. Of 30 varieties fruiting for the first time in 1923, Lloyd George was the highest yielder. Baumforth Seedling B produced about 20 per cent more fruit on unmanured soil, while Pyne Royal gave nearly 170 per cent greater yield on manured land. It is believed, however, that these figures may have been affected by the presence of mosaic disease.

**The tea plant, O. F. SCHLEINKOFER** (*Der Tee. Munich: Michael Beckstein, 1924*, pp. 126, pls. 26, figs. 5).—This book, illustrated with numerous reproductions of tea gardens and their architectural features and various operations in the growing, manufacture, and handling of the crop, contains a general discussion of tea growing in the region embracing eastern and southern Asia.

Second report of the tree protection examining board, covering the three years ending June 30, 1924, W. E. BRITTON, G. P. CLINTON, and W. O. FILLEY (*Connecticut State Sta. Bul.* 263 (1924), pp. 141-155, pls. 8, figs. 2).—The text of an act requiring the examination and licensing of parties engaged in professional tree repair work in Connecticut is again presented (E. S. R., 46, p. 340), in connection with a brief statement concerning operations under the act during the three years ended June 30, 1924. There is also included a brief article by Filley entitled Tree Surgery, which points out the need of research in determining the best methods of treating tree wounds and which questions the actual value of much tree repair work done in the past. A paper entitled Cavity Work, by J. F. Collins, contains the statement that his observations indicate that a large percentage (90+) of tree repairing in the past has resulted in failure, decay generally setting in behind the cement fillings. It is believed that the use of cement by untrained persons for filling other than small and globular cavities can not be conscientiously recommended.

The rose book, edited by W. MÜTZE and C. SCHNEIDER (*Das Rosenbuch. Berlin: Gartenschönheit, 1924, pp. 136, pls. 7, figs. 87*).—Beautifully illustrated, partly in color, this handbook contains information concerning the history and the development of the modern rose and lists a large number of present-day varieties, grouped according to their color and usefulness.

## FORESTRY

The forests (*Les Forêts. Rome: Inst. Internatl. Agr., Serv. Statis. Gén., 1924, pp. VII+125, figs. 2*).—A compilation of statistics concerning the size and distribution of the forests, annual lumber cut, important species, forest administration, etc., in the various countries of the world.

Our hardy conifers, edited by E. SILVA TAROUCA and C. SCHNEIDER (*Unsere Freiland-Nadelhölzer. Vienna: Hölder-Pichler-Tempsky, 1923, 2 ed., rev. and enl., pp. XII+315, pls. 18, figs. 319*).—A second enlarged and revised edition of the work previously noted (E. S. R., 30, p. 742).

Artificial reproduction of redwood (*Sequoia sempervirens*), W. METCALF (*Jour. Forestry, 22 (1924), No. 8, pp. 873-893*).—This paper, dealing with the reproduction of redwood, is a summary of information, for the most part previously noted (E. S. R., 48, p. 540).

Revised volume tables for second-growth redwood, D. BRUCE and F. X. SCHUMACHER (*Jour. Forestry, 23 (1925), No. 2, pp. 148-155*).—Finding that previously prepared volume tables (E. S. R., 46, p. 342) were inadequate in the range of values included, the authors herein present revised and extended tables having approximately twice the range of the preliminary tables and containing minor corrections for values of small trees. There is also added a new table giving volumes in cubic feet.

Growth and its relation to thinning sample plots studies in mixed hardwood stands, C. H. GUISE (*Jour. Forestry, 23 (1925), No. 2, pp. 156-159*).—Measurements taken in sample plots of mixed hardwoods, located in Cayuga County, N. Y., and subjected in the beginning to different grades of thinning, showed the greatest actual increase in diameter in the heavily thinned area. Although the control plot contained the greatest volume of wood, the volumes on the thinned plots, especially on the heavily thinned area, were found to be increasing at a much more rapid rate than on the control, leading the author to suggest that in 5 or 10 years the thinned plots will equal in volume the control. The mortality was appreciably higher in the control area, and indications were that this difference would become more acute in the near future, since many trees in this area were in a poor state of health due to crowding.

On the relation of the source of *Quercus pedunculata* acorns to the growth of the resulting trees [trans. title], A. CIESLAR (*Centbl. Gesam. Forstw.*, 49 (1923), No. 4-6, pp. 97-149, figs. 3).—As a result of studies begun in the spring of 1904 in the Mariabrunn (Austria) Forestry Experiment Station, in which 21 lots of *Q. pedunculata* acorns obtained from widely separate points in Europe were carefully compared in relation to germination and the rapidity and manner of growth of the resulting seedlings, the author concludes that the place of origin is an extremely important factor in the culture of this species, and recommends that acorns be obtained from areas having rainfall, temperature, and soil conditions comparable to those of the desired planting locality. In comparing the progeny of heavy and light weight acorns, it was found that heavy acorns resulted in larger and more rapidly growing seedlings. This advantage, however, disappeared entirely by the end of the eighteenth year. Acorns from a cooler climate yielded frost-resistant seedlings, while those from warmer climates gave tender plants. Considerable variation was noted in the tendency of the several lots to produce straight or crooked stems, and in general straight trunks were associated with larger diameters. Leaf size was found to be a reliable index to vigor, being closely associated with growing capacities. Oaks from acorns gathered near the ocean colored later in the autumn than did those gathered from farther inland.

Relative water-holding capacity of sphagnum and tree moss, J. F. KUMMEL (*Jour. Forestry*, 23 (1925), No. 2, pp. 181, 182).—Studies carried on at the Wind River Nursery, Stabler, Wash., showed that sphagnum moss is not only capable of absorbing twice as much water as ordinary tree moss found on trunks and large branches of hardwoods growing in moist environments, but also is able to retain moisture for a longer period.

The grazing of cattle and horses in pine plantations, P. W. STICKEL and R. C. HAWLEY (*Jour. Forestry*, 22 (1924), No. 8, pp. 846-860).—Studies, conducted by the Yale School of Forestry, upon the effects of grazing in red and white pine plantations indicated that limited cattle grazing may be of decided benefit to young plantings as follows: (1) In reducing fire hazards by the close cropping of grasses and shrubs, (2) in the suppression of hardwood sprouts, which are eaten in preference to the evergreens, and (3) in the development of deep paths which may serve as fire lines in combating running fires. On the other hand, because of their biting habits and general restlessness, horses were found much more destructive than cattle, and it is recommended, therefore, that in winter especially they be entirely excluded.

Report of the National Forest Reservation Commission for fiscal year ended June 30, 1923 (*U. S. Senate*, 68. Cong., 1. Sess., Doc. 59 (1924), pp. V+37, pls. 8, fig. 1).—This illustrated pamphlet contains information concerning accessions to and changes in the national forests made during the year ended June 30, 1923.

Forestry [at the Idaho Station] (*Idaho Sta. Bul.* 135 (1925), pp. 30, 31).—Observations upon black locust and catalpa plantations located at various altitudes indicated that the black locust can succeed even up to 4,500 ft. in sheltered localities, while the successful limit for catalpa is approximately 3,000 ft. Records taken in irrigated sections of southern Idaho showed that both the hardy catalpa and the black locust at 14 years of age are capable of yielding a large number of posts per acre. Posts set in alkali soils were observed to be shorter lived than those set in ordinary soils. Observations on second growth western yellow pine indicated that this species is capable of making a very rapid growth and should return a profit in the form of fuel, fence posts, and perhaps lumber.

**Second report on a forest survey of Illinois: The economics of forestry in the State**, H. H. CHAPMAN and R. B. MILLER (*Ill. Nat. Hist. Survey Bul.* 15 (1924), Art. 3, pp. VII+46-172).—A further contribution (E. S. R., 49, p. 341) to a comprehensive study of the forestry situation in Illinois. In the present instance the authors discuss the economic importance of wood in the State in the manufacture of farm implements, use as paper pulp, fuel, etc., and present data on the present condition of the small remaining forests.

**Annual report of the director of forestry of the Philippine Islands for the fiscal year ended December 31, 1923**, A. F. FISCHER (*Philippine Bur. Forestry, Ann. Rpt. Dir. Forestry, 1923, pp. 163, pl. 1*).—This is the usual annual statement (E. S. R., 50, p. 344).

**Quinquennial review of forest administration in the Province of Assam for the years 1919-20 to 1923-24, with the progress report of forest administration for 1923-24**, F. TRAFFORD and C. A. G. RIVAZ (*Assam Forest Admin. Qinq. Rev. 1920-24 and Rpt. 1923-24, pp. 23+59+2, pl. 1*).—This report, covering the five-year period 1919-20 to 1923-24 and the annual period 1923-24 (E. S. R., 50, p. 345), contains information concerning alterations in area, silvicultural and administrative activities, revenues, expenditures, etc.

**Annual report of the Forestry Department [Uganda] for the year ended 31st December, 1923**, R. FYFFE (*Uganda Forestry Dept. Ann. Rpt. 1923, pp. 16*).—In presenting the usual annual report (E. S. R., 52, p. 241), the author discusses planting activities, alterations in area, revenues, expenditures, etc.

**Report of the director of forests for the year ended 31st December, 1923**, E. H. F. SWAIN (*Queensland Dept. Pub. Lands, Rpt. Dir. Forests, 1923, pp. 30*).—This is the usual annual statement (E. S. R., 51, p. 44), containing information concerning silvicultural activities, forest protection, organization, surveys, timber operations, etc.

## DISEASES OF PLANTS

**Department of plant pathology and soil bacteriology**, T. F. MANNS and J. F. ADAMS (*Delaware Sta. Bul.* 139 (1925), pp. 24-29).—In a study of diseases of the sweet potato, the authors found additional evidence to strengthen their conclusions that pox is caused by a species of *Actinomyces*.

An investigation was begun on peach yellows and little peach, in which trees were grown under screen to prevent the entrance of carriers, but the rains dissolved enough copper from the screens to defoliate the trees for several weeks.

In a study of the diseases of cucurbits and their control, the principal work was carried on with downy mildew on cantaloupes. This disease is said not to make its appearance in Delaware until early planted melons begin to net, while cucumbers showed the disease before cantaloupes. Two different brands of copper-lime-arsenate dust were used for the control of this disease with about equally good results. Treating the vines with quickly available nitrogenous fertilizers did not check the attack of the disease. A species of *Alternaria* was found commonly occurring as a saprophyte on leaves attacked by *Macrosporium cucumerinum*. Inoculation experiments were conducted with this fungus on a considerable number of important truck crops, and, among the cucurbits, summer squash and cucumber showed the greatest resistance. Infections were secured on tomato and potato, but they are said to have borne no resemblance to the early blight of these hosts.

Some attention was given to diseases of canning peas, and the bacterial leaf spot due to *Bacterium pisi*, root rot, and a fungus described as *Aphanomyces* sp. associated with the root rot were observed.

Notes are given on the value of casein compounds in connection with orchard spraying, on apple scab studies, and on corn root rot. A test made of corn from the 1922 crop stored in the laboratory indicated that there was a reduction in the prevalence of the fungi causing root rot in corn, particularly of *Diplodia zeae* and *Gibberella saubinetii*.

In connection with some extension work on the control of black rot of grapes, additional research work was carried on with the organism. It was found that dry weather may arrest black rot and that infection may take place any time after the new shoot is 1 in. long, while the macroscopic lesions may not appear until the fruit is two-thirds or more grown. After initial infection has taken place no number of sprayings can control the disease. The primary infection on the basal nodes of new shoots is considered the source of carrying over infection for the succeeding year.

**Plant pathology** (*Idaho Sta. Bul. 135 (1925), pp. 35-39*).—In studies on potatoes, particular attention was paid to the transmission of mosaic and leaf roll, in which a considerable number of insects were tested, but negative results were obtained with all except the rose aphid, *Macrosiphum solanifolii*. The russet dwarf type of mosaic has been found in Idaho during the present season. Leaf roll has also occurred, and it has been learned that it is carried by the pink and green aphid. A new disease of potatoes called witches' broom is reported, and there is said to be some indication that this disease may belong to the so-called virus group. Isolated plantings in different parts of the State were made of seed potatoes, and the data indicate that seed lots which are most free from the virus group of diseases are those which have been grown in isolated settlements for a number of years without chance for contamination from introduced seed stock. In an experiment on the control of potato scab, inoculated sulfur did not give results to warrant its extensive use.

Extensive experiments were carried on with wheat and oats for the control of smut, in which various brands of copper carbonate, formaldehyde, copper sulfate, furfural, and various mercury compounds were tested. In general it was found that 3 oz. of copper carbonate per bushel of wheat gave as good control as the standard copper sulfate treatment. For spring sown wheat, 2 oz. of copper carbonate was found sufficient. Some of the mercury compounds are said to be promising. Of all the treatments tested for oat smut control, only the dip and spray formaldehyde methods gave satisfactory results.

In some experiments for the control of *Rhizoctonia* on potatoes, presprinkling the tubers and keeping them moist for from 24 to 48 hours was found to increase the control materially. The best control was obtained with Dupont dust No. 15. All the others proved less efficient than corrosive sublimate (1-1,000) presprinkled and formaldehyde (1-120 for 4 minutes' immersion).

For the control of tomato blight, tests were made of the resistance of a number of varieties, and some new selections are proving quite promising.

The bean disease investigations included a study of the fungus disease known as dry root rot of beans, caused by a species of *Fusarium*, and a test of the resistance of the variety Robust to mosaic.

The eelworm disease of clover and alfalfa was found in two counties of the State in 1924, and head smut of corn and stalk smut of rye were reported for the first time.

[Report of Washington Station] division of plant pathology, F. D. HEALD ET AL. (*Washington Col. Sta. Bul. 187 (1924), pp. 66-74*).—The wheat smut

investigations were continued, and the comparative value of copper carbonate and copper sulfate for seedings at different dates was tested. For heavily smutted seed, copper sulfate gave better protection for most of the dates, while with clean seed about equal protection was afforded by either copper sulfate or copper carbonate. Early seeding and very late seeding reduced the amount of smut. An attempt was made to determine the effect of soil fertility on the percentage of smut, but neither nitrate fertilizers nor barnyard manure had any appreciable effect, although there was a marked decrease in smut in crops grown in soils of low fertility. In tests of dust fungicides for the control of bunt in fall seedings, the best copper carbonate treatment was not quite equal to the standard copper sulfate, though both were much superior to the formaldehyde treatment. In general, the best seed treatment gave unsatisfactory results for fall seeded grain when conditions for high infection prevailed. A report is given on the relative value of a number of commercial and other compounds for the prevention of smut in spring seedings.

B. F. Dana reports studies of Rhizoctonia and other diseases of potatoes in which various forms of mosaic diseases have been isolated. The mosaic complexes in Washington are said not to agree in character with the published descriptions of these diseases in other localities. For the control of these diseases, the author found that the tuber indexing did not entirely eliminate spindle tuber and witches' broom, although the method of selection did reduce the amount of these diseases present. Witches' broom is apparently infectious and readily transmitted through the tuber.

The western blight or yellows of tomatoes was studied by the same author. Experiments with scions taken from plants in different stages of the disease showed that the infection was transmitted to the stock if the scion was infectious even to a slight degree.

L. W. Boyle reported on Fusarium rot of onions, the symptoms of which are said to be similar to those caused by Fusarium species in general. The rot of the bulbs in Washington is considered due primarily to species of Fusarium, and the bacterial rot accompanying it is considered secondary.

Additional investigations on the foot rot of wheat, which has been attributed to *Wojnowicia graminis*, are said to indicate that this disease is not one that is likely to become a serious factor in wheat production.

In connection with investigations of winter injury of fruit crops, F. D. Heald reports that a survey of Spokane Valley showed that apple orchards had suffered severe injury. All varieties were affected, but Wagener seemed to suffer more than others. Observations are said to have shown a fairly common occurrence of silvered foliage, such as is characteristic of the silver-leaf disease due to *Stereum purpureum*. The studies of the author, however, have led to the conclusion that the silver-leaf fungus did not make its appearance suddenly but had been prevalent for a number of years in the State, and it must be considered an important wound parasite that will greatly increase the damage in winter injured trees.

**Report of the Dominion botanist for the year 1922, H. T. GÜSSOW ET AL.** (*Canada Expt. Farms, Div. Bot. Rpt. 1922, pp. 74, figs. 11*).—"The present report furnishes an account of the work done by the members of the staff of the Central Laboratory, Ottawa, including such phases of work as relate to plant disease investigations carried on under the Destructive Insect and Pest Act appropriation, as well as the reports from officers in charge of the branch laboratories."

**Report of the Dominion botanist for the year 1923, H. T. GÜSSOW ET AL.** (*Canada Expt. Farms, Div. Bot. Rpt. 1923, pp. 55, figs. 10*).—"The main lines of

work carried on at the Ottawa Central Laboratory and other laboratories, including the Dominion plant disease survey, economic and general botany, forest pathology, nitroculture distribution, flax wilt, potato inspection and certification, and tobacco diseases, are set forth.

**Silver-leaf disease, IV, F. T. BROOKS and H. H. STOREY** (*Jour. Pomol. and Hort. Sci.*, 3 (1923), No. 3, pp. 117-141).—This paper is an account of the results of investigations continued (E. S. R., 42, p. 845) on silver-leaf disease since 1919, with some account of work by other investigators.

Some additional hosts for the silver-leaf fungus (*Stereum purpureum*) are mentioned, including certain roses and pears. Attention is directed also to attacks on peaches (under glass), Morello cherries, and apple varieties. Outbreaks, amounting almost to epidemics, on apple and plum, are ascribed to previous careless treatment of trees. Silver-leaf occurrence in nurseries is discussed as to critical times for infection. The influence of type is considered as to susceptibility in Victoria plum. Certain plum stocks prove to be more susceptible than others.

Arguments from pathogenicity are advanced against the separation of *S. rugosiusculum* from *S. purpureum*. The preference of *S. purpureum* for woody tissues not yet invaded by other organisms is pointed out, and the effects of this fungus are described.

One of the chief recovery factors in silvered fruit trees is the formation of a gummy substance impermeable to the fungus and tending to limit its activity.

*S. purpureum* readily infects newly exposed woody tissue not less than one year old. Pruning wounds are invaded chiefly by fungi of different kinds.

The best protection has been given by gas tar, which does not injure the bark if carefully applied. Information is presented as to the longevity of the spores of *S. purpureum* under different conditions, and as to the toxicity of various substances to the fungus in culture. Silvered plum leaves photosynthesize, but less actively than healthy leaves. Translocation of carbohydrates from silvered leaves proceeds more slowly than from healthy leaves, and silvered leaves also wilt more readily than do healthy leaves. The attempt to differentiate "true" from "false" silver-leaf is considered to be invalid.

There is no known cure for silver-leaf, though good cultivation and manuring may facilitate natural recovery. The disease can be prevented in great measure by the destruction of dead wood which might develop *S. purpureum*, by thinning and pruning cautiously, and by covering exposed tissues immediately with some antiseptic, as gas tar.

**A bacterial leafspot of Martynia, C. ELLIOTT** (*Jour. Agr. Research [U. S.]*, 29 (1924), No. 10, pp. 483-490, pls. 3).—A description is given of a bacterial disease found on leaves of *M. louisiana* growing in a beet field in Kansas. Attempts were made to transfer the organism to a number of other host plants but without success. A technical description is given of the causal organism, which is given the name *Bacterium martyniae* n. sp.

**The influence of time of maturation of wheat on the development of Puccinia graminis** [trans. title], J. BEAUVERIE (*Bul. Soc. Path. Vég. France*, 9 (1922), No. 4, pp. 255, 256).—Wheat after sugar beets, and supplied with 40 tons of manure, 400 kg. of superphosphate, 400 kg. of sylvinit, and 100 kg. of nitrate per hectare, showed advanced maturity and almost no rust; whereas wheat after sainfoin, supplied with the same fertilizers minus the farm manure and plus 80 kg. of cyanamide, showed considerably retarded maturity and heavy infection with *P. graminis*.

**Further studies on the relation of onion scale pigmentation to disease resistance, J. C. WALKER and C. C. LINDEGREN** (*Jour. Agr. Research [U. S.]*,

29 (1924), No. 10, pp. 507-514).—In continuation of investigations of onion smudge (E. S. R., 49, p. 843), the authors give a report of studies made to determine the effect of the soluble toxins occurring in the bulb scales on fungi other than *Colletotrichum circinans*. About a dozen species of organisms which attack the onion bulb were tested, and, with the exception of *Aspergillus niger*, the organisms grew quite as well in the extracts from the dry outer white scales as in the control, but when extracts from colored scales were used germination and growth were either retarded or entirely inhibited. *A. niger*, which normally attacks the outer scales, seemed to be little affected by the outer scale toxins.

**A serious potato disease** [trans. title], C. CRÉPIN (*Bul. Soc. Path. Vég. France*, 9 (1922), No. 4, pp. 237-243, figs. 2).—In a number of potato fields near the foot of the Forez Mountains in the Department of Loire, France, the author observed a rolling and drying-out of potato leaves, apparently related to some basal or underground trouble. On examination this was found to be associated with the tuber disease ascribed by Ducomet to *Vermicularia varians* (E. S. R., 22, p. 742).

**Potato dartoise in 1922** [trans. title], E. FOEX (*Bul. Soc. Path. Vég. France*, 9 (1922), No. 4, pp. 244-250).—A review is given of information available as furnished by different authors regarding potato dartoise, which is said to be widely distributed in France, and to be serious on account of its effects in lowering both quantity and quality of the potato crops.

**Dartoise (*Vermicularia varians*) and silver scab (*Spondylocladium atrovirens*) of potato tubers** [trans. title], C. CRÉPIN (*Rev. Path. Vég. et Ent. Agr.*, 10 (1923), No. 1, pp. 63-66, pls. 2).—The potato disease formerly described under the name dartoise by Ducomet as due to *V. varians* n. sp. (E. S. R., 22, p. 742) and the disease caused by *S. atrovirens*, producing often on the same tubers analogous symptoms, are described as regards certain characters, mostly microscopic.

**Potato wilt and filosity** [trans. title], C. PERRÉT (*Rev. Path. Vég. et Ent. Agr.*, 10 (1923), No. 2, pp. 168-171).—A premature drying out of potato stems observed in 1922 is attributed to the presence of *Vermicularia varians*, which was found in the great majority of fields affected. The main object of this note is to discuss the relation between the presence of dartoise on the tubers and the wilting of the stalk, drawing attention chiefly to abnormal tuber sprouting, of which an account is given.

**Dartoise of potato and its consequences** [trans. title], D. S. CAVADAS (*Rev. Path. Vég. et Ent. Agr.*, 10 (1923), No. 1, pp. 67-75, pls. 2).—This trouble is here dealt with as regards the morphology of the fungus in different nutrients and the consequences of parasitism. The alterations noted are very prejudicial economically. The sclerotia and the chlamydo-spores are very persistent, and through them the disease may be conserved indefinitely. Formol treatment of the soil for the destruction of the chlamydo-spores is said to be very expensive. Methods employing heat also keep down *Fusarium* and other soil-borne diseases.

**The biology of *Vermicularia varians*** [trans. title], D. CAVADAS (*Rev. Path. Vég. et Ent. Agr.*, 10 (1923), No. 2, pp. 138-140).—Experimentation reported here is said to be more recent than that at the base of the report above noted and to deal with phenomena analogous to those described by Crépin (see above). Both microchemical and micrographical study of the phenomena suggesting leaf roll or necrosis failed to bear out the hypothesis regarding such a character. The symptoms are described.

**Tolerance and resistance to the sugar cane mosaic**, C. W. EDGERTON and W. G. TAGGART (*Jour. Agr. Research [U. S.]*, 29 (1924), No. 10, pp. 501-506,

*pl. 1*).—A report is given of a study of a number of varieties of sugar cane to test the resistance to mosaic when grown under Louisiana conditions. The investigation has shown that resistant Purple canes can be selected in fields with a 100 per cent infection. This is not considered due to slight variations of the host, nor is it known whether the plant is gradually acquiring an immunity somewhat similar to acquired immunity in man and animals. There is said to be some evidence that resistant strains are being developed naturally in some sections of Louisiana, and by discarding the susceptible and selecting the most tolerant canes for seed, it is thought that it will be possible to develop varieties tolerant to mosaic in a much shorter time than if natural selection is allowed to take its course.

**Tests of fungicides on apple trees.—II, An analytical study of their effects on the trees,** N. H. GRUBB (*Jour. Pomol. and Hort. Sci.*, 3 (1924), No. 4, pp. 157-173).—In experimentation in progress at the East Malling Research Station since 1919, all fungicides tested reduced scab (*Venturia inaequalis*). Bordeaux mixture (6-20-100) controlled scab almost as effectively as lime sulfur (1:59) and more so than ammonium polysulfide. Of the fungicides used, Bordeaux (6-20-100) was least effective against apple mildew (*Podosphaera leucotricha*). Lime sulfur was somewhat more effective than a new brand of ammonium polysulfide. The fungicides used in 1920 clearly reduced the number of canker (*Nectria ditissima*) infections of Worcester Pearmain and James Grieve in the winter of 1920-21. Bordeaux caused considerable russetting. Lime sulfur used as a summer fungicide repeatedly caused heavy fruit drop in all varieties. This was much heavier from leader tipped than from untipped trees.

The effect of fungicides is not confined to the season of their application, being apparent in one case even three years later. The influence of fungicides on the size of the fruit has not been determined. An increased formation of fruit buds following lime sulfur may be only a natural sequence from the resulting fruit drop. Vigor of growth, as measured by weight of prunings, appears in nearly all cases to be increased by the use of the fungicides Bordeaux mixture and lime sulfur.

**Monilia blossom blight (brown rot) of apricots,** B. A. RUDOLPH (*California Sta. Bul.* 383 (1925), pp. 3-55, figs. 10).—The results are given of an extensive study of a blossom blight of apricots which is due to an imperfect form of *Sclerotinia* commonly referred to in American literature as *S. cinerea*. The perfect form of the fungus is said to grow but rarely in California. The *Monilia* form attacks the blossoms at about the time they are unfolding and having killed the blossoms passes to the twigs, destroying them. Later, the ripening fruit may be attacked, producing the well-known brown rot.

A large number of treatments for the control of the blossom blight were tested, and it was found very difficult to control it in badly infested orchards which are favorably situated for the development of the disease. Orchard sanitation, together with timely spraying, seemed to offer promise. Home-made Bordeaux mixture 8-8-50 gave the best control, though more dilute solutions may give good results where infection is less severe and climatic conditions are favorable for control. Sulfur-containing compounds are not recommended as the author reports they injure apricot trees. Oil emulsions as dormant sprays had some fungicidal value but not sufficient for the control of the disease in humid localities. Fungicidal dusts were ineffective in localities favorable for the growth of the fungus.

A bibliography of 103 titles is given.

**Mildew control during 1921** [trans. title], H. FAES, P. TONDUZ, and M. STAHELIN (*Ann. Agr. Suisse*, 23 (1922), No. 2, pp. 217-230, fig. 1).—Conditions

during 1921 did not greatly favor mildew outbreaks. Compared with copper applications, copperless sprays proved to be very inferior as regards fungicidal effects. A slight addition of casein (50 gm. per hectoliter of copper spray) gave a considerable degree of adhesiveness to the liquid. Copper in colloidal form gave results justifying its further trial.

[Contributions to the study of grape white rot (*Coniothyrium diploidiella*), H. FAES and M. STAEBELIN (*Ann. Agr. Suisse*, 23 (1922), No. 2, pp. 189-202, figs. 7; 24 (1923), Nos. 1, pp. 19-28, figs. 2; 3, pp. 339-348).—The progress of grape white rot since 1878 is outlined, as are also the life history and activities of the causal fungus, designated since about 1884 as *C. diploidiella*.

Spores of white rot, borne on old material, can infect the crop of the following year. The organism appears to act as a wound parasite, greatly favored by injuries caused by hail, tools, or animals. Injury is greatly increased by repeated hailstorms.

Spores retain germinability for at least two years. Development is related to a sufficiency of sugar in the berry and a moderately high temperature. This explains why this disease attains importance usually between late July and early September. Low temperatures retard the formation of pycnidia. Humidity plays a secondary part in the development of this fungus.

Inadequate results have followed the application of treatments to the berries directly. Alkaline bisulfites, sodium hyposulfites, and formalin, each used in connection with soap, gave the best results, though these proved injurious to the grapes in the concentrations employed.

White rot spores were found to retain germinability for at least three years, with vitality but little impaired, in tests running from 1920 to 1923.

Under the existing climatic conditions, the areas subject to hail and cultivating the grape variety Chasselas, pruned low, suffer most from white rot. The 1923 treatments gave unsatisfactory results. Most of the fungicidal applications caused serious burning but gave inadequate protection.

**Fungous and non-infectious troubles of ornamental trees**, G. P. CLINTON (*Connecticut State Sta. Bul.* 263 (1924), pp. 171-192).—Descriptions are given of a number of diseases and other injuries to which ornamental trees are subject, the data considered being noninfectious troubles, which include winter injuries, drought and heat injury, smoke and gas injury, spray injury, electric wiring and lightning injury, mechanical injury, etc. This is followed by a description of a considerable number of fungus diseases.

**The diagnosis of decay in wood**, E. E. HUBERT (*Jour. Agr. Research [U. S.]*, 29 (1924), No. 11, pp. 523-567, pls. 11, figs. 6).—The author claims that formerly the identification of the cause of timber rot was usually dependent upon the presence of fruiting bodies of the fungus. From a study of about 1,500 laboratory samples of woods, the author has described a method based upon gross, microscopical, and cultural characters, by which it is possible to recognize the causal organisms responsible for various decays, stains, etc.

## ECONOMIC ZOOLOGY—ENTOMOLOGY

**Some further facts relative to the principles underlying the making and use of nicotine dust**, T. J. HEADLEE and W. RUDOLFS (*New Jersey Stas. Bul.* 400 (1924), pp. 3-44, figs. 20).—This is a report of investigations conducted during 1923, in continuation of the work reported in Bulletin 381 (E. S. R., 50, p. 254). Tests were made of the evolution of nicotine gas from nicotine dusts, under field conditions, for control of the pea aphid. It was found that at a temperature of 70° F., or above, free nicotine-dolomite dust, even when

applied at the rate of 50 lbs. per acre, evolves practically all of its nicotine in 6 hours.

"The great bulk of this nicotine escapes in the first 3 hours, and there is practically none left after the first 9 hours. A temperature of 70° or above is necessary for rapid evolution of nicotine gas from this type of nicotine dust. The employment of nicotine dusts of this character at a temperature of 60° is largely useless, and at a temperature of 50° is a pure waste of time and money. Variation in the size of particles composing a crystalloid carrier of nicotine dust, ranging from 80-mesh to 270-mesh, has comparatively little influence on evolution, but the gas escapes more rapidly from the coarse material. The ordinary 100-mesh dolomite gives somewhere near the average evolution. Thickness of the film of nicotine on the particle makes a difference in the rate of nicotine gas evolution, and within limits thinner films give off gas more rapidly. The rate of nicotine gas evolution varies directly with the temperature and seems in accordance with the well-known principles governing the evaporation of water, but is modified by the presence of nicotine and various impurities in the nicotine solution used.

"The percentage of kill and percentage of reduction vary with the rate of evolution of nicotine gas. A quick release of nicotine gas giving a very high concentration is probably more effective in the percentage of reduction accomplished than a relatively slower but longer continued discharge where the same amount of total nicotine is concerned. The use of higher-content dusts, when the rate of nicotine gas evolution is approximately constant, is likely to be followed by a higher percentage of kill and a higher percentage of reduction, because the charge in the atmosphere about the insect is greater. The practical reduction is much better when the dust is applied before the lice reach a stage of heavy infestation, because a much longer time is required for the percentage of insects which escape destruction to multiply sufficiently to reach numbers serious to the crop. In New Jersey the problem of controlling the pea louse is to be met by destroying 90 to 95 per cent of the lice shortly after they reach an average of 50 individuals to 10 ft. of pea row."

**Sodium fluoride as an insecticide; its possibilities as a locust poison,** L. B. RIPLEY (*Bul. Ent. Research*, 15 (1924), No. 1, pp. 29-34).—The author reports investigations made of sodium fluoride as a stomach poison, which indicate that it may, in a number of cases, replace the use of arsenical poisons. He finds that, while effective, it is not so toxic as arsenite of soda to either cutworms or the brown locust. Grass or horse dung treated with a 2 per cent solution of sodium fluoride gave good results against adult locusts in the laboratory. Bait treated with a 1 per cent solution was effective against cutworms (*Euxoa* spp.) in the laboratory. Sodium fluoride is not repellent to cutworms, arsenite of soda is highly repellent, and Paris green repels to a lesser extent. Sodium fluoride dust probably does not act as a contact poison on adult locusts, or, if it does, strengths much stronger than 1:20 are required.

Sodium fluoride is considerably less toxic to higher animals than arsenite of soda. In the author's opinion, it should be investigated further as a promising substitute for arsenicals against various insects. Reference is made to investigations of Fulton (*E. S. R.*, 52, p. 253), who has found sodium fluoride to be as effective as white arsenic, with quicker action, when used against the European earwig.

**Spray stimulation,** F. B. HERBERT (*Jour. Econ. Ent.*, 17 (1924), No. 5, pp. 567-572, pl. 1).—It has been found that, while stimulation of deciduous fruit trees results from the use of a number of different sprays, the greatest

amount has occurred after using the heavy types of miscible oils. The stimulation is due partly to the heavy oil base and partly to the emulsifiers in them. The condition of the tree and soil and the time of spraying are factors in the amount of stimulation to be obtained from the oil spray. The spray must be applied between December 15 and February 1 to be certain of this effect. Although there may be some disadvantages, the advantages from spraying, particularly to prune, apricot, and cherry growers, include the following: (1) Early bloom, which causes the fruit to set early before the thrips appear, thereby insuring more and cleaner fruit, (2) the early formation of large green leaves, which cover the small fruit, protecting it from sunburn and frost, (3) the attainment of much of the growth of the fruit before the natural moisture has evaporated from the ground, (4) proper functioning of the tree, resulting in larger crops and larger fruit, and (5) earlier harvest, the fruit thereby reaching the market in time for better prices.

**Entomology [at the Idaho Station]** (*Idaho Sta. Bul. 135 (1925)*, pp. 28, 29, 32).—Experimental work with the alfalfa weevil during the year indicates that a single spray application is sufficient to obtain satisfactory control. Dusting experiments indicate that where calcium arsenate is used with sulfur or Mab sand the results compare favorably with those obtained by spraying. The imported parasite *Bathyplectes curculionis* was about four times more numerous in the southwest of Idaho than in the preceding year, in a few instances parasitism reaching as high as 25 per cent.

The clover-leaf weevil was found to be doing serious injury to Ladina clover. The first outbreak of the Colorado potato beetle in commercial potato growing districts of south Idaho was discovered during the year. The infestation, however, was limited to a single field, and an attempt was made to eradicate the pest. In control work with the fruit-tree leaf-roller it was found that the egg masses could be killed by using several of the commercial oil emulsions and homemade preparations. Of the commercial preparations Dormoil gave the best results, while with the homemade mixtures the best results were obtained with Diamond paraffin potash fish oil soap oil emulsion. In combating the snowy tree cricket in prune orchards almost complete eradication was secured by a single application of calcium arsenate dust or lead arsenate spray, at a cost for poison materials of \$3 to \$6 per 100 trees.

[**Report of the Washington Station**] division of entomology, A. L. MELANDER ET AL. (*Washington Col. Sta. Bul. 187 (1924)*, pp. 46-51).—Work with the orchard leaf roller (*E. S. R.*, 48, p. 553) is first reported upon. Lubricating oil sprays averaged more than 95 per cent destruction of the eggs. The lighter oils proved better than those of medium or heavy viscosity, and killed as high as 98.8 per cent. The proprietary oil sprays gave variable control, several being effective while others gave poor results. Three applications of lead arsenate led to the conclusion that it can not be depended upon for control of the leaf roller, since much of the injury by the caterpillars is done before the spray becomes effective.

A brief reference is made to oil sprays (*E. S. R.*, 52, p. 656).

Laboratory tests of various volatile poisons for the control of subterranean insects, conducted with the view to determining the amount required to saturate a given quantity of soil and the subsequent rate of killing of buried insects, are briefly reported. In the tests poison gas was generated by passing air through the poison, and the air was then drawn, by means of an aspirator, through a glass cylinder of soil, at the exit of which was placed some bean weevils for a living indicator and a jar of absorbing reagent for a chemical indicator. When slowly passed through the series of tubes the poison vapor

would first be taken up by the soil, and after the saturation point was reached would show on the two indicators. Carbon disulfide was found to take only half as long to saturate the soil as did carbon tetrachloride. With calcium cyanide a silver nitrate indicator showed emergence of gas in three or four minutes, and the weevils were dead in 28 minutes. At Toppenish, where wireworms were particularly destructive, single rows of seed, like peas or corn, were drilled into the ground early in the spring. When the seeds sprouted they attracted the wireworms, whereupon granulated calcium cyanide was drilled over the rows of seeds, and was astonishingly effective.

Brief reference is made to a crop pest survey of the State. Several destructive insects are recorded as newcomers to the State, including the asparagus beetle, discovered in the Yakima Valley; the squash bug, which has obtained a foothold near the mouth of the White Salmon River; Bruce's measuring worm (*Rachela bruceata*), known in British Columbia but now occurring in the Okanogan Valley; the satin moth (*Stilpnobia salicis*), which is already as destructive to willow and poplar in Whatcom County as it is in the quarantined district in Massachusetts; the cherry fruit-fly, rapidly spreading in the Palouse section; the cherry sawfly (*Hoplocampa cookei*), which has extended its range northward and is now reported from several localities in western Washington; the lilac miner (*Gracillaria syringella*), a minute European moth that is ruinous to lilac and privet in many cities of western Washington; and the European earwig (*Forficula auricularia*). Brief reference is also made to a number of the insects most destructive during the year.

**Proceedings of the Acadian Entomological Society for 1923** (*Acadian Ent. Soc. Proc.*, No. 9 (1923), pp. 72, pls. 6).—Papers presented in this annual report (E. S. R., 50, p. 844) include the following: Spraying in Relation to the Renovation of Old Orchards in New Brunswick, by G. P. Walker (pp. 8-13); Studies on a New Species of *Empusa* Parasitic on the Green Apple Bug (*Lygus communis* var. *novascotiensis* Knight) in the Annapolis Valley, by A. G. Dustan (pp. 14-36); The Garden Springtail (*Sminthurus hortensis* Fitch) as a Crop Pest, by W. H. Brittain (pp. 37-47); Insects of New Brunswick Injurious to Crops in 1923, by G. P. Walker (pp. 48-54); Insects of the Season 1923 in Nova Scotia, by J. P. Spittal (pp. 55-68); and Notes on *Agriotes mancus* Say, at Dartmouth, N. S., by R. P. Gorham (pp. 69-72).

Under the name *Empusa erupta* n. sp., A. G. Dustan describes and reports studies of the life history and development of a parasitic fungus discovered in 1920, which has caused a gradual decrease of the green apple bug (E. S. R., 37, p. 462) in orchards of Annapolis Valley, Nova Scotia. The life of this fungus is comparatively short, probably not extending over more than a month or, at most, six weeks. It is said that bugs, even though severely mutilated by it are still able to move over the foliage quite rapidly. This is due to the fact that the posterior half of the methoracic segment is invaded, and, though the larger wing and leg muscles are destroyed, the muscles of the pro- and meso-thorax are left untouched and the insect is still able to use the first two pairs of legs and the first pair of wings. The retention of the power of locomotion is of great importance is so far as the spread of the disease is concerned. A list of 14 references to the literature consulted is included.

**Insect collecting in Panama**, D. T. FULLAWAY (*Hawaii. Forester and Agr.*, 21 (1924), No. 3, pp. 94-98).—The author reports that he was able to secure seven different enemies of the pineapple mealybug in Panama, including four species of lady-beetles, two species of flies, and an encyrtid parasite of the

genus *Chrysoplatycerus*. As a general rule the pineapple plants were found to be free of mealybugs, and this was particularly so on the island of Taboga. Attention is called to the fact that the beetle-borer is a very severe pest in Central and South America and the West Indies, and that it must be kept out of Hawaii if the pineapple industry is to continue to flourish.

**Work of the division of entomology, E. JARVIS** (*Queensland Bur. Sugar Expt. Stas. Ann. Rpt.*, 23 (1923), pp. 47-51).—This report (E. S. R., 49, p. 758) deals particularly with the effect of paradichlorobenzene on cane attacked by the gray-back cockchafer beetle (*Lepidoderma albohirtum* Waterh.), an account of which has been noted (E. S. R., 50, p. 457). Brief references are made to the introduction of scoliid wasp parasites; the influence of chemotropism on cane beetles; injury from moth-borers including the large moth-borer (*Phragmatiphila truncata* Wlk.), the small moth-borer (*Polyocha* sp.), and an unidentified tineid moth-borer; the liberation of tachinid fly parasites; cane damaged by the army worm; and the heavy mortality among cane beetles resulting from climatic control.

**Report by the Government entomologist, H. W. SIMMONDS** (*Fiji Dept. Agr. Ann. Rpt. 1922*, pp. 3-5).—This report contains a brief account of the insects attacking coconuts, bananas, cotton, etc., during the year. Of particular importance was the discovery early in the year that the coconut scale *Aspidiotus destructor* had reached the island of Vanua Levu, where it is established in Bua Province. In June, the pink bollworm was discovered at Nadi, and subsequently found to be present throughout the group. Toward the close of the year the very destructive coconut leaf moth of Viti Levu (*Levuana iridescens*) was found to have spread to the islands of Caqalai and Moturiki in Lomaiviti.

**Orchard insects and their control** [trans. title], J. C. FAURE (*Prog. Agr. et Vitic. (Ed. l'Est-Centre)*, 45 (1924), Nos. 19, pp. 442-447, pl. 1; 21, pp. 490-496, pl. 1; 23, pp. 539-547, pl. 1).—This paper deals with some of the more important enemies of fruit trees in France, and particularly with means for their control. The insects and their injury are illustrated in colors.

**Insect pests and diseases of the Satsuma orange, H. L. DOZIER** (*Gulf Coast Citrus Exch. Ed. Bul. 1* (1924), pp. 103, pl. 1, figs. 75).—This is a summary of information on the more important insect enemies (pp. 6-82) and fungus diseases (pp. 82-94) of the Satsuma orange, with a discussion of spray materials and a spray schedule.

**The insect pests of citrus trees in Egypt, W. J. HALL** (*Egypt Min. Agr., Tech. and Sci. Serv. Bul. 45* (1924), pp. IV+30).—In this work the author deals with 12 species of scale insect enemies of citrus trees; 6 other Egyptian scale insects which do not attack citrus trees, although doing so in other countries; and 4 other insects which attack citrus trees in Egypt, including the Mediterranean fruit fly, cotton aphid, *Aphis leguminosae* Theo., and the white fly (*Aleyrodes* sp.). This is followed by an account of fumigation and other control measures and of 11 other pests, chiefly scale insects, likely to be introduced and the precautions taken at the ports of entry. Ten more pests of citrus trees occurring in other parts of the world are briefly referred to. Directions for the preparation of paraffin emulsion are given in an appendix.

**Insect pests of cranberries, D. J. CROWLEY** (*Washington Col. Sta. Bul. 187* (1924), pp. 104, 105).—In further work with the fireworm (E. S. R., 51, p. 158), the use of nicotine sulfate at the rate of 1 gal. to 400 gal. of water was found to give much more effective control than when used at a greater dilution. Fish oil soap is considered to be the most satisfactory spreader. On some bogs two applications of nicotine gave effective control, while others required four

and some as many as five sprays. Control by parasites is thought to be the factor involved, since on some bogs crops practically free from fireworm injury were produced where no spray had been applied. The antique tussock moth, which caused considerable damage on many bogs in 1923, appeared on only one bog in 1924.

Some of the principal insects attacking shade trees in Connecticut, W. E. BRITTON (*Connecticut State Sta. Bul.* 263 (1924), pp. 156-170).—Brief summarized accounts are given of the more important insect enemies of shade trees in Connecticut, together with notes on common insecticides.

**Ants, bees, and wasps: Their lives, comedies, and tragedies,** E. C. ASH (*London: Robert Holden & Co., Ltd.,* [1924], pp. 136, figs. 126).—A brief popular account.

**A new long-horned grasshopper damaging coconut palms in New Britain,** B. P. UVAROV (*Bul. Ent. Research,* 15 (1924), No. 1, pp. 35, 36, fig. 1).—Under the name *Habetia defoliaria*, the author describes a new grasshopper which has completely defoliated coconut palms at two or three places in New Britain, which lies near New Guinea.

**On a new injurious thrips affecting tea in India,** R. S. BAGNALL (*Bul. Ent. Research,* 14 (1924), No. 4, p. 455).—Under the name *Dendrothrips bispinosus*, the author describes a new thrips which was found badly damaging tea on an estate near Kotagiri, in the Nilgiri Hills, south India.

**On a new cixiid attacking coconut palms (Homopt.),** F. MUIR (*Bul. Ent. Research,* 14 (1924), No. 4, p. 456, fig. 1).—This is a contribution from the Hawaiian Sugar Planters' Experiment Station, in which the author describes a new cixiid, *Euryphepsia cocos*, which attacks coconut palms in the Solomon Islands.

**Fumigation with hydrogen cyanide for control of pear psylla,** R. L. WEBSTER (*New York State Sta. Bul.* 523 (1924), pp. 3-23, pls. 4, fig. 1).—This is a report of fumigation investigations conducted in four large pear orchards in western New York for the control of the pear psylla, in which the equipment of fumigating tents and methods used were similar to those used in the fumigation of citrus trees in southern California. The gas was generated by the use of sodium cyanide and sulfuric acid in the so-called "cyanofumer."

Under ordinary conditions, where leakage of gas through the tents was not excessive, all stages of the psylla, including the eggs, were killed by the use of the 75 per cent schedule employed in California. The experimental operations were carried on largely during daylight and without severe fumigation injury to foliage. Where damage to foliage occurred, the shade temperature at the time, or immediately following, ran above 80° F.

"Such severe fumigation injury, both to foliage and fruits, occurred on Kieffer trees during 1919 that experimental work had to be abandoned for the remainder of the summer. No such damage occurred during the continued fumigation of a severely infested pear orchard in 1920. The most severe fumigation injury to foliage occurred with trees fumigated at night, but this fumigation was followed by high temperatures the next day. The reinfestation of fumigated trees from other nearby unfumigated trees, or from adjacent woods, where the insects apparently spent the winter, decreased greatly the value of the fumigation work reported in this bulletin. In general, the conditions under which fumigation operations were carried on in New York were quite unfavorable as compared with those encountered in southern California. The New York work was handicapped by the large size and tall growth of pear trees, by continued rains which made consistent fumigation impossible, and by occasional high winds. Although many serious difficulties

were encountered during the experimental work on fumigation, none of these were considered as being insurmountable."

**The correct names of the leafhoppers infesting the apple and potato.** E. D. BALL (*Jour. Econ. Ent.*, 17 (1924), No. 5, pp. 594-600).—The author points out that there has been much confusion and misunderstanding with respect to the scientific and common names to be applied to the three species of leafhopper infesting the apple, namely, *Typhlocyba rosae* L., *Empoasca maligna* Walsh, and *E. fabae* Harr. For assistance in determination, keys are presented, one to the insects and another to the injury.

**Notes on the biology of *Pseudococcus gahani* Green, L. WILLIAMS** (*Ann. Appl. Biol.*, 11 (1924), No. 3-4, pp. 498-502).—This is an account of a mealybug indigenous to the British Isles, which occurs on red Ribes, Ceanothus, Laburnum, and potato tubers. The life period of the two sexes is very extended, ranging from 20 to 24 weeks, the females passing through five stages, while the males pass through six. There is said to be no danger of its becoming an economic pest, owing to its long life period.

**The present status of the citrophilus mealybug in southern California,** H. M. ARMITAGE (*Citrus Leaves*, 1924, No. 8, pp. 4-6, 9, fig. 1).—This is a review of the present status of *Pseudococcus gahani* Green, which is one of the most important citrus pests in southern California. It is pointed out that more than 500,000 ladybird beetles (*Cryptolaemus montrouzieri* Muls.) are now being reared and liberated monthly in the citrus orchards of southern California.

**The European corn borer and the latest methods of control,** L. CAESAR (*Ontario Dept. Agr. Circ.* 44 (1924), pp. 8, figs. 7).—A brief practical account of this pest.

**The life-history and habits of *Tortrix pronubana* Hb., with special reference to the larval and pupal stages,** R. C. FISHER (*Ann. Appl. Biol.*, 11 (1924), No. 3-4, pp. 395-447, pl. 1, figs. 16).—This is a report of studies of the life history of *T. pronubana*, including technical descriptions of its several stages, and of its economic importance, control, parasites, and relation to Dyar's hypothesis.

This lepidopteran has of late caused injury in glasshouses at the Royal Botanic Gardens, Kew, England, where there are two main broods during the year. A series of experiments have shown that, under glass, spraying with nicotine or lead arsenate is effective if applied before and immediately after the eggs hatch. Fumigation with hydrocyanic acid gas was found ineffective against the larvæ. Two hymenopterous parasites, not yet identified, were reared from the larvæ and pupæ, but the percentage of parasitism was extremely low. A list of host plants of *T. pronubana* under glass and in the open is given in an appendix, together with a bibliography of 23 titles.

**South African trypaneid Diptera in the collection of the South African Museum,** M. BEZZI (*Ann. So. African Mus.*, 19 (1924), pt. 3, pp. 449-577, pls. 4).—This is a synopsis of fruit flies of South Africa of the six subfamilies of Trypaneidae, as follows: Dacinae, in which 1 genus is erected and 11 new forms are described; Adraminae; Ceratitinae, in which 7 genera are erected and 26 new forms described; Schistopterinae, not yet found in South Africa; and the aberrant group of Rhabdochaetinae, in which 1 new species is described; and Trypaneinae, in which 1 genus is erected and 38 forms are described as new. Descriptions are given of 180 species of fruit flies recognized.

**Further notes on the Ethiopian fruit-flies, with keys to all the known genera and species,** M. BEZZI (*Bul. Ent. Research*, 15 (1924), Nos. 1, pp. 73-

118; 2, pp. 121-155).—This paper completes the author's notes of 1920 and earlier (E. S. R., 45, p. 257).

**International conference on the control of the olive fly** (*Conférence Internationale de Lutte Contre la Mouche de l'Olive*. Madrid: Gráficas Reunidas, S. A., 1923, pp. 162, pls. 3).—This is a report of the proceedings of an international conference held at Madrid in June, 1923. Included in the proceedings are discussions of The Agricultural Importance of *Dacus Oleae* Rossi in Portugal, by A. F. de Seabra (pp. 81-86); Control Work with the Olive Fly in Spain (pp. 87-108) and The Present Status of Natural Control of the Olive Fly by Parasites (pp. 123-128), both by Aguiló; The Results of Some Experiments on Control Measures for the Olive Fly, by P. Carrión (pp. 148-151); and a Report on the Eradication of the Olive Fly in the Province of Tarragona, by J. Valls y Torres (pp. 151-158).

**Oscinella frit Linn.:** An investigation to determine how far varietal differences may influence infestation of the oat plant, N. CUNLIFFE and J. C. F. FRYER (*Ann. Appl. Biol.*, 11 (1924), No. 3-4, pp. 465-481).—The authors report observations of an infestation of the stem and grain of 12 varieties of oats grown in widely separated localities, where they were subject to the attack of *O. frit*.

"The stem infestation showed an increase of 11 per cent only, 18 days after June 7. The attack on stems 12 in. in length (including blades) and over was only one-third as intense as that on the remaining stems; 20 per cent of the former were rendered incapable of producing panicles; 25 per cent of the hidden buds plus small tillers were destroyed. Infestation away from the growing point averaged 2 per cent. The infestation of the main grain reached 45.9 per cent, against 22.8 per cent for the bosom grain at Oxford, indicating the importance of the time factor."

Certain aspects of the damage to oats by the frit fly, J. C. F. FRYER and J. E. COLLIN (*Ann. Appl. Biol.*, 11 (1924), No. 3-4, pp. 448-464, figs. 3).—This is a report of a study which deals with the attack of the second brood of the frit fly on the oat grain.

The biology of *Anomala kansana* (Scarabaeidae, Coleop.), W. P. HAYES and J. W. MCCOLLOCH (*Jour. Econ. Ent.*, 17 (1924), No. 5, pp. 589-594, fig. 1).—This contribution from the Kansas Experiment Station deals with the life history and economic importance of this recently described species. It was found to have a one-year life cycle.

Simple methods of rearing wireworms (Elateridae), M. C. LANE (*Jour. Econ. Ent.*, 17 (1924), No. 5, pp. 578-582).—The author reports upon a few successful and simple methods of rearing one of the most difficult groups of insects with which the economic entomologist has to deal. The studies were confined largely to *Ludius novius* Hys. and *Pheletes occidentalis* Cand.

Preliminary report on the use of calcium cyanide as a soil fumigant for wireworms, R. E. CAMPBELL (*Jour. Econ. Ent.*, 17 (1924), No. 5, pp. 562-567).—In preliminary pot and field experiments, calcium cyanide used at the rate of from 130 to 400 lbs. per acre showed a decided toxicity for elaterid larvae, and indicated that about 200 lbs. per acre if properly applied would kill 75 per cent or more of the worms.

Life-history studies of the tobacco flea-beetle in the southern cigar-wrapper district, F. S. CHAMBERLIN and J. N. TENHET (*Jour. Agr. Research* [U. S.], 29 (1924), No. 12, pp. 575-584, figs. 7).—This is a report of biological studies conducted by the U. S. D. A. Bureau of Entomology, at Quincy, Fla., from 1918 to 1923, in connection with control work, an account of which has been reported in U. S. D. A. Farmers' Bulletin 1352, previously noted (E. S.

R., 50, p. 56). Brief technical descriptions of the several stages are included, that of the larva being by A. G. Böving.

In the southern cigar-wrapper district the tobacco crop is attacked by the overwintering brood and by two later generations of the tobacco flea-beetle, and there may be two and possibly three additional broods, which so overlap that it is impossible to tell them apart. Overwintering females may deposit as many as 200 eggs in cracks or crevices in the soil near the base of the plant. In the early spring months at Quincy the eggs hatch in about 11 days, whereas in summer about 5 days are required for incubation. The larvae live underground and feed upon the roots of tobacco and other solanaceous plants. The length of the larval stage was found to vary from 41 days in early spring to 11 days in midsummer at Quincy. About 5 days are required for the pupal stage, which is passed in small oval-shaped cells about an inch below the surface of the ground. The adults upon emerging remain near the ground and confine their feeding to the lower tobacco leaves, but in a short time they spread over the entire plant and feed on all parts of the foliage. In addition to tobacco, which is the preferred food plant, other solanaceous plants, both wild and cultivated, are fed upon to a considerable extent, and in the absence of solanaceous plants the beetles feed sparingly upon other wild and cultivated plants. Oviposition commences soon after emergence from hibernation and continues until early fall. The beetle is capable of flying a considerable distance, this being the most important means of dispersion. In the southern cigar-wrapper district hibernation is incomplete.

**The tulc billbug, W. B. TURNER** (*Jour. Econ. Ent.*, 17 (1924), No. 5, pp. 528-532).—This is an account of the life history of (*Sphenophorus*) *Calendra discolor* Mann, which sometimes injures small grains in California by eating into the stems near the head.

**Poisoning the boll weevil in the Piedmont section of South Carolina, C. B. NICKELS** (*South Carolina Sta. Circ.* 33 (1925), pp. 3-39, figs. 8).—Following an introductory account, experiments with calcium arsenate dust conducted on six farms are reported upon (pp. 9-24). The results, summarized in tabular form, show a maximum profit of \$71.20 per acre to have resulted from the application of calcium arsenate dust on a farm at Anderson and a minimum profit of \$11.83 per acre on a farm at Pickens, the average profit for all plats being \$29.85 per acre. It is pointed out, however, that these figures probably do not represent the profit which could be derived from the control of the boll weevil on the average farm in the Piedmont section, because of the fact that, for the tests conducted, fields were selected which would make good crops and in which the boll weevil threatened serious injury.

In tests of the calcium arsenate molasses mixture (pp. 25-34), about seven applications of a mixture of 1 lb. of calcium arsenate, 1 gal. of water, and 1 gal. of molasses were made at weekly intervals, commencing about the middle of June, followed by a spray consisting of 5 lbs. of calcium arsenate, 8 gal. of water, and 2 gal. of molasses when the cotton plants had put on a considerable amount of fruit, usually after August 1. A tabulation of results shows that in two of the experiments the yield of cotton was actually less on the treated than on the untreated plats. In only two experiments was the yield materially greater on the treated plats than on the checks, and even in these two the greater yield can not be attributed to the effects of the poison applications.

In 12 applications of the poison sold under the name of Hill's Mixture, which contains calcium arsenate, molasses, water, and other ingredients, practically the same results were obtained as those from the 1-1-1 calcium arsenate molasses mixture. No profit was secured from the use of the Florida

stripping method in the experiments conducted, the average total cost of the method having been \$1.54 per acre.

**The apple bud weevil, *Anthonomus cinctus* Koll.,** F. R. PETHERBRIDGE and J. W. COWLAND (*Ann. Appl. Biol.*, 11 (1924), No. 3-4, pp. 482-497, pl. 1, figs. 10).—This is a report of studies of a weevil which is very similar to the apple blossom weevil (*A. pomorum*). It is widely distributed on the Continent and occasionally, in certain districts, does serious damage to pear buds, and now and then is found injuring apples. It has not as yet been recorded on pears in England, but was found killing apple buds at Wisbech in 1921 and near Cambridge in 1922, and the adults have also been found in Kent.

"The eggs are laid in apple buds (usually fruit buds) in the autumn, one egg only in each bud. The larva hatches at the end of February and eats out the succulent portion of the bud. It pupates in May and changes to the weevil stage in June. The weevils puncture the leaf stalks, buds, and succulent portion of the shoots."

Descriptions are given of the various stages, and a comparison is made between this species and those closely allied. In the vicinity of Cambridge, a hymenopterous parasite, *Pimpla pomorum*, killed most of the larvae and pupae left on the trees after collecting.

**The lesser clover weevil, G. W. UNDERHILL** (*Va. State Crop Pest Comm. Quart. Bul.*, 6 (1924), No. 1, pp. 7, figs. 6).—This is an account of the clover bud weevil, based upon studies at the field station located in 1919 and 1920 at Chester and in May, 1921, moved to Smithfield, Va., for the rest of the season. Five internal parasites have been reared from the larvae, namely, *Microbracon mellitor* Say, *Microbracon* n. sp., *Bathyplectes exigua* Grav., *Bassus albicinctus* Ashm., and *Spilochalcis* sp. The eggs of this weevil are also parasitized by *Anaphes iole* Gir., and a fungus disease kills some larvae.

**The effect of weevily seed beans upon the bean crop and upon the dissemination of weevils, *Bruchus obtectus* Say and *B. quadrimaculatus* Fab.,** A. O. LARSON (*Jour. Econ. Ent.*, 17 (1924), No. 5, pp. 538-548).—Experiments carried on for several years by the U. S. D. A. Bureau of Entomology with the object of determining the influence of the weevily beans and cowpeas on the production of the crop as well as the probability of the infestation of the crop by weevils contained within the planted seeds, have shown that, while the planting of weevily beans reduces the yield, it does not appear to have any bearing on the infestation of the succeeding crop.

**Forty-fourth annual report of the Beekeepers' Association of the Province of Ontario, 1923** (*Ontario Dept. Agr., Beekeepers' Assoc. Ann. Rpt.*, 44 (1923), pp. 79).—The papers and reports presented at the annual convention of this association held at Toronto in December, 1923 (*E. S. R.*, 50, p. 57), include the following: Honey, by H. Root (pp. 10-13); Steam-heated Uncapping Equipment, by E. C. Hardie (pp. 18-20); Extracted Honey Production and Care of the Crop, by S. D. House (pp. 20-24); Foundation and Good Combs, by C. B. Gooderham (pp. 24-31); Placing of Foundation in Frames, by E. T. Bainard (pp. 31, 32); Control of Swarming in Out-Apiaries, by J. L. Byer (pp. 33-38); Ontario Honey Producers Cooperative, Limited, by F. W. Krouse (pp. 38-42); Freight Classification, by R. F. Holtermann (pp. 42, 43); Outdoor Wintering, by R. G. Houghton (pp. 44-50); Spring Management of Bees in Southern Ontario, by M. Pettit (pp. 50-54); Comb-honey Production, by H. G. Sibbald (pp. 54-57); Apiary By-products and Their Disposal, by J. Newton (pp. 58-61); Economy in Production, by R. F. Holtermann (pp. 61-63); Honey in Cooking, and Co-operation, by H. Root (pp. 65, 66); Report of the Provincial Apiarist, by F. E. Millen (pp. 66, 67); Apiary Inspection in

Wisconsin, by S. B. Fracker (pp. 68-72); The Alcohol-Formalin Treatment for American Foulbrood, by O. E. Barber (pp. 72-74); and Judging and Grading Extracted Honey, by W. A. Weir (pp. 75-78).

**Bee-keeping for beginners**, I. H. JACKSON (*London and Bombay: Blackie & Son Ltd., 1924, pp. 112, pls. 9, figs. 20*).—This is a brief practical account.

**Beekeeping in Wisconsin**, J. I. HAMBLETON (*Wis. Agr. Col. Ext. Circ. 174 (1924), pp. 24, figs. 12*).—This is a practical account of beekeeping as applied to Wisconsin conditions.

**New parasitic Hymenoptera of the subfamily Anteoninae (Bethyliidae)**, F. A. FENTON (*Ohio Jour. Sci., 24 (1924), No. 4, pp. 191-194, figs. 4*).—A number of dryinid wasps were reared from several species of Cicadellidae and Fulgoridae collected in Iowa in 1923, three of which are described as new under the names *Pseudogonatopus iowensis*, from *Liburnia lutulenta* Van Duzee; *Aphelopus bicolor*, found to parasitize *Erythroneura trifasciata* Say to an extent of 10 per cent; and *Chalcogonatopus nigrus*, from *Scaphoideus* sp., probably *immistus* Say.

**A new chalcid attacking bamboo in India (Hymenoptera)**, J. WATERSTON (*Bul. Ent. Research, 15 (1924), No. 1, pp. 69-71, figs. 2*).—Under the name *Eurytoma chrysothrix* the author describes a new species bred from bamboo in south India.

**The preparation and use of colloidal sulfur as a control for red spider**, E. R. DE ONG (*Jour. Econ. Ent., 17 (1924), No. 5, pp. 533-538*).—The toxic properties of two types of colloidal sulfur, prepared (1) by running hydrogen sulfide into a solution of sulfur dioxide and (2) by precipitating lime-sulfur solution with acid, were compared with a 2 per cent lime-sulfur solution containing 0.6 per cent sulfur, and the colloidal solutions proved more effective, especially at low temperatures. It is stated that the addition of 5 lbs. of ground or flowers of sulfur will probably prolong the length of time such solutions will remain effective, both as acaricides and fungicides.

**Some parasitic round worms of the rabbit, with descriptions of two new species**, A. C. CHANDLER (*U. S. Natl. Mus. Proc., 66 (1924), Art. 16, pp. 6, pls. 2*).—Under the name *Nematodirus leporis*, the author describes a new species found in the duodenum of the domestic rabbit at Houston, Tex. A brief account is given of *Obeliscus cuniculi* Graybill, described since the original draft of this paper was written.

## FOODS—HUMAN NUTRITION

**The relation of arginine and histidine to growth**, W. C. ROSE and G. J. COX (*Jour. Biol. Chem., 61 (1924), No. 3, pp. 747-773, figs. 10*).—The literature on the question of the relation of the amino acids arginine and histidine to maintenance and growth is reviewed, and experiments are reported in which comparisons were made of the growth of rats on diets supposedly balanced with respect to all constituents except nitrogen, this being supplied in the form of casein, completely hydrolyzed casein, hydrolyzed casein from which arginine and histidine had been removed by double precipitation with silver sulfate and barium hydroxide, and hydrolyzed casein plus arginine and histidine, respectively.

The animals receiving whole casein grew normally, those receiving hydrolyzed casein grew to maturity but more slowly, and those on the diet containing no arginine nor histidine did not grow and lost weight rapidly. On adding histidine to such a ration there was invariably a prompt resumption of growth at normal rate, but arginine was without effect even when added

in amounts more than equivalent to the sum of the arginine and histidine present in the original casein. The amount of histidine required for maintenance was 0.1 gm. of histidine monochloride per 100 gm. of food, for moderate growth from 0.2 to 0.3 gm., and for normal growth about 0.5 gm. equivalent to 2.5 per cent of the protein, the proportion of histidine normally present in casein.

These results are thought to indicate that histidine is an indispensable component of the diet, but that, contrary to the observations of Ackroyd and Hopkins (E. S. R., 37, p. 265), "arginine and histidine are not mutually interchangeable in metabolism. The experiments have no bearing upon the question of the indispensability of arginine, since it is quite likely that the Kossel-Kutscher method of precipitation does not remove arginine as completely as it does histidine."

**The influence of sodium chloride upon the level of blood uric acid,** V. J. HARDING, K. D. ALLIN, and H. B. VAN WYCK (*Jour. Biol. Chem.*, 62 (1924), No. 1, pp. 61-73, fig. 1).—Experiments on the effect of sodium chloride on the uric acid concentration in the blood of several normal women during the latter half of pregnancy are reported and discussed, with particular reference to certain conclusions of Folin, Berglund, and Derick in their recent paper on uric acid (E. S. R., 52, p. 667).

The ingestion of sodium chloride in connection with a diet predominating in protein or carbohydrate was found to lower the level of the blood uric acid and blood serum proteins, to increase the level of sodium chloride in the blood, and to bring about a marked total retention of water and sodium chloride. The decrease in the concentration of uric acid in the blood is attributed to the increased hydration of the blood, with consequent increased elimination of uric acid. On a constant sodium chloride intake but little difference was found in the level of the blood uric acid when on a protein or carbohydrate diet, thus tending to disprove the theory of Folin and his collaborators that the decrease in the level of the blood uric acid brought about by a high protein diet is due to increased elimination through the kidney.

**The urine sugar and its relation to the blood sugar,** H. F. HÖST (*Jour. Metabolic Research*, 4 (1923), No. 3-4, pp. 315-414).—In this extensive investigation, various methods of determining carbohydrates in the urine were first studied, and the Benedict-Osterberg method (E. S. R., 39, p. 112) with certain modifications was adopted as the most satisfactory. In this method control of the H-ion concentration was found to be an important factor for accuracy. This was secured in the determination of total carbohydrate by the addition of 4 gm. of sodium bicarbonate to 20 cc. of urine plus 20 cc. of the mercury solution. In the subsequent fermentation the pH value of the urine was brought to between 5.5 and 6.8, after which the urine was brought to boiling temperature, cooled, and 5 per cent of fresh ordinary commercial yeast and glucose to the extent of 1 part per 1,000 added. The reducing substances were determined after 48 hours in the thermostat.

Determinations were then made of the fermentable carbohydrate in the urine in a number of healthy persons, of persons with chronic or intermittent glycosuria, and of diabetics under various conditions of feeding, etc. Blood sugar determinations were also made. In the 7 healthy subjects the total sugar of the urine varied between 450 and 1,320 mg. during the 37 days of the experiment, with an average value of 871 mg. Corresponding figures for fermentable sugars were 180, 710, and 368 mg. The sugar excretion was least in the morning before breakfast, and was in general not altered by the administration of sodium bicarbonate or dilute hydrochloric acid. The blood sugar concentration was likewise not altered by alkali or acid.

Mixed food caused a marked increase in the sugar excretion and some increase in the blood sugar. Of single articles of food, bread caused an increase in sugar excretion which was more pronounced the coarser the bread. The blood sugar showed a greater increase after fine bread than after coarse bread. The maximum blood sugar concentration was always found during the first hour after the meal. A slight increase in sugar excretion resulted in 2 cases after eating 300 gm. of roast meat, but in 4 other experiments with meat, cabbage, and soup there was no increase in sugar excretion. Following the administration of glucose, the amount of blood sugar fluctuated within wide limits without having any effect on the fermentable sugar of the urine. In the 25 healthy persons investigated the fasting blood sugar was less than 110 mg. per 100 cc. Following the ingestion of 50 gm. of glucose dissolved in 200 cc. of water, the amount of blood sugar increased to varying degrees, the greatest concentration being 216 mg. In 6 of the subjects glycosuria occurred after the ingestion of the glucose. The intravenous injection of the same amount of glucose brought about a much more rapid rise in blood sugar.

In the transition cases the difference in the sugar excretion on a carbohydrate-free and carbohydrate-rich diet was very slight when determined on 24-hour samples. In the clinically sugar-free diabetics the amount of fermentable sugar in the urine was about the same as in the case of healthy persons, but with the onset of clinical glycosuria the fermentable sugar of the urine was suddenly increased. Changes in the blood sugar concentration caused by the administration of glucose did not cause any alteration in the excretion of sugar when the renal threshold was not passed. Single articles of food did not produce an increase in the urinary sugar without a simultaneous increase in blood sugar. In quantities of 300 gm., meat caused an increase in the blood sugar concentration in all of the diabetic subjects.

It is stated in conclusion that there are two kinds of sugar excretion in the urine: "(1) Physiological sugar excretion, which has no relation to the amount of glucose in the blood and which comprises sugars whose nature is not known, but which probably do not include glucose. After meals consisting of bread, as well as in urine which is concentrated, these physiological sugars may occur in such quantities that the reduction reactions commonly employed are positive. (2) Pathological sugar excretion caused by the passage of the glucose of the blood into the urine when the blood sugar concentration exceeds the renal threshold."

**On the type of sugar excreted in the urine of normal persons, K. TALLERMAN** (*Biochem. Jour.*, 18 (1924), No. 3-4, pp. 583-585).—To throw some light on the question as to whether the sugar normally circulating in the blood is  $\gamma$ -glucose, an examination was made of the sugar excreted in the urine of normal subjects after phlorhizin injection. It was assumed that since phlorhizin acts only by lowering the threshold value of the kidney for sugar, the sugar excreted in the urine would be of the same nature as that of the blood.

The tests for  $\gamma$ -glucose included reduction of Fehling's solution in the cold and decolorization of potassium permanganate. Negative results were obtained in all cases with the Fehling test, and with the other test there was no greater reduction of potassium permanganate than that produced by any average normal urine. A comparison of the copper-reducing power with the polarimetric reading gave only slight differences, nor was there any appreciable change in the polarimetric reading on standing. Similar results were obtained with the urine of two diabetic patients who had marked glycosuria but were practically free from ketosis.

It is concluded that since no evidence was obtained of the presence of  $\gamma$ -glucose in the urine it is unlikely that this form of sugar is the variety present in normal blood.

**Intestinal chemistry, I, II, O. BERGEIM** (*Jour. Biol. Chem.*, 62 (1924), No. 1, pp. 45-60).—Two papers are presented.

I. *The estimation of intestinal reductions.*—In this a new method of determining the reduction taking place in the intestines is described. This consists in the feeding of pure ferric oxide mixed with an equal amount of powdered agar to counteract a tendency to constipation and determining the extent of reduction by fecal analyses for reduced and unreduced iron, care being taken to collect the feces without sufficient exposure to air to cause oxidation.

Preliminary experiments conducted on rats showed that hydrated ferric oxide powder to the extent of 1 per cent of the diet or about one-fourth of this amount of a coarser ferric oxide is sufficient for the determination, the feces being collected for examination after two days on the experimental diet.

II. *Intestinal reductions as measures of intestinal putrefaction, with some observations on the influence of diet.*—The above method was used to test the reduction in rats of various types of food materials when fed alone and in combination. Analyses of the contents of different parts of the gastrointestinal tract after the feeding of the iron oxide were first made to determine the location of the reducing process. No reduction was found to take place in the stomach, practically none in the upper small intestine, more in the lower small intestine, and by far the largest amount in the cecum and large intestine, the region where intestinal putrefaction of protein predominates.

On starch-protein diets furnishing 20 per cent of protein, the reduction occurred to the greatest extent (71 per cent) with egg albumin, followed by meat (63 per cent), and lowest with casein (19 per cent). On diets containing 20 per cent of egg albumin, 1 per cent of agar, and various carbohydrates to make 100 per cent starch, sucrose, glucose, fructose, and maltose had but little effect in decreasing the reduction brought about by the egg albumin, but dextrin and lactose caused a marked decrease in reduction. Of the other foods tested, fruits and green vegetables alone or as constituents of diets gave moderately low reduction values. Milk when fed alone gave very low reduction values and when fed with other foods decreased the reduction. Several intestinal antiseptics failed to produce any permanent decrease, and intestinal stasis caused marked increase in reduction.

"Intestinal reduction as estimated by the method given is a useful index of intestinal putrefaction and gives additional information as to the degree of anaerobiosis that may exist in the intestine. As the organisms of true putrefaction presumably responsible for the more severe intestinal toxemias are anaerobic in character, the information thus obtained should be of value."

**Fat-soluble vitamins.—XVII, The induction of growth-promoting and calcifying properties in a ration by exposure to ultra-violet light, H. STEENBOCK and A. BLACK** (*Jour. Biol. Chem.*, 61 (1924), No. 2, pp. 405-422, figs. 10).—In this continuation of the series of studies previously noted (E. S. R., 51, p. 267), the effect upon the growth of young rats of the irradiation of rations containing considerable vitamin A and but little antirachitic vitamin was tested by the usual feeding experiments starting with rats taken at from 21 to 23 days of age and continuing for from 4 to 8 weeks. The ration first used consisted of hog millet 84, casein 12, and salt mixture 4 parts, fed ad libitum. The irradiation consisted in exposure of the material for 10 minutes to the radiations of a quartz mercury vapor lamp in 50-gm. quantities spread

out in thin layers in porcelain dishes. Later a synthetic ration was used, consisting of alcohol-extracted and heated casein 18, salt mixture 4, agar 2, yeast 8, and dextrin 68 parts. In a later experiment this ration was fortified by adding 0.3 per cent of alfalfa. Further modifications consisted in irradiating the ration in Pyrex and quartz flasks and in brown glass bottles in an atmosphere of air and of carbon dioxide. The effect was also tested of heating the irradiated ration for 45 minutes at 96° C. and of letting it stand for 24 hours at room temperature.

The reported growth curves showed consistently that by irradiation the rations could be activated to make them growth-promoting and bone-calcifying to the same degree as when rats were irradiated directly (E. S. R., 50, p. 363). That promotion of growth was due to the antirachitic rather than to the anti-ophthalmic vitamin was shown by the frequent appearance of ophthalmia and respiratory infection while the animals were still growing. Activation to the same degree took place under all the conditions employed except when the ration was exposed in brown bottles.

The statement of Goldblatt and Soames that the livers of irradiated rats are growth-promoting (E. S. R., 50, p. 666) was confirmed, and the same was found to be true of lung and muscle tissue of irradiated rats. The activity of the liver of irradiated rats was not destroyed by drying at 96° for 24 hours and keeping it in the laboratory in a stoppered bottle for 2 months. Inactive muscle and liver, when exposed to irradiations after removal from the body, became activated in growth-promoting and bone-calcifying properties. It is also reported that irradiated olive oil and lard have growth-promoting properties.

**Alimentary equilibrium.—Maintenance of the pigeon on a ration totally deprived of vitamin B** [trans. title], L. RANDOIN and H. SIMONNET (*Compt. Rend. Acad. Sci. [Paris]*, 179 (1924), No. 15, pp. 700-703, fig. 1).—The authors' theory of the interdependence of vitamin B and carbohydrates has been tested further by a comparison of the weight curves of pigeons fed the synthetic ration previously described (E. S. R., 51, p. 70) with and without vitamin B and a synthetic diet containing no carbohydrates with and without vitamin B.

According to the data presented, maintenance of weight was secured on all the rations except the supposedly complete ration without vitamin B, which resulted in rapid loss in weight followed by death.

**The antiscorbutic value of fresh and canned English tomatoes**, E. M. DELF (*Biochem. Jour.*, 18 (1924), No. 3-4, pp. 674-678).—With the technique employed in previous studies (E. S. R., 47, p. 568), English tomatoes, fresh and preserved in various ways, were tested for their content of vitamin C, with the following results:

The minimal protective dose for young guinea pigs of the raw fresh juice was between 1.5 and 2.5 cc., an amount somewhat greater than that required for fresh oranges and lemons. It is noted that in similar tests of locally produced South African tomatoes even larger amounts, 4 cc. daily, were necessary.

Commercially canned tomatoes prepared by plunging the fruit in boiling water for 2 minutes, peeling, and processing the peeled fruit without adding water in a water bath gradually heated to 190° F. and kept at that temperature for 45 minutes, were tested after from 4 to 9 months' storage. From 5 to 10 cc. was required for protection.

Of tomatoes canned in the laboratory by plunging into boiling water for 2 minutes, peeling, heating gently for 10 minutes, and then processing in cans at 100° C. for 5 minutes, from 7.5 to 10 cc. were required when fed immediately after canning, while after storage for nearly 4 years 10 cc. was insufficient.

Of canned tomato purée from 5 to 10 cc., equivalent to 15 cc. of the fresh juice, was required.

It is concluded that on canning tomatoes lose nearly three-fourths of their original value as a source of vitamin C, and that this loss is increased on storage.

**The nutritive properties of milk.—III, The effectiveness of the X substance in preventing sterility in rats on milk rations high in fat, H. A. MATTILL, J. S. CARMAN, and M. M. CLAYTON (*Jour. Biol. Chem.*, 61 (1924), No. 3, pp. 729-740, figs. 2).**—Continuing the investigation previously noted (*E. S. R.*, 49, p. 663), the authors first attempted to determine whether the failure of reproduction in rats on rations whose protein and vitamin content was supplied entirely by whole milk powder to the extent of 50 per cent of the ration was due to a lack of nucleoproteins. The addition of various nucleoprotein supplements did not lead to reproduction, as was noted in a preliminary report (*E. S. R.*, 51, p. 266). Examination of the sexual organs of both males and females showed in the former progressive degeneration of the testes from about 100 days on, which could not be attributed to lack of vitamin B. In the females, ovulation was normal and the failure to reproduce was apparently due to unsuccessful implantation of the uterus.

When the rations were supplemented with from 5 to 10 per cent of wheat embryo, reproduction occurred but the mortality of the young was high. With 5 per cent wheat embryo, third generation animals were obtained. Wheat embryo extracted with ether no longer prevented reproductive failures, thus confirming the conclusion of Evans and Bishop that the substance required for reproduction belongs to the fat-soluble group (*E. S. R.*, 52, p. 262). Further proof that the substance is identical with the vitamin X of Evans and Bishop was the reported success with lettuce leaves as a supplement to the milk diet. In the case of males, fertility was manifest only if the supplement was fed before about the one-hundred-and-fiftieth day of life. The damage wrought by the deficiency could not be overcome beyond that time. Females, however, were quickly restored to fertility after the supplemental feeding.

On a milk diet low in fat marked reproductive failures did not appear, a result confirming the observation of Anderegg (*E. S. R.*, 51, p. 860). "This fact is considered not as evidence against the existence of X, as some have held, but as an indication that the amount of X required for normal reproductive functions depends upon the nature of the diet. Until more information on this relationship and on the natural distribution of X is available, generalizations are unsafe."

**The experimental feeding of dried breast milk, L. W. SMITH (*Jour. Biol. Chem.*, 61 (1924), No. 3, pp. 625-631, figs. 4).**—A comparative study is reported of the antiscorbutic value of fresh breast milk and breast milk dried by a modification of the Just-Hatmaker roller process and fed freshly dried and after storage for two years. For further comparison, fresh cow's milk, a commercially dried milk (Dryco), and orange juice were also tested. The breast milk was fed in amounts of 60 and 120 cc. or their equivalents, the cow's milk in the amount of 100 cc. or its equivalent, and orange juice 10 cc.

With the smaller amount of the breast milk subnormal growth was obtained, which was less with the dried than with the fresh, and still less with the dried product which had been kept two years. There was, however, no evidence of scurvy in any of the guinea pigs at the end of five weeks. With the larger amount of breast milk normal growth was obtained in the case of the fresh, and slightly subnormal in the case of the dried product. Normal growth

was obtained with the cow's milk, both fresh and dried, and with the orange juice.

It is concluded that "breast milk dried by the method described retains about 80 per cent of its antiscorbutic value when first prepared and about 40 per cent of its original antiscorbutic content after 'aging' for a period of as long as two years."

**The muscular efficiency of patients with diabetes mellitus, R. FITZ and W. P. MURPHY** (*Arch. Int. Med.*, 34 (1924), No. 3, pp. 402-415, figs. 4).—Using groups of normal persons as controls, the authors have investigated the muscular efficiency of a number of diabetic patients before treatment had been followed for any length of time, and in a few cases have continued the tests during the period of insulin and dietetic treatment.

The comparison of the normal with the untreated diabetic patients showed that the majority of the latter were considerably weaker than the former, but without specific weakness of any of the special muscle groups tested. The men subjects appeared to be weaker than normal in proportion to their diminished weight and the women to have normal strength in proportion to their body weight. As was shown in a previous paper (E. S. R., 51, p. 366), by correct dietary and insulin treatment the physical strength of diabetic patients can be made to approach normal. The most important single factor in the diet is considered to be the total calories utilized. In the experience of the authors, a considerable time is required to recover strength lost during fasting or severe undernutrition, and for this reason it is considered best to de-sugarize with insulin rather than with the use of low calorie diets. Charts are given showing the relation between the calories of the diet and the strength of a diabetic patient and the relation between strength and weight in another well-treated diabetic patient.

"The best treatment for a diabetic patient should combine diet and physical exercise, so that as the patient gains weight he gains a more than proportional amount of strength and an increasing strength-weight ratio. Diabetic patients should not be fattened rapidly with insulin and high calorie diets. Such patients do not become as physically efficient as patients who gain weight more gradually on a lower diet and less insulin, and who remain thin but relatively strong, with high strength-weight ratios."

**The treatment of diabetes with insulin, W. D. SANSUM, N. R. BLATHERWICK, F. H. SMITH, M. L. LONG, L. C. MAXWELL, E. HILL, R. MCCARTY, and J. H. CRYST** (*Jour. Metabolic Research*, 3 (1923), No. 5-6, pp. 641-676).—This report of the methods followed and the results obtained in the first 100 cases of diabetes treated with insulin at the Santa Barbara Cottage Hospital, Santa Barbara, Calif., includes routine diets for use in severe acidosis and to furnish increasing calories from 1,000 to 3,000, tables of the approximate food values of 100-calorie portions of vegetables containing from 3 to 20 per cent carbohydrate and of various other articles of diet, and several recipes for diabetic diets. It is noted that in nearly every case in which the insulin treatment has been continued for a considerable length of time, growth in tolerance has resulted which is greater than in patients under dietetic management alone.

## ANIMAL PRODUCTION

**On the formulation of methods of experimentation in animal production, E. B. FORBES, H. S. GRINDLEY, ET AL.** (*Bul. Natl. Research Council*, 6 (1923), No. 33, pp. 54).—This is a report of the subcommittee on animal nutrition, discussing in detail the methods employed in conducting nutrition

and feeding experiments with animals. The main subdivisions of the bulletin are entitled General Procedure in Animal Experimentation; The Determination of Digestion Coefficients and Nitrogen and Mineral Balances; The Determination of the Total Balance of Matter and Energy, by H. P. Armsby; Feeding Experiments; and References to Literature on Methods and Equipment.

**The feeding of productive farm animals**, M. KLIMMER (*Fütterungslehre der Landwirtschaftlichen Nutztiere*. Berlin: Paul Parey, 1924, 4. ed., rev. and enl., pp. X+279, figs. 164).—This is another edition of the book previously noted (E. S. R., 46, p. 70). Nearly all parts of the book have been enlarged, while the chapters on vitamins, sweet and sour feeds, and the treatment of straws have been rewritten.

**Nutritive value of wheat**, J. L. ST. JOHN (*Washington Col. Sta. Bul. 187* (1924), pp. 36, 37).—In continuing this study (E. S. R., 49, p. 265), the effect of variations in the sodium content of rations of purified food materials has been studied. The preliminary results indicate that variations in the sodium content have a decided effect upon the growth and condition of the animals. Rations low in sodium produced rapid growth for a short time, followed by a decline in weight and in many cases by death. When larger amounts of sodium were included in the purified ration, the animals continued to grow normally and were healthy in appearance.

**Stage of maturity of sunflowers for ensilage** (*Canada Expt. Farms, Brandon (Man.) Farm Rpt. Supt. 1923*, pp. 39-41).—The desirability and palatability of sunflowers cut at six different stages of growth from the time of forming the heads until 50 per cent of the plants were ripe were compared.

The plants were all allowed to wilt 24 hours before ensiling. All the different cuttings were found to keep perfectly in the silos except for a small wastage on the top of each, but the sunflowers when 60 to 65 per cent in bloom made the most palatable silage, though the palatability of the silage from sunflowers cut when 35 to 37 or 100 per cent in bloom approached it very closely. The silage was least palatable from the most immature sunflowers.

Analyses of the silage made from the sunflowers at the different stages of maturity indicated that the moisture decreased with maturity, while the protein, fat, carbohydrates, and fiber generally increased, the last-named constituent showing a marked increase in the most mature stage.

**Trench silo** (*Canada Expt. Farms, Brandon (Man.) Farm Rpt. Supt. 1923*, pp. 11, 12, fig. 1).—A very satisfactory report is given of a test of a trench silo. In a trench 30 ft. long, 12 ft. wide, and 8 ft. deep, 45 tons of corn silage were made. Some difficulty from the earthen sides falling in the spring, when the frost came out of the ground, was experienced, however.

**Inspection of commercial feedstuffs**, P. H. SMITH, F. J. KOKOSKI, ET AL. (*Massachusetts Sta. Control Ser. Bul. 28* (1924), pp. 35).—This is a report of chemical and microscopical analyses of feeding stuffs inspected in the State during the year ended September 1, 1924 (E. S. R., 50, p. 774).

**Feeding stuffs report, 1923**, J. W. KELLOGG (*Penn. Dept. Agr. Bul. 391* (1924), pp. 267).—The guaranteed and found protein, fat, and fiber analyses and the contents as identified microscopically are given for the samples of feeding stuffs officially collected in 1923. The previous report was noted (E. S. R., 51, p. 274).

**Studies of the thyroid apparatus.—XI, The effect of thyro-parathyroidectomy on reproduction in the albino rat**, F. S. HAMMETT (*Jour. Metabolic Research*, 2 (1922), No. 4, pp. 417-427).—In continuing this series (E. S. R., 48, p. 870), the effect of thyro-parathyroidectomy at 45 and 56 days of age on the reproduction of male and female rats has been investigated. The young

produced were raised to 150 days of age. When no litters occurred from matings 200 days of age, the animals were killed.

Though conception occurred when completely or partially thyroidectomized males and females were mated, and as judged by the development of the secondary sex characters the internal secretions of the gonads were normal, there was an unusually large amount of sterility, late breeding, small litter size, and high mortality of the young at birth, during suckling, and after weaning. These results are concluded to be due to a general lowering of the anabolic level of the organism rather than to any direct effect of the secretions of the gonads of either sex.

**Studies of the thyroid apparatus, XIII-XV, F. S. HAMMETT** (*Amer. Jour. Anat.*, 32 (1923), No. 1, pp. 37-94).—Three papers are presented in continuation of this series of studies, noted above.

**XIII. *The effects of thyro-parathyroidectomy and parathyroidectomy at 100 days of age on the growth of the reproductive system of male and female albino rats*** (pp. 37-51).—In this paper the effect of the removal of the parathyroid or parathyroid and thyroid glands at 100 days of age on the subsequent growth of the reproductive system to 150 days of age was measured by comparing the ovary and uterus weights of females and the testicle and epididymis weights of control rats at the time of the operation with the weights of these organs in the operated animals at 150 days of age.

The effect of the removal of the thyroid apparatus was evidently much greater in females than in males. The ovaries and uterus in operated animals not only stopped growing but actually retrogressed, retrogression being greater in the gonad. In the males the growth of the testicle and epididymis was slightly retarded with the removal of the entire thyroid apparatus, but seemed to be not at all affected by the removal of only the parathyroid glands. The greater sensitiveness of the female reproductive organs to the toxemia created by a lack of the parathyroid gland and a close relationship between the ovary and the thyroid in addition to the control of the thyroid over the metabolic processes is pointed out. On the other hand, the male reproductive system is markedly resistant to the toxemia following parathyroid removal, and the growth of the testicle and epididymis is less retarded than body growth as a whole by the removal of the thyroid apparatus.

**XIV. *The effects of thyro-parathyroidectomy and parathyroidectomy at 100 days of age on the growth of the glands of internal secretion of male and female albino rats*** (pp. 53-74).—The removal of the thyroid apparatus at 100 days of age resulted in accelerated growth in the hypophysis of the male and retarded growth in the same gland of the female, and an absolute cessation of growth and a high degree of retrogression in the adrenals, pancreas, and thymus of both sexes, but being somewhat more marked in the females. The thymus was evidently the most dependent on the thyroid secretion for normal development and activity. The author believes that the general action of parathyroidectomy is more attributable to a generalized toxemia than to any specific functional relationships.

**XV. *The growth of the heart, lungs, liver, kidneys, spleen, submaxillary glands, and eyeballs in male and female albino rats thyro-parathyroidectomized and parathyroidectomized when 100 days of age*** (pp. 75-94).—The removal of the thyroid tissue at the age of 100 days was found to cause an inhibition and retrogression in the growth of the heart, liver, kidneys, and spleen to 150 days of age. Growth was retarded in the lungs and submaxillary glands, but definite retrogression did not occur.

The removal of the parathyroid gland only resulted in retardation of growth in various glands, probably due to the resulting toxemia. Peculiar effects in

stimulating growth in the spleen and submaxillary gland were apparent. Neither parathyroidectomy nor thyroidectomy affected the growth of the eyeballs in males, and retardation was only slight in females.

**How animals use their time on pasture** [trans. title], M. ELLINGBØ (*Tidsskr. Norske Landbr.*, 31 (1924), No. 3, pp. 110-125, fig. 1).—The results of a study of the time utilized in foraging and resting by cattle, sheep, and horses on pasture during three separate days are reported. There were found to be considerable variations in the length of the pasturing and the rest periods, but the hours of grazing were definitely increased with cows during the summer, with smaller increases for the other animals. The cows were found to ruminate while resting, but those resting for the shortest periods were the best producers.

**The nutritive properties of pinto beans and pinto bean straw and their use as feed for cattle**, H. W. TITUS (*New Mexico Sta. Bul.* 143 (1924), pp. 73).—This bulletin reports the results of three digestion experiments with steers.

In the first experiment 5 steers weighing about 500 lbs. at the start were fed a ration averaging 4 lbs. of coarsely ground pinto bean culls and 8.25 lbs. of corn stover cut in inch lengths. The experiment lasted 111 days, during which 3 digestion trials of 10 days in duration were conducted with 4 of the steers. The preliminary periods to the actual digestion trials necessitated keeping the animals in metabolism stalls for 42 days. Notwithstanding this handicap, the steers made average gains of 0.89 lb. per day, consuming an average of 12.21 lbs. of feed per 100 lbs. of gain. The average coefficients of digestibility for the different nutrients of the pinto beans as calculated for the different animals in the three trials are given in the table below. Efforts to make the steers consume more than 4 lbs. of the pinto beans daily failed, the steers soon scouring and going off feed. The impossible digestibility of the ash is pointed out as resulting from the use of too small coefficients for the ash of corn stover. Nitrogen balances were computed during the trials, and it was found that 3 were negative while 9 were positive. No explanation for the negative balances was offered.

The second and third experiments were conducted similarly to the first. Five steers averaging about 500 lbs. in live weight were used in the second experiment, which lasted 98 days. The average daily rations per steer were 11 lbs. 13 oz. of pulled pinto bean straw and 3 lbs. 3 oz. of coarsely ground corn for the first two-thirds of the experiment. During the last third of the experiment the amount of pinto bean straw was reduced 1 oz. per steer daily. The average digestibility of the pinto bean straw as computed is tabulated below. During this experiment the steers, though in metabolism stalls for 46 days, gained an average of 1.21 lbs. per day and consumed 771 lbs. of feed per 100 lbs. of gain. It is pointed out that the pinto bean straw had few leaves and consisted of roots as well as stems and empty pods. There was much residue not eaten, consisting mainly of coarse stems and roots. The nitrogen balances showed that all steers were storing large quantities of nitrogen during each of the experiments.

The six steers used in the third experiment were about 25 lbs. heavier than those used in the first two. The ration fed consisted only of pinto bean straw cut with a mowing machine and therefore of much better quality than that fed in the previous experiments. The amount given the steers was 15 lbs. daily during the digestion trials and the preliminary feeding periods, with 16 lbs. daily during the rest of the experiment. The animals were confined to the metabolism stalls 45 of the 115 days of this experiment and gained an average of 0.89 lb. per day, consuming 1,552 lbs. of feed per 100 lbs. of gain.

The author points out the similarity between the composition of the cut pinto bean straw and alfalfa hay, but from the average digestibility of the former, as appears in the table below, it may be seen that it is not as well utilized by the animal as alfalfa hay. The nitrogen balances of the steers receiving the pinto bean straw showed that nitrogen storage was greater during the first part of the experiment. The analysis of the feeds used and the data employed in calculating the digestibility of the feeds are tabulated in detail in the bulletin. Coefficients of digestibility were determined by the usual method and by the method of least squares. The coefficients determined by the former method follow:

*Average digestibility of pinto beans and pinto bean straw*

Feed	Coefficient of digestibility						
	Dry matter	Organic matter	Total nitrogen and crude protein	Crude fiber	Ether extract	Nitrogen free extract	Ash
	<i>Per cent</i>	<i>Per cent</i>	<i>Per cent</i>	<i>Per cent</i>	<i>Per cent</i>	<i>Per cent</i>	<i>Per cent</i>
Pinto beans (culls) .....	68.37	63.31	53.60	Neg.	40.96	84.02	145.76
Pulled pinto bean straw .....	50.07	53.43	35.61	44.48	22.69	63.76	25.77
Cut pinto bean straw .....	55.08	60.95	67.41	51.45	29.79	66.94	19.07

**Prickly pear as a fodder for cattle** (*Mysore Dept. Agr. Circ. 40 (1924)*, pp. 15, figs. 8).—This consists of directions for the use of prickly pear as a cattle feed, dealing mainly with the methods of removing the thorns either by pincers or by burning.

**Steer feeding [at the Caldwell Substation]** (*Idaho Sta. Bul. 135 (1925)*, pp. 47, 48).—Five lots of 10 2-year-old steers were used for comparing various rations of alfalfa in a 150-day test as follows: Lot 1, 20.7 lbs. of cut alfalfa hay and 9.7 lbs. of ground barley; lot 2, 23.8 lbs. of alfalfa hay and 9.7 lbs. of ground barley; lot 3, 24.3 lbs. of alfalfa hay and 9.7 lbs. of ground corn; lot 4, 23.4 lbs. of alfalfa hay and 22.5 lbs. of corn silage, and lot 5, 19.8 lbs. of alfalfa hay, 14.3 lbs. of corn silage, and 9.2 lbs. of ground barley.

The average daily gains made by the different lots were, respectively, 1.90, 1.79, 1.85, 1.46, and 2.11 lbs. The calculated costs of the rations and profits per steer are given, as well as the average feed consumption per 100 lbs. of gain by each lot.

**Steer feeding experiment, 1922-23** (*Canada Expt. Farms, Brandon (Man.) Farm Rpt. Supt. 1923*, pp. 8-10).—The rates and economy of gains made by 18- and 30-month-old steers were compared in a test lasting 163 days. The feeds used consisted of corn silage, oat straw, and a grain mixture of equal parts of oat chop and ground re-cleaned wheat screenings. During the latter part of the test the grain mixture was modified to consist of one-third barley chop, and mixed hay replaced part of the silage.

The yearlings made average daily gains of 1.24 lbs., as compared with 1.4 lbs. by the 2-year-olds. They also consumed only about two-thirds as much corn silage as the 2-year-olds, but the consumption of other feeds was within 10 per cent of the same. The calculated feed costs were for yearlings \$292.25, and for the 2-year-olds \$369.34. The feed cost of grain was greater for the older steers, but their better finish and greater gains resulted in a much larger profit per animal.

**Steer-feeding experiment** (*Canada Expt. Farms, Rosthern (Sask.) Sta. Rpt. Supt. 1923, pp. 6, 7*).—Four lots of steers were selected for testing the value of succulent feeds as additions to a ration of oat straw and grain consisting of ground oats at the beginning of the experiment with a gradual change to ground barley toward the end of the test. Lot 1 was composed of 18 2-year-old steers averaging 1,098 lbs. in weight, while the steers in the other lots averaged about 780 lbs. Lots 1 and 2 received sunflower silage, lot 3 received turnips from November 25 to March 15, and sunflower silage to the end of the experiment, and lot 4 received no succulent feeds.

Steers receiving silage throughout the 165 days of the experiment were better finished than those receiving no succulents. Turnip feeding did not produce as good a finish as silage, but the use of silage during the latter part of the feeding period for this lot finished them practically as well as lots 1 and 2. The finish of lot 4 receiving no succulents was decidedly inferior, though the average daily gains of all lots were very similar, varying from 1.87 lbs. for lot 4 to 2.06 lbs. for lot 2.

**Herd management [at the Washington Station]**, H. HACKEDORN and J. SOTOLA (*Washington Col. Sta. Bul. 187 (1924), p. 32*).—Records of the beef breeding herd have shown that cows calving in January and February can be wintered on from 2 to 2.5 tons of silage, 0.75 ton of alfalfa hay, and grain according to the condition of the animal. It is deemed advisable to give grain to cows suckling calves during the winter.

**The effect of exercise and feed on the vitality of sperm cells and breeding ability of bulls**, E. V. ELLINGTON (*Washington Col. Sta. Bul. 187 (1924), pp. 44, 45*).—This study (*E. S. R., 49, p. 275*) has been continued by making H-ion determinations of the semen in addition to the microscopic examinations. No relation was found between the H-ion concentration of the semen and the length of life of the sperms. The H-ion concentration of semen was universally lower than the H-ion concentration of the vaginal secretions of cows, but the pH of both showed little variability.

**The Southdown sheep**, edited by E. WALFORD-LLOYD (*Chichester, Eng.: Advertising Com. Southdown Sheep Soc., 1924, pp. 95, pls. 15, figs. 3*).—This consists of a series of popular articles on the history, characteristics, and management of Southdowns, with special articles on the management and success of the breed in various sections of the world.

**Sheep raising in Minnesota**, P. A. ANDERSON (*Minn. Univ. Agr. Ext. Spec. Bul. 87 (1924), pp. 12, figs. 4*).—Popular directions for raising sheep.

**Observations on range sheep management in New Mexico**, H. S. MOLES, J. G. KOGLER, and P. E. NEALE (*N. Mex. Agr. Col. Ext. Circ. 80 (1924), pp. 27, figs. 13*).—This is a popular description of the more accepted practices involved in the range management of sheep under New Mexico conditions.

**Relation of sheep to climate**, E. L. JOHNSON (*Jour. Agr. Research [U. S.], 29 (1924), No. 10, pp. 491-500, figs. 18*).—The author discusses the variations in the climate of various sections of the world which have been considered well adapted to sheep production. He finds that the densely populated sheep areas have mean temperatures ranging from 28 to 77° F., average monthly rainfall of from 0.3 to 4.5 in., and a relative humidity of from 55 to 70 per cent at the higher temperatures and from 65 to 91 per cent at the lower temperatures. The importance of having favorable conditions during the season of rutting, pregnancy, lambing, and the growth of the lambs is pointed out.

**Lambs and wool for market**, B. E. CARMICHAEL (*Md. Univ. [Agr.] Ext. Bul. 36 (1924), pp. 35, figs. 17*).—This is a popular discussion of lamb and wool production, with special reference to Maryland conditions.

**Lamb feeding [experiments at the Caldwell Substation]** (*Idaho Sta. Bul.* 135 (1925), pp. 48, 49).—In this experiment 500 lambs were fed in 7 lots for 100 days. The lambs averaged 60 lbs. at the beginning of the test, and made average daily gains and consumed amounts of feed per 100 lbs. of gain as follows: Lot 1, 0.30 lb. requiring 1,163 lbs. of alfalfa hay, 246 lbs. of barley, and 581 lbs. of corn silage; lot 2, 0.32 lb., requiring 1,221 lbs. of alfalfa hay, 237 lbs. of barley, and 314 lbs. of corn silage; lot 3, 0.30 lb., requiring 1,298 lbs. of alfalfa hay and 243 lbs. of shelled corn; lot 4, 0.29 lb., requiring 1,497 lbs. of alfalfa hay and 266 lbs. of wheat; lot 5, 0.29 lb., requiring 1,225 lbs. of alfalfa hay and 258 lbs. of barley; lot 6, 0.29 lb., requiring 1,041 lbs. of cut alfalfa hay and 256 lbs. of barley; and lot 7, 0.29 lb., requiring 1,318 lbs. of alfalfa hay and 261 lbs. of barley per 100 lbs. gain.

**Fat lamb raising** (*Queensland Agr. Jour.*, 22 (1924), No. 3, pp. 160, 161).—A brief summary of seven years' lamb raising trials conducted at the Cowra, Wagga, and Bathurst Experiment Farms from 1912 to 1919 is given. The results of individual experiments have been previously noted (*E. S. R.*, 50, p. 271).

The crossbred Border Leicester × Merino ewes showed to the best advantage as dams, while Dorset Horn rams proved to be the best sires. In the 1922-23 trials at the Bathurst and Cowra Farms excellent returns were realized from Lincoln × Merino ewes bred to Dorset and Ryeland rams. This was also true of the 1922 trials at the Wagga Farm, in which Dorset Horn and Corriedale rams were crossed with Border Leicester × Merino ewes.

**Experiments with crossbred Charmoise × Limousin lambs** [trans. title], C. VOITELLIER (*Rev. Zootech. [Paris]*, 2 (1923), No. 9, pp. 159-174, figs. 9).—Charmoise rams were crossed with Limousin ewes at the Vaulx-de-Cernay Experiment Station for Zootechny. The lambs produced were observed as to their rate of growth, the effect of castration at 15 days of age on the rate of growth, and the carcass yields when slaughtered at 6 months of age.

The general characteristics of the crossbred lambs compared equally with those sired in other experiments by Southdown rams. Castration caused a retardation in the growth, which was not regained at 6 months of age. The dressing percentages of both wether and ram lambs were similar, and thus there was no increase in the net weight as a result of castration.

**Recent progress in the wool industries**, A. F. BARKER (*Jour. Roy. Soc. Arts*, 72 (1924), No. 3755, pp. 861-869, figs. 5).—A popular lecture on wool production in England.

**The Australasian wool trade: Annual review and statistics, season 1923-1924**, DALGETY & Co. LTD. (*Dalgety's Ann. Wool Rev. Australasia*, 26 (1924), pp. 139).—This deals with conditions in the wool and mutton markets of Australia, New Zealand, and South Africa during the season 1923-24, as in a previous report (*E. S. R.*, 42, p. 770).

**[Swine feeding experiments at the Delaware Station]**, A. E. TOMHAVE (*Delaware Sta. Bul.* 139 (1925), pp. 12, 13).—The results of two experiments are reported.

**Alfalfa hay as a winter feed for brood sows**.—Sows wintered on corn and alfalfa hay with a small amount of tankage toward the end of gestation made somewhat greater gains than sows wintered on corn and tankage, and the former ration was much cheaper. The pigs were equally strong and uniform on both rations.

**Supplements to corn for growing fattening swine**.—In continuing the comparison of tankage and fish meal as supplements to corn for fattening swine

(E. S. R., 51, p. 173), fish meal again proved superior in amount and economy of gains produced. The average daily gains during the 58-day test were 1.65 lbs. per pig for the lot receiving fish meal and 1.05 lbs. for the lot receiving tankage.

**Studies in swine nutrition** (*Idaho Sta. Bul. 135 (1925), pp. 20, 21*).—In a study of the value of Canadian field peas for pork production, 4 lots of 8 120-lb. pigs were fed for 76 days on the following rations: Lot 1 cracked peas, lot 2 cracked peas and rolled barley (3:7), lot 3 rolled barley and tankage (15:1), and lot 4 cracked corn and tankage (9:1). The average daily gain of all lots was approximately 1.33 lbs. The amounts of feed required per 100 lbs. of gain were, respectively, as follows in the different lots: 378.4, 410.9, 438.3, and 409.5 lbs.

In a second experiment various forages were compared for fattening 44 spring pigs as follows: Lot 1 peas, lot 2 peas and 1 per cent rolled barley, lot 3 alfalfa and 4 per cent of a mixture of rolled barley and tankage (15:1), and lot 4 alfalfa and 4 per cent of a mixture of corn and tankage (12:1). The average daily gains of the four lots during this experiment were 0.95, 1.07, 1.17, and 1.3 lbs., respectively. Following the forage period these pigs were fed for 30 days in dry lot on the following rations: Lot 1 cracked peas, lot 2 cracked peas and rolled barley (7:2), lot 3 rolled barley and tankage (14:1), and lot 4 corn and tankage (10:1). The average daily gains and the feed requirements per 100 lbs. of gain were, respectively, as follows: Lot 1 1.49 and 362.2 lbs., lot 2 1.64 and 393.4 lbs., lot 3 2.02 and 411.3 lbs., and lot 4 2.01 and 414.7 lbs. The melting points and iodine numbers of the back and leaf fat of the hogs in both of the above experiments showed no particular differences according to the rations fed.

In a study of the effect of Canadian field peas on reproduction, 3 lots of 4 gilts averaging about 185 lbs. in weight were fed during a 150-day period, including gestation, on the following rations: Lot 1 a grain mixture of 1.5 parts of peas, 1 part of barley, 1 of oats, 1 of corn, and 1 of wheat, with all the alfalfa meal they would consume; lot 2 a grain mixture of 1 part of peas and 2 parts of barley, with alfalfa meal; and lot 3 peas alone. The average daily gains were slightly less in lot 3, and there was a tendency toward an occasional lack of appetite. The weights of the litters farrowed by this lot were also somewhat less. The results with lots 1 and 2 were practically equal.

**Swine investigations [at the Washington Station]**, R. T. SMITH (*Washington Col. Sta. Bul. 187 (1924), pp. 33, 34*).—Brief results of the following investigations are noted:

*Alfalfa or sweet clover followed by peas.*—The effect of limited and full rations with alfalfa pasture on the subsequent gains of hogs receiving pea forage has been studied. In two years' work pigs full-fed on alfalfa pasture weighed 15.3 lbs. more at the end of 46 days than limited-fed pigs, but the former groups required 63.9 lbs. more barley, 32 lbs. more millrun, and 15.4 lbs. more tankage per pig. The limited-fed pigs made 0.2 lb. greater average daily gains on peas, and both lots reached market weight (173 lbs.) at the same time.

In one trial sweet clover and alfalfa proved to be of equal value, though the sweet clover stayed green longer during the dry part of the late summer.

*The value of yeast for pigs.*—Two lots of approximately 75-lb. pigs were fed on a ration of rolled barley and millrun in the proportion of 100 to 25 parts, with 10 parts of tankage. One group received in addition approximately 1 per cent of yeast. At the end of the 62-day feeding period the yeast-fed pigs had a somewhat better coat of hair, but their average daily gains were only

1.09 lbs. as compared with 1.13 lbs. by the other lot. More feed was also required per unit of gain by the yeast-fed pigs.

*Winter rations for sows.*—In this test the tankage in a ration of barley and alfalfa hay was satisfactorily replaced by millrun. A tankage-fed lot was somewhat sleeker in appearance and made 0.06 lb. greater average daily gains during the experiment.

*Cost of keeping brood sows.*—One year's records show that a sow consumes as much concentrates during an average nursing period of 76.2 days as during the rest of the year. In nursing pigs 75 per cent of the losses occurred during the first week after farrowing.

*Pig feeding experiments (Canada Expt. Farms, Brandon (Man.) Farm Rpt. Supt. 1923, pp. 12-16, fig. 1).*—The results of several pig feeding experiments are summarized.

*Oats v. rape pasture, buttermilk v. tankage on pasture.*—Four lots of pigs averaging from 55 to 60 lbs. were used for comparing oats and rape as forage crops and buttermilk and tankage as supplements to a grain mixture of shorts, ground and re-cleaned wheat screenings, and feed flour 3:3:1 in addition to the forage crops. There were 11 pigs in each of three lots and 9 in the other lot. The forage crops were planted in 0.5 acre plats. The grain was fed as a slop mixed with water when tankage was fed or with buttermilk for comparison. The average daily gains were for the lot receiving oats and buttermilk 1.11 lbs., rape and buttermilk 1.21, rape and tankage 0.95, and oats and tankage 0.92 lb. The different methods of feeding had practically no effect on the type of the pigs.

*Buttermilk v. tankage without pasture.*—Four lots of 8 pigs each, averaging about 55 lbs. in weight, were used for comparing supplements of buttermilk and tankage to a ration consisting of 3 parts of shorts, 3 parts of ground re-cleaned wheat screenings, and 1 part of feed flour fed in dry lot and in small indoor pens. Buttermilk produced better gains in both dry lot and inside feeding, the average per day being, respectively, 1.15 and 1.13 lbs. as compared with 0.79 and 0.87 lb. for lots under similar conditions but receiving tankage in amounts equal to 10 per cent of the grain mixture. The feed consumption was practically the same as by the pigs in the above experiment and, therefore, pasture, dry lot, and indoor feeding are compared. Greater profits were calculated from the feeding with pasture.

*Oats v. barley.*—Two lots of pigs fed in dry lot and an equal number fed in pens were used for comparing rations consisting mainly of oats and barley. The rations fed to one indoor lot and one lot fed in dry lot were composed of 3 parts of barley chop, 1 part of feed flour, and 1 part of shorts, while the other lot had the barley chop replaced by oat chop. The gains were somewhat greater on the barley ration, averaging 1.27 and 1.15 lbs. per day, as compared with 0.89 and 0.97 lb. for the lots receiving oats.

[*Swine feeding experiments*] (*Canada Expt. Farms, Rosthern (Sask.) Sta. Rpt. Supt. 1923, pp. 11-16*).—The results of several hog feeding experiments are noted.

*Light and heavy feeding on pasture and dry lot.*—Six lots of 7 pigs each, averaging about 45 lbs. in weight, were selected for comparing heavy and light feeding on pasture and in dry lot. The heavy feeding consisted of 5 lbs. of grain per 100 lbs. of live weight at the start of the experiment, with a gradual reduction to 4 lbs. of grain per 100 lbs. of live weight near the end of the fattening period. Two lots were fattened on oat pasture, rape pasture, and in dry lot, one receiving a heavy and the other a light ration. With pasture the light ration was one-half the heavy ration and in dry lot two-thirds

the heavy ration. The amounts of pasture allowed were 0.75 acre for the heavy fed lots and 1.5 acres for the light fed lots.

The pigs in the four lots on pasture made very uniform gains, varying from 0.87 to 0.94 lb. per day, but there was less than 3.3 lbs. of grain eaten per pound of gain by the light fed lots, as compared with more than 4 lbs. of grain per pound of gain by the heavy fed pastured lots. The average daily gains of the heavy and light fed pigs in dry lot were 0.85 and 0.75 lb., the grain requirements per pound of gain being 4.25 and 3.89 lbs. The saving in the feed cost of fattening by the use of pasture is pointed out.

*Pasture and heavy and light feeding with purebred and crossbred hogs.*—The individual weights, grades, and sales returns are given of the pigs used in the above experiment, consisting of purebred Tamworths, Berkshires, and crossbreds between the two breeds in each lot. Better results from pasture were noted in the grades of the pigs throughout, and the largest number of selected pigs consisted of crossbreds in the oat pastured groups. The lots receiving pasture also matured more quickly.

*Pasture crops and breed comparison.*—Six boars each of the Berkshire and Tamworth breeds, averaging from about 100 to 150 lbs. in weight, were pastured on rape and oats, with the addition of a ration of oats, barley, and shorts fed as a slop. The most rapid gains were made on the oat pasture, but the gains made on rape pasture required slightly less feed.

*Self-feeder v. hand-feeding.*—Two lots of 11 pigs each, averaging about 50 lbs. in weight, were used for comparing self-feeding and hand-feeding in a 93-day test. The ration consisted of shorts, oats, and barley chop, fed as a slop to one lot and in a self-feeder to the other group. The hogs on the self-feeder made more rapid gains and consumed greater amounts of feed, but the estimated cost per pound of gain was 1.6 cts. less than for the hand-fed hogs. The hand-fed pigs more nearly approached the desirable bacon type at the conclusion of the experiment.

**Concerning the question of raising barrows** [trans. title], N. A. KRESTOV (*Izv. Opytn. Dona i Sev. Kavkaza (Jour. Agr. Research Don and North Caucasus)*, No. 4 (1924), pp. 62-71, 191).—In the English abstract of this article it is stated that two experiments with weanling pigs were conducted, in which linseed-oil cake was found to be a satisfactory substitute for all or part of the milk in the rations consisting largely of barley.

**Selection, care, and management of the boar**, R. G. KNOX (*Ontario Dept. Agr. Bul. 307 (1924)*, pp. 13, figs. 10).—General directions for the care, management, selection, and feeding of boars are given, with tabulated results of two winters' feeding of boars of various ages. The ration employed in each case consisted of a mixture of equal parts of barley and oats, whey, and mangels. The boars made satisfactory gains and were in good breeding condition in all cases.

**The feeding of animals by the method of equivalent feeds.**—**The feeding of young horses after weaning** [trans. title], A. M. LEROY (*Rev. Zootech. [Paris]*, 2 (1923), No. 9, pp. 207-217, figs. 2).—The use of the graphical method of calculating rations (E. S. R., 50, p. 471) is discussed, with special reference to the rations of colts from weaning to maturity.

**Stallion enrollment.**—XIII, Report of stallion enrollment work for the year 1924 with lists of stallions and jacks enrolled (*Indiana Sta. Circ. 120 (1924)*, pp. 48).—As in previous reports (E. S. R., 51, p. 376), this consists largely of a directory of enrollments and renewals of stallions and jacks standing for service in Indiana during the calendar year 1924.

**[Experiments with poultry at the Idaho Station]** (*Idaho Sta. Bul. 135 (1925)*, pp. 39-42).—The results of experiments with poultry are briefly noted.

*Poultry breeding investigations* (pp. 39, 40).—By careful breeding the egg production of the poultry flock has been increased from birds in 1921 of which only 35 per cent laid over 200 eggs to fowls in 1924 of which 56 per cent had laid over 200 eggs and 9 per cent over 250. The eggs of 68 hens and 44 pullets laid in 1923–24 were classified according to weight, shell color, texture, and shape, and the results given. A statistical analysis of the egg production at different seasons of the year showed significant correlations between the winter and the annual egg production. Early maturing birds had larger egg records, but no relation was observed between the number and the size of the eggs, although the size of the eggs was related to the size of the birds.

[*Feeding experiments*] (pp. 40–42).—In the studies of various rations for laying hens, 14 lots of pullets were selected.

Three lots were used for a test of the value of adding yeast, orange juice, and cod liver oil to the basal ration. A fourth pen was used as a control, and it was found that a very heavy mortality occurred in this pen receiving only grain and mash. Dry yeast also proved of little value for egg production, health, or fertility. The cod liver oil pen proved superior, with orange juice second, thus indicating that the vitamins of cod liver oil and orange juice are valuable with rations low in animal protein when no green feed is furnished.

Four pens were used for testing the value of certain constituents of sour milk. The results so far indicate that milk curd contains most of the valuable nutrients. Milk casein gave better results than milk whey or protein-free sour milk, but lactic acid and milk salts had no effect on production or the condition of the birds.

In other trials 50 per cent protein meat scraps produced larger amounts of eggs more economically than 60 per cent of meat meal. A 40 per cent pea meal mash supplemented with 4 per cent mineral mixture did not prove as successful as a mash containing 20 per cent pea meal and 20 per cent meat meal or meat scrap. Sour milk in unlimited quantities proved the most valuable supplement to pea meal. Semisolid buttermilk, while not as valuable as sour milk, gave better results than meat scrap or meat meal as a supplement to pea meal.

**A study of the relative values of certain succulent feeds and alfalfa meal as sources of vitamin A for poultry**, D. E. DAVIS and J. R. BEACH (*California Sta. Bul.* 384 (1925), pp. 3–14, fig. 1).—This bulletin reports the results of a 102-day study of the ability of various green feeds and alfalfa meal to prevent the occurrence of the nutritional disease resembling roup in poultry (*E. S. R.*, 52, p. 77).

In conducting the test, 10 lots of 6 3-months-old pullets were selected and fed on a basal mash consisting of 25 per cent each of bran, shorts, and ground barley or corn meal, 10 per cent soy bean meal, and 15 per cent meat scrap, and a scratch feed of equal parts of wheat, re-cleaned barley, and white corn or later yellow corn. The average food consumption per bird was 22 gm. of mash and 44 gm. of scratch feed per day. The different lots received supplements of 1 gm. per day per bird of the following feeds: Field-grown green barley cut when from 6 to 10 in. high, red clover cut when from 2 to 4 in. high, the large leaves of Jersey kale, roots and tender stems of green alfalfa, blue grass lawn clippings, the entire plant of artificially sprouted barley grown indoors to a height of 3 or 4 in., common market varieties of carrots, mangels, and alfalfa meal of good color containing 17.2 per cent protein and 25.4 per cent fiber. The tenth group was reserved as the control and received no supplemental feed. As birds developed evidence of nutritional disease in a lot the amount of green feed was increased. The

maximum amounts of the different supplements which it seemed necessary to feed during the experiments were kale, green alfalfa, blue grass, and carrots 1 gm. each; green barley and red clover 2 gm. each; alfalfa meal 8 gm.; sprouted barley 16 gm.; and mangels 32 gm.

All 6 birds in the control lot and 5 of the 6 in the mangel lot died of nutritional disease during the test. The birds receiving the blue grass were all healthy, while 1 each receiving kale, green alfalfa, and carrots developed lesions between the eighty-fifth and ninetieth days, which persisted to the close of the experiment. Birds in the other lots developed characteristic lesions earlier in the test. The lot receiving red clover showed a tendency to eat their eggs, and at least 2 individuals were picked to death.

The authors point out that field-grown green crops and carrots were good sources of vitamin A. At least 20 per cent of the sprouted barley or 10 per cent of alfalfa meal in the ration was necessary to supply an adequate amount of vitamin A. Mangels were concluded to be practically valueless as a source of this material.

The fattening of immature cockerels, R. E. LOUCH (*Natl. Poultry Jour.*, 5 (1924), No. 230, p. 275).—The results are summarized of two experiments in fattening young cockerels conducted at the Cheshire School of Agriculture. The fattening period in both experiments was of 3 weeks' duration, using 21 birds in each case. The ration used in the first experiment consisted of equal parts of barley meal, corn meal, and thirds mixed with water and fed as a slop in troughs. The birds averaged about 1 lb. in weight at the beginning of the test.

The average gains per bird during the 3 weeks were 0.9 lb., approximately 4.25 lbs. of grain being consumed per pound of gain. A summary of the weekly gains made showed that the gains were greatest during the first 2 weeks, 9.5 and 7.5 lbs., respectively, for the 21 birds as compared with 2.75 lbs. during the third week.

In the second experiment the birds were slightly heavier, averaging about 1.5 lbs., and the ration fed in the first experiment was modified by replacing the barley with ground oats. The total gains made by this lot of 21 birds during the first, second, and third weeks were 6.75, 17.75, and —7.5 lbs. The fattening process in both experiments was done at a profit over feed cost.

Commercial poultry farming, T. W. TOOVEY (*London: Crosby Lockwood & Son, 1924, 3. ed., pp. VIII+148, pls. [16], figs. 2*).—This is a description of the operation of the King's Langley Poultry Farm, dealing with the hatching, rearing, housing, feeding, management, and diseases of chickens and laying hens, with a chapter on Indian Runner ducks.

British poultry and poultry keeping, S. H. LEWER (*London: Feathered World, 1924, pp. 108, pls. 8, figs. 135*).—Mainly a description of the breeds of fowls, ducks, geese, and turkeys, containing several colored plates.

The production of rabbits [trans. title], J. BAGUÉ (*Porto Rico Dept. Agr. and Labor Sta. Circ. 76 (1924). Spanish ed., pp. 18, figs. 6*).—General directions for breeding, feeding, management, and caring for rabbits.

## DAIRY FARMING—DAIRYING

[Dairy cattle experiments at the Idaho Station] (*Idaho Sta. Bul. 135 (1925), p. 27*).—Based on the birth records in the station herd, the average gestation period has been found to be 280 days, with the gestation of males averaging 2.4 days longer than females. The first gestation period is slightly shorter, and the calves are somewhat smaller. The average birth weight of 13 Holstein bull calves was 103.8 lbs. and of 41 heifer calves 93.3 lbs. In

Jerseys, 18 bull calves averaged 64.3 lbs. and 16 heifer calves 54.2 lbs. at birth. Holstein calves apparently weigh more in proportion to their dams' weights than Jerseys. The weights of cows indicated that Holsteins and Jerseys increase at approximately the same rate per month during pregnancy. Young animals, however, increase more rapidly than mature ones.

**A study of the transmitting qualities of Holstein-Friesian dams for milk and butter fat production**, T. A. BAKER (*Delaware Sta. Bul.* 139 (1925), p. 13).—A statistical study of 500 365-day records in volume 33 of the Holstein-Friesian Advanced Register Year Book has evidenced a correlation of  $0.28 \pm 0.087$  for the milk yields and  $0.41 \pm 0.024$  for the butterfat yields of dams and daughters.

**Dairying in Kansas**, J. C. MOHLER ET AL. (*Kans. State Bd. Agr. [Quart.] Rpt.*, 42 (1923), No. 167, pp. VI+460, pl. 1, figs. 228).—A popular account of dairying in Kansas, with special reference to the recommended practices in the feeding, breeding, and management and the control of diseases of dairy cattle.

**Swiss bovine breeds** (*Schweizer Rinderrassen. [Muri, near Bern]: Komm. Schweiz. Viehzuchtverbände, [1924], pp. 83, figs. 32*).—A popular account of the cattle breeds of Switzerland (Schwyz, Simmental, Fribourg, and Eringer cattle) written in English and German.

**The influence of pasteurization and diet of the cow on the antiscorbutic potency of milk**, T. M. OLSON and L. COPELAND (*Jour. Dairy Sci.*, 7 (1924), No. 4, pp. 370-380, figs. 5).—The antiscorbutic properties of the milk from cows on a winter ration with and without silage and before and after pasteurization were compared at the South Dakota Experiment Station.

Guinea pigs were used as the experimental animals, the basal ration consisting of rolled oats, autoclaved alfalfa hay, water, and salt, the milk to be tested being supplied in addition. Four guinea pigs receiving the basal ration only showed symptoms of scurvy early, and all died between the nineteenth and thirtieth days. Four other guinea pigs having a basal ration supplemented with 30 (two animals), 45, and 60 cc. daily of pasteurized milk died in from 54 to 97 days, the maximum life being of one of those receiving only 30 cc. daily. All of four other pigs, receiving like amounts of raw milk from the college herd which received corn silage in their ration, made good growth. Twenty cc. or less of this milk proved insufficient for normal growth, though only one of the four pigs on rations of from 15 to 20 cc. of this milk showed scurvy symptoms and died.

Eight other guinea pigs receiving supplements of raw milk from a herd not receiving silage did not show normal growth, and all receiving less than 30 cc. developed scurvy in 30 days. Three of the pigs receiving 30 cc. or more also died, the first death occurring at 108 days, while one pig was still alive and growing at the conclusion of the test after 25 weeks.

The authors conclude that pasteurization and the use of dry roughage only in the winter ration materially diminish the vitamin C content of the milk produced.

**Relation between the diet, the composition of the blood, and the secretion of milk of dairy cows**, C. A. CARY and E. B. MEIGS (*Jour. Agr. Research [U. S.]*, 29 (1924), No. 12, pp. 603-624, figs. 12).—The effect of changes in the diet on the composition of the blood and milk has been studied in 8 experiments at the Bureau of Dairying, U. S. D. A.

The procedure in the experiment consisted generally in feeding the cows a ration supplying nearly adequate amounts of protein and energy for maintenance and production, followed by a period in which either or both the protein

and energy were reduced approximately 50 and 33 per cent, respectively. The quality of the protein was also changed with 3 of the cows. A deficiency feeding period was usually followed by one in which adequate rations were again supplied. Determinations were made during all periods of the reducing sugars, lipoid phosphorus, amino acid, nitrogen, protein, and free tryptophane content of the blood and plasma and the nitrogen, lactose, and fat content and yield of milk.

The effect of the changes in the diet on the composition of the blood and the milk are tabulated in detail and shown graphically. The relation between the composition of the blood and milk secretion is completely discussed. The results generally indicated that reductions in the energy content of the ration were accompanied by a sharp reduction in the amino acid nitrogen of the blood plasma. The even greater reductions in the protein of the ration did not greatly affect the amino nitrogen of the plasma. Changes in the quality of the protein have some effect, however, under different circumstances, efficient protein mixtures being associated with a low amino nitrogen content. Alterations in the amount or quality of the proteins tended to modify markedly the amount of free tryptophane in the blood.

Based on the changes occurring in the composition of the blood and the milk and the milk yield following dietary changes, the authors conclude that the effects on milk secretion are mainly due to alterations in the quantity and quality of the amino acids of the blood plasma.

**A study of the relation between feed consumption and milk secretion,** C. W. TURNER (*Jour. Dairy Sci.*, 7 (1924), No. 6, pp. 535-546, figs. 2).—Based on records of feed consumption, milk production, live weight, age, and the breeding of about 50 Holstein-Friesian cows on test at the Illinois Testing Plant at Dixon, Ill., the author has shown that feed consumption, based on digestible nutrients consumed, increases to the fourth month of lactation, after which it decreases but at a slower rate than milk secretion. This makes an excess of nutrients which go toward increasing body weight.

The data are presented by monthly periods in several tables.

**Feed cost of milk production as affected by the percentage fat content of the milk,** W. L. GAINES (*Jour. Agr. Research [U. S.]*, 29 (1924), No. 12, pp. 593-601, figs. 2).—This is a theoretical discussion of the relation of the fat content of milk to the feed cost of milk production, with the presentation of formulas for calculating the nitrogen required for maintenance and the production of milk containing varying fat percentages, with the calculated constants for each formula for Jersey and Holstein cattle. A formula for adjusting the price of milk in proportion to the cost of production is also suggested. The work was conducted at the Illinois Experiment Station.

**The official test in the South and the preliminary milking,** E. BRETNALL (*Jour. Dairy Sci.*, 7 (1924), No. 4, pp. 393-402, figs. 3).—The relative changes in the butterfat test of the milk of cows occurring under normal conditions and after about one-third of the milk has been left in the udder from the preceding milking were determined in a series of experiments at the Mississippi Experiment Station. It was found that variations in the fat percentage were usually small, and might be in either direction after leaving the milk in the udder. The milk yield was, however, in such cases usually increased decidedly. No advantage in the 2-day test was found for leaving the milk in the udder, and in many cases the butterfat test was lowered. This practice could be determined by comparing the milk yield at the first milking with that of succeeding milkings.

**Make the dairy pay**, F. E. BALL (*Colorado Sta. Bul.* 295 (1924), pp. 60, figs. 36).—Directions for testing milk and cream by the Babcock method are given, with other data relating to milk and cream production and handling.

**Milking machines.—VIII, The sanitary efficiency of a simplified type of milking machine**, F. L. MICKLE (*New York State Sta. Bul.* 524 (1924), pp. 3-48, pls. 12, figs. 2).—In continuing this series of studies (E. S. R., 47, p. 480), the bacterial contamination of milk by the Surge milker (a new and simplified type of milking machine) has been investigated at four farms under ordinary conditions of milking.

The tests indicated that with ordinary care milk having reasonably low bacterial counts may be produced with this milker. The numbers of bacteria were found to compare favorably with the bacterial counts of milk drawn by other milking machines, including the Empire and B-L-K milkers which were in ordinary use on these farms.

Due to the varying influence of different factors on the bacterial content of the milk, machines cared for in the usual manner were used for drawing sterile water from an artificial udder, previously described (E. S. R., 41, p. 277), into sterile pails. The results with the Surge, Empire, Pine Tree, and B-L-K milkers were compared at five different farms in this way. The various methods of sterilizing the machines both in the actual milking itself and in the tests with the artificial udder included the use of brine, chloride of lime, Sterilac solution, and hot water. Satisfactory results were obtained with all the machines when properly cleaned, but the Surge milker apparently contaminated the milk slightly less than the other types.

**Enzymatic studies on lactic acid bacteria, I, II** [trans. title]. A. I. VIRTANEN (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 134 (1924), No. 4-6, pp. 300-319, figs. 2; 138 (1924), No. 3-6, pp. 136-143).—Based on the number of bacteria in dried samples of the sediment of centrifuged milk which had previously been inoculated with *Streptococcus lactis*, the author estimated the average weight of a dried bacterium at  $\frac{10}{\sqrt{10}}$  mg., while the live weight ranged from 5 to 10 times as great. The rate and amount of action of the bacteria and the production of zymophosphates was studied with living and nonliving cells at different grades of acidity and phosphate concentration. There was an enzymatic reduction of methylene blue in aqueous solutions by the living organisms but not after drying.

The breaking down of a solution of  $Mg_2P_2O_7$  by *Bacillus casei*  $\epsilon$  in a glucose solution, with the formation of a zymophosphate, was found to be very rapid, resulting in the freeing of over 30 per cent of the phosphate in certain cases within 9 hours. There was a greater amount of phosphate freed when the glucose and phosphate were mixed in the proportion of 1.25 radicals of  $PO_4$  to 1 molecule of glucose than in the proportion of 2.6:1. Heating the bacteria to boiling or washing the bacteria eight times with water destroyed its ability to break down the phosphate compound. The operation of a coenzyme in the fermentation was thus indicated.

**The mold associated with the ripening of blue veined cheese**, N. S. GOLDING (*Mycologia*, 17 (1925), No. 1, pp. 19-32, pl. 1).—In a study of the organisms responsible for the characteristics of Wensleydale cheese, it was found that a mold resembling *Penicillium roqueforti* predominated. The reverse side of a growth on potato agar was yellow for *P. roqueforti* but green for the Wensleydale mold. The latter mold had no white patches of hyphae as occurred with the former organism. *P. roqueforti* never produced acid in whey gelatin but digested casein four times as fast as the Wensleydale mold. The latter variety also grew less freely on synthetic media containing saccha-

rose, galactose, levulose, or dextrose, but more freely when containing casein or peptone.

**Factors affecting the yield of ice cream,** H. W. GREGORY and V. C. MANHART (*Indiana Sta. Bul.* 287 (1924), pp. 3-31).—The authors have made a study of the yield of ice cream through questionnaires sent to five members of each of 28 State and other ice cream manufacturing associations. The results are tabulated to show, in the opinion of the 57 manufacturers reporting, the effect of the different processes and ingredients of ice cream on the overrun.

The factors affecting overrun were divided into three groups by the authors, composition of mix, preparation and treatment of mix, and freezing conditions. In regard to composition, binders and fillers, except gelatin, were reported to have no effect on overrun. Milk solids-not-fat tend to increase the overrun, while milk fat, sugar, and gelatin are deterrents. In the preparation of the mix, it is the opinion that aging increases overrun while pasteurizing reduces it. The freezing conditions favorable to overrun were deemed to be a temperature of from 32 to 36° F. for the incoming mix, with not over 5° of difference in the temperature of the incoming and outgoing brine and a horizontal freezer half full rather than the more common vertical type. Other conditions were reported as influencing the overrun, but with a greater variability of opinion.

**Overrun of ice cream** (*Idaho Sta. Bul.* 135 (1925), p. 28).—It was found possible to make a good quality ice cream from slightly acid products after neutralizing, but the use of calcium hydroxide resulted in a loss of 16.9 per cent and sodium hydroxide of 8.85 in the overrun.

**Sandiness in ice cream,** P. S. LUCAS and G. SPITZER (*Indiana Sta. Bul.* 286 (1925), pp. 12).—This is a more complete report of the investigation of the cause and influence of various factors on sandiness in ice cream (*E. S. R.*, 49, p. 580).

In making this study 124 mixes were prepared so that the fat content of each was approximately 8 per cent and the sum of the sugar, gelatin, and flavor contents was 11 per cent. The total solids contents were calculated to be 27, 30, 33, and 36 per cent by varying the solids-not-fat content. The mixes were pasteurized, emulsified, aged, and frozen, after which the product was periodically examined for sandiness while being held at 0° temperature. Milk powder was used in the preparation of part of the mixes, while others were prepared with condensed milk. Total solids, fat, and lactose determinations were made of the ice cream and of the mixes.

It was found that most of those samples containing approximately 7 per cent or more of milk sugar developed sandiness, while none containing less than 7 per cent of milk sugar was sandy. Sandiness is apparently not affected by carbonization, pasteurization temperatures varying from 145 to 164° F., ice cream powders or improvers, or by the amount of overrun.

The work was supplemented by chemical studies of the rate of crystallization of lactose in mixtures of various sorts at a temperature of from 32 to 34°. The prevention of sandiness may be accomplished by the avoidance of excessive milk solids not fat, thorough solution of all ingredients, thorough pasteurization, constant temperature in the hardening room, and holding the frozen creams for a minimum time.

**The bacterial content of ice cream,** A. C. FAY and N. E. OLSON (*Jour. Dairy Sci.*, 7 (1924), No. 4, pp. 330-356).—The bacterial content of the mix was determined on 28 samples at different stages in the production of ice cream at the Kansas Experiment Station. The average bacterial counts determined were as follows: Before pasteurizing (calculated from bacterial content of

butter and mix determined separately) 17,261,926, after pasteurizing 219,953, after homogenizing 277,475, before aging 191,782, before freezing 192,362, after freezing 236,688, and after hardening for 48 hours 186,320 bacteria per gram. By using more care in the production, the bacterial count of the hardened product was reduced from 617,357 in the first 8 mixes to 35,432 bacteria per gram in the last 20.

By making bacterial counts, it is possible to detect the use of dirty utensils, improper pasteurization, or the use of low-grade materials, though proper pasteurization may tend to conceal the latter. In studying the types of organisms in the ice cream, pasteurization was found to kill practically 100 per cent of the acid and gas-forming bacteria and an average of 99.0 per cent of those producing acid without gas formation in lactose. It also caused a decrease of 86 per cent in the gelatin liquefiers.

## VETERINARY MEDICINE

**Pocket handbook of meat inspection**, G. LEIGHTON (*Edinburgh: William Hodge & Co., Ltd., 1924, pp. VIII+126*).—This is a small handbook which gives a concise explanation of the meat inspection regulations of Scotland for 1924.

**Animal parasites and parasitic diseases**, B. F. KAUPP (*Chicago: Alexander Eger, 1925, 4. ed., rev., pp. XVI+9-250, pls. 18, figs. 81*).—This is a revised edition of the work previously noted (*E. S. R., 32, p. 79*).

**Biennial report of the Live Stock Sanitary Commission of Texas for the years 1923-24** (*Tex. Livestock Sanit. Comm. Bien. Rpt. 1923-24 pp. 23, figs. 2*).—Included in this report is an account of the tick eradication work, the outbreak of and control work with foot-and-mouth disease, scabies eradication work, tuberculosis eradication, and control work with anthrax.

**Yearly reports in regard to the progress made in veterinary medicine** [trans. title], edited by W. ELLENBERGER, K. NEUMANN, and O. ZIETZSCHMANN (*Jahresber. Vet. Med., 41-42 (1921-1922), pp. V+496*).—This yearbook, covering the years 1921 and 1922, is in continuation of those previously noted (*E. S. R., 50, p. 76*.)

**Annual administration report of the Civil Veterinary Department, Madras Presidency, for 1923-1924**, D. A. D. AITCHISON (*Madras Civ. Vet. Dept. Ann. Admin. Rpt. 1923-24, pp. 20*).—This is the usual annual report (*E. S. R., 50, p. 783*).

**Report on the Veterinary Department [Gold Coast] for the period April, 1923-March, 1924**, W. P. B. BEAL (*Gold Coast Vet. Dept. Rpt. 1924, pp. 16*).—This report includes an account of the occurrence of infectious diseases of livestock in the Gold Coast.

**Veterinary prescriptions**, G. GEROSA (*Ricettario del Veterinario. Milan: Istituto Sieroterapico, [1923], pp. VIII+279*).—This is a pocket handbook on materia medica, containing numerous prescriptions.

**On the toxic action of carbon disulphide** [trans. title], K. MUTO (*Jour. Japan. Soc. Vet. Sci., 2 (1923), No. 3-4, pp. 263-280, pl. 1*).—This is a first report, by the director of the Army Veterinary College at Tokyo, based upon experiments with mice, guinea pigs, and rabbits. He finds that 1.5 volume per cent of carbon disulfide in the air is the minimum lethal dose, causing an acute intoxication, while 3 volume per cent is sufficient to kill the animal within 10 minutes. Death is shown to be due to paralysis of the respiratory center. The respiration of the intoxicated animal is at first accelerated, then becomes slow, and finally stops. The blood pressure rises with the acceleration of respiration and suddenly falls at the stage of apnoea.

[Immunity] (*Brit. Med. Jour.*, No. 3337 (1924), pp. 1095-1111, figs. 5).—This symposium, held by the section of pathology and bacteriology of the British Medical Association at the 1924 meeting at Bradford, England, includes papers on the general subject of immunity with special reference to specificity and nonspecificity by R. A. O'Brien and W. J. Tulloch, and on special phases of the subject as follows: Chemical Structure and Specificity, by P. Hartley; The Specificity of Acquired Immunity and Non-specific Factors in Immunization, by T. J. Mackie; The Effects of Physical and Chemical Agencies on Bacterial Vaccines, by L. S. P. Davidson; The Mechanism of the Non-specific Reaction, by D. Campbell; The Effect of Detoxication on the Specific Antigenic Properties of *B. typhosus*, by E. M. Dunlop; and Some Products of Autolysed Tubercle Bacillary Cultures, with Special Reference to Their Antigenic and Curative Value in Tuberculous Infections, by R. Row.

**Anaphylaxis** (*Anafilassi. Milan: Istituto Sieroterapico, 1923, pp. 363*).—This volume consists of papers by different specialists on various phases of anaphylaxis as follows: A General and Historical Discussion of Anaphylaxis, by A. Lustig; Anatomical-Pathological Changes in Anaphylaxis, by A. C. Demel; Serum Anaphylaxis, by C. Comba; Food Anaphylaxis, by P. Rondoni; Anaphylactic Bronchial Asthma, by C. Frugoni; Anaphylaxis in Surgery, by G. Fichera; Tachyphylaxis, by D. C. Bianchi; Tubercular Hypersensitiveness and Its Relation to Anaphylaxis Immunity and the Specific Therapy of Tuberculosis, by F. Micheli; Idiosyncrasy and Paradoxical Phenomena, by A. Zironi; and Synthesis, by S. Belfanti.

[Report of the] division of veterinary science, J. W. KALKUS (*Washington Col. Sta. Bul. 187 (1924), pp. 80, 81*).—A brief statement of the status of work with bovine abortion, which is said to be responsible for from 85 to 90 per cent of the abortions and other reproductive troubles in western Washington.

The significance of *Bacterium abortus* antibodies (agglutinins and complement-fixing) found in the sera of calves at birth or after nursing, I. F. HUDDLESON and D. E. HASLEY (*Michigan Sta. Tech. Bul. 66 (1924), pp. 3-16*).—In this continuation of the work of the station on bovine infectious abortion (*E. S. R.*, 52, p. 481), the particular phase studied was the rôle played by the calf in the transmission of the disease.

The general plan followed was to examine by the complement fixation and agglutination tests the blood sera of calves from cows with a previous history of natural or artificial infection, starting if possible before the first nursing and continuing until after conception or parturition. Examinations for *B. abortus* were also made of the uterine exudate and milk of the dams and the organs and fetuses of the heifers slaughtered before parturition. In general, the technique followed was the same as described in an earlier paper (*E. S. R.*, 47, p. 584). In all 10 heifer calves and 1 bull calf were thus studied, the individual animals being under observation for periods varying from one to more than two years from the date of birth.

The blood serum of 1 calf and probably of 6 others was not tested before the ingestion of colostrum. All but 1 of these gave positive reactions to one or both tests at the first bleeding. In 1 the test was negative at first and positive one week later. Of the others tested before nursing, the blood sera of 3 were negative to both tests and became positive to one or both tests after nursing. In the one remaining case the blood was positive to both tests before nursing. This is thought to be a case of prenatal infection. The duration of the antibodies in the blood serum of the calves varied from 48 to 125 days.

All but 2 of the dams had been infected previously, and the presence of *B. abortus* was demonstrated in either the milk or uterine exudate at the time

the calves were born. The other 2, which had received injections of killed and living vaccines of *B. abortus*, never showed the presence of the organism.

The milk of 8 of the dams gave positive agglutination tests in dilutions of 1:200 or higher following parturition. Of the other three, 2 were not tested and 1 was negative. The blood serum in all cases gave positive results in one or both tests at the time of parturition.

Of the 10 heifer calves, 1 was accidentally killed before reaching breeding age, 6 were bred and slaughtered at different periods of gestation for examination of the fetus and uterus, and 3 were bred and gave birth to normal calves. The presence of *B. abortus* was not demonstrated in the uterus or fetus of any of the heifers slaughtered before parturition. Negative results were also obtained with the blood of calves and the blood serum and milk of the dams which calved normally.

These results are thought to demonstrate "the improbability of *B. abortus* persisting in the tissue of newborn calves from a prenatal infection or through the ingestion of milk containing *B. abortus* if demonstrable antibodies are interpreted as signifying an infection. There is no evidence to show that calves from infected cows are more susceptible to calves' diseases, or that the breeding efficiency is impaired in any way."

One point brought out incidentally in this investigation is the possibility of controlling the disease by separating infected from noninfected animals and keeping them in separate inclosures on the same premises. This was done in the present investigation, and although the experimental animals were cared for by the same person who also cared for the uninfected herd there was no transmission of infection. It is thought that the spread of the disease through such indirect means has been overestimated.

**Variations in the concentration of the globulin and albumin fractions of the blood plasma of young calves and a cow following the injection of *Bacillus abortus*. Variations in the concentration of the protein fractions of the blood plasma of pregnant and non-pregnant cows or of cows which have aborted, P. E. HOWE and E. S. SANDERSON (*Jour. Biol. Chem.*, 62 (1925), No. 3, pp. 767-788, figs. 5).**—This investigation of the effect of immunization with living bacteria (*B. abortus*) upon the distribution of the proteins of the blood sera included studies conducted on 4 calves and 1 cow. The general plan of the experiment was to produce a high titer serum by subcutaneous injections of living bacteria (*B. abortus*) and to compare the increase in antibodies with the composition of the proteins of the blood plasma. The calves all received colostrum from their mothers before being fed milk obtained from cows in advanced stages of lactation. Two of the calves at the age of 50 days were given a subcutaneous injection of 1 cc. of a suspension of *B. abortus* equal in density to a 24-hour bouillon culture of *B. typhosus*. Following a second injection 3 weeks later, 1 of the calves died and there was substituted another calf 41 days old. The injections were continued at 20-day intervals until the first calf was 200 days old. The final amounts given were 3.5 cc. for the first and 2.5 cc. for the substituted calf. Blood samples were taken in all cases just before and 2 days after each injection for determinations of complement fixing bodies, agglutinins, and the concentration of various globulin fractions. Similar experiments were conducted on the blood of a control calf and another calf was injected at varying intervals with washed rabbit corpuscles, and determinations were made of the hemolytic titer and the composition of the protein fractions of the blood.

Of the 5 cases studied, 2, including the 1 injected with washed rabbit corpuscles, did not produce detectable antibodies in any appreciable amount.

The other 2, whose blood was low in antibodies after the first suckling, developed a low titer with the first injection but showed no increase on subsequent injections. The control had a titer of from 1 to 20 following the colostrum feeding, and this was maintained with slight fluctuations until the end of the experiment.

There were no appreciable changes in the quantity or distribution of the proteins of the blood which could be attributed to the injection of *B. abortus* or of blood cells. In addition to the effect of age and the ingestion of colostrum, the slight fluctuations noted are attributed to the effect of the withdrawal of blood, the temporary effect of inoculation, and the response to changes in environment.

Analyses of the blood of a cow during the course of immunization against *B. abortus* with living bacteria showed a marked increase in globulin, with a slight decrease in albumin. The degree of immunity was not, however, directly related to the increase of globulin above the value obtained before immunization.

Data are also included on the composition of the blood of certain of the cows used at varying intervals following the original bleeding, when heifers, in the previously reported investigation by Smith and Little (E. S. R., 51, p. 478). Data are grouped according to the treatment received and according to whether the cows calved normally or aborted. In the case of normal calving, the data indicated that pregnancy and immunization do not cause any marked uniform change in the distribution of the protein fractions. In the cows which aborted there was in general an increase in the globulin and a slight decrease in the albumin content of the serum.

**The differentiation of primary isolations of *Bacterium melitensis* from primary isolations of *Bacterium abortus* (bovine) by their cultural and atmospheric requirements, J. M. BUCK (*Jour. Agr. Research [U. S.]*, 29 (1924), No. 12, pp. 585-591).**—Evidence is presented in this contribution from the Bureau of Animal Industry, U. S. D. A., that *B. melitensis* can be distinguished from *B. abortus* in primary cultures by guinea pig inoculation and subsequent cultivation of the tissues of the infected animal on serum agar at 37° C. under normal atmospheric conditions. Under the same conditions *B. abortus* does not develop. The failure to note any cultural differences between the two organisms in most of the studies hitherto reported is attributed to decreased sensitivity of the organisms to atmospheric conditions after prolonged artificial culture.

A list of 24 references to the literature is appended.

**Experimental studies on anthrax infection and anthrax immunity** [trans. title], T. TAMIYA (*Tokyo Imp. Univ., Govt. Inst. Infect. Diseases Sci. Rpts.*, 2 (1923), pp. 91-134, pls. 4).—Experimental studies were conducted upon guinea pigs to determine the manner of natural anthrax infection and the difference in reaction between immunized and nonimmunized animals toward injected bacilli. The results of these studies are summarized as follows:

Anthrax infection can be induced only with difficulty in the healthy membranes of the intestinal tract, but by ligating a portion of the tract, particularly in the region of the duodenum and appendix, the infection is more readily induced. In similar experiments conducted on animals treated with anthrax immune serum no infection was induced. Even in the ligated appendix only a local action resulted. The bacilli injected into the intestinal mucosa of both immunized and nonimmunized animals were frequently found in the intestinal contents, and those injected into immune animals had suffered no more change than those injected into nonimmunized animals.

If infection does not take place after passive immunization, the bacilli injected into the intestinal mucosa do not find their way to the tissues, although

there is no lowering of their virulence. This would seem to indicate that the immunization manifests itself by a heightened resistance of the tissues to invasion. This action is specific for anthrax serum and is not evident with immune serum of another kind or with normal horse serum. The latter occasionally shows a slight protective action, but it is qualitatively different from that of the specific serum.

**The valuation of malleins** [trans. title], H. KRÜGER (*Arch. Wiss. u. Prakt. Tierheilk.*, 50 (1924), No. 6, pp. 574-580).—A comparison is reported of three methods of standardizing malleins—the intracutaneous method of Schnürer, the complement-fixation method of Schreiber-Stickdorn, and a method similar to the Koch method of testing tuberculin by injections into tuberculous guinea pigs. The last method alone is considered to be of value.

**[Proceedings of the Eastern States Conferences on Eradication of Tuberculosis in Livestock]** (*East. States Conf. Erad. Tuberc. Livestock Proc.*, 1919, pp. 76; 1921, pp. 152; 1922, pp. 175; 5 (1924), pp. 136, figs. 12).—These are reports of the proceedings of the annual conferences held (1) at Chicago in October, 1919, and (2) in November, 1921, (3) at Hartford, Conn., in June, 1922, and (5) at Albany, N. Y., in June, 1924. The report of the proceedings of the fourth conference held at Concord, N. H., in June, 1923, remains unpublished.

**The diagnosis of bovine mastitis by milk examination**, A. L. SHEATHER (*Jour. Compar. Path. and Ther.*, 37 (1924), No. 4, pp. 227-242).—The investigations here reported show that a *Streptococcus* is the most frequent cause of contagious mastitis, and that it may also be caused by a diphtheroid bacillus. The information afforded by the use of bromocresol purple as an indicator of the reaction of a sample of milk does not permit a diagnosis of mastitis to be made in the majority of cases. The bacteriological examination of milk collected with every possible precaution against accidental contamination is the surest means of detecting animals infected with contagious mastitis.

**A study of the blood of normal horses** [trans. title], M. NAGAO (*Jour. Japan. Soc. Vet. Sci.*, 2 (1923), No. 3-4, pp. 251-262).—This records studies of the blood of geldings of from 5 to 19 years, respectively, each age being represented by from 2 to 15 animals. The number of red and white cells, with the percentages of the several varieties of leucocytes, are given for each animal examined, the details being presented in tabular form.

**Corynebacterial pyaemia of foals**, L. B. BULL (*Jour. Compar. Path. and Ther.*, 37 (1924), No. 4, pp. 294-298).—This is a report of investigations conducted at the Government laboratory of pathology and bacteriology at Adelaide Hospital, South Australia, in which a pyemia in foals with involvement of the lungs, alimentary canal, and mesenteric lymph glands is described. A diphtheroid bacillus with specific characteristics has been obtained in pure culture from the lesions, and it appears that this bacillus is the cause of the disease. It is pointed out that a similar disease in foals in Sweden has been described by Magnusson (*E. S. R.*, 50, p. 685), who isolated a bacillus with the same cultural characteristics as the one isolated from foals in South Australia.

**Equine piroplasmiasis in France** [trans. title], L. PANISSET and J. VERGE (*Rev. Gén. Méd. Vét.*, 33 (1924), No. 394, pp. 557-563).—The authors' investigations have shown that two forms of piroplasmiasis occur in France, which, though similar in their symptoms, are caused by two distinct parasites, one by *Piroplasma caballi*, the other by *Nuttallia equi*.

**Carbon tetrachloride as an anthelmintic for horses** [trans. title], L. DE BLIECK and E. A. R. F. BAUDET (*Tijdschr. Diergeneesk.*, 51 (1924), No. 7,

pp. 257-262; *abs. in Trop. Vet. Bul.*, 12 (1924), No. 4, p. 122).—The authors find carbon tetrachloride to be an excellent vermifuge for use against gastrophilus larvae, ascarids, oxyuris, and strongylids. A dose of 0.1 cc. per kilogram of body weight is recommended as safe and efficient.

**The possible use of arecoline hydrobromide as an anthelmintic**, I. C. ROSS (*Jour. Compar. Path. and Ther.*, 37 (1924), No. 4, pp. 246, 248-259).—The investigations here reported, which were conducted at the University of Sydney, Australia, have shown arecoline hydrobromide to be quite effective against tapeworms in the dog. It is quite ineffective against *Ascaris*, and probably against other nematodes. It may be safely and conveniently administered in aqueous solution containing 0.0625 grain per dram (0.001 gm. per cubic centimeter) at the rate of 0.0625 grain for dogs weighing from 5 to 10 lbs., 0.125 grain for dogs of from 10 to 20 lbs., 0.25 grain for dogs of from 20 to 30 lbs., and 0.5 grain for dogs over 30 lbs. It can be best administered when the stomach and small intestine are empty.

**Dr. Little's dog book**, G. W. LITTLE (*New York: Robert M. McBride & Co.*, 1924, pp. XX+345, pls. 32, figs. 19).—This is a semipopular account, largely of the accidents, parasites, and diseases to which the dog is subject.

**Studies on bacillary white diarrhoea in poultry in Delaware**, H. R. BAKER (*Delaware Sta. Bul.* 139 (1925), p. 14).—This is a brief tabulated summary of the breeding birds tested for white diarrhea during the years ended June 30, 1923 and 1924, respectively. Of the 1,868 fowls tested during the fiscal year 1924, 156, or 8.3 per cent, were found to be affected.

**Diphtheria of fowls: Its cause, prevention, and cure**, W. M. CROFTON (*Jour. Path. and Bact.*, 27 (1924), No. 4, pp. 456-458).—The author concludes that fowl diphtheria is caused by an influenzoid microbacillus. Its pathogenicity was established by its antigenic powers and confirmed by reproducing the disease in other hens.

## RURAL ENGINEERING

**Surface water supply of Snake River basin, 1919-1920** (*U. S. Geol. Survey, Water-Supply Paper* 513 (1924), pp. VI+318, pls. 2).—This report, prepared in cooperation with the States of Idaho, Oregon, Nevada, and Washington, presents the results of measurements of flow made on streams in the Snake River basin during the years ended September 30, 1919 and 1920.

**Administration report with statistical statements and accounts for 1922-23, Irrigation Department, Punjab**, W. P. SANGSTER ET AL. (*Punjab Irrig. Dept. Admin. Rpt.*, 1922-23, pp. [198], pls. 30).—The activities of the Irrigation Department, Punjab, for the fiscal year 1922-23 are presented.

**The "artesian well" as a potential source of danger**, C. N. and F. D. LEACH (*Amer. Jour. Pub. Health*, 14 (1924), No. 10, pp. 827-831, figs. 5).—In a contribution from the International Health Board of Manila, P. I., studies are reported of 46 artesian wells in the neighborhood of Manila.

The results showed that only 26 per cent of these wells are furnishing a potable water of good quality. Three of the negative wells, however, showed a high bacterial count. There is considered to be a strong possibility that the water from this small percentage of clean wells is contaminated by handling before reaching the consumer.

Of the wells examined, 45.6 per cent gave a positive dye test for leaky casings. Water for priming was obtained from nearby ditches. Eight of the 10 priming wells gave a positive presumptive test. Positive bacteriological tests were obtained from 71.7 per cent of the wells examined.

**Effect of temperature upon the friction of water in pipes**, F. E. GIESECKE (*Jour. Amer. Soc. Heating and Ventilating Engin.*, 30 (1924), No. 12, pp. 747-752, figs. 3).—In a contribution from the University of Texas a summary is given of data from hydraulic experiments, indicating the effect of temperature upon the friction of water in pipes. Tabular data to illustrate the results are included.

**Run-off for open ditch land drainage**, C. E. RAMSER (*Agr. Engin.*, 5 (1924), No. 10, pp. 222-226, fig. 1).—In a contribution from the U. S. D. A. Bureau of Public Roads data are summarized on the run-off from typical areas in Mississippi, western Tennessee, and western Iowa, the purpose being to demonstrate the importance of adequate run-off data as the basis for the design of open ditch drainage systems.

**Physical properties of materials.—I, Strengths and related properties of metals and wood** (*U. S. Dept. Com., Bur. Standards Circ. 181, 2. ed. (1924), pp. 204, pl. 1, figs. 60*).—This is the second edition of this publication (E. S. R., 46, p. 688).—It contains the values for tensile, compressive, and shearing strengths; ductility; modulus of elasticity; and other related properties of pure metals and their alloys and of wood. In addition to these, the properties of metals at elevated temperatures, and fatigue and impact properties, and the effect of heat treatment and cold working are also given. Other properties and uses of less commonly used metals are described briefly. Graphical representation is used in many cases to show the change of the properties of a material with changing conditions.

**The properties and uses of wood**, A. KOEHLER (*New York and London: McGraw-Hill Book Co., Inc., 1924, pp. XIV+354, figs. 129*).—In this contribution from the University of Wisconsin and the U. S. D. A. Forest Products Laboratory, an attempt is made to present in a nontechnical manner the more important facts concerning the properties of wood and how these properties affect its utilization. Chapters are included on the structure of wood, its physical properties, the mechanical properties or strength of wood, factors affecting the strength of wooden members, chemical properties of wood and their practical application, air seasoning of wood, kiln-drying, deterioration of wood, protection of wood against decay and fire, principal factors governing the use of wood, kinds and quantity of wood used for various purposes, measurement of timber products, and commercial grading and standard sizes of lumber.

**Utilizing poles and timber in farm building**, G. AMUNDSON (*Mich. Agr. Col. Ext. Bul. 24 (1924), pp. 36, figs. 47*).—Practical information on the utilization of poles and timber in the construction of houses and farm buildings, with particular reference to Michigan conditions, is presented. Numerous diagrammatic illustrations and working drawings of structures built of such materials are included.

**Foundations, abutments, and footings**, G. A. HOOL and W. S. KINNE (*New York and London: McGraw-Hill Book Co., Inc., 1923, pp. XIV+414, figs. [183]*).—This is a reference work covering the design and construction of foundations, abutments, and footings, and including a complete treatment of the elementary theory involved. Sections are included on soil investigation, excavation foundations, spread footings, underpinning, foundations requiring special consideration, bridge piers and abutments, and legal provisions regarding foundations and footings.

**Relative effects of some nitrogen compounds upon detonation in engines**, T. A. BOYD (*Indus. and Engin. Chem.*, 16 (1924), No. 9, pp. 893-895, figs. 3).—Studies are reported which showed that nitrogen in some of its compounds

exerts a greater influence upon the character of combustion in internal-combustion engines than any other element of small atomic number. The action of nitrogen is influenced in a large way by the elements of radicals attached to it. Thus in some of its compounds it is quite effective for suppressing detonation, in some it is almost neutral, and in some it exerts the remarkable effect of inducing detonation. For example, detonation is suppressed by aniline, it is affected very little by pyridine, and it is induced or increased by propyl nitrate.

In general the nitrogen compounds which are most effective for suppressing detonation are the primary and the secondary amines. Of these the aryl amines, or those that contain at least one aryl group, have much the larger influence for eliminating detonation from internal-combustion engines.

**A suggested mechanism for antiknock action**, G. L. WENDT and F. V. GRIMM (*Indus. and Engin. Chem.*, 16 (1924), No. 9, pp. 890-893, fig. 1).—Studies are reported the results of which suggest tentatively that during an explosion in an automotive engine the explosive flame is propagated by the emission of electrons from the reacting molecules, in that the advance of these electrons before the flame front ionizes and activates the unburned molecules, causing detonation at high temperatures and pressures. On this hypothesis the function of such materials as tetraethyl lead is to absorb electrons and to promote the recombination of ions previous to combustion, thus reducing the normal acceleration of the combustion rate.

It was found that tetraethyl lead and other antiknock compounds do actually have a marked effect in recombining gaseous ions at ordinary pressures and temperatures, while the knock inducers similarly tested have no effect. Attempts to reduce the rate of combustion by the application of magnetic and electrostatic fields were unsuccessful.

**Power for the farm from small streams**, A. M. DANIELS, C. E. SEITZ, and J. C. GLENN (*U. S. Dept. Agr., Farmers' Bul. 1430* (1925), pp. II+36, figs. 40).—This publication, prepared under a cooperative agreement between the Bureau of Public Roads and the Virginia Polytechnic Institute, presents data from a survey, the purpose of which is mainly to acquaint farmers with the possibilities of developing the power of small streams by converting it into electrical energy, and with the uses to which such power can be put.

**Let the creek light your home**, A. B. CRANE (*Wash. State Col. Ext. Bul. 124* (1924), pp. 15, figs. 11).—Practical information on the development of small hydroelectrical power plants on farms in Washington is presented.

**Fitting the farm saws**, L. M. ROEHL (*N. Y. Agr. Col. (Cornell) Ext. Bul. 94* (1924), pp. 36, figs. 42).—Practical information on the sharpening and fitting of farm saws is presented.

**Equipping an orchard spray machine for use in alfalfa fields**, C. WAKELAND (*Idaho Agr. Col. Ext. Circ. 25, reprint* (1924), pp. 4, figs. 4).—This is a reprint (*E. S. R.*, 47, p. 592).

**Emissive tests of paints for decreasing or increasing heat radiation from surfaces**, W. W. COBLENTZ and C. W. HUGHES (*U. S. Dept. Com., Bur. Standards Technol. Paper 254* (1924), pp. 171-187, fig. 1).—Experiments on the emissivity of heat from sheet iron, cotton duck, roofing material, artificial leather, and other fabrics covered with white paint, vitreous enamel, and aluminum paint are reported.

It was found that aluminum paint emits only from 30 to 50 per cent as much thermal radiation as the unpainted material and as the white paint, vitreous glass enamel, or other nonmetallic coatings. The application of these data to house radiators is discussed. It is pointed out that owing to the fact that house radiators are essentially convectors of heat, a gain of only from

10 to 15 per cent in heat dissipation into the room may be expected by covering the surface of the radiator with a paint which is free from flakes of metals.

**Fighting rust with sublimed blue lead** (*Chicago: Eagle-Picher Lead Co., 1923, pp. 80, figs. 23*).—Data are presented on the properties and uses of sublimed blue lead, with particular reference to preventing corrosion of iron and steel. Chapters are included on corrosion of iron and steel; rating of rust-proofing paints by the American Society for Testing Materials; sublimed blue lead; use of sublimed blue lead; suggested painting specifications for structural steel work; and estimates, data, and tables.

**Poultry house construction**, H. A. D. LEGGETT (*Vt. Agr. Col. Ext. Circ. 31 (1924), pp. 20, figs. 19*).—Practical information and working drawings for poultry houses adapted to conditions in Vermont are presented.

**Artificial illumination of poultry houses for winter egg production**, F. L. FAIRBANKS (*N. Y. Agr. Col. (Cornell) Ext. Bul. 90 (1924), pp. 28, figs. 19*).—Data from two years' studies on the artificial illumination of poultry houses for winter egg production are reported and discussed.

The results indicate that the general illumination of the pen is quite as important as the illumination of the floor. It was found that even with the proper intensity of light on the feeding floor a number of the birds did not come down to feed if the perches were dark, but that when the lighting unit was changed so as to throw light on the perches, and at the same time keep the proper floor intensity, all the birds came down to feed.

The details of the electrical apparatus used are presented. It was found that to find the number of lighting units that will be required for a pen of a given size, the number of square feet of floor space should be divided by 200; the nearest whole number will be the number of units required. The lighting units should be placed 6 ft. from the floor and 10 ft. apart along a line midway between the front of the house and the front of the dropping board.

**Poultry equipment made at home**, B. WINTON and W. C. BONEY (*Missouri Agr. Col. Ext. Circ. 151 (1924), pp. 16, figs. 24*).—Practical information and working drawings relating to equipment for the feeding, watering, and housing of poultry, with particular reference to conditions in Missouri, are presented.

**Some fundamentals of the ventilation of animal shelters**, R. W. TRULLINGER (*Agr. Engin., 5 (1924), No. 11, pp. 253-256, 258, fig. 1*).—In a contribution from the U. S. D. A. Office of Experiment Stations, a brief summary is given of some of the more important points of the available fundamental knowledge of ventilation as influenced by the specific requirements of livestock and poultry, and an analysis is given of what are considered to be the necessary preliminary considerations in a study of the ventilation of animal shelters.

Attention is drawn to the rather prevalent disagreement among investigators regarding the requirements of animals with reference to temperature and ventilation. It is concluded that the results of ventilation studies can be of no more than speculative accuracy unless they have been conducted under controlled conditions with animals, the health, comfort, economy, and productiveness values of which are known with a reasonable degree of accuracy as judged by suitable standards. This is considered to indicate the necessity of close cooperation between the agricultural engineer and animal husbandman in such work, and the employment of methods and apparatus similar to those used in respiration calorimetric studies to provide the proper basis for the design of ventilation systems.

**Cold storage on the farm**, R. R. GRAHAM (*Ontario Dept. Agr. Bul. 306 (1924), pp. 32, figs. 21*).—In this revision of Bulletin 207 (E. S. R., 29, p. 88),

practical information on the planning and construction of ice houses and cold storages for farm use, with particular reference to conditions in Ontario, Canada, is presented.

**Ice-making and cold-storage plants in Australia and New Zealand** (*U. S. Dept. Com., Bur. Foreign and Dom. Com., Trade Inform. Bul. 280 (1924), pp. II+33*).—Data on the particulars of ice making and refrigerator installations in Australia and New Zealand are presented.

**Home conveniences**, F. W. IVES (*New York and London: Harper & Bros., 1924, pp. XI+219, figs. 74*).—This is one of Harper's Handbooks, edited by W. C. O'Kane. Its purpose is to set forth briefly some of the things that make for comfort about the home and to aid the householder in the selection of appliances. While of an extremely popular nature, it is a striking example of the results of extensive fundamental work in agricultural engineering in which it is known that the late author was long engaged. It contains chapters on heating appliances, ventilation, cooking appliances, home laundry equipment, plumbing fixtures and accessories, disposal of waste, refrigeration for the household, cupboards and closets, cleaning devices, handy household devices, labor-saving kitchen devices, handy repairing conveniences, the electric motor and its application, the small internal-combustion motor and its application, lighting and light plants, the septic tank, methods of getting water into the house, and suggestions for reading.

**Studies on the biology of sewage disposal**, W. RUDOLFS ET AL. (*New Jersey Stas. Bul. 403 (1924), pp. 95, figs. 39*).—This is the third annual report of this joint project of the stations and the New Jersey State Department of Health (E. S. R., 51, p. 685). Separate studies have also been reported from time to time and noted in the *Record*.

Studies by F. L. Campbell and Rudolfs on operating and resting Imhoff tanks showed that practically all observations and determinations made on the resting and operating tanks pointed to a rise and then a fall in sludge digestive activity during the course of the tests. High amounts of ammonia were found to correspond with a low percentage of carbon dioxide production except in the cases during and shortly after sludge drawing, when the ammonia produced had not yet had a chance to accumulate. The carbonates reached the highest peaks shortly after those for carbon dioxide and ammonia. The total acidity did not coincide with the greatest carbon dioxide production. A comparison of pH values with carbon dioxide content showed, in general, an inverse relation. Apparently H-ion concentration gives a true index of the total activities taking place in the tank. Foaming phenomena occurred when the pH values of the liquid between the scum and sludge were below 7, and foaming subsided when the H-ion concentration was above the neutral point.

Bacteriological investigations by M. Hotchkiss on operating and resting Imhoff tanks apparently established the fact that in these tanks there is an inverse relationship between the numbers of albumin-digesting and hydrogen-sulfide producing bacteria. This is taken to indicate that different types of digestion dominate at different times.

Studies of the fauna of Imhoff tanks and sprinkling beds by J. B. Lackey indicated the probability that the protozoa of Imhoff tanks afford a fair criterion as to the proper working conditions therein. When the tanks foam or seem to digest poorly the number of protozoa is high, and when there is but little solid matter in the liquid the number tends to be small. It is considered questionable if their numbers are ever large enough to affect the bacteria in the tanks, the reverse being more likely. It was found that the number of

genera of protozoa in filter beds which occur with some regularity in numbers over 5,000 per cubic centimeter is small.

Studies by Rudolfs, Campbell, Hotchkiss, and Lackey on the digestion of fresh solids showed that a relation apparently exists between the total bacteria, total animal life, percentage of carbon dioxide of the gas, and the pH values obtained. Bacteria-producing carbon dioxide influenced the changes of the pH index. A fluctuation in bacteria seemed to be correlated with a fluctuation of microscopic animals. A rise and fall of H-ion concentration occurred with the rise and fall of carbon dioxide. The relation between chemical end products, other than carbon dioxide, and bacteria was not directly apparent. Fresh solids seemed to behave very similarly whether mixed with partially digested material or collected directly. Material digesting in an operating or resting tank seemed to follow in general the same course of digestion as fresh unseeded or contaminated solids.

Decomposing fresh material became acid and had a tendency to remain so for some time until the decomposition progressed far enough to produce alkaline products. When the liquid in the tanks registered a pH below 7 the solids rose and foaming resulted, while when the H-ion concentration was slightly above the neutral point foaming subsided and the scum receded.

Studies by Rudolfs and H. A. Trajkovich on fungi and algae of the sprinkling filter bed and their distribution indicated a seasonal fluctuation of fungi, reaching a maximum during the winter months.

Experiments on the physiology of fungus No. 2 (*Penicillium*) by Rudolfs and Trajkovich indicated that this organism was unable to live and reproduce in the absence of air, to produce ammonia, to decompose cellulose, or to liquefy gelatin.

A comparison by Rudolfs and Lackey of the digestion of fresh solids and fresh solids contaminated with partially digested material showed that the latter went through a course of digestion similar to the former, there being, however, a marked difference in the rapidity of digestion. Shortly after the contaminated fresh solids were collected the animal population decreased materially. After some time they multiplied enormously, and this increase was again succeeded by a more sparse animal population. The first stage coincided with the lowering of pH values, while the second occurred when no rapid changes were taking place in the H-ion concentration but while it was rising slowly above the neutral point.

Film removal studies by Rudolfs showed that when this process started within the filter bed, several species of protozoa increased rapidly in numbers, there being apparently a succession of groups. After some time when débris accumulated and fungi became more abundant, the large numbers of free swimming protozoa disappeared. The total growth fluctuated considerably during the year, but a steady increase of film took place until its accumulation resulted in a new slough.

**A survey of two hundred and one privies for intestinal parasites, W. C. BOECK** (*Amer. Jour. Pub. Health, 14 (1924), No. 10, pp. 839-841*).—In a contribution from the Harvard Medical School, data from an examination of excreta from 201 privies in a southern community are reported, which revealed an incidence of infection with *Endamoeba histolytica* cysts of practically 5 per cent. The incidence of other protozoa and helminthic infections was sufficiently high to consider the situation surprising, if not somewhat alarming. This infectious material is considered to constitute a potential danger to the community, and to account for the greater prevalence of amebic dysentery and helminthic infections among the people of the South as compared with those

of the North, where in general more adequate methods of excreta disposal are in force. The situation is considered to furnish an argument for continued rigid inspection of privies in the South, and for the extension of proper measures for excreta disposal.

## RURAL ECONOMICS AND SOCIOLOGY

The problem of business forecasting, edited by W. M. PERSONS, W. T. FOSTER, and A. J. HETTINGER, JR. (*Boston: Houghton Mifflin Co., 1924, pp. XIII+317, figs. 55*).—The papers presented at the eighty-fifth annual meeting of the American Statistical Association in Washington, D. C., in December, 1923, include the following which relate to agricultural phases of the problem:

*Forecasting agricultural conditions*, H. C. Taylor (pp. 227-236).—This has been noted (*E. S. R.*, 50, p. 198).

*Forecasting corn and hog prices*, H. A. Wallace (pp. 237-249).—For forecasting purposes, corn prices are regarded as a more valuable barometer of oncoming hog prices than are hog prices as a barometer of future corn prices. The varying size of the corn crop, which to an important extent is due to the effect of heat and drought during the six summer months, is held to be the chief cause for the variation of corn prices from their normal relationship with the general price level. The corn acreage does not vary greatly from one year to the next, and the matter of greatest importance in determining corn prices is the average acre yield. A study of December future corn prices is said to indicate that speculators are fully aware of the effect of the season on the new corn crop.

The corn-hog cycle is briefly described. Three factors which tend somewhat to modify the periodicity in corn and hog prices month by month are pointed out. A study of the 40-year period preceding the war for the purpose of discovering independent variables which apparently were acting some time in advance to cause changes in the winter price of hogs is set forth in detail, showing how a predicting formula was worked out.

*Agricultural and business cycles*, G. F. Warren and F. A. Pearson (pp. 250-264).—Of various measures of business conditions, the price of industrial stocks and the Harvard commodity price index show the highest correlation with the price of farm products. Since the price of stocks is, on the average, about six months quicker in showing trends than the Harvard index, it is said to be used for most comparisons. Certain products, such as hides, respond as promptly as does the stock market. In about six to nine months after the stock market rises or falls, the demand for pork, butter, and cheese responds. For products like milk and cotton the demand follows much more slowly. Apparently the price of starch crops follows industrial conditions with a lag of over two years. Some of the major forces that control the prices of farm products are said to be industrial conditions acting on demand, cycles of high and low production due to efforts to increase or reduce production, high or low yield of crops per acre due primarily to weather, and other factors such as hog cholera, most of which are noncyclical. Finally, it is believed that by combining the business cycle with the cycles of over and underproduction, and, in the case of crops, including the influence of weather, prices of farm products may be forecast with sufficient accuracy to be of service.

*Forecasting crops from weather conditions*, J. B. Kincer (pp. 265-276).—Two principal lines of research dealing with the relation of weather to crops are said to be one involving an effort to establish meteorological cycles, the recurring phases of which will show meteorological conditions similar to their

predecessors with a consequent reproduction of agricultural phenomena, and a second which has to do with the influence of weather on crop development during or shortly before the growing period and is characterized by a statistical determination of the relation between weather and yield. The second method is said to have received attention from a greater number of investigators and is considered the more promising. This paper points out and discusses some of the more formidable difficulties in investigational work and makes suggestions as to possible remedies.

**A study of farm organization and management in Mason and Fleming Counties, W. D. NICHOLLS, C. U. JETT, and Z. L. GALLOWAY** (*Kentucky Sta. Bul. 253 (1924), pp. 39-84, figs. 6*).—A study of 241 farms for the farm year of 1922 is presented here. These farms had an average area of 152 acres and an average investment of \$17,928, not including the value of the operator's dwelling. The average farm was found to have realized a labor income of \$1,029 and the best 15 an average of \$3,203. The average total receipts were \$3,714 per farm, which included the value of the cropper's share of tobacco and other crops raised on shares. The average total expenses were \$1,941, which included the value of the cropper's share of crops charged as cropper labor, also depreciation on farm buildings and machinery of \$226, unpaid family labor amounting to \$163, and a decrease in feed and supplies of \$75. The average total receipts for the best 15 farmers were \$7,124 and the average total expenses \$3,038. The receipts per 100 acres for the average of the 241 farms were \$2,443 and for the best 15 \$3,851. The expenses per 100 acres were \$1,277 for the average and \$1,642 for the best 15 farms. The business organization of 11 typical successful farms is shown.

**Land settlement and colonization in the Great Lakes States, J. D. BLACK and L. C. GRAY** (*U. S. Dept. Agr. Bul. 1295 (1925), pp. 88, figs. 12*).—Agents of the Department and the cooperating States interviewed 153 land companies, real estate dealers, and agents operating in the Great Lakes region and obtained progress records from 3,000 settlers. Those counties of Minnesota, Wisconsin, and Michigan which had less than 50 per cent of their total area classified by the 1920 census as improved land in farms were included.

Of the settlers surveyed, 583 had bought their land from 15 different land companies under as many plans of purchase and credit arrangements. Seven of the companies were selling land under 5- or 10-year contracts and giving no aid to settlers in the form of advances or credit; 6 were making advances to settlers in such forms as buildings and livestock, 4 of them in combination with easy terms of payment; 1 was making advances part of the time, the settler having an option in the matter; and 1 had made no advances, but provided liberal credit instead. The problems and methods of land settlement under these companies are described in detail.

From a summary of settlers' progress, it is indicated that in an average period of three years the land of the 583 settlers had increased in value \$1,176 per farm, or \$5.50 per acre per year. They had cleared 7.35 acres per farm, or 2.45 acres per year; had brushed 6.63 acres per farm, or 2.21 acres per year; and had cleared 2.43 acres of marsh per farm, or 0.81 acre per year. There were average increases per farm per year of \$193 in the value of buildings, \$131 in the value of livestock, and \$48 in the value of equipment and supplies. Cash on hand had decreased on the average \$411 and debt had increased \$262. The settlers on projects receiving little or no aid made larger net gains and cleared more land than those on projects receiving aid. The 120 belonging to the first group had about \$1,800 to start with, and a much larger number of them had come directly from farming.

In consideration of the special conditions and indications of progress on individual projects a brief analysis is given of each of the 15, and other significant types of land settlement agencies are briefly noted. The methods followed are discussed in detail from the standpoint of both the individual and the public interest.

[Report of the Washington Station] division of farm management, G. SEVERANCE (*Washington Col. Sta. Bul.* 187 (1924), pp. 56-61).—Preliminary data from a number of projects are reported.

*An economic study of small fruit production in western Washington.*—During the summer of 1924 complete farm records were secured from 100 small fruit farms in King and Pierce Counties, from which it is determined that the average return or deficit on the investment was -2.35 per cent for berries alone, -14.26 for berries plus dairy, 1.96 for berries plus poultry, and -1.2 per cent for all kinds of farming. The average gross value per farm on 100 farms in 1923 was \$2,206.19 for raspberries, \$1,776.43 for evergreens, \$829.55 for strawberries, and \$437.78 for loganberries.

*An economic study of poultry farming in western Washington.*—Records of the complete farm business for the year ended October 1, 1924, were secured from 107 farms where poultry raising was the major enterprise. Of this number 49 farms had from 500 to 999 hens, and this size group led among the farms on which poultry was the only or the major enterprise and among farms of 10 acres or less. A complete detailed statement of the egg sales on these farms shows that from hen flocks 91, from mixed flocks 125, and from pullet flocks 164 eggs were sold per bird during the year, the average value of eggs per bird from the several flocks, respectively, being \$2.22, \$3.70, and \$4.06.

*An economic study of the costs and methods of range cattle production in Texas.* V. V. PARE and G. S. KLEMMEDSON (*Cattleman*, 10 (1924), No. 12, pp. 9-20).—A study begun in the fall of 1921 by the Bureaus of Agricultural Economics and Animal Industry, U. S. D. A., of the costs and methods of producing calves on ranches in Texas is reported upon in these pages. Records were taken of operations for the years 1920 to 1922, inclusive, and are concerned with the types of ranges, the ranch layout, and the details of the system of management, covering an average of 38,511 cows and their calves for the three years. The ranches in this study are located in the northeastern portion of the range area of Texas.

Cattle producers on the average made no profits above their net costs, but lost \$4.59 per head in 1922. The annual operating cost was \$12.88 in 1922, \$12.77 in 1921, and \$16.72 in 1920. The annual operating cost of carrying a cow had decreased 23 per cent since 1920. The operating cost of producing a calf on these cattle ranches was \$19.25 in 1922, \$18.41 in 1921, and \$25.52 in 1920, these amounts not including any rent on land or interest paid or allowed on the operator's investment.

Some of the factors responsible for the success of a few well-managed ranches in keeping down costs and in the utilization of labor are brought out in the discussion of the management of grazing land, the carrying capacity of the ranges, the distribution of investment, the breeding herd, ranch improvements and equipment, winter feed, ranch management and labor, taxes, miscellaneous expenses, death and accident losses, and depreciation. A final table summarizes the most important factors which influenced the cost of producing a range calf at weaning time on 15 ranches southwest of Wichita Falls, Tex., in 1922.

*The cost of producing water buffalo milk.* C. O. LEVINE and S. T. TO (*Lingnaam Agr. Rev.*, 2 (1924), No. 1, pp. 1-8).—Data are recorded from 14

buffalo cows in the dairy of the Canton Christian College, mainly for the period from July 1, 1921, to May 1, 1922.

The average milk production for 365 days for the 14 cows was 1,985.22 lbs., containing 223.27 lbs. of butterfat. According to the prevailing prices this milk was produced at an average cost of 6 cts. per pound for feed consumed, and 17.7 cts. is the total cost per pound of milk produced, including, in addition to feed, labor, interest, repairs, and depreciation on investment, fuel, bottles, and other miscellaneous items. The cost of milk varied considerably with individual cows, being 23.9 cts. per pound for one cow and 12.8 cts. for another. The lowest producing cows invariably give milk at a greater cost than do the high producing cows.

**A short system of farm costing**, H. R. J. HOLMES (*New York: Oxford Univ. Press, Amer. Branch; London: Oxford Univ. Press, 1924, pp. 107*).—Simple double-entry systems of bookkeeping are discussed, as well as cost of production accounting. The latter is held to be particularly adapted to the needs of farmers of Great Britain. Directions are given for keeping farm records, consisting of a labor sheet and a corn, cake, hay, and livestock sheet. The daily routine operations and the closing of the accounts are described. Numerous illustrative sheets are included.

**The status of agricultural labor in lower Saxony as compared with that in the region east of the Elbe River** [trans. title], P. WAGNER (*Landw. Jahrb., 59 (1924), No. 5, pp. 713-775*).—The early social and agrarian history of lower Saxony is presented as revealed in the writings of Caesar, Tacitus, Pliny, and others, as well as in the written orders of Charles the Great with reference to the management of his estates. The history of the feudal system and inheritable servitude on the land in the Middle Ages up to its abolition by the edict of 1807 and by the regulations of 1811 is recounted.

The economic history of northeastern Germany is said to be that of feudal estates superimposed upon a system of free landholding. The author traces the distinctions between agricultural classes which arose out of the offices and functions of the personnel on these estates. In lower Saxony, on the other hand, up to the year 1300 practically all landholding was in the form of free and honorable tenure on crown lands. These were administered by a crown officer, or villicus, in units of various sizes, known as villications. As an example of this, the administration of the lands held by the monastery of St. Michaelis in Hildesheim is noted. The manifestations of this system in class development are pointed out. The villicus later became the meyer, or a leaseholder, and the system of leaseholding rights (meierrecht) became the basis for the relationship of peasants to the lord of the manor.

The economic position of the farm laborer in later centuries is traced, citing numerous historians and students of economic affairs.

**Crops and Markets, [March, 1925]** (*U. S. Dept. Agr., Crops and Markets, 3 (1925), Nos. 10, pp. 145-160; 11, pp. 161-176; 12, pp. 177-192; 13, pp. 193-208*).—Abstracts of the week's market reports, tabulated summaries of the receipts and prices of important classes of agricultural products and specific commodities on the domestic market, and notes with reference to foreign crops and markets are given in these numbers.

**Monthly Supplement to Crops and Markets, [March, 1925]** (*U. S. Dept. Agr., Crops and Markets, 2 (1925), Sup. 3, pp. 73-104, figs. 3*).—A brief report on farmers' intentions to plant a number of important crops, other than cotton, is presented by sections of the United States, with an analysis of the survey and its returns. The crop summary for March is presented with comment, and the usual estimated farm prices of important products, statistical report of the

livestock and meat situation, cold storage report of the month, and review of shipments of fruits and vegetables are given.

**The trend of agricultural prices in Canada**, H. MICHELL (*Sci. Agr.*, 5 (1924), No. 2, pp. 52-56).—This is a consideration of the relation of prices of agricultural commodities to manufactured goods and the relation of prices of grains to those of meat products.

**The agricultural depression**, G. F. WARREN (*Quart. Jour. Econ.*, 38 (1924), No. 2, pp. 183-213, fig. 1).—The author points out as fallacious the use of wholesale prices of farm products in cities as a measure of farm conditions and presents several methods of arriving at truer index numbers of farm prices. The difficulties peculiar to farming as a business, particularly in recent years, are discussed under the main topics of the variation in effects on farmers of different ages, the purchasing power of farm products, and the effect of a declining price level on agricultural prosperity. The wages of farm and city labor are contrasted. Declining prices in agriculture and in industry and the relation of cheap food to the building boom are other topics touched upon. The author forecasts a general downward tendency in the price level for some years, and holds that the pre-war level will be approximately reached in about a decade. Three things are held to be necessary for real prosperity on farms, a price level as high as the general range of prices at which the bulk of the indebtedness was incurred, adjustment between farm prices and prices of other commodities, and reasonable stability of the general price level.

**Preliminary report on agriculture and the farmer** (*Consensus*, 9 (1924), No. 3, pp. 52).—A special committee of the National Economic League was appointed to present a report on this subject. Each member received a questionnaire with reference to the causes and remedies of the situation in which agriculture is found. The questions, together with an analysis of the replies and comments of individual members, are given in this report.

**The economic condition of Soviet Russia**, S. N. PROKOPOVITCH (*London: P. S. King & Son, Ltd.*, 1924, pp. [3]+230).—This is an analysis of certain measures adopted by the Government in Russia since October, 1917. One chapter deals with the liquidation of large estates and changes in the peasants' farming. It is shown that leaders under the Soviet Government regarded the partition of land which took place in 1918 not as a State-organized agrarian reform but rather a local agrarian self-determination movement confined to the territory of the given district or community. This redistribution of land is said to have heralded the technical and economic retrogression of the peasants' farming, and the expectations of intensification in agricultural production were not justified. The communists grant that the psychology of the thrifty peasant is decidedly anticommunist.

Two groups of practical measures which marked the attempts at the introduction of communistic principles in agriculture are said to be, first, those pointing toward the creation of agricultural communes and Soviet farms, and second, those which had the object of contributing toward the gradual communization of the peasants' farming, the latter including the nationalization of agricultural revenue and the projects of regulation of peasant farming. Soviet farms had an advantage over the communes in that they were run from a single economic center and could carry out a single plan of production. The organizing force here, as elsewhere, was the industrial proletariat. Both attempts at implanting collective forms of farming ended in failure. The next attempt was to establish a régime of nationalization of farm products and the requisition of surpluses for a national food supply. In consequence a surplus was no longer produced. The complete nationalization of farming was pro-

jected but never carried out, and for it was substituted a food tax. The report of the commissariat of agriculture for 1921 points out that the transition to a food tax shows the tendency to assert the personal interest of the peasant as the main principle of agricultural policy.

**The measures taken and projected for the improvement of the social and moral conditions of the rural family** [trans. title], P. DE VUYST (*Inst. Internatl. Agr. [Rome], Actes 6. Assemblée Gén., 1922, II, pp. 811-830*).—This is the preliminary report presented to the general assembly of the International Institute of Agriculture in 1922, and is based upon the information which had been submitted by various countries before February 15 of that year. The efforts of these countries with reference to facilitating landownership, improving rural dwelling, the education of farm women, farm labor and housework, social and recreational activities, hygiene, roads, reuniting land parcels, and the development of leadership are reviewed. An extensive bibliography is drawn up.

**An inquiry into the improvement of the social and moral condition of the rural home** [trans. title], P. DE VUYST (*Inst. Internatl. Agr. [Rome], [Actes] 6. Assemblée Gén., 1922 [II], Sup. (1923), pp. 74*).—The answers or résumés of the answers returned by various countries to a questionnaire regarding their provisions against rural depopulation and controlling hygienic and social conditions in the country are given here, supplementing the above report.

**Ohio agricultural statistics for 1923**, C. J. WEST (*Ohio Dept. Agr. Off. Bul., Spec. Bul., May, 1924, pp. 72*).—This is the annual report of the cooperative crop reporting service, giving statistics of the production of crops and livestock in 1923, with comparisons.

**Virginia farm statistics, 1923** (*Va. Crop Rptg. Serv. Bul. 1 (1924), pp. 108, figs. 29*).—Statistics of agriculture in the State have been compiled jointly by the U. S. Department of Agriculture and the Virginia Department of Agriculture. The material is presented in three sections. The first treats of the acreage, yield, production, and value of the crops produced in 1923 by districts. The second section is devoted to the number of livestock on farms, its value, and car lot shipments of cattle, sheep, and hogs. Comparative data are presented in section 3.

**Acreage and yields of agriculture in the Republic of Austria for the year 1923** (*Anbauflächen und Ernteergebnisse in der Republik Österreich im Jahre 1923. Vienna: Österr. Bundesmin. Land u. Forstw., [1924], pp. 14*).—This annual report presents statistics for the later year as previously noted (*E. S. R., 51, p. 491*).

**Statistics of milk production for Switzerland for 1923** [trans. title], A. PETER ET AL. (*Landw. Jahrb. Schweiz, 38 (1924), No. 2, pp. 157-174; also in Ann. Agr. Suisse, 25 (1924), No. 2, pp. 237-255*).—Census returns showing the production of milk, the production and use of forage, the use of milk, the trade in milk and milk products, home consumption, and prices are presented for 1923, with comparisons.

**Statistics of agricultural and pastoral production, C. W. COUSINS** (*Union So. Africa Off. Census and Statis., Agr. Census No. 5 (1922), pp. VIII+42*).—Statistics of agriculture in the Union of South Africa for 1922 continue the series of annual reports (*E. S. R., 49, p. 193*).

## AGRICULTURAL EDUCATION

**Land-grant college education, 1910 to 1920.**—I, **History and educational objectives**, edited by W. C. JOHN (*U. S. Bur. Ed. Bul. 30 (1924)*, pp. VII+51, pls. 2).—This is part 1 of a survey of land-grant college education. Six papers are included, namely, Introduction, by W. C. John; An Appreciation of Senator Morrill, by J. L. Hills; Federal Legislation and Administration Pertaining to the Land-grant Colleges, by L. E. Blanch; The Land-grant Colleges in Relation to National Development, by E. D. Ball; The Land-grant Colleges and Educational Values, by A. A. Potter; and Analysis of Curricula and Statistical Summary, by W. C. John.

**Agricultural education and research in Scotland, I-IV**, A. M'CALLUM (*Scot. Jour. Agr.*, 6, (1923), Nos. 1, pp. 1-16; 2, pp. 149-163; 3, pp. 267-279; 4, pp. 418-430).—Early agricultural societies for the promotion of agriculture, the first lectureships in agriculture at the University of Edinburgh, the founding of the department of agriculture, and the introduction of courses leading to an agricultural degree are noted, leading up to an account of recent grants in aid of agricultural teaching and experimental work in Scotland. A review is given of the founding and the college activities of the West of Scotland Agricultural College, as well as those in the east and north of Scotland, respectively.

**Veterinary education in Scotland**, A. M'CALLUM (*Scot. Jour. Agr.*, 7 (1924), No. 1, pp. 45-58).—An account is given of the founding by the Highland Society of a veterinary school which later became the Royal (Dick) Veterinary College, and of the subsequent history of that institution and of the Glasgow Veterinary College created by a student of the founder of the first.

**The laboratory and the teaching of agricultural hydraulics** [trans. title], M. CONTI (*Rev. Facult. Agron. La Plata*, 3. ser., 15 (1924), No. 3, pp. 27-41, figs. 7).—The author gives a brief account of the agricultural hydraulics laboratory at the National University of La Plata in Argentina, describing various pieces of apparatus used for illustrating the properties and uses of water.

[**Rural education**] (*Natl. Ed. Assoc. U. S. Addresses and Proc.*, 62 (1924), pp. 651-738, 925-927, 957, 958).—The following papers, read at the meetings of the department of rural education of the National Education Association at Chicago and Washington in 1924, are published here: Value and Significance of Research in Rural Education, by E. J. Ashbaugh; Objective Studies in Rural Schools, by F. D. Cram; Discussion of the Report of the Committee on a Comparative Study of Instruction in Consolidated and One-teacher Schools, by L. M. Favrot; Report of the Committee on Constructive Studies, by N. Frost; The Porter School: A New Vision of the Rural School in Country Life, by M. T. Harvey; What Functions of a State Supervisor of Rural Schools Are Most Worth-while? by I. J. Simpson; How to get the most out of a Short Course for County Superintendents, by M. Trumper; Problems Involved in the Administration of State Aid for Transportation, by G. Howard, jr.; How to Raise the Standards of County Supervision through a Research Department, by J. A. Baer; Raising the Standards of County Supervision through Demonstration Teaching, by H. C. Moeller; A Comparison of Small and Large High Schools, by J. Roemer; Relation of Size to Cost of Operation in Certain Schools of Iowa, by T. C. Holy; The Plan and Cost of Operating the Schools of Prince George County, Virginia—Abstract, by R. K. Hoke; The Parent-teacher Association in Rural Schools, by Mrs. J. B. Cleaver; A Brighter Future for the Rural Child, by K. M. Cook; The Country: The Economic Basis of National

Life, by C. J. Galpin; and Educational Resources of Country Life, by J. E. Butterworth. Others relating to rural problems are A Rural School Community Program, by M. G. Bush, and Evening Schools in Our Rural Communities, by L. E. Johnson.

**Elementary agriculture for southern schools**, E. B. ROBBINS and J. C. IRELAND (*Atlanta, Ga.: Turner E. Smith Co., 1924, pp. VII+302, figs. 198*).—Certain general facts and practical topics have been selected and presented in a way intended to arouse the interest of the child in crops of the Southern States, principles of plant growth and soil improvement, farm equipment, and livestock.

**Industrial geography: Production, manufacture, commerce**, R. H. WHITEBECK (*New York: Amer. Book Co., 1924, pp. 608, figs. 373*).—The term "industrial" as used in this textbook involves the major forms of industry, including agriculture, mining, manufacturing, trading, and transportation. The United States is considered in detail, and the commodities of commerce which it produces in a large way are discussed in the first 12 chapters, 2 of which, however, deal with industrial resources, including water power, waterways, and irrigation and roads and railroads. Other commodities are given their major treatment in connection with those countries where they are respectively the most important. This is done in 20 chapters, which make countries or groups of countries the units of study.

**Grain trade documents**, S. K. THORPE (*Liverpool: Northern Pub. Co., Ltd., 1924, pp. [6]+170, pls. 4, figs. 2*).—An explanation of the use and application of documents employed in the grain trade is presented in the form of a text and handbook.

## MISCELLANEOUS

**Annual report of the director for the fiscal year ending June 30, 1924**, C. A. McCUE ET AL. (*Delaware Sta. Bul. 139 (1925), pp. 30*).—This contains the organization list, a report of the director including a financial statement for the fiscal year ended June 30, 1924, and departmental reports. The experimental work recorded is for the most part abstracted elsewhere in this issue.

**Work and progress of the [Idaho] Agricultural Experiment Station for the year ended December 31, 1924**, E. J. IDDINGS (*Idaho Sta. Bul. 135 (1925), pp. 55, fig. 1*).—This contains the organization list, a report of the director, and financial statements for the Federal funds for the fiscal year ended June 30, 1924, and for the remaining funds for the fiscal year ended December 31, 1924. The experimental work reported is for the most part abstracted elsewhere in this issue.

**Thirty-sixth Annual Report of the Massachusetts Agricultural Experiment Station, [1923]**, S. B. HASKELL ET AL. (*Massachusetts Sta. Rpt. 1923, pp. 15*).—This report consists of the organization list, a report of the director, a meteorological summary for the year, and a financial statement for the fiscal year ended June 30, 1923.

**Thirty-fourth Annual Report [of Washington College Station], 1924**, E. C. JOHNSON ET AL. (*Washington Col. Sta. Bul. 187 (1924), pp. 111*).—This contains the organization list, a report on the work of the station during the year, and a financial statement for the fiscal year ended June 30, 1924. The experimental work reported is for the most part abstracted elsewhere in this issue.

**Publications available for free distribution** (*Idaho Sta. Circ. 37 (1925), pp. 4*).—A list of the available publications of the station.

## NOTES

---

**Arkansas Station.**—A water system has been installed at the station farm, a substantial amount of land drainage completed, and several barns and other buildings erected.

**Iowa College.**—The new stock judging pavilion has now been occupied. The east wing of the cattle barn, 168 by 32 ft., is nearing completion.

**Nebraska Station.**—Harold Hedges, instructor in marketing in the Kansas College, has been appointed professor of rural economics in the station, effective August 1; and G. M. Bahrt assistant in agronomy, effective July 1. F. R. Nohavec, tractor testing engineer, has resigned effective August 1.

**New York State Station.**—Director R. W. Thatcher was given the degree of Doctor of Laws by Hobart College at its commencement exercises on June 15, in recognition of "his devoted and consistent efforts for the improvement of human welfare and the development of community spirit throughout that great and important factor of our national life—the farmers of America."

Appointments effective July 1 have been made to fill new positions created at the last session of the legislature for special investigations in canning crops, as follows: Chas. B. Sayre, associate in research (horticulture), and Leon K. Jones, Ph. D., associate in research (plant pathology). Hugh Glasgow, Ph. D., associate in research (entomology), has been transferred from his present duties to investigations of insect problems of canning crops.

L. R. Hawthorn, a graduate student at Cornell University, has been appointed assistant in research (horticulture), effective July 1, from funds made available under the Purnell Act. He will be occupied with the preparation of material for the Vegetables of New York, a three-volume work similar to the fruit books, which has been authorized by the legislature.

Leave of absence for graduate study for the academic year 1925-26 has been granted to J. E. Mensching, associate in research (agronomy), and G. L. Slate, assistant in research (horticulture).

**Texas Station.**—According to a note in *Kansas Industrialist*, A. H. Leidigh, assistant director of the station, has accepted a position as dean of agriculture and agronomy at the Texas Technological College, a State institution at Lubbock which is to open its doors to students next fall.

**Miscellaneous.**—An additional Peruvian experiment station has been established at Chuquibamba, north of Juliaca, at an altitude of 12,500 ft., and with Colonel Stordy as director. The farm or ranch contains about 18,000 acres, is stocked with about 15,000 sheep, and provided with modern equipment.

*Science* notes that the Rowett Institute of Research in Animal Nutrition has received from Duthrie Webster, a cattle breeder of Tarves, Scotland, funds for a permanent endowment for the maintenance of an experimental stock farm to be carried on in connection with the institute.

Dr. Percy Brigl, first assistant in the institute of physiological chemistry at the University of Tübingen, has been appointed professor and director of the institute of agricultural chemistry at the Agricultural High School at Hohenheim.

## INDEX OF SUBJECTS

NOTE.—The abbreviations "Ala.Col.," "Conn.State," "Mass.," etc., after entries refer to the publications of the respective State experiment stations; "Alaska," "Guam," "Hawaii," "P.R.," and "V.I." to those of the experiment stations in Alaska, Guam, Hawaii, Porto Rico, and Virgin Islands; "Can." to those of the experiment stations in Canada; and "U.S.D.A." to those of this Department.

- Ablerus*—  
*clisiocampae*, notes, 557.  
*mytilaspidis*, notes, 557.
- Abortion—  
 agglutination test for, 580.  
 bacilli in blood of calves from infected milk, 181.  
 control, 676.  
 disease, present status, U.S.D.A., 583.  
 immunization, 383, 780.  
 in cattle, 283; Wis., 283.  
 in cattle, immunization, 99.  
 in cattle, studies, 384.  
 in cows, use of vaccine for, Ky., 482.  
 in ewes, Mont., 483.  
 in mares, control, 484.  
 in mares, etiology, 181.  
 in mares, use of vaccine for, Ky., 482.  
 in swine, studies, Ill., 483.  
 rôle of calf in transmission, Mich., 882.  
 studies, Calif., 82; Conn.Storrs, 681; Kans., 481, 779; Mich., 382; Wash. Col., 882.  
 susceptibility of calves, fed infected milk, 82.  
 (See also *Bacillus abortus* and *Bacterium abortum*.)
- Abutilon avicennae, fall seeding experiments, 633.
- Accelerometers, accurate, U.S.D.A., 585.
- Accessory food factors. (See Vitamins.)
- Accounting, farm. (See Farm accounting.)
- Acetone manufacture from starch, fermentation processes in, 315.
- Acid—  
 formation as affected by ethyl alcohol, 626.  
 phosphate. (See Superphosphate.)
- Acids—  
 amino. (See Amino acids.)  
 effect on manganese, 515.  
 fatty. (See Fatty acids.)  
 organic, oxidation, effect of chloroform, 517.
- Acromonium fuliginosum* n.sp., description, 747.
- Acrithochaeta excisa*, life history notes, 155.
- Actinobacillosis in Australian cattle, 780.
- Actinomyces scabies*, control, 51.
- Acyrtosiphon pisi* on alfalfa, 254.
- Adenia digitata*, toxicity, 82.
- Adhatoda vasica* as green manure and cover crop, 732.
- Adirus trimaculatus* as rose pest, 663.
- Adrenaline, effect on carbon dioxide production, 626.
- Adrenals as affected by castration in rats, 480.
- Adsorption by activated sugar charcoal, 110.
- Aedes*—  
*albopicta*, bionomics, 155.  
*pecuniosus*, biology, 557.  
*vexans*, parasite of, 358.
- Aegeria opalescens* control, Calif., 57.
- Aenoplex plesiotypus*, notes, U.S.D.A., 456.
- Aeration—  
 effect on plant growth, 512.  
 effect on soy bean growth, 125.  
 in leaves, estimation, 517.  
 of soils, effect of barometric pressure, 116.
- Age and area theory, reply to criticism, 219.
- Ageratum cuttings, stimulation, 239.
- Aggregates, road. (See Road materials.)
- Agrarian—  
 reform in Czechoslovakia, 392.  
 reform in Rumania, 392.  
 revolution in Rumania, treatise, 94.
- Agricultural—  
 advisory committee, international, report, 94.  
 and business cycles, 892.  
 associations in Switzerland, 790.  
 Bank of South Africa, reports, 192.  
 building materials in Germany, prices, 491.  
 chemistry. (See Chemistry.)  
 clubs, junior, 795.  
 college education, treatise, 898.  
 college in Burma, notes, 800.  
 colleges, list of workers in agriculture, U.S.D.A., 95.  
 colleges, statistics, 195, 298.  
 (See also Alabama, Arizona, etc.)  
 colonization. (See Colonization and Land settlement.)  
 conditions, forecasting, 892.  
 (See also Agriculture.)

## Agricultural—Continued.

- cooperation—  
 development and status, U.S.D.A., 592.  
 factor in stabilizing the market, U.S.D.A., 592.  
 in Bulgaria, 790.  
 in Denmark, U.S.D.A., 95.  
 in France and Italy, 95.  
 in India, higher finance of, 691.  
 in Russia, 95.  
 supplement, U.S.D.A., 297.  
 treatise, 194.
- credit in Germany, effect of depreciation of currency, 691.  
 credit, report on, 191.  
 Credits Act, use of, 393.  
 crisis in Switzerland, 394.  
 crisis, 1920–1923, 389.  
 depression, 896.  
 Economic Conference of Oregon, report, 490.  
 economics laboratory manual, 794.  
 (See also Rural economics.)
- education—  
 and research in Denmark, 96.  
 and research in Scotland, 898.  
 and research in United States, U.S.D.A., 596.  
 in Australia, notes, 798.  
 in Cornwall, 597.  
 in Scotland, 100, 695.  
 promotion by foreign missions, 701.  
 (See also Agricultural colleges, Agricultural instruction, Agricultural schools, etc.)
- education, vocational—  
 Arkansas plan, 96.  
 future of, 495.  
 in Mississippi, minimum financial goal, 96.  
 measuring results, 495.  
 teaching, 494.  
 work of Federal Board for, 696.
- engineering. (See Engineering.)
- experiment stations. (See Experiment stations.)
- exports and imports, statistics of, summary, U.S.D.A., 297.  
 exports, financing, 493.  
 exports, index numbers of volume, U.S.D.A., 297.  
 extension, report, Calif., 96.  
 high school in Ontario, 793.  
 hydraulics laboratory in Argentina, 898.
- instruction—  
 in Ireland, 396.  
 in Mauritius, 397.  
 linking with community projects, 495.  
 (See also Agricultural education.)
- intelligence and phytopathology, 746.  
 journals, new, 799.  
 labor in lower Saxony, history, 895.

## Agricultural—Continued.

- labor in Seneca Co., New York, 392.  
 lectures in Mauritius, 397.  
 machinery. (See Threshing machines.)  
 mechanics, treatise, 598.  
 movements, sociological implications, 790.  
 nature study, course of instruction in, Calif., 597.  
 phenology, possibilities, 16.  
 prices in Canada, 896.  
 prices in Germany, 789.  
 production—  
 and distribution, adjusting, W.Va., 493.  
 costs in South Dakota, 390.  
 in Denmark, 494.  
 surplus, in America and German needs, U.S.D.A., 297.
- products—  
 American, market in United Kingdom, 594.  
 in Italy, regulation of selling price, 394.  
 marketing. (See Marketing.)  
 prices in Germany, 491.  
 quality, relation to climate, 114.  
 progress, seventy-five years of, 737.  
 regions of North Dakota, N.Dak., 694.  
 research in—  
 Denmark, 96.  
 Scotland, 100, 695, 898.  
 United States, U.S.D.A., 596.  
 Research Institute in India, notes, 798.  
 schools, courses in Rhine Province, 597.  
 shows, students' competitions at, 696.  
 situation, relation to population, 694.  
 statistics—  
 international yearbook, 792.  
 of Australia, 95.  
 of Austria, 897.  
 of Canada, 95, 792.  
 of Chile, 95.  
 of Denmark, 395, 792.  
 of Finland, 395.  
 of France, 194.  
 of Great Britain, 792.  
 of Greece, 793.  
 of India, 95, 395, 396.  
 of Japan, 793.  
 of Netherlands, 395.  
 of Norway, 194, 792.  
 of Ohio, 897.  
 of Siam, 194.  
 of Sweden, 792.  
 of Union of South Africa, 897.  
 of United Kingdom, 395.  
 of Virginia, 897.
- teachers, training, 194.  
 tenancy. (See Land tenancy and Land tenure.)  
 wages in Switzerland, 788.
- Agriculture—  
 adjustment to climate, 114.  
 American, and European market, treatise, 193.

## Agriculture—Continued.

- and American business, 693.
- and farmer, 896.
- and foreign relations, 693.
- and rural life in England, history, 789.
- and taxation, 393.
- and the guild system, treatise, 94.
- at Washington meeting of American Association, 102.
- British, modern methods for. treatise, 193.
- British, possibilities, treatise, 193.
- British, treatise, 96.
- course of study, 696.
- courses for normal college students in Transvaal, 397.
- courses in Rhine Province, 597.
- courses in, types, 298.
- Department of. (*See* United States Department of Agriculture.)
- electricity in, research features, 688.
- elementary, for southern schools, 899.
- elementary, in rural schools, 793.
- for countrywomen, day courses in, 597.
- in Algeria, 395, 695.
- in Denmark, 790.
- in France, 494.
- in Germany, postwar period, 395.
- in India, foundations, treatise, 193.
- in South Africa, geographical factors, 790.
- in Switzerland, 391.
- in Uruguay, relation to livestock crisis, 394.
- junior project work in, 597.
- on irrigated lands, 182.
- proposed graduate schools, at Harvard University, 798.
- teaching, treatise, 298.
- type for Akron, Colorado, region, U.S. D.A., 828.

*Agriotes mancus*, notes, 852.

*Agromyza lantanae*, notes, 356.

## Agronomic—

- experiments, rôle of statistics in, 731.
- Research Institute in France, notes, 800.

*Agrotis c-nigrum*. (*See* Cutworm, spotted.)

Air content of butter and margarine, 775.

Air-cleaning devices, notes, 185.

*Alabama argillacea*. (*See* Cotton worm.)

Alaska Stations, report, 598.

Albanian-American School of Agriculture and Mechanic Arts, notes, 798.

Albinism, human, 825.

*Albizia moluccana* as green manure and cover crop, 732.

## Alcohol—

- industrial, manufacture, fermentation processes in, 315.
- light doses, effect on mice, 632.
- (*See also* Ethyl alcohol and Methyl alcohol.)

Alder leaf-beetle, biology and control, Me., 661.

*Aleyrodes*—

*citri*. (*See* Whitefly, citrus.)

*vicini* n.sp., life history, 154.

sp., notes, 853.

## Alfalfa—

- and barley, feeding value, Nev., 468.
- anthracnose, studies, Miss., 242.
- as affected by sodium chloride, 723; N.J., 724.
- as cover crop, Calif., 39; Wash.Col., 837.
- as feed for horses, 300.
- as forage crop, Utah, 732.
- breeding experiments, 823; Mich., 334.
- caterpillar, notes, Kans., 452.
- culture, U.S.D.A., 828.
- culture experiments, Alaska, 528; Oreg., 436.
- cutting experiments, Kans., 433; Wash.Col., 829.
- duty-of-water experiment, Wash.Col., 830.
- eelworm disease, notes, Idaho, 844.
- feeding tests, Idaho, 869.
- fertilizer experiments, Kans., 433.
- for Vermont, 831.
- germination and growth, effect of sulfur, 423.
- hard-coated seed, growing experiments, 831.
- hardy, value, Mich., 497.
- hay, analyses, Calif., 70.
- hay as winter feed for brood sows, Del., 871.
- hay, feeding value, Mich., 570, 772; Miss., 275.
- hay production, Ky., 434.
- hay v. clover for milk production, Pa., 275.
- hay v. timothy hay for horses, N.Y. Cornell, 772.
- insects affecting, Kans., 452.
- irrigation experiments, Calif., 33; Kans., 433; Utah, 733.
- leaves, protein from, 802.
- meal, feeding value, Tex., 573.
- meal, vitamin A in, Calif., 875.
- nematode and crown wart, notes, Utah, 745.
- nitrogen fertilization experiments, 123.
- origin, 737.
- pasture and peas for pigs, Wash.Col., 872.
- pasture studies, Kans., 433.
- plant juice, nitrogenous constituents, 610.
- plusia, notes, Kans., 452.
- production in New York, 134.
- protein content, as affected by nitrogenous fertilizers, 530.
- root development, Mich., 317.
- seed from different sources, Mich., 334.
- seed from southern France, characteristics, 733.
- spacing experiments, Kans., 434.

- Alfalfa—Continued.  
 time of cutting, Ill., 433.  
 value in rotations, Mont., 435.  
 variety tests, Kans., 433; Wash.Col., 829.  
 weevil, control, Idaho, 851.  
 weevil in Europe, parasites of, 662.
- Alga, fresh water, absorption of various ions, Calif., 25.
- Alimentary equilibrium, 863.
- Alkali—  
 content of soils as related to crop growth, 812.  
 in soil, dispersing power, 21.  
 land reclamation, Oreg., 419.  
 poisoning of livestock, studies, 199.  
 soils in Hungary, reclamation, 813.  
 soils, reclamation, Calif., 20.  
 soils, replaceable bases in, Calif., 319.  
 soils, studies, 116, 419.  
 studies, 812.  
 vertical movement in irrigated clay soils, 812.  
 water, use on soils, Calif., 21.
- Alkalies of soil, bibliography, U.S.D.A., 620.
- Alkaline reaction of cotton plant, 427, 519.
- Alkaloids, plant, treatise, 309.
- Almond seedlings, bitter and sweet, identification, Calif., 40.
- Almonds—  
 Caldwell system of training, Calif., 42.  
 pollination studies, Calif., 41.  
 pruning experiments, Calif., 42.  
 sweet, factor for bitterness in, 221.  
 use for various food products, U.S.-D.A., 507.  
 varieties in United States, U.S.D.A., 540.
- Alternaria*—  
*brassicæ* on cauliflower, 747.  
*citri*, notes, Fla., 242.
- Alternaria* rot of lemons, Calif., 53.
- Altitude, high, studies in Utah, 798.
- Aluminum—  
 chloride, effect on phosphorus recovery from soils, 817.  
 hydroxide cream for concentration of bacteria, 380.  
 salts, effect on wheat seedlings, N.J., 725.
- Amathusia phidippus*, notes, 361.
- American—  
 Association for Advancement of Science, editorial, 101.  
 Home Economics Association, meeting, 196.  
 Soil Survey Association, proceedings, 17.
- Amino acids—  
 and proteins, interrelations, 665.  
 basic, from casein, 708.  
 optical properties, 803.
- Ammonia—  
 determination in soil, 612.  
 fumes, effect upon pears in cold storage, Calif., 53.  
 in urine, determination, 412.
- Ammonification of amine nitrogen, 512.
- Ammonium—  
 chloride, fertilizing value, 123, 422.  
 nitrate as an explosive, 623.  
 nitrate, fertilizing value, 123, 422.  
 salts, determination, 806.  
 salts, fertilizing value, 526.  
 sulfate, effect on soil bacteria, 514.  
 sulfate, effect on soy beans, 326.  
 sulfate, fertilizing value, 422.
- Amsacta albistriga*, campaign against, 554.
- Amyl acetate as grasshopper bait, Minn., 556.
- Amylase in milk and cheese, U.S.D.A., 503.
- Amylase in *Rhizopus* spores, 126.
- Anaerobes, infection in animals, 280.
- Anagrus gtraulti* affecting beet leafhopper, Calif., 58.
- Anaphes iole*, notes, 858.
- Anaphylaxis, papers on, 882.
- Anaplasma argentinum*, notes, 778.
- Anaplasmosis in Chile, 778.
- Anarsia lineatella*. (See Peach wig borer.)
- Anasa tristis*. (See Squash bug.)
- Ancylostoma caninum*, notes, 182.
- Anemia—  
 in avitaminous animals, effect of ultraviolet light, 67.  
 infectious equine, epidemic, Calif., 81.  
 infectious equine, experimental transmission, Wyo., 384.  
 infectious equine, in South Africa, 85, 484.  
 pernicious, of sheep and goats, 483.  
 regeneration of hemoglobin and diet factors in, 260.
- Angoumois grain-moth, control by fumigation, 359.
- Anicetus annulatus*, notes, 557.
- Animal—  
 calorimetry, studies, 665.  
 chromosomes. (See Chromosomes.)  
 diseases—  
 in Ajmer-Merwara, 377.  
 in Burma, 776.  
 in Germany, 580.  
 in India, 280.  
 in Kenya Colony, 776.  
 in Madras, 881.  
 in South Africa, 82.  
 in southern Brazil, 580.  
 in Texas, 881.  
 in the Gold Coast, 881.  
 studies, Kans., 481.  
 (See also specific diseases.)  
 fats. (See Fats.)  
 growth and regeneration curves, similarities, 678.  
 husbandry, textbook, 794.  
 nutrition, 674.  
 Nutrition Institute, report, Pa., 274.  
 nutrition, treatise, 267.  
 nutrition, zinc in, importance, 161.  
 parasites and parasitic diseases, treatise, 881.

**Animal**—Continued.

- production, methods of experimentation, 865.
- products of commercial importance, textbook, 794.
- reproduction and inheritance, Kans., 427.
- shelters, ventilation, 889.
- tissues, stain for, 378.

**Animals**—

- domestic, origin, 823.
- fat production in, technique for study, 109.
- first aid to, treatise, 480.
- meat-producing, composition of edible viscera, 158.
- on pasture, time used in foraging and resting, 868.
- useful, of China, 795.
- (See also Cattle, Livestock, Mammals, Sheep, etc.)

**Anomala**—

- antiqua*, notes, 154.
- kansana*, biology, 856.

**Anopheles**, zoophilism with, 358.

(See also Malaria and Mosquitoes.)

**Anteoninae**, new, notes, 859.**Antestia lineaticollis** egg parasites, sex ratio, 333.**Anthelmintics**—

- critical tests, 776.
- tests with hogs, Ohio, 84.

**Anthemella rex** affecting beet leafhopper, Calif., 58.**Anthocyan pigments**, relation to summer injury in plants, 139.**Anthocyan**s in grapes, 610, 803.

(See also Pigments.)

**Anthomyiinae** of New York, systematic study, N.Y.Cornell, 457.**Anthonomus**—

- cinctus*, studies, 858.
- eugenii* in California, 662.
- grandis*. (See Boll weevil.)
- pomorum*, life history and control, 560.

**Anthraxnose**. (See *specific host plants*.)**Anthrax**—

- control, 881.
- infection and immunity, 884.
- sensitivity and immunity, 482.
- symptomatic. (See Blackleg.)

**Antibodies**—

- formation after mallein injections, 180.
- production in cutaneous immunity to anthrax, 482.
- specific, in rabbits' serum, 282.

**Antibody transmission** in colostrum, Mo., 679.**Antidiabetic hormone** from yeast, 765.**Antineuritic vitamin**. (See Vitamin.)**Antiscorbutic**. (See Scurvy.)**Antiscorbutic vitamin**. (See Vitamin C.)**Ants**—

- Argentine, affecting beet leafhopper, Calif., 58.
- Argentine, eradication, 454.

**Ants**—Continued.

- Argentine, in Valencia, 663.
- bees, and wasps, treatise, 854.
- faculty of communication in, evolution, 155.
- in Porto Rico, importance, 257.
- insecticides for, Utah, 752.
- pavement, notes, Md., 457.
- white. (See Termites.)

**Apanteles**—

- aristotelidae*, notes, 757.
- glomeratus*, notes, 659.
- glomeratus*, parasite of, 561.
- hidaridis* n.sp., description, 361.
- n.spp., description, 361.
- ornigis*, notes, Iowa, 358.

**Aphaenogaster fulga aquia**, notes, Md., 457.**Aphanomyces** sp., notes, Utah, 745.**Aphanomyces** sp., value in sprays, Del., 844.**Aphelenchus ritzema-bosi**, notes, 551.**Aphelinoidea plutella** affecting beet leafhopper, Calif., 58.**Aphelinus**—

- mali*, biological study, N.Y.Cornell, 359.
- mali*, parasite of woolly aphid, 257.
- spp., notes, 557.

**Aphelopus bicolor** n.sp., description, 859.**Aphididae**, reproduction in, 156.**Aphids**—

- affecting cherries, West.Wash., 56.
- control in cauliflower seed bed, N.Y. State, 553.
- on citrus, fumigation, 357.
- rosy, notes, Mich., 355.
- toxicity of fatty acids for, 655.
- woolly, control, 554.
- woolly, host plants, 554.
- woolly, life history studies, Tenn., 553.
- woolly, parasite of, 257.
- (See also Apple aphids, woolly.)

**Aphis**—

- abbreviata*, studies, Me., 253.
- brassiccae*. (See Cabbage aphid.)
- forbesi*. (See Strawberry root aphid.)
- gossypii*. (See Cotton aphid.)
- leguminosae*, notes, 853.
- rumicis*. (See Bean aphid.)
- sorbi*, control, 60.
- spiraeicola*, control, Fla., 755.
- spiraeicola*, life history, 754.
- spiraeicola* on Spiraea and citrus, 753.
- spp., parasite of, N.Y.Cornell, 360.

**Aphyces** spp., notes, 557.**Apiary inspection law** of Kansas, 359.**Apiculture**. (See Beekeeping.)**Aplanobacter dissimulans**, notes, 146.**Apparatus**—

- for analysis of air in metabolism studies, 615.
- for continuous extraction of plant materials, 503.
- for continuous percolation of solutions through soil, N.J., 719.
- for determining sulfuric index of oils, 411.

## Apparatus—Continued.

- for distilling oils, 11.
- for inflating larvae, 56.
- for measuring volume of roots, 217.
- for rapid electrolytic analysis, 711.
- for recording carbon dioxide consumption, 806.
- for study of carbon dioxide evolution from soil, N.J., 724.
- for studying growth and nutrition of children, 261.
- for testing flour quality, 12.
- new micromelting point, 310.
- turbidiscopes, description, 11.

## Apple—

- and thorn skeletonizer, present status, 355.
- aphid, rosy, control, 60.
- aphid, woolly, control, Calif., 57.
- aphid, woolly, parasite of, N.Y.Cornell, 359.
- (See also Aphids, woolly.)
- aphids, effects of oil spray, 658.
- bitter pit, cause, 449.
- bitter pit, studies, Calif., 52.
- black rot, control, Pa., 243.
- blister-mite, control, Oreg., 759.
- blossom weevil, control, 560.
- blotch, control, Mo., 247; N.J., 744; Pa., 243.
- blotch, notes, Ill., 440.
- bud weevil, studies, 858.
- bud worm, notes, Ky., 453.
- diseases in Hudson Valley, N.Y.State, 543.
- diseases, notes, Calif., 49.
- fire blight, control, Kans., 449.
- fire blight, studies, Tenn., 549.
- fruits, growth rate, N.J., 738.
- Jonathan spot and soft scald, notes, 651.
- orchard, removal, Kans., 486.
- orchard, twenty years' profits from, N.Y.State, 92.
- orchards, cover crops for, Wash.Col., 837.
- orchards, winter injury, Wash.Col., 845.
- pectin pulp, feeding value, U.S.D.A., 78.
- peels, quercetin in, identification, 502.
- roots, resistance to low temperature, N.H., 218.
- rust, control, Kans., 450.
- sappy bark, studies, Calif., 49.
- scab, control, Kans., 450; Pa., 243.
- scab, notes, Del., 844.
- scab, spraying experiments for, N.Y.State, 543.
- scald control in barrels, test of oiled materials, 653.
- scald in cold storage, studies, 52.
- seeds, germination, N.Y.State, 46.
- tree borer, round-headed, control, 61, 256.
- tree borer, round-headed, summary, 657.

## Apple—Continued.

- trees, fertilizer experiments, 140, 141.
- trees, variation in yield, Me., 428.
- trumpet leafminer, studies, Iowa, 357.
- Apples—
- Baldwin, effect of environment, 839.
- barreled, United States grades, N.C., 94.
- blooming data, N.J., 738.
- breeding experiments, Ill., 440; N.Y.State, 728.
- cold storage, 539.
- cost of production, Minn., 390.
- Delicious, straw mulch for, Kans., 440.
- fertilizer experiments, Del., 836; Idaho, 836; Ill., 440; Kans., 440; N.Y.State, 442, 443; Pa., 233.
- freezing injury, 652.
- internal browning, studies, Calif., 52.
- Jonathan, breakdown in, 538.
- Jonathan, stored, examination, Wash.Col., 837.
- keeping quality as affected by storage temperature, Calif., 40.
- leaf temperature, studies, Wash.Col., 837.
- notes, Alaska, 536; N.Y.State, 46.
- pollen studies, 739.
- pollination studies, 342, 839; Calif., 41.
- prices and prospects for production, N.J., 787.
- propagation, N.Y.State, 537.
- propagation, bud and root selection, 236.
- propagation, place of stocks in, 428.
- pruning experiments, Ky., 442.
- root development, factors affecting, 838.
- spraying experiments, 646; Ind., 141; Kans., 450; N.J., 738.
- spur growth and bud production, 140.
- storage studies, Iowa, 651.
- varieties for Iowa, Iowa, 442.
- varieties, key for identification, 141.
- variety tests, S.C., 537.
- Apricot—
- blossom blight, studies, Calif., 848.
- branches, growth and correlation in, Calif., 40.
- brown rot, studies, Calif., 848.
- buds, development, effect of environment, Calif., 41.
- fungus diseases in Valais, 150.
- oil, sulfuric index, 411.
- Apricots—
- Caldwell system of training, Calif., 42.
- copper content, Calif., 62.
- drying, Calif., 14.
- effect of crowding, Calif., 41.
- keeping quality, 539.
- preservation by freezing, Calif., 15.
- pruning experiments, Calif., 42.
- Arboretum, Cuban, history and organization, 344.
- Areca nut koleroga, notes, 544.

- Areca nut root disease, studies, 545.  
 Arecoline hydrobromide as an anthelmintic, 886.  
*Argus persicus*, longevity, 258.  
 Arginine and histidine, relation to growth, 859.  
 Arizona—  
     Station, notes, 398.  
     University, notes, 398.  
 Arkansas—  
     Station, notes, 398, 900.  
     University, notes, 98, 398.  
 Armillaria disease of oak, studies, Calif., 49.  
*Armillaria mellea* on black walnut, 749.  
 Army worm, damage to sugar cane, 853.  
 Arsenic—  
     anthelmintic value, 777; Ohio, 84.  
     determination in dipwashes, 203.  
     determination in lead arsenate, 711.  
     effect on plant growth, Mont., 447.  
     water-soluble, determination, 712.  
 Arsenical dipping tanks, oxidation in, 178.  
 Artesian wells, potential source of danger, 886.  
 Artichoke plume moth, control, Calif., 58.  
 Artichokes—  
     Globe, Botrytis rot of, 649.  
     Jerusalem, culture experiments, Alaska, 528.  
 Ascaridae, key to genera, 480.  
*Ascaridia*—  
     *galli*, control, Calif., 59.  
     *perspicillum* in chickens, Kans., 485.  
 Ascarids in hogs, treatment, Calif., 81; Ohio, 85.  
 Ascaris—  
     human and pig, 683.  
     sensitization, 281.  
*Ascaris*—  
     *lumbricoides* eggs, effect of low temperatures, 561.  
     spp. parasitizing equines, 85.  
 Ash constituents, upward transfer, effect of ringing, 125.  
 Asparagus—  
     beetle, control, 753.  
     beetle, notes, Wash.Col., 852.  
     crowns, growing and handling, Calif., 739.  
     culture, handbook, 342.  
     fertilizer experiments, N.J., 738.  
 Aspen in central Rocky Mountain region, U.S.D.A., 644.  
 Aspen, quaking, pathology, 353.  
*Aspergillus niger* on figs, 451.  
 Asphalt shingles, fungus destructive to, 452.  
*Aspidiotus*—  
     *destructor*, notes, 853.  
     *perniciosus*. (See San José scale.)  
 Association of—  
     Land-Grant Colleges, convention, 1.  
     Official Agricultural Chemists, proceedings, 708.  
     Official Seed Analysts, proceedings, 737.
- Asters, China, diseases, control, N.Y.State, 543.  
*Asympsiella india*, notes, 361.  
*Atherigona* spp.—  
     genitalia, 155.  
     life history notes, 155.  
 Atoms, treatise, 201.  
 Autointoxication, intestinal, theory, 364.  
 Auximones and plant growth, 28.  
 Avitaminosis—  
     effect of a one-sided diet, 67.  
     metabolism investigations in, 463.  
     mineral metabolism in, 66.  
     nitrogen metabolism in, 66, 67.  
     (See also Vitamin A, B., etc.)  
 Avocados—  
     pollination experiments, 343.  
     vitamin A in, 65.  
 Axle skeins, gather, standardization, 288.  
 Azalea—  
     leaf-beetle, notes, Me., 661.  
     leaf miner, studies, 660.  
*Azotobacter*—  
     *chroococcum*, notes, 720.  
     spp. as affected by radioactive mineral, 22.  
*Azotobacter*—  
     in Polish soils, 320.  
     in timbered soils, Idaho, 813.  
 Azoturia, blood, urine, and tissue juices in, 684.  
 Baby beef. (See Cattle, baby beef.)  
 Bacillus, coliform, formation of antidiabetic hormone by, 766.  
*Bacillus*—  
     *abortus*—  
         and *Bacterium melitensis*, differentiation, 884.  
         carbon dioxide requirements, 481.  
         immunity of guinea pigs against, Mich., 481.  
         injection, effect on proteins of blood plasma, 883.  
         (See also *Bacterium abortum* and *Abortion*.)  
     *acidophilus*, metabolism, 163.  
     *amylobacter*, notes, 720.  
     *amylovorus*, new host for, 449.  
     *anthracis*, attenuation of virulence, 379.  
     *atrosepticus*, synonymy, 350.  
     *avisepticus*, notes, 782.  
     *bifidus*, metabolism, 162.  
     *botulinus*—  
         growth, optimum pH value and nutritional substances, 164.  
         in human and animal excreta, 164.  
         infections in animals, 778.  
         inhibitive effect of sugars and salt, 165.  
         spores, resistance to disinfectants, 165.  
         type B, isolation from feces, 164.  
         type C. and *B. paratbotulinus*, comparison, 482.  
     *chauvoei*, immunization against, 378.

**Bacillus**—Continued.

- chauvoei* infections in animals, 778.  
*coli communis*, substances formed by, relation to yeast growth, 162.  
*coli*, glucose-fermenting action as affected by insulin, 611.  
*coli*, increased resistance of suckled calf to, Mo., 679.  
*gallinarum*, notes, 782.  
*granulobacter pectinovorum*—  
 fermentation of pentoses by, 611.  
 l-leucic acid produced by, 611.  
*histolyticus* infections in animals, 778.  
*lathyri*, notes, 146.  
*melanogenes*, synonymy, 350.  
*melitensis*. (See *Bacterium melitensis*.)  
*necrophorus*. (See *Necrobacillosis*.)  
*oedematiens* infections in animals, 778.  
*parabotulinus* and *B. botulinus* type C, comparison, 482.  
*paratyphosus abortus equi*, notes, 484.  
*pfaffi*, notes, 782.  
*phytophthorus*, synonymy, 350.  
*prodigiosus*, substances formed by, relation to yeast growth, 162.  
*proteus*, substances formed by, relation to yeast growth, 162.  
*pyocyaneus*, substances formed by, relation to yeast growth, 162.  
*radiciola*, notes, 148.  
 (See also Nodule bacteria.)  
*rettgeri*, notes, 782.  
*solanisaprus*, synonymy, 350.  
*sporogenes* infections in animals, 778.  
*subtilis* in strainer cotton, Calif., 80.  
*subtilis*, substances formed by, relation to yeast growth, 162.  
*vulgatus*, synthesis of vitamin B by, 64.  
*welchii* infections in animals, 778.

**Bacon**—

- factories in England and Scotland, 674.  
 Wiltshire, 674.

**Bacteria**—

- anaerobic. (See Anaerobes.)  
 concentration, 380.  
 effect on solubility of phosphates, 320.  
 growth in synthetic medium, 162.  
 in milk, soil, etc. (See Milk, Soils, etc.)  
 nitrogen-fixing, effect of surface tension on growth, Idaho, 814.  
 nitrogen-fixing, in Vesuvian soils, 22.  
 spores, heat resistance, 113.  
 thermal death-points, relation to pasteurization, 277.  
 thiosulfate, biology of, 117.

Bacterial metabolism, studies, 162.

Bacteriologic culture media. (See Culture media.)

**Bacteriology**—

- dairy, history, 177.  
 studies, N.Y.State, 519.

Bacteriosis, studies, 52, 146.

**Bacterium**—**abortum**—

- agglutinability, effect of preservatives, Mich., 382.  
 and *B. melitensis*, differentiation, 580.  
 avirulent strain for vaccination of cattle, Mich., 581.  
 controlled vaccination experiments with, Calif., 83.  
 strains, serological study, Mich., 382.

(See also *Bacillus abortus* and *Abortum*.)

- angulatum*, notes, Fla., 247.  
*avisepticum*, studies, Calif., 82.  
*citri*. (See Citrus canker.)  
*delphinii* n.comb., description, 54.  
*flaccumfaciens*, notes, 148.  
*malvacearum*, notes, 132.  
*marginatum* on gladioli, 654.  
*martyniae* n.sp., notes, 846.  
*melitensis-abortus* group, relation to human health, U.S.D.A., 580.  
*melitensis* and *B. abortum*, differentiation, 580, 884.  
*phaseoli sojense*, studies, 651.  
*pisi*, notes, Del., 844.  
*pruni*, notes, Calif., 49.  
*pullorum*, notes, 782; Kans., 481.  
*translucens secalis* n.var., description, 448.

*tumefaciens*, studies, 146.

Bahia grass, seeding experiments, Fla., 224.

Bamboo, new chalcid attacking, 859.

**Banana**—

- anthracnose, studies, 653.  
 industry in British Empire, 344.  
 root borer, summary, 558.

**Bananas**—

- insects affecting, 356, 853.  
 vitamin A in, 65.

Banks, function in financing farmers, U.S. D.A., 591.

Barberry eradication, Mont., 447; U.S.D.A., 546.

Bark parenchyma, nitrogen storage in, 426.

**Barley**—

- analyses, 530.  
 and alfalfa, feeding value, Nev., 468.  
 as affected by sulfur, U.S.D.A., 34.  
 as a grazing crop, Ga.Coastal Plain, 225.  
 breeding experiments, Kans., 433; Mich., 334.  
 Brio, new variety, 437.  
 culture experiments, Alaska, 528; Nebr., 529.  
 dietetic value, 365.  
 feeding value, Ky., 470.  
 for pigs, methods of feeding, Mont., 471.  
 genetic studies, 30, 31.  
 germination tests, Mont., 435.  
 infection by *Ustilago nuda*, 648.  
 inheritance in, Minn., 244.  
 leaf blotch, notes, 448.

## Barley—Continued.

- leaf rust, aecial stages, 545.
- rotation experiments, U.S.D.A., 827.
- seeding experiments, Nebr., 529.
- smut, control, Kans., 445.
- starch determination in, 112.
- stripe rust, notes, 648.
- time of plowing, Kans., 434.
- v. oats for pigs, Can., 873.
- v. rye for pigs, Mont., 471.
- varietal resistance to *Helminthosporium sativum*, Minn., 244.
- varieties, Calif., 33; U.S.D.A., 827.
- variety tests, Idaho, 828; Ind., 226; Kans., 433; N.J., 732; Nebr., 529; S.C., 528; Utah, 732; Wash.Col., 829.
- vitamins in, 564.
- yields after fallow, Oreg., 435.
- yields and agronomic data, Can., 733.
- yields and quality, factors affecting, 530.

Barns, ventilation, 388.

Barometric pressure and soil aeration, 116.

Barrows, raising, 874.

Baskets, standard, for fruits and vegetables, U.S.D.A., 296.

*Bassus albicinctus*, notes, 858.

*Bassus laticinctus*, notes, N.Y.Cornell, 256.

*Bathyplectes*—

*curculionis*, notes, Idaho, 851.

*exigua*, notes, 858.

*Batrachetra arenosella*, relation to nutfall of coconuts, 358.

## Bayer 205—

chemotherapy, 280.

effect on *Trypanosoma* spp., 779.

for mal de caderas, 582.

## Bean—

aphid, control, 753.

beetle, Mexican—

in South Carolina, S.C., 553.

in Southeast, U.S.D.A., 256.

new insecticides for, Tenn., 555 studies, Ohio, 757.

chocolate spot disease, notes, 146.

crop, effect of weevily seed beans, 858.

dry root rot, notes, Idaho, 844.

hybrids, anthracnose resistance in, Mich., 346.

hybrids, color factors in, Me., 430.

leaf beetle, transmission of cowpea mosaic by, 546.

leafhopper, control, Fla., 251.

leaves, nitrogen distribution in, 325.

mildew on Limas, control, Pa., 243.

streak disease, 146.

weevil, four-spotted, longevity and fecundity, 661.

weevil, notes, Mich., 355.

weevils, fumigation, 157.

wilt, effect of moisture, 148.

yeast spot on Limas, 448.

## Beans—

adzuki, linked inheritance in, 333.

breeding experiments, Mich., 334.

## Beans—Continued.

canning, value of scalding, U.S.D.A., 460.

cull, feeding value, Mich., 80.

fall seeding experiments, 633.

Insect infestation, preventive action of clay, N.J., 750.

Lima, variety tests, Wash.Col., 829.

pinto, nutritive properties, N.Mex., 868.

seeding experiments, N.Y.State, 543.

size differences, relation to pattern and pigmentation, Me., 431.

variety tests, Ga.Coastal Plain, 232; Guam, 226.

yields and agronomic data, Can., 733.

(See also Mung beans, Soy beans, Velvet beans, etc.)

Bearings, lubrication of, theory, 687.

*Beauveria oryzae* n.sp.,  $\alpha$  and  $\beta$ , description, 747.

## Bee—

larva, morphology, 560.

louse in United States, U.S.D.A., 660.

moth caterpillars, transmission of foulbrood by, 758.

## Bee—

cuts, selection and preparation, 62.

scrap v. milk for laying hens, Can., 571.

slaughtering, cutting, and curing, U.S.D.A., 270.

specific dynamic action, 665.

viscera, composition, 159.

(See also Cattle, beef.)

Beekeeper's guide, Mich., 257.

## Beekeeping—

commercial, 663.

for beginners, treatise, 859.

in Ontario, papers on, 858.

in the Northwest, 663.

in Wisconsin, 859.

notes, Kans., 452.

Beer manufacture, fermentation processes in, 315.

Beer, vitamins in, 564.

## Bees—

ants, and wasps, treatise, 854.

foulbrood. (See Foulbrood.)

native California, studies, Calif., 59.

sealed and unsealed brood, 459.

seasonal management, Mich., 257.

studies, N.J., 752.

(See also Honey.)

## Beet—

leafhopper, natural enemies, 60; Calif., 58.

leafhopper, notes, 149.

leafhoppers, fluctuation in numbers of spring brood, 658.

pulp, dried, feeding value, Can., 374.

seed, longevity, 340.

sugar industry of Wisconsin, 534.

sugar juices, dry substance in, determination, 205.

## Beets—

fertilizer experiments, 723.  
field or fodder. (See Mangels.)  
sugar. (See Sugar beets.)

Belting formula application, effect of creep on, 586.

Benzyl phenol, anthelmintic value, 776.

Berberi epidemiology, effect of lack of exercise, 463.

Bermuda onions, American-grown, marketing, U.S.D.A., 593.

Berries. (See Fruits, small, and Raspberries, Strawberries, etc.)

Berseem, culture experiments, Calif., 33.

Bethel mildew, notes, 544.

## Beverages—

alcoholic, manufacture, fermentation processes in, 315.  
carbonated, from fruit sirups, Calif., 14.

## Bibliography of—

anemia, infectious equine, in South Africa, 85.

anthelmintics, 777.

*Aphelinus mali*, N.Y.Cornell, 360.

aphididae, reproduction in, 156.

apple-tree borer, round-headed, 256.

apple trumpet leaf miner, 358.

apricot blossom blight, Calif., 848.

Ascaris, human and pig, 684.

birds of New York City region, 153.

blood, chemical changes in, 777.

Borna disease, 584.

bud moths, U.S.D.A., 255.

bumblebees, 257.

canning of vegetables, preliminary operations, U.S.D.A., 460.

caterpillars, venomous, 358.

cell sap density, 424.

clover, white, 832.

clover-seed worm, N.Y.Cornell, 256.

Coccaceae, N.Y.State, 520.

cockleburs, U.S.D.A., 178.

cockroaches, 156.

cost of living in factory town, N.Y. Cornell, 296.

cotton seed bug, Egyptian, 357.

engineering, agricultural, research at experiment stations, U.S.D.A., 485.

*Erythroneura* spp., Ky., 753.

formaldehyde and serum proteins, reaction, 801.

grain heating by insects, 555.

hookworm of cattle, 781.

inanition, 564.

insects in decaying hickory, 753.

insulin, 611.

intestinal autointoxication, 364.

land tenancy in Philippines, 190.

metals, fatigue of, 388.

micrococci, N.Y.State, 520.

milk, chemistry, U.S.D.A., 503.

milk, colloidal problems of, 10.

nodular typhlitis in pheasants, 86.

potatoes, size of seed sets, U.S.D.A., 36.

proteins, nutritive value, 364.

## Bibliography of—Continued.

proteins, tryptophan and cystine in, 803.

range studies, U.S.D.A., 466.

sewage disposal on the farm, 787.

soil alkalies, U.S.D.A., 620.

squash bug parasites, 157.

strongylids of South African equines, 85.

sweet corn varieties for canning, 140.

tepany beans, digestibility, 664.

termites, 753.

*Theileria* spp., 583.

tobacco diseases, U. S. D. A., 247.

transpiration, 626.

vitamins, fat-soluble, experiment station work in, U.S.D.A., 462.

vitamins, water-soluble, 805.

wheat root rots, 649.

zoology, economic, 495.

Bichloride of mercury. (See Corrosive sublimate.)

Bile, effect on swine erysipelas bacillus, 283.

Bile for prevention and cure of rickets, 263.

Biochemistry, principles, treatise, 108.

## Biology—

physical, treatise, 795.

principles, treatise, 551.

Bios and vitamin B, significance of terms, 110.

Bios, chemically pure, isolation, 110.

Birch leaf skeletonizer, notes, Mich., 355.

## Birds—

banded, returns from, U.S.D.A., 250.

of New York City region, 153.

protection, directory of officials for, U.S.D.A., 452.

relation to foot-and-mouth disease, 282.

winter, food habits, U.S.D.A., 354.

Bird's-foot trefoil, hard-coated seed, growing experiments, 831.

Black pigment in chickens, genes for extension of, 128.

Black scale, control, 357.

Blackberries, preservation by freezing, Calif., 15.

## Blackberry—

blister mite, control, Calif., 60.

orange rust, studies, 451.

psyllid, control, N.J., 752.

seeds, germination, N.Y.State, 46.

Blackhead in chicks, notes, Kans., 481.

## Blackleg—

and gas gangrene in cattle, 780.

immunization, 378.

studies, Kans., 481.

*Blatta orientalis*, notes, 156.

Blight disinfectants, color indicators for, 746.

*Blacus leucopterus*. (See Chinch bugs.)

Blister mite, control, Utah, 752.

## Blood—

analysis, system, 614.

analysis, treatise, 113.

## Blood—Continued.

- chemical changes in, significance, 777.
- platelets in rats, 261.
- serum of cow, bacteriolytic action for *Bacillus coli*, Mo., 679.
- sugar after insulin injection, 265.
- sugar curve, effect of food on, 64.
- sugar, determination, 806.
- sugar, estimation, 615.
- sugar, relation to urine sugar, 860.
- sugar, variations in nature of, 764.
- typing, new clinical method, 580.

Blue grass leaf spot, notes, 448.

Blueberries, culture, N.J., 237.

Blueberry leaf-beetle and allied species, Me., 660.

Boars, selection, care, and management, 874.

Boll weevil, poisoning, S.C., 857.

*Bombyx mori*. (See Silkworms.)

## Books on—Continued.

irises, 143.  
 land tenure in England, history, 91.  
 leucocytes, 281.  
 meat inspection, 881.  
 metabolism, basal, 362.  
 milk and science, 373.  
 milk testing, 12.  
 muskrat farming, 676.  
 nitrate industry, 622.  
 nitrogen, industrial, 817.  
 organotherapy and vaccine and serum therapy, 178.  
 painting, paper hanging, etc., 689.  
 pecans, production, 642.  
 perfumes, industry, 413.  
 pharmacology, 776.  
 photosynthesis, 819.  
 pigments, 201.  
 pigs, 172, 770.  
 plant breeding, 827.  
 plant products, chemistry of, 409.  
 plants, climbing, 144.  
 plants, flowering annuals, 741.  
 plants for exhibition, 741.  
 plants, ornamental, 643.  
 plants, perennial, 741.  
 plants, poisonous to livestock, 280.  
 poisons, 178.  
 polysaccharides, 609.  
 poultry farming, 876.  
 rhododendrons, 239, 642.  
 rhododendrons and hybrids, 144.  
 rice, 534.  
 roses, 144, 344, 741, 841.  
 roses, wild, in British Isles, 344.  
 rural church, 494.  
 rural economics, 299.  
 rural social problems, 94.  
 salts, complex, 409.  
 school and country life, 795.  
 Sequoia trees, 345.  
 sewing, 696.  
 shrubs, culture, 642.  
 soil management and crop production, 696.  
 soils, 115.  
 soy beans, 636.  
 starches, 609.  
 steel and timber structures, 183.  
 sugar machinery, 615.  
 tea plant, 840.  
 textiles, 197.  
 truck crops, manuring, 421.  
 vegetable products of commercial importance, 794.  
 vegetables, culture, 341.  
 veterinary hygiene, 480.  
 veterinary medicine, surgery, and obstetrics, 280.  
 veterinary prescriptions, 881.  
 veterinary science, 197.  
 water gardening, 741.  
 weather, 315.  
 wood, 887.  
 zoology, economic, 495.

## Boll weevil—

American cotton, menace to India, 154.  
 control in South Carolina, 559.  
 new preparation for, S.C., 553.  
 situation in Arizona, 559.  
 studies, S.C., 559.  
 Bollworm, new cotton, notes, 154.  
 Bollworms, cotton, parasites of, 154.  
*Bombus* spp., studies, Calif., 59.  
 Bombyliidae of the Ethiopian region, 660.  
 Bonaset leaf-beetle, notes, Me., 661.  
 Borax treatment for citrus blue mold rot, 451.  
 Boric acid, effect on crops, 426.  
 Borna disease outbreak in Hesse, 584.  
 Botany—  
     economic and general, notes, Can., 846.  
     textbook, 397.  
 Botryosphaeria and Physalospora, comparison, 248.  
*Botryosphaeria ribis* on currant, 248.  
*Botrytis*—  
     *cinerea*, effect of heat, 146.  
     *cinerea*, on Globe artichokes, 649.  
     sp., notes, 352; Calif., 49.  
 Botulinus—  
     toxin, effect of sunlight and heat, 464.  
     toxin, potency, 282.  
 Botulism in fowls, account, Ill., 86.  
 Botulism or limberneck in chickens, West Wash., 386.  
 Boys'—  
     clubs, organization and programs, 795.  
     4-H clubs in Missouri, 795.  
 Braconidae, Javanese, descriptions, 361.  
 Brain, respiratory activity and vitamin B content, 65.  
*Brassica campestris* oil production in Argentina, 228.  
*Braula cocca* in United States, U.S.D.A., 660.  
 Bread—  
     milk content, determination, U.S.D.A., 505.  
     quality, rôle of H-ion concentration, 202.  
     (See also Flour.)  
 Breadstuffs, import requirements in Germany, U.S.D.A., 297.  
 Breeding. (See Heredity, Hybridization, Inbreeding, and Plant breeding.)  
*Brevicoryne brassicae*. (See Cabbage aphid.)  
 Brick, crushed, for concrete blocks, 585.  
 Bridges—  
     highway, impact tests, U.S.D.A., 184.  
     steel highway, specifications, U.S.D.A., 287.  
 Broilers, Easter, raising, Ohio, 476.  
 Brome grass—  
     culture, U.S.D.A., 828.  
     leaf blotch, notes, 448.  
 Bronchopneumonia, verminous, in pigs, control, 283.  
 Brown—  
     bast census, 151.

- Brown**—Continued.  
 rot fungus, studies, Calif., 49.  
 rot of fruits, cause, 450.  
 vegetable weevil, studies, 662.
- Brownian molecular movement** in plants, 425.
- Bruchus**—  
*obtectus*. (See Bean weevil.)  
*quadrifasciatus*, control by fumigation, 359.
- Bucculatrix canadensisella**, notes, Mich., 355.
- Buckthorn aphid**, studies, Me., 253.
- Buckwheat**—  
 cost of production, W.Va., 589.  
 variety tests, N.J., 732.
- Bud moth**—  
 studies, U.S.D.A., 254.  
 worms affecting cherries, West.Wash., 56.
- Bud mutation theory**, critique, Me., 428.
- Bud worm**, green, notes, U.S.D.A., 255.
- Buffalo**—  
 mange parasite, bionomics, 154, 760.  
 milk, butter from, 177.  
 treehopper, injury to apples caused by, 156.
- Building materials**—  
 heat transmission through, 288.  
 properties, 887.
- Bulb diseases**, control, 645.
- Bulls**—  
 dairy, care and management, U.S.D.A., 276.  
 dairy, selection and management, Mo., 276.  
 vitality and breeding ability, Wash. Col., 870.  
 (See also Sires.)
- Bumblebees**—  
 life history and habits, 257.  
 systematic and biological notes, 158.
- Bunt**. (See Wheat smut, stinking.)
- Bureau of Plant Industry**, directory of field activities, U.S.D.A., 796.
- Bush sickness**, studies, 282.
- Bushes**, spraying, paper on, West.Wash., 598.
- Business forecasting**, treatise, 892.
- Bustumum phlebotomum**, preparasitic stages, 781.
- Butter**—  
 adulteration, detection, U.S.D.A., 506.  
 air content, 775.  
 colloidal chemistry, U.S.D.A., 503.  
 color in, reduction, 279.  
 control, papers on, U.S.D.A., 575.  
 fat. (See Milk fat.)  
 from buffalo milk, analysis and quality, 177.  
 green color in, 279.  
 imports into United Kingdom, U.S. D.A., 594.  
 keeping qualities, relation to yeasts and molds, 775.
- Butter**—Continued.  
 making problems, papers on, U.S. D.A., 575.  
 manufacture from sweet cream, Utah, 774,  
 manufacture, use of vacuum in, Calif., 81.  
 marketing, cooperative, papers on, U. S.D.A., 593.  
 vitamin A in, 65.  
 water content, 775.
- Butterfat**—  
 autooxidation, 10.  
 droplets and electrical charge, agglutination, 278.
- Buttermilk**—  
 fat loss in, reducing, Ill., 479.  
 v. tankage for pigs, Can., 873.
- Butternut trees**, sirup from, Mich., 445.
- Cabbage**—  
 aphid, effect of length of day, Tenn., 553.  
 aphid, parasite of, N.Y.Cornell, 360.  
 blackleg, resistant variety, Pa., 233.  
 blackleg, studies, Pa., 243.  
 breeding experiments, Del., 836.  
 clubroot, notes, N.Y.State, 50.  
 clubroot, relation to soil temperature and moisture, 244.  
 feeding, effect on milk flavor, U.S.D.A., 578.  
 fertilizer experiments, Ohio, 23.  
 fertilizer requirements, Pa., 233.  
 hypoglycemia-producing principle in, 667.  
 inheritance of bolting in, 139.  
 maggot, control, Pa., 252.  
 maggot control, effect on seed-bed diseases, N.Y.State, 50.  
 maggot, notes, 252.  
 preparation for market, U.S.D.A., 43.  
 seed bed diseases, studies, N.Y.State, 50, 543.  
 seed, longevity, 340.  
 worm in Ontario, life history and control, 356.  
 yellows, control, Miss., 242.  
 yellows resistant varieties, Kans., 446.
- Cacao**—  
 collar crack disease, notes, 150.  
 habits of branching, 237.  
 new disease of, 249.  
 products, fat determination in, 713.  
 thread disease, types, 150.
- Caccobius mutans* in human intestines, 155.
- Cacoecia**—  
*argyrospila*. (See Fruit-tree leaf-roller.)  
*rosaceana*. (See Rose leaf-tyer.)
- Cactus**—  
 jointed, in Cape Province, 639.  
 prickly pear, in Australia, 556.  
 prickly pear, use as cattle feed, 869.
- Caeoma nitens*, uninucleated ascidiospores in, 451.
- Cake flour laboratory**, 259.

- Calandra*—  
*granaria*. (See Granary weevil.)  
*oryza*. (See Rice weevil.)  
 Calcium buffer values, determination, 612.  
 Calcium—  
 and phosphorus absorption, relation to diet, 763.  
 arsenate dust, effect on boll weevil, 559.  
 biphosphate, effect on acid soils, 621.  
 carbonate, effect on acid soils, 621.  
 carbonates, chemico-physical effect, 723.  
 chloride, effect on acid-sugar-pectin gels, 62.  
 chloride, effect on black alkali soil, Calif., 21.  
 chloride, effect on white pine, 353.  
 cyanamide, decomposition, 212.  
 cyanamide, fertilizing value, 120.  
 cyanamide, guanidinium salts from, 212.  
 cyanide—  
 as soil fumigant, 459, 856.  
 for killing condemned chickens, 782.  
 for rosy apple aphid, 60.  
 forms and use as insecticide, 156.  
 fumigation of citrus trees, 357; Calif., 56.  
 insecticidal value, Calif., 56.  
 deposition in rats, effect of management of cow supplying milk for diet, 176.  
 deposition in rats on special milk rations, 66.  
 determination in animal substances, 614.  
 dietary sources, 260.  
 effect on orange trees, Calif., 26.  
 fluosilicate, insecticidal value, 555.  
 in blood serum in cases of gout, 465.  
 ion concentration, regulation, 612.  
 metabolism—  
 in avitaminosis, 66.  
 in boys, 160.  
 in laying hens, Ky., 75.  
 of cows, effect of protein in rations, Mo., 478.  
 nitrate, effect on black alkali soil, Calif., 21.  
 nitrate, fertilizing value, 123, 422.  
 oxalate crystals in plants, 427.  
 phosphate, effect on acid soils, 621.  
 requirement of animals, relation to calcium in feeds, 671.  
 silicate, effect on acid soils, 621.  
 silicates, synthetic, as source of lime, 818.  
 sulfate. (See Gypsum.)  
 (See also Lime.)  
 Calendar, simplification, U.S.D.A., 414.  
*Calandra discolor*, life history, 857.  
 Calf—  
 pneumonia, notes, Conn.Storrs, 681.  
 scours, notes, Conn.Storrs, 681.  
 viscera, composition, 159.
- California—  
 Station, notes, 300, 599, 697.  
 Station, report, 97.  
 University, notes, 300, 599, 697.  
*Callidium* sp., notes, 662.  
 Calomel, anthelmintic value, Ohio, 84.  
 Calves—  
*Bacterium abortum* antibodies in serum, Mich., 882.  
 beef, fattening, U.S.D.A., 72.  
 feeding, 676.  
 feeding experiments, Calif., 71; Can., 375; Kans., 467; Ohio, 467; S.C., 567, 578; Wash.Col., 767.  
 growth and nutrition, 678.  
 protein requirements, 268.  
 raising on minimum milk products, Minn., 579.  
 self-feeders for, 678.  
 suckling, *Bacterium abortum* from feces, Calif., 83.  
 v. yearlings, marketing, Miss., 269.  
 wintering, 671.  
 Cambium curculio, studies, 157.  
*Camnula pellucida*. (See Grasshopper, clear-winged.)  
 Camphor cultivation from *Cinnamomum camphora*, 142.  
 Canada Experimental Farms, reports, 796.  
 Canal weeds, peculiar organs of, 830.  
 Canaries, breeding, treatise, 552.  
 Candy—  
 and candy materials, fumigated, hydrocyanic acid absorbed by U.S.D.A., 561.  
 from fruit products, Calif., 14.  
 Cane beetles—  
 climatic control, 853.  
 effect of chemotropism, 853.  
 Cankerworms, studies, U.S.D.A., 254.  
 Canned food—  
 growth of paratyphoid-enteritidis organisms in, 266.  
 thermal process time for, 62.  
 Canning operations, scalding, precooking, and chilling in, U.S.D.A., 459.  
 Cantaloups. (See Muskmelons.)  
*Capillaria columbae*, description, 361.  
 Capons v. cockerels, value, Can., 570.  
 Cappariaceae, evolution in, 330.  
 Carabao. (See Water buffalo.)  
 Carbohydrate—  
 metabolism, relation to phosphates, 566.  
 metabolism, studies, 764,765.  
 Carbohydrates—  
 and glucosides, treatise, 108.  
 and vitamin B, interdependence, 863.  
 in tomato leaves, N.Y.Cornell, 45.  
 translocation in sugar maple, 27.  
 transportation in plants, 27.  
 upward transfer, effect of ringing, 125.  
 Carbolic acid emulsion for mealybug control, Calif., 57.  
 Carbon—  
 bisulphide as mosquito larvacide, 155.

## Carbon—Continued.

## dioxide—

absorption in photosynthesis, 425.  
atmosphere, preparation in greenhouse, 327.

consumption, apparatus for recording, 806.

cycle in nature, treatise, 320.

distribution in greenhouses, 234, 327.

effect on *Bacterium abortum*, Mich., 383.

effect on plant growth, 424.

evolution from soil, apparatus for study, N.J., 724.

given off by eggs during incubation, W.Va., 77.

in air of houses, effect of plants, 126.

production, effect of adrenaline, 626.

production, effect of ethyl alcohol, 626.

production, effect of lactic acid, 626.

production from organic acids, relation to iodine absorption, 517.

production of roots, relation to plant feeding power, 28.

ratio to heat production in cattle, 168.

requirements of *Bacillus abortus*, 481.

disulfide, effect on soil bacteria and plant growth, 721.

disulfide, toxic action, 881.

## tetrachloride—

and chenopodium, anthelmintic value, 776.

anthelmintic value in foxes, 182.

as anthelmintic for horses, 885.

toxicity, 280.

toxicity, effect of diet, 584.

Carbonate-bicarbonate titrations, mixed indicator for, 203.

Carnations, culture, N.J., 737.

Carophyllaceae seeds, morphological differences, 639.

*Carpocapsa pomonella*. (See Codling moth.)

Carrot seed-producing industry in California, 640.

## Carrots—

effect of preceding crop, R.I., 23.

varieties in United States, 640.

## Casein—

basic amino acids from, 708.

chemistry, U.S.D.A., 503.

commercial, fat determination in, U.S. D.A., 506.

compounds, notes, Del., 844.

specific dynamic action, 665.

Cassava leaves, vitamin A in, 65.

## Cassavas—

seeding and topping tests, 132.

variety tests, 132; Guam, 226.

*Cassia*—

*hirsuta* as green manure and cover crop, 732.

*occidentalis* seeds, toxicity, 284.

Castor oil production in Argentina, 228.

Castration, effect on ductless glands of rats, 480.

Catalpa plantations, Idaho, 842.

Caterpillars, venomous, and urticarial affections, 358.

Catnip, wild, relation to cucurbit mosaic, 647.

## Cattle—

Africaner, characteristics and uses, 169.

baby beef, finishing, Mich., 72.

beef, cost of production, Calif., 491.

beef, effect of winter rations on pasture gains, W.Va., 568.

beef, feeding experiments, Calif., 71; Ill., 466; Miss., 269; Wash.Col., 767.

beef, herd management, Wash.Col., 870.

beef, production in range area, U.S. D.A., 672.

beef, wintering, 369; S. C., 568.

breeding, first principle, 676.

breeding in India, 269.

breeds of Switzerland, 877.

carbon dioxide: heat ratio, 168.

dairy, breeding, papers on, U.S.D.A., 576.

dairy, feeding experiments, 275, 276; Calif., 78; Fla., 275; Guam, 275;

Ill., 476; Kans., 477; Mich., 80; Mont., 477; Pa., 275; Utah, 80.

dairy, inheritance in, Ill., 429.

dairy, mineral requirements, Mich., 71.

disease, fatal, on coastal plains of Texas, Tex., 83.

diseases, U.S.D.A., 583.

diseases of reproductive organs, Mich., 381.

dual-purpose, in Minnesota, 672.

effect of wintering on pasture gains, 568.

feeding experiments, 268; Ohio, 467.

(See also Cattle, beef and dairy, Calves, Cows, and Steers.)

gestation period and birth weight, Idaho, 876.

industry, effect of tariff, 692.

international trade in, U.S.D.A., 583.

judging, treatise, 174.

of Campine region, studies, 478.

pasture, time used in foraging and resting, 868.

plague. (See Rinderpest.)

poisoning. (See Livestock poisoning, Plants poisonous, and specific plants)

production, range, costs and methods, 894.

## Cattle—Continued.

- protein requirements for milk production, 676.
- rations for fattening, Utah, 767.
- Red German, characteristics, 478.
- tick eradication, 280.

(See also Tick.)

(See also Calves, Cows, Heifers, and Steers.)

## Cauliflower—

- disease, correlation with strawberry red plant, 748.
- diseases, studies, N.Y.State, 543.
- leaf spot, studies, 744.

(*Cecidomyia*) *Mayetiola destructor*. (See Hessian fly.)

Cedar reforesting upon Shume Forest Reserve, 444.

## Celery—

- bacterial blight, control, N.Y.Cornell, 245.
- blanching, new method, 640.
- diseases in Florida, Fla., 649.
- golden self-blanching variety, 99.
- hypoglycemia producing principle in, 667.
- premature seeding, Mont., 640.
- seed stalk, early development, 139.
- yellow, resistant strains, Mich., 346.

Cell salts, effect on intermediary metabolism, 161.

Cell sap density, relation to environment, 424.

(See also Plant cells.)

Cellulose decomposition, factors affecting, 323.

*Cenangium populneum*, notes, 152.

*Cenchrus viridis*, striped grass looper affecting, 61.

## Centipede—

- affecting asparagus, Calif., 57.
- garden, notes, 459.

*Cenrosema* spp. as green manure and cover crop, 732.

*Cephalobus subelongatus*, notes, 551.

*Cephalolia claeidis* n.sp., description, 359.

*Cephalosporium acremonium*, notes, Ill., 245.

*Ceratitis capitata*. (See Fruit fly, Mediterranean.)

*Cercospora* n.sp., notes, 748.

## Cereal—

- chemistry, treatise, 609.
- collar disease, notes, 747.
- diseases. (See specific hosts.)
- experimental station at Rieti, Italy, 633.
- food products, insects in, control, 454.
- Fusarium disease, 645.
- rust, control by high temperature, 646.
- rust, effect of weather, 646.
- (See also Rusts and specific host plants.)
- Septoria diseases, 448.
- smut. (See Smut and specific host plants.)

## Cereals—

- culture experiments, Oreg., 436; U.S. D.A., 527.
- fumigated, hydrocyanic acid absorbed by, U.S.D.A., 561.
- nursery trials, Idaho, 828.
- seeding experiments, U.S.D.A., 827.
- time of plowing tests, Mont., 435.
- time of seeding, effect on vegetative rhythm, 625.
- variety tests, U.S.D.A., 827.

(See also Grain and specific grains.)

*Ceresa bubalus*. (See Buffalo treehopper.)

*Cerotoma trifurcata*. (See Bean leaf beetle.)

*Chaetoxorista javana*, parasite of *Setora nitens*, 554.

*Chalcozonotopus nigrus* n.sp., description, 859.

Charcoal, activated sugar, adsorption by, 110.

*Chariestcrus cuspidatus*, notes, 582.

## Chayote—

- fruit or leaves, vitamin A in, 65.
- leaves, proteins, digestibility, 63.

## Cheese—

- amylase in, U.S.D.A., 503.
- brands and standards, U.S.D.A., 575.
- colloidal chemistry of, U.S.D.A., 503.
- fumigated, hydrocyanic acid absorbed by, U.S.D.A., 561.
- Gouda, making, 177.
- imports into United Kingdom, U.S. D.A., 594.
- Jack, manufacture from goat's milk, Calif., 80.
- making, papers on, U.S.D.A., 574.
- making, treatise, 279.
- marketing, cooperative, U.S.D.A., 593.
- mold, characteristics, 279.
- quality, effect of clarification of milk, Pa., 279; Utah, 774.
- Wensleydale, mold associated with ripening, 879.

## Chemical—

- analysis, handbook, 806.
- dictionary, 409.
- elements in agriculture, rotation, Mich., 24.
- synonyms and trade names, dictionary, 108.
- synthesis, treatise, 108.

## Chemistry—

- agricultural, studies, Pa., 201.
- colloid, applications, 609.
- colloid, treatise, 609.
- definitions of terms used in, 409.
- dictionary, 609.
- in industry, treatise, 309.
- neglected chapter in, 109.
- relation to food, treatise, 258.
- Chenopodium oil, anthelmintic value, 777; Ohio, 84.
- Cherokee rose, analyses, Calif., 70.
- Cherries—
  - blooming data, N.J., 738.

## Cherries—Continued.

- fertilizer experiments, Kans., 440.
- insects affecting, West.Wash., 56.
- nonsetting, cause and remedies, Calif., 41.
- notes, Alaska, 536; N.Y.State, 46.
- pollination, 342; Calif., 839.
- preservation by freezing, Calif., 15.
- Seneca, description, N.Y.State, 46.
- sour, culture, West.Wash., 97.
- spray schedule for, West.Wash., 56.
- storage studies, Calif., 41.
- varieties for Iowa, Iowa, 442.

## Cherry—

- diseases, West.Wash., 53.
- fruit-fly, notes, Wash.Col., 852.
- leaf beetle, notes, Me., 661.
- leaf spot, control, Kans., 450.
- sawfly, notes, Wash.Col., 852.
- seeds, germination, N.Y.State, 46.
- slug, notes, West.Wash., 56.
- trees, young, pruning, Wis., 538.

## Chestnut trees surviving blight, 550.

Chestnuts, Japanese, *Schizophyllum commune* affecting, 749.

## Chicago rate case, paper on, 168.

## Chicken—

- cholera, studies, Kans., 485.
- louse, notes, 355.
- pox and roup vaccine, use, Ky., 485.
- pox vaccine, value, Calif., 82.
- specific dynamic action, 665.

## Chickens—

- condemned, killing with cyanide, 782.
- effect of cod-liver oil, 675.
- experimental, prevention of weak legs in, 274.
- extension of black in, genes for, 128.
- Leghorn, variability in weight, 172.
- mineral mixture for, Ohio, 476.
- roundworm parasite, Kans., 485.
- Single-Comb White Leghorn, postnatal growth, 772.
- White Leghorn, length and variability of bones, 772.
- (See also Chicks, Fowls, Hens, and Poultry.)

## Chick-peas in warehouses, fumigation, 359.

## Chicks—

- development, effect of thyroid grafts, 368.
- early, rearing, Mich., 773.
- feeding experiments, Can., 570; Wis., 573.
- growth, effect of cod-liver oil, 675.
- growth, effect of feed, 372.
- nutritional requirements, 173.
- sex relation to shape and weight of eggs, 629.
- X-chromosomes in somatic cells, 219.

## Child—

- labor on Maryland truck farms, 492.
- labor on New Jersey farms, 591.
- welfare, relation to dairy industry, U.S.D.A., 574.

## Children—

- feeding, 64.
- (See also Infants, feeding.)
- growth and nutrition, photographic method of study, 261.
- growth studies, 362.
- height-weight table, 64.
- in cotton-growing areas of Texas, welfare, U.S.D.A., 791.
- nutrition of, mineral elements, 160.
- optimum amount of milk for, U.S.D.A., 563.

## Children's teeth, effect of diet on caries in, 763.

## Chili pepper stem and fruit rot, description, 349.

*Chilomenes scamaculata*, color variations in, 155.

## Chinch bug attacks, difference of susceptibility of sorgo and milo to, Kans., 433.

## Chinch bugs—

- affecting Sudan grass, Kans., 466.
- on corn, campaign against, Mich., 355.

## Chlamydozoospores, formation in oak oidium, 746.

## Chloride—

- in leaf tissue fluids of Egyptian and upland cotton, 327.
- metabolism on cow's milk and breast milk, 362.

*Chloridea obsoleta*, notes, Va.Truck, 44.

## Chlorides—

- effect on orange trees, Calif., 26.
- in plant tissue fluids, determination, 111.

## Chloroform, effect on—

- oxidation of organic acids, 517.
- respiration of dead and living tissue, 516.

## Chromosomes—

- in corn, 328.
- somatic, of chicks, 219.

## Chrysanthemum—

- cuttings, diseases and parasites, 746.
- gall-midge, biology and control, Md., 456.
- nema, notes, 551.

*Chrysomphalus*—

- anidum*, control, 61.
- spp., winter mortality, 454.

*Chrysopa californica* affecting beet leaf-hopper, Calif., 58.

## Cicadellidae of Ithaca region, synopsis, N.Y.Cornell, 758.

*Cirphis unipuncta*, notes, 154.*Cirrospilus flavicinctus*, notes, Iowa, 358.

## Citricola scale, parasites of, 556.

## Citrus—

- aphid, control, Fla., 755.
- aphid on *Spiraea*, studies, 753, 754.
- blue mold rot, borax treatment, 451.
- canker eradication in Florida, 550.
- canker organism, life history, Fla., 242.
- canker, susceptibility of citrus species and hybrids, 54.
- dieback, studies, Fla., 248.

## Citrus—Continued.

- disease control, Calif., 54.  
 fruit marketing agencies, operating methods and expense, U.S.D.A., 93.  
 fruit, new *Phomopsis* of, 352.  
 fruits, new aphid attacking, 754.  
 fruits, spraying experiments, Fla., 250.  
 fruits, transportation from Porto Rico, U.S.D.A., 539.  
 (See also Lemons, Oranges, etc.)  
 orchard survey, results, Calif., 39.  
 propagation, importance of bud selection in, 238.  
 red spider, control, Calif., 60.  
 rust mite, entomogenous fungus attacking, 361.  
 scab, factors affecting, 54.  
 scale insects control, fumigation v. spraying, Calif., 60.  
 seedlings, variability in, Calif., 40.  
 stocks, studies, Calif., 39.  
 trees, calcium cyanide fumigation, Calif., 56.  
 trees, growth and composition, effect of certain ions, Calif., 820.  
 trees in Egypt, insect pests, 853.  
 trees, propagation and culture in Egypt, 344.  
 trees, winter-injured, fruit from, Calif., 39.  
 white fly. (See White fly, citrus.)
- Clay—  
 colloids, electric charge of, 811; Calif., 20.  
 flocculation and sedimentation, 121.  
 fractions, properties, 121.  
 permeability, calculation of coefficient, 619.  
 rôle in mineral acidity of soils, 22.  
 soils, leaching, Utah, 719.  
 soils under irrigation, alkali movement in, 812.
- Clays, chemistry and physics, treatise, 811.  
 Clemson College, notes, 100, 399.  
*Cleome spinosa*, alternation of sexes, 127.
- Climate—  
 adjustment of agriculture to, 114.  
 effect on quality of agricultural products, 114.  
 of British Columbia, 115.  
 of lower Rio Grande Valley, Tex., 493.  
 of Maryland and Delaware, 316.  
 of Netherlands Indies, 508.  
 of southern Africa, 616.  
 relation to sheep production, 870.  
 (See also Meteorology.)
- Climatic laws, treatise, 808.
- Climatological—  
 data. (See Meteorological observations.)  
 history of Ohio, 316.
- Clitoria cajanifolia* as green manure and cover crop, 732.
- Closterocerus tricinctus*, notes, Iowa, 358.
- Clothes moth, new insecticide for, 554.
- Clothing handbook for club members, 696.

## Clover—

- Altaswede red, characteristics, 831.  
 behavior, Mich., 334.  
 bird's-foot, seed production, 334.  
 bud weevil, studies, 858.  
 crimson, breeding experiments, Mich., 334.  
 crimson, seed production, U.S.D.A., 135.  
 diseases and control in Egypt, 745.  
 diseases, studies, Ky., 446.  
 eelworm disease, notes, Idaho, 844.  
 Egyptian. (See Berseem.)  
 germination and growth, effect of sulfur, 423.  
 hard-coated seed, growing experiments, 831.  
 hay, feeding value, Ind., 169.  
 hay, United States grades for, U.S.D.A., 92.  
 inoculation, tests, 797.  
 leaf weevil, life history, 355.  
 leaf weevil, notes, Idaho, 851; Kans., 452.  
 mixed hay, United States grades for, U.S.D.A., 92.  
 mosaic disease, relation to temperature, 350.  
 powdery mildew, differences in susceptibility to, 546.  
 red, American strains, susceptibility to mildew, Tenn., 528.  
 red, culture experiments, N.J., 732.  
 red, hard seeds and broken seedlings in, 831.  
 red, origin, 737.  
 red, seed production, 334.  
 red, source-of-seed tests, Ohio, 733.  
 red, strains and nationalities, productivity, 135.  
 red, variety tests, Idaho, 828.  
 rotation experiments, N.Y.Cornell, 526.  
 seed from southern France, characteristics, 733.  
 seed, Russian, Carophyllaceae in, 639.  
 seed worm, studies, N.Y.Cornell, 255.  
 sitones, notes, Kans., 452.  
 spray irrigation for, 287.  
 subterranean, behavior, Fla., 224.  
 subterranean, notes, 134.  
 sweet. (See Sweet clover.)  
 v. alfalfa hay for milk production, Pa., 275.  
 white, treatise, 832.
- Clovers, nomenclature, 227.
- Club work. (See Boys' clubs and Girls' clubs.)
- Cocccae, studies, N.Y.State, 519.
- Coccidae—  
 in Pusa collection, list, 155.  
 south Indian, notes, 155.
- Coccidencyrus foutiersi* n.sp., description, 663.
- Coccidiosis—  
 of poultry, account, Ill., 86.  
 studies, Calif., 82.

- Coccinellids of South India, 154.  
*Coccophagus* spp., notes, 557.  
*Coccus pseudomagnolarum*, parasites of, 556.
- Cockerels—  
 immature, fattening, 876.  
 standardbred, improving flocks with, Ohio, 474.  
 v. capons, value, Can., 570.
- Cocklebur as poisonous plants. U.S.D.A., 178.
- Cockroach—  
 American, notes, 156.  
 Australian, notes, 361.
- Cocoa, fumigated, hydrocyanic acid absorbed by, U.S.D.A., 561.  
 Cocoa meal, feeding value, Vt., 677.
- Coconut—  
 bud rot in Porto Rico, 151.  
 industry in Indo-China, 540.  
 industry in Portuguese India, 540.  
 leaf moth, notes, 853.  
 oil, Hanus iodine values, 205.  
 oil, sulfuric index, 411.  
 palm, replacement of terminal bud, 328.  
 press cake, vitamin A in, 65.  
 scale, notes, 853.
- Coconuts—  
 culture experiments, Guam, 232.  
 insects affecting, 356, 853.  
 nut fall of, 151.
- Cod liver oil—  
 chemistry of, 263.  
 concentrate, clinical experience, 263.  
 durability of vitamin A in, 462.  
 feeding to cows, effect on milk, 774.  
 hardened, potency of vitamin A in, 461.  
 manufacture and by-products, 805.  
 value to laying hens, 273.  
 vitamin A in, 65.
- Codfish—  
 insulin from, 804.  
 specific dynamic action, 665.
- Codling moth—  
 control, 554.  
 habits, N.Y.State, 552.  
 in walnuts, control, Calif., 56.  
 in Yakima Valley, life history, U.S. D.A., 456.  
 life history notes, Calif., 57.  
 notes, Mich., 355.  
 studies, N.J., 750.
- Coffee—  
 black rot, hibernating stage, 544, 545.  
 borer, notes, 554.  
 bug egg parasites, sex ratio, 333.  
 dieback, notes, 545.  
 diseases, notes, 653.  
 investigations, 642.  
 Liberian, fungus affecting, 151.  
 new disease of, 249.
- Colchicum culture and botanical characters, handbook, 344.
- Cold storage—  
 holdings, U.S.D.A., 693.  
 on the farm, 889.  
 plants in Australia and New Zealand, 890.
- Collargol for destruction of *Bacterium abortus*, Mich., 382.
- Colleges. (See Agricultural colleges.)
- Collembola from Italy, list, 753.
- Colletotrichum*—  
*fulcatum*, notes, La., 548.  
*lindemuthiarum* spore production, effect of lactic acid, 346.  
 sp., notes, 151.  
*trifolii*, studies, Miss., 242.
- Colloid chemistry—  
 applications, 609.  
 of milk and dairy products, U.S.D.A., 503.  
 treatise, 609.
- Colloidal—  
 materials for mixing oils and hard water, U.S.D.A., 441.  
 problems of milk and dairy products, 10.
- Colloids—  
 decomposition of neutral salts by, 509.  
 removal, effect on soil properties, 419.  
 soil, binding power, 211.  
 soil, composition, U.S.D.A., 508.  
 soil, estimating, 619.  
 soil, heat of wetting, 418.
- Colocasia* spp., new food plants for the South, U.S.D.A., 340.
- Colonization—  
 in Argentina, need for, 394.  
 in Chile, 91.  
 on farms in western Australia, 91.
- Colopha eragrostidis*, parasite of, N.Y. Cornell, 360.
- Color—  
 blindness, incidence in, 524.  
 chemical constitution, treatise, 201.  
 effect on internal temperature of plants, 139.  
 indicators for blight disinfectants, 746.  
 inheritance and pattern characters of poultry, 430.  
 inheritance in beans, Me., 430, 431.  
 inheritance in fowls, 128.  
 inheritance in potatoes, 32.  
 of hydrangea blossoms, studies, 143.  
 science of, treatise, 201.  
 tests for vitamins, 313.
- Colorado—  
 College, notes, 300.  
 River problems, discussion, Ariz., 685.
- Colostrum—  
 antibody transmission in, Mo., 679.  
 mineral constituents, U.S.D.A., 576.
- Colts, feeding, method of equivalent feeds, 874.
- Commercial statistics of Japan, 793.
- Community organization for country life program, 194.

Complement, variation, during scurvy, 264.

Concrete—

- blocks, cinder, in piers, tests, 183.
- crushed brick aggregate for, 585.
- drain tile, curing conditions, 87.
- line posts, construction, Mich., 488.
- nonuniformity, causes, U.S.D.A., 184.
- pavement tests, methods, 87.
- pavements, design, U.S.D.A., 184.
- pavements, reinforced, survey, U.S. D.A., 783.
- popular mechanics handbook, 585.
- quality, effect of damp sand curing, 87.
- strength in tension and compression, 687.

Condenser for distilling oils of wide boiling range, 11.

Coniferous—

- nursery stock, shading, 643.
- timber soils, studies, Idaho, 816.

Conifers—

- hardy, treatise, 841.
- northeastern, seed destruction by squirrels, 240.
- resin formation in, 427.
- transpiration studies, 345.

*Coniothyrium diplodiella*—

- notes, 549.
- studies, 849.

Connecticut—

- Dairymen's Association, proceedings, 676.
- State Station, notes, 398.

*Conotrachelus anaglypticus*, studies, 157.

*Contarinia johnsoni*. (See Grape-blossom midge.)

Cooperation. (See Agricultural cooperation.)

Cooperative—

- movement in Russia, treatise, 95.
- societies in Punjab, 790.

Copper—

- absorption from artificially colored vegetables, 259.
- acetates as non-staining sprays for grapes, 549.
- and lime sulfur sprays, anticryptogamic values, 746.
- carbonate duster, miniature, 746.
- carbonate for smut control, Kans., 445.
- carbonate for wheat stinking smut control, Kans., 50; Mich., 50.
- content of apricots, Calif., 62.
- indispensability in fungicides, 148.
- salts value in viticulture, 746.
- sprays, modification of leaf-surface conditions by, 746.
- sulfate, anthelmintic value, Ohio, 84.
- sulfate treatment for stomach worms, Ohio, 483.
- toxicity, 746.

Copperas. (See Iron sulfate.)

Corn—

- and hog prices, forecasting, 892.
- and soy beans, culture, Mo., 436.
- as sugar crop in Russia, 736.
- Belt Meat Producers' Association, proceedings, 168.
- borer, European, control, 855.
- borer, European, in Ontario, 355.
- borer, European, migratory habits, 456.
- borer, European, spread in Ohio, Ohio, 756.

(See also Insects.)

*Entomophthora* sp., notes, 755.

Enzyme actions, chemistry, treatise, 409.

*Epilachna corrupta*. (See Bean beetle, Mexican.)

Epithelioma, contagious, relation to faulty nutrition in pigeons, 68.

*Epitrix*—

- cucumcris*. (See Potato flea-beetle.)
- parvula*. (See Tobacco flea-beetle.)

*Epiurus indagator*, notes, U.S.D.A., 456.

Equidae, nematode parasites of, 385.

Equines, blood of, 82.

*Eriochloa punctata*, striped grass looper affecting, 61.

*Erionota thrax*, notes, 361.

*Eriophyes*—

- oleivorus*. (See Citrus rust mite.)
- pyri*. (See Pear leaf blister-mite.)

*Eriosoma lanigerum*. (See Apple aphid, woolly.)

## Erysiphaceae—

- notes, 645.
- overwintering, 746.
- use of soda against, 646.

*Erythrina lithosperma* as green manure and cover crop, 732.

Erythrodextrin in waxy corn, 329.

*Erythroneura*—

- spp. on grapes, Ky., 753.
- tricincta*. (See Leafhopper, three-banded.)

Esca, paper on, 746.

Estate accountancy, 491.

Etherization, effect on renewal of growth, 45.

## Ethyl—

- acetate-carbon tetrachloride mixture as fumigant, 662.
- alcohol, effect on carbon dioxide production by radishes, 626.
- alcohol, reaction of protoplasm to, 215.

## Ethylene—

- dichloride, anthelmintic value, 776.
- effect on respiration of lemons, 626.
- gas, use for blanching celery, 640.
- glycol, properties and uses, 11.

*Eublemma amabilis*, notes, 155.

## Eucalyptus—

- growth in California plantations, Calif., 742.
- of Western Australia, key, 742.

*Euctheola rugiceps*, studies, U.S.D.A., 256.

Eugenics and genetics, treatise, 822.

*Eupelmus allynii*, notes, Iowa, 358.

*Euphalcrus citri*, parasite of, 154.

Euphorbia, notes, 582.

*Euplectrus* sp., notes, 361.

*Eurymus eurytheme*. (See Alfalfa caterpillar.)

*Euryphlepsia cocos* on coconut palms, 854.

*Eurytoma chrysothrix* on bamboo, 859.

*Eutettix tenella*. (See Beet leafhopper.)

*Euthrips tritici*. (See Flower thrips.)

*Eutreta xanthochaeta*, notes, 356.

## Ewes—

- breeding, wintering, Mont., 72.
- Merino, cross-breeding, Pa., 270.
- (See also Sheep.)

*Faascus* sp., notes, 352.

## Experiment station—

- bulletins, list, U.S.D.A., 97.
- new, in Peru, 900.

## Experiment stations—

- list of workers in agriculture, U.S.D.A., 95.
- work and expenditures, U.S.D.A., 496.
- (See also Alabama, Arizona, etc.)

Explosives, velocity of detonation, 89.

Export trade, financing, 493.

Extensimeter, description, 12.

Extension work. (See Agricultural extension.)

Fallow, methods of handling, U.S.D.A., 828.

Fallowing experiments, Kans., 434; U.S.D.A., 527.

## Farm—

- account book entries, 1769–1782, 789.
- accounting, 788, 895.
- animals. (See Livestock and Animals.)
- building, styles, effect of prices, 491.
- buildings, utilizing poles and timber in, 887.
- bureau movement, sociological implications, 790.
- credit. (See Agricultural credit.)
- drainage, methods of survey and design, Minn., 584.

## Farm—Continued.

drainage systems, construction, Minn., 585.

economics, management and distribution, textbook, 197.

families, colored, cost of living, U.S.D.A., 791.

homes and families, survey, Iowa, 694. labor. (See Agricultural labor.)

management, Mont., 491.

mechanics, Mich., 386.

## organization—

and cost of production, Kans., 489; U.S.D.A., 190.

and costs on cotton farms, S.C., 588.

and management, Ill., 490; Ky., 893; W.Va., 589.

and management in Indiana, U.S.D.A., 290.

in Kansas, U.S.D.A., 588.

in Minnesota, U.S.D.A., 490.

plumbing, U.S.D.A., 389.

power survey, national, summary, 487.

products. (See Agricultural products.)

tenancy. (See Land tenancy and Land tenure.)

## Farmer—

and agriculture, 896.

reclamation, financial troubles, 182.

relation to taxation and national indebtedness, 393.

## Farmers—

bankruptcy among, causes, 393.

cooperative business organizations, development. U.S.D.A., 592.

difficulties and complaints, 182.

## Farming—

as business, treatise, 197.

dairy. (See Dairy farming.)

economic study, N.Dak., 291.

partnerships in Tuscany, 690.

(See also Agriculture.)

## Farms—

business analysis, Ky., 489.

developing, on South Dakota ranges, 390.

eighty-acre, in Indiana, income from, U.S.D.A., 91.

Fasting and undernutrition, treatise, 564.

Fat excretion, 665.

Fat, extracting from cacao products, 713.

Fat globules, agglutination, 278.

Fat production in animals, technique for study, 109.

## Fats—

autoxidation, 10.

import requirements in Germany, U.S. D.A., 297.

origin and significance, 109.

separation of unsaponifiable matter from, 712.

(See also Oils.)

Fat-soluble A. (See Vitamin A.)

## Fatty—

acid series, insecticidal properties, 655.

acids, odd v. even carbon, catabolism, 666.

Fauna of France, 154.

Feces, lipoids in, source, 665.

Feeding device, new, for experimental rats, 261.

Feeding experiments. (See Cows, Pigs, etc.)

## Feeding stuffs—

composition, Calif., 70.

home-grown, for fattening hogs, 370.

in New York State, analyses, 766.

inspection and analyses, Mass., 866; Me., 268; N.H., 567; N.J., 167; Vt., 167, 671.

inspection and analysis in North Carolina, 670.

inspection and analysis in Pennsylvania, 866.

new, for dairy cows, U.S.D.A., 78.

official samples, composition, N.Y. State, 71.

succulent, feeding value, Can., 870.

valuation, 166.

wet v. dry, for pigs, 769.

Fence posts, treatment, Mont., 485.

*Fenusia pumila* on birch, 454.

## Fermentation—

biochemical aspects, 624.

industries, treatise, 315.

Ferments. (See Enzyme.)

Ferric chloride, effect on phosphorus recovery from soils, 817.

Ferric glycerophosphate v. soluble ferric phosphate for soy beans, N.J., 725.

Ferrous sulfate, anthelmintic value, 776.

(See also Iron.)

Fertilization of crops, broadcast and row, 817.

## Fertilizer—

experiments, 322; Calif., 24; Del., 119; N.Y.Cornell, 526.

experiments at Pusa, 120.

experiments at Wellcome Tropical Research Laboratories, 120.

experiments in Sweden, 621.

experiments with fine waste mixed fertilizers, 121.

(See also special crops.)

handbook, American, 123.

instruction, treatise, 816.

materials from potassic rock, 514.

mixtures, computation, U.S.D.A., 324.

requirements of soils. (See Soils.)

## Fertilizers—

and Feeding Stuffs Act, report, 767.

and use, 211.

composition and cost, changes in, N.Y. State, 819.

composition and prices in 1923, N.Y. State, 24.

for crops in Pennsylvania, 621.

from superphosphate treated with ammonia, 514.

home mixing, 215.

- Fertilizers—Continued.  
 inspection and analyses, Conn.State, 623; Me., 623; N.H., 724; Oreg., 515; S.C., 24; Tex., 515.  
 inspection and analyses—  
   in Kansas, 819.  
   in Maryland, 123.  
   in North Carolina, 215, 724.

- in Uganda, 241, 843.
- in United Provinces, 345.
- practical, treatise, 345.
- survey of Illinois, 843.
- textbook, 196.

## Forests—

- California coniferous, succession in, as affected by fire, 144.
- mapping, use of airplane in, 345.
- national, accessions and changes in, 842.
- national, of Arizona, U.S.D.A., 444.
- of the world, statistics, 841.
- of tropical America, treatise, 345.

*Forficula auricularia*. (See Earwig, European.)

## Formaldehyde—

- and serum proteins, reaction between, 801.
- for potato seed treatment, Mont., 447.
- hot, for potato seed treatment, Kans., 445.

## Foulbrood, American—

- transmission by the moth caterpillars, 758.
- treatment, 859.

## Foundations, abutments, and footings, treatise, 887.

## Fowl cholera—

- account, Ill., 86.
- studies, Calif., 82.
- summary, N.J., 181.

## Fowl—

- diphtheria, cause, prevention, and cure, 886.  
 pest, European, in United States, 782.  
 tick, longevity, 258.  
 typhoid, account, Ill., 86.  
 typhoid, bacteriological study, 782.  
 (*See also* Chickens, Hens, Poultry, etc.)  
 Foxtail bacterial disease, notes, Ark., 148.  
*Frankliniella tritici bispinosa*, control, Fla., 250.  
 Freemartins, development of genitalia, 130.  
 Fresnoes, cost of grading with, U.S.D.A., 184.  
 Frit fly, damage to oats, 856.  
 Frog as host of *Echinostomum conoidcum*, 584.

## Fruit—

- bud formation, experiment station investigations on, U.S.D.A., 442.  
 crops, winter injury, Wash. Col., 845.  
 cuttings, rooting capacity in greenhouse, Calif., 40.  
 farms, child labor on, 591.  
 flies, Ethiopian, keys, 855.  
 fly, Mediterranean, in Australia, 757.  
 fly, Mediterranean, notes, 853.  
 fly, Mediterranean, winter trapping, 757.  
 juices, carbonated beverages from, Calif., 14.  
 maggot affecting cherries, West.Wash., 56.  
 pickers, seasonal, housing in Scotland, 191.  
 ripe, brown rot in, control, Calif., 49.  
 seeds, storage and germination, N.Y. State, 46, 442.  
 tree leaf-roller, control, Idaho, 851; Mont., 453; Utah, 752.  
 tree leaf-roller, studies, N.Y.State, 552.  
 trees, dying in Hudson Valley, N.Y. State, 543.  
 trees, fertilizer experiments, 140.  
 trees for Iowa, Iowa, 442.  
 trees in mild climate, rest period, 45.  
 trees, stone, fungi associated with die back in, 149.  
 trees, top-working, 640.  
 trees, variation in yield, Me., 428.  
 trees, winter injury and sour sap disease, Calif., 49.

## Fruits—

- American, treatise, 342.  
 citrus. (*See* Citrus fruits.)  
 cold storage, 539.  
 cooperative marketing in United States, 93.  
 culture, Alaska, 536; Can., 341, 639.  
 dried, fumigated, hydrocyanic acid absorbed by, U.S.D.A., 561.  
 dried, packaging, Calif., 14.  
 dropping, factors affecting, Del., 822.  
 drying, Calif., 14.  
 new and noteworthy, N.Y.State, 46.

## Fruits—Continued.

- of Queensland, marketing, 394.  
 phenological data, N.J., 738.  
 pollination studies, 342.  
 preservation by freezing, Calif., 15.  
 production and prices in Canada, 640.  
 small, pollination studies, 342.  
 small, production, economic study, Wash.Col., 894.  
 spray schedules for, Mo., 236.  
 standard containers for, U.S.D.A., 296.  
 stone, diseases, U.S.D.A., 653.  
 stone, unreported diseases of, 248.  
 use in candy, Calif., 14.  
 (*See also* Orchards, Apples, Peaches, etc.)  
 Fuels, liquid, Government specifications, 784.  
 Fumariaceae, evolution in, 330.  
 Fumigation v. spraying for citrus scale insects, Calif., 60.  
 Fungi—  
 apical growth of hyphae, 216.  
 differentiation, Mich., 346.  
 growth on culture media, 216.  
 in wood, effect of methods of seasoning, U.S.D.A., 249.  
 injurious to cultivated plants in Turin, 148.  
 parasitic, biology, 746.  
 phytopathogenic, action at a distance, 746.  
 wood-destroying, resistance to moist and dry heat, 55.  
 wood-destroying, staining hyphae, 353.  
 Fungicidal powders for wheat smut, 148.  
 Fungicide and insecticide guarantee in Canada, 253.  
 Fungicides—  
 analyses, Conn.State, 537.  
 copper in, indispensability, 148.  
 on apple trees, tests, 848.  
 (*See also* Sprays and specific kinds.)  
 Fungus—  
 cultures, central bureau for, 645, 746.  
 diseases of plants in Egypt, 745.  
 spores, germinating and staining, 447.  
 Fur-bearing animals, laws, U.S.D.A., 55.  
 Furfural, determination, 804.  
 Fusarium—  
*cepae* on onions, 348.  
*lini*, notes, Minn., 245.  
*lycopersici*—  
 control, Ark., 247.  
 notes, 351.  
 strains, Kans., 446.  
*moniliforme*—  
 ascigerous stage and synonymy, 448.  
 notes, Ill., 245.  
 on seed corn, Kans., 445.  
 studies, Tenn., 544.  
*oryzae*  $\alpha$  and  $\beta$ , description, 747.  
*oxysporum*, notes, Pa., 243.  
 sp. on wheat, 747.  
 spp. causing wilt, studies, Tenn., 544.

- Fusarium*—Continued.  
 spp., notes, Minn., 648; N.J., 744.  
 spp. on sweet potatoes, N.J., 744.  
*Fusarium* wilt, notes, 549.  
*Fusicladium*—  
*dendriticum*. (See Apple scab.)  
*effusum*, notes, 152.  
 Galerucella, systematic account and new species, Me., 660.  
 Gambo hemp, studies, 634.  
*Gambusia holbrooki*, spermatogenesis, 433.  
 Game laws for 1924–25, U.S.D.A., 55.  
 Game, protection, directory of officials for, U.S.D.A., 452.  
 Garbage, sifted, fertilizing value, 121.  
 Garden springtail as crop pest, 852.  
 Gardening—  
 handbook, 640.  
 in California, treatise, 344.  
 treatise, 138, 341, 540, 642, 741.  
 Gardens—  
 of South Africa, treatise, 344.  
 plans and sketches, treatise, 540.  
 (See also School gardens.)  
 Gas—  
 analysis apparatus, 615.  
 engines. (See Engines, internal-combustion.)  
 gangrene and blackleg in cattle, 780.  
 house waste, fertilizing value, 819.  
 Gases absorbed on charcoal, insecticidal value, Tenn., 555.  
 Gasoline tests, effect on carburetor adjustment, 487.  
 Gelatin, specific dynamic action, 665.  
 Genetics and eugenics, treatise, 822.  
 (See also Heredity and Hybridization.)  
*Geocoris pallens* affecting beet leafhopper, Calif., 58.  
 Geography—  
 economic, treatise, 598.  
 industrial, textbook, 899.  
 political, New World problems in, textbook, 196.  
 Georgia—  
 Coastal Plain Station, reports, 299.  
 College, notes, 697.  
 Geotropic excitation in roots, conduction, 217.  
 Geranium stem rot, notes, 749.  
 Germ cells in potatoes, formation and degeneration, 126.  
 German scientists, American tour, 500.  
 Germination—  
 chemical aspects, 624.  
 physiological aspects, 516.  
 tests, duplicate, variations, 737.  
 tests, laboratory and field, 737.  
*Gibberella*—  
*moniliformis* n.comb., description, 448.  
*saubinetii*, notes, Del., 844; Ill., 245; Minn., 648.  
*saubinetii* on seed corn, Kans., 445.  
 Gipsy moth—  
 control in New Jersey, 557.  
 spread and winds, 355.  
 Girls—  
 clubs, organization and programs, 795.  
 4-H clubs in Missouri, 795.  
 Gizzard worms in poultry, Kans., 481.  
*Gladiolus*—  
 culture, Alaska, 536.  
 leaf and corm disease, 654.  
 Gliadin, specific dynamic action, 665.  
*Gliricidia maculata* as green manure and cover crop, 732.  
*Gliricicola porcelli*, control, Calif., 59.  
*Gloeosporium musarum*, studies, 653.  
*Glomerella*—  
*cingulata*, notes, 549.  
 sp., notes, 151.  
 Glow worm, Indian, habits and life history, 552.  
 Glucokinase from yeast, 765.  
 Glucose—  
 equivalent of sugars, 806.  
 fermentation as affected by insulin, 110.  
 fermentation by *Bacillus coli*, effect of insulin, 611.  
 fermentation, effect of insulin, 203.  
 Glucosides and carbohydrates, treatise, 108.  
 Glutathione production in bacterial cultures, 611.  
 Gluten—  
 determination in wheat flour, factors affecting, 112.  
 quality, relation to lipoids, 202.  
 Glutenin imbibitional properties, determination, 13.  
 Glycerin, use in diabetic diets, 464.  
 Glycerol—  
 identification, 614.  
 manufacture from sugar, fermentation processes in, 315.  
 Glyceryl margarate, including in diabetic diet, 766.  
 Glymol, coloring matter for, Mich., 314, 796.  
*Glyphina eragrostidis*, parasite of, N.Y. Cornell, 360.  
 Goats, Angora, weights of fleeces, Tex., 569.  
 Goat's milk, Jack cheese from, Calif., 80.  
 Golter—  
 in Michigan, survey and prevention, 265.  
 prevention and cure, 366.  
 relation to iodine in food and drink, 68.  
 Goldenrod leaf-beetle, notes, Me., 661.  
*Gonatopus contortulus* affecting beet leafhopper, Calif., 58.  
*Goniocotes gigas*, control, Calif., 59.  
 Goose septicaemia, outbreak, 684.  
 Gooseberries—  
 culture and relation to white-pine blister rust, U.S.D.A., 343.  
 fertilizer experiments, 141.  
 notes, Alaska, 536.  
 varieties, 237.  
 Gooseberry seeds, germination, N.Y. Cornell, 46.

- Gouda cheese making, 177.  
 Gousiekte in sheep, 84.  
 Gout, effect on calcium in blood, 465.  
 "Gouwziekte" veld, vegetation and flora, 82.
- Gracillaria*—  
*azaleella*, studies, 660.  
 spp., notes, 361.  
*syringella*, notes, Wash.Col., 852.
- Grain—  
 airtight storage, 155.  
 cooperative marketing in United States, 93.  
 dressed, statistical analysis of yield, 526.  
 fall seeded, spring fertilization, Mich., 796.  
 fertilizer experiments, Del., 119.  
 for laying hens, comparison, Mont., 476.  
 futures, statistical information, U.S. D.A., 393.  
 growing in Great Britain, early estimates, 194.  
 heating caused by insects, 555.  
 manuring experiments, 722.  
 mixtures for cows, tests, Kans., 477.  
 mixtures for laying hens, Ky., 475.  
 newly threshed, dormancy, 737.  
 nutritive and vitamin values, as affected by manure, 212.  
 small, drill calibration, relation to stand and yield, 828.  
 small, hay production, Mont., 435.  
 stubble, spring v. fall plowing, U.S. D.A., 828.  
 testing in Montana, Mont., 638.  
 trade documents, 899.  
 weevils, fumigation against, U.S.D.A., 661.  
 winter, fertilizer experiments, 723.  
 yield, relation to seed size, 731.  
 yields and rainfall in Sicily, 16.  
 (See also Cereals and Oats, Rye, Wheat, etc.)
- Granary weevil, resistance to high and low temperatures, 458.  
 Granite weathering, 323.
- Grape—  
 anthracnose in Florida, 549.  
 berry moth, notes, Mich., 354.  
 bitter rot, notes, 549.  
 black rot in Florida, 549.  
 black rot, notes, Del., 844.  
 blossom midge, notes, Mich., 355.  
 buds, microscopic studies, Calif., 43.  
 downy mildew, notes, 746.  
 leafhopper, control, 355, 658; Calif., 56; N.Y.State, 533.  
 leafhopper, studies, Ky., 753.  
 mildew control in France, 749.  
 mildew, notes, 544.  
 phylloxera and viticulture, 756.  
 pigments, chemistry, 610, 803.  
 powdery mildew, control, N.Y.State, 553.  
 rootworm, control, N.Y.State, 558.
- Grape—Continued.  
 white rot, notes, 549.  
 white rot, studies, 849.
- Grapefruit—  
 blue mold rot, control, 451.  
 canning, Calif., 14.  
 melanose, control, Fla., 241.  
 Phomopsis from Isle of Pines, 352.  
 transportation from Porto Rico, U.S. D.A., 539.
- Grapes—  
 Almeria, production in Spain, 343.  
 American, grafting, N.Y.State, 538.  
 changes during ripening, 641.  
 culture in Australia, 641.  
 culture in English greenhouses, 341.  
 culture in Yugoslavia, 142.  
 culture, treatise, 641.  
 drying, Calif., 14.  
 fertilizer experiments, Mich., 740; N.Y.State, 537.  
 grafted, value, N.Y.State, 443.  
 Illinois, pruning and training, 641.  
 improvement in Prussia, 740.  
 leaf and fruit color, correlation, N.Y. State, 729.  
 notes, N.Y.State, 46.  
 preservation by freezing, Calif., 15.  
 pruning, Calif., 43.  
 pruning, Wash.Col., 837.  
 varieties new for California, 343.  
 variety tests, S.C., 537.
- Grapevines, dusting, Calif., 56.
- Grass—  
 gall midges, notes, 155.  
 looper, striped, studies, 61.  
 mixed hay, United States grades for, U.S.D.A., 92.  
 rotation experiments, N.Y.Cornell, 526.  
 seed production, 334.  
 seeds, longevity, 340.
- Grasses—  
 composition, Wyo., 368.  
 culture experiments, Calif., 33; Ga. Coastal Plain, 225; Guam, 226.  
 forage, imported into Porto Rico, 530.  
 nomenclature, 227.  
 of New South Wales, 830.  
 of Pennsylvania, manual, 732.  
 pasture and lawn, studies, Fla., 224.  
 seasonal productivity, 133.  
 Septoria diseases, 448.  
 variety tests, Idaho, 828; Kans., 433.  
 wild, rôle in corn injury from sugar cane borer, 61.  
 (See also Meadows, Pastures, and specific kinds.)
- Grasshopper—  
 clear-winged, studies, Minn., 556.  
 long-horned, on coconut palms, 854.
- Grasshoppers—  
 notes, Mich., 355.  
 synopsis, Utah, 454.
- Grassland in peat soil, Chilean nitrate for, 513.  
 (See also Grasses, Meadows, and Pastures.)

- Gravel for roads. (*See Road materials.*)  
 Gravimetric microchemical technique, notes, 612.
- Grazing—  
 areas, improvement in India, 830.  
 cost in England, 391.  
 of cattle and horses in pine plantations, 842.  
 (*See also Range.*)
- Green manure—  
 crops, legume and nonlegume, comparison, N.J., 721.  
 crops, studies, Md., 420.  
 methods of handling, U.S.D.A., 828.  
 value, 121.  
 value at different stages of growth and decomposition, 721.
- Green manuring for potato scab control, 51.
- Greenhouse—  
 crop yields, analysis, 233.  
 insects, summary, Mich., 252.  
 leaf-tyer, on celery, Fla., 251.  
 leaf-tyer, studies, 659.  
 soil, formaldehyde treatment, 233.
- Greenhouses, carbon dioxide distribution in, 234, 327.
- Grosbeaks, food habits, U.S.D.A., 354.
- Grouse locusts, inheritance in, studies, Kans., 428.
- Growth and nutrition of children, photographic method of study, 261.
- Growth, studies, 362.
- Growth-promoting accessory. (*See Vitamins*)
- Guam Station, report, 299.
- Guanidinium salts, preparation, 212.
- Guanylurea sulfate—  
 action on plant growth, 122.  
 fertilizing value, 422.
- Guignardia bidwellii*, notes, 549.
- Guinea pigs—  
 as diagnostic reagent for tuberculosis, 632.  
 immunization against abortion, Mich., 481.  
 inheritance of characters in, Kans., 427.  
 lowered birth rate in winter, cause, 632.
- Gutta percha trees, studies, 145.
- Gymnoconia interstitialis*, uninucleated acidiospores in, 451.
- Gypsum—  
 brands and composition, Oreg., 515.  
 effect on acid soils, 621.  
 effect on potassium availability, Ky., 421.  
 fertilizing value, 120.  
 use, 121.
- Gyropus ovalis*, control, Calif., 59.
- Habetia defoliaria* n.sp., description, 854.
- Habroneum* spp. parasitizing equines, 85.
- Hadronotus antestiae*, sex ratios, 333.
- Haemonchus contortus* in cattle and sheep, 280.
- Halticus citri* on celery, Fla., 251.
- Hampton Institute—  
 agricultural training in, 298.  
 notes, 100.
- Haploa lecontei*, notes, Ky., 453.
- Hardwood cuttings, propagation, 837.
- Hardwoods, mixed, growth relation to thinning, 841.
- Hare, European, in North America, 551.
- Harlequin bug, control, Ky., 453.
- Harvard Biological Institute in Cuba, 344.
- Hay—  
 and silage, proportions for long yearling steers, Wash.Col., 767.  
 of *Hyparrhenia rufa*, value, 34.  
 replacement by other feeds, 275.  
 (*See also Meadows, Grasses, and Alfalfa, Timothy, etc.*)
- Haymaking, artificial, studies, 688.
- Health—  
 demonstration and nutrition, U.S. D.A., 562.  
 public, and diet, symposium, 461.  
 relation to *melitensis-abortus* group, U.S.D.A., 580.
- Heart, seasonal changes in weight, 669.
- Heat—  
 effect on botulinus toxin, 464.  
 of wetting for estimating colloidal material in soils, 619.  
 of wetting of soil colloids, 418.  
 production in cattle, ratio of carbon dioxide to, 168.  
 resistance of bacterial spores, studies, 113.  
 transmission through building materials, 288.  
 (*See also Temperature.*)
- Heating plants, small, oil burners for, 489.
- Hedobia pubescens* on Loranthaceae, 554.
- Heifers—  
 cost of raising, N.Y.Cornell, 590.  
 development, relation to feeding and age of calving, Kans., 276.  
 protein requirements, Mo., 373.  
 (*See also Cows.*)
- Heliophila unipuncta*. (*See Army worm.*)
- Heliothis obsoleta*. (*See Bollworm and Corn earworm.*)
- Helminthosporium*—  
*pedicellatum* n.sp., description, 649.  
*sativum*, resistance of barley to, Minn., 244.  
 spp., notes, 649.  
 spp. on barley, 347.
- Helminthosporium* root rot of wheat, 347.
- Hemerophila pariana*, present status, 355.
- Hemiptera from Italy, list, 753.
- Hemiteles areator*, biological notes, 561.
- Hemlock—  
 growth and silvicultural requirements, 741.  
 western, habits and characteristics, 345.
- Hemoglobin regeneration in anemia, 260.

- Hemp—  
 breeding experiments, Mich., 334.  
 fall seeding experiments, 633.  
 irrigation experiments, Calif., 33.  
 sex in, effect of environment, 525.  
 yields and agronomic data, Can., 733.
- Hen, crowing, genitalia of, 333.
- Hen ovary, action of follicular hormone, 730.
- Henequen fiber, production in Yucatan, U.S.D.A., 337.

- studies, textbook, 696.

## House—

- flies, bacterial disease of, 558.
- painting, paper hanging, etc., treatise, 689.

*Howardia zamiae*, parasite of, 663.

## Humin formation in protein hydrolysis, 108.

## Humus, properties, 121.

## Hurricanes, West Indian, and other tropical cyclones, U.S.D.A., 416.

## Hybridization, inheritance in, 29.

(See also Plant breeding and specific animals and plants.)

*Hydnum septentrionale*, parasite of trees, 646.

## Hydrangea, soil acidity studies, N.J., 738.

## Hydrangeas, color control in, 143.

## Hydrochloric acid, effect on botulinus spores, 165.

## Hydrocyanic acid—

- absorption and retention by fumigated food products, U.S.D.A., 561.
- gas for fumigation of chick-peas in warehouses, 359.
- gas treatment of nursery stock, status, 554.
- liquid, fumigation costs, 356.

## Hydrodynamics, treatise, 584.

## Hydroelectric power—

- in Washington, 182.
- systems of Italy, 183.

## Hydrogen cyanide, fumigation for pear psylla, N.Y.State, 854.

## Hydrogen-ion concentration—

- determinations, standardization of methods, 111.
- in soil, measurement, 204.

## Hydrophobia. (See Rabies.)

*Hylobius perforatus* on olives, 662.

## Hymenoptera—

- new parasitic, 859.
- parasitic, from Java and Sumatra, 361.

*Hyparrhenia rufa*, hay from, value, 34.*Hypera punctata*, life history, 355.*Hyphantria cunea*. (See Webworm, fall.)

## Hyphomycosis of horses, studies, 781.

*Hypoderma conoideum*, frog as intermediate host of, 584.

## Hypoderma larvae destruction, 359.

## Hypoglycemia-producing principle in vegetables, isolation, 667.

## Hypophyseal substance injection, effect on ovulation, 631.

## Hypophysis as affected by castration in rats, 480.

## Ice cream—

- bacterial content, 880.
- colloidal chemistry of, U.S.D.A., 503.
- formulas and standardization, Nebr., 580.
- making on the farm, Mich., 775.
- manufacture, effect of sugar in, Mo., 679.
- manufacture problems, Pa., 279.
- overrun, Idaho, 880.
- plant and manufacture, treatise, 377.
- problems, papers on, U.S.D.A., 574.
- quality, factors affecting, Ill., 479.
- quality, measuring, 775.
- sandiness in, Ind., 880.
- sugar substitutes in, Mich., 377.
- viscosity studies, Kans., 479.
- yield, factors affecting, Ind., 880.

## Ice houses, planning and construction, 890.

## Ice making in Australia and New Zealand, 890.

## Icterohemoglobinuria in cattle, studies, Calif., 81.

## Idaho Station—

- notes, 398.
- publications available, 899.
- report, 899.

*Idiocerus* spp.—

- control, 554.
- life history notes, 155.

*Illinoia pisi*. (See Pea aphid.)

## Illinois—

- Station, notes, 98, 498.
- Station, report, 496.
- University, notes, 98, 498, 697.

## Imhoff tanks, operating and resting, studies, N.J., 890.

## Immunity—

- local, studies, 580.
- permanent acquired, and tissue resistance, 680.
- symposium on, 882.

## Immunization. (See Anthrax, Hog cholera, Tuberculosis, etc.)

## Imperial Forestry Institute, courses of study at, 793.

## Inanition, biological and sociological aspects, treatise, 564.

## Inbreeding, human, for eight generations, 825.

## Incubating plant, electrically equipped, 586.

## Incubation—

- experiments, 676.
- problems, Utah, 773.
- studies, Kans., 474.
- Indian meal moth, control by fumigation, 359.

## Indiana Station, notes, 98, 599.

- Indicator, mixed, for carbonate-bicarbonate titrations, 203.
- Indigofera* spp. as green manure and cover crop, 732.
- Indole derivatives, condensation with aldehydes, 108.
- Industry, self-government in, U.S.D.A., 574.
- Infants—  
 atrophic, calcium and fat metabolism, 563.  
 feeding, 64.  
 feeding, review of literature for 1923, 362.  
 mineral metabolism, effect of heat treatment of milk, 764.  
 premature, growth studies, 362.  
 respiratory metabolism, 261.  
 (See also Children.)
- Influenza, equine. (See Pleuropneumonia.)

 and fungicide guarantee in Canada, 253.  
 law of Connecticut, Conn.State, 537.
- Insecticides—  
 analyses, Conn.State, 537.  
 desirable qualities, Wis., 56.  
 new, for Mexican bean beetle, 555.  
 nonarsenical, studies, 158.  
 toxicity, apparatus for testing, 356.  
 (See also Sprays and specific forms.)
- Insects—  
 affecting pecans, systematic and biological study, Miss., 252.  
 boring, detection, 662.  
 collecting in Panama, 852.  
 control in Pennsylvania, 646.  
 control, nicotine for, 535.  
 economic, control in Pennsylvania, 657.  
 economic, in Porto Rico, 453.  
 economic, in Uganda, 554.  
 forest. (See Forest insects.)  
 heating of grain by, effect of fumigation, 555.  
 injurious, and parasites from Italy, list, 753.  
 injurious in Canada, 355.  
 injurious in Madras, 154.  
 injurious in New Brunswick, 852.  
 injurious in Samoa, 356.  
 injurious to crops. (See special crops.)  
 instructions for killing, use in India, 155.  
 Mexican, in National Museum of Natural History, list, 154.  
 natural control, papers on, 355.  
 of Mandalay, 554.  
 of Quelpart Island, 554.  
 of south India, notes, 155.  
 on imported nursery stock, 554.  
 orchard. (See Orchard insects.)  
 personality of, 750.  
 resistance to fumigation, effect of temperature, Calif., 57.
- Insects—Continued.  
 scale. (See Scale insects.)  
 subterranean, control, Wash.Col., 851.  
 succession in decaying hickory, 753.  
 sucking, control, 646.  
 used as food in Burma, 155.
- Insulin—  
 and nature of diabetes, 464.  
 clinical assaying, 667.  
 convulsions in mice, effect of sugars, 567.  
 effect on carbohydrate and phosphorus metabolism, 766.  
 effect on glucose fermentation, 110.  
 effect on glucose-fermenting action of *Bacillus coli*, 611.  
 effect on lactic fermentation of glucose, 203.  
 effect on normal and diabetic blood, 765.  
 effect on phosphate excretion, 566.  
 from codfish, 804.  
 intradermal v. subcutaneous injection, 366.  
 lecture on, 265.  
 manufacture in England, 11.  
 studies, 611.  
 treatment of diabetes, 865.  
 use, 366.
- Intarvin—  
 fat, use in diabetes, 264.  
 food value, 264.  
 including in diabetic diet, 766.  
 metabolism, 666.  
 physiological behavior, 264.  
 use in diabetes, clinical results, 666.
- International—  
 Congress of Agriculture, arrangements for, 200.  
 dairy organizations, U.S.D.A., 574.  
 Institute of Agriculture, organizing dairy statistics, U.S.D.A., 596.  
 Rubber Conference, proceedings, 346.
- Intestinal—  
 autointoxication, theory, 364.  
 chemistry, 862.  
 contents, reaction, relation to diet and flora, 163.
- Iodine—  
 absorption of compounds, changes in, 517.  
 determination, 712.  
 determination in biological material, 613.  
 dietary source from dried kelp, 366.  
 gradient of permeability to, in seed coats, 29.  
 in food and drink, relation to goiter, 68.  
 in Michigan water supply, 265.  
 number of soy bean oil, 636.  
 numbers of cottonseed and coconut oils, 205.
- Ionolization, use of term, 29.

- Iowa—  
 College, notes, 98, 900.  
 Cooperative Livestock Shippers, proceedings, 168.  
 Station, notes, 98.
- Ips* spp., notes, Calif., 58.
- Iridomyrmex humilis*. (See Ants, Argentine.)
- Irises—  
 culture and hybridization, 741.  
 handbook, 143.
- Iron—  
 availability as affected by ammonium sulfate, 326.  
 availability for plants, factors affecting, 326.  
 availability for wheat, 123.  
 deficiency in pigs, 271.  
 determination in biological substances, 411.  
 solubility in culture solutions, effect of pH values, N.J., 725.  
 solubility in nutrient solutions, Calif., 27.  
 sulfate, anthelmintic value, Ohio, 84.  
 sulfate, effect on black alkali soil, Calif., 21.  
 supply in nutrient medium, 624.  
 (See also Ferric.)
- Irrigation—  
 and drainage water, comparison of composition, 486.  
 development of West under, 182.  
 experiments, Utah, 783.  
 (See also special crops.)  
 in Punjab, 886.  
 of lower Rio Grande Valley, Tex., 493.  
 projects, development, Senate hearing, 182.  
 spray, value, 287.  
 supplemental, for Willamette Valley, Oreg., 287.  
 water, measurement, Mont., 287.  
 water, saline, studies, Calif., 21.  
 works of Ajmer-Merwara District, report, 687.
- Isoptera from Italy, list, 753.
- Jalysus spinosus* affecting tomato, 60.
- Japanese beetle—  
 in Pennsylvania, 657.  
 insecticide for, 158.  
 notes, Mich., 458.
- Jaragua grass, behavior, Fla., 224.
- Jaundice, leptospiral, in dogs, 782.
- Jelly formation, action of calcium chloride on, 62.
- Journal bearings, behavior, effect of oiliness, 186.
- Kafir—  
 culture, U.S.D.A., 828.  
 inheritance studies, 32.  
 seed, ground, feeding value, Kans., 477.  
 v. corn for hogging down, Kans., 469.  
 varieties, U.S.D.A., 827.
- Kaloterms minor*, control on power-line poles, Calif., 59.
- Kansas—  
 College, notes, 99, 198, 498, 599, 697.  
 Station, notes, 198, 398, 697.  
 Station, report, 496.
- Kaoliang, varieties, U.S.D.A., 827.
- Kelp, dried, use for iodine deficiency in diet, 366.
- Kemp fibers in Merino sheep, characteristics, 768.
- Kentucky—  
 Station, notes, 198.  
 Station, report, 496.  
 University, notes, 198.
- Kidney—  
 inheritance of absence of, 524.  
 respiratory activity and vitamin B content, 65.
- Kidneys—  
 effect of intravenous mercurochrome, 680.  
 seasonal changes in weight, 669.
- Kikuyu grass—  
 characteristics and botanical description, 533.  
 value for poultry, 372.
- Kleidotoma* sp., notes, Iowa, 358.
- Koufri, effect on physical properties of soil, 622.
- Kudzu, culture experiments, N.J., 732.
- Lactation, dietary needs for, 176, 464.
- Lactic acid—  
 bacteria in milk, enzymatic studies, 879.  
 effect on carbon dioxide production, 626.  
 manufacture, fermentation processes in, 315.  
 production in diabetes after insulin injection, 265.
- Lactobacillus*—  
*acidophilus* and *L. bulgaricus*, comparison, 611.  
*bulgaricus* and *L. acidophilus*, comparison, 611.  
*thermophilus*, description, 278.
- Lactose determination methods, 411.
- Ladybird beetles, notes, Mich., 354.
- Laetilia coccidivora* attacking mealybugs, Fla., 251.
- Lambs—  
 and wool for market, 870.  
 crossbred, characteristics, 871.  
 docking and castrating, 270.  
 fattening, Nebr., 568.  
 feeding experiments, 171; Idaho, 871; Ill., 468; Kans., 467, 468; Nev., 468; Ohio, 468; Wash.Col., 672.  
 forage crops for, S.Dak., 170.  
 raising, 871.  
 raising in New South Wales, 672.  
 (See also Sheep.)
- Lamprophorus tenebrosus*, habits and life history, 552.
- Lamziekte and loin disease, comparison, Tex., 84.

## Land—

- clearing, studies, Minn., 88.
- credit. (*See* Agricultural credit.)
- cut-over. (*See* Cut-over land.)
- grant colleges. (*See* Agricultural colleges.)
- plaster. (*See* Gypsum.)
- purchase in northern Ireland, 91.
- question in Finland, 392.
- reclamation, Federal, achievements, 182.
- reclamation policies, U.S.D.A., 90.
- revenues in Great Britain, 743.
- settlement, Calif., 91.
- settlement and colonization in Great Lakes States, U.S.D.A., 893.
- settlement in Australia, 95.
- settlement, organized, after reclamation, 182.
- subdivision, in Sweden, 788.
- tenancy, share in rice districts in Philippines, 189.
- tenure in England, history, treatise, 91.
- tenure, relation to plantation organization, U.S.D.A., 293.
- tenure, Spanish, in Philippines, 189.
- tenure, studies, Nebr., 589.
- values, relation to rents, Tex., 189.

## Lantana—

- effect of sodium arsenite, 830.
- insects, introduction into Hawaii, 356.
- Larch, western, germination, factors affecting, 541.

## Larvae, device for inflating, 56.

*Lasioderma serricorne*. (*See* Tobacco beetle.)

*Laspeyresia interstinctana*. (*See* Clover-seed worm.)

Laurel leaf-beetle, biology and control, Me., 661.

## Lead—

- acetate, basic, preparation, 501.
- arsenate and lime-sulfur spray, chemical studies, N.Y.State, 501.
- arsenate, determination of lead and arsenic in, 711.
- arsenate, determination of water-soluble arsenic in, 712.
- arsenate solubility in digestive fluids of bee, 560.
- boring beetle, notes, 662.
- determination in lead arsenate, 711.
- hydrogen arsenate, sticker for, N.J., 751.
- number of maple products, determination, 713.
- number of vanilla extracts, 713.

Leaf crumpler, notes, U.S.D.A., 255.

Leafhopper, three-banded, notes, Mich., 355.

## Leafhoppers—

- affecting apple and potato, correct names, 855.
- of Ithaca region, synopsis, N.Y.Cornell, 758.

## Leaves—

- carbohydrate and water content, relation, 425.
- dried, absorptive capacity for carbon dioxide, 425.
- nitrogen in, diurnal variations in, 326.
- rust infection of, study in Petri dishes, Conn.State, 647.
- wound responses of, 518.

Lecithin in milk and in mammary gland, U.S.D.A., 576.

## Legume—

- bacteria, isolating, Wash.Col., 822.
- roots, mycorrhizal fungi in, 645.
- seeds, longevity, 340.

## Legumes—

- and Sudan grass, ensiling, 68.
- culture experiments, Calif., 33; S.C., 528.
- for green manuring, comparison, 132.
- for hay, variety tests, Fla., 224.
- inoculation, Mich., 796; N.J., 732.
- (*See also* Nodule production.)
- mycorrhizal fungus in, 746.
- new, characteristics and green manure value, 830.
- nitrogen experiments, 123.
- rotation experiments, Alaska, 528.
- urease in root nodules, 28.
- variety tests, Guam, 226; Idaho, 828.
- (*See also* Green manure and Alfalfa, Clover, etc.)

Leguminous seeds, hard-coated, growing experiments, 831.

## Lemon—

- Alternaria rot, notes, Calif., 53.
- blue mold rot, control, 451.
- juice, antiscorbutic fraction, 710.
- oil for red spider control, 300.

## Lemons—

- growth and fruit bud differentiation, Calif., 39.
- respiration as affected by ethylene, 626.

Lentils, fall seeding experiments, 633.

*Lentinus lepideus*, notes, 55.

*Lenzites* spp., notes, 55.

*Lepidoderma albohirtum*, notes, 853.

## Lepidoptera—

- of Japan, notes, 660.
- of New York, N.Y.Cornell, 455.

*Lepidosaphes ulmi*. (*See* Oyster-shell scale.)

*Leptinotarsa decemlineata*. (*See* Potato beetle, Colorado.)

*Leptochloa nealleyi*, striped grass looper affecting, 61.

*Leptosphaeria avenaria* n.sp., notes, 448

*Leptospira icterohaemorrhagiae*—

- in wild rats, 55.

notes, 782.

*Lepus europaeus pallas* in North America, 551.

*Lepyronia quadrangularis*, injury to corn, 454.

- Lespedeza—  
 hay, feeding value, Miss., 275.  
 Korean, culture experiments, Tenn.,  
 528.
- Lethol, test for ox warbles, 359.
- Lettuce—  
 culture, Ill., 440.  
 grading, packing, and handling, 394.  
 greenhouse production, U.S.D.A., 441.  
 hypoglycemia-producing principle in,  
 667.  
 leaves, irradiated, antirachitic prop-  
 erties, 763.  
 seed germination, 737.  
 strain tests, Idaho, 836.
- Leucaena glauca* as green manure and  
 cover crop, 732.
- l-Leucic acid formation, 611.
- Leucocytes—  
 monograph, 281.  
 relation to mammary secretion, 376.
- Leurocerus ovivorus*, notes, 361.
- Levuana iridescens*, notes, 853.
- Lice, biting, control, Calif., 59.
- Light—  
 artificial, effect on egg production,  
 Pa., 272.  
 artificial, plant growth in, 625.  
 effect on plants, 327.  
 (See also Sunlight.)
- Lights in chicken house, automatic switch  
 for, Mich., 476.
- Ligyrrus rugiceps*. (See Sugar cane beetle.)
- Lilac—  
 effect of ringing, 125.  
 minor, notes, Wash.Col., 852.
- Limberneck—  
 in fowls, account, Ill., 86  
 or botulism in chickens, West.Wash.,  
 386.
- Lime—  
 arsenate. (See Calcium arsenate.)  
 control law of Oregon, Oreg., 515.  
 deficiency and soil acidity, studies, 21.  
 effect on assimilation of phosphorus,  
 Ohio, 213.  
 effect on availability of phosphoric  
 acid, 212.  
 effect on black alkali soil, Calif., 21.  
 effect on decomposition of organic mat-  
 ter, 323.  
 effect on hydrangeas, 143.  
 effect on nodulation of soy beans, 339.  
 effect on yield and nitrogen in soy  
 beans, N.J., 735.  
 fertilizing value, 120; Del., 119.  
 for poultry, source, Calif., 75.  
 forms, comparison, 818.  
 high-calcium and high-magnesium, ef-  
 fect on soil reaction, 324.  
 in cylinder soils, 119.  
 inspection and analyses in Maryland,  
 623.  
 niter. (See Calcium nitrate.)  
 nitrogen. (See Calcium cyanamide.)  
 relation to crop production, Va., 422.
- Lime—Continued.  
 rôle and importance in agriculture,  
 818.  
 water purification by, 389.  
 (See also Calcium and Liming.)
- Limekiln, plans and specifications, 819.
- Limestone—  
 brands and composition, Oreg., 515.  
 effect on phosphoric acid in super-  
 phosphate, 514.  
 grit v. oyster shell for poultry,  
 Calif., 75.  
 ground, fertilizing value, Ohio, 23.  
 in rations, effect on egg production,  
 Ky., 76.  
 making more available for farmers,  
 819.
- Lime-sulfur—  
 liquid, v. sulfur dust for apples, Ind.,  
 141.  
 spray and lead arsenate, chemical  
 studies, N.Y.State, 501.
- Liming—  
 crop response to, relation of soil re-  
 action, 17.  
 in western Ohio, 422.  
 studies, Guam, 214.
- Limnaea stagnalis*, development of liver  
 fluke in, 584.
- Limnerium crassifemur*, variability of life  
 cycle, 561.
- Linkage—  
 in Oenothera, 431.  
 in rats and mice, variations in, 128.
- Linseed oil—  
 irradiated, antirachitic properties, 762.  
 production in Argentina, 228.
- Lipeurus heterographus*, notes, 355.
- Lipochromes in etiolated wheat seedlings,  
 610.
- Lipoids, effect on gluten quality, 202.
- Liquors, malted, dietetic value, 365.
- Listroderes nociva*, studies, 662.
- Listronotus latiusculus*, notes, 758.
- Lithocolletis platani*, parasite of, 663.
- Liver—  
 fluke development to cercarial stage,  
 584.  
 injury from carbon tetrachloride, effect  
 of diet, 584.  
 respiratory activity and vitamin B  
 content, 65.  
 seasonal changes in weight, 669.
- Livestock—  
 and animal products statistics of  
 Canada, 95, 792.

## Market—

gardens. (See Truck crops.)  
reports, U.S.D.A., 192, 296, 493, 595,  
693, 789, 895.

## Marketing—

cooperative, and city marketing prob-  
lems, 192.

cooperative central, organization,  
Minn., 93.

cooperative, commodity plan, U.S.D.A.,  
593.

dairy products, U.S.D.A., 593.

in North Carolina, N.C., 94, 296, 393.  
movement, cooperative, sociological  
implications, 791.

of Kansas wheat, Kans., 489.

programs for cooperative organiza-  
tions, U.S.D.A., 591.

studies, Calif., 92.

Markets for agricultural products, effect  
of European conditions, 693.

Marl digging demonstrations, Mich., 24.

Marog, effect on physical properties of  
soil, 622.

Marsh lands of northern Michigan, map-  
ping, 17.

*Marsonia potentillae*, notes, 352.

Martynia bacterial disease, notes, 846.

## Maryland—

State Beekeepers' Association, report,  
663.

Station, notes, 698.

University, notes, 198, 698.

## Massachusetts—

College, notes, 198, 599.

Station, notes, 599.

Station, report, 899.

## Mastitis—

diagnosis, 885.

notes, Conn.Storrs, 681.

papers on, U.S.D.A., 583.

*Matricaria nigellacifolia*, intoxication due  
to, 82.

Matthiola, crosses between mutant and  
ancestral types, Calif., 40.

*Matthiola incana*, reversionary character  
in, 330.

May apple rust, expulsion of acidiospores  
by, 450.

*Mayetiola destructor*. (See Hessian fly.)

Meadow fescue. (See Fescues.)

## Meadows—

fertilizer experiments, 723.

nitrogen fertilization, 513.

(See also Hay, Grass, and Grassland.)

Meadowsweet leaf-beetle, biology and con-  
trol, Me., 661.

## Mealybug—

citrophilus, in California, 455, 855.

of British Isles, biology, 855.

on pear trees, control, Calif., 57.

Mealybugs, control, Fla., 251.

(See also Pineapple mealybug.)

## Meat—

bill, reducing, 62.

distribution and prices in Great Brit-  
ain, 693.

## Meat—Continued.

fumigated, hydrocyanic acid absorbed  
by, U.S.D.A., 561.

inspection, handbook, 881.

packer as distributor of dairy prod-  
ucts, U.S.D.A., 574.

powdered dried, digestibility, 259.

putrefaction, relation to bacterial  
count, 460.

scrap, feeding value, Tex., 572.

scrap grades, feeding value, Calif., 74.

vitamin A in, 65.

(See also Beef, Pork, etc.)

Meats, import requirements in Germany,  
U.S.D.A., 297.

Media. (See Culture media.)

Medicine, German-English dictionary of  
terms, 580.

*Megachile* spp., studies, Calif., 59.

*Megapariopsis opaca*, notes, U.S.D.A., 256.

*Meibomias*, new American, 831.

*Melampsora lini*, resistance of flax to, 645.

*Melanconium fuliginum*, notes, 549.

*Melanogaster ampelophila*. (See Pomace  
fly.)

*Melanotus* sp. on sugar cane, 454.

*Meligethes aeneus*, trap-control experi-  
ments, 554.

Melon insects, control, Kans., 452.

Melons, culture in English greenhouses,  
341.

*Menopon biseriatum*, control, Calif., 59.

Menotoxin, effect on viability of sperma-  
tozoa, 524.

Mercuric chloride solutions, fungicidal  
value, effect of hardness of water, 647.

Mercurochrome injection, effect on kidneys,  
680.

Mercury, metallic, insecticidal value, 554.

Merker grass, breeding experiments, Fla.,  
224.

*Merulius*—

*lachrymans*, notes, 452.

spp., notes, 55.

*Mestocharella javensis* n.sp., description,  
361.

## Metabolism—

basal, constancy of, 761.

basal, in vitamin B deficiency, 262.

basal, of women, variations in, 160.

basal, treatise, 362.

cage, description, 63.

calcium and fat, of atrophic infants,  
563.

intermediary, stimulating action of  
food, 64.

## Metals—

and wood, strengths and related  
properties, 887.

fatigue of, studies, 386, 387.

*Metarrhizium anisopliae*, notes, U.S.D.A.,  
256.

*Metastrongylus apri* in pigs, 283.

## Meteorological—

conditions in 1816, U.S.D.A., 715.

fallacies, 114.

## Meteorological—Continued.

observations, Alaska, 507; Guam, 208; Ky., 415; Mass., 208, 415, 617; Me., 415; Mont., 415; N.J., 716; U.S.D.A., 115, 315, 316, 414, 415, 617, 715; Wyo., 716.  
tables for Lansing, Mich., 316.

notes, 398, 599, 699, 900.

report, 598.

*Nicotiana rustica*—

inheritance of characters in, 522.

nicotine content, N.Y.State, 534; Pa., 252.

source of nicotine for insect control, 535.

## Nicotine—

content of *Nicotiana rustica*, Pa., 252.  
dust, making and use, N.J., 849.

dust preparation, improved method, Calif., 48.

dust, tests, N.J., 752.

dust v. sprays, Pa., 252.

dusts, loss of nicotine during storage, U.S.D.A., 656.

for insect control, source, 535.

loss from nicotine-soap preparations, cause, 309.

sulfate treatment for stomach worms, Ohio, 483.

## Nicotine—Continued.

toxicity and volatility, correlation, Calif., 59.

Night blindness, inheritance of, 430.

*Nitella clavata*, absorption of various ions, Calif., 25.

## Nitrate—

accumulation, relation to soil moisture, Utah, 719.

Chilean, as top-dressing for grassland on peat soil, 513.

industry, statistical review, treatise, 622.

nitrogen determination, 11.

of ammonia. (See Ammonium nitrate.)

of lime. (See Calcium nitrate.)

of soda. (See Sodium nitrate.)

## Nitrates—

determination, methods, 204.

in South African soils, seasonal variation, 512.

movements in soil and subsoil, 120.

toxicity, movement, and accumulation in arid soils, N.Mex., 317.

## Nitrification—

and nitrifying organisms, 118.

as affected by dicyandiamide and guanylurea sulfate, 122.

chemical, and sunlight, 420.

effect of rotations, 816.

experiments, 121.

in South African soils, 211.

of manure, 622.

of phosphorus nitride, 514.

Nitrifying organisms, isolation methods, 118.

Nitroculture distribution, notes, Can., 846.

## Nitrogen—

amide and amino acid, from alfalfa plant, 610.

and carbon determination, 202.

and organic matter in soils, maintenance in dry-land cultivation, 815.

assimilation by microsiphones, 512.

atmospheric, assimilation by forest soils, 512.

atmospheric, fertilizers, greenhouse experiments, 422.

availability, effect of phosphoric acid-potash ratio, N.J., 722.

basic, from alfalfa plant, 610.

compounds, effect on detonation in internal-combustion engines, 888.

determination, wet combustion method, 612.

distribution in bean leaves, 325.

economy of soil, effect of fertilizers, 421.

fertilization, effectiveness and profit, 723.

fertilization of meadows, 723.

fixation as affected by radioactive mineral, 22.

fixation in forest soils, 512.

fixation, soil conditions for, 815.

in leaves, diurnal variations in, 326.

## Nitrogen—Continued.

- in tree nutrition, function, 236.
- in weeds, 536.
- industrial, treatise, 817.
- lime. (*See* Calcium cyanamide.)
- metabolism in avitaminosis, 66, 67.
- metabolism of micrococci, N.Y.State, 520.
- metabolism of plants, Calif., 25.
- of acid amines, ammonification, 512.
- peat as source of, value, 622.
- storage in bark parenchyma, 426.
- survey, 323.
- upward transfer, effect of ringing, 125.
- use in muck fertilization, Mich., 722.
- use on meadows, 513.

Nitrogen-fixing bacteria in Vesuvian soils, 22.

## Nitrogenous—

- fertilizers, comparison, 422.
- fertilizers, new, of Great Britain, 122.
- fertilizers on Silesian soils, 323.
- materials, determination of nitrate and ammonia in, 204.

Nodular typhlitis in pheasants, 86.

## Nodule—

- bacteria in muck humus, 122.
- (*See also* *Bacillus radicolica*.)
- formation of soy beans, effect of fertilizers, 338, 339.
- (*See also* Legumes, inoculation.)

Nonpartisan League, effect, 791.

Noodles, analyses, 713.

## North Carolina—

- College, notes, 300, 699.
- Station, notes, 699.

## North Dakota—

- College, notes, 300.
- Station, notes, 300.

Novarsenobenzol, anthelmintic value, 777.

Nun moth polyhedral disease, cause, 554.

Nursery stock, injury from hydrocyanic acid gas, 554.

Nut meats, fumigated, hydrocyanic acid absorbed by, U.S.D.A., 561.

Nut trees, top-working, 640.

## Nutrient—

- media. (*See* Culture media.)
- solution, continuous renewal, effect on soy bean growth, 125.
- supply, high, effect on apparatus of assimilation, 123.

## Nutrients—

- effect on plant development, 123.
- of grasses, loss through ensiling, 268.

## Nutrition—

- activities in public schools, U.S.D.A., 562.
- animal. (*See* Animal nutrition.)
- clinic as project for part-time school girls, 96.
- effect on incidence of disease, 480.
- in green semiparasites, 425.
- laboratory, report, 62.
- of children, mineral elements in, importance, 160.

## Nutrition—Continued.

- Pirquet method of determining, criticism, 461.
- plant. (*See* Plant nutrition.)
- relation to disease, 280.
- studies in Berlin orphan asylum, 160.
- work in Labrador, U.S.D.A., 562.
- (*See also* Diet, Malnutrition, and Undernutrition.)

## Nuts—

- culture in northern United States, 143.
- pollination studies, 342.
- tryptophan and cystine in, 802.

*Nuttallia equi*, notes, 885.

Nyctalopia inheritance with myopia, 430.

*Nymphula depunctalis*, notes, 154.

## Oak—

- annular rot, 646.
- golden, origin, 152.
- root fungus, studies, Calif., 49.
- soils, composition, 511.

Oaks, growth, relation to source of seed, 842.

## Oat—

- and tare silage. (*See* Silage.)
- grass, tall, seed production, 334.
- smut, control, Idaho, 844; Kans., 445.
- speckled blotch, notes, 448.
- stem rust resistant varieties, 347.

## Oats—

- breeding experiments, Kans., 433; Mich., 334.
- cost of production, W.Va., 589.
- culture experiments, Alaska, 528; Nebr., 529.
- drill calibration, relation to stand and yield, 828.
- effect of preceding crop, R.I., 23.
- fall seeding experiments, 633.
- fertilizer experiments, 723; S.C., 528.
- field experiments, 533.
- forage yields, Mont., 435.
- Fowlds Hull-less, notes, S.Dak., 137.
- germination tests, Mont., 435.
- hulless v. ground, feeding value, Can., 673.
- inheritance in, Wash.Col., 825.
- Kanota, genetic studies, Kans., 433.
- Markton, smut immune variety, U.S. D.A., 35.
- natural crossings in, 727.
- rotation experiments, Mont., 435; N.Y. Cornell, 526; U.S.D.A., 827.
- seeding experiments, Ga.Coastal Plain, 225; Idaho, 828; Nebr., 529.
- spray irrigation for, 287.
- time of plowing, Kans., 434.
- v. barley for pigs, Can., 873.
- v. corn for work horses, N.Y.Cornell, 771.
- v. corn for work mules, Mo., 272.
- v. rape pasture for pigs, Can., 873.
- varieties, Calif., 33; N.Y.Cornell, 635; U.S.D.A., 827.
- varieties and characteristics, treatise, 832.

## Oats—Continued.

variety tests, 337; Fla., 224; Ga. Coastal Plain, 224; Idaho, 828; Ind., 226; Kans., 433; Mich., 796; Miss., 226; N.J., 732; Nebr., 529; S.C., 528; Wash.Col., 829.

wild, varieties in California, Calif., 33. yields, U.S.D.A., 527.

yields after fallow, Oreg., 435.

yields and agronomic data, Can., 733.

*Obeliscus cuniculi*, notes, 859.

Ocean temperatures, forecasting rainfall from, 207.

Ochotona, synopsis of genus, 153.

*Ochrosidia immaculata*, parasite of, 62.

Odonate fauna of Palni and Nilgiri Hills, 155.

*Gecanthus* spp. (See Cricket, tree.)

Oedipodinae, taxonomic and ecological study, Utah, 454.

## Oenothera—

*brevistylis*, style length and fertility, variations in, 330.

*lamarekiana*, chromosomes, mutant characters in, 329.

Oenothera, linkage with crossing over in, 431.

*Oesophagostomum columbianum*, life history notes, 82, 181.

## Oestrous cycle—

in cows, studies, 631.

in mice, effect of alcohol, 632.

in swine, external signs and vaginal changes, 631.

Oestrus in sows, nature of secretion during, 631.

## Ohio—

State University, notes, 600, 700, 797.

Station, monthly bulletin, 497, 796.

Station, notes, 700.

## Oil—

burners for small heating plants, 489.

crankcase, dilution problem, 187.

crankcase, water in, 186.

of *Brassica campestris* production in Argentina, 228.

palms in Brazil, beetle affecting, 359.

seed crops in Argentina, 228.

seeds, high tryptophan content, 802.

sprays, effect on apple aphids, 658.

sprays, notes, Wash.Col., 851.

sprays, preparation and use, Wash. Col., 656.

Oiled materials for apple scald control, tests, 653.

## Oils—

distilling, condenser for, 11.

emulsified, mixing with hard water and lime sulfur, U.S.D.A., 441.

identification, 411.

lubricating, specific heats, 586.

separation of unsaponifiable matter from, 712.

viscosity at high temperatures, 687.

(See also Fats, Cottonseed oil, Olive oil, etc.)

Oleomargarine. (See Margarine.)

*Olethreutes chionosema* spp., notes, U.S. D.A., 255.

## Olive—

fly, control, international conference on, 856.

fly in Corfu, campaign against, 660. industry in Morocco, 142.

oil, Palestine, composition, 412.

oil, preparation and refining in southern Europe, Calif., 413.

oil production in Argentina, 228.

oil, sulfuric index, 411.

trees, flowering, fruiting, and vegetative development, 740.

## Olives—

culture and manufacture into oil, 343.

fertilizer experiments, 642.

Palestine, composition, 412.

pickling in Mediterranean countries, Calif., 207.

production in Spain, France, and Italy, Calif., 237.

*Onchocerca caecutiens* of Guatemala, 760.

## Onion—

bulb disease, studies, 348.

Fusarium rot, notes, Wash.Col., 845.

maggot in Canada, 355.

milk, studies, 670.

scale pigmentation, relation to disease resistance, 846.

smut in Indiana, 650.

## Onions—

behavior during and after storage, 235.

Bermuda, American-grown, marketing, U.S.D.A., 593.

effect of preceding crop, R.I., 23.

production, economic study, Iowa, 788.

rest period, studies, 235.

variety tests, Utah, 738.

wild, disease, S.C., 544.

*Oospora*—

*scabies*. (See Potato scab.)

sp. on cheese, 280.

*Ophideres fullonica*, notes, 361.

## Ophthalmia—

in rats, studies, 462.

of cattle, transmission and treatment, 180.

## Opossum—

genital tract, motility, 524.

polynuclear ova and polyovular follicles in, 630.

## Orange—

beverages, notes, Calif., 14.

black rot, notes, Fla., 242.

blue mold rot, control, 451.

by-products as cattle food, Calif., 70.

melanose, control, Fla., 241.

pulp, feeding value, Calif., 79.

Tortrix, life history, 756.

trees, effect of concentration of nutrient solution, 27.

trees, growth and composition as affected by salts, Calif., 26.

- Oranges—  
 bud selection as related to quality, 238.  
 freezing on trees, U.S.D.A., 317.  
 green spotting of, Fla., 242.  
 introduced, culture experiments, Guam, 232.  
 keeping quality, 539.  
 Satsuma, insect pests and diseases, 853.  
 transportation from Porto Rico, U.S.D.A., 539.
- Orchard—  
 cover crops, tests, Mont., 441.  
 grass, culture experiments, Mo., 533.  
 grass, seed production, 334.  
 improvement instruction in Herefordshire, 696.  
 insects, control, 853.  
 lands injury from waterlogged soils, Mont., 450.  
 leaf roller, control, Wash.Col., 851.  
 spray machine, use in alfalfa fields, 888.  
 temperature studies, Calif., 41.  
 trees dying, cause, Colo., 822.
- Orchards—  
 management, 640.  
 renovation, relation to spraying, 852.  
 soil management, 537.  
 (See also Fruits, Apples, Peaches, etc.)
- Oregon Agricultural Economic Conference, report, 490.
- Organ weights, seasonal changes in, relation to meteorological conditions, 669.
- Organic—  
 compounds for fumigation of grain weevils, U.S.D.A., 661.  
 matter, action of lime compounds on, 319.  
 matter and nitrogen in soils, maintenance in dry-land cultivation, 815.  
 matter in plants, transportation, 27.  
 matter in soil and sulfur, studies, Wash.Col., 814.  
 matter in soil, maintenance, 815.  
 matter, iodine determination in, 712.  
 substances, synthesis of, treatise, 108.
- Organisms. (See Bacteria and Microorganisms.)
- Organotherapy and vaccine and serum therapy, treatise, 178.
- Ornamental plants, shrubs, and trees. (See Plants, Shrubs, and Trees.)
- Ornithodoros coriaceus*, oviposition, Calif., 60.
- Orthoptera—  
 Indian, collection and study, 155.  
 of Italy, list, 753.  
 of Utah, list, Utah, 454.
- Oryctes rhinoceros*—  
 and other palm pests in Burma, 154.  
 control, 554.
- Oscinella frit* infestation of oats, varietal differences, 856.

- caribaea* n.sp., description, 352.
- citri*, notes, 352.
- vezans*, control, Va.Truck, 44.

*Phorbia cepetorum*. (See Onion maggot.)*Phorocera parva*, notes, 659.

## Phosphate—

- fertilizers for Iowa soils, 213.
- of lime. (See Calcium phosphate.)
- Rhenania, fertilizer experiments, 723.
- rock, analysis, 711.
- rock, solubility, studies, 120.

## Phosphates—

- availability in ferruginous soils, 212.
- availability in soil, determination, 311.
- comparison, 123, 323, 623, 723.
- effect on nodulation of soy beans, 339.
- in soil solution, concentration, Calif., 20.
- inorganic, in blood after insulin injection, 265.
- solubility in soil, effect of bacteria, 320.

## Phosphoric acid—

- availability in basic slag phosphates, 817.
- available in Pusa soils, 120.
- in cylinder soils, 119.
- on Silesian soils, 323.
- preparation, 213.

## Phosphoric acid-potash ratio, effect on nitrogen availability, N.J., 722.

## Phosphoric oxide in superphosphate, solubility, effect of limestone, 514.

## Phosphorite—

- ground, activity in fallow and cropped soils, 623.
- origin and pulverization, studies, 623.

## Phosphorus—

- and calcium absorption, relation to diet, 763.
- assimilation, effect of lime, Ohio, 213.
- depletion, effect on wheat growth, 426.
- determination in animal substances, 614.
- dietary sources, 260.
- effect on tomatoes, Ill., 440.
- fertilizers, qualitative study, Fla., 238.
- in livestock industry, 670.
- inorganic, determination in serum, 613.
- metabolism in avitaminosis, 66.
- metabolism of cows, effect of protein in rations, Mo., 478.
- nitride, nitrification, 514.
- organic, of urine, 807.
- recovery, effect of iron and aluminum salts, 817.

## Photography, aerial, 345.

Photoperiodism of *Tephrosia candida*, 126.

## Photosynthesis—

- absorption of carbon dioxide in, 425.
- effect of infinitesimal traces of chemical substances on, 820.
- physiology, treatise, 819.

*Phragmatiphila truncata*, injury from, 853.*Phyllocoptus oleivorus*, entomogenous fungus attacking, 361.*Phyllosticta*—

- phaseolina*, notes, Pa., 243.
- solitaria*, control, Mo., 247.

*Phylloxera vastatrix*. (See Grape phylloxera.)

## Physalospora and Botryosphaeria, comparison, 248.

*Physalospora matorum* on currant, 248.*Phytalus smithi*, notes, 636.*Phytonomus*—

- nigrirostris*. (See Clover-bud weevil.)
- posticus*. (See Alfalfa weevil.)

## Phytopathological—

- collaboration, European, 645.
- information, 645.
- service of Holland, organization, 645.

## Phytopathology—

- in Russia, development, 646.
- international, 645.
- proposed division, 645.

*Phytophaga destructor*. (See Hessian fly.)*Phytophthora*—

- cactorum*, notes, 150.
- capsici* n.sp., description, 349.
- fabieri*, notes, 249.
- infestans*, mycoplasma, stage, 645.
- (See also Potato blight, late.)
- nicotianae*, notes, Fla., 247.
- phaseoli*, notes, Pa., 243.
- sp., notes, 352.
- spp. on rhubarb, Pa., 243.

## Phytophthora rot of tomato, eggplant, etc., 548.

## Phytosterols—

- of corn endosperm, 110.
- studies, N.Y.State, 708.

## Pickles, fermented, making, U.S.D.A., 114.

## Picric acid method for sugars, modifications, 111.

## Pig—

- club members, lessons for, 696.
- foods, 674.
- house, individual farrowing, for Ohio, construction, 188.
- houses for Indiana, construction, 188.
- industry, papers on, 674.
- viscera, composition, 159.

## Pigeon, complete sex reversal in, 129.

## Pigeon's egg, unfertilized, parthenogenetic cleavage, 131.

## Pigeons—

- homing, care and training, 250.
- nutritive requirements, studies, 68.
- parasite of, 361.

## Pigments, properties and tests, manual, 201.

(See also Anthocyan and Color inheritance.)

## Pigs—

- breeders' annual, 674.
- care, management, and breeding, U.S. D.A., 770.
- cost of production in Philippines, 690.
- diseases, 674.
- fattening on peanuts, Ala., 471, 472.
- fattening, outdoor v. indoor, 770.
- feeding experiments, 370, 673, 768; Calif., 73; Can., 673, 873; Del., 871; Fla., 270; Idaho, 872; Kans., 469; Ky., 470; Mich., 74, 371; Mont., 471; Pa. 270; S.C., 569; Utah, 770; Wash.Col., 872.
- (See also Sows, brood.)
- home slaughtering and marketing, 674.
- inheritance in, 222.
- iron deficiency in, 271.
- judging, Wash.Col., 474.
- litters, frequencies of sex combinations in, 629.

## Pigs—Continued.

- mineral mixture for, Ala., 473.
- nitrogen and mineral metabolism, effect of sodium-potassium ratio, 370.
- parasites of, 683.
- photographing, Ohio, 474.
- potatoes as feed for, S.Dak., 171.
- prices at public markets, 692.
- production, textbook, 770.
- raising, relation to corn production and prices, U.S.D.A., 595.
- raising, treatise, 172.
- records of production, use, 674.
- reproduction, effect of exercise, Kans., 469.
- self-feeders for, construction, Ohio, 770.
- self-feeding v. hand-feeding, Can., 673.
- sex ratio, effect of size of litter, 629.
- sexual abnormalities, 674.
- sexual and fall, protein supplements for, Minn., 470
- transportation by motor truck, U.S. D.A., 184.
- type for market production, Ill., 469.
- weight, relation to food consumed and rate of gain, 770.

(See also Sows and Swine.)

- Pikas, American, revision, U.S.D.A., 153.
- Piling, protection against marine borers, Calif., 60.
- Pimpla pomorum*, parasite of apple bud weevil, 858.
- Pine—
  - and hemlock mixed stands, value, 145.
  - blister rust. (See White pine blister rust.)
  - forests, California, rôle of fire in, U.S. D.A., 542.
  - lands, western yellow, growth on cut-over and virgin soil, 542.
  - lodgepole, seedlings, heat-resisting capacity, U.S.D.A., 47.
  - longleaf, French turpentine system for, U.S.D.A., 444.
  - plantations, effects of grazing in, 842.
  - red, habits and characteristics, 345.
  - resin ducts in, anatomy, 427.
  - siskin, food habits, U.S.D.A., 354.
  - slash, western yellow, decay, 452.
  - soils, composition, 511.
  - western yellow—
    - acceleration of growth after logging, 144.
    - growing season, 644.
  - seedlings, heat-resisting capacity. U.S.D.A., 47.
  - white. (See White pine.)
- Pineapple—
  - bran, feeding value, 376, 673.
  - mealybug, enemies of, in Panama, 852.
- Pineapples, fertilizer experiments, Guam, 232.
- Pipe culverts, pressure on, U.S.D.A., 585.
- Pipits, food habits, U.S.D.A., 354.
- Pipunculus* spp. affecting beet leafhopper, Calif., 58.

*Piroplasma caballi*, notes, 885.

## Piroplasmosis—

- equine, in France, 885.
  - tick biting experiments in, 778.
- Piroplasms in bovines, 583.

## Plant—

- alkaloids, treatise, 309.
- breeding, founders, 823.
- breeding, handbook, 827.
- breeding in Germany, 628.
- breeding in Ontario, 341.
- breeding in Scotland, 227.
- breeding in semi-arid regions of Arizona, 823.
- breeding, methods and principles, 437. (See also Heredity, Hybridization, and specific plants.)
- cells, action of X-rays on, 216. (See also Cell.)
- chromosomes. (See Chromosomes.)
- cuttings, effect of carbohydrate-nitrate content on root production, 138.
- cuttings, stimulation, 239.
- disease legislation in Canada, 645.
- disease legislation, international, 645.
- diseases—
  - and pests, S.C., 836.
  - and pests, combating, international cooperation, 645.
  - and pests, control methods, 148.
  - classification, 646.
  - control in Pennsylvania, 646.
  - control in West Virginia, 646.
  - in Florida, list, Fla., 242.
  - in Mississippi, list, Miss., 243.
  - on alkaline and sour soils, 645.
  - studies, Can., 845. (See also Fungi and different host plants.)
- growth—
  - and auxinones, 28.
  - effect of aeration, 512.
  - effect of ammonium sulfate, 326.
  - effect of carbon dioxide, 424.
  - effect of carbon disulfide, 721.
  - effect of decreased oxygen pressures, 424.
  - effect of dicyandiamide, 122.
  - effect of electric currents, 808.
  - effect of guanylurea sulfate, 122.
  - effect of nutrients, 123.
  - effect of pressure, 518.
- lice on truck crops, Pa., 252.
- material for long-distance shipments, handling, U.S.D.A., 232.
- materials, continuous extraction apparatus for, 503.
- nutrition studies, Calif., 24, 26.
- parasites, diagnosis, serum-agglutination in, 146.
- Pathology, Congress at Strassburg, 745.
- pathology, extension work in, U.S.D.A., 495.
- pathology in Holland, 554.
- pathology linking with animal pathology, 746.

## Plant—Continued.

- pigmentation. (See Pigments)  
 products, chemistry of, treatise, 409.  
 products, microsublimation, apparatus  
 for, 310.  
 protection and instruction, 645.  
 protective media, evaluation, 645.  
 roots, alkali injury to, Calif., 24.  
 species, origin, review of theory, 628.  
 succession in New South Wales, 830.  
 symbiosis, studies, 427.  
 tissue fluids, chlorides in, determina-  
 tion, 111.  
 tissue, isoelectric point for, signifi-  
 cance, 124.  
 tissues, cicatrization after freezing,  
 518.  
 Plantain root beetle borer, summary, 558.  
 Plantation organization, relation to land  
 tenure, U.S.D.A., 293.  
 Plants—  
 as affected by light, 327.  
 Brownian molecular movement in, 425.  
 climbing, treatise, 144.  
 composition, effect of soil composition,  
 Wash.Col., 814.  
 control of growth factors in, 424.  
 cultivated, in Poland, diseases and  
 pests, 148.  
 desert. (See Desert.)  
 domesticated, tracing civilization  
 through, 726.  
 economic, in New South Wales, keys,  
 830.  
 effect of cereal straw, N.Y.State, 513.  
 effect on air in houses, 126.  
 effect on reaction of culture media,  
 Calif., 25.  
 feeding power, relation to carbon  
 dioxide production of roots, 28.  
 fertilization in, physiological incom-  
 patibilities, 127.  
 fiber. (See Fiber.)  
 flowering annuals, handbook, 741.  
 for exhibition, treatise, 741.  
 fungi affecting, in Turin, 148.  
 gregarious flowering in, causes, 127.  
 growth and blooming in continuous  
 artificial illumination, 625.  
 imports, U.S.D.A., 520.  
 inhibitory substance in, isolation, 219.  
 manganese in, Ky., 426.  
 medicinal, in Hungary, fungus dis-  
 eases, 646.  
 new food, for the South, U.S.D.A.,  
 340.  
 nitrogen metabolism, 325; Calif., 25.  
 ornamental—  
   culture, 143, 643; Can., 341, 639.  
   notes, Alaska, 536.  
   phenological data, N.J., 738.  
   pruning, West.Wash., 598.  
 parasitic diseases in Valley of  
 Bareges, 745.  
 perennial, culture, treatise, 741.  
 photosynthesis. (See Photosynthesis.)

## Plants—Continued.

- plastids in, evolution, 519.  
 poisonous to livestock, U.S.D.A., 480.  
 poisonous to livestock, treatise, 280.  
   (See also Livestock poisoning and  
   specific plants.)  
 respiration. (See Respiration.)  
 stinging crystals in, 427.  
 teratology, 519.  
 tolerance to acid conditions, Del., 811.  
 transpiration. (See Transpiration.)  
 transplanting, relation to hardening,  
 234.  
 transport of organic substances in, 27.  
 useful, of China, 795.  
 variation. (See Variation.)  
*Plasmodiophora brassicae*. (See Cabbage  
 clubroot.)  
*Plasmopara viticola*—  
   notes, 746.  
   signal service regarding attacks, 150.  
 Plastids in plants, evolution, 519.  
*Platygaster vernalis*, polyembryonic de-  
 velopment, 360.  
*Platynota tinctana*, notes, 757.  
*Platyptilia*—  
   *carduidactylia*, control, Calif., 58.  
   *pusillidactyla*, notes, 356.  
*Plenodomus fuscomaculans*, notes, Calif.,  
 49.  
*Plesiocoris rugicollis*, biology, 658.  
 Pleuropneumonia, equine contagious, treat-  
 ment, 684.  
*Pleurotopis*—  
   *lividiscutum* n.sp., description, 361.  
   sp., notes, Iowa, 358.  
*Plodia interpunctella*. (See Indian-meal  
 moth.)  
 Plow bolts, simplified list, 586.  
 Plowing tests, Utah, 719.  
 Plowing without turning furrow, 785.  
 Plum pits, germination, N.Y.State, 46.  
 Plumbing—  
   house, hydraulics and pneumatics, 689.  
   in the farmhouse, U.S.D.A., 389.  
 Plums—  
   blooming data, N.J., 738.  
   Caldwell system of training, Calif., 42.  
   culture in Pacific States, U.S.D.A., 237.  
   effect of time of harvesting on quality,  
   142.  
   Hall, description, N.Y.State, 46.  
   keeping quality, 539.  
   notes, Alaska, 536.  
   storage studies, Calif., 41.  
   varieties, Mont., 441.  
   varieties for Iowa, Iowa, 442.  
   wild, plum pocket on, 352.  
   winter hardiness, Ky., 442.  
*Plutella maculipennis*. (See Diamond-  
 back moth.)  
 Pneumococci inhalation, production of im-  
 munity in mice by, 682.  
*Poa fertilis*, seed production, 334.  
*Podontia affinis*, notes, 361.  
*Podosphaera leucotricha*, control, 848.  
*Pocillocoris hardwicki*, notes, 361.

- Poisonous plants. (*See* Plants, poisonous.)  
 Poisons, effects, treatise, 178.  
 Poles, utilization in farm buildings, 887.  
 Pollards and wheat bran, composition and feeding value, 167.  
*Polychrostita vitcana*. (*See* Grape berry moth.)  
*Polynema eutettixi* affecting beet leafhopper, Calif., 58.  
 Polyneuritis—  
   avian, effect of ultraviolet light, 366.  
   avian, nerve paralysis in, 566.  
   mechanism of production in pigeons, 68.  
*Polyocha* sp., notes, 853.  
*Polyporus volvatus* on western yellow pine slash, 452.  
 Polysaccharides, treatise, 609.  
*Polyscelis modestus* parasite of Hessian fly, 663.  
 Pomace fly—  
   inheritance of egg size in, 221.  
   Mendelian inheritance in, 427.  
 Pomegranate sirup, preparation, Calif., 14.  
 Pond-lily leaf-beetle, notes, Me., 661.  
 Pop corn, selective fertilization among gametes, 432.  
*Popillia japonica*. (*See* Japanese beetle.)  
 Poplar—  
   cankers in Ontario, 353.  
   Cytospora, notes, Utah, 745.  
   disease, notes, 152.  
   stumps, annual sprouts from, Pa., 240.  
 Poppies, fall seeding experiments, 633.  
 Pork—  
   production. (*See* Pigs.)  
   products, flavoring from fish meal, 769.  
   products, prices at public markets, 692.  
   proteins, biological value, 762.  
   soft, studies, Fla., 270.  
*Porosagrotis orthogonia*, effect of weather, Mont., 453.  
*Porthetria dispar*. (*See* Gipsy moth.)  
 Potash—  
   deposits in United States, hearings on, 214.  
   in cylinder soils, 119.  
   production from Minnesota shale, 817.  
 Potassium—  
   availability, effect of sulfur and gypsum, Ky., 421.  
   availability in soil, measurement, Pa., 214.  
   bearing rocks, uses for fertilizers, 514.  
   biphosphate, effect on acid soils, 621.  
   carbonate, effect of acid soils, 621.  
   chloride, effect on nodulation of soy beans, 339.  
   chloride, fertilizing value, Del., 119.  
   effect on orange trees, Calif., 26.  
   in blood serum, determination, 411.  
   phosphate, effect on acid soils, 621.  
   silicate, effect on acid soils, 621.  
   solubility, effect of fertilizers and cropping, Ohio, 214.  
   Potassium—Continued.  
     sulfate, effect on acid soils, 621.  
     sulfate, fertilizing value, 526.  
 Potato—  
   beetle, Colorado, notes, Idaho, 851.  
   black wart, account, 149.  
   blackleg, cause, 350.  
   blackleg, control, Mont., 447.  
   blight, late, control, Fla., 242.  
   blight, late, oospores of, 645.  
   dartrose, studies, 847.  
   degeneration diseases, importance and spread, Me., 246.  
   digging machine tests, 289.  
   disease, serious, in France, 847.  
   diseases of curl type, 645.  
   diseases, studies, Utah, 748.  
   diseases, summary, Mich., 346.  
   flea-beetles, control, Va.Truck, 44.  
   floral parts of different varieties, 228.  
   inspection and certification, notes, Can., 846.  
   internal rust spot disease, 645.  
   leaf roll—  
     control, N.Y.State, 548.  
     effect of locality of origin, 51.  
     effect of origin of tubers, 645.  
     notes, Me., 246.  
     studies, Ind., 547; Utah, 745.  
     transmission, 748; Idaho, 844.  
     transmission in N. Wales, 645.  
   leafhopper in alfalfa, notes, Mich., 355.  
   meal, analyses, U.S.D.A., 78.  
   mosaic—  
     condition of leaves, 645.  
     control, N.Y.State, 548.  
     notes, Me., 246; Wash.Col., 845.  
     relation to temperature, 350.  
     studies, Utah, 745.  
     transmission, Idaho, 844.  
     visibility of symptoms, 645.  
   phloem, anatomical and microchemical alterations in, 645.  
   Rhizoctonia, control, Idaho, 844; Wash.Col., 748.  
   Rhizoctonia, notes, Wash.Col., 845.  
   scab, control, 51; Idaho, 844; Mich., 346; N.J., 743.  
   scab, effect of sulfur, Mich., 351.  
   seed treatments, effect of presprinkling with water, 449.  
   selection farm at Oostwold, 645.  
   silage. (*See* Silage.)  
   silver scab, studies, 847.  
   skin spot, relation to corky scab, 645.  
   spindle tuber disease, notes, Me., 246; N.J., 743.  
   stipple streak disease, 645.  
   tuber resistance to Phytophthora, 645.  
   tubers, healing of wounds in, 218.  
   tubers respiration, relation to black-heart, Calif., 349.  
   wart immune varieties, list, 635.  
   wart immunity, inheritance, Pa., 243.  
   wart, varietal immunity, 148.

## Potato—Continued.

- wilt and filosity, 847.
- wilt, control, Pa., 243.
- witches' broom, notes, Idaho, 844; Wash.Col., 845.

## Potatoes—

- Birgitta, new variety, 438.
- breeding experiments, Mich., 334; N.J., 732; Utah, 732; Wash.Col., 829.
- cost of production, W.Va., 589.
- costs and profits, N.J., 787.
- culture, Ky., 338; U.S.D.A., 828.
- culture experiments, Idaho, 828; Minn., 35; Mont., 437; Oreg., 436; U.S.D.A., 527.
- culture in Quebec, 338.
- development, effect of nutrients, 123.
- dusting v. spraying, N.Y.State, 533, 534.
- early, premature tuber formation, 645.
- effect of fertilizers in relation to soil moisture, N.J., 724.
- effect on following wheat crop, 439.
- feeding, effect on milk flavor, U.S. D.A., 578.
- feeding value, S.Dak., 171.
- fertilizer experiments, 723; Minn., 35; S.C., 528.
- fertilizer requirements, Pa., 233.
- field experiments, factors affecting, W.Va., 734.
- germ cells in, formation and degeneration, 126.
- growth as affected by various nutrient solutions, Md., 518.
- inheritance of tuber color in, 32.
- King Edward, inheritance of color pattern, 32.
- manuring experiments, 722.
- marketing, Calif., 92.
- mutations in, Me., 428.
- papers on, 833.
- production, effect of meteorological factors, 349.
- rotation experiments, N.Y.Cornell, 526.
- row competition and border effect, N.Y. State, 534.
- seed, disinfection studies, N.J., 745.
- seed, factors affecting value, 228.
- seed, hot formaldehyde treatment, Kans., 445.
- seed, size of sets, U.S.D.A., 36.
- seed, source and cutting, Mont., 438.
- seed, valuation, 645.
- seed, vigor of sprouts relation to position on seed piece, 635.
- seedling experiments, Idaho, 828; N.J., 732.
- size-of-seed experiment, depression of check-row yields, 635.
- source of seed tests, S.C., 528.
- spray irrigation for, 287.
- spraying and dusting experiments, N.J., 743.
- spraying experiments, Kans., 446; Mich., 351.

## Potatoes—Continued.

- spraying v. dusting, Mich., 346.
  - storage tests, 830.
  - tipburn injury, relation to color in tissue, 139.
  - varieties, Minn., 35.
  - varieties, synonyms, 635.
  - variety tests, 830; Alaska, 528; Ga. Coastal Plain, 225; Idaho, 828; Utah, 732.
  - ventilated storage for, 438.
- Poultry—
- accounts, U.S.D.A., 92.
  - anatomy and physiology, 772.
  - breeding, Idaho, 875.
  - breeding for egg production, Ind., 173; Utah, 773.
  - breeds, egg production in, Conn. Storrs, 173.
  - breeds in Australia and New Zealand, 163.
  - British, description of breeds, 876.
  - business, four-year plan of development, West.Wash., 391.
  - cost of production, N.J., 787.
  - cross breeds, inheritance in, Kans., 430.
  - culling and feeding, 773.
  - culling directions, 675.
  - culling, principles and practice, Mich., 77.

 public, of Philadelphia, U.S.D.A., 562.  
 rural, elementary agriculture in, 793.  
 rural high, type for, 298.  
 rural, junior projects in, 96.  
 rural, papers on, 898.  
 rural, uses of auditoriums in, 794.  
 southern, elementary agriculture for,  
 899.
- Science and milk, treatise, 373.
- Sclerotinia*—  
*cinerea*, cause of brown rot, 450.  
*cinerea*, notes, Calif., 49.  
*sclerotiorum*, notes, 151.
- Sclerotium oryzae* on rice, notes, 747.
- Scolytus rugulosus.* (*See Shot hole borer.*)
- Scurvy—  
 effect of pregnancy on, 367.  
 effect on subsequent nutrition and  
 growth of guinea pigs, 669.  
 variation of complement during, 264.
- Scutigera immaculata*—  
 affecting asparagus, Calif., 57.  
 notes, 459.
- Scythe, use, 488.
- Seed—  
 analyst, relation to uniform weed leg-  
 islation, 737.

## Seed—Continued.

- coat, structure and development, 516.
- coats, semipermeable, relation to entrance of toxic solutes, 29.
- control service in Denmark, 231.
- inspection in Vermont, Vt., 638.
- testing, 638.
- testing in Montana, Mont., 638.
- testing station for England and Wales, report, 639.
- tests for 1924, N.H., 737.
- treatment with corrosive sublimate, effect of presoaking, Fla., 242.
- treatments, 49.
- treatments, stimulating effect, N.J., 726.

## Seeds—

- agricultural, inspection, Ind., 836.
- buried, vitality, 726.
- from overseas, effect of voyage on germination, 38.
- germination, papers on, 737.
- germination, physiological aspects, 516.
- health of, 647.
- imports, U.S.D.A., 520.
- longevity, 340, 638.
- oil. (*See Oil seeds.*)
- origin, determination, 535.
- registered, growing in Alberta, 836.
- sterilization with uspulun, effect, 347.
- tropical, viability test, 536.
- water absorption, effect of temperature, 624.

## Self-feeders—

- construction and use, Ohio, 770.
- for calves, 678.
- for cows, Ill., 477.
- for pigs, Can., 673.
- v. hand-feeding for pigs, Can., 874.

## Semen, undescribed constituent of, 630.

## Senegin, reaction of protoplasm to, 215.

## Septoria diseases of cereals and grasses, 448.

*Septoria lycopersici*, control, N.J., 744; U.S.D.A., 548.

## Sequoia trees, treatise, 345.

Sericulture. (*See Silkworms.*)

## Serradella—

- behavior, Fla., 224.
- spray irrigation for, 287.

*Serratia marcescens*, studies, N.Y.State, 519.

## Serum proteins and formaldehyde, reaction between, 801.

## Sesame oil, sulfuric index, 411.

*Sesbania aculeata* as green manure and cover crop, 732.*Setaria* spp. parasitizing equines, 85.*Setora nitens*, parasite of, 554.

## Sewage—

- disposal at Jamshedpur, 215.
- disposal, biology, 786; N.J., 890.
- disposal plant, bacteriological study, N.J., 188.
- disposal, studies, 389

## Sewage—Continued.

- disposal systems, 786.
- sludge, fertilizing value, 121.
- Sewerage systems for farm homes, 587.
- Sewing—
  - essentials, textbook, 696.
  - manual, 794.
- Sex ratio, studies, 629, 630.
- Sex reversal, complete, in adult pigeon, 129.
- Sexually mature condition in immature females, induction, 130.
- Sheep—
  - Blackface, types of fibers in, 170.
  - breeding, 169.
  - club, manual, 794.
  - diseases. (*See specific diseases.*)
  - feeding experiments, Calif., 72; Ind., 170.
  - Italian, breeds, 370.
  - management, Kans., 467.
  - on pasture, time used in foraging and resting, 868.
  - production, relation to climate, 870.
  - raising in Minnesota, 870.
  - range, management in New Mexico, 870.
  - scab, infectivity of kraals, 84.
  - shearing methods, 672.
  - Southdown, history, characteristics, and management, 870.
  - stomach worms in, Ohio, 433.
  - viscera, composition, 159.
  - Wensleydale, inheritance in, 332.
  - (*See also Ewes and Lambs.*)
- Shelter belt investigations, U.S.D.A., 527.
- Shipping fever. (*See Pleuropneumonia.*)
- Shot hole borer affecting cherries, West. Wash., 56.
- Shrimps, vitamin A in, 65.
- Shrubs—
  - culture, treatise, 642.
  - germination studies, 516.
  - of Indiana, 444.
- Shume Forest Reserve, reafforestation with cedar, 444.
- Signiphora pulchra*, notes, 557.
- Silage—
  - and hay, proportions for long yearling steers, Wash.Col., 767.
  - bacterial flora, 376.
  - beet pulp and tops, composition, U.S.D.A., 267.
  - changes in chemical composition, 268.
  - corn, feeding value, Ind., 169; Miss., 169, Utah, 80.
  - corn stover v. corn, Mich., 369.
  - corn v. corn and soy bean, feeding value, Miss., 169.
  - corn v. sorghum, feeding value, S.C., 577.
  - corn v. sorghum, for milk production, Fla., 275.
  - feeding value, 276.
  - from mixture of Sudan grass and legumes, 68.

## Silage—Continued.

- grass, analyses, 167.  
 green forage, composition and feeding value, 167.  
 Napier grass v. Japanese cane, Fla., 275.  
 oat and tare, feeding value, 375.  
 potato, feeding value, U.S.D.A., 78.  
 sorghum, feeding value, Miss., 169.  
 sunflower, Miss., 169.  
 sunflower, composition and digestibility at different stages, Ill., 79.  
 sunflower, feeding value, Calif., 78; Ill., 79, 80; Mont., 477.  
 sunflower, quality relation to acidity, Mont., 69.  
 sunflower v. corn, Can., 375; Wash. Col., 767.
- Silica, effect on availability of phosphoric acid, 212.
- Silicon determination, sources of error in, 614.
- Silkworms—  
 bacterial disease, 659.  
 raising in Burma, 155.
- Silos, trench, for North Dakota, 488.
- Silver-leaf disease, studies, 846.
- Siphonophora rosae floridae*, parasite of, N.Y.Cornell, 360.
- Sires—  
 Holstein-Friesian, comparison, Mo., 376.  
 purebred, selection, S.Dak., 276.  
 (See also Bulls.)
- Sisal industry in British Empire, 229.
- Sitophilus*—  
*granaria*. (See Granary weevil.)  
*oryza*. (See Rice weevil.)
- Sitostanol preparation, 709.
- Sitosterol preparation, 709.
- Sitosterol reduction, 709.
- Sitotroga cerealella*. (See Angoumois grain moth.)
- Skim milk—  
 powdered, feeding value, 371.  
 use in sprays, 56.
- Sleeping sickness, prevention, 480.
- Sludge, activated, use as fertilizer, 215.  
 (See also Sewage.)
- Smilacin, reaction of protoplasm to, 215.
- Smimthurus hortensis* as crop pest, 852.
- Smimthurus* sp., control, Va.Truck, 43.
- Smut control tests, Utah, 747.
- Smut treating machine, construction, Calif., 50.  
 (See also specific hosts.)
- Smuts, biology, 746.
- Snails, effect on sugar cane root disease, 449.
- Snotsiekte in cattle, 84.
- Snow bunting, food habits, U.S.D.A., 354.
- Snow, fertilizing value, Can., 423.
- Soap-nicotine preparations, deterioration, 309.
- Soda, use as fungicide, 646.

## Sodium—

- arsenite samples, composition, 82, 178.
- biphosphate, effect on acid soils, 621.
- carbonate, effect on acid soils, 621.
- carbonate, effect on ammonification and nitrification, Idaho, 813.
- carbonate formation, Calif., 21.
- chloride, effect on alfalfa, 723; N.J., 724.
- chloride, effect on ammonification and nitrification, Idaho, 813.
- chloride, effect on uric acid concentration in blood, 860.
- chloride, tolerance of plants as affected by temperature, Calif., 25.  
 (See also Salt.)
- determination, iodometric method, 806.
- effect on orange trees, Calif., 26.
- fluoride as an insecticide, 850.
- fluosilicate, insecticidal value, Tenn., 555.
- hypochlorite, phenol coefficient of disinfecting powers, 776.
- nitrate, effect on apples, Pa., 233.
- nitrate, effect on nodulation of soy beans, 339.
- nitrate, effect on nutrition of tomato, N.Y.Cornell, 44.
- nitrate, effect on sugar beets, 834.
- nitrate, fertilizing value, 422, 526.
- phosphate, effect on acid soils, 621.
- silicate, effect on acid soils, 621.
- sulfate, effect on acid soils, 621.
- sulfate, effect on ammonification and nitrification, Idaho, 813.
- Soil—  
 acidity—  
 and lime deficiency, studies, 21.  
 and organic matter, studies, 319.  
 and solubility as affected by sulfur, 423.  
 measuring intensity factor, 613.  
 of air-dried samples, 619.  
 papers on, 17.  
 qualitative tests for, 310.  
 relation to soil type groups, 811.  
 studies, 319; N.J., 741.  
 (See also Lime, Limestone, Liming, and Soils, acid.)
- analysis, mechanical, methods, 121.
- analysis, value, 209.
- bacteria, effect of carbon disulfide, 721.
- bacteria, effect of cyanamid, 513.
- biology studies, progress, 118.
- blowing, control, U.S.D.A., 828.
- colloids, binding power, 211.
- colloids, composition, U.S.D.A., 503.
- colloids, estimating, 619.
- colloids, heat of wetting, 418.
- colloids, removal, effect, 419.
- conservation, studies, Kans., 420.
- constituents and plant withdrawals, Calif., 20.
- cultivation, motorized, in Germany, 785.
- erosion as research problem, 386.

## Soil—Continued.

- erosion, cause and prevention, 22.
- fertility, rebuilding, 233.
- fertility studies, Ind., 211; Ky., 421; Mich., 317; Wash.Col., 814.
- fertility studies at Rothamsted, 211.
- granulation, effect of water, 418.
- improvement studies at Rothamsted, 816.
- management, West.Wash., 322.
- management and crop production, treatise, 696.
- management and fertilization in Arkansas, 816.
- materials, thermal diffusivity and conductivity, 811.
- microorganisms as affected by rice culture, Calif., 23.
- moisture, determination, Calif., 810.

- of the Biesbosch in South Holland, studies, 618.
- of the Dollards of Groningen, 618.
- of Transvaal, Waterberg sandy, 210.
- of United States, textural composition, 208.
- of West Virginia, analyses and fertility, W.Va., 511.
- organic matter in. (*See* Organic matter.)
- organic, profiles, 417.
- peat. (*See* Peat.)
- percolation of water through, Calif., 19.
- phosphate availability, determination, 311.
- properties and classification, 717.
- replaceable bases in, Calif., 318.
- reservoir capacity, Wash.Col., 810.
- resistance to acidification, 116.
- salt content, relation to crop yield, 121.
- sampling, Mich., 717.
- sterilization, effect, 646.
- sterilization, effect on microorganisms, N.J., 720.
- sterilization for vegetables, Kans., 449.
- sterilization, studies, 234, 321.
- studies, Ill., 420; Wash.Col., 814, 815.
- subgrade, field tests, U.S.D.A., 184.
- supporting value as affected by bearing area, 687.
- total surface, effect of temperature on, 117.
- treatise, 115.
- Vesuvian, nitrogen-fixing bacteria in, 22.
- Vesuvian, streptothrices in, 22.

## Soils—Continued.

- water freezable in, U.S.D.A., 783.
- waterlogged, orchard injury from, Mont., 450.
- Solar phenomena, systematically varying period in, U.S.D.A., 414.
- Solar radiation. (*See* Radiation.)
- Solutions, nutrient. (*See* Nutrient.)
- Sorghum—
  - breeding experiments, 823; Kans., 433.
  - culture experiments in Russia, 735.
  - experiments on Great Plains, U.S.D.A., 37.
  - fall seeding experiments, 633.
  - grain, inbreeding, 32.
  - injurious after-effects, 834.
  - insects affecting, Kans., 452.
  - silage. (*See* Silage.)
  - smut, control, Kans., 445.
  - variety tests, Fla., 224; Guam, 226; Kans., 433; Wash.Col., 829.
  - Yolo, breeding experiments, Calif., 33.
  - Yolo, culture experiments, Calif., 32. (*See also specific kinds.*)
- Sorgo—
  - as sugar crop in Russia, 736.
  - forage yields, Mont., 435.
  - honey, irrigation experiments, Calif., 33.
  - sirup, jellying in, cause, 13.
  - v. grain sorghum as forage crop, U.S.D.A., 37.
  - varieties, yields, Fla., 224.
  - variety tests, Fla., 224; Guam, 226; Kans., 433; Wash.Col., 829.
- South Carolina Station, report, 598.
- Sow thistle, growth and reproduction, N. Dak., 231.
- Sows—
  - brood, cost of keeping, Wash.Col., 873.
  - brood, feeding and litters, Mont., 371.
  - brood, nutritive requirements, Kans., 469.
  - brood, winter rations, Pa., 270.
  - genital organs, nature of secretions during oestrus, 631.
  - winter rations for, Wash.Col., 873. (*See also* Pigs.)
- Soy bean—
  - bacterial pustule, studies, 650, 651.
  - forage, feeding value, S.C., 569.
  - hay, feeding value, Miss., 275.
  - hay for milk production, Pa., 275.
  - hay, yields, Ga:Coastal Plain, 225.
  - meal, feeding value, Ill., 466.
  - mosaic disease, relation to temperature, 350.
  - oil iodine number, 636.
  - oil meal, feeding value, Ill., 476; Ind., 169; Ohio, 473.
  - proteins, digestibility, 63.
- Soy beans—
  - and corn, culture, Mo., 436.
  - assimilation-respiration balance, 626.
  - culture experiments, Alaska, 528.
  - effect of aeration and continuous renewal of nutrient solution, 125.

## Soy beans—Continued.

- fall seeding experiments, 633.
- feeding value, Ill., 466; Ind., 169.
- history and culture, treatise, 636.
- inoculation, effect, Kans., 434.
- mottling in, cause, 825.
- nodulation, N.J., 732.
- nodulation, effect of mineral fertilizers, 338, 339.
- protein and oil content, factors affecting, 636.
- sources of iron for, N.J., 725.
- variety tests, Ga. Coastal Plain, 224; Guam, 226; Ind., 226; Kans., 433; Miss., 226; N.J., 732; S.C., 528; Wash.Col., 829.
- vitamin A in, 65.
- yield and nitrogen in, effect of lime, N.J., 735.

Sparrow, English, in Washington, West. Wash., 354.

Specie differences, origin and inheritance of, 128.

Species concept, symposium, 127.

Species, origin, Willis' theory of, 628.

## Spelt—

- and rye, sterile hybrid, notes, 628.
- history, distribution, and use, U.S. D.A., 34.
- stripe rust, notes, 648.

Spermatomicros, suggested name, 630.

## Spermatozoa—

- flocculation, relation to surface charge, 826.
- physiology of, 730.
- viability, effect of menotoxin, 524.

*Sphaeceloma ampelinum*, notes, 549.

Sphaeropsidales, precipitins of, studies, Mich., 346.

*Sphaeropsis malorum*, growth on culture media, 216.

Sphagnum and tree moss, water-holding capacity, 842.

*Sphenophorus discolor*, life history, 857.

Spices, total ash determination, 801.

Spider flower, alternation of sexes, 127.

Spiders, red. (*See* Red spider.)

*Spilochalcis* sp., notes, 858.

## Spinach—

- canning, value of precooking, U.S.D.A., 459.
- Fusarium blight, 351.
- hypoglycemia-producing principle in, 667.
- leaves, new protein from, 708.
- rust, notes, 351.
- vitamins in, effect of preparation, 262.

Spinacin, new protein from spinach, 708.

*Spirochaeta morsus-muris*, notes, 761.

*Spondylocladium atrovirens*, studies, 847.

## Spray—

- machine for alfalfa fields, 888.
- materials and equipment, Mo., 236.
- materials, combined, preparation and use, U.S.D.A., 441.

## Spray—Continued.

- mixture, dry-mix, tests, N.J., 738.
- mixture, triple, 657

## Spraying—

- and dusting experiments, N.J., 751.
- and dusting experiments, cooperative, 646.
- dust. (*See* Dusting.)
- relation to renovation of orchards, 852.
- stimulation to fruit trees, 850.
- (*See also* Apples, Potatoes, etc.)

## Sprays—

- commercial v. home-mix, Pa., 252.
- copper. (*See* Copper.)
- lead arsenate and lime sulfur, chemical studies, N.Y.State, 501.
- spreading power and measurability, 554.
- use of skim milk in, 56.
- (*See also* Insecticides, Fungicides, and specific forms.)

Springs, steel, heat treatment, 488.

Springtails, control, Va.Truck, 43.

## Spruce—

- cone worm, notes, Mich., 355.
- Engelmann, germination, factors affecting, 541.
- seedlings, heat-resisting capacity, U.S. D.A., 47.
- soils, composition, 511.

## Squash bug—

- common, parasite of, 156.
- notes, Wash.Col., 852.

Squirrels, destruction of conifer seeds by, 240.

"Staggers" or "Pushing Disease" of cattle in Natal, 82.

Stain for microorganisms and tissues, 378.

Stains, biological, standardization, N.Y. State, 519.

Stallions, enrollment, Ind., 874.

Staphylococci rôle in epizootic lymphangitis, 483.

*Staphylococcus muscae*, notes, 558.

## Starch—

- determination, 112.
- in sorgo sirup, 13.
- of wheat, viscosities, determining, 13.
- storage in pear and apricot trees, Calif., 42.

## Starches—

- rate of digestion by amylase, U.S.D.A., 503.
- treatise, 609.

Starling, European, spread in North America, U.S.D.A., 749.

Statistics, rôle in agronomic experiments, 731.

## Steel—

- and timber structures, treatise, 183.
- bars, new billet and rerolled, comparative tests, 287.
- springs, heat treatment, 488.

Steer calves, winter rations, Miss., 269.

## Steers—

- cost of fattening, Mont., 467.
- feeding experiments, Can., 869, 870; Idaho, 869; Ky., 466; Mich., 369; Miss., 169; Mo., 369, 466; N.Mex., 868.
- finishing, Miss., 269.
- v. heifers and yearlings, feeding experiments, Calif., 71.
- winter feeding, Ind., 168.

(See also Cattle.)

*Stemphylium parasiticum*, notes, 649.

*Stereum purpureum*—

- notes, Wash.Col., 845.
- studies, 846.

## Sterility—

- genetic aspects, 280.
- in dairy cattle, U.S.D.A., 583.

Sterols, separation of unsaturated from saturated, 709.

*Stilpnotia salicis*, notes, Wash.Col., 852.

Stock. (See Livestock.)

Stock foods. (See Feeding stuffs.)

## Stomach worms in—

- cattle and sheep, 280.
- lambs, Miss., 283.
- sheep, treatment, Ohio, 483.

Stomata, rôle in transpiration of plants, 517.

Stomatitis, mycotic, of cattle, U.S.D.A., 84.

Stone, crushed, tests, U.S.D.A., 783.

Storage room, winter, for homes, Mich., 489.

Storms, tropical, of North Atlantic Ocean, U.S.D.A., 416.

*Strategus antaeus*, injury to peach trees, 454.

Straw, detrimental effect on plants, N.Y. State, 513.

Straw humification experiments, Wash. Col., 815.

## Strawberries—

- breeding, 142.
- cost of production, Utah, 788.
- cost of production and marketing, Ky., 490.
- culture, Mo., 237.
- culture experiments, Guam, 232; N.J., 738.
- insects affecting, Mo., 156.
- mulching studies, Mont., 441.
- preservation by freezing, Calif., 15.
- production in Florida, 142.
- Sitka hybrid, Alaska, 536.
- variety tests, Ga.Coastal Plain, 232.

## Strawberry—

- black root, Mich., 53.
- diseases, notes, Utah, 745.
- fruit rots, notes, 352.
- leather rot, studies, 150.
- mollislose, notes, 352.
- purple leaf blotch, notes, 748.
- red plant, studies, 748.
- root aphid, studies, Tenn., 553.
- srup, pasteurized, vitamin C in, Calif., 65.

## Streams—

- pollution, in New York State, 188.
- small, farm power from, U.S.D.A., 888.

Streptothrices in Vesuvian soils, 22.

Stripe rust in United States, 648.

*Stromatinia lava* on apricots, 150.

Strongylids, equine, in South Africa, 85.

Stump removal, costs, Minn., 88.

Sublimed blue lead, use against corrosion of iron and steel, 889.

Subsolling experiments, 118.

## Sudan grass—

- and legumes, ensiling, 68.
- culture, U.S.D.A., 828.
- fall seeding experiments, 633.
- irrigation experiments, Calif., 33.

## Sugar beet—

- culture in arid Russia, 736.
  - curly-top disease, studies, 149.
  - industry in United States and Canada, 834.
  - late blight, relation to rainfall, 351.
  - Phoma rot, notes, Utah, 745.
  - pulp and tops, composition, U.S.D.A., 267.
  - root maggot, life history, Utah, 752.
  - seed from selected roots, 339.
- (See also Beet.)

## Sugar beets—

- breeding experiments, Mich., 334.
- culture experiments, 339; La., 534.
- effect of sodium nitrate, 834.
- fall seeding experiments, 633.
- fertilizer experiments, Mich., 735.
- inoculation, 735.
- irrigation and growth, 534.
- irrigation experiments, Utah, 733.
- production in Minnesota, 834.
- rotation experiments, Mont., 435.
- seed production, 834.
- spacing experiments, 339.
- tests, Mich., 834.

## Sugar cane—

- beetle, studies, U.S.D.A., 256.
- borer moths attraction to light, 154.
- borer, notes, 554.
- borer on corn, effect of wild grasses, 61.
- borers, new remedy, 154.
- bud variations and sports in, 735.
- buds, effect of cold, 229.
- burning before cutting, effect, 38.
- culture in Queensland, 439.
- cutting back, effect, 38.
- diseases in 1923 and 1924, La., 548.
- experiments, 439.
- fertilizer experiments, 132, 636.
- flowers, fertility, 735.
- imported varieties, studies, 439.
- insects affecting, 356.
- insects affecting in Fiji, 556.
- irrigation experiments, 735.
- juice, clarification, 113.
- juice, removal of albumin from, hot v. cold liming for, 412.
- juice, super-defecation, 205.
- marketing, U.S.D.A., 294.

## Sugar cane—Continued.

- mosaic. (See Sugar cane mottling disease.)
- mottling disease, notes, La., 548.
- mottling disease, tolerance and resistance to, 847.
- root borer, notes, 636.
- root disease, rôle of snails in, 449.
- root rot, data, 149.
- root rots, notes, La., 548.
- spacing experiments, 835.
- Uba, characteristics, 137.
- Uba, deterioration, 735.
- variety tests, 132, 636; Guam, 226.

## Sugar—

- content, effect on quality of ice cream, Mo., 679.
- crops, culture in arid regions, 736.
- effect on viability and growth of *Bacillus botulinus*, 165.
- excreted in normal urine, type, 861.
- factory products, surface tension, 315.
- in blood. (See Blood sugar.)
- in normal urine, nature, 806.
- industry of world, 534.
- machinery, treatise, 615.
- raw, removing gummy and waxy material, 13.
- refining, basic operations, 114.
- refining industry of New York, historical sketch, 114.
- substitutes in ice cream, Mich., 377.

## Sugars—

- determination, method, 111.
- effect on insulin convulsions in mice, 567.
- (See also Glucose, etc.)

## Sulfate—

- of ammonia. (See Ammonium sulfate.)
- of potash. (See Potassium sulfate.)

## Sulfur—

- and soil organic matter, studies, Wash.Col., 814.
- colloidal, preparation and use, 859.
- cycle in soil, 117.
- cycle in soils, plants, and animals, Mich., 24.
- effect on barley, U.S.D.A., 34.
- effect on crops and soils, 423.
- effect on potassium availability, Ky., 421.
- effect on potatoes, Mich., 351; N.J., 732.
- inoculated, and rock phosphate, fertilizing value, Ky., 421.
- inoculated and uninoculated, for potato scab, N.J., 743.
- metabolism, 364.
- metabolism of cows, effect of protein in rations, Mo., 478.
- mixtures. (See Lime-sulfur.)
- organic compounds produced in bacterial cultures, 611.
- oxidation, 819.
- oxidation by *Thiobacillus thiooxidans*, N.J., 720.

## Sulfur—Continued.

- oxidation, effect on solubility of minerals, 515.
- Sulfuric acid, effect on strength of cotton fiber, 227.
- Summer fallow tillage, principles, Wash. Col., 620.
- Sun spots—
  - and tropical cyclones, 114.
  - effect on temperature, 208.
- Sunflower—
  - growth, relation to climatic conditions, 632.
  - oil production in Argentina, 228.
  - seed oil, sulfuric index, 411.
  - silage. (See Silage.)
- Sunflowers—
  - culture experiments, Alaska, 528.
  - fall seeding experiments, 633.
  - seeding experiments, Idaho, 828; Wash.Col., 829.
  - stage of maturity for ensilage, Can., 866.
  - variety tests, Mont., 435.
- Sunlight—
  - effect on botulinus toxin, 464.
  - effect on chemical nitrification, 420.
  - effect on egg production, Kans., 475.
  - (See also Light.)
- Superphosphate—
  - ammoniated, fertilizing value, 422.
  - fertilizing value, 526.
  - (See also Phosphates, comparison.)
  - treated with ammonia, fertilizers from, 514.
- Sweating sickness in calves, 84.
- Swedes, breeding experiments, 437.
- Sweet clover—
  - breeding experiments, Mich., 334.
  - culture, U.S.D.A., 828.
  - culture experiments, N.J., 732.
  - culture in Alberta, 736.
  - hay production, Mont., 435.
  - Hubam, behavior, Fla., 224.
  - seed coat and germination studies, 516.
- Sweet corn—
  - breeding experiments, 823.
  - canning, effect of scalding, U.S.D.A., 460.
  - drying, chemical aspects, Md., 207.
  - fertilizer experiments, Ohio, 23.
  - injury from high temperature, relation to color in stalks, 139.
  - sirup from stalks, 207; Minn., 205.
  - varieties for canning, 140.
- Sweet pea germination, notes, Can., 639.
- Sweet potato—
  - diseases, Del., 843.
  - diseases, control, N.J., 744.
  - meal, feeding value, U.S.D.A., 78.
  - mosaic disease, notes, Fla., 242.
  - pox, control, N.J., 744.
  - Pythium rootlet rot, description, 547.
  - rots, control, Kans., 446.

- Sweet potato—Continued.  
 stem rot, control, Miss., 242.  
 stem rot, studies, N.J., 351.  
 weevil in Jamaica, summary, 559.
- Sweet potatoes—  
 and peanuts, hogging down, S.C., 569.  
 canning, effect of precooking, U.S.D. A., 460.  
 cost of production in New Jersey, 690.  
 culture, Ga.Coastal Plain, 225.  
 fertilizer tests, Fla., 224.  
 marketing, Calif., 92.  
 studies, N.J., 534.  
 variety tests, 132; Ga.Coastal Plain, 225; S.C., 528; Utah, 732.  
 yield and shape, effect of fertilizers, N.J., 732.
- Sweetening compounds, synthetic, chemistry of, 805.
- Swine—  
 erysipelas bacillus, effect of bile, 283.  
 erysipelas, immunization against, 683, 781.  
 (See also Pigs.)
- Symbiosis of plants, studies, 426.
- Sympiesis* spp., notes, Iowa, 358.
- Symptomatic anthrax. (See Blackleg.)
- Synchytrium*—  
*endobioticum*, immunity to, 148.  
 spp., notes, 448.
- Synetaeris* sp., notes, 659.
- Tachinid fly parasites, liberation, 853.
- Tafia, effect on physical properties of soil, 622.
- Tankage—  
 feeding value, Tex., 572.  
 v. buttermilk for pigs, Can., 873.
- Tannery waste, feeding value, Calif., 74.
- Tapeworm, control, Kans., 481.
- Tapeworms in dogs, treatment, 886.
- Taphrina bullata*, control, 748.
- Taros—  
 insects affecting, 356.  
 new food plants for the South, U.S. D.A., 340.
- Tarostenus unwittatus*, egg and first-stage larva, 559.
- Tartar emetic, anthelmintic value, 777.
- Tax revision in Kansas, Kans., 691.
- Tea—  
 in India, thrips affecting, 854.  
 pests in Dutch East Indies, control, 554.  
 plant, treatise, 840.  
 seed oil, sulfuric index, 411.
- Teacher's professional library, list of books, 795.
- Teeth—  
 formation, effect of light and diet, 763.  
 of children, caries in, effect of diet, 763.
- Telenomus*—  
*latisulcus*, notes, 361.  
*truncativentris*, sex ratios, 333.
- Teleonemia lantanae*, notes, 356.
- Temperature—  
 and rainfall, correlation, 207.  
 and sun spots, 208.  
 effect on absorption of water by cotton, 533.  
 effect on corn and sunflower growth, 632.  
 effect on flax wilt, 348.  
 effect on protein consumption, 761.  
 effect on total surface of soil, 117.  
 region map, 809.  
 requirements of hot spot manifolds, 89. (See also Climate and Soil temperature.)
- Tennessee Station, report, 598.
- Tepary beans—  
 breeding experiments, 823.  
 digestibility, 663.
- Tephrosia*—  
*candida*, photoperiodism, 126.  
 spp. as green manure and cover crop, 732.
- Teratology in plants, 519.
- Termites—  
 distribution, classification, and biology, 753.  
 in Porto Rico, 657.  
 new, in Canal Zone, Panama, 657.  
 notes, Mich., 355.
- Terraces, Mangum, planning and construction, Ill., 22.
- Tetanus, prevention, 480.
- Tetralin as fuel in internal-combustion engines, 784.
- Tetramorium caespitum*. (See Ants, pavement.)
- Tetraneura colophoidea*, parasite of, N.Y. Cornell, 360.
- Tetranychus telarius*. (See Red spider.)
- Tetrastichodes platanellus* n.sp., description, 663.
- Tetrastichus*—  
*australasiae* n.sp., description, 361.  
*diarthronomyiae*, notes, Md., 457.  
*radiatus*, life history, 154.
- Tetrigidae, inheritance in, studies, Kans., 428.
- Texas—  
 College, notes, 399.  
 Station, history and work, 397.  
 Station, notes, 700, 900.
- Textiles, textbook, 197.
- Thecla* spp., notes, 356.
- Theileria* spp., studies, 583.
- Thielavia basicola* on watermelon, 352.
- Thielaviopsis*—  
*paradoxa* on coconut palm, 353.  
 sp., studies, 545.
- Thiobacillus thiooxidans*, studies, N.J., 720.
- Thiosulfate bacteria, biology of, 117.
- Thistle oil production in Argentina, 228.
- Threshing—  
 losses from types of harvester-threshers, Utah, 785.  
 machines, belt and pulley speeds for, 289.

- Thrips—  
 control in cauliflower seed bed, N.Y. State, 553.  
 injury to snap beans, Fla., 251.  
*Thrips tritici*, notes, Mich., 355.  
 Thymus as affected by castration in rats, 480.
- Thyroid—  
 apparatus, studies, 866, 867.  
 feeding, effect on fowl plumage, 675.  
 gland as affected by castration in rats, 480.  
 survey of Cincinnati school children, 165.  
 survey of Minnesota school children, 166.  
 survey of Montana school children, 166.  
 weight and body weight, correlation, 368.
- Thyro-parathyroidectomy, effect on rats, 866, 867.
- Thysanoptera from Italy, list, 753.
- Tick eradication, 881.
- Ticks in native cattle and deer in Panama, 778.  
 (See also Cattle tick.)
- Tillage, summer fallow, principles, Wash. Col., 620.
- Tilletia secalis*, threatening development in Russia, 646.
- Timber—  
 decayed, heat treatment, 55.  
 deterioration and preservative treatment, 585.  
 seasoning, effect on fungi, U.S.D.A., 249.  
 utilization in farm buildings, 887.  
 (See also Lumber and Wood.)
- Timothy—  
 hay, United States grades for, U.S. D.A., 92.  
 hay v. alfalfa hay for horses, N.Y. Cornell, 772.  
 seed production, 334.  
 variety tests, N.J., 732.
- Tinea* spp., notes, 554.
- Tiphia*—  
*inornata*, notes, U.S.D.A., 256.  
 sp., selective parasitism by, 62.
- Tipulids in nun moth areas, outbreak, 554.
- Tischeria malifoliella*, studies, Iowa, 357.
- Tissues, respiratory capacity and vitamin B content, 65.
- Tmetocera ocellana*. (See Bud moth.)
- Tobacco—  
 bacterial leaf spot, notes, Fla., 247; Ky., 446.  
 beetle, control by fumigation, 359.  
 black shank, studies, Fla., 247.  
 Burley, ash analyses, Ky., 434.  
 cost of production, Ky., 490.  
 culture experiments, Ga.Coastal Plain, 225.  
 culture for nicotine extraction, Calif., 33.  
 curing tests, S.C., 528.
- Tobacco—Continued.  
 diseases, cause and control, U.S.D.A., 247.  
 diseases, notes, Can., 846.  
 diseases, studies, Fla., 246.  
 extracting nicotine from, 535.  
 fertilizer experiments, 736; Ga.Coastal Plain, 225; Ky., 434.  
 flea-beetle in dark fire-cured tobacco district, U.S.D.A., 61.  
 flea-beetle, life history studies, 856.  
 flea-beetles, control, Va.Truck, 44.  
 high-nicotine, studies, N.Y.State, 534.  
 marketing, U.S.D.A., 294.  
 mosaic disease, studies, Ky., 446.  
 nicotine content, factors affecting, 138.  
 parthenocarpy and parthogenesis in, 522.  
 plants, healthy and diseased, analyses, Conn.State, 537.  
 powder and lime dressing, test for ox warbles, 359.  
 root rot, notes, Ky., 434.  
 root rot, resistant strains, Ky., 446.  
 solution for spraying, preparation, 657.  
 wildfire, studies, Fla., 247.
- Tomato—  
 blight, control, Idaho, 844.  
 blossoms, blighting, 60.  
 catsup, fermentation in, N.Y.State, 503.  
 diseases, Calif., 48; N.J., 744.  
 fruit worm, notes, Va.Truck, 44.  
 leaf spot, control, U.S.D.A., 548.  
 mosaic disease, relation to temperature, 350.  
 Phytophthora rot, notes, 548.  
 "sleepy disease," notes, 549.  
 stripe disease, cross inoculations, 52.  
 wilt, control, Ark., 247.  
 wilt resistant varieties, Miss., 242.  
 wilt spread by infected seed, 351.  
 wilt, studies, Kans., 446.  
 yellows, studies, Wash.Col., 845.
- Tomatoes—  
 addition to milk ration of calves, 678.  
 breeding, use of statistical data in, 235.  
 canning, diseases, Utah, 745.  
 canning industry, Calif., 441.  
 canning, value of scalding, U.S.D.A., 460.  
 culture for canning factory, Ind., 837.  
 effect of carbon dioxide, 234.  
 effect of pinching leaders, Can., 537.  
 English, vitamin C in, 863.  
 fertilizer experiments, 233; Ill., 440; N.J., 738; Ohio, 23; S.C., 537.  
 fertilizer requirements, Pa., 233.  
 from pure line selections, yields, Mont., 441.  
 genetic linkage between size and color factors, 729.  
 greenhouse, production, U.S.D.A., 640.  
 inheritance in, Pa., 522.

## Tomatoes—Continued.

- inheritance of plant type, Pa., 233.
- nematodes affecting, Calif., 50.
- nutrient requirements, N.Y.Cornell, 44.
- ripe, radioactivity, 519.
- spraying and dusting, Va.Truck, 44.
- strain tests, Utah, 739.
- triploidy in, 628.
- variety tests, Ga.Coastal Plain, 232; Idaho, 836; Kans., 441; S.C., 537.

## Top minnow, spermatogenesis, 433.

*Tortrix*—

- citrana*, life history, 756.
- pronubana*, life history and habits, 855.

*Torula ligniperda* in wood tissue, 353.*Toxoptera graminum*, parasite of, N.Y. Cornell, 360.*Trachysphaera fructigena* n.g. and n.sp., description, 249.

## Tractor engine—

- air cleaners, tests, 586.
- fuel consumption, effect of carburetor adjustment, Calif., 86.

## Tractors, tests, Nebr., 288.

## Traffic control and safety, U.S.D.A., 184.

*Trametes* spp., notes, 55.

## Transpiration—

- of coniferous seedlings, studies, 345.
- of plants, rôle of stomata in, 517.
- of white pine, factors affecting, 625.

## Tree—

- growth, effect of meteorological factors, 809.
- repair work, examination and licensing for, Conn.State, 841.
- seedlings, relative resistance to excessive heat, U.S.D.A., 47.
- surgery, papers on, Conn.State, 841; West.Wash., 397.

## Trees—

- affected with brown bast, census, 151.
- and shrubs of Mexico, 444.
- and shrubs of Yellowstone National Park, 240.
- annual rings, rôle in climatic study, 809.
- coniferous. (See Conifers.)
- germination studies, 516.
- native, identification, 444.
- nutrition, rôle of nitrogen in, 236.
- ornamental, diseases and other injuries, Conn.State, 849.
- rodent enemies, 353.
- shade, insects affecting, Conn.State, 854; Kans., 452.
- spraying, paper on, West.Wash., 598.

## Trench—

- fever, prevention, 480.
- silo, test, Can., 866.

*Trichloris pluriflora*, striped grass looper affecting, 61.*Trichogramma minutum*, notes, U.S.D.A., 456.*Trichopoda pennipes*, biology, 156.*Trichosoma columbae*, notes, 361.*Trichostrongylus* spp. parasitizing equines, 85.*Trifolium lupinaster*, culture experiments, Alaska, 528.*Trioxa*—

- buatoni* n.sp., description, 357.
- tripunctata*. (See Blackberry psyllid.)

*Triticum dicoccum dicoccoides*, genetic relation and synthetic form, 223.

## Truck—

- crop pests, control, 753.
- crops, diseases, Pa., 243.
- crops, fertilizer experiments, Ohio, 23.
- crops, manuring experiments, treatise, 421.
- crops, plant lice affecting, Pa., 252.
- farms, child labor on, 492, 591.

## Trucks. (See Motor trucks.)

## Trypaneidae of South African museum, 855.

## Trypanosomiasis in animals, treatment, 779.

## Tryptophane in proteins, 802.

## Tsetse in the Transvaal, 82.

## Tsetse-fly disease, prevention, 480.

## Tuber tissue, isoelectric point for, 124.

## Tubercle bacilli—

- bile-treated, for vaccination of cattle, 282.
- concentration, 380, 381.
- in milk, thermal death point, 177.
- methods of cultivating, 682.

## Tuberculin—

- derivatives, diagnostic and sensitizing properties, 180.
- old, sensitiveness to, 483.

## Tuberculosis—

- avian, in swine, Ill., 483.
- avian, transmission through eggs, 582.
- bovine, notes, 280.
- chronic, prevention, 381.
- control, U.S.D.A., 583.
- eradication, 881.
- eradication, Eastern States Conference on, 885.
- immunity, studies, 180.
- immunization with bile-treated bacilli, 282, 683.
- of fowls, 485; Ill., 86.
- prevention, 480.
- pulmonary bovine, inoculation experiments with chickens, Calif., 81.
- vaccination by ingestion in laboratory animals, 180.
- vaccination of cattle against, 282.

## Tule billbug, life history, 857.

## Turbidimeter, description, 310.

## Turbidiscopes, description, 11.

## Turkey eggs, hatching artificially, Calif., 75.

## Turnips—

- breeding experiments, 437.
- notes, Alaska, 536

## Turpentine—

- anthelmintic value, Ohio, 84.
- beetle, red, on pine and cypress, Calif., 58.

- Turpentine**—  
 pine trees, methods, U.S.D.A., 444.  
 studies in Greece, 742.
- Tuskegee Institute, agricultural training**  
 in, 298.
- Tussock moth**, antique, notes, Wash.Col.,  
 854.
- Tylenchus dipsaci***—  
 in seeds of composites, 152.  
 on wild strawberry, 352.
- Typhlocyba***—  
*comes*. (See Grape leafhopper.)  
*rosae*, notes, 855.
- Typhoid**, equine. (See Pleuropneumonia.)
- Typhoid fever**, prevention, 480.
- Typhoid fly**. (See House flies.)
- Typhus fever**, prevention, 480.
- Ultraviolet**—  
 irradiation, antirachitic properties im-  
 parted by, 762, 763.  
 light, effect on anemia in avitaminous  
 animals, 67.  
 light, effect on avitaminoses, 366.  
 light, effect on egg production, Kans.,  
 475.  
 light, effect on poultry production  
 and growth, 797.  
 light, effect on properties of rations.  
 862.  
 radiation, oxy-products, photolysis,  
 668.  
 rays as treatment for rickets, 565.
- Uncinaria stenocephala***, notes, 182.
- Undernutrition and fasting**, treatise, 564.  
 (See also Diet deficiency and Nutri-  
 tion.)

- Vitamin—  
A and B in pumpkin, 762.  
A deficiency in poultry, 782; Calif., 77.  
A determination, modified technique, 804.  
A in eggs, effect of prolonged storage, 664.  
A in fresh eggs, 664.  
A in Indian foods, 64.  
A in milk, variations, U.S.D.A., 562.  
A of cod liver oil, durability, 462.  
A of hardened cod liver oil, stability, 461.  
A requirement of chicks, 173.  
A requirement of pigs, Ill., 469.  
A, sources in poultry feeds, Calif., 875.  
antineuritic, in poultry flesh and eggs, 161.
- Vitamin—Continued.  
antineuritic, in yeast, preparing concentrates, 462.  
B and bios, significance of terms, 110.  
B and carbohydrates, interdependence of, 863.  
B and V factor, differentiation, 681.  
B, concentration, 709.  
B deficiency, basal metabolism in, 262.  
B deficiency, effect on oxidative processes, 65.  
B, ferric ferricyanide reaction for, 805.  
B in barley, malt, and beer, 564.  
B in evaporated milk, 201.  
B, synthesis by intestinal bacteria, 64.  
C deficiency, effect on resistance to bacterial infection, 179.  
C deficiency, sensitization of organism to, 365.  
C, diffusibility, 711.  
C from lemon juice, 710.  
C in barley, malt, and beer, 564.  
C in English tomatoes, 863.  
C in milk, factors affecting, 877.  
C in pasteurized strawberry sirup, 65.  
C, reducing properties, 711.  
D, significance of term, 110.  
deficiency. (See Avitaminosis.)  
requirements of chicks, Can., 570.  
requirements of poultry, 273.  
studies, summary, 463.  
X, effect on fertility, 864.  
X, effect on milk production in rats, 176.  
X, studies, 262.
- Vitamins—  
color test for, 313.  
fat-soluble, experiment station work on, U.S.D.A., 462.  
fat-soluble, studies, 862.  
immunologic significance, 179.  
in foods for children, 64.  
in honey, 64.  
in preserved milk, U.S.D.A., 562.  
in spinach, effect of preparation, 262.  
relation to production and hatchability of eggs, Kans., 475.  
rôle in bacterial growth, 162.  
water-soluble, studies, 805.
- Vocational education. (See Agricultural education, vocational.)
- Vuilleminia comedens* on oak, 646.
- Wagon wheels, design, 288.
- Waite Agricultural Institute, notes, 798.
- Walls, heat loss through, 688.

black, for timber and nuts, U.S.D.A., 240.  
roots, effect of hydroxyl-ion concentration, Calif., 27.  
rot, notes, 749.  
trees, growth and composition, effect of certain ions, Calif., 820.
- Walnuts—  
culture in California, Calif., 344.  
drying, Calif., 14.

## Walnuts—Continued.

- moldy and black-meated, cause, Calif., 39.
- Persian, culture in California, 143.
- spraying and dusting experiments, Calif., 56.
- varieties, variation in blight susceptibility, Calif., 53.

## Washington—

- College, notes, 400.
- College Station, notes, 400.
- College Station, report, 899.

*Wasmannia auropunctata*, notes, 257.

## Wasps—

- attacking fall webworm, 561.
- bees, and ants, treatise, 854.
- branonid, from India, catalogue, 155.

## Water—

- absorption and desorption by soda—boiled cotton, 532.
- absorption and germination of seed corn, 335.
- absorption by corn seeds, effect of temperature, 624.
- bacteriophage and self-purification, 389.
- buffalo milk, cost of production, 894.
- content of butter, 775.
- excretally polluted, effects of storage, 685.
- films, function in soil granulation, 418.
- freezable in soils, U.S.D.A., 719, 783.
- friction in pipes, effect of temperature, 887.
- gardening, treatise, 741.
- in crankcase oils, 186.
- in Montana, base exchange in, 685.
- iodine determination in, 712.
- irrigation. (*See* Irrigation water.)
- percolation through soils, Calif., 19.
- powers of Great Salt Lake basin, 286.
- purification by lime in Dutch East Indies, 389.
- rain. (*See* Rain.)
- suitable for livestock, 671.
- supply, artesian, in North Dakota, 685.
- supply of—
  - Columbia River and Pacific slope basins, 286.
  - Hawaii, 87.
  - Hudson Bay and upper Mississippi River, 485.
  - Michigan, iodine in, 265.
  - North Atlantic slope basins, 286, 783.
  - Pacific slope basins in Washington and upper Columbia River basin, 685.
  - Santa Clara Valley, 783.
  - Snake River basin, 886.

## Watermelon—

- pulp and rind, analyses, Calif., 71.
- wilt resistance in, Utah, 739.

## Watermelons—

- culture experiments, Ga.Coastal Plain, 232.
- marketing, Calif., 92.
- Thielavia basicola* on, 352.
- Water-soluble B. (*See* Vitamin B.)
- Water-soluble C. (*See* Vitamin C.)
- Weather—
  - and maple sugar production, Mich., 416.
  - as affected by moon, 114.
  - Bureau, report, U.S.D.A., 714.
  - conditions, forecasting crops from, 892.
  - effect on corn production, 114.
  - of mid-latitudes, effect of tropical cyclones, 808.
  - of 1924, U.S.D.A., 714.
  - phenomena, treatise, 315.
  - relation to solar radiation, 808.
  - reports, Pacific radio-telegraphic, 100.
  - systematically varying period in, U.S.D.A., 414.
  - (*See* also Meteorological observations and Meteorology.)
- Webworm, fall, attacked by wasps, 561.
- Weed—
  - control, studies, Idaho, 828.
  - legislation, relation to seed analyst, 737.
- Weeds—
  - economic importance, 794.
  - in New South Wales, 39, 830.
  - nitrogen content, 536.
  - of cranberry bogs, N.J., 737.
- Weirs, semicircular, tests, 584.
- Wells, artesian—
  - in North Dakota, 685.
  - potential source of danger, 886.
- Western Washington Station, bi-monthly bulletin, 97, 397, 598.
- Whale meat and bone, analyses, Calif., 71.
- Wheat—
  - baking quality, effect of storage, 258.
  - behavior and adaptation, Calif., 33.
  - bran and pollards, composition and feeding value, 167.
  - bran, tryptophan and cystine in, 802.
  - breeding experiments, 823; Calif., 33; Mich., 334; Utah, 732.
  - bunt. (*See* Wheat smut, stinking.)
  - chromosome number, relation to morphological and physiological characters, 220.
  - cost of production, W.Va., 589.
  - cost of production in United States and Canada, 191.
  - crosses, segregation and correlated inheritance in, 521.
  - culture, continuous, N.J., 721.
  - culture experiments, Alaska, 528; Kans., 433; Nebr., 529.
  - cutting, optimum stage, 230.
  - delayed germination in, 737.
  - deterioration, studies, Tenn., 544.
  - diseases and control in Egypt, 745.

## Wheat—Continued.

- drill calibration, relation to stand and yield, 828.  
 dwarfness in, 220.  
 earliness, effect of environment, Calif., 25.  
 effect of preceding crop, Ky., 434; Utah, 733; Wash.Col., 829.  
 endosperm, phytosterols of, N.Y.State, 708.  
 exports from United States, future, 694.  
 fall v. spring plowing, Wash.Col., 829.  
 farmers of Kansas, more profit for, U.S.D.A., 690.  
 fertilizer experiments, 121, 230; Kans., 434,  
 flour. (*See* Flour.)  
 foot rot, control, Kans., 445.  
 foot rot, notes, Wash.Col., 845.  
 forage yields, Mont., 435.  
 forecasts in Punjab, 692.  
 furrow-drilled, yields, Mont., 435.  
 Fusarium affecting, 747.  
 germination, relation to after-ripening conditions, 132.  
 germination tests, Mont., 435.  
 glume blotch, notes, 448.  
 growth, effect of depletion of phosphorus, 426.  
 growth in sand and solution cultures, 28.  
 growth, relation to proportions of nutrients, 123.  
 growth studies, Calif., 25.  
 hard, in alfalfa, germination, 737.  
 hybrids, genetic and cytological studies, 429.  
 in water culture, salt requirement, Mich., 518.  
 inheritance of earliness, 728.  
 inheritance, studies, Wash.Col., 825.  
 insect survey, Hessian fly, Ohio, 456.  
 iron availability in nutrients, 123.  
 irradiated, antirachitic properties, 763.  
 Kansas, marketing, Kans., 489.  
 Kansas, quality, Kans., 439.  
 Mesopotamian, milling and baking tests, 835.  
 milling and baking tests, Calif., 33.  
 nematode disease, notes, S.C., 544.  
 New Zealand-grown, tests, 230.  
 nutrient solutions for, Mich., 325.  
 nutritive value, Wash.Col., 866.  
 periodicity of growth, Wash.Col., 829.  
 protein and ash in, converting to uniform moisture base, U.S.D.A., 312.  
 protein in, factors affecting, 440; Calif., 38.  
 proteins, biological value, 762.  
 quality, factors affecting, Kans., 410.  
 Red Fife, quality, 638.  
 respiration, effect of lactic acid, 626.  
 root development, 736.

## Wheat—Continued.

- root hairs, protoplasm of, effect of pH, 124.  
 root rot in Idaho, 347.  
 root rots, Minn., 648.  
 rosette disease, control, U.S.D.A., 347.  
 rotation experiments, 230; N.Y.Cornell, 526; Oreg., 435; U.S.D.A., 827; Utah, 732.  
 rust, control, Kans., 445.  
 rust development, relation to climate, 645.  
 rust infection, relation to time of maturation, 846.  
 seed coats, gradient of permeability to iodine, 29.  
 seed, Kanred, detecting mixtures in, 138.  
 seeding experiments, Ga.Coastal Plain, 225; Nebr., 529.  
 seedlings as affected by aluminum salts, N.J., 726.  
 seedlings, etiolated, lipochromes, 610.  
 smut, control, Idaho, 844; Ohio, 448.  
 smut, dust seed treatments for, 148.  
 smut, hot water treatment, present status, 546.  
 smut, stinking, control, Kans., 50, 445; Mich., 50, 346.  
 smut, stinking, relative resistance of varieties to, U.S.D.A., 545.  
 smut, stinking, resistance to, Calif., 50.  
 smut, studies, Wash.Col., 844.  
 species, reduction division in, 824.  
 speckled leaf blotch, notes, 448.  
 spring, fall seeding experiments, 633.  
 spring, seeding experiments, Idaho, 828.  
 spring, time of plowing, Kans., 434.  
 spring, varieties, U.S.D.A., 827.  
 spring, variety tests, Idaho, 828; Mont., 435; Utah, 732; Wash.Col., 829.  
 spring, yields after fallow, Oreg., 435.  
 spring, yields and agronomic data, Can., 733.  
 starch determination in, 112.  
 starches, viscosimetric study, 13.  
 State testing mill report, 436.  
 stem rust, urediniospore germination, 347.  
 straw mulching, effect on potato wilt, Pa., 243.  
 stripe rust, notes, 648.  
 time of maturation, effect on rust, 846.  
 tolerance for alkali, 812.  
 varieties, Calif., 33.  
 variety tests, Ga.Coastal Plain, 224; Ind., 226; Kans., 433; Mo., 334; N.J., 732; Nebr., 529; S.C., 528.  
 Velvetnode, inheritance of pubescent nodes in, 332.  
 winter, breeding experiments, Kans., 433.  
 winter, culture, U.S.D.A., 828.

## Wheat—Continued.

- winter, effect of summer fallow, Idaho, 829.
- winter, frost resistance, 835.
- winter, in dry areas of the western United States, U.S.D.A., 637.
- winter, seeding experiments, Idaho, 828; Utah, 719, 733.
- winter, testing, Ill., 433.
- winter, varieties, U.S.D.A., 827.
- winter, variety tests, Idaho, 828; Mont., 435; Utah, 732; Wash.Col., 829.
- winter, yields, U.S.D.A., 527.
- winter, yields after fallow, Oreg., 435.
- Yeoman II, tests, 637, 638.
- yield and protein in, relation to moisture and nitrogen, 637.
- yield and rainfall in Ohio, 507.
- yield following fallow and substitutes, 227.
- yield following potatoes, 439.
- yield reduction, cause, Mont., 435.
- yield, relation to length of growth period, Calif., 38.
- yield relation to loss of leaf surface, 328.

## Wheat-rye hybrids, hairy neck in, 223.

## Wheel—

- scrapers, economical use, U.S.D.A., 585.
  - track widths, standardization, 288.
- Wheels, dishing, standardization, 288.
- Whey, feeding value, 769.

## White—

- ants. (*See* Termites.)
- fly, citrus, and parasites in India, 154.
- fly, notes, 853; Fla., 251.

## White pine—

- blister rust in Pacific Northwest, 451.
- blister rust outbreak in Maine, 550.
- chemical injuries to, 353.
- growth studies, 145.
- transpiration, effect of temperature and humidity, 625.
- western, fall sowing and delayed germination of seed, 541.
- western, germination, factors affecting, 541.

## Willow leaf-beetles, biology and control, Me., 661.

## Wind power for farm electric plants, 785.

## Winds and gipsy moth spread, 355.

## Winds and moisture, laws of, 808.

## Wine industry in Yugoslavia, 142.

## Wireworms—

- control, N.J., 752.
- rearing, 856.
- soil fumigant for, 856.

## Wisconsin—

- Station, notes, 200, 400, 700, 797.
- University, notes, 200, 400, 700.

*Wohlfartia vigil* larvae, in conjunctiva of man, 454.*Wojnowicia graminis*, notes, Wash.Col., 845.

## Women, basal metabolism, variations in, 160.

## Wood—

- and metals, strengths and related properties, 887.
  - composition and durability, relation, 486.
  - decay, diagnosis, 849.
  - fire-killed, pulping qualities, 445.
  - fungi in, effect of methods of seasoning, U.S.D.A., 249.
  - kiln drying and preservation, 85.
  - properties and uses, treatise, 557.
  - tissue, *Torula ligniperda* in, 353.
  - utilization, demonstration courses in, U.S.D.A., 496.
  - zinc chloride absorption and penetration into, 585.
- (*See also* Lumber and Timber.)

## Wood-destroying fungi, resistance to heat, 55.

## Woods—

- identification, 345.
- Indian, anatomical notes, 241.
- of New Zealand, Keys, 742.
- Philippine, identification, 241.

## Wool—

- characters of Welsh sheep, improvement, 170.
- clip of 1925, Mich., 768.
- physical properties, 672.
- production in England, progress in, 871.
- production in Maryland, 870.
- review, annual, of Australia, 394.
- trade, Australasian, statistics, 871.
- yield, effect of age, Ky., 468.

Woolly aphid. (*See* Aphids, woolly.)

## World's Dairy Congress—

- proceedings, U.S.D.A., 573.
  - report of delegates of Argentina, 479.
- World's Forestry Congress, notes, 799.

## Wyoming—

- Station, notes, 400.
- University, notes, 400.

*Xanthosoma* spp., new food plants for the South, U.S.D.A., 340.X-rays. (*See* Roentgen rays.)*Xylocopa* spp., studies, Calif., 59.

## Yams, variety tests, 132.

## Yautias, new food plants for the South, U.S.D.A., 340.

## Yeast—

- antidiabetic hormone from, preparation, 765.
- antineuritic substance in, effect of nitrous acid, 462.
- development and nutrition, 627.
- dried, reducing properties, effect of heat, 65.
- extracts, clarification, 11.
- fate in intestines of man and rat, 564.
- feeding to poultry, Calif., 75.

## Yeast—Continued.

- fermentation, effect on imbibitional properties of glutenin, 12.
  - for fattening pigs, Mich., 74.
  - growth, relation to substances formed by bacteria, 162.
  - value for pigs, Wash.Col., 872.
- Yeasts and mold in butter, effect on keeping quality, 775.

Yellow fever, prevention, 480.

*Zelus socius*, notes, Calif., 58.

## Zinc—

- arsenite, determination of water-soluble arsenic in, 712.
  - chloride, absorption and penetration into wood, 585.
  - in animal nutrition, importance, 161.
- Zoology, economic, treatise, 495.

# EXPERIMENT STATION RECORD

Editor: H. L. KNIGHT.

## CONTENTS OF VOL. 52, No. 1

	Page
Editorial notes:	
The thirty-eighth convention of the Association of Land-Grant Colleges.....	1
Recent work in agricultural science.....	10
Notes.....	98

## SUBJECT LIST OF ABSTRACTS

### AGRICULTURAL CHEMISTRY—AGROTECHNY

Chemistry of dairy products from a colloidal standpoint, Palmer.....	10
Factors concerned in autoxidation of fats, Greenbank and Holm.....	10
Clarification of yeast extracts with neutral lead acetate, Reynolds.....	11
Pectin and its hypothetical precursor "protopectin," Tutin.....	11
Ethylene glycol—its properties and uses, Fuller.....	11
Insulin and its manufacture, Carr.....	11
Condenser for distilling oils of wide boiling range, Calderwood.....	11
A simple turbidiscopes, Horne and Rice.....	11
Determination of nitrate nitrogen, Scales and Harrison.....	11
Testing milk and its products, Farrington and Woll.....	12
Tests of flour quality with Chopin extensimeter, Bailey and Le Vesconte.....	12
Physico-chemical properties of flours, VIII, Sharp and Gortner.....	12
A viscosimetric study of wheat starches, Rask and Alsberg.....	13
Removal of gummy matters from sugar, Keyworth and Forster.....	13
Starch in sorghum sirup, Willaman and Davison.....	13
Fruit products.....	14
Freezing fruit for by-product use.....	15
Making vinegar in the home and on the farm, LeFevre.....	15

## METEOROLOGY

	Page
Organization of agricultural meteorology in Germany, Holdefleiss.....	16
Correlation between production of grain and rainfall in Sicily, Eredia..	16
Phenology and possibilities of application to agriculture, Werneck....	16
Character and consequences of rainfall of Montpellier, Chaptal.....	16

## SOILS—FERTILIZERS

Report of fourth annual meeting of American Soil Survey Association..	17
Soil survey of O'Brien County, Iowa, Elwell and Meldrum.....	18
Soil survey of Beadle County, South Dakota, Watkins et al.....	18
Analyses of soils of the Cattavia Valley, Rhodes, Ferrara and Sacchetti..	18
Characteristics of the peat in northern France, Demolon and Dupont..	18
[Soil studies at the California Station].....	19
[Soil moisture studies at the California Station].....	19
Composition of soil solution as indicated by displacement method.....	19
Concentration of phosphate in soil solution by displacement method....	20
Relations of increases in water-extractable soil constituents to their withdrawals by plants and to crop yields.....	20
Electric charge of clay colloids.....	20
[Soil alkali studies at the California Station].....	20
[The use of alkali water with least injury to the soil].....	21
Dispersing power of alkali in soil, De Dominicis.....	21
Study of soil acidity and lime deficiency, Vincent.....	21
Soil washing: The cause and methods of prevention, Stewart and Wood..	22
Saving soil by use of Mangum terraces, Lehmann and Hanson.....	22
Radioactivity and nitrogen fixers, Kayser and Delaval.....	22
Nitrogen-fixing bacteria in Vesuvian soils, Riccardo.....	22
The streptothrices in Vesuvian soils, Riccardo.....	22
Effect of rice culture on microorganisms of soil.....	22
Yield of crop plants as influenced by those preceding, Burgess.....	23
Effects of manure on crop growth.....	23
Manures and fertilizers for truck crops, Gourley and Magruder.....	23
Commercial fertilizers.....	24
Marl digging demonstrations, Musselman.....	24
Rotation of elements in agriculture: Sulfur, Giltner and Snyder.....	24
Commercial fertilizers in New York in 1923, Van Slyke.....	24
Analyses of commercial fertilizers, 1923-24, Brackett and Stackhouse....	24

## AGRICULTURAL BOTANY

[Studies in] plant nutrition.....	24
[Plant nutrition studies at the Citrus Experiment Station].....	26
Relations between growth and composition of young orange trees and concentration of the nutrient solution employed, Reed and Haas....	27
Transport of organic substances in plants, Dixon and Ball.....	27
The translocation of carbohydrates in the sugar maple, Adams.....	27
CO <sub>2</sub> production of plant roots as a factor in feeding power, Parker.....	28
"Auximones" and the growth of the green plant, Clark and Roller.....	28
Urease in the nodules on the roots of leguminous plants, Werner.....	28
Sand and solution cultures of Marquis wheat, Bakke and Erdman.....	28
A gradient of permeability to iodine in wheat seed coats, Braun.....	29

## GENETICS

Electrical mutations and inheritance by hybridization, Piròvano.....	29
Electrogenetics, Ragionieri and Meunissier.....	29
The part played by heredity in plants: Electrogenetics, Piròvano.....	29
Genetics.....	29
Heterosis and dominance of size factors in Raphanus, Frost.....	30
Inheritance in barley.—I, The lateral florets and rachilla, Engledow....	30
Inheritance in barley.—II, The awn and lateral floret, Engledow.....	30
Inheritance in barley.—III, The awn and lateral floret (contd.), Engledow.....	31
Methods of corn breeding, Hayes and Alexander.....	31
A primitive sporophyte in maize, Eyster.....	31
A second factor for primitive sporophyte in maize, Eyster.....	32

	Page
A hybrid between different species of cotton, Kearney.....	32
Inheritance of the colour pattern of King Edward potato, Collins.....	32
Seed progeny of a potato with faintly coloured tubers, Kelly.....	32
Inbreeding grain sorghum, Conner and Karper.....	32

## FIELD CROPS

[Field crops experiments in California].....	32
[Field crops work in Uganda in 1922 and 1923], Simpson, Hewett, et al.....	34
Emmer and spelt, Martin and Leighty.....	34
Influence of sulfur as a fertilizer on barley, Windisch.....	34
The germination of cottonseed, Toole and Drummond.....	34
The salt content of cotton fiber, Kearney and Scofield.....	35
Markton, an oat variety immune from covered smut, Stanton et al.....	35
Potato investigations at the North Central Station, 1914-1923, Bergh.....	35
Size of potato sets: Comparisons of whole and cut seed, Stuart et al.....	36
Handling rough rice to produce high grades, Smith.....	36
Sorghum experiments on the Great Plains, Vinal, Getty, and Cron.....	37
[Cutting back cane not profitable], Verret.....	38
Loss of sugar due to burning cane before cutting, Frank.....	38
Relation of yield of wheat to length of period of growth.....	38
[Studies on factors influencing protein content of wheat].....	38
Agricultural seeds from overseas: Effect on germination, Moodie.....	38
Prolific weeds, Blakely.....	39

## HORTICULTURE

[Horticultural investigations at the California Station].....	39
Preparation of cabbage for market, Hauck.....	43
Spraying and dusting cantaloupes, Zimmerley et al.....	43
Dusting and spraying eggplants, Spencer et al.....	43
Dusting and spraying tomatoes, Davis, Spencer, and Zimmerley.....	44
Nitrate of soda in the nutrition of the tomato, Work.....	44
The rest period of deciduous fruit trees in a mild climate, Hodgson.....	45
Studies of fruit seed storage and germination, Tukey.....	46
New and noteworthy fruits, VII, Hedrick.....	46
Development of pecan buds and production of pollen, Woodroof.....	46

## FORESTRY

[Forestry investigations at the California Station].....	47
Relative resistance of tree seedlings to excessive heat, Bates and Roeser.....	47
Hardwood lands after logging, Herbert.....	48

## DISEASES OF PLANTS

Plant pathology.....	48
Seed treatments, Gabel.....	49
Relative susceptibility of races and varieties of Indian corn to smut.....	49
[Wheat smut investigations].....	50
Control of stinking smut or bunt of wheat, Coons.....	50
Copper carbonate method of controlling bunt, Melchers and Walker.....	50
Nematode investigations.....	50
Cabbage bed diseases and Delphinium root rots, Gloyer and Glasgow.....	50
Control of cucumber mosaic in the greenhouse, Doolittle.....	50
The influence of locality of origin on potato leaf roll, Gram.....	51
Common scab of potatoes, Part II, Millard.....	51
Studies in bacteriosis, VIII, Paine and Bewley.....	52
[Deciduous fruit disease investigations].....	52
[Plant disease investigations at the Citrus Experiment Station].....	53
Cherry troubles in western Washington, Frank.....	53
Black root of strawberry, Coons.....	53
Citrus disease control.....	54
Further studies on susceptibility to citrus canker, Peltier and Frederick.....	54
Relation of environmental factors to citrus scab, Peltier and Frederick.....	54
Bacterial leafspot of Delphinium, Bryan.....	54
Effect of heat on structural-timber-destroying fungi, Snell.....	55

## ECONOMIC ZOOLOGY—ENTOMOLOGY

	Page
Game laws for the season 1924-25, Lawyer and Earnshaw.....	55
Laws relating to fur animals for 1924-25, Ashbrook and Earnshaw.....	55
<i>Leptospira icterohemorrhagiae</i> in wild rats of Baltimore, Robinson.....	55
A device for inflating larvae, Mosher and Holbrook.....	56
Use of skim milk in preparation of certain spray materials, Robinson.....	56
Choose sprays carefully, Wilson and Fluke.....	56
[Insect enemies of the cherry in western Washington], Frank.....	56
[Entomological investigations at the California Station].....	56
A stilt-bug, <i>Jalysus spinosus</i> Say, destructive to the tomato, Phipps.....	60
Natural enemies of beet leafhopper ( <i>Eutettix tenella</i> Baker), Severin.....	60
Calcium cyanide dust for rosy apple aphid, Wagoner.....	60
Lubricating-oil emulsion as a control for <i>Chrysomphalus aonidium</i> in greenhouses, Weigel and Broadbent.....	61
The striped grass looper, <i>Mocis repanda</i> Fab., in Texas, Vickery.....	61
Certain wild grasses in relation to injury to corn by the "borer" ( <i>Diatraea saccharalis</i> Fab.) in Louisiana, Jones and Bradley.....	61
The spotted cutworm, a cranberry pest, Franklin and Lacroix.....	61
Method for extermination of round-headed apple-tree borer, Johannsen.....	61
The elm leaf beetle, Pettit.....	61
The tobacco flea-beetle in Kentucky and Tennessee, Morgan and Gilmore.....	61
Selective parasitism by <i>Tiphia</i> sp., Jaynes and Gardner.....	62

## FOODS—HUMAN NUTRITION

Nutrition laboratory, Benedict.....	62
How to reduce the meat bill, Light and Stuart.....	62
Copper content of apricots.....	62
Effect of CaCl <sub>2</sub> on acid-sugar-pectin gels, Halliday and Bailey.....	62
Thermal process time for canned food, Ball.....	62
Continuation and extension of work on proteins, Osborne and Mendel.....	63
Digestibility of the proteins of some foodstuffs, Jansen and Donath.....	63
The stimulating action of food on metabolism, I, Laufberger and Šefčík.....	64
What to feed the children, Mendenhall.....	64
Vitamins, I, II.....	64
The A-vitamin-content of different Indian foodstuffs, Jansen and Donath.....	64
Respiratory capacity of tissues and their content of vitamin B, Rohr.....	65
Effect of heat on dried yeast and its vitamin value, Hess and Rohr.....	65
Vitamin investigations.....	65
Influence of diet and management of the cow upon the deposition of calcium in rats receiving daily milk in their diet, Boas and Chick.....	66
Nitrogen and mineral metabolism in avitaminosis, Hirabayashi.....	66
Experiments on nitrogen metabolism in avitaminosis, Collazo.....	67
The effect of a one-sided diet on avitaminosis, Asada.....	67
Can ultraviolet light hinder development of anemia? Suski.....	67
Does salt hasten nerve disturbances in avitaminous animals? Suski.....	68
Production of symptoms of avian polyneuritis, Rando and Simonnet.....	68
Pathogenesis of deficiency disease, XVII, McCarrison.....	68
Inverse relation between iodine and goiter, McClendon and Hathaway.....	68

## ANIMAL PRODUCTION

Ensiling a mixture of Sudan grass with a legume, Wright and Shaw.....	68
Acidity in relation to quality in sunflower silage, Blish.....	69
Schweizer electrical and Italian methods of green forage preservation.....	70
[Composition of livestock feeds].....	70
Composition of feeding-stuffs collected in New York, Van Slyke.....	71
Mineral feeding investigations, Reed and Huffman.....	71
[Beef cattle feeding experiments at the University of California].....	71
Finishing baby beef, Brown and Branaman.....	72
Fattening beef calves, Ray, rev. by Semple.....	72
Feeding trial [with sheep at the California Station].....	72
Winter feeding of breeding ewes, Joseph.....	72
[Comparative rations for fattening hogs].....	73
Yeast for fattening swine, Brown and Edwards.....	74
Hogging off corn, Brown and Edwards.....	74

	Page
[Investigations with poultry at the California Station]-----	74
Calcium metabolism in the laying hen, II, Buckner et al.-----	75
A nutritional disease of poultry caused by vitamin A deficiency, Beach--	77
Feeding market egg layers for winter production, Shoup-----	77
Poultry culling is profitable, Foreman-----	77
Relation of antecedent egg production to sex ratio of fowl, Jull-----	77
Carbon dioxide given off by eggs during incubation, Atwood and Weakley--	77

## DAIRY FARMING—DAIRYING

Values of various new feeds for dairy cows, Woodward et al.-----	78
[Feeding experiments with dairy cattle at the California Station]-----	78
The sunflower as a silage crop, Nevens-----	79
Sunflowers as a silage crop for dairy cows, Nevens-----	80
Corn silage in a dairy ration, Carroll-----	80
Feeding cull beans to dairy cows, Reed and Burnett-----	80
[Experiments of the dairy industry department, California Station]-----	80
<i>Flavobacterium suaveolens</i> isolated from dairy wastes, Soppeland-----	81

## VETERINARY MEDICINE

[Investigations of diseases of animals at the California Station]-----	81
Ninth and tenth reports of director of veterinary education and research--	82
[Abortion studies at the California Station]-----	82
Further observations on <i>Hypoderma bovis</i> and <i>H. lineatum</i> , Laake-----	83
Notes on fatal disease of cattle in Texas (loin disease), Schmidt-----	83
Mycotic stomatitis of cattle, Mohler-----	84
Snotsiekte in cattle, Mettam-----	84
Sweating sickness in calves.—Preliminary report, Du Toit-----	84
Gousiekte in sheep, Theiler, Du Toit, and Mitchell-----	84
Sheep scab: The infectivity of kraals, Du Toit-----	84
Anthelmintic experiments with hogs, Mote-----	84
Infectious anaemia of equines under South African conditions, De Kock--	85
Strongylids and other nematodes parasitic in African equines, Theiler--	85
Some surgical poultry problems, Johnson-----	86
[Diseases of poultry], Graham and Tunnicliff-----	86
[Diseases of poultry], Graham and Boughton-----	86
Nodular typhlitis in pheasants in North America, Schwartz-----	86
South African parasitic nematodes, Monnig-----	86

## RURAL ENGINEERING

Agricultural engineering [studies at the California Station]-----	86
Surface water supply of Hawaii, July 1, 1920, to June 30, 1921-----	87
Curing conditions of concrete drain tile, Miller-----	87
How damp-sand curing improves quality of concrete, Crook and Faulkner--	87
Comparative utility of concrete pavement tests, Bragg-----	87
Investigations in stump and stone removal, Thompson and Schwantes--	88
Velocity of detonation of various types of explosives-----	89
Temperature requirements of hot spot manifolds, Kegerreis and Berry--	89
A roller for use on peat land, Stewart-----	90
A colony brooder house that starts chicks right, Card and Hanson-----	90

## RURAL ECONOMICS AND SOCIOLOGY

Land reclamation policies in the United States, Teele-----	90
Land settlement-----	91
Report of committee on land purchase in Northern Ireland, Percy et al--	91
Recent colonization in Chile, Jefferson-----	91
Group settlement in western Australia, Colebatch-----	91
A history of land tenure in England, Ghosh-----	91
Farming on 80-acre farms in central Indiana, Hawthorne and Robertson--	91
Twenty years' profits from an apple orchard, Hedrick-----	92
Poultry accounts, Lee and Haynes-----	92
U. S. grades for timothy, clover, and mixed hays, Parker-----	92
Marketing-----	92

	Page
Cooperative marketing of fruits, livestock, and grain in United States	93
Cooperative central marketing organization, Black and Price	93
Cooperative citrus-fruit marketing agencies, McKay and Stevens	93
Cooperative dairy marketing plans, Macklin	93
Farmers' Market Bulletin, [September, 1924]	94
The agrarian revolution in Roumania, Evans	94
Agriculture and the guild system	94
[Report of the] advisory agricultural committee, Geneva	94
Rural social problems, Galpin	94
Agricultural cooperation in Denmark, Christensen	95
Impressions of the co-operative movement in France and Italy, Rothfeld	95
Co-operative movement in Russia, Blanc	95
Statistical annual of the Republic of Chile.—VII, Agriculture, 1921-22	95
[Statistics of agriculture for Australia, 1911-12 to 1921-22]	95
Estimates of area and yield of principal crops in India, 1921-22, Ghosh	95
Livestock and animal products statistics, 1922, Horning	95

#### AGRICULTURAL EDUCATION

Workers in agricultural colleges and experiment stations, 1923-24	95
Annual report of the director of agricultural extension, Crocheron	96
Features of the Arkansas plan in vocational agriculture, Matthew	96
Financial goal in vocational agriculture in Mississippi, Hubbard	96
The pioneer manual labor schools, Coates	96
Agricultural education and research in Denmark, M'Callum	96
The science and practice of British farming, Watson and More	96
Junior projects in outlying rural schools, Green	96
A class project in poultry husbandry, Bruner	96
Type instruction sheets in home economics, Farnsworth	96
Nutrition clinic as a project in part-time continuation school, Otteson	96
Posters prepared by school children in milk-for-health programs, Hoover	97
Motion pictures of the United States Department of Agriculture	97

#### MISCELLANEOUS

List of bulletins of the experiment stations, 1921 and 1922, Pennington	97
Report of College and Station of California, 1923, Hunt, Haring, et al.	97
Quarterly Bulletin [of Michigan Station], edited by Shaw and Hill	97
Bi-Monthly Bulletin [of the Western Washington Station]	97

## CONTENTS OF VOL. 52, NO. 2

Editorial notes:	Page
Agriculture at the Washington meeting of the American Association...	101
Some recent visits by English scientists and a notable address.....	105
Recent work in agricultural science.....	108
Notes.....	198

## SUBJECT LIST OF ABSTRACTS

### AGRICULTURAL CHEMISTRY—AGROTECHNY

Principles of biochemistry, Robertson.....	108
Chemical synthesis, Hepworth.....	108
Chemical synonyms and trade names, Gardner.....	108
The carbohydrates and the glucosides, Armstrong.....	108
Humin formed by acid hydrolysis of proteins, VIII, Burr and Gortner...	108
A neglected chapter in chemistry: The fats, Armstrong and Allan.....	109
Substances adsorbed on surface of fat globules, Palmer and Samuelson...	109
Technique for study of fat production in animals, Anderson and Mendel...	109
The phytosterols of the endosperm of corn, Anderson.....	110
Effect of insulin on fermentation of glucose by yeast, Travell and Behre...	110
Isolation of substance having properties of "bios," Eddy et al.....	110
Vitamin B and bios, Smith.....	110
Adsorption by activated sugar charcoal, [III], Miller.....	110
$\pi_0$ in electrometric measurements of H-ion concentrations, Sørensen and Linderstrøm-Lang.....	111

	Page
Tests of method for chlorides in plant tissue fluids, Lawrence and Harris	111
Modifications of the picric acid method for sugars, Willaman and Davison	111
Estimation of starch in barley and wheat, Ling et al	112
Factors influencing the determination of gluten in wheat flours, Dill	112
The composition and decomposition of eggs, Thomson and Sorley	113
Food analysis: Typical methods and interpretation of results, Woodman	113
Practical chemical analysis of blood, Myers	113
Heat resistance studies.—I, Esty and Williams	113
Cane juice clarification—theory and practice, Brewster	113
The early sugar refining industry of New York, Browne	114
Cane sugar refining at the present day, Perkins	114
Making fermented pickles, LeFevre	114

## METEOROLOGY

The adjustment of agriculture to climate, Kincer	114
Climate and quality of product, Friedrich	114
The weather as a factor in crop production, Musbach and King	114
Certain meteorological fallacies, Koenig	114
Sun spots and the frequency of tropical cyclones, Visser	114
Meaning of precipitation = run-off + evaporation + drainage, Fischer	114
Climatological data for the United States by sections, [May-June, 1924]	115
Climate of British Columbia	115

## SOILS—FERTILIZERS

Treatise on soils for farmers and foresters, Mitscherlich	115
Rapid method of taking soil samples from field plots, Deatrick and Bryan	115
The Georgia soil survey, Lowry	115
Soil survey of Benson area, Arizona, Carpenter and Bransford	115
Soil survey of Durham County, North Carolina, Perkins et al	115
The soils of Brazos, Camp, Ellis, and Washington Counties, Fraps	116
Soil series, H-ion concentration, and lime requirement, Jones	116
The resistance of soils to acidification, Demolon and Dupont	116
Alkali soil investigations, II, Joffe and McLean	116
The aeration of soils, Bouyoncos and McCool	116
Influence of heat on the total surface presented by soil elements, Smolik	117
Iron, aluminum, and manganese in Hawaiian soil solution, McGeorge	117
The cycle of sulfur in soil, Klein and Limberger	117
Nitrification and the nitrifying organisms, I, Gowda	118
Further progress in the improvement of arable land, Stoklasa	118
Sub-soiling trials in Essex	118
Manuring for profitable production, Corrie	118
Manure, fertilizers, and lime on Sassafra silt loam soil, Schuster	119
Changes in soils by long crop and fertilizer treatment, Blair and Prince	119
Different fertilizer experiments on moor soils, Christensen	120
[Soil and fertilizer studies in India, 1922-23]	120
[Soils and fertilizer experiments at Khartum], Joseph	120
Fertilizer experiments with fine waste and mixed fertilizers, Bodler	121
The value of some green manures, Koch	121
Possibilities and limitations of bacterized peat, Manns	122
Action of dicyandiamid and guanyl urea sulfate on growth, McGuinn	122
The new nitrogenous fertilisers of Great Britain, Russell	122
Nitrogen experiments with legumes, Schneidewind	123
Fertilizer value of different phosphates, Niklas et al	123
The American fertilizer hand book, 1924	123
Commercial fertilizers	123

## AGRICULTURAL BOTANY

The influence of nutrients on the development of plants, Lakon	123
Effects of high nutrient supply on apparatus of assimilation, Maiwald	123
Molecular proportions in nutrient solution and growth of wheat, Sewell	123
Availability of Fe in solutions for wheat, Tottingham and Rankin	123
Effect of H ion on protoplasm of root hairs of wheat, Addoms	124
An isoelectric point for plant tissue and its significance, Robbins	124

	Page
Relation of aeration and continuous renewal of nutrient solution to growth of soybeans in artificial culture, Allison and Shive.....	125
Effect of ringing a stem on upward transfer of nitrogen and ash, Curtis..	125
Amylase in spores of <i>Rhizopus tritici</i> and <i>R. nigricans</i> , Harter and Weimer.....	126
The influence of plants on the air in houses, Rigg et al.....	126
The formation and degeneration of germ cells in the potato, Young.....	126
The photoperiodism of <i>Tephrosia candida</i> , McClelland.....	126
Observations on the causes of gregarious flowering in plants, Seifriz.....	127
Alternation of sexes and production of fruit in spider flower, Stout.....	127
The physiology of incompatibilities, Stout.....	127
[The species concept], Shull, Harper, Reed, and Stakman.....	127

## GENETICS

The chemistry of embryonic development, Needham.....	128
Some facts as to origin and inheritance of specific characters, Sumner....	128
Some observations on the inheritance of color in fowls, Kopeć.....	128
Genes for the extension of black pigment in the chicken, Lippincott.....	128
Variations of linkage in rats and mice, Castle and Wachter.....	128
Effect of X rays on linkage in <i>Drosophila melanogaster</i> , Mavor and Svenson.....	129
Crossingover in <i>Drosophila melanogaster</i> , Mavor and Svenson.....	129
A case of complete sex-reversal in the adult pigeon, Riddle.....	129
Reproductive ducts and canals in the free-martin, Bissonnette.....	130
Induction of a sexually mature condition, Allen and Doisy.....	130
Some effects of unilateral ovariectomy in rabbits, Asdell.....	130
Cytological changes in unfertilized tubal eggs of the rat, Mann.....	131
Parthenogenetic cleavage and rôle of water absorption by ovum in formation of subgerminal cavity in the pigeon's egg, Bartelmez and Riddle..	131
Hereditary defects in mice and the Roentgen ray, Bagg and Little.....	131

## FIELD CROPS

[Field crops work at St. Vincent, 1921 and 1922], Watts et al.....	132
[Field crops in Bihar and Orissa, 1921-22 and 1922-23], Dobbs et al....	132
[Field crops work in Punjab, India], Milne et al.....	132
Relation of after-ripening conditions to germination of cereals, Gassner..	132
The seasonal productivity of herbage grasses, Stapledon.....	133
Alfalfa production for New York, Dalton.....	134
A note on subterranean clover, Williams and Davies.....	134
Crimson clover: Seed production, Westgate, rev. by Pieters.....	135
Productivity of different strains of red clover, Williams.....	135
Corn growers face worst seed shortage in years, Hackleman.....	136
Culture of Pima and upland cotton in Arizona, Cook and Martin.....	136
Delfos cotton.....	136
Ratoon cotton, Harland.....	136
Experimental work on cotton, 1922, Shearer et al.....	136
Cotton culture in western Madagascar, Reynier.....	137
[Report of the work of] the British Cotton Growing Association.....	137
Occurrence and distribution of <i>Festuca rubra</i> in Great Britain, Howarth..	137
Some tentative statements concerning Fowlds Hulluss oats, Hume.....	137
How to grow rice in the Sacramento Valley, Jones.....	137
The Uba cane.....	137
Factors which influence the nicotine content of tobacco, Thatcher et al..	138
Method of detecting mixtures in Kanred wheat, Johnston and Bower....	138

## HORTICULTURE

A treatise on gardening, Randolph.....	138
Influence of carbohydrate-nitrate content of cuttings on roots, Starring..	138
Relation of anthocyan pigments to summer injury, Hoffman.....	139
Inheritance of "bolting" in cabbage, Sutton.....	139
Factors influencing early development of seed stalk of celery, Thompson..	139
Sweet corn varieties for canning, Culpepper and Magoon.....	140
Fruit spur growth and fruit bud production, Auchter and Schrader....	140

	Page
Pot experiments on the manuring of fruit trees, III, Wallace.....	140
A proposed key to commercial apples, Carpenter and Stafford.....	141
[Apple fertilizer studies at Craibstone].....	141
Liquid lime sulphur v. sulphur dust for apple, Cullinan and Baker.....	141
Effect of premature harvest of plums and pears. Overholser.....	142
Strawberry production in Florida, Jenkins and Kelley.....	142
Notes on strawberry breeding, Spinks.....	142
The American cranberrybush, Darrow.....	142
Vine cultivation and the wine industry in Jugo-Slavia, Markoff.....	142
The olive in Morocco, Ruby.....	142
Camphor cultivation from <i>Cinnamomum camphora</i> , Howard et al.....	142
Some notes on nut growing in the northern United States, Spence.....	143
Flowers every day in the year, Hansen.....	143
Breeding ornamental Hibiscus, II, Mendiola and Unite.....	143
Color control in forcing hydrangeas, Connors.....	143
A handbook of garden irises, Dykes.....	143
Rhododendrons and the various hybrids, Millais.....	144
Roses and how to grow them, rev. by McFarland.....	144
A little book of climbing plants, Hottes.....	144

## FORESTRY

Management of forest properties in the California pine region, Show.....	144
Forestry in the Malay Peninsula, Cubitt.....	144
Discontinuous growth rings in California redwood, Fritz and Averill.....	144
Acceleration of growth in western yellow pine after cutting, Krauch.....	144
Quality and growth of white pine, Tarbox.....	145
Rattan.....	145
Gutta percha.....	145
Damar and copal.....	146

## DISEASES OF PLANTS

Studies in bacteriosis, IX, X, Paine and Lacey.....	146
A critical study of crown gall, Robinson and Walkden.....	146
The killing of <i>Botrytis cinerea</i> by heat, Smith.....	146
A study of the growth in culture of <i>Verticillium albo-atrum</i> , Chaudhuri.....	147
The more injurious fungi of cultivated plants at Turin, 1921, Voglino.....	148
Diseases and pests of cultivated plants in Poland in 1921-22, Garbowski.....	148
Methods of controlling diseases and pests, I, Vogt.....	148
Copper sulfate as fungicide and anticryptogamic, Crivelli.....	148
On the occurrence of maize rust in the Philippines, Reyes.....	148
Fungicidal powders for wheat smut, Ponsard.....	148
Effect of moisture on a seed-borne bean disease, Leonard.....	148
A bacterial disease of foxtail ( <i>Chaetochloa lutescens</i> ), Rosen.....	148
Varietal immunity of potatoes to wart disease, I, Roach.....	148
Potato black wart, Volkart, Neuweiler, and Perrin.....	149
Data regarding root rot in sugar cane, variety EK 28, Geerts.....	149
Studies on curly-top disease of the sugar beet, Carsner and Stahl.....	149
Fungi associated with "die back" in stone fruit trees, I, Cayley.....	149
Apricot fungus diseases in Valais, Faes and Staehelin.....	150
Leather rot of strawberries, Rose.....	150
Signal service regarding attacks of <i>Plasmopara viticola</i> in 1921, Voglino.....	150
Collar crack of cocoa, Bunting.....	150
"Thread" diseases of cocoa in the Gold Coast, Dade.....	150
Bud rot of coconut in Porto Rico, Tucker.....	151
Nut fall of coconuts, Gadd.....	151
Liberian coffee disease, Bunting.....	151
A brown bast census, Reeve.....	151
The wilt disease of safflower, Joshi.....	151
Soft rot of <i>Vanilla planifolia</i> Andrews, Ragunathan.....	151
Pecan scab with special reference to early spring infections, Demaree.....	152
Spraying for pecan scab control in Mississippi in 1923, Neal et al.....	152
A disease of poplar, Foëx.....	152
The origin of "golden" oak, Williamson.....	152
Dissemination of <i>Tylenchus dipsaci</i> in seeds of composites, Godfrey.....	152

## ECONOMIC ZOOLOGY—ENTOMOLOGY

	Page
Breeding, feeding, and other life habits of meadow mice, Bailey.....	153
Revision of the American pikas (genus <i>Ochotona</i> ), Howell.....	153
Birds of the New York City region, Griscom.....	153
Guide to collection of arachnids, myriapods, and insects, Herrera.....	154
The fauna of France, illustrated, III, Perrier.....	154
Proceedings of entomological meeting at Pusa, 1923, edited by Fletcher..	154
The pyrethrum insecticide from Dalmatia, Juillet.....	155
Calcium cyanide the new poison, Winchell.....	156
Injurious insect pests of strawberries, McBride.....	156
Notes on <i>Periplaneta americana</i> L. and <i>Blatta orientalis</i> L., Adair.....	156
Studies on the injury to apple by <i>Ceresa bubalis</i> , Goodwin and Fenton....	156
Reproduction in the Aphididae, Uichanco.....	156
The biology of <i>Trichopoda pennipes</i> Fab., Worthley.....	156
Occurrence of <i>Muscina pascuorum</i> in North America in 1922, Johnson....	157
Notes on <i>Muscina pascuorum</i> Meigen during 1923, Johnson.....	157
The cambium curculio, Brooks and Cotton.....	157
Fumigation of <i>Bruchus obtectus</i> and <i>B. quadrimaculatus</i> , Larson.....	157
Nonarsenical stomach-poison insecticides, Moore and Campbell.....	158
Systematic and biological notes on bumblebees, Frison.....	158

## FOODS—HUMAN NUTRITION

Viscera from meat-producing animals, Powick and Hoagland.....	158
Specific dynamic action of proteins in thin and fat individuals, Gibbons..	160
Day to day variations in basal metabolism of women, Hafkesbring and Collett.....	160
The importance of mineral elements in the nutrition of children, Orr....	160
Nutrition studies in a Berlin orphan asylum, Rost et al.....	160
The importance of zinc in animal nutrition, Bertrand and Benzon.....	161
The influence of cell salts on intermediary metabolism, Tadenuma.....	161
Antineuritic vitamin in poultry flesh and eggs, Hoagland and Lee.....	161
Food accessory factors (vitamines) in bacterial growth, IX, Robertson..	162
Studies in bacterial metabolism, LXX-LXXII, Kendall and Haner.....	162
Reaction of intestinal contents and diet and flora, Hudson and Parr....	163
<i>Bacillus botulinus</i> in human and animal excreta, Easton and Meyer....	164
Isolation of <i>B. botulinus</i> , type B, from feces, Wheeler and Humphreys..	164
Optimum and limiting hydrogen-ion concentrations for <i>B. botulinus</i> and quantitative estimation of its growth, Dozier.....	164
Inhibitive influence of sugars and salt on <i>B. botulinus</i> , Dozier.....	165
Resistance of spores of <i>B. botulinus</i> to disinfectants, Dozier.....	165
Thyroid survey of 47,493 elementary-school children in Cincinnati, Olesen	165
Thyroid enlargement among Montana school children, Foard.....	166
Thyroid enlargement among Minnesota school children, Olesen and Clark..	166

## ANIMAL PRODUCTION

The valuation of foodstuffs for animal production, Buchholz.....	166
Influence of the antenatal feeding of parent rats, Korenchevsky and Carr	166
Composition, feeding value, and use of green forage silage, Hansson.....	167
A contribution to the study of grass silage, I, Fascetti.....	167
Bran and pollard: Their relative composition and qualities, Foster....	167
Analyses of feeding stuffs and registrations for 1924, Cathcart.....	167
Commercial feeding stuffs, Hills, Jones, and Anderson.....	167
Principal breeds of livestock of New Caledonia and Australia, Manetti..	167
Proceedings of conventions of Corn Belt Meat Producers' Association and of Iowa Co-operative Livestock Shippers.....	168
The ratio of carbon dioxide to heat production in cattle, Braman.....	168
Winter steer feeding, 1922-1923, Skinner and King.....	168
Steer feeding experiments, Goodell.....	169
Africander cattle, Reinecke.....	169
Second report on sheep breeding.....	169
Sheep feeding.—XII, Fattening western lambs, Skinner and King.....	170
Forage crops for lambs, Wilson and Kuhlman.....	170
Investigations comparing urea with peanut cake, Völtz et al.....	171

	Page
Potatoes as a feed for fattening pigs, Wilson and Kuhlman-----	171
Pigs and their management, Potts-----	172
The correlation between speed and massiveness of horses, Prawocheński--	172
Weight of Leghorn chickens at hatching, 35 days, and maturity, Latimer--	172
Nutritional requirements of baby chicks.—IV, Vitamin A, Hart et al--	173
Breeding for increased egg production, Riley-----	173
Statistical study of egg production in Plymouth Rocks, Dunn-----	173
Rules and regulations for Utah Intermountain Egg-Laying Contest, Alder	174

## DAIRY FARMING—DAIRYING

The principles of dairying.—Testing and manufactures, Judkins-----	174
Early, medium, and late maturing varieties of silage corn, White et al--	174
Judging cattle, Pusch, rev. by Attinger-----	174
Some results of dairy improvement associations, Tailby-----	174
Relation of milk production to the twinning tendency, Hunt-----	174
Effect of an incomplete removal of milk from the udder, Davidson-----	175
The rate of milk secretion as affected by an accumulation of milk in the mammary gland, Ragsdale et al-----	175
Unique dietary needs for lactation, Evans-----	176
Influence of diet and management of the cow on deposition of calcium in rats receiving a daily ration of the milk, Boas and Chick-----	176
On the coagulation of milk by rennin, Bostrom-----	177
The history of dairy bacteriology, Walts-----	177
The thermal death-point of the tubercle bacillus in milk, Brown-----	177
Observations on butter from buffalo milk, Degli Atti-----	177
Gouda or sweet-milk cheese-making, Hamilton-----	177
Report of the creamery license division for 1924, Goss-----	177

## VETERINARY MEDICINE

Report of proceedings of Fifth Pan-African Veterinary Conference-----	177
Comments on the Pharmacopoeia and National Formulary, DuMez-----	177
Toxicology or the effects of poisons, Underhill-----	178
Cocklebur (species of Xanthium) as poisonous plants, Marsh et al-----	178
The composition of various samples of arsenite of soda, Van Zyl-----	178
Oxidation in arsenical dipping tanks, Van Zyl-----	178
Organic substances, sera, and vaccines in therapeutics, Jones-----	178
Immunologic significance of vitamins, IV, Werkman et al-----	179
Discovery of causal organism of foot-and-mouth disease, Frosch and Dahmen-----	179
The virus of foot-and-mouth disease-----	179
Formation of antibodies following mallein, Brocq-Rousseu et al-----	180
Attempts at vaccination against tuberculosis by ingestion, Calmette et al--	180
Studies in tuberculosis immunity, I, Ebersson-----	180
Transmission and treatment of infectious ophthalmia, Jones and Little--	180
The susceptibility of calves to contagious abortion, Quinlan-----	181
The etiology of contagious abortion in mares, Román-----	181
The life-history of <i>Oesophagostomum columbianum</i> , Veglia-----	181
Fowl cholera, Black-----	181
An <i>Eimeria</i> n. sp. found in the faeces of an eland, Triffitt-----	182
Anthelmintic efficiency of C Cl <sub>4</sub> in foxes, Hanson and Van Volkenberg---	182

## RURAL ENGINEERING

A survey of reclamation-----	182
Development of irrigation projects-----	182
Hydro-electric power in Washington, Part I, Magnusson-----	182
Electrical service for rural districts in Ontario, Gaby-----	183
The Italian hydroelectric industry, Dominian-----	183
Steel and timber structures, edited by Hool and Kinne-----	183
Cinder block efficiency in pier tests-----	183
Public Roads, [August-October, 1924]-----	183
Reinforcing and the subgrade in the design of concrete pavements, Pauls--	184
The effect of haul on the cost of earthwork, Harrison-----	185
Car carburetion requirements, Kegerreis and Chenoweth-----	185
Air-filters, Dollinger-----	185

	Page
Recent observations of air-cleaning devices, Grimes.....	185
Testing of air-cleaners, Squyer.....	186
The mechanism of lubrication, III, Barnard et al.....	186
Water in crankcase oils, Clayden.....	186
Factors affecting the rate of crankcase-oil dilution, Eisinger.....	187
A possible solution of the crankcase-oil dilution problem, Anderson.....	187
Rectification of diluted crankcase-oil, Skinner.....	187
Practical hog houses for Indiana, Norman and Schwab.....	188
The Ohio individual farrowing house, Wuichet and Twitchell.....	188
Investigation of pollution of streams.....	188
A bacteriological study of a sewage disposal plant, Gaub.....	188

## RURAL ECONOMICS AND SOCIOLOGY

Rents and agricultural land values in theory and in practice, Buechel.....	189
Economic and social aspects of Philippine rice tenancies, Hester et al.....	189
Input as related to output in farm organization studies, Tolley et al.....	190
Wheat and wheat products, Marvin et al.....	191
Housing of casual labour, Pratt.....	191
Report on agricultural credit, Tory.....	191
[Reports of the Land Bank of South Africa, 1922 and 1923], Herold et al.....	192
The single-tax complex of some contemporary economists, Brown.....	192
Crops and Markets, [September, 1924].....	192
Co-operative livestock marketing in the United States.....	192
Co-operative marketing of milk in the United States.....	192
Cooperative marketing and city marketing problems.....	192
American agriculture and the European market, Nourse.....	193
The possibilities of British agriculture, Rew and Russell.....	193
The farmer's problem.....	193
The foundations of Indian agriculture, Leake.....	193
Developing rural social work, Ramsdell.....	193
Community organization for the country life program, Burr.....	194
Organized co-operation, Dillon.....	194
Monthly Supplement to Crops and Markets, [September, 1924].....	194
The world's cotton crops, Todd.....	194
Early estimates of grain growing in Great Britain.....	194
Annual agricultural statistics, 1921 [and 1922].....	194
Report on crop yields in Norway, 1923.....	194
[Agricultural statistics of Siam, 1922 and 1923].....	194

## AGRICULTURAL EDUCATION

Teacher training in agriculture.....	194
Statistics of land-grant colleges: Year ended June 30, 1922, Blauch.....	195
The public school system of Arkansas, Part I, Mann et al.....	195
[Seventeenth meeting of the American Home Economics Association].....	196
The new world problems in political geography, Bowman.....	196
Elements of forestry, Moon and Brown.....	196
Judging Kansas live stock, Elling.....	196
Poultry raising for club members, Hall and Neely.....	196
Twenty lessons on dairying for dairy club members, Buchanan.....	196
Principles of veterinary science, Hadley.....	197
The business of farming, Roberts.....	197
Farm economics: Management and distribution, App.....	197
Home economics in education, Bevier.....	197
Textiles, Dooley.....	197
Home accounts, Linn.....	197

# LIST OF EXPERIMENT STATION AND DEPARTMENT PUBLICATIONS ABSTRACTED

<i>Stations in the United States</i>	Page	<i>U. S. Department of Agriculture—Con.</i>	Page
Arkansas Station:			
Bul. 193.....	148	Farmers' Bul. 1240, How to	
Connecticut Storrs Station:		Grow Rice in the Sacramento	
Bul. 121.....	174	Valley, J. W. Jones.....	137
Bul. 122.....	173	Farmers' Bul. 1411, Crimson	
Delaware Station:		Clover: Seed Production, J.	
Bul. 138.....	119	M. Westgate, rev. by A. J.	
Illinois Station:		Pieters.....	135
Circ. 292.....	136	Farmers' Bul. 1432, Culture of	
Indiana Station:		Pima and Upland Cotton in	
Bul. 281.....	168	Arizona, O. F. Cook and R.	
Bul. 282.....	170	D. Martin.....	136
Bul. 283.....	141	Farmers' Bul. 1438, Making	
Circ. 118.....	177	Fermented Pickles, E. Le-	
Circ. 119.....	173	Fevre.....	114
Mississippi Station:		Crops and Markets:	
Bul. 222.....	169	Vol. 2—	
Circ. 52.....	136	No. 10, Sept. 6, 1924..	192
Circ. 53.....	152	No. 11, Sept. 13, 1924..	192
Missouri Station:		No. 12, Sept. 20, 1924..	192
Bul. 215.....	156	No. 13, Sept. 27, 1924..	192
New Jersey Stations:		Vol. 1, Sup. 9.....	194
Bul. 394.....	188	Bureau of Biological Survey:	
Bul. 399.....	167	North Amer. Fauna 47, Re-	
Hints to Poultrymen, vol.		vision of the American	
12, No. 12, Sept., 1924..	181	Pikas (Genus Ochotona),	
South Dakota Station:		A. H. Howell.....	153
Bul. 205.....	137	Bureau of Public Roads:	
Bul. 207.....	170	Public Roads, vol. 5—	
Bul. 208.....	143	No. 6, Aug., 1924.....	183
Bul. 209.....	171	No. 7, Sept., 1924.....	183, 185
Texas Station:		No. 8, Oct., 1924.....	183, 184
Bul. 316.....	116	Bureau of Soils:	
Bul. 318.....	189	Field Operations, 1920—	
Utah Station:		Soil Survey of Durham	
Circ. 52.....	174	County, North Car-	
Vermont Station:		olina, S. O. Perkins	
Bul. 237.....	167	et al.....	115
		Field Operations, 1921—	
		Soil Survey of the	
		Benson Area, Ari-	
		zona, E. J. Carpenter	
		and W. S. Brans-	
		ford.....	115
		Weather Bureau:	
		Climat. Data, vol. 11, Nos.	
		5-6, May-June, 1924....	115
<i>U. S. Department of Agriculture</i>			
Bul. 1274, Cockleburs (Species			
of Xanthium) as Poisonous			
Plants, C. D. Marsh, G. C.			
Roe, and A. B. Clawson.....	178		
Bul. 1277, Input as Related to			
Output in Farm Organization			
and Cost-of-production Stud-			
ies, H. R. Tolley, J. D. Black,			
and M. J. B. Ezekiel.....	190		

# EXPERIMENT STATION RECORD

Editor, H. L. KNIGHT.

## EDITORIAL DEPARTMENTS

Agricultural Chemistry and Agrotechny—SYBIL L. SMITH.  
Meteorology—W. H. BEAL.  
Soils and Fertilizers—R. W. TRULLINGER.  
Agricultural Botany, Bacteriology, and Plant Pathology—W. H. EVANS, Ph. D.,  
W. E. BOYD.  
Genetics—W. H. EVANS, W. E. BOYD, H. M. STEECE, J. W. WELLINGTON, G.  
HAINES.  
Field Crops—H. M. STEECE.  
Horticulture and Forestry—J. W. WELLINGTON.  
Economic Zoology and Entomology—W. A. HOOKER, D. V. M.  
Foods and Human Nutrition—SYBIL L. SMITH.  
Animal Husbandry, Dairying and Dairy Farming—G. HAINES.  
Veterinary Medicine—W. A. HOOKER, SYBIL L. SMITH.  
Rural Engineering—R. W. TRULLINGER.  
Rural Economics and Sociology and Agricultural Education—LOUISE MARBUT.  
Indexes—MARTHA C. GUNDLACH.  
Bibliographies—MARTHA L. GERICKE.

## CONTENTS OF VOL. 52, No. 3

	Page
Recent work in agricultural science.....	201
Notes.....	300

### SUBJECT LIST OF ABSTRACTS

#### AGRICULTURAL CHEMISTRY—AGROTECHNY

Atoms, Perrin, trans. by Hammick.....	201
On the science of color, Ostwald.....	201
Color and chemical constitution, Martinet and Alexandre.....	201
Pigments: Their properties and tests, "Technicus".....	201
Agricultural chemistry [studies at the Pennsylvania Station].....	201
Bread troubles in the light of hydrogen-ion concentration, Clark.....	202
Lipoids, a factor influencing gluten quality, Working.....	202
Effect of heat on peroxidase in milk, Spitzer and Taylor.....	202
Effect of insulin on the lactic fermentation, Noyes and Estill.....	203
A mixed indicator for carbonate-bicarbonate titrations, Simpson.....	203
On the determination of arsenic, chiefly in dipwashes, Van Zyl.....	203
Measurement of H-ion concentrations, Billmann.....	204
Determination of nitrate and ammonia in nitrogenous materials, Shedd.....	204
Determination of moisture in wheat and flour, I, Snyder and Sullivan.....	205
Hanus iodine values of cottonseed and coconut oils, Bankston and Vilbrandt.....	205
Determination of dry substance in beet sugar juices, Brown.....	205
Super-defecation of cane juice, Horne.....	205
Cornstalk sirup investigations, Willaman, Burr, and Davison.....	205
Cornstalk sirup investigations, Willaman, Burr, and Davison.....	207
Some chemical aspects of sweet corn drying, Appleman.....	207
Olive pickling in Mediterranean countries, Cruess.....	207

## METEOROLOGY

	Page
Forecasting seasonal rainfall from ocean temperatures, McEwen.....	207
The eleven-year sun spot period and temperature fluctuations, Droste...	208
Meteorological observations, 1922.....	208
Observations at the Massachusetts Station, Ostrander and Bower.....	208
Nitrogen in the rainwater at different points in Kentucky, Freeman....	208
Sulfur in rainfall in Kentucky, Johnson.....	208

## SOILS—FERTILIZERS

The composition of the earth's crust, Clarke and Washington.....	208
The distribution of soil material in the United States, Jennings.....	208
Value of soil analysis limited to single cropping system, McGeorge.....	209
Hancock County soils, Smith, De Turk, Bauer, and Smith.....	209
Soil survey of Cole County, Missouri, Sweet and Wildermuth.....	209
Soil survey of Benton County, Oregon, Carpenter and Torgerson.....	210
Representative Transvaal soils.—VIII, Waterberg sandy soil, Marchand..	210
Further studies on soil profiles, McCool and Weidemann.....	210
Factors influencing the binding power of soil colloids, Middleton.....	211
Nitrification in some South African soils, Part II, Hall.....	211
[Soil fertility studies of the Indiana Station].....	211
Soil improvement: Fertilisers and their use, Russell.....	211
Relation of manure to nutritive and vitamin value of grain, McCarrison..	212
Decomposition of calcium cyanamide on storage, Jacob et al.....	212
Preparation of guanidinium salts from cyanamide, Blair and Braham.....	212
The influence of silica, lime, and soil reaction upon the availability of phosphates in highly ferruginous soils, McGeorge.....	212
Phosphorus in calcareous and noncalcareous soils, Ames and Schollenberger ..	213
Phosphate fertilizers for soil improvement, Warner.....	213
Preparation of phosphoric acid, Ross, Mehring, and Jones.....	213
A biological measurement of availability of potassium in soils, Haley....	214
Soil potash as affected by fertilizers and cropping, Ames and Simon....	214
Authorizing investigations of potash deposits.....	214
Liming of soils, Guerrero.....	214
Mineral resources of the United States in 1923.....	215
The Jamshedpur sewage disposal works, Temple and Sarangdhar.....	215
The home mixing of fertilizer, Wiancko.....	215
Analyses of fertilizers—spring season, 1924.....	215

## AGRICULTURAL BOTANY

Morphology and physiology of the genus <i>Eidamia</i> , Horne and Williamson..	215
Observations on the reaction of protoplasm to some reagents, Seifriz....	215
Observations on the action of X-rays on plant cells, Williams.....	216
Experiments on the growth of fungi on culture media, Brown.....	216
On the apical growth of fungal hyphae, Smith.....	216
Growth studies—III, Measuring growth of roots, Priestley and Pearsall..	217
Studies in growth.—IV, Correlations in development, Pearsall.....	217
The conduction of geotropic excitation in roots, Snow.....	217
Experiments on resistance of apple roots to low temperatures, Potter....	218
Healing of wounds in potato and propagation, Priestly and Woffenden....	218
Isolation of inhibitory substance from plants, Mallmann and Hemstreet..	219
Age and area: A reply to criticism, with further evidence, Willis.....	219

## GENETICS

Somatic chromosomes of the chick and their possible sex relations, Hance..	219
The form of spotting of the Argentine horse, Krieg.....	219
The relation between chromosome number, morphological characters, and rust resistance in segregates of partially sterile wheat hybrids, Sax....	220
Dwarfness in wheat accompanied by unexpected ratios, Waldron.....	220
The factor for bitterness in the sweet almond, Heppner.....	221
Inheritance of egg size in <i>Drosophila melanogaster</i> , Warren.....	221
Pericarp studies in maize.—I, Anderson and Emerson.....	222
The Japanese rabbit and gametic purity, Castle.....	222

	Page
Experiments and observations on inheritance in swine, Kronacher.....	222
The genetic relation between <i>Triticum dicoccum dicoccoides</i> and a similar morphological type produced synthetically, Love and Craig.....	223
"Hairy neck" segregates from wheat-rye hybrids, Leighty and Taylor.....	223

## FIELD CROPS

[Forage crops investigations in Florida], Stokes.....	224
[Field crops at Georgia Coastal Plain Station, 1922 and 1923].....	224
[Agronomic experiments in Guam, 1922], Guerrero.....	226
[Crop variety tests on the Soils and Crops Experiment Farm].....	226
[Crop tests at the Moses Fell Annex Farm], Reed and Moore.....	226
[Field crops work in Mississippi, 1923], O'Kelly et al.....	226
Report of the summer fallow substitute section committee, Champlin.....	226
[Field crops work in Tortola, British Virgin Islands, 1920-1923], Watts.....	227
[Field crops work in Aberdeen, Scotland].....	227
[Report of] Scottish Society for Research in Plant-Breeding, Drummond.....	227
[Field crops in Central Provinces and Berar, 1922-23], McDougall et al.....	227
Nomenclature of grasses and clovers, Stapledon.....	227
Corn selection for exhibit purposes, Helm.....	227
A program of corn improvement, Woodworth.....	227
Length of cotton fiber from bolls at different heights on the plant, Kearney and Harrison.....	227
Effect of sulphuric acid on breaking load of cotton, Vincent.....	227
Oil seed crops in Argentina, Paulsen.....	228
Floral parts of the potato as aids in identification of varieties.....	228
Factors affecting value of potatoes for seed, Profeit and Findlay.....	228
The physiology of the germination of rice, the growth of seedlings, and the condition of the seed beds, Kondo.....	229
Experiments with rice, Montanari and Matus.....	229
The present position of sisal hemp cultivation, Goulding.....	229
The effect of cold on the buds of sugar cane, Fawcett.....	229
[Results with wheat at Iredell (N. C.), 1911-1921], Williams et al.....	230
Experiments with wheat, Sutton.....	230
Testing of New-Zealand-grown wheats, Foster.....	230
The best stage for cutting wheat, Calder.....	230
Report of the Danish State Seed Control, 1921-22, Dorph-Petersen.....	231
Perennial sow thistle: Growth and reproduction, Stevens.....	231

## HORTICULTURE

How to pack living plant material for long-distance shipment, Galloway.....	232
[Horticultural investigations at the Georgia Coastal Plain Station].....	232
[Horticultural investigations at the Guam Station], Guerrero.....	232
[Horticultural investigations at the Pennsylvania Station].....	232
[Horticultural investigations at Cheshunt, England].....	233
Carbon dioxide investigations [at Cheshunt, England].....	234
Some relations of hardening to transplanting, Loomis.....	234
Influence of the time of maturity of onions on the rest period, Boswell.....	235
Influence of time of maturity of onions on storage, Boswell.....	235
The use of statistical data in tomato breeding, Brown and Hoffman.....	235
The function of nitrogen in the nutrition of the tree, Gardner.....	236
Spraying Missouri fruits, Talbert.....	236
Bud and root selection in the propagation of the apple, Sax.....	236
The beauty and use of the vintage pear, Durham.....	236
Plum and prune growing in the Pacific States, Kinman.....	237
Blueberry culture, Beckwith.....	237
Dewberry growing, Darrow.....	237
An experiment with gooseberry varieties, 1910-1920, Esbjerg.....	237
The Van Fleet raspberry, a new hybrid variety, Darrow.....	237
Strawberry culture in Missouri, Talbert.....	237
Head, cane, and cordon pruning of vines, Bioletti and Jacob.....	237
Culture of olives used for pickling, Cruess.....	237
The habit of budded cacao, Harland and Parga.....	237
Bud selection and quality in Washington Navel orange, Shamel et al.....	238
[A qualitative study of phosphorus fertilizers], Ruprecht.....	238

	Page
The date-palm in antiquity, Popenoe.....	238
Filberts, Schuster.....	238
Stimulation of cuttings, Herele.....	239
The production of Narcissus bulbs, Griffiths.....	239
Rhododendrons, their names and addresses, Wilding.....	239
Planting home grounds, MacDonald.....	239

## FORESTRY

Forest types in Rocky Mountains as affected by climate and soil, Bates.....	239
The trees and shrubs of Yellowstone National Park, Hawkins.....	240
Small rodents and northeastern conifers, Pulling.....	240
[Forestry investigations at the Pennsylvania Station], Ferguson.....	240
Black walnut for timber and nuts, Mattoon and Reed.....	240
Identification of Philippine woods by anatomical characters, Kanehira.....	241
Anatomical notes on Indian woods, Kanehira.....	241
The work of a forest protective association, Hawes.....	241
Forestry almanac.....	241
Thirteenth report of the State forester, 1923, Elliott.....	241
Report of the forest branch, [British Columbia], 1923, Caverhill et al.....	241
Report on forest administration for the year 1923, Cubitt.....	241
Annual report on the forestry department for 1922, Fyffe.....	241

## DISEASES OF PLANTS

Report of plant pathologist, Burger.....	241
[Plant disease investigations of the Mississippi Station], Neal.....	242
Botany and plant pathology.....	243
<i>Puccinia graminis poae</i> in the United States, Stakman and Levine.....	243
Reaction of barley varieties to <i>Helminthosporium sativum</i> , Hayes et al.....	244
Relation of soil temperature and soil moisture to infection by <i>Plasmiodiophora brassicae</i> , Monteith.....	244
Control of celery blight by spraying and dusting, Dye and Newhall.....	245
Corn root, stalk, and ear rot diseases, and their control, Holbert et al.....	245
A study of wilt resistance in flax, Barker.....	245
Importance of potato degeneration diseases, Folsom and Schultz.....	246
Tobacco disease investigations, Tisdale.....	246
Tobacco diseases and their control, Johnson.....	247
Tomato wilt and its control in Arkansas, Elliott.....	247
Apple blotch control in Missouri, Talbert.....	247
Botryosphæria and Physalospora on currant and apple, Shear et al.....	248
<i>Physalospora malorum</i> on currant, Stevens.....	248
Two hitherto unreported diseases of stone fruits, Lindegren and Rose.....	248
Dieback of citrus, Ruprecht.....	248
A disease of cocoa and coffee fruits, Tabor and Bunting.....	249
Effect of kiln drying, steaming, and air seasoning on fungi, Hubert.....	249
Root-knot nematode, Watson.....	249

## ECONOMIC ZOOLOGY—ENTOMOLOGY

Damage to range grasses by the Zuni prairie dog, Taylor and Loftfield.....	250
Returns from banded birds, 1920 to 1923, Lincoln.....	250
A method of caring for and training homing pigeons, Devlin.....	250
Report of the entomologist [of the Florida Station], Watson.....	250
Annual report of the State entomologist [Georgia] for 1922, Williams.....	252
Annual report of the entomology department, Harned.....	252
Entomology [at the Pennsylvania Station], Frost and Horsfall.....	252
[Economic insects in the County of Holland, England], Miles.....	252
Greenhouse insects, McDaniel.....	252
<i>Nicotiana rustica</i> as a source of nicotine for insect control, Haley et al.....	252
The fungicide and insecticide guarantee, McMahan.....	253
The European earwig, Fulton.....	253
The buckthorn aphid ( <i>Aphis abbreviata</i> Patch), Patch.....	253
On the destroyer of lucerne, the pea leaf-louse, Jablonowski.....	254
The cankerworms, Porter and Alden.....	254
The bud moth, Porter.....	254

	Page
The clover-seed caterpillar ( <i>Laspeyresia interstinctana</i> Clemens), Wehrle.....	255
Round-headed apple-tree borer and its control, Petch.....	256
The rough-headed corn stalk-beetle, Phillips and Fox.....	256
Studies of Mexican bean beetle in Southeast, Howard and English.....	256
Seasonal management for commercial apiaries, Kelty.....	257
Miscellaneous biological observations on bumblebees, Plath.....	257
Ants, Wolcott.....	257
Woolly aphid parasite, <i>Aphelinus mali</i> (Hald.), Newman.....	257
Longevity of the fowl tick ( <i>Argas persicus</i> ), Newman.....	258

## FOODS—HUMAN NUTRITION

Food products, Sherman.....	258
Chemistry in relation to food, Monier-Williams.....	258
Feeding the family, Rose.....	258
Foods and drugs, Bartlett.....	258
Effect of storage on baking quality of common and durum wheats, Mangels.....	258
The cake flour laboratory, Patterson.....	259
The digestibility of powdered dried meat, Langworthy and Holmes.....	259
Observations on the absorption of copper, Drummond.....	259
Dietary sources of calcium and phosphorus, Holmes.....	260
The value of egg yolk in supplementing diets deficient in calcium, Tso.....	260
Regeneration of hemoglobin and diet factors in prolonged severe experimental anemia, Whipple and Robscheit-Robbins.....	260
The energy metabolism of normal, full term infants, Conklin et al.....	261
Photographic method for studying nutrition of children, Clough.....	261
New feeding device for use with experimental rat, Parsons and Alexander.....	261
Blood platelets in rats, Shulman and Mendel.....	261
[Studies on vitamin X].....	262
Methods of preparation and vitamins of spinach, Stanley and Stillman.....	262
The basal metabolism in vitamin B deficiency, Deuel and Weiss.....	262
Studies on the chemistry of cod liver oil, II, Dubin and Funk.....	263
Results in rickets treated with concentrate from cod liver oil, Fischer.....	263
Clinical experience with the active principle of cod liver oil, Chaplin.....	263
The antirachitic action of yolk of egg, Hess and Weinstock.....	263
Prevention and cure of rickets by means of bile, Kapsinow and Jackson.....	263
Variation of complement of guinea pigs during scurvy, Koch and Smith.....	264
Studies of glyceryl tri-margarate (intarvin), I, Heft et al.....	264
The food value of intarvin, Benedict et al.....	264
The use of intarvin fat in diabetes mellitus, Keefer et al.....	264
Insulin, MacLean.....	265
Production of lactic acid in diabetes following insulin, Tolstoi et al.....	265
A table of standard diets for use in diabetes, Pybus and Lyon.....	265
Thyroid enlargement in Michigan: The state-wide survey, Olin.....	265
The iodine content of Michigan water supplies, Eldridge.....	265
Bacteria of paratyphoid-enteritidis group and poisonings, Geiger et al.....	266

## ANIMAL PRODUCTION

Animal nutrition, Wood.....	267
Some chemical characteristics of soft corn, Bushey.....	267
Composition of sugar-beet pulp and tops and of silage, Sherwood.....	267
Silage investigations of the German Agricultural Society.....	268
Commercial feeding stuffs, 1923-24, Bartlett.....	268
Nebraska feeders' day, Derrick.....	268
Protein requirements for the growth of cattle, II, Forbes et al.....	268
[Experiments with beef cattle at the Mississippi Station], Barnett.....	269
Cattle-breeding in Central Provinces and Berar for 1922-23, Wallace.....	269
Beef on the farm—slaughtering, cutting, curing, Black and McComas.....	270
Cross-breeding Merino ewes with mutton rams, Henning.....	270
Docking and castration of lambs, MacMillan.....	270
Pig feeding experiment, Scott.....	270
[Experiments in fattening swine at the Pennsylvania Station], Grimes.....	270
Rice polish versus corn, Barnett.....	270
Soft pork studies, Scott.....	270
Iron deficiency in pigs, McGowan and Crichton.....	271

	Page
Cotton seed meal poisoning, McGowan and Grichton.....	271
Care and management of farm work horses, Williams and Krantz.....	272
Corn versus oats for work mules, Trowbridge.....	272
The origin of the Shepherd dog, Tracy.....	272
[Poultry experiments at the Mississippi Station], Clayton.....	272
[Experiments with poultry at the Pennsylvania Station].....	272
The research program of the department of poultry husbandry, Thompson.....	273
Adding vitamin-rich substances to normal rations for poultry, I, Orr et al.....	273
Prevention of weak legs in experimental chickens, Collier.....	274
Notes on the management of farm poultry, Ellison, trans. by Martinez.....	274

## DAIRY FARMING—DAIRYING

[Report of] the Institute of Animal Nutrition, Forbes.....	274
Experiments with dairy herd, Scott.....	275
[Feeding experiments with dairy cattle in Guam], Edwards.....	275
[Feeding experiments with dairy cattle at the Pennsylvania Station].....	275
Relative values of alfalfa, soy beans, and lespedeza hays, Moore.....	275
Partial replacement of hay, De Ruyter de Wildt and Brouwer.....	275
Feeding experiments with silage, Rae and Gardner.....	276
Feeding and age of calving and development of dairy heifers, Reed et al.....	276
Care and management of dairy bulls, Dawson.....	276
Selection and management of the dairy bull, Ragsdale.....	276
Purebred dairy sires: Influence on production, Olson and Gilcreast.....	276
The influence of diet and sunlight upon the growth-promoting and anti-rachitic properties of the milk, Luce.....	277
On the producing of milk having a low bacterial content, Sadler et al.....	277
Studies on pasteurization, XI, XII, Ayers and Johnson.....	277
Elimination of germs from dairy utensils, III, Prucha and Harding.....	278
On the agglutination of fat globules, I, Van Dam et al.....	278
Agglutination of butterfat droplets and their electrical charge, Sirks.....	278
[Dairy products experiments at the Pennsylvania Station].....	278
Reduction of high colour in butter, Brown.....	279
Green colour in butter, Brown.....	279
Cheese making, Sammis.....	279
A mold of cheese, Boekhout and Beynum.....	279

## VETERINARY MEDICINE

Encyclopaedia of veterinary medicine, edited by Wooldridge.....	280
National Veterinary Medical Association of Great Britain and Ireland, Limited, annual congress at Aberdeen, 1924.....	280
Report of Louisiana State Live Stock Sanitary Board, Flower.....	280
[Annual reports of the Civil Veterinary Department, United Provinces, for the years ended March 31, 1922 and 1923], Oliver and Hickey.....	280
Plants poisonous to live stock, Long.....	280
Investigations of the chemotherapy of Bayer 205, Fourneau et al.....	280
Studies on the toxicity of carbon tetrachloride, Schultz and Marx.....	280
The leucocyte in health and disease, Bond.....	281
Ascaris sensitization, Ransom, Harrison, and Couch.....	281
The hush-sickness investigation, Aston.....	282
Further studies on the potency of botulinus toxin, Bronfenbrenner.....	282
Foot-and-mouth disease, with special reference to 1914, Mohler.....	282
Birds in relation to the foot-and-mouth disease of cattle, M[cAtee].....	282
Appearance of specific antibodies in the serum of rabbits by injections of living tubercle bacilli, Fried and Proctor.....	282
Vaccination of cattle against tuberculosis, Calmette and Guérin.....	282
Udder diseases of dairy cows, Bunyea.....	283
Contagious abortion of bovines, Rivera.....	283
Contagious abortion in cattle, Hadley.....	283
[Stomach worms in lambs], Barnett.....	283
Verminous broncho-pneumonia in pig from <i>Metastrongylus apri</i> , Bisset.....	283
Influence of the bile on the swine erysipelas bacillus, Kolda.....	283
Toxicity of seeds of <i>Cassia occidentalis</i> L. for the horse, Henry et al.....	284
Avian variola, Basset.....	284
Bacillary white diarrhoea of chicks, Newsom.....	285
Auricular scabies (parasitic otitis) in silver black foxes, Allen.....	285
Filariasis, with especial reference to Australia, Cilento.....	285

## RURAL ENGINEERING

	Page
Experimental study of air lift pumps, Ward and Kessler.....	285
Surface water supply of Oregon, 1919-1920.....	286
Surface water supply of North Atlantic slope drainage basins, 1921.....	286
Water powers of the Great Salt Lake basin, Woolley.....	286
Measurement of irrigation water, Murdock and Barker.....	287
Supplemental irrigation for the Willamette Valley, Powers.....	287
Studies of field spraying in 1922, Krüger.....	287
Drain wet fields, Jones and Zeasman.....	287
Standard specifications for steel highway bridges.....	287
Tests of new billet steel and rerolled steel reinforcing bars, Kommers.....	287
Transmission of heat through building materials, Rowley.....	288
The gas engine on the farm, Behrends and Fairbanks.....	288
Nebraska tractor tests, 1921, 1922, and 1923, Brackett et al.....	288
Farm motor trucks in New England and Central Atlantic States, Church.....	288
Standardization of wheel track widths for farm hauling, Korschak.....	288
Belt speeds for the electrical driving of threshing machines, Riefstahl.....	289
Tests of a potato digging machine, Rudzki.....	289
Sharpening crosscut saws.....	289
Poultry house construction, Lee.....	289
Chemical changes occurring in a sprinkling filter, Campbell and Rudolfs.....	290

## RURAL ECONOMICS AND SOCIOLOGY

Farm organization in Clinton County, Indiana, Hawthorne and Dixon.....	290
Economic study of farming in North Dakota, Willard and Reynoldson.....	291
Economic study of dairying in Herkimer County, New York, Misner.....	292
Cost of producing milk, Severance and Baker.....	292
Relation of land tenure to plantation organization, Brannen.....	293
Assessment of farm and city real estate in Kansas, Englund.....	294
An economic study of rural store credit in New York, Spencer.....	295
The cost of living in a small factory town, Noble.....	296
Standard baskets for fruits and vegetables, Downing and Spilman.....	296
Crops and Markets, [October, 1924].....	296
Farmers' Market Bulletin, [May and June, 1924].....	296
Supplement to agricultural cooperation reading list, compiled by Gardner.....	297
The German food situation and import requirements for 1924, Hess.....	297
Economic needs of Germany and surplus production in America, Hess.....	297
Summary of statistics of agricultural exports and imports.....	297
Monthly Supplement to Crops and Markets, [October, 1924].....	297

## AGRICULTURAL EDUCATION

Statistics of land-grant colleges: Year ended June 30, 1921, Blauch.....	298
Hampton's school of agriculture, Doggett.....	298
Tuskegee's work in agriculture, Hubert.....	298
A type rural high school, Nelson and Windes.....	298
Curriculum making in home economics, Armentrout et al.....	298
Types of courses of study in agriculture, Windes.....	298
Teaching agriculture, Berry.....	298
Elements of rural economics, Carver.....	299

## MISCELLANEOUS

[Annual Report of Florida Station, 1923], Newell et al.....	299
[Reports of Georgia Coastal Plain Station, 1922 and 1923], Starr.....	299
Report of the Guam Station, 1922, Edwards and Guerrero.....	299
Thirty-sixth Annual Report [of Mississippi Station], 1923, Ricks et al.....	299
Thirty-seventh Report of Pennsylvania Station, [1924], [Watts].....	299

Editor: H. L. KNIGHT.

## EDITORIAL DEPARTMENTS

Agricultural Chemistry and Agrotechny—SYBIL L. SMITH.  
Meteorology—W. H. BEAL.  
Soils and Fertilizers—R. W. TRULLINGER.  
Agricultural Botany, Bacteriology, and Plant Pathology—W. H. EVANS, Ph. D.,  
W. E. BOYD.  
Genetics—W. H. EVANS, W. E. BOYD, H. M. STEECE, J. W. WELLINGTON, G.  
HAINES.  
Field Crops—H. M. STEECE.  
Horticulture and Forestry—J. W. WELLINGTON.  
Economic Zoology and Entomology—W. A. HOOKER, D. V. M.  
Foods and Human Nutrition—SYBIL L. SMITH.  
Animal Husbandry, Dairying, and Dairy Farming—G. HAINES.  
Veterinary Medicine—W. A. HOOKER, SYBIL L. SMITH.  
Rural Engineering—R. W. TRULLINGER.  
Rural Economics and Sociology and Agricultural Education—LOUISE MARBUT.  
Indexes—MARTHA C. GUNDLACH.  
Bibliographies—MARTHA L. GERICKE.

## CONTENTS OF VOL. 52, NO. 4

	Page.
Editorial notes:	
Passage of the Purnell Act for the more complete endowment of experiment stations.....	301
The agriculture appropriation act, 1925-26.....	302
Recent work in agricultural science.....	309
Notes.....	398

## SUBJECT LIST OF ABSTRACTS

### AGRICULTURE CHEMISTRY—AGROTECHNY

Chemistry in industry, edited by Howe.....	309
The plant alkaloids, Henry.....	309
Deterioration of soap-nicotine preparations, McDonnell and Nealon.....	309
A new micromelting point apparatus, Clevenger.....	310
Platinized aluminum cathodes in electroanalysis, France and Eckert.....	310
Turbidimetric estimation of precipitates, Hibbard.....	310
Comparison of qualitative tests for soil acidity, Harper and Jacobson.....	310
The rapid determination of available phosphate in soil, Atkins.....	311
Tables for converting crude protein and ash content to a uniform mois- ture base, Shollenberger and Coleman.....	312
The Van Slyke method for amino-acid nitrogen, Lamson.....	312
Detection and determination of pyruvic acid, Simon and Piaux.....	312
Color reactions of fat-soluble factors, Bezssonoff.....	313
The influence of certain factors on the hydrogen ion concentration of milk.—II, Temperature changes, Duncombe.....	313
The relation of natural acidity in milk, Rice and Markley.....	313

	Page
Determination of adulterants in butter fat, Spitzer and Epple.....	314
[Aniline dye for coloring glymol].....	314
Sweetened condensed milk, II, Fisher and Rice.....	314
Surface tension of sugar factory products, Lindfors.....	315
The fermentation industries, Furness.....	315

## METEOROLOGY

Why the weather? Brooks et al.....	315
Monthly Weather Review, [July-August, 1924].....	315
Climatological data for United States by sections, [July-August, 1924]..	316
Meteorological tables, Seeley and Whittier.....	316
Our climate, Spencer.....	316
A climatological history of Ohio, Alexander.....	316
Bioclimatic observations in Egyptian desert in March, 1923, Williams....	316
Rainmaking, Humphreys.....	317
Substitution of fruit temperatures for air temperatures in regulating orchard heating for oranges, Young.....	317

## SOILS—FERTILIZERS

Report of the section of soils [at the Michigan Station], McCool et al....	317
The toxicity, movement, and accumulation of nitrates and other salts oc- curring in arid soils, Craig.....	317
Replaceable bases in soils, Kelley and Brown.....	318
Reaction of the soils of Germany, Lemmermann and Fresenius.....	319
The soil acid question, Densch, Hunnius, and Pfaff.....	319
Acidity and soil organic matter, Vincent.....	319
The cycle of carbon dioxide in nature, Lundegårdh.....	320
Presence of Azotobacter in Polish soils, Ziemięcka.....	320
Influence of bacteria on phosphates in soil, Stoklasa and Křička.....	320
Methods of preventing injury.—III, Soil disinfection, Vogt.....	321
Partial sterilization of soil, Rivière and Pichard.....	321
Soil survey of Sussex County, Delaware, Snyder et al.....	321
Soil survey of Screven County, Georgia, Long et al.....	321
Soil survey of Greene County, Iowa, Goke and Orrben.....	321
Soil survey of Caldwell County, Missouri, De Young and Jordan.....	322
Soil survey of Tompkins County, New York, Howe et al.....	322
Crop yields on soil experiment fields in Iowa, Stevenson et al.....	322
The management of western Washington soils, McCollam.....	322
Fertilizer experiments at Lauchstädt and Gross Lübars, Schneidewind....	322
Action of stable manure in decomposition of cellulose in tilled soil, Bar- thel and Bengtsson.....	323
Nitrogen survey.—Part IV, European countries, Curtis and Ernst.....	323
Action of nitrogen and phosphoric acid on Silesian soils, Meyer et al....	323
Comparative tests of phosphatic fertilizers, Rousseaux.....	323
Weathering of granite, Blanck and Petersen.....	323
Residual effects of forty years' continuous manurial treatments.—I. Effect of lime on soil organic matter, White and Holben.....	323
The effect on present soil reaction of long-continued applications of equivalent amounts of high-calcium and high-magnesium limes, Bur- gess.....	324
Use of molasses as fertilizer, Fauque.....	324
Use of molasses as fertilizer on the Island of Mauritius, De Sornay.....	324
The computation of fertilizer mixtures, Merz and Ross.....	324

## AGRICULTURAL BOTANY

[Work in plant physiology at the Michigan Station], Hibbard.....	325
Nitrogenous metabolism of the higher plants, Part II, Chibnall.....	325
Diurnal variations in nitrogen content of foliage leaves, Chibnall.....	326
Influence of ammonium sulphate on plant growth, Jones and Shive.....	326
Carbon dioxide in relation to glasshouse crops, I, Owen.....	327
Carbon dioxide in relation to glasshouse crops, II, Owen and Williams....	327
Chlorid content of the leaf tissue fluids of cotton, Harris et al.....	327
Effect on certain plants of altering daily period of light, Adams.....	327

	Page
Replacement of the terminal bud in the coco-nut palm, Petch and Gadd.....	328
Loss of leaf and damage in late attacks on wheat, Roebuck and Brown.....	328
Indicator significance of the natural vegetation of the southwestern desert region, Shantz and Piemeisel.....	328

## GENETICS

Chromosomes in maize and maize relatives, Longley.....	328
A rare carbohydrate in waxy maize, Weatherwax.....	329
On the distribution of mutant characters among the chromosomes of <i>Oenothera lamarckiana</i> , De Vries and Boedijn.....	329
An attempt to improve through selection the style length and fertility of <i>Oenothera brevistylis</i> , Davis.....	330
A reversionary character in stock and its significance, Saunders.....	330
Interspecific hybrids in <i>Crepis</i> , II, Collins and Mann.....	330
Studies on the inheritance of the weight of new-born rabbits, Kopeć.....	331
Genetics of the Japanese rabbit, Castle.....	332
On the "Japanese" rabbit, Punnett.....	332
The genetics of the Wensleydale breed of sheep, I, Dry.....	332
Inheritance of pubescent nodes in a cross of wheat, Love and Craig.....	332
Linked inheritance of certain characters in the adzuki bean, Kakizaki.....	333
Sex ratio data for two chalcid egg parasites of the coffee bug, Dry.....	333
Notes on the genitalia of a crowing hen, Gatenby and Brambell.....	333

## FIELD CROPS

Native American forage plants, Sampson.....	334
Forage plants and their culture, Piper.....	334
[Agronomic work in Michigan], Spragg and Megee.....	334
Report of Northeast Missouri Field (1924), Etheridge and Helm.....	334
Seed production with different grasses and clover, Lindhard and Bagge.....	334
Factors affecting water absorption and germination of seed corn, Dungan.....	335
Effects of foreign pollen on corn, Kiesselbach and Cook.....	336
Effect of the opening processes upon the staple of cotton, Foster.....	336
Community cotton production, Cook and Martin.....	336
Cotton production, Perkins.....	336
Cotton production in Virginia, Patteson.....	336
The dasheen, a southern root crop for home use and market, Young.....	336
A study of flax and kindred fibres, III, Searle.....	337
Production of henequen fiber in Yucatan and Campeche, Edwards.....	337
Variety tests with oats, 1915-1920, Larsen.....	337
Potato growing in Kentucky, Gardner and Mathews.....	338
Potato culture, Lavoie.....	338
Size of seedling tests with [rice], Torres.....	338
Effect of spacing on three varieties of rice, Rodrigo.....	338
Relation of different amounts of water to rice, Reyes.....	338
Effect of mineral fertilizers on nodulation of soy beans, Perkins.....	338
A note on the nodulation of soy beans, Perkins.....	339
Sugar beets from selected and unselected roots, Lindhard.....	339
Culture experiments with sugar beet strains, 1922, Lindhard.....	339
Spacing experiments with sugar beets in Moravia, Chmelař and Šimon.....	339
Taros and yautias, promising new food plants for the South, Young.....	340
How long do seed species retain germination power? Dorph-Petersen.....	340

## HORTICULTURE

My garden book, Weathers.....	341
The vegetable garden, Bennett, rev. by Kruhm.....	341
Vegetable culture, Dybowski.....	341
[Horticultural investigations at Rosthern, Sask.], Munro.....	341
[Plant breeding activities at Vineland (Ont.)].....	341
Grapes, peaches, melons, and how to grow them, Sanders and Lansdell.....	341
Asparagus, Loisel, rev. by Lesourd.....	342
The mushroom industry of Pennsylvania, Mason.....	342
American fruits, Fraser.....	342
Importance of proper pollination in fruit fields, Auchter.....	342
[Fruit pollination], Hooper.....	342

	Page
New problems found in cherry pollination, Schuster.....	342
The cold storage of pears, Overholser and Latimer.....	342
Currants and gooseberries, Darrow, Detwiler, et al.....	343
New grape varieties for California, Husmann.....	343
The Almeria grape industry of the Old World, Cruess.....	343
The olive: Its culture and manufacture into oil, Bonnet.....	343
Avocado pollination tests, Clark.....	343
The banana and its cultivation.....	344
The propagation and cultivation of citrus trees in Egypt, Brown.....	344
Date palm in Egypt, Brown.....	344
Walnut culture in California, Batchelor.....	344
A handbook of Crocus and Colchicum for gardeners, Bowles.....	344
The roses of Britain, Wolley-Dod.....	344
Roses, Lachaume, rev. by Bellair.....	344
Mountain flowers, Marret.....	344
Gardening in California: Landscape and flower, McLaren.....	344
The Soledad garden and arboretum in Cuba, Fairchild.....	344
Gardens of South Africa, Fairbridge.....	344

## FORESTRY

Practical forestry from a workman's point of view, Drummie.....	345
A forest manual, Razous.....	345
Forest administration in the United Provinces for 1923, Billson.....	345
Aerial photography in forestry, logging, and engineering, Wilson.....	345
Identification of woods with a hand lens, Bienfait and Pfeiffer.....	345
Studies in transpiration of coniferous tree seedlings, Pearson.....	345
Western hemlock; red pine.....	345
The giant Sequoia, Ellsworth.....	345
Timbers of tropical America, Record and Mell.....	345
The story of rubber, Sturmer.....	346
The Rubber Conference, Brussels, 1924.....	346

## DISEASES OF PLANTS

[Plant pathology work at the Michigan Station], Coons.....	346
Effect of lactic acid on <i>Colletotrichum lindemuthianum</i> , Hopkins.....	346
Helminthosporium species on cultivated barley in California, Paxton.....	347
The resistance of oat varieties to stem rust, Mackie and Allen.....	347
A Helminthosporium root rot of wheat in Idaho, Raeder.....	347
The relation of temperature and hydrogen-ion concentration to uredinio- spore germination of biologic forms of stem rust of wheat, Hursh.....	347
The rosette disease of wheat and its control, Johnson et al.....	347
The action of Uspulun on seeds in germination, Czarnowski.....	347
Acromania, or "crazy-top," a growth disorder of cotton, Cook.....	348
Influence of soil temperature on flax wilt, Jones and Tisdale.....	348
The occurrence of Mycosphaerella wilt of muskmelons in Japan, Hemmi.....	348
A Fusarium bulb rot of onion and its development, Walker and Tims.....	348
Blight of peppers caused by <i>Phytophthora capsici</i> sp. nov., Leonian.....	349
Influence of meteorological factors on potato disease, MacMillan.....	349
Respiration of potato tubers in blackheart, Bennett and Bartholomew.....	349
Potato blackleg with reference to the etiological agent, Jennison.....	350
<i>Corticium vagum</i> as a factor in potato production, Richards.....	350
Relation of air temperature to mosaic disease, Johnson.....	350
Potato disease work, Kotila.....	351
A Fusarium blight of spinach, Hungerford.....	351
Destructive rust ( <i>Puccinia subnitens</i> ) on spinach in Northwest, Barss.....	351
Relation of rainfall to late blight of sugar-beet, Richards.....	351
The stem rot of sweet potatoes, Poole.....	351
The spread of tomato wilt by infected seed, Elliott and Crawford.....	351
<i>Thielavia basicola</i> on watermelon in Oregon, McKay.....	352
A "plum pocket" on <i>Prunus subcordata</i> in Oregon, Zeller.....	352
Leaf scorch or mollisiose of the strawberry, Stone.....	352
Rhizoctonia brown and other rots of strawberries, Dodge and Stevens.....	352
Distribution of <i>Tylenchus dipsaci</i> on wild strawberry in Oregon, McKay.....	352
A new species of Schizonella, Parthasarathy Iyengar and Narasimhan.....	352

	Page
A new <i>Phomopsis</i> of citrus in California, Fawcett.....	352
A <i>Phomopsis</i> in grape fruit from the Isle of Pines, W. I., Horne.....	352
<i>Thielaviopsis paradoxa</i> on the cocoanut palm in Florida, Fulton.....	353
Pathology of quaking aspen in Utah in relation to regulation, Meinecke.....	353
The life history of <i>Rosellinia caryae</i> n. sp., Bonar.....	353
Chemical injuries to the eastern white pine, Snell and Howard.....	353
Observations on two poplar cankers in Ontario, Moss.....	353
Lightning injury to <i>Hevea brasiliensis</i> , La Rue.....	353
<i>Torula ligniperda</i> : A Hyphomycete occurring in wood tissue, Siggers.....	353
A staining method for hyphae of wood-inhabiting fungi, Hubert.....	353

## ECONOMIC ZOOLOGY—ENTOMOLOGY

Rodent enemies of fruit and shade trees, Silver.....	353
Food habits of some winter bird visitants, Gabrielson.....	354
The English sparrow in western Washington, Couch.....	354
Report of the section of entomology [of the Michigan Station], Pettit.....	354
Report of the Entomological Society of Ontario, 1923.....	355
Applied entomology of Palestine, Buxton.....	356
Notes on insect pests in Samoa, Swezey.....	356
Introduction in Hawaii of insects attacking lantana, Perkins and Swezey.....	356
An apparatus for testing the toxic values of contact insecticides under controlled conditions, Tattersfield and Morris.....	356
Fumigation with liquid hydrocyanic acid: Comparison of costs, Ramsay.....	356
Egyptian cotton seed bug ( <i>Oxycarenus hyalinipennis</i> ), Kirkpatrick.....	356
A new psyllid injurious to fig trees, Laing.....	357
Fumigation checks aphids, Kelly.....	357
Control of the resistant black scale, Woglum and La Follette.....	357
The apple trumpet leafminer ( <i>Tischeria malifoliella</i> Clem.), Dunnam.....	357
Venomous caterpillars and the urticarial affections produced, Lapie.....	358
<i>Batrachetra arenosella</i> and nutfall of coconuts, Corbett and Gater.....	358
On zoophilism with <i>Anopheles</i> .—A review, Howard.....	358
A mermithid parasitic in adult mosquito in British Columbia, Steiner.....	358
Ox warble flies, MacDougall.....	359
A new hispid beetle injurious to oil palms in Brazil, Maulik.....	359
Effective use of hydrocyanic-acid gas in the protection of chick-peas ( <i>Cicer arietinum</i> ) warehoused in 240-pound sacks, Back and Cotton.....	359
Laws, rules, and regulations: Apiary inspection law.....	359
A biological study of <i>Aphelinus mali</i> Hald., Lundie.....	359
Polyembryonic development of <i>Platygaster vernalis</i> , Leiby and Hill.....	360
Report on parasitic Hymenoptera from Java and Sumatra, Gahan.....	361
Descriptions of Javanese Braconidae, Rohwer.....	361
Is there an entomogenous fungus attacking the citrus rust mite in Florida? Speare and Yothers.....	361
<i>Capillaria columbae</i> (Rud.) from the chicken and turkey, Graybill.....	361

## FOODS—HUMAN NUTRITION

Basal metabolism in health and disease, DuBois.....	362
Review of the literature for 1923 on infant feeding, Moffett.....	362
Metabolism of some mineral constituents of cow's milk and of breast milk in the same infant.—II, Chloride metabolism, Wang and Davis.....	362
Studies in growth, I, II, Talbot.....	362
The nutritive value of proteins, Mitchell.....	363
Cottonseed flour as human food, Macy and Outhouse.....	364
Sulfur metabolism, Lewis.....	364
Intestinal auto-intoxication, Alvarez.....	364
Mammary secretion, V.—I, II, Hartwell.....	364
The dietetic value of barley, malt, and malted liquors, Southgate.....	365
Sensitization of guinea pig to vitamin C deficiency, Mouriquand et al.....	365
Studies on effect of ultraviolet light on avitaminoses, I, Krizenecky.....	366
Observations on the use of insulin, Lyon.....	366
Insulin and the skin, Müller and Corbitt.....	366
Goitre, McCarrison.....	366
Iodine deficiency in the dietary supplied by use of kelp, Turrentine.....	366

	Page
Pellagra, Owensby.....	367
Deficiency diseases, with special reference to rickets, Mellanby.....	367
Effect of pregnancy on scurvy in guinea-pigs, Gerstenberger et al.....	367

## ANIMAL PRODUCTION

Studies of the thyroid apparatus, XXVI, Hammett.....	368
The endocrine glands and the development of the chick, I, Willier.....	368
Wyoming forage plants and their chemical composition, 6, Cundy.....	368
Soft corn—how to store and feed it.....	369
Shelled corn in fattening two-year-old cattle, Trowbridge and Fox.....	369
[Silage from corn stover and from normal corn for steers], Brown.....	369
Beef cattle investigations, 1923-24, McCampbell.....	369
Breeds of Italian sheep, Scipioni.....	370
Influence of variations in the sodium-potassium ratio on the nitrogen and mineral metabolism of the growing pig, Richards et al.....	370
Merits of home-produced foods for pig-feeding, Crowther and Chalmers.....	370
[Feeding experiments with swine at the Michigan Station], Brown.....	371
Feeding brood sows and growing the litters, Joseph.....	371
Influence of various foodstuffs on the growth of chickens, Malarski.....	372
Kikuyu grass for poultry, Sutton.....	372
Seasonal and annual egg-production-correlation tables, Hervey.....	372

## DAIRY FARMING—DAIRYING

Milk and science, Lindet.....	373
Minimum protein requirement for growing dairy heifers, Swett et al.....	373
Experimental feeding [with dairy cattle], Rothwell.....	374
Feeding trials with silage, Fishwick.....	375
Grass silage and its relation to milk, II, Dalla Torre.....	376
Pineapple "bran" as a feed for dairy cows, Henke.....	376
Better sires—better stock.—Build better by breeding, Davis.....	376
A comparison of Holstein-Friesian sires, based on the average "mature equivalent" fat production of the daughters, Turner and Ragsdale.....	376
Relation of leucocytes to mammary secretion, Weatherford and Emmel.....	376
Influence of certain factors on H-ion concentration of milk, I, Duncombe.....	376
Studies concerning the handling of milk, compiled by Williams et al.....	377
Simple method of determining the keeping quality of milk, Fuller et al.....	377
A study of methods for bacterial analyses of market milk, Coledge.....	377
Ropy or slimy milk, Kalkus.....	377
[Sugar substitutes in ice cream], Reed.....	377
Ice cream plant and manufacture, Reid.....	377

## VETERINARY MEDICINE

[Reports of Civil Veterinary Department in Ajmer-Merwara for 1922-23 and 1923-24], Jerrom.....	377
An improved neutral red light green double stain, Twort.....	378
Immunisation of animals against infection by <i>Vibrion septique</i> and <i>Bacillus chauvoei</i> , Allen and Bosworth.....	378
Attenuation of virulence of <i>Bacillus anthracis</i> in spore form, Ducloux.....	379
Dangers in the immunization of cattle against foot-and-mouth disease by the subcutaneous injection of virulent blood, Basset.....	379
The rabies parasite, <i>Encephalitozoon rabiei</i> , Manouelian and Viala.....	380
Antirabic vaccination of animals, Kondo.....	380
Report on the search for a method for the active immunization of suckling calves of cows refractory to rinderpest, Doutressoulle.....	380
Concentration of bacteria by aluminum hydroxide cream, Saelhof.....	380
The use of volatile hydrocarbons in the concentration of tubercle bacilli, Andrus and MacMahon.....	381
The diagnosis of tuberculosis in domestic carnivora, Verge.....	381
The prevention of tuberculosis and various chronic infections, Vallée.....	381
Report of section of animal pathology [of Michigan Station], Hallman.....	381
[Studies on bovine infectious abortion at Michigan Station], Huddleson.....	382
The immunology of bovine infectious abortion, Buck and Creech.....	383

	Page
Infectious abortion of cattle, Moussu.....	384
Transmission of swamp fever by means of secretions, Scott.....	384
A new nematode, <i>Cylindropharynx ornata</i> , from the zebra, with keys to related nematode parasites of the Equidae, Cram.....	385
Limberneck or botulism in chickens, Johnson.....	386

## RURAL ENGINEERING

Research in agricultural engineering, 1923, Trullinger.....	386
Report of section of farm mechanics [at Michigan Station], Musselman.....	386
Soil erosion as a research problem, McPheeters.....	386
Experiments in plowing cut over land.....	386
An investigation of the fatigue of metals, Moore and Kommers.....	386
An investigation of the fatigue of metals, Moore and Jasper.....	387
Electricity in agriculture abroad, Lundquist.....	388
The 30X30 Missouri poultry house, Kempster.....	388
The relation of farm animals to proper ventilation of barns, Kelley.....	388
Farm plumbing, Warren.....	389
Water purification by means of lime, II, Smit.....	389
"Bacteriophage" and self-purification of water, Flu.....	389
Some sewage disposal investigations, Stewart.....	389

## RURAL ECONOMICS AND SOCIOLOGY

The agricultural crisis, 1920-1923, Enfield.....	389
Work of cost of production division, S. Dak. Department of Agriculture.....	390
Annual report [of the] cost of production division, [1922], Byrne.....	390
A handbook on South Dakota farm production costs, Benedict.....	390
Developing farms on western South Dakota ranges, Worsham.....	390
The cost of producing apples in Minnesota, 1916-1920, Brierley et al.....	390
The cost of grazing, Ruston.....	391
The financial progression of a ten acre poultry plant, Shoup.....	391
Profits from Swiss agriculture for 1922-23, I, II, Laur et al.....	391
The land question in Finland, Metzger.....	392
Land reform in the Republic of Czechoslovakia, Hollmann.....	392
Agrarian reform in Rumania, Hollmann.....	392
A study of farm labor in Seneca County, New York, Gillett.....	392
Insolvencies among farmers, Ashby.....	393
How to use the new Agricultural Credits Act of 1923, Myrick.....	393
Interests of the farmer in taxation and national indebtedness, McKenzie.....	393
Farmers' Market Bulletin, [October, 1924].....	393
Grain futures: Daily data.....	393
Grading, packing, and handling head lettuce in New York, Underwood.....	394
Review of methods of marketing of Queensland fruit, Ranger et al.....	394
Thirty-fifth annual wool review, Winchcombe, Carson, Ltd.....	394
Regulation of selling price of agricultural products, Italy, Mosca.....	394
The livestock crisis in the La Plata region, Boerger.....	394
A bill creating the national colonization fund, Coni.....	394
The explanation for the Swiss agricultural crisis, Howald.....	394
Economic position of German agriculture in the postwar period, Sagawe.....	395
[Agricultural statistics for the United Kingdom, 1906-1920].....	395
Agriculture in Denmark, Jacobsen.....	395
[Agricultural statistics for the Netherlands].....	395
Agriculture and industry in the economic life of Finland, Kovero.....	395
Agriculture [in the southern territories of Algeria].....	395
Agricultural statistics of India, 1921-22, Ghosh.....	395
Yield per acre of principal crops in India for 1921-22, Ghosh.....	395
Area and yield of principal crops in India, 1922-23, Ghosh.....	396

## AGRICULTURAL EDUCATION

Report of the Commissioner of Education for 1924, Tigert.....	396
Milpitas—a rural school project in teacher training, Smith and Olvey.....	396
Attempts to introduce manual education into American schools, Coates.....	396
The Antioch adventure in home economics, Turner.....	396

	Page
The study and teaching of agricultural economics, Ashby.....	396
[Agricultural and technical instruction in Ireland].....	396
The development of the Hokkaido Imperial University.....	396
The college of agriculture on the Island of Mauritius.....	397
[Agricultural lectures at the college of agriculture of Mauritius].....	397
Agricultural courses at the Potchefstroom School of Agriculture.....	397
A textbook of general botany, Holman and Robbins.....	397
Government publications useful to teachers, compiled by Windes.....	397

## MISCELLANEOUS

Thirty-sixth Annual Report of the [Michigan Station, 1923], Hill et al..	397
Texas Agricultural Experiment Station system, Youngblood.....	397
Bi-monthly Bulletin [of Western Washington Station, November, 1924]..	397

# LIST OF EXPERIMENT STATION AND DEPARTMENT PUBLICATIONS ABSTRACTED

## *Stations in the United States*

	Page
California Station:	
Bul. 377.....	342
Bul. 379.....	344
Tech. Paper 14.....	349
Tech. Paper 15.....	318
Hawaiian Sugar Planters' Station:	
Ent. Ser. Bul. 16.....	356
Illinois Station:	
Circ. 293.....	369
Iowa Station:	
Bul. 220.....	357
Bul. 221.....	322
Kentucky Station:	
Circ. 34.....	338
Michigan Station:

## CONTENTS OF VOL. 52, No. 5

---

Editorial notes:	Page
Soils and soil fertility investigations at the experiment stations-----	401
Recent work in agricultural science-----	409
Notes-----	498

### SUBJECT LIST OF ABSTRACTS

#### AGRICULTURAL CHEMISTRY—AGBOTECHNY

The " <i>Chemical Age</i> " chemical dictionary.—Chemical terms-----	409
The chemistry of plant products, Trier-----	409
The chemistry of enzyme actions, Falk-----	409
Complex salts, Thomas-----	409
Alteration of H-ion concentration in bacterial cultures, Sierakowski-----	409
Chemical factors influencing quality of wheat and flour-----	410
Studies on the oil and ammonia content of cottonseed, Sievers-----	410
Sulfuric index of cottonseed oil and olive oil, Morton and Spencer-----	411
Methods of determining lactose, Bleyer and Steinhauser-----	411
Estimation of iron in small quantities in biological substances, Murray--	411
Method for small amounts of potassium in blood serum, Lebermann-----	411
Note on the estimation of uric acid by the Hopkins-Folin method, Garry--	412
Colorimetric method for direct estimation of ammonia in urine, Orr-----	412
Effect of cold and hot liming on the removal of albumin, Farnell-----	412
Chemical composition of Palestine olives and their oil, Menchikowsky--	412
The preparation and refining of olive oil in southern Europe, Cruess----	413
Vinegar, Schollenberger-----	413
Industry of perfumes according to theories of modern chemistry, Otto--	413

## METEOROLOGY

	Page
Records of total solar radiation intensity and their relation, Kimball.....	413
A systematically varying period of 28 months, Clough.....	414
Let us simplify our calendar and publish standardized summaries, Marvin.....	414
Monthly Weather Review, [September–October, 1924].....	414
Climatological data for the United States, [September–October, 1924].....	415
Meteorological summaries for the year 1923.....	415
Meteorological observations [at the University of Maine], Stevens.....	415
Observations at the Massachusetts Station, Ostrander and Bower.....	415
Meteorological report for the year 1923, Burke.....	415
West Indian hurricanes and other tropical cyclones, Mitchell.....	416
The weather and maple sugar production, Herbert.....	416

## SOILS—FERTILIZERS

Soil survey of Page County, Iowa, O'Neal and Devereux.....	416
Soil survey of Garrard County, Kentucky, Kerr and Averitt.....	416
Soil survey of Cherokee County, North Carolina, Journey et al.....	417
Soil survey of McCook County, South Dakota, Watkins et al.....	417
Soil survey of Union County, South Dakota, Kerr et al.....	417
A study of several organic soil profiles, McCool and Weidemann.....	417
Secular and seasonal changes in the soil solution, Burd and Martin.....	418
The influence of water on soil granulation, Bouyoucos.....	418
The heat of wetting of soil colloids, Anderson.....	418
Influence of removal of colloids on soil properties, McCool and Wheeting.....	419
Note on the absorption of bases by soils, Comber and Saint.....	419
Alkali soil investigations, III, IV, Joffe and McLean.....	419
Alkali land reclamation investigations in Oregon, Johnston and Powers.....	419
Sunlight and chemical nitrification, Żółciński.....	420
Conservation of the soil [at the Kansas Station].....	420
[Soil studies at the Illinois Station].....	420
Green-manuring crops for soil improvement, McCall.....	420
The comparative effects of additions of nitrogen, phosphorus, and potas- sium on the nitrogen economy of a Wooster silt loam soil, Morris.....	421
[Soil fertility studies at the Kentucky Station].....	421
The 5-year rotation fertilizer experiment, Thorne.....	421
The manuring of market garden crops, Dyer and Shrivell.....	421
Greenhouse experiments with atmospheric nitrogen. Allison et al.....	422
Cultural tests with nitrogenous fertilizers, Demolon and Monbrun.....	422
Liming in western Ohio, Slipher.....	422
Lime and crop production in Virginia, Hutcheson and Wolfe.....	422
Some effects of sulfur on crops and soils, Adams.....	423
The fertilizing value of rain and snow.....	423

## AGRICULTURAL BOTANY

Density of cell sap in relation to environmental conditions, Korstian.....	424
Experimental control of growth factors in plants, Branscheidt.....	424
Growth acceleration under decreased oxygen pressures, Heumann.....	424
The growth factor carbon dioxide, Spigatis.....	424
Absorption of CO <sub>2</sub> the first step in photosynthesis, Spoehr and McGee.....	425
Relation between carbohydrate and water content in foliage leaves, Horn.....	425
Brownian molecular movement in the plant world, Neumann.....	425
Studies on nutrition in green semiparasites, Kostytschew et al.....	425
Storage of nitrogen in bark parenchyma, Kern.....	426
The function of manganese in plants.....	426
Benefit to wheat due to depletion of available phosphorus, Gericke.....	426
[Influence of boric acid and other substances in small proportions].....	426
Symbiosis of plants as a chemical problem, II, Zellner.....	426
Resin formation in conifers, Franck.....	427
The anatomy of resin ducts in <i>Pinus silvestris</i> , Muench.....	427
Alkaline reaction of the cotton plant, Mills.....	427
Stinging crystals in plants, Herbert.....	427
Waxy endosperm in New England maize, Mangelsdorf.....	427

## GENETICS

	Page
Human inheritance, Morgan.....	427
Studies in animal reproduction and inheritance.....	427
Studies of inheritance in the grouse locusts (Tettigidae).....	428
Permanence of tree performance in a clonal variety, Sax and Gowen.....	428
Place of stocks in propagation of clonal varieties, Sax and Gowen.....	428
Mutations of the potato, Folsom.....	428
A study of certain hybrids of wheat species, Sax and Gaines.....	429
Inheritance of white seedlings in maize, Demerec.....	429
[Inheritance in dairy cattle].....	429
The inheritance of a retinal abnormality in white mice, Keeler.....	429
Pedigree in which nyctalopia is inherited with myopia, Kleiner.....	430
A study of the inheritance of the characteristics in which the Single Comb White Leghorns and the Jersey Black Giants differ.....	430
Experiments with plumage colour and pattern factors in poultry, Agar.....	430
Color factors in bean hybrids, Sax and McPhee.....	430
Association of size with seed-coat pattern and pigmentation, Sax.....	431
Further evidence of linkage with crossing over in <i>Oenothera</i> , Shull.....	431
Selective fertilization among gametes from the same individuals, Jones.....	432
Ovogenesis during sexual maturity, Papanicolaou.....	432
Sex-ratios and spermatogenesis in the top-minnow, Geiser.....	433

## FIELD CROPS

[Field crops investigations in Illinois].....	433
[Report of field crops work in Kansas, 1922-1924].....	433
[Field crops work in Kentucky, 1923].....	434
[Field crops investigations in Montana], McKee et al.....	434
Dry-farm crop rotation experiments at Moro, Oregon, Stephens.....	435
Corn and soybeans, Etheridge and Helm.....	436
Methods and principles of root crop improvement, Fruergaard.....	437
Svälöf Brio barley, Tedin.....	437
Comparison of Pima cotton with upland varieties in Arizona, King et al.....	437
Cotton, Balls.....	437
Production of seed flax, Dillman.....	437
[Potato experiments in Montana], Harrington.....	437
Svälöf Birgitta potato, Lundberg.....	438
Ventilated storage for potatoes, Marble.....	438
Studies on the rice plant and on rice cultivation, Joshi and Gadkari.....	438
Heating the water for the rice seed bed, Tarchetti.....	439
Experiments with sugar cane from 1902 to 1923, Easterby and Patten.....	439
Studies of imported varieties of sugar cane, Cross.....	439
The cultivation of sugar cane in Queensland, Easterby.....	439
Yields of wheat following potatoes, Welton and Morris.....	439
[Factors influencing the quality of Kansas wheat].....	439
Factors which influence the quantity of protein in wheat, Swanson.....	440

## HORTICULTURE

[Horticultural investigations at the Illinois Station].....	440
[Horticultural investigations at the Kansas Station].....	440
[Investigations at Montana Station], Harrington and Thornber.....	441
Mixing emulsified mineral lubricating oils, Yothers and Winston.....	441
Lettuce growing in greenhouses, Beattie.....	441
Report on survey of the canning tomato industry, Yaw.....	441
Station investigations on fruit-bud formation, Wellington.....	442
How to store and germinate fruit seed.....	442
[Winter hardiness of peaches and plums in Kentucky].....	442
[Pruning studies at the Kentucky Station].....	442
Varieties of tree fruits for Iowa planting, Lantz.....	442
Twenty-five years of fertilizers in New York orchard, Hedrick and Tukey.....	442
Do fertilizers pay in New York apple orchards?.....	443
Fruit setting in the J. H. Hale peach, Gardner and Johnston.....	443
Behavior of American grapes grafted on vigorous stocks, Gladwin.....	443
Improving grapes by grafting.....	443

## FORESTRY

	Page
Tree habits: How to know the hardwoods, Illick.....	444
Shrubs of Indiana, Deam.....	444
The national forests of Arizona.....	444
Trees and shrubs of Mexico (Passifloraceae-Scrophulariaceae), Standley.....	444
Forestry in the Dutch East Indies, Kempster.....	444
Forestry in Brunei and Labuan, Cubitt.....	444
Forest administration in British India for the year 1922-23.....	444
Reafforestation with cedar, Tanganyika Territory, Maber.....	444
The French turpentine system applied to longleaf pine, McKee.....	444
Butternut produces "maple" syrup, Herbert.....	445
The quebracho forests of South America, Kerr.....	445
The pulping qualities of fire-killed wood, Cameron and Lodge.....	445

## DISEASES OF PLANTS

Diseases of plants.....	445
[Plant disease investigations].....	446
Department of botany and bacteriology, Swingle.....	447
Germination of teliospores of rusts at Columbia, Missouri, Maneval.....	447
Staining germinating spores, Davis.....	447
Seed-borne parasites—a general consideration of the problem, Orton.....	447
An ascigerous stage and synonymy for <i>Fusarium moniliforme</i> , Wineland.....	448
Morphology of <i>Nectria galligena</i> and <i>N. coccinea</i> , Zeller.....	448
Notes on Synchytrium, McMurphy.....	448
Septoria diseases of cereals and certain grasses, Weber.....	448
Bacterial blight of rye, Reddy, Godkin, and Johnson.....	448
Seed treatment to prevent smuts of wheat, Thomas.....	448
Yeast-spot of Lima beans, Wingard.....	448
The bacterial pathogen of corn stalk rot, Rosen.....	448
Non-inheritance of terminal bud abortion in Pima cotton, Kearney.....	448
The bacterial spot of pepper, Higgins.....	449
Presprinkling with water and Rhizoctonia control, Reader and Hungerford.....	449
Snails as predisposing agents of cane "root disease" in Louisiana, Rands.....	449
[Soil sterilization for vegetables].....	449
A new host for the fire blight organism, <i>Bacillus amylovorus</i> , Snow.....	449
[Control of fire blight on apples].....	449
Bitter pit in apples: The crushed cell theory, Herbert.....	449
Expulsion of aecidiospores by the Mayapple rust, Dodge.....	450
Orchard injury from waterlogged soils, Burke.....	450
[Orchard disease investigations in Kansas].....	450
Fungus causing brown rot of fruits in America, Roberts and Dunegan.....	450
Peach diseases, Young and Hesler.....	451
Uninucleated aecidiospores in <i>Caeoma nitens</i> , Dodge.....	451
Fig smut studies, Smith and Phillips.....	451
Borax treatment of citrus fruits for blue mold rot, Fulton and Bowman.....	451
White pine blister rust in the Pacific Northwest, Boyce.....	451
Decay of western yellow pine slash from <i>Polyporus volvatus</i> , Schmitz.....	452
A fungus destructive to asphalt shingles, Stevens.....	452

## ECONOMIC ZOOLOGY—ENTOMOLOGY

Directory of officials for birds and game, Lawyer and Denmead.....	452
Individual and age variation in <i>Microtus montanus yosemite</i> , Howell.....	452
Injurious insects and other pests [and bees].....	452
[Economic insects in Kentucky].....	452
[Report of the Montana Station] entomology department, Cooley.....	453
Economic entomology in Porto Rico, Wolcott, trans. by Seín.....	453
[Notes on economic insects].....	453
The control of insects in cereal food products, Doane.....	454
Taxonomic and ecological study of the Oedipodinae in Utah, Henderson.....	454
The so-called cotton flea, Hunter.....	454
Citrophilus mealybug as a major pest of citrus in California, Armitage.....	455
Dust and spray mixtures for currant aphid, Parrott and Harman.....	455
The Lepidoptera of New York and neighboring States, Forbes.....	455

	Page
The codling moth in the Yakima Valley, Newcomer and Whitcomb.....	456
Migration—an important habit of the European corn borer, Barber....	456
Hessian fly, wheat insect survey, 1924, Faxon.....	456
The biology and control of the chrysanthemum midge, Hamilton.....	456
A systematic study of the Anthomyiinae of New York, Hockett.....	457
The Japanese beetle, Pettit.....	458
Life history and biology of <i>Echocerus cornutus</i> (Fab.), Shepherd.....	458
Temperatures fatal to the powder-post beetle, Snyder and St. George..	458
<i>Cylindrocopturus jatrophae</i> Fall, a new economic insect, Vorhies.....	458
Relative resistance of the rice weevil and granary weevil to high and low temperatures, Back and Cotton.....	458
Sealed and unsealed brood, Merrill.....	459
The garden centipede, of economic importance in the West, Wymore....	459

#### FOODS—HUMAN NUTRITION

Hygienic fundamentals of food handling, Thom and Hunter.....	459
Scalding, precooking, and chilling in canning, Magoon and Culpepper..	459
Relation of the bacterial count to the putrefaction of meat, Weinzirl..	460
Critical studies of Pirquet's nourishment theory, Tsurumi and Nakatate..	461
The composition of typical Korean diets, Van Buskirk.....	461
[Diet and the public health].....	461
Stability of vitamin A of cod-liver oil towards hardening, Zilva.....	461
A note on the durability of vitamin A of cod-liver oil, Poulsson.....	462
Ophthalmia in rats on rations deficient in vitamin A, Yudkin.....	462
Experiment station work on the fat-soluble vitamins, Smith.....	462
Action of nitrous acid on antineuritic substance in yeast, Peters.....	462
Metabolism investigations in avitaminosis, Shinoda.....	463
Lack of exercise as a determining factor in beri-beri, Blacklock.....	463
Mineral content of human milk in normal and rachitic families, Telfer..	463
Pellagra in relation to milk supply in the household, Wheeler.....	463
Unique dietary needs for lactation, Evans.....	464
Glycerin, its use in the diet of diabetic patients, Thomas.....	464
Insulin and the nature of diabetes mellitus, Cammidge.....	464
Effect of sunlight, daylight, and heat on botulinus toxin, XXIV, Schoen- holz and Meyer.....	464
Calcium content of the blood serum in gout, Coates and Raiment.....	465

#### ANIMAL PRODUCTION

Range investigations by the experiment stations, Beal et al.....	465
Pasture values and methods for horses, cattle, sheep, and swine.....	466
[Feeding experiments with beef cattle at the Illinois Station].....	466
Steer feeding [at the Kentucky Station].....	466
The use of molasses in fattening yearling steers, Trowbridge.....	466
Can the Montana farmer fatten beef cattle for market? Arnett.....	467
Fattening calves, yearlings, and two-year-olds, Bohstedt.....	467
Full feeding of calves on grass versus dry lot.....	467
[Experiments with sheep at the Kansas Station].....	467
Effect of age upon yield of wool.....	468
[Lamb feeding experiments at the Illinois Station].....	468
Lamb feeding investigations, 1922-23, Paterson and Marston.....	468
Some lamb-feeding results secured by the Kansas Station, Paterson....	468
Fattening lambs with barley and alfalfa, Fleming.....	468
Feeding lambs for market, Bell and Bohstedt.....	468
[Experiments with swine at the Illinois Station].....	469
[Investigations with swine at the Kansas Station].....	469
[Hog feeding experiments at the Kentucky Station].....	470
Feed requirements and cost of gains of pigs, Ferrin and McCarty.....	470
[Experiments with swine at the Montana Station].....	471
Peanuts for fattening hogs in the dry lot, Grimes and Salmon.....	471
Peanut meal as a protein supplement in the dry lot, Grimes and Salmon..	472
Comparison of soy bean oilmeals for supplementing corn for hogs, Robison..	473
Corn substitutes for hogs, Robison.....	473
Rickets and paralysis in swine as affected by nutrition, Bohstedt et al....	473

	Page
A simple mineral mixture for fattening pigs, Grimes and Salmon-----	473
Swine judging, Smith-----	474
Photographing pigs with the aid of the "focus frame," Bohstedt-----	474
[Poultry investigations at the Kansas Station]-----	474
[Poultry experiments at the Kentucky Station]-----	475
Poultry investigations, Kennard and White-----	476
Value of certain grains for laying hens-----	476
Report of egg-laying contest for 1924, Hannas and Clickner-----	476
A simple mineral mixture for chickens, Kennard-----	476
Raising Easter broilers, Kennard-----	476
An automatic switch for poultry houses, Ferguson-----	476

## DAIRY FARMING—DAIRYING

[Feeding experiments with dairy cattle at the Illinois Station]-----	476
[Feeding experiments with dairy cattle at the Kansas Station]-----	477
[Experiments with dairy cattle at the Montana Station]-----	477
Relation between age, weight, and fat production, Turner et al-----	478
Factors affecting the percentage of fat in cows' milk, Turner-----	478
The metabolism of calcium, magnesium, phosphorus, and sulfur in dairy cows fed high and low protein rations, Monroe-----	478
Effect of gestation upon lactation in the dairy cow, Ragsdale et al-----	478
A study of the cattle of the Campine region-----	478
The characteristics of the Red German cattle, Svirenko-----	478
The cow tester's handbook, McDowell-----	478
Milk, Porcher-----	478
Contribution to the study of the rising of cream on milk, Gründler-----	479
[Experiments in dairying at the Illinois Station]-----	479
Process of manufacture and germ content of condensed milk, Ruche-----	479
Ice cream investigations-----	479
Report of Argentine delegates to World's Dairy Congress, Pimentel et al-----	479

## VETERINARY MEDICINE

Veterinary hygiene.—I, Hygiene of productive farm animals, Klimmer--	480
First aid to animals, Leonard-----	480
The influence of nutrition on the incidence of disease, Orr-----	480
Prevention of disease, Bruce-----	480
Stock-poisoning plants of the range, Marsh-----	480
Effects of castration upon the albino rat, Matsuba-----	480
The present status of the family Ascaridae, Stiles and Brown-----	480
Diseases of farm animals-----	481
<i>Bacillus abortus</i> (Bang), with reference to CO <sub>2</sub> requirements, Smith-----	481
Immunization against <i>Bacterium abortus</i> (Bang) infection, Huddleson--	481
[Infectious abortion in mares and in cows]-----	482
Sensitivity to anthrax and the nature of antianthrax immunity, Zironi--	482
Production of antibodies in cutaneous antianthrax immunity, Gratia-----	482
Toxico-immunologic and serologic relationship of <i>B. botulinus</i> , type C, and <i>B. parabortulinus</i> , "Seddon," XXII, Pfenninger-----	482
The rôle of staphylococci in epizootic lymphangitis, Bigot and Velu-----	483
Sensitiveness to tuberculin and the antigenic properties, Markert-----	483
Avian tuberculosis-----	483
[Studies with sheep by Montana Station veterinary department], Welch--	483
Pernicious anemia of the sheep and goat, Donatien and Lestoquard-----	483
Treatment for stomach worms of sheep, Bell-----	483
[Infectious abortion in swine]-----	483
Infectious abortion of mares in Argentina, Ruppert and Porcel-----	484
Infectious anemia of the horse in South Africa, De Kock-----	484
Prevention and control of poultry diseases, Bushnell and Hinshaw-----	484
[Bacillary white diarrhea]-----	484
Control of bacillary white diarrhoea, 1923-1924, Gage and Flint-----	484
[Chicken cholera studies]-----	485
[Roup and chicken-pox vaccine]-----	485
The tuberculosis of domesticated fowl, Eber-----	485
Parasitological investigations-----	485

## RURAL ENGINEERING

	Page
Progress in agricultural engineering at the stations, Trullinger-----	485
[Agricultural engineering studies at the Montana Station], Murdock---	485
Surface water supply of Hudson Bay and upper Mississippi basins, 1921--	485
Drainage construction on Newlands Reclamation Project, Walker-----	485
[Removal of an apple orchard at the Kansas Station]-----	486
Public Roads, [November, 1924]-----	486
Static load tests on pavement slabs, Thompson-----	486
Durability and chemical composition in wood, Hawley et al-----	486
Summary of the national farm power survey, Kinsman-----	487
Saving gasoline by proper carburetor adjustment, Jones and Straub---	487
Heat-treatment of steel springs, Rockefeller-----	488
Heat treatment of steel springs, Wood-----	488
The use of the scythe, Campbell-----	488
Concrete line posts, Musselman-----	488
Trench silo for North Dakota, Miller-----	488
Materials for poultry house construction, Gross-----	488
Poultry houses for Kansas, Taylor and Ward-----	488
Dairy farm buildings, MacInnes and Brooks-----	489
The home storage room, Gallagher-----	489
Oil burners for small heating plants, Myers-----	489

## RURAL ECONOMICS AND SOCIOLOGY

Studies in the economics of agriculture-----	489
[Investigations in agricultural economics at the Kentucky Station]-----	489
Report of Oregon Agricultural Economic Conference-----	490
Farm organization and management [investigations at Illinois Station]--	490
A study of farm organization in southwestern Minnesota, Pond and Tapp--	490
The influence of prices on styles of farm buildings, Bruno-----	491
Estate accountancy, Dunlop-----	491
[Report of Montana Station] farm management department, Currier----	491
A survey to determine the cost of producing beef in California, Adams---	491
The cost and income of the farm poultry flock, Johnson and Frame----	492
Child labor on Maryland truck farms, Channing-----	492
Adjusting agricultural production and distribution in south central West	
Virginia to meet home market demands, Armentrout et al-----	493
Financing agricultural exports from the United States, Edwards-----	493
Crops and Markets, [November, 1924]-----	493
Monthly Supplement to Crops and Markets, [November, 1924]-----	493
The lower Rio Grande Valley of Texas, Potts-----	493
Agricultural production in Denmark, Faber-----	494
Some economic and social phases of French agriculture, Hobson-----	494
Increases and decreases in the open country of Ohio, 1910-1920, Lively--	494
Diagnosing the rural church, Fry-----	494

## AGRICULTURAL EDUCATION

New methods in teaching vocational agriculture, Schmidt-----	494
Agricultural education: Desirable programs for the future, Snedden---	495
Linking class instruction in agriculture with the community, Montegut--	495
How can we measure actual results in vocational agriculture? Smith---	495
Extension work in plant pathology, 1923, Meier-----	495
Outlines of economic zoology, Reese-----	495
Demonstration courses in wood utilization-----	496

## MISCELLANEOUS

Work and expenditures of the experiment stations, 1922, Allen et al-----	496
Thirty-sixth Annual Report [of Illinois Station, 1923], Mumford-----	496
[Report of Kansas Station, 1923-1924], Farrell-----	496
Report of the Kentucky Station for 1923, Part I, Cooper-----	496
Abstracts of papers not in bulletins, finances, meteorology, index-----	497
Montana Station: Report, 1923, Linfield et al-----	497
Quarterly Bulletin [of the Michigan Station], edited by Shaw and Hill--	497
Monthly Bulletin of Ohio Experiment Station, [July-October, 1924]-----	497
Summary of publications-----	497

# LIST OF EXPERIMENT STATION AND DEPARTMENT PUBLICATIONS ABSTRACTED

<i>Stations in the United States</i>		<i>Stations in the United States—Con.</i>	
Alabama Station:	Page	New Jersey Stations:	Page
Bul. 222-----	473	Hints to Poultrymen, vol.	
Bul. 223-----	471	13—	
Bul. 224-----	472	No. 2, Nov., 1924-----	488
California Station:		No. 3, Dec., 1924-----	476
Circ. 279-----	413	New York Cornell Station:	
Circ. 280-----	441	Mem. 68-----	455
Circ. 281-----	491	Mem. 76-----	479
Illinois Station:		Mem. 77-----	457
Thirty-sixth Ann. Rpt. 1923_	420,	New York State Station:	
429, 433, 440, 466, 468, 469,		Bul. 508-----	443
476, 479, 483, 490, 496		Bul. 509 (pop. ed.)-----	442
Iowa Station:		Bul. 516-----	442, 443
Circ. 92-----	442	Bul. 517-----	455
Kansas Station:		Ohio Station:	
Circ. 106-----	484	Mo. Bul., vol. 9—	
Circ. 108-----	468	No. 7-8, July-Aug.,	
Circ. 109-----	468	1924-----	413, 421,
Bien. Rpt. 1923-24_	410, 420, 427,	448, 451, 456, 476, 497	
428, 430, 433, 439, 440, 445, 449,		No. 9-10, Sept.-Oct.,	
450, 452, 466, 467, 469, 474, 477,		1924-----	467, 468,
479, 481, 484, 485, 486, 489, 496		473, 474, 476, 483, 497	
Kentucky Station:		Oregon Station:	
Thirty-sixth Ann. Rpt. 1923,		Bul. 209-----	435
pt. 1_ _ _	415, 421, 426, 434, 442,	Bul. 210-----	419
446, 452, 466, 468, 470,		Porto Rico Department of Agri-	
475, 482, 485, 489, 496		culture and Labor Station:	
Maine Station:		Bul. 32 (Spanish ed.)-----	453
Bul. 315_ _	415, 428, 430, 431, 497	Texas Station:	
Maryland Station:		Circ. 34-----	493
Bul. 268-----	420	Utah Station:	
Bul. 269-----	456	Bul. 191-----	454
Massachusetts Station:		Circ. 53-----	497
Control Ser. Bul. 27-----	484	Virginia Station:	
Met. Buls. 431-432, Nov.-		Bul. 237-----	422
Dec., 1924-----	415	Washington College Station:	
Michigan Station:		Pop. Bul. 130-----	474
Quart. Bul., vol. 7, No. 2,		West Virginia Station:	
Nov., 1924_ _	416, 443, 445, 458,	Bul. 188-----	493
476, 481, 488, 489, 497			
Minnesota Station:			
Bul. 213-----	470		
Missouri Station:			
Bul. 219-----	492		
Bul. 220-----	436		
Bul. 221-----	478		
Bul. 222-----	478		
Bul. 223-----	466		
Montana Station:			
Thirtieth Ann. Rpt. 1923_ _	415,		
434, 437, 441, 447, 450, 453, 467,			
471, 476, 477, 483, 485, 491, 497			
Nevada Station:			
Bul. 106-----	468		

## *U. S. Department of Agriculture*

Bul. 1217, Mixing Emulsified Mineral Lubricating Oils with Deep-well Waters and Lime-sulphur Solutions, W. W. Yothers and J. R. Winston-----	441
Bul. 1235, Life History of the Codling Moth in the Yakima Valley of Washington, E. J. Newcomer and W. D. Whitcomb-----	456

<i>U. S. Department of Agriculture.—Con.</i>		<i>U. S. Department of Agriculture.—Con.</i>	
	Page		Page
Bul. 1245, Stock-poisoning Plants of the Range, C. D. Marsh.....	480	Bureau of Soils:	
Bul. 1265, Scalding, Precook- ing, and Chilling as Prelimi- nary Canning Operations, C. A. Magoon and C. W. Culpepper.....	459	Field Operations, 1921—	
Bul. 1271, A Study of Farm Organization in Southwestern Minnesota, G. A. Pond and J. W. Tapp.....	490	Soil Survey of Page County, Iowa, A. * M. O'Neal, jr., and R. E. Devereux.....	416
Farmers' Bul. 1328, Production of Seed Flax, A. C. Dillman..	437	Soil Survey of Gar- rard County, Ken- tucky, J. A. Kerr and S. D. Averitt..	416
Farmers' Bul. 1418, Lettuce Growing in Greenhouses, J. H. Beattie.....	441	Soil Survey of Cherokee County, North Caro- lina, R. C. Journey et al.....	417
Circ. 318, The National Forests of Arizona.....	444	Soil Survey of Mc- Cook County, South Dakota, W. I. Wat- kins et al.....	417
Circ. 327, The French Tur- pentine System Applied to Longleaf Pine, E. R. McKee..	444	Soil Survey of Union County, South Da- kota, J. A. Kerr et al.....	417
Circ. 328, Directory of Officials and Organizations Concerned with the Protection of Birds and Game, 1924, compiled by G. A. Lawyer and T. Denmead.....	452	Weather Bureau:	
Circ. 329, Extension Work in Plant Pathology, 1923, F. C. Meier.....	495	Let Us Simplify Our Calendar and Publish Statistical Data in Stand- ardized Summaries, C. F. Marvin.....	414
Misc. Circ. 26, The Cow Tester's Handbook, J. C. McDowell..	478	Mo. Weather Rev.— Vol. 52—	
Misc. Circ. 29, Demonstration Courses in Wood Utilization..	496	No. 9, Sept., 1924..	414, 416
Crops and Markets:		No. 10, Oct., 1924..	413, 414
Vol. 2—		Sup. 24, 1924.....	416
No. 18, Nov. 1, 1924..	493	Climat. Data, vol. 11, Nos. 9-10, Sept.-Oct., 1924..	415
No. 19, Nov. 8, 1924..	493	Office of Experiment Stations:	
No. 20, Nov. 15, 1924..	493	Work and Expenditures of the Agricultural Experi- ment Stations, 1922, E. W. Allen, W. H. Beal, E. R. Flint, et al.....	442, 462, 465, 485, 496
No. 21, Nov. 22, 1924..	493		
No. 22, Nov. 29, 1924..	493		
Vol. 1, Sup. 11, Nov., 1924..	493		
Bureau of Public Roads:			
Public Roads, vol. 5, No. 9, Nov., 1924.....	486		

# EXPERIMENT STATION RECORD

Editor: H. L. KNIGHT

## EDITORIAL DEPARTMENTS

Agricultural Chemistry and Agrotechny—SYBIL L. SMITH.  
Meteorology—W. H. BEAL.  
Soils and Fertilizers—R. W. TRULLINGER.  
Agricultural Botany, Bacteriology, and Plant Pathology—W. H. EVANS, Ph. D.,  
W. E. BOYD.  
Genetics—W. H. EVANS, W. E. BOYD, H. M. STEECE, J. W. WELLINGTON,  
G. HAINES.  
Field Crops—H. M. STEECE.  
Horticulture and Forestry—J. W. WELLINGTON.  
Economic Zoology and Entomology—W. A. HOOKER, D. V. M.  
Foods and Human Nutrition—SYBIL L. SMITH.  
Animal Husbandry, Dairying, and Dairy Farming—G. HAINES.  
Veterinary Medicine—W. A. HOOKER, SYBIL L. SMITH.  
Rural Engineering—R. W. TRULLINGER.  
Rural Economics and Sociology and Agricultural Education—LOUISE MAREBUT.  
Indexes—MARTHA C. GUNDLACH.  
Bibliographies—MARTHA L. GERICKE.

## CONTENTS OF VOL. 52, No. 6

	Page
Recent work in agriculture science.....	501
Notes .....	599

### SUBJECT LIST OF ABSTRACTS

#### AGRICULTURAL CHEMISTRY—AGROTECHNY

Preparation of a basic arsenate of lead, Streeter and Thatcher.....	501
Combined lead arsenate and lime-sulfur, Thatcher and Streeter.....	501
Isolation and identification of quercetin from apple peels, Sando.....	502
Tomato products investigations.....	503
Continuous extraction apparatus for quantities of materials, Sando.....	503
Chemistry of dairy products from a colloidal standpoint, Palmer.....	503
The chemistry of casein, Van Slyke.....	503
On the presence of amylase in milk and cheese, Sato.....	503
The heat coagulation of milk, Sommer.....	503
Factors influencing the heat coagulation of milk and the thickening of condensed milk, Leighton and Deysher.....	503
The crystals found in sweetened condensed milk, Sato.....	503
Factors affecting keeping quality of sweetened condensed milk, Miyawaki.....	504
The keeping quality of butterfat, Holm and Greenbank.....	504
Sediments of evaporated milk, Sato.....	504
Solubility of milk powder as affected by moisture, Supplee and Bellis..	504
The keeping quality of dry milk, Supplee.....	505
A new method for the determination of the water content of milk powder and the properties of its colloidal constituents, Hauser.....	505

	Page
Freezing point of colostrum milk, normal milk, and end milk of lactation; and its practical value for detection of water added, Sato.....	505
Necessity for legislative control in the sale of milk breads, Allen.....	505
The acetic index in the analysis of butter, Savini.....	506
Fat in commercial casein, Jephcott and Ratcliffe.....	506
Methods for the control of saponified cresol solutions, Chapin.....	506
Utilization of almonds for various food products, Sievers and Rabak.....	507

## METEOROLOGY

Weather reports, Georgeson et al.....	507
Wheat yield and rainfall in Ohio, Welton and Morris.....	507
The climate of the Netherlands Indies, V. Braak.....	508

## SOILS—FERTILIZERS

The chemical composition of soil colloids, Robinson and Holmes.....	508
Neutral salt decomposition by colloids, Hümmelchen and Kappen.....	509
Soil survey of Crenshaw County, Alabama, Stroud et al.....	510
Mason County soils, Smith, DeTurk, Bauer, and Smith.....	510
Soil survey of Mississippi County, Missouri, DeYoung and Wildermuth.....	510
Soil survey of Spartanburg County, South Carolina, Latimer et al.....	511
The soils of Tennessee and their future needs, Mooers.....	511
Analyses and fertility of West Virginia soils, Bryan and Deatrlick.....	511
Composition of forest soil, Némec and Kvapil.....	511
Survey of the soils of the lowlands of southern Tegal, White.....	511
Soil moisture investigations in Canada, Hopkins.....	512
The response of plants to aeration of the roots, Knight.....	512
Ammonification of amine nitrogen by soil microsiphones, Guittonneau.....	512
Utilization of mineral nitrogen by soil microsiphones, Guittonneau.....	512
Assimilation of atmospheric nitrogen by forest soils, Némec and Kvapil.....	512
Seasonal variation of nitrates in black turf at Onderstepoort, Van Wijk.....	512
The detrimental effect of cereal straw on plants.....	513
Nitrogen fertilization of meadows, Lang and Kuchler.....	513
Top-dressing grassland in peat soil with Chilean nitrate, Witte.....	513
Effect of cyanamid on the microorganisms in soil, Allison.....	513
Fertilizers containing nitrogen and phosphoric acid produced by treating superphosphate with ammonia, Andreassen and Raaschou.....	514
The nitrification of phosphorus nitride, Allison.....	514
Influence of the admixture of different grades of limestone on the solubility of phosphoric oxide in superphosphate, Hall and Vogel.....	514
The utilization of potassic rocks, Messerschmitt.....	514
Sulfur oxidation and solubility of soil minerals, Stephenson and Powers.....	515
The action of manganese on vegetation, D'Ippolito.....	515
Commercial fertilizers, Robinson.....	515
Commercial fertilizers in 1923-1924, Fraps and Asbury.....	515
A guide for fertilizer users, McCollam.....	515

## AGRICULTURAL BOTANY

Physiological aspects of germination, Blackman.....	516
Structure of seed coat and delayed germination in <i>Melilotus alba</i> , Martin.....	516
Germination studies of some shrubs and trees, Pammel and King.....	516
Comparative studies on respiration, XXIV-XXVII, Ray.....	516
Stomatal regulation of plant's transpiration, Zhemchuzhnikov.....	517
Quantitative estimation of aeration in leaves, Andrews.....	517
Some wound responses of foliage leaves, Wylie.....	518
Cicatrization in plant tissues after freezing, Russell.....	518
The effect of pressure on growth, Andrews.....	518
Growth of potato plants in "six types" of nutrient solutions, Johnston.....	518
Salt requirements of Marquis wheat, Hibbard and Gershberg.....	518
Alkaline reaction of the cotton plant, Power and Chesnut.....	519
Radioactivity of ripe tomatoes, Langworthy.....	519
The evolution of plastids in plants, Emberger.....	519
Cases of teratology in plants, Chassignol.....	519
[General studies in bacteriology at the New York State Station].....	519

	Page
Studies on the Coccaceae, I-V, Hucker.....	519
The natural vegetation of the United States, Shantz and Zon.....	520
Seeds and plants imported from October 1 to December 31, 1922.....	520

## GENETICS

Any hereditary character and what we need to know about it, Riddle....	520
A hypothesis of "valence" in heredity and evolution, Getzendaner.....	521
Correlation among quantitative characters in maize, Kempton.....	521
Segregation and correlated inheritance in crosses between Kota and Hard Federation wheats for rust and drought resistance, Clark.....	521
Statistical studies of inheritance in the tomato, Myers.....	522
Studies in Indian tobaccos, Nos. 4, 5.....	522
Litter production and the sex ratio in various strains of rats, King....	523
On Mendelian factors in radishes, Uphof.....	523
Studies in Indian fibre plants, No. 3, Howard.....	523
Gamete production in crosses with "rogues" in peas, Brotherton.....	524
Absence of kidneys associated with abnormalities in mice, Bagg.....	524
The problem of incidence in color blindness, Danforth.....	524
Effect of menotoxin on the viability of spermatozoa, Macht and Elvers...	524
Motility of the opossum genital tract and the vaginal plug, Hartman....	524
The effect of corpus luteum on behavior of rats, Macht and Seago.....	525
The back color of Russian rabbits and its meaning, Lenz.....	525
Influence of environment on sex in hemp, <i>Cannabis sativa</i> L., McPhee...	525

## FIELD CROPS

Research fundamental to the solving of crop-plant problems, Ball.....	526
Experiments in crop rotation and fertilization, Wiggans.....	526
Studies in crop variation, III, Mackenzie.....	526
Experiments with fallow in north-central Montana, Morgan.....	527
Work of the Sheridan Field Station, 1917 to 1923, inclusive, Towle....	527
[Field crops work at the Alaska Stations], Georgeson.....	528
[Field crops work in South Carolina].....	528
[Field crops work in Tennessee, 1923], Mooers and Essary.....	528
[Field crops experiments in Northumberland, England], Gilchrist.....	529
[Field crops experiments in Mysore], Krishnayya et al.....	529
Spring small grains, Kieselbach and Lyness.....	529
Notes on some recently imported forage grasses, Fernández García.....	530
Effect of nitrogenous fertilizers on protein of alfalfa, Behlen.....	530
Analyses of the barleys of 1922 and the malts made from them, Hind....	530
Influence of soil, season, and manuring on barley, 1923, Russell.....	530
Influence of soil, season, and manuring on barley, Lancaster.....	530
Effects of fertilizers on the yield and ear characters of corn, Wolfe....	531
Handling the soft-corn crop, Richey.....	531
Spacing experiments with Acala cotton in southern California, McKeever	531
[Cotton investigations in South Carolina].....	531
Cotton variety experiments at the main station, 1912 to 1922, Stroman...	532
The moisture relations of cotton, II, III, Urquhart and Williams.....	532
Breaking strength of cotton yarns and the twist, English.....	533
Kikuyu grass ( <i>Pennisetum clandestinum</i> , Chiov.), Stapf.....	533
Field experiments [with oats], Berry and O'Brien.....	533
Growing orchard grass in south Missouri, Helm.....	533
Experiments with potatoes, I, II.....	533
Sprays outrank dusts for potatoes.....	534
Rice, Copeland.....	534
Sugar beets in Louisiana, Kidder and Coates.....	534
The reference book of the sugar industry of the world.....	534
Sweet potato studies in New Jersey, Schermerhorn.....	534
Investigations with high-nicotine tobacco.....	534
<i>Nicotiana rustica</i> as nicotine source for insect control, Haley et al....	535
Common vetch and its varieties, McKee and Schoth.....	535
New ways of determining the origin of seed, Tryti.....	535
A viability test for some tropical seeds, Tolentino.....	536
Nitrogen content of weeds, Campbell.....	536

## HORTICULTURE

	Page
[Horticultural investigations at the Alaska Stations], Georgeson.....	536
[Horticultural investigations at the New York State Station].....	537
[Horticultural investigations at the South Carolina Station].....	537
[Horticultural work at Brandon, Man., in 1923], McKillican.....	537
Report on commercial insecticides and fungicides.....	537
Orchard soil management, Faurot.....	537
A preliminary report on Jonathan breakdown, Daly.....	538
How to prune the young cherry tree, Roberts.....	538
The grafting of American grapes, Gladwin.....	538
Cool storage of fruit: Experiments conducted during 1923, Adam.....	539
Transportation of citrus fruit from Porto Rico, Hill and Hawkins.....	539
The coconut in Indo-China, Guillaume.....	540
The coconut industry in Portuguese India, Correia Afonso.....	540
Almond varieties in the United States, Wood.....	540
The book of gardens and gardening, edited by Townsend.....	540
Gardens: A note-book of plans and sketches, Forestier, trans. by Fox....	540

## FORESTRY

Factors affecting reproduction after logging in northern Idaho, Larsen....	540
Douglas fir reproduction under various cutting methods, Roeser.....	541
Fall sowing and delayed germination of western white pine, Wahlenberg..	541
Growth on western yellow pine lands in central Idaho, Korstian.....	542
The rôle of fire in the California pine forests, Show and Kotok.....	542

## DISEASES OF PLANTS

[Plant disease investigations at the New York State Station].....	543
Plant diseases.....	544
Plant pathology, Sherbakoff.....	544
[Plant diseases, Mysore, 1922-23], Anantaraman.....	544
[Report of mycological section, Mysore], Krishnayya.....	544
Report of work during 1922-23 [Mysore], Narasimhan.....	544
A new method of obtaining mosaic "virus," Johnson and Mulvania.....	545
Aerial stages of the leaf rusts of rye and barley, Mains and Jackson....	545
Resistance of wheat to bunt on Pacific Coast, Tisdale, Martin, et al.....	545
The present status of the hot water treatment in Indiana, Gregory.....	546
Chemical eradication of the common barberry, Thompson.....	546
Differences in the susceptibility of clover to powdery mildew, Mains....	546
Transmission of cowpea mosaic by the bean leaf-beetle, Smith.....	546
The "mosaic disease" of the hop, Salmon.....	547
Potato leaf roll in Indiana, Gardner and Kendrick.....	547
Pythium rootlet rot of sweet potatoes, Harter.....	547
Control of leafroll and mosaic in potatoes by roguing, Stewart.....	548
Growing disease-free seed potatoes.....	548
The sugar cane disease situation in 1923 and 1924, Edgerton et al.....	548
Phytophthora rot of tomato, eggplant, and pepper, Kendrick.....	548
The control of tomato leaf-spot, Pritchard and Porte.....	548
"Sleepy disease" of the tomato, Bewley.....	549
Fire blight, McClintock.....	549
Grape diseases, especially black-rot and anthracnose, Rhoads.....	549
Ripe rots of grapes and the copper acetates, Rhoads.....	549
Citrus canker eradication for quarter ending June 30, 1924, [Stirling]....	550
Chestnut trees surviving blight, Kelley.....	550
Physiological specialization in <i>Fomes pinicola</i> , Schmitz.....	550
Blister rust infection at Kittery point, Maine, Posey and Ford.....	550
South American leaf disease of Para rubber, Rands.....	550
Spike disease of sandal, Iyengar.....	550
The transmission of sandal spike, Coleman.....	551
On some plant parasitic nemas and related forms, Steiner.....	551

## ECONOMIC ZOOLOGY—ENTOMOLOGY

Principles of animal biology, Shull.....	551
The European hare ( <i>Lepus europaeus pallas</i> ) in North America, Silver....	551
Revised encyclopedia of canaries.....	552

	Page
The kea or mountain-parrot, Myers.....	552
Habits and life-history of the Indian glow-worm, Hutson and Austin.....	552
Agricultural entomology and parasitology, Guénaux.....	552
[Report of the New York State Station] division of entomology.....	552
Insect pests.....	553
Entomology [studies at the Tennessee Station], Marcovitch.....	553
[Contributions on economic insects].....	554
The insect fauna of Quelpart Island (Saishiu-to), Okamoto.....	554
Report by the entomologist, Mandalay, for 1923, Ghosh.....	554
Report of work in [Mysore], 1923, Kunhi Kannan.....	554
Annual report of the Government entomologist [of Uganda], Hargreaves.....	554
Foreign insect pests on imported nursery stock in 1923, Sasser.....	554
Status of hydrocyanic acid gas treatment of nursery stock, Davis.....	554
Fumigation and heating of grain caused by insects, Back and Cotton.....	555
New insecticides for Mexican bean beetle and other insects, Marcovitch.....	555
Promising plant insecticides, Marcovitch.....	555
The minor pests of sugar-cane in Fiji, Veitch.....	556
Biological control of prickly-pear in Australia, Hamlin.....	556
Observations on the clear-winged grasshopper, Parker.....	556
The parasitic enemies of the citricola scale, Compere.....	556
Parasitism of scales—San José and oyster shell, Siegler and Baker.....	557
The green peach aphid and its control, Gurney and Brereton.....	557
The fight against the gipsy moth in New Jersey, Headlee.....	557
Fourth year's work against gipsy moth in New Jersey, Weiss et al.....	557
Larval stages and biology of Australian mosquitoes, Cooling.....	557
Synonymic list of Culicidae of the Australian region, Cooling.....	557
Malaria, with especial reference to Australia, Cilento.....	557
Importance of flaxseed count in predicting fly-free date, Drake et al.....	557
Rearing flies for experimental purposes, with biological notes, Glaser.....	558
A bacterial disease of adult house flies, Glaser.....	558
Plantain root beetle borer, Jardine.....	558
Dusting and spraying to control grape root-worm, Hartzell.....	558
Effect of rainfall on the hickory bark beetle, Blackman.....	559
Egg and first-stage larva of <i>Tarsostenus univittatus</i> , St. George.....	559
The sweet potato weevil, Gowdey.....	559
Late applications of calcium arsenate dust for boll weevil, Nickels.....	559
Cotton boll weevil situation in Arizona, Bemis.....	559
[Boll weevil investigations].....	559
The apple blossom weevil, Miles.....	560
Solubility of arsenate of lead in digestive fluids of honey bee, Tietz.....	560
Morphology of the honeybee larva, Nelson.....	560
Attacks of <i>Vespa communis</i> on <i>Hypantria cunea</i> , Smulyan.....	560
Biological observations on <i>Hemiteles areator</i> Grav., Faure.....	561
On the variability of the life cycle of a new ichneumonid parasite of the larvae of <i>Neurotoma nemoralis</i> , Paillet.....	561
Eggs of <i>Ascaris lumbricoides</i> and low temperatures, Bakker.....	561

## FOODS—HUMAN NUTRITION

Absorption of hydrocyanic acid by food products, II, Griffin and Back.....	561
Methods of educating the public to the value of milk.....	562
Milk in the diet.....	562
Milk in relation to child life and health, Davies.....	562
[Nutrition activities in the public schools].....	562
The use of evaporated, condensed, and dried milk in the dietary.....	562
The nutritional value of milk.....	562
The calcium metabolism of atrophic infants, Hickmans.....	563
Fasting and undernutrition, Morgulis.....	564
Existence of dietary factor essential for reproduction, Evans.....	564
Barley, malt, and beer for vitamins B and C, Harden and Zilva.....	564
The fate of bakers' yeast in the intestine, Rettger et al.....	564
Newer clinical signs of early rickets, Moore.....	565
The underlying cause in the pathogenesis of rickets, Findlay.....	565
Organization of a special clinic for rickets, Wyman and Weymuller.....	565
Rickets as influenced by the diet of the mother, Hess and Weinstock.....	565
Correlation of evidences of rickets, DeBuys and Von Meysenbug.....	566

	Page
The nervous paralysis of the polished rice disease, Kato.....	566
Phosphates and carbohydrate metabolism, I, Sokhey and Allan.....	566
Efficiency of sugars in relieving symptoms from insulin, Herring et al....	567

## ANIMAL PRODUCTION

Inspection of commercial feeding-stuffs, Kraybill et al.....	567
[Experiments in beef production at the South Carolina Station].....	567
Effects of winter rations on pasture gains of beef calves and yearlings, Sheets and Tuckwiller.....	568
Effect of winter rations on subsequent pasture gains of steers, Sheets....	568
Fattening western lambs, 1923-1924, Fox.....	568
Weights of fleeces of Angora goats on range, Lush and Jones.....	569
[Feeding experiments with swine at the South Carolina Station].....	569
Alfalfa and horses, Hudson.....	570
[Poultry investigations at the Dominion experimental farms], Elford....	570
Influences of various protein feeds on laying hens, Sherwood.....	572
New chick feeding facts, Hart et al.....	573
Egg production, costs, and receipts on New Jersey poultry farms, Allen...	573
Fifth western Washington egg-laying contest, Shoup.....	573

## DAIRY FARMING—DAIRYING

Proceedings of the World's Dairy Congress.....	573
Utilization of energy in milk production and body increase, Fries et al...	577
[Experiments with dairy cattle at the South Carolina Station].....	577
Effect of cabbage and potatoes on flavor and odor of milk, Babcock...	578
Raising the dairy calf when whole milk is sold, Eckles and Gullickson...	579
The bacterial flora of milking machines, Robertson.....	579
Filtration and clarification of milk, Dahlberg and Marquardt.....	579
Successful cream whipping, Hening.....	580
Ice cream formulas and standardization, Davis et al.....	580

## VETERINARY MEDICINE

Lang's German-English dictionary, edited and rev. by Meyers.....	580
Animal diseases in southern Brazil, Schmidt.....	580
Annual report on infectious diseases of animals in Germany.....	580
A new clinical method for blood typing, Grubzit and Clark.....	580
Specific dressings.—A study of local immunity, Besredka.....	580
Relation of the melitensis-abortionus group to human health, Evans.....	580
Serological differentiation of <i>B. abortus</i> and <i>B. melitensis</i> , Futamura...	580
The agglutination test for bovine infectious abortion, Mathews.....	580
Studies on a non-virulent living culture of <i>Bact. abortus</i> , Huddleson...	581
Investigations upon flagellate infections, Strong.....	582
Experimental treatment of "mal de caderas" with Bayer 205, Dios....	582
Report of experimental work to determine whether avian tuberculosis is transmitted through the eggs of tuberculous fowls, Fitch et al....	582
Diseases of dairy cattle.....	583
International trade in dairy cattle, Mohler.....	583
The piroplasms found in bovines.—I, The Theilerias, Brumpt.....	583
Experiments with anti-hog cholera serum and hog cholera virus, Porter...	583
Outbreak of Borna disease of the horse in Hesse, Swick and Seifried....	584
The frog as the second intermediate host of a trematode parasite of the duck and hen, Nöller and Wagner.....	584
Development of the liver fluke up to cercaria in <i>Limnaea stagnalis</i> , Nöller and Sprehn.....	584
Influence of diet on the liver injury produced by C Cl, Davis.....	584

## RURAL ENGINEERING

Hydrodynamics, Lamb.....	584
Semi-circular weirs calibrated at Purdue University, Greve.....	584
Farm drainage methods (survey and design), 1908-1922, Roe.....	584
Farm drainage methods (construction), 1908-1922, Roe.....	585
The deterioration and preservative treatment of timber, Dawson.....	585

	Page
Relation of temperature and pressure to the absorption and penetration of zinc chloride solution into wood, MacLean.....	585
Crushed brick makes good concrete block.....	585
Popular mechanics concrete handbook No. 1.....	585
Public Roads, [December, 1924].....	585
Accurate accelerometers developed by the Bureau of Public Roads, Teller.....	585
Laboratory strength-tests of motor-truck wheels, Greene.....	585
California air-cleaner tests, 1924 series, Hoffman.....	586
Specific heats of lubricating oils, Leslie and Geniesse.....	586
A discussion of creep in power belting, Jones.....	586
Plow bolts.....	586
Principles of electric motors and control, Fox.....	586
Hatching chicks electrically, Bell.....	586
Building the dairy barn, Fish.....	587
Sewerage systems for farm homes, Fish, Hastings, and King.....	587

## RURAL ECONOMICS AND SOCIOLOGY

A study of farm organization in central Kansas, Grimes et al.....	588
Farm organization and cost of production on cotton farms in Anderson County, S. C., in 1922, Jensen.....	588
Organization and management of typical West Virginia farms, Dadisman.....	589
Landlords of Nebraska farms, Rankin.....	589
Economic studies of dairy farming in New York, II, Misner.....	589
Cost of producing milk and some factors influencing the cost, Misner.....	590
Work of children on truck and small-fruit farms in southern New Jersey.....	591
The function of the local bank in financing the farmer, Harshaw.....	591
Factors in price conciliation in the milk industry, King.....	591
Development of farmers' cooperative business organizations, Elsworth.....	592
Cooperation as a factor in stabilizing the market, Miller.....	592
Status of trade associations in the dairy industry, Little.....	592
Creameries and cream shipping stations in North Dakota, Benton.....	592
The cooperative marketing movement, Sapiro.....	593
Cooperative marketing of milk.....	593
Cooperative marketing of manufactured products.....	593
Fundamental aspects of dairy marketing, Weld.....	593
The cooperative advertising of dairy products, O'Keefe.....	593
Marketing and distribution of American-grown Bermuda onions, Stevens.....	593
Market for American agricultural products in the United Kingdom, Arner.....	594
International trade in dairy products: Significant trends, Taylor.....	594
Some aspects of the international trade in dairy produce, Ruddick.....	594
Monthly Supplement to Crops and Markets, [December, 1924].....	594
Crops and Markets, [December, 1924].....	595
Corn and hog correlations, Wright.....	595
Agriculture and dairying in the world's economic equilibrium, Anderson.....	596
The collection and distribution of milk and dairy products statistics by the International Institute of Agriculture at Rome, Longobardi.....	596

## AGRICULTURAL EDUCATION

Research and education in agriculture in the United States, True.....	596
Instruction in dairying in educational institutions.....	596
Extension methods in dairy education.....	597
Motion pictures and dairy education, Balderston.....	597
An extension program in crop production for the Western States, Lloyd.....	597
Agricultural education in Cornwall, Borlase.....	597
Day courses in agriculture for countrywomen, Pratt.....	597
Teaching plan and organization of subject matter in the Rhine Province.....	597
Outlines of course of instruction in agricultural nature study, Kern.....	597
Junior project work in agriculture, Gayman.....	597
The health of rural school children, Mueller.....	597
The field of research in the economics of the home, Kneeland.....	597
Agricultural mechanics, Smith.....	598
Economic geography, Whitbeck and Finch.....	598

## MISCELLANEOUS

	<b>Page</b>
Report of the Alaska Agricultural Experiment Stations, 1923, Georgeson-	598
Thirty-second Annual Report of [Minnesota Station, 1924], Coffey-----	598
Forty-third Report of New York State Station, [1924], Thatcher-----	598
Thirty-seventh Report of the South Carolina Station, [1924], Barre-----	598
Thirty-sixth Annual Report of [Tennessee Station], 1923, Mooers et al--	598
Bi-monthly Bulletin [of Western Washington Station, January, 1925]--	598

# LIST OF EXPERIMENT STATION AND DEPARTMENT PUBLICATIONS ABSTRACTED

<i>Stations in the United States</i>	
Alaska Stations:	Page
Rpt. 1923.....	507, 528, 536, 598
California Station:	
Outlines of Course of In-	
struction in Agricultural	
Nature Study for the	
Rural Schools of Cali-	
fornia (rev., 1924), O. J.	
Kern.....	597
Connecticut State Station:	
Bul. 258.....	537
Illinois Station:	
Soil Rpt. 28.....	510
Indiana Station:	
Bul. 284.....	547
Louisiana Stations:	
Bul. 191.....	548
Bul. 192.....	534
Maryland Station:	
Bul. 270.....	518
Michigan Station:	
Tech. Bul. 64.....	518
Tech. Bul. 65.....	581
Circ. 65.....	570
Minnesota Station:	
Bul. 214.....	556
Bul. 215.....	579
Bul. 216.....	584
Bul. 217.....	585
Thirty-second Ann. Rpt.	
1924, pt. 1.....	598
Missouri Station:	
Circ. 130.....	533
Nebraska Station:	
Bul. 201.....	529
Bul. 202.....	589
Bul. 203.....	580
Bul. 204.....	568
New Hampshire Station:	
Bul. 213.....	567
New Jersey Stations:	
Bul. 398.....	434
Hints to Poultrymen, vol.	
13, No. 4, Jan., 1925.....	573
New York Cornell Station:	
Bul. 433.....	589
Bul. 434.....	526
New York State Station:	
Bul. 518.....	533, 534
Bul. 519.....	558
Bul. 520.....	538
Bul. 521.....	501
Bul. 522.....	548

Bul. 371.....	573
<i>U. S. Department of Agriculture</i>	
Bul. 1281, Relative Utilization of	
Energy in Milk Production	
and Body Increase of Dairy	
Cows, J. A. Fries, W. W.	
Braman, and D. C. Cockrane.....	577

<i>U. S. Department of Agriculture—Con.</i>		<i>U. S. Department of Agriculture—Con.</i>	
	Page		Page
Bul. 1282, Almond Varieties in the United States, M. N. Wood.....	540	Bul. 1310, Experiments with Fallow in North-central Montana, G. W. Morgan.....	527
Bul. 1283, The Marketing and Distribution of American-grown Bermuda Onions, W. M. Stevens.....	593	Bul. 1311, The Chemical Composition of Soil Colloids, W. O. Robinson and R. S. Holmes...	508
Bul. 1286, South American Leaf Disease of Para Rubber, R. D. Rands.....	550	Circ. 332, Chemical Eradication of the Common Barberry, N. F. Thompson.....	546
Bul. 1288, The Control of Tomato Leaf-spot, F. J. Pritchard and W. S. Porte...	548	Circ. 333, Handling the Soft-corn Crop, F. D. Richey.....	531
Bul. 1289, Common Vetch and Its Varieties, R. McKee and H. A. Schoth.....	535	Circ. 335, An Extension Program in Crop Production to Reenforce Range Livestock, Dairying, and Human Nutrition for the Western States, W. A. Lloyd.....	597
Bul. 1290, Transportation of Citrus Fruit from Porto Rico, R. G. Hill and L. A. Hawkins...	539	Proceedings of the World's Dairy Congress, 1923, vols. 1 and 2.....	503, 504, 505, 506, 562, 564, 573, 580, 583, 590, 591, 592, 593, 594, 596, 597
Bul. 1294, The Rôle of Fire in the California Pine Forests, S. B. Show and E. I. Kotok...	542	Crops and Markets: Vol. 2—	
Bul. 1296, A Study of Farm Organization in Central Kansas, W. E. Grimes, J. A. Hodges, R. D. Nichols, and J. W. Tapp.....	588	No. 23, Dec. 6, 1924...	595
Bul. 1297, Effect of Feeding Cabbage and Potatoes on Flavor and Odor of Milk, C. J. Babcock.....	578	No. 24, Dec. 13, 1924...	595
Bul. 1299, Relative Resistance of Wheat to Bunt in the Pacific Coast States, W. H. Tisdale, J. H. Martin, et al....	545	No. 25, Dec. 20, 1924...	595
Bul. 1300, Corn and Hog Correlations, S. Wright.....	595	No. 26, Dec. 27, 1924...	595
Bul. 1302, Development and Present Status of Farmers' Cooperative Business Organizations, R. H. Elsworth.....	592	Vol. 1, Sup. 12, Dec., 1924...	594
Bul. 1305, Utilization of Almonds for Various Food Products, A. F. Sievers and F. Rabak.....	507	Bureau of Agricultural Economics: Atlas of American Agriculture: Part I, The Physical Basis of Agriculture.—Section E, Natural Vegetation, H. L. Shantz and R. Zon.....	520
Bul. 1306, Work of the Sheridan Field Station for the Seven Years from 1917 to 1923, Inclusive, R. S. Towle.....	527	Bureau of Plant Industry: Inventory of Seeds and Plants Imported, Oct. 1 to Dec. 31, 1922 (No. 73).....	520
Bul. 1307, Absorption and Retention of Hydrocyanic Acid by Fumigated Food Products, Part II, E. L. Griffin and E. A. Back.....	561	Bureau of Soils: Field Operations, 1921— Soil Survey of Crenshaw County, Alabama, J. F. Stroud et al.....	510
Bul. 1308, Chemical and Physical Methods for the Control of Saponified Cresol Solutions, R. M. Chapin.....	506	Soil Survey of Mississippi County, Missouri, W. DeYoung and R. Wildermuth...	510
		Soil Survey of Spartanburg County, South Carolina, W. J. Lattimer et al.....	511
		Bureau of Public Roads: Public Roads, vol. 5, No. 10, Dec., 1924.....	585

# EXPERIMENT STATION RECORD

Editor, H. L. KNIGHT

## EDITORIAL DEPARTMENTS

Agricultural Chemistry and Agrotechny—SYBIL L. SMITH.  
Meteorology—W. H. BEAL.  
Soils and Fertilizers—R. W. TRULLINGER.  
Agricultural Botany, Bacteriology, and Plant Pathology—W. H. EVANS, Ph. D.,  
W. E. BOYD.  
Genetics—W. H. EVANS, W. E. BOYD, H. M. STEECE, J. W. WELLINGTON, G.  
HAINES.  
Field Crops—H. M. STEECE.  
Horticulture and Forestry—J. W. WELLINGTON.  
Economic Zoology and Entomology—W. A. HOOKER, D. V. M.  
Foods and Human Nutrition—SYBIL L. SMITH.  
Animal Husbandry, Dairying, and Dairy Farming—G. HAINES.  
Veterinary Medicine—W. A. HOOKER, SYBIL L. SMITH.  
Rural Engineering—R. W. TRULLINGER.  
Rural Economics and Sociology and Agricultural Education—LOUISE MARBUT.  
Indexes—MARTHA C. GUNDLACH.  
Bibliographies—MARTHA L. GERICKE.

## CONTENTS OF VOL. 52, NO. 7

Editorial notes:	Page
The St. Louis conference on the Purnell Act.....	601
Recent work in agricultural science.....	609
Notes .....	697

## SUBJECT LIST OF ABSTRACTS

### AGRICULTURAL CHEMISTRY—AGROTECHNY

Chemical encyclopaedia, Kingzett.....	609
Chemical dictionary, Remy.....	609
Colloid chemistry, Alexander.....	609
Fifth report on colloid chemistry and its applications, Donnan et al.....	609
Starches, Nivling.....	609
The polysaccharides, Pringsheim.....	609
Modern cereal chemistry, Kent-Jones.....	609
Nitrogenous constituents of juice of alfalfa plant, I, Vickery.....	610
Nitrogenous constituents of juice of alfalfa plant, II, Vickery.....	610
The chemistry of grape pigments, II, Anderson and Nabenhauer.....	610
The lipochromes of etiolated wheat seedlings, Coward.....	610
Recent work on insulin, Best.....	611
The influence of insulin on <i>Bacillus coli</i> , McGuire and Falk.....	611
Fermentation of pentoses by <i>B. granulobacter pectinovorum</i> , Peterson et al.....	611
Formation of <i>l</i> -leucic acid in fermentation, Schmidt et al.....	611
Organic compounds of sulphur in bacterial cultures, McLeod and Gordon.....	611
<i>Lactobacillus acidophilus</i> and <i>L. bulgaricus</i> , Kulp and Rettger.....	611
A note on the gravimetric microchemical technique, Dienes.....	612

	Page
The buffer mechanism for the calcium concentration, Kugelmass	612
Determination of nitrogen with carbon, Anderson and Schutte	612
The determination of ammonia in soil, Bengtsson	612
Methods of studying the strength of soil acids, Tidmore and Parker	613
Modification of molybdc method for phosphorus, Benedict and Theis	613
Estimating iodine in biological material, Kelly and Husband	613
A micro method for the determination of silicon, Bertrand	614
Determination of Ca, Mg, and P in animal substances, Dienes	614
Identification of glycerol by a bacterial method, Castellani and Taylor	614
Examination of peat materials by food stuff analyses, Dachnowski	614
A system of blood analysis.—Supplement V, Folin and Trimble	614
Estimation of sugar in the blood, Calvert	615
An apparatus for the exact analysis of air, Carpenter	615
Sugar machinery, Wallis-Taylor	615
The manufacture of vanillin, May	615

## METEOROLOGY

Solar and terrestrial radiation, Ångström	615
Vegetation of southern Africa, with notes on environment, Cannon	616
Climatological data for the United States, [November-December, 1924]	617
Observations at the Massachusetts Station, Ostrander and Bower	617

## SOILS—FERTILIZERS

Soil survey of the San Simon area, Arizona, Carpenter and Bransford	617
Soil survey of the Victorville area, California, Koehler and Cosby	617
Soil survey of Alcorn County, Mississippi, Jones and Lowe	618
Nature of soils of Biesbosch in South Holland, Maschhaupt and Hissink	618
[The Dollard soils of the Province of Groningen], Maschhaupt	618
Changes which alluvial soils undergo after diking, Hissink	618
Calculation of the coefficient of permeability of clay, Terzaghi	619
Heat of wetting for estimating colloidal material in soils, Bouyoucos	619
Effect of drying upon the acidity of soil samples, Rost and Fieger	619
Bibliography relating to soil alkalies, compiled by King et al	620
Soil temperature determinations from April to October, 1924, Hudig	620
The principles of summer-fallow tillage, McCall and Wanser	620
Chemical factors in denitrification, Fowler and Kotwal	221
Determination of fertilizer requirements of soils, Mitscherlich	221
Field experiments with fertilizers in Sweden, Von Feilitzen	221
Fertilizer suggestions for Pennsylvania, Gardner and Patrick	221
Influence of phosphate, biphosphate, carbonate, silicate, and sulfate of calcium, sodium, and potassium in acid soils, Miyake et al	221
Nitrification of stable manure in cultivated soils, Barthel and Bengtsson	622
Influence of koufri, marog, and tafla on soil, Mosséri	622
The availability of nitrogen in peat, Lipman and Wank	622
Nitrate facts and figures, 1924, compiled by James	622
Ammonium nitrate as an explosive, Cook	623
Test of phosphatic fertilizers, Brioux and Tardy	623
Origin of phosphorite and the degree of its pulverization, Lebediantzev	623
Ground phosphorite and soils not having an acid reaction, Lebediantzev	623
Agricultural liming materials	623
Report on commercial fertilizers, 1924, Bailey	623
Commercial fertilizers, 1924, Bartlett	623
Commercial fertilizers, Hills, Jones, and Anderson	624

## AGRICULTURAL BOTANY

Can the H-ion concentration of living protoplasm be determined? Scarth	624
Iron supply in a nutrient medium, Reed and Haas	624
Biochemical aspects of fermentation, Slator	624
Chemical aspects of germination, Baker and Hulton	624
Temperature coefficient of absorption in seeds of corn, Shull	624
The rate of growth of green and albino maize seedlings, Kempton	625
Influence of time of seeding of cereals on vegetative rhythm, Martinet	625

	Page
Growth of plants in artificial light, II, Hendricks and Harvey-----	625
Effects of air temperature and relative humidity on <i>Pinus strobus</i> , Dole-----	625
Comparative studies on respiration, XXI, Irwin and Weinstein-----	626
Comparative studies on respiration, XXII, Smith-----	626
Comparative studies on respiration, XXIII, Hutchinson-----	626
Assimilation-respiration balance as related to length of day, Eaton-----	626
Effect of ethylene upon respiration of lemons, Denny-----	626
The development and nutrition of yeast, [I], II, Tait and Fletcher-----	627
Origin of prairies in Illinois, Woodard-----	627
Age and area: A review of J. C. Willis' theory, De Vries-----	628

## GENETICS

[Plant breeding activities at the Dahlem Station], Höstermann-----	628
Triploidy in the tomato, Lesley and Mann-----	628
A dominant lethal chlorophyll mutation in maize, Kempton-----	628
Hereditary intra-uterine deficiency in dominant white mouse, De Aberle-----	628
A sterile hybrid of spelt and rye, Blaringhem-----	628
Some natural violet hybrids of North America, Brainerd-----	629
Shape and weight of eggs in relation to sex of chicks, Jull and Quinn-----	629
Studies on the sex-ratio and related phenomena, III, Parkes-----	629
Studies on the sex-ratio and related phenomena, IV, Parkes-----	629
Studies on the sex-ratio and related phenomena, V, Parkes-----	630
An undescribed constituent of semen, Fish-----	630
Effect of pregnancy upon postpubertal ovogenesis, Allen and Atcheson-----	630
Selective elimination of ova in the adult ovary, Allen et al-----	630
Polynuclear ova and polyovular follicles in the opossum, Hartman-----	630
External signs and vaginal changes and the ovarian cycle, McKenzie-----	631
An inhibition in ovulation by the intraperitoneal injection of anterior hypophyseal substance in the domestic fowl, Walker-----	631
The corpus luteum of the oestrous cycle in the ox ovary, McNutt-----	631
The cyclic changes of the tubular part of the genitalia of ox during the oestrous cycle.—Second paper, Murphey-----	631
Studies of the oestral flow of the pig, Zupp-----	631
A method of determining the prenatal mortality in a given pregnancy of a mouse without affecting its subsequent reproduction, MacDowell et al-----	631
Effect of light doses of alcohol upon the estrus cycle, MacDowell-----	632
Deficiency effects in guinea-pigs, Meyer-----	632

## FIELD CROPS

Growth of corn and sunflowers in relation to climatic conditions, Hanna-----	632
Fall seeding of spring crops, Pushkarev-----	633
Irrigated pastures, Hansen-----	633
The Rieti Experiment Station for Cereals, Maylin-----	633
Corn in Connecticut, Jones, Slate, and Brown-----	633
Moisture and viability of seed corn subjected to low temperatures, Scott-----	634
Cotton experiments, 1924, Childs-----	634
Cotton in Australia, Harding-----	634
Studies of gambo hemp, Horst-----	634
Results of experiments with oats in New York, Love and Craig-----	635
Variation in vigor of sprouts from quarters of single tubers, Bushnell-----	635
Depression of check-row yields by adjoining rows, Musgrave-----	635
Varieties of potatoes tested at Ormskirk from 1915-1924, Salaman-----	635
Report on the potatoes sent for immunity trials, 1923, Salaman et al-----	635
Observations on the time of blooming of rice flowers, Jones-----	635
The soy bean: Its history, culture, and uses, Bottari-----	636
Protein and oil of soybeans and iodine number of soybean oil, Stark-----	636
Sugar-cane experiments, 1921-1923, Bovell and D'Albuquerque-----	636
The relation of moisture and available nitrogen to the yield and protein content of wheat, Neidig and Snyder-----	637
Varietal experiments with hard red winter wheat, Clark and Martin-----	637
Report of trials of Yeoman II wheat, 1922-23, Parker-----	637
Report on quality of a new form of wheat, Humphries and Hutchinson-----	638
Quality of Red Fife wheat in England, Humphries and Hutchinson-----	638
Ten years' grain and seed testing in Montana, McKee and Whitcomb-----	638

	Page
Agricultural seed inspection, Lutman-----	638
Seed testing investigations and miscellaneous work-----	638
Official Seed Testing Station for England and Wales [1923], Saunders----	639
Morphological differences of the seeds of some species of Carophyllaceae [found in Russian clover seed], Kamenskii-----	639
The jointed cactus, Schonland-----	639
Cuscuta in Iowa, Wittrock-----	639

## HORTICULTURE

[Horticultural investigations at Canadian experimental stations]-----	639
Memorial of hundredth anniversary of the Dahlem Experimental Station-----	639
Red as a protective color in vegetation, Harvey-----	640
Handbook of vegetable gardening, Becker-----	640
Field notes on carrots, Morse-----	640
Premature seeding of celery, Starring-----	640
A new method for blanching celery, Harvey-----	640
Greenhouse tomatoes, Beattie-----	640
Fruit statistics of Canada, 1920-23-----	640
Orchard management, Gourley-----	640
Top-working fruit and nut trees by the Biederman method, Kinnison-----	640
Cranberry picking studies, Franklin-----	640
Some results of recent experiments in pruning raspberries, Johnston-----	640
Manual of American grape-growing, Hedrick-----	641
Two years' work in pruning and training Illinois grapes, Vogele-----	641
Changes occurring in grapes during ripening, Copeman-----	641
Problems of the viticultural industry, Lyon-----	641
The California raisin industry, Colby-----	641
Smyrna fig culture, Savage-----	642
Fertilizer studies with the olive, Bonnet-----	642
Report of an investigation of coffee, Prescott-----	642
Pecan growing, Stuckey and Kyle-----	642
The pecan in Texas, Burkett-----	642
Rhododendrons for amateurs, Cox-----	642
Shrubs for amateurs, Bean-----	642
The week-end gardener, Farthing-----	642
The little garden for little money, Brewster-----	642
Planning and planting for the home beautiful, Fargo-----	643

## FORESTRY

Ecological effects of shading coniferous nursery stock, Korstian-----	643
The Rainbow forest plantations, 1924, Hicock-----	643
Forest planting in the intermountain region, Korstian and Baker-----	643
Growth, returns, and uses of planted cottonwood in Iowa, MacDonald-----	644
Aspen in the central Rocky Mountain region, Baker-----	644
The growing season of western yellow pine, Pearson-----	644
The caoutchouc in Indo-China, Carton-----	644
Forest administration of the Central Provinces, 1922-23, Farrington-----	644

## DISEASES OF PLANTS

Report of the International Conference of Phytopathology and Economic Entomology, Holland, 1923, edited by Schoevers-----	645
Cooperative dusting and spraying experiments in 1921-----	646
The relation of cucurbit mosaic to wild catnip, Muncie-----	647
Effect of hardness of water on mercuric chloride solutions, Gilman-----	647
The health of seed, Doijer-----	647
Studies of insect transmission and cross-inoculation of mosaic on the Solanaceae, Cucurbitaceae, and Leguminosae, Elmer-----	647
Rust infection of leaves in Petri dishes, Clinton and McCormick-----	647
Stripe rust of cereals and grasses in the United States, Humphrey et al.--	648
Infection of barley by <i>Ustilago nuda</i> , Tisdale and Tapke-----	648
Root-rots of wheat, Henry-----	648
Botrytis rot of the Globe artichoke, Link et al-----	649
Celery diseases in Florida, Foster and Weber-----	649

	Page
Influence of broken pericarp on germination and yield of corn, Meyers	649
The nodal infection of corn by <i>Diplodia zeae</i> , Durrell	649
Malformations of cotton plants in Haiti, Cook	650
Onion smut in Indiana, Gregory	650
Bacterial pustule of soybean, Wolf	650
A study of bacterial pustule of soybean, Hedges	651
Apple storage investigations, Plagge and Maney	651
Freezing injury of apples, Diehl and Wright	652
Oiled materials in control of scald on barrel apples, Brooks and Cooley	653
Diseases of stone fruits on the market, Rose	653
Studies on banana anthracnose, Toro	653
Diseases of coffee and trees used for shade, Kern and Whetzel	653
Progress report on big bud and reversion of black currants, Lees	653
The structure of reverted black currants, Ridler	654
Disease of gladioli caused by <i>Bacterium marginatum</i> , McCulloch	654
Depth distribution of <i>Heterodera radicum</i> in Florida soils, Godfrey	654

## ECONOMIC ZOOLOGY—ENTOMOLOGY

Hérons of the United States, Pearson	655
Insecticidal properties of the fatty acid series, Siegler and Popenoe	655
Oil sprays: Their preparation and use for insect control, Melander et al.	656
Making oil sprays, Melander	656
Loss of nicotine from dusts during storage, McDonnell and Young	656
Preparation from tobacco of a solution for spraying, Shedd and Olney	657
Lead arsenate, lime sulfur, and tobacco dust as a mixture, Streeter	657
[Economic insects and their control in Pennsylvania]	657
New termites and hitherto unknown castes from the Canal Zone, Snyder	657
Comparative resistance of woods to <i>Cryptotermes brevis</i> , Wolcott	657
Tree cricket injury to prunes, Yothers	658
Control and biology of capsids on apple trees, Rostrup and Thomsen	658
Calcium cyanide dust for control of the grape leaf hopper, Quayle	658
Fluctuation in beet leafhoppers in San Joaquin Valley, Severin	658
The effects of oil spray on apple aphids, Sullivan and McBride	658
A bacterial disease of silkworms, Glaser	659
The greenhouse leaf-tyer, <i>Phlyctaenia rubigalis</i> , Weigel et al.	659
Dosing the root borer with paradichlorobenzene, McIntosh	659
A supposedly beneficial insect discovered to be a citrus pest, Basinger	659
The azalea leaf miner (Lepid.: Tineidae), Trimble	660
Notes on Japanese Lepidoptera and their larvae, VI, VII, Wileman	660
The Bombyliidae of the Ethiopian region, Bezzi	660
Combating the olive fly in Corfu, Sordinas	660
The bee-louse, <i>Braula cocca</i> , in the United States, Phillips	660
The blueberry leaf-beetle and some of its relatives, Fall and Woods	660
Longevity and fecundity of <i>Bruchus quadrimaculatus</i> Fab. as influenced by different foods, Larson and Fisher	661
Fumigation against grain weevils, Neifert et al.	661
Ethyl acetate-carbon tetrachloride mixture, Back and Cotton	662
Application of the Röntgen tube to detection of boring insects, Yaghi	662
Another lead boring beetle, Chamberlin	662
Studies of the parasites of the alfalfa weevil in Europe, Chamberlin	662
The brown vegetable weevil, McCarthy	662
Injuries to peppers in California by <i>Anthonomus eugenii</i> Cano, Campbell	662
An enemy of the olive in Japan, <i>Hylobius perforatus</i> , Poutiers	662
Report of the Maryland State Beekeepers' Association	663
The presence of the Argentine ant in Valencia, Font de Mora	663
New chalcidids from France, García Mercet	663
<i>Polyscelis modestus</i> Gahan, a minor parasite of the Hessian fly, Myers	663
<i>Adirus trimaculatus</i> Say, a rose pest, Champlain	663

## FOODS—HUMAN NUTRITION

The digestibility of tepary beans, Deuel	663
Vitamin A content of fresh eggs, Murphy and Jones	664
Effect of long storage on vitamin-A content of eggs, Jones et al.	664
Hydrogen ion concentration in the human duodenum, Hume et al.	664

	Page
Animal calorimetry.—[XXV], Dynamic action of proteins, Rapport.....	665
Animal calorimetry.—[XXVI], Weiss and Rapport.....	665
Fat excretion, II, Sperry and Bloor.....	665
Catabolism of odd and even carbon fatty acids in man, Lundin.....	666
Clinical observations with odd-carbon-atom fat (intarvin), Modern.....	666
Clinical assaying of insulin and the insulin requirement, Wilder.....	667
A hypoglycemia-producing principle from vegetables, Dubin and Corbitt.....	667
The uric acid problem.—An experimental study, Folin et al.....	667
Uric acid excretion, Koehler.....	668
Photoactivity of substances curative of rickets, Kugelmass and Mc- Quarrie.....	668
The photo-activity of substances curative of rickets.....	669

## ANIMAL PRODUCTION

Seasonal changes in organ weights, Brown et al.....	669
Effect of acute scurvy on subsequent growth, Anderson and Smith.....	669
Phosphorus in the live stock industry, Theiler, Green, and Du Toit.....	670
Grassland and the grazing animal, Stapledon et al.....	670
Feed inspection report, 1923, Halverson and Nixon.....	670
Commercial feeding stuffs, Hills, Jones, and Anderson.....	671
Waters suitable for live stock in New South Wales, Ramsay.....	671
Beef cattle investigations on the farm, 1923-24, McCampbell.....	671
Beef-cattle production in the range area, Parr.....	672
Dual-purpose cattle merits demonstrated in Minnesota, Hodgson.....	672
Lamb-raising trials, season 1923, Elliott.....	672
Lamb feeding experiments at the Irrigation Substation, Hackedorn et al.....	672
Sheep shearing, Kruger.....	672
Methods of investigating the physical properties of wool, Tänzer.....	672
[Hog feeding tests by Canadian Department of Agriculture], Rothwell.....	673
"Pineapple bran" mixture versus barley and tankage for hogs, Henke.....	673
Pig breeders' annual, 1923.....	674
Pig breeders' annual, 1924.....	674
Economy and effect of corn in the winter feeding of horses, Rothwell.....	674
The police dog, Brockwell.....	674
The effect of feeding thyroid on the plumage of the fowl, Cole and Reid.....	675
Investigation of body form and egg production, Weinmüller.....	675
Egg weight in relation to production, Part II, Jull.....	675
Culling for efficient egg production, Rice.....	675
Effect of cod liver oil on the growth of young chickens, Dunn.....	675
Experiments in incubation, Rugg and Pederick.....	676
The present outlook for the poultryman, Hervey and Platt.....	676
Muskrat farming, [Edwards].....	676

## DAIRY FARMING—DAIRYING

Report of proceedings of Connecticut Dairymen's Association, 1924.....	676
On the protein requirement of milk production, Fries et al.....	676
Feeding cocoa meal to dairy cows, Ellenberger and Newlander.....	677
Optimum root crop ration as shown by experiments, Hansson.....	677
[Carrying capacity of irrigated pastures], Hansen.....	678
Studies in growth and nutrition of dairy calves, IX, X, McCandlish.....	678
Similarities between the curves of growth and of regeneration, Brody.....	678
The change of form with age in the dairy cow, Brody and Ragsdale.....	679
Interpretation of dairy pedigrees, Gowen.....	679
Effect of sugar content in manufacture of commercial ice cream, Reid.....	679

## VETERINARY MEDICINE

Normal immunity reactions of the cow and the calf with reference to antibody transmission in the colostrum, Nelson.....	679
Tissue resistance and permanent immunity, Nukada and Matsuzaki.....	680
Effect of intravenous injection of mercurochrome, Hill and Bidgood.....	680
On the nature of the heat-labile substance ("V") required for the growth of the bacillus of Pfeiffer, Thjötta.....	680

	Page
A filterable virus infection of rabbits, I, II, Andrews and Miller-----	681
Infectious abortion (fifth report), White, Rettger, and McAlpine-----	681
Our experimental knowledge of foot-and-mouth disease, Vallée-----	682
The specific microorganism of foot-and-mouth disease, Haring-----	682
The California foot-and-mouth disease outbreak, Mohler-----	682
Production of immunity in mice by inhalation of pneumococci, Stillman--	682
Experiences with the cultivation of tubercle bacilli, Corper-----	682
Calmette's protective inoculation against tuberculosis, K[rause]-----	683
On the iodized swine erysipelas vaccine, Fujimura-----	683
The common parasites of hogs, Stouder-----	683
The question of the human and pig <i>Ascaris</i> , Payne et al-----	683
The blood, urine, and tissue juices in azoturia, Hayden and Tubangui---	684
The blood, urine, and tissue juices in azoturia, Hayden-----	684
Pyotherapy in so-called contagious pleuropneumonia, Bemelmans-----	684
An outbreak of goose septicemia, Beaudette-----	684

## RURAL ENGINEERING

Artesian-water supply of the Dakota sandstone, Meinzer and Hard-----	685
The San Juan Canyon, southeastern Utah: A reconnaissance, Miser-----	685
A discussion of certain Colorado River problems, Smith-----	685
Surface water supply of Pacific slope basins, 1921-----	685
Base exchange in ground water by silicates in Montana, Renick-----	685
Effects of storage on artificially polluted waters, Frederick-----	685
Size and depth of sand for filters-----	686
Report on irrigation works of Ajmer-Merwara, 1922-23, Gibson et al-----	687
Public Roads, [January, 1925]-----	687
Strength of concrete in tension and compression, Finkbiner-----	687
Supporting value of soil and the bearing area, Goldbeck and Bussard-----	687
The viscosity of oils at high temperatures, Fortsch and Wilson-----	687
Does the $zn/p$ function fit the facts? Becker-----	687
Industrial electricity, Timbie-----	688
Research features of application of electricity to agriculture, Trullinger--	688
Artificial haymaking-----	688
Heat loss through wall constructions, Kolfiaath-----	688
Tests on the hydraulics and pneumatics of house plumbing, Babbitt-----	689
House painting, Sabin-----	689

## RURAL ECONOMICS AND SOCIOLOGY

Farming partnerships in Tuscany as exhibited, Casabianca-----	690
More profit for the wheat farmers of central Kansas, Tapp and Grimes--	690
Costs of the sweet potato industry in New Jersey, 1922, Waller and Weiss--	690
The cost of raising swine under existing conditions, Peña-----	690
Depreciation of currency and effects on agricultural credit, Von Altrock--	691
The higher finance of agricultural co-operation in India, Calvert-----	691
Development of cooperative fire insurance in New York, Bartlett-----	691
Tax revision in Kansas, Englund-----	691
Wheat forecasts in the Punjab, Trevaskis-----	692
The statistical measurement of the elasticity of demand for beef, Schultz--	692
The determination of hog prices, Wentworth and Ellinger-----	692
Interim report on meat, poultry, and eggs, Linlithgow et al-----	693
Cold-storage holdings to October, 1924-----	693
Crops and Markets, [January, 1925]-----	693
Agriculture and American business, Barnes-----	693
Agriculture and foreign relations, Barnes-----	693
European economic conditions which affect the markets, Smith-----	693
The future of wheat export from the United States, Taylor-----	694
Permanent agriculture, population, and national progress, East-----	694
The agricultural regions of North Dakota, Willard-----	694
Social survey of Black Hawk and Buchanan Counties, Iowa, Von Tun- geln and Eells-----	694
Monthly Supplement to Crops and Markets, [January, 1925]-----	694
Horses, mules, and motor vehicles-----	695
Agriculture [in Algeria in 1923], Steeg-----	695

## AGRICULTURAL EDUCATION

	Page
Agricultural education and research in Scotland, Constable et al.....	695
[Seventh and eighth reports with reference to the work of the Federal Board for Vocational Education in agriculture and home economics]..	696
Orchard improvement instruction in Herefordshire, Manning.....	696
Students' competitions at agricultural shows, Gregg.....	696
Manual in agriculture: Growing things.....	696
Crop production and soil management, Cox.....	696
Studies in horticulture, Lloyd, edited by Davenport.....	696
Lessons for pig club members, Millin.....	696
Poultry raising for club members, Hall and Neely.....	696
Boys' and girls' club work: Clothing handbook.....	696
Essentials of sewing, Cook.....	696
The country theatre, Seckerson.....	696

# LIST OF EXPERIMENT STATION AND DEPARTMENT PUBLICATIONS ABSTRACTED

## *Stations in the United States*

	Page
Arizona Station:	
Bul. 100.....	685
Connecticut State Station:	
Bul. 259.....	633
Bul. 260.....	647
Bul. 261.....	623
Bul. 262.....	643
Connecticut Storrs Station:	
Bul. 123.....	681
Bul. 124.....	633
Florida Station:	
Bul. 173.....	649
Iowa Station:	
Bul. 222.....	651
Bul. 223.....	644
Bul. 224.....	694
Kansas Station:	
Bul. 234.....	691
Maine Station:	
Bul. 318.....	679
Bul. 319.....	660
Off. Insp. 113.....	623
Massachusetts Station:	
Met. Buls. 433-434, Jan.- Feb., 1925.....	617
Minnesota Station:	
Tech. Bul. 22.....	648
Missouri Station:	
Research Bul. 67.....	679
Research Bul. 68.....	679
Research Bul. 69.....	679
Montana Station:	
Bul. 166.....	633, 678
Bul. 167.....	638
Bul. 168.....	640
New Jersey Stations:	
Hints to Poultrymen, vol. 13, No. 5, Feb., 1925.....	676
New York Cornell Station:	
Bul. 435.....	691
Bul. 436.....	635
North Dakota Station:	
Bul. 183.....	694
Porto Rico Department of Ag- riculture and Labor Sta- tion:	
Bul. 33.....	657

## *Stations in the United States—Con.*

# EXPERIMENT STATION RECORD

Editor: H. L. KNIGHT

## EDITORIAL DEPARTMENTS

Agricultural Chemistry and Agrotechny—SYBIL L. SMITH.  
Meteorology—W. H. BEAL.  
Soils and Fertilizers—R. W. TRULLINGER.  
Agricultural Botany, Bacteriology, and Plant Pathology—W. H. EVANS, Ph. D.,  
W. E. BOYD.  
Genetics—W. H. EVANS, W. E. BOYD, H. M. STEECE, J. W. WELLINGTON, G. HAINES.  
Field Crops—H. M. STEECE.  
Horticulture and Forestry—J. W. WELLINGTON.  
Economic Zoology and Entomology—W. A. HOOKER, D. V. M.  
Foods and Human Nutrition—SYBIL L. SMITH.  
Animal Husbandry, Dairying, and Dairy Farming—G. HAINES.  
Veterinary Medicine—W. A. HOOKER, SYBIL L. SMITH.  
Rural Engineering—R. W. TRULLINGER.  
Rural Economics and Sociology and Agricultural Education—LOUISE MARBUT.  
Indexes—MARTHA C. GUNDLACH.  
Bibliographies—MARTHA L. GERICKE.

## CONTENTS OF VOL. 52, No. 8

	Page
Editorial notes:	
The promotion of agricultural education by foreign missionaries-----	701
Recent work in agricultural science-----	708
Notes-----	797

## SUBJECT LIST OF ABSTRACTS

### AGRICULTURAL CHEMISTRY—AGROTECHNY

Proceedings of Association of Official Agricultural Chemists, 1923-----	708
Spinacin, a new protein from spinach leaves, Chibnall-----	708
Note on the basic amino acids yielded by casein, Leavenworth-----	708
Studies with phytosterols, I-V-----	708
The phytosterols of wheat endosperm, Anderson and Nabenhauer-----	708
Separation of unsaturated from saturated sterols, Anderson and Naben- hauer-----	709
Reduction of sitosterol—Sitostanol, Anderson and Nabenhauer-----	709
Sitosterol, Anderson and Nabenhauer-----	709
The concentration of vitamin B, Levene and Van der Hoeven-----	709
The antiscorbic fraction of lemon juice, II, Zilva-----	710
Reducing properties of antiscorbic preparations, Connell and Zilva-----	711
Differential dialysis of antiscorbic factor, II, Connell and Zilva-----	711
Apparatus with rotating anode for rapid electrolytic analysis, Bertiaux--	711
The analysis of phosphate rock, Lundell and Hoffman-----	711
Determination of lead and arsenic in lead arsenate, Hedges and Stone-----	711
Determining arsenic in lead arsenate and zinc arsenite, Roark-----	712
The determination of iodine in food, drink, and excreta, McClendon-----	712
Separation of unsaponifiable matter from fats and oils, Kerr and Sorber--	712

Determination of fat in cacao products, Feldstein.....	713
Analyses of noodles of known composition, Buchanan.....	713
The lead number of maple products, Clemens.....	713
The lead number of vanilla extracts, Clemens.....	713
Detection of methyl in presence of ethyl alcohol, Kling and Lassieur....	714

## METEOROLOGY

Report of the chief of the Weather Bureau, 1923-24.....	714
The weather of 1924, Henry.....	714
The year 1816—the causes of abnormalities, Milham.....	715
Monthly Weather Review, [November-December, 1924].....	715
Periodicities, solar and meteorological, Chree.....	715
Variation in solar radiation intensities, Kimball.....	716
The dustfall of February 13, 1923, Winchell and Miller.....	716
[Meteorological observations at the New Jersey Experiment Stations]....	716
Climatological data for Wyoming, Hepner.....	716

## SOILS—FERTILIZERS

Agrological studies, soil classification, and physical analysis, Da Silva...	717
Chemical analysis of soil, Valmari.....	717
The sampling of soils, Veatch.....	717
Soil survey of Choctaw County, Alabama, Smith et al.....	717
Soil survey of Andrew County, Missouri, Sweet and Jordan.....	717
Soil survey of Antelope County, Nebraska, Hayes et al.....	718
Soil survey of Deuel County, Nebraska, Wolfanger et al.....	718
Soil survey of Perkins County, Nebraska, Wolfanger et al.....	718
The cultivated soils of the east coast of Sumatra, Van Heurn.....	718
Device for continuous percolation through soil, Allison.....	719
Tank experiments on soil moisture, Pittman.....	719
[Leaching of heavy clay soils], Thomas.....	719
Percentage of water freezable in soils, Wintermyer.....	719
Plowing and cultural tests [at the Utah Station], Bracken.....	719
Seeding of winter wheat with furrow drill and ordinary drill, Bracken...	719
[Soil microbiological studies at the New Jersey Stations].....	720
Microorganisms and soil fertility, Waksman and Starkey.....	720
Soil bacteriological studies, Düggele.....	720
Study of anaerobiosis in arable soil, Winogradsky.....	720
Behavior of soil bacteria toward carbon disulfide, Maassen and Behn....	721
Continuous growing of wheat and rye, 1922, Lipman and Blair.....	721
Continuous growing of corn with legume and nonlegume, Lipman and Blair.....	721
Effect of green manure on the subsequent crop, Hartwell and Pember....	721
Action of manure on potatoes when applied in different ways, Meyer....	722
The use of nitrogen in muck fertilization, Harmer.....	722
Influence of varying ratios of phosphoric acid and potash on the crop with different nitrogenous materials, Lipman and Blair.....	722
Urea as a nitrogenous fertilizer, its influence on soil reaction, Brioux....	722
Fertilizer experiments with nitrogen on meadow, Alves and Nolte.....	723
Effectiveness and profit of nitrogen fertilization, Nolte and Leonhards....	723
Fertilizer experiments with Rhenania phosphate, Gehring and Pommer...	723
Quicklime and calcium carbonates on mineral soils, Ramann.....	723
The influence of sodium chloride upon alfalfa, Lomanitz.....	723
Inspection of commercial fertilizers for 1924, Kraybill et al.....	724
Analyses of fertilizers, spring season (supplement), 1924.....	724
Fertilizer report, August 1 to December 31, 1922, Kellogg.....	724
How is one protected against fraud in commercial fertilizers? Neubauer..	724

## AGRICULTURAL BOTANY

Apparatus used in a study of CO <sub>2</sub> evolution, Starkey and Shive.....	724
Influence of soil moisture on potatoes, Martin and Shive.....	724
Influence of sodium chloride on the growth of alfalfa, Lomanitz.....	724
Ferric glycerol phosphate and soluble ferric phosphate as sources of iron for soybean plants in solution cultures, Marsh.....	725

	Page
Iron solubility tests in culture solutions at different pH values, Marsh	725
Influence of soluble aluminum salts on wheat seedlings, Barnette	725
Notes on the stimulating influence of seed treatment, Silbert	726
The vitality of buried seeds, Goss	726
Peru as a center of domesticated plants, Cook	726

## GENETICS

Chromosomal chimeras in the Jimson weed, Blakeslee and Belling	727
Studies of oogenesis in mammals with rats and mice, Kremer	727
Natural crossings in oats at Akron, Colorado, Stanton and Coffman	727
Relations of five factor pairs for virescent seedlings in maize, Demerec	727
The inheritance of brown aleurone in maize, Kvakan	727
Inheritance of xantha seedlings in maize, Trajkovich	727
Studies on the inheritance of earliness in wheat, Florell	728
An experiment in breeding apples, II, Wellington	728
Color of grape leaves at time of foliation and fruit color, Gladwin	729
Correlation studies on winter fecundity, Hays, Sanborn, and James	729
Genetic linkage between size and color factors in the tomato, Lindstrom	729
The comparative physiology of spermatozoa, II, III, Gellhorn	730
Physiological investigations of spermatozoa and ova, Gellhorn	730
The reciprocal influence of the ovaries and uterus, Takakusu	730
The follicular hormone of the hen ovary, Allen et al.	730
The effect of selective breeding on host resistance, Webster	731

## FIELD CROPS

The rôle of statistics in agronomic experimentation, Love	731
Relation of seed size to the yield of small grain crops, Kiesselbach	731
Some green manures and cover plants, Holland	732
The grasses of Pennsylvania, Gress	732
Legume inoculant work	732
[Field crops experiments in New Jersey], Lipman et al.	732
[Agronomic experiments in Utah], Bracken et al.	732
Report of the Dominion cerealist for the year 1923, Newman	733
Characteristics of clover and alfalfa seed from France, François	733
Home-grown vs. foreign red clover seed, Thatcher	733
Jala maize, Kempton	733
Cotton culture in Argentina, Winters	734
I, Cotton improvement. II, Behavior during acclimatization, Griffing	734
Inoculation increases pea yield and quality for canning, Whiting et al.	734
Influence of plot size and replication with potatoes, Westover	734
Sorghum, Zhdanov	735
The influence of lime on soybeans, 1922, Lipman and Blair	735
Sugar beet fertilization, Price	735
The inoculation of sugar beets, Némec	735
Studies on fertility of sugar-cane flowers	735
Deterioration of Uba sugar cane, De Froberville	735
[Experimental work with sugar cane in Queensland, 1923], Easterby	735
The culture of sugar crops in arid regions, Pushkarev	736
Growing sweet clover, Cutler and Buckley	736
Fertilizer experiments with tobacco, 1919-20-1922-23, Beets	736
Root development in wheat, Lees	736
Report of the State testing mill, crop 1922, Bailey	736
Results of seed tests for the year ending June 30, 1924, Eastman	737
Proceedings of Association of Official Seed Analysts of North America	737
Weeds of cranberry bogs, Beckwith and Fiske	737

## HORTICULTURE

[Horticultural investigations at the New Jersey Stations]	737
[Horticultural investigations at the Utah Station], Wilson and Abell	738
Growing and handling asparagus crowns, Jones and Robbins	739
Pollen studies with the pear and the apple, Kobel	739
Commercial fertilizers for grapes, Partridge	740

	Page
Development and status of grape improvement in Prussia, Wortmann	740
The biology of the olive, Priego	740
Report of the cranberry substation [New Jersey], Beckwith	740
Outdoor flowering annuals, Kache and Schneider	741
The culture of perennials, Cloud	741
Iris for the beginner, edited by Sturtevant	741
How to grow roses, Pyle	741
Roses in the garden, Connors	741
The book of water gardening, Bisset	741
Garden improvement, Henslow	741
The horticultural exhibitor: A guide to success, Macself	741

## FORESTRY

Hemlock: Its place in southern New England, Merrill and Hawley	741
Cultivation of forest plantations, Chittenden	742
Growth of Eucalyptus in California plantations, Metcalf	742
Key to the eucalyptus of Western Australia, Kessell and Gardner	742
Some New Zealand woods, Garratt	742
Turpentine studies in Greece, Oekonomopulos	742
Report of the Royal Commission on Pulpwood, Canada, Picard et al.	743
Report of His Majesty's woods, forests, and land, Buxton and Gower	743
[Annual report of New Zealand State Forest Service, 1924], Ellis et al.	743

## DISEASES OF PLANTS

Report of the department of plant pathology, Martin et al.	743
Plant pathology, Richards	745
Plant parasitic diseases in the Valley of Baresges, Dufrenoy	745
Fungus diseases of cultivated plants in Egypt and their control, Snell	745
Congress of Plant Pathology, Strassburg, 1923	745
A new chapter in plant pathology, Quanjer	746
Notes on the biology of rusts and smuts, Blaringhem	746
The toxicity of copper, Chabrolin	746
A miniature copper carbonate duster, Hoffman	746
Color indicators for blight disinfectants, Cardinell	746
A mycorrhizal fungus in the roots of legumes and other plants, Jones	746
A cereal collar disease, Miège	747
Observations on <i>Sclerotium oryzae</i> in Cochin China, Vincens	747
Fusarium attack on wheat, Doyer	747
Smut control test, Bracken	747
Alternaria leafspot and brownrot of cauliflower, Weimer	747
Control of damping off of cotton seedlings by the use of Uspulun, Rosen	747
Three new diseases of the hop, Salmon and Wormald	747
Potato diseases, Hill	748
Potato leaf roll [Loire], Perret	748
The Rhizoctonia disease of the potato, Dana	748
Pear leaf blister ( <i>Taphrina bullata</i> , Tul.), Briton-Jones	748
The purple leaf blotch of strawberry, Briton-Jones	748
Red plant in strawberries and "cauliflower disease," Ballard and Peren	748
Grape mildew control [in France], Cadoret	749
Geranium stemrot caused by <i>Pythium complectens</i> n. sp., Braun	749
<i>Schizophyllum commune</i> on Japanese chestnut, Biers	749
<i>Armillaria (Armillariella) mellea</i> and walnut rot, Gard	749

## ECONOMIC ZOOLOGY—ENTOMOLOGY

Spread of the European starling in North America, Cooke	749
Report of the department of biology for 1923, Nelson	750
Personality of insects, Dixon and Eddy	750
Report on entomology [New Jersey Stations], Headlee et al.	750
Entomology [studies at the Utah Station], Hawley	752
Injurious insects and their parasites recorded from Italy, Leonardi	753
The control of truck crop pests by dusting, Cory	753
The succession of insects living in hickory, Blackman and Stage	753
Problems and methods in forest entomology, Tragardh	753

	Page
The termites, Hegh.....	753
The grape leafhoppers of bluegrass Kentucky, Jewett.....	753
The citrus aphid, <i>Aphis spiraeicola</i> Patch, Yothers and Cole.....	753
Some field observations on the new aphid, Bradon.....	754
The new citrus aphid, Watson and Beyer.....	754
Life history of the new citrus Aphid, Beyer.....	754
Controlling the citrus aphid ( <i>Aphis spiraeicola</i> ), Watson and Beyer.....	755
The grape phylloxera and viticulture, Schneider-Orelli.....	756
The European corn borer, Huber and Neiswander.....	756
Report of progress of the orange Tortrix investigation, Basinger.....	756
Australian fruit crop endangered by fruit fly, Blake.....	757
Winter trapping of the fruit-fly, <i>Ceratitidis capitata</i> (Weid.), Newman.....	757
The Mexican bean beetle, <i>Epilachna corrupta</i> Muls., Miller.....	757
The Cicadellidae of the vicinity of Ithaca, New York, Buys.....	758
The mint flea-beetle, <i>Longitarsus menthae</i> new species MS, Gentner.....	758
The parsley weevil, a potential pest, Chittenden.....	758
Transmission of foulbrood by caterpillars of bee moth, Vincens.....	758
Treatment for red-spider, McDaniel.....	759
Apple blister-mite and its control, Childs.....	759
Bionomics of the sarcoptic mange parasite of the buffalo, Timoney.....	760
The "blinding filaria" of Guatemala, Fülleborn.....	760
Rat-bite disease in the United States, Shattuck and Theiler.....	760

## FOODS—HUMAN NUTRITION

On the constancy of the basal metabolism, Lusk and DuBois.....	761
The effect of temperature on protein intake, Denis and Borgstrom.....	761
Biological value of proteins of wheat, eggs, and pork, Mitchell and Carman.....	762
Biological food tests.—VII, Vitamins of pumpkin, Morgan and Francis.....	762
Antirachitic properties imparted to inert fluids by ultraviolet irradiation, Hess and Weinstock.....	762
Antirachitic properties imparted to inert fluids and to green vegetables by ultra-violet irradiation, Hess and Weinstock.....	763
Influence of light on the formation of teeth, Mellanby.....	763
Effect of diet on caries in the teeth of children, Mellanby et al.....	763
Relation of calcium and phosphorus in the diet to the absorption of these elements from the intestine, Orr et al.....	763
Effect of heat treatment of milk feedings on the mineral metabolism of infants, Daniels and Stearns.....	764
Studies on carbohydrate metabolism, I, Winter and Smith.....	764
Studies on carbohydrate metabolism, II, III, Hutchinson et al.....	765
Effects of insulin on normal metabolism, Blatherwick et al.....	766
Methods of including invarin and glyceryl margarate in the diabetic diet, Reynolds and Marlatt.....	766

## ANIMAL PRODUCTION

Analyses of feeding stuffs collected in New York State.....	766
Report on Fertilizers and Feeding Stuffs Act, 1906, Lord Clinton et al.....	767
Beef cattle feeding experiments, Hackedorn, Sotola, and Bean.....	767
Rations for fattening cattle, Carroll.....	767
Kemp fibres in the Merino sheep, Duerden.....	768
The 1925 wool clip, Brown.....	768
Pig-feeding trials at Hutton, 1920-1923, Green and Richardson.....	768
Hog rations, Carroll.....	770
Self-feeders for hogs, Bohstedt and Robison.....	770
Swine production, Russell.....	770
Textbook of swine production, Dettweiler and Müller.....	770
Feeding work horses, Harper.....	770
Alfalfa and horses, Hudson.....	772
The biology of the fowl, Evans.....	772
Length and variability of bones of White Leghorn, Schneider and Dunn.....	772
Postnatal growth of the Single-Comb White Leghorn chicken, Latimer.....	772

	Page
Poultry [experiments at the Utah Station], Alder-----	773
Rearing early chicks, Card-----	773
The culling and feeding of poultry, Kaupp-----	773

## DAIRY FARMING—DAIRYING

Intrauterine development of fetus in relation to milk yield, Gowen-----	773
Production of milk with antirachitic properties, Lesné and Vagliano----	774
Contribution to investigations of milk, Schmitt-----	774
Pasteurization of milk, Ruehle-----	774
Fat droplets in pasteurized cream, Rahn and Mohr-----	774
Methods of dairy manufacture, Wilster-----	774
The water content of butter, Rahn-----	775
The air content of butter, Rahn and Mohr-----	775
The air content of margarine, Rahn and Mohr-----	775
Relation between yeasts and moulds and keeping of butter, Shutt-----	775
Farm ice cream making, Lucas-----	775
Measuring quality in ice cream, Fisher and Judkins-----	775
Dry milk, Lendrich-----	775
Sodium hypochlorite.—IV, Disinfecting power, Zoller and Eaton-----	776

## VETERINARY MEDICINE

Report on the Civil Veterinary Department, Burma, for 1924, Blake-----	776
[Reports of veterinary research officer of Kenya], Walker and Kearney--	776
Handbook of pharmacology including materia medica, Ghosh-----	776
Critical tests of miscellaneous anthelmintics, Hall and Shillinger-----	776
Wandering of certain nematode larvae in body of their hosts, Fülleborn--	777
Chemical changes in the blood and their clinical significance, Myers-----	777
Anaerobic infections in animals, Gaiger-----	777
Anaplasmosis in Chile, Descazeaux-----	778
Rats as possible carriers of foot-and-mouth disease, Beattie and Peden--	778
Immunization against foot-and-mouth disease, Waldmann and Trautwein--	778
Foot-and-mouth disease-----	778
Tick biting experiments in piroplasmosis, Clark and Zetek-----	778
Bayer 205 and trypanosomiasis in animals, Van Saceghem-----	779
Establishing a tuberculosis-free dairy herd, S. E. B.-----	779
Infectious abortion investigations, Lienhardt et al.-----	779
Vaccination against bovine infectious abortion, Zwick-----	780
Actinobacillosis in Australian cattle, Dodd-----	780
Blackleg and gas gangrene in cattle, Leclainche and Vallée-----	780
Parasitic stages in life history of cattle hookworm, Schwartz-----	781
Investigations on immunization against swine erysipelas, Schmidt-----	781
A contribution to the knowledge of hyphomycosis destruens, Witkamp-----	781
Leptospiiral jaundice in dogs (yellows), Okell et al.-----	782
[A vitamin deficiency disease of poultry in California], Dryden-----	782
Bacteriological study of fowl typhoid and allied infections, Edington-----	782
European fowl pest found in poultry in the United States, Mohler-----	782
The outbreak of the European fowl pest, Kaupp-----	782
The new poultry disease, Stafseth-----	782
[Use of calcium cyanide in the] killing of condemned chickens, Winchell--	782

## RURAL ENGINEERING

Ground water in Santa Clara Valley, California, Clark-----	783
Surface water supply of North Atlantic slope drainage basins, 1922-----	783
[Irrigation experiments at the Utah Station], Pittman and Stewart-----	783
Pumping for drainage in the San Joaquin Valley, California, Weir-----	783
Public Roads, [February, 1925]-----	783
Rural highway mileage, income, and expenditures, Anderson-----	783
Highway transportation costs, Agg and Carter-----	784
United States Government specification for lubricants and liquid fuels--	784
Tetralin, Nathan-----	784
Wind power for farm electric plants, Pancratz-----	785

	Page
Ploughing without turning the furrow, in Austria, Kallbrunner-----	785
Motorized soil cultivation, Sievers-----	785
A study of threshing losses on the Nephi-Levan ridge, Bracken-----	785
Drying by means of air and steam, Hausbrand-----	785
Studies on the biology of sewage disposal, Hotchkiss-----	786
Investigation of farm sewage disposal systems, Driftmier-----	786

## RURAL ECONOMICS AND SOCIOLOGY

Report of investigational work in agricultural economics, Waller-----	787
The relative economy of ox labour in South African farming, Parish-----	787
The formation of small holdings in Sweden, Pettersson-----	787
The onion industry in Pleasant Valley, Iowa, Erwin and Harter-----	788
Cost of producing strawberries, Wilson-----	788
How to keep a cash account on a farm, Hart-----	788
Agricultural wages in Switzerland, Laur and Nater-----	788
Assessment and equalization of real estate in Kansas, Englund-----	788
Facts regarding cooperative livestock shipping in Ohio, Wallace-----	788
Crops and Markets, [February, 1925]-----	789
Monthly Supplement to Crops and Markets, [February, 1925]-----	789
The price situation in agriculture, 1920-21 to 1922-23, Fensch-----	789
The agrarian phase of the Mexican Revolution of 1910-1920, Phipps-----	789
A short history of English agriculture and rural life, Hall-----	789
Every-day life on an old Highland farm, 1769-1782, Grant-----	789
Where farming pays, and why, Meakin-----	790
Agricultural associations in Switzerland, Laur and Nater-----	790
Agricultural co-operation in Bulgaria, Orechkoff-----	790
Report on co-operative societies in the Punjab for 1923, Calvert-----	790
Geographical factors affecting agriculture in South Africa, Wellington-----	790
Conference on sociological implications of agricultural movements-----	790
The cost of living among colored farm families, Kirkpatrick and Sanders-----	791
The welfare of children in cotton-growing areas of Texas-----	791
International yearbook of agricultural statistics for 1923-----	792
Live stock and animal products statistics, 1923, Horning-----	792
Agricultural statistics, 1923, Thompson-----	792
[Agricultural statistics for Denmark]-----	792
[Agricultural statistics for Norway]-----	792
[Agricultural statistics for Sweden, 1924]-----	792
Statistical report on agricultural production in Greece for 1921-----	793
The statistics of agriculture, industries, and commerce, 1922, Hirata-----	793

## AGRICULTURAL EDUCATION

The agricultural high school in Ontario, McMillan-----	793
Courses of study at the Imperial Forestry Institute, 1924-1925-----	793
Preparation of rural teachers in high schools, Carney-----	793
Elementary agriculture in rural schools, Shinn-----	793
Teaching home relationships, Jacobson-----	794
Some practical uses of auditoriums in rural schools, Allen-----	794
Southern field crops, Duggar-----	794
A study of weeds, Ritchey-----	794
Animal husbandry for schools, Harper-----	794
4-H sheep manual, Darlow and Lowrey-----	794
Vegetable and animal products of importance, Astruc and Chadefaux-----	794
The education of the consumer, Harap-----	794
Red Cross course in food selection-----	794
Sewing manual, Eddy-----	794
Rush work-----	794
Agricultural economics laboratory manual, Forster-----	794
Principles of economics, Bye-----	795
The school and country life, McCready-----	795
List of books for a teacher's professional library, compiled by Wright-----	795

	Page
Suggestions for local leaders for junior agricultural clubs, Whitehouse--	795
Organization and programs for boys' and girls' clubs, Hall-----	795
Plans for conducting boys' and girls' 4-H club work in Missouri, Martin--	795
Small school gardens-----	795

## MISCELLANEOUS

Elements of physical biology, Lotka-----	795
Useful plants and animals of China, Klautke-----	795
Report of the New Jersey Experiment Stations, 1923, Lipman et al-----	795
Report of the Utah Experiment Station for 1923 and 1924, Peterson et al--	796
[Reports of Dominion Experimental Farms, 1923 and 1924], Archibald--	796
Quarterly Bulletin [of the Michigan Station], edited by Shaw and Hill--	796
Monthly Bulletin of the Ohio Agricultural Experiment Station-----	796
Directory of field activities of the Bureau of Plant Industry-----	796

Bibliographies—MARTHA L. GERICKE.

## CONTENTS OF VOL. 52, No. 9

	Page
Recent work in agricultural science-----	801
Notes-----	900

### SUBJECT LIST OF ABSTRACTS

#### AGRICULTURAL CHEMISTRY—AGROTECHNY

Reaction between formaldehyde and serum proteins, Henley-----	801
Total ash determination in spices, Mehring-----	801
A protein from the leaves of the alfalfa plant, Chibnall and Nolan-----	802
A protein from the leaves of <i>Zea mays</i> , Chibnall and Nolan-----	802
The tryptophane and cystine content of various proteins, Jones et al.----	802
A method for the fractional analysis of incomplete protein hydrolysates, Wasteneys and Borsook-----	803
A note on Dakin's method as applied to edestin, Osborne et al.-----	803
The optical properties of some amino acids, Keenan-----	803
A contribution to the chemistry of grape pigments, III, Anderson-----	803
Insulin from the cod fish.—Direct application of picric acid, Dudley-----	804
Studies on pentose metabolism, I, Youngburg and Pucher-----	804
Fat-soluble vitamins, XX, Steenbock et al.-----	804
Vitamin studies: Water-soluble growth-promoting factors, I, Davidsohn--	805
A critical study of the Jendrassik reaction for water-soluble B, Levine--	805
Cod-liver oil and its by-products, Holmes-----	805
The chemistry of synthetic sweetening compounds, Dyson-----	805
Merck's catalogue of reagents, Merck-----	805
Handbook of volumetric analysis, Sutton, rev. by Sutton and Johnson--	806
Method for quantitative determination of ammonium salts, Lövgren-----	806

	Page
Iodometric method for sodium in serum, Kramer and Gittleman.....	806
The graphic determination of carbon dioxide output and the respiratory quotient with the differential spirometer, Helmreich and Wagner.....	806
The determination of sugar in small amounts of blood, Gilbert and Bock.....	806
The nature of the sugar in normal urine, I, Greenwald et al.....	806
The organic phosphorus of the urine, Youngburg and Pucher.....	807

## METEOROLOGY

Climatic laws, Visher.....	808
The laws of winds and moisture, Visher.....	808
Effects of tropical cyclones upon the weather of mid-latitudes, Visher....	808
[Fluctuations in solar radiation and their relation to weather].....	808
Atmospheric electric currents and the growth of plants, Blackman.....	808
Influence of meteorological factors on tree growth, I, Nakashima.....	809
The use of the annual rings of trees in climatic study, Douglass.....	809
The temperature region map, Parkins.....	809
Rainfall map of Sweden, Wallen.....	809
[Heaviest rainfall ever recorded on the Island of Guam].....	809

## SOILS—FERTILIZERS

The moisture equivalent as influenced by the amount of soil used in its determination, Veihmeyer et al.....	810
The reservoir capacity of soil [at the Irrigation Substation], Wright....	810
Thermal diffusivity and conductivity of soils, Ingersoll and Koepf.....	811
Chemistry and physics of clays and other ceramic materials, Searle.....	811
The electrical charge on a clay colloid, Dayhuff and Hoagland.....	811
A study of the tolerance of plants to acid conditions, Tarr.....	811
Soil acidity in relation to soil type groups in Texas, Hendrickson.....	811
Vertical movement of alkali under irrigation, Shutt and Macoun.....	812
"Alkali" content of soils as related to crop growth, Shutt and Macoun....	812
Alkali studies.—I, Tolerance of wheat in Idaho, Neidig and Magnuson....	812
The alkali soils in Hungary and their reclamation, De'Sigmond.....	813
On the nature of burn-outs, Shutt and Macoun.....	813
[Soil bacteriological studies at the Idaho Station].....	813
[Soil studies at the Washington Station].....	814
[Sulfur and soil organic matter studies at Washington Station], Neller....	814
[Soil studies at the Irrigation Substation], Singleton.....	815
Soil organic matter maintenance, Wanser and Ingham.....	815
Soil organic matter in dry-land agriculture, Jones and Yates.....	815
Soil conditions which promote nitrogen fixation, Winters.....	815
Nitrate studies on Purdue rotation field No. 6, Baldwin et al.....	816
Soil improvement, Russell.....	816
Soil management and fertilization, Nelson and Sachs.....	816
Coniferous timber soil studies.....	816
Mathematical expression of the influence of the fertilizing elements contained in or added to the soil, Lagatu.....	816
Fertilizer instruction, Prjanischnikow, trans. by Von Wrangell.....	816
The leaching of fertilizers from soils, Joachim.....	816
Fertilizer spreaders, Leonhards.....	817
Industrial nitrogen, Kempton.....	817
Possible potash production from Minnesota shale, Schmitt.....	817
Final report on availability of phosphoric acid in basic slag phosphates, Haskins et al.....	817
Effect of iron and aluminum salts on phosphorus recovery from soils and sand treated with Tennessee rock or acid phosphate, Wolkoff.....	817
Synthetic calcium silicates as a source of lime, I, Barnette.....	818
The rôle and importance of lime in agriculture, Lenglen.....	818
Making limestone more available for farmers, Roberts.....	819
Some questions in the oxidation of elementary sulfur, Rippe.....	819
Fertilization with gas house waste, Kützing.....	819
Commercial fertilizers.....	819
Changes in fertilizers in New York from 1914 to 1924, Van Slyke.....	819

## AGRICULTURAL BOTANY

	Page
The physiology of photosynthesis, Bose-----	819
Effect of traces of chemical substances on photosynthesis, Bose-----	820
Effects of certain ions on citrus and walnut trees, Reed and Haas-----	820
A study of the June drop of fruits in Delaware, Detjen-----	822
Orchard conditions affected by arsenicals and other factors, Headden---	822
[Report of] division of bacteriology, Vandecaveye-----	822

## GENETICS

Genetics and eugenics, Castle-----	822
The founders of the art of plant breeding, Werkenthin-----	823
Plant breeding in Arizona, Uphof-----	823
Results of Mr. Houwink's experiments concerning the origin of some domestic animals, V, Lotsy and Kuiper-----	823
An introduction to cytology with special reference to cotton, Denham---	823
The cytology of the cotton plant, I, II, Denham-----	823
The reduction division in some wheat species, De Mol-----	824
The genetics of geographical variation, I, Goldschmidt et al-----	824
Mottling of soybeans, Woodworth and Cole-----	825
Study of some correlations in the peanut, Nevano-----	825
The Pratt family: A record of human inbreeding, Hanson-----	825
Some varieties of white rabbits, Castle-----	825
Inheritance studies and crop breeding, Gaines-----	825
On human albinism, Zimmermann-----	825
Studies on the physiology of reproduction, I, Walton-----	826
Fertility in mice, Parkes-----	826
The functional ability of transplanted ovaries in rats, Wiesner-----	827

## FIELD CROPS

Limitations in Student's method with field experiments, Salmon-----	827
Handbook of breeding of agricultural plants, Fruwirth-----	827
Experiments with cereals at Akron 1908 to 1922, Coffman-----	827
Crop rotation and cultural methods at Akron from 1909 to 1923, Brandon---	827
Drill calibration and its relation to stand and yield, Hulbert-----	828
[Field crops experiments in Idaho, 1924]-----	828
[Field crops experiments in Washington], Barbee et al-----	829
[Agronomic] work done under the economic botanist for 1922-23, Burns---	830
Simple contrivances for studying root development, Venkatraman-----	830
Seed of root crops produced in 1923 and its market, Lunden-----	830
The grasses and fodder plants of New South Wales, Breakwell-----	830
Characteristics and green manure value of 60 new legumes, Keuchenius---	830
Experiments with growing hard-coated leguminous seeds in soil, Witte---	831
New American Meibomias, Blake-----	831
Alfalfa for Vermont, Van Alstine-----	831
Altaswede red clover, Cutler and Buckley-----	831
"Hard seeds" and broken seedlings in red clover, Nelson-----	831
White clover ( <i>Trifolium repens</i> L.), Erith-----	832
Check-row planting of maize, Mundy-----	832
Cotton growing in Salvador, Choussy-----	832
Oats: Their varieties and characteristics, Hunter-----	832
Variations in varieties of canning peas, Hall-----	832
Canning peas-----	832
Anatomy, embryology, and ecology of <i>Arachis hypogea</i> , Reed-----	832
[Fourth and fifth annual reports] of the Nebraska Potato Improvement Association, edited by Werner and Morrow-----	833
Rice, Main-----	833
Rice in Egypt, Anhoury-----	833
Different varieties of rye as nurse crops in seeding meadows, Witte---	833
The injurious after-effects of sorghum, Breazeale-----	834
The sugar beet industry, Geddes-----	834
Sugar beets in Minnesota, McGinnis-----	834
Tests with sugar beets, Down-----	834
Seed production in beets during the first year, Munerati-----	834
Effect of increased sodium nitrate on sugar beets, Urban and Souček---	834

	Page
"Light and air" in cane cultivation, Rosenfeld.....	835
Nature and measurement of frost resistance in winter wheat, Newton.....	835
Baking qualities of Mesopotamian wheat.....	835
Growing registered seed in Alberta, Cutler and Fryer.....	836
Inspection of agricultural seeds, Proulx et al.....	836

## HORTICULTURE

[Horticultural investigations at the Delaware Station], Detjen.....	836
[Horticultural investigations at the Idaho Station].....	836
Protecting South Carolina from plant diseases and crop pests, Berly.....	836
[Horticultural investigations at the Washington Station].....	837
Growing tomatoes for the canning factory, Brown.....	837
Asexual propagation as an aid to the breeding of rootstocks, Malloch.....	837
Some factors influencing root development, Hatton et al.....	838
A test to determine whether environment has produced different strains of Baldwin, Howe.....	839
Pollination and the sterility problem, Gourley.....	839
Pollination of the sweet cherry, Tufts and Philp.....	839
The nectarine as a future commercial fruit in New York, Wellington.....	840
Raspberry investigations, Grubb.....	840
The tea plant, Schleinkofer.....	840
Second report of the tree protection examining board, Britton et al.....	841
The rose book, edited by Mütze and Schneider.....	841

## FORESTRY

The forests.....	841
Our hardy conifers, edited by Silva Tarouca and Schneider.....	841
Artificial reproduction of redwood ( <i>Sequoia sempervirens</i> ), Metcalf.....	841
Revised volumé tables for redwood, Bruce and Schumacher.....	841
Growth and its relation to thinning mixed hardwood stands, Guise.....	841
Relation of source of <i>Quercus pedunculata</i> acorns to growth, Cieslar.....	842
Relative water-holding capacity of sphagnum and tree moss, Kummel.....	842
Grazing cattle and horses in pine plantations, Stickle and Hawley.....	842
Report of the National Forest Reservation Commission for 1923.....	842
Forestry [at the Idaho Station].....	842
Second report on a forest survey of Illinois, Chapman and Miller.....	843
Report of director of forestry of Philippine Islands for 1923, Fischer.....	843
Forest administration in the Province of Assam, Trafford and Rivaz.....	843
Report of the Forestry Department [Uganda] for 1923, Fyffe.....	843
Report of the director of forests for 1923, Swain.....	843

## DISEASES OF PLANTS

Department of plant pathology and soil bacteriology, Manns and Adams.....	843
Plant pathology.....	844
[Report of Washington Station] division of plant pathology, Heald et al.....	844
Report of the Dominion botanist for the year 1922, Güssow et al.....	845
Report of the Dominion botanist for the year 1923, Güssow et al.....	845
Silver-leaf disease, IV, Brooks and Storey.....	846
A bacterial leafspot of Martynia, Elliott.....	846
Time of maturation of wheat and <i>Puccinia graminis</i> , Beauverie.....	846
Onion scale pigmentation and disease resistance, Walker and Lindegren.....	846
A serious potato disease, Crépin.....	847
Potato dartrose in 1922, Foex.....	847
Dartrose and silver scab of potato tubers, Crépin.....	847
Potato wilt and filosity, Perret.....	847
Darose of potato and its consequences, Cavadas.....	847
The biology of <i>Vermiculari varians</i> , Cavadas.....	847
Tolerance and resistance to sugar cane mosaic, Edgerton and Taggart.....	847
Tests of fungicides on apple trees, II, Grubb.....	848
Monilia blossom blight (brown rot) of apricots, Rudolph.....	848
Mildew control during 1921, Faes, Tonduz, and Staehelin.....	848
[Contributions to the study of grape white rot], Faes and Staehelin.....	849
Fungous and non-infectious troubles of ornamental trees, Clinton.....	849
The diagnosis of decay in wood, Hubert.....	849

## ECONOMIC ZOOLOGY—ENTOMOLOGY

	Page
Some further facts relative to nicotine dust, Headlee and Rudolfs.....	849
Sodium fluoride as an insecticide, Ripley.....	850
Spray stimulation, Herbert.....	850
Entomology [at the Idaho Station].....	851
[Report of Washington Station] division of entomology, Melander et al.....	851
Proceedings of the Acadian Entomological Society for 1923.....	852
Insect collecting in Panama, Fulliaway.....	852
Work of the division of entomology, Jarvis.....	853
Report by the Government entomologist, Simmonds.....	853
Orchard insects and their control, Faure.....	853
Insect pests and diseases of the Satsuma orange, Dozier.....	853
The insect pests of citrus trees in Egypt, Hall.....	853
Insect pests of cranberries, Crowley.....	853
Some insects attacking shade trees in Connecticut, Britton.....	854
Ants, bees, and wasps: Their lives, comedies, and tragedies, Ash.....	854
A new grasshopper damaging coconut palms in New Britain, Uvarov.....	854
On a new injurious thrips affecting tea in India, Bagnall.....	854
On a new cixiid attacking coconut palms (Homopt.), Muir.....	854
Fumigation with hydrogen cyanide for control of pear psylla, Webster.....	854
The correct names of leafhoppers infesting apple and potato, Ball.....	855
Notes on the biology of <i>Pseudococcus gahani</i> Green, Williams.....	855
Present status of citrophilus mealybug in southern California, Armitage.....	855
The European corn borer and the latest methods of control, Caesar.....	855
The life-history and habits of <i>Tortrix pronubana</i> Hb., Fisher.....	855
South African trypaneid Diptera in the South African Museum, Bezzi.....	855
Further notes on the Ethiopian fruit-flies, with keys, Bezzi.....	855
International conference on the control of the olive fly.....	856
<i>Oscinella frit</i> Linn.: An investigation to determine how far varietal differences may influence infestation of oat plant, Cunliffe and Fryer.....	856
Certain aspects of the damage to oats by the frit fly, Fryer and Collin.....	856
The biology of <i>Anomala kansana</i> , Hayes and McColloch.....	856
Simple methods of rearing wireworms (Elateridae), Lane.....	856
Use of calcium cyanide as a soil fumigant for wireworms, Campbell.....	856
Life-history studies of the tobacco flea-beetle in the southern cigar-wraper district, Chamberlin and Tenhet.....	856
The tulle billbug, Turner.....	857
Poisoning boll weevil in Piedmont section of South Carolina, Nickels.....	857
The apple bud weevil, <i>Anthonomus cinctus</i> , Petherbridge and Cowland.....	858
The lesser clover weevil, Underhill.....	858
Effect of weevily seed beans on the bean crop and the dissemination of weevils, <i>Bruchus obtectus</i> Say and <i>B. quadrimaculatus</i> Fab., Larson.....	858
Forty-fourth report of the Beekeepers' Association of Ontario, 1923.....	858
Bee-keeping for beginners, Jackson.....	859
Beekeeping in Wisconsin, Hambleton.....	859
New parasitic Hymenoptera of the subfamily Anteoninae, Fenton.....	859
A new chalcid attacking bamboo in India (Hymenoptera), Waterston.....	859
Preparation and use of colloidal sulfur for red spider, De Ong.....	859
Some parasitic round worms of the rabbit, Chandler.....	859

## FOODS—HUMAN NUTRITION

The relation of arginine and histidine to growth, Rose and Cox.....	859
Influence of sodium chloride on level of blood uric acid, Harding et al.....	860
The urine sugar and its relation to the blood sugar, Host.....	860
The type of sugar excreted in the urine of normal persons, Tallerman.....	861
Intestinal chemistry, I, II, Bergeim.....	862
Fat-soluble vitamins, XVII, Steenbock and Black.....	862
Alimentary equilibrium.—Maintenance of the pigeon on a ration totally deprived of vitamin B, Randoin and Simonnet.....	863
The antiscorbutic value of fresh and canned English tomatoes, Delf.....	863
The nutritive properties of milk, III, Mattill et al.....	864
The experimental feeding of dried breast milk, Smith.....	864
Muscular efficiency of patients with diabetes mellitus, Fitz and Murphy.....	865
The treatment of diabetes with insulin, Sansum et al.....	865

## ANIMAL PRODUCTION

Page

The formulation of methods of experimentation, Forbes, Grindley, et al.	865
The feeding of productive farm animals, Klimmer	866
Nutritive value of wheat, St. John	866
Stage of maturity of sunflowers for ensilage	866
Trench silo	866
Inspection of commercial feedstuffs, Smith, Kokoski, et al.	866
Feeding stuffs report, 1923, Keilogg	866
Studies of the thyroid apparatus, XI, Hammett	866
Studies of the thyroid apparatus, XIII-XV, Hammett	867
How animals use their time on pasture, Ellingbø	868
Nutritive properties of pinto beans and straw for cattle, Titus	868
Prickly pear as a fodder for cattle	869
Steer feeding [at the Caldwell Substation]	869
Steer feeding experiment, 1922-23	869
Steer-feeding experiment	870
Herd management [at the Washington Station], Hackedorn and Sotola	870
Effect of exercise and feed on breeding ability of bulls, Ellington	870
The Southdown sheep, edited by Walford-Lloyd	870
Sheep raising in Minnesota, Anderson	870
Observations on range sheep management in New Mexico, Moles et al.	870
Relation of sheep to climate, Johnson	870
Lambs and wool for market, Carmichael	870
Lamb feeding [experiments at the Caldwell Substation]	871
Fat lamb raising	871
Experiments with crossbred Charmoise×Limousin lambs, Voitellier	871
Recent progress in the wool industries, Barker	871
The Australasian wool trade, season 1923-1924, Dalgety & Co. Ltd.	871
[Swine feeding experiments at the Delaware Station], Tomhave	871
Studies in swine nutrition	872
Swine investigations [at the Washington Station], Smith	872
Pig feeding experiments	873
[Swine feeding experiments]	873
Concerning the question of raising barrows, Krestov	874
Selection, care, and management of the boar, Knox	874
The feeding of young horses after weaning, Leroy	874
Stallion enrollment.—XIII, Report for 1924	874
[Experiments with poultry at the Idaho Station]	874
A study of the relative values of certain succulent feeds and alfalfa meal as sources of vitamin A for poultry, Davis and Beach	875
The fattening of immature cockerels, Louch	876
Commercial poultry farming, Toovey	876
British poultry and poultry keeping, Lewer	876
The production of rabbits, Bagué	876

## DAIRY FARMING—DAIRYING

[Dairy cattle experiments at the Idaho Station]	876
A study of the transmitting qualities of Holstein-Friesian dams, Baker	877
Dairying in Kansas, Mohler et al.	877
Swiss bovine breeds	877
The influence of pasteurization and diet of the cow on the anti-scorbutic potency of milk, Olson and Copeland	877
Relation between diet, blood, and milk of dairy cows, Cary and Meigs	877
The relation between feed consumption and milk secretion, Turner	878
Feed cost of milk production as affected by the fat content, Gaines	878
The official test in the South and the preliminary milking, Brintnall	878
Make the dairy pay, Ball	879
Milking machines.—VIII, Sanitary efficiency of a simplified type, Mickle	879
Enzymatic studies on lactic acid bacteria, I, II, Virtanen	879
The mold associated with the ripening of blue veined cheese, Golding	879
Factors affecting the yield of ice cream, Gregory and Manhart	880
Overrun of ice cream	880
Sandiness in ice cream, Lucas and Spitzer	880
The bacterial content of ice cream, Fay and Olson	880

## VETERINARY MEDICINE

	Page
Pocket handbook of meat inspection, Leighton.....	881
Animal parasites and parasitic diseases, Kaupp.....	881
Report of the Live Stock Sanitary Commission of Texas for 1923-24....	881
Yearly progress made in veterinary medicine, edited by Ellenberger et al.	881
Report of Civil Veterinary Department, Madras, 1923-1924, Aitchison....	881
Report on the Veterinary Department [Gold Coast] for 1924, Beal.....	881
Veterinary prescriptions, Gerosa.....	881
On the toxic action of carbon disulphide; Muto.....	881
[Immunity] .....	882
Anaphylaxis .....	882
[Report of the] division of veterinary science, Kalkus.....	884
Significance of <i>Bacterium abortus</i> antibodies found in the sera of calves at birth or after nursing, Huddleson and Hasley.....	882
Variations in concentration of blood plasma, Howe and Sanderson.....	883
Differentiation of primary isolations of <i>Bacterium melitensis</i> from <i>Bac-</i> <i>terium abortus</i> (bovine), Buck.....	884
Experimental studies on anthrax infection and immunity, Tamiya.....	884
The valuation of malleins, Krüger.....	885
[Proceedings of Eastern States Conferences on Tuberculosis Eradication].	885
The diagnosis of bovine mastitis by milk examination, Sheather.....	885
A study of the blood of normal horses, Nagao.....	885
Corynebacterial pyaemia of foals, Bull.....	885
Equine piroplasmosis in France, Panisset and Verge.....	885
Carbon tetrachloride as an anthelmintic for horses, Blicke and Baudet...	885
The possible use of arecoline hydrobromide as an anthelmintic, Ross...	886
Dr. Little's dog book, Little.....	886
Studies on bacillary white diarrhoea in poultry in Delaware, Baker....	886
Diphtheria of fowls: Its cause, prevention, and cure, Crofton.....	886

## RURAL ENGINEERING

Surface water supply of Snake River basin, 1919-1920.....	886
Report for 1922-23, Irrigation Department, Punjab, Sangster et al.....	886
The "artesian well" as a potential source of danger, Leach.....	886
Effect of temperature upon the friction of water in pipes, Giescke.....	887
Run-off for open ditch land drainage, Ramser.....	887
Physical properties of materials.—I, Metals and wood.....	887
The properties and uses of wood, Koehler.....	887
Utilizing poles and timber in farm building, Amundson.....	887
Foundations, abutments, and footings, Hool and Kinne.....	887
Effects of some nitrogen compounds upon detonation in engines, Boyd...	887
A suggested mechanism for antiknock action, Wendt and Grimm.....	888
Power for the farm from small streams, Daniels et al.....	888
Let the creek light your home, Crane.....	888
Fitting the farm saws, Roehl.....	888
Equipping an orchard spray machine for use in alfalfa fields, Wakeland...	888
Emissive tests of paints, Coblentz and Hughes.....	888
Fighting rust with sublimed blue lead.....	889
Poultry house construction, Leggett.....	889
Illumination of poultry houses for winter egg production, Fairbanks...	889
Poultry equipment made at home, Winton and Boney.....	889
Some fundamentals of the ventilation of animal shelters, Trullinger...	889
Cold storage on the farm, Graham.....	889
Ice-making and cold-storage plants in Australia and New Zealand.....	890
Home conveniences, Ives.....	890
Studies on the biology of sewage disposal, Rudolfs et al.....	890
A survey of 201 privies for intestinal parasites, Boeck.....	891

## RURAL ECONOMICS AND SOCIOLOGY

The problem of business forecasting, edited by Persons et al.....	892
Farm organization in Mason and Fleming Counties, Nicholls et al.....	893
Land settlement and colonization in Great Lakes States, Black and Gray...	893
[Report of Washington Station on] farm management, Severance.....	894
Costs of range cattle production in Texas, Parr and Klemmedson.....	894

	Page
The cost of producing water buffalo milk, Levine and To-----	894
A short system of farm costing, Holmes-----	895
The status of agricultural labor in lower Saxony as compared with that in the region east of the Elbe River, Wagner-----	895
Crops and Markets, [March, 1925]-----	895
Monthly Supplement to Crops and Markets, [March, 1925]-----	895
The trend of agricultural prices in Canada, Michell-----	896
The agricultural depression, Warren-----	896
Preliminary report on agriculture and the farmer-----	896
The economic condition of soviet Russia, Prokopovitch-----	896
Measures for improvement of conditions of the rural family, De Vuyst-----	897
Improvement of the conditions of the rural home, De Vuyst-----	897
Ohio agricultural statistics for 1923, West-----	897
Virginia farm statistics, 1923-----	897
Acreage and yields of agriculture in Austria for the year 1923-----	897
Statistics of milk production for Switzerland for 1923, Peter et al-----	897
Statistics of agricultural and pastoral production, Cousins-----	867

#### AGRICULTURAL EDUCATION

Land-grant college education, 1910 to 1920.—I, History and educational objectives, edited by John-----	898
Agricultural education and research in Scotland, I-IV, M'Callum-----	898
Veterinary education in Scotland, M'Callum-----	898
The laboratory and the teaching of agricultural hydraulics, Conti----- [Rural education]-----	898
Elementary agriculture for southern schools, Robbins and Ireland-----	899
Industrial geography: Production, manufacture, commerce, Whitbeck-----	899
Grain trade documents, Thorpe-----	899

#### MISCELLANEOUS

Annual report of the director for 1924, McCue et al-----	899
Work and progress of the [Idaho] Station for 1924, Iddings-----	899
Report of the Massachusetts Station, [1923], Haskell et al-----	899
Thirty-fourth Report [of Washington Station], 1924, Johnson et al-----	899
Publications available for free distribution-----	899

# LIST OF EXPERIMENT STATION AND DEPARTMENT PUBLICATIONS ABSTRACTED

<i>Stations in the United States</i>	<i>Page</i>	<i>Stations in the United States—Con.</i>	<i>Page</i>
California Station:		Porto Rico Department of Agriculture and Labor Station:	
Bul. 383.....	848	Circ. 76 (Spanish ed.).....	876

- WEATHER BUREAU—C. F. Marvin, *Chief*.  
 BUREAU OF ANIMAL INDUSTRY—J. R. Mohler, *Chief*.  
 BUREAU OF PLANT INDUSTRY—W. A. Taylor, *Chief*.  
 FOREST SERVICE—W. B. Greeley, *Forester*.  
 BUREAU OF CHEMISTRY—C. A. Browne, *Chief*.  
 BUREAU OF SOILS—Milton Whitney, *Chief*.  
 BUREAU OF ENTOMOLOGY—L. O. Howard, *Entomologist*.  
 BUREAU OF BIOLOGICAL SURVEY—E. W. Nelson, *Chief*.  
 BUREAU OF PUBLIC ROADS—T. H. MacDonald, *Chief*.  
 BUREAU OF AGRICULTURAL ECONOMICS—H. C. Taylor, *Chief*.  
 BUREAU OF HOME ECONOMICS—Louise Stanley, *Chief*.  
 BUREAU OF DAIRYING—C. W. Larson, *Chief*.  
 FIXED NITROGEN RESEARCH LABORATORY—F. G. Cottrell, *Director*.

OFFICE OF EXPERIMENT STATIONS—E. W. Allen, *Chief*.

## THE AGRICULTURAL EXPERIMENT STATIONS

### ALABAMA—

- College Station: *Auburn*; M. J. Funchess.<sup>1</sup>  
 Canebrake Station: *Uniontown*; W. A. Cammack.<sup>1</sup>  
 Tuskegee Station: *Tuskegee Institute*; G. W. Carver.<sup>1</sup>

### ALASKA—*Sitka*: C. C. Georgeson.<sup>1</sup>

### ARIZONA—*Tucson*: J. J. Thornber.<sup>1</sup>

### ARKANSAS—*Fayetteville*: D. T. Gray.<sup>1</sup>

### CALIFORNIA—*Berkeley*: E. D. Merrill.<sup>1</sup>

### COLORADO—*Fort Collins*: C. P. Gillette.<sup>1</sup>

### CONNECTICUT—

- State Station: *New Haven*; } W. L. Slate, jr.<sup>1</sup>  
 Storrs Station: *Storrs*; }

### DELAWARE—*Newark*: C. A. McCue.<sup>1</sup>

### FLORIDA—*Gainesville*: W. Newell.<sup>1</sup>

### GEORGIA—

- Experiment*: H. P. Stuckey.<sup>1</sup>  
*Tifton*: Coastal Plains Station; S. H. Starr.

### GUAM—*Island of Guam*: C. W. Edwards.<sup>1</sup>

### HAWAII—

- Federal Station: *Honolulu*; J. M. Westgate.<sup>1</sup>  
 Sugar Planters' Station: *Honolulu*; H. P. Agee.<sup>1</sup>

### IDAHO—*Moscow*: E. J. Iddings.<sup>1</sup>

### ILLINOIS—*Urbana*: H. W. Mumford.<sup>1</sup>

### INDIANA—*La Fayette*: G. I. Christie.<sup>1</sup>

### IOWA—*Ames*: C. F. Curtiss.<sup>1</sup>

### KANSAS—*Manhattan*: F. D. Farrell.<sup>1</sup>

### KENTUCKY—*Lexington*: T. P. Cooper.<sup>1</sup>

### LOUISIANA—

- State Station: *Baton Rouge*; }  
 Sugar Station: *Baton Rouge*; }  
 North La. Station: *W. R. Dodson*.<sup>1</sup>  
*Calhoun*;  
 Rice Station: *Crowley*;  
 Fruit and Truck Station: *Hammond*;

### MAINE—*Orono*: W. J. Morse.<sup>1</sup>

### MARYLAND—*College Park*: H. J. Patterson.<sup>1</sup>

### MASSACHUSETTS—*Amherst*: S. B. Haskell.<sup>1</sup>

### MICHIGAN—*East Lansing*: R. S. Shaw.<sup>1</sup>

### MINNESOTA—*University Farm, St. Paul*: W. C. Coffey.<sup>1</sup>

### MISSISSIPPI—*A. and M. College*: J. R. Ricks.<sup>1</sup>

### MISSOURI—

- College Station: *Columbia*; F. B. Mumford.<sup>1</sup>  
 Fruit Station: *Mountain Grove*: F. W. Faurot.<sup>1</sup>  
 Poultry Station: *Mountain Grove*; T. W. Noland.<sup>1</sup>

### MONTANA—*Bozeman*: F. B. Linfield.<sup>1</sup>

### NEBRASKA—*Lincoln*: E. A. Burnett.<sup>1</sup>

### NEVADA—*Reno*: S. B. Doten.<sup>1</sup>

### NEW HAMPSHIRE—*Durham*: J. C. Kendall.<sup>1</sup>

### NEW JERSEY—*New Brunswick*: J. G. Lipman.<sup>1</sup>

### NEW MEXICO—*State College*: Fabian Garcia.<sup>1</sup>

### NEW YORK—

- State Station: *Geneva*; } B. W. Thatcher.<sup>1</sup>  
 Cornell Station: *Ithaca*; }

### NORTH CAROLINA—*Raleigh*: B. W. Kilgore.<sup>1</sup>

### NORTH DAKOTA—*Agricultural College*: P. F. Trowbridge.<sup>1</sup>

### OHIO—*Wooster*: C. G. Williams.<sup>1</sup>

### OKLAHOMA—*Stillwater*: C. T. Dowell.<sup>1</sup>

### OREGON—*Corvallis*: J. T. Jardine.<sup>1</sup>

### PENNSYLVANIA—

- State College*: R. L. Watts.<sup>1</sup>  
*State College*: Institute of Animal Nutrition;  
 E. B. Forbes.<sup>1</sup>

### PORTO RICO—

- Federal Station: *Mayaguez*; D. W. May.<sup>1</sup>  
 Insular Station: *Rio Piedras*; R. M. Ramos.<sup>1</sup>

### RHODE ISLAND—*Kingston*; B. L. Hartwell.<sup>1</sup>

### SOUTH CAROLINA—*Clemson College*: H. W. Barre.<sup>1</sup>

### SOUTH DAKOTA—*Brookings*: J. W. Wilson.<sup>1</sup>

### TENNESSEE—*Knoxville*: C. A. Mooers.<sup>1</sup>

### TEXAS—*College Station*: B. Youngblood.<sup>1</sup>

### UTAH—*Logan*: William Peterson.<sup>1</sup>

### VERMONT—*Burlington*: J. L. Hills.<sup>1</sup>

### VIRGINIA—

- Blacksburg*: A. W. Drinkard, jr.<sup>1</sup>  
*Norfolk*: Truck Station; T. C. Johnson.<sup>1</sup>

### VIRGIN ISLANDS—*St. Croix*: J. B. Thompson.<sup>1</sup>

### WASHINGTON—

- College Station: *Pullman*; E. C. Johnson.<sup>1</sup>  
 Western Station: *Puyallup*; W. A. Linklater.<sup>1</sup>

### WEST VIRGINIA—*Morgantown*: H. G. Knight.<sup>1</sup>

### WISCONSIN—*Madison*: H. L. Russell.<sup>1</sup>

### WYOMING—*Laramie*: J. A. Hill.<sup>1</sup>

<sup>1</sup> Director.

<sup>1</sup> Superintendent.
