SINCE the sixth edition of this standard volume of tables was reviewed in NATURE for July 5, 1915, extensive changes have been made, in the form of new data on both new and old topics. The volume has grown to 450 pages, and the number of tables given from 409 to 579. The new tables include useful material dealing with astrophysics, meteorology, geochemistry, atomic and molecular data, colloids, photography, etc. A great improvement is the renumbering of the pages; in the sixth and fifth editions new matter was inserted without altering the paging, with the result that there was no logical sequence of tables. This fault has now been rectified, and the tables have been arranged in order according to subject. The volume can be obtained from the London agents for the Smithsonian Institution, Messrs. W. Wesley and Son, 28 Essex Street, Strand, W.C.2.

Letters to the Editor.

The Late Srinivasa Ramanujan.

IN the notice contributed to the issue of NATURE for June 17 last, Prof. Hardy was unable to give any account of the late Srinivasa Ramanujan's early life, and made no attempt to describe his appearance or character. The June number of the Journal of the Indian Mathematical Society has memorial articles by Prof. P. V. Seshu Aiyar, of Madras, and Dewan Bahadur Ramachandra Rao, and the first of these gives biographical details that have not hitherto been published in England.

Ramanujan was born at Erode on December 22, 1887.[1] His mother, a shrewd and cultured lady who is still alive, was the daughter of a Government official at Erode, his father a cloth-merchants' accountant at Kumbakonam, and it was in the latter town that his boyhood was spent. As is usual with Brahmin boys, he was sent to school at the age of five; before he was seven he was transferred to the Town High School, and there he remained until 1904, leading an inactive life and building an astounding edifice of analytical knowledge and discovery on the foundation of Carr's "Synopsis of Pure Mathematics," the only book on higher mathematics to which he had access. Having matriculated already in 1903, he went from the Town School to the Government College at Kumbakonam, but in January, 1905, his progress was stopped, and a scholarship on which he was dependent forfeited, owing to a weakness in English of which those who recall his fluency and the range of his vocabulary in later life will be surprised to learn.

Of Ramanujan's next few years no clear account has come to my notice. After a stay at Vizagapatam, he joined the Pachaiyappa's College at Madras, but, failing in his first examination, he gave up the idea of taking a university course. A nomadic period, during which his own researches progressed, came to an end in the summer of 1909, when he married and returned to Madras in search of permanent employment. There Prof. Seshu Aiyar, who had seen something of him at Kumbakonam in 1904, gave him a letter of introduction to Mr. Ramachandra Rao, at that time district collector at Nellore. Possibly Ramanujan was too timid to make direct use of the letter; Mr. Rao's story follows in his own words:—

"Several years ago, a nephew of mine, perfectly innocent of mathematical knowledge, spoke to me: 'Uncle, I have a visitor who talks of mathematics. I do not understand him. Can you see if there is anything in his talk?' And in the plenitude of my mathematical wisdom, I condescended to permit Ramanujan to walk into my presence. A short, uncouth figure, stout, unshaved, not over-clean, with one conspicuous feature—shining eyes—walked in, with a frayed note-book under his arm. . . . He was miserably poor. He had run away from Kumbakonam to get leisure in Madras to pursue his studies. He never craved for any distinction. He wanted leisure; in other words, simple food to be provided for him without exertion on his part, and that he should be allowed to dream on.

"He opened his note-book and began to explain some of his discoveries. I saw quite at once that there was something out of the way, but my knowledge did not permit me to judge whether he talked sense or nonsense. Suspending judgment, I asked him to come over again. And he did. And then he had gauged my ignorance and showed me some of his simpler results. These transcended existing books, and I had no doubt that he was a remarkable man. Then step by step he led me to elliptic integrals, and hypergeometric series, and at last his theory of divergent series, not yet announced to the world, converted me. I asked him what he wanted. He said he just wanted a pittance to live on so that he might pursue his researches. It is a matter of considerable pride to me that I was in some way useful to this remarkable genius in his earlier days. In a year's time, I introduced him to Sir Francis Spring (the president of the Madras Port Trust), who gave him a sinecure post in his office."

The last two sentences conceal that, throughout the interval of a year, not only was Mr. Rao trying to find some scholarship for which Ramanujan's original work might qualify him in spite of failure in examinations, but he was also maintaining Ramanujan in Madras at his own expense.

At the Port Trust Ramanujan remained until Dr. G. T. Walker, on an official visit to Madras, was made acquainted with his history, and joined forces with Sir Francis Spring. Their combined attack on the University and the Government of Madras resulted in the creation of a research studentship, which was of sufficient value to set him wholly free, and secured him access to the lectures and the library of the university; he was in possession of this studentship when I met him in 1914.

To Prof. Hardy's account of his correspondence and my intervention I have little to add. My task was an easier one than I anticipated. From the Government and the University of Madras I had every encouragement. On the other hand, Ramanujan was ready to put complete confidence in me simply because to him and his friends I came from outside the official machine. The only cold water was thrown

[1] This is the year given by Seshu Aiyar, and the date is consistent with the undisputed statements that Ramanujan was twenty-six when he came to England and thirty-two when he died; I have no doubt that the date 1888 commonly given is due to a natural misinference from these last figures.

from the India Office in London, but my efforts had succeeded before this reached Madras.

Throughout his life Ramanujan kept religiously to a diet of vegetables, fruit, and rice, and in England, outside his own rooms, food and clothing were a continual trial to him. I have known him ask with unaffected apologies if he might make his meal of bread and jam because the vegetables offered to him were novel and unpalatable, and with a pathetic confidence he has appealed to me for advice under the discomforts of shoes and trousers. His figure was short, and until his health gave way it was stout. His skin, never of the darkest, grew paler during his stay in England. His head gave the impression, which photographs show to have been false, of broadening below the ears, which were small. His face was clean-shaven, with a broad nose and a high forehead, and always his shining eyes were the conspicuous feature that Mr. Rao observed them to be in 1910.

Ramanujan walked stiffly, with head erect, and his arms, unless he was talking, held clear of his body, with hands open and palms downward. In conversation he became animated, and gesticulated vividly with his slender fingers. He had a fund of stories, and such was his enjoyment in telling a joke that often his words struggled incomprehensible through the laughter with which he anticipated the climax of a narrative. He had serious interests outside mathematics; he was always ready to discuss whatever in philosophy or politics had last caught his attention, and Indians speak with admiration of a mysticism of which his English friends understood little.

Perfect in manners, simple in manner, resigned in trouble and unspoilt by renown, grateful to a fault and devoted beyond measure to his friends, Ramanujan was a lovable man as well as a great mathematician. By his death I have suffered a personal loss, but I do not feel that his coming to England is to be regretted even for his own sake. Prof. Hardy speaks of disaster because of the hopes he entertained. If he pictures Ramanujan as he might have been throughout a long life, tormented by a lonely genius, unable to establish effective contact with any mathematicians of his own class, wasted in the study of problems elsewhere solved, Prof. Hardy must agree that the tragedy averted was the greater. Shortly before he left England, at a time of great depression, Ramanujan told me that he never doubted that he did well to come, and I believe that he would have chosen as he did in Madras in 1914 even had he known that the choice was the choice of Achilles.

University College, Reading, December 7.

The Mechanics of Solidity.

THE letters under this title from Mr. R. G. Durrant, Mr. V. T. Saunders, and Dr. H. S. Allen (NATURE, December 2 and 23 and January 6) are very interesting and suggestive, but melting points are of little value in discriminating between the hard and soft varieties of the same steel, and molecular weights, volumes, and frequencies have not yet any very definite significance in relation to solid metallic mixtures. My initial proposal that certain simple measurements might with advantage be substituted for the complicated tests now used by engineers and metallurgists was a "practical," if myopic, one; it has evidently been misunderstood, so perhaps I may be allowed to state the case in greater detail.

By "solidity" I meant to imply all the properties covered by the adjectives strong, elastic, stiff, flabby, tough, hard, mild, brittle, and many others. Solidity may eventually be specified in terms of atoms and molecules, but the specification would be very complicated, and I cannot at present "take sanctuary among the atomists"; solidity may be referred to its origins or to its manifestations, and for the moment the latter course seems to be the only practicable one. Solidity may be analysed in various ways, but Hertz has explained the meaning of "strength" very clearly, and it is convenient to take strength as the starting point; solidity seems to comprise elasticity, strength, and something more, namely, the variation of elasticity and strength with deformation. Isotropic solidity appears to be a continuum which fades into fluidity; it would be very desirable to know how many dimensions define this continuum, but the problem of mechanical testing is rather simpler, viz. How many dimensions are important, and what is the best way to measure them?

For the convenience of readers of NATURE who are unfamiliar with current engineering practice I may refer to the recent report of the Steel Research Committee of the Institution of Automobile Engineers; this, of course, is primarily a report on certain metals, but incidentally it serves as a report on the tests employed. The procedure is as follows: Test pieces are cut to three standard shapes and broken under prescribed conditions; four different measurements are made on the first piece and one measurement on the second and third pieces. The second and third tests are each repeated three times, and Brinell measurements are made on all test pieces. The report represents practice of a very high standard, and the foregoing programme is carried out thrice for each of some two hundred mechanical varieties of twenty chemically distinct steels; the report records about ten thousand measurements in all, each of them involving considerable care and labour. I feel sure the committee would endorse my view that in certain tests the concordance of nine individual measurements leaves a great deal to be desired; whatever these tests may determine, they do not determine anything very accurately.

To obviate all possibility of misconception, I should state the proposed alternative plainly. Six simple mechanical properties of a metal—density, two elasticities, and their temperature coefficients—can be measured fairly easily and with some precision; the temperature coefficient of intrinsic energy makes a doubtful seventh. The connection between these properties and practical engineering is admittedly obscure, but in the writer's limited experience this is true also of some of the other tests. None of the six properties referred to are customarily measured, but the single one that is well known—the thermal coefficient of density—bears a decided general resemblance to a strength, the particular strength to which Hertz has appropriated the word "hardness." My suggestion is that these six properties, and possibly others, would be worth investigating, and that some of them may prove convenient indicators of mechanical consistency; they would certainly serve as indicators of uniformity, and it may be doubted whether the other tests do much more.

Both Mr. Durrant and Mr. Saunders refer to the question of definitions, and these are certainly required for many of the attributes of solidity; hardness, however, appears to be an exception, and has been defined by Locke, Hertz, and Clerk-Maxwell. A definition established in the seventeenth century and supported by such high authorities cannot lightly be set aside; it seems that Mr. Saunders is right, and that "Brinell hardness" is not hardness. Verbal difficulties of this kind beget confusion, but, as Locke says: "Vague and insignificant forms of speech and abuse of language have so long passed for mysteries of science; and hard and misapplied words, with little or no meaning, have, by prescription, such a right to be mistaken for deep learning and height of speculation, that it will not be easy to persuade, either those who speak or those who hear them, that they are but the covers of ignorance and hindrance of true knowledge." J. INNES.

Stellar Development in Relation to Michelson's Measurement of the Diameter of Betelgeux.

ABOUT thirty-five years ago Sir Norman Lockyer held that certain of the reddish stars are probably in an early stage of development. It was given out yesterday in Press dispatches from Chicago that Prof. Michelson had announced to the American Physical Society and the American Association for the Advancement of Science that the experiments with the Mount Wilson 8-ft. reflector at Pasadena, California, had enabled him successfully to measure the diameter of α Orionis by interference methods, and that the diameter is about 300,000,000 miles, or approximately three hundred times that of our sun. The volume of Betelgeux is therefore about 27,000,000 times that of the sun; so that, if concentric with the sun, the surface of Betelgeux would extend about to the orbit of Venus.

Now Betelgeux is a single star, and the mass, therefore, is not definitely known; yet if the mass be not immensely larger than that of the sun we shall have to conclude that the density is slight. Hence this red star is in an early stage of development, which confirms Lockyer's views first put forth about 1886. If we make the density equal to that of our sun, Betelgeux could not fill the orbit of Venus without giving the star 27,000,000 times the solar mass, which is quite inadmissible.

Dr. Elkin's Cape heliometer measures made the parallax of Betelgeux 0·023″ and of Sirius 0·37″, so that Betelgeux is only sixteen times more remote than Sirius; and if we neglect a slight difference in magnitude, largely due to colour, we may conclude that Betelgeux gives about 256 times the radiation of Sirius, which is itself ten-thousandfold more luminous than our sun. Accordingly, Betelgeux gives about 2,560,000 times the sun's light. Now with any admissible mass of Betelgeux this immense luminosity indicates an early stage of development, corresponding to the large absolute diameter found by Michelson. T. J. J. SEE.

Heredity and Variation.

IN a brief criticism of Sir Archdall Reid's letter to NATURE (November 25, p. 405) in which he sought to attach new meanings to certain well-recognised biological terms, I pointed out (NATURE, December 2, p. 440) that if his contention that all characters are both innate and acquired in exactly the same sense and degree is true, then it would follow that all variations are also of one type, while experimental biologists are universally agreed that this is not the case. At least two categories of variations are postulated, whether they be called blastogenic and somatogenic, germinal and somatic, mutations and fluctuations, genotypes and phenotypes, innate and acquired, karyogenetic and cytogenetic, or by any other terms which contrast an inherited and a non-inherited departure from the parental type.

Yet Sir Archdall Reid's only attempt to answer my criticism—that the universally admitted existence of two types of variations undermines his whole position—is the very weak one of quoting Darwin's tentative theory of pangenesis, which no modern biologist would consider seriously as an explanation of heredity, variation, or anything else. He says (NATURE, January 6, p. 596): "If we believe with Darwin in his theory of pangenesis that the parts of the child are derived from the similar parts of the parent . . . the distinction between variations and modifications vanishes." But we do not believe anything of the kind. The advance of knowledge made any such belief impossible a generation ago. Even Sir Archdall Reid himself admits this when he says later in the same letter (p. 598) that "Darwin . . . went hopelessly wrong . . . in his theory of pangenesis"! Why, then, did he quote it as a reply to my criticism?

This is only one, but it appears to me to be the most fundamental, of the many contradictions in which Sir Archdall Reid has landed himself in his attempt to remodel the usage of well-established terms to his own liking. R. RUGGLES GATES.

King's College, Strand, W.C.2, January 15.

The Mild Weather.

A SPELL of mild weather set in shortly before Christmas and continued until the second week of January. It followed a sharp touch of frost, when the sheltered thermometer at Greenwich registered 16° on December 13, and for two consecutive days, December 12 and 13, the temperature remained below the freezing point, whilst for ten consecutive days the thermometer did not rise to 40°. A few facts relative to the mild spell may be of interest.

Greenwich temperatures are used throughout; they refer to the civil day, commencing at midnight, and naturally differ at times from the ordinary meteorological day readings ending at some hour between 7 and 9 a.m. The results used are absolutely comparable.

The period dealt with is from December 21 to January 10, twenty-one consecutive days. This period for 1920–21 was warmer than any corresponding period in the last eighty years—since 1841. The mean maximum temperature, the mean minimum temperature, and the mean temperature obtained from the mean of maximum and minimum were all the highest. These three readings for the 21-day period in 1920–21 are: 52·0°, 43·4°, and 47·7° F. The next highest means, for 1872–73, are 51·2°, 42·8°, and 47·0°, followed by 1915–16 with 50·9°, 41·9°, and 46·4°, and by 1852–53 with 51·3°, 40·7°, and 46·0°.

Dealing with the first ten days of January this year, they are the warmest on record for this period for eighty years, with the mean (mean maximum and minimum) 47·8°, followed by 1873 and 1916 with 46·8°, and by 1853 with 46·0°.

Considering the days with a temperature of 50° or above for the 21-day period, December 21 to January 10, there were 17 days in 1852–53, 15 in 1872–73, 14 in 1920–21, and 13 in 1876–77. The absolute maximum temperature in the recent warm period rose to 56° on three days, and in the past there has been no temperature higher than 57°.

The mild weather we have just passed through had ten nights with the minimum temperature at 45° or above, which is more than in any corresponding period since 1841, and in all there were previously only two periods with more than five such warm nights.

The mean temperature for the twenty-one days to January 10 this year is about 10° warmer than the normal. CHAS. HARDING.

Nature of Vowel Sounds.

By Prof. E. W. Scripture.

II.

In a preceding paper (Nature, January 13, p. 632) it was explained that the analysis of vowel curves showed (1) that the fundamental, or voice tone, must consist of a series of puffs, and not of smooth vibrations; and (2) that the overtones, or the specific vowel tones, must be quite independent of the fundamental—that is, they can just as well be inharmonic as harmonic to it.

The Manufacture of Vowels.

For the manufacture of vowels Helmholtz used tuning-forks that gave smooth vibrations and not puffs; moreover, the only overtones tried were harmonic to the fundamental. Some years ago I made an attempt to manufacture vowels on the principles discovered by the analysis of vowel curves.

The fundamental was produced by a puff siren (Fig. 7) similar to the familiar one of Seebeck.

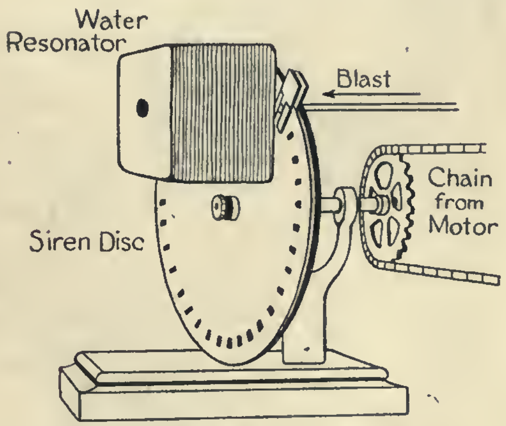

Fig. 7.—Puff siren with water resonator.

As a slit passes across the blast tube a jet of air issues for an instant. This is heard as a faint puff. As the disc is rotated more rapidly the puffs come oftener, until at one region a low tone appears. With still greater rapidity the pitch of the tone rises.

When a brass resonator is placed in front of the tube of the siren it sounds loudly when the frequency of the puffs is the same as that of the tone of the resonator, and also less loudly when it is in some other harmonic relation. For inharmonic relations the resonator is silent. Resonators with hard wells, therefore, cannot be used to produce sounds containing inharmonic components.

The soft-walled resonators of the mouth can be imitated by spreading pieces of meat over wire frames. As this has its inconveniences, a wire frame may be covered with a layer of absorbent cotton soaked in water. Such a resonator is shown in Fig. 7. The walls are quite inelastic. When such a water resonator is placed in front of the tube of the siren, it responds equally well to all tones of the siren, whether harmonic or inharmonic. Two or more resonators can be combined to meet the requirements for various vowels.

The theory of this vowel siren can be illustrated by the diagrams in Fig. 8. The puffs come as sharp blows almost instantaneous in character; they are indicated by the crosses. When such a blow strikes a resonator with soft walls, it arouses a vibration in the cavity that dies away very rapidly, as is indicated in the first line of the figure. The vibration is entirely gone before the next puff hits it. The response of the resonator is quite independent of the frequency of the puff. When, however, a puff strikes a resonator with hard walls, it arouses a vibration that dies away

Fig. 8.—Vibrations in a resonator in response to puffs. The puffs are indicated by the crosses. The first line shows the response of a resonator with soft walls. In the second line the puffs hit a resonator with hard walls in such a way as to maintain strong vibrations. In the third line the puffs hit the same resonator in a way to produce little or no effect.

very slowly. When the next puff comes, the result depends on its relation to the vibration still going on in the cavity. If the puff hits the resonator at a moment when its frequency would be a sub-multiple of the frequency of the resonator, then it will reinforce the vibration and make the resonator tone louder. This is illustrated in the second line of the figure. If, on the other hand, it hits the resonator at a moment one-half a period short of a harmonic relation, it will kill the vibration it finds. A very weak tone may be aroused by puffs with a frequency that is not a sub-multiple of the frequency of the resonator, but no strong response can be obtained outside the harmonic relation.

The siren with water resonators was constructed with the aid of the Hodgkins fund of the Smithsonian Institution of Washington. It produced most of the typical vowels with success. Under the Carnegie Institution the work was continued with an attempt to imitate more closely the conditions in the living body. Although the cheeks can be represented by water resonators, the roof of the tongue is somewhat more difficult; the roof of the mouth is quite an approach to a hard resonator. To imitate these conditions, a resonator was made of a skull supplied with cheeks and a tongue of gelatine. The tongue was removable, so that models of different forms could be inserted. The voice tone was obtained from a vox humana organ-pipe. The ultimate object was to find vowel resonators that would respond with specific vowels to any tone. These were then to be mounted on a reed organ as an extra register. All tones issuing from the organ could be made to pass through one of the vowel cavities, and the organ would thus sing the vowels. In most singing the consonants are a subordinate matter, and such an organ would aid the singing of a choir or a congregation. The beauty of such a vowel register in a large organ in a cathedral is quite beyond imagination. This investigation was also supported by the Hodgkins fund, but was discontinued on account of the work required for the study of speech curves.

The Structure of Vowels.

The study of speech curves and the making of vowel-producing instruments show that two groups of elements are to be found in a vowel.

The first is the voice tone. Three properties of this tone are to be considered. The pitch of the tone is given by the rapidity with which the laryngeal puffs are repeated. If V indicates the number of puffs per second, then $V=f(t)$ is the general expression of the fact that the pitch of the voice tone depends on the elapsed time. It might be supposed that, in singing a vowel on a given note, the pitch would remain constant. A study of a record by the tenor Caruso (not yet published) shows that he never keeps his voice on a constant pitch during a vowel, but makes continual small changes. A study of the vowel "oh" used as an interjection shows that the pitch of the voice tone changes to express the emotion and the meaning of the interjection according as it is spoken to express sadness, admiration, or doubt. In fact, it is quite possible to obtain an equation for V for each of the three cases. In ordinary speech the pitch of the voice tone changes from instant to instant. Every individual vowel has a melody of its own. This melody varies with the emotion, the meaning, and possibly other factors.

The intensity of the voice tone depends on the energy of the puffs from the larynx. If I indicates the puff energy, then $I=f(t)$ expresses the fact that the intensity varies from moment to moment. The speech curves show changes of intensity that express emotion and meaning. Even in song—as Caruso's curves show—the intensity is constantly varied in a way that makes his song a production of art, and not a mechanical performance.

The third factor of this group is the musical character of the voice tone. This depends on the *shape* of the puff from the larynx. The matter is of such importance that the following statement seems to be needed.

After a tuning-fork has been struck its vibrations slowly die away. Its curve is really not that of a simple sinusoid, but that of a frictional sinusoid

$$y=a.e^{-\epsilon\frac{2\pi}{T}t}, \quad \ldots \quad (1)$$

where y is the elongation at the moment t, a the amplitude or maximum elongation, T the period, e the basis of the natural system of logarithms, and ϵ the factor of friction or damping. The period T is affected by the factor of friction, but the amount is so small that it can be neglected here. The effect is to cause a decrease in the amplitude. When the value of ϵ is great, the curve is that of a sharp puff. When it is less, the puff is more gentle. If it were 0, the ordinary simple sinusoid would be obtained.

The puff from the larynx may be of a complicated form that should be represented by the sum of a series of frictional sinusoids. The complete equation would be

$$y=\Sigma a.e^{-\epsilon t}\sin\frac{2\pi}{T}t. \quad \ldots \quad (2)$$

This comprises the whole of the vibration of a single puff. It is a free, and not a forced, vibration. The musical or unmusical quality of the voice depends solely on the presence or absence of the various members of (2). The quality of the voice that distinguishes a Caruso from a costermonger lies exclusively in the laryngeal puff. This fact is of importance as contradicting the almost universally accepted theory of vocal training that is based on "tone-placing" by the supposed action of the vocal cavities as resonators to give the musical quality to the tone from the larynx.

The other group of elements comprises the tones aroused in the vocal cavities. A puff striking a cavity arouses one or more vibrations of the form of a frictional sinusoid as in (1). Each cavity will have its own factor of friction and its own period. As shown by the vowel siren, this response will be a free vibration independent of the voice tone and the periods that go to the vibration that makes up the puff. Every change in the sizes or openings of the cavities will alter the periods of these vibrations. The possible combinations for the cavities of the chest, pharynx, mouth, and nose provide for an almost endless variety of vowels.

The speech curves show quite unexpectedly that there is no such thing as a constant vowel. The vowel "o" in "so" changes its specific vowel character from beginning to end. The least change is found in German; more change appears in American. There is so much change in English that an American hears the vowel "o" as a sound starting like "oh" and ending like "oo." The statement that this English vowel is a diphthong composed of two vowels is incorrect. The vowel is a single sound that gradually changes greatly in character. There is no objection to calling it a diphthong provided it be recognised—as the speech curves show—that all diphthongs are really single vowels that change greatly in character. At the same time, it must be recognised that what is called a single vowel may change even more in character than a so-called diphthong; the change in a very short vowel, as in "but," is often surprising.

Just what constitutes the differences between the different vowels is a problem at present beyond the reach of science. The ear tells us that there are many sounds which we group together under the type "ah"; many others that would go to form the type "oo," etc. The speech curves show that the multiplicity of varieties under each type is almost beyond belief. In a general way we know that the impression from "ah" is that of a higher tone than from "oo," from "ee" higher than from "ah," and so on. All details of the tones in a single vowel are lacking. Every investigator has differed from every other one in regard to what tones constitute any particular vowel. As shown in this article, we can get so far as to say on what principles a vowel is built up. We can even get curves of the vowels of an accuracy that leaves nothing to be desired. We have not, however, any method of analysing these curves accurately into a series of frictional sinusoids with independent periods and factors of friction. We must probably wait for some mathematician to do for this problem what Fourier did for harmonic motion.

Toxic Root-interference in Plants.

THE earlier investigations of the late Mr. Spencer Pickering at the Woburn Experimental Fruit Farm on the action of grass on fruit trees, which were described in the third (1903) and thirteenth (1911) reports issued from that station, sufficed to show that, in spite of some variability in degree, there is a definite deleterious effect on the health and development of fruit trees caused by grass grown immediately around them. That this is a general result and not a matter of special soil or other local conditions at Woburn has been demonstrated by independent experiments conducted in this country at Long Ashton, Wisley, and other places. So marked is the crippling effect of the grass in some cases that death of the trees has resulted. On the other hand, the presence of numerous grass orchards in apparently healthy and vigorous condition in many parts of the country made the existence of any direct toxic action on the part of the grass, such as Mr. Pickering was led to postulate, appear doubtful. It was evident that the action, if any, must be relatively complex, and the later work at Woburn now shows that this is so. In the seventeenth (1920) annual report from that centre new evidence is recorded which indicates not only direct toxicity of grass on fruit trees, but also a similar effect for any one plant on another when the two are grown in close association.

It is therein claimed that the action of grass is shown to be due to toxic substances derived from the grass, and is not the indirect result of any adverse effect on soil conditions as regards aeration, available moisture, or plant food. In a series of experiments in which apple trees were grown in pots and the grass in shallow, perforated trays resting on the soil of the pots, the injurious effect was secured, notwithstanding that the grass roots, by being confined to the soil in the tray, could neither impoverish the soil in the pot below, nor deprive it of oxygen or water. A similar result was obtained when the grass was grown in sand, instead of soil, in the perforated trays. The presence of grass roots in the soil in which the tree was growing was thus immaterial for the manifestation of the dwarfing effect, and it follows that nothing which might be abstracted from the soil by them could be held accountable for the results. The converse view that grass added to the soil something deleterious to the tree appears to offer the only explanation, the toxic material presumably being conveyed from the trays to the soil in the pots by means of the drainage water from the former. Direct evidence was secured on this point by utilising for watering the trees the leachings from the grass trays, the trays in this case not resting on the soil of the pots, but being placed elsewhere. The injurious effect on the tree was as marked as before. When, however, the leachings were allowed to stand for twenty-four hours exposed to the air before being used for watering the pots, the trees apparently were unaffected.

It was considered by Mr. Pickering that these experiments prove that the leachings contain an oxidisable substance derived from the roots of the grass which in its unoxidised form is detrimental to the growth of the trees, but after oxidation is no longer of a toxic character. The suggestion that it is nothing more than carbon dioxide given off by the grass roots was, according to him, disproved by the results of a series of experiments in which the plants were grown in pots as above, "with or without a surface crop in the trays, watering them in one case with ordinary water, in another case with a saturated solution of carbon dioxide, and in a third case with clear lime water, which, since lime absorbs carbon dioxide, would presumably have the reverse effect of the carbon dioxide water." They were of a purely negative character, and in no way indicated that the toxic action of the surface crop was modified by the differential treatment. Also bearing on this point are observations, direct and indirect, in several of the numerous series of experiments made which tend to show that the toxin after "oxidation" actually serves as a nutrient to plants exposed to its action. As to the nature of this substance and the manner in which it is communicated by the roots to the soil, no positive views are put forward, but Mr. Pickering held that there was no reason to assume that it is excreted by the roots, and he was inclined to attribute its origin to the débris which roots furnish to the medium in which they grow.

The later phases of Mr. Pickering's investigations were mainly directed towards proving that the grass injury to fruit trees is only a particular case of the action of one growing crop on another. By means of experiments on lines similar to those already reviewed, he showed for a wide variety of plants a corresponding toxic effect, and, moreover, demonstrated that the action is reciprocal. It is not confined to plants of a different kind; it is at least equally marked when the associated plants are similar. Further, it follows that the individual plant tends to restrict its own growth through the toxin which it produces so long as that remains "unoxidised" in the immediate range of the root system.

A new light is thus thrown on the question of soil drainage, it being evident that soil conditions facilitating rapid removal of the toxin or its oxidation must tend to promote healthier growth, provided that food supplies do not escape. Differences in efficiency of drainage may accordingly be held to account for the divergences of grass effect on trees which have been recorded in various localities.

With every plant exerting a direct toxic effect on all others within its range, the phenomena of root-interference do not merely represent the outcome of competition for food supplies. Mr. Pickering gave particular attention to the aspect of the case where similar plants are grown massed together, and his observations are interesting not only in themselves, but also because of considerations raised by them of economic significance as applied to agricultural and horticultural crops. He found that where the mass of soil available is below a certain limit, the total amount of plant growth produced is independent of the number of plants present. This holds whether the individual plants are grown with their roots in separate compartments of the soil-containing receptacle, so that root-interference is eliminated, or in a similar-sized vessel without divisions which permits unrestricted root-interference; but it applies only to cases where the plants are of the same age. When some are younger than others, the latter grow more vigorously at the expense of the former in the undivided containers, but the total combined growth falls considerably short of the amount which the mass of soil is capable of producing with plants of equal age. The latter point is, however, reached when plants of unequal age are grown in the divided vessels with no root-interference. In such cases the toxic action of the older plant on the younger was thus definitely illustrated where root-interference was possible and the available growth standard was not nearly reached, indicating that the plants were prevented from utilising all the nutrient present.

The question of range of root-interference has become latterly of considerably increased importance in fruit culture. The present high cost of labour has driven fruit-growers to consider how to reduce the expenses of cultivation of their orchards and plantations. In some cases this has been attempted by grassing them down, but the trees generally suffer so severely that this method can be practised successfully only where local conditions minimise grass influence. Cover cropping, followed by the ploughing in of the cover crop to serve as green manure, is also receiving attention, particularly on account of the increasing difficulty of obtaining adequate supplies of farmyard and stable manure. Where the trees are grown on strong and relatively deep-rooting types of root-stocks, such as the stronger free stocks for apples, the toxic effect of the cover crop or grass may be relatively negligible, provided that the soil is deep and well-drained. With superficial rooting types of root-stock, such as the Paradise or dwarfing stocks for apples, however, the toxic influence of the surface crop will certainly be more strongly marked, and may be sufficiently pronounced to render grassing or cover cropping other than for periods of short duration not only dangerous in many cases, but entirely impracticable in some. The use of the latter forms of root-stock is accordingly open to objection on this score, and, in so far as the grower may be debarred from these alternatives in the treatment of his plantations, and confined to clean cultivation, the modern English policy of advocacy of dwarfing stocks may perhaps prove to be misguided.

The recent announcement of the closing down of the Woburn Experimental Fruit Farm, followed so closely by that of the regretted death of its distinguished director, marks the end of the most important systematic attempt to grapple with the problems of fruit culture since the days of Thomas Andrew Knight. Hotly disputed as some of the conclusions reached there have been, the general value of its contributions to pomological science stands, nevertheless, beyond question. Although further development of the subject in this country must now be left to other stations, the influence of Woburn will persist, and future investigators will find their work materially simplified not only by the constructive results achieved there, but also by the illustrations afforded of the pitfalls to which field experiments in pomology are liable.

Obituary.

Sir William Peterson, K.C.M.G.

NOT only his own university, but also the university world at large, has suffered a great loss by the regretted death, on January 4, of Sir William Peterson at the comparatively early age of sixty-four. Among university presidents Peterson's range of college experience and activities was exceptional and probably unrivalled. A Scottish education at the High School and University of Edinburgh was followed by a course at the University of Göttingen, from which he went with high classical distinction to Oxford as a scholar of Corpus. After Oxford an assistant mastership at Harrow introduced him to the life of an English public school, and as assistant professor of classics at Edinburgh he strengthened his association with that ancient university. From that post he was selected at an unusually early age for the principalship of the newly established University College of Dundee, over the growth of which he watched for thirteen years. Its affiliation with St. Andrews gave him intimate acquaintance with that ancient institution.

When, therefore, Peterson went to McGill in 1895 to enter upon the main work of his life, he carried with him the classical and literary spirit of the old Scottish and English universities, the critical training of Germany, and experience in directing university work on modern lines at an industrial centre. It was an excellent preparation for one who had to build at Montreal on the foundations so nobly laid by the distinguished Canadian man of science, Sir William Dawson. He had to deal with the practical needs of a young country busy in developing great natural resources, and at the same time to uphold the best intellectual traditions of the motherland. Both aims were kept steadily in view during his twenty-five years as principal of McGill.

Peterson had the good fortune to secure the support of men whose ample means were reinforced by high ideals of civic duty. Sir William Macdonald had already begun his generous benefactions to the university in aid of applied science. To the Schools of Engineering and Physics and of Chemistry and Mining, and for the foundation and endowment of the Macdonald College of Agriculture, Household Science, and Teaching, he gave during his life or by his will more than 12,000,000 dollars. The School of Medicine had already gained a well-earned fame, but large contributions from Lord Strathcona helped to confirm its place in the front rank of medical institutions. The same benefactor supplied the money for building and endowing the Royal Victoria College for Women, and, in conjunction with Sir W. Macdonald, that for the Conservatorium of Music, both in close alliance with McGill.

In giving direction to these and other streams of munificence, Peterson found a large and congenial field for his marked organising ability. His knowledge of English and Scottish universities and the close connection he maintained with them gave him a great advantage in filling the numerous posts created by the new foundations.

A striking proof of the growth of McGill under Peterson's rule, of the large lines on which he planned, and of the insatiable demands of a great and growing modern university is furnished by the fact that his successor in office, Sir Arthur Currie, found it necessary to appeal for a further sum of 5,000,000 dollars to carry on the work. That the graduates of the university and the citizens of Montreal responded by subscribing more than 6,000,000 dollars indicates the confidence felt in McGill as Peterson left it.

Peterson's selection as one of the trustees of the Carnegie Foundation for the Advancement of University Teaching—of which he was for some time chairman—opened up for him a new field of experience, since it gave him an intimate acquaintance with the leading university presidents of the United States, and made him familiar with all aspects of American university life. It emphasised the unique position he held among heads of universities.

The strain put upon Peterson by the war broke him down. An ardent believer in the British Empire, he spared no personal effort in speech and writing to maintain Canada's interest and full share in the struggle for its safety. What he accomplished in his own institution to this end is best shown by the terms in which the Carnegie Foundation made it a grant of a million dollars "in recognition of the noble and devoted service and sacrifice of McGill towards Canada's part in the Great War." It was while speaking in support of an appeal for the sick and wounded that the collapse occurred which closed his academic career.

G. R. P.

Alexander Muirhead, F.R.S.

ALEXANDER MUIRHEAD, F.R.S., who died at Shortlands, Kent, on December 13, 1920, was born in East Lothian in 1848. His father, John Muirhead, abandoned farming and was attracted to London in the early days of cable telegraphy, starting a business in Regency Street, Westminster, in partnership with Mr. Latimer Clark. Young Alexander, who was afflicted with partial deafness all his life, the result of a childish accident, went to University College School, Gower Street, and then to the college, where he made rapid progress in chemistry and mathematics, and became a devoted pupil of De Morgan. He afterwards worked at St. Bartholomew's Hospital under Mathiessen, in whose laboratory, amongst other things, he worked out the problem of the Latimer Clark standard cell, and laid the foundation of life-long accurate work in connection with electrical standards. He took the D.Sc. in 1872, in electricity, and became scientific adviser to his father's firm, where John Perry and many another later distinguished man took advantage of the opportunities, then novel, for accurate and absolute electrical measurement.

Muirhead's great achievement was the invention of the artificial line with distributed capacity, and the consequent duplexing of submarine cables. This he accomplished, in the first instance at Aden, with great and permanent success.

After carrying on research work in his own private laboratory, and perfecting the electrical standards of capacity, which he practically established and afterwards handed over to the National Physical Laboratory, Muirhead began instrument-making at Elmers End, constructing especially those beautifully designed instruments employed in cable telegraphy.

In 1894 Muirhead's attention was directed to the possibility of practical telegraphy by means of Hertzian waves, and he afterwards devoted his attention to getting them recorded by a syphon-recorder, with elimination of all disturbances, and with accurate tuning. He communicated a joint paper to the Royal Society on this subject (see Proc. Roy. Soc., A, vol. lxxxii., 1909, pp. 240–256).

But in the early 'nineties a serious illness had made Muirhead permanently lame, and his bodily disabilities were such that only his pertinacious and enthusiastic spirit enabled him to continue in harness and to remain as mentally alert as ever. He gave sound and helpful advice in connection with the Pacific cable, and his judgment and experience and scientific caution, together with his profound devotion to accuracy, were universally respected.

Muirhead was elected a fellow of the Royal Society in 1904, but a few years later a slight paralytic stroke added to the already formidable incapacities which prevented him from taking his true place among British men of science. By the few who really knew him he was highly esteemed and much beloved. Oliver Lodge.

An excellent Colonial servant of the Empire has passed away in the person of William Harris, Government Botanist and Assistant Director of Public Gardens in Jamaica. Mr. Harris was born at Enniskillen on November 15, 1860, and after some years' experience in gardening was in 1879 taken on the staff at the Royal Botanic Gardens, Kew. Two years later he was appointed, on the Director's recommendation, to take charge of King's House Garden, Jamaica, Sir Daniel Morris then being Director of Public Gardens and Plantations. In due course Mr. Harris acted as superintendent in each of the five gardens in that island. On Mr. W. Fawcett's retirement in 1908, Mr. Harris became Superintendent of the Public Gardens in the Department of Agriculture; in 1917 he was appointed Government Botanist, and in 1920, a few months before his death, he was promoted to be Assistant Director. By his loss botanical exploration in Jamaica has suffered greatly. He was an indefatigable collector, and spent his holidays in the botanical exploration of every part of the island, roughing it in the bush, with the most meagre shelter for the night. Last year he suffered from his throat, and went to Kansas City, where his eldest son was living, to consult a specialist. The disease was found to be cancer, and he died in hospital on October 11, 1920. Mr. Harris had been a fellow of the Linnean Society since 1899. Botanically, he is commemorated by the genera Harrisia, Britton (Cactaceæ), and Harrisella, Fawc. and Rend. (Orchideæ), and many species have been named after him.

The death occurred on Friday, January 7, of Mr. S. A. Vasey, who for twenty-eight years directed the *Lancet* laboratory. Mr. Vasey was born on March 9, 1866, and received his medical education at Charing Cross Hospital Medical School, but he was early attracted to chemistry, and in 1883 became a fellow of the Chemical Society, and assistant to Prof. Heaton at the medical school. Prof. Heaton was at that time also supervising the *Lancet* laboratory, so Mr. Vasey joined him there as assistant, and on the death of the former in 1893 he took entire charge. His investigations covered an extraordinarily wide field; he undertook inquiries into the physics of gas lighting and cooking, the standardisation of disinfectants, the chemistry of natural waters, the food value of oysters and the risks involved in their breeding and supply, and many similar questions relating to public health. These topics will be sufficient to indicate the extent of the work he accomplished. Mr. Vasey was largely self-taught, and he was remarkable for the natural and easy way in which he applied the facts of science to the most commonplace occurrences of life. By his untimely death both the public health service and our contemporary have lost an old and trusted servant.

The death has occurred of the veteran microscopist, Mr. Thomas Maltwood, in his ninety-fourth year. Mr. Maltwood was a fellow of the Royal Microscopical Society, and took an active part in the proceedings of that society in the middle of last century. He is best known as the inventor in 1858 of the Maltwood finder, which consists of a scale of vertical and horizontal lines reproduced photographically upon a glass plate, by reference to which the location of a particular object or structure in a microscopic specimen may be recorded.

The death of Mr. Walter Pitt is announced in *Engineering* for January 14. Mr. Pitt was one of the leading authorities on harbour construction plant, and was chairman of the firm of Messrs. Stothert and Pitt, Ltd., of Bath. He was born in 1853, and was a member of the Institutions of Civil Engineers and Mechanical Engineers; he served on the council of the latter body from 1907 to 1917, and was chairman of the institution's research committee on wire ropes.

Notes.

THE Royal Geographical Society and the Alpine Club for some time have been planning an expedition to scale Mount Everest. The political obstacle which stood in the way has now, fortunately, been removed by the permission granted by the Tibetan Government, on representation by the Government of India, for the expedition to pass through Tibet. Mount Everest, which lies on the borders of Tibet and Nepal, probably within the latter State, has an altitude of 29,142 ft. The surrounding mountainous country has never been explored, and, in consequence, much preliminary work is required before the actual ascent begins. In the *Geographical Journal* for January Brig.-Gen. the Hon. C. G. Bruce discusses the lines of approach and the probability of the feat being accomplished. The route proposed by Gen. Bruce is from Darjeeling through Sikkim to Kampa Dzong in Tibet, and then eastward for about 120 miles by the Taya Sampo Valley, through the Tingri Maidan, to the northern slopes of Mount Everest. This route he believes would enable a base to be established both as high as, and as near as possible to, Everest itself. It might be possible to arrange for supplies to be sent through Nepal up the Arun River or by other routes. This year an expedition is to make a preliminary reconnaissance of the ground, and in 1922 the actual attempt will follow. So far the highest altitude reached in mountain-climbing is 24,600 ft., attained by the Duke of the Abruzzi's party on Mount Godwin-Austen in 1909. Bad weather prevented a higher altitude being gained. Dr. Longstaff reached 24,000 ft. on Gurla Mandhata in 1905. In the ascent of Mount Everest an attempt will be made to push a camp to at least 25,000 ft., and, by use of ample porterage and the best of food, to have the climbing party in perfect fitness for the last effort.

AN article in the *Pioneer Mail* of November 19 last "from a correspondent in Mesopotamia" throws doubt on the general optimistic estimates of the results that may be achieved there by irrigation. The difference between the former widespread fertility of the country and its recent barrenness is usually attributed to political influences; but the author considers that it is due to changes in the soil and in climatic conditions, and not to deterioration of the population. He explains the recession of the sea for 100 miles from Ur of the Chaldees by an upheaval which has so lowered the gradient that the irrigation of that area must prove unusually difficult. There appears, however, to be no trustworthy evidence of essential climatic change, and the retreat of the sea is probably due to silting. The arguments based on possible changes in the soil appear more weighty; the author holds that the good soil is limited to narrow strips beside the rivers, and that most of the land "may easily prove to be irreclaimable," as "a gigantic subsoil sea charged with salts" has slowly collected under the plains. He considers this waterlogging incurable by simple drainage as in India, owing to the lack of adequate slope. The conditions described in the article indicate that irrigation in Mesopotamia is a far more difficult undertaking than in India.

SIR OLIVER LODGE'S suggestions for the designation of the unit of positive electricity (NATURE, December 9, p. 467), and Prof. Soddy's rejection of them, provide the theme for a humorous ode in *Punch* of January 12. The concluding lines are as follows:

"And then the bellicose and caustic SODDY,
Who treats Sir OLIVER as if he were Poor Pillycoddy,
Or any ordinary hoddy-doddy,
Winds up with a sardonic observation
Upon the modern 'hydrophobic school,
With its inveterate aversion to anything wet;'
Showing that by a curious transmigration
The hate which theologians as a rule
Monopolised may now be met
In the most learned and exalted set
Of those whose scientific zeal and piety
Form the chief glory of the Roy'l Society."

It is typical of our ever-welcome contemporary to take a broad survey of individual and national characteristics, and to present them with knowledge as well as wit. We admire one and enjoy the other, and are flattered that correspondence in our pages should have provoked such sprightly verse. We trust, however, that the transference of the *odium theologicum* to scientific controversy will remain a fancy, even though Mr. Punch may thereby lose opportunities for his inimitable banter.

A SOCIETY for scientific research into psychic phenomena has been formed in Glasgow, with Mr. A. J. Balfour as president. Other officers are as follows:—*Vice-Presidents:* Prof. W. Macneile Dixon, Sir George Beilby, Dr. A. K. Chalmers, the Duchess of Hamilton, Miss Janie Allan, Mr. J. Arthur Findlay, Mr. Peter Fyfe, Prof. R. Latta, the Rev. John Lamond, Dr. Neil Munro, Dr. L. R. Oswald, Lord Sands, Prof. W. B. Stevenson, and Dr. Henry J. Watt. *Chairman of Council:* Prof. W. Naeneile Dixon. *Vice-Chairman:* Mr. J. Arthur Findlay. *Hon. Librarian:* Dr. J. Knight. *Hon. Secretary:* Miss Margaret H. Irwin, 58 Renfield Street, Glasgow.

THE short general account of the annual meeting of the Headmasters' Association published in last week's issue of NATURE ascribed to Dr. Mary Bell the remark that "there is no sin in a child helping itself to the contents of the mother's purse in order to buy presents for a teacher." Dr. Bell writes to say that these words do not represent exactly what she said. The meaning she intended to convey was that "the impulse to gratify a self-regarding instinct by gaining recognition by giving flowers to a teacher might be so powerful as to outweigh any idea of stealing on the part of the child. The stealing is wrong, but the thing to tackle is the desire to gain recognition, or whatever it was that led to the giving of the flowers, without the wherewithal to do so."

A GENERAL meeting of the Association of Economic Biologists will be held at 2.30 p.m. on Friday, January 28, in the botanical lecture theatre of the

Imperial College of Science, South Kensington, S.W.1. Mr. Llewellyn Lloyd will describe greenhouse white-fly and its control, and Mr. W. B. Brierley will give his personal impressions of some American biologists and their problems. Mr. Brierley was one of three foreign representatives invited to attend the American Phytopathological Conference held last year, and afterwards visited the chief educational and research institutions in Canada and the United States and many geographical areas of botanical and agricultural interest.

THE Air Ministry has issued a table showing the numbers of aircraft of all nationalities which departed for and arrived from the Continent and the total numbers of passengers who travelled on Continental air services during the quarter October-December, 1920. The totals of departures and arrivals of aircraft to and from the Continent since the opening of the first service on August 26, 1919, until the end of 1920 were: Departures, 2131; arrivals, 2022; grand total, 4153. British machines contributed 3321 to the latter figure, French 721, Belgian 104, and other nationalities 7.

THE PRINCE OF WALES has expressed his intention of being present at the Hunterian festival dinner of the Royal College of Surgeons on February 14 to receive the diploma of honorary fellowship to which his Royal Highness was elected on July 24, 1919.

DR. ROBERT S. WOODWARD retired from the presidency of the Carnegie Institution of Washington at the end of last year, and the duties of that office have been assumed by Dr. John C. Merriam.

IN the December issue of *Man* Mr. J. J. S. Whitaker gives an account of recent archæological research at Motya which has been going on since 1906, and of which no information, except a few letters in English newspapers, has hitherto been procurable. Motya differs from its sister-cities in Sicily which have passed from one control to another and in course of time have undergone total transformation. Motya, once destroyed, ceased to exist as a town, and its site remained desolate. One remarkable discovery is that of a cemetery in which the burials are formed by single urns, the contents of which, so far as it has been possible to determine them, consist almost completely of the cremated remains, not of human beings, but of domestic and other animals. If this conclusion is verified it will raise a very interesting problem for the archæologist and anthropologist.

A COMMITTEE has been appointed to organise a presentation to Prof. Percy F. Kendall upon the occasion of his retirement from the chair of geology at the University of Leeds, which will take place under the age-limit in June next. As a teacher Prof. Kendall has been stimulating and successful; as a scientific worker he has shown himself possessed of a brilliantly original mind, and he has achieved especially notable work in glacial geology and in studies of coal and the coalfield. Some recognition of this work is richly earned. Sir William Garforth is the chairman of the presentation committee, and the treasurer is Mr. J. E. Bedford, of Arncliffe, Headingley, Leeds.

ENCEPHALITIS lethargica, a disease characterised by stupor and paralysis, which came prominently into notice in 1918, is stated to have made its appearance again in France. A number of cases are reported from Marseilles, and at Douai an epidemic is said to be raging. It is suggested that the malady is periodic in appearance, like influenza, and it is of interest that epidemics of stupors are again and again recorded by the old medical writers. Cases apparently cured seem to be subject to fresh attacks, and there is some evidence that the cured cases may be "carriers" of the virus and convey infection to others.

"ANILIN-VIOLET in Copying Pencils Acting as a Spreading Caustic" is the subject of a review in *Medical Science: Abstracts and Reviews* for December (vol iii., No. 3, p. 239). If the point of a violet copying pencil penetrates into and is broken off in the tissues the result is quite different from a similar accident occurring with an ordinary graphite lead pencil. If the removal of the violet point be delayed it slowly dissolves, and the area of tissue around undergoes sub-acute inflammation with irritation of the nerve-twigs and pain at first, followed by anæsthesia owing to destruction of the nerves. The tissues undergo necrosis or death, and finally a sinus leading to the surface forms, through which the violet-coloured débris is discharged. There is an absence of suppuration, as the anilin-violet is an antiseptic.

DRS. CALMETTE AND GUÉRIN, of the Pasteur Institute, Paris, state that they have been able to protect animals against tuberculosis by means of a vaccine. Ten healthy heifers, six of which were vaccinated, were housed with five tuberculous cows for thirty-four months and then slaughtered. Of the four unvaccinated heifers three showed advanced tuberculosis. Of the six vaccinated heifers two which had been vaccinated only once showed a small amount of tuberculosis, while the four other animals which had been vaccinated three times showed no trace of the disease. It is now proposed to experiment with apes, and for this purpose an island has been acquired in French Guinea and liberal grants have been made by the Government for building and equipping laboratories and for their upkeep. The vaccine referred to is probably that described by Dr. Calmette (*Ann. de l'Inst. Pasteur*, vol. xxxiv., 1920, p. 554), which consists of tubercle bacilli that have been grown on a glycerin-bile medium for several generations.

IN the *Journal of Anatomy* for October (vol. lv., part i., p. 68) Mr. G. S. Sansom describes observations on the parthenogenetic segmentation of the ovum of the water-vole (*Microtus amphibius*) within the ovary. The process continues as far as the formation of two blastomeres and the division of these so as to give rise to the four-celled stage. Conditions of atresia of the follicles then become so acute that further development is impossible.

ACCORDING to the *Scottish Naturalist* (November-December), a walrus was seen off the Shetlands on many occasions from early in July until the middle of October. When first seen, about twenty-four miles north-west of Lerwick, the animal followed a fishing-boat for some distance. It is described by the lighthouse-keepers as bearing tusks about 15 in. long; it was almost black on the top of its head, but lighter about the rest of the head and back. This issue also contains an account of the breeding of the brambling in Perthshire, which makes the first authentic record of the breeding of this finch in the British Isles.

THE curious discovery of a diurnal variation in the size of human red-blood corpuscles is announced by Dr. Price Jones (*Journal of Pathology and Bacteriology*, vol. xxiii., p. 371). They are smallest on first waking in the morning, soon swell up when the subject becomes active, and reach a maximum about noon, which is maintained until bedtime. Short, violent exertion imposes a sudden rise on this daily curve, followed by a rapid return to normal; gentle exercise of longer duration has no special effect. Resting quietly in bed is evidently not the same as sleeping soundly, since it does not abolish the diurnal variation. Forced, violent breathing, whereby much carbon dioxide is washed out of the blood, causes a marked shrinkage, which disappears again in less than half an hour. The obvious inference that the size of the red cells varies inversely with the alkalinity of the blood is confirmed by experiments *in vitro*; but whether the phenomenon is due to the cells behaving like pieces of gelatin or to osmotic changes due to the exchange of salts between the plasma and cells is left undecided. It is possible that the increase of size in venous blood is of use in delaying the passage of the corpuscles along the pulmonary capillaries until the excess of CO_2 has been eliminated.

IN vol. v., part 8, of the Scientific Results of the Australasian Antarctic Expedition several kinds of insects from Macquarie Island are brought to light. Hitherto only a single species of springtail and two of shore-inhabiting flies were known from that desolate place. The present report, by Dr. R. J. Tillyard, is accompanied by appendices by Prof. C. T. Brues and Mr. A. M. Lea. Described therein are two new species of springtails, a new genus of wingless Diapriid Hymenoptera, and the larvæ and adults of a new Staphylinid beetle. It is noteworthy that the island contains no trees and the hillsides are clothed with dark green tussock grass, scattered among which are patches of the more brightly coloured Maori cabbage (*Stilbocarpa polaris*). Penguin "rookeries" are a striking feature of the island, and wherever they are present the vegetation is destroyed. The Collembola and the wingless Hymenopteron occurred under stones in these "rookeries," while among the great masses of kelp cast ashore during stormy weather various flies undergo their transformations. A Pyralid caterpillar and the larva and pupa of a Tipulid fly are also described in this report, without definite names being assigned to them. The occurrence of these few insects on this desolate island affords an interesting problem to students of geographical distribution.

A COMPLETE and up-to-date catalogue of all the species and subspecies of birds of the Nearctic and Neotropical regions from northern Greenland to Tierra del Fuego, including the West Indies, the isles of the Caribbean Sea, and those of the South Atlantic and Pacific Oceans the faunal relations of which are American, is attempted in the "Catalogue of Birds of the Americas," by Charles B. Cory (the Field Museum of Natural History, Chicago, Zoological Series, vol. xiii., 1918–19). The first instalments issued form vol. ii., those of vol. i. being held over in order that Mr. Cory may have the benefit of Prof. Ridgway's latest investigations on the aquatic and gallinaceous groups, which will appear in the concluding volumes of that author's great work on the birds of North and Middle America. The parts under notice deal with the forms comprised in the orders Strigiformes, Psittaciformes, Coraciformes, Trogones, Coccyges, Scansores, and Piciformes. The geographical distribution of each species and its racial forms, often numerous, is concisely given, also a short and judiciously selected series of synonyms—a very desirable adjunct in these days of never-ending changes in nomenclature, resulting in the disappearance of time-honoured names in favour of obscure dug-outs. Another important feature is the author's footnotes, devoted mainly to descriptions of the plumage of the many new species and still more numerous subspecies described since the publication of Prof. Ridgway's volumes, and of the American forms added to the great "Catalogue of the Birds of the World" published by the Trustees of the British Museum. Mr. Cory's work will be greatly appreciated by all who are engaged in the study of birds generally, and of their geographical distribution in particular.

THE inheritance of ten factors in the cow-pea (*Vigna sinensis*) has been studied by Dr. S. C. Harland (*Journal of Genetics*, vol. x., No. 3). The characters investigated included the presence of anthocyanin in stem and leaf-stalk, the colour of the seed-coat pattern, and pod and flower colour. The presence of anthocyanin is due to a dominant factor, while the seed-coat colours, which are black, brown, buff, maroon, red, and white, are believed to be due to various combinations of four factors. Several other relationships of factors are also made out. In another paper by the same author the results of breeding experiments with the castor-oil plant, *Ricinus communis*, are given. The presence of bloom on various parts of the plant is due to a single partly dominant factor, while the spininess of the capsule is also partially dominant to its absence. As regards stem colour, crosses between green and mahogany brown indicated the presence of two factors which show repulsion. Dr. Harland has also crossed certain varieties of the tropical hyacinth bean, *Dolichos lablab*. He finds the indeterminate habit of growth dominant to the determinate. Two white-flowered varieties gave a purple F_1, due to the presence of the factors C and R, the former producing a purplish seed-coat and stipular hairs, the latter, in the presence of C, converting white flower into purple, purplish seed-coat into black, and causing pigmentation at the nodes.

THE Oreodontidæ from Upper Eocene to Pliocene genera are reviewed by F. B. Loomis in a paper on *Ticholeptus* (*Merycochaerus*) *rusticus* (*Amer. Journ. Sci.*, vol. l., p. 281, 1920). The wealth and variety of material for the study of these artiodactyls, especially in Lower Miocene strata, and their peculiar limitation to American deposits render the diagram of their evolution useful to students of the mammalia.

BULLETIN 663 of the U.S. Geological Survey on "The Structural and Ornamental Stones of Minnesota," by Oliver Bowles, is effectively illustrated with coloured plates of polished specimens—a method of imparting information that in our islands has, we think, been left to private enterprise. A publication of this kind is obviously a distinct service to a community that also contributes liberally to research in the so-called "purer" branches of geology.

SOME broad features of Hawaiian petrology are dealt with by S. Powers in the *American Journal of Science* (vol. l., p. 256, 1920). The olivine nodules in the basalts are regarded as early products of differentiation brought up from lower levels, and the occasional trachytes that are described seem to be due to differentiation in local volcanoes after their connection with the main subterranean cauldron had been cut off. Useful maps are given of several of the islands.

ATTENTION may be directed to a very convenient glossary of the economic mineral productions of the United States published by the U.S. Geological Survey under the title of "Useful Minerals of the United States," Bulletin 624, a revision of Bulletin 585. This consists of two parts—the first a geographical index, in which the various States of the Union are given in alphabetical order, and under each the most important mineral productions of that State, also alphabetically arranged. The second part consists of a list of the names of some six hundred minerals in alphabetical sequence, in which the composition and general uses of each are given briefly, together with a list of the States in which it occurs in important quantities or in some noteworthy form. The work thus forms a very convenient index to the mineral production of the United States, and it would be a very great advantage if all important mining countries published lists on similar lines. The suggestion might with great advantage be followed by our Imperial Mineral Resources Bureau.

LIVERPOOL Observatory at Bidston, under the directorship of Mr. W. E. Plummer, has issued its report for the years 1917–19, which is published by the Mersey Docks and Harbour Board. It has not been found possible to issue annual reports as was the custom prior to the war. The signal-gun for time, which is for definite nautical purposes, was fired, without alteration for summer time, one hour after Greenwich mean noon. Seismological observations are regularly recorded, and in the tables published notes are made respecting the different phases. Temperature records in the reports are from thermometers mounted on the north side of the observatory; in former years, when observations were made from instruments mounted on the south side, the results gave too high a reading. There were 76 days in 1917 with no sunshine, 68 days in 1918, and 68 days in 1919. For wind velocity it is still assumed that the velocity of the wind is three times greater than that of the cups of the Robinson anemometer, although this factor is recognised as too large. The detailed daily meteorological observations are most complete, and a summary is given for the several months and for the year. The number of hours that the different winds blew during each day affords very useful information and is of great interest as associated with the varying character of the weather. There is much that can be followed with advantage at other subsidiary observatories.

VOL. XIV. of the Collected Researches of the National Physical Laboratory extends to more than 300 pages, and is devoted entirely to optics. Its characteristic feature is the aid it affords to the manufacturer of optical instruments, and of telescopes in particular. One of the fifteen papers reprinted is devoted to a description of the methods adopted at the Laboratory for the calculation of telescope objectives, and a second gives the corrections to the curvatures of the lenses of an objective when the glass of a new melt is not quite identical in refractive index with the glass previously used. Charts for assisting in the selection of suitable glasses for cemented doublets are given, and those cases in which the curvatures do not allow a doublet to be cemented are met by the substitution of a cemented triplet. In a paper devoted to refractometers of the critical-angle type, such as are used in commercial testing, it is pointed out how extensive the powers of these instruments are and how the actual instruments have in the past fallen short of the accuracy possible owing to mechanical defects. Modifications of the original Zeiss form of construction are suggested which, when the instrument is used with the proper precautions, should raise the accuracy considerably.

A MARKED degree of red sensitiveness in some "ordinary" gelatino-bromide plates was observed and recorded many years ago; it seems possible that the key to this unexpected result has been found by Mr. F. F. Renwick, who contributes a paper on "The Action of Soluble Iodides on Photographic Plates" to the January issue of the Journal of the Royal Photographic Society. Mr. Renwick finds that by treating a plate for a few seconds with a very dilute solution of potassium iodide there is really no fogging effect (as Dr. S. E. Sheppard stated about a year ago), but that the plate is rendered markedly orange and red sensitive. This he demonstrates by bathing an ordinary plate for from 15 to 60 seconds in a 1 in 20,000 potassium iodide solution, washing it with water and exposing it to a spectrum. This appears to be the first instance recorded of a colourless solution conferring colour sensitiveness. Mr. Renwick has tried a fair number of different salts, but so far has discovered only one other that acts similarly. Sodium or potassium cyanide in solution of a strength of one in from 2000 to 10,000 gives an exactly similar effect. The author leaves a theoretical discussion of these results to a future occasion.

THE investigation of soap solutions by Dr. McBain and his students at the University of Bristol has been continued by the demonstration that aqueous sodium oleate at temperatures between 0° C. and 25° C. can exist in any one of three forms: clear oily liquid sol, clear transparent elastic gel, or white opaque solid curd, all at one and the same concentration and temperature. Hitherto the last two types have not been differentiated; probably all previous communications dealt with soap curd, and some confusion has been introduced into the discussion of the nature of gels on this account. Soap sol and gel have been shown to be identical in all respects except elasticity and rigidity, which are characteristic of the gel form alone. A curd is a sol or gel from which nearly all the soap has been abstracted through the formation of white curd fibres of barely microscopic diameter. These researches, described in the December issue of the Journal of the Chemical Society, have important bearings on the theory of gels, and support the micellar view of Nägeli.

MESSRS. J. AND A. CHURCHILL announce for early publication a new edition—the eighth—of Lee's "Microtomist's Vade-Mecum." It has been prepared by Dr. J. B. Gatenby, who has had the collaboration of several other well-known biologists; thus Prof. Bayliss contributes a chapter on the theory of dyes and staining, Dr. Da Fano has recast the chapters on neurological methods, Dr. A. Drew has written a chapter on protozoological techniques, Dr. W. Cramer and the editor a section dealing with the fatty substances, the chapter on bone and teeth has been revised by Dr. J. T. Carter, and sections on mitochondria, Golgi apparatus, fat and yolk, chromatin, chromosomes and nucleoli, embryology, microchemical tests, colloid intra-vitam dyes, and tissue culture methods have been contributed by Dr. Gatenby.

WE have received a copy of the new edition of its catalogue of second-hand scientific instruments from the firm of Charles Baker, of 244 High Holborn, W.C.1. It is divided into twelve sections, each of which deals with a particular class of apparatus. Prominent sections are those devoted to microscopes, surveying instruments, physical apparatus of various types, and photographic material. That on microscopes contains some seventy items, ranging from single sliding-tube instruments to those carrying all the modern improvements. The firm has also a number of second-hand scientific books and periodicals for sale, including collections of various journals of microscopy and NATURE, vols. xxviii. to civ.

Our Astronomical Column.

APPROACHING RETURN OF PONS-WINNECKE'S COMET.—Among the periodical comets due to return this year that of Pons-Winnecke presents the most interesting possibilities. The comet will be near the earth at the time it arrives at perihelion at about the end of June or early in July next, and as its orbit lies very near that of the earth a meteoric shower seems highly probable.

The first abundant exhibition of meteors from this source appears to have taken place on June 28, 1916, when it was witnessed by Mr. W. F. Denning at Bristol, who pointed out in NATURE of July 27 of that year the significant resemblance of orbit between the meteors and Pons-Winnecke's comet.

The last return of the comet to perihelion occurred on September 1, 1915, and, the shower of meteors having been observed at Bristol ten months later, the stream must be fully 600,000,000 miles long. If the display should fail to be visible at the end of June next it should certainly return next year.

The radiant point is situated a few degrees north-east of the star Eta in Ursa Major, and the radiation appeared to be very diffused in June, 1916, so that it was difficult to ascertain the exact centre. In former years the comet of Pons-Winnecke was always sufficiently distant from the earth to escape contact of its materials with our atmosphere, but during the last half-century the planet Jupiter has materially disturbed its orbit, and brought that section near perihelion extremely close to the earth.

STELLAR PARALLAXES.—Yerkes Observatory Publications, vol. iv., part 3, contains parallaxes of fifty-two stars obtained photographically with the great Yerkes refractor by Mr. G. van Biesbroeck and Mr. H. S. Pettit. A yellow colour-filter was used, and the bright stars were cut down 6 mags. or thereabouts by a double rotating sector. The stars are partly fundamental ones, partly faint stars with large p.m. The following are some of the more interesting results:—Aldebaran 0·047″, Castor 0·059″, Procyon 0·307″, B.D. +67·552° 0·106″ (this is the first determination made for this star), Lal. 21185 0·382″, ζ Herculis 0·095″, Barnard's p.m. star 0·509″, and Vega 0·114″. The average probable error is 0·010″.

Two more Publications of the Allegheny Observatory (vol. v., Nos. 4 and 5) have been received, and contain parallaxes of eighty stars, many of them now determined for the first time. The average probable error is 0·008″. There are only two parallaxes exceeding 0·1″, viz. Pi II. 123 0·145″ and O.A.N. 21338 0·134″ (first determination). Other interesting stars are α Trianguli 0·045″, δ Cephei 0·006″, 54 Piscium 0·096″, β Andromedæ 0·033″, Furuhjelm's companion to Capella 0·071″ (this is easier to measure than Capella itself, and from the common p.m. the parallax must be appreciably the same), η Geminorum 0·016″, Lal. 33439 0·095″ (Adams and Joy found 0·087″ spectroscopically), and Pi XXIII. 218 0·092″.

CATALOGUE OF NOVÆ.—The Japanese *Astronomical Herald* for October, 1920, contains a very useful catalogue of novæ, giving their R.A. and decl. for 1900, the date of outburst, and other particulars. Tycho Brahe's star of 1572 is No. 1, and Mr. Denning's nova of last August No. 41. The average in the last thirty years has been just one per annum. The nova of 1885 in the Andromeda nebula and the other faint novæ recently detected in spiral nebulæ have not been included in the list. The galactic co-ordinates are given, and the distribution of novæ in the four quadrants is as follows:

Galactic Long.	No. of Novæ
0° to 90°	14
90° to 180°	8
180° to 270°	3
270° to 360°	16

The deficiency in the third quadrant does not seem to be explicable as a result of south declination, for there are practically as many stars south of the equator as north of it (twenty to twenty-one). There are fourteen stars south of decl. −20°, which is the full number to be expected in this zone, one-third of the whole sphere. Hence the unsymmetrical distribution gives some grounds for conjecturing that the galaxy may be nearer to us in the first and fourth quadrants.

Federal Science during the World-war: Geology in Austria-Hungary in 1914–19.

By Prof. Grenville A. J. Cole, F.R.S.

In Nature, vol. xciv., p. 94, on the last day of the eventful year 1914, a sketch was given of the publications of the Geologische Reichsanstalt of Vienna from 1911 to 1913. The reduction in the scope of the institute, necessitated by political rearrangements, was recently referred to with some regret, and, now that international communications are restored, we are enabled to welcome the volumes issued during the years of war. The maintenance of the *Jahrbuch* in its well-known handsome form is a remarkable testimony to the energy of Dr. Tietze and his staff. While machine-guns rattled above the glaciers of the Ortler and slaughter surged from Caporetto to the sea, the Reichsanstalt not only discussed questions of philosophic interest, but even printed the results in anticipation of the return of happier times. Colour-printed maps and sections and photogravures of fossils accompany these volumes, which from January, 1914, to December, 1918, occupy a width of 15 cm. on our shelves. The *Verhandlungen* give us an extra thickness of 7 cm. This method of statement may appear crude in a matter of scientific output; but could we have claimed as much from H.M. Stationery Office in London if a lithe and indefatigable enemy had been battering our defences no farther away than the line Middlesbrough—Baugh Fell—Morecambe Bay?

Many of the recent papers in the *Jahrbuch* naturally treat of local details, and describe observations made during long mapping in the field; but few of them are devoid of wider applications. The fascinating mass of the Wetterstein on the northern wall of Tirol occupied O. Ampferer and O. Schlagintweit in the *Verhandlungen* in 1912. K. C. von Loesch (*Jahrb.*, 1914, p. 1) has now made a close study of its "Schollenbau" and that of the parallel Mieminger range immediately to the south, which is well known to travellers down the Inntal between Imst and Innsbruck. Von Loesch is particularly concerned with the lateral movements that followed, after an interval of repose, the main overfolding from the south. His summing up fails to give a comprehensive view of the westerly movements of the isolated blocks—a feature first indicated by Ampferer. One would like to know whether these may be fairly compared with the settling down and spreading of the front of a wave that has subsided on a shore. The question of how far the tension evidenced by "explosive" outbreaks of rocks in Alpine mines and tunnels is a heritage from the Miocene movements is considered a few pages later by K. A. Weithofer, of Munich ("Ueber Gebirgsspannungen und Gebirgsschläge," *Jahrb.*, 1914, p. 99). His paper discusses such occurrences in general, and concludes that no single explanation applies equally to all.

E. Fugger (1914, p. 369) describes the delightful country of the Tennengebirge south of Salzburg, where the Triassic rocks of the Eastern Alps first reveal their beauty and fascination to the traveller on the road to Radstadt. He quotes from F. Wähner an explanation of the double gorge of the Salzach above Golling, where a climb is made to the Lueg Pass along a dry ravine partly choked with glacial detritus. After the Ice age the river failed to return to its old groove, from which it was banked out by débris, and it carved the deep and impassable gorge of the Oefen close alongside. A rock-ridge only 200 m. wide separates the two ravines.

As an example of research into the stratigraphical problems of the Eastern Alps we may cite W. Hammer's far-seeing paper on the Bündnerschiefer of the Upper Inntal, with its numerous sections, and two coloured maps on the large scale of 1 : 25,000 (1914, pp. 441–566). The Bündnerschiefer, corresponding with the *schistes lustrés* of the Western Alps, occupy small areas south of Landeck on the margin of the gneiss, and present the usual difficulties of correlation. Hammer records interesting breccias with limestone fragments containing radiolaria; but fossil evidence is practically wanting. He inclines to the view that the beds are metamorphosed elements of Upper Cretaceous rather than older Mesozoic strata. Exotic Triassic masses appear among them in a disconcerting way (section on p. 453, etc.), and pebbles of Triassic rocks occur in conglomerates of the Bündner series.

Hammer continues (1918, p. 205) his studies in the Landeck district by a description of the zone of phyllites, associated with mica-schists, that runs along the north side of the Silvretta and Oetztal gneiss from St. Anton on the Arlberg to the village of Roppen in the Inntal. The series dips towards and under the gneiss, just as the Bündnerschiefer do from an opposite direction. The phyllites are overlain unconformably by the Verrucano, which was formed between the Armorican movements and the Triassic period. Their relations with the gneisses seem due to the early earth-movements, but here and there intrusive gneisses have invaded them. An interesting type (p. 216), the "Feldspathknotengneis," occurs in the phyllite series, and is marked by the development of albite in an originally sedimentary rock. The growth of the felspar has no connection with contact-action.

F. Angel and F. Heritsch, both of Graz, found an almost ideal working-ground on the Stubalp, part of the noble wall of crystalline rocks that hems in the basin of Graz on the west. The position of Austria in the world-war was so enforced and so anomalous that we may sympathise with these geological enthusiasts when they write of their mountain fastness: "Die Liebe zur Heimat, die Freude an den Bergen hat uns immer wieder dorthin geführt, wo wir den Jammer des Krieges vergessen konnten. Die Forscherlust war die Begleiterin unserer Wanderungen." F. Angel contributes detailed petrographic studies of the rocks encountered, which include both a sedimentary and a gneissic series; but the chief point of general interest lies in Heritsch's conclusion (p. 203) that the whole mass and its present structure are of pre-Cambrian age. The Stubalp thus seems to be an antique block worked up, perhaps, but by no means obliterated in the later tectonics of the Alps.

The attention given in these recent volumes to Bohemia, mainly through the work of Czech geologists, leaves a serious heritage to the revived States that look to Prague as their intellectual centre. The old question of the Silurian "colonies," and the work of J. E. Marr in giving them a tectonic significance, come up again in E. Nowak's researches on the southern edge of the basin (1914, p. 215) and in F. Wähner's paper (1916, p. 50) on the structure of central Bohemia, which recognises in the basin the remains of a formerly extensive and crumpled mountain range. This seems to have existed in Upper Devonian times, and one is tempted to ask if, with the north-east strike impressed upon its constituents, it cannot be regarded as part of the Caledonian continent so well revealed in north-western Europe. The main folding, however, in Bohemia and Moravia, accompanied by great intrusions of granite and the formation of large areas of gneiss, occurred in connection with the "Variscan" movements—that is, in Upper Devonian and Lower Carboniferous times—thus heralding, and still at a long distance, the Armorican movements of the west. This fact is emphasised by Radim Kettner, writing from Příbram (1917, p. 251).

In the same year (p. 267) J. Woldřich examined the Cretaceous fauna of Neratovic, where concretions containing 50 per cent. of calcium phosphate interestingly occur. This discovery is compared with the presence of phosphatic nodules in the Cretaceous of France and England, and (p. 321) the fauna is described in relation to its western representatives. In the volume for 1915 (p. 1) C. Zahálka contributes a far-reaching memoir on the Cretaceous system in the Sudetic region and its equivalents in the western lands of Central Europe. This includes many pleasant references to the comradeship shown to the author by French geologists, and the name of Valmy, where the First Republic answered the proclamation of the coalised kings, appears here happily (p. 109) in connection with field-work on the zone of *Inoceramus labiatus*. There is much in this extensive paper to interest English geologists, who must, by the way, not overlook Richard J. Schubert's paper (1915, p. 277) on otoliths of Barton Cliff in Hampshire, collected by H. Elliot Watson and sent to the author by Col. C. D. Shepherd. Schubert's death at the head of his company in the heroic fight at Gorlice on the Russian front (obituary by O. Ampferer, 1915, p. 261), removed a very active and much-loved personality from the ranks of the Reichsanstalt.

British and Indian geologists may also note Rudolf Zuber's contributions to the geology of the Punjab (1914, p. 327), resulting from explorations organised by an English oil company in 1913. There are two highly suggestive diagrams showing the interlocking of different types of Eocene strata, including the salt-clay series, and their folding in the great Himalayan movements to form the present Salt Range.

Broad questions of petrography have not escaped the attention of the Reichsanstalt, such as Bruno Sander's "Beiträge aus den Zentralalpen zur Deutung der Gesteinsgefüge" (1914, p. 567), in which the stratified and folded structures in many crystalline rocks are recognised as of earlier date than the crystallisation of their present mineral constituents; or the extensive study of peridotites and their allies involved in F. Kretchmer's memoir on "Der metamorphe Dioritgabbrogang im Spieglitzer Gebirge" (1917, p. 1). Palæontology is represented by a number of short papers, including one by J. V. Želizko (1918, p. 113) on a small species of lion from the Pleistocene of Wolin, in southern Bohemia. One large folio memoir, on Oxynoticeras, by J. von Pia, was issued in 1914; it includes the usual considerations in regard to what constitutes a genus or a species, to which we are accustomed when ammonites are brought into the arena. In critical biography E. Tietze's "Einige Seiten über Eduard Suess" (1916, p. 333), a paper of more than 200 pages, is a very memorable review of the recent history of geology. Even the papers on economic subjects reflect the calm detachment of the institute, encouraged to carry on its work with a cosmopolitan outlook, during a catastrophe that has broken the bonds of man to man by more than inexorable death. Even F. von Kerner's study (1916, p. 145) of the water-supply in the Middle Dalmatian karst-region, with its valuable series of sections, will be to the advantage of the Slavonic peoples rather than to those who blasted their trenches on the Carso in the hope of retaining a sovereignty at Trieste. And so, indeed, it should be always. The Austro-Hungarian *Festland* has become broken into horsts and *Graben*; but will not time smooth the fault-scarps that now loom up as separating walls? The best guarantee of scientific co-operation is to be seen in the names of those who have, during years of bitterness and division, contributed in serene hopefulness to the sum of human knowledge.

Measurements of the Angular Diameters of Stars.

AFTER the successful measurement of Capella as a double star by Prof. A. Michelson's interferometer method applied to the 100-in. reflector at Mount Wilson, it was known that he intended to attempt the more difficult feat of measuring stellar diameters. The most hopeful stars to choose for the purpose are the giant red stars. Prof. Eddington made some estimates of their angular diameters in his inaugural address to Section A of the British Association last August (NATURE, September 2, 1920, p. 14). Taking the temperature and surface brightness derived from the distribution of energy in the spectrum, the angular diameter (which is independent of the assumed distance) is deducible from the apparent magnitude. The highest estimate for any star was that for Betelgeux, the value being 0·051″.

The daily Press of December 31 announced that Prof. Michelson read a paper before the American Physical Society in which he stated that he had determined that the diameter of Betelgeux was 260,000,000 miles, or three hundred times that of the sun. As the assumed distance of the star was given as 150 light-years, we may infer that the measured angular diameter was 0·061″—a close agreement with Prof. Eddington's estimate.[1] Once the angular diameter of a single Ma star is determined, those of all the stars of the same spectral type can be deduced from their apparent magnitudes. The huge bulk of Betelgeux is a striking illustration of Prof. H. N. Russell's theory of giant and dwarf stars. Its density is presumably very low, otherwise an improbably high value of the mass would result.

Some further details of the result obtained at Mount Wilson were communicated in a letter from Prof. G. E. Hale which was read at the meeting of the Royal Astronomical Society on January 14. The apparatus consists of two periscopes fixed to a frame at the object-end of the tube of the 100-in. Hooker reflector. The outer mirrors are some 20 ft. apart, but the distance is capable of being varied. The inner mirrors are about 4 ft. apart; this is merely a matter of convenience, the beams being brought down the tube on opposite sides of the Cassegrain mirror. An additional plane mirror is used for reflecting the light up the polar axis. The measurement of a star's diameter is effected by varying the distance between the outer mirrors and finding the points at which the interference fringes disappear. The actual observation is very tedious and difficult; it was stated that half an hour was required each time the mirror was moved before the visibility of the fringes could be tested. Moreover, in measuring a star disc, observations are

[1] A later communication gives 0·046″ as the measured diameter.

required in different azimuths to ascertain that we are dealing with a single circular disc, and not with two neighbouring discs, as in the case of Capella. The resulting angular diameter is 0·045"; Prof. Eddington had predicted 0·051" from the visual magnitude and assumed surface brightness, and Prof. Seeliger deduced 0·042" in a somewhat similar manner. The linear diameter found (about 300 times that of the sun) depends on the assumed parallax, which, unfortunately, is decidedly uncertain; further determinations seem urgently to be called for. Prof. Lindemann pointed out the extraordinarily low density that such a diameter implies if we assume that the mass is of the order of twenty-five times that of the sun.

Other stars for which a diameter determination is hopeful are Antares and Aldebaran, and possibly Arcturus. Sirius and Vega will doubtless be attempted, but with less prospect of success.

A. C. D. C.

Culture and Environment in the Cameroons.

FEW areas in the African continent present problems of greater interest to the anthropologist than the Cameroons. Although the Germans produced a considerable amount of literature relating to the area while it was under their rule, there is still a great deal of work to be done before the complex ethnology of the country is elucidated. Capt. L. W. G. Malcolm, who saw service in the Cameroons during the war, is preparing a monograph which will be one of the first-fruits of our occupation. At a recent meeting of the Royal Anthropological Institute he gave a preliminary account of certain questions connected with the distribution of types of culture and its relation with the geographical environment.

In the Cameroons there are three main racial stocks, namely, the Bantu-speaking tribes, the Sudanese, and the Pygmies. Subsidiary immigrant races occupy certain areas in the north-east. Between the Bantu-speaking tribes and the Sudanese there are a number of tribes, some of which do not speak Bantu languages, and there is a distinct boundary between the Bantu-speaking and Sudanese races which is determined solely by the geographical nature of the country.

The material culture of the grassland area reveals the fact that the problem is of a most complex character. When dealing with tribes of mixed affinities it is extremely difficult to determine the various strata. Not only is there a local mixing of the tribes, but there are also various elements which have been brought in by invading tribes. This is particularly the case in Bagam, where the tribe has been influenced particularly from Bamum, in the north-east, while from Babanki, in the north, various forms of iron weapons have been introduced. The Balis have introduced among the grassland tribes the sleeveless gowns worn by the men. After Hausa and Fulani elements and the influence of the forest-belt tribes have been eliminated, it would appear that the chief characteristics of the grassland culture are weapons of copper, iron, and brass; socketed spearheads; a simple bow made from raphia palm, with a flat bowstring; arrows with wooden points; shields, either plaited or reinforced with wood; wooden slit-gongs; drums with skin tympana and wooden tautening wedges; flanged iron bells; iron-working (smelting and smithing); brass castings (Bagam and Bamum); pottery (coiled in the north-east); jutan cloth and woven fibre; decorative art with triangles and zigzags; cicatrisation; filing or chipping of the incisors; smoking pipes of metal and clay; animal and ancestral cults; and the use of carved masks and images. One of the most obvious and striking peculiarities of the grassland culture, however, is the quadrangular hut, with pyramidal or conical roof, ranged in streets, which differs distinctively from the forest-belt hut standing in its own irregularly placed clearing.

Capt. Malcolm's careful analysis of the culture of one area only of the Cameroons, even in this preliminary form, was not merely an indication of the extremely interesting material which still awaits investigation; it was also a valuable object-lesson of the method of studying a backward population which should form the essential basis of our administration in this and similar areas.

The Science Masters' Association.

AT the invitation of the Board of the Faculty of Natural Science, the annual meeting of the Science Masters' Association was held in Oxford on January 4–7. About two hundred members attended, and by the kindness of the Master of Balliol and the President of Trinity they were housed in these two colleges.

The meeting began on the evening of January 4 with the address of the president (Mr. A. Vassall, of Harrow) on "Some Aspects of Science and Education." Mr. Vassall dealt with education in science from the preparatory school to the university, and showed the evils of teaching in the earlier stages as if all the boys were ultimately to become specialists. The teaching should be such as to give every boy an opportunity of realising the scope and aims of science. It should impart to every boy the understanding of scientific problems necessary for the equipment of a modern State, and not be merely a training for future work in science, which in many cases will never be taken up seriously.

A lecture on spectroscopy, given by Prof. T. R. Merton, was concerned largely with the part played by observation and technique; observation cannot be effective with faulty apparatus. In the spectroscopy of gases the influence of traces of impurities is very great, and many beautiful experiments were shown to illustrate the methods of dealing with them. The conditions under which nitrogen gives a band spectrum and a line spectrum were shown; a tube was exhausted and filled with helium sufficiently free to enable the conditions for obtaining either a band spectrum or a line spectrum to be demonstrated. Also, a striking experiment was shown by which the presence of neon in the atmosphere was made evident. The method of getting hydrogen into and out of tubes by means of a heated side-tube of palladium was illustrated, and the curious fluorescence of parts of the human body was shown by illuminating the audience by light of wave-length about 3660 A.U., obtained by using a quartz mercury vapour lamp and a screen of special glass devised by Prof. R. W. Wood.

There were demonstrations in the various University laboratories, illustrating much of the teaching work of the University and some of the current investigations. Demonstrations were also given of the use of the microscope for the study of crystallisation, by Mr. T. V. Barker, who had prepared a pamphlet outlining a course of study suitable for schools, and of glass-blowing by Mr. B. Lambert, who gave many valuable hints on dealing with operations which are constantly a source of difficulty in making apparatus. All these demonstrations were repeated next day, and the association is greatly indebted to the distinguished University teachers who expended so much time and care on them.

A lecture on the control of growth was given by Mr. J. S. Huxley. After explaining the characteristics of the life-cycle of all animals, the lecturer showed how the growing stage could be accelerated or retarded by external conditions in the case of some lower organisms, and illustrated cases where it can be reversed. Two opposing processes may be distinguished, and by stimulating one or the other the progress of the resultant change can be controlled. An interesting case was related of an Australian soldier whose mind, as the result of shell-shock, reverted to the infantile stage, but, happily, on his return to Australia it developed again to the normal condition. Mr. Huxley went on to describe experiments with mice, the average life of which had been extended about 20 per cent. beyond the normal duration, and the treatment of a rat which had its youth restored after reaching a state of marked senility. In conclusion, the opinion was expressed that in the course of time it would be possible to extend the duration of man's life very appreciably.

A lecture on indicators and the law of mass action was delivered by Brig.-Gen. Hartley. The lecturer pointed out and illustrated the confusion resulting from the idea of neutralisation, and showed that the way to obtain a clear insight was to regard the indicators as weak acids or bases (fortunately the tautomeric changes need not be considered here) and work quantitatively in terms of the hydrion concentration from the known dissociation constants. Brig.-Gen. Hartley illustrated this by making four sets of solutions in which the hydrion concentration varied by factors of 10 from 10^{-3} to 10^{-10} (made by adding to $N/10$ acetic acid the calculated amounts of a solution of sodium acetate, as by this method the accidental introduction of impurities does not seriously alter the hydrion concentration), and adding to all the members of each series methyl-orange, methyl-red, phenolphthalein, and litmus respectively. It was then evident between what limits of concentration the colour change occurs in each case. Graphs were made showing the resultant hydrion concentration when various amounts of a particular alkali were added to 25 c.c. of a given acid. From these graphs it was at once evident what would be a suitable indicator and how sharp the colour change would be. Some further graphs showed the immense difference that would result if the constant for water were to have a different value.

In a lecture on the Hedjaz Mr. D. G. Hogarth gave an account of the geographical conditions and a most interesting review of the political positions since 1914 and their bearing on the war in the East.

Throughout the meeting there was an exhibition of apparatus and books by manufacturers and publishers.

Research on the Pink Boll-worm.

THE pink boll-worm, the larval stage of the Tineinid moth, *Gelechia gossypiella*, Saunders, is responsible for considerable damage to cotton in most cotton-growing regions, and its importance in Egypt has led to an extensive study of its habits and of methods of control (H. A. Ballou, 1920, "The Pink Boll-worm," Report of Ministry of Agriculture, Egypt; L. H. Gough, 1919, "On the Effect Produced by the Attacks of the Pink Boll-worm on the Yield of Cotton-seed and Lint in Egypt," *Agricultural Journal of Egypt*, vol. ix.).

The pink boll-worm was first discovered in Egypt in 1910, probably having been introduced in cotton from India, and in 1912 it had attained a position of first importance as a pest of cotton in that country, and since that time it has been the principal pest of this crop.

In its adult state *Gelechia gossypiella* is a small moth with a wing-spread of between 15 and 19 mm. The general colour of fresh specimens is coppery-brown with blackish spots varying in size and intensity. The eggs are laid on the green parts of the cotton plant, and the larvæ make their way to a boll or bud, where they feed inside the developing seeds or upon the ovules. When fully grown, the larva measures 10 to 12 mm. in length, the pinkish colour occurring in broad transverse bars on a yellow ground, and may pupate in the boll or seed or enter the earth. The larval state lasts from ten to nineteen days, but late in the season the larva, instead of pupating when full grown, may enter a resting stage, in which it may remain for as long as thirty months. This is the most important stage in the life of the insect, and the principal effort at control is directed at the larvæ before and during this stage.

The pink boll-worm damages cotton-seed in the boll, and its attacks result in reduced and weakened lint and reduced seeds, which may be light in weight and of low germinating power.

Legislation has made it compulsory for all plants to be pulled, and the remaining bolls destroyed, by a certain date, which varies between December 15 and January 15 in different districts; it has enforced the provision of approved machines for treating all seed in the ginneries by heat or fumigation, and made it compulsory for all stores containing cotton-seed to be screened from May to August to prevent the escape of adults.

The first campaign on a large scale against the pink boll-worm was carried out in 1916, and aimed at the destruction of resting larvæ in the bolls left in the field after the crop had been gathered. The method which is recommended for the future is for the cotton sticks to be removed from the field before cleaning, taken to a central place, and there cleaned by drawing through a comb or rake, no sticks to be allowed into a village until all have been passed by an inspector as clean, and the unclean sticks destroyed.

The picking of the crop should be as early as possible, as the attack of the pink boll-worm is more severe late in the season, and also the later larvæ are more likely to pass into the resting stage by which the infestation of the following year is caused.

Treatment of cotton-seed by heat at a temperature of from 53° to 73° C. was found to be effective in destroying all resting-stage larvæ, while having little effect on the percentage of germination of the seed.

The Optical Glass Industry.

THE *Daily Telegraph* published in its issues of December 28 and 29 two articles on the optical glass industry in this country. In a leading article of January 6 it says that, as England gave her scientific experimenters no assistance, supremacy in this highly skilled industry passed over to Germany, the Government of which had had the insight and the foresight to gauge its actual and potential value. When war broke out in 1914 there was but one firm—Messrs. Chance Brothers and Co., Ltd.—manufacturing optical glass in the British Empire. The consequence was that during the first year of the war our armies and our fleets could not be equipped with the optical glass required. Thanks to the brilliant research work of Sir Herbert Jackson and his colleagues on the Glass Research Committee of the Institute of Chemistry; to the investigations and work of Messrs. Chance Brothers; and, later, to the work done by the Derby Crown Glass Co., Ltd., by the end of the war British optical glass was as good as German, and was being produced in quantities sufficient to meet every demand. Messrs. Chance Brothers were manufacturing in one year optical glass sufficient to meet three years of the whole world's peace demand before the war. The Derby Crown Glass Co., which, before it was requested to do so by the Optical Munitions Department of the Ministry of Munitions, had not made an ounce of optical glass, is now producing some seventy or more different types and varieties "of a quality," says Prof. Cheshire, "which challenges comparison with the best in the world." Nor is this all. The establishment of the British Scientific Instrument Research Association, of the Department of Technical Optics at the Imperial College of Science and Technology, and of the Department of Glass Technology at the University of Sheffield, and the work of the National Physical Laboratory are all designed to consolidate and extend the ground gained, so that our manufacturers may keep in the front rank and not again allow themselves to be outstripped. But, the *Daily Telegraph* points out, the industry is again exposed to the full blast of German competition, more formidable now than ever because of the state of the German exchange. The editorial article in our contemporary concludes by endorsing the demand of the industry that the Government shall implement the verbal assurances given during the war, and, by a system of importation only under licence for a period of, say, seven years, enable this industry—"of all others a key industry"—to be safely tided over this abnormal period.

Mineral Resources of the United States.

ATTENTION may be directed to Bulletin No. 666 of the United States Geological Survey, recently issued, entitled "Our Mineral Supplies," which gives a brief account of the mineral resources of the United States, compiled from the point of view of the importance of rendering the United States economically independent of the rest of the world so far as mineral output is concerned. Even before America took part in the war it was recognised that her stocks of imported minerals were likely to be exhausted, or at any rate seriously depleted, and that it was necessary to take measures to ascertain how far it was possible to replace these minerals from home resources. Certain minerals were imported from choice rather than from necessity, because they could be obtained of higher grade, or more conveniently, or more cheaply from abroad, and in these cases it was only necessary to stimulate the home production. In a few other cases the minerals were imported because they either did not occur at all or did not occur in workable quantities or under workable conditions within the United States. The list of such minerals is, however, surprisingly short. All minerals are here classified under three heads, namely: Class 1, domestic mineral supplies adequate to all probable peace and war needs of the United States; Class 2, domestic mineral supplies sufficient for a large part of the peace and war needs of the United States; and Class 3, domestic mineral supplies inadequate in quantity or quality, or both, for the peace and war needs of the United States. This last class includes only asbestos, chromite, graphite, manganese ore, monazite, nickel, nitrates, platinum, potash salts and tin, and in only three of these, namely, monazite, nitrates and potash, was there no production at all in 1913, and only in the case of nitrates was there no production in 1917. In many cases, even amongst those minerals that occur but sparingly, the production had increased immensely during those four years. Thus, for example, the production of chromite was 255 tons in 1913 and 43,725 tons in 1917. Although not written with that object, this bulletin gives a vivid impression of the wonderful natural resources of the United States.

University and Educational Intelligence.

BRISTOL.—Mr. W. A. Andrews has been appointed lecturer on applied chemistry at the Merchant Venturers' Technical College in succession to Capt. H. Stanley. Mr. Andrews is at present a member of the staff of the Cardiff Technical College.

CAMBRIDGE.—The alternative scheme drawn up by one-half of the Syndicate on the relation of women students to the University will be submitted to the Senate for approval on February 12. A grace is proposed expressing the approval of the Senate of the incorporation of Girton and Newnham Colleges into a University, which Cambridge University would assist and co-operate with in various ways. The women's colleges have given notice that they will not take any steps towards the formation of a separate University even if the report is approved, so that the question will not apparently be much affected whichever way the voting goes.

Prof. Burkitt has offered the University, on behalf of a number of people interested in Oriental archæology, a sum of 20*l*. annually to enable the University to become "a subscribing learned society" to the British School of Archæology in Jerusalem. This will give the University the power to nominate one student at the school.

WE have received a copy of the annual report and statement of accounts of Livingstone College, E.10, for the year 1919–20. For more than three years during the war the buildings were used as a hospital for wounded soldiers, but they have now reverted to their proper function of training missionaries in the elements of practical medicine and surgery. The usefulness of the college has been extended by the decision to admit women as students. It is also announced that a special residential vacation course will be held in July this year on the care of health in the tropics with practical clinical work. In spite of the strictest economy the debit balance increased by 360*l*. during the year, and the deficit now amounts to 931*l*. Donations towards the financial needs of the college are earnestly solicited.

FROM the *Pioneer Mail* for December 24 we learn that the Raja of Mahmudabad inaugurated the Muslim University of Aligarh on the morning of December 17. The proceedings began with a recitation from the Koran, after which the Raja Sahib, who is the first Vice-Chancellor of the new University, read his inaugural address. He gave some account of the history of various Islamic universities, and expressed the hope that the new institution would cause a revival of old Islamic arts and sciences as well as bring modern science within the reach of Muslim youths. The same evening, at the dinner given by the Vice-Chancellor, the latter suggested that the new University should endeavour to raise funds to render it independent of Government assistance; to start this fund he himself promised to give a lakh of rupees (6666*l.*).

THE *Daily Mail* is offering four scholarships, each of the total value of 250*l.*, for students who intend to study for the degree of Bachelor of Commerce at London University. Candidates must be British-born, and they must be engaged, or about to engage, in whole-time business employment. The qualifying examination will be the London Matriculation Examination of June, 1921, and candidates must enter for this in addition to applying for the scholarships. Application forms for candidates living within the 20-mile radius of London will be available at the Efficiency Exhibition, which will open at Olympia on February 10; those living outside this radius can obtain the forms after that date by applying for the catalogue of the exhibition, price 1*s.* 3*d.*, to "Efficiency Catalogue," *Daily Mail*, Carmelite House, London, E.C.4. Candidates must show that they are engaged, and intend to continue to be engaged, in whole-time employment in business and that they propose to pursue a regular course of study for the degree in commerce. The scholarships will be tenable for four years, and payments of the grant will be subject to the student's progress.

THE second Congress of Universities of the Empire will be held at Oxford on July 5–8 of this year. As at the first congress, which met in London in 1912, it is expected that there will be a large attendance of representatives of the universities of the United Kingdom and of the King's Dominions overseas. For a month all delegates from overseas will be the guests of the home universities; the latter will be visited in turn either before or after the full meeting of the congress. In August last letters were addressed to all the universities overseas, and in October a similar circular was sent to all the universities of the United Kingdom, asking for suggestions for the agenda for the coming congress. A sub-committee consisting of the officers of the Bureau and the Vice-Chancellors of Oxford and Cambridge sat to consider the answers received, and it was decided that the second congress should be devoted to considerations of the chief fields of university activity, particularly to those which are new and likely to be viewed from diverse points of view. The agenda therefore consists of subjects dealing with the position of the universities with regard to secondary, adult, technological, and commercial education; with university curricula, research, and finance; and with the problems of the interchange of teachers and students between different universities. Lord Curzon, Mr. A. J. Balfour, Lord Haldane, Lord Crewe, Lord Balfour of Burleigh, Lord Shaftesbury, Lord Robert Cecil, and Lord Kenyon will preside at successive meetings of the congress.

IN March of last year a Royal Commission was appointed to inquire into the financial resources and working of the University of Dublin and of Trinity College, Dublin, and to consider the application made by the University for State financial assistance. The report of the Commission, of which Sir Archibald Geikie was chairman, has been issued as a Parliamentary Paper (Cmd. 1078). The Commissioners estimate that the annual cost over and above the present expenditure of the college of carrying into effect various recommendations will be 49,000*l.*, and that a further sum of 113,000*l.* will be required to provide for new buildings and equipment, reconstruction, and necessary repairs. They are unanimously of opinion that the existing resources of the University of Dublin should be augmented from public funds by an immediate non-recurrent grant of 113,000*l.* and an annual subsidy of 49,000*l.* The following are some of the annual grants recommended:—Physics, 1350*l.*; Dunsink Observatory, 900*l.*; chemistry, 2228*l.*; botany, 2050*l.*; geology, 1400*l.*; zoology, 2150*l.*; medicine, 5692*l.*; engineering, 4270*l.*; agriculture, 2000*l.*; the library, 1588*l.*; research or travelling exhibitions, 2400*l.* Of the capital expenditure 31,500*l.* is recommended for new construction and renovation for the School of Chemistry; 2000*l.* for gardens for the School of Botany; 7000*l.* for a new building for the School of Zoology; 16,000*l.* for a new building for bacteriological research; 19,500*l.* for the Department of Physiology; 25,000*l.* for the extension of premises and equipment of the Department of Engineering; and 12,400*l.* for a new library building and equipment.

ENGINEERING education in the United States is carried on in two types of institution: universities and independent institutes (Higher Education Circular, No. 20, of the Bureau of Education, 1920). The American university differs in its organisation from the universities both of Latin America and of Europe. Typically, it contains a number of "schools" to which students are admitted direct from the secondary schools, and one or more divisions, such as medical and law schools, to which students are admitted only after they have completed two years' training in one of the schools mentioned above. Engineering is a school which offers professional training leading to engineering degrees to students straight from the secondary schools; generally, engineering schools are administered as separate units. The independent institutes are usually devoted solely to engineering, and, academically, the training they provide is of the same standard as that offered by the universities. Both provide a course lasting four years which leads to the degree of B.S. in some branch of engineering; it is at the same time, in spirit and in tendency, a professional course fitting young men for the immediate practice of their professions. In consequence, the curriculum is determined by the requirements of the profession, and, therefore, somewhat rigidly prescribed. Recently the tendency has been to lengthen the training, and several universities are now offering five- and six-year courses. The expenses of foreign students attending American institutions vary; tuition fees range from 150 to 300 dollars per annum in the privately endowed schools, and in State-supported institutions from 20 to 125 dollars a year. Living expenses are assessed at 500 to 700 dollars per annum, and further allowance must be made for travelling expenses when the institution is some distance from ports of entry. A list is given of 127 schools providing four-year courses in engineering which show an enrolment of 51,400 students; one school alone, the Massachusetts Institute of Technology, has accepted 2291 students, while fourteen others have each more than 1000 pupils.

Calendar of Scientific Pioneers.

January 20, 1907. Agnes Mary Clerke died.—Widely known for her astronomical writings, Miss Clerke, like Mary Somerville, Caroline Herschel, Ann Sheepshanks, and Lady Huggins, was an honorary member of the Royal Astronomical Society.

January 21, 1892. John Couch Adams died.—Few scientific achievements have aroused more interest or more controversy than the discovery of Neptune, and the careers of few astronomers have opened so brilliantly as that of Adams, who simultaneously with Leverrier worked out the calculations demonstrating the existence of this planet. After working at the problem for two years Adams in September, 1845, communicated his results to Challis, and in October to Airy. Leverrier's papers were published shortly afterwards, and Neptune was first seen by Galle at Berlin on September 23, 1846. Adams, who was born in Cornwall on June 5, 1819, became Lowndean professor in the University of Cambridge in 1858, and in 1861 succeeded Challis as director of Cambridge Observatory.

January 22, 1799. Horace Bénédict de Saussure died.—Saussure was the first great explorer of the Alps. A naturalist and a physicist, he has been called "the founder of experimental geology," and he is said to have been the first to place meteorology on a reasonable basis.

January 22, 1840. Johann Friedrich Blumenbach died.—For more than fifty years Blumenbach held the chair of anatomy at Göttingen, and wrote works on physiology, anatomy, embryology, and ethnology which became European text-books.

January 22, 1867. Sir William Snow Harris died.—A prominent worker in electricity, Harris by his new form of lightning conductor added greatly to the safety of ships at sea.

January 22, 1900. David Edward Hughes died.—Son of a bootmaker who emigrated to America, Hughes in 1855 patented his type-printing telegraph, and in 1857 came to England. In 1878 he patented his microphone. Recognised as one of the greatest scientific inventors of the age, he amassed a fortune of nearly half a million sterling, which was given mainly to London hospitals and scientific societies.

January 24, 1877. Johann Christian Poggendorf died.—Poggendorf was for fifty years editor of the *Annalen der Physik und Chemie.*

January 24, 1914. Sir David Gill died.—Astronomer-Royal at the Cape of Good Hope, Gill was one of the best known astronomers of his day. He is especially remembered for his great geodetical operations, his determination of the solar parallax, and his pioneering work in connection with the photographic survey of the heavens.

January 26, 1631. Henry Briggs died.—On the foundation of Gresham College, London, Briggs was appointed to the chair of geometry, the first of its kind in England. He was also the first to hold the Savilian chair of geometry at Oxford.

January 26, 1823. Edward Jenner died.—After twenty years' experimenting, Jenner on May 14, 1796, made his first vaccination. Three years later seventy London doctors declared their confidence in his discovery, which was soon promulgated throughout the world. Parliament acknowledged the country's indebtedness to him by voting him sums totalling 30,000*l*.

January 26, 1895. Arthur Cayley died.—Senior wrangler in 1842, Cayley for many years was a law conveyancer, but in 1863 became first Sadlerian professor of mathematics at Cambridge.

E. C. S.

Societies and Academies.

LONDON.

Aristotelian Society, January 3.—The Very Rev. Dean W. R. Inge, president, in the chair.—C. A. **Richardson**: The new materialism. The new materialism takes the form of a denial of anything corresponding to the idea of "mind" or "subject." Unlike the old doctrine, it does not affirm the reality of atoms; its ultimate stuff is sense-material. It reduces the subject of experience to a series of sense-data, and the sense-data are conceived as ontologically independent of the subject. Against this it was argued that the subject of experience is a real metaphysical existence. Experience consists in spiritual activity, and one type of this activity is sense-experience. The content, sense-data, is the particular form the activity assumes, and the form is determined by the interaction of individual subjects. The most pressing philosophical need of the day is to come to an agreement on this point. Until we are agreed as to whether there exists the subject or mind there must be disagreement on the fundamental matter of philosophy, namely, the entities in terms of which theories may be formulated. Without a common platform philosophy will be left behind, a curious relic, by the intuitive wisdom of the vast mass of humanity.

DUBLIN.

Royal Dublin Society, December 21.—Dr. F. E. Hackett in the chair.—J. J. **Dowling** and D. **Donnelly**: The measurement of very short intervals of time by the condenser-charging method. An investigation of the degree of accuracy obtainable in the measurement of short time intervals by a method in which the time interval is determined by observing the charge taken up by a condenser connected to a source of steady electromotive force through a known resistance during the interval in question. It was found possible to measure intervals of thirty millionths of a second with an accuracy of one millionth of a second.—J. J. **Dowling** and J. T. **Harris**: An apparatus is described whereby a spark-gap, included in the secondary circuit of a high-tension transformer, is rendered conducting during one-half of each cycle, thus permitting a current to flow in one direction only. The primary current energises an electromagnet which sets into vibration the diaphragm of a König manometric flame, situated in the spark-gap. A subsidiary winding allows the magnet to be polarised by a steady current so as to cut out each alternate flame oscillation. Various tests of the apparatus are described which indicate that very complete rectification is obtainable.—J. J. **Dowling**: A sensitive valve method for measuring capacities, with some important applications. A steady source of alternating e.m.f. is connected to a circuit consisting of a high resistance in series with a condenser. The drop of potential across the resistance is proportional to the capacity of the condenser. The filament and grid of a three-electrode valve respectively are connected to the ends of the resistance, and variations of the capacity of the condenser thus bring about corresponding variations in the plate current. The greater part of this is balanced by an opposed steady current derived from a battery connected through an adjustable resistance to the galvanometer terminals. Using a galvanometer of high sensitivity, very small variations can be detected. The application of this principle to the construction of an ultra-micrometer and of a micro-pressure gauge are described. Displacements of the order of 10^{-7} cm. are easily measurable. Further work is in progress.

PARIS.

Academy of Sciences, December 27.—M. Henri Deslandres in the chair.—H. **Douvillé**: The Eocene of Peru. From the examination of a number of fossils sent by Prof. Lisson (of Lima) it is concluded that the views of Grzybowski, published in 1899, must be modified. Only the upper portion of the Payta strata can still be attributed to the Pliocene; the remainder of the Tertiary Peruvian layers reproduces very closely the constitution of the Californian Eocene, and, like the latter, contains lignite and oil. —P. **Termier** and W. **Kilian**: The age of the glistening schists of the Western Alps. The age of these deposits has been much discussed with widely varying deductions. The authors, after a survey of the existing data, conclude that there is certainly Lias in these strata, and very probably some of the Upper Trias.—C. **Richet** and H. **Cardot**: The hereditary transmission of acquired characters in micro-organisms. A study of the influence of toxic substances (antiseptics) on the lactic bacillus, of the immunity acquired by successive generations, and of the transmission of this acquired immunity to antiseptics.—G. **Charpy** and J. **Durand**: The melting point of coal. It is well known that with certain coals a rise of temperature produces a softening, sometimes called the melting point. This agglomeration point is very important from the point of view of coke manufacture, but it would appear that no exact measurements of this temperature have been made. A description is given of the method devised to give definite readings, with results for eight coals. The "melting point" is characteristic for a given coal, and is independent of the amount of volatile matter present.—L. E. **Dickson**: Polynomials equivalent to determinants.—S. **Bays**: Cyclic systems of Steiner.—G. **Giraud**: Reply to a note by M. Fubini on automorph functions.—P. **Humbert**: Hypertoroidal functions and their connection with hyperspherical functions.—T. **Varapoulos**: The zeros of the integrals of a class of differential equations.—R. **Birkeland**: Resolution of the general algebraical equation by hypergeometrical functions of several variables.—B. **de Fontviolant**: Calculation of the strengths of circular bridges.—H. **Godard**: Observation of the Skjellerup comet made at the Bordeaux Observatory (38-cm. equatorial). Position given for December 17. The comet is a nebulosity of about 1′ diameter without visible nucleus: 11th magnitude.—M. **Michkovitch**: Observation of the Skjellerup comet made at the Marseilles Observatory (26-cm. Eichens equatorial). Position given for December 20.—A. **Hansson** and H. **Jelstrup**: Spectrum of Nova Aquilæ III. in July, 1920. The two photographs, one of two hours' and the other of one hour's exposure, showed a large number of bright lines on a background of continuous spectrum, and, consequently, the identification of the bright lines proved to be difficult. A table of the wave-lengths of the lines identified is given, and includes lines attributed to calcium, helium, iron, hydrogen, and to the element characteristic of nebulæ.—L. **Bloch**: Comparison of the theories of Lorentz and Mie.—P. **Vaillant**: The variations in the electrical conductivity of calcium sulphide with temperature. When a thin layer of calcium sulphide previously exposed to sunlight is heated its electrical conductivity rapidly increases, passes through a very marked maximum, and then decreases almost to zero. The phenomenon is closely connected with the state of phosphorescence.—G. **Contremoulins** and E. **Puthomme**: The determination of the time of exposure in radiography.—P. **Lebeau** and A. **Damiens**: The composition of some coke-oven gases. Analyses of four samples of coke-oven gas made by a method described in an earlier publication. Compared with coal-gas, the main differences are the lower percentage of hydrogen and the high proportion (20 per cent.) of nitrogen.—H. **Le Chatelier**: Remarks on the preceding paper.—M. **Godchot**: The catalytic addition of hydrogen to suberone. By the action of reduced nickel and hydrogen at 175° C. suberone is converted into suberol. Attempts to form a six-carbon ring from suberone by the action of active nickel at 240° C. were unsuccessful, differing in this respect from *cyclo*heptane.—P. H. **Fritel**: The presence of the genera Phragmites and Nephrodium in the Pleistocene clays of Benenitra (Madagascar).—A. **Nodon**: Solar action and the recent atmospheric disturbances.—P. **Mazé**: Researches on the assimilation of carbon dioxide by green plants. The fresh leaves were heated to 60° C. under reduced pressure and the distillate was received in an ice-cooled receiver. In no case could formaldehyde be detected, but nearly all plants gave ethyl alcohol, acetaldehyde, and nitrous acid. Beans and maize collected in fine weather gave acetylmethylcarbinol, elder leaves gave hydrocyanic acid and glycollic aldehyde, whilst lactaldehyde was obtained from poplar leaves.—A. **Desgrez** and H. **Bierry**: Nitrogen equilibrium and carbohydrates in the food ration. Below a certain limit no other food can replace carbohydrates.—A. **Mayer**, M. **Plantefol**, and F. **Vlès**: Poisoning by the nitrohalogen methanes. Chloropicrin has the most powerful toxic effect; bromopicrin and dichlorodinitromethane are from eight to ten times less active.—R. **Anthony**: Tubular pseudo-hermaphroditism in male Cetaceans.—A. **Dehorne**: The spermatogenesis of *Corethra plumicornis* and eupyrene chromosomes.—M. **Doyon**: Participation of the cellular nuclei in the phenomena of secretion. The anti-coagulating properties of the nucleinic acid of the intestine.—A. **Malaquin**: Sexual and asexual reproduction.—L. **Cavel**: The purification of sewage by the activated-sludge method.

SYDNEY.

Royal Society of New South Wales, December 1.—Mr. J. Nangle, president, in the chair.—Dr. J. A. **Pollock**: The stethoscope, with a reference to a function of the auricle. Various forms of stethoscope are considered; the acoustic determination of surface vibrations has a definite dynamical aspect when the disturbances are very small. Detection in all the instances described depends on the movements of the surface relative to a steady mass elastically connected with it. In detecting small movements with the old-fashioned stethoscope, or after the manner of the tracker, the mechanism is supplied by the head and ear, the auricle having the very definite function of acting as the elastic connection between the mass and the surface. In other cases where the air disturbances are led by tubes directly into the ear passages the mechanical action is recognisable as associated with the instruments.—A. R. **Penfold**: The essential oils of *Leptospermum odoratum* and *L. grandiflorum*. The principal constituents of the former are eudesmene and aromadendrene (sesquiterpenes), eudesmol (sesquiterpene alcohol), α- and β-pinene, with smaller amounts of a rose-odour alcohol, esters, and phenols. This is the first time that eudesmene has been found occurring in Nature. *Leptospermum grandiflorum* consists principally of the same two sesquiterpenes with an unidentified sesquiterpene alcohol.—M. B. **Welch**: Eucalyptus oil-glands. The oil was formerly considered to be present as a single globule contained in a small cavity, but it would now appear that it is rather in the form of an emulsion in cavities which usually approach the surface. Oil occurs also in the stems, buds, fruit, and, in rare species, in the barks. The glands are often more or less devoid of contents, and in the different species show decided variation in arrangement and number. Their origin is evidently due to the separation of certain cell-tissues and their later disintegration.—Dr. G. **Harker**: The temperature of the vapour arising from boiling saline solutions. It is shown that the temperature of the vapour can be obtained well over 100° C. by boiling the solution in a hypsometer, either by a Bunsen flame or by admission of steam from water boiled in a separate vessel. With a solution of calcium chloride boiling normally at 115° C. a temperature of 106° C. was obtained for the vapour at a point 10 in. above the boiling solution. It is claimed that under the conditions of the experiment superheating could not take place.—J. H. **Maiden**: Notes on two Acacias. (1) The first is a spreading shrub, which may, however, assume an erect habit and become 10 ft. high. Its affinities are shown in that it was formerly known as *Acacia doratoxylon* var. *angustifolia*. It differs from that species in its habit, in its smaller size, in the short sessile flower-spikes, which are axillary and not racemose, and in the hairy ovary. It is found chiefly in the New England granite country from Howell, near Tingha, as far north as Stanthorpe and the Toowoomba district in Queensland. (2) The second wattle is submitted as a form or race of *Acacia pycnantha*, Benth., or a new species. In its ordinary morphological characters it resembles closely the species named, but there are important differences in the seedlings, the percentage of tannin in the bark, and other characters which lead the author to propose it as a new species. The type comes from Jerrabomberra, in the Federal Territory, near Queanbeyan.—E. **Cheel**: A native tea-tree, *Leptospermum flavescens* var. *grandiflorum*. This plant occurs in the deep creeks and river-beds from Penrith, extending to the Blue Mountains on the western line, and from Douglas Park to Braidwood on the southern line and tablelands. It was suggested that the plants were quite different from any other species, and the oil obtained from the leaves by Mr. A. R. Penfold tends to confirm this view.

Books Received.

The Foundations of Chemical Theory. By Prof. R. M. Caven. Pp. viii+266. (London: Blackie and Son, Ltd.) 12s. 6d. net.

A Physician's Anthology of English and American Poetry. Selected and arranged by Dr. C. A. Wood and Dr. F. H. Garrison. Pp. xxiii+346. (London: Oxford University Press.) 8s. 6d. net.

Les Hommes Fossiles: Eléments de Paléontologie Humaine. By Prof. M. Boule. Pp. xi+491. (Paris: Masson et Cie.) 40 francs.

Penrose's Annual. Volume 23 of the Process Year Book and Review of the Graphic Arts. 1921. Edited by W. Gamble. (London: P. Lund, Humphries and Co., Ltd.; Bradford: The Country Press.) 10s. 6d. net.

Personal Beauty and Racial Betterment. By Prof. K. Dunlap. Pp. 95. (London: H. Kimpton.) 6s. net.

Practical Dental Metallurgy. By Prof. J. D. Hodgen. Fifth edition, completely revised. Pp. 436. (London: H. Kimpton.) 15s. net.

Lubricating and Allied Oils: A Handbook for Chemists, Engineers, and Students. By E. A. Evans. (The Directly-Useful Technical Series.) Pp. xv+128. (London: Chapman and Hall, Ltd.) 9s. 6d. net.

Science Masters' Association: Oxford Meeting, January 5–6, 1921. Practical Suggestions towards the Study of Crystals in Schools. By T. V. Barker. (Oxford: The Holywell Press.) 1s. net.

Paläontologie und Abstammungslehre. By Prof. K. Diener. Zweite auflage. Pp. 137. (Berlin and Leipzig: W. de Gruyter and Co.) 1s. 9d.

The Theory of Direct-Current Dynamos and Motors. By J. Case. Pp. xiii+196. (Cambridge: W. Heffer and Sons, Ltd.) 15s. net.

An Introduction to the Chemistry of Plant Products. By Dr. P. Haas and T. G. Hill. Vol. i.: On the Nature and Significance of the Commoner Organic Compounds of Plants. Third edition. Pp. xiii+414. (London: Longmans, Green and Co.) 16s. net.

A Text-Book of Physics. By Dr. W. Watson. Seventh edition, revised by H. Moss. Pp. xxvi+976. (London: Longmans, Green and Co.) 21s. net.

Department of Applied Statistics (Computing Section), University of London, University College. Tracts for Computers. Edited by Karl Pearson. No. ii.: On the Construction of Tables and on Interpolation. Part i.: Uni-variate Tables. By Karl Pearson. Pp. 70. 3s. 9d. net. No. iii.: On the Construction of Tables and on Interpolation. Part ii.: Bi-variate Tables. By Karl Pearson. Pp. 54. 3s. 9d. net. (London: Cambridge University Press.)

General Practice and X-Rays: A Handbook for the General Practitioner and Student. By Alice V. Knox. Pp. xiv+214+xxxii plates. (London: A. and C. Black.) 15s. net.

Diary of Societies.

THURSDAY, JANUARY 20.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Dr. A. Harden: Biochemistry (Vitamines).

ROYAL SOCIETY, at 4.30.—Sir Robert Hadfield, Bart., S. R. Williams, and I. S. Bowen: The Magnetic Mechanical Analysis of Manganese Steel.—Dr. W. S. Tucker and E. T. Paris: A Selective Hot-wire Microphone.—E. A. Milne and R. H. Fowler: Siren Harmonics and a Pure Tone Siren.—Prof. L. V. King: The Design of Diaphragms capable of Continuous Tuning.

LINNEAN SOCIETY, at 5.—Prof. E. H. C. Walsh: Lhasa and Central Tibet.

ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts), at 5.—Lord Montagu of Beaulieu: The Cost of Air Ton-miles compared with Other Forms of Transport.

ROYAL SOCIETY OF MEDICINE (Dermatology Section), at 5.

INSTITUTION OF MINING AND METALLURGY (at Geological Society), at 5.30.—R. E. Palmer: Some Observations on Mining by the Opencast or Stripping Method.—E. A. Wraight: The Standardisation of Materials Employed in Mining and Milling Plant.—A. M. Pontic: Notes on the High-level Diamond Deposits of Brazil.

INSTITUTION OF AUTOMOBILE ENGINEERS (London Graduates' Meeting), at 8.—W. H. Wardall: Cylinder and Piston Wear.

CHEMICAL SOCIETY, at 8.—J. V. Backes, R. W. West, and M. A. Whiteley: Quantitative Reduction by Hydriodic Acid of Halogenated Malonyl Derivatives. Part I., The Amides of Sym. Dialkyl and Aryl Substituted Amides of Mono- and Di-bromomalonic Acid.—B. M. Gupta: An Investigation on the Influence of Negative Groups of Different Character on the Reactivity of Hydrogen Atoms Carried by the Same Carbon Atom. Part I.—J. Brönsted: The Influence of Salts upon the Chemical Equilibria in Solution.—H. Hepworth: The Action of the Grignard Reagent on Certain Nitric Esters.—G. T. Morgan and H. D. K. Drew:

Researches on Residual Affinity and Co-ordination. Part III., Reactions of Selenium and Tellurium Acetylacetones.—G. T. Morgan and D. C. Vining: Dihydroxynaphthaldehydes.—G. T. Morgan: Ortho-chlorodinitrotoluenes. Part II.—C. K. Ingold: The Conditions Underlying the Formation of Unsaturated and of Cyclic Compounds from Halogenated Open-chain Derivatives. Part I., Products Derived from α-Halogenated Glutaric Acids.—A. Findlay and W. Thomas: Influence of Colloids on the Rate of Reactions involving Gases. I., Decomposition of Hydroxylamine in Presence of Colloidal Platinum.—M. Nierenstein: The Constitution of Catechin. Part III., Synthesis of *aca*Catechin.—K. G. Naik: The Formation and Properties of Dithioketones ($R_2C=S=S$) and Dithioethers ($R_2S=S$). Part I., The Preparation of Certain Dithioketones and Dithioethers.—W. N. Haworth and E. L. Hirst: The Constitution of the Disaccharides. Part V., Cellobiose (Cellose).—S. H. C. Briggs: The Elements Regarded as Compounds of the First Order.—J. D. Morgan and R. V. Wheeler: Phenomena of the Ignition of Gaseous Mixtures by Induction Coil Sparks.—E. J. Williams: Chloroform Solutions of Hydrogen Chloride.—L. J. Hudleston and H. Bassett: Equilibria of Hydrofluosilicic Acid.—E. Newbery: Chlorine Overvoltages.—P. Rây and P. V. Sarkar: Compounds of Hexamethylenetetramine with Complex Metallic Salts and Acids.

RÖNTGEN SOCIETY (in Physics Laboratory, University College), at 8.15.—M. A. Codd: Increasing the Efficiency of X-ray Tubes by an Improved Design of Coil and Interrupter.

FRIDAY, JANUARY 21.

ROYAL SOCIETY OF ARTS (Indian Section), at 4.30.—Prof. R. S. Troup: Indian Timbers.

ROYAL SOCIETY OF MEDICINE (Otology Section), at 5.—T. R. Rodger: Cavernous Sinus Thrombosis.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Prof. A. Keith: The Principles of Craniology applied to Clinical and Racial Problems.

INSTITUTION OF MECHANICAL ENGINEERS, at 6.—H. J. Smith: The Mechanical Loading of Ships.

INSTITUTION OF ELECTRICAL ENGINEERS (at Faraday House, Southampton Row), at 6.30.—H. J. Howard: Electric Welding.

GEOLOGISTS' ASSOCIATION (at University College), at 7.30.—G. Barrow: The Origin and Age of Post-Eocene Brick-earths near London.

JUNIOR INSTITUTION OF ENGINEERS (at Caxton Hall), at 8.—B. H. Joy: Motor Yachts.

ROYAL SOCIETY OF MEDICINE (Electro-Therapeutics Section), at 8.30.—Dr. W. J. Turrell: The Therapeutic Activity of the Galvanic Current.

SATURDAY, JANUARY 22.

BRITISH MYCOLOGICAL SOCIETY (in Botanical Department, University College, Gower Street), at 11 a.m.—F. T. Brooks: Some Tomato Fruit Diseases.—Dr. E. J. Butler: The Imperial Bureau of Mycology.—Miss G. Lister: A New Genus of the Mycetozoa from Japan.—T. Petch: Thread Blights.—Dr. H. Wager: The Action of Gravity on the Fungi.—J. Ramsbottom: Exhibit of Lantern Slides showing Fungal Infection of Orchid Seeds.

PHYSIOLOGICAL SOCIETY (at King's College), at 4.

MONDAY, JANUARY 24.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Prof. A. Keith: The Principles of Craniology applied to Clinical and Racial Problems.

ROYAL SOCIETY OF ARTS, at 8.—A. E. L. Chorlton: Aero Engines (Howard Lectures).

ROYAL SOCIETY OF MEDICINE (Odontology Section), at 8.—Sir Frank Colyer: Old Dental Instruments.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—F. C. Cornell: The Lower Reaches of the Orange River.

MEDICAL SOCIETY OF LONDON, at 8.30.—Dr. A. Feiling: Multiple Neuritis.

TUESDAY, JANUARY 25.

ROYAL HORTICULTURAL SOCIETY, at 3.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir Gerald P. Lenox-Conyngham: The Progress of Geodesy in India.

INSTITUTION OF CIVIL ENGINEERS, at 5.30.—Resumption of Discussion on paper by Prof. T. B. Abell on Reinforced Concrete for Ship-Construction.—G. Ellson: Cannon Street Bridge Strengthening.—F. W. A. Handman: Reconstruction of a Viaduct.

ROYAL SOCIETY OF MEDICINE (Medicine Section), at 5.30.—Dr. P. J. Cammidge: Some Observations Bearing on the Etiological Classification of Diabetes Mellitus.—Dr. E. P. Poulton: The Treatment of Peptic Ulcer by Means of Gastric and Gastro-duodenal Tubes.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—Dr. F. M. D. Berry: Serbia and Jugo-Slavia Before the War and After.

ROYAL ANTHROPOLOGICAL INSTITUTE (Annual General Meeting), at 8.15.

WEDNESDAY, JANUARY 26.

ROYAL SOCIETY OF ARTS, at 4.30.—A. Abbott: The Origin and Development of the Research Associations Established by the Department for Scientific and Industrial Research.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Prof. A. Keith: The Principles of Craniology applied to Clinical and Racial Problems.

INSTITUTION OF CIVIL ENGINEERS (Students' Meeting), at 6.—F. E. Wentworth-Sheilds: The Lay-out and Equipment of Docks (Vernon-Harcourt Lecture).

THURSDAY, JANUARY 27.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Dr. A. Harden: Biochemistry (Vitamines).

ROYAL SOCIETY, at 4.30.—*Probable Papers.*—K. Sassa and Prof. C. S. Sherrington: The Myogram of the Flexor-reflex evolved by a Single Break-shock.—Sir Almroth Wright: "Interaction" Between Albuminous Substances and Saline Solutions.—Dr. S. Russ, Dr. Helen Chambers, and Gladwys M. Scott: The Local and Generalised Action of Radium and X-rays upon Tumour Growth.

ROYAL SOCIETY OF MEDICINE (Balneology and Climatology Section), at 5.30.—Dr. G. L. Pardington: Advancing Years and Balneotherapy (Presidential Address).

INSTITUTION OF ELECTRICAL ENGINEERS (at Institution of Civil Engineers), at 6.—G. A. Juhlin: Temperature Limits of Large Alternators.

ROYAL SOCIETY OF MEDICINE (Urology Section), at 8.30.—T. Walker: Obstruction After Suprapubic Prostatectomy and an Open Operation for its Prevention.

FRIDAY, JANUARY 28.

ASSOCIATION OF ECONOMIC BIOLOGISTS (at Imperial College of Science), at 2.30.—Dr. L. Lloyd: Greenhouse White Fly and its Control.—W. B. Brierley: Personal Impressions of Some American Biologists and their Problems.

ROYAL SOCIETY OF MEDICINE (Study of Disease in Children), at 5.—Dr. P. Parkinson: A Case of Patent Ductus Arteriosus.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Prof. A. Keith: The Principles of Craniology applied to Clinical and Racial Problems.

PHYSICAL SOCIETY OF LONDON (at Imperial College of Science), at 5.—Prof. H. Nagaoka: The Magnetic Separation of the Neon Lines and Runge's Rule.—Capt. E. V. Appleton: A Method of Demonstrating the Retro-active Property of a Triode Oscillator.—Dr. D. Owen and R. M. Archer: The Quickness of Response of Current to Voltage in a Thermionic Tube.

ROYAL SOCIETY OF MEDICINE (Epidemiology and State Medicine Section), at 8.30.—Dr. A. S. M. MacGregor: Some Features of Current Small-pox in Glasgow.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Sir James Dewar: Cloudland Studies

University Appeals.

A FEW weeks ago announcement was made that in a lightning campaign the sum of 1,580,000*l.* had been obtained as a centennial endowment fund for McGill University, Montreal. The amount subscribed exceeded what the campaign was started to raise, and it included contributions of one million dollars each from the Government of the Province of Quebec and the Rockefeller Foundation.

There have recently been three similar appeals for funds for university institutions in this country; but, whatever may be the ultimate result, they have not yet been marked by the ready and overflowing aid rendered to McGill University. In October last the University of Birmingham appealed for 500,000*l.* to relieve the financial strain under which it is working, and in December the University of Leeds, as well as the University Colleges of Newcastle-upon-Tyne—the College of Medicine and Armstrong College—each asked for a like amount to enable them to adjust themselves to the conditions in which they have been placed by the devaluation of monetary standards, greatly increased expenses, and an overwhelming influx of students. Scarcely a single university can now meet its financial obligations, and all of them need additional funds to provide accommodation in the form of lecture-rooms and laboratories and new members of the teaching staff to bring the classes within reasonable proportions.

It is not generally realised outside university institutions how greatly the number of students in them has increased since the war. In the year 1912–13 the number of university students in the British Isles was roughly 27,000, or just under six per ten thousand of the population. At the present time the number is more than 40,000, and is approaching one per thousand of the population. There are about as many ex-Service men alone undergoing some form of higher education in universities and colleges, with the assistance of Government grants, as the total number of whole-time university students in these islands before the war. To some extent, no doubt, the increase represents an accumulation of students who were prevented by active service from taking the university courses they had contemplated; but even allowing for this, there is decided evidence that a growing desire exists for the highest and best education the country can provide.

The fees paid by university students can never represent more than a moderate fraction of the total income. In the year 1913–14 the total income of colleges and institutions of university standing in England in receipt of grants from the National Exchequer was about 700,000*l.*, of which 28 per cent. was derived from tuition fees and 34 per cent. from the State. In Welsh institutions 27 per cent. of the total income came from fees and 55 per cent. from the State. (At that time, therefore, the greater part of university education in England and Wales could have been freed from all fees by an additional sum of about 200,000*l.*) Details are not available to show similar proportions at the present time, but it is probably correct to say that students' fees provide about 30 per cent. of the income of university institutions.

This contribution is much higher relatively than that made by students in State-aided institutions in the United States. At Cornell University in 1914–15 the fees were 20 per cent. of the income; at the University of California 10 per cent.; and at Oklahoma only 2 per cent. On an average, the proportion of tuition fees to the incomes of our universities is at least three times that of like institutions in America. It would be unreasonable, as well as detrimental to the best national interests, therefore, to suggest that our universities might look for additional income by increasing the charge for the education provided.

The sources from which the necessary funds must be obtained are private benefactions, local authorities, or the Treasury. It must be confessed that with regard to the first of these we are far behind the New World. In the three years 1916–19 the universities of the British Isles received in gifts from private bodies and individuals a little more than one and a half million pounds—almost exactly the amount that friends of McGill University recently collected in the same number of weeks as the result of their appeal for further endowment. The benefactions to university institutions in the United States amount annually, indeed, to at least ten times what is received from private sources in our islands for like purposes. It cannot be said, therefore, that the field of private benefaction here has been exhausted, but only that it has not yet been stimulated into action as it has been in the United States. Whatever the reason, our millionaires, with few exceptions, have not shown that belief in higher education which is common across the Atlantic, and of which every week brings us further examples.

These are difficult days in which to extract support for higher education from local ratepayers, yet something might be done to adjust the charge more evenly in some parts of the country. County authorities often leave the boroughs in which university institutions exist to bear the greater part of the burden, though students from their areas partake freely of the advantages offered. The time has come when a complete survey should be made of the present position as regards the provision of higher education in all parts of the country, the habitations of the students, contributions of local authorities, and related matters. It might then be possible to secure equitable payment in rates for benefits received.

Failing substantial gifts from private benefactors, and with the ratepayer unwilling to add to his commitments, universities must turn to the Treasury for further support if they are to continue to exist. The Civil Service Estimates for 1920–21 included a total grant of 1,000,000*l.* to be paid out of the Exchequer for the maintenance of university institutions in the United Kingdom. This grant is inadequate to enable the universities to fulfil efficiently the duties which have been placed upon them. The bulk of the students—more than 25,000 out of 40,000—are ex-Service men receiving maintenance grants from the Government. The State has undertaken to provide for the training of these students, and the universities ought not to be left to face the financial difficulties in which they are involved chiefly because of the additional provision they have to make for means of instruction. Assuming the expenditure to be as economical as efficiency will permit, it would seem but an act of common justice for the Treasury grant to be increased to meet it while the ex-Service men are under training. While we trust that the recent appeals will meet with most generous support from rich citizens, we suggest that the State should also accept more fully its responsibility for the desperate condition in which many university institutions now find themselves.

The Theory and Practice of Psycho-analysis.

(1) *The Elements of Practical Psycho-analysis.* By P. Bousfield. Pp. xii+276. (London: Kegan Paul, Trench, Trubner, and Co., Ltd., 1920.) Price 10*s.* 6*d.* net.

(2) *Psychoneuroses of War and Peace: Thesis Approved for the Degree of Doctor of Medicine in the University of London.* By Dr. Millais Culpin. Pp. vii+127. (Cambridge: At the University Press, 1920.) Price 10*s.* net.

(3) *A Manual of Psychiatry.* Edited by Dr. A. J. Rosanoff. Fifth edition, revised and enlarged. Pp. xv+684. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1920.) Price 22*s.* net.

THE subject of psycho-analysis is one that is looming very large on the psychological horizon at the moment, and as these three books have a considerable bearing on the matter, a few words on the general principles involved may not be out of place.

Meaning literally an analysis of the mind, the application of the term has come to be limited to a special technique originated and elaborated by Freud and his followers. It has long been known that the mind is capable of many activities which may be quite outside the consciousness of the individual concerned, and Janet, the French psychiatrist, pointed out that the curious losses of memory and other symptoms occurring in cases of hysteria were due to a splitting up or a dissociation of the mind. This dissociation was regarded as a purely passive disruptive process owing to the difficulty found by the individual in making a satisfactory adjustment to certain environmental factors. Freud, however, introduced the conception of an active process of splitting of the mind which he described as repression. His theory was to the effect that an unpleasant experience which, if retained in the memory, would disturb the equilibrium and peace of the conscious mind was liable to be repressed, and thenceforward to be retained in the unconscious mind with the limitation of being unrecallable to consciousness.

Such repressed ideas or memories still, however, had the power of influencing the stream of consciousness, and particularly if they were associated with the experience of a vivid, emotional reaction at the time of their original inception; it is as if the repressed idea took down with it into the unconsciousness a mass of emotional energy which, being unable to disperse through the consciousness by the normal channels of expression, remained a hidden focus of unrest and disturbance to the proper functioning of the mind as a whole. The technique of psycho-analysis was then adapted for the searching of the mind by a method of free association and by the examination of dreams so that the active repression was circumvented. The result was that the hidden idea, with its emotional attachment, technically a complex, was restored to the consciousness, and the emotion dispersed by proper expression and by the relief of the symptoms to which it had hitherto given rise.

Up to this point the mass of opinion is entirely in agreement as to the value of the Freudian conception, and the method of an unbiassed search for forgotten or repressed complexes by a psychological analysis of the mind is in common use by modern investigators in the subject. Unfortunately, however, Freud carried his theory to a stage to which a great deal of exception must be taken. He claims that all these repressed ideas are invariably associated with the experience of some sexual emotion, and by an ingenious system of thought he demonstrates conclusively to himself and his devotees that all experience is referable in terms of sexual satisfaction or dissatisfaction. Thus the sensations of the infant suckling at the breast are to be regarded as essentially sexual in their nature; the affection of a child for its parent is a manifestation of a homo-sexual tendency when it is directed to the similar-sexed parent, and is of hetero-sexual import if the affection be shown to the opposite-sexed parent.

Much use of the phenomena of symbolism is made by the Freudians in the interpretation of dreams as sexual representations, but for those readers who are interested in the matter, and who may look into some of the Freudian writings, it is only right to point out that a proposition such that the sexual organs of the male may be symbolised by any elongated object—*e.g.* a walking-stick, a Zeppelin, etc.—though quite defensible in the positive sense, may yet be quite indefensible when applied in the negative direction. Thus if a patient dreams that he has bought a new walking-stick, or that he is being chased by a Zeppelin, one cannot permit oneself to be satisfied with the deduction that here is undoubted proof of the sexual origin of the dream; yet on such grounds are many of the most advanced Freudian dogmas based.

Psycho-analysis, then, is the process by which all the symptoms and dreams of a patient are reduced to terms of sex, as opposed to the psychological analysis in which due regard is paid to the existence of other instincts, and bitter has been the conflict between the adherents of the two schools of thought. Of late there has been schism amongst the leaders of the psycho-analytic movement. Jung states that the sexual impulse is not the all in all of psychology, but that a more general "vital impulse" is at the root of all the trouble; Brill asserts that it is not the sexual instinct, but the fundamenal "desire for power" which, by its expression or repression, is the cause of all the psychological ills; Freud himself has said that there are other instincts, but that none but that of sex has yet been investigated. It may, therefore, be deduced that the psycho-analytic cult will gradually lose its virulence and a more rational view hold the field.

(1) It is, then, with no little surprise that one finds a book such as Mr. Bousfield's "Elements of Practical Psycho-analysis" being written at the present day. In his introduction the author says that it was written so that readers without any systematic study of psychology may easily grasp the psycho-analytic principles. This is a bad commencement; no one should attempt an examination of a debatable subject like this without some understanding of the modern views on the mind, and certainly no one should be allowed to practise the technique without a proper psychological training. However, apart from its aims, the book is purely a simplified and dogmatic child's version of the thorough-going Freudian views; the most indefensible assumptions are given as undisputed facts, and throughout the book only the sexual instinct appears to have any practical bearing on the matters under discussion. It is interesting to note that the author precisely dissociates himself from Freud on the very point of the acknowledgment of the existence of other instincts, which acknowledgment, as already stated, Freud has himself made; but the crowning feature of the book is the last chapter, in which the author attacks the Freudian acceptance of the theory of determinism. We hope that, for the sake of his own peace of mind, Mr. Bousfield will soon make the discovery that determinism has only a purely philosophic bearing on the question of psycho-analysis, and that a discussion on this point is out of place in an avowedly practical text-book. The last chapter, apart from the rest of the work, makes one wonder whether Mr. Bousfield does not belong, as do his anticipated readers, to the ranks of those who have had no previous systematic knowledge of psychology.

(2) It is with relief that one turns to a book such as the "Psychoneuroses of War and Peace,"

by Dr. Culpin. This is a work in which the Freudian conceptions are much used, but they are given in a manner which presents both sides of the case. Dr. Culpin is not childishly dogmatic; his reasoning is lucid and without partisanship; his results are given favourable or the reverse; and, above all, his book is enlightening. It makes one think for oneself whether one is a beginner or a scholar in psychology.

(3) "A Manual of Psychiatry," edited by Dr. A. J. Rosanoff, is, of course, a very different production from the two dealt with above. It is a comprehensive text-book, covering the whole ground of the field of mental disease, and, though one may not agree with it on all points, yet as a general text-book the subject-matter is handled very clearly, the practical details in the treatment of the insanities are sound, and the references indicate a careful and thorough familiarity with the writings of all the modern psychiatrists. A chapter is devoted to the Freudian teachings; they are inserted as excerpts from Freudian publications, no reference being made to the actual views of the author himself, or to any criticism which might be given. The chapters on the Stanford revision of the Binet-Simon tests for mental deficiency and the free association tests for use in analysis, with the very full "frequency of association" tables, are striking and useful innovations in a text-book of this kind.

The Teaching of Palæontology.

An Introduction to Palaeontology. By Dr. A. Morley Davies. Pp. xi+414. (London: Thomas Murby and Co., 1920.) Price 12*s.* 6*d.* net.

Invertebrate Palaeontology: An Introduction to the Study of Fossils. By H. L. Hawkins. Pp. xix+226+xvi plates. (London: Methuen and Co., Ltd., 1920.) Price 6*s.* 6*d.* net.

Palaeontology: Invertebrate. By H. Woods. Fifth edition. (Cambridge Biological Series.) Pp. viii+412. (Cambridge: At the University Press, 1919.) Price 12*s.* 6*d.* net.

IN pre-war days we were accustomed to rely overmuch on Germany for text-books of zoology and palæontology. In the latter science all that this country could show for fossil invertebrates was the useful examination-candidate's manual by Mr. Woods and one of the British Museum guides, which, though written for another purpose, was used as a text-book by some teachers. Now, thrown more on our own resources, we have not only a revised edition of the Cambridge book, but also a corresponding work from Dr. Morley Davies, of the Imperial College of Science, and a more general introduction by Mr. Hawkins, of University College, Reading. Apart from brief chapters on vertebrates and plants by Dr. Davies, each of these books deals only with invertebrates, so that it is easy to draw comparisons which may be profitable.

Mr. Woods and Dr. Davies both cater for university students, and both describe the phyla of the Invertebrata in succession, thus producing essentially zoological text-books, in which extinct forms take a predominant place. Mr. Hawkins deals rather with principles, not so much describing fossils as using them to explain the methods and conclusions of palæontological science. It is his book, not that of Dr. Davies, which really merits the title "An Introduction to Palæontology."

All the same, for the discipline of the schools it is the text-books that are necessary, and, while the value of Mr. Woods's method has been proved by an experience of twenty-seven years, we welcome the novel treatment by Dr. Davies. As becomes a teacher in the school of Huxley, he has introduced the more intensive study of selected types. In dealing with the Brachiopoda (with which, as the commonest of fossils, he selects to open), he does not, as does Mr. Woods, begin with the general anatomy of the phylum, but, map in hand, he guides his pupils to a pit in the Cornbrash and lets them collect those characteristic species *Terebratula intermedia* and *Ornithella obovata.* These are examined and their common characters noted; then closer examination brings out the points of difference, especially in the arm-loop. The features of these fossils are next elucidated by a study of modern forms, and on the way we are introduced to the conceptions of relation to environment, ontogeny, phylogeny, comparative morphology, chronology, and classification. At last the student, now or never thoroughly interested, passes to the systematic account, in which such common fossils as *Leptaena rhomboidalis, Productus productus, Conchidium Knighti,* and *Spirifer striatus* receive more detailed treatment. Is not this an admirable method? If only Dr. Davies had followed it more consistently throughout!

Both Dr. Davies and Mr. Hawkins deal with some technical matters of which students too often are left in ignorance. Such are the collection, preservation, and investigation of fossils, the rules of zoological nomenclature, and the terminology and nomenclature of rock-divisions and time-divisions. On these last thorny questions both authors are, in our opinion, sound, and these sections of Dr. Davies's book in particular should be an ever-present help to all working palæontologists.

Mr. Woods and Dr. Morley Davies are, as instructors of youth, chiefly concerned to get some facts into the heads of their pupils. They have not much space for philosophic discussion (what they have they make good use of), and none at all for that general talk which can brighten the way or inspire the reader to further effort. Whichever of them you choose to follow as guide, you will be well advised to take Mr. Hawkins with you as philosopher and friend. His drawings and photographs are admirable, and, considering the price of the book, are as much a credit to the publisher as to his own skill. They will greatly help the reader who has not at hand the more purely descriptive works, or whose acquaintance with fossils is not already that which seems demanded by some of the chapters. The chapter on materials explains the nature of fossils and distinguishes the various modes of preservation and their relation to different kinds of rocks. Thus it answers questions constantly asked by the casual finder of fossils. Is it, however, quite true that amber inclusa represent "the most perfect type of preservation"? Were this so, it should be possible to dissolve out the organisms and to remount them in a manner more convenient for study. He who attempts this will find that there is nothing to get out. What one sees in the amber is but an imprint—the ghost, as it were, of some insect, the material body of which has vanished. The preservation of chitin in some fine clays, as of the Oesel Eurypterus, is really more complete.

Again, to apply the term "cast" to an external imprint, and the term "mould" to an internal filling of some dissolved shell, seems to reverse the ordinary usage. Here Dr. Davies and Mr. Woods more nearly approach accuracy. There are four cases to distinguish: a single valve of a mussel may leave in the rock an external imprint or impression, and an internal imprint; the complete shell of a mussel or a snail, or the test of a sea-urchin, may have been dissolved away, leaving the complete external mould (from which a plaster cast can be taken) and the complete infilling of matrix (which is a natural cast of the interior).

The geological distribution and the succession of life-forms, which constitute the real basis of palæontology as an independent science, are attended to by Mr. Woods in paragraphs under the zoological divisions, and are summarised by Dr. Davies in a compact but clear appendix. Under the heading "Historical Biology" they make up the second half of Mr. Hawkins's book. Anyone who has attempted a similar history knows how hard it is to vary the phrasing, to bring out the broad masses, and to avoid a mere list of names. "Lucina and Corbis are common throughout the era. Cyclodonts are abundantly illustrated by Cardiidæ, Protocardia and Discors are especially frequent in the Eocene, Cardium itself is common in the Crags. Teleodonts are the predominant forms. Venus (pl. xvi., Fig. 1), Dosinia (pl. xvi., Fig. 2), Meretrix and Paphia have numerous species in the later Cainozoic; Tellina, Macoma, Psammobia and——" but, no! the pen denies its office. Let us rather turn back to the interesting chapters "Geological Palæontology" and "Biological Palæontology," where the author shows what light may be thrown by fossils on climatic and other conditions at diverse times and places, and on the problems of phylogeny, morphogeny, specialisation, degeneration, and orthogenesis.

The profound studies of Echinoidea by Mr. Hawkins entitle his opinions on those difficult questions to the utmost respect. But, dealing as we are here with educational books, we prefer to conclude with an opinion based on his successful work as teacher, an opinion with which examiners ought to agree. Recognition of species (fossil-spotting) should not be demanded of average students. "The chronological distribution of families and genera will give ample precision for elementary needs." "The most elementary student ought to know that Ammonites are not found in Cainozoic rocks; but he ought *not* to know the difference between *Dactylioceras commune* and *Peronoceras annulatum*. If the latter detail has been forced into his unprepared mind, some point of more general application and greater importance must have been omitted or ejected."

F. A. BATHER.

Sugar Technology and Fermentation.

(1) *The Sugar-beet in America.* By Prof. F. S. Harris. (The Rural Science Series, edited by L. H. Bailey.) Pp. xviii + 342 + xxxii plates. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1919.) Price 12s. net.

(2) *The Manufacture of Sugar from the Cane and Beet.* By T. H. P. Heriot. (Monographs on Industrial Chemistry, edited by Sir Edward Thorpe.) Pp. x + 426. (London: Longmans, Green, and Co., 1920.) Price 24s. net.

(3) *The Carbohydrates and Alcohol.* By Dr. S. Rideal and Associates. (Industrial Chemistry.) Pp. xv + 219. (London: Baillière, Tindall, and Cox, 1920.) Price 12s. 6d. net.

(1) THE beet-sugar industry in North America is of comparatively recent date, although it was undertaken nearly a century ago by men,

as the author remarks, "who had more enthusiasm than knowledge." It may now be said to be firmly established, thanks largely to the magnificent work carried out in the experimental stations of the United States Department of Agriculture. Prof. Harris has produced a compact and useful treatise on a subject which is of the greatest interest to us in the United Kingdom, and also to those in other parts of the Empire where the beetroot might be cultivated. The manufacture of sugar from beet presents numerous difficulties, and all who are interested in the subject would do well to study the present little volume. The text is clearly written, and the information it gives is concise and complete. A valuable feature is the list of books, periodicals, bulletins, and reports, in the English language, which is appended.

(2) Most teachers of specific branches of science prefer to write a book for the guidance of students in which the subject-matter is arranged in that particular manner and sequence to which they give preference. The book before us is one of that class. It is written by a sugar expert for the guidance of his students. We believe that Mr. Heriot is the only lecturer in Great Britain on sugar technology—a subject of such vast importance to the British Empire. The reviewer is the chairman of the Empire Sugar Supply (Technical) Committee, which issued a preliminary report in July, 1919. Information had been obtained from the Dominions, Dependencies, Colonies, and Protectorates of the Empire showing to date the production and consumption of sugar in the Empire, and the possibilities of increasing the production to such an extent as to render the Empire self-supporting as regards this commodity were considered. The report has been sent to members of the Government and to numerous other Members of Parliament and high officials. Up to the present, however, the only movement on the part of the Government has been the appointment of a committee of experts to visit India and report on the possibilities of extending sugar production in that part of the Empire.

The appearance of Mr. Heriot's book is a welcome sign that the teaching of sugar technology within the United Kingdom is now progressing. The problem of Empire sugar needs a sufficiency of trained scientific experts, for the industry is no longer one that can be left in the hands of rule-of-thumb workers. Its principles require a knowledge of agriculture, botany, chemistry, and engineering, which can only be gained at an institution such as that with which Mr. Heriot is connected.

The text of the book is divided into ten parts, covering well the whole field included under the title, whilst the numerous illustrations add much to its value. The first five chapters, dealing with scientific principles, cover but thirty-two pages, and they should certainly be extended in future editions. They are, by reason of their brevity, dogmatic rather than educational, and as an instance the opening chapter on the formation of sugar by plants may be cited. Nothing is said of plant respiration, whilst in the converse phenomenon, photosynthesis, formaldehyde is given as the first product. It is stated, without authority, that formaldehyde has been detected in minute quantities in the leaves of plants, but reference should have been made to a paper by Jörgensen and Kidd in 1917 in which it is shown that formaldehyde arises from chlorophyll in the absence of carbon dioxide.

Although a detailed description of analytical methods would be out of place in the present volume, chap. xv., covering twelve pages, is meagre—so much so as to make it of no value whatever. Under "reducing sugars," for example, the following may be quoted from the text: "A measured volume of Barreswill's (Fehling's) solution is diluted with water and boiled. The juice is then gradually added until the whole of the copper is precipitated as cuprous oxide. From the volume of the juice thus added, the reducing sugars per 100 of juice can be calculated."

The main portion of the book is devoted to technology, and here the matter is well chosen. Mr. Heriot has certainly added a useful volume to the literature of sugar manufacture, and one which was needed in our Empire, since it embraces the manufacture of sugar from both cane and beet.

(3) This book is one of a series the object of which is to give a "general survey" of industries "showing how chemical principles have been applied and have affected manufacture." "The subject," says the editor, "will be treated from the chemical rather than the engineering standpoint." The impossibility of giving more than an outline of the subject is admitted, but it is hoped to stimulate greater interest in certain industries to which the nation has paid insufficient attention.

Commencing with an introduction of fifteen pages dealing generally with the carbohydrates, cellulose, starch and its hydrolytic products, and the sugars, the remainder of the text is divided into six parts, each subdivided into sections. It deals with starch, dextrin, glucose, maltose, cane-sugar, beet-sugar, sugar refining, minor sources of sugar, caramel, malting, brewing, wine, potable and industrial alcohol, vinegar, acetic acid, acetone, and glycerin.

The task of writing such a book as that before us is no easy one, needing, as it does, the securing of collaborators having both practical and scientific knowledge of the various industries. Whilst it is not for us to criticise the qualifications of Dr. Rideal's collaborators, our reading of the book has led us to the conclusion that it is a condensed account of existing treatises rather than a succinct and original outline of the various chemical industries. References to the literature are given at the end of each part, and these, we submit, would have been better included in the text, so that the reader would know exactly where to find an expansion of any specific phase of the subject. References to journals such as that of the Society of Chemical Industry, without indicating definite papers, are of little use to those who are not specialists, but wish to glean further information on specific points.

The major portion calls for little comment on the score of accuracy, but there are some errors and mis-statements, and among them the following may be cited. Wheat is said in one place to contain 55–65 per cent. of starch, whilst in another place the average starch content is stated to be 68 per cent. The statement that the cheapest form of starch is that derived from the potato is inaccurate, and we can scarcely agree that wheat starch is used as a paste for bill-posting, etc. ! The title "Cane Sugar" and "Beet Sugar" for the sections dealing with the manufacture of sugar from cane and beet respectively might tend to revive the fallacy that sugar from the two sources differs. Goldthorpe barley is a broad-eared, not a narrow-eared, two-rowed barley; it belongs to the variety *Hordeum zeocriton*, not to *Hordeum distichum*. The statement that by the malting process "the insoluble starch of the grain is converted into soluble fermentable sugar" is one long ago exploded.

As a general criticism of this book, we regret being unable to come to any other conclusion than that the editor has failed to achieve his object. We hope that in the near future, with the collaboration of his expert advisers, he will recast the volume so as to eliminate errors and to give a clear and concise outline of the chemical industries dealt with.

ARTHUR R. LING.

Our Bookshelf

Magic in Names and in Other Things. By E. Clodd. Pp. vii + 238. (London: Chapman and Hall, Ltd., 1920.) Price 12s. 6d. net.

DEALING with the question of magic in names, Mr. Clodd expounds with interesting detail a chapter in folk-lore familiar to serious students, but well deserving treatment in a more popular form. His book is, in the main, a study of magic, or, to use the new word, "mana," "the sense of a vague, impersonal, ever-acting, universally diffused power" immanent in all things. His special subject, the name, is well defined in a quotation from Mr. Cornford which appears on his title-page: "Language, that stupendous product of the collective mind, is a duplicate, a shadow-soul, of the whole structure of reality; it is the most effective and comprehensive tool of human power, for nothing, whether human or superhuman, is beyond its reach." Hence the preliminary discussion of the mana in a man's hair or spittle, through which the magician can work evil against the owner, merges into a detailed consideration of the name. Evil can be worked against you by anyone who knows your name, and hence it is wise to have two names, one concealed, one for daily use. This leads to the more serious name of power, curses and charms, passwords and spells, the "mantram" of the Hindu, by means of which even the gods themselves can be coerced. The Mohammedan knows the Ninety-and-Nine Names of Allah, and by repeating them over and over again for days he gains magical power. This exposition, always clear and impressive, even if at times the religious views of the author are disclosed with undue emphasis, is supported by an accumulation of interesting facts drawn from a wide range of study of the thought of primitive peoples and of popular belief throughout the world. Folk-lore, as an expression of primitive psychology, has too long remained the possession of the expert, and any attempt to popularise it is welcome. This is Mr. Clodd's achievement, and his exposition of this chapter of popular belief proves the value of the study as a key to unlock the mind of man, which no historian or sociologist in the future can safely neglect.

The Civil Servant and his Profession. Pp. viii + 124. (London: Sir Isaac Pitman and Sons, Ltd., n.d.) Price 3s. 6d. net.

THE Society of Civil Servants has organised a series of lectures on various aspects of the profession, and the book under notice contains five of the lectures which were given in March last, with an introductory address by Sir Cecil Harcourt Smith. The first lecture, by the late Sir Robert Morant, deals with the administrative side of the Civil Servant's profession; the second, by Lord Haldane, with the legal aspects; the third, by Sir Sidney Harmer, is on the subject of national museums and scientific research; the fourth, by Mr. E. F. Wise, treats of the relationship between the Civil Service and industry; and the last, by Mr. J. Lee, deals with the psychology of the Civil Servant. This collection of lectures will give the public some idea of the diversity, importance, and highly technical nature of the work which is performed by the staff of men and women who constitute the Civil Service.

The British Journal Photographic Almanac and Photographer's Daily Companion, 1921. Edited by George E. Brown. Pp. 840. (London: Henry Greenwood and Co., Ltd., n.d.) Price 2*s*. net.

THE sixtieth issue of this welcome annual appears only a week or two later than in pre-war time, and the edition is increased from 25,000 to 30,000. This indicates a gradual progress towards normal conditions. On the other hand, the volume is about seventy pages fewer than last year, and the price is increased. The obvious reticence of advertisers with regard to quoting prices, which we remarked on a year ago, still impresses one, though perhaps less strongly. The editor contributes a lengthy article on general photographic procedure which cannot fail to be of assistance to beginners. The usual "Epitome of Progress" is an excellent summary, extending to nearly 100 pages, of the notable events, business items, legal matters, novelties in apparatus and equipment (including raw materials used in photography), and new methods or modifications of them. After the extensive collection of formulæ follows "A History in Brief of Photographic and Photomechanical Processes," giving the year and sometimes the month and day of the chief events, beginning with Thomas Wedgwood's experiments, published by Davy in 1802. Of the other new matter, we are particularly glad to see that the editor has given a table which he calls "Corresponding Focal Powers and Focal Lengths." The focal powers are given in diopters, and the corresponding focal lengths in centimetres and in inches. Many lens problems are so very much more simple when calculated in diopters instead of in focal lengths that we hope this table will be extended in next year's issue, and that there will be added to it a few simple instructions as to its use. C. J.

Physiology and Biochemistry in Modern Medicine. By Prof. J. J. R. MacLeod, assisted by Roy G. Pearce, A. C. Redfield, and N. B. Taylor, and by Others. Third edition. Pp. xxxii + 992 + 9 plates. (London: Henry Kimpton, 1920.) Price 42*s*. net.

A NOTICE of an earlier edition of this work appeared in NATURE of December 18, 1919 (p. 389). That a new edition should be required in a year's time shows that the book has been found to meet the purpose for which it was written. The opportunity has been taken to recast the section on the nervous system, which has been excellently done by Dr. Redfield adding to it an account of the fundamental principles of the physiology of muscle and nerve. These changes will add to the value of the book to those for whom it is primarily intended, particularly to the medical man who wishes to apply advances in physiology to his clinical practice. Recent work on such questions as the effects of deficient oxygen supply, on "vitamins," on the capillary circulation, and on wound shock has been duly incorporated. A good account of the problem of the carriage of oxygen and carbon dioxide in the blood, still a disputed one, will also be found. Although the price of the book seems rather high, it may reasonably be held that good value is obtained. It might be worth consideration, however, whether the omission of some of the coloured plates would not enable a wider circulation to be ensured by a lower price. The further such knowledge as that contained in the book is spread, the better will it be for the advance of medical science and practice. W. M. B.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

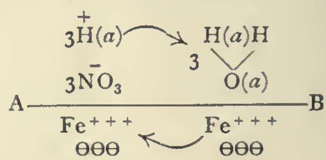
The Passivity of Metals.

CHROMIUM, iron, cobalt, nickel, copper, and bismuth are said to exhibit the phenomenon of passivity. These metals have electrode potentials varying from about Fe = +0·06 to Bi = −0·67 volt—that is, they are not very electro-positive. They also all exhibit dual valencies. This suggests that passivity may be due to an electrical double layer on the surface of the metal, especially when it is remembered that an anode of iron becomes passive in nitric acid of sufficient concentration.

The chief theories of passivity assume that a layer of oxide, nitride (St. Edme, *Comptes rendus*, vol. lii., p. 930, 1861), or gas is formed on the surface. St. Edme's view is founded upon the fact that ammonia is formed when passive iron is heated in dry hydrogen. But Finkelstein (*Zeit. phys. Chem.*, vol. xxxix., p. 91, 1901), from the results of his investigation of the polarisation capacity of passive iron, concludes that there can be no opaque layer on the surface, and he thinks that passive iron is ferric iron, whereas ordinary iron (active) is ferrous iron.

It is here suggested that passivity is produced by a layer of nitric acid or of nitrate ions firmly adhering to the surface of the metal. This view is not incompatible with either St. Edme's or Finkelstein's results. In fact, it seems as if there is considerable similarity between the surface of a passive metal and that of the disperse phase in a metal sol.

A consideration of the chemical forces yields the following model of the polarisation effects at the surface of a metal in an aqueous solution of an electrolyte, say iron in dilute nitric acid:



AB is the cross-section of a surface drawn between the liquid and the metal. Below AB is the Helmholtz electrical double layer, which we may conveniently regard as due to a layer of positive metal ions, and a layer of their valency electrons, two of which ions and their associated electrons are shown in the figure. The ions are represented in the ferric state, but this is not essential to the argument. Above AB, in the liquid phase, is a layer of molecules, which are polarised at a given moment in a regular surface lattice if the metal is pure. Obviously, the composition of this layer will depend upon that of the bulk of the liquid and upon the affinities of the iron ions for the nitric acid and the water. We may regard the nitric acid as ionised, but not so the water, because its ionisation is known not to be increased by the presence of dissolved electrolytes. Owing to the symmetry of the water molecule, it is impossible to say which H atom will break away and which will remain in the OH group in the event of ionisation.

Now it is highly probable that the chemical force, between ions even, is not wholly electrical, and we may assume that the nitrate ion and the water molecule will be attracted to their respective iron ions with forces which result in the setting up of an e.m.f. in the metal. If this e.m.f. is large enough, one of the metal ions will be discharged into the liquid momentarily as ferric nitrate, and in the model the atoms marked (*a*) will form water, the remaining H will be momentarily liberated, and positive current will flow as indicated by the arrows.

Two factors will make for passivity: a low electrode potential and homogeneity of the double layer above AB. Impurities in the metal will modify its electrode potential as well as the composition of the double layer. We find passivity a common property of the noble metals almost irrespective of the composition of the double layer, whereas with highly positive (active) metals passivity is never observed. In the case of intermediate metals passivity occurs only with certain kinds of double layers, and if these are unstable periodic action may result. Since the forces are not wholly electrical there is less chance for an electrostatic equilibrium—and consequent passivity—to be set up, and for this reason it seldom occurs with these metals.

A sufficient disturbance of the surface layer, by scratching, touching with a more electro-positive metal such as zinc, placing in a magnetic field, or heating, will, in conformity with experience, activate passive iron. It is significant that Smits and Lobry de Bruyn (Proc. K. Akad. Wetensch. Amsterdam, vol. xxi., p. 382, 1919) find that chlorine ions activate anodically polarised iron. Thus it seems that iron ions in the surface of the metal have a preferential affinity for Cl′ over NO_3'.

W. Hughes.

Bedford Modern School, January 10.

The Space-Time Hypothesis before Minkowski.

It is, perhaps, not generally realised that the theory of space and time, to which Minkowski was led on experimental grounds, had been formulated on general principles sixty-five years previously by Hamilton, the Irish mathematician. The point is, however, of interest, not merely as a question of priority, but for the insight it affords into the philosophic basis of the theory, as well as for the useful mathematical methods it suggests.

It is curious, therefore, that there should be a lack of recognition that the world of Minkowski is in all points identical with the system of quaternions of Hamilton, and that the latter mathematician specifically regarded this system as a four-dimensional expression of space and time, in which space bears to time the relation which $\sqrt{-1}$ bears to unity, time being the scalar part of the quaternion.

Quotations may be given from Hamilton's letters and manuscripts, cited in his "Life" by Graves, which leave no doubt on this matter.

Thus, vol. ii., p. 478:

"Let me suggest one leading thought, which will perhaps sound paradoxical, that time and space are imaginary, each with respect to the other. . . . Any expression for the peculiar relations of space in the forms of time, or for those of time in the forms of space, must therefore involve a seeming contradiction . . . it will be a 'mathematical imaginary.' This seems to me to be the clue, the secret of the matter."

Vol. iii., p. 635:

"The mathematical quaternion . . . in technical language may be said to be 'time *plus* space,' or 'space *plus* time,' and in this sense it has, or at least it involves a reference to, four dimensions."

In another place:

"My real is a kind of fourth dimension equally inclined to all directions of space."

Many other allusions will be found which prove that this idea was fundamental in the views of Hamilton, and that he held to it with the greatest tenacity, although there were at that period no experimental considerations to justify it, and although De Morgan and other mathematicians seem to have discouraged it, or ridiculed it. At the same time it does not appear that Hamilton has given an analysis of space and time which exhibits with sufficient clearness the concept of direction in space as being peculiarly attached to the symbol $\sqrt{-1}$, and the concept of positive and negative unity as being similarly connected with the two directions of time, towards the future and the past.

It is, however, easy to supply such an analysis, the clue being given by noting that to define a number by the equation $x^2+1=0$ virtually defines it as "a unit which cannot be differentiated from its own negative by any *qualitative* distinction."

It indeed appears to have been in the thought of Hamilton, as it must occur to anyone who considers the matter, that the connection between a root of the equation $x^2+1=0$ and a direction of space is to be looked upon as more than a mere symbolism; but the general philosophic bearing of such considerations on the whole nature of space and time is scarcely appropriate for discussion here. It may, however, be remarked that they indicate a point of view in which time and three-dimensional Euclidean space lose their apparently contingent character, and approach the necessity of the laws of arithmetic, of which they appear as a kind of derivative.

It should be added that practical advantage might be derived by mathematicians from the application of the methods of quaternions to the theory of relativity, for, besides offering a convenient mode of development of the geometry of four dimensions, either Euclidean or hyperbolic, according as Tq or $\sqrt{Sq^2}$ is taken as the element of length, they suggest important possibilities in connection with the inversion of a linear quaternion function analogous to the physical applications by Tait of the linear vector function.

Heredity and Acquired Characters.

Will you permit a statement from a humble student? Between twenty-two and twenty-seven years ago, while in Malabar, opportunity was taken by me to ascertain whether the arms of rowers on the backwaters and the arms of the toddy-drawers were longer in proportion to the height than in the case of the rest of the population, for here seemed to offer a test whether "inheritance of the effects of use" was evident. In both cases the men belonged to a caste which had not changed its occupation for many hundreds, perhaps some thousands, of years: the former indigenous, while legend attributed the ancient home of the latter to Ceylon, where they were occupied in the same way—climbing and tapping the palm-trees for toddy. The stretch of arms in rowing demands no explanation, but it may be mentioned that the rowers were not engaged in rowing as they might be in England, but often continuously for long periods. Thus on first acquaintance they rowed (eighteen of them) forty-six miles to where I was, halted an hour or so to cook and eat a meal, and rowed back again the same distance, covering the ninety-two miles within twenty-four hours—not at all as a feat, but just in the ordinary way of work.

The climbing of the palms in this region needs some remarks, because whereas toddy-drawers are usually sustained by a strap round the back to ease the strain on the arms, in Malabar the whole weight of the body is borne by the arms alone, legs straight, feet held together by a grummet, the hands embracing the stem. Climbing in this manner is fatiguing, and when he has reached the top the climber works for about a quarter of an hour preparing the spathe, changing his pots, and so on, all the while upheld by the arms, which are thus on the stretch for a considerable portion of each day. It seemed, therefore, worth while to examine by careful measurements with instruments for anthropological work whether the continual straining of the arms during many generations affected the length of arms in relation to length of body-height. The result was that it did not. The arms of the hereditary rowers and of the hereditary climbers are no longer in proportion to height than of those engaged in occupations involving no strain of the arms. Writing far from home, I am unable to give you measures. FREDERICK FAWCETT.

Algiers, January 12.

Popular Science Lectures on Natural History.

THE lectures to juveniles at the Royal Institution by Prof. J. Arthur Thomson have been undoubtedly a great success, and I cannot help thinking that there are others, especially among our young men fresh from the universities, who could give lectures of this kind to popular audiences. If so, can they be discovered? They may be difficult to find, for success in this field requires a rare combination of gifts. It is absolutely necessary for such a lecturer to possess, besides knowledge and enthusiasm, a good voice and manner; his speech must be fairly loud, good, and clear, and his personality distinctly pleasing, or he will fail to win his audience. Unfortunately, few scientific men are good public speakers. It is also much to be regretted that many writers on biology and natural history adopt a style so learned and pedantic that both young and old are repelled.

Huxley, the younger Buckland, Gosse, and Hugh Miller are gone, and few follow in their steps. How sadly are the themes of beauty, mutual aid (so well treated by Kropotkin), and symbiosis neglected by modern writers! Those who do treat of these subjects seem to deal with them in a cold, dry way. The leading idea in Prof. Thomson's lectures is conquest by animals of the elements, and no other lecturer or writer has developed the subject as Prof. Thomson has done.

In conclusion, may I ask whether it would be possible to arrange courses of lectures on the same lines in different parts of London? It seems a pity that such lectures should be confined to the Royal Institution. Eager South London audiences can be found for Shakespeare's plays, and I believe good lectures on natural history would also appeal to such audiences, especially if well illustrated and well delivered.

H. NEVILLE HUTCHINSON.

Royal Societies' Club, January 10.

Anglo-American University Library for Central Europe.

IN connection with the above library, we are endeavouring to supply the various university libraries on the Continent with the scientific journals they urgently need.

Among the periodicals for which we have received a pressing demand NATURE is frequently mentioned, and I very much hope that you will be good enough to publish this letter in your columns so that any of your readers having copies of your journal from 1914 onwards may hear of our appeal. Any numbers of the periodical which readers may feel they can dispense with will be gratefully welcomed.

The library is entirely non-political and non-sectarian, its sole object being to enable humanity at large to benefit in the future, as it has done in the past, from the research of European scholars. Such research has been brought almost to a standstill from the fact that European centres of learning have been cut off since 1914, first of all by the blockade, and more recently by the exceedingly unfavourable position of the foreign exchanges, from English and American thought.

I fervently hope that some of your readers may be able to help in supplying the literary needs of Central Europe. A copy of the prospectus of the library will be gladly sent to anyone desiring a fuller account of its work and objects. B. M. HEADICAR,
Hon. Secretary.

London School of Economics, Clare Market, London, W.C.2, January 21.

Greenland in Europe.

WHATEVER lapse may be imputed to the London school-book of 1812, noticed by Mr. MacRitchie in NATURE of January 13, p. 647, it is not shared by the Rev. J. Goldsmith's "Geography, on a Popular Plan, Designed for the Use of Schools, and Young Persons," in its fifth edition at the earlier date of 1808. For that author, in a very interesting account of Greenland, at p. 46 remarks that many so-called "ice islands" "are to be met with on the coasts of Spitzbergen, to the great danger of the shipping employed in the Greenland fishery." He further instances the peril to which "Lord Mulgrave" was thus exposed in 1772, when by an opportune rising of the wind his ships, "after labouring against the resisting fields of ice, arrived at the west end of Spitzbergen." At this critical time, however, "Lord Mulgrave" was Capt. Phipps. T. R. R. S.

January 20.

Electric Light and Vegetation.

MR. PENDRED's interesting observations on the growth of vegetation beside the electric lights in the Cheddar caves (NATURE, vol. cv., p. 709, August 5, 1920) reminds me of some observations described by Mr. E. Cheel in the *Australian Naturalist*, vol. ii., 1912, p. 117. Of a number of plane-trees growing about Sydney railway station some were close to the large electric lights, and Mr. Cheel noticed that the branches nearest the lights retained their leaves from a month to a month and a half longer than the more distant branches of the same tree and than the trees distant from the lights. When the new leaves were opening in spring a similar period elapsed between the dates of opening of those near the lights and those distant therefrom, the branches subject to illumination being that much later in getting their leaves. THOS. STEEL.

Sydney, New South Wales.

The Sparrowhawk.

By J. H. OWEN.

THE sparrowhawk, in a perfectly wild state, is one of our most interesting birds to study. During the nesting period, and especially through the latter part of the incubation period and the whole of the nestling period, it is comparatively easy to observe and photograph the bird. With patience, photographs can be obtained at the nest of the birds, old and young, for something like a fortnight after the young have left the nest. This is because the cock, and in some cases the hen, deposit the kills on the nest, which becomes a larder to a large extent, and the young return to the nest for a meal whenever they are in need of food.

The young are helped to procure food and partly trained by the old birds for a still further period before they are finally dispersed to seek their own living. If the nesting period be considered to start when the building of the nest is begun, and to end at the dispersal of the young, it is of great length. I have seen new nests, practically complete except for the lining of the cup and a few minor details, as early as February 17. I usually search for new nests during the second half of March, and find quite a lot of pairs building them. Birds that do not start during March appear to use old nests of pigeon, jay, hawk, or even magpie as foundations, but they are in a minority in the neighbourhood of Felstead, in Essex, for at least three-quarters of the nests I find are entirely new. Of course, weather conditions have considerable influence on the building of nests; in rough, boisterous, or wet weather and on foggy days operations cease. In a forward year, such as 1916, complete sets of eggs may be found before the end of April; in a normal year it is unusual to find such sets until between May 14 and 21. The bird lays, as a rule, on alternate days, but occasionally there is a period of seventy-two hours between eggs, and sometimes even more. The full set consists of four to six eggs, rarely of seven or more. Very old birds produce fewer eggs, which are less heavily pigmented as the age of the bird increases, while the eggs of a young hen are not so evenly or so heavily pigmented, as a set, as are those of a fully mature bird.

The incubation period varies somewhat, but can be put at approximately thirty-three days. The eggs usually take a long time to hatch, even after they are chipped; it is quite usual for two whole days to elapse after the egg is chipped before the chick emerges—I have known this period to be as long as four days. This is probably because the eggs are not moistened by the hen, the shell is very thick, and the membrane very tough. I have often watched a hen helping a chick to break free from the shell. In such cases I have seen the hen eat the shells, but I feel convinced now that this is not the usual method of disposing of them. Usually they are carried some distance from the nest and dropped.

Like the chicks of all birds of prey, those of the sparrowhawk are covered with short, thick, white down when hatched, and their eyes are open; but the plumage does not show until the bird is more than fourteen days old. The nestling period is about twenty-eight days, and by the end of that time the young birds have mostly acquired their juvenile plumage; but the down does not finally disappear until they are some seven weeks old. During incubation the nest gets flecked with down from the hen, and is a beautiful sight just before incubation ends, if the weather has been good. If the first set of eggs has been taken, the second nest never gets anything like so well flecked; the supply is limited, and has been used up. This may be a survival of what still happens in the nests of ducks and geese. When the young are hatched, this down disappears very quickly; it is partly removed by the weather, but largely by the hen, which probably mistakes it for the feathers of victims. The nest is kept particularly clean all through the incubation and nestling periods until just before the young leave the nest. Then the nest again becomes beautifully and liberally flecked with down; but this time it is shed by the young birds.

When the hen begins to lay, she lines the bottom of the nest with bits of bark, touchwood, and dead leaves, and during the incubation period she adds material, sometimes to the rim and sometimes to the well of the nest, with the object of making the nest stronger and more comfortable. During the nestling period more is added, this time probably partly for sanitary reasons, to keep the young off material contaminated by contact with dead, and often decaying, victims. Dr. T. Lewis has even seen the cock bird bring twigs to the nest during the nestling period.

The hen, in my experience, does all the incubating, and usually the cock procures food for her. This she eats on the larger limbs of trees in the neighbourhood of the nest tree. The cock brings it to some position upwind of her and calls. If she wants it she goes to him and takes it, and they remain together a short time; then he goes away. If, after two or three calls, she does not join him, he flies through the nest tree calling; if she still takes no notice he goes to a favourite feeding-place, not very far from the nest as a rule, eats what he wants, and flies off again. The hen normally sits back to wind (Fig. 1). The proximity of an observation hut upsets her, and she will place herself as near back to wind as possible while keeping the hut still in view. If, however, it rains she will, hut or no hut, turn her back to it. If it rains hard she will gradually move her wings out from her body to cover more completely the well of the nest, and finally get such a spread on them that the primaries are parted, and each acts as a watercourse from her back and wings.

FIG. 1.—Incubating: normal position when easy in mind: very low in nest.

If it is very hot and the sun shines on the nest, she will get up from time to time and stretch or stand beside the eggs (Fig. 2). Sometimes she will preen herself, but she never stays off the eggs for long at a time. If she is very near hatching she will not relieve herself by more than a stretch, although she may be in agony from the direct rays of the sun. All she does is to rise slightly on the eggs and pant with her whole body.

For the first few days after the young are hatched she may be said generally to be covering them completely. As they get stronger and more vigorous they scramble from under her at will if the weather is fit. If it is raining, or the sun is directly on the nest, they have to go under cover. Later, when the weather is suitable, she may be on the nest, but the young may be all clear of her. At such times she will often shut her eyes and nod on the nest.

In wet weather she makes an umbrella of her body. She puts her back to the direction of the storm, the young collect, heads together, in the middle of the nest, and she shuffles over them. She usually opens and depresses her wings so far as the occasion demands. Of course, there are variations of position in this as in everything else. On one occasion, in a very heavy thunderstorm, the hen stood more between the young and the direction of the storm, and threw one wing over the young; then she gradually sank down until this wing was upheld by them (Fig. 3). In storms she usually crouches over the young, but gradually sinks lower until she is resting on them. Always, as she shuffles over them, she looks for the youngest nestling, and pulls it into the most protected position with her bill. Even when brooding is a thing of the past, the approach of a storm will bring her on to the nest very quickly, and she covers it immediately rain begins to fall. If she brings food to the nest she breaks it up first, but if the cock deposits food on the nest during the storm she takes no notice of it. When the storm passes away she will break such food up and then dry herself thoroughly on some branch from which she can watch the nest. She opens her wings and tail, and either faces the wind or has her back to it. She may get in a place where the sun can help the drying, but mostly she trusts to the wind. Sometimes her feathers are almost closed; at other times they are open to their widest extent; the amount of spread varies constantly. After drying is completed she preens herself thoroughly, pay-

FIG. 2.—Off the nest owing to sun: a pause and look round before returning.

ing particular attention to the flight and tail feathers.

Very interesting, too, is the sight of the hen making efforts to shield the young from the direct rays of a hot sun. When they are small enough for her to do so, she makes a sunshade of her wings and body that will protect them all. She first gets directly between them and the sun, and then she partly opens and depresses her wings, and moves forward until the young are completely in the shade. There she stays in a sort of crouch over them until the sun has moved behind some foliage. The whole time she is in great distress, for her entire body seems to pant, and her tongue works rapidly to and fro.

Fig. 3.—Brooding in heavy thunderstorm.

If the young are too big for her to shelter all of them completely, she does what she can. She gets between the sun and the middle of the nest, partly spreads her tail, and opens her wings slightly, standing with her feet apart. The young then take turns to make use of the shade her body affords (Fig. 4). She stays like that as long as it is necessary, and, as before, seems to suffer greatly from the heat the whole time.

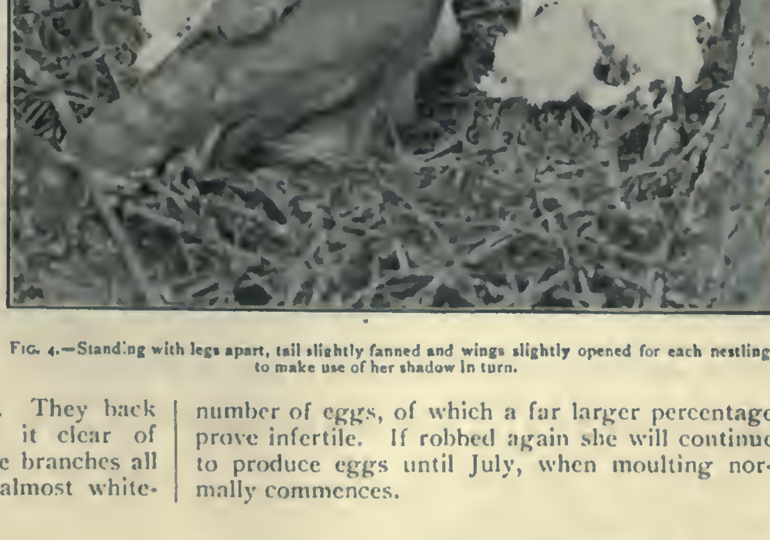

Fig. 4.—Standing with legs apart, tail slightly fanned and wings slightly opened for each nestling to make use of her shadow in turn.

The young do not foul the nest with excrement, so that the old bird has not to remove it. They back to the edge of the nest and eject it clear of the rim from a very early age. The branches all round and below the nest become almost white-washed during the nestling period unless rain comes to clear it away. When the nestlings are nearly ready to leave the nest, less care is taken about keeping it spick-and-span. They are able to feed themselves, and are allowed to do so. What bones they do not swallow are permitted to accumulate on the nest, and by the time the nest is finally deserted it may be covered deep with bones of victims, and many more bones will be found on the ground below the nest.

The cock is the procurer of food, but he takes no part in breaking it up. If the hen is killed during the nestling period he will continue to bring food so long as the nestlings are alive. If they are less than twenty days old they probably all die. If they are over that age they can tear enough food off to keep going, and the majority would survive. If the cock is killed, the hen perforce becomes the hunter, and provides food for the young and herself. I have heard, on very credible authority, that it is by no means uncommon in this case for the hen to get an unmated cock to help her.

There is only one brood in the year. A bird that is robbed lays again, but usually a smaller number of eggs, of which a far larger percentage prove infertile. If robbed again she will continue to produce eggs until July, when moulting normally commences.

The Institute of Human Palæontology, Paris.

ON December 23, 1920, the Institute of Human Palæontology in Paris was formally declared open by His Serene Highness Prince Albert of Monaco, its founder. The interest and active participation of the Prince in more than one branch of research have long been highly appreciated by the scientific world. The study of marine biology and oceanography already owed much to his valuable assistance and support when, more than twenty years ago, a visit to the Grimaldi Cave at Mentone first turned his attention to prehistoric archæology. Since that time all the more important cave explorations in Southern France and Northern Spain, which have enabled French archæologists to throw a flood of light on the character, art, life, and environment of prehistoric man, have been carried out under his auspices, at his expense, and frequently on lines suggested by him, while he has been responsible for the publication of the results in a manner and with a wealth of illustration which are not likely to be surpassed. Now, by the foundation of this institute as a headquarters in France for the systematic investigation of problems related to the origin and development of man, the Prince of Monaco has ensured the prosecution of this branch of scientific research in the most favourable conditions.

The Institute of Human Palæontology is situated in the Boulevard Saint Marcel. The building, which was nearing completion when war broke out, contains a large amphitheatre for lectures and meetings, a spacious library, and a number of rooms fitted up as laboratories, for examining and photographing the material furnished by excavation. Collections of specimens from the sites which have already been explored, as well as reproductions of the paintings and drawings found on the walls of the French and Spanish palæolithic caves, are exhibited in the building. An endowment of two million francs is attached to the Prince of Monaco's foundation, and an additional sum has been promised should it be rendered necessary by any further increase in the cost of living. The institute is under the direction of M. Marcelin Boule, assisted by a council consisting of MM. Salomon Reinach, Dislère, Verneau, and Louis Mayer.

FIG. 1.—The Institute of Human Palæontology. Front elevation.

Among those who were present at the opening ceremony were the President of the French Republic, M. Millerand, H.I.H. Prince Roland Bonaparte, M. Honnorat, then Minister of Public Instruction, the Belgian and Italian Ambassadors, the Argentine and Persian Ministers, M. Lacroix, secretary of the Academy of Sciences, the president of the Academy of Medicine, and representatives of the College of Medicine, the Collège de France, the Pasteur Institute, and the various scientific societies.

An inaugural address was delivered by the Prince of Monaco, in which he defined eloquently the broad aims of human palæontology. It was, he said, the prehistory of humanity. Only a few years had elapsed since men of science had recognised human handiwork in flints embedded in geological strata, and had seen in them man's first attempts at fashioning weapons for the chase and for defence. On these stones had been based a science which revealed our past and freed our judgment from the power of baseless philosophies and superstition. Investigation which traced the human species back to remote epochs revealed its relation to the animal world, from which it seemed slowly to have evolved. The prehistory of man began at that point when the human family was distinguished from other animals by a development of the brain which enabled it to diminish the part played by the muscles, and to employ moral force to carry on the struggle for existence: an artificial weapon took the place of the natural weapon, while, as shown by the paintings and drawings of the caves of Spain and Southern France, man was already capable of æsthetic emotion and sentiment.

FIG. 2.—The Institute of Human Palæontology. Sculptured group. Negresses and dead orang-utan.

FIG. 3.—The Institute of Human Palæontology. View of library showing bison killed by the Prince of Monaco.

The lesson of the history of mankind was, on the one hand, that man, though favoured by the laws of the universe, was still nothing more than a plaything in the hands of the forces of Nature; on the other, it helped us to surmount the bounds of a narrow philosophy which would reject all idea of relationship between man and the other members of the living world, and would wish to debar us from a study which placed mankind in an appropriate rank in the life of the globe. In the Prince's own words: "C'est pour aider l'Anthropologie à franchir les barrières qui la séparent de la vérité complète que je fonde l'Institut de Paléontologie humaine en lui donnant toute l'indépendance nécessaire pour conduire notre esprit vers la lumière. Et je confie ses intérêts à des hommes qui servent la Science avec une sincérité capable de développer sa force et de protéger sa marche contre l'influence des interventions passionnées."

At the conclusion of the Prince's address, brief speeches were made by M. Honnorat, Minister of Public Instruction, M. Perrier, and M. Le Corbeiller, president of the Municipal Council, the last named speaking on behalf of the city of Paris. Lastly, M. E. Cartailhac, the veteran archæologist, expressed his joy at the creation of the institute, which, he said, had been his dearest wish throughout his career as an archæologist.

The Institute of Human Palæontology is the materialisation of a conception of the aims and methods of prehistoric archæology formed by the Prince of Monaco when first he turned serious attention to the subject. It is, in a sense, a pendant to the institute he has founded for the study of oceanography, for, as he said in his inaugural address, "L'Océanographie, qui embrasse les origines du Monde, m'a rapproché de l'Anthropologie qui renferme les plus profonds secrets de l'Humanité." The reward which the Prince will seek for his munificent benefaction will lie in the results which may be expected from the facilities for study and research which he has placed at the disposal of science; but this reward will in itself be only a further addition to the debt already owed to him by archæology. His Serene Highness Prince Albert has indeed erected "a monument more lasting than brass."

Obituary.

DR. J. B. CROZIER.

DR. JOHN BEATTIE CROZIER (born at Galt, Canada, on April 23, 1849; died in London on January 8) was a thinker who knew how to combine philosophic breadth with scientific substance. His first master in speculative thought was Herbert Spencer, but he soon began to deviate from what he took to be the materialistic outcome of Spencer's psychology. The fault he found was that Spencer, in investigating mind, failed to view it adequately except from the objective side, as correlated with the brain and nervous system. This correlation itself Crozier accepted in the most thoroughgoing way; but, as the body is an organic unity, so also, he held, must the mind be unitary; and, by introspection, he found a "scale in the mind," not unlike that of the Platonic psychology, though it was for him an independent discovery. In this scale, truth, beauty, and love are at the top; such feelings as honour, ambition, and self-respect in the middle; and such qualities as greed and, in general, animal appetite at the bottom. This led Crozier to a metaphysical doctrine (though he was inclined to repudiate the term metaphysics) according to which the higher attributes of mind are superior not only in quality, but also, correspondingly, in ultimate strength.

What this scale or order in the mind points to, though it does not actually prove it, is dominance of the universe by a Supreme Intelligence. This view Crozier arrived at early, as may be seen in some extremely interesting chapters of "My Inner Life" (1898), and preserved to the end, as is set forth in "Last Words on Great Issues" (1917). It did not amount, he frankly admitted, to a religious creed. Having no mystical turn, he set to work in a scientific spirit on the investigation of human history, where, if anywhere, verification might be expected. The clue was the newly demonstrated theory of biological evolution, in which his master was Darwin. In the history of civilised peoples, on a wide survey, he found laws of progress; and these he made it his purpose to bring out in his central and best-known work, "The History of Intellectual Development."

In this and his other books, which grouped themselves naturally around it, Crozier carried out with approximate completeness, with literary interest diffused over the whole, and in the end with considerable acceptance on the part of the public, the scheme he had set before himself in the beginning. Presiding over his studies of historical evolution was his other great leading idea, that of social consensus—no doubt more vividly realised through his occupation with the profession of medicine. As the individual mind, like the body, is an organic whole, so is a society considered mentally as well as in its physical interconnection; and, apart from society, the individual is unintelligible.

Quite rightly, in his latest book, Crozier claims to have anticipated much recent development of a general theory which he had already styled the "doctrine of the herd." His versatility went along with a capacity for close study and a gift of illumining social observation; and where he was not an expert he was ready to be corrected by experts.

BY the death of MR. EDMUND J. SPITTA on January 21, at sixty-eight years of age, microscopical science has lost another earnest student and exponent. While in general medical practice for many years, Mr. Spitta found time to contribute to more than one branch of microscopy, and his retirement to Hove several years ago enabled him to devote the remaining years of his life to the subject. He took an active part in the proceedings of the Quekett Microscopical Club, of which he was a past-president, and of the Royal Microscopical Society, of which, as well as of the Royal Astronomical Society, he was a past vice-president. Mr. Spitta made some contributions to the subject of pond life, but it was particularly photomicrography and the optics of the microscope to which he directed his energies. So far back as 1898 he published, in collaboration with Mr. Charles Slater, an "Atlas of Bacteriology" containing more than a hundred plates of photomicrographs of bacteria. More recently he brought out his "Photomicrography," and many of his photomicrographs of diatoms are of great excellence. His book on "Microscopy," the third edition of which was published last year, is a general treatise on the construction, optics, and use of the microscope. To the Royal Microscopical Society Mr. Spitta contributed in 1911 a note on Winkel lenses and oculars and a report on the value of some Grayson's rulings, the latter entailing a considerable amount of work, and in 1913 he reported on a collection of lenses and other optical apparatus made by Joseph Jackson Lister, the father of Lord Lister, and presented to the Royal Microscopical Society on the death of the latter.

WE regret to learn of the death of PROF. FRÉDÉRIC HOUSSAY, professor of zoology at the Sorbonne since 1904, and dean of the faculty of science since 1919. Houssay's first piece of work, done under the direction of Lacaze Duthiers, was on the operculum and pedal glands of gastropod molluscs, and he presented this as a thesis for his doctorate in 1884. The same year he left for Persia as a member of the Dieulafoy mission, and returned in 1886. Soon afterwards he began a series of studies in vertebrate embryology, of which perhaps the best known is his contribution to the discussion on the vertebral nature of the skull (1890). After following the development of the skull of axolotl, he supported the view that the skull is segmental and represents ten segments. Houssay next turned to the study of dynamical morphology, and published on this subject two important works, "La forme et la vie" (1900) and "Morphologie dynamique" (1910). He devoted special attention to the functional significance of the form of the body, tail, and fins of fishes, studying the movements in relation to form and stability, and he published the main results in 1912 ("Forme, puissance, et stabilité des poissons"). Almost his last work was a continuation of the same line—a study of the flight of birds and the form of their wings, for which he made detailed measurements of 238 skeletons. We join with our French colleagues in regretting the loss of an ingenious worker and a courteous colleague.

WE regret to announce the death, on January 5, of CAPT. HAROLD STUART FERGUSON, at seventy years of age. Educated at Eton and Wimbledon, Capt. Ferguson passed into Woolwich and obtained a commission in the Royal Artillery, but after a few years' service in that corps he resigned his commission and sailed for India. He eventually became English tutor to the three Princes of Travancore, and when they no longer needed tutelage he was appointed second in command of the Nair Brigade of native troops maintained by H.H. the Maharajah of Travancore From that time until his retirement in 1904 he held various appointments under the Travancore Government, including the directorship of the Trevandrum Museum and Public Gardens, where his great love of animals and birds ensured the very careful management of the wild creatures kept in captivity. His collectors at the same time brought in valuable collections of animals, birds, and plants. While in India he was elected a fellow of the Linnean Society, and on his retirement he interested himself greatly in the Zoological Society's Gardens at Regent's Park, and some time before his death he was elected a member of the council of the society. A man of science, a keen sportsman, and a charming companion, Capt. Ferguson died much regretted by a host of friends.

THE death is announced of PROF. CARL TOLDT, who held the senior chair of anatomy in the University of Vienna for twenty-four years. Prof. Toldt was born in Tirol in 1840, and with him disappears almost the last of the great general anatomists—men who worked at comparative as well as at human anatomy. He was well known for his "Atlas of Anatomy," which appeared in 1896, and soon ran through seven editions. He contributed many papers to anatomical literature, the best known being those which treat of the morphology of the mandible.

Notes.

AT the meeting of the Royal Society on March 3 a discussion on isotopes will be opened by Sir J. J. Thomson.

A WIRELESS Press message from Moscow on January 21 stated that Prince P. Kropotkin had contracted inflammation of the lungs, and a fatal issue was feared. Prince Kropotkin's many friends in this country will be glad to know that a later telegram encourages hope of recovery, and says that his illness is apparently due to bronchitis.

SIR FRANCIS YOUNGHUSBAND, president of the Royal Geographical Society, announced at the meeting of the society on January 24 that the chief of this year's expedition to Mount Everest will be Col. Howard Bury, while the actual reconnaissance of the mountain will be in the charge of Mr. Harold Raeburn, who will leave England for India in March.

THE Galton anniversary meeting will take place on February 16 at the Connaught Rooms, Great Queen Street, Kingsway, London, W.C.2. The Galton lecture will be given by Dr. W. Bateson, at 8.45 p.m., on "Common Sense in Racial Problems," and will be preceded by the Galton dinner, for which tickets may be obtained at the offices of the society, 11 Lincoln's Inn Fields, London, W.C.2

THE Department of Scientific and Industrial Research announces that the Research Association for the British Jute Industry has been approved by the Department as complying with the conditions laid down in the Government scheme for the encouragement of industrial research. The secretary of the committee engaged in the establishment of this association is Mr. Frank S. Cathro, 1 Royal Exchange Place, Dundee.

THE following lecture arrangements have been made in connection with the Royal College of Physicians of London:—The Milroy lectures (on "Respiratory Efficiency in Relation to Health and Disease") will be delivered by Dr. Martin Flack on February 17, 22, and 24; the Goulstonian lectures (on "Glycæmia and Glycosuria") by Dr. G. Graham on March 1, 3, and 8; and the Lumleian lectures (on "Some Points in the Etiology of Skin Diseases") by Dr. A. Whitfield on March 10, 15, and 17. The lecture-hour in each case will be 5 o'clock.

THE physiological laboratory in the central offices of the University of London at South Kensington, of which the director is Prof. A. D. Waller, appears to be in some risk either of extinction or of mutilation by removal to another site. The London County Council, possibly under misapprehension as to the present status of the laboratory, threatens to withdraw the grant hitherto made, while the Senate of the University requires the rooms in July for its clerical staff. If the grant ceases the laboratory is to be closed. If it continues, or funds are provided from another source, the laboratory is to be accommodated elsewhere than on its present site. A letter of protest from Sir E. Sharpey Schafer has been published in the *Times*, and resolutions in favour of maintaining the laboratory in its present situation have been passed by various bodies of physiologists. It would be unfortunate if a valuable centre for research were dismantled in order to find room for work which could so much more easily be done elsewhere.

WE trust that an immediate inquiry will be instituted by the Ministry of Agriculture and Fisheries into the alleged effect of the discharge of oil from motor-propelled vessels at sea, to which Sir Arthur Shipley has directed attention in the columns of the *Times*. According to the *Naturalist* for January, gulls, razorbills, and guillemots have recently been picked up along the Yorkshire coast dead or dying, their plumage so saturated with oil that they were unable to fly or dive. Moreover, sedentary forms of rock-pool organisms are dying, and the inshore fisheries suffering in consequence, codling, coalfish, and other species haunting the inshore rocks being very scarce this year. It seems possible that unless remedial measures are taken disaster may overtake our fisheries.

THE United States Department of Agriculture has just issued a Circular (No. 135) directing attention to the fact that unless fur-bearing animals are rigidly conserved, the time is not far distant when many of the more valuable species will be exterminated. That this is no alarmist's cry is shown by the fact that both trappers and fur-dealers have urged the Government to take immediate steps to promulgate protection in the form of a close season and the infliction of penalties for furs taken out of condition. It is suggested that State Game Commissions and agricultural experiment stations should promote the raising of fur-bearers such as foxes, skunks, and musk-rats, and that other species less amenable to captivity should be conserved in sanctuaries.

IN the Kelvin lecture to the Institution of Electrical Engineers on January 13, Sir William Bragg gave an interesting and luminous account of the way in which the study of the properties of the electron has led to a better understanding of the structure of the atom. His concluding remarks indicate that the improvements he has been able to introduce into his X-ray spectrometer have enabled him to establish the fact that the atoms have different properties in different directions. This supports the theories of Lewis and Langmuir that some of the electrons constituting an atom do not participate in the orbital motion about the nucleus which is characteristic of the electrons of the Rutherford atom, as developed by Bohr and Sommerfeld, but, on the contrary, are restricted to certain portions of the outer surface of the system, in which they describe small closed orbits and so produce magnetic fields which serve as bonds of attachment between atoms.

IN co-operation with the Anglo-Batavian Society, the University of London has made arrangements for an interchange of lectures on medical subjects between London and the Netherlands. The first lecture of the series to be given by Dutch professors was delivered by Prof. Wertheim-Salamonson, of Amsterdam, on January 17 at the Royal Society of Medicine, the Vice-Chancellor of the University of London presiding. The subject chosen was "Tonus and Reflexes," one to which the lecturer has devoted much attention. The chief point discussed was the participation in reflexes obtained normally, but especially in some nervous affections, of that remarkable state of shortening into which voluntary muscles can be put by certain conditions—a state in which no electrical changes are to be detected and, as it appears, very little, if any, chemical or thermal changes take place. The lecturer was inclined to attribute the phenomena to effects through the sympathetic supply of muscle. The next lecture will be given by Prof. Boeke, of Leyden, on February 16, the subject being "The Modes of Termination of Nerve-fibres in Muscle."

A DISCUSSION, in which a number of kinema experts participated, took place before the Illuminating Engineering Society on January 18 on "The Use and Abuse of Light in Studios for Kinema-film Production." The making of films by artificial light involves the use of illuminations vastly higher than those usual in ordinary lighting, and cases have been mentioned of alleged injury to the eyes of actors arising from exposure to very powerful lights at close quarters. The subject is being considered by the Ministry of Health Committee on the Causes and Prevention of Blindness, the chairman of which, the

Right Hon. G. H. Roberts, made a few remarks at the meeting. Eye-troubles have been attributed to the glare of the intense visible light from certain illuminants, and it has also been suggested that the presence of a high proportion of ultra-violet rays may be an influential factor. It seems evident that the region of the spectrum best suited to film production needs further investigation. Possibly ultra-violet rays of very short wave-length, such as may be liable to affect the eyes, might be excluded without prejudice to photographic effect. The view was expressed by several speakers that the use of very powerful unscreened arcs in studios is rarely necessary, and that the best results are obtained by adopting screening and diffusing devices yielding conditions resembling natural lighting. The Illuminating Engineering Society has prepared a list of queries for circularisation which should yield useful information on these points.

WE have received the following communication from the U.S. National Research Council:—Dr. Henry A. Bumstead, professor of physics and director of the Sloane Physical Laboratory at Yale University, and for the past half-year on leave from the University as chairman of the National Research Council of Washington, D.C., died suddenly on the train on the night of December 31 while returning to Washington from Chicago, where he had been in attendance at the meetings of the American Association for the Advancement of Science and affiliated societies. The following resolution was unanimously adopted at a special meeting of the Interim Committee of the National Research Council held on January 3: "That the National Research Council learns of the death of Dr. Henry A. Bumstead, chairman of the Council, with great sorrow and a profound sense of loss. Dr. Bumstead in his association with the Council had revealed to its officers and members not only a high capacity for administration and a most loyal fidelity to the aims and work of the Council, but also a sweetness of disposition and personal attractiveness which had won for him the devoted and affectionate regard of all his colleagues in the Council. In his death the Council and the scientific world lose a man of most eminent attainments, highest character, and lovable personality. The National Research Council extends to the bereaved wife and family its deepest sympathy and condolence, and wishes to express to them its full appreciation of the great value of the services which Dr. Bumstead rendered it in the period of his association with it and the great loss which it suffers by his untimely death. But may we all remember that 'that life is long that answers life's great ends.'"

PROF. E. WESTERMARCK publishes in *Acta Academiae Aboensis*, part i., an important paper on "The Belief in Spirits in Morocco," the result of several expeditions into that country. It is mainly concerned with an elaborate account of the Jinn or underground spirits which interfere in every phase of human life. Men have been taken to their kingdom or have cohabited with the Jinniya or female spirits. Prof. Westermarck describes in detail the nature and doings of these spirits, prophylactic measures adopted against them, remedies for troubles caused by them, and measures for bringing them under control. He disputes the views of Robertson Smith, who regarded the belief in them to be a survival of totemism; nor can they be regarded originally as the spirits of the dead. Prof. Westermarck regards the conception of the Jinn to be "a generalisation on a much larger scale. These spirits seem to have been invented to explain strange and mysterious phenomena which suggest a volitional cause, especially such as inspire men with fear; but Robertson Smith's theory that their special haunts are places most frequented by wild beasts cannot be accepted. In their present form their original home was Arabia, whence they migrated to Morocco, where the general scheme of belief was mixed up with the local animistic beliefs of the Berber tribes."

THE American Museum of Natural History has arranged for a third Asiatic Expedition in co-operation with the American Asiatic Association and *Asia*. The Chinese Government has been invited to delegate to the expedition men who have had preliminary instruction in various branches of science, so that they may assist and, at the same time, be trained in modern methods of scientific exploration. In return for such help and facilities a duplicate set of the collections will be deposited in Peking to form the basis of a Chinese national museum. To aid this, the American Museum undertakes to train selected Chinese in museum work. It is proposed that the field work shall last for five years. From headquarters in Peking parties will work in the interior of China, Central Asia, Manchuria, and Kamchatka. The zoological collections will help to furnish a hall of Asiatic life in the American Museum of Natural History, where are already the specimens obtained by Mr. R. C. Andrews, the leader of the first and second Asiatic Expeditions. In *Natural History*, the journal of the museum, Mr. Andrews dwells on the fragmentary nature of our knowledge of this region. Some exaggeration is allowed for in propaganda, but when Mr. Andrews says, in italics, "Knowledge of the fossils of Eastern Asia rests almost entirely upon the report on a small collection of teeth and fragmentary bones purchased in the medicine-shops of Tientsin and described by a German named Schlosser," then we recognise that several fragments of knowledge have failed to catch the eye of the writer.

REPORT No. 10 of the Industrial Fatigue Research Board forms a preliminary account of some of the investigations now being undertaken by Messrs. J. Loveday and S. H. Munro into the boot and shoe industry. A historical sketch of the industry is given, and a detailed description of modern processes follows. The daily variations of output of various groups of workers in five factories are then recorded. As in almost all other industries, the Saturday output was found to be low (sometimes only 77 per cent. of the average), but the chief interest of the observations lies in the comparison between the skilled workers with a large output and the relatively unskilled, who showed an output 10 to 50 per cent. smaller. It was found that the former maintained a much more uniform output, and usually they improved slightly from day to day until they reached their acme on Friday. The relatively unskilled workers, on the other hand, showed a more irregular output, which generally fell off after the second or third working day of the week, and sometimes after the first working day. Another section of the report affords striking evidence of the value of rest-pauses. A firm which desired to increase its output without adding new machinery determined to make the experiment of working the double presses with a team of three girls, each operative working forty minutes in each hour and resting twenty minutes, instead of with two girls working continuously throughout the day. In a short time it was found that the total output from the presses had increased 44 per cent., *i.e.* the girls were producing individually nearly as much as they had been able to do previously, but in two-thirds the time.

A COPY has reached us of the first number (January) of the *Journal of Industrial Administration*, the official organ of the Institute of Industrial Administration, which was founded in the spring of last year. The scope of the journal is, it is announced, to be wider than that merely of reporting the proceedings of the institute on the lines usual with professional societies; its editor indicates that his chief aim will be to make the publication "a medium for the pooling of the experience of those interested in the administration of industrial enterprises, so that it may serve the urgent purpose of assisting in the policy of practical education for members." A prominent feature is to be the special section devoted to the discussion by correspondence of the problems connected with industrial administration; the object of this section is to provide members resident in any part of the world with a medium for exchanging views on administrative questions affecting their occupation on an open platform, and in a manner which will, whilst assisting members individually, conduce to the greatest usefulness of the institute. Particulars are given of instructional courses, open to members and non-members, to be held in London; these courses begin on February 2, and deal with production estimating and production costing. The journal contains an abstract of an address on "The Industrial Question" given by Viscount Haldane, O.M., at the inaugural meeting of the institute held on October 23 last. The editorial offices have been established at 110 Victoria Street, S.W.1.

AN important paper by Lord Lovat on recent progress in British forestry appears in the Journal of the Royal Society of Arts for January 7. It begins with a short account of the movement leading to the passing of the Forestry Act in August, 1919, which created the Forestry Commission and empowered this body to expend 3,500,000*l.* in afforestation during the ensuing ten years. Lord Lovat further points out the part which private landowners should play in this great national work, and discusses at some length the relations between forestry and such subjects as hill pasture, land given over to sport, small holdings, and soldier settlements. The paper concludes with an authoritative statement of the operations of the Forestry Commission during its first year. A good beginning has been made; 69,000 acres of land have been acquired and extensive nurseries started, in which there are growing already 129,000,000 seedlings and transplants.

THE burning coal-seams that are a conspicuous feature in the coalfields of the western United States lead G. Sherburne Rogers (U.S. Geol. Surv., Prof. Paper 108–A) to remark that a pile of coal exposed to the direct rays of the sun would be liable to become heated and finally to ignite. From his observations in Montana he concludes that "the physical factors promoting spontaneous combustion are a finely divided condition of the coal, a slight increment of heat from an outside source, and a sufficient volume of coal to retard loss of heat by radiation." The absorption of oxygen by coal when warmed generates further heat, and the process is thus self-accelerating. Parr and Francis are quoted as showing that at 120° C. to 140° C. a critical stage arises, when the occluded oxygen combines with some of the hydrocarbons, producing carbon dioxide and water, accompanied by a rapid rise in temperature. Ignition occurs at 350° C. to 450° C. The fine dust of lignite, it appears, may ignite at 150° C., and of gas-coal at 200° C. The burning of coal-seams in the west is associated with the cuts formed by small and rapid streams. The metamorphic effects of the heat on the overlying rocks have been studied by the author, and include the production of spherulitic glass and of holocrystalline diopside-plagioclase slag.

THE November and December issues for the past year of the Journal of the Franklin Institute contain an important paper on the annealing of glass by Messrs. L. H. Adams and E. D. Williamson, of the geophysical laboratory of the Carnegie Institution of Washington. In order to supply the information demanded by the American glass manufacturers as to the proper method of annealing, the authors have determined the rate of disappearance of an initial stress in glass at any temperature. They find that the reciprocal of the stress increases with the time at a uniform rate which depends on the kind of glass and the temperature at which it is maintained. A table of rates for common glasses at various temperatures is given. As a result of their investigations the authors recommend that glass, and especially optical glass, should be annealed by raising the temperature in about 1½ hours to the value specified in one of the tables as suitable for that glass. This temperature is about 50° C. less than that in common use at the present time. The glass is maintained for four hours at that temperature and then allowed to cool, at first slowly, then rapidly, so that the cooling is over in about three hours, and the whole process lasts only eight hours. This is more effective than the old process, involving greater heating and slow cooling, which lasted twenty hours.

PARTICULARS have reached us of the Elmendorf paper-tester, which indicates the resistance offered by a sample of paper to tearing. A compound pendulum of weight P and equivalent length l is swung always from the same initial angle, and in the course of its downward swing it tears a suitably cut sample of paper held partly by a clamp secured to the pendulum and partly by the fixed support carrying the axis. The pendulum rises on the far side to an angle ϕ_1. When swung without tearing the paper it rises to an angle ϕ_2. The difference in the potential energy of the pendulum at the angles ϕ_1 and ϕ_2 is the work done in tearing the paper, and is equal to $Pl(\cos\phi_1 - \cos\phi_2)$. If the length of tear is d and the tearing resistance to be determined R,

$$R = \frac{Pl}{d}(\cos\phi_1 - \cos\phi_2).$$

In its present form the pendulum has the shape of a segment of a circle pivoted at the centre and calibrated round the circumference. It is held in its initial position by a spring stop. A light pointer mounted frictionally on the axis is set initially against the stop, where it is held until the pendulum commences its return swing; then it moves with the pendulum, and so the extent of the swing is recorded. The calibration can be such that R is read direct. The apparatus can be seen at the office of Messrs. R. J. Marx, 133–39 Finsbury Pavement, E.C.2.

AMONG the announcements of Mr. John Murray is "The Life of Alfred Newton," by A. F. R. Wollaston, in which the many activities of this former professor of zoology in the University of Cambridge will receive attention. The work will also contain a chapter describing Cambridge in the middle of last century, by Sir Arthur E. Shipley, and personal reminiscences of Prof. Newton by Dr. H. Guillemard.

ERRATA.—Dr. T. J. J. See sends the following corrections of values given by him in his letter on the measurement of the angular diameter of Betelgeux printed in last week's issue of NATURE, p. 663:—Lines 16 and 24, "orbit of Venus" should be "orbit of Mars." Lines 33–35 should read: "Sirius, which is itself twenty-fivefold more luminous than our sun. Accordingly, Betelgeux gives about 6500 times the sun's light."

Our Astronomical Column.

PONS-WINNECKE'S COMET.—The reappearance of this periodical comet is expected shortly, and the ensuing perihelion passage is likely to occur at nearly the same time of the year as in 1869, when it was on June 29, and in 1892, when it was June 30. On the former occasion the comet was first seen on April 9, and on the latter March 18. The following is an ephemeris:—

1921		Perihelion June 21 R.A.	Perihelion June 21 Decl. N.	Perihelion June 13 R.A.	Perihelion June 13 Decl. N.
		h. m. s.	° ′	h. m. s.	° ′
Feb.	3	13 26 10	19 8	13 45 16	17 8
	11	13 36 11	20 48	13 58 4	18 31
	19	13 45 32	22 51	14 11 0	20 17
Mar.	7	14 2 0	28 16	14 37 8	24 59

The date of perihelion passage is a little uncertain, so that for purposes of sweeping two series of positions are given, one on the assumption that it will occur on June 21 and the other on June 13. The comet will probably be rediscovered in February or March, and the meteoric shower connected with it, should it recur, may be expected on the night following June 27.

THE MAGELLANIC CLOUDS.—Dr. E. Hertzsprung has a paper on these clouds in Monthly Notices (vol. lxxx., No. 9). It is based on Mr. R. E. Wilson's measures of the radial velocity of nebulæ (Lick Obs. Pubs., vol. xiii.). On the whole, Mr. Wilson found low velocities for the gaseous nebulæ. There were, however, notable exceptions in the cases of seventeen nebulæ in the greater cloud, which showed average recessions of 276 km./sec., and one in the lesser cloud which showed 168 km./sec. It was a reasonable inference that the clouds were external to our galaxy; indeed, this was already thought probable on other grounds. On studying the individual motions it was seen that they showed a steady upward tendency as one went southward. Mr. Wilson suggested in explanation a rotation of the cloud; Dr. Hertzsprung points out that it is simpler to assume that the variation is a perspective effect, due to different parts of the cloud being at different angular distances from the apex of motion. He applies analysis to the observations, and finds as the most probable solution that the velocity of the greater cloud (corrected for the solar motion) is 608 km./sec. towards R.A. 4h. 31m., S. decl. 4° 42′ (galactic long. 168°, S. lat. 30°). The single nebula observed in the lesser cloud gives a result consistent with the two clouds having the same motion. The greater cloud is 63·7° from the apex, which gives a velocity of 560 km./sec. at right angles to the line of sight. Taking the distance as 10,000 parsecs, this implies an angular velocity of somewhat more than a second per century, the position angle being 348° and 55° for the greater and lesser clouds respectively.

It will be remembered that Dr. Hertzsprung was one of the first to give a trustworthy estimate of the distance of the clouds, based on methods quite similar to those applied later to the globular clusters by Dr. Shapley.

INVESTIGATION OF THE EINSTEIN SPECTRAL SHIFT.—Bulletin No. 64 of Kodaikanal Observatory contains a full account of a second investigation of this effect by Mr. J. Evershed. Mr. Evershed's former result (Bulletin No. 39) indicated considerably more than half the shift predicted by Einstein. In view of Dr. St. John's much smaller result, he planned a more extensive research, using the Anderson 6-in. grating, which was carried out in the spring of 1918. The spectrum of the sun both near the centre and near each pole was compared with the carbon arc. The results are corrected for solar and terrestrial rotation and the earth's radial velocity. The lines used are not the same as those of Dr. St. John, but the strongly marked triple carbon bands extending from 3876·59 to 3881·78. The mean values of the shift, sun *minus* arc, are:

Sun's centre ...	+0·0037 Å.
(omitting one discordant day)	
Sun's north limb ...	+0·0071 Å.
Sun's south limb ...	+0·0100 Å.
Einstein's value ...	+0·0082 Å.

Mr. Evershed notes that the late Mr. Pocock found a similar discordance between the measures at the sun's north and south limbs.

The Forestry Department of Edinburgh University.

SO far back as 1887 a lectureship in forestry was inaugurated at Edinburgh University. The courses given were mainly attended by students taking the University degree in agriculture. It was a far-sighted step to take at that time; since it is a great advantage to the scientific agriculturist to have some acquaintance with the aims and objects of the forester with whom he has so commonly to work side by side on the countryside. On the closure of the forestry branch at the Coopers Hill College in 1905, the training of the Indian forestry probationers was left in the hands of the universities. Recognising the altered conditions and the growing demand for the trained forest officer—for the Colonial Office was now beginning to require qualified men—Edinburgh University, which is pre-eminently a scientific and Empire university, instituted an ordinance for the degree of B.Sc. in forestry in 1909.

FIG. 1.—Forestry and Agricultural Building, University of Edinburgh.

Under this ordinance full courses in all the branches of pure forestry are given, and at least six months' practical work in forestry is required of the student for the degree. The subjects for the forestry Preliminary Examination for matriculation to the University are English, mathematics, Latin, and French or German, thus ensuring that the future forest officer shall have that acquaintance with modern languages which is indispensable to him.

During his first year the student takes the first science courses in pure science of the University in botany, zoology, natural philosophy, and chemistry. In the second and third years the forestry subjects proper, together with the allied science branches, including geology and surveying, are taken. In order to make full provision for the allied sciences, which form so important a branch of the training of the future forest officer, special lectureships in forest botany, forest mycology, forest zoology, forest engineering, and forest chemistry were inaugurated, as also a course in Indian forest trees. Students for the agricultural degree of B.Sc. have the option of taking the introductory forestry course, which is one of the courses under the forestry ordinance. More recently courses in tropical forestry and in Indian geology have been sanctioned. The fact that all the branches of applied science are dealt with by specialists in their individual subjects is of great importance in properly equipping the forest officer for his future life-work. In the past it has often occurred, both in Continental schools and in this country, that one lecturer was maintained, in order to save expense, to deliver courses in forest botany and forest entomology, with, perhaps, geology or another subject thrown in. The students' time-table for the degree is well filled up. The terms, three in the year, are of ten weeks each, and the hours, from 9 a.m. to 5 p.m. five days a week, are taken up with lectures, tutorials, and laboratory work. A part of most Saturdays is devoted to excursions, whilst the vacations are occupied, to the limit desirable in the interests of the student, with the practical courses in forestry.

In order to give full effect to the ordinance, the University had to make provision in the important question of buildings, laboratories, and so forth, and in this matter the department may claim to be second to none in the country. New buildings were erected containing a large lecture hall to accommodate 130 students, and several museums, including a sylviculture museum, a protection museum, a wood and economic products museum, and a museum for Indian and Colonial timbers. Then there are laboratories, a workshop fitted with a circular saw, a planing machine, and a lathe for the instruction of students, rooms for the members of the staff, a students' room, and a library. Additional rooms for the museum and laboratory of the lecturer in forest zoology were also provided in the building. These various parts of the building are fitted up with valuable collections of specimens, serving as object-lessons for the training of the students.

This accommodation was just completed before the outbreak of war. The site and building cost 19,500*l*., and at present prices it is easy to reckon that its value to-day is nearer 40,000*l*. than 20,000*l*. The equipment and fittings cost about 2000*l*., and the same remark applies to them. It is difficult to make even a guess at the value of the specimens which fill the museums. Towards this outlay, which is exclusive of museum specimens, the University furnished 15,200*l*., the Development Fund contributing 6300*l*. The other expenditure on the forestry department proper for the period of years 1910–11 to 1919–20, to which allusion is made, on salaries, etc., amounted to 8800*l*., of which 6600*l*. was furnished from the University funds and 2200*l*. from State funds; so that out of a total outlay during the period of 30,300*l*. the University provided 21,800*l*. as against 8500*l*. received from the State. In addition, the University paid from its own funds the salaries of the lecturers conducting the applied science subjects, forest botany, and so forth. Last year a chair in forestry was instituted and endowed within the University with the help of a grant from the Development Fund.

For the practical work, through the courtesy of their proprietors, Edinburgh University has had the use of the woods on the estates of the Duke of Atholl, Col. W. Steuart-Fothringham of Murthly, the Earl of Mansfield of Scone, and Viscount Novar of Novar and Raith, and of the Speyside Woods. The students are taken out to these areas and instructed in nursery work, in planting and felling, in sylviculture, and in the protection, utilisation, and scientific measurement of the woods. Arrangements have recently been made with the War Office by which a forest garden has been established on the War Office estate at Dreghorn, situated a few miles from Edinburgh, where a fine large nursery is being laid out; and the Stobs estate of several thousand acres, also belonging to the War Office, has been made available for practical work by the students, the University in return advising on the management of the woods of these estates. The Forest of Dean is used for advanced practical work, and the visits which were made to Continental forests before the war are now being resumed.

FIG. 2.—Protection Museum, Forestry Department, University of Edinburgh.

At the outbreak of war there were 50 students in the department; last year 168 students took forestry courses in the University, and this year the number has reached 170. The 40 students who have taken the forestry degree since 1911 are now serving in the Indian Forest Service and in the various Colonial Forest Services (South Africa, Canada, and New Zealand), in the Home Forestry Service, and in the Home universities. At the present moment there are in Edinburgh University sixteen Indian forestry, nine Colonial Office, and ten South African probationers—a total of thirty-five.

The University may thus be considered to have met a national need in placing itself in a position to give a full scientific training to the forest officers of the Empire.

The International Physiological Congress, 1920.

SUMMARY OF PAPERS.

SINCE more than two hundred papers and demonstrations were given at the above congress, which was held in Paris in July, a mere mention of the more outstanding communications is all that is possible in this summary. For a general account of the congress Prof. Fraser Harris's article in NATURE of September 16 may be consulted.

Of new apparatus, those described by Hess (Zürich) and Wilson (Cairo) may be specially mentioned. The former demonstrated a cardio-phonograph, a viscosimeter, and stereoscopic photographs. The latter exhibited a stethograph, a portable ergograph, a micro-nitrometer, a colorimeter, and a chronograph with electro-magnetic signal. The pursuit-meter described by Miles (Boston) for detecting the influence of nutrition, fatigue, industrial conditions, etc., on neuro-muscular co-ordination, and the demonstration (without the aid of the microscope) by Fredericq (Liége) of cilia, spermatozoa, etc., in motion, by means of intense illumination, were of particular interest. Philippson (Brussels) demonstrated an apparatus for showing the precise moment of coagulation of an organic liquid; another for recording modifications in the viscosity of fluids; and a method for measuring the electrical resistance of cells and tissues. The crescograph shown by Bose (Calcutta), which is claimed to magnify growth and other movements ten million times, was closely examined and much criticised. Mention may also be made of the display of well-made physiological apparatus by several French and Swiss firms.

Morpurgo (Turin) showed a number of artificially united rat-pairs (so-called Siamese twins). He finds that when two animals of different size are united the weaker dies from inanition, as a result of failure to hold its own in the joint distribution of nutritive substances. Rochon-Duvigneaud (Paris) finds that the foveæ in the retina of birds may be central, ex-central, or double; since complete decussation occurs at the optic chiasma, each has a unilateral connection. A communication by Minkowski (Zürich) dealt with the course of the optic fibres in man and other mammals.

Botazzi (Naples), by very slowly varying its temperature, finds that mammalian striated muscle (diaphragm) shows a distinct shortening at 0° C. (cold-contracture) and another, already well known, at 45° (heat-contracture). He believes that these changes, which are reversible, are due to the sarcoplasm. Heat rigor (63° C.), which is irreversible, he regards as due to contraction of the connective-tissue. Parnas (Warsaw), in his communications on muscle physiology, supported a view which is opposed to that of A. V. Hill on the question of the fate of lactic acid during the relaxation phase, favouring the combustion theory. Langley (Cambridge) suggested that muscle atrophy after denervation is due to fatigue (fibrillation), resulting from the irritation set up in the neural region of the muscle. He also spoke upon nerve suture and regeneration. The conditions of industrial fatigue were dealt with in a paper by Lee (New York).

The question of fat metabolism in its broadest aspect was the subject of a communication by Halliburton (London), the vitamine problem being specially considered. Gosset, Camus, and Monod (Paris) described a method for obtaining permanent biliary fistulæ in the dog. Both Foa (Parma) and Lombroso (Messina) dealt with the metabolism of fats in the liver; they showed that their destruction is much greater during digestion than during fasting. Lombroso also discussed the action of enterokinase upon the proteolytic activity of pancreatic juice. Brinkman (Groningen) showed that the cholesterol-phosphatide quotient controls the permeability of cell-membranes, those of erythrocytes in particular, and pointed out that this factor is all-important in the pathology of anæmias. The question of intermediary metabolites and their relation to heat production was dealt with by Graham Lusk (New York), who found that in the dog 58 grams of glucose increased heat production by 4·3 Calories, while 50 grams of glucose *plus* 8 grams of lactic acid caused an increase of 4·8 Calories. When lactic acid was replaced by 3 grams of acetic acid, the increase observed was 7·3 Calories. This last result is similar to that obtained when fat and glucose are metabolised together, and suggests that acetic acid may be an intermediary metabolite of fat, but not of glucose. E. and May Mellanby (London) showed that the cause of rickets is probably want of fat-soluble A vitamine in the diet. When this is lacking the development of bones and teeth is defective.

With intact kidneys a small dose of uræmic blood causes intense diuresis, while a large dose arrests the flow of urine. After denervation no result is obtained. This was demonstrated by Pi Suner and Bellido (Barcelona).

Macleod (Toronto) showed that in decerebrate cats the respiratory centre can be stimulated during slight anoxæmia without any decided change in the CO_2 tension or the H-ion concentration of the arterial blood; greater degrees of anoxæmia cause paralysis of the centre. Krogh (Copenhagen) demonstrated that the respiration of aquatic animals is not influenced by CO_2, but only by the amount of oxygen. The same author, employing the frog's tongue, finds that capillaries can be caused to dilate independently of the influence of the arterioles supplying the part. Waller (London) described a ready method of determining the CO_2 output under varying conditions of work; he also demonstrated the electrical emotive response in man. The effect of different kinds of exercise on the respiratory exchange in man was also dealt with by Liljestrand, Linhard, and Stenstrom (Stockholm), and as affected by gymnastic exercises by Langlois (Paris). The transport of CO_2 by hæmoglobin formed the subject of a communication by Buckmaster (Bristol). The crystallisation of hæmoglobin of the bat was described by Amantea and Kryszkowsky (Rome); these authors also dealt with the physiology of spermatozoa.

The glycogen-content of leucocytes and the nature of amœboid movement were discussed by de Haan (Groningen); amœboid movement is stated to be dependent partly on viscosity (colloid) and partly on HCO_3 ($NaHCO_3$). De Haan and Feringa produced evidence of the apparent formation of eosinophil leucocytes from lymphocytes. Doyon (Lyons) demonstrated that incoagulability of the blood after peptone injections is due to an antithrombic substance of nuclear origin—a nucleo-protein—containing 3 per cent. of phosphorus. Nucleinate of soda was also shown to be a strong anti-coagulant. Gautrelet (Paris) found no fatal effects or any alteration in the viscosity or the H-ion concentration of the blood after an intravenous injection of oil (1 c.c. per kilo. body-weight).

Sharpey Schafer (Edinburgh) proved that the pulmonary blood-vessels are supplied by vaso-motor nerves by showing that stimulation of the depressor nerve causes a fall in pulmonary pressure independently of the aortic system. He also exhibited cats in which both cervical sympathetics had been cut at an interval of a few weeks, showing paradoxical contraction of the pupil and dilatation of arterioles on the side of the first section. The mechanism of paradoxical dilatation of the pupil following cocainising of the cervical sympathetic was also discussed in a communication sent by Byrne (New York).

Feenstra (Utrecht) confirms the work of Zwaardemaker on the inter-availability of potassium and other radio-active salts in Ringer's solution. Dubois and Duvillier (Lille) showed that after section of the cervical cord double vagotomy may still produce cardiac acceleration provided the blood-pressure is sufficiently high. Wertheimer and Boulet (Lille) showed tracings to demonstrate that in frogs poisoned by $BaCl_2$ it is possible either to provoke or to arrest heart-block by an induction shock, according to the phase of the normal rhythm at which the heart is stimulated. Barry (Cork) showed in the toad's heart that reversal of action may take place (ventricle beating before auricle) during recovery from the effect of nicotine. Einthoven (Leyden) described experiments which appeared to show that the positive electrical change during vagal stimulation described by Gaskell in the tortoise auricle is due to mechanical stretching by contraction of the lung. De Boer (Amsterdam) reported the results of his study of the effects of varying rates of conduction on the form of the ventricular electrogram. He also described a method for obtaining delirium cordis in the frog-ventricle. Danielopolu (Bucharest) records observations upon the effects of various conditions—clinical and experimental—upon the human electro-cardiogram.

In a communication by Heger (Brussels) the cause of the relative hypertrophy of the right ventricle which occurs in man and animals acclimatised to residence at a high altitude is ascribed to a persistent pulmonary hyperæmia.

Anaphylaxis was the subject of communications by Kopaczewski (Paris) and Pesci (Turin).

Communications dealing with the central nervous system were few in number. Among them was one by Amantea (Rome) on the effect of application of strychnine to the sensori-motor region of the cerebral cortex on experimentally excited epilepsy; one by Camus and Roussy (Paris) on polyuria produced by lesions at the base of the brain; and one by Lafora (Madrid) on the functions of the corpus callosum.

According to Abelous (Toulouse), cholesterol is manufactured in the spleen, which organ may be stimulated to increased production in this direction by secretin. A paper by Rothlin (Zürich) was devoted to the effects of adrenalin and β-iminazolethylamine (active principle of secretin) on gastric secretion; the former inhibits, and the latter, if injected subcutaneously or intramuscularly, stimulates. Quantitative studies on the adrenalin output of the adrenal glands was the subject of a communication by Stewart (Cleveland). Bazett (Oxford), as the result of cross-circulation experiments, finds that adrenalin is of little importance as regards pressor reflexes, but that it functions by maintaining a normal tone in the arterioles or capillaries. Negrin y Lopez finds that after "piqûre" and double vagotomy the blood-pressure always rises, but if the animal has been adrenalectomised a fall occurs. Gayda (Turin) finds that tadpoles fed with thyroid give off more heat than normal ones.

Pézard (Paris) confirmed the experience of others that castration leads to the appearance of the opposite sex-characters in fowls. Athias (Lisbon) showed that after total castration pituitrin always contracts the uterus, while adrenalin does so only in the rabbit and hedgehog; it inhibits contraction of the uterus of the dog and cat.

There were also presented many communications dealing with problems of chemical physiology and with the action of particular drugs the contents of which do not lend themselves to a short summary.

R. K. S. LIM.

Liquid Fuel from Coal.

By PROF. JOHN W. COBB.

A PAPER entitled "Coal as a Future Source of Oil-fuel Supply," which has a very special interest at the present time, was read by Sir Arthur Duckham at a meeting of the Institution of Petroleum Technologists held at the Royal Society of Arts on October 19, 1920. It marks the recognition of a new state of affairs which is rising out of the enormous increase, actual and contemplated, in the use of liquid fuel and the by no means unlimited supply of natural petroleum. America is already concerned with the conservation of its own supplies of the latter, and there is every necessity for a careful and extended examination of any method which appears to be practicable for producing liquid fuel from solid deposits.

The demands that have to be met are of various kinds, and require products differing widely in the degree of their refinement. One extreme is encountered in providing for the delicate mechanism of the motor-car engine, and the other in meeting the grosser requirements of a steam boiler, particularly in the raising of steam for the propulsion of battleships and other sea-going vessels.

The Scottish shale industry is old-established, and an example of the practicability of obtaining oils by retorting, but the proved quantities of suitable oil-producing shale in this country are not very great. Sir Arthur Duckham has addressed himself to a discussion of what may be done by way of treating coal so as to obtain the best value in oils and tars. In reviewing possible lines of development he expresses the belief that the industrial future of this country lies in the conversion of the coal at the pit's mouth into liquid and gaseous fuels. "Liquid fuels will be recognised as the medium for providing energy for all transport by land, sea, or air with the exception of electrical transport for congested areas, while gaseous fuels will be used direct for the great majority of heating purposes and for the generation of electricity." He points out that "full experience has been gained in America of the transmission of gas over long distances," and then that "there is no question that, starting in the big industrial districts which lie near the coalfields, gas can be supplied in sufficient quantities and can economically replace solid fuel." In this way the author emphasises the production of gas, oil, and tar together from coal as being the right direction in which to go, and proceeds to discuss the various technical and commercial considerations which should influence the choice of process and plant for the purpose.

In this Sir Arthur Duckham is completely at home, and, although primarily a gas engineer of assured reputation, he displays no reverence for traditional and accepted methods when these appear to him to be only second best. He is, however, compelled to lament at an early stage the impossibility of supplying financial or thermal balance-sheets with any degree of confidence. This difficulty is inevitable at any time with unproved processes, and at the present time there are peculiar difficulties on the financial side which are not confined to the problem he is discussing, but apply to all schemes involving extensive reconstruction.

In order to deal in turn with established methods, the author reviews the position of gasworks, coke-ovens, and gas-producers. He describes the evolution of gas-making as it is conducted for the purpose of public supply, pointing out how "it started as a low-temperature process, and gradually became, with the improvement of materials of construction and advanced knowledge, a high-temperature process." He indicates the extent to which gas undertakings have been hampered by "antiquated and restrictive legislation," based upon the conditions of the past, and indicates quite rightly that the recent removal of these restrictions should make for rapid development.

The form of gasworks plant which meets with Sir Arthur's approval is evidently the continuous vertical retort with steaming, increasing the temperature about the bottom of the retorts and highly superheating the steam before it enters. The hot waste gases from the plant are to go through waste-heat boilers, so raising the quantity of steam required for steaming the retorts in return for a small extra capital expenditure and the cost required to drive the fan on the outlet boilers. The author points out in this connection what is so frequently ignored by the less informed advocates of low-temperature carbonisation, that in the continuous vertical retort a really fractional distillation can be attained. "The products of distillation are driven away as made, and have to pass through no higher temperature than that at which they are evolved, whilst if water-gas is made at the same time in the retort by steaming, this process protects the hydrocarbons and gives a greater quantity of a lighter quality tar." The weakness of gasworks practice, from the author's point of view, is that the coal has to be conveyed to the gasworks and the coke removed from it.

In dealing with coke-ovens it is argued that they meet a definite but limited demand for a specific article, namely, hard coke for blast-furnace work, and that on this account the erection of coke-ovens for supplying gas- and tar-oils to meet national needs is not feasible.

The author turns aside for a moment to indicate the possibility of using much more coke-oven gas for town supply, and points out that the chief difficulty in the way at present is the variation in its quality. That difficulty is not, however, insuperable.

He expresses, too, a belief that gas will in the future be used instead of coke in the smelting of iron-ore, but it is possible that in coming to that conclusion the high output and efficiency of a modern blast-furnace plant have not been taken sufficiently into account.

Sir Arthur does not regard gas-producers very favourably, though he admits their power of giving a large supply of heat-units in the form of gas at a low cost. His main criticism is that the tar-oils recovered are not valuable. "The condition in which they come from the plant makes them difficult to work up, and, according to the tar distillers, the final products do not compare at all favourably in value with the final products from other methods of destructive distillation of coal." In justice to the gas-producer it may be pointed out, however, that most of the criticisms under this head might be applied equally well to products of other processes of low-temperature distillation, and often mean simply that the tar is very poor in aromatic constituents, different from gasworks tar, and cannot be worked conveniently along with it.

In speaking of low-temperature carbonisation the author makes the pertinent observation that its advantages are too obvious. He goes on to indicate that the difficulties it presents are very real, and, of course, it cannot attain his ideal because so much of the fuel is finally left in the solid form.

The whole of these considerations and criticisms of the shortcomings of different processes have been leading up to a proposal of something different—total gasification in some form of plant which differs from a gas-producer in that air is not used for gasification of the fixed carbon, and, therefore, nitrogen in quantity is not present in the gas. "The principle of this process is the partial carbonisation of coal in a vertical retort superimposed on a water-gas generator, the retort being heated externally by means of the products of combustion of the producer during the blow period, and internally by the passing of the water-gas made up through the charge in the retort."

This comprehensive survey ends with the formulation of an ideal system of manufacture to meet the demands for liquid and gaseous fuels. It is to gasify coal completely, preferably in one vessel, recovering in a liquid form the maximum amount of volatiles in the coal (working with any coal) and preserving the resulting ammonia. It would be of the combined vertical retort water-gas-producer type, with recuperators, waste-heat boilers, and mechanical arrangements making for labour-saving and for high thermal and chemical efficiency. It is to the treatment in some such plant as this that the author looks for increasing our home-produced oil-fuel supplies, and no doubt he is willing to take his share in the skilful design and careful experimental work involved.

Sheep Panics.

A SHEEP panic on the night of December 10–11, in which the sheep broke their folds in twenty parishes in an area extending some twenty miles in the highest part of Cambridgeshire, has been attracting attention. These panics have often occurred, for sheep are notoriously timid and nervous animals. On November 3, 1888—an intensely dark night, with occasional flashes of lightning—tens of thousands of folded sheep jumped the hurdles and were found scattered the next morning. Every large farm from Wallingford to Twyford was affected, and those on the hill country north of the Thames most so. Again, on the night of December 4, 1893, another very remarkable panic among sheep occurred in the northern and middle parts of Oxfordshire, extending into adjoining parts of the counties of Warwick, Gloucester, and Berks.

Various causes for these panics have been suggested, but only one reasonable explanation has been satisfactorily adduced. The 1893 panic was, at the time, fully investigated by Mr. O. V. Aplin, who published in the Journal of the Royal Agricultural Society the result of his inquiries and the conclusions he drew from the extensive evidence collected. The conclusion arrived at was that the cause of the panic was simply thick darkness. Very few people, probably, have ever been out in a really dark night, and it is impossible for anyone who has not had this experience to imagine what it is like and the sense of helplessness it causes. That a thick darkness of this kind was experienced in the early part of the night of the recent panic (at a time agreeing with that at which, so far as was known, the sheep stampeded) was proved by abundant evidence. One report said that it was between 8 and 9 p.m. when such a thick and heavy darkness came on that a man could not see his own hand. Another witness wrote that a little before 8 o'clock there was an extraordinary black cloud travelling from north-west to south-east, which appeared to be rolling along the ground. The darkness lasted for thirty or forty minutes, and during that time it was like being shut up in a dark room. Later in the night—long after the panics—there were several flashes of lightning.

Mr. Aplin states that animals probably see perfectly well on ordinary dark nights, and we can imagine a bewilderment coming over them when they find themselves overtaken by a thick darkness in which they can see nothing. Folded sheep (and it was the small folds that the sheep broke most) in moving about would knock against their feeding-troughs and one another, and the first one that got a fright from this and made a little rush would probably come into collision with one or two others, and it would need nothing more to imbue the whole pen with the idea that there was some cause for fear. Then they would all make a rush, and their terror and the momentarily recurring incentives to, and aggravations of, it in the shape of collisions would only subside when the sheep had broken out and were in the open, clear of one another and of their troughs and hurdles.

If this is the explanation of the panic, then it is easy to understand why folded sheep are so much more likely to suffer than those lying in open fields. The heavy, oppressive atmosphere accompanying the thick darkness, the susceptibility of sheep to atmospheric disturbance, and their nervous and timid dispositions would all tend to increase the fright the sheep experienced. The cause of the panic being a cloud rolling along so low down as (apparently) to touch the ground, the tops of the hills and the high-lying ground would naturally be most affected; and this is observed to be the case, although locally the usual direction followed by thunderstorms has indicated a line along which sheep stampeded on nearly every farm.

The Work and Discoveries of Joule.[1]

By SIR DUGALD CLERK, K.B.E., F.R.S.

THE greatest generalisation in the early history of physical science was made late in the seventeenth century by Sir Isaac Newton when he enunciated the laws of motion and deduced from them the existence in space of attraction between planets and the sun. Mechanical science has been built up on Newton's fundamental propositions and discoveries. The discovery by Joule in the middle of the nineteenth century of the mechanical equivalent of heat and his suggestion and determination of the existence of an absolute zero, together with the adaptation of Carnot's cycle of 1824 to the theory of heat as a mode of motion, provide generalisations of equal importance to Newton's law of gravitation, and from them fundamental thermodynamic laws are deduced: the equivalence of energy in different forms, conservation of energy and dissipation of energy. Joule's discovery, in fact, called the modern science of thermodynamics into existence.

Manchester has been the home of many highly distinguished men—great scientific men, great inventors, and great masters of industry and business—but it is fortunate indeed in its connection with two of the greatest discoverers in the history of the world, Dalton and Joule. Joule read his first paper before the Manchester Literary and Philosophical Society in the year 1841 upon the subject of "The Electric Origin of the Heat of Combustion." He contributed a long series of papers from that year until 1879, a period of thirty-eight years, and he dealt with a great variety of subjects, including experimental investigations on the phenomena of the voltaic current, the determination of the specific heat of bodies, heat and constitution of elastic fluids, mirage, freezing point of thermometers, galvanometers, dip circle, solar photographs, duty of electro-magnetic engines, magnetic storms, polarisation of platinum plates, mercurial air-pumps, and telescopic oscillations.

The debt of the practical engineer to Joule and his great associates is very real, but the science of thermodynamics did not supply the fundamental laws from which heat-engines were invented and developed. The steam-engine had been developed by Newcomen, Smeaton, and James Watt long before the birth of the science of thermodynamics. What is true of the steam-engine is true also of the hot-air engine and the internal-combustion engine; all the known types of heat-engine at present in use were invented before the year 1850, and practical experimental examples of both hot-air and internal-combustion engines were then in operative existence. Thermodynamics supplied the laws of the conversion of heat into mechanical work by which these engines are governed; it explained the relative perfection of engines already in existence, but it did not create these engines. It performed the very important service of dispelling the errors of thought which hindered the future advance of heat-engines Such errors as to the theory of the regenerator and the theory of compression and expansion in all steam and internal-combustion engines, held by the most eminent engineers and scientific men so late as from 1845 to 1853, were rendered impossible by the splendid work of Joule, Kelvin, Rankine, and their Continental colleagues. The knowledge of thermodynamics has thus an increasing effect upon instructed engineers of the present generation. It is quite obvious that although the origin of heat-engines cannot be ascribed to Joule's work, yet the improvement and final development towards a maximum conversion of heat into mechanical work are rendered possible to the engineer of to-day by his great discoveries. Engineers and engine-designers are most grateful to Joule, and look back on his achievements as those of the utmost intellectual and practical importance.

Giant and Dwarf Stars.[2]

THE amount of light received from a star determines its *apparent magnitude* (m), the ratio for two stars differing by one magnitude being 2·512. The *absolute magnitude* (M) is what the apparent magnitude would be if the star were at the standard distance of 10 parsecs, which corresponds to a parallax of 0·1″. If π is the parallax of a star in seconds of arc,

$$M = m + 5 + 5 \log \pi.$$

In this equation m is not difficult to measure, and hence if π or M is determined the other can be found.

Russell took all stars for which fairly accurate values of π were available, and from the above equation computed M. Then, plotting M as ordinate and type of spectrum as abscissa, he found that (1) all white stars are far brighter than the sun; (2) range of brightness increases with redness; (3) all faint stars are red; and (4) all red stars are very bright or very faint.

Adams and Kohlschütter found that the relative intensity of selected lines in the spectrum of a star depended on the absolute magnitude from measurements on the spectrum. M being determined, the

[1] Abstract of the first Joule Memorial Lecture delivered on Tuesday, December 14, 1920, to the Manchester Literary and Philosophical Society.

[2] Abstract of a lecture delivered before the Royal Society of Victoria, Melbourne, on October 14, 1920, by Dr. J. M. Baldwin, Government Astronomer.

equation gives π, and thus the parallax can be measured spectroscopically. This work brought out very clearly the division of the red stars into a very bright group and a very faint group, with no stars of intermediate brightness.

The absolute magnitude depends on mass, density, and surface brightness. The only information as to mass is obtained from binary stars, and for these the total range in mass is only from nineteen times that of the sun to one-quarter that of the sun.

The surface brightness for stars with similar spectra must be nearly equal, and thus the average red star of the bright group, which gives out 1000 times as much light as the average red star of the faint group, must have 1000 times the surface and 30,000 times the volume of the latter. Hence the terms "giant" and "dwarf." If the masses are equal the densities will be in the ratio 30,000 to 1.

For special classes of stars the relative surface brightness can be obtained, and it is found that the very white stars give out 500 times as much light per unit-surface as the very red stars. For the giant stars the density increases from the red stars to the white, while for the dwarf stars the density increases from the white stars to the red. As the giant stars contract and get hotter the increase in surface brightness nearly balances the decrease in surface, and the stars remain nearly constant in brightness, as is actually found to be the case. After a limiting density is reached cooling follows further contraction, and both the surface brightness and surface decrease together, and a rapid diminution of light is the result. This also is confirmed by observation.

University and Educational Intelligence.

LONDON.—Among the proceedings of the Senate on January 19 are the following:—

Miss Philippa Chicheley Esdaile, D.Sc. (Manchester), has been appointed as from February 1 to the University readership in biology tenable in the Household and Social Science Department of King's College for Women. Miss Esdaile has held a zoological research studentship and an honorary research fellowship in the University of Manchester, where she has also been assistant demonstrator in the Zoological Department. In 1914 Miss Esdaile was elected to a research fellowship at University College, Reading, and from 1915 to 1920 she was acting head of the Department of Zoology at Bedford College during the absence on war service of Dr. Marett Tims. Since last August she has been senior lecturer on zoology at Birkbeck College. She is the author of various publications, especially on salmon-scale research.

The following doctorates were conferred:—*Ph.D. in Philosophy:* Mr. N. K. Datta, an internal student, of University College, for a thesis entitled "The Vedanta: Its Place as a System of Metaphysics." *D.Sc. in Mathematics:* Mr. S. R. U. Saveer, an external student, for a thesis entitled "On the Instability of the Pear-shaped Figure of Equilibrium of a Rotating Mass of Homogeneous Liquid."

A resolution was adopted expressing the gratification with which the Senate had heard of the anonymous donation of 20,000*l*. made to the authorities of the Middlesex Hospital Medical School for the endowment of the University chair of physiology there tenable.

A LECTURE on "Agricultural Botany" will be given by Prof. R. Biffen at King's College, Strand, W.C.2, on Saturday morning, February 5, at 11 o'clock, in connection with the London County Council's lectures for teachers. The chair will be taken by Sir A. Daniel Hall.

THE War Work Council of the Y.M.C.A. in the United States of America has recently made a grant of 1,960,000 dollars for the fund out of which it provides scholarships and other educational assistance for ex-Service men. The grant makes the funds available for this purpose amount to 6,100,000 dollars. Free scholarship awards representing an expenditure of 2,367,895 dollars have been given to 38,582 former Service men, and in all the sum of 5,050,000 dollars has been apportioned to scholarships.

A COURSE of nine public lectures on "Problems of Modern Science," to be given on Wednesdays at 5.15 p.m., began at King's College on January 19 with a lecture by Prof. J. W. Nicholson on Mathematics. The other subjects and lecturers in the course are as follows:—January 26, Astronomy, Prof. J. B. Dale; February 2, Physics, Prof. O. W. Richardson; February 9, Chemistry, Prof. S. Smiles; February 16, Geology, Prof. W. T. Gordon; February 23, Biology, Prof. A. Dendy; March 2, Botany, Dr. R. Ruggles Gates; March 9, Physiology, Prof. W. D. Halliburton; and March 16, Anatomy, Prof. E. Barclay-Smith. The lectures are free, and cards of admission can be obtained from the Lecture Secretary, King's College, Strand, W.C.2. A stamped addressed envelope should be enclosed.

WITH commendable promptness the Association of Science Teachers has published a new edition of the "Book List" which was issued about a year ago. Sections on zoology, natural history, and astronomy have been added in the present volume, in which the old list has been extended and revised in many ways. The compilation should be of great assistance to those who are responsible for the selection of science books for use in class, for reference by both pupils and teachers, or for general school libraries. Its special value lies in the fact that the books included are in every case recommended by teachers who are exceptionally well qualified to judge of their suitability. "Book List, 1920," may be obtained at the price of 2s. from the Hon. Secretary, Association of Science Teachers, 10 Gresley Road, London, N.19.

FIGURES compiled by the U.S. Bureau of Education showing the public expenditure on education and the incomes of the various colleges, etc., in the United States are issued in *School Life* for December 1 last. The figures for 1918 and previous years are taken from the annual report of the Commissioner of Education; those for 1919 and 1920 are estimated. Throughout the period investigated, from 1870 onwards, the yearly increase in expenditure on education has grown successively larger. In 1870 the charge for elementary schools was 2 dollars per head of the population; it is now 9.50 dollars per head. The income of colleges, universities, and technical schools for 1920 was two and one-third times as much as it was in 1910 and thirty-six times what it was in 1870. The total sum which it is estimated was spent on education in the United States during 1920 is 1,224,000,000 dollars; this sum is approximately half the world's expenditure for educational purposes, although the people served represent only one-seventeenth of the world's population.

PART I. of the Indian Bureau of Education Publication entitled "Selections from Educational Records" has been received. It consists of reprints of a number of documents relating to education in India for the period 1781–1839, which illustrate the gradual growth of the feeling of responsibility for Indian education in the minds of Englishmen. The records which have been utilised come mainly from the Government of India, though a few have been obtained from the record offices of the larger States. They therefore give a general survey of the whole topic rather than detailed descriptions of conditions at any one place. The arrangement is chiefly chronological, but in places documents dealing with the same subject have been brought together irrespective of their real sequence. Brief narratives have been inserted between some of the records in order that the reader may have the less difficulty in following the train of events which led to the production of the various documents.

THE Department of Industrial Administration at the College of Technology, Manchester, has now been running for more than two years, and, judged by the prospectus of classes for the 1920–21 session, it has successfully organised a very elaborate and complete scheme of teaching. It offers a full-time course in industrial administration, which includes a series of forty-two lectures by the director, Prof. Stanley Kent, and others, a short course of laboratory work in industrial fatigue, and visits to works in the neighbourhood. Still more elaborate is the six months' course of training in welfare work, which is designed to supplement the University course on social study. The part-time student is offered two evening courses, each of twenty-six lectures, whilst shorter courses of a more technical nature are offered in engineering and in the cotton industry. Also Prof. T. H. Pear is giving a course of lectures in industrial psychology. In order to ensure that the Department should be kept in close touch with practice, a number of experts have been invited from time to time to deliver public lectures. Some of these lectures have been reprinted and issued in volume form, and they were very favourably reviewed in the columns of NATURE a few months ago. Again, the department is undertaking advanced research work on a diversity of subjects, which include psychological problems of industry, the working conditions in various industries, and technical questions dealing with machine- and hand-cutting tools.

THE annual report of the Royal Technical College, Glasgow, for the year 1919–20 contains not only an account of its activities during the past year, but also a brief summary of events and conditions at the institution during the war period. The most important of the latter was the recognition of the college as a school of university standing by the Treasury University Grants Committee: a preliminary recurrent grant of 3000*l*. and two non-recurrent grants of 6000*l*. and 4000*l*. respectively to meet special expenditure arising out of the war were made. The balance-sheet of the college still shows a deficit, however—the income is 54,084*l*. and the expenditure 57,490*l*.—in spite of the fact that students' fees already bring in 30 per cent. of the total income and annual grants of 1000*l*. each have been received from the Bellahouston Trustees and the Carnegie University Trust. The number of students attending courses during 1919–20 rose to 5690, of which 1135 were day and 4555 evening pupils—figures which exceed those for 1913–14 by 466 and 213 respectively. To meet this influx while the staff was much under strength the first-year courses were triplicated. A summary giving the number of enrolments in each department of the college shows that for full-time students chemistry is the great attraction, while of the evening students the majority attend courses in mechanics. The latter are designed to provide for the higher studies which can be developed from the series of affiliated evening classes conducted by the neighbouring county education authorities in conjunction with the college. A Ferguson research fellowship in chemistry of the value of 200*l*. per annum has been founded by the trustees of the Ferguson Bequest Fund.

Calendar of Scientific Pioneers.

January 27, 1823. Charles Hutton died.—A labourer's son and largely self-taught, Hutton became professor of mathematics at the Royal Military Academy, Woolwich. From Maskelyne's experiments he calculated for the first time the mean density of the earth.

January 27, 1851. John James Audubon died.—Of French descent, Audubon was born at New Orleans, and devoted his life to the study of the birds of North America.

January 27, 1873. Adam Sedgwick died.—The contemporary of Murchison and Lyell, Sedgwick was "one of the greatest leaders in the heroic age of geology."

January 28, 1687. Johann Hevel or Hevelius died.—Seven years before the end of the disastrous Thirty Years' War, which nearly extinguished the study of science in Germany, Hevelius built an observatory and set up a printing press at Danzig, and by his subsequent labours earned for himself the reputation of "the greatest observer after Tycho Brahe."

January 29, 1859. William Cranch Bond died.—The first director of Harvard Observatory, Bond in 1848, simultaneously with Lassell, discovered Hyperion, one of the satellites of Saturn; and on November 15, 1850, observed the "Crape" ring, a dusky ring within the inner portion of Saturn's bright ring.

January 30, 1888. Asa Gray died.—Born in 1810, Gray for many years occupied the chair of natural history at Harvard and wrote numerous works on the flora of North America.

February 1, 1873. Matthew Fontaine Maury died.—A naval officer and first director of the Naval Observatory at Washington, Maury became the foremost hydrographer of his day.

February 1, 1903. Sir George Gabriel Stokes died.—Lucasian professor at Cambridge for fifty-four years, secretary and president of the Royal Society, Member of Parliament, and foreign associate of the Institute of France, the influence of Stokes in the world of science was scarcely less than that of Kelvin. His own investigations referred mainly to the motion of fluids and to optics. He was a pioneer in the discovery and development of spectrum analysis, discussed the nature of fluorescence, and is regarded as the virtual founder of the modern science of geodesy.

February 2, 1704. Guillaume Antoine de l'Hospital, Marquis de St. Mesme, died.—His "Analyse des Infiniments Petits" (1696) was the first treatise on the infinitesimal calculus.

February 2, 1907. Dmitri Ivanovitsch Mendeléeff died.—Mendeléeff was born in 1834 at Tobolsk, in Siberia, and from an exile he gained his first knowledge of science. In 1850, his father being dead, the family removed to Petersburg, where at the age of thirty-two, having established a reputation as an investigator, he was made professor of general chemistry in the University. Three years later, in March, 1869, before the Russian Chemical Society, he enunciated the "periodic law." Foreshadowed by Newlands and others and confirmed by Lothar Meyer, this great generalisation, connecting the properties of the elements with their atomic weights, made his name widely known, and by it he was able to predict the existence of elements hitherto unknown but afterwards discovered.

E. C. S.

Societies and Academies.

LONDON.

Royal Society, January 20.—Prof. C. S. Sherrington, president, in the chair.—Sir Robert **Hadfield**, S. R. **Williams**, and I. S. **Bowen**: The magnetic mechanical analysis of manganese steel. Tests were made on six rods quenched in water, when they are in the non-magnetic condition, and three were afterwards annealed, which rendered them magnetic. The changes in length of the rods when subjected to magnetic fields were determined (Joule effect). In the case of the rods in the magnetic condition the change was an increment for all field strengths. No change in length could be detected for the non-magnetic specimens. The effect on the intensity of magnetisation when subjected to longitudinal stress (Villari effect) was investigated. An absolute method of measuring the intensity of magnetisation when comparatively small was adopted, and for all field strengths the application of tensile stress increased the intensity of magnetisation of the magnetic specimens. The non-magnetic rods showed no change in intensity of magnetisation by being stretched. They showed an intensity of magnetisation about 1/36th of that of the specimens in the magnetic condition, due entirely to oxidation of the skin of the rods.—Dr. W. S. **Tucker** and E. T. **Paris**: A selective hot-wire microphone. The instrument consists of an electrically heated grid of fine platinum wire placed in the neck of a Helmholtz resonator. The effect of a sound having the same frequency as that natural to the resonator itself is to produce an oscillatory motion of the air in the neck of the resonator, which in turn causes changes in resistance of the platinum-wire grid. The total resistance change comprises a steady fall in resistance due to an average cooling of the grid, and a periodic change due to the to-and-fro motion of the air. Two methods of using the microphone are described: (1) A bridge method, and (2) an amplifier method. Curves are given showing the sharpness of resonance as measured by the bridge method. Results of experiments on cooling the grid by low-velocity air-currents are described. The principal resistance changes to be expected when the grid is cooled by an oscillatory air-current are: (1) A steady drop due to an average cooling; (2) a periodic resistance change of the same frequency as that of the sound; and (3) a periodic resistance change of frequency twice that of the sound. Further deductions are that the steady change of resistance is proportional to the *intensity* of the sound, while the periodic resistance change in (2) is proportional to the *amplitude*.—E. A. **Milne** and R. H. **Fowler**: Siren harmonics and a pure-tone siren. The ordinary siren can be regarded as a point source of air of variable flux, the flux being proportional to the area of the orifice exposed by the holes in the disc. The relative intensities of the harmonics for a siren with circular holes and a circular orifice are calculated, and it is concluded that a fairly pure note should be obtained from a siren of this type, in which the distance between the centres of adjacent holes is twice the diameter of the holes. If the original is rectangular in section, the holes can be so shaped that the area of the orifice exposed varies exactly as the sine of the displacement.—L. V. **King**: The design of diaphragms capable of continuous tuning. Continuous tuning is achieved by the application of air-pressure (or suction). The diaphragm is constructed from a single piece of metal, and consists of a thick, undeformable, central disc connected by a thin, concentric, annular portion to a heavy, circular rim fitted accurately on a rigid mounting. The application of air-pressure over the interior of the diaphragm alters the tension of the thin annular portion, so that the rigid central portion vibrates about the static equilibrium position with a different pitch. To realise sharp tuning and high sensitivity, diaphragms of this type should be made with almost optical precision in the form of accurate solids of revolution.

Royal Meteorological Society, January 19.—Mr. R. H. Hooker, president, in the chair.—Mr. R. H. **Hooker**: Presidential address: Forecasting the crops from the weather. Mr. Hooker remarked that forecasts of the harvest fell into two main groups, viz. those which predicted the recurrence of good and bad crops in cycles, and those which computed the actual amount by which the yield was improved or damaged by the weather during or shortly before the growing period. He outlined the evolution of the methods of ascertaining relationships between the weather at different seasons of the year and the subsequent harvest. Originally writers such as Gilbert and Lawes could only examine the meteorological conditions in years of exceptional abundance or scarcity. A great advance was made when Sir Rawson Rawson and, later, Sir Napier Shaw, from the study of an entire sequence of crops and previous weather conditions, suggested formulæ from which the crop might be calculated, while still wider possibilities were opened by the methods of correlation. Mr. Hooker emphasised the necessity of taking the past weather into account in predicting the harvest, as it was abundantly clear, from comparison with actual forecasts in India and elsewhere, that the weather was responsible for developments in the plant which were not visible to an observer surveying the young crops in the fields; and, although much work still remained to be done, the time was ripe for using such statistics to confirm or modify the results of direct observation of the growing plants.

ROME.

Reale Accademia nazionale dei Lincei, November 7.—Signor V. Volterra, vice-president, in the chair.—S. **Pincherle**: Certain functional equations.—O. M. **Corbino**: Electronic theory of electric conductivity in magnetic field.—F. **Millosevich**: Paternoite, a new mineral from Calascibetta, Sicily. This is a borate of magnesia containing chlorine, similar in appearance to stassfurtite, and found in the saline deposits of Monte Sambuco.—B. **Longo**: The "flowerless apple" (*Pyrus apetala*, Mönch). This plant only produces small aborted pistilliferous flowers, and does not present any trace of stamens. These flowers possess carpels disposed in two planes, some of which contain more or less imperfect ovules. By fertilising with the pollen of other kinds of apples the author has obtained actual seeds, which it is proposed to try growing.—A. **Denjoy**: "Sur une classe d'ensembles parfaits discontinus."—O. **Onicescu**: Spaces admitting infinitesimal translation along lines of zero length.—A. **Clementi**: A new hypothesis regarding the physiological significance of protamines and histones in nuclear exchanges.—The president, Signor Volterra, directed attention to the cost of printing scientific publications, and urged the necessity of State aid for this purpose. The losses by death sustained by the Academy during the last session include Senators Righi and Celoria and Profs. Cuboni, Beccari, Rajna, and Giglioli.

MELBOURNE.

Royal Society of Victoria, October 14.—Prof. A. J. Ewart, president, in the chair.—D. K. **Picken**: A generalisation of elementary geometry. The subject of this paper was an outstanding defect of generality in elementary geometry associated with the ambiguity (equal or supplementary) in certain fundamental angle theorems. The appropriate principle of generality was first arrived at by the author in a paper on Simson's line read to the Edinburgh Mathematical Society in May, 1914. Later consideration had made it clear that the principles in question are basic to the elementary geometry of the straight line, of parallels, and of the circle, and are of wide applicability in the geometrical theory dependent upon these. —Dr. J. M. **Baldwin**: Giant and dwarf stars (see p. 711).

SYDNEY.

Linnean Society of New South Wales, November 24.—Mr. J. J. Fletcher, president, in the chair.—G. H. **Hardy**: Revision of the Chiromyzini (Diptera). A study of the genus Metoponia and its allies, following on Miss Irwin-Smith's study of the larva of *M. rubriceps*, Macquart.—J. **Mitchell**: Some new Brachiopods from the Middle Palæozoic rocks of New South Wales. From rocks of Upper Silurian age at Bowning, Hatton's Corner, and near Molong, one genus and four species are described as new.—Vera **Irwin-Smith**: Nematode parasites of the domestic pigeon (*Columba livia domestica*) in Australia. The only Nematode hitherto recorded from this host in Australia is *Ascaridea columbae*, Gmelin, from both New South Wales and Queensland. Records of two further species are added, and a new generic name is proposed for *Strongylus quadriradiatus*, Stevenson.—J. H. **Maiden**: A few notes on the botany of Lord Howe Island (sixth paper). This brief paper supplements existing information in regard to hybrid Howeas, which have been under cultivation in the Sydney Botanic Gardens for a number of years. There are notes on indigenous plants hitherto unrecorded, of which *Adiantum formosum*, R. Br., is the most important. A number of records of introduced plants are also given.

Books Received.

The Child's Path to Freedom. By N. MacMunn. Second edition. Pp. 163. (London: G. Bell and Sons, Ltd.) 2s. 6d. net.

A Concise Geometry. By C. V. Durell. (Cambridge Mathematical Series.) Pp. viii+319. (London: G. Bell and Sons, Ltd.) 5s. net.

My Electrical Workshop. By F. F. Addyman. Pp. viii+249. (London: Wireless Press, Ltd.) 7s. net.

A Text-book of Practical Chemistry. By G. F. Hood and Major J. A. Carpenter. Pp. xii+527. (London: J. and A. Churchill.) 21s. net.

The Fundamental Processes of Dye Chemistry. By Prof. H. E. Fierz-David. Translated by Dr. F. A. Mason. Pp. xiv+240+xiv plates. (London: J. and A. Churchill.) 21s. net.

Volumetric Analysis for Students of Pharmaceutical and General Chemistry. By C. H. Hampshire. Third edition. Pp. iv+124. (London: J. and A. Churchill.) 7s. 6d. net.

Farm Crops Laboratory Manual and Note Book. By F. W. Lathrop. Pp. 118. (Philadelphia and London: J. B. Lippincott Co.) 4s. 6d. net.

Oil Firing for Kitchen Ranges and Steam Boilers. By E. C. Bowden-Smith. Pp. ix+102. (London: Constable and Co., Ltd.) 9s. net.

The Science of Ourselves. (A Sequel to "The Descent of Man.") By Sir B. Fuller. (Oxford Medical Publications.) Pp. ix+326. (London: Henry Frowde and Hodder and Stoughton.) 16s. net.

Die Anaphylaxie. By Prof. Ch. Richet. Autorisierte Uebersetzung von Dr. J. Negrin y López. Pp. iv+221. (Leipzig: Akademische Verlagsgesellschaft.)

Diary of Societies.

THURSDAY, JANUARY 27.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Dr. A. Harden: Biochemistry (Vitamines).

ROYAL SOCIETY, at 4.30.—K. Sassa and Prof. C. S. Sherrington: The Myogram of the Flexor-reflex evolved by a Single Break-shock.—Sir Almroth Wright: "Interaction" between Albuminous Substances and Saline Solutions.—Dr. S. Russ, Dr. Helen Chambers, and Gladwys M. Scott: The Local and Generalised Action of Radium and X-rays upon Tumour Growth.

NEWCOMEN SOCIETY (at Iron and Steel Institute), at 5.—R. Jenkins: Rise and Fall of the Iron Manufacture in Sussex.

ROYAL SOCIETY OF MEDICINE (Balneology and Climatology Section), at 5.30.—Dr. G. L. Pardington: Advancing Years and Balneotherapy (Presidential Address).

INSTITUTION OF ELECTRICAL ENGINEERS (at Institution of Civil Engineers), at 6.—G. A. Juhlin: Temperature Limits of Large Alternators.

LONDON DERMATOLOGICAL SOCIETY, at 6.—Dr. W. K. Sibley: Acne (Chesterfield Lecture).

CONCRETE INSTITUTE, at 7.30.—J. A. Howe: Geology in Relation to Building Stones.

WIRELESS SOCIETY OF LONDON (at Royal Society of Arts), at 8.

SOCIETY OF ANTIQUARIES, at 8.30.

ROYAL SOCIETY OF MEDICINE (Urology Section), at 8.30.—T. Walker: Obstruction After Suprapubic Prostatectomy and an Open Operation for its Prevention.

FRIDAY, JANUARY 28.

ASSOCIATION OF ECONOMIC BIOLOGISTS (at Imperial College of Science), at 2.30.—Dr. L. Lloyd: Greenhouse White Fly and its Control.—W. B. Brierley: Personal Impressions of Some American Biologists and their Problems.

ROYAL SOCIETY OF MEDICINE (Study of Disease in Children), at 5.—Dr. P. Parkinson: A Case of Patent Ductus Arteriosus.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Prof. A. Keith: The Principles of Craniology applied to Clinical and Racial Problems.

PHYSICAL SOCIETY OF LONDON (at Imperial College of Science), at 5.—Prof. H. Nagaoka: The Magnetic Separation of the Neon Lines and Runge's Rule.—Capt. E. V. Appleton: A Method of Demonstrating the Retro-active Property of a Triode Oscillator.—Dr. D. Owen and R. M. Archer: The Quickness of Response of Current to Voltage in a Thermionic Tube.

JUNIOR INSTITUTION OF ENGINEERS, at 8.—J. W. Wardell: Manufacture of Portland Cement.

ROYAL SOCIETY OF MEDICINE (Epidemiology and State Medicine Section), at 8.30.—Dr. A. S. M. MacGregor: Some Features of Current Small-pox in Glasgow.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Sir James Dewar: Cloudland Studies.

MONDAY, JANUARY 31.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Prof. W. S. Handley: The Pathology and Treatment of Lupus.

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.—J. W. Simpson: Presidential Address to Students and Distribution of Prizes.

ROYAL SOCIETY OF ARTS, at 8.—A. E. L. Chorlton: Aero Engines (Howard Lectures).

MEDICAL SOCIETY OF LONDON, at 8.30.—Dr. A. Feiling: Multiple Neuritis.—Dr. F. G. Crookshank: Handprints in Mongolian and Other Imbeciles.

TUESDAY, FEBRUARY 1.

ROYAL SOCIETY OF ARTS (Colonial Section), at 4.30.—Dr. G. C. Creelman: Modern Agriculture.

INSTITUTION OF CIVIL ENGINEERS, at 5.30.—Brevet-Major G. le Q. Martel: Bridging in the Field.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—P. King: The Cinematograph Camera: Various Models and General Description of Same.

WEDNESDAY, FEBRUARY 2.

ROYAL SOCIETY OF ARTS, at 8.—A. F. Baillie: Oil-burning Methods in Various Parts of the World.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Prof. W. G. Howarth: Mucocele and Pyocele of the Nasal Accessory Sinuses.

GEOLOGICAL SOCIETY OF LONDON, at 5.30.

SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (Annual General Meeting) (at Chemical Society), at 8.—Presidential Address.—F. W. Smith: Extract of Red Squill (*Scilla maritima*) as a Rat Poison.—W. Lowson: The Composition of Harrogate Mineral Waters.

THURSDAY, FEBRUARY 3.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. W. A. Herdman: Oceanography (Great Exploring Expeditions).

ROYAL SOCIETY, at 4.30.—*Probable Papers*.—Dr. G. B. Jeffery: The Field of an Electron on Einstein's Theory of Gravitation.—Dr. M. N. Saha: A Physical Theory of Stellar Spectra.—W. F. Darke, J. W. McBain, and C. S. Salmon: The Ultra-microscopic Structure of Soaps.—Dr. J. Mercer: Linear Transformations and Functions of Positive Type.

LINNEAN SOCIETY, at 5.—Miller Christy: Wistman's Wood, Dartmoor; Specimens of Slides.—Dr. Agnes Arber: Leaf-tips of Monocotyledons.—T. A. Dymes: Seedlings of *Ruscus aculeatus*, with Remarks on their Germination and Growth.

ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts), at 5.30.—Major G. Dobson: The Use of Meteorology to Aviation and *Vice-versa*.—Wing-Comdr. H. W. S. Outram: Ground Engineering.

CHEMICAL SOCIETY, at 8.

FRIDAY, FEBRUARY 4.

ROYAL ASTRONOMICAL SOCIETY (Geophysical Discussion), at 5.—On Gravity at Sea: Opened by Prof. G. W. Duffield, and continued by Sir S. G. Burrard, Dr. H. Jeffreys, Dr. J. W. Evans, and Dr. A. M. Davies. Chairman: Sir Arthur Schuster.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Prof. C. W. G. Bryan: The Early and Late Effects of Injuries of the Diaphragm, with Social Reference to Wounds jointly involving Thoracic and Abdominal Viscera.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Dr. A. D. Waller: The Electrical Expression of Human Emotion.

SATURDAY, FEBRUARY 5.

GILBERT WHITE FELLOWSHIP (at 6 Queen Square, W.C.1), at 3.—Lecture.

Anthropology and Empire.

ANTHROPOLOGY has been slow to secure recognition as having a practical bearing on the affairs of life. The Royal Anthropological Institute, which has just completed the fiftieth year of its existence, while steadily pursuing its main object of promoting the study of man, has constantly insisted upon the importance of this science as a fundamental element in certain departments of legislation and administration, particularly in relation to the native peoples of our Colonies and Dependencies. Until comparatively recently it has obtained a sympathetic hearing more often than a tangible result.

It is unnecessary to enumerate here the many occasions on which this subject has been brought to the notice of the Government at home and of the authorities in our Dependencies. The latest attempt to secure official recognition of the place of anthropological studies in the training of administrative officials was initiated by Sir Richard Temple at the Birmingham meeting of the British Association in 1913. He advocated the establishment of an Imperial School of Anthropology attached to one of the universities. Unfortunately, the outbreak of war interrupted a movement which had secured wide and influential support.

It is important to note that the conception of the vital importance of "applied anthropology" as an essential part of the training of an administrator is not academic in origin. Its strongest advocates are, or have been, men like Sir Herbert Risley, Sir Bampfylde Fuller, Sir Richard Temple, Sir Everard im Thurn, and Sir Reginald Wingate, to name a few only, who have themselves had a prolonged administrative experience, and have found a knowledge of native manners and customs essential to the successful performance of their duties. Sir Reginald Wingate, in particular, as Governor-General of the Sudan, asked the Universities of Oxford and Cambridge to provide instruction in anthropology to probationers for the Sudan Service, and it was at his special request that Prof. and Mrs. Seligman were sent to the Sudan to collect information which might be available for this purpose.

It is a matter of common experience that sympathy based upon knowledge is a first essential for both administrator and trader. Habits, customs, beliefs, and, particularly, etiquette must be intimately known and thoroughly understood. Ignorance of etiquette has been responsible for more than one punitive expedition, costly in both life and money. During the war, when comparatively large numbers of British officers had to be drafted to Indian battalions, it was found essential that they should receive instruction, not merely in the language, but also in the social grades, customs, and beliefs of their troops. Knowledge of native manners, customs, and beliefs has proved a bond of sympathy between governors and governed. Successful administrators have acquired this knowledge painfully and as a result of many mistakes. As one observer of considerable experience has said, the knowledge which had taken years to gain could have been acquired by a trained anthropologist in a few weeks.

If sympathetic knowledge is a factor of such importance in the relations between individuals, it is a paramount consideration in determining the character of administrative regulations and legislative measures which deal with the native in the mass. Success in maintaining law and order depends, in the long run, on the avoidance of any infringement of the customary rights of individuals and social units, as well as of any offence to the modes of thought and beliefs of the subject population. Further, when European culture comes intimately and extensively into touch with a lower culture, it is inevitable that many customs and beliefs of the less highly advanced must seem repugnant and even intolerable when judged by the standard of the more civilised race. Cannibalism and the practice of *sati* in India are cases in point. It is a matter of experience, however, that any modification or restriction of custom should be attempted only after very careful consideration of its place in the life of the people and of the possible consequence of any change. The suppression of the *lobola*, or "bride-price," in South Africa, under the mistaken impression that it was a sale, led to a great deal of ill-feeling and injustice; during the period in which it was interdicted, no marriage was regarded by the natives as legal, and, more important, one of the main factors in their social organisation had disappeared. A little knowledge of anthropology and anthropological method would have averted action which led to much distrust of British rule.

At the present moment the government of our subject races is beset with difficulties. How deep-rooted these difficulties are possibly only anthropologists and administrators in intimate touch with native feeling are fully aware. Native races tend to die out after contact with a civilisation which brings European diseases and European vices in its train; but this is not invariably the case. In some areas the removal of the checks on over-population, such as female infanticide and inter-tribal warfare, has brought about an increase, as in South Africa. In the case of the dying races the excellent system of segregation in reservations, even with an assured food supply and medical attention, appears merely to delay the inevitable. The possibility of preserving these peoples offers a vast field for anthropological research. The problem is not merely humanitarian. The exploitation of the tropics, which is inevitable as the world's needs increase under the pressure of population, depends on labour which will have to be drawn from native races, as, owing to climatic and other causes, white labour will not be available. This, however, is no argument in favour of compulsory or indentured labour. Primitive peoples, though often called lazy, do not differ materially from civilised peoples in their attitude towards labour; they work according to their needs and desires. The labour problem can be solved only by a careful study of primitive economics and industry. Such study should serve as a basis for a system of education and development which will foster native arts and handicrafts. The gradual improvement of native methods of agriculture will have an important bearing on the food supply of the future. But here, again, there is need for knowledge and sympathy before any change is introduced, as native methods are hedged round by custom and belief.

In cases where the native population is numerous and on the increase, the social and political question has been forced into prominence. During and after the war political agitators penetrated to the remotest parts of the Empire. The cases of India and South Africa are singular only in being widely known. Can anthropology assist the State in solving the difficult problem of converting what is now a danger into a useful section of the community? The far-sighted proposals introduced into the Parliament of the Union of South Africa last year by General Smuts suggest an answer. Study of native institutions will indicate such as may be utilised to develop the political sense of the native through local self-government, and at the same time suggest lines of development along which he may be led until he reaches a stage at which he will be fitted to take such a part in the political organism as time and experience may suggest to be desirable in the interests of himself and of the community at large.

The greater amount of attention which has been paid to primitive races has tended to obscure the fact that the study of the peoples of these islands has a bearing on practical affairs of an equal, if not greater, importance. Sir Francis Galton, when president of the Anthropological Institute in the late eighties of last century, insisted upon the importance of the study of our own population. He himself had then for many years been collecting data bearing upon the distribution of intelligence among the different classes of the population and upon the problems of heredity. The report of the Inter-Departmental Committee on Physical Deterioration, published in 1904, furnished evidence of the utterly inadequate extent of our knowledge of the physical characters of the population of these islands. Medical inspection of schools, which includes certain physical measurements, and is now extended permissively to observations of a specifically anthropological character, as well as the institution of a Ministry of Health, has done something to remedy this defect in certain directions. Anthropologists, however, are well aware how far the results have been, or are likely to be, vitiated by an imperfect knowledge of the distribution of racial characters. The institution of an anthropological survey presents many difficulties not entirely confined to expense. There can, however, be little doubt as to its practical value, not only in connection with the health and physique of the population, but also because of its bearing upon the study of mental character, the influence of heredity and environment, the relation of race and disease, the incidence of insanity and crime, and a number of other questions intimately bound up with and affecting the character of future social legislation.

The Determination of Sex.

Mechanismus und Physiologie der Geschlechtsbestimmung. By Prof. Richard Goldschmidt. Pp. viii+251. (Berlin: Gebrüder Borntraeger, 1920.) Price 32 marks.

THOUGH Prof. Goldschmidt's treatise on sex-determination is in scope similar to the text-books published by Doncaster and by Morgan in 1912, knowledge has increased so rapidly since then that there is plenty of room for a new statement. Moreover, as the author has himself devoted several years to the study of a special case which departs from the ordinary rules, his views will be of interest to geneticists. Up to a point, the mechanism of sex-determination is clear. On the one hand, we know that in several birds and some Lepidoptera the female is heterozygous in sex, but we have equally sound proof that in man and in several insects other than Lepidoptera the condition is reversed, the female being homozygous and the male heterozygous in respect of the sex-factor. The evidence for these conclusions is mainly either genetical or cytological. With the exception of Drosophila, which, after some doubt, observers have agreed to regard as having the male XY and the female XX, there is no specific form in which positive evidence of both kinds, genetical as well as cytological, can yet be produced. The absence, however, of such convergent testimony need not trouble us at this stage, for each class of proof is by itself adequate so far as it goes. On the whole, also, though difficulties are met with in special examples, the evidence from operative and other collateral observations agrees well with the conclusions deduced from genetical and cytological sources.

Sex being, then, decided by the contribution which one or other of the gametes makes to the offspring, how shall we account for cases in which these seemingly predetermined consequences can by interferences of various kinds be disturbed? Evidence of this description falls into several classes, and its consideration forms a chief purpose of the present book. Hitherto the most famous is that provided by R. Hertwig's experiments on frogs. By delaying fertilisation, he found that the proportion of males could be greatly increased. The suggestion that the females had died off was shown to be inapplicable, and there seemed to be no escape from the conclusion that eggs which in the ordinary course would have become females did after, and presumably because of the delay in fertilisation, become males. The fact, however, that the maturation-divisions in the case of the frog occur after the eggs are laid offered, as Hertwig pointed out, a possible, if rather unlikely, solution; for the artificial delay might have some influence in deciding which elements should be extruded in the polar bodies, and thus the sex-ratio might be disturbed. Quite recently Seiler, a colleague of Prof. Goldschmidt's, claims to have actually witnessed consequences of this kind following upon the introduction of special conditions in the case of the Psychid moth Talæporia, and to have obtained cytological evidence that a rise of temperature during the reduction-division caused the X-chromosome to stay more often inside the egg, and so increased the proportion of males, whereas a lowering of the temperature had the contrary effect. In the case of the frog, even if the delay does act in the way surmised, various difficulties remain to be elucidated, and before definite conclusions can be reached as to sex-determination in Amphibia, and fishes also, we require strict genetical proof as to which sex in those animals is heterozygous in the sex-factor.

Much more serious difficulty arises from a class of fact to which Standfuss was, I believe, the first to introduce us. He found that in Lepidoptera hybridisation might affect the sexes differentially, producing in certain crosses males only, in others predominantly males (the few females being sterile), and similar phenomena proving that the influence of the cross was not alike for the two sexes. A result obtained by an amateur named Brake led Prof. Goldschmidt to investigate a most remarkable case of such differential influence. *Lymantria dispar,* the gipsy moth, is represented by various races all over the northern temperate regions. The sexes are very different, the male being small and dark, the female large and pale in colour. The original observation was that, whereas crosses in the form Japanese ♀ × European ♂ gave in F_1 the two sexes distributed as usual, the reciprocal cross, European ♀ × Japanese ♂, produced normal males, but *females more or less modified in the male direction.* Eggs, therefore, which, if fertilised by the sperm of European males, would have produced females gave rise to "intersexual females," as Prof. Goldschmidt calls them, when the sperm came from these Japanese males. To investigate this curious problem, he proceeded to Japan before the outbreak of the war, and when Japan became involved he went to the United States, where he was interned and encountered other serious difficulties when that nation also joined the Allies. But in the course of his travels he was able to collect and experiment with a long series of species or local races inhabiting various parts of Europe, Japan, and North America, raising something like 50,000 specimens. Obscure as the meaning of the phenomena still is, there can be no question that when the full interpretation is unravelled the work will be admitted to have an importance at least proportionate to the astonishing labour which has gone to its production.

In outline the main result claimed is that the various races can be arranged in a scale ranging from the "strongest" to the "weakest," and, this series once established, the consequences of matings made between races occupying different positions on the scale can be predicted with considerable accuracy. Intersexual females appeared whenever the male of a "stronger" race was mated with the female of a "weaker." The intersexuality in its several degrees might affect all the sexual characters, primary or secondary, and in its higher manifestations the instincts also. Where such a diversity of features is concerned, a quantitative scale must obviously be largely a matter of individual judgment, but it is claimed that the amount to which these females were modified in the male direction was roughly proportional to the interval between the parent races on the scale of strength; and in the extreme case, when the strongest male was mated with the weakest female, the brood generally consisted of males only, which are interpreted as being in part aboriginal, genetically determined males, and in part individuals which would have been females but for the disturbing influence which has transformed them into males.

Other matings led to the production of intersexual *males*. The discrimination between the two kinds of intersexes was not, to judge from the illustrations, so difficult as one would have expected. The intersexual males appeared with some regularity in F_2 from the cross mentioned above (Japanese ♀ × European ♂) as giving all normals in F_1 and in certain other families besides. There were also some considerable families all-female. Throughout the complicated series of matings glimpses of order appear which suggest that a comprehensive solution is not very far off. It has, nevertheless, not yet been attained. One of the most curious features, as yet inexplicable, is the fact that in the matings giving all-male families females occasionally appear which are perfectly normal, though their sisters are supposed to have been wholly transformed into males.

The interpretation which Prof. Goldschmidt proposes cannot be adequately expressed in a brief statement. He is under the influence of the theory that each sex contains the potentialities of the other, a conception to which it is now not easy to attach a precise, still less a factorial, meaning. He is disposed to regard the sex ultimately assumed by a given zygote as decided by a struggle or reaction taking place between two components: (1) the sex-factors brought in by X-chromosomes, and (2) a substratum conceived of as inherent probably in the cytoplasm, and capable by its own development of conferring potentialities opposite to those borne by the factors proper. To these opposing elements numerical values are assigned, arbitrarily as it appears to me, and I have been unable to discover in what way the analysis thus offered differs from a restatement of the empirically observed facts, nor is the representation of the all-male and all-female families as alternative end-products of a balanced reaction at all satisfactory. During the period covered by Prof. Goldschmidt's experiments, phenomena closely analogous have been discovered by J. W. H. Harrison in the Bistoninæ. Evidently we are thus brought into touch with a set of facts, probably abundant in nature, which must be accounted for before the problem of sex-determination is disposed of; but, paradoxical as these occurrences are, they do not justify a return to earlier stages of confusion. The problem created by the existence of intersexes, gynandromorphs, and other sex-monstrosities has always been realised. The case of the free-martin, though its true nature is now settled by the brilliant work of Lillie (well summarised in Prof. Goldschmidt's book), proves that influences as yet little understood may be taking part in these determinations.

An interesting attempt was lately made by Morgan and Bridges to apply the chromosome theory rigorously to a number of mosaic gynandromorphs which have appeared from time to time in the pedigreed work on Drosophila. The parental composition being known, it could be shown from the distribution of the sex-linked factors that in nearly every case these curious patchworks might be represented as resulting from a presumably accidental elimination of a sex-chromosome from the affected parts of the body. The result was certainly a striking one; but this interpretation is not readily applicable to intersexual forms which are not mosaics. Admitting, however, that in mosaics *something* may have been eliminated from the affected patches, the suggestion that this something is the sex-chromosome raises the questions: Why do not the miscellaneous variations, to which the chromosomes of somatic tissues are conspicuously liable, more frequently show their consequences as somatic patchworks? and, conversely, Why are the chromosomes of normally dissimilar tissues not themselves dissimilar? But, apart from difficulties to which that line of argument must immediately lead, the occurrence of the intersexes among Prof. Goldschmidt's moths can scarcely be a consequence of accidental elimination, inasmuch as they came with extraordinary regularity. Appeals to the action of "hormones," from which he hopes a good deal, are a mere veiling of the difficulty. No one will dispute that these products are part of the proximate mechanism by which the effects of sexual differentiation are produced; but the problem of sex-determination is to discover the influence which primarily causes that differentiation to proceed in one direction rather than in the other; and herein, where the evidence of gametic differentiation is insufficient, we are left without any plausible conjecture. In considering the characteristics of partly or wholly sterile forms, it may be worth remembering that in proportion as a zygote is sterile, it *may* be retaining elements which, if it were fertile, would be extruded in its gametes. May not this retention influence the characters of the zygote?

Like its predecessors, this book expressly abstains from the attempt to deal with the problem of sex-determination in plants. We cannot quarrel with the wisdom of that decision, for the truth is that we are very far from any workable scheme which can be applied to them; but it is unfortunate that the diagram put forward by Correns as a representation of his views on sex in Bryonia should be chosen as the model of a "digametic" system of sex-determination. The author does imply that he has misgivings about that illustration, which, as I have elsewhere shown, is quite inconclusive. The incautious reader could scarcely avoid the inference that the scheme of sex-determination applied to animals is one which had been proved to hold in the case of a flowering plant—a very misleading conclusion.

Another region of the subject still altogether obscure is the genetical relation of the unisexual to the functionally hermaphrodite forms in animals. Prof. Goldschmidt's book contains all that can yet be said on that difficult question. There are, of course, various sorts of monœcism, and for scarcely any of them have we yet even an acceptable cytological scheme, still less any genetical evidence.

The book, as a whole, is very well done, and may be recommended to all students who wish to have the latest presentation of the facts in a clear and readable form. As I have implied, there is a want of lucidity in the discussion of the problem of the intersexes, and trouble would be saved to the reader if he were at once told that he will not be presented with a real solution. If he reads the book carefully he will discover that for himself; but the series of facts is exceptionally interesting and, at the present stage of genetical theory, of such vital importance that the effort will not be wasted.

W. BATESON.

Anæsthetics.

Anaesthetics: Their Uses and Administration. By Dr. Dudley Wilmot Buxton. Sixth edition. (Lewis's Practical Series.) Pp. xiv + 548 + viii plates. (London: H. K. Lewis and Co., Ltd., 1920.) Price 21*s*. net.

THE appearance of this new edition is to be welcomed because great advances have been made during the past few years, and also several other text-books on this subject have been for some time out of date and even out of print.

Although the size of the new volume is not much increased, Dr. Buxton has found means to add much fresh material and to re-write a great deal of the old. The chapter on the history of anæsthetics remains one of the most readable in the book, and will repay perusal by anyone not otherwise interested in the subject.

Within the past few years, and especially during the war, many new methods of anæsthesia have been devised or perfected, and many new problems attacked with more or less success. It is naturally to the chapters dealing with these methods and difficulties that one turns with the greatest curiosity. Nothing appears to have been forgotten, and each subject is discussed clearly and as fully as the space of one volume allows. The advantages of the administration of warm anæsthetic vapours are dealt with and the apparatus is described. Perhaps the section devoted to the use in major surgery of nitrous oxide with oxygen is one of the most important to the student of to-day. The advantages of this method of anæsthesia are shown to be real, although it has no doubt suffered from the too hearty advocacy of enthusiasts. In cases of severe shock, in both military and civil practice, its merits are so great as to make its use almost obligatory. On the other hand, many anæsthetists, and certainly most surgeons, will agree that as a routine method for abdominal sections it is not suitable. Dr. Buxton wisely points out that on the count of safety alone its advantages have so far been assumed rather than proved, and he agrees with Page that in cases of marked arterial degeneration, emphysema, or obstructed air passages its use is contra-indicated.

The subject of intratracheal insufflation of ether is fully dealt with, and perhaps that of intravenous ether infusion receives more space than it deserves, as some of its leading exponents seem now to use it but little. This may be due to the more extended use of rectal etherisation combined with oil, which, although a little troublesome, has proved very useful in plastic surgery about the head, and especially in bad cases of Graves' disease.

Many subjects concerning which it has been difficult to obtain a connected account without reference to the original papers are clearly and sufficiently summarised in this edition. Among these, one notices the sections dealing with acapnia, anoci-association, acidosis, and shock with its allied conditions. Dr. Buxton is certainly to be congratulated on having not only modernised, but also improved what was already one of the very best text-books on the subject.

Mathematical Text-books.

(1) *An Elementary Treatise on Differential Equations and their Applications.* By Prof. H. T. H. Piaggio. (Bell's Mathematical Series. Advanced Section.) Pp. xvi+216+xxv. (London: G. Bell and Sons, Ltd., 1920.) Price 12*s*. net.

(2) *Elementary Algebra.* Part i. By C. V. Durell and G. W. Palmer. (Cambridge Mathematical Series.) Pp. viii+256+xlvi. (Answers.) (London: G. Bell and Sons, Ltd., 1920.) With introduction, price 4*s*. 6*d*.; without introduction, price 3*s*. 6*d*.

(3) *A Short Course in College Mathematics: Comprising Thirty-six Lessons on Algebra, Coordinate Methods, and Plane Trigonometry.* By Prof. R. E. Moritz. Pp. ix+236. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1919.) Price 10*s*. 6*d*. net.

(4) *Arithmetic.* Part ii. By F. W. Dobbs and H. K. Marsden. (Bell's Mathematical Series.) Pp. xii+163+xi. (Answers.) (London: G. Bell and Sons, Ltd., 1920.) Price 3*s*. 6*d*.

(1) OF the two volumes that head the list it is difficult to speak too highly. The scope of that on differential equations is stated most succinctly to teachers by the mere statement that it covers the course for the London B.Sc. Honours, Schedule A of the second part of the Tripos, and some of the work for the London M.Sc. and for the Tripos, part ii. The author has clear views of the equipment of the students who are likely to use the book—an elementary knowledge of the differential and integral calculus, and a little co-ordinate geometry. In the old days it was quite possible for a respectable mathematician to become, with comparatively little effort, also a respectable mathematical physicist. Owing to the remarkable extension of specialisation in both subjects, this is no longer the case. It is perhaps all the more essential that the living interest of such a branch of the subject as this should be maintained at every stage, and it is here that the crucial test is made of the powers of the mathematician who also aspires to be a great teacher. He is not content merely to "give an account of the central parts of the subject in as simple a form as possible." He is careful that the various stages of the journey shall lead to Pisgah heights from which may be viewed the Promised Land to which the adventurous may make their way, and some province or other of which, according to taste or opportunity, they may some day make their own. Nor are the names and records of the older guides forgotten, and as each fresh height is scaled historical notes give just enough to fix the chronology and to whet the appetite for further information about those who first made their own the notable peaks and crags around the young climber.

In the first chapter we are glad to see the influence of the remarkable chapters published by Dr. Brodetsky last year in the *Mathematical Gazette*, and of Prof. Wada's paper on graphical solution. Chap. iv., on simple partial differential equations, with their genesis, the construction of simple particular solutions, and the procedure from simple to complex solutions with the help of Fourier's series, is a welcome innovation at so early a stage.

Chap. vi., on singular solutions, abandons any attempt at an analytical treatment at this stage of the student's development, and appeals to geometrical intuition. Chap. ix. deals with solution in series, following the method of Frobenius. Here we find among the examples the equations associated with the names of Bessel, Legendre, and Riccati, with a sketch of the hypergeometric equation and its twenty-four solutions. The nature of an existence theorem is explained in chap. x. The methods of Picard and Cauchy are followed by a discussion of the method of Frobenius, and here plentiful references are given for the benefit of those whose knowledge of the theory of series is inadequate. The references, indeed, are plentiful throughout. We may note one that is of little use to many of us—Stodola's "Steam Turbine," which has been unobtainable for some time past. In the miscellaneous examples the author, in a large number of cases, adds to the theorems to be solved the physical applications.

An appendix contains useful references for further reading.

By a strange oversight, chap. v. begins with types of equations "solvable for p," where not only has p not been defined, but the letter has also been repeatedly used on previous pages in different senses. Of course, the third line in ex. i. of paras. 52 and 53 will reveal the new signification to a smart reader, though the private student, as a rule, will be completely at sea for a time. There are other minor points, which will, no doubt, be attended to in the second edition; but space forbids us to say more than that, in this most interesting volume, Prof. Piaggio has proved himself to be a teacher of remarkable insight and skill.

(2) We know of no better introduction to the elements of algebra than that by Mr. Durell, of Winchester, and the late Mr. Palmer, of Christ's Hospital. The authors have contrived a course in which there is scarcely a page without ample evidence of intimate care controlled by a profound knowledge of youthful psychology. To many, the greatest attraction in the book is the fact that so large a proportion of it is adapted for *viva voce* work, and in accordance with modern ideas the material is throughout selected so as to bring the pupil as soon as possible within sight of the applications of the subject to the affairs of everyday life, and to such elementary scientific work as may be fairly expected to have come within his experience. The usual explanatory matter, which few boys and girls ever read, is reduced to a minimum, and placed in an "introduction" of about twenty pages. Useful extensions of various sections for the benefit of the few irrepressibles who cannot be kept back, and for the budding engineers and future specialists, are added in a final chapter. The writer of this notice can speak with personal experience of the successful manner in which a training on these lines copes with the inertia which lies at the base of most, if not, indeed, of all, of the difficulties that confront the beginner. In the hands of a sound teacher the pupil's rate of progress will be as rapid as he chooses, and the book may be placed with confidence in the hands of the private student. The collection of sixty odd pages of well-graded revision papers of various stages of difficulty adds considerably to the general value of the book.

(3) The short course of college mathematics by Prof. Moritz, professor of mathematics in Washington University, was originally devised to meet the demand during the war for short courses. So far as it goes, the treatment is thorough; the sixty pages on graphic methods are well and plentifully illustrated, and the student who has mastered the book should have a sound grasp of the essentials of trigonometry.

(4) The second part of Messrs. Dobbs and Marsden's "Arithmetic" consists of collections of papers, with the minimum of explanatory text, covering easy mensuration, financial subjects, graphs, and applications of elementary arithmetical notions to such problems as specific gravity, map-reading, etc. About half the book is given to revision papers. There is considerable variety in the carefully selected sets of questions.

Our Bookshelf.

Heredity and Evolution in Plants. By C. Stuart Gager. Pp. xv+265. (Philadelphia: P. Blakiston's Son and Co., 1920.)

THIS little book is an expansion of several chapters of the author's "Fundamentals of Botany." It is intended for beginners and general readers, and presents in a fresh way a very readable and well-illustrated account of the phenomena of heredity and evolution from the strictly botanical point of view. The author begins quite unexpectedly with two chapters on the life-history of a fern, and this concise account, followed by a chapter on fundamental principles, forms a background for the treatment of the subject proper. The definition of heredity as "the genetic relationship that exists between successive generations of organisms" omits to recognise the fact that the conception of heredity is fundamentally concerned with resemblances and differences as they occur in genetically related organisms. Later chapters deal with Mendelism, evolution, Darwinism, and experimental evolution. A very good balance is preserved between the historical and the descriptive methods, with a sprinkling of illustrations, the majority of which are new to text-books.

A chapter on the evolution of plants touches upon such problems as alternation of generations, evolution of the sporophyte, and the evidence from comparative anatomy, and ends with a hypothetical ancestral tree of relationships. One of the subjects best treated is that of geographical distribution, which discusses the means of dispersal, peculiarities of distribution, effects of glaciation and cultivation on distribution, endemism, the "age and area" hypothesis of Willis, etc., with numerous illustrative cases from the recent literature. The final chapters deal with the fossil record and the various hypothetical relationships of the groups of vascular plants.

The book is well produced and relatively free from typographical errors. We notice a slip (p. 42) in the statement regarding the multiplication of the offspring from a mustard plant. Many general readers will find enjoyment and information in a perusal of this little book.

R. R. G.

Practical Chemistry: Fundamental Facts and Applications to Modern Life. By N. H. Black and Dr. J. Bryant Conant. Pp. xi + 474. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1920.) Price 11*s*. net.

THE title of "Practical Chemistry" might lead to the impression that the book, written by two American teachers, was a laboratory manual. That is not the case. The text-book is an admirably clear and interesting introduction to chemistry, in which, it is true, the practical applications of the subject are not neglected. The attitude of the authors is completely modern, and the appearance of the book is greatly improved by numerous well-executed illustrations, and reproductions of photographs of actual plant and apparatus used in industry. Portraits of famous chemists, brief historical details, and numerous experiments are given. At the end of each chapter is a list of "Topics for Further Study," which often contain interesting suggestions. Any attempt to stimulate thought is welcome in a text-book, and the present volume is rich in such efforts.

In addition to a careful and accurate account of the familiar topics, many recent discoveries are included in a very readable manner. For instance, accessory factors in diet, the purification of water by chlorine, the hydrogenation of oils, the cleansing power of soap, and the really practical processes used in the fixation of nitrogen are all discussed in sufficient detail to make them intelligible. A useful summary is added to each chapter, together with a list of interesting questions. The authors are to be congratulated on producing a really interesting book; clear and accurate, with a freshness of treatment which is grateful to the hardened reader of elementary text-books. As an introductory text-book for elementary students, and for use in the higher forms of schools, this may with confidence be recommended.

J. R. P.

Physiology. By Dr. Ffrangcon Roberts. (Students' Synopsis Series.) Pp. viii + 389. (London: J. and A. Churchill, 1920.) Price 15*s*. net.

THE student of physiology has such a wide choice of text-books dealing more or less exhaustively with the subject that the entry of a new volume into the list might be regarded as unnecessary. This book, however, is intended to meet a special need incurred by the growth of the science. The application of physical and chemical methods to the elucidation of the problems of the body, the war-time accumulation of new facts and ideas, and the advances in the sister sciences have so altered the material and increased the size of the new editions of the standard text-books that an orderly arrangement is in danger of being obscured by the mass of detail. This is a real difficulty to the student, and furnishes a valid reason for the issue of this volume of the Students' Synopsis Series. The book is definitely intended to supplement, and not to supplant, the larger text-books. It assumes that the student has already an acquaintance with the elements of physiology and has had some experience of practical work. It also assumes that he has a considerable knowledge of physics and chemistry, without which its treatment of such a topic as the reaction of the blood, though ably presented, would by its brevity fail to convey the necessary instruction. The book admirably fulfils its purpose, and Dr. Roberts is to be congratulated upon his success in accomplishing the difficult task of compiling a summary of the salient facts of physiology which is readable, clear, concise, and up to date. The volume is well edited and its illustrations are apposite.

P. T. HERRING.

Landscape Architecture. By Prof. H. V. Hubbard and Theodora Kimball. Pp. 132. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1920.) Price 6*s*. 6*d*. net.

THIS work sets out to provide a comprehensive classification of the field of landscape architecture, and attempts to show in detail both the "subjects making up the field, and the relation of the field itself to tangent fields." The scheme resolves itself into a series of some thirteen to fourteen hundred headings, under which published literature, notes and other manuscript material, maps, plans, photographs, and other pictorial matter may be arranged. These headings are placed in groups according to their relationship with each other, and the groups themselves are classified. Landscape art must be much more highly organised in the United States than it is here to justify the publication of such an elaborate scheme as this, the chief *raison d'être* of which is the convenient docketing of papers in one form or another. We doubt if there are half a dozen firms of landscape gardeners in this country whose accumulation of material is so extensive as to need extraneous assistance in arranging it, but to any such this work is no doubt capable of affording valuable suggestions. It shows, at any rate, how extensive is the area covered by landscape art, and how far-reaching are its ramifications when followed out to their full extent.

W. J. B.

Nucleic Acids: Their Chemical Properties and Physiological Conduct. By Prof. W. Jones. Second edition. (Monographs on Biochemistry.) Pp. viii + 150. (London: Longmans, Green, and Co., 1920.) Price 9*s*. net.

SINCE the first edition of this monograph was reviewed in NATURE for April 1, 1915, our knowledge of physiological chemistry has been considerably extended. The four hypothetical nucleotides required by the nucleotide theory of the structure of plant nucleic acid have now been prepared, and new facts regarding the purine fermentation in various animals have been brought to light. The work concludes with a bibliography of no fewer than twenty pages.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

The Arrangement of Atoms in Crystals.

IN NATURE for January 6, p. 609, was published a note in which some figures given in my paper on "The Arrangement of Atoms in Crystals" (*Phil. Mag.*, vol. xl., August, 1920) were contrasted with similar figures given by Wyckoff (*Amer. Journ. Sci.*, [iv], vol. l., pp. 317–60, November, 1920). These figures were estimates of the distances between atoms of metal, carbon, and oxygen in the crystals calcite, $CaCO_3$, rhodochrosite, $MnCO_3$, and siderite, $FeCO_3$. In this note it is stated that our data differ considerably, "the deviations rising to 0·6 Å. in the distance from carbon to metal."

There are no discrepancies of this magnitude between Wyckoff's results and mine. The large differences to which the note directs attention are due to errors in quoting the results given in my paper, owing, I think, to a misconception of the structure which Wyckoff and I agree in assigning to these crystals.

I give the correct figures, the distances being expressed in Angstrom units:

	Wyckoff.		Bragg.	
	I.	II.	Experimental	Sum of radii
Ca–O ...	2·30	2·42	2·30	2·35
C–O ...	1·21	1·28	1·42	1·47
Ca–C ...	3·04	*3·206*	*3·206*	
Mn–O ...	1·96	2·13	2·10	2·11
C–O ...	1·22	1·32	1·42	1·47
Mn–C ...	2·83	*3·072*	*3·072*	

If I understand Wyckoff's results rightly, we are in agreement as to the type of structure in the case of these carbonates, and the symmetry of the crystal alone suffices to fix the positions of the calcium and carbon atoms. The distance between them can be calculated from the molecular volume of calcite, Avogadro's number N, and the crystal axial ratios. The dimensions of the calcite structure have been made the subject of careful investigation (Uhler, *Phys. Rev.*, July, 1918), as it has been used for standard X-ray wave-length determinations. Taking the value $d_{(100)}=3·028$ Å. given by Uhler, it follows that this distance from calcium to carbon atoms is 3·206 Å. Wyckoff gives the value 3·04 Å., and so ascribes to the whole structure a smaller scale. If, as I believe, his scale is too small, all his figures should be increased in the ratio 3·206 to 3·04. A similar increase of scale holds for rhodochrosite. Under I. are given Wyckoff's values, and under II. those values increased in what I believe to be the correct ratio.

Wyckoff gives figures which differ from mine for the distance between carbon and oxygen atoms. He has made a very careful determination of a certain parameter (denoted by "u" in his paper), and I believe his value for it, 0·25, to be much more trustworthy than my approximate value 0·30. Wyckoff's value confirms a determination 0·25–0·27 by W. H. Bragg (Trans. Roy. Soc., A, vol. ccxv., pp. 253–74) in 1915—a determination which I did not know when I published my figures. If the figures in column II. are accepted, this would mean that my estimate of the "diameter" of carbon in compounds is too high, and that a better value would be nearer that of fluorine, 1·35 Å. This is the only serious discrepancy between our results, and it does not seem to me that it affects in any way the general conclusions which I drew in my paper.

The figure 2·47 Å., quoted as being given by me for the distance Ca–C, has presumably been arrived at by the author of the note by adding the radii for these atoms. As they are partially separated by the oxygen atoms which surround the calcium atom, there is no direct connection between the sum of the radii and the distance between them. I used in my calculations the theoretical value obtained as above.

May I take this opportunity to correct another error in the note? The figures given for the "diameters" of the electro-negative elements are quoted correctly from my paper, but those given for the metals are one-half the value which I gave under this head.

W. L. BRAGG.

Manchester University, January 22.

A Case of Coloured Thinking with Thought-forms and Linked Sensations.

COLOURED thinking is such a peculiar condition that those interested in it will welcome the details of a well-marked case of it. It must be distinguished from linked sensations such as coloured hearing—one of the synæsthesiæ—in which heard sounds call up colours, as when the low notes of the organ suggest violet or the high notes white or yellow, etc.

Coloured thinking or chromatic mentation (psychochromæsthesia) is the visualising of concepts as coloured, the ability to think of a letter of the alphabet, a number, a date, a month, or a name as associated with some colour or other—white, black, red, green, etc. To those who have never experienced this sort of thing it is unintelligible.

One coloured thinker thus expressed himself: "When I think at all definitely about the word January the name appears to me reddish, whereas April is white and May yellow; the vowel 'i' is always black, the letter 'o' white, and 'w' indigo-blue. Only by a determined effort can I think of 'b' as green or blue, for to me it has always been and must be black; to imagine August as anything but white seems to me an impossibility, an altering of the inherent nature of things."

Of course, the same person who has coloured hearing—the commonest of the linked sensations—may likewise have coloured thinking, although most coloured thinkers do not also have linked sensations. The case the interest of which I think sufficiently great to report on now is one both of linked sensations and of coloured thinking. But there is also a third element of interest in it, namely, that of thought-forms. A thought-form or psychogram is the visualising of, say, the numerals or letters of the alphabet or months of the year in such a way that they seem to form some definite figure in space—for instance, an arc of a circle or a ladder sloping up to the right or left, and so forth. A psychogram is the uncoloured form of a concept or a series of them; the psychochrome is the concept itself exteriorised in colour.

The case the coloured thoughts, linked sensations, and thought-forms of which I subjoin is that of a student of this University (Miss A. M.), who has all the features characteristic of these cases. She has been a coloured thinker ever since she can remember; the colours have not altered with lapse of time, they are exceedingly definite, they do not agree with the colours seen by other thinkers for any one given concept, and, finally, the "seer" cannot account for them in any way.

The only feature in the present case not quite typical is that it is not so clearly hereditary as is usually observed. Miss A. M. says that neither of her parents is a coloured thinker, though her "mother associates colours with the characters of people." This has been called "individuation," and is not so uncommon as might be imagined.

The classic discussion of this sort of thing is to be found in Sir Francis Galton's "Inquiries into Human Faculty and its Development" (London, Macmillan, 1883). This has been reprinted in Everyman's Library. Since that time very little has been written in English on the subject. With the exception of a letter in Nature (vol. xliv., p. 223, 1891) and two papers by Miss M. A. Calkins in the *American Journal of Psychology* (1892), there has been nothing published on the subject until my articles in 1905 and 1908 respectively appeared in the *Edinburgh Medical Journal* and in the *Journal of Abnormal Psychology* (Boston, U.S.A.). The *British Review* of April, 1913, published a popular account of colour-hearing by C. C. Martindale.

D. Fraser Harris.

Dalhousie University, Halifax, Nova Scotia,
December, 1920.

Appendix.

Coloured Concepts or Psychochromes of Miss A. M.

a, creamy-white; b, shade clearer than "d"; c, pink; d, indigo, dirty (gritty) blue; e, black (wet); f, dry brown; g, black on white; h, darkish fawn, like chocolate blancmange; i, black; j, dirty, pearly, bluish-white; k, clear brown, edged with mustard-yellow; l, yellow; m, jade-green; n, pea-green; o, black; p, darker green, bluer; q, black, with red tinge; r, dry red; s, crimson, scarlet; t, deep black-red; u, dark grey, almost black; v, very dark navy, blue and green; w, not so dark, green and navy; x, brownish-mustard-yellow, very ugly; y, almost neutral bluish-green; z, like "x," but a little yellower.

Sunday, golden-yellow, with a fleck of green in the middle; Monday, pretty light green; Tuesday, dark blue with red flecks; Wednesday, soft, deeper green; Thursday, like Tuesday, with more red; Friday, brown, soft like suède gloves; Saturday, bright scarlet.

January, clear, intense pale green, like ice; February, dirty light reddish-brown; March, green and red at end; April, fresh, pale yellow; May, very pale green, almost white; June, green; July, yellow and royal blue; August, golden-yellow; September, red and brown (autumn); October, navy blue; November, brown with yellow edges; December, dirty, almost colourless, made up of black, navy blue, and dark green.

Christmas, pink (Christ), red and green (mas); Easter, creamy-white.

1, black; 2, creamy-yellow; 3, red, pale; 4, brown; 5, bright, wet red; 6, dull indigo; 7, ugly yellow; 8, white; 9, green; 10, black; 11, black and yellow; 12, creamy-yellow.

The twenties, yellow; the thirties, reddish; the forties, brown; etc. The hundreds are the same.

Synaesthesiae.

Pains have colours, but following the colours of the names, *i.e.* sore, red; ache, opaque-whitish; sprain, greenish-red; cut, blue and red; bruise, blue and red.

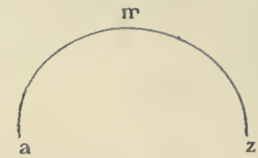
Tastes are only slightly coloured: acid are sharp, penetrating yellow; sweet, soft yellow. Odours, only slightly, either grey or yellow: a musty smell is grey and red; acrid, yellowish-grey. Touch, not at all: heat is yellow, and different degrees different shades up to a pure white, which is cold.

Music is the only thing that makes Miss A. M. see purple and violet. Deep organ notes blend from blue to purple, but only music. Even the names "purple" and "violet" she sees only by the letters which make them up. If "violet" had not a "t" at the end it would be merely dark blue, and the same with the "r" in purple. The lowest organ notes are, to her, deep purple, like a bruise, while the very high notes are yellow and pink.

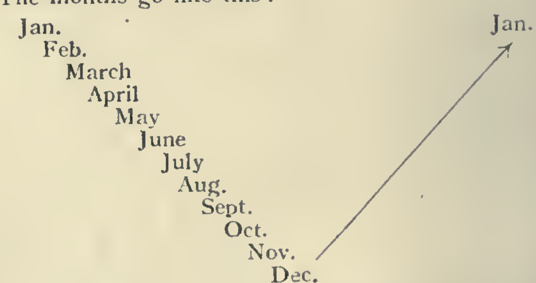
Psychograms.

Numerals go like this:

The alphabet goes like this:



The months go like this:



The week between Christmas and New Year's Day stretches back to January.

Days of the week go like this:

Sat. Sun. Mon. Tues. Wed. Thurs. Fri. Sat.

Heredity and Acquired Characters.

Mr. J. T. Cunningham remarks (Nature, January 13, p. 630): "Provided that biologists understand one another, it is, perhaps, not an insuperable barrier to the progress of biology that Sir Archdall Reid is unable to understand their terminology." Prof. MacBride declares (*ibid.*): "I have attended many congresses of biologists, and I have never found evidence of confusion in their minds as to what was meant by an 'acquired character.'" I feel humbled, but not enlightened.

As far as I am able to understand Mr. Cunningham's letter, he regards as "acquired" everything which develops in response to use, and everything else as "innate." Herein he agrees with Lamarck and Sir Ray Lankester, but differs from a host of other writers, including Spencer, Wallace, Romanes, and Weismann, all of whom regarded the effects of injuries as "acquired" characters. He differs even from himself, for he has, when arguing in favour of the transmission of acquirements, attributed the evolution of antlers to the effects of irritation (injury). He differs in the same issue of Nature from Prof. MacBride, according to whom "'acquired character' is a technical term; by it is meant a quality, *i.e.* the degree of development of an organ, which is produced as a response to function, altered from the normal in response to an alteration of the environment from the normal." Whence it follows that, while Mr. Cunningham would term the muscular development of the ordinary man "acquired," Prof. MacBride would call it "innate," and would limit the term "acquired" to such developments as the blacksmith displays. If everyone worked as blacksmiths, Prof. MacBride would differ still more from Mr. Cunningham, for the whole of development would then be termed by the former "innate" and by the latter "acquired." To Mr. Cunningham the English language is always an acquirement; to Prof. MacBride it is innate if learned in England, but acquired if learned in France.

Formal definitions of the meanings of the terms "innate" and "acquired" when applied to characters are extremely rare in biological literature—unless such terms as "germinal" and "somatic" be attempts at definition. However, Romanes made the attempt. This is what he says ("An Examination of Weismannism," p. 5): "By a congenital character is meant any individual peculiarity, whether structural or mental, with which the individual is born. By an acquired character is meant any peculiarity which the individual may subsequently develop in consequence of its own individual experience." Elsewhere (p. 214) he defines congenital (plasmogenetic) characters as "variations due to admixtures of germ-plasm in acts of sexual fertilization (and, therefore, present at birth), as distinguished from somatogenetic characters—variations which have been acquired independently of germ-plasm." Somatic characters he defines as "characters acquired by the soma (*i.e.* variations acquired after birth by the action of the environment), as distinguished from characters produced and potentially present from the first by a union of two masses of germ-plasm—plasmogenetic characters." Romanes's language may be lacking in precision, but evidently he supposed that there is something peculiarly "innate" about a "germinal" character and something peculiarly "acquired" about a "somatic" character. Unlike Prof. MacBride, he gives all these terms their ordinary or dictionary meanings—and so, I believe, do most biologists.

Dr. Ruggles Gates (NATURE, January 20, p. 663) believes I contradict myself. It is possible he has not grasped my meaning. An illustration may help. Before me are two pencils. Comparing these individuals, I find that their differences as regards length are great, but as regards colour small. Dr. Gates will agree that I am not entitled to transfer the terms by which I described the differences between the individuals to the characters wherein they differ—*i.e.* I am not entitled to call the lengths of the pencils great and their colours small. That way lies confusion of thought. Now consider two living individuals, the one an Englishman and the other a scarred negro. They differ in colour innately—they are in this respect by nature different; their germ-plasms are unlike; even if reared under exactly similar conditions of nurture they would be unlike. They differ in scars by acquirement; here they have had not unlike natures, but unlike nurtures; if reared under similar conditions they would be like. In brief, the colour difference is blastogenic, while the difference in scars is somatogenic. All this is intelligible; the words are used correctly. They are given their ordinary meanings; they are not in the least technical. But are we now entitled to transfer our descriptive terms from the differences between individuals to the characters in which they differ? Are we entitled to call skin-coloration "innate" and scars "acquired"? We are now comparing, not separate individuals, but the characters wherein they differ. In effect, we are comparing the characters of the same individual. How is skin-colour more innate and less acquired than a scar? They are both ancient products of evolution, both depend on germinal potentiality, both develop in response to some form of nurture, and both are situated in the soma.

Dr. Ruggles Gates writes: "I pointed out (NATURE, December 2, p. 440) that if his contention that all characters are both innate and acquired in exactly the same sense and degree is true, then it would follow that all variations are also of one type, while experimental biologists are universally agreed that this is not the case. At least two categories of variations are postulated . . . blastogenic and somatogenic. . . . Yet Sir Archdall Reid's only attempt to answer my criticism that the universally admitted existence of two types of variations undermines his whole position is the very weak one of quoting Darwin's tentative theory of pangenesis." But I did not quote the theory of pangenesis *against* Dr. Gates; I was merely trying to make my meaning clear. And surely the word "variation" indicates, not a character as such, but a difference between individuals. Resemblances do not necessarily exclude differences. A cleft lip is always a character in both man and rabbit; but it is a variation in the former, but not in the latter. A sixth digit resembles all other digits in that it is a product of nature and nurture; and yet (if the parent has it not) it is none the less a variation. So also a sixth digit resembles a scar in that it is a product of potentiality and stimulus; and yet it differs from the latter in that the unlikeness from the parent is innate, whereas it is acquired in the case of the scar. The resemblances between the two do not necessarily eliminate their differences. How, then, is my whole position undermined?

Man and the Scottish Fauna.

I AM grateful to your reviewer (NATURE, December 30, 1920, p. 568) for his appreciation and for pointing out slips and misprints in my "Influence of Man on Animal Life in Scotland," but on some points of fact I would venture to disagree with other of his remarks.

Geologists will not be perturbed by his difficulty in believing in the persistence of evidence of man's presence in Scotland from times earlier than the formation of the 25-ft. beach. Sections of many places have shown that the 25-ft. beach, of estuarine material, *rests upon* the boulder clay, so that it is certainly not "clear that the land ice was grinding over all after the elevation which formed the younger 25-ft. beach." On the contrary, the evidence is that the 25-ft. beach was formed subsequent to the disappearance of the ice-fields. The relations of the 50-ft. beach are not so clear, but facts have to be explained on reasonable suppositions. And the occurrence of kitchen-middens of molluscan shells along the ridge of the 50-ft. beach in the Forth Valley is more easily accounted for on the supposition I have advocated—that they were collected while the 50-ft. beach was still a sea-margin—than on that of your reviewer, who would have the kitchen-middeners collect their shell-fish on the sea-side, now a great distance away, and thereafter scale first the 25-ft., and afterwards the 50-ft., beach before sitting down to their simple meals.

On the strength of a reference by Thomas the Rhymer, your reviewer suggests that I have erroneously omitted the green woodpecker from the list of banished Scottish animals. But both ornithologists (such as Yarrell and Newton) and etymologists (as in Wright's "Dialect Dictionary") are agreed that the word "wodewale," on which the whole value of the citation hangs, is a general word for a woodpecker, and applied to the great spotted as well as to the green woodpecker. The word has no specific significance. There seems to be, indeed, no evidence, past or present, that the green woodpecker has been a native of Scotland.

In naming the brown trout *Salmo trutta*, I followed the considered opinion of such an expert in fish nomenclature as Mr. C. T. Regan, of the British Museum (Natural History); my statement regarding the success of the introduction of Loch Leven trout to New Zealand did not pretend to record any *first* achieved success, and as it stands is correct; and the two "caricatures, and poor at that," specified by your reviewer happen to be reproduced from photographs of specimens mounted by skilled taxidermists, and now exhibited in the Royal Scottish Museum.

JAMES RITCHIE.

I SHOULD be sorry indeed if, in reviewing his book, I had given Dr. Ritchie the impression that I undervalued it as a contribution to prehistoric research. I did no more than express difficulty in accompanying Dr. Ritchie to the full extent of his conclusions, and surprise that, from first to last, he takes no notice of the 25-ft. beach.

I admit that I expressed myself too positively in saying that it was "*clear* that the land ice was grinding over all after the elevation which formed the younger 25-ft. beach." But many years of personal examination of the features of the Scottish seaboard have left on my mind a strong impression that some agent more powerful than sub-aerial denudation has masked or obliterated by far the greater extent of the 50-ft. beach. Such an agent may have been subsidence, glacial action, or "trail" (earth thawing and flowing after prolonged freezing, as in the "earth-glaciers" of the Rockies).

Some support to this view may be found in the late Prof. James Geikie's Munro lectures, "Antiquity of Man in Europe," 1914: "At the head of Loch Torridon well-formed terminal moraines rest directly upon the 45–50-ft. beach" (p. 273).

Prof. Geikie considered (p. 279) that the formation of that beach was followed by "partial subsidence," and continued:

"We cannot actually demonstrate that snowfields and glaciers reappeared at this stage. . . . Nevertheless, we are not without evidence suggestive of the appearance at this time of inconsiderable glaciers amongst our highest mountains. These glaciers undoubtedly existed at a later date than the glaciers that dropped their moraines on the 45–50-ft. beach. It is therefore only reasonable to infer that the high-level corrie glaciers in question were probably contemporaneous with the formation of the 25-ft. to 30-ft. beach."

The occurrence of kitchen-middens on the 50-ft. beach can scarcely be taken to prove the presence of man when the sea stood at that level. On the summit of the Fell of Barhullion in Wigtownshire, 450 ft. above the present sea-level and $1\frac{1}{2}$ miles distant from the nearest beach, are the remains of a fortified enclosure. The refuse-heap of this encampment contains a large quantity of limpet-shells. Loch Spouts, in Ayrshire, is on high ground two or three miles from the sea. Dr. Munro has recorded that when the crannog in that swamp was explored, in the midden were found "large quantities of the shells of whelks, limpets, and hazel-nuts" ("Lake-dwellings of Europe," p. 420).

Prof. Geikie cited the discovery of a canoe near Perth as evidence that Neolithic man was in occupation when the sea washed the 50-ft. beach. I have been unable to find any detailed record of the finding of this canoe, and if, as Prof. Geikie says, it was made of pine, I should hold that to be incompatible with very high antiquity. Having taken part in the excavation of many crannogs, I have never seen any submerged timber, except oak and yew, that retained a firmer consistency than cheese.

Dr. Ritchie expresses the opinion that "there seems to be . . . no evidence, past or present, that the green woodpecker has been a native of Scotland." In Wallis's "History of Northumberland," 1769, vol. i., p. 319, it is stated that this species "has been observed in some of our vale-woods, but is not common. It was frequent in Dilston Park before the wood was cut down." Two instances of its occurrence in the valley of the Tweed are recorded in Mr. Evans's "Fauna of the Tweed Area," p. 109. Dr. Ritchie seems to be in error in attributing to Newton and Yarrell the use of the name "woodwall" as a generic term for all three British species of woodpecker. Yarrell strictly confines it to the green woodpecker, though he admits that Willughby and Ray use the term in a looser sense ("British Birds," third edition, vol. ii., p. 149), while Newton merely mentions it among the popular names for woodpeckers in general. The great and lesser spotted woodpeckers do not utter any song or bell-like note, and it seems fairly clear that it is the green woodpecker that figures in the ballad of Robin Hood (*cura* Ritson):

The Woodwele sang and would not cease,
Sitting upon a spray,
So loud he wakened Robin Hood
In the Greenwood where he lay.

It is probable that the green woodpecker, yaffle, or woodwale disappeared from Scotland with the forest that sheltered it.

THE REVIEWER.

Literature for Men of Letters and Science in Russia.

AT the beginning of this year an appeal was issued for funds to enable a certain number of scientific and literary publications to be sent to the House of Science and the House of Literature in Petersburg, where the remnant of the intellectual life of Russia is mostly congregated. The British Committee for Aiding Men of Letters and Science in that country has assured itself that such publications will reach their destination, and has made arrangements for their transmission. There are probably many authors who would be willing to send copies of their works in the form of excerpts or otherwise to Russian workers who have been cut off from the outside world since the revolution. The British Committee will be glad to receive any such books or papers of a non-political type and to send them to Petersburg. It cannot guarantee delivery to individuals, but it can ensure that publications will reach the Houses of Literature and Science. Parcels for transmission should be addressed to the above Committee, care of Messrs. Wm. Dawson and Sons, Ltd., Continental Department, Rolls Buildings, Fetter Lane, E.C.4.

L. F. SCHUSTER.

The Mild Weather.

APROPOS of Mr. Charles Harding's letter (NATURE, January 20), one result of the extraordinary weather in the south of England since the third week of December was that on January 24 I saw forty or fifty plants in flower of the minute Crucifer (*Hutchinsia petraea*) on limestone screes close to Bristol. Some of the seedlings were 2 in. high, with five or six flowering heads and with seed-pods already developed. Last year a few were in flower on February 12, but even this is remarkably early, for March–April is the usual time in the district for this rare plant, and most of the books give March–May. On January 5 I saw a hazel in full blossom between Gunnersbury and Kew.

H. STUART THOMPSON.

The Forest Resources of India.[1]

MORE than one-fifth of the total area of British India (including the Shan States), comprising some 250,000 square miles, is under the control of the Forest Department. In this vast area the diversity of climate, soil, and vegetation is very great. The forest vegetation ranges from that of the arid, semi-desert tracts of North-west India and the alpine scrub on the higher slopes of the Himalayas to the luxuriant evergreen forests of parts of Assam, Burma, and the west coast of India, while the total number of woody plants comprises approximately 5000 distinct species. The number of valuable timbers and other commercial products available in the forests is very large, and many of them are as yet imperfectly known. Among the best-known timber trees are red cedar (*Cedrela Toona*), deodar (*Cedrus deodara*), satinwood (*Chloroxylon Swietenia*), rosewood (*Dalbergia latifolia*), padauk (*Pterocarpus dalbergioides*), sandal (*Santalum album*), sal (*Shorea robusta*), and teak (*Tectona grandis*). The principal minor products are classified under bamboos, grass, fibres, oil-seeds, tanning materials, essential oils, gums, resins, rubber, drugs, and lac. Minor forest industries which are likely to develop considerably in the near future are the paper-pulp industry, which offers great scope for the utilisation of bamboos and grasses, and the production of turpentine and rosin from the resin of *Pinus longifolia*. During the last twelve years the Indian resin factories have increased their output tenfold.

FIG. 1.—Main building of the Forest Research Institute, Dehra Dun. From "The Work of the Forest Department in India."

Forest crops usually require long periods of time to attain maturity, and the effect on growth and development of any particular method of treatment often only manifests itself after a number of years. The forest officer, therefore, who can himself rarely hope to see the full results of his own work, must possess in an unusual degree the qualities of patience, imagination, and foresight, and must, as a rule, be content with the knowledge that he is working for the good of posterity. The early efforts of forest officers in India to demarcate and protect the forests from destruction, and, by careful treatment, to enable

[1] "The Work of the Forest Department in India." Prepared under the direction of the Inspector-General of Forests to the Government of India, April, 1920. (London: Harrison and Sons.) Price 1s.

the forests to produce a regular and increasing supply of timber and other products, met with much bitter opposition from short-sighted commercial interests and from the local population which had been accustomed to regard the forests as the free gift of Nature. The present generation, however, is enjoying the fruits of the labours of devoted pioneers, who in the face of great opposition have built up "a property of constantly increasing value, the future importance of which it is hardly possible to over-estimate." In view of the general apathy regarding scientific forestry which prevailed in Great Britain itself until the vital importance of forest resources was emphasised by the recent war, it is indeed remarkable that during the last seventy years the importance of forestry in India has been steadily kept in view by British administrators. In this respect, indeed, India may well claim to have set a worthy example to the rest of the British Empire.

The most noteworthy event in the early history of scientific forestry in India was the enunciation of a definite and far-sighted forest policy by Lord Dalhousie in 1855, which was followed by the appointment of Dr. Brandis as Superintendent of Forests in Pegu in 1856. In 1874 the superior forest staff consisted of seventy-one officers; in 1918 this number had risen to 257, while schemes now under consideration are expected to raise this figure to 350. It is instructive to compare with these figures the following details of the average annual surplus forest revenue, in lakhs of rupees, during the quinquennial periods mentioned:

Period	Revenue
1864–68	13·6
1869–73	17·0
1874–78	20·8
1904–08	116·0
1909–13	132·3
1914–18	160·2

The value of Indian forest resources, however, must not be judged mainly by financial results. The first duty of the Forest Department is to provide the ordinary domestic and agricultural requirements of the local population in respect of timber, fuel, grass, grazing and other products. Large quantities of such produce are utilised by right-holders and free-grantees, while in times of famine the people are often largely dependent on the forests for their existence. The forests also provide congenial employment for a considerable portion of the population, and it is estimated that some five millions of people in India are directly or indirectly dependent on forestry for their livelihood for the greater part of the year. In many cases, also, the primary object of the forester in establishing and preserving forest vegetation is

FIG. 2.—Teak plantation eighteen months old at Kaptai, Chittagong tract. From "The Work of the Forest Department in India."

to prevent injurious erosion and to regulate the storage of rainfall.

The future development of the forest resources of India depends chiefly on three factors:

(1) Creating or increasing the market for individual products. Valuable work in this direction was done at the recent Empire Timber Exhibition by emphasising the uses and handsome appearance of several common Indian timbers, which hitherto were practically unknown in home trade circles. This kind of work necessitates, on one hand close co-operation between forest officers and the commercial world, and on the other co-operation between forest officers and those men of science who are engaged in studying the properties of forest products. With reference to the latter point, recent progress has been made by attaching a cellulose expert (to investigate paper-making materials), a tannin expert, an expert in wood-technology, and others, to the Forest Research Institute at Dehra Dun.

Fig. 3.—Bamboo rafts at Ma'ne Muk, Kasalong river, Chittagong hill tract. From "The Work of the Forest Department in India.

(2) Providing improved transport facilities in the shape of roads and mechanical appliances with the object of lessening the cost of extraction and making it possible to work areas which are at present inaccessible. An important step recently taken in this connection is the addition of a special engineering branch to the Indian Forest Department.

(3) Improved methods of sylvicultural management, the success of which primarily depends on research work carried out by sylviculturists, botanists, zoologists, chemists, and other men of science with the object of increasing available knowledge regarding the requirements of individual species, and the factors which favour or impede their healthy growth and development. Such work is the bed-rock of all truly progressive forestry. It is of little use to build up a market for a product unless a sustained supply of it can be assured and concentrated on those areas where its exploitation can be provided for most efficiently and at a minimum cost. Moreover, until a detailed knowledge of the requirements of individual species has been acquired, the maximum yield of any particular product cannot be obtained. That there is much to be done under this head is evident from the fact that, although the conditions of soil and climate over a large part of the forest area in the Indian Empire are exceptionally favourable to vegetative growth, the present yield from the best of the Indian forests is considerably below that of intensively worked European forests. That the importance of this kind of work is not being overlooked by the Indian forest authorities is indicated by the fact that at the Forest Research Institute, which was established at Dehra Dun in

1906 at the instance of Sir S. Eardley Wilmot, provision was made for research work in sylviculture, forest botany, zoology, and chemistry, as well as in forest economic products. A scheme now under consideration contemplates a large increase in the establishment and equipment of this institute, involving the acquisition of a site of 1000 acres and an expenditure of some 500,000*l*.

It is interesting to note that, as the work of the Forest Department has increased in volume and complexity, the organisation which sufficed when forest work was relatively simple and of a routine nature has proved to be no longer suitable, and in recent years there has been a considerable advance in the direction of decentralisation. Thus the major provinces now have complete control over their forest revenue and expenditure, while the provincial chief conservators carry out many of the duties which previously were performed by the head of the department. Similarly, it is now recognised that a great deal of research in sylviculture and economic products must be carried out by local officers in the provinces, and not by the staff of the Central Research Institute at Dehra Dun. At the same time, the value of the assistance and advice which can be obtained from officers who are given opportunities of studying those aspects of problems which are usually not accessible to local provincial officers is fully realised. The Forest Department, in this respect, appears to have realised from actual experience the importance of (1) freedom for the development of local initiative, and (2) mutual good-will, which renders possible loyal co-operation and co-ordination of work for the common good—principles which, after all, constitute the foundation of the British Empire itself.

In a recent publication issued by the Government of India it is noted that the Indian forest estate constitutes a "huge mine of wealth, the fringe of which has been barely touched," and whether regarded from the commercial or the scientific point of view the magnitude and many-sided interest of the work which lies before the officers of the Indian Forest Department to-day can scarcely be surpassed. Finally, the forest officer in India who is brought into intimate contact with men of all degrees, ranging from the aboriginal tribes of remote forest tracts to captains of industry and scientific experts, has it in his power to do much to promote the good-will and co-operation between men of different classes, occupations, races, and creeds which are so important to-day for the welfare of the British Empire and, indeed, of civilisation itself.

The Investigation of Gravity at Sea.

By PROF. W. G. DUFFIELD.

THE most notable attempt to measure the variation of the force of gravity over the surface of the oceans was that made by Hecker in the early years of the present century; in 1901 he surveyed a track across the Atlantic from Lisbon to Bahia, following this up a few years later with the investigation of the Indian and Pacific Oceans and the Black Sea.

Helmert had developed a formula for the variation of gravity with latitude from observations collected from a large number of land stations, and the immediate object of Hecker's investigation was to test its application to determinations made over great ocean depths. The problem of an oceanographic gravity survey has long fascinated geophysicists, because observations on board ship are practically made from the surface of the geoid, and should lead to the determination of the shape of that much-discussed figure; and what is also of importance, its solution should likewise lead to a knowledge of the extent to which isostatic compensation is complete over otherwise inaccessible parts of the globe.

Since observations of gravity must be made with great accuracy if they are to be of any value for such purposes, the examination of the gravitational acceleration at sea is attended by great difficulties; on a moving ship, rolling and pitching produce vertical accelerations which are individually indistinguishable from deviations from the true value of g. Reliance must therefore be placed upon suitable damping devices which will reduce the effect upon the instruments of such extraneous accelerations, or at least enable their mean value to be determined within narrow limits of error.

Hecker's original method depended upon the simultaneous measurement of the atmospheric pressure by means of a mercury barometer and a boiling-point apparatus; the latter determination is independent of the local value of gravity, and, if equated to ρgh for the mercury column, gives the necessary information for the evaluation of g. A fine constriction in the barometer tube provided a heavy damping factor which reduced the amplitude of the oscillations of the mercury surface; some of Hecker's instruments recorded photographically upon a moving film and provided a trace from which the normal level of the mercury might under favourable conditions be gauged.

Hecker considered that his observations showed that Helmert's formula held good within, roughly, one part in 30,000 for both deep and shallow seas, indicating a high degree of isostatic compensation; his conclusions have, however, been subject to a good deal of unfavourable criticism both on this and on the other side of the Atlantic, and it is true that disappointing inconsistencies appear in successive boiling-point determinations and in the simultaneous readings of the four barometers, which possessed different amounts of "lag," and that in certain other respects objections may be urged which prevent us from accepting the verdict on the evidence placed before us; nevertheless, it was pioneering work, and the difficulties to be encountered were largely unknown, and certainly untried, when the investigation was begun. Whether Hecker's conclusion be confirmed or refuted, those who follow will not fail to benefit by his early experiences.

With a view to a further oceanographic gravity survey, Hecker constructed apparatus based upon a different principle, one which had been unsuccessfully tested at sea by William Siemens in 1859. This time he used a barometer with a sealed cistern, so that the column of mercury should be supported by the pressure of the contained air; the cistern was immersed in a vacuum flask packed with cork shavings to keep the temperature, and therefore the pressure of the air, as steady as possible. Hecker arranged that four of these instruments should be mounted at the corners of a rectangular box containing apparatus for the photographic registration of the heights of the mercury columns. The box was mounted upon central gimbals, designed to maintain the barometers vertical as the ship rolled or pitched. It is clear that if the pressure within the cistern is known from temperature observations, the value of g is obtainable.

Lecturing in July, 1913, Prof. A. E. H. Love suggested that the voyage of the British Association to Australia in the following year might afford a valuable opportunity for once more testing the value of gravity at sea, and urged upon British astronomers and physicists the importance of the problem. His appeal proved irresistible. The time for preparation for so great an undertaking was very short; nevertheless, it was found possible, largely through the generous provision of instruments by the Meteorological Office and the Cambridge Scientific Instrument Co., to accumulate apparatus whereby tests could be carried out by three separate methods. Profs. Hecker and Helmert were anxious to have the instrument already described tested at sea, and willingly offered it for trial during the voyage; it was, therefore, brought from Strassburg in June, 1914, and installed on s.s. *Ascanius* in Liverpool.

Of the other pieces of apparatus one depended upon much the same principle as that of Siemens and Hecker—namely, the equilibrium of a column of mercury supported by air pressure within a closed vessel—but there were important differences; it was arranged that the lower surface of the mercury should always be brought to the same level in the cistern, an adjustment determined by an electric contact with a point which completed a telephone buzzer circuit. This ensured a constant volume for the enclosed air. The height of the barometer column was not directly observed, but estimated by measuring the length of the thread of mercury, which it was necessary to introduce into the apparatus through a fine capillary tube in order to secure contact at the lower surface. Assuming that the temperature remained constant, a defect in gravity would demand the addition of mercury in order to lengthen the barometer column sufficiently to balance the pressure of the air in the reservoir. The sensitivity could be made great by adopting a high ratio between the cross-section of the barometer tube and that of the capillary index tube through which the mercury was introduced.

A valuable suggestion for the improvement of this apparatus came from Sir Horace Darwin, who pointed out that the bulk of the difficulty occasioned by fluctuations of temperature might be overcome by employing such a volume of mercury within the apparatus that its expansion would automatically provide the additional height of mercury in the barometer tube necessary to balance the increase of pressure of the air in the reservoir due to a rise in temperature.

The third method consisted in comparing the readings of a mercury barometer with those of an aneroid; both were open to the atmosphere, and, as in the boiling-point method, we have the equation $\Pi = \rho g h$ to give us the variations of g, Π being now given by the aneroid, and h and ρ by the barometer and its attached thermometer. The aneroid was specially constructed and kindly lent by Sir Horace Darwin for this research. On board a ship the voyage of which carries it through many degrees of latitude one of the greatest difficulties is to obviate the effects of large changes of temperature. On the outward voyage this difficulty was very largely overcome by the generous installation by Messrs. Alfred Holt and Sons of a special refrigerating chamber on s.s. *Ascanius*, which served as an excellent laboratory. It was furnished with a separate system of brine pipes, and though at first there were rather large fluctuations, two engineers on day and night duty eventually became so adept at regulating the flow of brine that during the latter stages of the voyage the variation amounted to considerably less than one degree over a period of twenty-four hours, even though the observer was frequently within the chamber for an hour or more at a time. In future work it should, if possible, be arranged that it is not necessary for the experimenter to remain in the chamber for lengthy periods, as it is detrimental to health; but the experience does suggest that it is possible to overcome the very serious difficulty of maintaining a large room at an approximately steady temperature throughout the voyage.

Unfortunately, the outbreak of war at the time the British Association reached the shores of Australia led to the ship being commandeered for troops, so it was not possible to make use of this laboratory on the return voyage, and a good deal of the experience gained was wasted. A place was, however, found in the refrigerating chamber of the P. & O. R.M.S. *Morea* for all the apparatus, so the test was continued, though under very unfavourable conditions on the homeward journey.

It had scarcely been hoped, when the expedition was planned, to do more than obtain experience and information which would serve as a guide for future work upon gravity at sea, and more than this is not claimed for the results. Briefly, it may be stated that leaks which developed in Hecker's apparatus, and a troublesome temperature gradient between the cistern and the stem of the barometers, demand radical alterations in its design if it is to be rendered efficient. For the brief period of the voyage when the gravity barometer could be favourably observed, results were obtained which seemed to indicate that the method was one of promise, and it may be of interest to state that new apparatus of this type is in course of construction; the design has been modified in the light of experience gained at sea, and of a mathematical examination of the instrument by Sir Arthur Schuster. One specially favourable feature of the instrument is the possibility of completely immersing it in a constant-temperature bath.

Though the particular aneroid "pumped" with the motion of the ship more than was hoped, and had a reduction factor and zero which changed slightly during the voyage, the aneroid method is one which should be further examined, and certain directions in which alterations in the design are desirable were indicated by the experience on the voyage to Australia. With it the general variation of gravity with latitude over the ocean is readily shown, but whether it may be trusted to discriminate between such variations as may be found over deep and shallow waters must be a matter for further examination. We may note, as a matter of interest, that such indications as were obtained with this method suggested a defect of gravity over great ocean depths, along continental seaboards (especially when there was a coastal range of mountains), and an excess of gravity at island stations; but, as we have stated, a more rigorous test with improved apparatus is necessary before this can be accepted. The problem has therefore arrived at an interesting stage; Hecker's observations are in favour of nearly full compensation, whereas the slight evidence of the later work, so far as it goes, suggests that compensation is incomplete.

Reference has already been made to the instrument constructed in 1859 by William Siemens—in that year he was carried in a warship across the Bay of Biscay, his real object being the determination of ocean depths, which he took for granted would be shown by a diminished value of *g*. Dissatisfied with his first apparatus, he did not make a further attempt until 1875, when he constructed an instrument which depended upon balancing the pressure of a column of mercury against the tension of a spring, and this he tested on a cable-laying ship over a portion of the voyage between the Thames and Nova Scotia. The results, in spite of anomalies as regards latitude variation, which puzzled Siemens, show a surprising measure of agreement between predicted and observed depths, which, so far as they go, are in accord with the aneroid observations just referred to. This must not, however, be overemphasised, since Siemens was dissatisfied with this apparatus. Though not really directed at the solution of the problem under discussion—Siemens's "bathometers" were graduated in fathoms—these instruments are of interest in that they appear to have been the first involving gravity measurements to be submitted to an actual test at sea.

Since the Australian meeting of the British Association in 1914, further work has been carried out under the auspices of an influential committee of that body, and certain other points have received attention. From a series of experiments carried out last year on H.M.S. *Plucky*, it appears that the ship's motion through the air may very appreciably affect the pressure recorded by an open barometer, even when carried in cabins below deck; hence, as the "lag" of this instrument is in general different from that of the instrument with which it is being compared, it is very undesirable to adopt barometers of the open type for gravity determinations. On board the destroyer effects as large as one millibar were found to be due to the relative motion of the ship and the air; no doubt a similar disturbing influence affects the readings of a barometer in a building about which a wind is blowing.

Another matter which was examined on H.M.S. *Plucky* was the Eötvös effect; going east with the earth, the centripetal force is greater than when steaming west; consequently a correction for motion in longitude is indicated. After eliminating windage effects, a change equivalent to 0·1 mb. was observed when the course was altered from E. to W. when steaming at 22 knots.

There are other points the investigation of which is not yet complete: the best diameter of capillary tubing to be used in the barometer tube to damp down the effects of the ship's vertical motion, the influence of the throbbing of the ship's engines upon the barometer reading—there is some suspicion that certain divergences between gravity readings in harbour and in the open sea may be accounted for by the change in capillary forces due to this cause—the best form of constant-temperature chamber for use at sea, steady to 1/100 degree: these and allied questions are engaging the attention of those who are contemplating a fresh attack upon the problem.

Obituary.

Prof. H. A. Bumstead.

THE death of Prof. H. A. Bumstead, professor of physics in Yale University, which occurred with tragic suddenness on January 1 when he was travelling from Chicago to Washington, will be felt with the keenest regret by a large number of men of science in this country. There are few American men of science with more English friends than had Prof. Bumstead, and none whose friendship and companionship were more highly prized. Born in 1870, he graduated at Johns Hopkins in 1891. He began in 1893, as instructor in physics in Sheffield Science School, that connection with Yale which continued without interruption until his death, where, for fourteen years, he had been professor of physics and director of the Sloane Physical Laboratory. Prof. Bumstead was the most enthusiastic and devoted of Yale men. He came over to Cambridge in 1904, and worked for a year at the Cavendish Laboratory; the result of his work is contained in a paper in the *Philosophical Magazine* for June, 1906, p. 292, on the heating effects produced by Röntgen rays in different metals. On his return to America he made, in spite of serious ill-health, important researches on the properties of α-rays.

Excellent as Prof. Bumstead's published work is, it gives but an inadequate idea of his powers, or of his singularly clear and sane judgment. He edited the collected works of Willard Gibbs—the greatest physicist ever associated with Yale. When America joined in the war, he threw all his energies into the application of science to the purposes of the war, and at the end of 1917 he came over to this country as Scientific Attaché to the American Embassy. Prof. Bumstead's duties were to co-ordinate the scientific work done in America and in England and France, so that the results obtained in one country should be as soon as possible at the services of the others. For this work his personal qualities and scientific attainments made him especially fitted, and he did most valuable work whilst he was in this country. He was at the time of his death president of the National Research Council in the United States.

Prof. Bumstead had a singularly attractive and charming personality. Sympathetic, modest, without a trace of self-assertion, he was the most delightful companion and most valued friend.

J. J. T.

PRINCE P. A. KROPOTKIN.

THE death of Prince P. A. Kropotkin at Dmitrov, near Moscow, on Friday last, January 28, deprives the world of a picturesque figure and science of a devoted student. For many years Prince Kropotkin was an esteemed contributor to the columns of NATURE, and when he left England to return to Russia in 1917 he wrote to express regret that the very close relationships which had existed between him and us for so long were being severed. He said at the same time that he had been a reader of NATURE from the first number, and had even been permitted to receive it while a prisoner in the fortress of St. Peter and St. Paul in St. Petersburg.

Prince Kropotkin was born on December 9, 1842. At the age of fifteen he entered the select military school at St. Petersburg; on leaving he joined a Cossack regiment stationed on the Amur, and while aide-de-camp to the commander of the General Staff in Eastern Siberia, he crossed North Manchuria from Transbaikalia to the Amur and up the Sungari to Kirin, travelling in all as many as 50,000 miles. In 1867 he abandoned a military career, and returned to St. Petersburg, where he entered the University, and devoted himself seriously to geographical work. He then became closely associated with political movements, and gave himself up to propaganda. In 1873 he was arrested and imprisoned, but escaped in the following year and made his way to England, shortly afterwards going to Switzerland. After the assassination of Alexander II., Kropotkin was expelled from Switzerland, and settled in Savoy, where he was arrested in 1883 on a charge of organising a dynamite outrage, and was condemned to five years' imprisonment, but was released in 1886. He then returned to England, and remained here until June, 1917.

In 1876 Kropotkin published his "Researches on the Glacial Period," in which he described a journey in Finland and a short visit to Sweden, both made in 1871, under the auspices of the Russian Geographical Society, for the special purpose of studying the glacial formations and the eskers. His conclusions were that this low tableland was once covered by an immense ice-sheet, which, creeping from Scandinavia, crossed the Gulf of Bothnia and traversed southern Finland in a direction south by east, leaving behind it the marks of its course in the shape of numberless striæ and moraines.

Perhaps Kropotkin's most notable work was "Mutual Aid, a Factor in Evolution," published in 1902. The view put forward was that in the case of animals there is very little evidence of any struggle for existence among members of the same species, though plants, beyond all doubt, jostle their own kin out of existence. Animals, as a rule, are banded together for mutual protection, and those that have the best organisation for mutual defence are those that thrive best. Among men, mutual aid is more general than among animals; among savages, it is the chief factor in evolution. Kropotkin traced the growth of the modern benefit societies, co-operative associations, and trade unions back through successive stages of the history of a nation—through the State, the medieval city with its fortifications and hired defenders, the village communities, and finally to the clan, showing how man has attained his present position chiefly by practising mutual aid. There is no doubt that in the development of this thesis Kropotkin was keenly interested, and that the work itself represents, more closely than anything else he did, the main trend of his conception of the meaning of life and progress.

Kropotkin was a pioneer advocate of the intensive cultivation of crops, and in a suggestive little book entitled "Fields, Factories, and Workshops" he described what was done in this direction in Guernsey, as well as indicated how similar principles of culture could be applied elsewhere. His view was "that 600 persons could easily live on a square mile, and that with cultural methods already used on a large scale 1000 human beings —not idlers—living on 1000 acres could easily, without any kind of overwork, obtain from that area a luxurious vegetable and animal food, as well as the flax, wool, silk, and hides necessary for their clothing."

These two latter works reveal Kropotkin's unbounded faith in man and his hope for a high human destiny through the reconstruction of society and communal production. His knowledge extended over a wide scientific field, and his interest in its advancement never failed. His many friends in this country will long cherish his memory with affection and esteem.

The death occurred, on January 18, of Mr. Rupert Farrant, at the age of thirty-six years. Mr. Farrant was educated at the Westminster Hospital, and he studied also at King's College and St. Bartholomew's Hospitals; after he had qualified as a practitioner in 1906, he held many resident posts in various London hospitals. In 1909 he was made a fellow of the Royal College of Surgeons, and on two occasions he delivered Hunterian lectures at the college. Mr. Farrant made a special study of the ductless glands, especially of the thyroid, in connection with the general metabolism of the body, and he put forward a theory of a correlated cycle of changes in the histological appearance and functional activity of the gland under the influence of toxins. He saw active service at Gallipoli, in Egypt, in Mesopotamia, and in France, where he received injuries by a shell explosion, from the concussion of which he never completely recovered.

It is with deep regret that we learn of the sudden death, on January 31, in his fiftieth year, of Dr. J. C. Cain, editor of the Chemical Society's publications since 1906, and author of leading works on synthetic dyestuffs and intermediate products.

We much regret to announce the death, on January 30, at sixty-five years of age, of Mr. C. E. Fagan, secretary of the British Museum (Natural History), to whose expected retirement after a long period of devoted service reference was made in our Notes columns on January 13, p. 638.

Notes.

The gold medal of the Royal Astronomical Society has been awarded by the council to Prof. H. N. Russell for his contributions to the study of stellar evolution. It will be presented to Prof. Russell at the annual general meeting to be held on Friday, February 11, when the president of the society, Prof. A. Fowler, will deliver an address on the notable work for which the award has been made.

The Lords Commissioners of the Treasury have appointed Sir Robert Robertson, K.B.E., F.R.S., Director of Explosives Branch, Research Department, Woolwich, to be Government Chemist in succession to Sir J. J. Dobbie, who has retired.

A memorial lecture on the life and work of the late Sir William Abney is to be delivered to the Royal Photographic Society of Great Britain by Mr. Chapman Jones. April 26 next has been provisionally fixed for the date.

The council of the Chemical Society has arranged to hold the anniversary dinner at the Hotel Cecil on Thursday, March 17 (the day of the annual general meeting), at 7 for 7.30 p.m., and to invite, as guests of honour, the past-presidents who have attained their jubilee as fellows of the society.

Dr. W. R. G. Atkins, of Trinity College, Dublin, has been appointed head of the department of general physiology at the Plymouth Laboratory of the Marine Biological Association.

Sir Norman Moore, president of the Royal College of Physicians, has appointed Dr. Herbert Spencer to deliver the Harveian oration on St. Luke's Day (October 18), and Dr. Michael Grabham, of Madeira, to deliver the Bradshaw lecture in November. The council has appointed Dr. Major Greenwood to deliver the Milroy lectures in 1922.

A discussion on gravity at sea will be held in the rooms of the Royal Astronomical Society, Burlington House, to-morrow, February 4, at 5 p.m. The chair will be taken by Sir Arthur Schuster. Prof. W. G. Duffield will open the discussion, which will be continued by Sir S. G. Burrard, Dr. H. Jeffreys, Dr. J. W. Evans, and Dr. A. Morley Davies.

A special joint meeting of the Society of Chemical Industry and of the Institution of Mechanical Engineers will be held at the rooms of the institution, Storey's Gate, Westminster, S.W.1, on Friday, March 4, at 6 p.m., when M. Paul Kestner, president of the Société de Chimie Industrielle, will read a paper on "The De-gassing and Purification of Boiler Feed-water."

At the meeting of the London Mathematical Society to be held in the rooms of the Royal Astronomical Society at Burlington House, W.1, on Thursday, February 10, at 5 p.m., Prof. A. S. Eddington will deliver a lecture on "World Geometry." The lecture will be concerned with the mathematical side of the general theory of relativity, with especial reference to electricity and gravitation and the work of Prof. H. Weyl. Visitors from other societies will be welcome.

In the issue of Nature for January 27 there appeared an illustration (p. 699, Fig. 2) of a sculptured group from the decoration of the building of the Institute of Human Palæontology in Paris. The official description which was supplied with the photograph stated, no doubt by inadvertence, that the anthropoid forming part of the group was an orang-utan. A close inspection, however, shows that it is undoubtedly a gorilla.

Science of January 14 announces that the Rockefeller Foundation has given to France complete control over the elaborate anti-tuberculosis organisation established in the Department of Eure-et-Loir at a cost of 4,000,000 francs. The organisation consists of twenty-four dispensaries, four complete isolation services, and a departmental sanatorium and laboratory. The system will serve as a model for similar organisations to be established by the Government throughout the country. The Rockefeller Foundation is now assisting in the anti-tuberculosis campaign in thirty-eight of the eighty-seven Departments of France, and work is contemplated which will last for another two years.

At the annual general meeting of the Royal Meteorological Society on January 19 the following were elected officers and members of council:—*President:* Mr. R. H. Hooker. *Vice-Presidents:* Mr. J. Baxendell, Mr. W. W. Bryant, Sir Napier Shaw, and Dr. E. M. Wedderburn. *Treasurer:* Mr. W. V. Graham. *Secretaries:* Mr. J. S. Dines, Mr. L. F. Richardson, and Mr. G. Thomson. *Foreign Secretary:* Mr. R. G. K. Lempfert. *Councillors:* Mr. C. E. P. Brooks, Capt. C. J. P. Cave, Mr. J. E. Clark, Mr. R. Corless, Dr. H. N. Dickson, Mr. G. M. B. Dobson, Mr. F. Druce, Mr. J. Fairgrieve, Mr. H. Mellish, Mr. M. de C. S. Salter, Dr. G. C. Simpson, and Mr. F. J. W. Whipple.

The Minister of Health, with the concurrence of the University Grants Committee, has appointed a Committee "to investigate the needs of medical practitioners and other graduates for further education in medicine in London, and to submit proposals for a practicable scheme for meeting them." The members of the Committee are as follows:—The Earl of Athlone (chairman), Mr. H. J. Cardale, Sir Wilmot Herringham, Sir George Makins, Sir George Newman, Sir Robert Newman, Sir Edward Penton, Sir E. Cooper Perry, Mr. J. Dill Russell, and Dr. T. W. Shore. Mr. A. L. Hetherington will act as secretary of the Committee, and all communications should be addressed to him at the Ministry of Health, Whitehall, London, S.W.1.

At a meeting of the award committee, consisting of the presidents of the principal representative British engineering institutions, held in London on Tuesday, January 25, the first triennial award of the Kelvin gold medal was made to Dr. W. C. Unwin, who was, in the opinion of the committee, after consideration of representations received from leading engineering bodies in all parts of the world, the most worthy to receive this recognition of pre-eminence in the branches of engineering with which Lord Kelvin's scientific work and researches were closely identified. The arrangements for the presentation of the medal will be announced shortly. The Kelvin gold medal was established in 1914 as part of a memorial to the late Lord Kelvin and in association with the window placed in Westminster Abbey in his memory by British and American engineers.

The members of Mr. L. H. Dudley Buxton's expedition have now returned from a stay of some weeks in the Island of Malta. The object of the expedition was to collect material for a study of the physical anthropology of this island. About 1000 adults, men and women, were measured. The fine series of ancient bones which Prof. Zammit excavated in the Hypogæum at Hal-Saflieni and elsewhere was collected together and measured. A long series of skeletal remains from a modern ossuary was also examined. A special visit, lasting for two days, was paid to Gozo by Mrs. Jenkinson and Miss Moss to work at the physical anthropology of that island. The expedition has collected an immense mass of valuable material, which will take some time to arrange and digest. As soon as this work is sufficiently far advanced Mr. Buxton hopes to submit a preliminary account of the results of the expedition to the Royal Anthropological Institute.

At an extraordinary general meeting of the Chemical Society held in May, 1919, for the purpose of dealing with various modifications of the by-laws, amongst which was the provision for the admission of women as fellows on the same terms as men, the council was authorised to apply to the Crown for a supplemental charter giving the power to make the necessary alterations in the by-laws. The petition for the supplemental charter received the assent of his Majesty the King, and all the additional powers sought by the society were thus secured. The new by-laws recommended by the council received the approval of the general body of fellows at an extraordinary general meeting held on April 29, 1920, and came into operation on June 1. At the ballot for the election of fellows held on December 2 last, of the ninety-seven who were elected fellows twenty-one were women, and amongst the candidates for whom a ballot will be held on February 17 appear the names of six women.

Reference was made last week to correspondence in the *Times* on the effects of the discharge of oil from ships into the sea. Oil enters the sea in various ways, *e.g.* the "steaming-out" of the "tankers" and accidental leakages. The "benzene" oils must evaporate quickly, but the heavy fuel-oils may be more persistent. So far the evil is local, and there is no evidence of any widespread effect upon the larger fisheries. Sir Arthur Shipley suggests, on the authority of Prof. A. Meek, that 1916–17–18 were bad years for plaice fry, and that some factor was in operation during that period which was detrimental to fish-life. This factor may have been the discharge of oil from sunken ships. On the other hand, there is strong statistical evidence that plaice were more abundant in the North Sea during the years 1919–20 than during the years immediately before the war. This is also the case in the Irish Sea, 1910 being a maximum, 1918 a minimum, while 1920 and 1921 tend towards another maximum. Prof. H. E. Armstrong refers to the failure of the Loch Fyne herring fishery, and suggests that this was due to "floating defilement from the Clyde," but the herrings are now returning to Loch Fyne. The question is a very complex one, and investigation is obviously called for. In connection with the subject discussed, Lord Rayleigh refers in the *Times* of January 27 to experiments made by his father in 1889, which showed that a continuous film of oil on the surface of water need not be so much as a ten-millionth part of an inch in thickness. "On the basis of his figures it may be calculated that the ocean could be covered by 500,000 tons of oil—not beyond the carrying power of a fleet of very large ships."

SIR ROBERT HADFIELD contributed recently an article to the *Iron and Coal Trades Review* on "The World Hunger for Steel." It appears that in 1913 the exports of steel from the three chief steel-producing countries were as follows:—Germany, 5,500,000 tons; Great Britain, 5,000,000 tons; and the United States of America, 2,750,000 tons. Against this the estimates of the exports in 1920 were as follows:—Germany, 200,000 tons; Great Britain, 3,300,000 tons; and the United States, 4,300,000 tons. The statistics of production reinforce the lesson given by the export figures. In 1913 the world's production in pig-iron amounted to about 76,000,000 tons; last year it is estimated to have been not more than 56,000,000 tons. Taking these figures as well-founded, it will be recognised readily that the world is very short of supplies of iron and steel. Sir Robert Hadfield points out that this shortage is a very serious matter, and that the development of modern civilisation must be greatly hindered unless increasing supplies can be obtained. He estimates the shortage of steel at from 25,000,000 tons to 30,000,000 tons. He then goes on to consider the question of costs of production, and points out how vital is the price of fuel. Two months ago it is estimated that the cost of coal at the pit's mouth in this country was 34*s.* a ton, whilst in America it was about half that figure. In both countries it takes about 1¾ tons of coal to produce 1 ton of iron. There are, however, countries where coal is produced more cheaply than in America, and Sir Robert states that in South Africa, India, and China it is being raised and sold at very little more than 5*s.* a ton. In spite of these considerable differences of price, he holds the view that there is no reason why there should not be a greatly increased production in this country owing to the demand caused by the shortage of steel, which has been emphasised. Whether this will prove to be the case depends principally upon the extent of co-operation between employers and employed.

FROM the *Brooklyn Museum Quarterly* for April, 1920, we learn that the expedition sent by that museum to make collections in the coastal waters of Peru has been most successful. Mr. R. C. Murphy, who was in charge of the expedition, reports large collections of marine animals and plants and geological specimens. A series of kinematograph pictures of wild life on the coast and of the Peruvian guano industry was also obtained. Special attention was paid to the investigation of the conditions of marine life dependent on the Humboldt current.

IN the *Museums Journal* for January Mr. E. N. Fallaize formulates a scheme for the classification of the subject-matter of anthropology, in which human structure and activities rank before divisions of time and space. The reasons for the arrangement are discussed, and the actual scheme will follow in the February issue. The Headmaster of Winchester gives sound advice on lantern-slides of Renaissance art; Prof. Aldred Barker, of Leeds, reviews a guide to carpet-knotting and weaving; and Mr. R. L. Hobson, of the British Museum, writes on Pountney's "Old Bristol Potteries." A technical criticism of the Wallace Collection from the museum curator's point of view, and other reviews and notes, make up an interesting number. Dr. Bather, who has taken charge of the journal for ten months, now hands over the editorship to Mr. J. Bailey, who is retiring from the Victoria and Albert Museum.

WE have recently received the July number (vol. ii., No. 3) of the *Queensland Naturalist*, which, owing to the difficulties of the past few years, has been in abeyance since April, 1917. It is the organ of the Queensland Field Naturalists' Club, and is described in the foreword of the present number as the only journal of its kind published in a State which is, from a natural history viewpoint, probably the richest field in the whole of Australia. The editor refers to the success of the club in initiating or aiding efforts for the better protection of the fauna and flora of the Macpherson and Bunya ranges, and of particular birds and animals. Among the short articles included in this number is a description of a new fossil plant from Petrie's Quarry, near Brisbane, and a critical account, by Mr. C. T. White, of two native phalloid fungi, one of which is endemic in South-Eastern Queensland.

THE myriopods, or more correctly the Diplopoda, of the sub-family Pyrgodesminæ, are small creatures from ¼ in. to ⅜ in. long, with the back curiously covered with processes or tubercles, and bearing also bristles or papillæ. These latter gather the dirt, and often so encrust the body as to mask its form and merge its colour in that of the ground, so, though they cannot really be rare, from the Orient we have hitherto known representatives of only two genera, the Pyrgodesmus and Lophodesmus of Pocock (1892). Now in the Records of the Indian Museum (vol. xix., part 4) Dr. F. Silvestri describes five new genera based on species from Cochin, Ceylon, and New Guinea. His Latin descriptions are illustrated by excellent drawings, which, in the absence of an artist's name, we must assign to the author's own pen. Some of these show the body *humo indutum*, others *humo denudatum*.

IN spite of war difficulties, Dr. Annandale, in his Report on the Zoological Survey of India for the years 1917–20, has been able to record an amount of work important in itself and remarkable as conducted by a scientific staff of four persons only. The purely zoological inquiries happened to deal with various aspects of river- and lake-life. Thus the return to India of troops infected with Schistosoma and the fears that the infection might spread led to an extensive search for possible molluscan hosts; the results, fortunately negative, saved the expenditure of large sums of money on needless precautions. Some interesting points of wider application crop up in some of these investigations. The resemblance of the fauna in a muddy creek of the Ganges to that of the deep sea is assigned by Dr. Kemp to the common factors of a muddy bottom and low visibility. The discovery that the peculiar sculpture of the shell in certain Viviparidæ is connected with the persistence of structures present on the edge of the mantle in the embryos of smooth-shelled forms bears on the origin of the varied ornament in those molluscs. These and many other interesting results have suggested to Dr. Annandale the need for a survey of the macroscopic fauna of the lakes of Asia.

At the request of Alderman F. C. Clayton, some members of the botanical department of Birmingham University visited the Birmingham Water Department's reservoirs at Shustoke, near Whitacre, on October 14 last. The water in the smaller of the two reservoirs (about 8 acres in extent) had been drained off at the end of July for cleaning purposes, leaving the bottom covered to a depth of 1½ ft. to 2½ ft. with a mixture of vegetation and mud. The small reservoir had not previously been cleaned, except at the sides, since its completion in 1883. The vegetation appeared to have consisted mainly of green algæ, together with a number of aquatic flowering plants and a marginal zone of *Fontinalis antipyretica*. The algæ were represented by a number of genera, *Cladophora fracta* being the dominant species. An allied species, probably a form of *C. crispata*, occurs regularly in the slow sand filter-beds at the neighbouring waterworks. During the cooler months this alga often covers the bottoms of the filter-beds with a matted felt of algal filaments, locally known as "blanket weed." So long as the alga remains on the bottom it appears to assist materially in the process of filtration. On the advent of hot weather the alga tends to rise, and has to be removed. Another feature of interest is the very rapid colonisation by plants of the drying, muddy bottom of the reservoir. Although only some two and a half months had elapsed since the lowering of the water-level, the surface of the mud was already occupied by an open association of plants which included algæ, together with patches of stunted land forms of aquatic flowering plants. In addition to the true aquatics, semi-aquatics, and even land plants, were spreading rapidly in a centrifugal direction over the surface.

On Friday, January 28, a general meeting of the Association of Economic Biologists, presided over by Sir David Prain, was held in the Imperial College of Science. Mr. E. E. Green showed a large Gasteropod which has been introduced into Ceylon, and is now present in destructive numbers. Dr. Llewellyn Lloyd gave an account of his investigations on the greenhouse white-fly and measures for its control, and described interesting new details in the structure and life-history of the insect. The only successful treatment is hydrocyanic fumigation, this being carried out at intervals of fourteen days in summer and of twenty-five days during the winter months. Light is a very important factor; the temperature should be between 40°–60°, and the dosage ¼ oz. of sodium cyanide to every 1000 cubic ft. space. Atmospheric humidity is relatively unimportant, but if cyanide-burning of the foliage is to be eliminated the plants should have dry roots. An animated discussion took place, in which Mr. Green, Prof. V. H. Blackman, Dr. Imms, Dr. Hargreaves, Mr. Dykes, and Mr. Emptage participated. Mr. Brierley then gave a paper on "Personal Impressions of some American Biologists and their Problems." Mr. Brierley was one of the three foreign representatives invited to the American Phytopathological Congress in 1920, and afterwards visited the principal scientific institutions and many regions of botanical or agricultural interest.

The system of colour notation introduced by Munsell in 1905 has been found of such practical value by the manufacturers of colours and of coloured goods in America that the U.S. Bureau of Standards has undertaken an examination of the system with a view to its improvement. An account of the work done by Messrs. Priest, Gibson, and McNicolas forms Technologic Paper No. 167 of the Bureau. Colours are specified by their hue, their purity or chroma, and their brightness, luminosity, or "value," and the Munsell atlas contains coloured cards of six different hues—grey, red, yellow, green, blue, and purple—each in different degrees of purity and luminosity. These cards have been examined by means of the spectrophotometer, and curves which show the amount of light reflected of each wave-length are given. From these it appears that the Munsell "values" are proportional to the square roots of the amounts of sunlight reflected, and the authors suggest that in future editions of the atlas the numbers indicating the luminosities should be proportional to the logarithms of the reflections. In order to secure this and other suggested improvements, the Optical Society of America and the Bureau are now consulting those interested in colours.

One of the largest steel-frame buildings which have been constructed by welding methods in Great Britain is illustrated in *Engineering* for January 14. This building constitutes the new workshops of Messrs. the Double Arc Electric Welders, Ltd., and is situated in Glasgow. The steelwork throughout was welded by the company on its system. The name of this firm is derived from the special flux with which it coats its welding electrodes. The flux is conducting, and it is claimed that an independent arc is formed between the flux and the work, as well as the arc between the electrode and the work; this gives the double arc. The building is 27 ft. wide and 50 ft. long; there are five roof principals carried on columns having welded-on bases. The roof principals are built of angles and channels, both of which members are welded to the webs of the columns. The secondary members of the trusses, together with purlins, etc., are all welded at the points of attachment. Even the steel door-frames are welded. Electric welding would appear to offer many points of advantage in the field of construction, and is obtaining a sound footing.

The latest catalogue (No. 409) of Mr. F. Edwards, 83 High Street, Marylebone, W.1, consists of particulars of nearly a thousand books, maps, engravings, and drawings relating to North America (United States and Canada). Many items will be of interest to readers of NATURE, *e.g.* a number of works on the Indian tribes of North America, Audubon's "The Birds of America," the very rare book by T. Morton entitled "New England Canaan, or New Canaan," and the silver ticket of Benjamin Franklin's membership of the Royal Society of Edinburgh. The catalogue will be sent free of charge by the publisher.

IN the Fauna of British India Series the further volumes which the editor, Sir Arthur E. Shipley, with the assistance of Dr. Guy A. K. Marshall and the sanction of the Secretary of State for India, has arranged for are: Butterflies (Lycænidæ and Hesperiidæ), Mr. N. D. Riley; The Ixodidæ and Argasidæ, Prof. G. H. F. Nuttall and Mr. C. Warburton; Leeches, Mr. W. A. Harding; The Diptera Brachycera, Mr. E. Brunetti; The Operculata, Mr. G. K. Gude; The Curculionidæ, Dr. G. A. K. Marshall; The Carabidæ, Mr. H. E. Andrewes; The Meloidæ, Mr. K. G. Blair; The Erotylidæ and Endomychidæ, Mr. G. J. Arrow; The Culicidæ, Capt. P. J. Barraud, Major S. R. Christophers, and Mr. F. W. Edwards; The Chrysomelidæ, Mr. S. Maulik; The Oligochætæ, Lt.-Col. J. Stephenson; The Scolytidæ and Platypodidæ, Lt.-Col. Winn Sampson, together with a revised edition of Mammalia by Mr. Martin A. C. Hinton and Mr. R. C. Wroughton, and of Birds (4 vols.) by Mr. E. C. Stuart Baker.

THE list of new books and new editions added to Lewis's Medical and Scientific Circulating Library during October to December, 1920, has reached us from Messrs. H. K. Lewis and Co., Ltd., 136 Gower Street, W.C.1. Although intended primarily for subscribers to the library, it should be of great service to all who wish to keep in touch with medical and scientific literature, being practically a complete catalogue of important books in English on medicine and science issued during the period named. It is carefully classified according to subjects, and will be sent gratis upon application.

MESSRS. L. OERTLING, LTD., Turnmill Street, London, E.C.1, ask us to announce that they are recommencing their service of attendance to balances in customers' own laboratories throughout the United Kingdom. This service was discontinued during the war owing to the extreme pressure of work in the firm's manufacturing departments and to the lack of mechanics possessing the necessary technical ability.

Our Astronomical Column.

PLANETS NOW VISIBLE.—In the second week of February all the bright planets will be visible to the naked eye. Venus, Mars, and Mercury will be in the western sky, while Jupiter and Saturn will appear in the eastern.

Mercury will be at greatest elongation on February 15, when it sets about $1\frac{3}{4}$ hours after the sun. Venus will set on February 13 at 9.40 p.m., and Mars at 8.32 p.m. On February 9 the crescent of the new moon will be in conjunction with Mercury, and with Mars on February 11. Venus will be a very conspicuous object, but Mars will appear unduly faint, owing to its great distance from the earth.

Jupiter rises on February 14 at 7.33 p.m. and on February 28 at 5.52 p.m., while Saturn rises about 40 minutes later. These objects are situated in the southern part of Leo, and will be in the same region as the moon on February 23.

THE DIAMETERS OF STARS.—*Popular Astronomy* for January states that the observations of the diameter of Betelgeux were made on December 13 by Mr. F. G. Pease and Dr. J. A. Anderson, the method being due to Prof. A. A. Michelson. The measured diameter is given as 0·047″.

Prof. H. N. Russell, before the result was known, published the following estimates of the angular diameters of the brighter red stars:—Betelgeux, 0·031″; Antares, 0·028″; Aldebaran, 0·024″; Arcturus, 0·019″; β Crucis, 0·026″; and β Gruis, 0·020″. All these are within the range of possible measurement. The angular diameters of the stars of types A, B, and F are very much smaller (Sirius being 0·007″), and there is little prospect of success with them.

It is of interest to note that the parallax of Arcturus has recently been redetermined at Yerkes Observatory by Messrs. O. J. Lee and G. van Biesbroeck (*Pop. Astr.*, January). The result, 0·095″±0·006″, is larger than previous values. Russell's angular diameter would imply a linear diameter of one-fifth astronomical unit, or twenty-two times that of the sun. The thwart velocity would be 24 astronomical units per annum, or 70 miles/sec.

MINOR PLANETS.—The remarkable body HZ was observed at Algiers, January 12·3, in R.A. 0h. 17·5m., N. decl. 26° 52′, mag. 13·8. The planet has now been under observation for $2\frac{1}{2}$ months, and the orbit already published in this column, with perihelion near Mars and aphelion near Saturn, is fully confirmed. Such an orbit is obviously of a cometary character, yet careful scrutiny has failed to show any sign of nebulosity.

Nine hundred and thirty-three minor planets have now received permanent numbers. The difficulty of keeping such a large number under regular observation is considerable, so it is satisfactory to note that tables giving the approximate perturbations by Jupiter of about 100 planets have lately been published in *Astr. Nachr.*, which should be of great assistance in preparing accurate ephemerides. One planet in particular, 170 Maria, has been studied in great detail by K. Boda (*Astr. Nachr.*, 5080). This belongs to the Hestia type (period about $\frac{1}{3}$ of Jupiter's), and has small eccentricity, but considerable inclination. The tables are compared with observations from 1877 to 1916. The largest residuals (Obs.—Tab.) are + 58″ in 1889 and − 50″ in 1904. Greater accuracy could not be attained without very elaborate tables.

The chief centres of minor planet observation during the past year have been Algiers (MM. Gonnessiat and Jekhowsky), Barcelona (Prof. Comas Sola), Heidelberg (Dr. Max Wolf), and Hamburg. Marseilles observatory has assisted by circulating observations and ephemerides.

The London School of Tropical Medicine.

THE London School of Tropical Medicine, which in its new domicile in the Hospital for Tropical Diseases in Endsleigh Gardens, Euston Road, London, recently, under Royal auspices, commemorated its nativity, came into being twenty-one years ago.

The idea of a school emanated from Sir Patrick Manson, who at the time was Medical Adviser to the Colonial Office; it was at once grasped by his far-seeing official chief, the late Right Hon. Joseph Chamberlain; and it was aptly embodied forthwith in the benign fabric of the Seamen's Hospital Society, the solicitude of which for the brotherhood of the sea includes all the tropics in its range.

FIG. 1.—The museum, London School of Tropical Medicine.

Not only did the society accept the idea, it also magnanimously advanced the funds needed for its realisation, and in October, 1899, the young school was actually established, under the ægis of Sir Patrick Manson, as an adjunct to the society's branch hospital at the Albert Dock.

The school was, above all, designed to give practical training in the fundamental laboratory methods of investigating disease while keeping the laboratory in touch with the wards of the hospital, and collating the lessons of laboratory and clinic in set lectures by specialists versed in the medical and sanitary problems of the tropics, the ultimate object being not merely to teach a class how the prevalent diseases of tropical countries are recognised and treated, but also to train the individual man for the experimental investigation of disease in the course of his own career and field of opportunity abroad. It was, moreover, recognised as a vital necessity that members of the teaching staff should go afield from time to time in order to keep in touch with tropical diseases in their endemic areas.

In the early days of the school the main laboratory course was, perforce, conducted by a single whole-time teacher; but as—thanks to the powerful advocacy of Mr. Joseph Chamberlain—the financial position improved, additional whole-time teachers were appointed, a helminthologist and a protozoologist in 1905 and a medical entomologist in 1907, and so gradually the laboratory teaching became both fuller and more intensive.

Thus prior to the war the school in its sequestered situation at the docks had assumed its present stature, if not its present finish. It had been affiliated to London University; the practical worth of its curriculum was held in world-wide regard by the medical profession; its bead-roll included the names of nearly two thousand students drawn from every medical vocation and medical service in the tropical Dominions, as well as from many foreign countries; it had undertaken fifteen oversea expeditions for the study of specific pathological problems; and it was steadily countenanced by annual grants from official sources. That at this stage the school had also acquired public esteem outside official and professional circles may be inferred from the benefactions for the advancement of knowledge that were entrusted to its administration. In 1909 a scholarship of the annual value of 50*l.* was founded by Lord and Lady Sheffield; in 1912 a munificent bequest of 10,000*l.* by Lord Wandsworth was allotted by Sir William Bennett for the institution of a scholarship; and in the same year a sum of 70,000*l.* was collected for general purposes by Mr. Austen Chamberlain as a filial tribute to the memory of the founder.

FIG. 2.—A portion of the class laboratory, London School of Tropical Medicine.

The war, which revealed so clearly to this island its dumb dependence on the unconquerable soul of the merchant seaman, brought at its close to the Seamen's Hospital Society a practical expression of gratitude and admiration so full as to reflect some of its splendour on the society's Tropical School. As a tribute to the dauntless spirit maintained during the war by the merchant seaman, the British Red Cross Society and the Society of St. John together gave to the Seamen's Hospital Society the sum of 100,000*l.* for the purchase of the large building in Endsleigh Gardens which had been used in war-time as an officers' hospital, and for its endowment as a hospital in the first instance for sailors and soldiers who had contracted tropical diseases on service, and ultimately for the sailors in perpetuity. Room in this new Hospital for Tropical Diseases being available, the society decided that the kindred school should be included in the project. This decision was applauded by the school's sponsors at the Colonial Office, and by the stimulating influence of Lord Milner it attracted the necessary financial co-operation of a liberal and appreciative section of the public. Early in the year 1920, therefore, the school was translated from the remote, uncouth neighbourhood of the docks to an accessible London quarter strong in academic associations.

Re-established under such favourable auspices in a central position, the school now prosecutes its original design in all its fullness with an ampler staff and equipment. The well-avouched scheme of a main laboratory course, supplemented by clinical demonstrations and a system of lectures, is unchanged, as it both meets the wants of the man who already has some knowledge of tropical conditions and inspires the man to whom tropical responsibilities are prospective. The clinical instruction, moreover, which appeals so strongly to the practitioner coming home for a season for professional rejuvenation, is improved by the institution of a special clinical laboratory attached directly to the hospital and administered by its staff.

It is, however, to the advanced student—to the inquirer whose interests are not entirely engrossed in medical practice and who appreciates the unlimited opportunities for research that the tropics afford—that the recent developments of the school are more particularly adapted. The departments of protozoology, medical entomology, and helminthology have been reconstituted as distinct units, leaving the original nucleus of tropical pathology as a fourth independent unit. Each unit has its own director, assistant, and subordinate staff, and is equipped to accommodate the individual student who contemplates pursuing some special line of study abroad, or desires to work out particular material collected abroad, or has some set object of his own outside any participation in the general laboratory course in which all the departments co-operate as before. By this arrangement, which also permits a director or an assistant alternatively to go abroad without disturbance of the home routine, research in tropical medicine is doubly seconded. The advanced or special student will also benefit by the proximity of the Tropical Diseases Bureau, which is now housed with the school, and is about to permit a considerable part of its books and serials to be incorporated, as a permanent loan, in a common library.

The changes thus briefly outlined, however, illustrate that inexorable concatenation of pain with pleasure which supplied one of the texts of Socrates' valedictory discourse; for much as the school has gained by its removal, it has lost—for the present, whatever recompense may lie in the womb of Time—the mess and all the concurrent social amenities which graced its old home in the wilderness.

New Experiments on the Inheritance of Somatogenic Modifications.

By Prof. Arthur Dendy, F.R.S.

IT has long been suspected that the problem of the transmission from parent to offspring of somatogenic modifications ("acquired characters") might be solved more readily by physiological experiments directly involving the complex metabolism of the body than by crude surgical operations such as the amputation of limbs. This suspicion has been justified in a remarkable manner by the work of Messrs. M. F. Guyer and E. A. Smith, recently published in the *Journal of Experimental Zoology* under the general title "Studies on Cytolysins."[1] The physiologists, through their brilliant investigations of serum reactions, have placed a whole armoury of new weapons in the hands of the zoologist, and have even furnished him with a chemical means of determining the degree of relationship, and consequently the correct systematic position, of different "species" of animals. We now have to thank them for giving us a new means of approach to what is perhaps the most difficult problem in biological science.

It has been known for some time that the injection of foreign proteids into the blood of a vertebrate animal calls forth a most profound physiological response, and Messrs. Guyer and Smith have taken full advantage of this knowledge in devising their experiments. Bordet showed a quarter of a century ago that when the red corpuscles of the rabbit are repeatedly injected into the blood of the guinea-pig the latter acquires the power of destroying them, and serum prepared from these "sensitised" guinea-pigs will rapidly dissolve the red corpuscles of the rabbit *in vitro*, while the serum of untreated guinea-pigs has little or no effect. This experiment formed the commencement of our knowledge of a whole class of substances known as "cytolysins," which appear in the blood as the appropriate "antibodies" in response to the injection of such substances as red corpuscles, leucocytes, nervous tissue, spermatozoa, and crystalline lens, all of which, "when injected into the blood of an unrelated species, will form lytic substances more or less specific for the antigen used in the sensitising process," the antigens being presumably the characteristic proteids of the substances injected.

The "antibody" or "antitoxin" may be produced in large excess of the amount actually required to destroy the injected foreign proteid, and a highly sensitised serum may thus be obtained. It was with such a serum, sensitised to the crystalline lens of the rabbit, that Messrs. Guyer and Smith conducted their experiments. The serum was prepared by grinding up rabbits' lenses with normal salt solution and injecting the fluid into fowls. A "lens-sensitised" serum was thus obtained, *i.e.* a serum which would dissolve the lens-substance of the rabbit.

When this lens-sensitised serum is injected into the veins of a pregnant rabbit the young exhibit a tendency to develop defective eyes—especially as regards the lens, which may be more or less opaque or liquefied. The eyes of the parent are not affected, possibly because in the adult eye the blood-supply to the lens is so meagre that the sensitised serum cannot reach it, or the adult lens may be too tough to be affected by minute quantities of the lysin. The lens of the developing embryo, however, is a very

[1] "Some Prenatal Effects of Lens Antibodie" (*Journ. Exp. Zool.*, vol. xxvi., May, 1918); "Transmission of Induced Eye Defects" (*op. cit.*, vol. xxxi., August, 1920).

delicate structure with an abundant blood-supply, and no doubt the lysin reaches it through the maternal and fœtal circulation.

So far, of course, there is no question of any transmission of somatogenic modifications, or "inheritance of acquired characters." The authors have shown, however, that when the young rabbits with defective eyes in their turn produce offspring the defect is inherited. Moreover, it does not gradually diminish and finally disappear in succeeding generations, like the curious somatogenic modification of the shell investigated by Agar in Simocephalus, but actually tends to increase from generation to generation, until the whole eye may almost disappear. The transmission has now been observed through six generations, and—what is still more important as showing that we are dealing with a true case of the "inheritance of acquired characters"—the defect may be transmitted through the male parent only, thus precluding the possibility that it may be due to the action of the maternal blood upon the offspring *in utero*.

How the germ-cells are affected by the lens lysin is, of course, entirely unknown, and Messrs. Guyer and Smith are commendably cautious with regard to theoretical considerations. It would seem, however, that we have here as clear-cut a case of the inheritance of somatogenic characters as we are ever likely to obtain, and one which may be expected to throw much light on the problem of heredity in general.

The Planet Mars.

MR. G. H. HAMILTON (Lowell Observatory Bulletin, No. 82) gives a detailed account, with many drawings, of his observations of the planet Mars at Flagstaff during the apparition of 1918. His observations closely corroborate those of Lowell. He notes that the dark band round the polar cap appears only when the cap is melting; when it is forming, its edges are indistinct. This difference is opposed to the merely optical character of the dark band upheld by some authorities. He also saw a large lake travelling away from the polar cap until it joined the Lucus Hyperboreas. It behaved like surface-water resulting from the melting cap. Mr. Hamilton also claims to have seen the same seasonal development of the canals, proceeding equatorwards, that Lowell described. He notes that the seeing depends on the Martian atmosphere as well as on our own; the details were sometimes blurred and dim, with excellent local seeing.

Conferenze e Prolusioni for December last contains a lecture on Mars by Prof. Pio L. Emanuelli, of the Vatican Observatory. Prof. Emanuelli denies the existence of the geometrical canals, pinning his faith to the results of the largest telescopes. He quotes an interesting observation by Prof. Hale made with the 60-in. reflector at Mount Wilson in 1909. The seeing was very good, permitting the use of a power of 800; the structure of the surface appeared exceedingly complex, far more so than could be shown in a sketch; the dark areas were covered with fine details, not, however, arranged in geometrical patterns. The two canals from the Sinus Sabæus were seen as broad stripes, resolved into minute detail like interrupted and twisted filaments. Prof. Emanuelli quotes similar results from the Yerkes Observatory, and those made in 1909 by M. Antoniadi with the 30-in. refractor at Meudon. He makes, however, no allusion to the necessity of prolonged observation, at various seasons of the Martian year, required to gain an insight into the nature of the processes going on on the planet's surface.

The Journal of the Astronomical Society of India (vol. x., Nos. 7, 8, and 9) contains an article on Mars by Dr. D. N. Mallik, who confines himself, however, to the single question of the Martian origin of the stray wireless signals, concerning which there was considerable discussion in the daily Press last year. Dr. Mallik has no difficulty in establishing the utter improbability of such an origin, though he inclines to the view that animal and vegetable evolution on the two planets would proceed on similar lines, so that if higher forms of life are present on Mars they would be comparable with those on the earth. He is less convincing on the subject of the hopelessness of arranging mutually intelligible signals, assuming the simultaneous desire to communicate and the conquest of the mechanical difficulties. There is little doubt that under these conditions the united intelligence of the two planets would at least make some progress in communication. The problem recalls the decipherment of cuneiform, being easier in some respects and more difficult in others.

A. C. D. C.

Land Reclamation.

ATTEMPTS are being made to reclaim some of the many waste acres in the British Isles, and the problems of reclamation are fully discussed in the 1919 volume of the Journal of the Royal Agricultural Society of England. The general problem is dealt with by Mr. W. Gavin. There is no definite information available as to the extent of either the total uncultivated land or the uncultivated land likely to be capable of cultivation in this country, but Sir Daniel Hall in his report to the Reconstruction Committee tentatively suggested 250,000 acres as the probable area reclaimable for agricultural purposes. Land reclamation has been going on more or less continuously since the beginning of agriculture, and in a closely settled country like England the greater part of the land showing prospects of immediate profitable cultivation has been reclaimed. Therefore, to reclaim the remaining waste land generally requires an expenditure in excess of the immediate value of the land when reclaimed. In some few districts there is land which would pay to reclaim, and in many cases private owners could do the work more cheaply than could the State. On the other hand, such reclamation adds to the national wealth more than the actual value of the land, so that the State can afford to spend more than a private owner. Further, in times of industrial depression it may be of social advantage to the State to provide employment by starting some reclamation schemes.

At a time such as this, when maximum home production is of vital importance to the well-being of the country, Mr. Gavin appeals to all landowners and occupiers to endeavour by some means to increase their cultivated-land area, even though it may not yield immediate profits. It must be remembered that some years must elapse before the full value of any reclamation scheme becomes apparent, though in any case the labour expended is never in vain, since the reclaimed land is sheer gain to the cultivated area, and means an increase not only in production, but also in national wealth by the commercial exchange promoted and the new addition of rates and taxes.

The scientific and technical problems of land reclamation are dealt with by Dr. E. J. Russell, who discusses especially the reclamation of sandy and clay soils. In devising reclamation schemes for a given area the first essential is to find the defects of the soil and then to decide on some means of remedying them. This cannot be done simply by analysis; field trials must be made, though analysis affords considerable aid by indicating the points on which the field tests should give information. Of the two methods possible the safer, but also the slower, is to set up on a typical part of the land to be reclaimed a series of trials based on the analytical data. The other method, which is quicker and almost as safe, is to compare in detail the waste land and the cultivated soil immediately surrounding it. In this way any important defects would be revealed and remedies could be considered.

For farming reclaimed sandy lands three methods are in general use: the winter feeding of sheep, market-gardening, and the growing of special crops. The last-named is practised at Methwold, where the reclamation scheme has been very successful. The crops grown are specially suited to the conditions, and an intelligent use of artificial fertilisers is required so as to reduce to a minimum the possibility of loss.

With regard to clay soils, reclamation can generally be effected either by conversion into arable land or by utilisation as grass land. In the arable land scheme lime is absolutely indispensable, while other manures, especially basic slag, are also necessary. If the land is to be used as grass land, there must be adequate drainage and heavy dressings of basic slag. If, however, the percentage of clay rises above certain limits—37 per cent. for a 30-in. rainfall and 35 per cent. for a 40-in. rainfall—then the grass scheme does not pay, for not only does drainage become too expensive, but also the grass suffers in dry weather by the shrinking and cracking of the soil. Such land, if allowed to run wild in England, is soon covered with a dense growth of bushes, and to reclaim this it is necessary first to clear the land and stub the roots, and then to improve the soil. These are expensive processes, and, although such schemes have been worked in some cases, it is improbable that any individual would undertake them at the present day. The only thing, therefore, is to hope that proper afforestation methods will be used.

University and Educational Intelligence.

CAMBRIDGE.—Dr. W. L. H. Duckworth, Jesus College, has been appointed to the newly created readership in anatomy, and Mr. V. C. Pennell, Pembroke College, as an additional junior demonstrator in anatomy.

New statutes have been framed for the establishment of the degrees of M.Litt. and M.Sc. for research students of the University. These will not be operative when approved until the change in the statutes can be effected, but they should be in operation in the coming academical year.

In connection with the growth of the department of biochemistry, it is proposed that two additional University lecturers and one additional demonstrator in biochemistry should be appointed.

Two fly-sheets have been circulated to resident members of the Senate in opposition to the scheme for a separate women's university at Cambridge—a scheme which is to be voted on next week. One comes, naturally, from the supporters of scheme A, which was defeated last term. The alternative offered by the other members of the Syndicate obviously has no more attractions now than formerly to those who wish to offer women full membership of the University. The second fly-sheet comes from the party which claims a desire to redress any real grievance under which women students suffer without giving them any hand in the control of men's education. The signatories of this report include three of the original signatories of report B, who now definitely oppose their own proposal. They urge the appointment of a new Syndicate to draft a statute giving women titular degrees with no voting power in the University, and reserving rights to the University over the number of women students whom it will undertake to teach. Other privileges, but no powers, are to be granted to the women, and machinery is to be provided by which women teachers could confer with the Boards of Studies in the University. It is something that the centre party on this question, with whom lies the ultimate decision between the two extreme wings, should have got so far forward as to admit the justice of the women's claims to degrees. The nature of the reception of their proposal by the women's colleges will be awaited with some interest, but it may be anticipated that at most it will amount to lukewarm acceptance, and that it will satisfy neither the women's desires nor demands.

The Lees Knowles lectures will be given by Major-Gen. Sir F. H. Sykes on "Aviation Before, During, and After the War."

LONDON.—H.R.H. the Prince of Wales has consented to accept the honorary degrees of Master of Commerce and Doctor of Science, which will be conferred on him on Presentation Day in May of this year. On only one occasion in the history of the University have honorary degrees been conferred—in 1903, when their Majesties the King and Queen (then Prince and Princess of Wales) received respectively the Doctorate of Laws and the Doctorate of Music. On the same day degrees were also conferred on Lords Kelvin and Lister, both of whom have since died. The Prince will thus be only the fifth honorary graduate of the University—the third on the roll of living persons on whom such degrees have been conferred.

SIR FREDERICK BLACK will distribute prizes and certificates at the Sir John Cass Technical Institute, Aldgate, on Thursday, February 10, and will unveil the memorial window erected by the governors of the institute to the memory of members of the staff and students who fell in the war. He will also give an address on "Liquid Fuel in Peace and War."

ON Tuesday next, February 8, at 8 p.m., Mr. F. H. Carr will open a discussion on "Post-Graduate Training in Industrial Chemistry" at a meeting of the Old Students' Association of the Royal College of Science, London, to be held in the Imperial College Union, Prince Consort Road, South Kensington. Non-members of the association interested in the subject are invited to be present. The annual dinner of the association, which had been arranged for February 8, has been postponed to Tuesday, March 8, when the annual general meeting will be held.

THE eighteenth annual dinner of "Old Centralians" (the Old Students' Association of the City and Guilds (Engineering) College of the Imperial College of Science, London) will be held at 7 p.m. on Friday, February 11, at the Hotel Cecil, London, and it is hoped that every past student of the college will make an attempt to be present. Invitations have been accepted by Sir A. Keogh, Prof. H. E. Armstrong, Sir Richard Gregory, the professors of the City and Guilds (Engineering) College, and others. Tickets (price 15s. each) may be obtained from Mr. G. W. Tripp, Lyndhurst, Hayes Road, Bromley, Kent.

The Military Education Committee of the University of London has arranged a course of six lectures on the scientific aspects of warfare, to be delivered on Mondays, commencing February 14, at 5.30 p.m., in the Theatre of King's College, Strand. The subjects of the lectures will be:—Chemical Warfare, Prof. A. J. Allmand; Transportation Services, Lt.-Col. F. R. M. de Paula; Wireless Telegraphy and Telephony, Mr. Philip R. Coursey; Military Railways, Lt.-Col. V. M. Barrington-Ward; Sound Ranging, Prof. E. N. da C. Andrade; and Intercommunication during the War, Major R. E. Priestley. Admission to the lectures is free, without ticket.

A copy of the first annual report of the library committee of the British Red Cross Society and Order of St. John Hospital Library has been received. The library is the outcome of a petition for the reorganisation of the War Library of the British Red Cross Society, and it has now a record of more than a year's splendid work behind it. The men of the Army and Navy who are still suffering from the effects of the war have the first claim on the library, after which civilian hospitals are supplied so far as possible. During the past year 33 British military hospitals oversea have received consignments of books from the library, while as many as 488 civilian institutions have been supplied. An interesting feature is the growing demand for special books by individual patients, and it is in this direction that readers of Nature may be of assistance. No request is made for funds, for it is estimated that the grant made by the British Red Cross Society will pay the working expenses of the library, but an urgent appeal is addressed to all who have books and magazines to spare. Gifts of books and papers should be sent to the British Red Cross Society and Order of St. John Hospital Library, 48 Queen's Gardens, London, W.2.

The Vice-Chancellor of the University of London, Dr. Russell Wells, visited the Horticultural College, Swanley, on January 27 and addressed the students. The occasion was a memorable one, for the college is now recognised by the University for preparation for the new degree of B.Sc. in horticulture. The Vice-Chancellor was greeted by Sir John Cockburn, acting chairman for the board of governors, and the principal, Miss F. M. G. Micklethwait, members of the board of governors, and other distinguished guests, including Dr. Goodchild (of the University of London), Mr. Dallinger (representing the Ministry of Agriculture), Dame Meriel Talbot, Mr. Salter Davies (Director of Education, Kent Education Committee), and Mr. Dykes (secretary of the Royal Horticultural Society), were also present. The Vice-Chancellor in his address said that he was one of those who had had a great deal to do behind the scenes with the founding of the new B.Sc. in horticulture, which had been proposed by Sir Albert Rollit. One of the difficulties had been to convince some of the members of the Senate that gardening was worthy of academic distinction. Practical experience proved, however, that the "rule of thumb" gardener could not progress far without expert advice, and he hoped in the future such advice would be provided by Swanley College.

Calendar of Scientific Pioneers.

February 3, 1862. Jean Baptiste Biot died.—Biot worked assiduously all his life at physics and made valuable contributions on the polarisation of light. His famous balloon ascent with Gay-Lussac, his geodetical work with Arago, his biographical writings, and his activity as a member of the French Institute all made his name widely known.

February 3, 1890. Christoforus Henricus Diedericus Buys-Ballot died.—Director of the Meteorological Institute and professor of experimental physics at Utrecht, Buys-Ballot was an initiator of weather reports and international meteorology.

February 3, 1894. Edmond Frémy died.—The author with Pelouze of a large treatise on chemistry, Frémy was an investigator and teacher of industrial chemistry, and in his later years succeeded in making artificial rubies.

February 4, 1615. Giovanni Battista della Porta died.—The compiler of "Magia Naturalis," a volume of physical experiments, and the inventor of the camera obscura, Porta rendered many services to the science of his day.

February 5, 1907. Nikola Alexandrovitch Menschutkin died.—A contemporary and fellow professor of Mendeléeff at Petersburg, Menschutkin added to the knowledge of chemical structure and was a pioneer in the study of chemical dynamics.

February 6, 1804. Joseph Priestley died.—Five years younger than Black and two years younger than Cavendish, Priestley—the father of pneumatic chemistry—was born near Leeds in 1733, and was trained for the Nonconformist ministry. Attracted to the study of chemistry and electricity, he discovered several gases. His discovery of oxygen or "dephlogisticated air" was made in 1774, when he was librarian to Lord Shelburne. In spite of his own discoveries, Priestley clung to the phlogistic theory, leading Cuvier to describe him as "le père de la chimie moderne qui ne voulait pas reconnaître sa fille." From 1780 to 1791 he was a Unitarian minister at Birmingham. A lover of freedom and known for his sympathy with the French Revolution, on the second anniversary of the fall of the Bastille, July 14, 1791, a mob set fire to his house. His library, apparatus, note-books, and register of experiments were all destroyed. Priestley himself fled to Heath Forge, near Dudley, and thence by Kidderminster and Worcester to London. Three years later he sailed for America, passing the last ten years of his life at Northumberland, Pennsylvania.

February 7, 1903. James Glaisher died.—Head of the magnetical and meteorological department at Greenwich Observatory, Glaisher made many balloon ascents for scientific purposes.

February 9, 1811. Nevil Maskelyne died.—Like Lalande and Messier, Maskelyne was attracted to astronomy by the solar eclipse of July 25, 1748. He became Astronomer-Royal in 1765, founded the Nautical Almanac, and made improvements in methods of observing.

February 9, 1865. James Melville Gilliss died.—Trained for the United States Navy, Gilliss published the first American volume of astronomical observations and prepared the first American star catalogue. In 1861 he succeeded Maury as director of the Naval Observatory at Washington.

February 9, 1883. Henry John Stephen Smith died.—Savilian professor of geometry at Oxford, Smith did important work in elliptic functions, theory of numbers, and modern geometry. He has been called the greatest disciple of Gauss.

E. C. S.

Societies and Academies.

LONDON.

Geological Society, January 19.—Mr. R. D. Oldham, president, in the chair.—Dr. L. J. **Wills** and B. **Smith**: The Lower Palæozoic rocks of the Llangollen district, with especial reference to the tectonics. The general sequence of rocks and details of their components in various localities are given. The Lower Palæozoic rocks are, in the main, folded on approximately east-and-west axes, to which the cleavage and some of the major faults are closely parallel in direction. The folding and part of the faulting are Devonian, and appear to have set up torsional stresses affecting a greater area than that considered here. The concertina-folding in the synclinoria appears to be related to the tough anticlinal nodes of the northern Ordovician outcrops. The master-faults separate blocks of country which appear to have been displaced laterally in post-Carboniferous times. The minor faults appear to be adjustments that allow the strata to comply with torsional stresses.

PARIS.

Academy of Sciences, January 3.—M. G. Lemoine in the chair.—E. **Picard**: Certain functions connected with closed surfaces.—P. **Termier** and L. **Joleaud**: The age of transport phenomena in the region of Avignon.—L. **Fabry**: The use of geocentric latitudes for facilitating the identification of the minor planets. Two minor planets were notified in Circular 138 of the Marseilles Observatory which appeared to be new. The author has applied the method of geocentric latitudes to the photographic observations, and shows that one of these is identical with Mnemosyne (57).—R. **de Forcrand**: The melting point of heptane and the law of alternation of melting points. Hexane gave a melting point of −93·5° C., as against −95° C. found by Guttmann, and octane −57·4° C. (Guttmann −98·2° C.). It has been shown that the melting points of many series of carbon compounds show an irregular-toothed curve, such that in passing from a compound with an even number of carbon atoms to the next higher homologue with an odd number the melting point fell. The data for the C_1 to C_8 paraffin hydrocarbons appeared to give an exceptional curve, but with the substitution of −57·4° C. for the −98·2° C. of Guttmann the curve becomes normal, and would indicate −94° C. as the melting point of heptane. Pure heptane was prepared and found to have a melting point of −94·75° C.—H. **Parenty**: The reconstitution of certain invisible details of old pictures. With reference to a recent paper by A. Chéron on the use of radiography for the recognition of ancient pictures, the author recalls a paper published in 1913 in which photography was used for the same purpose, and mentions two cases in which his conclusions based on ordinary photographs have been confirmed.—P. **Vuillemin**: The aberrations of floral symmetry.—M. **Angelesco**: Certain completely integrable linear differential equations.—A. **Petot**: Shocks in the change-gears of motor-cars.—M. **Dumanois**: The determination of a criterion of general fatigue in internal-combustion motors. A discussion of a formula for the factor of safety in the construction of internal-combustion motors, with special reference to Diesel engines.—H. **Corblin**: A compressor with a membrane. The gas compressor described and illustrated has, in effect, a liquid piston, with an elastic metallic membrane separating the liquid and the gas being compressed. The compression is nearly isothermal, and air can be carried from atmospheric pressure to 100 kg. per sq. cm. at one step.—J. **Guillaume**: Observations of the sun made at the Lyons Observatory during the third quarter of 1920. Observations were made on eighty-eight days during the quarter and the results are shown in three tables, giving the number of spots, their distribution in latitude, and the distribution of the faculæ in latitude.—L. A. **Herdt** and R. B. **Owens**: The direction of ships at the entrance of ports and channels by a submerged electric cable. An account of experiments carried out in Canada in 1904, and suggestions for the development of the method.—M. **Liénard**: Scalar and vector potentials due to the motion of electric charges. A formula recently developed by Anderson (*Phil. Mag.*, August, 1920) is not in agreement with one given by the author in 1898. A mathematical investigation of the cause of the discrepancy is given.—G. **Ferrié**, R. **Jouaust**, R. **Mesny**, and A. **Perot**: Studies in radiogoniometry. Under normal conditions the direction of the electromagnetic waves in wireless telegraphy can be determined within 1°, but under certain conditions the azimuth of a transmitting post varies capriciously, and at certain times during the day no position can be found. These effects have been carefully studied, but although there is some evidence of a seasonal influence the exact cause of these deviations has not yet been elucidated.—A. **Chéron**: The radiography of pictures. In the preparation of the canvas at the present time white lead is used, whilst in early times calcium carbonate and wax were preferred. These differ markedly in transparency to the X-rays, and the materials of old and modern paints also show differences in this respect. Hence radiography may serve to distinguish between old and modern pictures, and in certain cases can bring out restorations.—E. **Rengade**: Saline double decompositions and the phase rule. It is shown by experiment that if a mixture of sodium nitrate and ammonium chloride is treated with a quantity of water insufficient for complete solution, crystals of sodium chloride are formed. This is opposed to the conclusion arrived at by M. Raveau in a recent communication.—G. **Denigès**: Remarks on a recent note by M. A. Bolland on the microchemical reactions of iodic acid. A claim for priority.—A. **Kling** and D. **Florentin**: The properties and constitution of the group $(CO.Cl_2)$. The complete substitution of hydrogen by chlorine in the group $—OCH_3$ gives rise to abnormal properties. From its reactions it has a modified structure and behaves as phosgene *plus* chlorine.—C. **Dufraisse**: The ethylene isomerism of the ω-bromostyrolenes. Both these stereo-isomers are liquids at the ordinary temperature, and differ in colour and smell. An account is given of their reciprocal transformations.—J. **Durand**: The action of the alkaline metals on the ether oxides. It has hitherto been supposed that ordinary ethyl ether and its homologues are without action on sodium and the other alkaline metals, but the author shows that this is not the case. Details of the reaction between sodium (or the liquid alloy of sodium and potassium) on ethyl and *iso*amyl ethers, veratrol, ethylbenzyl ether, and diphenyl ether are given. The exact mechanism has still to be worked out.—F. **Grandjean**: The existence of equidistant differentiated planes normal to the optic axis in liquid crystals.—P. **Négris**: The glacial oscillations of the Quaternary period and the corresponding movements of the lithosphere.—E. **Chaput**: Observations on the ancient alluvium of the Seine.—E. **Mesnard**: Contribution to the history of earthquakes.—P. **Lesage**: Saline plants and period of anomalies.—G. **Nicolas**: Contribution to the study of the mechanism of the fertilising action of sulphur. Sulphur increases the assimilation of carbon from the air by the action of chlorophyll.—M. **Barlot**: A new reagent for Lactarius and Russula. The reagent is methyl chloroantimoniate in methyl alcohol solution. The colour reactions with eighteen species of Russula are given.—A. **Pézard**: The law of "all or nothing" or of functional constancy relating to the action of the testicle.—M. **Bezssonoff**: The antiscorbutic action of raw potato, ground and intact.—J. **Nageotte**: The structure of the cornea.—R. **Dubois**: Maternal affection in the electric skate (*Torpedo mormorotae*). Just before the birth of her young a specimen of this fish gave strong electric shocks, but after the birth of seven young the fish, although vigorous, gave no more shocks, and with the young fish about it could be readily handled. When the young were removed the shocks were as strong as before. This shows that the electrical discharge is not a reflex action, but voluntary, and can be suppressed when likely to be a danger to the young.—MM. **Cluzet**, **Rochaix**, and **Kofman**: The bactericidal action of the radiation from radium tubes employed in radium therapy.—F. **d'Herelle**: The bacteriophage micro-organism, the agent of immunity in plague and barbone.—A. **Paine** and A. **Peyron**: The neoplasic transformation of striated muscular fibre with visceral metastasis in the evolution of experimental sarcoma in birds.

Diary of Societies.

THURSDAY, February 3.

Royal Institution of Great Britain, at 3.—Prof. W. A. Herdman: Oceanography (Great Exploring Expeditions).

Royal Society, at 4.30.—Dr. G. B. Jeffery: The Field of an Electron on Einstein's Theory of Gravitation.—Dr. M. N. Saha: A Physical Theory of Stellar Spectra.—W. F. Darke, J. W. McBain, and C. S. Salmon: The Ultra-microscopic Structure of Soaps.—Dr. J. Mercer: Linear Transformations and Functions of Positive Type.

China Society (at School of Oriental Studies), at 5.—E. H. C. Walsh: Central Tibet and Lhasa.

Linnean Society, at 5.—Miller Christy: Wistman's Wood, Dartmoor; Specimens of Slides.—Dr. Agnes Arber: Leaf-tips of Monocotyledons.—T. A. Dymes: Seedlings of *Ruscus aculeatus*, with Remarks on their Germination and Growth.

Royal Aeronautical Society (at Royal Society of Arts), at 5.30.—Major G. Dobson: The Use of Meteorology to Aviation and *Vice-versa*.—Wing-Comdr. H. W. S. Outram: Ground Engineering.

Royal Society of Medicine, at 5.30.—Prof. F. Hobday: The Diseases of Animals which are Contagious to Man.

London Dermatological Society, at 6.—Dr. W. Griffith: Parasitic Diseases of the Skin (Chesterfield Lecture).

Chemical Society, at 8.—Informal Meeting.

Royal Society of Medicine (Obstetrics and Gynæcology Section), at 8.—F. C. Pybus: An Unusual Type of a Tuberculous Peritubal Cyst.—Dr. T. W. Eden and F. L. Provis: X-ray Treatment of Uterine Fibroids and Chronic Metritis.

FRIDAY, February 4.

Royal Society of Medicine (Laryngology Section), at 4.

Royal Astronomical Society (Geophysical Discussion), at 5.—On Gravity at Sea: Opened by Prof. G. W. Duffield, and continued by Sir S. G. Burrard, Dr. H. Jeffreys, Dr. J. W. Evans, and Dr. A. M. Davies. Chairman: Sir Arthur Schuster.

Royal College of Surgeons of England, at 5.—Prof. C. W. G. Bryan: The Early and Late Effects of Injuries of the Diaphragm, with Special Reference to Wounds jointly involving Thoracic and Abdominal Viscera.

Institution of Mechanical Engineers (Informal Meeting), at 7.—F. R. Wade and Others: Our Part in the Industrial Crisis of To-day.

Junior Institution of Engineers, at 8.—W. H. Ballantyne: Surface Tension and Some of its Industrial Applications.

ROYAL SOCIETY OF MEDICINE (Anæsthetics Section), at 8.30.—Drs. Rowbotham and I. Magill: Anæsthesia in the Plastic Surgery of the Face and Jaws.
ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Dr. A. D. Waller: The Electrical Expression of Human Emotion.

SATURDAY, FEBRUARY 5.

GILBERT WHITE FELLOWSHIP (at 6, Queen Square, W.C.1), at 3.—Lecture.

MONDAY, FEBRUARY 7.

VICTORIA INSTITUTE (at Central Buildings, Westminster), at 4.30.—Dr. A. J. McC. Routh: Motherhood.
ROYAL INSTITUTION OF GREAT BRITAIN, at 5.—General Meeting.
ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Prof. H. Platt: The Surgery of the Peripheral Nerve Injuries of Warfare.
SOCIETY OF ENGINEERS (at Geological Society), at 5.30.—Lord Headley: Presidential Address.
ARISTOTELIAN SOCIETY (at University of London Club, 21 Gower Street), at 8.—Prof. R. F. A. Hoernle: Contributions to a Phenomenology of Meaning.
SOCIETY OF CHEMICAL INDUSTRY (London Section) (at Chemical Society), at 8.—Dr. O. Silberrad: The Erosion of Bronze Propellers.
SURVEYORS' INSTITUTION, at 8.—A. H. Davis: The Acquisition of Land for Public Purposes in Egypt.
ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—Dr. J. M. Arthur: Mount Kenya.
MEDICAL SOCIETY OF LONDON, at 9.—G. E. Gask: Surgery of the Lung and Pleura (Lettsomian Lecture).

TUESDAY, FEBRUARY 8.

ROYAL HORTICULTURAL SOCIETY, at 3.
INSTITUTION OF CIVIL ENGINEERS, at 5.30.—G. Ellson: Cannon Street Bridge Strengthening.—F. W. A. Handman: Reconstruction of a Viaduct.
ZOOLOGICAL SOCIETY OF LONDON, at 5.30.—Dr. P. Chalmers Mitchell: Report on the Additions made to the Society's Menagerie during the months of November and December, 1920.—Dr. C. F. Sonntag: I. The Comparative Anatomy of the Tongues of the Mammalia. II., Fam. Simiidæ. 2. A Contribution to the Anatomy of the Three-toed Sloth (*Bradypus tridactylus*).—Prof. J. P. Hill: Exhibition of, and Remarks upon, a Fœtus of the Three-toed Sloth (*Bradypus tridactylus*).—R. I. Pocock: Notes on the External Anatomy of the Three-toed Sloth (*Bradypus tridactylus*).—Lieut.-Col. S. Monckton Copeman: Note on the Capture of a Rare Parasitic Fly, *Hammomyia* (*Hylephila*) *unilineata*, Zett.—D. M. S. Watson: The Basis of Classification of the Theriodontia.
ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—R. Davis: A New Method for the Measurement of Photographic Filter Factors.—F. C. Toy: A Description of a Monochromatic Illuminator designed for a Special Purpose.—Dr. L. A. Levy and T. Thorne Baker: High-speed Radiography.
QUEKETT MICROSCOPICAL CLUB (at 11 Chandos Street, W.1), at 7.30.—Annual General Meeting.
ROYAL SOCIETY OF ARTS, at 8.—E. C. de Segundo: Some of the Problems of Unemployment.
ROYAL ANTHROPOLOGICAL INSTITUTE, at 8.15.—Prof. A. Keith: Tailed Men.
ROYAL SOCIETY OF MEDICINE (Psychiatry Section), at 8.30.—Dr. W. A. Potts: Mental Tests.

WEDNESDAY, FEBRUARY 9.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Prof. H. Platt: The Surgery of the Peripheral Nerve Injuries of Warfare.
ROYAL SOCIETY OF MEDICINE (Surgery: Proctology Sub-section), at 5.30.—W. B. Gabriel: The Results of an Experimental and Histological Investigation into Seventy-five Cases of Rectal Fistulæ.—H. Graeme Anderson: Method of Abdomino-perineal Excision of the Rectum in Three Stages.
INSTITUTION OF CIVIL ENGINEERS (Students' Meeting), at 6.—J. H. Barker: Machinery Applied to Mass Production.
ROYAL SOCIETY OF ARTS, at 8.—Prof. W. Rothenstein: Possibilities for the Improvement of Industrial Art in England.
INSTITUTION OF AUTOMOBILE ENGINEERS (at Institution of Mechanical Engineers), at 8.
INSTITUTION OF AUTOMOBILE ENGINEERS (Graduates' Meeting) (at 28 Victoria Street), at 8.

THURSDAY, FEBRUARY 10.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. W. A. Herdman: Oceanography (Problems of the Plankton).
ROYAL SOCIETY, at 4.30.—Rev. John Roscoe: A *Résumé* of the Results obtained by the Mackie Anthropological Expedition to Uganda.
LONDON MATHEMATICAL SOCIETY (at Royal Astronomical Society), at 5.—Prof. A. S. Eddington: World Geometry (Lecture).
INSTITUTION OF ELECTRICAL ENGINEERS (at Institution of Civil Engineers), at 6.—Discussion on Electric Appliances for Domestic Purposes, to be introduced by Dr. E. Griffiths and F. H. Schofield in a Paper on Some Thermal Characteristics of Electric Ovens and Hot Plates.
OPTICAL SOCIETY, at 7.30.—R. S. Whipple: The Design and Construction of Scientific Instruments.—T. Smith: The Galilean Binocular.—R. J. Trump: A Shutterless Continuous-feed Kinematograph.
ROYAL SOCIETY OF MEDICINE (Neurology Section) (at National Hospital for Paralysis and Epilepsy), at 8.

FRIDAY, FEBRUARY 11.

GILBERT WHITE FELLOWSHIP.—Founders' Day Celebrations.
ROYAL ASTRONOMICAL SOCIETY (Anniversary Meeting), at 5.
ROYAL SOCIETY OF MEDICINE (Clinical Medicine, Surgery), Joint Meeting, at 5.—Dr. H. Mackenzie, J. Berry, and Others: Discussion: The Medical and Surgical Treatment of Graves' Disease.
ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Prof. A. G. T. Fisher: Loose Bodies in Joints.
PHYSICAL SOCIETY OF LONDON (at Imperial College of Science), at 5.15.—Discussion on Absolute Measurements of Electrical Resistance, and Instruments Based on the Temperature-variation of Resistance.—Sir Richard Glazebrook and F. E. Smith: Absolute Measurements of Electrical Resistance.—Resistance Thermometry: Prof. H. L. Callendar: The Compensated Resistance Bridge, and Instrument for the Measurement of Radiation.—C. R. Darling: The Early Work of Siemens on the Resistance-Pyrometer.—C. Jakeman: The Measurement of Steam Temperatures.—The Hot-Wire Microphone: Major W. S. Tucker: The Function of the Convection Current in the Hot-Wire Microphone.—Capt. E. J. Paris: Theory of the Tucker Microphone.—Anemometry and Heat Convection: Prof. J. T. McGregor Morris: A Hot-Wire Anemometer.—Dr. J. S. G. Thomas. A Directional Hot-Wire Anemometer.—A. H. Davis: An Instrument for Measuring Convected Heat.—Miscellaneous Applications: Dr. G. A. Shakspear: A Gas Permeameter.—Prof. Leonard Hill: The Caleometer.—E. A. Griffiths: Liquid Depth Gauge (Distant Reading Type).—Dr. Daynes: A CO_2 Recorder.—Dr. E. Griffiths: Electrical Hygrometers.
MONTESSORI SOCIETY (at University College), at 5.45.—Miss M. Drummond: The Psychological Basis of the Montessori Method.
ROYAL SOCIETY OF MEDICINE (Ophthalmology Section), at 8.30.—B. T. Lang: Scotometry.—Dr. T. H. Butler: Late Infections after Sclerectomy.—M. L. Hepburn: Some Notes on Trephining.
ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Dr. F. W. Aston: Isotopes and Atomic Weights.

SATURDAY, FEBRUARY 12.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. A. Fowler: Spectroscopy (Experimental Spectroscopy).
PHYSIOLOGICAL SOCIETY (at National Institute for Medical Research, Mount Vernon, Hampstead), at 4.

The Promotion of our Optical Industries.

THE Government has promised to introduce in the House of Commons early next session a Bill to safeguard and foster certain key industries in this country. Of these the optical glass and optical instrument industries deserve special consideration, for their importance is likely to be overlooked because they are relatively small industries, not employing large aggregations of capital or big numbers of firms and employees. It is dangerous for any nation to estimate the value and necessity of a particular industry by taking account merely of the capital sunk in it and of the number of people it employs. It is rather to the character of the industry and to the part it plays in the industrial life of the nation, both in peace and in war, that we must look if we are rightly to measure its intrinsic national value.

There are differences of opinion as to the best method of promoting the development of an incipient industry, whether by subsidies or by safeguards against unrestricted and unregulated foreign competition, but there is none as to the need for immediate action in the case of industries which are essential to the proper functioning of the nation's industrial system in peace and are vital to its safety in war. Adequate measures must be taken to foster these key industries, regardless of whether a general economic principle, sound in ideal circumstances or as a general proposition, is violated.

It is not difficult to show that the manufactures of optical glass and of optical instruments fall in this category. First, it must be realised that the manufacture of optical instruments in this country stands or falls with the manufacture of optical glass in this country. If the British optical instrument industry is to be maintained and to develop so as to turn out products equal, at least, to the best products of other nations, it must not be dependent on foreign sources for the supply of optical glass, but must have an adequate home supply, equal, again, at least to the best available anywhere. Owing mainly to our national neglect of scientific workers, supremacy in the optical glass industry, which was established in this country as early as 1837, passed over to Germany, the Government of which had the insight and the foresight to gauge its actual and potential value. Not only did the Prussian Government bear the expense of the prolonged series of scientific investigations commenced by Schott and Abbe in 1881, but also, in order to capture the world trade, large State subsidies were made continuously to the industry down to the declaration of war in 1914. In that year there was but one firm manufacturing optical glass in the British Empire, with the consequence that during the first year of the war our armies and our fleets could not be equipped with the optical glass required.

By the intensive research of our scientific workers; by lavish expenditure; by the energetic enterprise of manufacturers in building workshops, installing plant, and, under conditions of great difficulty, training labour to perform the highly skilled operations needed, these deficiencies were overcome; and by the end of the war British optical glass was as good as German, and it was being produced in quantities sufficient to meet every demand. The optical instrument industry developed correspondingly, and instruments for all the varied purposes of the Army, the Navy, and the Air Force were manufactured equal to, and in many cases surpassing, the best that Germany could make. The position now is that we have the buildings, the plant, the organisation, the technical knowledge and the technicians, and the skilled labour needed to maintain these industries at their present high level of efficiency. Moreover, as a guarantee of future progress, the industry has established the British Scientific Instrument Research Association, and the Imperial College of Science and Technology has formed a Department of Technical Optics, so that the study of this branch of science, hitherto neglected in this country, may be raised to the highest university status.

It is undeniable that the preservation of the optical glass and optical instrument industries is absolutely vital in war. The skilled labour needed for this industry cannot be hurriedly improvised, as it can and was, for example, in the engineering trades. There is no kindred industry from which, for example, the optical glass grinders and polishers can be drawn in time of emergency. The optical glass maker and the optical instrument maker require a long training, and if these industries are allowed to decline and another war occurs, we shall find ourselves in a position more dangerous even than was our situation in 1914.

A flourishing and efficient optical instrument industry is not less vitally important to the nation's peaceful pursuits than it is for purposes of warfare. The general use of optical instruments in industries is growing and must grow. The increasing use of the microscope in the textile and steel industries, and the application of the polarimeter for testing purposes in the sugar and essential oil industries, are but two of many examples that could be cited to show the growing dependence of our great national industries upon the optical instrument industry. The development and perfection of optical instruments and the invention of new types in this country will be brought to a standstill unless the instruments are manufactured here, where British inventors and designers can keep in close touch with the manufacturers. Moreover, this industry, springing directly from the loins of science, and progressing as scientific knowledge widens, is one of the most highly skilled industries we have. Its expansion means a definite increase in the numbers of technical scientific workers and of the most highly skilled artisans; and the national wealth, in any comprehensive conception of the term, must be increased by the increase of the numbers of such educated and skilled classes.

What is the position of these industries to-day? As the *Daily Telegraph* says in a leading article on January 6: "The industry is again exposed to the full blast of German competition, more formidable now than ever because of the state of the German exchange." Open competition, in these abnormal circumstances, is impossible.

There are two main objects which the Bill to be introduced should secure and reconcile. On one hand, if the industry is to be saved, the manufacturers must be protected from foreign competition aggravated by the state of the exchange; and, on the other, the users of scientific instruments must not be prejudiced or hampered, either by being unable to obtain the best instruments or by having to pay an extravagant price for them. These apparently conflicting interests are not merely reconcilable; they are interdependent. If the British optical instrument industry should dwindle and die, the scientific users of instruments will be at the mercy of foreign manufacturers, they will have to pay a heavy price for such dependence, and they will be handicapped as compared with scientific workers in foreign countries possessing a flourishing scientific instrument industry. Similarly, if the scientific users cannot obtain the best instruments for their work, or if they have to pay an exorbitant price for them, their work will be hampered, their demand for instruments will decrease, and the manufacturers will ultimately suffer.

The industries, through the British Optical Instrument Manufacturers' Association, ask shortly for the following measures of protection:—

(1) No optical glass or scientific instruments to be imported into this country for a period of, say, seven years, except under licence.

(2) Such licences only to be granted in respect of goods which are not being made in Great Britain in the required quantities or of the required quality.

(3) An expert licensing committee to be set up.

(4) The optical instrument manufacturers are prepared, in order to guarantee reasonable prices, to submit to a control of profits.

The manufacturers are satisfied and confident that, under such conditions for a limited period, they would be able to establish the optical glass and optical instrument industries on a sound and stable basis, and also be able at the end of the period to meet any foreign competition in the open market. On the other hand, unless they secure this limited protection, it is more than probable—indeed, it is almost certain—that the manufacture of optical glass in this country will cease, and that, in consequence, some of the largest British manufacturers of optical instruments will greatly curtail their production. The proposed measures seem to protect adequately the interests of the scientific users. Moreover, such a system of control of imports for a limited period seems preferable to anything in the nature of a permanent tariff. It is not likely to have on the industry the emasculating effect of a protective tariff; provided that the period be limited, and that the licensing committee adopt an enlightened policy, prohibition of imports, except under licence, is rather calculated to act as a stimulus on the development of the industry.

There is, finally, one point not dealt with in the proposals outlined above. In return for this shield from danger during a limited period, the country may well ask: What guarantee is there that the manufacturers are taking due measures to promote and prosecute the scientific research and scientific methods on which alone ultimately these, or any other, industries can be made efficient and able to stand against foreign competition? The leading manufacturers have combined to form a scientific instrument research association, and in addition many of them are engaged continuously in scientific research. But it is not clear that all the manufacturers who are demanding the legislative measures outlined above are contributing in either or both of these ways to the advancement of the industry. It is worth considering whether the proposed licensing committee should not take this factor into consideration in any specific case in which it is asked to grant or to refuse a licence.

British Mammals.

British Mammals. Written and illustrated by A. Thorburn. (In two volumes.) Vol. i. Pp. vii+84+25 plates. (London: Longmans, Green, and Co., 1920.) Price 10*l.* 10*s.* net two vols.

THE success of "British Birds" and "A Naturalist's Sketch-book" has induced Mr. Thorburn and his publishers to issue companion volumes on "British Mammals," the first of which is now before us. Although the subject of our native beasts has already been somewhat exhaustively dealt with by Millais, Barrett-Hamilton, Harting, Lydekker, Coward, Adams, etc., there is yet room for Mr. Thorburn's book, because he is an artist-naturalist of such unique quality and observation that anything he may give us is worthy of publication and permanent value. In his case the common truism that there is always room at the top applies definitely. Pictures of natural history are always in demand, and we cannot have too many of those of the highest quality, since the exponents who possess genius are so few. Wherefore, even if the author's text is short, it is quite sufficient and extremely accurate so far as it goes, whilst the illustrations of the various species and subspecies, especially the smaller ones, are of such remarkable accuracy and beauty that it is not too much to say they have not been, and never will be, surpassed. Where Mr. Thorburn excels all other artists of mammals or birds is in his supreme rendering of the colour and texture of fur and feather, as well as in his perfect association of natural background with the subject under treatment. He also introduces just the right botanical features found in association with the creatures he depicts, and skilfully inserts little and surprising notes of colour, such as a bluebell, an orange-tip butterfly, a golden kingcup, or a humble daisy, which often makes a charming picture out of what is really a dull and unattractive subject. This is pure skill, and the result of a severe artistic training combined with a knowledge of Nature.

Those of us who collect books of naturalist history find that there are few the text and illustrations of which stand the test of years. Processes of reproduction, as well as science and observation, are apt to become out-of-date and useless to the practical naturalist of to-day, since within the last few years this class of art and literature has reached a level never approached in past times. "The value of a book," once said Lord Rosebery, "is its price in the second-hand catalogues." Wherefore it behoves us, in these days of heavy expenditure and high taxation, to purchase our treasures with an eye to the future, and those of us who can afford a "Thorburn" book will be wise, for the work of this great artist must be limited, and will certainly rise in value.

The artist's pictures of dormouse, hedgehog, badger, fox, shrews, and various species of bats are quite little gems. His eye sees with Pre-Raphaelite exactness almost every hair on the lesser shrew, the smallest mammal in the world, and gives it that delicious softness which it possesses. If there is one picture that is a *tour de force,* it is the mole, a very difficult creature to paint. We have kept a mole alive and seen it gobbling a worm with the almost indecent haste so admirably depicted. There is the correct and strenuous position of the hind-legs, the holding of the powerful fore-paws, and the perfectly rounded line of the head as it gobbles its prey with a true gourmand's rapidity. Most artists would be content to paint just a dead mole, but Mr. Thorburn gives it life and character. Space does not permit us to criticise the numerous plates in which the artist has succeeded in giving us satisfactory renderings of our native beasts. He has a critical audience to satisfy, since he is apt to think that we now know our own mammals, few in number though they are; but special attention may be directed to the bats, which, although unlovely things, yet require an accuracy of delineation that calls for the highest care and exactitude. Mr. Thorburn has evidently taken the trouble to depict these somewhat elusive beasts from life, and is to be congratulated on his success. No artist-naturalist, however, is free from criticism, and if we find fault with a few inaccuracies, they are only such as occur in all works where fresh models are unavailable.

In the case of the bearded seal—a rare mammal that, Mr. Thorburn says, has occurred only once in British waters (twice would be more accurate, as a specimen was killed in the Beauly Firth a few years ago, and recorded in the *Field*)—the artist has evidently painted his picture from a cured skin in which the oil and tanning have spoiled the original colour, which in Nature (as we have seen) is a fine pearly grey. The eyes, too, are round and prominent, as in the common seal, and not sunk and overshadowed by the cranial sockets. The picture, too, of the otter is not a success, the neck being far too long. Also we are not enamoured with the little pen-and-ink tailpieces. Some are fairly good, but the majority are drawn too coarse to render fur accurately. This is doubtless due to the fact that the book is printed on a pure hand-made paper, which, whilst admirable for the text, does not permit the use of anything but blocks exhibiting coarse lines. It is to be regretted that, as yet, English firms of reproducers are still far behind those of the Continent in this class of reproduction.

These and a few other inaccuracies of detail are, however, but trifling detriment in a work which will always remain one of permanent value, and both Mr. Thorburn and his publishers are to be congratulated on having issued so valuable and magnificent a production. We look forward with pleasure to the second volume, which, if it is as good as the first, will satisfy the most exacting naturalists and connoisseurs of beautiful art-books.

Improvement of the Race.

Applied Eugenics. By Paul Popenoe and Prof. Roswell Hill Johnson. (Social Science Text-books.) Pp. xii+459. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1920.) Price 14*s*. net.

EVERYONE is agreed as to the desirability of improving the intrinsic qualities of the race, but the difficulty is to know what can wisely be done. The question, What is practicable? is much harder to answer than the question, What is desirable? But towards an answer to the more difficult question this very competent book by Mr. Paul Popenoe and Prof. Roswell Hill Johnson makes a definite contribution. "Emphasis has been laid on the practical means by which society may encourage the reproduction of superior persons and discourage that of inferiors."

The authors begin by estimating the relative importance of the two indispensable factors—hereditary nature and environing nurture. Their reasoned bias is evident in the sentence: "It is his nature, not his nurture, that is mainly responsible for his character." Perhaps it is not very profitable to discuss which of two necessary components is the more important in a resultant. So far as social efficiency in the wide sense is concerned—which includes character and working power—we hold that the man with five talents often goes further than the man with ten, simply because his nurture was better. But we have no statistics to prove this. The authors go on to a shrewd discussion of the transmissibility of exogenous modifications, giving as their verdict "Not proven." But here, again, they seem to us to draw their bow too tightly, not attaching sufficient importance to the *rôle* that nurtural peculiarities may have as the liberating stimuli of germinal variations. From emphasis on "nature" rather than on "nurture" and from rejection of the postulate of transmissible modifications, the authors pass logically to the conclusion that man is much more "born" than "made"; so what eugenics must look forward to is having more children well born. What this means biologically is clearly explained in the chapter on the laws of heredity. Civilised man has to some extent thrown off the yoke of natural selection—a fact that in itself suggests the desirability of some other mode of sifting to safeguard the interests of the race. This desirability is corroborated by the fact that where natural selection still operates on civilised mankind, especially in the way of a differential death-rate, it is not doing much to improve the race. In some ways it is rapidly hastening race degeneracy. It is here that practical eugenics comes in with suggestions towards "raising the level of the race by the production of fewer people with physical and mental defects, and more people with physical and mental excellences." What are these suggestions?

The first suggestion is the restriction of the marriage and reproduction of defectives. Good stock is spoiled by mingling with bad; many infants would better not be born; much misery is perpetuated; the cost to the State is enormous. The proposal is "to prevent the reproduction of those feeble-minded, insane, epileptic, grossly defective or hopelessly delinquent people, whose condition can be proved to be due to heredity, and is therefore probably transmissible to their offspring." But how is the restriction to be effected? The authors answer: By segregation, sterilisation in certain cases, and a good banns law. Besides these coercive methods, the first of which is regarded as urgently necessary, the authors look to an increasingly enlightened social conscience. The objections to coercive methods are considered in a fair-minded and temperate manner, but we confess to have less faith than the authors have in the wisdom of tribunals. We should not like our neighbours to decide whether we are to have permission to marry, and it is well known that such conditions as feeble-minded and epileptic are not very precise. It is interesting to speculate what human history would have been if eugenics boards had segregated—well, perhaps we had better not mention names.

On the positive side the authors write admirably. Sex-selection is a reality; if it were better educated and given wider opportunities, it might become a very potent factor in racial progress. To promote a higher marriage-rate among superiors, the authors make a plea for clean living, for simpler living, for a wider education of faculties, for a franker approbation of the married state as more normal than celibacy, and against the persistent prolongation of the training period beyond the early twenties. At the same time, the authors assure us that the people, as a whole, are not marrying less than they used to do; what is wrong is postponement or avoidance of marriage among the more individuated. Not only so, but when they marry they do not have enough children. They do not want to, and the reasons for this are not wholly selfish. A careful analysis is submitted, and attention is directed to the desirability of certain educational and economic changes which may counteract the tendency to race-suicide. There is a point here that seems to be often overlooked in regard to eugenic education. The authors say: "Perhaps the time is not so far distant when babies will be considered an integral part of a girl's curriculum." But while that may be very useful for the girls who marry, is it not apt to be a refined cruelty towards the many who find no mates?

The authors go on to discuss, in relation to eugenics, such subjects as the colour line, immigration, and war—all with the objectivity, scholarship, and fair-mindedness that are characteristic of the whole book. There is a useful chapter on the value of genealogical outlook, both ethically and scientifically. Preoccupation with it may lead to loss of perspective; but to call genealogy a fad is a betrayal of foolishness and vulgarity. The authors' studies end with an emphasis on good environment (euthenics), and this corrects what seems to us a slight partiality in the early chapters. We strongly recommend the book as an all-round, well-documented, level-headed answer to the question: What is practicable in the way of eugenics?

The First Great Alpine Traveller.

The Life of Horace Bénédict de Saussure. By D. W. Freshfield, with the collaboration of H. F. Montagnier. Pp. xii + 479. (London: Edward Arnold, 1920.) Price 25*s*. net.

A LIFE of de Saussure, author of the "Voyages dans les Alpes," has long been desired, and that has now been supplied by an Englishman singularly fitted for the task, Dr. Douglas Freshfield, who was incited so long ago as 1875 by Ruskin, and has been ever since, directly or indirectly, gathering materials. The handsome volume before us is the result. No one has a better knowledge of mountains than Dr. Freshfield, for when a boy, in 1859 and 1860, he accompanied his father and mother on riding tours through several parts of the Alps, and has repeatedly returned thither. He has also explored many other mountain chains, and has published his experiences. In 1869 he described a journey through the Central Caucasus and Bashan, in the course of which he ascended Kasbek and one of the twin summits of Elbruz. In 1896 he published his splendid work on "The Exploration of the Caucasus," and his journey of 1899 "Round Kangchenjunga" was yet more adventurous, though rendered rather less successful by persistently bad weather; while since then, in "Hannibal Once More," he has discussed the route of the Carthaginian general across the Alps, suggesting one considerably south of those generally supported, for which there is undoubtedly much to be said.

Horace Bénédict de Saussure, born at Geneva in 1740, was a man of good family, strong intellect, and remarkably wide education. He could write with ease both Latin and Greek; in addition to French, he knew German, Dutch, and English well enough to converse easily with the educated men of each country, and had a wide knowledge for that day of mathematics, metaphysics, and natural science, especially geology, mineralogy, and chemical physics. In his youth, though the summit of Mont Blanc was visible from the quay of Geneva, very few travellers had penetrated so far as Chamonix until, in 1742, an English party proved that the glaciers of Savoy more than rivalled those of Grindelwald, already known through Scheuchzer's "Itinera Alpina."

De Saussure married early, and as his wife added to his means he was able to gratify his love for travel. Though at times suffering from dyspepsia, he had a strong constitution, and was for more than ten years after 1774 able to lead, with but one interruption, "a life of various activity as a hard-working professor, a man of science, a citizen, and a mountain traveller." In this time he made his principal Alpine explorations, which culminated in 1787–88 and 1789 in the ascent of Mont Blanc, the stay for thirteen days on the Col du Géant, and the tour of Monte Rosa. But evil times were approaching, for the Revolution in France soon found its imitators at Geneva. De Saussure's sense of duty drew him into politics in the vain hope of averting their evils, with the result that he was impoverished and his life more than once in peril. Dr. Freshfield gives us the pitiful story in all its details until in 1794 de Saussure had a stroke of paralysis which, though his brain remained clear and he was able to write two volumes of his "Voyages" and to seek alleviation by visiting baths, ultimately proved fatal on January 22, 1799.

Dr. Freshfield has spared no pains in accomplishing his task, which has evidently been to him a labour of love. De Saussure was the great forerunner of scientific Alpine exploration—a man better qualified than any successor until the days of Principal J. D. Forbes. The latter corrected some of the mistakes into which his illustrious predecessor had fallen, and put the question of glacier motion on a surer footing, about the year 1843, in his "Travels through the Alps of Savoy and other Parts of the Pennine Chain." This gave an increasing stimulus to Alpine travel, which culminated in the foundation of the Alpine Club in 1857, since which date scientific investigation of the Alps and the conquest of mountain difficulties have made wonderful progress. It is scarcely more than 120 years since de Saussure died, yet the pictures representing him on his greatest glacier excursion, and some of his geological speculations, seem to us strangely antiquated. Nevertheless they show him to have been a man of true courage and of a really scientific mind; and this reference to pictures reminds us that Dr. Freshfield has added to the value of his work by a number of well-selected illustrations, among which are not only excellent portraits of de Saussure and of some of his relations and friends, but also representations of places of interest in his history.

T. G. BONNEY.

X-Ray Analysis and Mineralogy.

Lehrbuch der Mineralogie. By Prof. P. Niggli. Pp. xii+694. (Berlin: Gebrüder Borntraeger, 1920.) Price 80 marks.

THIS book, written by the professor of mineralogy and petrography at the University and "Technischen Hochschule" of Zurich, but published in Berlin, is a comprehensive work of some originality. It is illustrated by a large number of figures, which are practically all reproductions of drawings made by the university artist from material supplied by the author. The result is doubtless effective from the author's point of view and for rapid production, but the illustrations are much coarser than would satisfy an average author or publisher in this country, especially in the case of so large and expensive a book.

The work possesses a particular value, however, as being that of a colleague of Prof. Laue, who was called from Munich, after his discovery of the diffraction of X-rays by the planes of atoms in crystals, to become professor of physics at Zurich University, and this fact is revealed by the constant references to the analysis of crystals by X-rays. Indeed, it must prove somewhat embarrassing and bewildering to a student who is not of some years' standing in scientific study to find in the first few pages statements which really embody the complex results of the most recent research—on the structure of the atom, or on the screw-structure of certain point-systems, for instance—alongside the most elementary treatment of the properties of crystals. It amounts more or less to the revelation of their innermost point-system and space-lattice structure before even the obvious characters and attributes of crystals have been touched upon.

The book is, indeed, in its general character, very like a collection of notes for lectures, illustrated by wall diagrams, only very rarely going into any detail with the subject in hand at the moment. Even the names of original authorities, when mentioned at all, are only given as an afterthought in brackets, or in an occasional note in small print, while references to published memoirs are entirely absent. However, a list of textbooks and works of reference is given at the end of the book. The lecture-room impression is still further emphasised by the large amount of tabular matter in the book. Thus the historic sequence of the acquirement of our knowledge of crystals is practically ignored, and information of all kinds—old and new, some easy of comprehension and some quite beyond the understanding of all but those well versed in the elements of the subject—is laid indiscriminately before the reader.

Having said this much, and being forewarned as to these limitations, it is indisputable that the book has many good points, chief of which is that it will be of considerable use to mineralogists, and especially to those of a petrological bent; for chemical crystallography is largely ignored, except as it concerns naturally occurring crystallised substances. Next must come the valuable fact that the book is not only written under the influence of the knowledge acquired during the last seven years by means of X-ray analysis, but also inspired by the presence in the same university of the discoverer of this remarkable method of probing crystal structure. It is also noticeable that certain sections of the book are specially good, chiefly from their novel mode of presentation and illustration. The four pages of drawings of crystals showing their optical properties are of a very original character, and if one were not reminded so forcibly of the wall diagram by their grouping in such closely compacted numbers, the effect would have been more pleasing and the result more striking.

Doubtless the main use for the book will be as an aid to the author's own students, in affording an authentic account of their professor's lectures. The book covers an immense amount of ground, but is, in the main, elementary and superficial, besides being crudely and cheaply illustrated. It is largely redeemed, however, by the many references to X-ray results and by its occasional bursts of originality. A. E. H. T.

Our Bookshelf.

Penrose's Annual. Vol. xxiii. of The Process Year Book and Review of the Graphic Arts, 1921. Edited by William Gamble. Pp. xii + 88 + plates. (London: Percy Lund, Humphries, and Co., Ltd.; Bradford: The Country Press, 1921.) Price 10*s*. 6*d*. net.

This is the second issue after the war, and there is evidence that the editor has now been able to resume the high level of quality that he had attained before the publication of these instructive annuals was interrupted by the exigencies of military service. The volume may not be quite so thick as, but it seems to us superior to, last year's in many ways, especially in the quality and variety of its specimens of reproduction. The editor, in his summing up of the year's progress, finds no striking new departure to record, though there is much evidence of progress in many directions. The activity during the year has been rather in laying foundations that may well be expected to lead to future advances than in the realisation of improvements. Rotary photogravure holds its own, and is doubtless firmly established, as in the *Times Weekly Edition Illustrated Supplement*, but it appears that the production of the cylinders cannot be ensured within the short time necessary to enable a daily newspaper to be produced entirely by this process. The shortage of skilled labour in the process trade is becoming acute.

Among the several interesting and useful articles is a contribution from Prof. Namias, who finds that bichromated papers (as carbon tissue) may be impregnated with the chromate, and yet remain stable for a very considerable time, if not indefinitely, by using a neutral chromate with a small quantity of an alkali, preferably caustic potash. Such paper does not spontaneously deteriorate. To prepare it for use, the sheets may be hung in a box in which is a small dish containing acetic acid for about half an hour. Obviously other methods of acidification may be adopted. Dr. Reginald S. Clay suggests a method of photography in colour by means of a series of interference units (Newton's rings).

The New Hazell Annual and Almanack for the Year 1921. By Dr. T. A. Ingram. Thirty-sixth year of issue. Pp. lvi + 823. (London: Henry Frowde, Hodder and Stoughton, 1921.) Price 7*s*. 6*d*. net.

We are always glad to see this useful annual, which is invaluable for reference in many matters. The volume gives the "most recent and authoritative information concerning the British Empire, the nations of the world, and all the important topics of the day." It contains among other details, including interesting astronomical and meteorological data, a useful list of all the scientific and other societies in the United Kingdom, and the names of the holders of the various Nobel prizes from the date of their foundation. There are also many valuable articles dealing with such diverse subjects as the statistics of education in the British Isles and the present state of aviation. A wide field is surveyed, and the positions of all the outstanding points are recorded.

Das Schmerzproblem. By Prof. A. Goldscheider. Pp. iv + 91. (Berlin: Julius Springer, 1920.) Price 10 marks.

In this little monograph Prof. Goldscheider, whose earlier researches into cutaneous sense physiology are well known, criticises the evidence relied upon by v. Frey to establish the specificity of the peripheral basis of cutaneous pain. The following sentence expresses sufficiently the author's point of view: "The sensation of pain, therefore, owes its existence to a heightening of irritability produced by the stimulus; unlike other sensations, it is not the simple expression of an excitation due to a peripheral stimulus, but presupposes an increased tonus of the sensory nerve-cell in comparison with the physiological condition" (p. 89).

Many of Prof. Goldscheider's criticisms are interesting, but the value of his book as a contribution to psycho-physiology is greatly diminished by his failure to take account of the recent researches of Dr. Henry Head and the latter's colleagues.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Flint Implements from the Cromer Forest Bed.

THE discovery to which this letter relates was made towards the end of September of last year. For the past eighteen months I have spent a considerable amount of time investigating the deposits forming the cliffs of the north-east coast of Norfolk, and have already published a paper dealing with certain humanly fashioned flints found at, and in the neighbourhood of, Mundesley (Proc. Prehis. Soc. E. Anglia, vol. iii., part ii., pp. 219–43). I devoted my attention during last year to the district of Cromer, and have now to record the discovery of a flint-workshop site, which, in my opinion, is referable to the lowermost division of the Pliocene Forest Bed series. As is well known, the Cromer Forest Bed is generally regarded as of Newer Pliocene age, and was laid down after the deposition of the marine Weybourn Crag (latest beds of the Norwich Crag), and before the commencement of the great Pleistocene glaciations. In the Geological Survey memoir, "The Pliocene Deposits of Britain," Mr. Clement Reid states: "Where most complete, the 'Forest Bed' consists of three divisions—an Upper and a Lower Fresh-water Bed and an intermediate estuarine deposit." In many places along the coast the upper portion of the Cromer Forest Bed series can be seen in section towards the base of the cliff, but the lower part, being covered by beach material, can seldom be observed except when a succession of north-westerly gales has caused the sea to scour away the sand and shingle. It is now, however, possible at low water to examine the basal portion of the Cromer Forest Bed deposits when the receding tide has laid bare certain areas which only a comparatively short time ago were covered by great masses of Glacial and other strata in the then existing cliff. The site at Cromer where the humanly fashioned flints dealt with in this letter were found covers an area of foreshore about 150 yards long by 100 yards wide, and is almost opposite the north-western termination of the sea-wall at that place.

The implementiferous horizon is exposed at low water beyond the seaward extension of the shingle beach, and consists of a great number of flints of varying sizes which, for the most part, appear by their coloration and condition to be referable to the well-known Stone Bed occurring beneath the Crag deposits of Norfolk. Associated with these Stone Bed flints are (*a*) examples of paramoudras, (*b*) a few quartzite pebbles, (*c*) very numerous specimens of clay-ironstone pebbles and rolled pieces of chalk (the flint bed in several places rests upon solid stratified chalk which often shows *Pholas* borings in its surface), and (*d*) small pieces of mineralised bone (Mr. Savin, of Cromer, informs me that two molar teeth of *Elephas meridionalis* have been recovered from this site), belemnites, and other chalk fossils. Lastly, there are to be found scattered about amongst these relics numerous examples of humanly fashioned flint flakes and implements which generally exhibit upon their flaked surfaces a brilliant and arresting yellow-ochreous coloration. It is to be remarked also that many of the large blocks of Stone Bed flint show upon their surfaces flake-scars which are of the same ochreous shade, and the conclusion is drawn that these large flint masses represent the cores from which the ancient Cromerians obtained the raw material used in the manufacture of their artefacts. The position of the workshop site at Cromer is indicated in Fig. 1, which gives a diagrammatic cross-section of the cliff, beach, and foreshore.

The association upon the limited area of foreshore mentioned above of cores, flakes, and implements of varying sizes would appear to preclude the possibility of these specimens having drifted down the coast from some other site, as the sorting action of the tides would militate against such an association. Moreover, many of the Cromer flints collected do not exhibit marked signs of rolling by water. But the strongest evidence in support of the view that the specimens secured are referable to some period prior

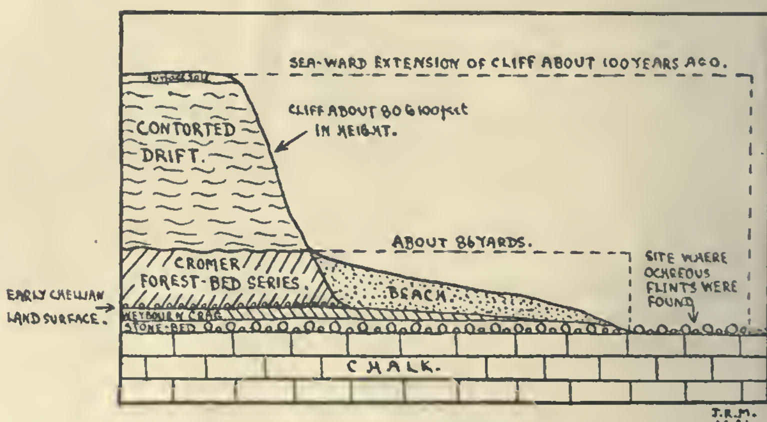

FIG. 1.—Diagrammatic cross-section of cliff, beach, and foreshore at Cromer showing probable relationship of implementiferous horizon to the cliff deposits. (Not drawn to scale.)

to that in which the Glacial deposits forming the Cromer cliffs were laid down is afforded by the fact that the ochreous artefacts have been made almost exclusively from pre-Crag Stone-Bed flints. These latter specimens, often very large and massive, are, to all intents and purposes, sedentary, and have remained so ever since the epoch when they were brought to their present position in pre-Crag times. Thus, when it is realised that many of these large sedentary specimens bear flake-scars exhibiting the same ochreous colour as is to be seen upon the implements and flakes lying near them, it becomes clear that the people who flaked the flints did so at a time when the Stone Bed was exposed, and prior to the deposition of the well-known "Lower Till" and Contorted Drift of Norfolk. And as the coloration of the pre-Crag flints is so markedly different from that of the ochreous specimens, it seems equally clear that the flaking of the latter is not referable to pre-Crag times, but to some later epoch.

I explain these facts in the following manner: After the laying down of the marine Weybourn Crag an emergence of the land took place, and in course of time the Crag suffered considerable erosion. This erosion in places laid bare the sub-Crag Stone Bed, and it would seem that the land surface then existing was inhabited by the makers of the ochreous specimens, who proceeded to use the large, sound pre-Crag flints in implement-making. In support of these conclusions it may be mentioned that in "The Pliocene Deposits of Britain" (p. 40) Mr. Clement Reid states: "There seem never to be more than a few feet of Crag beneath the Forest Bed." Again (p. 149) he states: "It is not improbable that there may also be another land surface beneath the *Lower* Fresh-water Bed, for in one place the Weybourn Crag below the Forest Bed has a rather weathered appearance; but of this one cannot be certain." Further (p. 151) it is stated: "The making of trial borings in 1886 and 1888 showed that the eroded surface beneath the deposit [the Forest Bed] was one of the most marked features, and that there was always a more or less gravelly base to the Forest Bed, beneath which the Crag was cut into by numerous channels or hollows."

As patches of Weybourn Crag are still to be seen near the workshop site at Cromer, and as a very careful search has failed to discover any flints of the same order and colour either in the Stone Bed, where it is exposed at West Runton and Sheringham, or in the upper strata of the Cromer Forest Bed series, it is concluded that the ochreous specimens now described are referable to the earliest member of this series, and are represented elsewhere, in all probability, by the "gravelly base" mentioned by Mr. Clement Reid. I have been able to ascertain that the Stone Bed extends for some distance underneath the shingle beach, and, if excavations could be made, would no doubt be found to occur under the cliff itself. The seaward termination of the shingle beach, where the Stone Bed outcrops, is about 86 yards from the foot of the cliff, and it can be regarded as in every way probable that the workshop site, at present exposed, was covered by the cliff one hundred years ago. In fact, the rate of recession of the cliffs to the south-east of Cromer is much in excess of that allowed for in this estimate. All the above conclusions regarding the geological age of the workshop site and the recession of the cliff at this part of the coast are shown diagrammatically in Fig. 1. It would appear that the sea is gradually uncovering and removing many of the ochreous implements and flakes, as to the south-east of Cromer a number of such specimens may be found upon the shore. These examples exhibit marked signs of rolling and the effects of what is known as "beach action."

The first discovery of flaked flints, claimed as being of human origin, in the Cromer Forest Bed was made by Mr. W. J. Lewis Abbott, who published his original paper in *Natural Science* in 1897 (vol. x., p. 89). I have seen Mr. Abbott's specimens, which are of quite a different order from those with which this letter deals. The number of flints recovered from the workshop site at Cromer now amounts to 249, and they comprise cores, half-finished and complete implements of Early Palæolithic Chellean forms, rostro-carinates, choppers, flake implements, racloirs or side scrapers, points, scrapers of ordinary type, and simple flakes. The majority of the specimens are of massive size, and indicate that the people who shaped them were capable of delivering flake-removing blows of great accuracy and strength. One very large artefact, weighing 7 lb. 6 oz., is flaked into the form of a massive rostrate implement, and, if not used in both hands, could have been wielded only by an individual possessed of great strength and size of hand. The occurrence of several examples at the Cromer site of implements exhibiting flaking upon two opposite surfaces, which approximate in their form to the earliest Chellean artefacts, leads me to regard the whole assemblage of ochreous flints as referable to this cultural stage.

The presence of such an industry in a stratum of, apparently, Upper Pliocene age would seem to be of some interest and importance, and I hope to exhibit the Cromer flints, and to describe them in detail, in the near future.

J. REID MOIR.

Ipswich, January 20.

MR. REID MOIR has submitted sixty of the yellow-stained worked flints from beneath the Forest Bed of the Cromer shore to me, and has asked me to add a few words to his brief report. They are a most impressive collection on account of their abundance, frequently large size, and uniform lustrous surface and orange-brown colour. I have no doubt of their having been shaped by man. Very usually one surface of the flint is a flat orange-brown area produced by a single blow. Others show flaking on both upper and lower surface. Later marginal chipping—subsequent to the ochreous staining of the flint—appears as blue-grey or as black conchoidal scars. Whilst most of the specimens appear to be eminently fitted for use as rubbers in skin-dressing, some show more complete resemblance to coarsely worked ovate implements of Chellean character, and others are distinctly rostro-carinate. The most remarkable among them is the extraordinarily large and heavy rostrate implement weighing 7 lb. 6 oz. It is 10 in. in length and measures 5 in. in breadth and 4 in. in thickness at the butt-end. This huge implement is most definitely shaped by flaking of undoubted human origin. It is almost free from ochreous-yellow stain. Careful drawings of it of the natural size must be published for the use of archæologists. The whole "find" deserves really accurate illustration by figures giving both the actual size and the natural colour. The cost of such illustration is beyond the resources of our learned societies, but may possibly be met by the generosity of those who have enthusiasm for "prehistorics."

E. RAY LANKESTER.

January 29.

Modern Pass and Honours Degrees.

ALLOW me to express agreement with the article on "Scientific Education in the Metropolis" in NATURE of January 20, p. 653, where you deprecate the premature specialisation of a so-called honours degree under modern regulations, as contrasted with the old plan whereby a pass degree in a great variety of subjects had to be taken before specialisation in one subject was allowed. In the old days all the subjects were compulsory, and the range of knowledge required for Matriculation and for First and Second B.Sc. was quite considerable. A candidate who graduated with credit under those strenuous conditions might fairly be considered educated—to some extent even in the Humanities; and, at any rate, he had a severe training in working at subjects for which he had no special aptitude, but of which he ought not to be ignorant, as well as at those subjects which could be assimilated by him without effort.

I hold that the pass degree system in a modern university, if of a proper standard, as it was and I hope still is at the University of Birmingham, for instance, is generally of far more value to candidates and more helpful to their future development than a narrowly specialised course, which is so much easier. A man is engaged on his own specialty more or less all his life, but unless he gains access to the outlying districts of knowledge during his student stage, and under the stimulus of preparation for an examination test, he may never know anything about those other subjects at all.

Reference to an old London University Calendar will show the list of subjects that had individually and separately to be taken and passed in during my own student period—in addition to any attempt to carry some one or more to a higher grade so as to secure specific honours tested by a separate and supplementary additional paper :—

Matriculation.	First B.Sc.	Second B.Sc.
Latin	Mathematics (Trig. and Conics)	Organic Chemistry
Greek	Physics	Physiology
French or German	Inorganic Chemistry	Geology and Palæontology
Arithmetic and Algebra	Zoology	Logic and Moral Philosophy.
Geometry	Botany.	
English Language		
English History and Geography		
Mechanics		
Chemistry.		

Then, on this basis of general knowledge, the doctorate gave an opportunity of carrying some subdivision of one of these subjects to a very much higher stage. Options must be allowed sooner or later, of course, but the question is how soon an option should be allowed. A multitude of options at an early stage is liable to produce a crop of specialists. Such a crop may be necessary for the world's work, but the process of raising it can scarcely be called an education suited to the development of a human being.

While writing, and without presuming to comment on anything concerning London organisation, may I, as an outsider, venture to express a hope that Finsbury Technical College will not be closed? The admirable work done there in the past, and the great names associated with it, entitle it to be held in honour. Let us hope that its benefits will be continued to a generation seemingly more desirous of instruction than ever before. OLIVER LODGE.

Heredity and Biological Terms.

WILL you allow me space for a short comment on the recent discussion in NATURE on Sir Archdall Reid's letters? The chief point raised by Sir Archdall Reid seems to me to be of great importance, and very far from being a side-issue. The usual custom of speaking of "characters" in living beings as either "innate" *or* "acquired": the product of either nature *or* nurture: or of describing them by other pairs of terms of similar import, does lead to much confusion in the minds of many when studying the production of "characters," and very especially that of human characters. Some seventeen years ago, when making a study of this kind, I was aided greatly by many communications I had with Sir Archdall Reid, and particularly by an article entitled "Biological Terms," published in the final number of *Bedrock* in 1914, which virtually sets forth the main position advocated by him in the present discussion. I do not intend to touch on any conflicting views on modes of hereditary transmission which may enter into this discussion, but are not strictly relevant to Sir Archdall Reid's main contention, except to say that the particular difficulty which he points out and strives to conquer can concern only those biologists who do not regard the modern Lamarckian hypothesis as established, or even as verisimilar. If that hypothesis were verified the whole contention would fail.

Sir Archdall Reid's chief point is that it would be a great benefit to science if all branches of it which deal with life adopted a like classification of "characters." At present biologists generally classify characters as "innate" *or* "acquired," while physiologists tend to classify characters from the point of view of the influences, or "nurture," which produce them. He takes, for instance, the case of a hand, a sixth digit on it, and a scar on it. The physiologist says all these characters are products of some kind of nurture, and tries to find out what kind it is. That is the physiologist's business. The biologist, concerned mainly with "nature," says the hand and the sixth digit are "innate" and the scar "acquired." In a certain sense both are right. But the physiologist's language implies that all "characters" are both inborn and acquired, while the biologist's implies that some are "inborn" and some "acquired." The language of the physiologists is always clear, while that of the biologists is very often obscure. Hence, probably, the absence among physiologists of the great divergences of opinion which exist among biologists.

Physiologists are mainly concerned with the development of the individual; biologists with heritage and evolution (or change in the heritage). Assuming that most biologists of the present day hold that heritage passes down the germ-tract, may it not be argued justly that if the child has a hand like the parent, there is no change in "nature" or "nurture"; that if the child has a sixth digit which the parent had not, there is a change in nature, or heritage, but none in "nurture"; and that if the child has a scar, there is no change in heritage, but only one in nurture? It therefore appears to me that Sir Archdall Reid's chief contention is very soundly based. If we think of a hand, scar, and sixth digit as "*characters*," as the physiologist does, they are all alike products of nature and nurture (innate and acquired); if we think of them as *likenesses and differences between individuals*, the hand indicates an innate likeness, the digit an innate difference, and the scar an acquired difference; and if we think of them in *terms of the germ-plasm*, the hand and the scar indicate no change, but the digit is a change (or, in biological language, a "variation").

The burden of Sir Archdall Reid's complaint is that biologists have thought and expressed themselves in terms of "characters," not of the germ-plasm; and that this has largely caused the misleading question, widespread beyond all scientific borders, as to whether "nature" or "nurture" is the stronger influence. This is especially notable in relation to the production of "characters" in the higher animals, and most of all to that of the most distinctive characters of man. Sir Archdall Reid thus insists that a vague terminology has caused neglect of the evolution of the power of developing in response to functional activity; and that, with a more precise terminology, the simple statement, "*Variations are the sole cause of non-inheritance; apart from variations, like exactly begets like when parent and child develop under like conditions*," will cover almost the whole field and thus leave biology free to deal with the many problems of immense scientific and practical importance which concern it.

In my own inquiries I have found that the common assumption of human characters being rigidly divisible as to their origin into two groups, "innate" *or* "acquired," constitutional *or* environmental, is a cause of much confusion; and I think that the import of Sir Archdall Reid's exposition of this matter has not been accorded adequate attention or weight. Nor, after studying the discussion of it in NATURE, can I see any material difference between the views of Sir Ray Lankester and those of Sir Archdall Reid.

London, February 1.

The Scientific Glassware Industry.

I HAVE read with very great interest the article on the optical glass industry published in NATURE of January 20, and should like to direct attention to the condition of the scientific and illuminating branches of the glass industry, which are in the same position as the optical section and of equal importance to the nation. The manufacture of scientific glassware, practically non-existent in the country prior to 1914, was undertaken by several glass-makers at the urgent request of the Government, which, shortly after the outbreak of hostilities, discovered that the prosecution of the war was in danger of being impeded owing to the lack of supplies of these articles. The progress made in the manufacture of this apparatus has been very remarkable, especially when taking into consideration the comparatively short time it has been in existence in this country and the great difficulties with which the manufacturers had to contend. The latter have, however, succeeded in producing glass which is in many cases superior to German or Austrian pre-war glass, although it is freely admitted that in the early days the glass produced was in some cases of extremely bad quality. This has now been remedied, and one may fairly claim that, as regards both the quality of the glass and the technique and workmanship, British-made scientific apparatus now is among the best that can be produced anywhere.

The industry is, however, in grave danger of being again completely lost to this country. Owing to prevailing conditions Germany, Austria, and Czecho-Slovakia are trading under conditions which make it impossible for British manufacturers to compete, and the factories have no alternative but to cease work almost immediately unless the Government gives some very definite assurance that the promises it made when it asked the manufacturers to undertake this work will be very shortly redeemed. The industry has not been in existence sufficiently long to enable the manufacturers to create reserves to fight and meet this competition in the ordinary way. On the contrary, the present loss to those engaged in the industry is extremely large, and it is mainly for this reason that they cannot continue production without the assistance of the Government, the most suitable form of which would be legislation on the lines of the Dyes Bill. The large majority of users of industrial and scientific apparatus have considered this question, and have joined with the manufacturers in urging upon the Government the necessity for immediate action in order that they shall not again have to rely upon foreign countries—and possible future enemies—for supplies of glass which is so vital, not only to the scientific and industrial worlds, but also to the very defence of the nation.

Greenland in Europe.

WITH reference to the letter by "T. R. R. S." in NATURE of January 27, p. 694, I may be allowed to add some explanatory remarks which could not be included in the very condensed synopsis of my Cardiff paper. The map showing Spitsbergen as "Greenland" appears in "An Easy Introduction to the Arts and Sciences," by R. Turner, jun., LL.D., late of Magdalen Hall, Oxford, author of "An Easy Introduction to Geography," etc. The copy cited is the fifteenth edition of that work, and it was issued in 1812 by Longman and other London booksellers. The first edition may be assumed to have been printed about twenty years earlier, with or without that map.

It is difficult for us to determine how far the nomenclature of the 1812 edition was then regarded as old-fashioned. To this very day we call the ocean that stretches from the west coast of Spitsbergen southward to the Arctic Circle "the Greenland Sea." For what length of time that expanse of water has borne that name is an interesting question; at any rate, there is no room for doubting that our seventeenth-century whalers and mariners regarded the Spitsbergen region as specially "Greenland."

As for the passage from Goldsmith's Geography, quoted by "T. R. R. S." as indicating another point of view, he will find, I think, on fuller consideration, that it does not conflict with the map of 1812, because Goldsmith's statement that icebergs or ice-floes "are to be met with on the coasts of Spitzbergen, to the great danger of the shipping employed in the Greenland fishery," clearly implies that the scene of "the Greenland fishery" lay off the western seaboard of Spitsbergen. That the latter name was given in the first place to the mountain peaks is manifest; indeed, an Arctic voyager of 1653 illustrates the different application of the two terms. On his outward voyage towards Vaigatz his ship sighted the distant peaks of "Spitzbergen" to northward, but when a visit was afterwards paid to the great whaling station in that archipelago he speaks of the land as "Greenland." Probably the two names have been used interchangeably for many generations.

DAVID MACRITCHIE.

Edinburgh, January 29.

The Mild Weather.

IN continuation of the letter on the above subject in NATURE of January 20, it may be of interest to give a few facts for the calendar month of January, since high temperatures were so persistent throughout. From the beginning to the end of the month there was a neck-to-neck race for record temperature between the Januarys of 1916 and 1921. The temperature at Greenwich for the civil day as published by the Registrar-General's weekly returns shows the supremacy for warmth to be claimed by January of the present year, when the mean for all the maximum readings was 50·0° F., the minimum 40·8°, and the mean of the mean maximum and minimum 45·4°. For January, 1916, the corresponding means were 50·4°, 40·1°, and 45·3°. There is only a trifling difference between the results for the two Januarys, which are the warmest during the last eighty years. In January, 1916, the days were slightly warmer than in 1921, whilst in January, 1921, the nights were appreciably warmer than in 1916.

The two years 1916 and 1921 are the only instances with the January mean maximum temperature 50° or above, and they are also the only instances with the mean minimum temperature 40° or above. In January, 1916, there were nineteen days with the shade temperature 50° or above, and eighteen such warm days in January, 1921; whilst in 1916 there were three nights with the temperature 45° or above, and in 1921 nine correspondingly warm nights. In both years the mean temperature for January was 7° above the normal.

The Leader Cable System.

SO far back as 1893 the idea was conceived of using electric signals transmitted through a submarine cable to guide ships past dangerous places. But it was not until Prof. R. B. Owens, of McGill University, began investigating the subject that what is now known as the leader cable system took practical shape. Prof. Owens took out certain patents in 1901–3, and these were later presented to the Admiralty, which has decided to allow anyone who wishes to do so to use them without paying royalty.

When Prof. Owens first began his researches the thermionic-valve amplifier was not in existence, and from lack of this important adjunct to its efficiency the leader cable could not be put to practical use, as the signals originated by it were not strong enough for navigational purposes. The invention of the amplifier enabled this defect to be overcome, with the result that during the war leader cables were employed both by ourselves and by the Germans. Such cables have since been laid at Portsmouth, New York, and Brest.

In all these installations the underlying principle employed is that devised by Prof. Owens, but considerable improvements have been made in the details of the apparatus and in the manner of using it. These advances are mainly the result of work carried out at various Admiralty experimental stations, particularly at Portsmouth, where a cable 17 nautical miles in length has been laid along the eastern approach to the harbour. The working of this cable was demonstrated to the foreign naval attachés recently.

A leader cable system comprises a submarine cable laid in any waters where it is desired to facilitate navigation. The sea end of the cable is earthed, whilst the shore end is taken into a transmitting station and there connected to one terminal of an alternating dynamo, the other terminal of the alternator being connected to earth or the sea. In the cable at the shore station a power-operated signalling key is inserted by means of which the current in the cable can be made or broken so as to transmit through the cable any pre-arranged signals or Morse letter. In order that a ship may be able to locate the cable and follow along it a receiving apparatus is fitted in her, or a portable set may be taken on board by the pilot. This apparatus consists of two coils of wire, one on the port and one on the starboard side, which are connected to an amplifier and telephones on the vessel's bridge through a change-over switch. In the telephones the signals given out by the cable are heard as a sharply pitched musical note.

The electric current in a leader cable is an alternating one, and the actual field distribution arising therefrom is complicated by the fact that the return current appears to be mainly concentrated between the cable and the sea surface. Considering the case of a continuous current in the cable and a return path through sea water in the vicinity of the cable, the resultant magnetic field in the air above the cable will contain circular lines of force due to the constant current in the cable and horizontal lines of force due to the return current in the sea water. Assuming the return current to be distributed uniformly and thus to constitute a sheet of current the magnetic field of which is horizontal and at right angles to the cable, the resultant field will be horizontal directly over the cable, vertical some distance away, and again approximately horizontal, but in the reverse direction, at a considerable distance from the cable.

If instead of a current of constant intensity an alternating current is passed through the cable, electric currents in a direction opposed to those in the cable will be induced in the sea water, and the intensity of these induced currents will be greatest near the cable. Above the surface of the water the lines of force due to these induced currents will be slightly curved to the surface, but the general direction of the field will be opposed to that due to the current in the cable. In the final resultant field the points of inversion are moved towards the cable. With increase in the frequency of alternation the induced currents increase in intensity, and as a result the points of inversion (X and Y, Fig. 1) move closer together as the frequency increases.

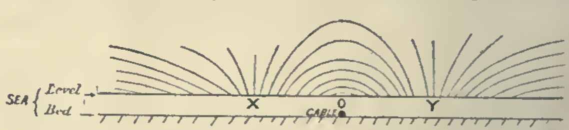

FIG. 1.—Approximate distribution of magnetic field caused by an alternating current in the cable.

When the hull of a ship is brought into the vicinity of the cable that part of the ship—and the space adjacent to it—farthest removed from the cable will be screened to some extent. The ship being a good conductor, electric currents are induced in its outer surface when an alternating current flows through the cable. When the ship is broadside on to the cable these sheets of current flow fore and aft and give rise to a magnetic field parallel to the surface of the ship. If the intensity of the magnetic alternating field giving rise to these induced currents is greater on one side of the ship than on the other, then the resulting magnetic field will be greater on the former side.

When a steel or iron ship lies directly over the cable the intensity of the magnetic field is appreciably increased because of the presence of the ship, but the intensity is small over the deck because of the screening effect of the hull. If on each side of the ship a square frame is placed, and if on these frames a number of turns of wire are wound, thus forming a coil, some of the lines of force will pass through these coils. When the ship lies directly over the cable the number of lines of force passing through each coil will be equal, and the strength of the signals heard in each coil will be equal also. But when the ship is on one side of the cable the strength of the signals received in the coil nearest the cable will be the louder. By this variation in the strength of signals the navigator is able to tell which side of the cable his ship is on.

Experiments made at Portsmouth show that the best position for the coils to be placed is with their centre not farther than within 18 in. from the ship's side and the bottom edges of the coils inclined outward at an angle of 15° to the vertical. When they are so placed screening is satisfactory up to 400 yards, the maximum range is approximately 600 yards, and fairly good signals are obtained even if the cable is approached at a steep angle.

The range at which signals from a leader cable can be received will be largely increased if in place of coils being used two electrodes are towed astern of the ship, these being insulated cables of approximately 50 and 150 yards in length, with the insulation at the outboard ends of the cables stripped back for a distance of 6 ft. so as to make good electrical connection with the sea. The inboard ends of the cables are connected to the receiving apparatus on the bridge through a twin wire led from the stern. The chief difference when using the electrodes instead of coils is that, as with the former there is no screening effect, the signals received do not indicate which side of the leader cable the ship is on. To ascertain this it is necessary to maintain a steady course for some few minutes and to observe whether the strength of the signals increases or decreases.

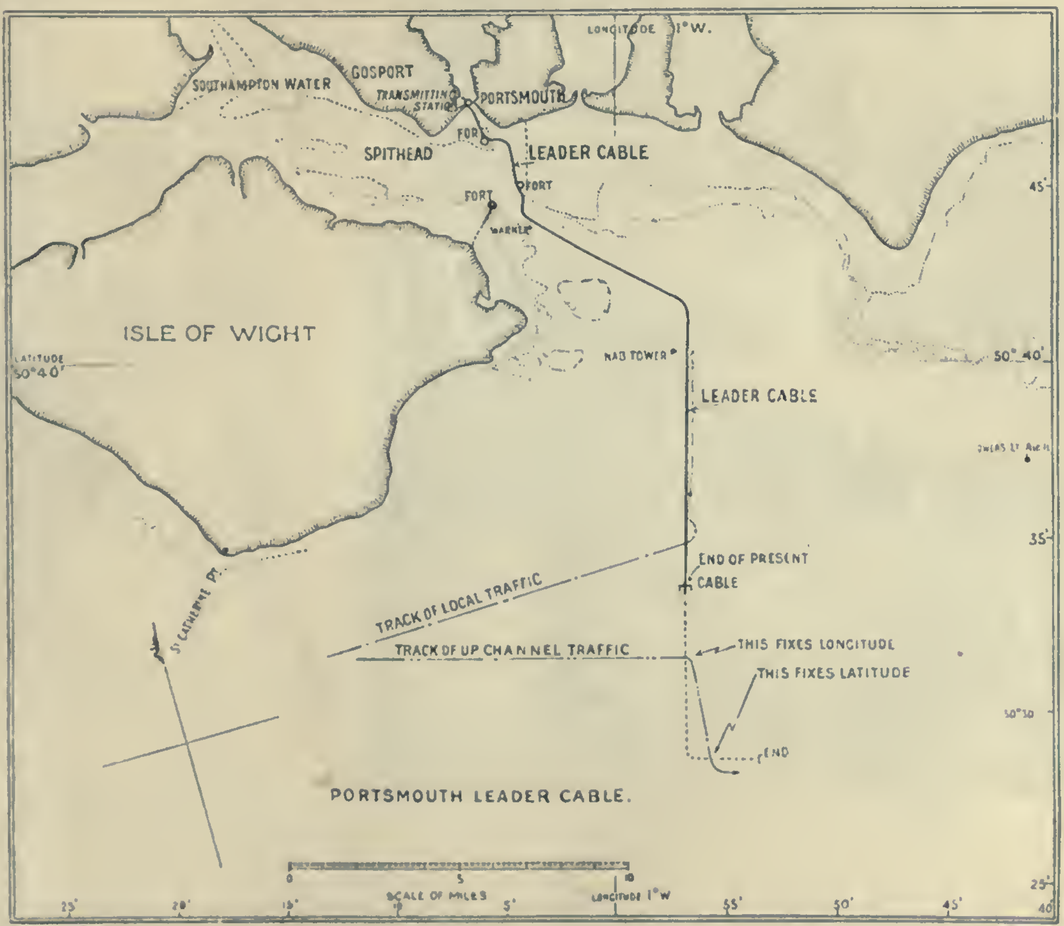

FIG. 2.—Position of Portsmouth leader cable. The broken line turning east from the end of the cable indicates the direction of a proposed extension of the cable which would enable ships proceeding up-Channel to fix their position in thick weather by crossing the cable twice at the points indicated.

In the receiving apparatus aboard ship two leads are taken from each coil to a change-over switch installed on the bridge in such a position that it is easy of access to the navigating officer. Two leads are taken from this switch to an amplifier of the three-valve low-frequency transformer type, using a 4-volt filament battery and a 60-volt anode potential. The telephones are connected directly with the amplifier, and can be fitted with a head-piece or a single receiver. By using a more powerful amplifier it is possible to install a loud-speaking telephone repeater which will enable the signals to be heard by all standing on the bridge. By working the change-over switch the navigating officer is able to detect, from the strength of the signals in the coils, which side of the cable his ship is on, as the signals will manifestly be loudest in the coil nearest to the cable.

The greatest length of leader cable in use is forty miles. For a longer distance than this it would be necessary to pay special attention to decreasing the continuity resistance of the cable and the capacity between the core and earth in order to reduce the current attentuation. This would probably lead to a very expensive cable being required. So far experiments have not been carried out in a greater depth than 30 fathoms, but there is evidence that as the depth of water increases, the strength of signals to one side (say 300 yards) from the cable does not decrease so rapidly as is the case directly over the cable, but the motion of a ship does not materially affect the reception of cable signals by her. It is also possible for a ship to receive visual signals, instead of audible ones, from a leader cable. In that case electric lamps are lighted by the current from the cable. But the visual system has not been developed to such a practically useful stage as the system described above.

Lake Victoria and the Sleeping Sickness.[1]

ONE need not yet have reached extreme old age to remember something of the extraordinary interest excited by the discovery of the great Victoria Lake and the unveiling of the sources of the Nile by Speke and Grant. A wide field for the imagination was opened up by the news of a vast expanse of water, second only to Lake Superior among fresh-water lakes, in the interior of the African continent. Dr. Carpenter's narrative enables us to substitute reality for romance, and to make the acquaintance of a country of great beauty and charm, marred, unfortunately, by the terrible plague of sleeping sickness.

FIG. 1.—Fly beach on Damba Isle; a favourite breeding ground is under the bushes at the gap on the right. From "A Naturalist on Lake Victoria."

The main object of the author in his visit to the great lake was the investigation of the bionomics of *Glossina palpalis*, the tse-tse fly which carries the trypanosome of sleeping sickness. This important work, which was carried on under the auspices of the Tropical Diseases Committee of the Royal Society, involved a residence of about four years on one or other of the numerous islands which stud the northern part of the lake, preceded by a stay of some months at Jinja, on the mainland. The outbreak of war in August, 1914, caused an unfortunate interruption in Dr. Carpenter's labours; for the exigencies of active service kept him employed in various parts of German and Portuguese East Africa until November, 1918, when he was released from duty and returned to Uganda.

In spite of this and other intermissions, the author has been able to put upon record, as Prof. Poulton remarks in his preface, a really wonderful body of observations. The earlier chapters of his work contain a useful *résumé* of our present knowledge of the natural history of *G. palpalis* in its relation to other factors which contribute to the spread of the disease, such as the presence of game. It is needless to say that for the greater part of this now intimate knowledge we are indebted to the admirably devised and painstaking observations and experiments of Dr. Carpenter himself, as may be seen at greater length in the official reports of the Sleeping Sickness Commission. It is satisfactory to know that the author, as a result of his careful study of the habits of the pest, sees some hope, if not of exterminating the fly in certain regions, yet of diminishing its numbers to a point at which it may cease to be dangerous. This, it appears, can be done by constructing artificial shelters which are highly attractive to the fly, and systematically destroying the pupæ that are formed therein. An alternative plan, viz. the extermination of the Situtunga antelope (*Tragelaphus Spekei*), the

[1] "A Naturalist on Lake Victoria: with an Account of Sleeping Sickness and the Tse-Tse Fly." By Dr. G. D. H. Carpenter. Pp. xxiv+333+2 plates. (London: T. Fisher Unwin, Ltd., 1920.) Price 28s. net.

natural reservoir of the trypanosome, is pronounced by Dr. Carpenter to be impracticable.

His descriptions of the sights and sounds of the lake and its islands give a lively idea of the interest of the naturalist's surroundings. "The colouration," he says, "in the bright sunlight during one of the clear days characteristic of the heavy rains is really wonderful in its brilliancy. From high ground one looks over the top of vividly green forest towards distant purple islands set in a sparkling deep blue lake, which is stirred into white-capped waves by the prevailing south-east breeze. So clear is the atmosphere at this time, especially in the evenings, that from Bugalla Island some of the individual houses at Entebbe, on the mainland, twenty-five miles away, could be distinguished with the naked eye."

Some of the voices of the night are thus described: "The thunderous snortings of hippos, the muffled bark of the Situtunga, break in upon the continuous shrill tinkling sound, curiously suggesting sleigh bells, produced by thousands of small frogs along the shore. Crickets chirp all round and in the house, and during the rains one enormous species, sitting just inside the mouth of its burrow, makes the earth resound with a continuous high-pitched buzzing."

The last seven chapters of the book contain a mass of valuable observations on the fauna, especially of the group of islands south of Entebbe, and of the Sesse archipelago in the north-west portion of the lake. The chapters on the insect life are of especial interest, more particularly the minute account of the wonderful mimic, *Pseudacraea eurytus*, in relation to which Dr. Carpenter's criticism of the mutation theory will be read with interest. The book is well illustrated by photographic views and other plates, which are excellently reproduced. F. A. D.

Industrial Research Associations.

IX.—BRITISH BOOT, SHOE, AND ALLIED TRADES RESEARCH ASSOCIATION.

By JOHN BLAKEMAN.

DURING the year 1918 a few prominent Northampton business men felt that it would be advantageous to encourage scientific research in connection with the boot, shoe, and leather industries. The Northampton Boot Manufacturers' Association was approached and promised support, as also did the more prominent leather manufacturers; but at first it was intended that only a local research scheme should be set on foot, conducted jointly by the Northampton boot, shoe, and leather manufacturers. The Research Department was asked for advice, and the secretary, Sir Frank Heath, having attended a conference at Northampton on September 24, 1918, urged strongly that a British Research Association for the boot and shoe industry should be established which should be national in its scope, and should work in co-operation with the Government Department. It was also decided that a separate association should be formed for leather manufacture, but that the Boot and Shoe Research Association should invite leather manufacturers to membership, as they would have many problems in common.

The Northampton Boot Manufacturers' Association promised an annual subscription of 375*l*. for five years, which has been raised by a levy of 7*d*. each on the average number of employees, while the minimum subscription for any firm is three guineas per annum. The council of the Research Association has undertaken that the total contributions from members shall be not less than 500*l*. per annum for five years, and the Research Department will then contribute a sum equal to that contributed by members up to a limit of 1500*l*. per annum.

The association began in Northampton as a local effort, and its organisation has consequently centred round the Northampton Technical School. The work that has been accomplished so far has been made possible only by having the equipment and staff of the technical school available. The organisation, however, is such that if at any time the association develops to such an extent that it would be an advantage to separate from the technical school, this could be done without difficulty. In any case, the work that the association has set before itself can be done efficiently only by national effort, and as interest in the work spreads, the question of the relation of the association to other centres of industry and to educational institutions will have to be reconsidered.

The main objects of the association are:

(1) To establish a reference index for the trade by the systematic collecting, filing, and circularising of information, and the building up of a technological museum.

(2) To establish a scientific laboratory for analysing, testing, and standardising materials used in boot and shoe manufacture.

(3) To investigate the applications of science and scientific methods to the industry.

(4) To investigate suggestions for new materials and processes.

(5) To improve scientific and technological teaching in connection with the industry.

The boot and shoe industry is somewhat peculiar in its character. It does not effect any chemical or physical change in the structure of materials, but simply collects the highly finished products of other industries, assembles them, and converts them into boots. There are a large variety of materials used, the chief one being leather, and little attempt has been made in the past to apply scientific tests to these materials or to standardise them. The materials have to fulfil certain technical conditions, both in manufacture and in wear, and the Research Association will study these materials with the object of expressing their properties in terms of physical and chemical constants, and of seeking the correlation between them and the practical properties required in manufacture and wear.

In the manufacture of boots there are also a very large number of small processes of a highly specialised character, for which a large variety of extremely complex machines are required. The development of these machines comes to-day almost entirely from the engineering side, although they are subject to the criticism of the practical boot and shoe man who operates them. So far there has been little effort to reduce these processes to written descriptions with the object of arriving at an agreement as to the best methods of performing them.

A materials chart and a processes chart have been printed and issued to members (copies of which may be obtained from the secretary, Technical School, Northampton). The objects of these charts are as follows:—

(*a*) To present in a concise form a survey of the problems which may arise in the working of the association, and of the questions on which information may be desired.

(*b*) To form a basis for the systematic filing of information.

(*c*) To secure the co-operation of members of the association in collecting the most useful information.

Specimen entries from these charts are given below:

MATERIALS CHART

Departments			*a.* Standardising	*b.* Chemical analysis	*c.* Testing	*d.* Kinds	*e.* Comparison	*f.* Suitability	*g.* Substitutes	*h.* Cost	*i.* Sources	*k.* Terminology	*l.* Literature
3	Lasts	Measurements											
12	Patterns	Geometrical tools											
24	Clicking	Calf (full chrome)											
37	Clicking	Lineo linings											
55	Closing	Linen threads											
58	Closing	Rubber adhesives											
86	Bottom stock	Insoles											
111	Lasting	Toe hardeners											
126	Attaching	Welting needles											
153	Finishing	Edge trimmer cutters											
187	Cleaning	Patent abrasives											

PROCESSES CHART

Departments			*a.* Methods	*b.* Machines	*c.* Combinations	*d.* Speed	*e.* Quality	*f.* Organisations	*g.* Costing	*h.* Comparisons	*i.* Physical effects	*k.* Terminology	*l.* Literature
3	Patterns	Standard cutting											
26	Clicking	Cutting outsides											
42	Closing	Skiving											
92	Bottom stock	Channelling											
120	Lasting	Pulling over											
131	Attaching	Welt sewing											
170	Finishing	Edge setting											
194	Cleaning	Sizing											

Each square in the charts is intended to suggest a field of investigation—*e.g.* M. 111 *b* would deal with the chemical analysis of toe hardeners, P. 120 *b* with the various machines used for pulling over. The materials chart contains 192, and the processes chart 200, entries.

In the preliminary period to date, the association has investigated problems proposed by members, some minor and some important, and has separated out the problems for immediate investigation. Among those which have been attacked are:—

(1) Analyses of tanning liquors.

(2) Detection of adulterants in linings.

(3) Detection of free acid in insole leathers.

(4) Tensile strength of threads, waxed and unwaxed.

(5) Tensile strength of linings, loops, etc.

The most important of the questions demanding prompt investigation are:—

(1) The suitability of various leathers for welted insoles, the properties required, and the methods of manufacture most likely to yield those results. A special committee is conducting this investigation. A general investigation of sole leathers is to come later.

(2) The cracking of patent leather.

(3) Complete analyses of gums and adhesives used in the industry.

(4) The testing of all threads used in the industry, and the effects of gums and waxes on them.

(5) Finishing of chrome leather soles.

(6) The effects of perspiration on leather.

A large amount of experimental work has been done on the mechanical behaviour of leather under tension, repeated bending to test fatigue effects, and abrasion. Some of these results have been given in a printed paper entitled "Experiments on the Wearing of Bottom Stock Leather under Abrasion," copies of which may be obtained from the secretary at the address given above.

The nature of the problems which are considered likely to be of immediate importance may be illustrated by the questions which have arisen in the work of the special committee on welted insole leather. This committee was set up to consider the properties required in leather to render it satisfactory for welted insoles, to seek the relation between different tannages and the extent to which the desired properties are produced, and to set up a standard for an adulterant-free welted insole.

During the process of manufacture the leather must be such as admits of a satisfactory and durable seam in the process of welt sewing and in wear. It should behave in an ideal manner in its relation to the perspiration from the feet. Most of the English tanners who produce this kind of leather have submitted samples of their products, and these samples are being submitted to the following kinds of tests:—

(1) Wearing tests on hot and dry feet.
(2) Chemical analyses giving percentage of ash, fat, moisture, hide substance, tannin, and water solubles.
(3) Microscopic examination of fibres.
(4) Physical and chemical tests, including tension, abrasion, fatigue on repeated bending, water penetration, drying after wetting, and the tearing strength given by the channel cut in a standard manner.

In conclusion, it must be stated that the Boot and Shoe Research Association has been set up on a very modest scale, with some uncertainty as to the extent to which scientific methods can be applied to the industry. Experience to date has shown that definite and important lines of investigation do exist, and it is hoped that the work of the association will extend.

Obituary.

Dr. J. C. Cain.

Dr. John Cannell Cain, whose death occurred suddenly at his residence in Brondesbury Park on Monday morning, January 31, at the early age of forty-nine, was the eldest son of the Rev. Thomas Cain, of Stubbins, Lancashire, and was born on September 28, 1871, at Edenfield, near Manchester. He received his education at the Victoria University (Owens College) and at the Universities of Tübingen and Heidelberg, obtaining the B.Sc. in the Honours school at Owens in 1892, and the D.Sc. at Tübingen in 1893. It was after he had migrated from Tübingen to Heidelberg in the autumn of 1893 that the writer of this notice first met him. He returned to Owens College for a short time in 1894, where he worked with W. A. Bone, but it is evident that at this period he was already feeling drawn towards that field of organic chemistry to which he ultimately devoted his life, for in 1895 he resisted the lure of research in the rapidly developing organic school at Manchester and entered the works of Messrs. Levinstein, Ltd., of Crumpsal Vale, where he remained until 1901. It was during this period of his career that the writer became intimately acquainted with him, for they lived in the same house at Cheetham Hill, the writer working at research at Owens College, and Cain at Crumpsal. Many were the discussions on colour chemistry which were held during the evenings, and it was here that it was decided to write the book which ultimately appeared under the title of "The Synthetic Dyestuffs" in 1905.

Cain did not, however, remain long at Levinstein's, and in 1901 he became head of the chemistry and physics departments of the Municipal Technical School at Bury, in Lancashire, where he started, with Frank Nicoll, the important series of researches on the rate of decomposition of diazo-compounds, three parts of which were published during 1902 and 1903. At this stage he also commenced his study of the diphenyl compounds, an investigation which, as will be seen, he continued at a later date elsewhere. As an outcome of his research work, Cain obtained the degree of D.Sc. in the University of Manchester in 1904, being one of the first three to receive the highest degree of the newly created University. Nevertheless, his love for the practical side of his science prompted him in 1904 to leave the Bury Technical School and to take up the post of manager and head chemist to Messrs. Brook, Simpson, and Spiller, of London, a position in which he remained until 1906, when he was appointed editor of the Chemical Society's publications, an office he held at his death.

During the period of his editorship Cain spent much of his spare time at research, and in 1907 published his theory of the constitution of the diazo-compounds, an ingenious attempt to harmonise much conflicting evidence, which, although it has not found general acceptance, yet still affords the simplest means of explaining many of the reactions of these very reactive substances. In 1908 Cain published the first edition of his "Chemistry of the Diazo-Compounds," a book which contains a complete account of these valuable substances. Although during this period he was handicapped by the strenuous work required by his office, and to a certain extent by the lack of laboratory accommodation, he was able to continue his research work on the diphenyl compounds, and in conjunction with Miss Micklethwait, Dr. Brady, and others he published three parts of the series. Perhaps one of the most interesting features arising out of this work was the final demonstration that there are two distinct *o*-dinitrobenzidines yielding distinct acetyl derivatives and distinct dinitrodiphenyls, phenomena which, it is suggested, are due to a form of isomerism which depends on the limitation of the free rotation of the singly linked carbon atoms.

During the war Cain placed his services where they were most needed, and as chief chemist to the Dalton Works of British Dyes, Ltd., at Huddersfield, he was responsible for much of the work which has led to the reorganisation of our dye industry. He also, for a short time, acted as superintendent to H.M. factory at Hackney Wick. The services he rendered to the Chemical Warfare Committee were especially valuable, because to him was allotted the task of searching the literature for substances likely to be of a noxious character. This, to the writer's knowledge, he did in no uncertain manner.

During recent years Cain produced a new edition of the "Chemistry of the Diazo-Compounds," a valuable and interesting book on the "Intermediate Products," and a revision of vol. i. of "Roscoe and Schorlemmer." It will be seen, therefore, that Cain was an organic chemist of no mean order, especially in connection with the theory and practice of his favourite subject. That he was an editor who carried out the duties of his editorship with the thoroughness which characterised all his actions the publications of the Chemical Society for fifteen years bear witness; but it will be neither as an organic chemist nor as an editor that he will be remembered best, because he occupied a position alone, in that he possessed a knowledge of chemistry and of chemical data which can only be described as encyclopædic. He was, in fact, a living "Beilstein," and no question seemed to come to him amiss. Woe betide the man who ventured to ignore the previously published work of others, Cain soon pointed out his error to him. The writer can recall an instance in which he had happened to forget a previous paper published by himself on the same subject and to which Cain at once directed his attention.

Cain had an exceedingly lovable disposition. His loss to his friends will be grievous, and to science one which it will be hard to repair.

J. F. T.

CHARLES EDWARD FAGAN, C.B.E., I.S.O.

MR. C. E. FAGAN, secretary of the Natural History Departments of the British Museum, died at his residence in West Kensington on January 30, after an illness which commenced about a month earlier. A short account of the value of his services to the museum was published in NATURE of January 13, p. 638, in a notice of his impending retirement, which was to have taken place on March 31 next.

Mr. Fagan's immediate ancestors were in the Diplomatic Service, and he himself possessed to a remarkable degree qualities which might well have led to high distinction in the same career if he had adopted it. He was born at Naples on Christmas Day, 1855, when his father was Secretary of the Legation in that city. At the age of nine he came to England and was placed under the charge of Sir Anthony Panizzi, being sent to school at Leytonstone. After Sir Anthony's retirement from the post of principal librarian of the British Museum, Mr. Fagan was frequently at his house, where Mr. W. E. Gladstone sometimes joined them in a game of whist. In 1873 he entered the British Museum, and he afterwards followed the natural history collections to the South Kensington branch, where the remainder of his work was done. He became assistant secretary in 1889, and he was appointed secretary of the Natural History Departments in 1919, in special recognition of his services, as a part of the reorganisation consequent on the retirement from the directorship of his contemporary, Sir Lazarus Fletcher, who died on January 6 last.

Mr. Fagan was a man of wide and varied tastes. He had a strong love for natural history; but he was also interested in art, on which he was well informed, and in European history. He could speak with authority of the Napoleonic campaigns, on which he had a good library, and he had also a wide knowledge of the history of the Victorian era. He was joint-author with Mr. Andrew W. Ture of a book on this subject, entitled "The First Year of a Silken Reign." He was interested in every form of sport, and he never missed a University boat race from the year in which he came to London to the last year of his life. His knowledge of the history of English racing was of good service to the museum in the formation of a collection of distinguished racehorses. During the recent war he organised propaganda work, which was important in informing our Allies of the efforts made by this country in the great struggle. In view of his ancestry, which was partly Italian, and of his artistic tastes, it is not surprising that he had a special affection for Italy, which he often visited.

It is impossible to speak too highly of the services Mr. Fagan rendered to the Natural History Museum. Events beginning with Sir William Flower's illness while still director placed important responsibilities in his hands, and the administrative experience thus gained was of the greatest use to Flower's successors in that post, while he worthily upheld the interests of the museum during periods of interregnum. He possessed conspicuous tact and remarkable insight, and he had an extraordinary capacity for forming a correct judgment on a difficult question. These qualities gave him an exceptional position in the museum, and his colleagues who sought his assistance rarely left him without feeling that they had gained by hearing his opinion. The view which he took of the functions of the National Museum was a broad one. Its obvious purposes were to serve as a treasure-house for the accumulation of specimens and to educate students and the general public in all that pertains to natural history. But he thoroughly realised the importance of making it a centre of research, and there can be no question that his initiative was responsible for many new departures which have materially assisted in the advancement of knowledge. In his opinion, an institution supported out of public funds had the responsibility of giving practical service to the nation, and he welcomed opportunities of showing that this could be done. The consultative functions of the museum have been increasingly appreciated in recent years, and particularly during the war, a result largely due to his influence. Its advice has been repeatedly sought by other Government Departments in such matters as the protection of birds and other animals in our Colonial possessions, the part played by insects and arachnids in the spread of disease, and the extraordinary development of the whaling industry during the last fifteen years, in questions relating to fishery problems, and in many other practical applications of zoology, botany, geology, and mineralogy.

On many occasions Mr. Fagan was specially concerned in promoting scientific expeditions, among which may be mentioned those to Ruwenzori, 1907, and to Dutch New Guinea, 1909–11 and 1912–13, the collections in the museum being largely augmented in these ways. By his personal influence he was responsible for inducing private benefactors to present numerous collections and important specimens. He was hon. treasurer to the International Ornithological Congress in 1905 and to the Society for the Promotion of Nature Reserves, British representative on the International Committee for the Protection of Nature in 1913, and a member of the Council of the Royal Geographical Society and of other scientific bodies. He organised the exhibits of the British section of the International Shooting and Field Sports Exhibition, Vienna, 1910, of the Festival of Empire and Imperial Exhibition (game fauna section), Crystal Palace, 1911, and of the British section, Ghent Exhibition, 1913, illustrating the relation of entomology to tropical diseases.

At the age of twenty-one Mr. Fagan married Miss Stronach, who died in 1905, and he leaves one son. His career was one long record of single-minded service, strenuously and successfully performed. His influence on the Natural History Museum, from the commencement of its existence as an independent branch of the British Museum, has left a permanent mark on its character. His disposition was essentially sympathetic, and he never permitted himself to express uncharitable opinions of others. He is deeply mourned by his many friends, and particularly by his colleagues, who recognised his lovable qualities and the great value of his services to the museum and to science.

Sidney F. Harmer.

C. Simmonds.

We regret to announce the death, on January 15, of Mr. Charles Simmonds, one of the Superintending Analysts in the Government Laboratory. Born at Stourbridge in 1861, Mr. Simmonds was educated privately, and, selecting the Civil Service as a career, secured one of the chemical studentships at South Kensington established by the Commissioners of Inland Revenue for training the staff of their laboratory, then at Somerset House. This was afterwards raised to the status of a separate Government Department under Sir Edward Thorpe as the first "Government Chemist." Mr. Simmonds was entrusted (*inter alia*) with the investigation into the composition of "Pottery Glazes and Fritts" for the information of the Royal Commission appointed to report on that subject, and contributed an article under this title to Thorpe's Dictionary of Applied Chemistry, as well as several papers of a kindred nature to the Journal of the Chemical Society, viz. "Lead Silicates in relation to Pottery" (1901); "Constitution of certain Silicates" (1903); "Reduced Silicates" (1904); and (in conjunction with Sir Edward Thorpe) "Influence of Grinding upon the Solubility of Lead in Lead Fritts" (Manchester Memoirs, 1901). Mr. Simmonds was also the author of a treatise on "Alcohol," published by Messrs. Macmillan and Co., which is admittedly the most up-to-date and comprehensive work in English on the subject, and he was up to the last a frequent contributor to the pages of Nature.

Mr. Edward C. Bousfield, whose death is announced, received his professional training at St. Bartholomew's Hospital, and after qualifying spent a number of years in general practice, at the same time carrying out a good deal of research work in microscopy and bacteriology. He was one of the first to take up photomicrography, and published a useful manual on the subject. He afterwards established a clinical research laboratory, and became bacteriologist to the metropolitan boroughs of Camberwell and Hackney.

It was reported from Copenhagen on February 1 that the official Soviet Press Agency had denied the report of the death of Prince Kropotkin, whose obituary notice we published last week. We have been hoping that later messages would confirm this news; but a wireless Press report from Moscow states that Prince Kropotkin died there on Tuesday, February 8.

Notes.

NEXT week's issue of NATURE, February 17, will be a special number devoted to articles upon the principle of relativity. We have been fortunate in securing contributions from leading authorities upon this subject, including Prof. Einstein himself, and the whole number will form the most important presentation of its various scientific aspects yet published. The principle is of such wide significance, and so many books and papers have been written upon it, that a synoptic statement of its structure and consequences will be of permanent value.

THE Actonian prize of the Royal Institution has been awarded to Prof. G. E. Hale, director of the Mount Wilson Solar Observatory, California, for his contributions to solar physics. On Saturday next, February 12, at 3 o'clock, Prof. A. Fowler will begin a course of three lectures at the institution on spectroscopy. The Friday evening discourse on February 11 will be delivered by Dr. F. W. Aston on isotopes and atomic weights, and on February 18 by Mr. Solomon J. Solomon on strategic camouflage.

THE newly incorporated Institute of Physics has issued a pamphlet describing its objects and giving the regulations for the admission of members. The institute proposes to grant diplomas to members indicating a high standard of professional competency, and hopes in this way to secure proper recognition of the professional status of the physicist. It will serve also to co-ordinate the work of existing societies connected with physics and its applications. Any member of a "participating society" is eligible as an ordinary member of the institute, but to become an associate or a fellow he must satisfy certain other conditions which relate generally to his training as a physicist and to the importance of the work in physics in which he has been engaged. The annual subscriptions are: for fellows and associates, two guineas and one guinea respectively, while ordinary members pay no subscription. A member of two or more participating societies pays a reduced subscription to those societies, and under certain conditions the charges for the publications of the societies are reduced. The office of the institute is at 10 Essex Street, W.C.2.

SIR JAMES J. DOBBIE, whose recent retirement from the position of Government Chemist and Principal of the Government Laboratory, held by him since 1909, was referred to last week, has to his credit a considerable amount of research work, particularly relating to the constitution of the alkaloids. He has also devoted much attention, in conjunction with the late Prof. Hartley, to the study of absorption spectra, with special reference to the relation between absorption and chemical constitution, and a large number of papers on these subjects were published in the Transactions of the Chemical Society between 1898 and 1912. Quite recently he contributed papers to the Royal Society (conjointly with Dr. Fox, of the Government Laboratory) on the absorption of light by elements in a state of vapour in relation to their molecular constitution. As Government Chemist Sir James Dobbie has been responsible for numerous important investigations for various Government Departments, such as the nature of the pigments used for postage and other stamps, the properties of celluloid, the preservation of the timber in the roof of Westminster Hall, etc. During the war a large amount of difficult and responsible work was thrown upon the Government Laboratory in connection with the War Trade Department, the analysis of metals and alloys for the Air Board and Admiralty, and the examination of food-supplies for the Expeditionary Forces. Chemical stations were established at the principal supply depôts, and it is acknowledged that the almost total absence of complaints from the Front as to the quality of the food was largely due to the work of the Government Laboratory. Sir James Dobbie is a past-president of the Institute of Chemistry, and is just about to complete his term of office as president of the Chemical Society. We trust that his right to complete enjoyment of his well-earned *otium cum dignitate* may not be long delayed.

A NUMBER of conferences on questions of national interest are announced for the *Daily Mail* Efficiency Exhibition to be held at Olympia on February 10–26. The meetings of the first four days will be devoted to personal efficiency and public health; on February 10 Dr. C. W. Saleeby will speak on child welfare and maternity, and Mr. E. B. Turner, Dr. Latham, and Mr. E. Farmer on industrial fatigue. Sir H. Baldwin, Prof. E. L. Collis, and Mr. F. Watts will discuss preventable diseases on February 11. Both conferences arranged for February 14 will deal with fatigue elimination; the speakers will be Major F. Gilbreth, Mr. Eric Farmer, Dr. H. M. Vernon, and Prof. A. F. Stanley Kent. Fuel efficiency will be discussed on February 17 and 18, when Mr. F. W. Goodenough will deal with coal gas and Capt. R. H. Montgomery with motor fuel. A number of evening medical conferences have also been arranged by the Middlesex Hospital. On February 14, 16, and 23 Dr. W. B. Tuck will speak on the relations between chemical research and medicine, health and pharmacology; and Dr. W. S. Lazarus-Barlow will discuss fluorescence, X-rays, and radium on February 15, 18, and 25. All conferences will be open to visitors to the exhibition, but societies and individuals desirous of taking part in them should apply for special tickets to the Higher Production Council, 66 Victoria Street, London, S.W.1.

MR. L. BOLTON, a senior examiner in the Patent Office, London, has been awarded the prize, amounting to about 1300*l.*, offered by the *Scientific American* for the clearest explanation for general readers of Prof. Einstein's theory of relativity.

AT the annual meeting of the Yorkshire Numismatic Society, held at Leeds University on February 5, the society's first annual medal was presented to Mr. T. Sheppard, curator of the Hull Museums, in recognition of his contributions to the study of numismatics.

A DESTRUCTIVE earthquake occurred on February 4 on the Isthmus of Tehuantepec separating the Gulf of Mexico from the Pacific. According to messages received in the United States from Mexico City, considerable loss of life was caused and much damage to property.

A JOINT meeting of the Faraday Society and the Manchester Literary and Philosophical Society will be held at 36 George Street, Manchester, to-morrow, February 11, at 6.30 p.m. The meeting will be presided over by Sir Henry Miers, president of the Manchester Literary and Philosophical Society, and Prof. A. W. Porter, president of the Faraday Society. The subject to be discussed will be "Measurements of Surface Tension," and it will be opened by Dr. Allan Ferguson.

DR. W. CROOKE discusses certain curious rites at the accession of Rajas in India in the January issue of *Man*. In Vedic times the Raja used to start in his chariot and shoot an arrow at an animal from the herd of one of his relations. Even so recently as 1886, when Madhava Rao Sindhia was invested, the farm was given over to plunder, the sufferers being afterwards compensated at the cost of the State. When a Rajput Raja came to the throne his first duty was to perform the "inaugural foray" by marching against and sacking a town belonging to a neighbouring chief. These are what French anthropologists call *rites de passage*, ceremonies at periods of crisis performed with a magical intent. They represent the period of anarchy occurring between the death of a Raja and the accession of his successor. The new Raja performs an act of bravery or redresses an admitted grievance, such acts being of happy augury for the future reign.

DRS. R. W. HEGNER and G. C. Payne in the *Scientific Monthly* for January (vol. xii., No. 1, p. 47) give a summary of the intestinal protozoa of man in health and disease. They express the hope that the discussion of the subjects presented in this paper will stimulate investigation, and they plead for a carefully organised survey of the intestinal protozoa among civil communities.

WE have received the report of the Research Defence Society for the last quarter of 1920. The society has now been in existence since January, 1908, and its propaganda work has been very valuable in the cause of biological science. The president and treasurers of the International Medical Congress of 1913 have handed over to the society the surplus of the funds of the congress, amounting to some 35*l*. Mr. Stephen Paget is no longer hon. secretary, having been elected vice-chairman of committee, but he will continue writing and advising for the society. Miss Dorothy Burgiss-Brown remains as secretary.

IN connection with the attempt to scale Mount Everest, which is to be made by the Royal Geographical Society and Alpine Club's expedition, it is of interest to learn the views of Col. H. H. Godwin-Austen, whose surveying experiences in Kashmir date back to 1857 and in Bhutan to 1863. Col. Godwin-Austen, in an article in the *Surrey Advertiser* for January 22, expresses the opinion that the best men for the task will be found in the Survey Department of India, and he believes that the number of climbers even in the reconnaissance party projected for the coming summer should be small. He recalls some of his experiences in the first surveys made in Sikkim and the views of Mount Everest which he had from Senchal, near Darjeeling, in 1863. Incidentally, he thinks that the discovery of a route to Mount Everest may not prove a very difficult task.

WE have received from Messrs. W. and A. K. Johnston several sheets of the survey on a scale of 1 : 125,000 of the Gold Coast, prepared under the direction of Major F. G. Guggisberg and engraved and printed in Edinburgh. Each sheet is ½° square, with full reference in the margin to conventional signs and orthography. Hill features are shown by brown shading, but there are no contours; water features and names are in blue, and boundaries in red and brown. The maps are clear and finely engraved, and contain a great deal of information without any crowding or illegibility. The sheets published cover the whole of the Gold Coast, and join in the north the War Office 1 : 250,000 sheets of Ashanti.

Two useful articles on Spitsbergen appear in *Naturen* for September–October, 1920, the publication of the Bergen Museum. Prof. B. J. Birkeland, in writing on the climate, has been at pains to collect most of the meteorological data, some of them previously unpublished, which have been taken at various times. In addition to means of seven years from the Norwegian wireless telegraph station at Green Harbour and Swedish records from Cape Thordsen and Mossel and Treurenberg Bays, Prof. Birkeland gives five years' records from Axel Island, in Bell Sound, three years' from South Cape, and several years' from different stations in Edge and Barents Islands. The South Cape, Edge Island, and Barents Island records, having been made by winter hunters, are in most cases incomplete for the summer months. No data are given from the former Russian station in Horn Sound or from the German station in Cross Bay. The second paper, by Mr. O. Holtedahl, deals with the geology of Spitsbergen and Bear Island, and includes two revised geological sketch-maps, besides several illustrations.

IN 1902 Miss Rathbun, of Washington, described three specimens of a tiny prawn found in the Galapagos and belonging to the crustacean group Caridea. On them she established a new genus Discias, the representative of a new family combining highly specialised characters with others that appear to be primitive. In the Records of the Indian Museum (vol. xix., part 4) Dr. S. Kemp describes a new, but closely related, species from five specimens (male and female) found on a sponge in the Andaman Islands, which are "separated from the Galapagos Islands by almost exactly half the circumference of the globe." A full-page shaded drawing of an "ovigerous female" is reproduced by photogravure—a luxury indicating the importance attached to the discovery; but if Dr.

Kemp was the artist he should have included a scale. Among the many figures in this part of the Records the magnification is given in only four cases.

IN the Proceedings of the United States National Museum (vol. lviii., No. 2344) Messrs. C. P. Alexander and W. L. McAtie deal with the crane-flies and their allies (Tipuloidea) found in the District of Columbia. These insects are prevalent in almost all parts of the world, and they are restricted only by intense cold and dryness. Water or moisture is a necessary condition for the development of most species, and, consequently, deserts form efficient barriers to their dispersal. Among the more interesting features in this paper is a note on the occurrence of the rare and primitive insect *Protoplasa Fitchii*; several larvæ which are referred to this species were found in a decayed drift log, but the adults were not bred out. The winter-gnats (Trichocera) are represented by three species, and the authors follow other recent writers in referring this genus to the Rhyphidæ. The greater part of the paper is devoted to the rich fauna belonging to the family Tipulidæ, which is represented by 40 genera and more than 190 species. The authors include notes on the larval habits of all species wherever known, and they append useful synoptic keys to the various groups along with their genera and species.

PROFS. A. C. SEWARD and B. Sahni have contributed to the Palæontologia Indica (vol. vii., Mem. 1, in Memoirs of the Geological Survey of India, 1920) a memoir entitled "Indian Gondwana Plants: A Revision." The specimens were mostly among those described by Feistmantel, but a revision of the species in the light of modern knowledge had become necessary. The memoir is illustrated by seven fine folio plates, partly photographic, partly from drawings by Mr. T. A. Brock, as well as by a few figures in the text. The senior author was helped in the early stages of his work by Miss Ruth Holden, a young American botanist, whose premature death while on medical service in Russia is a grave loss to science. Prof. Sahni came in at a later period, and hopes to continue work on the same lines in his own country. Two quite distinct floras are dealt with: the Lower Gondwana, of Permo-Carboniferous age, and the Upper Gondwana, which is Jurassic. As regards the former, the authors point out that their results suggest a closer resemblance between the Indian plants and their contemporaries in Europe and North America than had hitherto been realised. For example, the Gondwana genus Nœggerathiopsis is now merged in the familiar Cordaites. The specimens from the Upper Gondwana include several good examples of Williamsonia fructifications, very similar to the well-known European fossils, and to those from Mexico recently described by Dr. Wieland. This illustrates the author's conclusion that the examination of the Indian Jurassic species has revealed additional evidence of the remarkable uniformity of Jurassic floras of widely separated regions. The specimens described in the memoir are impressions, not petrifactions showing the structure, but use has frequently been made of modern methods to bring out such microscopic details, *i.e.* of the epidermis, as can be recognised.

THE Archives of the Cambridge University Forestry Association (No. 4, October, 1920) contains an illustrated article by Mr. H. Stone on the origin of the so-called medullary rays in wood. This paper, which advocates a new theory, contains some information about bird's-eye maple and the cause and nature of the pith-flecks which are so characteristic of birch and certain other woods. The author also discusses the capricious occurrence in the natural orders and in allied genera of the broad compound rays which give rise to "figure" in oak, beech, and plane.

THE Queensland Geological Survey Publication No. 267 (1920) is a description of petrified plant remains from the Queensland Mesozoic and Tertiary formations, by Prof. Birbal Sahni. The series includes two ferns belonging to the genus Osmundites which were previously known only from Jurassic rocks in New Zealand; seven species of gymnospermous woods, six of which are described as new; and three species of angiospermous woods, two of which are new.

THE Norwegian Meteorological Institute has published its Jahrbuch for 1919, containing records of the observations of more than seventy stations. Hourly records are given for Kristiania and Aas, daily means for twelve stations between Mandal in the south and Vardö in the north, and monthly means for the other stations. An appendix gives the observations at Green Harbour, Spitsbergen, for the year 1918–19. The institute has also published "Nedböriagttagelser i Norge," giving the precipitation records for 1919 for 491 stations and a large-scale coloured map showing the distribution of the year's precipitation.

DR. MURRAY STUART'S final report on the Srimangal earthquake of July 8, 1918, is published in the last part of the Memoirs of the Geological Survey of India (vol. xlvi., 1920, pp. 1–70), the principal results having been already given in a preliminary report (see NATURE for April 3, 1919, p. 91). The new memoir contains full details of the nature of the shock and the damage to property, a discussion of the seismograms at distant observatories, and an account of the changes of level in the central district. The epicentre is situated in the Balisera Valley, 3½ miles south of Srimangal railway station, and the epicentral area (the longer axis of which is directed about west-north-west) is crossed centrally at right angles by the line of levels made in 1911–12 from Silchar to Comilla. During the winter of 1919–20 the levelling along this line was repeated by the trigonometrical survey, and this shows that in the interval no settlement had taken place on the north-east side of the epicentral axis. Nor is there any evidence of disturbance on the other side of the axis until the low range of hills six miles west of Srimangal is crossed, but from this range to a distance of thirty miles from the town a subsidence of from 1½ in. to 9 in. has occurred. It would thus seem that "the earthquake was due to subsidence along the southern side of a normal fault cutting the rocks below the alluvium of the Sylhet district, and situated approximately under the major axis of the epicentral area."

La Nature for January 22 contains an illustrated article by M. Léon Laffitte on the methods which are being used by the French naval authorities to refloat those vessels which were torpedoed during the war and sank in situations which render them dangerous to navigation. Maps are given on which the position and name of each submerged wreck are marked. No numbers are mentioned by the author, but the maps show that at least 200 vessels, many of them near the entrances to the larger ports, were lost. The operations are directed by three captains of the fleet, and in most cases are carried out by the compressed-air method, temporary wooden patches being fixed by divers over the holes made in the sides of the vessel by the torpedoes. It is found possible to carry out this work down to a depth of 180 ft.

In a paper read recently before the Institution of Petroleum Technologists Mr. F. H. Garner, of the Mellon Institute, Pittsburgh, discussed the importance of the carbonisation constant of lubricating oils. This constant is determined by exposing the oil to a definite temperature in an oxidising atmosphere, and then measuring the quantity of asphaltene produced. The carbonisation constant is closely connected with the content of resinous matter in the oil, which may be extracted by utilising the selective adsorption of charcoal for these resins. The Conradson coke test was brought forward as an important means of discriminating between different lubricating oils, and it was shown that this criterion was particularly valuable in connection with internal-combustion engines.

Dr. H. E. Armstrong has a charming address on "Detective Work in the Potbank" in the current issue of the Transactions of the Ceramic Society. He shows that, if rightly interpreted, the story of the "crime" committed when, say, iron rusts, so that a valuable strong metal is changed to a worthless powder, is as exciting in its way as the shilling-shocker detective story. He utilises the discovery of the composition of limestone to give his views on the general principles which obtain in the application of science to the manufacture of pottery in particular and to the industries in general. The title of Dr. Armstrong's address is singularly appropriate, because much of the so-called application of science to the industries is an application of the detective instinct in locating sources of loss.

It appears from the *Procès-Verbaux* of the last meeting of the International Committee of Weights and Measures that it will be proposed at the general conference in September next that the functions of the International Bureau shall no longer be confined to the construction and verification of standards of length and mass, but extended to include other units and standards, as well as the determination of physical constants. In the event of this being agreed to by the countries participating in the metric convention, a commencement will probably be made with electrical units and standards. The conference will also consider a proposition to increase the fixed annual budget of the Bureau from the present figure of 100,000 francs to 250,000 or 300,000 francs. The periodical recomparisons of the iridio-platinum national prototypes of the metre and the kilogram are now in progress at the Bureau, and preliminary observations on four of the metres seem to indicate that all of them have undergone a small diminution of length, of the order of half a micron, since their original verification more than thirty years ago. The investigation of the properties of nickel-steel alloys, which led to the discovery of invar, has been resumed, and it has been found that by the addition of 12 per cent. of chromium to alloys of the invar type a metal ("elinvar") is obtained which exhibits a constant modulus of elasticity throughout a wide range of temperature.

A report has now been issued by the Department of Scientific and Industrial Research giving particulars of the work accomplished by the lubricants and lubrication committee. The report fills 126 pages, and contains a large amount of interesting information. A bibliography has been compiled, to be published separately, containing classified references to every published work or paper on lubricants or lubrication of definite importance; abstracts of a large number of important papers are also given in the bibliography, and a complete translation of Prof. Otto Faust's researches on the increase in the viscosity of certain liquids with pressure appears in the report. Research work has also been carried out on behalf of the committee; complete reports and the results of each individual research are given in appendices to the report. There are also a summary of the existing knowledge of lubrication and recommendations for future research on lubricants and lubrication. The tests on the viscosity of liquids at high pressure are of particular interest; in Mr. Hyde's experiments, carried out at the National Physical Laboratory, it was found that all the oils tested showed a rapid increase in viscosity with pressure, and the increase was much greater for the mineral than for the animal and vegetable oils. Castor (vegetable) and Trotter (animal) gave almost identical results up to about 4 tons per sq. in., but at 8 tons per sq. in. the Castor had increased to 5·5 times and the Trotter to 5 times their atmospheric values. The report can be obtained from His Majesty's Stationery Office, price 2*s.* 6*d.* net, and those interested in this subject are recommended to procure a copy.

We have received from the British Scientific Apparatus Manufacturers, Ltd., 198 rue Saint-Jacques, Paris (5e), a general catalogue (in French) of the instruments and apparatus manufactured by its members. This company was formed in February last with the object of making British scientific products more widely known in foreign countries; it serves generally as an advertising medium and a connecting link between manufacturers at home and consumers abroad. The first action of the company was to establish a showroom in Paris, which is now well stocked with samples. Not only can visitors to the showroom obtain full information regarding the apparatus, but also in most cases facilities are available for the demonstration of the exhibits. Although the showroom has been open for a few months only, the results are most encouraging, and a considerable number of inquiries are being dealt with daily. Paris is found to be essentially suitable for a centre of this sort, as is shown by the fact that the visitors' book already contains names of visitors from thirteen different countries. The general catalogue is divided into nine sections under the following headings;—(1) Chimie, Industries chimiques. (2) Electricité, Industrie électrique. (3) Marine. (4) Aviation, Aérodynamique. (5) Métallurgie, Mécanique de précision, etc. (6) Médecine, Bactériologie, Physiologie, Ophtalmologie, etc. (7) Topographie, Géodésie, Astronomie, Météorologie, Dessin. (8) Physique expérimentale. (9) Photographie, Cinématographie. It will be seen that the range of apparatus covered is very extensive. In connection with their Paris showroom the "B.S.A.M." have formed a reference library of English scientific and technical books which are at the disposal of visitors. The showroom is under the management of Mr. F. C. Dannatt.

DR. NORMAN R. CAMPBELL is bringing out, through Messrs. Methuen and Co., Ltd., a work entitled "What is Science?" the aim of which is to explain what science really is and the kind of satisfaction which may be derived from its study. Two other books in Messrs. Methuen's spring list make an especial appeal to readers of NATURE, viz. "Atomic Theories," by F. H. Loring, and "Biological Chemistry: The Application of Chemistry to Biological Problems," by Prof. H. E. Roaf. The first-named volume is written to give in a concise and simple form an account of all the important theoretical and experimental researches on the atom, its structure, and the arrangement of electrons in atoms, in molecules, and in ions. The second may be regarded as an introduction to the more specialised branches of its subject. It will consist of three sections, dealing respectively with a brief description of the parts of organic and physical chemistry which relate to biological chemistry; the accumulation of energy by plants and the interconversion of carbohydrates, fats, and proteins; and the liberation of energy from the food substances.

Our Astronomical Column.

INTERESTING BINARY STARS.—Mr. J. S. Plaskett investigates, in vol. i., No. 2, of the Publications of the Dominion Astrophysics Observatory, Victoria, B.C., the orbit of the spectroscopic binary U Coronæ. Both spectra are visible, each being of type B3. The following are the elements of the two stars in terms of the sun, the brighter star being placed first:—Radii, 2·90, 4·74; masses, 4·27, 1·63; and densities, 0·175, 0·015. Taking the surface intensity of the bright star to be −2·7 magnitudes, as compared with the sun, of which the absolute magnitude is 4·86, the distance is deduced as 400 parsecs. It is, however, noted that the fainter star, though of the same spectral type, has only one-eighth of the surface brightness; this indicates that the correlation of surface brightness with type is less close than some physicists have assumed.

Two other eclipsing binaries of type B, μ^1 Scorpii and V Puppis, are discussed by Miss A. C. Maury in *Popular Astronomy* for January. The masses come out fairly large in these cases, $(m+m_1)\sin^3 i$ being 16·5 and 33 respectively. These would not be very different from the real masses, for, owing to the occurrence of partial eclipses, i cannot differ very much from 90°. μ^1 Scorpii is stated to be of the β Lyræ type, showing double eclipse and continual variation. Stellar tides are suggested in explanation of part of the change of light, and also of changes in the character of the spectrum.

A famous visual binary, 70 Ophiuchi, is discussed by F. Pavel, of Neubabelsberg, in *Ast. Nach.*, No. 5082. It is shown that the irregularities are explicable on the assumption that the principal star is describing the following small orbit owing to an unseen companion:—$T=1809{\cdot}0$, $a=0{\cdot}033''$, $e=0{\cdot}1$, $\lambda=150°$, $i=0°$, period$=6{\cdot}5$ y. The author then obtains for the orbit of the visual pair:—$T=1895{\cdot}965$, $a=4{\cdot}495''$, $e=0{\cdot}4988$, $\phi=29{\cdot}016°$, $\omega=166{\cdot}648°$, $\Omega=122{\cdot}184°$, $i=58{\cdot}743°$, period$=87{\cdot}710$ y. He obtains 0·36 for the ratio of masses, and 1·06 times the sun for the joint mass of the system on the assumption that the parallax is 0·225″.

THE GREEN RAY OR FLASH.—It has often been noticed when the sun is setting behind a well-defined horizon that the last appearance of the disc is a bright green flash. Various explanations have been put forward, some asserting that it was a case of complementary colour, due to fatigue of the retina. This was negatived by the flash being seen at sunrise. Another view was that the sea-water had something to do with it, but it was found that the effect could also be seen at a distant land horizon. There remained the explanation of atmospheric dispersion; but here again there were diversities of view, some holding that the normal colour dispersion would suffice, others invoking abnormal phenomena of the nature of the mirage.

L'Astronomie for December contains an interesting research by MM. A. Danjon and C. Rougier, of the Strasbourg Observatory. They installed a spectroscope on the roof of Strasbourg Cathedral, and were able to demonstrate that the phenomenon arises from normal dispersion. There is an image of the sun produced in light of each wave-length, and as the sun gets low these images are more and more widely separated. When the sun was a few degrees above the horizon the observers were able to obtain a spectrum showing red only when the slit was at the lower limb, and a spectrum with the red absent when it was at the upper limb. When the altitude is less the blue and violet are altogether absorbed, and the green image of the sun's upper limb is the last visible at sunset. Their horizon was formed by distant low hills, but they point out that a sea horizon may be better in that the presence of the bands of water-vapour helps to separate the red light from the green. The spectra obtained are reproduced in the article, and seem to settle the nature of the phenomenon beyond a doubt.

Applied Entomology.

BULLETIN 805 of the United States Department of Agriculture deals with "Two Leafhoppers Injurious to Apple and Nursery Stock," and gives an account of the apple leafhopper and the rose leafhopper. Of the two species, the apple leafhopper causes the greater damage, and is most prevalent in the eastern States, attacking a large variety of plants, on which it chiefly injures the tender terminal leaves, causing them to turn brown. The rose leafhopper also attacks a large variety of plants, and is especially prevalent in the north-western States. Full accounts of the life-histories and descriptions of the insects in all stages are given, and sprays for controlling them recommended.

Farmers' Bulletin 650 of the United States Department of Agriculture deals with the San José scale, which attacks many species of trees, causing considerable damage to, and sometimes killing, fruit trees. During the summer the scale reproduces exceedingly rapidly, the life-cycle taking thirty-three to forty days, and, although it has a large number of parasites, they are insufficient to act as an effective check. The scale is distributed on nursery stock, etc., and the young are also probably spread by wind, other insects, and birds. The scale can be kept in check by thorough annual spraying when the plants are dormant, lime-sulphur wash being recommended for this purpose.

In Farmers' Bulletin 1061 an account is given of the Harlequin cabbage bug, which occurs in all but the northern States, and is a very bad pest of cabbages and allied plants. Removal of wild crucifers and remains of crops, trap-crops, and hand-picking are effective, and also contact insecticides, but co-operation between neighbouring growers is necessary to control this pest.

Farmers' Bulletin 1086 gives an account of "How Insects Affect the Rice Crop in the United States." The most important pest is the rice water-weevil, the larva of which feeds amongst the roots of the rice plant at the base of the stalk, causing considerable damage to the crop. The stink bug attacks the soft grains of the rice while they are forming. The fall Army worm or Southern grass worm occasionally becomes abundant and damages rice fields in the spring, but is easily destroyed by flooding the fields. The caterpillar of the rice-stalk borer feeds in the stalk and causes the head to die. These pests are controlled by thorough cultivation, by suitable flooding and draining of the fields, and by keeping the fields and banks clear of weeds.

In Farmers' Bulletin 1101 an account is given of "The Argentine Ant as a Household Pest." This ant occurs in scattered localities throughout the South. Owing to its encouraging aphids and scale insects, it causes considerable trouble to fruit-growers and others, while it causes much annoyance by swarming in houses. The ant has been distributed in foodstuffs, and is also carried by floods. Formulæ are given for tree-banding mixtures and for poisons for use in houses and in the open.

Farmers' Bulletin 1104 deals with the book lice or Psocids which frequently occur in houses and other buildings, and may occasionally increase in numbers to such an extent that it is necessary to take steps to destroy them, for which purpose fumigation with sulphur or hydrocyanic acid is recommended.

In the *Journal of Agricultural Research* (vol. xviii., No. 9, 1920) an account is given by J. M. Aldrich of "The European Frit Fly in North America." This pest occurs principally in the regions in which winter wheat is grown, from the Great Lakes to the Ohio River and westward to the Missouri, but it is generally distributed over most of the country. A full description, with figures, is given of the life-history, and also a plate of the adult and puparium. As many as four broods were obtained in the summer, the first, from larvæ which had lived through the winter, in April. Eggs and larvæ are usually found on the young and tender shoots and also sometimes upon or within the glumes, wheat, barley, and various grasses being attacked. It is recommended that wheat should be sown late in the fall or early in the spring in order to escape the attack of this insect.

In the same journal (vol. xix., No. 1, 1920) an account of "The Banana Root Borer," which is a widely distributed pest of the banana, is given by G. F. Moznette. The larvæ of this weevil, *Cosmopolites sordidus*, feed in the roots of the plant, and the damage done to young plants causes them soon to wither and die. Full descriptions of all stages and of the life-history are given in the paper, which is illustrated by four plates. Destruction of infested plants and trapping of adults by means of strips of banana-trunks placed on the ground are advised.

The European corn-borer has recently been introduced into the United States, being first discovered there in 1917, and has already spread over considerable areas in the North-east, and it seems likely to do more damage than any native species (State of Illinois, Department of Registration and Education, Division of Natural History Survey, Bulletin, vol. xiii., art. 10, "The European Corn Borer and some Similar Insects," by W. P. Flint and J. R. Malloch). The larva of this moth, *Pyrausta nubilalis*, Hubner, feeds on all parts of the plant above the ground, many species of plants being attacked, but corn appears to be preferred. An account is given of the life-history of this insect, which may have two broods in the year, the winter being spent as full-grown larvæ which hibernate in the stems of the food plant. This pest is probably chiefly spread in the stems of its plant-host, although, as the moth is a fairly strong flyer, it might also be disseminated in the latter stage. A number of native borers closely resemble the European corn-borer, and descriptions are given to enable it to be distinguished therefrom.

Bulletin, vol. xiii., No. 11, 1920, of the same series is concerned with "A Study of the Malarial Mosquitoes of Southern Illinois. 1. Operations of 1918 and 1919," by S. C. Chandler. An account is given of a survey of the mosquitoes of two districts of Southern Illinois in which malaria occurred frequently, in addition to less thorough work at other points. The breeding areas were examined, and larvæ were most plentiful in fairly clean, still water in which there was vegetation. Two of the species found are capable of transmitting malaria. To get rid of the mosquitoes drainage is the most effective measure. Clearing the edges of the ponds, etc., of vegetation is also suggested, as well as oiling the surface of the water, and the use of larvicides. Houses should be screened or fumigated.

The Department of Agriculture, Ceylon, Bulletin No. 46, by N. K. Jardine, gives an account of "Field Experiments with Anti-Tortrix Fluids." The experiments showed a greater yield from the treated plots than from the control, and the quality of the tea was not lowered. In treating a substance intended for human consumption, such as tea, the use of poisons is not possible, and as contact poisons are useless against the tea tortrix, owing to its rolling itself up in a leaf, it was necessary to find some other substance which would serve the purpose, and lead chromate was found to be very suitable. The formulæ used are given and also the cost of each and of the spraying. Samples from the control and sprayed plots were tested by tea-brokers, and their reports are given, the tea treated with the sprays, especially that containing resin and sodium carbonate, in addition to lead chromate, being generally preferred. Rain was found to have little effect, provided the spray had dried.

Food and its Preservation.[1]

THE work done under the direction of the Food Investigation Board of the Department of Scientific and Industrial Research during the year 1919, although its primary object may be said to have been of a practical nature and mainly devoted to the various means of preserving animal and vegetable food, serves well to show how such an object requires previous investigation of many fundamental and purely scientific problems. On account of the strictures that have been made as to the support of pure science by the Department in question, we may take note that it is pointed out in the report before us that "the application to industry of many of the researches is not immediate, and often not obvious." Such results will be especially referred to in the course of this article, but it is not intended thereby to minimise the value of the practical work of the Board.

With regard to the freezing of meat and fish, a valuable series of researches was undertaken on the phenomena occurring in the freezing and thawing of systems containing colloids and electrolytes, with especial reference to the separation of the constituents of such systems and to the diffusion of salts through their solid phases. Our knowledge of the properties of these systems has been greatly enlarged by this work, and a general report on it is now being prepared. Attention may be particularly directed to the fact that by sufficiently rapid cooling to a temperature which corresponds to the eutectic of a saline solution the separation of frozen water as a visible phase is avoided. Thus, on thawing, the system returns to its original state and the irreversible separation of the colloidal material does not take place, as happens on slow freezing at a temperature only a few degrees below the freezing point of the system.

The conditions of growth of bacteria and moulds were naturally subjects of immediate interest. It is well known that bacteria growing in a particular medium, after a period of multiplication, gradually die off. This is shown by Dr. Graham-Smith, in the report, to be due, not to accumulation of toxic products of their own activity, but to the exhaustion of some specific food material. Bacteria of another species are able to grow in a medium which has previously been exhausted by a different species so far as its own growth is concerned. An interesting fact brought out by researches on the "black-spot" mould (shown to be a species of Cladesporium) is that it will grow at a temperature of -5° C. It is clear that the protoplasm in the cells does not freeze, although the expressed juices of plants usually freeze between -2° and -3° C. No doubt capillary forces are responsible for the lowering of the freezing point in the narrow cells.

The question of the discoloration of fruit led to an investigation on the nature of the enzymes responsible for oxidation in plants. An important fact in relation to the general theory of the mechanism of oxidation was brought out in an examination of linseed oil. It was found that the oil oxidises slowly in air without the presence of any kind of catalyst, although in the oxidation system of the cell there is evidence of the presence of a catalyst accelerating autoxidation. In connection with enzymes the work on pectin production may be mentioned.

Of more strictly chemical interest is the discovery that glycerol can be replaced in fats by mannitol, such fats being similar to the corresponding glycerol esters and behaving in the same way as foods. Other work giving an insight into the chemistry of the production of glycerol itself was also undertaken. Of practical importance for workers with the products of degradation of proteins is the method devised by Mr. Foreman for estimating the simpler products of bacterial decomposition. A curious fact is that the equilibrium position reached in the autolysis of beef is not the same as that in the case of mutton, suggesting that the presence of more than one phase in the heterogeneous system of the cell must be taken into consideration.

The work of the Engineering Committee of the Board, as would be expected, has been mainly industrial, but the systematic investigation of the heat-flow through various materials and the loss of heat by convection from plane surfaces may be referred to here as of general scientific interest.

We may note, finally, that the Board has obtained a grant to build and equip a research station at Cambridge for biochemical and biophysical investigations at low temperatures.

The Older Palæolithic Age in Egypt.

PROF. C. G. SELIGMAN, at a meeting of the Royal Anthropological Institute on January 11, read an important paper on "The Older Palæolithic Age in Egypt," embodying the results of an attempt made in 1914 to secure definite stratigraphical evidence of the antiquity of implements which, if found in Europe, would be classed as Chellean, Acheulean, or Mousterian. The sites visited were Abydos, Thebes, Tel-el-Amarna, Meir, and Wady Sheikh, and a short trip was made to the Fayum. Some areas, however, may be described as flintless; flints of Palæolithic type were very common in the neighbourhood of Thebes and Abydos, but were scarce near Meir and Tel-el-Amarna, and did not include either Chellean or Acheulean types. Wady Sheikh showed no definite Palæolithic types, but specimens of early historic date were valuable for the light they threw on the patination of high desert specimens.

The implements found included hand-axes (Chellean type), hand-axes with borer point (not found in Europe), and finely worked ovates (Acheulean type). The points, side scrapers, borers, hollow scrapers, and tanged points (spear- or arrow-heads) Prof. Seligman grouped together as Mousterian, not because they were specially typical of the Mousterian culture, but for reasons connected with the localities of the finds, stratigraphy, and patination. Also included in the group were two forms not occurring in Europe, namely, "crescents" and a heavy drawing-tool, for which the name "tortoise point" was proposed. Forms transitional to Capsian, or Capsian, were notched flakes, end-scrapers, hollow end-scrapers, nose end-scrapers, end-borers, and asymmetric end-borers. From the morphological point of view the river-drift types were unmistakable, while the Mousterian types, so far as the borers, scrapers, and points were concerned, could be paralleled precisely from European forms, while the non-European forms could either be derived from well-known types or were produced by an identical process. A certain number of implements could not readily be referred to Chellean, Acheulean, or Mousterian technique, and, although they might be classed in Europe as Aurignacian of a coarse type, Prof. Seligman was inclined to regard them as highly developed Mousterian modified by Capsian influence from the north.

The great majority of the implements from the Thebaïd present a more or less lustrous surface of various shades of reddish-brown. Specimens of different shades of dull white occur, but only in wadies and "wash-outs." This marked difference in coloration was undoubtedly due to the fact that the white specimens had only comparatively recently been weathered out of the gravels forming the banks of the wadies.

In reference to the stratigraphical evidence for the age of these implements, Prof. Seligman gave a detailed account of the geological character of the area in which they were found. Implements of a highly developed Mousterian type, without the characteristic brown patina of the palæoliths which have been exposed to weathering, have been found *in situ* in undisturbed gravels of Pleistocene age.

An interesting discussion followed the reading of the paper, in which several points of importance were touched upon. Mr. Reginald Smith argued that while patination was an indication of great age, absence of patination did not indicate the reverse; the oldest types of French cave implements showed no patination. He also asked if Prof. Seligman had been able to correlate relative antiquity of type and shade of patination. In reference to the geological data, he was of the opinion that further evidence was required to establish the Mousterian character of some of the implements, especially in the case of those not collected by Prof. Seligman himself. Mr. M. Burkett briefly reviewed recent French work on this subject, and cited the results of a correlation of type and patina which had recently been made by the Abbé Breuil in a series from Tebessa (Southern Algeria). Mr. H. Peake pointed out that the Mousterian industry appeared to have developed further in Africa than in Europe, where its development had been interrupted by the Aurignacian type, and he suggested that this might be due to more favourable climatic conditions on the former continent. It had been stated that no Sofutrian culture was found in Africa, but in this case it was difficult to account for the resemblance between certain Saharian and the Solutrian implements. Prof. Fleure said that Prof. Seligman's evidence pointed to a continuous development from Mousterian to Capsian; geographical conditions suggested that at this period there was a great difference between the climates of Africa and Europe.

Tides in Small Seas.

TWO important papers on the tides in small seas have recently been published by the Vienna Akademie der Wissenschaften. The first, in Bd. 96 of the *Denkschriften*, is the latest of a series of researches by R. Sterneck, jun., on the tides of the Adriatic; the second, in Bd. 129 of the *Sitzungsberichte*, is the sixth part of A. Defant's researches on tides in "Mittel- und Randmeeren, in Buchten und Kanalen," and concerns the tides of the Irish Sea. Both investigations are applications of hydrodynamical principles, assuming from observation just sufficient to give or replace the "boundary conditions" where the sea communicates with the larger body of water. Both treatments depend on the elongated nature of the sea in question and utilise charts of soundings after the manner initiated by Chrystal for the longitudinal seiches of lakes. Defant makes separate applications to the Bristol Channel, Liverpool Bay, and Solway Firth. In each case the assumed type of motion may be regarded as a longitudinal oscillation sustained by the tides outside, together with a transverse gradient maintained by the longitudinal current in virtue of the earth's rotation.

Sterneck considers separately the four chief semi-diurnal and the three chief diurnal harmonic constituents; Defant considers mainly the semi-diurnal spring tides. In each case the agreement with observation is remarkable. That for the Irish Sea is not so close as that for the Adriatic, but this is to be expected when the deviations from a canal of slowly varying section and the ratio of tidal range to water-depth are taken into account. Friction is neglected altogether by Sterneck for the Adriatic, but is an important element in Defant's explanation of the Irish Sea tides, in which the amount is of the same order as that used by G. I. Taylor. The negligible importance of friction in the Adriatic may be ascribed to its greater depth and much smaller currents as compared with the Irish Sea. Sterneck calculates the longest free period of the Adriatic to be about 23 hours as against the 16 hours of previous calculations by the "Merian" formula. The larger number agrees well with the observed seiches, and shows the possible error of rough methods. Defant estimates the longest free period of the Irish Sea to be about 18 hours.

J. P.

Paris Academy of Sciences: Loutreuil Foundation.

REQUESTS for grants to the amount of 219,600 francs were received by the Academy. Six of these were refused on the ground that they were presented by persons belonging to universities already in receipt of funds from M. Loutreuil. A total sum of 131,200 francs is allocated by the council of the foundation to the following:

I. *Grants to Establishments named by the Founder.*

(1) National Veterinary School of Alfort: 8000 francs for the construction of a special room for researches relating to the therapeutics of cutaneous and respiratory diseases.

(2) National Veterinary School of Lyons: 3200 francs to François Maignon, for the purchase of

instruments and apparatus for his researches on nutrition.

(3) National Veterinary School of Toulouse: 3000 francs to Jean Lafon, for his researches on the comparative physiology of the secretions in different animal species.

II. *Grants to Establishments Called to the Consultative Committee of the Foundation by the President of the Academy.*

(1) Conservatoire national des Arts et Métiers: 6000 francs to Henri Chaumat, for his studies on the electrical and magnetic properties of electrolytic iron.

(2) Central Electrical Laboratory: 10,000 francs for the researches, under the direction of Paul Janet, on the absolute standards of the international ohm.

III. *Grants Given on Personal Application.*

(1) 10,000 francs to Charles Alluaud and to R. Jeannel, for the study of the zoological and botanical material collected by them in the high mountains of eastern Africa and for the publication of the results.

(2) 5000 francs to Jules Baillaud, for the establishment of a recording microphotometer of the type suggested in 1912 by P. Koch.

(3) 3000 francs to Henry Bourget, director of the Marseilles Observatory, for the *Journal des Observateurs*.

(4) 2000 francs to Clément Codron, for his researches on the sawing of metals.

(5) 5000 francs to the School of Anthropology, for the publication of the *Revue d'Anthropologie*.

(6) 4000 francs to Justin Jolly, for the publication of a work on blood and hæmatoporesis.

(7) 7000 francs to Louis Joubin, for the publication of the results of the French Antarctic Expedition.

(8) 3000 francs to the late Jules Laurent, for the publication (under the direction of Gaston Bonnier) of a work on the flora and geography of the neighbourhood of Rheims.

(9) 3000 francs to Henri Brocard and Léon Lemoyne, for the publication of the second and third volumes of their work entitled "Courbes géométriques remarquables planes et gauches."

(10) 2000 francs to A. Menegaux, for the *Revue française d'Ornithologie*.

(11) 5000 francs to Charles Nordmann, for his researches on stellar photometry.

(12) 8000 francs to the Zi-Ka-Wei Observatory, in China (director, R. P. Gauthier), for recording time-signals from distant centres.

(13) 2000 francs to O. Parent, for his studies on a group of Diptera.

(14) 10,000 francs to G. Pruvot and G. Racovitza, directors of the *Archives de Zoologie expérimentale et générale*, for this publication.

(15) 6000 francs to Alcide Railliet, for the publication of researches on the parasites of the domestic animals of Indo-China.

(16) 4000 francs to J. J. Rey, for the publication of a botanical geography of the Central Pyrenees.

(17) 10,000 francs to Maximilien Ringelmann, for researches relating to the physical and mechanical constants of metals intended to be used in the construction of agricultural machines.

(18) 12,000 francs to the Academy of Sciences, for the establishment of a catalogue of scientific and technical periodicals in the libraries of Paris.

It was pointed out by the council in 1917 that, although the special object of this foundation was the promotion of original research, up to that time requests for assisting work to be carried out according to a well-defined scheme had been exceedingly few in number. For the three years 1914–17 the majority of the requests had for their object the establishment or improvement of equipment more suitable for teaching than for personal work. These remarks still apply, and a possible modification in the method of dealing with the revenue of this foundation is foreshadowed.

University and Educational Intelligence.

BIRMINGHAM.—At a special degree congregation held in the Great Hall of the University on Saturday, February 5, the honorary degree of Doctor of Laws was conferred on the Prime Minister, the Right Hon. David Lloyd George, who had a most enthusiastic welcome. After receiving the degree the Prime Minister made a short speech in which he expressed his admiration of the way in which the universities of the country had come to her aid in the great war, and his own surprise at the discovery of the vital importance of the universities, not only as centres of culture and learning, but also as essential factors in the strength of the nation. He paid a generous tribute to the energy and foresight of the founder of the University of Birmingham (Mr. Joseph Chamberlain), and hoped that the Midland area generally, realising its obligation, would come to the assistance of the University in this its time of serious financial need.

On behalf of the subscribers to the Poynting Memorial Fund, the portrait of the late Prof. J. H. Poynting (by Mr. Bernard Munns) has been presented to the University, and Mr. W. Waters Butler has presented the portrait of the late Prof. Adrian Brown by the same artist. The council has expressed its warm appreciation of these gifts, both of which now hang in the Great Hall of the University.

In response to the appeal for 500,000*l.*, the sum of 280,144*l.* has been received or promised.

CAMBRIDGE.—Dr. C. S. Myers, Gonville and Caius College, has been appointed reader in experimental psychology, and Mr. F. A. Potts, Trinity Hall, demonstrator of comparative anatomy.

A grant of 150*l.* from the Craven Fund has been made to the managing committee of the British School at Athens in aid of further excavations at Mycenæ.

A LECTURE on "The Innervation of Striped Muscle Fibres and Langley's Receptive Substance" will be given at the rooms of the Royal Society of Medicine, 1 Wimpole Street, W.1, by Dr. J. Boeke, professor of embryology and histology in the University of Utrecht, at 5 p.m. on Wednesday, February 16. This lecture has been arranged under a scheme for the exchange of lecturers in medicine between England and Holland. Four other Dutch lecturers will also give one lecture each, particulars of which will be announced later. The chair at the lecture of February 16 will be taken by Prof. W. M. Bayliss. Admission is free, without ticket.

THE University of Bristol will shortly possess as fine a block of university buildings as can be found in the United Kingdom outside Oxford and Cambridge. The entire expense of erecting these buildings was, from the outset, undertaken jointly by Mr. George A. Wills and Mr. Henry H. Wills. The cost of completing the work will vastly exceed even the liberal sum contemplated when the gift was originally made. Additional contributions were made by the two brothers during the course of the war, and since the present year commenced they have placed in the hands of the University an additional benefaction of as much as 200,000*l*., hoping to enable the buildings and design to be fully carried out. It is reassuring to note that these two public-spirited citizens are not allowing their munificent gift of 1913 to fail of fulfilment even in the difficult circumstances of the present time.

THE universities in Australia are apparently suffering, like our own institutions, from an inability to make their incomes meet their expenditures under post-war conditions. At Sydney the University authorities have decided to raise the fees in all the various schools, in some cases by as much as 50 per cent., in order to meet the increased cost of materials. Melbourne University has issued an appeal for 100,000*l*., towards which it has obtained only the sum of 30,000*l*., subscribed in small amounts; it hopes to raise a further sum of 20,000*l*. in a similar way, but no large gifts have yet been made. Sir W. H. Irvine, Lieutenant-Governor of Victoria, discussed the situation at Melbourne on January 31, according to a *Times* correspondent, and suggested that wealthy Victorians might well follow the example set by Sir J. Langdon Bonython in South Australia, who has presented the sum of 40,000*l*. to Adelaide University.

WE learn from an article in the *Times Educational Supplement* that the Vice-Chancellor of the University of Madras, Mr. K. Srinivasa Iyengar, who is now a member of the Madras Executive Council, laid great stress on the neglect of science and technology in India in his recent convocation address. The careers of 18,500 graduates of the University had been traced, and of this number about 3700 were engaged in teaching, 765 had taken up medicine, while only 56 had devoted themselves to science; the remaining 14,000 were divided between law and Government administrative service, with a big majority for the former. The Vice-Chancellor concluded his account of the statistics he had accumulated with the words: "You will search in vain for any solid contribution to the sum of human knowledge among the magnificent number." These facts have been appreciated by many leaders of Indian thought, and several of the more wealthy men have endeavoured by their munificence and influence to create a stronger feeling for science. The Indian Institute of Science at Bangalore owes its existence to the late Jamsetji Tata, and some eight years ago the late Sir Taraknath Palit made over money and land of the aggregate value of 15 lakhs of rupees (100,000*l*.) to the University of Calcutta for the promotion of scientific and technical education in Bengal. University chairs of chemistry and physics which can be filled only by persons of Indian birth were created from this fund. In 1913 Sir Rash Behary Ghose gave 10 lakhs of rupees (66,666*l*.) to the University for the establishment of chairs of applied mathematics, physics, chemistry, and botany, all in relation to agriculture; these again can be held only by Indians. A year or so ago this gift was supplemented by a further sum of 11 lakhs of rupees (73,332*l*.), given by Sir Rash Ghose for the proposed technological branch of the College of Science. This gift enabled the University to send Sir Prafulla Chandra Rây, the dean of the faculty of science, on a three months' tour of the universities of Great Britain. Sir P. C. Rây is a distinguished chemist who has been closely associated with numerous industrial concerns in Bengal, and he has been appointed to supervise the equipment of the technological department, while four young research workers are being trained in London under the terms of Sir Rash Ghose's gift.

Calendar of Scientific Pioneers.

February 10, 1868. Sir David Brewster died.—A founder of the British Association and the biographer of Newton, Brewster made important discoveries in optics, for which he was awarded the Rumford, Royal, and Copley medals of the Royal Society.

February 10, 1878. Claude Bernard died.—A great physiologist, Bernard for many years held the chair of experimental physiology at the Collège de France.

February 10, 1891. Sonia Kovalevsky died.—One of the best known of women mathematicians, Sonia or Sophie Kovalevsky studied under Weierstrass, and after her husband's death in 1883 became professor of higher mathematics at Stockholm.

February 11, 1650. René Descartes died.—Born in 1596, and educated by the Jesuits, Descartes served for a while in the Army, and in 1629 settled in Holland, where his principal works were written. He has been called "the father of modern philosophy." He made many improvements in mathematics, and is regarded as the founder of analytical geometry. His theory of vortices, devised to explain the motion of the heavenly bodies, held the field until it was superseded by the Newtonian philosophy. He died at Stockholm, but his remains now rest in Paris. On the pedestal of his statue at Tours is inscribed, "Je pens, donc je suis."

February 11, 1868. Jean Bernard Léon Foucault died.—To Foucault we owe the demonstration, by means of the pendulum and the gyroscope, of the rotation of the earth. In 1850 he showed that light travelled more slowly through water than through air. He was physicist to the Paris Observatory.

February 12, 1787. Ruggiero Giuseppe Boscovich died.—The Society of Jesus has produced many notable workers in science, but none with a wider reputation than Boscovich. He was a mathematician, physicist, and astronomer, and is remembered for the famous theory of matter which he propounded. For some years he resided in Paris. His last days were passed in neglect and misery, and he died insane at Milan.

February 12, 1799. Lazaro Spallanzani died.—Holding various chairs at Modena and Padua, Spallanzani was interested in all branches of science, but his main discoveries related to physiology. He especially studied digestion and fertilisation.

February 13, 1839. Edward Turner died.—The first professor of chemistry in the University of London, Turner made many accurate determinations of atomic weights.

February 13, 1909. Hans Peter Jürgen Julius Thomsen died.—An educationist, administrator, and technologist, Thomsen held the chair of chemistry at Copenhagen. He made long and important investigations in thermo-chemistry, comparable with those of Berthelot.

February 14, 1744. John Hadley died.—A mathematician and scientific mechanist, Hadley produced the first serviceable reflecting telescope and invented the reflecting quadrant.

February 15, 1680. Jan Swammerdam died.—While practising as a doctor at Amsterdam and Leyden, Swammerdam became one of the earliest and most successful entomologists. He especially studied the anatomy of the bee.

February 15, 1736. Stephen Gray died.—The first recipient of the Copley prize of the Royal Society, Gray was a pensioner in the Charterhouse, London, where he made many successful electrical experiments.

E. C. S.

Societies and Academies.

LONDON.

Royal Society, January 27.—Prof. C. S. Sherrington, president, in the chair.—K. **Sassa** and Prof. C. S. **Sherrington**: The myogram of the flexor-reflex evoked by a single break-shock. In the spinal preparation excess of the reflex contraction over maximal twitch indicates that summation of successive contraction-waves is present in the former. Repetitive discharge from the reflex centre occurs, therefore, in response to a stimulus consisting of a single induction shock.—Sir Almroth **Wright**: "Intertraction" between albuminous substances and saline solutions. It is demonstrated by means of experiments in which serum is directly superimposed upon heavier salt solutions, and of corresponding experiments in which lighter salt solutions are superimposed upon heavier serum, that the fluids thus brought into conjunction interpenetrate with extreme rapidity. The phenomena are due to an interaction between the salts and the albuminous substances. The designation "intertraction" is applied to this form of interaction; and it is suggested that these forces supplement diffusion. In supplementary experiments it is shown that by intertraction microbes lodged in serum are rapidly carried down into heavier, or caught up into lighter, salt solutions.—Dr. S. **Russ**, Dr. Helen **Chambers**, and Gladwys M. **Scott**: The local and generalised action of radium and X-rays upon tumour growth. The local effects of the β- and γ-rays from radium and X-rays upon rat tumours, under varying conditions, were obtained by exposing the tumour only to measured quantities of radiation. When large doses are employed destructive action upon the tumour-cells is observed; as the dose is reduced the action tends to become stimulative in character, so that the tumour-cells grow more rapidly. The generalised effects of the rays used were obtained by submitting the whole animal to the radiation, the tumour being screened. Large generalised doses could not be borne by the animals; with repeated small doses an increase in body-weight and in resistance towards tumour growth was observed. The bearing of the observations on radiation treatment in man is discussed.

PARIS.

Academy of Sciences, January 10.—M. Georges Lemoine in the chair.—P. **Marchal**: The utilisation of ladybirds against insects harmful to cultivation in the South of France. Specimens of *Cryptoloemus Montrouzieri* obtained from America have been cultivated at Mentone, and colonies were liberated in that town and the neighbourhood. It was proved that the insects could pass the winter in the open air in spite of an unusually low temperature.—M. **Lugeon** and J. **Villemagne**: An old glacial bed of the Rhone between Léaz and Pont-Rouge des Usses (Haute-Savoie).—A. **Schaumasse**: Observations of the Skjellerup comet (1920*b*) made with the bent equatorial at Nice Observatory. Positions are given for December 16, 20, and 23. The comet was of 10·5 magnitude, about 1·5′ diameter, with an ill-defined nucleus.—G. **Fayet** and A. **Schaumasse**: Provisional elements of the new comet 1920*b* (Skjellerup).—H. **Godard**: Observations of the Skjellerup comet made at the Bordeaux Observatory with the 38-cm. equatorial.—S. **Posternak**: The tetrabasic polymolybdates.—E. **Chaput**: Observations on the old alluvia of the Seine.—L. **Cayeux**: The mineralogical evolution of the oolitic iron minerals of France, independent of the time factor.—A. **Guilliermond**: The morphological constitution of the cytoplasm.—E. **De Wildeman**: The theories of myrmecophily.—G. **Mangenot**: The "fucosane grains" of the Pheophyceæ.—H. **Lagatu**: The respective *rôles* of the three bases, potash, lime, and magnesia, in cultivated plants. The K : Ca : Mg ratios for a large number of plants are plotted on a rectangular isosceles triangle. The results explain experimental figures recently obtained by the use of calcined dolomite as a manure.—E. **Lombard**: A collection of phenomena, clinical and experimental, permitting the study of the functional state of the vestibular apparatus in its relations with organic equilibrium.—M. **Doyon**: The anti-coagulating action of the nucleic acid of the pancreas. The stability and characters of the nucleated plasma.—A. **Mayer**, H. **Magne**, and L. **Plantefol**: The toxicity of the chlorinated methyl carbonates and chlorocarbonates. Thirteen chlorine derivatives of methyl carbonate were studied; the results are expressed graphically with substituted chlorine atoms as abscissæ and minimum focal concentrations as ordinates.—P. **Chabanaud**: A new Batrachian in intertropical Africa. The larva found appears to be that of *Triton Poireti*, although there are some differences.

January 17.—M. Georges Lemoine in the chair.—C. **Guichard**: Couples of two O_1 congruences, reciprocal polars, with respect to a linear complex.—T. **Varopoulos**: Functions having a finite or infinite number of branches.—C. **Trémont**: The testing of thin metal sheets by stamping. Two methods are described, one for metal sheets utilised for their rigidity, the other for resistance to shock. Some data obtained with sheets of steel, copper, brass, and aluminium are given.—H. **Villat**: The initial flow of a liquid through an orifice opened suddenly.—R. **de Mallemann**: The variation of the rotatory power of tartaric acid. The marked increase in the rotatory power of solutions of tartaric acid caused by the addition of certain weak acids (boric, molybdic, tungstic, etc.) has been attributed to the formation of new chemical compounds of high rotatory power. The author describes modifications of rotatory power produced by the chlorides and nitrates of the alkalis and alkaline earths which appear to be due to another cause. The rotatory power diminishes and then changes its sign; the dispersion changes follow a definite law.—G. **Chaudron**: Reversible reactions of carbon monoxide with the oxides of iron. The composition of the gaseous phase in this equilibrium has been determined by an interference method. Below 580° C. there is a single system corresponding to the equation

$$Fe_3O_4+4CO \rightleftharpoons 4CO_2+3Fe.$$

Below 580° C. there are two equilibria corresponding to

$$Fe_3O_4+CO \rightleftharpoons 3FeO+CO_2.$$
$$FeO+CO \rightleftharpoons Fe+CO_2.$$

A diagram is given, plotted from the experimental figures showing the three branches of curves corresponding to these systems.—J. B. **Senderens**: The catalytic decomposition of the chloroacetic acids. Whilst acetone is readily formed by the catalytic decomposition of acetic acid, the chloroacetic acids are split up in quite a different manner. Monochloroacetic acid gives carbon monoxide and dioxide, aqueous hydrochloric acid, and a little ethylene chloride; trichloroacetic acid gives the same gases with a little phosgene, with a condensed liquid containing chloroform, tetrachloroethylene, and a little hexachloroethane. Thoria and kaolin have practically identical catalytic actions in these decompositions; but animal charcoal gives different products with trichloroacetic acid, 85 per cent. of the distillate consisting of chloroform.—M. **Delépine** and P. **Jaffeux**: The two homologues of ethylene sulphide, 1 : 2-thiopropane and 1 : 2-thiobutane. These two sulphides have been prepared in a pure state, and their principal physical constants are given and compared with the isomers described by Grichkévitch-Trokhimovsky.—R. **Fosse**: The synthesis of cyanic acid by the oxidation of formamide and of oxamic acid. Formamide was oxidised by potassium permanganate in strongly ammoniacal solution and the resulting solution heated with ammonium chloride; urea was proved to be present by the xanthydrol reaction.—C. **Dufraisse**: The auto-oxidation of α-bromostyrolene.—O. **Mengel**: The inter-Glacial and post-Glacial tectonic movements of the eastern end of the Pyrenees.—C. **Dufour**: The values of the magnetic elements at the Val-Joyeux Observatory on January 1, 1921.—Ad. Dawy **de Virville**: Modification of the form and structure of a moss (*Hypnum commutatum*) kept under water. After six months marked changes in the mode of growth were observed.—E. **Miège**: The action of chloropicrin on the germinative faculty of seeds. The destruction of parasitic insects on seeds with chloropicrin vapour is readily carried out, but in some cases the seeds are injuriously affected. Leguminous seeds are not injured by this treatment.—P. **Mazé**: The chemical mechanism of the assimilation of carbon dioxide by green plants.—A. **Pézard**: The latent period in experiments of testicular transplantation and the law of "all or nothing."—M. **Marage**: The limits of audition.—C. **Porcher** and L. **Panisset**: Experimental researches on colostrum. Colostrum is not a special fluid secreted by the mammary gland, but the product of phagocytosis of ordinary milk; it is a product of retention. The lactose is absorbed, and the phagocytes attack the colloids and fat globules.—E. **Kayser**: The influence of light radiations on the azotobacter.—H. **Vallée** and H. **Carré**: The adsorption of the aphthous virus.

Books Received.

The Development of Institutions under Irrigation. By Prof. G. Thomas. Pp. xi+293. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd.) 16s. net.

Laboratory Projects in Physics: A Manual of Practical Experiments for Beginners. By F. F. Good. Pp. xiii+267. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd.) 9s. net.

The Origin and Development of the Nervous System from a Physiological Viewpoint. By Prof. C. M. Child. Pp. xvii+296. (Chicago: University of Chicago Press; London: Cambridge University Press.) 1.75 dollars net.

An Introduction to Zoology for Medical Students: By Prof. C. H. O'Donoghue. Pp. x+501. (London: G. Bell and Sons, Ltd.) 16s. net.

Mechanism, Life, and Personality: An Examination of the Mechanistic Theory of Life and Mind. By Dr. J. S. Haldane. Second edition. Pp. vii+152. (London: J. Murray.) 6s. net.

Diary of Societies.

THURSDAY, FEBRUARY 10.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. W. A. Herdman: Oceanography (Problems of the Plankton).

ROYAL SOCIETY, at 4.30.—Rev. John Roscoe: Certain Ethnological Features of Uganda.

LONDON MATHEMATICAL SOCIETY (at Royal Astronomical Society), at 5.—Prof. A. S. Eddington: World Geometry (with particular reference to Weyl's Electromagnetic Theory).—J. Brill: Note on the Electromagnetic Equations.—J. E. Littlewood: Researches in the Theory of the Riemann Zeta-function.—S. Pollard: A New Condition for Cauchy's Theorem.—I. J. Schwatt: (1) An Independent Form of the Numbers of Bernoulli; (2) Euler's Numbers of Higher Order; (3) Certain Numbers which are related to Euler's Numbers of Higher Order.—S. Timoshenko: (1) The Tension of a Prism one of the Cross-sections of which remains Plane; (2) The Analogy with Membranes in the Case of the Bending of a Prism.

CHILD-STUDY SOCIETY (at Royal Sanitary Institute), at 6.—Dr. G. H. Miles: Vocational Tests.

INSTITUTION OF ELECTRICAL ENGINEERS (at Institution of Civil Engineers), at 6.—Discussion on Electric Appliances for Domestic Purposes, to be introduced by Dr. E. Griffiths and F. H. Schofield in a Paper on Some Thermal Characteristics of Electric Ovens and Hot Plates.

LONDON DERMATOLOGICAL SOCIETY, at 6.—Dr. Sibley: Alopecia (Chesterfield Lecture).

OPTICAL SOCIETY, at 7.30.

ROYAL SOCIETY OF MEDICINE (Neurology Section) (at National Hospital for Paralysis and Epilepsy), at 8.

FRIDAY, FEBRUARY 11.

ROYAL ASTRONOMICAL SOCIETY (Anniversary Meeting), at 5.

ROYAL SOCIETY OF MEDICINE (Clinical Medicine, Surgery), Joint Meeting, at 5.—Dr. H. Mackenzie, J. Berry, and Others: Discussion: The Medical and Surgical Treatment of Graves' Disease.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Prof. A. G. T. Fisher: Loose Bodies in Joints.

PHYSICAL SOCIETY OF LONDON (at Imperial College of Science), at 5.—Discussion on Absolute Measurements of Electrical Resistance, and Instruments Based on the Temperature-variation of Resistance.—Sir Richard Glazebrook and F. E. Smith: Absolute Measurements of Electrical Resistance.—Resistance Thermometry: Prof. H. L. Callendar: The Compensated Resistance Bridge, and Instrument for the Measurement of Radiation.—C. R. Darling: The Early Work of Siemens on the Resistance-Pyrometer.—

C. Jakeman: The Measurement of Steam Temperatures.—The Hot-Wire Microphone: Major W. S. Tucker: The Function of the Convection Current in the Hot-Wire Microphone.—Capt. E. J. Paris: Theory of the Tucker Microphone.—Anemometry and Heat Convection: Prof. J. T. McGregor Morris: A Hot-Wire Anemometer.—Dr. J. S. G. Thomas. A Directional Hot-Wire Anemometer.—A. H. Davis: An Instrument for Measuring Convected Heat.—Miscellaneous Applications: Dr. G. A. Shakspear: A Gas Permeameter.—Prof. Leonard Hill: The Caleometer.—E. A. Griffiths: Liquid Depth Gauge (Distant Reading Type).—Dr. Daynes: A CO_2 Recorder.—Dr. E. Griffiths: Electrical Hygrometers.

MONTESSORI SOCIETY (at University College), at 5.45.—Miss M. Drummond: The Psychological Basis of the Montessori Method.

JUNIOR INSTITUTION OF ENGINEERS (at Caxton Hall), at 8.—F. A. Simpson: Some Limit Gauges.

INSTITUTE OF INDUSTRIAL ADMINISTRATION (at Central Hall, Westminster), at 8.—Sir Lynden Macassey: Present-Day Industrial Psychology.

ROYAL SOCIETY OF MEDICINE (Ophthalmology Section), at 8.30.—B. T. Lang: Scotometry.—Dr. T. H. Butler: Late Infections after Sclerectomy.—M. L. Hepburn: Some Notes on Trephining.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Dr. F. W. Aston: Isotopes and Atomic Weights.

SATURDAY, FEBRUARY 12.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. A. Fowler: Spectroscopy (Experimental Spectroscopy).

PHYSIOLOGICAL SOCIETY (at National Institute for Medical Research, Mount Vernon, Hampstead), at 4.

MONDAY, FEBRUARY 14.

BIOCHEMICAL SOCIETY (at University College).

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 4.—Sir Charters J. Symonds: Hunterian Oration.

INSTITUTE OF ACTUARIES, at 5.—F. A. A. Menzler: The Census of 1921: Some Remarks on Tabulation.

ROYAL GEOGRAPHICAL SOCIETY (at Lowther Lodge), at 5.—Lt.-Col. E. A. Tandy: The Circulation in the Earth's Crust.

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting) (at Chartered Institute of Patent Agents), at 7.

INSTITUTION OF MECHANICAL ENGINEERS (Graduates' Special Lecture), at 7.—Sir John Dewrance: Generation of Steam.

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.—W. E. Willink: The Cunard Building.

ROYAL SOCIETY OF ARTS, at 8.—Dr. E. K. Rideal: Applications of Catalysis to Industrial Chemistry (Cantor Lecture).

MEDICAL SOCIETY OF LONDON (at 11 Chandos Street, W.1), at 8.30.—Sir James Galloway and Others: Discussion on Skin Disease: Its Relation to Internal Disorder.

ROYAL SOCIETY OF MEDICINE (War Section), at 9.

TUESDAY, FEBRUARY 15.

ROYAL SOCIETY OF MEDICINE (Therapeutics and Pharmacology Section), at 4.30.—Dr. J. H. Burn: A Comparison of Digitalis Tinctures by Different Physiological Methods.—Dr. P. Hamill: Pituitary Extracts given by the Mouth (Experimental).—Dr. Donaldson: Pituitary Extracts given by the Mouth (Clinical).

ROYAL SOCIETY OF MEDICINE, at 5.—General Meeting.

ROYAL STATISTICAL SOCIETY, at 5.15.—Dr. J. Bonar: The Mint and the Precious Metals in Canada.

INSTITUTION OF PETROLEUM TECHNOLOGISTS (at Royal Society of Arts), at 5.30.—P. de Chambrier: Working Petroleum by means of "Pits" and "Galleries."

WEDNESDAY, FEBRUARY 16.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Dr. F. W. Edridge-Green: The Cause and Prevention of Myopia (Arris and Gale Lecture).

ROYAL SOCIETY OF ARTS, at 8.—Dr. W. Cramp: Pneumatic Elevators in Theory and Practice.

ROYAL METEOROLOGICAL SOCIETY, at 8.—M. de Carle S. Salter: A New Method of Constructing Average Monthly Rainfall Maps.—G. A. Clarke: An Unusual Pilot-balloon Trajectory.

ROYAL MICROSCOPICAL SOCIETY, at 8.

HUNTERIAN SOCIETY (at Sion College), at 9.—Dr. H. H. Bashford: The Ideal Element in Medicine.

THURSDAY, FEBRUARY 17.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. W. A. Herdman: Oceanography (The Sea-Fisheries).

ROYAL SOCIETY, at 4.30.—*Probable Papers.*—Dr. C. Chree: A Comparison of Magnetic Declination Changes at British Observatories.—Prof. H. M. Macdonald: The Transmission of Electric Waves Around the Earth's Surface.—Prof. T. H. Havelock: The Stability of Fluid Motion.—Prof. W. H. Young: The Transformation of Integrals.—J. L. Haughton and Kathleen E. Bingham: The Constitution of the Alloys of Aluminium, Copper, and Zinc containing High Percentages of Zinc.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. Martin Flack: Respiratory Efficiency in Relation to Health and Disease (Milroy Lecture).

LINNEAN SOCIETY, at 5.—Prof. G. B. De Toni: A Contribution to the Teratology of the Genus Datura.—Capt. J. Ramsbottom and A. J. Wilmott: A Plant Collection from Macedonia.—Dr. G. C. Druce: Shetland *Plantago* and Other Plants from the Northern Isles.

ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts), at 5.30.—F. Handley Page: The Handley Page Wing.

INSTITUTION OF MINING AND METALLURGY (at Geological Society), at 5.30.—E. H. Clifford: A Scheme for Working the City Deep Mine at a Depth of 7000 ft.

INSTITUTION OF ELECTRICAL ENGINEERS (at Institution of Civil Engineers), at 6.—Prof. E. Wilson: Magnetic Susceptibility of Low Order: I. Instrumentation.

INSTITUTION OF AUTOMOBILE ENGINEERS (London Graduates' Meeting) (at 28 Victoria Street), at 7.30.—E. L. Bass: Engine Lubrication.

CHEMICAL SOCIETY, at 8.—L. J. Hudleston and H. Bassett: Equilibria of Hydrofluosilicic Acid. Part I. Mixtures of Hydrofluosilicic and Hydrofluoric Acids.—R. G. Fargher and H. King: Additive Compounds of Antipyrylaminodiacetic Acid and its Salts with Neutral Salts.—H. Bassett and T. A. Simmons: The System, Picric Acid—Phenyl Acridine.—F. S. Kipping: Organic Derivatives of Silicon. Part XXIV. *dl*-Derivatives of Silicoethane.—F. W. Atack: The Structural Isomerism of Oximes. Part I. Criticism of the Hantzsch-Werner Hypothesis of the Geometrical Isomerism of Carbon-Nitrogen Compounds.—F. W. Atack: The Structural Isomerism of Oximes. Part II. Constitution of Oximes.—F. S. Kipping: Organic Derivatives of Silicon. Part XXV. Saturated and Unsaturated Silicohydrocarbons Si_4Ph_8.

RÖNTGEN SOCIETY (at University College), at 8.15.—N. E. Luboshez: Intensifying Screens and Secondary Radiation.

FRIDAY, FEBRUARY 18.

ASSOCIATION OF ECONOMIC BIOLOGISTS, Annual General Meeting (in Botanical Lecture Theatre, Imperial College of Science), at 2.30.—Sir David Prain: Some Relationships of Economic Biology.

GEOLOGICAL SOCIETY OF LONDON, at 3.—Anniversary Meeting.

ROYAL SOCIETY OF ARTS (Indian Section), at 4.30.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—J. F. Dobson: The Function of the Kidneys in Enlargement of the Prostate Gland (Arris and Gale Lecture).

INSTITUTION OF MECHANICAL ENGINEERS, at 6.—Annual General Meeting.—F. M. Farmer: The Desirability of Standardisation in the Testing of Welds.

INSTITUTION OF ELECTRICAL ENGINEERS (Students' Section) (at King's College, Strand), at 6.30.—L. B. Atkinson: Presidential Address.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—S. J. Solomon: Strategic Camouflage.

SATURDAY, FEBRUARY 19.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. A. Fowler: Spectroscopy (Regularity in Spectra).

Introduction.

SINCE 1905, when Prof. A. Einstein published his Principle of Relativity in its special form, much attention has been devoted to the subject in scientific circles, and during the last two or three years keen interest has been shown in it by many general readers of intellectual type. Nearly a thousand books, pamphlets, and papers have appeared in which the principle as a whole is described, or some of its aspects are discussed, and among these are a few which aim at making its character and consequences clear without the mathematical expressions which give it precise significance. A praiseworthy essay of this kind is that by Mr. L. Bolton, a senior examiner in the Patent Office, published in the *Westminster Gazette* on Monday by arrangement with the *Scientific American*, which awarded it a prize of five thousand dollars as the clearest explanation of Einstein's principle for general readers.

It is not difficult to understand why such wide interest is taken in this principle. No special knowledge is required to realise that measurements of space and time are essentially relative, and as all thinking people have pondered over the metaphysics of infinity and eternity, they are attracted by a conception in which these ideas are involved. The physicist is concerned with the principle because it developed out of experimental results of a negative kind, and is intimately associated with electromagnetic theory; the astronomer because it gives a new interpretation of effects not explained by the Newtonian law; and the mathematician because it provides him with a new space-time geometry. The principle has thus points of contact with many fields of scientific activity, and it is on this account that the present issue of NATURE is devoted to it.

We are gratified that so many leading authorities have been able to favour readers of this journal with surveys of the foundations of the principle or with their views as to the stability of the framework based upon them. Our own function has been limited to suggesting the scope of each article in the series, and, so far as possible, securing that the range of the whole covers the chief points around which discussion has centred. The writers have not seen one another's contributions, so that each article is an independent statement complete in itself so far as it goes. The order of the articles in the series is, therefore, important, and we believe that adopted will be considered appropriate to these columns.

Prof. Einstein describes the natural sequence of ideas which led to the conception of his principle, and Mr. Cunningham follows with a historical sketch of the conditions which demanded a revision of æther theories in relation to problems of absolute motion. The astronomical consequences—the displacement of light by the gravitational field of the sun, the movement of the perihelion of Mercury's orbit, and the displacement of solar spectrum lines (not yet established)—are dealt with by Sir Frank Dyson, Dr. Crommelin, and Dr. St. John respectively. The relation of Riemann's geometry of n-dimensions to the principle is outlined by Prof. Mathews; and the four articles which follow, by Mr. Jeans, Prof. Lorentz, Sir Oliver Lodge, and Prof. Weyl, are concerned mainly with physical aspects. How differently philosophers and astronomers regard the meaning and measurement of time is described by Prof. Eddington, and this article, with those by Dr. Norman Campbell and by Miss Wrinch and Dr. Jeffreys, leads naturally to the metaphysical conceptions presented by Prof. Wildon Carr.

Whatever may be the ultimate place taken by the principle of relativity in the history of science, no idea has ever proceeded by more logical steps from the rank of hypothesis to theory. In two cases predicted phenomena for which no satisfactory alternative explanation is forthcoming have been confirmed by observation, and the third is still a subject of inquiry. In this journal we are concerned mainly with the bearing of the principle upon physical science, and only incidentally with its metaphysical aspects. We may remark, however, that the absolute in Nature is not abolished by the principle. Measurements of time and space cease to be absolute and depend upon the motion of the observer, but things like energy and the velocity of light are independent of such motion and remain as absolute as ever they were.

A Brief Outline of the Development of the Theory of Relativity.

By PROF. A. EINSTEIN.

[Translated by Dr. Robert W. Lawson.]

THERE is something attractive in presenting the evolution of a sequence of ideas in as brief a form as possible, and yet with a completeness sufficient to preserve throughout the continuity of development. We shall endeavour to do this for the Theory of Relativity, and to show that the whole ascent is composed of small, almost self-evident steps of thought.

The entire development starts off from, and is dominated by, the idea of Faraday and Maxwell, according to which all physical processes involve a continuity of action (as opposed to action at a distance), or, in the language of mathematics, they are expressed by partial differential equations. Maxwell succeeded in doing this for electro-magnetic processes in bodies at rest by means of the conception of the magnetic effect of the vacuum-displacement-current, together with the postulate of the identity of the nature of electro-dynamic fields produced by induction, and the electro-static field.

The extension of electro-dynamics to the case of moving bodies fell to the lot of Maxwell's successors. H. Hertz attempted to solve the problem by ascribing to empty space (the æther) quite similar physical properties to those possessed by ponderable matter; in particular, like ponderable matter, the æther ought to have at every point a definite velocity. As in bodies at rest, electromagnetic or magneto-electric induction ought to be determined by the rate of change of the electric or magnetic flow respectively, provided that these velocities of alteration are referred to surface elements moving with the body. But the theory of Hertz was opposed to the fundamental experiment of Fizeau on the propagation of light in flowing liquids. The most obvious extension of Maxwell's theory to the case of moving bodies was incompatible with the results of experiment.

At this point, H. A. Lorentz came to the rescue. In view of his unqualified adherence to the atomic theory of matter, Lorentz felt unable to regard the latter as the seat of continuous electromagnetic fields. He thus conceived of these fields as being conditions of the æther, which was regarded as continuous. Lorentz considered the æther to be intrinsically independent of matter, both from a mechanical and a physical point of view. The æther did not take part in the motions of matter, and a reciprocity between æther and matter could be assumed only in so far as the latter was considered to be the carrier of attached electrical charges. The great value of the theory of Lorentz lay in the fact that the entire electrodynamics of bodies at rest and of bodies in motion was led back to Maxwell's equations of empty space. Not only did this theory surpass that of Hertz from the point of view of method, but with its aid H. A. Lorentz was also pre-eminently successful in explaining the experimental facts.

The theory appeared to be unsatisfactory only in *one* point of fundamental importance. It appeared to give preference to one system of co-ordinates of a particular state of motion (at rest relative to the æther) as against all other systems of co-ordinates in motion with respect to this one. In this point the theory seemed to stand in direct opposition to classical mechanics, in which all inertial systems which are in uniform motion with respect to each other are equally justifiable as systems of co-ordinates (Special Principle of Relativity). In this connection, all experience also in the realm of electro-dynamics (in particular Michelson's experiment) supported the idea of the equivalence of all inertial systems, *i.e.* was in favour of the special principle of relativity.

The Special Theory of Relativity owes its origin to this difficulty, which, because of its fundamental nature, was felt to be intolerable. This theory originated as the answer to the question: Is the special principle of relativity really contradictory to the field equations of Maxwell for empty space? The answer to this question appeared to be in the affirmative. For if those equations are valid with reference to a system of co-ordinates K, and we introduce a new system of co-ordinates K′ in conformity with the—to all appearances readily establishable—equations of transformation

$$\left.\begin{aligned} x' &= x - vt \\ y' &= y \\ z' &= z \\ t' &= t \end{aligned}\right\} \text{(Galileo transformation),}$$

then Maxwell's field equations are no longer valid in the new co-ordinates (x', y', z', t'). But appearances are deceptive. A more searching analysis of the physical significance of space and time rendered it evident that the Galileo transformation is founded on arbitrary assumptions, and in particular on the assumption that the statement of simultaneity has a meaning which is independent of the state of motion of the system of co-ordinates used. It was shown that the field equations for *vacuo* satisfy the special principle of relativity, provided we make use of the equations of transformation stated below:

$$\left.\begin{aligned} x' &= \frac{x - vt}{\sqrt{1 - v^2/c^2}} \\ y' &= y \\ z' &= z \\ t' &= \frac{t - vx/c^2}{\sqrt{1 - v^2/c^2}} \end{aligned}\right\} \text{(Lorentz transformation).}$$

In these equations x, y, z represent the co-ordinates measured with measuring-rods which are at rest with reference to the system of co-ordinates, and t represents the time measured with suitably adjusted clocks of identical construction, which are in a state of rest.

Now in order that the special principle of relativity may hold, it is necessary that all the equations of physics do not alter their form in the transition from one inertial system to another, when we make use of the Lorentz transformation for the calculation of this change. In the language of mathematics, all systems of equations that express physical laws must be co-variant with respect to the Lorentz transformation. Thus, from the point of view of method, the special principle of relativity is comparable to Carnot's principle of the impossibility of perpetual motion of the second kind, for, like the latter, it supplies us with a general condition which all natural laws must satisfy.

Later, H. Minkowski found a particularly elegant and suggestive expression for this condition of co-variance, one which reveals a formal relationship between Euclidean geometry of three dimensions and the space-time continuum of physics.

Euclidean Geometry of Three Dimensions.	*Special Theory of Relativity.*
Corresponding to two neighbouring points in space, there exists a numerical measure (distance ds) which conforms to the equation $ds^2=dx_1^2+dx_2^2+dx_3^2$.	Corresponding to two neighbouring points in space-time (point events), there exists a numerical measure (distance ds) which conforms to the equation $ds^2=dx_1^2+dx_2^2+dx_3^2+dx_4^2$
It is independent of the system of co-ordinates chosen, and can be measured with the unit measuring-rod.	It is independent of the inertial system chosen, and can be measured with the unit measuring-rod and a standard clock. x_1, x_2, x_3 are here rectangular co-ordinates, whilst $x_4=\sqrt{-1}\,ct$ is the time multiplied by the imaginary unit and by he velocity of light.
The permissible transformations are of such a character that the expression for ds^2 is invariant, *i.e.* the linear orthogonal transformations are permissible.	The permissible transformations are of such a character that the expression for ds^2 is invariant, *i.e.* those linear orthogonal substitutions are permissible which maintain the semblance of reality of x_1, x_2, x_3, x_4. These substitutions are the Lorentz transformations.
With respect to these transformations, the laws of Euclidean geometry are invariant.	With respect to these transformations, the laws of physics are invariant.

From this it follows that, in respect of its *rôle* in the equations of physics, though not with regard to its physical significance, time is equivalent to the space co-ordinates (apart from the relations of reality). From this point of view, physics is, as it were, a Euclidean geometry of four dimensions, or, more correctly, a statics in a four-dimensional Euclidean continuum.

The development of the special theory of relativity consists of two main steps, namely, the adaptation of the space-time "metrics" to Maxwell's electro-dynamics, and an adaptation of the rest of physics to that altered space-time "metrics." The first of these processes yields the relativity of simultaneity, the influence of motion on measuring-rods and clocks, a modification of kinematics, and in particular a new theorem of addition of velocities. The second process supplies us with a modification of Newton's law of motion for large velocities, together with information of fundamental importance on the nature of inertial mass.

It was found that inertia is not a fundamental property of matter, nor, indeed, an irreducible magnitude, but a property of energy. If an amount of energy E be given to a body, the inertial mass of the body increases by an amount E/c^2, where c is the velocity of light *in vacuo*. On the other hand, a body of mass m is to be regarded as a store of energy of magnitude mc^2.

Furthermore, it was soon found impossible to link up the science of gravitation with the special theory of relativity in a natural manner. In this connection I was struck by the fact that the force of gravitation possesses a fundamental property, which distinguishes it from electro-magnetic forces. All bodies fall in a gravitational field with the same acceleration, or—what is only another formulation of the same fact—the gravitational and inertial masses of a body are numerically equal to each other. This numerical equality suggests identity in character. Can gravitation and inertia be identical? This question leads directly to the General Theory of Relativity. Is it not possible for me to regard the earth as free from rotation, if I conceive of the centrifugal force, which acts on all bodies at rest relatively to the earth, as being a "real" field of gravitation, or part of such a field? If this idea can be carried out, then we shall have proved in very truth the identity of gravitation and inertia. For the same property which is regarded as *inertia* from the point of view of a system not taking part in the rotation can be interpreted as *gravitation* when considered with respect to a system that shares the rotation. According to Newton, this interpretation is impossible, because by Newton's law the centrifugal field cannot be regarded as being produced by matter, and because in Newton's theory there is no place for a "real" field of the "Koriolis-field" type. But perhaps Newton's law of field could be replaced by another that fits in with the field which holds with respect to a "rotating" system of co-ordinates? My conviction of the identity of inertial and gravitational mass aroused within me the feeling of absolute confidence in the correctness of this interpretation. In this connection I gained encouragement from the following idea. We are familiar with the "apparent" fields which are valid relatively to systems of co-ordinates possessing arbitrary motion with respect to an inertial system. With the aid of these special fields we should be able to study the law which is satisfied in general by gravitational fields. In this connection we shall have to take account of the fact that the ponderable masses will be the determining factor in producing the field, or, according to the fundamental result of the special theory of relativity, the energy density—a magnitude having the transformational character of a tensor.

On the other hand, considerations based on the metrical results of the special theory of relativity led to the result that Euclidean metrics can no longer be valid with respect to accelerated systems of co-ordinates. Although it retarded the progress of the theory several years, this enormous difficulty was mitigated by our knowledge that Euclidean metrics holds for small domains. As a consequence, the magnitude *ds*, which was physically defined in the special theory of relativity hitherto, retained its significance also in the general theory of relativity. But the co-ordinates themselves lost their direct significance, and degenerated simply into numbers with no physical meaning, the sole purpose of which was the numbering of the space-time points. Thus in the general theory of relativity the co-ordinates perform the same function as the Gaussian co-ordinates in the theory of surfaces. A necessary consequence of the preceding is that in such general co-ordinates the measurable magnitude *ds* must be capable of representation in the form

$$ds^2 = \sum_{uv} g_{uv} dx_u dx_v$$

where the symbols g_{uv} are functions of the space-time co-ordinates. From the above it also follows that the nature of the space-time variation of the factors g_{uv} determines, on one hand the space-time metrics, and on the other the gravitational field which governs the mechanical behaviour of material points.

The law of the gravitational field is determined mainly by the following conditions: First, it shall be valid for an arbitrary choice of the system of co-ordinates; secondly, it shall be determined by the energy tensor of matter; and thirdly, it shall contain no higher differential coefficients of the factors g_{uv} than the second, and must be linear in these. In this way a law was obtained which, although fundamentally different from Newton's law, corresponded so exactly to the latter in the deductions derivable from it that only very few criteria were to be found on which the theory could be decisively tested by experiment.

The following are some of the important questions which are awaiting solution at the present time. Are electrical and gravitational fields really so different in character that there is no formal unit to which they can be reduced? Do gravitational fields play a part in the constitution of matter, and is the continuum within the atomic nucleus to be regarded as appreciably non-Euclidean? A final question has reference to the cosmological problem. Is inertia to be traced to mutual action with distant masses? And connected with the latter: Is the spatial extent of the universe finite? It is here that my opinion differs from that of Eddington. With Mach, I feel that an affirmative answer is imperative, but for the time being nothing can be proved. Not until a dynamical investigation of the large systems of fixed stars has been performed from the point of view of the limits of validity of the Newtonian law of gravitation for immense regions of space will it perhaps be possible to obtain eventually an exact basis for the solution of this fascinating question.

Relativity: The Growth of an Idea.

By E. Cunningham.

Saccheri, in his "Logica Demonstrativa," published in 1697, ten years after Newton's "Principia Mathematica," lays down a distinction between *real* and *nominal* definitions which should be kept in mind if we are to do justice to Newton. Euclid defines a square as a four-sided figure the sides of which are all equal, and the angles of which are all right-angles. That is what he means by the name "square." It is a *nominal* definition. It remains to be shown that such a figure exists. This is done in Book I., Prop. 46. The definition then becomes *real*. Euclid is not guilty of the error of presupposing the existence of the figure.

Newton prefixes to his principles of natural philosophy certain definitions of absolute, true, and mathematical space and time. The former remains fixed and immovable; the latter flows uniformly on, without regard to material bodies. He strives here against the imperfections of language to give words to the thought in the back of his mind. The philosopher attacks him on these definitions; he has no right to presuppose that these words correspond to any reality. What then? Suppose these offending definitions removed, or recognised as purely nominal. Then the definitions of velocity, acceleration, mass, and force are nominal, too, and the whole of Newton's structure of dynamics is a paper scheme of words and relations which may or may not correspond to the world of sense.

But that is exactly what it is. That is what all scientific theory is, until experiment demonstrates that the correspondence exists. The justification of Newton's theory comes, not in the discovery of a time that flows uniformly on, but in the fact that the observed phenomena of the tides, of planetary motion, and of mechanics in general do fit on to his scheme. But the fit does not consist in the agreement of clock-time or solar time with absolute time. It is in the mutual agreement of the motions of clocks, earth, planets, moon, tides, and the rest; so that it matters not a whit whether the time variable used in the calculations flows uniformly on, or whether it is the merest variable number devoid of any physical significance whatever.

Thus the great paradox, the stumbling-block of absolute rotation, is not one of logic. Nature thrusts it upon us. While we would all admit that *a priori* rotation relative to empty space is a meaningless term, yet there remain Newton's bucket and Foucault's pendulum; and, strive as we will, Newton's way of looking at them remains the simplest. We would all fain think that "acceleration relative to empty space" is an empty phrase, and yet Nature is such that Newton's system of dynamics made modern science possible. Whatever we may say of Newton's definitions, therefore, his space and time are natural products of Nature's laboratory, to be purified, perhaps, but not to be rejected as spurious.

The nineteenth century was the æther age. From Arago, in 1820, to Michelson and Morley (1881–1905), followed by Trouton, Noble, Rankine, and Brace, vain attempts were made to discover the earth's velocity through the æther. But what, after all, was this elusive medium? To Faraday doubtless it was as real as anything in the universe. His resolute insistence on the need for a medium of transmission of electrical action, his discovery of the induction of currents by changing magnetic fields, Maxwell's advocacy of his views, and the demonstration of the electromagnetic nature of light, led up directly to the electron theory of Lorentz and Larmor, in which the æther appears as the background of all material phenomena. Yet the æther, after all, was but a name, and the electron theory a formal scheme of relations; like Newton's scheme, it was to be verified by its correspondence with actual observation. When it comes to observation, the only possibility is to note the behaviour of material bodies. Thus the æther with the associated ideas of electric and magnetic intensity ranks *pari passu* with Newton's absolute time and space. It has no likeness with matter; it is even doubtful whether it is of such substantiality that any element of it has identity. It has been said of Larmor's account of it that it reduces the universe to a set of differential equations, which, of course, is to a great extent true of Newton's work also.

But the notable thing about this theory is that it leaves the problem of absolute motion and absolute rotation exactly at the point where Newton left it. It gives a reasonable account of the failure of Michelson and Morley and the rest to discover the earth's velocity relative to the æther, just as Newton's theory would show why its velocity in absolute space cannot be determined. The æther-builders succeeded too well, and constructed, not one, but an infinity of æthers, any one having a uniform translatory motion relative to any other. But in the new theory, as in the old, a body may be said in an absolute sense to be devoid of rotational motion.

With the lack of determinateness in the æther goes a similar ambiguity in the measures of time and space. Each of these æthers has its proper scale of time and space. Events which are simultaneous in one æther are not simultaneous in another, and, since none can tell which is the true æther, none can tell whether two events are simultaneous or not. This is where the theories of Lorentz and Larmor lead us; and yet they only suggest it without demonstrating it. For neither of them professed to give a complete account of the structure of matter. The relations they propose for the æthereal action need to be supplemented by hypotheses as to the nature of the electron before they make a complete scheme; and when it comes to this Lorentz suggests a hypothesis, that of the contracting electron, which is devised specially for the purpose of getting the æther to conceal itself.

This brings us to the point at which Einstein makes his very modest suggestion (1905) of testing the hypothesis that in the nature of things we must not expect ever to find evidence of an absolute velocity of the earth through space. The ground had been well prepared. The electron theory as generally accepted was taken as it stood. The only new idea was that whereas his predecessors clung to the thought that one æther with its associated system of space-time measurement was real and the rest fictitious, Einstein, in the absence of any distinguishing features, ranks them all alike. To which some replied, "Give us back our absolute time and our æther." Yet Einstein had logic on his side, for the definitions of æther and of time are definitions *quid nominis*, not *quid rei*.

Looking back, we realise two great gaps in the special principle of relativity as Einstein propounded it in 1905. The first is the same which revealed itself in Newton's theory. "Uniform motion in a straight line" is left as a phrase with meaning, a situation as intolerable to the philosopher as the recognition of "absolute rest." Further, while it accepted the electromagnetic theory intact as a common basis of the structure of matter, it took no account of the other common property of matter, gravitation, of which so far the electromagnetic theory offered no explanation. Einstein at once realised the gaps, however, and saw a relation between them. Gravitational problems are problems of acceleration. The magnitude of the velocity of an observer does not affect his sense of gravity, but the experience of the man in the lift is that his acceleration does so. Thus Einstein perceived that to settle his difference with the philosopher he must first reconcile gravitation. Whether he would ever have done it without the genius of Minkowski we cannot tell. But as a matter of history the pure mathematician, who surely had learned much from Riemann and Helmholtz, was the first to emphasise the profound unity between the categories of space and time that was suggested by Einstein's work. A universe of determinate relations, in which everything proceeds according to known laws, is one which may be surveyed as a great whole in which past, present, and future are one. It is a four-dimensional unity, and for Einstein any plane section through it could be the present. The history of a particle is a simple chain of points in that whole, a "world-line."

Now events moved fast. Minkowski gave the notion of a four-dimension universe. Riemann had initiated a method of geometry in any number of dimensions; Einstein had glimpsed the possibility that, taking gravitation into account, light might be subject to acceleration, which, being interpreted in Minkowski's fashion, meant that the ordinary Euclidean expression for the element of length in a four-dimension space must be generalised. This made the work of Riemann not only useful, but also prophetic. In 1853 he had written that "the ground of the measure relations existing in the universe, if continuous, must consist in the binding forces acting upon it." This really implies the whole relativity doctrine; it asserts that the measure relations of the phenomena perceived in the universe are incapable of determination on any absolute scale, independent of the phenomena themselves. Sixty years later Einstein perceives that the gravitational field must be included among those binding forces, and must affect profoundly the measure relations in every physical aspect. Having foreseen this, Riemann had proceeded to develop a non-Euclidean geometry in any number of dimensions, and thus the germ of the calculus that Einstein needed was created. With what success it was wielded is now well known.

Not so well known is the more recent work of Weyl. Einstein finds in universal gravitation the ground of the measure relations of the universe. But equally universal is the fact of electricity, and this universal "binding force" must equally take a part in those relations. The acuteness of Riemann's vision is doubly emphasised when we hear that Weyl discovers a further generalisation of his geometrical method which provides for electricity a place as natural and convincing as that taken by gravitation in Einstein's theory. But that is history yet in the making, and this article seeks only to traverse the course of history already complete.

Relativity and the Eclipse Observations of May, 1919.

By Sir Frank Dyson, F.R.S.

In 1915 Prof. Einstein predicted, as a consequence of the generalised theory of relativity, that a ray of light from a star would be bent in its passage through the sun's gravitational field. The amount of this deflection he gave as $1{\cdot}75''(a/r)$, where a is the sun's radius, and r the nearest distance of the ray to the sun's centre. As a ray of light reaches us in the direction of the tangent to its path, the apparent position of a star, photographed during an eclipse of the sun, should therefore be displaced by an angle $1{\cdot}75''(a/r)$ outwards from the sun's centre. The field of stars surrounding the sun should thus be distorted in a definite manner by an amount within the range of accurate astronomical observation. In Fig. 1, if a, b, c are the positions of the stars as seen at ordinary times, and if S is the centre of the sun during an eclipse, then the positions in which the stars are seen or photographed during an eclipse will be A, B, C. If a were at a distance 30′ from the sun's centre the displacement aA would be $0{\cdot}87''$, and if B were at a distance 90′ from the sun's centre its displacement would be $0{\cdot}27''$. These are, roughly speaking, the greatest and least displacements which can be obtained in practice. Nearer than 30′ from the sun's centre a star's image is liable to be drowned in the corona. At greater distances than 90′ good images can scarcely be obtained with a simple object glass, while a doublet or other combination introduces some difficulties.

These displacements, though small, are ten times as large as those met with in determinations of stellar parallax, and are determined in a precisely similar manner by comparison of photographs taken at different epochs. The field of stars photographed during the eclipse must be compared with the same field photographed when the sun is in another part of the sky. Experience shows that telescopes of as long focal length as practicable should be used, and that the eclipse field and comparison field should be photographed under as nearly as possible identical conditions as regards both the instruments themselves and the position of the field in the sky. With these precautions there was every reason to suppose that, given favourable weather, successful results would be obtained.

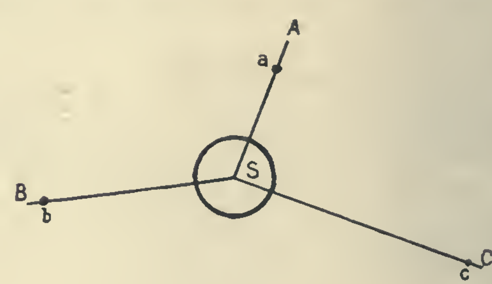

Fig. 1.

In the short time available for preparation it was not possible to arrange for the telescopes to be mounted equatorially, and the field of stars was reflected into fixed telescopes by cœlostat mirrors. The possibility had to be faced that the mirrors might suffer some distortion from the sun's heat. Apart from this, two of the mirrors did to some extent spoil the sharpness of the stellar images.

Three series of photographs were taken. Prof. Eddington and Mr. Cottingham at Principe had very cloudy weather, but obtained photographs showing a few stars. The check field obtained on two nights shortly after the eclipse gave images similar to those on the plates taken during the eclipse. The temperature during the eclipse was 77° F., and 76·5° F. when the check fields were taken. There was no reason to suppose any change of scale, and on this assumption the plates when measured gave for the deflection at the sun's limb $1{\cdot}61'' \pm 0{\cdot}30''$.

Dr. Crommelin and Mr. Davidson in Brazil were favoured with ideal weather conditions. They found, however, that the images on the eclipse plate differed from those taken the previous night, and from those taken on the same field of stars two months later. This is attributed to the effect of the sun's heat in distorting the cœlostat mirror. If it is assumed that the scale has changed, then the Einstein deflection from the series of plates is $0{\cdot}90''$; if it is assumed that no real change of focus occurred, but merely a blurring of the images, the result is $1{\cdot}56''$; little weight is, however, attached to this series of photographs.

With a smaller lens of 4-in. aperture and 19-ft. focus the same observers were extremely successful. The images taken during the eclipse are in sharp focus and exactly similar to those on the comparison field. The result of measurement gave $1{\cdot}98'' \pm 0{\cdot}12''$ for the deflection at the limb; seven stars were photographed, and the individual displacements, both in right ascension and in declination, were in good accordance with the law $1{\cdot}75''(a/r)$. It has been pointed out by Prof. H. N. Russell that the photographs show a difference of scale of one part in 12,000 in the horizontal and vertical directions of the cœlostat mirror, and that if allowance be made for this the results for individual stars will be in still closer accordance.

The result of the eclipse, particularly of the second series of photographs at Sobral, is a close verification of Einstein's predicted displacements $1{\cdot}75''(a/r)$ radial from the sun's centre.

We proceed to consider the objections raised against this result. It has been suggested that allowance was not made correctly for the ordinary terrestrial refraction. The method adopted was that usually employed in astronomical photography, the second order terms being omitted, as they in no case amount to more than $0{\cdot}02''$. The possibility of distortion of the film of the photographs, owing to the presence of the corona, has also been suggested. Examination of the plate in Phil. Trans., vol. ccxx., will show how different the conditions are from those cases in which distortion of the film has been observed. The possible displacements on the eclipse photographs could not amount to $0{\cdot}05''$ for any of the stars, and would be in the wrong direction.

Prof. Anderson made the interesting suggestion that a possible error might arise from the fall of temperature in the air as the moon's shadow moves over the place of observation, thus causing an exceptional refraction. It has been shown by Prof. Eddington and Sir Arthur Schuster (NATURE, vol. civ., pp. 372, 468) that this effect would in all cases be very much smaller than the quantities in question. Further, it happens that at Sobral, owing to cloud in the early morning, which checked the normal daily rise of temperature, the fall during the eclipse was not more than 2° or 3° F.

The possibility that the observed displacements may be due to refraction by gaseous matter surrounding the sun has received a good deal of consideration. If such an atmosphere is controlled entirely by the sun's gravitation, an impossibly high density is required. Prof. Newall has investigated the consequences of assuming that gravitation is partly balanced near the sun by electrical forces and radiation pressure assumed to vary as the inverse square of the distance from the sun's centre. To obtain agreement with the eclipse observations, he finds it necessary that 0·999 of the weight of the gas should be thus balanced. The difficulties of such a supposition have been pointed out by Prof. Lindemann (*Observatory*, April, 1920). Further, Dr. Crommelin has directed attention to the fact that several comets have approached nearer the sun than paths of the rays of some of the stars photographed at the eclipse, yet their motion has not been retarded, or their substance entirely vaporised, although they were for two hours at this small distance from the sun and moving with a velocity of 300 kilometres a second.

Relativity and the Motion of Mercury's Perihelion.

By DR. A. C. D. CROMMELIN.

THE effect of Einstein's law in changing the position of Mercury's perihelion is sometimes looked on as something mysterious and recondite; but in reality anything that disturbs the law of inverse squares in the smallest degree is bound to produce such a shift; and as in all the systems known to us such disturbing factors exist, the line of apses is invariably in motion.

It is easy to show that when the central force falls off more rapidly than the ratio of inverse squares, the apse-line *advances*; for we may consider the inverse square law as holding, with the addition of a small superposed force, outward in the outer half of the orbit, and inward in the inner half. These additional forces clearly cause the outward or inward motion to persist a little longer than it would otherwise do, thus delaying the attainment of the apses. It is proved in Tait and Steele's "Dynamics of a Particle," p. 127, that if the force vary as r^n, the apsidal angle in a nearly circular orbit is $\pi(3+n)^{-\frac{1}{2}}$. Put $n=-2(1+d)$, where d is very small, then the apsidal angle is $\pi(1-2d)^{-\frac{1}{2}}=\pi(1+d)$. Or, in a complete revolution, the apse advances $2\pi d$, which is a constant for all orbits.

This was the hypothesis advanced by Prof. Asaph Hall to explain the motion of Mercury's apses. The shift in the case of Mercury is $0{\cdot}1''$ per revolution. Applying this to the moon, it would give an apsidal advance of $135''$ per century above the amount indicated by Newtonian theory. At the time Prof. Newcomb adopted the Hall formula, there appeared to be such an excess of motion of the lunar perigee; but further research, both on the side of theory (Prof. Brown) and on that of observation (Dr. Cowell and others), has emphatically proved that the actual excess is far smaller, and quite consistent with the $2''$ per century resulting from Einstein's theory. Thus Brown found $14643527''$ and $14643511''$ for the theoretical centennial motion on two different assumptions of the earth's oblateness (Mon. Notices, vol. lxiv., p. 532). His discussion gave as the observed value $14643523''$, while Cowell found $14643538''$. In any case, the difference between theory and observation is very much smaller than that required by Hall's law. The latter is thus definitely put out of court, and it becomes a matter of regret that Newcomb adopted it in his tables of the four inner planets. It meant a more drastic alteration of the Newtonian law than that effected by Einstein; the former alters the law in all circumstances, while the latter leaves it unaltered for bodies at rest, but introduces a term that increases the force where there is relative motion.

The second suggestion in explanation of the motion of Mercury's apse is oblateness of the sun. It is easy to show that the attraction of an oblate body falls off more rapidly than the inverse square, thus producing advance of the apse of a satellite. Most of the satellites of the solar system afford examples; the most striking case is Jupiter V., the apse of which makes two entire revolutions in a terrestrial year. Where the satellite does not revolve in the equatorial plane of its primary, there is a second effect of oblateness; it causes the satellite's orbit-plane to shift, its pole describing a circle round the planet's pole. We may refer, for example, to the system of Mars. H. Struve determined the position of the pole of Mars and the amount of oblateness from observations of its satellites; similarly the position of Neptune's pole can be approximately inferred from the change in the orbit-plane of its satellite.

The amount of oblateness of the sun necessary to account for the motion of Mercury's perihelion is not great. Newcomb deduced that the necessary excess of the equatorial diameter over the polar would be slightly more than $\frac{1}{2}''$; the existence of even this small excess is rendered highly improbable by the very numerous measures of the solar disc, notably the heliometer measures in connection with the Venus-transits of 1874 and 1882; these were discussed by Dr. Auwers, and seemed, if anything, to indicate that the polar diameter is the greater. A further objection is that the solar equator is inclined 3° $21'$ to Mercury's orbit, and its oblateness would produce a diminution of $2{\cdot}6''$ per century in the inclination of Mercury's orbit. Observation, if anything, indicates a shift of the inclination in the opposite direction, and the amount $2{\cdot}6''$ is so far beyond the probable error as to render the theory of solar oblateness untenable. The above points were established by Newcomb, "Elements of the Four Inner Planets," in 1895, so that it is strange to find this untenable hypothesis still freely suggested in the United States.

It is fairly obvious that the portion of the zodiacal light that is inside Mercury's orbit would produce effects of the same general kind as those arising from solar oblateness. Now observations of the zodiacal light indicate a smaller inclination to the ecliptic than 7°, the inclination of Mercury's orbit. Thus J. F. J. Schmidt found values ranging from 4° to 0°, and Prof. Douglas's photograph, taken at Flagstaff, Arizona, on March 19, 1901, shows the light almost symmetrical on each side of the ecliptic. Now, unless the mean plane of the light agreed with that of Mercury's orbit, its gravitational effect on the apse of that planet would be accompanied by a shift of its orbital plane, not verified by observation. It has been found impossible to assign any position to hypothetical perturbing matter that would explain the apse motion of Mercury without causing other anomalies in the elements of that planet and of Venus, which are negatived by observation. Moreover, there is the difficulty that the zodiacal light, if of sufficient mass to produce such an effect, should give us more light than it does. Dr. H. Jeffreys examines the question in Mon. Not., vol. lxxx., p. 138. He shows that if the light arises from reflection by the molecules of a gas, the effect on Mercury would be only 1/3000 of that observed. If the light arises from reflection by solid particles, he takes 10 km. as their maximum admissible diameter (probably far in excess of what is really tenable); he still finds that their gravitational effect would be only 1/20 of that required. He makes similar calculations for the corona, reaching like conclusions.

Hence we seem to be driven by exhaustion to the Einstein law as the only satisfactory explanation. It clearly can have no effect on orbital planes, so it produces accordance in apsidal motion without introducing other anomalies. Further, it was not an *ad hoc* hypothesis; it was reached on independent grounds, and it was an undesigned coincidence that it fitted so well for

Mercury's apsidal motion. For the expression $3\left(\frac{\text{velocity of planet}}{\text{velocity of light}}\right)^2$, which is the angular motion of the apse (in fractions of a circumference) per revolution of the planet, involves no empirical or arbitrary constant. We can express the reason for the advance in simple terms thus: At infinity the relative velocity is zero, and the law is the Newtonian one, but the nearer we approach the central orb the higher becomes the velocity, and the greater the extra force. Hence we have another case of the force falling off more rapidly than the inverse square, which we have seen to lead to apsidal advance.

It is interesting to note that the advance per revolution varies as (velocity)^2 or as $1/a$. Hence the advance per century varies as $a^{-5/2}$, or it falls off much more rapidly with increase of a than the Hall law, which gives $a^{-3/2}$. In the course of centuries this would discriminate between them, independently of the lunar test; but the orbits of Venus and the earth are so nearly circular that the time for that test has not yet arrived.

In the case of Mars we may note that F. E. Ross's rediscussion of the observations of that planet and of the mass of Venus takes off some $2''$ from Newcomb's value of its excess of apsidal motion in a century. When we further remove the Einstein term $1{\cdot}3''$, we are left with some $2{\cdot}7''$; as the actually observed quantity is the product of $2{\cdot}7''$ by the eccentricity $(1/11)$, it falls well within the limits of observational error.

The Displacement of Solar Lines.

By Dr. Charles E. St. John, Mount Wilson Solar Observatory, Pasadena, California.

THE agreement of the observed advance of Mercury's perihelion and of the eclipse results of the British expeditions of 1919 with the deductions from the Einstein law of gravitation gives an increased importance to observations on the displacement of absorption lines in the solar spectrum relative to terrestrial sources, as the evidence on this deduction from the Einstein theory is at present contradictory. Particular interest, moreover, attaches to such observations, inasmuch as the mathematical physicists are not in agreement as to the validity of this deduction, and solar observations must eventually furnish the criterion.

Prof. Eddington's view, if I understand it, is that the theory cannot claim support from the present evidence, nor can observed displacements not agreeing with the theory be on that account regarded as in the slightest degree adverse to it, the only possible conclusion in his view being that there are certain causes of displacement of the lines acting in the solar atmosphere and not yet identified ("Space, Time, and Gravitation," p. 130).

The great majority of metallic lines observed for differences between their wave-lengths in the sun and terrestrial sources do show displacements. These differ in most cases from those deduced from the Einstein law of gravitation in ways as yet unexplained. If reasonable solar causes can be adduced to account for the wide discrepancies between theory and observation, the position of the generalised theory of relativity would be greatly strengthened.

According to the theory, the displacements are to the red, and are proportional to wave-length, being independent of the intensity of the lines and of the element to which they belong. Observational results differ from those deduced from the theory in at least four important ways. The observed displacements are not proportional to the wave-length; they differ from element to element in the same spectral region; for the same element and spectral region they vary with line-intensity; the displacements show both large positive and negative divergences from the calculated values. Interesting examples are found in Jewell's early work (*Astrophysical Journal*, vol. iii., p. 89, 1896). The relative values here are of high weight, and the data are important in that the range of elements is wider than occurs in more recent investigations. Divergences in the four directions from the calculated displacements are shown in the following extract from his observations on the differences in wave-length between 115 solar and arc lines:—

			Mean λ	Δ λ Obs.	Δ λ Cal.	Obs. – Cal.
Calcium	H,K,	4227	4042	+0·019	+0·009	+0·010Å
Calcium	Int.	1–6	5227	+0·004	+0·011	–0.007
Iron	,,	10–40	3950	+0·008	+0·008	±0·000

Aluminium	,,	15–20	3950	+0·006	+0·008	–0·002
Nickel	,,	10–15	3530	+0·017	+0·008	+0·009
Nickel	,,	1–5	3625	+0·005	+0·008	–0·003
Copper	,,	6–9	3262	+0·006	+0·007	+0·009
Potassium	,,	00–0	4046	–0·008	+0·009	–0·017

For statistical discussion the quantity of data available is as yet quite inadequate even in the case of iron, the most widely studied element. Not only should the terrestrial and solar wave-lengths be known to high precision over the widest possible range of spectrum, but also the pressure shift per atmosphere. Unfortunately, there are no published data on the wave-lengths and pressure displacements of the iron lines, in which, over a long spectral range, the errors due to pole-effect in the arc are reduced to the magnitude of the calculated Einstein displacement. For other metallic elements the data are even more deficient. With a sufficiently large and varied accumulation of material there is hope that the complex solar conditions may be analysed, and the contributions to the observed effects arising from the various causes determined with some certainty. The pressing need is for data of the requisite accuracy and variety. This need adds interest to determinations of wave-lengths and of pressure displacements, and to investigations of the characteristic behaviour of spectrum lines, as all such data will have a part in solving one of the most absorbing questions in cosmic physics.

Evershed adduces his observations upon the spectrum of Venus as evidence of an "earth-effect" driving the gases from the earth-facing hemisphere of the sun, and he would by this hypothetical action explain the observed displacements of the solar lines, and thus negative the deduction from the Einstein theory. Two series of Venus observations have been made by Dr. S. B. Nicholson and myself. The details will appear in a forthcoming Contribution from the Mount Wilson Observatory. Our observations indicate that the displacements of the Venus lines to the violet relative to skylight are due to non-uniform illumination of the slit when the guiding is done upon the visual image, the effect increasing with the refraction and becoming more evident the smaller the image. The explanation is based upon the observation that spectrograms taken at low altitudes give larger displacements to the violet than those taken on the same night at higher altitudes, and that the displacements correlate with the cotangent of the altitude and the reciprocal of the diameter of the planet at the time of observation.

In respect to the observations at Mount Wilson on the lines of the cyanogen band at λ3883, I have as yet found no grounds for considering them seriously in error. The explanation of the results adverse to the theory based upon dissymmetry appears inadequate (*Observatory*, p. 260, July, 1920), and the assumption that the adverse results are due to superposed metallic lines seems to be negatived by the observations of Adams, Grebe, Bachem, and myself that for these lines there is no displacement between the centre and limb of the sun. Metallic lines as a class shift to the red in passing from the centre to the limb. If, then, metallic lines are superposed on these band lines in such a way as to mask the gravitational displacement to the red when observed at the centre of the sun, this should be revealed by a shift to the red at the limb.

The lines of the cyanogen bands are under investigation in the observatory laboratory both as reversed in the furnace and as produced in the arc under varying pressure. The measures show no evidence of a displacement to the red under decreased pressure as indicated by Perot's observations.

The present programme at Mount Wilson aims at an accumulation of varied and extensive data that will furnish a suitable basis from which to approach the general question of the behaviour of Fraunhofer lines relative to terrestrial sources.

Non-Euclidean Geometries.

By Prof. G. B. Mathews, F.R.S.

The ordinary theory of analytical geometry may be extended by analogy as follows: Let $x_1, x_2, \ldots x_n$ be independent variables, each ranging over the complete real (or ordinary complex) continuum. Any particular set $(x_1, x_2, \ldots x_n)$, in that order, is said to be a point, the co-ordinates of which are these x_i; and the aggregate of these points is said to form a point-space of n dimensions (P_n). Taking $r<n$, a set of r equations $\phi_1=0$, $\phi_2=0$, $\ldots$ $\phi_r=0$, connecting the co-ordinates, will in general define a space P_{n-r} contained in P_n. Theorems about loci, contact, envelopes, and the principle of duality all hold good for this enlarged domain, and we also have a system of projective geometry analogous to the ordinary one.

Physicists are predominantly interested in metrical geometry. The ordinary metrical formulæ for a P_3 may be extended by analogy to a P_n; there is no logical difficulty, but there is, of course, the psychological fact that our experience (so far) does not enable us to "visualise" a set of rectangular axes for a P_n if $n>3$; not, at least, in any way obviously analogous to the cases $n=2, 3$.

In ordinary geometry, for a P_3 we have the formula

$$ds^2=dx_1^2+dx_2^2+dx_3^2$$

for the linear element called the distance between two points (x), $(x+dx)$. Riemann asked himself the question whether, for every P_n, this was necessarily a typical formula for ds, on the assumption that solid bodies can be moved about in space without distortion of any kind. His result is that we may take as the typical form, referred to orthogonal axes,

$$ds^2=\Sigma dx^2/N^2,$$

where

$$N=1+\tfrac{1}{4}\alpha\Sigma x^2,$$

and α is an arbitrary constant, called the *curvature* of the P_n in question. This curvature is an intrinsic property of the P_n, and should not be considered as a warp or strain of any kind. When $\alpha=0$, we have the Euclidean case. As an illustration of the theory that can be actually realised, take the sphere $x^2+y^2+z^2=r^2$ in the ordinary Euclidean P_3. By putting

$$D=u^2+v^2+4r^2,$$
$$Dx,\ Dy,\ Dz=4r^2u,\ 4r^2v,\ (u^2+v^2-4r^2)r,$$

the equation $x^2+y^2+z^2=r^2$ becomes an identity, and we may regard the surface of the sphere as a P_2 with (u, v) as co-ordinates. The reader will easily verify that

$$ds^2=(du^2+dv^2)\div\{1+\frac{1}{4r^2}(u^2+v^2)\}^2;$$

so we have a case of Riemann's formula with $\alpha=r^{-2}$. We *cannot* find a similar formula for the surface of an ellipsoid, because a lamina that "fits" a certain part of the ellipsoid cannot be freely moved about so as to remain in contact with the surface.

To avoid misunderstanding, it should be said that Riemann's expression for ds^2 is not the only one that is taken to be the typical or standard formula. The important thing is that, given any formula for ds^2, in a P_n, we can, by direct calculation, find an expression for the curvature of P_n in the neighbourhood of any assigned point (x). It is only when this curvature is everywhere the same that we have a P_n for which the axiom of free mobility is valid. When the curvature varies from place to place we are not entitled, for instance, to assume that we can carry about an invariable foot-rule for purposes of physical measurement.

In the simpler theory of relativity we have a formula

$$ds^2 = dx^2 + dy^2 + dz^2 - c^2dt^2, \quad . \quad . \quad . \quad (1)$$

where c is a real constant. As it originally presents itself, x, y, z are ordinary rectangular coordinates, t is the time, and c the experimental velocity of light. By a suitable choice of units we can make the value of c any finite constant that we please. Following Minkowski, I shall call (x, y, z, t) a world-point; the aggregate of these points may be provisionally called a space-time world $P(x, y, z, t)$.

When $t = t_0$, a constant, $dt = 0$ and (1) reduces to the ordinary Euclidean formula. We may express this by saying that the sub-world $P(x, y, z, t_0)$ is Euclidean. Actual experiments take time; so we cannot verify this assertion by observation. If, however, two observers, at different places, make measurements which begin and end at the same instants, we may expect their results to be consistent. As Prof. Einstein has pointed out, the question of simultaneity (and, indeed, of time itself, as an *observed* quantity) is a more difficult one than appears at first sight.

The main difficulty about (1), as it seems to me, is that the expression on the right is not a definite form; hence in the neighbourhood of every "real" point (x, y, z, t) there is a real region for which ds^2 is negative. It is possible that the difficulty of interpretation is more apparent than real, as is the case in some well-known examples. For instance, a hyperbola may be analytically defined as an ellipse of semiaxes a, bi, where a, b are real; and, *moreover*, v. Staudt's theory of involution gives an actual geometrical meaning to the algebraic definition.

If, with $i^2 = -1$, we put $ct = i\tau$, the formula (1) becomes

$$ds^2 = dx^2 + dy^2 + dz^2 + d\tau^2, \quad . \quad . \quad . \quad (2)$$

the typical formula for a Euclidean P_4. This makes it very tempting to assume that the successions of phenomena in our world of experience are, so to speak, sections of a *space-world* $P(x, y, z, \tau)$, obtained by giving τ purely imaginary values. This point of view has been taken by Minkowski and others.

The mathematical theories of abstract geometry and kinematics are so complete that physicists have a definite set of hypotheses from which to choose the one most suited to their purpose; and besides this they have to frame axioms and definitions about time, energy, etc., with which the pure mathematician is not concerned.

Whatever may be the ultimate form given to the theory of relativity, the predictive quality of its formulæ gives it a high claim to attention, and it certainly seems probable that, for the sake of what Mach calls economy of thought, we may feel compelled to change our ideas of "actual" space and time.

In an article like this it is impossible to go into detail; the following references may be useful to readers who desire further information:—"The Elements of Non-Euclidean Geometry," by J. L. Coolidge, is rather condensed, but very conscientious and trustworthy; one of the best analytical discussions of the metrical theory is in Bianchi's "Lezioni di Geometria Differenziale," chap. xi.; and Lie's "Theorie der Transformationsgruppen," vol. iii., chaps. xx.–xxiv., contains a most valuable critique of Riemann and Helmholtz. The article "Geometry" in the "Encyclopædia Britannica" (last edition) gives an outline of the theory and numerous references. Finally, there is an elaborate "Bibliography of Non-Euclidean Geometry" by D. M. J. Somerville (see NATURE, May 16, 1912, vol. lxxxix., p. 266).

The General Physical Theory of Relativity.

By J. H. JEANS, Sec. R.S.

THE relativity theory of gravitation, which is at present the centre of so much interest, owes its existence to an earlier physical theory of relativity which had proved to be in accord with all the known phenomena of Nature except gravitation. The gravitational theory is only one branch, although a vigorous and striking branch, of a firmly established parent tree. The present article will deal solely with the main trunk and roots of this tree.

Newton's laws of motion referred explicitly to a state of rest, but also showed that the phenomena to be expected from bodies in a state of rest were precisely identical with those to be expected when the same bodies were moving with constant velocity. Indeed, Newton directed special attention to this implication of his laws of motion in the following words:—

COROLLARY V.: *The motions of bodies included in a given space are the same among themselves, whether that space is at rest, or moves uniformly forwards in a right line without any circular motion.*

"A clear proof of which we have," continues Newton, "from the experiment of a ship, where all motions happen after the same manner whether the ship is at rest, or is carried uniformly forward in a right line."

Thus no experiment on board ship can ever disclose the ship's velocity through the sea. The matter stands differently to one who is free to experiment with both the ship and the sea. Let a sailor walk to the end of the bowsprit and drop his lead into the sea. A circular ripple will spread out; but every sailor knows that the point at which his line enters the water will not remain at the centre of this circle. The velocity with which the point of entry advances from the centre of the circle will give the velocity of the ship through the sea.

If our earth is ploughing its way through a sea of æther, an experiment conceived on similar lines ought to reveal the velocity of the earth through the æther. The famous Michelson-Morley experiment was designed to this end. Our earth was the ship; the physical laboratory at Chicago was the bowsprit. The dropping of the lead into the sea was represented by the emission of a light-signal, and the wave-front emanating from this signal was the ripple on the sea of æther. In the original experiments of Michelson and Morley it was not possible to watch the progress of the ripple directly, but sufficient information was obtained by arranging mirrors to reflect the signal back to the starting-point. In the recent experiments of Majorana this difficulty is obviated, although at the cost of some loss of refinement.

From these and other experiments the result invariably emerges that the wave-front appears to be a sphere having the observer at its centre. Thus on the hypothesis that our earth is surrounded by a sea of æther, experiment shows that the velocity of the earth relative to this sea of æther is *nil*. We cannot suppose that the true velocity is always *nil*, for the earth is known to be describing circles around the sun at a speed of 30 km. a second, while the experiments were sensitive enough to detect a velocity of one-hundredth part of this.

In view of the complete success which has attended the hypothesis of relativity, it would scarcely seem to be necessary to do more than mention the various early hypotheses put forward to account for these and similar experimental results. Such were the hypotheses that the earth drags the æther along with it (Arago, 1818); that matter moving through the æther is contracted, as a result of its motion, in just such a way as eternally to conceal the earth's motion through the æther from our measurements (FitzGerald, 1893; Lorentz, 1895); and that light is a phenomenon of corpuscular emission (Ritz). Each of these hypotheses explained some only of the facts to be explained, and failed with others.

The theory of light has progressed largely through the construction of mechanical models. Every such model, if fruitful, suggests new laws to be tested. So long as the laws suggested in this way are confirmed by observation, the model stands; as soon as a predicted law is found to fail, the model must be amended or abandoned. Notable examples of such models have been the corpuscular model of Newton, the elastic-solid æther of Young and his followers, and the electromagnetic æther of Faraday and Maxwell. The first two of these have long ago served their purpose and passed away. The time has now clearly come when the last of these optical models, the electromagnetic æther, must be either amended or abandoned, and the indications are strong that the less drastic course will not suffice.

The construction of mechanical models is not, however, the only known means of guidance to the discovery of new laws of Nature. An even more fruitful means of progress has been provided by tentative generalisation of known laws. Proved laws *a, b, c, d* . . . are found to be special cases of a more general law A, and the truth of A is then seen to involve not only the detailed laws *a, b, c, d* . . . which have led to A, but also other detailed laws *p, q, r, s* . . . In this way we may be guided to test the suggested new laws *p, q, r, s* . . . , and the generalisation A is, of course, strengthened or discredited according as *p, q, r, s* . . . are confirmed by observation or not. Conspicuous instances of successful generalisations of this kind are provided by the conservation of energy and the second law of thermodynamics.

Early in the present century Einstein and Lorentz suggested a tentative generalisation of this type, which is now known as the hypothesis of relativity. Since all experiments so far performed had failed to disclose the velocity of the earth through the assumed æther, it was natural to generalise in the first place to the tentative principle that this velocity could not, from the nature of things, ever be revealed by any experiment whatever. Generalised somewhat further by the removal of the local reference to our earth, the hypothesis assumed the form that all phenomena of Nature are the same for an observer moving with any uniform velocity as they are for an observer at rest. This somewhat crude form of statement shows that the hypothesis merely generalises Newton's corollary V. quoted above, so as to make it apply to all the phenomena of Nature. Since, however, the acceptance of the hypothesis makes it impossible to define what is meant by a state of rest, it is better to express the hypothesis in the form that all the phenomena of Nature are the same for any two observers who move relative to one another with a constant velocity.

This hypothesis is known already to be true as regards the mechanical forces considered in Newton's laws. Naturally, also, it is true as regards the optical phenomena investigated in the Michelson-Morley and similar experiments, for it is out of these phenomena that the hypothesis arose. The crucial test occurs when laws in other fields of science are deduced from the hypothesis and compared with observation. The hypothesis has been very thoroughly tested in the field of electromagnetism, and in every single case has emerged triumphant. As conspicuous instances of its success may be mentioned: The explanation of Fizeau's water-tube experiment, the prediction of the law connecting electronic mass with velocity, and the prediction of ponderomotive electromagnetic forces in moving media.

One final, and therefore crucial, test remains: gravitation. It was soon noticed that the hypothesis was inconsistent with the exact truth of Newton's gravitational law of force mm'/r^2. Thus the hypothesis of relativity predicts that a freely moving planet cannot describe a perfect ellipse about the sun as focus. This prediction is made on quite general grounds, just as the conservation of energy predicts that a stream of water cannot flow uphill. But the conservation of energy by itself is powerless to predict what will be the actual course of a stream of water, and in precisely the same way the hypothesis of relativity alone is powerless to predict what will be the orbit of a planet. Before this or any other positive gravitational predictions can be made, additional hypotheses must be introduced. The main trunk of the tree is the relativity hypothesis already mentioned; these additional hypotheses form the branches. The trunk can exist without its branches, but not the branches without the trunk. Whether the branches have been placed on the trunk with complete accuracy is admittedly still an open question—it must of necessity remain so until the difficult questions associated with the gravitational shift of spectral lines have been finally settled—but the main trunk of the tree can be disturbed by nothing short of a direct experimental determination of the absolute velocity of the earth, and the only means which can possibly remain available for such a determination now are gravitational.

The Michelson-Morley Experiment and the Dimensions of Moving Bodies.

By Prof. H. A. Lorentz, For.Mem.R.S.

As doubts have sometimes been expressed concerning the interpretation of Prof. Michelson's celebrated experiment, some remarks on the subject will perhaps not be out of place here. I shall try to show, by what seems to me an unimpeachable mode of reasoning, that, if we adopt Fresnel's theory of a stationary æther, supposing also that a material system can have a uniform translation with constant velocity v without changing its dimensions, we must surely expect the result that was predicted by Maxwell.

Let us introduce a system of rectangular axes of co-ordinates fixed to the material system, the axis of x being in the direction of the motion. Then, with respect to these axes, the æther will flow with the velocity $-v$. The progress of waves of light, relatively to them, may be traced by means of Huygens's principle; for this purpose it suffices to know the form and position of the elementary waves. For the sake of generality I shall suppose the propagation to take place in a material medium of refractive index μ, so that, if c is the velocity of light in the æther, the velocity in the medium when at rest would be c/μ. The elementary wave formed in the time dt around a point P will be a sphere of radius $(c/\mu)dt$, of which the centre P′ does not, however, coincide with P, the line PP′ being in the direction opposite to that of OX, and having the length $(v/\mu^2)dt$ (Fresnel's coefficient).

If Q is any point on the surface of the sphere, PQ can be considered as an element of a ray of light, and $w = \mathrm{PQ}/dt$ will be the velocity of the ray. Confining ourselves to terms of the second order, *i.e.* of the order v^2/c^2, and denoting by δ the angle between the ray and OX, we have

$$\frac{1}{w} = \frac{\mu}{c} + \frac{v}{c^2}\cos\delta + \frac{v^2}{2\mu c^3}(1+\cos^2\delta) \quad . \quad . \quad (1)$$

Now, let A and B be points having fixed positions in the material system. The course s of a ray of light passing from A to B will be determined by the condition that the integral

$$\int \frac{ds}{w} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

is a minimum. Using the above value of $1/w$, it is easily shown that, if quantities of the second order are neglected, the course of the ray is not affected by the translation v, so that, if L_0 is the path of the ray in the case $v = 0$, and L the real path, these lines will be distant from each other to an amount of the second order only. Hence, if in the case of a translation v we calculate by means of (1) the integral (2), both for L and L_0, the two values will differ by no more than a quantity of the fourth order; indeed, since the integral is a minimum for L, the difference must be of the second order with respect to the distances between L and L_0, and these distances are already of the second order of magnitude.

It is seen in this way that, so long as we neglect terms of an order higher than the second, we may replace

$$\int_{L} \frac{ds}{w} \text{ by } \int_{L_0} \frac{ds}{w},$$

an argument that must not be overlooked in the theory of the experiment. On the ground of it we shall commit no error if, in determining the paths L_1 and L_2 of two rays that start from a point A, and are made to interfere at a point B, we take no account of the motion of the apparatus. The change in the difference of phase produced by the translation will be given by the difference between the values which the integral

$$\int \frac{v^2}{2\mu c^3}(1+\cos^2\delta)\,ds$$

takes for the lines L_1 and L_2 so determined. If, along the first of them, $\cos^2\delta = 1$, and along the second $\cos^2\delta=0$, and $\mu=1$, the change will be the same as would be produced by a lengthening of L_1 in the ratio of 1 to $1+v^2/2c^2$. As no displacement of the fringes has been observed, we are led to the well-known hypothesis of a contraction of moving bodies in the direction of translation, in the ratio of 1 to $1-v^2/2c^2$.

We could now try to extend the above considerations to cases in which v/c, though always below 1, is no longer a small fraction. This would require somewhat lengthy calculations, into which, however, we need not enter here, because we know by the theory of relativity that the true value of the coefficient of contraction is $\sqrt{1-v^2/2c^2}$. I may remark here that there can be no question about the reality of this change of length. Suppose that, in studying the phenomena, we use a system of rectangular co-ordinates x_1, x_2, x_3, and a time t, and that in this system the velocity of light is c in all directions. Further, let there be two rods, I. and II., exactly equal to each other, and both placed in the direction of x_1, I. at rest in the system of co-ordinates, and II. moving in the direction of its length with a velocity v. Then, certainly, if the length of a rod is measured by the differences of the values which the co-ordinate x_1 has at the two ends at one and the same instant t, II. will be shorter than I., just as it would be if it were kept at a lower temperature. I need scarcely add that if, by the ordinary transformation of the theory of relativity, we pass to new co-ordinates x_1', x_2', x_3', t' in such a manner that in this system the rod II. is at rest, and if now we measure the lengths by the difference between the values of x_1' which correspond to a definite value of t', I. will be found to be the shorter of the two.

The question arises as to how far the dimensions of a solid body will be changed when its parts have unequal velocities, when, for example, it has a rotation about a fixed axis. It is clear that in such a case the different parts of the body will, by their interaction, hinder each other in their tendency to contract to the amount determined by $\sqrt{1-v^2/c^2}$. The problem can be solved by the ordinary theory of elasticity, provided only that this theory be first adapted to the principle of relativity. Indeed, we can still use Hamilton's principle:—

$$\delta\int_{t_1}^{t_2}dt\int(\mathrm{T}-\mathrm{U})d\mathrm{S}=0 \quad . \quad . \quad . \quad . \quad (3)$$

(dS, element of volume; T, kinetic, and U, potential, energy, both per unit of volume), if, by some slight modifications, the integral is made to be independent of the particular choice of co-ordinates. That this can be done, even in the general theory of relativity (theory of gravitation), is due to the possibility of expressing the length of a line-element in the four-dimensional space x_1, x_2, x_3, x_4 $(x_4=t)$ in "natural units"—*i.e.* in such a manner that the number obtained for it is the same whatever be the co-ordinates chosen—and of measuring angles in a similar way. As is well known, the length ds of a line-element is given by the formula:—

$$ds^2=\Sigma(ab)g_{ab}dx_a dx_b, \quad . \quad . \quad . \quad . \quad (4)$$

where the ten quantities g_{ab} $(g_{ab}=g_{ba})$ are the gravitation potentials, and the angle δ between two elements is determined by

$$\cos\delta\, ds\, d's=\Sigma(ab)g_{ab}dx_a d'x_b \quad . \quad . \quad . \quad (5)$$

In the sums, each of the indices a and b is to be given the values 1, 2, 3, 4. When the value 4 is excluded, as will be the case in some of the following formulæ, a Greek letter will be used for the index.

We can also find an invariant value l for the distance between two material particles P and P′ infinitely near each other. To this effect we have to consider the word-lines L and L′ of these particles in the space x_1, x_2, x_3, x_4. Let Q be the point of L corresponding to the chosen time x_4, and Q′ a point of L′ such that QQ′ is at right angles to L. Then the length of QQ′, determined by means of (4), will be the value required. Similarly, if P″ is a third particle, infinitely near P and P′, and Q″ the point of its word-line so situated that QQ″ is perpendicular to L, the angle P′PP″ will be taken to be the angle between the elements QQ′ and QQ″ determined according to (5).

As to the co-ordinates x_1, x_2, x_3, x_4, it may be recalled that, in a field free from gravitation, they may be chosen in such a manner (x_1, x_2, x_3 being at right angles to each other) that the velocity of light has the constant magnitude c; the potentials g_{ab} will in this case have the values

$$g_{11}=g_{22}=g_{33}=-1,\ g_{44}=c^2,\ g_{ab}=0 \text{ for } a\neq b.$$

These may be called the normal values of the potentials, and a system of co-ordinates for which they hold a normal system.

Let us now consider a solid body M, and let us first conceive it to be placed in a normal system of co-ordinates (S_0), and to be at rest in that system, free from all external forces. The body may then be said to be in its natural state, and its particles may be distinguished from each other by their co-ordinates ξ, η, ζ with respect to three rectangular axes fixed in the body. In all that follows, these quantities will be constant, and so will be the mass $\rho d\xi d\eta d\zeta$ of an element, ρ being the density in the natural state.

We shall now suppose the body to be placed in a system of co-ordinates x_1, x_2, x_3, x_4 (S), not necessarily normal, and to have some kind of motion in that system. It is this motion, in which x_1, x_2, x_3 will be definite functions of ξ, η, ζ, and x_4, which we want to determine by means of Hamilton's principle properly modified.

In order to get the new U, I shall introduce the dilatations ξ_ξ, η_η, ζ_ζ, and shearing strains ξ_η, η_ζ, ζ_ξ, with respect to the axes ξ, η, ζ. These quantities are defined as follows:—

Let P, P′ be the particles ξ, η, ζ, and $\xi+d\xi$, η, ζ, and let l be their distance in the state considered (system S), and l_0 their distance in the natural state (system S_0), these distances being both determined in the manner specified in what precedes. Then

$$\xi_\xi = (l - l_0)/l_0.$$

Again, if P″ is the particle ξ, $\eta + d\eta$, ζ, and if the angle P′PP″, calculated as stated before, has in the two cases the values δ and $\delta_0 (= \frac{1}{2}\pi)$, we shall have

$$\xi_\eta = \delta_0 - \delta.$$

The six deformations ξ_ξ . . . will be considered as infinitely small. In the problem we have in view, they are of the order of magnitude v^2/c^2, so that our final result will be correct to that order.

If we put

$$U = A(\xi_\xi^2 + \eta_\eta^2 + \zeta_\zeta^2) + \tfrac{1}{2}B(\xi_\xi + \eta_\eta + \zeta_\zeta)^2 + \tfrac{1}{2}A(\xi_\eta^2 + \eta_\zeta^2 + \zeta_\xi^2), \quad . \quad (6)$$

the well-known expression for the potential energy of an isotropic elastic body, U will be invariant for any change of co-ordinates.

As to the kinetic energy T, it is to be replaced by an expression containing $\rho \frac{ds}{dt}$. Finally, we must write, instead of (3),

$$\delta \int_{t_1}^{t_2} \int \left(-c\rho - \frac{1}{c} U \right) \frac{ds}{dt} \, dt \, d\xi \, d\eta \, d\zeta = 0.$$

We have still to add the formulæ that are found by working out the above definitions of ξ_ξ, ξ_η, etc., viz. :—

$$\xi_\xi = -\tfrac{1}{2}\Sigma(\alpha\beta) g_{\alpha\beta} \frac{\partial x_\alpha}{\partial \xi} \frac{\partial x_\beta}{\partial \xi} + \frac{\left[\Sigma(\alpha\beta) g_{\alpha\beta} v_\beta \frac{\partial x_\alpha}{\partial \xi} \right]^2}{2\Sigma(ab) g_{ab} v_a v_b} - \tfrac{1}{2},$$

$$\xi_\eta = -\Sigma(\alpha\beta) g_{\alpha\beta} \frac{\partial x_\alpha}{\partial \xi} \frac{\partial x_\beta}{\partial \eta} + \frac{\Sigma(\alpha\beta) g_{\alpha\beta} v_\beta \frac{\partial x_\alpha}{\partial \xi} \cdot \Sigma(\alpha\beta) g_{\alpha\beta} v_\beta \frac{\partial x_\alpha}{\partial \eta}}{\Sigma(ab) g_{ab} v_a v_b}$$

(v_1, v_2, v_3 are the components of the velocity, and $v_4 = 1$).

In our problem the body is supposed to move in a normal system of co-ordinates. By this our formulæ simplify to[1]

$$\delta \int_{t_1}^{t_2} \int \left(-c^2\rho - U \right) \left(1 - \frac{v^2}{c^2} \right)^{\frac{1}{2}} dt \, d\xi \, d\eta \, d\zeta = 0, \quad . \quad (7)$$

$$\xi_\xi = \tfrac{1}{2}\Sigma(\alpha) \left(\frac{\partial x_\alpha}{\partial \xi} \right)^2 + \frac{\left[\Sigma(\alpha) v_\alpha \frac{\partial x_\alpha}{\partial \xi} \right]^2}{2(c^2 - v^2)} - \tfrac{1}{2},$$

$$\xi_\eta = \Sigma(\alpha) \frac{\partial x_\alpha}{\partial \xi} \frac{\partial x_\alpha}{\partial \eta} + \frac{\Sigma(\alpha) v_\alpha \frac{\partial x_\alpha}{\partial \xi} \cdot \Sigma(\alpha) v_\alpha \frac{\partial x_\alpha}{\partial \eta}}{c^2 - v^2}$$

[1] If in (7) we replace $(1 - v^2/c^2)^{\frac{1}{2}}$ by $1 - v^2/2c^2$, omitting the constant term $-c^2\rho$ and neglecting $U.v^2/2c^2$, we are led back to the ordinary formula (3).

When applied to a revolving body, these equations will enable us to determine the deformation that is produced, wholly independently of the theory of relativity, by centrifugal force, a deformation that will in reality far surpass the changes we want to consider. To get free from it we can consider the ideal case of a "rigid" body—*i.e.* a body for which the moduli of elasticity A and B in (6) are infinitely great. The centrifugal force will then have no effect on the dimensions, but the changes required by the theory of relativity will subsist. The assumption has also the advantage of simplifying the calculations; indeed, since U becomes infinitely great, the term $-c^2\rho$ in (7) may be omitted.

I have worked out the case of a thin circular disc rotating with constant speed about an axis passing through its centre, at right angles to its plane. The result is that, if v is the velocity at the rim, the radius will be shortened in the ratio of 1 to $1 - \frac{1}{8}\frac{v^2}{c^2}$. The circumference changing to the same extent, its decrease is seen to be exactly one-fourth of that of a rod moving with the same velocity in the direction of its length. That there would be a smaller contraction was to be expected; indeed, the case can be compared to what takes place when a hot metal band is fitted tightly around a wheel and then left to cool.

At first sight our problem seems to lead to a paradox. Let there be two equal discs A and B, mounted on the same axis, A revolving and B at rest. Then A will be smaller than B, and it must certainly appear so (the discs being supposed to be quite near each other) to any observer, whatever be the system of co-ordinates he chooses to use. However, we can introduce a system of co-ordinates S′ revolving with the disc A; with respect to these it will be B that rotates, and so one might think that now this latter disc would be the smaller of the two. The conclusion would be wrong because the system S′ would not be a normal one. If we leave S for it, we must at the same time change the potentials g_{ab}, and if this is done the fundamental equation will certainly again lead to the result that A is smaller than B.

The Geometrisation of Physics, and its Supposed Basis on the Michelson-Morley Experiment.

By SIR OLIVER LODGE, F.R.S.

SO much has been written about the Michelson-Morley experiment that it would be needless to refer to it here, had it not been interpreted by philosophic writers in an interesting but over-violent and, as some think, illegitimate manner. Historically it really does lie at the root of the remarkable attempt which is being made to geometrise physics, and to reduce sensible things like weight and inertia to a modification of space and time. The work of great Geometers has been pressed into the service, and a differential-invariant scheme of expression has been utilised to do for physics in general, and especially for gravitation, what Maxwell's equations did for electric and magnetic forces. The prominent merit of these equations is that they replace any apparent predilection for forces acting at a distance, by explicit recognition of a modified medium (or at least a modified space) in contact with the accelerated particle.

The beauty and ingenuity of this scheme, and of the reasoning associated with it, are apt to overpower the judgment at times, and to lead to pseudo-philosophic conclusions which are not really justified, and some of which are repugnant to common-sense. It is scarcely wise to seek to interpret physically every link in a chain of mathematical reasoning. If the chain is coherent and if the terminal hooks are firm—that is, if the end results are intelligible and verifiable—no more need be expected from any system of equations. The astonishing thing is that statements of such extensive generality can be written in so compact a form, and that so considerable a range of experience can be summarised in terms of a pure hypergeometry, even though that be of a complex character.

It is undeniable that mathematicians, with a self-denying ordinance about coefficients, can thus attain remarkable criteria, and are able to anticipate definite results; but we need not seek to engraft their modes of expression on the real world of physics. We need not consider realities superseded, because a system of pure space and time can be devised which can formulate, and be consistent with, the movements observed by ordinary men and animals. What we observe is not motion and position alone: a wealth of colour, form, and beauty is also within our ken, and will not readily evaporate into a geometrical modification of empty space.

The Relativity argument is based on a policy of exclusion. It rejects everything that seems unnecessary; it dispenses with many of our long-standing conceptions; and accordingly is hailed as a simplification. The first simplification was the denial of any test for motion through a continuous fundamental medium, and a consequent ignoring of such a medium. The second step was to eliminate gravitational and other forces, with further denial of a power of discrimination between different kinds of acceleration. A third simplification, and further introduction of coefficients, enabled electro-magnetic forces to be similarly eluded. And if our conceptions permit of any further simplification, perhaps the additional properties of matter studied by Chemists and Biologists and Artists may be extruded too, and the rich fullness of the universe be impoverished into a mental abstraction.

To summarise, then :—

In such a system there is no need for Reality; only Phenomena can be observed or verified : absolute fact is inaccessible. We have no criterion for truth; all appearances are equally valid; physical explanations are neither forthcoming nor required; there need be no electrical or any other theory of the constitution of matter. Matter is, indeed, a mentally constructed illusion generated by local peculiarities of Space. It is unnecessary to contemplate a continuous medium as a universal connector, nor need we try to think of it as suffering modification transmitted from point to point from the neighbourhood of every particle of gravitational or electrified matter: a cold abstraction like a space-time-manifold will do all that is wanted, or at least all that the equations compel. And, as a minor detail, which will bring us to the point, it is not necessary to invoke a real FitzGerald contraction in order to explain the result of the Michelson Experiment.

The Experiment.

With this prelude, which merely summarises a great deal more that in time I wish to say, let us proceed to the M.M. Experiment and recall attention to what it really does demonstrate rather than to what it is too often imagined to prove.

Take a horizontal square slab of stone (or wood), float it above an annular trough of mercury so that it can be steadily turned round a vertical axis. Fix mirrors to its surface, so arranged that a beam of light, split into halves, can be sent, one half to and fro lengthways, and the other half to and fro breadthways, each half travelling an equal distance as fixed by the slab. Reunite the two half-beams, observe the interference bands so formed, and see if they shift in a periodic manner during a leisurely rotation of the stone and observer through all azimuths.

If light is really a wave and not a projectile motion, and if we are living in a virtual drift of æther due to our real orbital motion through that medium, and if the stone or other material of the slab preserves and determines unalterably the actual distances travelled by the two half-beams of light in the interval between their split and their reunion—then the bands should undergo a sinuous shift, with amplitude representing a lag of the order 10^{-8}, as the stone revolves.

But, on the electrical theory of matter, cohesion is a residual chemical affinity or electrostatic attraction; and such attraction is known to be modified electrokinetically if the charged atoms are in rapid motion through the dielectric medium; hence it becomes not only possible but likely that the dimensions of the slab will change if we are moving through the æther; the square being subject to a slight distortion. And the change metrically to be expected, in accordance with electrical theory, is found on examination to be also of the order 10^{-8}, and in fact was ultimately shown by Larmor to be of a precisely compensating character. ("Æther and Matter," 1900. p. 175.)

The fact is that the lines of force on an isolated charged sphere redistribute themselves, if it be moving through the æther, as if it had become a stationary oblate spheroid with axis in the direction of motion. Such a spheroid becomes the static representation of a moving sphere, and may be held to take its place as the most symmetrical figure; for the only way in which we can infer the virtual shape of an electron is by the distribution of its field.

Æther being incompressible, I expect that the change is really a pure constant-volume distortion, consisting of a pair of lateral extensions and a longitudinal contraction, as suggested in my B.A. address "Continuity," 1913, in the Birmingham volume, p. 25 (or in a separate publication by Dent and Son, pp. 58 and 111). But all that is significant for present purposes is the ratio of the longitudinal to the lateral change—a ratio commonly spoken of as the FitzGerald or FitzGerald-Lorentz contraction.

It is customary to consider this as only a longitudinal shrinkage, but it is just as easy to allow for a possible lateral change too:—

The velocity of light through the medium being always c, and the speed of the light-conveying medium relatively to the matter of the block being v, the effective or resultant speed for the to-and-fro cross-current light-journey is $\sqrt{(c^2-v^2)}$, while for the up- and down-stream journeys the effective speeds are $(c-v)$ and $(c+v)$ respectively.

The intended perpendicular distances marked out on the slab being both x, the distance along-stream becomes, say, βx (whichever side of the slab gets periodically into that position as it rotates), and the distance across-stream may be called γx; so the respective single journeys are

$$\text{(along)} \quad \beta x = (c-v)t_1 = (c+v)t_2$$
$$\text{(across)} \quad \gamma x = \sqrt{(c^2-v^2)}t_3.$$

The observation does not consist in measuring either t_1 or t_2 or t_3; nor is even x measured with precision. The whole object of the experimenter is to measure the small excess,

$$t_1 + t_2 - 2t_3,$$

to express it as a fraction of wave length, and to compare it with the distance $2x$. Repeated observations show that the excess is actually zero. And with this additional datum,

$$t_1 + t_2 = 2t_3,$$

it is mere algebra to reckon that the necessary effective contraction is

$$\beta/\gamma = \sqrt{(1-v^2/c^2)};$$

while if we choose to add the constant volume relation, $\beta\gamma^2 = 1$, we get also

$$\gamma = (1-v^2/c^2)^{-\frac{1}{6}}.$$

The experiment therefore verifies the FitzGerald contraction, and tends to confirm the electrical theory of matter.

I was interested, when visiting the University of Chicago last winter, to find that Prof. Michelson himself was perfectly satisfied with this sort of view of his experiment, and did not consider that its interpretation necessitated any revolutionary considerations. The FitzGerald contraction is a peculiarity which could scarcely have been detected in any other way, since it is really an affair of the æther—the connecting medium in which all molecules are embedded—and affects every kind of matter to the same extent.

An objection has been raised, with apparent seriousness, that this contraction cannot be real, since, if it were, the rim of a spinning-wheel would contract more than the spokes, and so the ratio of circumference to diameter would not be π. This is an instructive and rather humorous example of the prevalent tendency to control physics by geometry. We might argue similarly that the rim of a wheel could not be a fraction of a degree cooler than the spokes; and it might be held—indeed it has been held—that the state of strain in an actual rotating wheel or disc would require non-Euclidean geometry to express it. If the propositions of geometry require physical measurements to sustain them, they can scarcely be of the kind we have been accustomed to associate with the name of Euclid. And if a special geometry has to be invented in order to account for a falling apple, even Newton might be appalled at the complications which would ensue when really difficult problems are tackled. Nevertheless, that is the kind of geometry to which relativity introduces us—a geometry based on hypothetical laboratory measurements with scales and clocks, and one the propositions of which can be interfered with by metrical observations. It is therefore sometimes called a "natural" geometry, free from metaphysics; it might equally well be called an abstract sort of theoretical physics, and not geometry at all.

Relativity Explanation of the Experiment.

It is well known that the simple interpretation above given of the M.M. experiment is not palatable to relativists; they consider that it is a forced and arbitrary explanation, and that they can account for the M.M. result more naturally by employing a geometrical device and by applying certain general hypotheses. The Principle of simple relativity is that a transformation to uniformly moving axes can make no difference to anything essential; and the accompanying obsession is that no observer can detect any apparent change in the velocity of light.

In order to apply these principles, the method adopted by a Relativist is to take two observers instead of one, to supply them with personal clocks and measuring rods, and then to make one of them fly through the laboratory at speed v; thus rendering accurate measurement rather difficult for him, and introducing some confusion into his ideas of space and time—especially as he is not to be allowed to know that he is moving. He may be at rest in the æther, but everything not attached to him or to his medium will be rushing along; accordingly objects will appear to be contracted, and all clocks but his own will seem to go slow.[1] The only thing

[1] It is not easy to explain without symbols why earthbound clocks should appear to go slow to an aviator, and an aviator's clock appear to go slow to a man on the ground. The plain man would think that they would both appear to go fast during approach, and slow during recession; but the meaning is not so simple as that. Nor is it because a pendulum has lengthened, or anything physical or real of that sort. The argument appears to be that the other man's clock must be estimated as relatively slow, by each of two observers moving relatively to each other, because otherwise they could measure different velocities of light; which, though not repugnant to common-sense, is contrary to the basic Principle of Relativity.

unaltered is speed, for he is allowed to compensate every confusion about space by an equal opposite confusion about time. However, he is provided with an instantaneous camera for taking snapshots which he can afterwards study, and he does his best; he makes his observations of times and distances, and records them with dashed letters. Meanwhile the other more comfortably situated observer, attached to the slab and the laboratory furniture (who also considers himself at rest, though the first man may think of him as rushing through the æther), records, undashed, the readings of his peculiar instruments too.

A relativist, not caring in the least which or whether either of these sets of measurements has any absolute meaning, but assuming them to be made accurately, applies the transformation of Lorentz and Larmor for change of co-ordinates between sets of axes moving relatively to each other; and thereby finds that if the laboratory readings are x and t, while the flying man's readings are x' and t' (each being supposed to have a local space and time of his own, absolute space and time having no meaning), the following relations must hold—

$$x' = \frac{x - vt}{\sqrt{(1 - v^2/c^2)}}; \quad t' = \frac{t - vx/c^2}{\sqrt{(1 - v^2/c^2)}}.$$

From these simple but important, and indeed fundamental, equations it comes out that if $x'/t' = c$ for the flying man. then $x/t = c$ for the other observer likewise. So the result is just as if nothing at all was moving, except light, and in fact as if bodily motion through the light-conveying medium were meaningless. Hence everybody should be satisfied, without any appeal to, or confirmation of, any physical theory whatever. The null (or dull) result of the experiment now requires no explanation; there is no need even to emphasise the double to-and-fro journey of the light; single journeys serve; for the apparent speed of light is (really, has been assumed) the same in all directions, no matter what it be referred to. Distances and times may appear different to different observers, but they are arbitrary or conventional appearances at best, and they tend to compensate each other.

Hence arises the $r = ct$ and $r' = ct'$ superstition, about the concentricity of a wave front round each one of a group of observers initially at the origin however much they may have scattered since; because, apart from gravitation, $x^2 + y^2 + z^2 - c^2t^2$ must be independent of axes of reference; or, what is the same thing in our simple case,

$$\frac{x - ct}{x' - ct'} = \frac{x' + ct'}{x + ct} = \text{constant} = \sqrt{\frac{c - v}{c + v}}.$$

And the other peculiarities of the simpler theory of relativity immediately follow: some of them very surprising and interesting.

For instance, take the composition of motions: If a thing is moving with speed $u = x'/t'$, relatively to an origin which itself is moving in (say) the same direction with speed v referred to a fixed origin, then the resultant speed $w = x/t$, referred to the same fixed origin, will be obtained by aid of the above transformation for moving axes reduced to relative rest—

$$x = \beta(x' + vt'); \ t = \beta(t' + vx'/c^2);$$

whence we get

$$w = \frac{x}{t} = \frac{u + v}{1 + uv/c^2}$$

a curious expression for the combined velocities. [Likening it to a rotation of axes, with $v/c = \tanh\theta$, the summation is not $\tanh\theta_1 + \tanh\theta_2$ but $\tanh(\theta_1 + \theta_2)$.] It gives simple summation for slow speeds, and an unattainable maximum c for high speeds. If either or both of the component velocities attain the magnitude c, the resultant w attains the same maximum, and cannot exceed it. But the most notable property of this expression is that it gives practically the same expression as Fresnel's æther-intuition gave, for light travelling down a stream of water—an expression verified by Fizeau's famous experiment. For let the speed u be that of light inside a dense material medium, say $c \div \mu$, and let the material medium be itself travelling in the same direction at speed v, then the resultant speed of the light would be, by the above expression,

$$w = \frac{c^2 + \mu vc}{\mu c + v},$$

or, what is the same thing,

$$w = c/\mu + v.\frac{1 - 1/\mu^2}{1 + v/\mu c}$$

And this, to a high degree of approximation, is practically identical with the Fresnel-Fizeau result, viz.:

$$w = c/\mu + v(1 - 1/\mu^2).$$

That such a result—which was supposed to give some kind of information about the behaviour of æther inside dense matter—can be obtained irrationally by a simple geometrical device, is surely surprising.

Again, the variation of the mass factor in momentum, which was originally predicted from the electrical theory of matter and afterwards verified, exhibits itself as an outcome of the relativity expression without any physical theory at all. The inertia of an electric charge, and indeed of all energy, seems to come out likewise. Light has a mass-factor, but not a conserved or invariable one, while matter has both a fixed and a variable term in its factor; which is a notable and suggestive pair of facts.

From the point of view of the above relativity composition of velocities, the Michelson-Morley result is obvious; for if the speed u under observation is already c, as it is in that experiment, it is useless to compound another velocity, $\pm v$, with it; because, if that is the law of composition, the resultant velocity still comes out c, no more and no less.

It may be said that whereas most experimenters assume an absolute time, the relativist assumes one absolute unattainable or unexceedable velocity. That is the assumption on which his whole argument is based; and, as an instinctive intuition, there may be a foundation for it (see below), and even for the further assumption that the fundamental absolute velocity is either equal to, or of the same order as, the velocity of light.

It must not be supposed however that the Michelson-Morley experiment substantiates the structure thus begun upon it. It does not really prove that the velocity of light in a moving medium is the same in all directions; that is a gratuitous but fundamental hypothesis, not really based on any experiment—certainly not on one which only deals with to-and-fro journeys over matter-fixed distances. Nevertheless, whether or not this foundation-stone of Relativity is well and truly laid, the structure built over it is of remarkable interest; and possibly can sustain itself by its own consistency, and by its attachments to other facts, even if it be admittedly arched over the particular experiment on which it was originally supposed to be founded.

A Few Remarks on the More General Theory of Relativity.

The consistency of all these things, including the conservation of energy and momentum, with simple relativity, amply accounts for the enthusiasm with which brilliant mathematicians, untrammelled by a sense of physical reality, have absorbed and developed the idea.

Indeed, as we know, Einstein was enticed to go on and try a transformation to accelerated axes also, to identify gravitation and inertia, to ally both with the so-called centrifugal force, and to reduce them all to a still more elaborate geometry, in which the Lorentz transformation is inadequate, and Euclidean propositions are superseded. He found ready to his hand a recondite scheme, provided for other and less worldly purposes by Gauss and Riemann; but, to make use of it, he had to introduce a fresh agnostic principle, a Principle of Equivalence. He must assume that we cannot discriminate between a whirling table and a gravitational field; that we have no criterion between a falling apple and a rising Earth; and that it is only prejudice which makes us feel assured about a rotating Earth, and unwilling to contemplate a diurnally revolving star. Geometrically they are all the same; and a suitable space-time system can be devised, and expressed in equations, which will account for, or at least express, most things observed in astronomy, and some additional things more allied with physics.

Now we must admit that if we are permitted to discard relativity as a *philosophy* and accept it as a *method*, the form of the most striking of its equations is advantageous, and represents an advance in symbolism, quite apart from any unphysical contributions to its origin and any lack of legitimacy about its birth. For the weight of an apple must be really, as it always has been hypothetically and vaguely, attributable to a gravitationally modified æther pressing down on each particle. Similarly the path of a planet from instant to instant can be expressed more intimately by a variational equation, involving always the next step, than by an action-at-a-distance formula, or by a merely kinematic summary which integrates the result over an entire orbit. But this powerful and ingenious method of research can be interpreted, in words, so as to suggest nothing more than a warping of an unreal emptiness—a sort of return to Descartes' vortices without their imagery, a rejection of Copernicus and Galileo and Newton.

Whereas what is really wanted for a truly Natural Philosophy is a supplement to Newtonian Mechanics, expressed in terms of the medium which he suspected and sought after but could not attain, and introducing the additional facts, chiefly electrical—especially the fact of variable inertia—discovered since his time. Such a philosophy would insist that the specific state of the medium throughout a gravitational field must be the immediate consequence, indeed the absolute essence, of the existence of each material particle; their separate potentials being combined by simple addition without any second-order complications. Equally an electric field must be part of the actual constitution of an electron, and inseparable from it: though the compounding of electric fields need not be so simple a matter, since charges in proximity do interfere with each other.

If we could understand the structure of the particle, in terms of the medium of which it is composed, and if we knew the structure of the rest of the medium also, so as to account for the potential stress at every point—that would be a splendid step, beyond anything accomplished yet. But that the particle is a singularity in the medium, and that its inertia and gravitational field are essential to, and part of, its very existence, must certainly be true; and this is what the Einstein theory, in its own peculiar geometrical unphysical way, has grasped. There are not half a dozen diverse but interlocked things in Nature: there is one definite quiescent medium, full of exceedingly fine-grained turbulent energy, with consequent properties which, when unravelled, will supply the key to all the non-mental phenomena occurring in it. Provided always that the locking up of small regions of this turbulence, not merely in the travelling form of light-waves, but in the potentially stationary form of electrons, can also be explained and understood.

Relativity, as a consecutive point-to-point method of arriving at results, is a first step towards this ideal, but it is not a Newtonian step; it is rather a blindfold method of investigation, like Entropy and Least Action.

The Fundamental Velocity.

To make a philosophic scheme of existence complete, more than the expression of a static instant is required, there must be duration likewise: the universe is not merely a Being but truly a Becoming; Time has to be associated with Space. This can only be done by a velocity factor of some kind; but to arrive at an appropriate factor, relativists have not dived down into the æther, as someone must ultimately dive, and dissected out the intrinsic speed of its turbulence—which is really the fundamental velocity in existence—they have utilised the more obvious and conspicuous *consequence* of this fundamental speed, viz. the uniform velocity with which the æther can convey a great variety of signals. Indeed their attachment to appliances like clocks and rods has led them to pay almost undue reverence to the æther's power of transmitting waves at a high and otherwise unattainable speed. It is true that these waves are among our methods of receiving and conveying information; but too much attention may be paid to the mere reception of information; and what is spoken of as "warping" is not limited to space alone. For some philosophers speak as if the duration of an event could be extended by merely delaying the reception of the news of its end; as if we could prolong a man's life by evading the tidings of his death, and might be entitled to say, without absurdity, that a man who died at seventy had lived seventy-one years and a lot of miles, if we had travelled so far that the messenger took a year to reach us. That such things can be gravely uttered is surely a tribute to the beauty and complexity of the mathematical scheme which can temporarily so warp the judgment even of the most competent.

If I am wrong in this I share a fraction of rashness with the admirable audacity of Einstein in the *Weltmacht oder Niedergang* sort of attitude which he takes up about his predicted shift of spectral lines. I feel a doubt whether those lines will be found shifted—at least when the observation is made outside a strong gravitational field—but I should be quite content either way, and would not think of asking anyone to abandon the method of relativity on that account.[2]

For undoubtedly general relativity, not as a philosophic theory but as a powerful and comprehensive method, is a remarkable achievement; and an ordinary physicist is full of admiration for the equations and the criteria, borrowed from hyper-Geometers, applied by the genius of Einstein, and expounded in this country with unexampled thoroughness and clearness by Eddington. But, notwithstanding any temptation to idolatry, a physicist is bound in the long run to return to his right mind; he must cease to be influenced unduly by superficial appearances, impracticable measurements, geometrical devices, and weirdly ingenious modes of expression; and must remember that his real aim and object is absolute truth, however difficult of attainment that may be, that his function is to discover rather than to create, and that beneath and above and around all Appearances there exists a universe of full-bodied, concrete, absolute, Reality.

[2] Since the above paragraph was in type a Circular, dated January, 1921, has reached me from Prof. Slipher, of the Lowell Observatory at Flagstaff, Arizona, recording an extravagant rate of recession—something like a thousand miles a second—for two specified nebolæ, presumably of the spiral class. But both nebulæ are reported to have large and brilliant nuclei; and if the concentration of their aggregate mass were sufficient—that is, if their M/R or $\rho\kappa_2$ were some two or three thousands of times greater than that of our sun, and therefore of a totally different order from that of our stellar system—the observation could be interpreted, not as recession, but as an Einstein shift of spectral lines.

Electricity and Gravitation

By PROF. H. WEYL.

[Translated by Dr. Robert W. Lawson.]

MODERN physics renders it probable that the only fundamental forces in Nature are those which have their origin in gravitation and in the electromagnetic field. After the effects proceeding from the electromagnetic field had been co-ordinated by Faraday and Maxwell into laws of striking simplicity and clearness, it became necessary to attempt to explain gravitation also on the basis of electromagnetism, or at least to fit it into its proper place in the scheme of electromagnetic laws, in order to arrive at a unification of ideas. This was actually done by H. A. Lorentz, G. Mie, and others, although the success of their work was not wholly convincing. At the present time, however, in virtue of Einstein's general theory of relativity, we understand in principle the nature of gravitation, and the problem is reversed. It is necessary to regard electromagnetic phenomena, as well as gravitation, as an outcome of the geometry of the universe. I believe that this is possible when we liberate the world-geometry (on which Einstein based his theory) from an inherent inconsistency, which is still associated with it as a consequence of our previous Euclidean conceptions.

The great accomplishment of the theory of relativity was that it brought the obvious principle of the *relativity of motion* into harmony with the existence of *inertial forces*. The Galilean law of inertia shows that there is a kind of obligatory guidance in the universe, which constrains a body left to itself to move with a perfectly definite motion, once it has been set in motion in a particular direction in the world. The body does this in virtue of a tendency of persistence, which carries on this direction at each instant "parallel to itself." At every position P in the universe, this tendency of persistence (the "guiding field") thus determines the infinitesimal parallel displacement of vectors from P to world-points indefinitely near to P. Such a continuum, in which this idea of infinitesimal parallel displacement is determinate, I have designated as an "affinely connected" one (*affin zusammenhängend*). According to the ideas of Galileo and Newton, the "affine connection" of the universe (the difference between straight and curved) is given by its geometrical structure. A vector at any position in the universe determines directly and without ambiguity, at every other position, and by itself (*i.e.* independently of the material content of the universe), a vector "equal" to itself. According to Einstein, however, the guiding field (*Führungsfeld*) is a physical reality which is dependent on the state of matter, and manifests itself only infinitesimally (as a tendency of persistence which carries over the vectors from one point to "indefinitely neighbouring" ones). The immense success of Einstein's theory is based on the fact that the effects of gravitation also belong to the guiding field, as we should expect *a priori* from our experience of the equality of gravitational and inertial mass. The planets follow exactly the orbit destined to them by the guiding field; there is no special "gravitational force" necessary, as in Newton's theory, to cause them to deviate from their Galilean orbit. In general, the parallel displacement is "non-integrable"; *i.e.* if we transfer a vector at P along two different paths to a point P′ at a finite distance from P, then the vectors, which were coincident at P, arrive at P′ in two different end-positions after travelling these two paths.

The "affine connection" is not an original characteristic of the universe, but arises from a more deeply lying condition of things—the "metrical field." There exists an infinitesimal "light-cone" (*Lichtkegel*) at every position P in the world, which separates past and future in the immediate vicinity of the point P. In other words, this light-cone separates those world-points which can receive action from P from those from which an "action" can arrive at P. This "cone of light" renders it possible to compare two line-elements at P with each other by measurement; all vectors of equal measure represent one and the same *distance* at P. In addition to the determination of measure at a point P (the "relation of action" of P with its surroundings), we have now the "metrical relation," which determines the congruent transference of an arbitrary distance at P to all points indefinitely near to P.

Just as the point of view of Einstein leads back to that of Galileo and Newton when we assume the transference of vectors by parallel displacement to be integrable, so we fall back on Einstein when the transference of distances by congruent transference is integrable. But this particular assumption does not appear to me to be in the least justified (apart from the progress of the historical development). It appears to me rather as a gross inconsistency. For the "distances" the old point of view of a determination of magnitudes in terms of each other is maintained, this being independent of matter and taking place directly at a distance. This is just as much in conflict with the principle of the *relativity of magnitude* as the point of view of Newton and Galileo is with the principle of the *relativity of motion*. If, in the case in point, we proceed in earnest with the idea of the continuity of action, then "magnitudes of condition" occur in the mathematical description of the world-metrics in just sufficient number and in such a combination as is necessary for the description of the electromagnetic and of the gravitational field. We saw above that, besides inertia (the retention of the vector-direction), gravitation was also included in the guiding field, as a slight variation of this, as a whole, constant inertia. So in the present case, in addition to the force which conserves space- and time-lengths, *electromagnetism* is also included in the metrical relation. Unfortunately, this cannot be made clear so readily as in the case of gravitation. For the phenomena of gravitation are easily obtained from the *Galilean principle*, according to which the world-direction of a mass-point in motion follows at every instant the parallel displacement. Now it is by no means the case that the ponderomotive force of the electromagnetic field should be included in our Galilean law of motion, as well as gravitation, for a charged mass-point does not follow the guiding field. On the contrary, the correct equations of motion are obtained only by the establishment of a definite and concrete law of Nature, which is possible within the framework of the theory, and not from the general principles of the theory.

The form of the law of Nature on which the condition of the metrical field is dependent is limited by our conception of the nature of gravitation and electricity in still greater measure than it is by Einstein's general principle of relativity. When the metrical connection alone is virtually varied, the most simple of the assumptions possible leads exactly to the *theory of Maxwell*. Thus, whereas Einstein's theory of gravitation gave certain inappreciable deviations from the Newtonian theory, such as could be tested by experiment, our interpretation of electricity—one is almost tempted to say unfortunately—results in the complete confirmation of Maxwell's laws. If we supplement Maxwell's "magnitude of action" (*Wirkungsgrösse*) by the simplest additional term which also allows of the virtual variation of the "relation of action," we then arrive at *Einstein's laws of the gravitational field*, from which, however, there are two small deviations:

(1) That *cosmological term* appears which Einstein appended later to his equations, and which results in the spatial closure (*Geschlossenheit*) of the universe. A hypothesis conceived *ad hoc* by Einstein to explain the generally prevailing equilibrium of masses results here of necessity. Whereas Einstein has to assume a pre-stabilised harmony between the "cosmological constant" which is characteristic for his modified law of gravitation, and the total mass fortuitously present in the universe, in our case, where no such constant occurs, the world-mass determines the curvature of the universe in virtue of the laws of equilibrium. Only in this way, it appears to me, is Einstein's cosmology at all possible from a physical point of view.

(2) In the case where an electromagnetic field is present, Einstein's cosmological term must be supplemented by an additional term of similar

character. This renders the existence of charged material particles possible without requiring an immense mass-horizon as in Einstein's cosmology.

At first the *non-integrability of the transference of distances* (*Streckenübertragung*) aroused much antipathy. Does not this mean that two measuring-rods which coincide at one position in the universe no longer need to coincide in the event of a subsequent encounter? Or that two clocks which set out from one world-position with the same period will possess different periods should they happen to encounter at a subsequent position in space? Such a behaviour of "atomic clocks" obviously stands in opposition to the fact that atoms emit spectral lines of a definite frequency, independently of their past history. Neither does a measuring-rod at rest in a static field experience a congruent transference from moment to moment.

What is the cause of this discrepancy between the idea of congruent transfer and the behaviour of measuring-rods and clocks? I differentiate between the determination of a magnitude in Nature by "persistence" (*Beharrung*) and by "adjustment" (*Einstellung*). I shall make the difference clear by the following illustration: We can give to the axis of a rotating top any arbitrary direction in space. This arbitrary original direction then determines for all time the direction of the axis of the top when left to itself, by means of a *tendency of persistence* which operates from moment to moment; the axis experiences at every instant a parallel displacement. The exact opposite is the case for a magnetic needle in a magnetic field. Its direction is determined at each instant independently of the condition of the system at other instants by the fact that, in virtue of its constitution, the system *adjusts* itself in an unequivocally determined manner to the field in which it is situated. *A priori* we have no ground for assuming as integrable a transfer which results purely from the tendency of persistence. Even if that is the case, as, for instance, for the rotation of the top in Euclidean space, we should find that two tops which start out from the same point with the same axial positions and encounter again after the lapse of a very long time would show arbitrary deviations of their axial positions, for they can never be completely isolated from every influence. Thus, although, for example, Maxwell's equations demand the conservational equation $de/dt=0$ for the charge e of an electron, we are unable to understand from this fact why an electron, even after an indefinitely long time, always possesses an unaltered charge, and why the same charge e is associated with all electrons. This circumstance shows that the charge is not determined by persistence, but by adjustment, and that there can exist only *one* state of equilibrium of the negative electricity, to which the corpuscle adjusts itself afresh at every instant. For the same reason we can conclude the same thing for the spectral lines of atoms. The one thing common to atoms emitting the same frequency is their constitution, and not the agreement of their frequencies on the occasion of an encounter in the distant past. Similarly, the length of a measuring-rod is obviously determined by adjustment, for I could not give *this* measuring-rod in *this* field-position any other length arbitrarily (say double or treble length) in place of the length which it now possesses, in the manner in which I can at will predetermine its direction. The theoretical possibility of a determination of length by adjustment is given as a consequence of the *world-curvature*, which arises from the metrical field according to a complicated mathematical law. As a result of its constitution, the measuring-rod assumes a length which possesses this or that value, *in relation to the radius of curvature of the field*. In point of fact, and taking the laws of Nature indicated above as a basis, it can be made plausible that measuring-rods and clocks adjust themselves exactly *in this way*, although this assumption—which, in the neighbourhood of large masses, involves the displacement of spectral lines towards the red upheld by Einstein—does not appear anything like so conclusive in our theory as it does in that of Einstein.

The Relativity of Time.

By Prof. A. S. Eddington, F.R.S.

THE philosopher discusses the significance of time; the astronomer measures time. The astronomer goes confidently about his business and does not think of asking the philosopher what exactly is this thing he is supposed to be measuring; nor does the philosopher always stop to consider whether time in his speculations is identical with the time which the world humbly accepts from the astronomer. In these circumstances it is not surprising that some confusion should have arisen.

In many globular clusters there are stars which oscillate in intrinsic brightness; let us select two such stars from different clusters and invite all the astronomers in the universe to measure the true interval of time between the moments of maximum light of the two stars. They must, of course, make whatever measurements and calculations they consider necessary to allow for the finite velocity of light. It may easily happen that the astronomers on Arcturus report that the two maxima were simultaneous; whereas those on the earth report an interval of *ten years* between the same two maxima. There is here no question of observational error; the recognised terrestrial method necessarily gives a discordant result when used on Arcturus, owing to its different motion.

Our first impulse is to blame the astronomers.

Evidently they are not giving us the true time-interval; and now that they are informed of the discordance they ought to give up their out-of-date procedure. But the astronomers reply: "Tell us, then, how we ought to find this 'true time.' By what characteristics are we to recognise it?" No answer has been given. Michelson and others sought in vain for an answer; for if our velocity through the æther could be defined, it would single out one universal system of time-measurement which might reasonably (if somewhat arbitrarily) be called true. Meanwhile the phrase *true time* is a "meaningless noise." It is idle to contest with those who hold that the thing exists and ought to be regarded. "Who would give a bird the lie, though he cry 'Cuckoo' never so?"

The direction of Northampton measured by astronomers at Cambridge is due west; measured by astronomers at Greenwich it is north-west. It is no use to tell them that they must adopt a different plan, and find a "true direction" of Northampton which does not show these discordances. They reply: "We are perfectly aware that there must be discordances, as you call them; but that is in the nature of a relative property like direction; as for this true direction which shall be the same from all stations, we have no idea what you are talking about."

The time determined by astronomers and in general use is thus a fictitious time, or, in the usual phrase, it is *relative* to terrestrial observers. Similarly it has been found that extension in space is also relative. When the Copernican theory led to the abandonment of the geocentric view of the universe, the revolution did not go far enough; it was thought that we could pass to the heliocentric outlook by merely allowing for what in pure geometry would be called a change of origin. Actually a more profound transformation is necessary. For example, the Michelson-Morley experiment is a terrestrial experiment, but its theory is treated from a heliocentric point of view; that is to say, account is taken of the varying orbital motion of the earth; it furnishes a proof of the famous FitzGerald contraction, and much ingenuity has been spent on an electrical explanation of this curious property of matter. Einstein's theory waves this aside with the remark: "Of course, your results appear strange when you describe the apparatus in terms of a space and time which do not belong to it. Your electromagnetic discussion is no doubt valid, but it is leading you away from the root of the matter; the immediate explanation lies in the difference between the heliocentric and geocentric space and time systems."

It was shown by Minkowski that all these fictitious spaces and times can be united in a single continuum of four dimensions. The question is often raised whether this four-dimensional space-time is real, or merely a mathematical construction; perhaps it is sufficient to reply that it can at any rate not be less real than the fictitious space and time which it supplants. Terrestrial observers divide the four-dimensional world into a series of sections or thin sheets (representing space) piled in an order which signifies time; in other words, the enduring universe is analysed into a succession of instantaneous states. But this division is purely geometrical. The physical structure of the enduring world is not laminated in this way; and there is nothing to prevent another observer drawing his geometrical sections in a different direction. In fact, he will do so if his motion differs from ours.

Now it may seem that we have been paying too much deference to the astronomers: "After all, they did not discover time. Time is something of which we are immediately conscious." I venture to differ and to suggest that (subject to certain reservations) time as now understood *was* discovered by an astronomer—Römer. By our sense of vision it appears to us that we are present at events far distant from us, so that they seem to occur in instants of which we are immediately conscious. Römer's discovery of the finite velocity of light has forced us to abandon that view; we still like to think of *world-wide* instants, but the location of distant events among them is a matter of hypothetical calculation, not of perception. Since Römer, time has become a mathematical construction devised to give the least disturbance to the old illusion that the instants in our consciousness are world-wide.

Without using any external senses, we are conscious of the flight of time. This, however, is not a succession of world-wide states, but a succession of events at one place—not a pile of sheets, but a chain of points. Common-sense demands that this time-succession should be essentially different from the space-succession of points along a line. The preservation of a fundamental distinction between timelike succession and spacelike succession is essential in any acceptable theory. Thus in the four-dimensional world we recognise that there are two types of ordered succession of events which have no common measure; type A is like the succession of instants in our minds, and type B is the relation of order along a line in space. Proceeding from the instant "here-now," I can divide the regions of the world into two zones, according as they are reached by a succession of type A (my absolute past and future), or of type B (my absolute "elsewhere"). This scheme of structure is very different from the supposed laminated structure of the older view. Since we believe that this distinction of types A and B corresponds to something in the actual structure of the world, it is likely to determine the various natural phenomena that are observed. Thus it determines the propagation of light, since it is found that the line of a light-pulse is always on the boundary between the two zones above-mentioned. More important still, a particle of matter is a structure which can occupy a chain of points only of type A. Since we are limited by our material bodies, it must be this type of succession which we immediately experience; we are aware of the existence of the other type only by deduction from the indications of our external senses.

Objection is sometimes raised to the extravagantly important part taken by light-signals and light-propagation in Einstein's discussion of space and time. But Einstein did not invent a space and time depending on light-signals; he pointed out that the space and time already in general use depended on light-signals and equivalent processes, and proceeded to show the consequences of this. Turning from fictitious space and time to the absolute four-dimensional world, we still find the velocity of light playing a very prominent part. It is scarcely necessary to offer any excuse for this. Whether the substratum of phenomena is called *aether* or *world* or *space-time,* one requirement of its structure is that it should propagate light with this velocity.

The resolution of the four-dimensional continuum into a succession of instantaneous spaces is not dictated by anything in the structure of the continuum. Nevertheless, it is convenient, and corresponds approximately to our practical outlook on the world; and it is rarely necessary to go back to the undivided world. We have to go back to the undivided world when a comparison is made between the phenomena experienced by observers with different motions, who make the resolution in different directions. Moreover, a world-wide resolution into a space and time with the familiar properties is possible only when the continuum satisfies certain conditions. Are these conditions rigorously satisfied? They are not; that is Einstein's second great discovery. It is no more possible to divide the universe in this way than to divide the whole sky into squares. We have tried to make the division, and it has failed; and to cover up the consequences of the failure we have introduced an almost supernatural agency—gravitation. When we cease to strive after this impossibility—a mode of division which there was never any adequate reason for believing to be possible—gravitation as a separate agency becomes unnecessary. Our concern here is with the bearing of this result on time. Time is now not merely relative, but local. The relative time for an observer is a construction extended by astronomers throughout the universe according to mathematical rules; but these rules break down in a region disturbed by the proximity of heavy matter, and cannot be fulfilled accurately. We can preserve our time-partitions only by making up fresh rules as we require them. The local time for a particular observer is always definite, and is the physical representation of the flight of instants of which he is immediately aware; the extended meshwork of co-ordinates radiating from this is drawn so as to conform roughly to certain rules—so as not to violate too grossly certain requirements which the untutored mind thought necessary at one time. Subject to this, time is merely one of four co-ordinates, and its exact definition is arbitrary.

To sum up, world-wide time is a mathematical system of location of events according to rules which on examination can only be regarded as arbitrary; it has not any structural—and still less any metaphysical—significance. Local time, which for animate beings corresponds to the immediate time-sense, is a type of linear succession of events distinct from a pure spacelike succession; and this distinction is fully recognised in the relativity theory of the world.

Theory and Experiment in Relativity.[1]

By Dr. Norman Campbell.

"SPACE" and "time" are the conceptions of theory, not of laws. They are neither necessary nor useful in the statement of the results of any experiment. The experimental concepts with which, like all theoretical ideas, they are connected are such magnitudes as length, area, volume, angle, period (of a system), or time-interval. The numerical laws of experimental geometry involve two or more "spatial" magnitudes and no other magnitudes; for example, the area of a rectangle is proportional to the product of the lengths of its sides. There are no laws relating "temporal" magnitudes only.

Relativity neither adds to nor subtracts from the collection of spatial and temporal laws. The laws which it explains all involve magnitudes that are not spatial or temporal. And this is fortunate. For the subject has been so completely examined that it is very improbable that any proposed new laws could be true. If relativity predicted anything inconsistent with firmly established experiment, Nature would not devote a special number to discussing it.

It may be objected that relativity does predict new and strange laws; it predicts that the velocity of light in a region remote from material bodies is always the same; and it predicts unfamiliar experiences of observers travelling at great speeds or in the neighbourhood of concentrated mass. But, it may be replied, the measurement of the velocity of light does not involve only spatial and temporal magnitudes; we do not measure that velocity as we do the velocity of a material body; an element of theory is always involved. Again, we do *not* observe any disturbance of geometrical laws in the neighbourhood of the densest bodies we know. And as for Prof. Eddington's observers in aeroplanes travelling with half the velocity of light, no two human

[1] Since it is impossible to make a short article on a large subject anything but a summary, perhaps I may be permitted to refer any reader who is interested to my "Physics: The Elements" for a fuller discussion of many of the questions raised.

beings have smoked, or, if the doctrines of relativity are true, ever will smoke, cigars—let alone make accurate measurements—in such aeroplanes, and afterwards compared their experiences. If we pretend to talk about experiments, let us be sure that we do talk about experiments, and not about something that cannot possibly happen.

However, it may not be useless to ask what would happen if we did find our spatial laws untrue, in the manner suggested, at speeds that can be realised. I suggest that we should make our laws true once more by changing slightly the meaning of the terms in them. The technical terms of science are labels attached to collections of observations that can be grouped into laws, which those terms are used to describe. If we find that the supposed laws are not true, the terms become meaningless; we might abandon them altogether; but generally we discover that, by a slight regrouping of the facts according to the new laws, we can make once more a collection of the facts to which the old term may be applied appropriately to state the new laws in almost precisely the old form.

Consider, for example, the term "simultaneous." Primarily, two events were judged to be simultaneous by direct perception. Using this test and examining a limited range of experience, we found the law that events that are simultaneous to one observer are simultaneous to another. But later we found that the law was not valid for more extended experience, including the sound and flash from a gun. That discovery made "simultaneous" meaningless, and with it all the temporal magnitudes; there was no longer any way of assigning uniquely a numeral to represent the time-interval between two events. So we changed the meaning of "simultaneous," and introduced a "correction" (very complicated, as sound-rangers know); by this means we made "simultaneous" once more the expression of a law, and reproduced our specifications for measuring time-intervals in exactly the old form, but, of course, with rather different content. If we encountered new difficulties when we extended our observations to events in systems moving with great relative speeds, we could, I think, introduce a new "correction" for speed, and reproduce once more the form of our old laws and our old methods of measurement. At any rate, the resulting change of form need not be so great as to cause any appearance of paradox.

I conclude, therefore, that nothing that the most extravagant imagination has suggested so far could make us diverge appreciably from our present spatial and temporal laws. But it is otherwise with our theories. The experimental physicist has a theory of time and space, although he may not be conscious of it. It is based on Cartesian geometry.[2] It likens "space" to an array of black dots in a cubical lattice, and "time" to a series of ticks from a metronome. It connects the position of a body with the individual characteristics of the dots that it "occupies," and the magnitudes length, area, volume with the number of those dots. The time of an event it connects with the individual characteristics of the ticks. The theory explains well some spatial laws, but in some directions it is misleading. Thus it fails to make a distinction between lengths and areas, which (in the last resort) must be measured by the superposition of rigid bodies,[3] and volumes, which cannot be measured by such superposition. It should be noted that the dots and ticks, the "points" and "instants" of mathematically minded philosophers, are purely theoretical ideas. They have no meaning apart from the theory, and, like the position of a hydrogen molecule, cannot be determined by experiment.

Prof. Einstein has altered and expanded this theory. In conjunction with Minkowski, he has altered it by merging the dots and ticks, formerly independent, into a single array of world-points, and by making the arrangement of these points quite different from that of a cubic (or Euclidean) lattice. He has expanded it by introducing the idea of the "natural path" of a body among the points, which enables him to explain the laws of dynamics without the (theoretical) idea of forces. But his propositions still form a theory, and they still contain purely theoretical ideas, which cannot be determined by experiment—the world-point or the infinitesimal "interval," which must be integrated before it can be related to measured magnitudes.

These changes are very disturbing to the experimenter. He wants theories to explain laws. Explanation involves not only the possibility of deducing the laws (for that is easily attained), but also the introduction of satisfactory ideas. In the older types of physical theory this "satisfactoriness" was obtained by means of an analogy between the ideas of the theory and the concepts of some experimental laws. Thus in the older theory of space the points were related in a way analogous to that in which small material bodies can be related. In the new theory this analogy fails. For the mathematician the passage from flat three-dimensional space to curved four-dimensional space is trivial; for the experimenter it is vital, because we do not actually experience any arrangements at all analogous to those of points in such a space. The satisfactoriness of the theory, for those who press it on our attention, is derived, not from material analogy, but from the intrinsic elegance and beauty of the relations involved, the faculty for appreciating which distinguishes the pure mathematician from his fellows.

It is not surprising, therefore, that experimenters have found difficulty in accepting the theory as an ultimate solution of their problem. The old theories explained, because they inter-

[2] It is interesting to notice that, though the theory is sometimes called Euclidean, Euclid had never heard of it. No Greek geometer would have known what you meant if you had told him that space was three-dimensional.

[3] "Rigid bodies" is a label attached to a collection of facts grouped in laws, the laws that make possible the measurement of lengths and areas.

preted in terms of familiar ideas; even to the most revolutionary of mankind, familiarity is a source of some satisfaction. The new theory is based on ideas utterly unfamiliar, and it might be urged that anything based on them must be the precise contrary to explanation. But if we ask why we are so ready to accept theories based on material analogy, we shall find our reason in the fact that such theories have actually turned out to possess the amazing property of predicting unsuspected laws. The theory of relativity also possesses that property. Ought we not to extend, so as to include it, our notions of the proper limits of physical theory, and to rid ourselves of the discomfort of unfamiliarity by the simple process of studying its ideas so closely that they become an integral part of our mental equipment?

It may be asked, Do theories, indeed, aim at nothing but satisfactoriness and prediction? Is not their object rather to discover the true nature of the real world? Such questions must be answered by questions. Do physicists (I say nothing of mathematicians or philosophers) believe that anything is real for any reason except that it is a conception of a true law or of a true theory? Have we any reason to assert that molecules are real except that the molecular theory is true—true in the sense of predicting rightly and interpreting its predictions in terms of acceptable ideas? What reason have we ever had for saying that thunder and lightning really happen at the same time, except that the conception of simultaneity which is such that this statement is true makes it possible to measure time-intervals? When these questions are answered it will be time to discuss whether relativity tells us anything about real time and real space.

The Relation between Geometry and Einstein's Theory of Gravitation.

By DOROTHY WRINCH and DR. HAROLD JEFFREYS.

THE term "geometry" has been used ever since the time of Euclid to denote two completely distinct subjects; but the formal similarity of their propositions has been so close as to obscure until recently the entire dissimilarity of their status in scientific knowledge. The Greek geometers seem to have been inspired originally by the need for a satisfactory method of surveying; at the same time, their logical turn of mind led them to present their results in the now familiar form of a deductive science. The characteristics of such a science are that a certain number of primitive propositions p_1, now called postulates, are stated at the beginning, and that from these, by a process of pure logic, further propositions q_1 are one by one developed. But this development is quite a separate process from that of deciding whether the primitive propositions are true or not, and if this is not done it is impossible to assert that the deduced propositions are true.

Different sets of primitive propositions p_2, p_3, . . . would give different sets of deduced propositions q_2, q_3, . . . and the complete working out of these is a science in itself; its results are all, therefore, of the form "p_1 implies q_1," "p_2 implies q_2," and so on. Euclid actually used in his development several postulates which he never explicitly stated, but which have been made explicit by modern writers; our present object, however, is not to indicate these, but to consider his geometry in the perfectly deductive form it would have had if he had actually stated them. We have noticed that in any other system in which any one of Euclid's postulates is false, many of his deduced propositions are also false. This, however, does not affect his method in the least; all his arguments are independent of the truth of the postulates, and in every case it is possible to assert—and this is all the modern geometer asserts—that *if* the postulates are true the propositions are true. A system like Euclid's is, therefore, a part of pure logic; the large division of pure logic that includes it as a very special case is pure geometry. Of the many systems of pure geometry now known, all are on just the same footing, and there is no sense in which any one of them is preferable to any other.

Euclid's contemporaries, however, were not interested merely in his logical method; they wished to identify the furrows in their fields with his lines, and the fields themselves with his surfaces; and to have some justification for this it was necessary to assume that his postulates were true of them. Only one example is needed to show how formidable an assumption this was. In order to prove one of his earliest propositions, Euclid assumes that a triangle can be picked up, transported bodily, and deposited on top of another. Imagine this process carried out when the triangles are fields! The impossibility of carrying it out implies that a most important proposition was not proved for the very case to which they contemplated applying his geometry, and hence that, so far as the knowledge of that day went, there was not the slightest reason for believing that geometry was applicable for its original purpose of earth-measurement. Yet its results, in so far as they were capable of being applied in actual surveying, seem to have been instantly accepted. Why? It may have been due partly to lack of disposition to criticise something that the critics felt they could not have done better themselves, a mental attitude that may perhaps still occasionally exist; but the chief reason was probably that some of the deduced propositions were directly verifiable, such as the proposition that the equality of corresponding sides of triangles in pairs implies that of corresponding angles; also many propositions about areas, expressed in numerical form, could be verified with some accuracy. As a result of these successes the whole system was accepted. But this could not have been a demonstration of the truth of the system; however many times a congruence proposition is verified for particular pairs of triangles, it will never be possible to prove it true for the next pair without the further assumption of some *principle of empirical generalisation* that is not included among the postulates.

Thus the grounds on which Euclid's results have been generally adopted in practice are not those of logical deduction from postulates known to be true *a priori*, as was for centuries believed; they are largely based on empirical generalisation. Thus two sciences with different fundamental data, but with many formally similar propositions, have grown up: the original name of *Euclidean geometry* will here be retained for Euclid's own development, while the experimental science of measurement will be called *mensuration*. The latter was not developed on its own account, the reason being probably that it is a physical science, and that so long as a theory gives results in accordance with observation, physicists in general show little disposition to investigate the security of its foundations.

All experimental science depends on some postulate or postulates that imply that empirical generalisation is justifiable: no amount of experiment will enable us to make any inference unless we have some principle that enables us to generalise the results. Theories involving such a principle may be called *extensive*, while those not involving one may be called *intensive*. The latter include the whole of logic. Now no process of generalisation is used in pure geometry; every proposition is proved immediately and with complete certainty for every instance of its terms. Thus all pure geometry, Euclidean or otherwise, is intensive, while all physical sciences, including mensuration, are extensive. Thus, in the first great subdivision of scientific knowledge, geometry and mensuration fall on opposite sides, and nothing but confusion can arise from any attempt to treat them as identical. In geometry postulates are made about *any* point, or *any* line; in mensuration these are necessarily unverifiable, for they would have to be tested for every possible instance before they could be treated as postulates. They can thus be obtained only by generalisation from results that *are* obtained by experiment, and therefore cannot possibly be primitive propositions.

It may be remarked in passing that generalisation was condemned by traditional logic. The fact that scientific men have not studied its validity for themselves is the chief reason for the present chaotic condition of the theory of scientific knowledge. This important and basic principle appears to involve necessarily the notions of *probability* and *combination of observations*; yet in works purporting to be theories of scientific knowledge these topics are habitually ignored altogether or else relegated to the last chapter. Much credit is due to Dr. N. R. Campbell for placing the theory of probability in its proper position in his recent "Elements of Physics." The value of his treatment is injured by the adoption of the Venn definition of probability, which is logically unsound and scientifically inapplicable; but to accord probability its true status in scientific knowledge is the first great advance in the theory.

This neglect of mensuration, while geometry was making rapid progress, has led physicists to give undue attention to the latter subject and an undue physical status to its concepts, especially to that of *space*. Metrical geometry has come to be regarded as the theory of the measurement of space; but space has no status among the subject-matter of mensuration. A physical measurement of length is always of the form: "When the zero mark on the (so-called rigid and straight) scale is in contact with the particle A, and the edge of the scale is in contact with the particle B, B lies between the nth and $(n+1)$th divisions of the scale." This involves no reference to space. Even the notion of rigidity, which is often regarded as spatial, is not so in practice. It is an experimental fact that many bodies exist which under ordinary treatment have the property that, if the distance between two points of the one can be made to include the distance between two points of the other, in some configuration, then, however the bodies are displaced, this remains true; and our rigid scales are such bodies. This, with the purely mechanical process of scale dividing, is all that is needed to make measurement possible. In actual physical calculation, again, we simply use the measures themselves without any reference to "space"; and the final result can be stated wholly in terms of such measures. If the notion of space is introduced at any stage of the investigation, it necessarily eliminates itself before the close. There are, of course, many so-called measurements of length in physics, such as the diameter of the earth and the distance of the sun, which cannot be made by means of rigid scales; these are not, in the strict sense, measured at all, but inferred from measures of certain angles by means of physical laws obtained from other experiments. Time, as actually used in physics, is on a similar footing to distance measures, and not to space.

The relations between the measured positions of bodies at different times form the subject of dynamics, which reduces to mensuration in a special case. It is an extensive science, and therefore epistemologically quite different from any four-dimensional geometry, which must from its nature be intensive. For this reason we consider that the theory of gravitation must be treated on extensive lines, and disagree with Prof. Eddington's presentation of Einstein's theory as a section of geometry. The principle of the irrelevance of the mesh-system, in particular, does not seem to be presented in its true light in his

"Space, Time, and Gravitation." This principle states that there are relations between the coefficients in the formula for ds^2 which hold, no matter what system of co-ordinates is chosen. Eddington regards the co-ordinate system as decided upon arbitrarily, having no real physical importance, and always eliminating itself in any actual physical process, while the only thing that has physical importance is space-time, which he treats on purely geometrical lines. From this point of view the principle is evidently correct; but it is not the point of view of physics. In physics the co-ordinate systems actually chosen are adopted entirely because they give specially simple forms to relations between measured quantities, and thus are not chosen arbitrarily. It would therefore be conceivable, and indeed not improbable, that there could be no relations between the g's that would not have special forms with ordinary co-ordinate systems. On the other hand, the properties of space-time never appear in physical laws; thus it is space-time that eliminates itself when the problems are reduced to terms of measurement, and the irrelevance of the mesh-system is a proposition, not about the unimportance of convention, but about physical measurements themselves. Hence it is a part, not of geometry, but of dynamics, and can be arrived at only by extension. Now that the predictions of the theory have been verified, the proper course to adopt is to derive the form of ds^2 from the experimental results that these express, and to regard the principle as an interesting experimental result.

Einstein's own presentation differs somewhat from Eddington's, but is also open to some objections. In his "Relativity, the Special and the General Theory" (English translation) Einstein states on p. 2 that he uses the term "geometry" in its usual sense of the logical connection of ideas (? propositions) among themselves. Then, on p. 3, he introduces the further proposition that two points on a practically rigid body always correspond to the same distance, however the body may be displaced, and considers that this converts geometry into a branch of physics. This is not the case; it can only give series of implications between propositions of the truth of which we are ignorant, until some of these propositions have been proved by sensory experience, which is not a part of geometry; they also require a process of generalisation to yield results of sufficient generality to form the basis of a geometry, so that a science reached in this way must be extensive.

On p. 9 of his book, Einstein's attitude towards "space" is closer to ours than to Eddington's, for he resolves to shun the word entirely, admitting that he cannot form the slightest conception of its meaning, and replaces it by the notion of position (*i.e.* measured position) relative to a practically rigid body of reference. In the latter part of the book he appears to regard space, not as a primary entity of Nature, but merely as a conventional construct, composed of the aggregate of all possible values of the three position co-ordinates. In this form the notion may be useful in theoretical work, but we cannot attribute any ultimate physical importance to a thing we have constructed ourselves. In fact, he makes it clear on p. 60 that the principle of relativity is a postulate to be tested by experience: a suggestion offered as possibly true, but with no *a priori* necessity about it. Its validity, in the opinion of its author, rests wholly on the success of its physical predictions. Consequently, as was stated above, the correct procedure now is to deduce the theory from the facts originally predicted by it, with whatever further postulates may be necessary.

Although we have criticised the chief current expositions of the Einstein theory, it is the omission of physicists to provide any satisfactory analysis of the foundations of their own subject that is chiefly at fault, and the remedy is a proper discussion of the relation of physical laws to the observations on which they are founded, and of the probability of inferences based upon them.

We may devote some attention to the question of the comparison of standards at different places, which must play an important part in any theory of measurement. Before the publication of the special theory of relativity, the accepted view was comparatively simple: the measured length of the conventional rigid bar was supposed to be the same however it was displaced and turned, and the same applied to the period of vibration of a clock or an atom (in the former case subject to the known influence of temperature and gravity). This gave a convenient basis for comparison of standards, for all could be expressed in terms of some standard instruments. The special theory, however, showed that this statement is not merely inconvenient as a working rule, but also demonstrably false, for a bar must have different measured lengths according as it is moving relative to the observer along or across the direction of its length. The possibility of a comparison was restored by Einstein's system of light signals; time and length standards were supposed unaltered by displacement, provided the observer was moving with them. But whether he was moving with them or not, a certain interval $\int ds$, measured between consecutive vibrations of the clock or between points on the bar, remained unaltered. Also the condition that $\int ds$ was stationary for small variations in the path was found to give the conditions satisfied by a particle moving at a great distance from matter.

Thus this differential element ds had a dual importance in the special relativity theory. In the general theory this is generalised, but it may be noticed that it is just possible that the two *rôles* may really be separated in a gravitational field. The consequences of this would be peculiar. It is well known that the assumption that ds, taken through a period of vibration of an atom, is independent of position, leads to the prediction of a shift of solar spectral lines; though this is so mixed up with shifts arising from other causes that it is impossible to say definitely whether it has been observed or not. But it is not so well known that the assumption that would lead to no spectral shift leads to the result that the wavelength on emission of light from a particular type of atom is a function of position; thus the abandonment of *ds* as the fundamental measured quantity would not make it possible to carry both length and time standards about unaltered. Probably the difficulties arising from the hypothesis that *ds* does not play two parts are so great as to render it quite unplausible.

The Metaphysical Aspects of Relativity.

By PROF. H. WILDON CARR.

THERE is a possible misconception in the application of the term "metaphysical" to the new principle of relativity which it is advisable to clear up. In the great era of the triumphant advance of the positive sciences, which began about the end of the first third of the nineteenth century, metaphysics was decried as the main obstacle to scientific progress. Following the lead of Auguste Comte, the workers in the sciences held it up to scorn as obscurantism. The derision and reproach which were then poured on it have clung to it ever since. There are many to-day who acknowledge, indeed, that metaphysics must be assigned a place in the hierarchy of the sciences, but interpret the Aristotelian definition, "that which follows or comes after physics," as indicating a dark realm of the yet unknown, or even of the unknowable, which surrounds the clear zone of positive knowledge, into which we may peer, but will discern nothing. The objects of metaphysics—the soul, the cosmos, the deity—are in this view vain imaginings, not objects of which there can be knowledge in the scientific meaning—that is, objects amenable to the experimental method. Such a view simply ignores the scientific tradition. Modern science is the result of the formulation and adoption of the experimental method, but the experimental method is not self-evident or inherently rational; it depends on a metaphysical concept, and its rationality can be established only by metaphysical principles. To contrast, then, the experimental method with the principles on which it depends, to describe one as the realm of science and the other as the realm of ignorance or unknowability, is from any philosophic point of view stultifying, and, in the literal sense, absurd.

What has made it possible to consider metaphysics as an unreal science, or as a realm of unreal fancy, is the peculiar position in regard to the natural sciences in which the purely mathematical sciences stand. Mathematics does not use the experimental method, and in the hierarchy of the sciences mathematics seems sufficient of itself for the foundation and support of the whole superstructure. But mathematics is only an abstract science of quantity; its concepts lack the one essential character which experimental science calls for—concreteness—and this metaphysics alone can supply.

The modern era of philosophy from Descartes onwards has been dominated by the insistence of the scientific problem—that is, the problem of the ultimate nature of the reality we study in physical science by the experimental method. This interest in the nature of scientific reality replaces the main interest of the philosophy of the mediæval period, which was concerned with the origin and destiny of the human soul, and, more generally, with the relation of man to God. If modern philosophy may be said to join hands with the ancient philosophy of Greece, it is not in the identity of its interest; for, though the Greeks were mathematicians, they had no conception of the experimental method as we practise it, and it is even doubtful if it could have been made to appeal to them on the ground of rationality.

The principle of relativity is the direct outcome of the application of the experimental method, and the full force of its appeal is based on our absolute confidence in the metaphysical concept of reality which is the ground and reason of that method. The experimental method has taken possession of the modern mind, and it assumes for us something like the unmodifiable character of an instinct. If experiment proves a certain velocity to be constant under conditions which require us to predict its variation; if experiment shows the movement of a source of light to be without the expected effect on the velocity of propagation—well, it is our concept of the nature of reality which must adapt itself to the experiment. The prediction is based on the concept that space and time provide an absolute system of reference; the null result of the experiment negatives that concept, and henceforth space and time are "shadows"; they must vary, because under varying conditions velocity is constant.

Those who affirm that the principle of relativity is purely mathematical, and not metaphysical, and, therefore, resent the intrusion of metaphysics into the discussion of its equations, conceive the principle to be purely methodological, to be concerned only with abstract quantitative measurement, and merely to substitute a very complex and difficult set of equation-formulæ for a discarded simpler one, in the interest of greater precision and accuracy alone. Those who take this view seem to me to misapprehend the significance of the principle. It is to be understood only when taken in its historical connection with the metaphysical constructions of the great philosophers.

Since Descartes, the speculations of philosophy have centred round the concepts of substance and cause, and the principle of relativity in its two phases, special relativity (the restricted theory) and general relativity, is essentially concerned with these two concepts. The first phase, in its negativity towards the æther hypothesis, is a reform of the notion of substance; and the second, in its rejection of influence and its substitution of equivalence for attraction in a new theory of gravitation, is a reform of the notion of cause.

Two opposing principles in regard to both these concepts—substance and cause—have been struggling to establish themselves throughout the modern period—one taking as its type the objective or passive aspect presented by the world to the mind of the observer, the other taking as its type the subjective activity of the mind itself in perceiving, imagining, understanding, willing, and acting. The first type we have in Descartes' concept of material substance as consisting in extension alone, and in his concept of cause as the mechanical action and interaction of a definite quantity of movement imparted to the extended substance—the concept of a mechanism which embraces the whole universe, organised and unorganised, exclusive only of the other substance, thought or thinking, present in human beings alone. Later we have the same type in the more familiar concepts of Newton—absolute time and absolute space. "Absolute time, in itself, and from its own nature, flows equally, without relation to anything external." "Absolute space, in its own nature, without relation to anything external, remains always similar and unmovable." The other type of concept we have in Leibniz's monadology. Substance is not passive, but active; cause is not movement, but force. What does nothing is nothing. Time and space are *ordines rerum non res*. Things are centres of active force.

It is with these concepts of substance and cause that the principle of relativity is primarily and mainly concerned, and these concepts are metaphysical constructions. Experimental facts have called for the formulation of the principle, but those facts themselves have slight importance in the practical sphere; it is their theoretical consequences which are far-reaching and revolutionary. They are facts which prove to be decisive in regard to metaphysical problems. The experiments are concerned with such infinitesimals as forty-two seconds in relation to a century, or a variability of 2¾ in. in the diameter of the earth. It is not the facts themselves, therefore, that are important, but their significance. According to the view which I have put forward in my book, "The General Principle of Relativity in its Philosophical and Historical Aspect" (Macmillan and Co.), the principle of relativity definitely decides for us that our universe is monadic, and that our science does not derive its validity from a reality independent of the monads, but from a power inherent in the monads to co-ordinate ever-varying points of view. By monads I mean minds, but minds conceived as metaphysical reals.

The point of supreme and central importance in the principle of relativity in its bearing on metaphysics is its negative attitude to the concept of absolute space and absolute time continua. The principle accepts the null result of the experiments as decisive in regard to the non-reality in the physical sense of such continua, and it refuses to recognise any necessity to construct *ad hoc* a hypothetical absolute space-time system. On the other hand, it claims to provide a formula which expresses the identity of an event for two observers in different systems who pronounce it to be one and the same, without the necessity of affirming an absolute order independent of their systems of reference.

Why does this seem paradoxical and in contradiction to our ordinary experience? Because our experience consists in the observation of events which we do not cause; which we refer to in our intercourse with our fellows as common to them and to us; and to which throughout life we, automatically or consciously, react. We argue by what appears to us the most perfectly natural reasoning that the identity of an event for two different observers implies an absolute order by reference to which alone differences of observation can be reconciled. This absolute order, we think, can be nothing else but the determination of every event in regard to every other event in an absolute coexistence in space and in an absolute succession in time. We conceive, therefore, an absolute space-time order, and suppose our private space-time systems are related to it. Such is the course of reasoning which appears natural, and such is the logical necessity from which it appears impossible to escape. Metaphysicians have long disputed it, but their arguments have been generally set aside as logomachies. Experiment has now falsified it.

What sort of thing, then, is the relativist universe? Substance and cause—that is, the principle of unity and the principle of uniformity—are definitely transferred from the object to the subject of experience. I do not mean that object and subject are dissociated; I mean that substance and cause are declared to be functions of the essential activity, and not of the passivity of experience. Thus the universe depends on the subject of experience, not, indeed, in the old and often derided sense in which the philosopher is caricatured as evolving an external world out of his own inner consciousness, as the spider spins its web, but in the sense that the universe is the co-ordination which the observer effects. The universe has four dimensions—the three dimensions of space, and the one dimension of time. The principle of co-ordination is that every observer uses his own axes of dimension, taking his system of reference as fixed in relation to all systems which for him are moving, and he is able to do so because his four axes are variable, and every change in his own system of reference, relatively to other systems, is compensated by a variation in his axes of co-ordination which preserves the ratio constant.

The universe, then, which the principle of relativity affirms is a universe in which there is no absolute space-time order; in which every event is exhausted in the contradictory descriptions of observers in different systems of reference; in which systems of reference are ultimate without being absolute, and relative without being externally conditioned; in which every system is self-sufficing and contains its own norm, a norm which remains constant by changing as the system changes. In such a universe, are mathematics and physical science possible? The relativist claims that they are capable of infinitely greater precision and consistency than they could ever attain while obstructed by the old concept.

Bibliography of Relativity.

A BIBLIOGRAPHY of all books, pamphlets, papers, articles, and other publications on the subject of relativity has been prepared by Dr. H. Forster Morley, director of the International Catalogue of Scientific Literature. The list includes nearly 650 titles, arranged in chronological order from 1886 to the end of last year. It would occupy about thirty columns of NATURE, and, much as we should like to print it in full, limitations of space render this impossible. We have, therefore, extracted from Dr. Morley's bibliography the titles of published books and pamphlets upon relativity and related subjects, and also the references to articles, notes, or other contributions which have appeared in the pages of NATURE. The complete bibliography is so valuable that we trust it will be published in full either by a scientific society or in a leading work on relativity. Dr. R. W. Lawson has kindly added the titles of a number of German works.

Notes.

The new session of Parliament was opened by the King in person on Tuesday. Reference was made in the King's Speech to a measure to be introduced into the House of Commons "to deal with the safeguarding of essential key industries of the country, and with certain aspects of unfair and abnormal industrial competition."

A meeting of the organising committees of all the Sections of the British Association will be held at Burlington House on Friday, February 25, to consider possible arrangements for joint programmes and related matters for the Edinburgh meeting of the Association in September next. Dr. Ethel Thomas, recorder of Section K (Botany), asks us to say that she would be glad to hear as soon as possible before February 25 from those who propose to offer papers for the Edinburgh meeting, and no doubt the recorders of other Sections would like to receive similar early notice.

Support for the appeal for the protection of the optical glass industry which appeared as a leading article in Nature of February 10 comes in the form of a series of resolutions passed by the Optical Society at its general meeting on the same date. The importance of optical munitions is emphasised, and it is pointed out that such supplies can be maintained only if the necessary materials, manufacturing establishments, and skilled labour are available. No other industry can by adaptation of existing resources produce the class of work required. The supply of optical glass required by this country should also be ensured. Another point made is that although the world's pre-war demand for optical glass was only about 25 tons per annum, some sixty different varieties are required; experience has shown that manufacture under these conditions cannot be a commercial proposition. In conclusion, it is urged that, in the interest of research, no obstacle should be allowed to prevent men of science from obtaining the instruments necessary for their work. The society is convinced that the optical industries of this country must be preserved and developed, and the President of the Board of Trade is to be asked to receive a deputation to explain more fully the position of these industries.

The gold medal of the Royal Astronomical Society was presented on February 11 to Prof. H. N. Russell for his work on the theory of star-development. The retiring president, Prof. A. Fowler, recalled in his address that Prof. Russell had introduced them in that very room to the giant and dwarf theory nearly eight years ago. Although a theory on the same lines (the division of the stars into two groups in which the temperature is rising and falling respectively) had been proposed many years earlier by Sir Norman Lockyer, it ran so counter to the then accepted views that he (Prof. Fowler) acknowledged that he had remained unconverted for some time; but recently several lines of evidence have converged to support the truth of the theory, namely, (1) the accumulation of additional parallaxes, both visual and spectroscopic; (2) the theoretical researches of Prof. Eddington and others on the physics of giant stars and the correlation of temperature with mass; and (3) the recent optical confirmation of the immense bulk of the typical red giant star Betelgeux. There is now little dispute as to the main lines of the theory, though there is room for much further work, in which Prof. Russell is taking a prominent part, on the problem of the nebulæ and Wolf-Rayet stars and their place in the scheme of development. Prof. Russell, in returning thanks, expressed his indebtedness to Prof. E. C. Pickering for determining the spectral type of his parallax stars, and noted that Prof. Hertzsprung and himself had put forward the theory simultaneously.

In recent years M. l'Abbé Breuil has contributed to *L'Anthropologie* a series of memoirs on the rock-paintings of Spain. In the last of these (June, 1920) he sums up the general results to which his studies have led him, and states his belief that all known examples can be arranged in an evolutionary series dating from the closing phases of the Ice age to the dawn of the Neolithic period. In a lecture given at the Institut Français, Cromwell Gardens, S.W., on February 9, the Abbé exhibited a series of original slides illustrating the remarkable art which flourished in southern France and throughout the Spanish Peninsula during the age of the Reindeer, and summed up for his hearers the conclusions reached after many years of systematic investigation. He believed that in the region covered by the art of the cave-men three centres or localities of independent or semi-independent development could be distinguished, North Spain and South-West France forming one centre, East Spain a second, and South Spain a third. The paintings and engravings in the first and second of these cave-areas were, he believed, the work of different peoples; although both were hunters, both giving graphic and realistic representations of the animals they followed and captured, the mammoth, reindeer, bison, and horse. In South Spain, on the other hand, the influence of a pastoral people was to be observed on cave art; it is in this centre that the final degradation of the earlier realistic art of the north into the later linear, conventional form of the south could be detected. There seems reason to believe that it may be possible to trace the evolution of an alphabetical system from the original graphic art of the earlier cave-men. The cave art of South Spain has many points in common with the art of the Bushmen of South Africa.

Owing to the recent decision of the Government that, for the present, no new schemes which involve the expenditure of public money shall be proceeded with, the Ministry of Agriculture and Fisheries informs bee-keepers that no further progress can be made at present with the Bee Disease Bill which was introduced into the House of Lords on December 20 last. The Ministry has also been making preliminary arrangements for the establishment of a Bee Advisory Committee which, it was hoped, would represent thoroughly every section of the bee-keeping industry; its function would be to advise the Ministry on all apicultural matters, including the question of legislation respecting bee diseases. In view of the need for economy and for the postponement of legislation, it will be necessary to delay the formation of this Committee. In the meantime, it is hoped that bee-keepers will take steps to organise themselves in order to arrive at a means of expressing an agreed opinion on the measures to be taken for the protection and furtherance of the industry. Arrangements for the examination of diseased bees no longer exist at the Department of Comparative Anatomy, The Museum, Oxford. Pending the appointment by the Ministry of a bacteriologist to undertake such work, Dr. J. Rennie has kindly consented to carry out examinations and to furnish reports to the bee-keepers concerned. In future, therefore, specimens, together with the name and address of the sender, should be sent to Dr. J. Rennie, Marischal College, University of Aberdeen.

SIR ROBERT HORNE, President of the Board of Trade, in opening on February 10 the Efficiency Exhibition organised by the *Daily Mail* at Olympia, referred to the importance of science and research to industry. In the past we had been too much accustomed to develop business without regard for the sciences or arts; now that attitude is passing away, and the sciences, arts, and industry are working well together. As examples of the success which has attended the co-ordination of effort, Sir Robert mentioned the Dorman appliances for the transmission of wave-energy through water, and the progress which has been made in preserving the health of the nation. We are compelled to defer an account of some of the exhibits of scientific interest until next week, but wish now to direct particular attention to the stand organised by London University, on which Prof. Fleming has arranged a number of the original valves and lamps used by him when he was evolving the thermionic valve. The series enables a view to be obtained of the genesis of one of the most valuable of modern inventions, which was itself the outcome of purely scientific research.

SIR ERNEST SHACKLETON, the *Times* announces, is planning a two years' expedition to Arctic regions, and proposes to leave England in May or June next, accompanied by a dozen men chosen chiefly from those who accompanied him on former expeditions. He proposes to sail for Hudson's Bay, where 150 dogs will be embarked, and then to proceed, *via* Baffin's Bay, through Lancaster Sound to Axel Heiberg Land. The passage of Lancaster Sound and Barrow Strait and the course to be followed to the northward must depend largely on ice conditions. The main object of the expedition is said to be to explore the region between Axel Heiberg and the Parry Islands. Parts of this area were explored between 1898 and 1902 by Otto Sverdrup's expedition in the *Fram*, when surveys were made by G. Isachsen of the coasts of Axel Heiberg, Ellef Ringnes, and Amund Ringnes Lands. Stefansson, travelling from Prince Patrick Island, visited the region in 1915 and 1916, and discovered two new islands in the Gustav Adolf Sea and one in the Prince Gustav Sea, besides finding that Ellef Ringnes Land is in reality two islands. The American Crocker Land Expedition under Mr. D. B. Macmillan in 1916 reached King Christian Island, travelling south-westward from Ellesmere Land. A great deal of work, however, remains to be done, and there is little doubt that Sir Ernest Shackleton intends to push eastward into the unknown Beaufort Sea, where land possibly exists, although Peary's Crocker Land has been disproved and Stefansson has found a relatively narrow continental shelf. It is reported that Sir Ernest Shackleton has bought the Norwegian whaling vessel *Foca I.*, which will shortly leave Tromsö for England. For some years this vessel has been used in carrying stores and men to Spitsbergen for a Norwegian mining company.

SIR LYNDEN MACASSEY in his address on February 11 to the Institute of Industrial Administration upon present-day industrial psychology attributed our present industrial discontent (i) to the failure of Capital to give sufficient attention to the question of administration, and (ii) to the lack of economic information, both general and particular to their respective industries, among the workers. He pleaded for a re-valuation of the factors of production so as to reach a nobler conception of the responsibilities and possibilities of administration. It will be generally agreed that in the past far too much has been left to chance, and that the time has come when this side of our industrial life must be completely overhauled. There may, perhaps, be less general agreement with Sir Lynden's view that a second condition of securing efficiency in production is that Labour shall be regarded as entitled to "know the facts," obtained from an efficient costing system, about the industries in which it is engaged. Yet facts of this kind have infinitely greater weight than an unsupported statement of the management in which, unfortunately, the men have probably little or no faith. Sir Lynden is inclined to underestimate the extent to which welfare work is regarded with suspicion, and his suggestion for its extension will meet with considerable criticism from those who are demanding that they shall be allowed an increased share in all branches of management.

THOUGH the various British firms which are specialising in the manufacture of organic research chemicals continue to add from time to time to the range of products made, their lists are still far behind those issued by the German firms before the war in the variety and complexity of organic chemicals offered. The slow progress made is due to difficulties with which all chemists have become familiar since 1914, and not the least of these is the uncertainty of the Government policy towards the fine chemical industry as a whole. Meanwhile, research work must go on, and since the date of the Sankey judgment research chemists have again begun to make use of German sources of supply, which, it may be added, are no longer so abundant, cheap, and various as they were in 1914, though they appear to be rapidly improving. As it seemed possible that the Dyestuffs (Import

Regulation) Act, 1920, might interfere with the importation of such chemicals, the council of the Institute of Chemistry addressed a letter to the Board of Trade inquiring whether licences would be necessary for the import of small quantities of organic chemicals (including intermediate products used in the manufacture of dyes, etc.) required solely for research purposes. The Board of Trade in its reply states that whilst it is not possible to regard small quantities of organic intermediate products which may be required for research purposes as being outside the scope of the Act, the Board will be prepared to issue general licences for the importation of such products to approved research institutions, covering periods of three months and limited only as to total quantities. This procedure obviates the necessity of separate applications for a large number of small items, but it will be a condition of the issue of such a general licence that a detailed return shall be furnished, at the end of the three months during which the licence is in operation, of the quantities of each product actually imported under it. This ruling indicates that the authorities are prepared to interpret the Act in such a way as not to hamper the prosecution of research.

The Parkin prize, value 100*l.*, will be offered by the Royal College of Physicians of Edinburgh for the best essay "On the Effects of Volcanic Action in the Production of Epidemic Diseases in the Animal and in the Vegetable Creation, and in the Production of Hurricanes and Abnormal Atmospheric Vicissitudes." Essays intended for competition, which is open to competitors of all nationalities, must be written in English, and must reach the secretary not later than December 31, 1921. Each essay must bear a motto, and be accompanied by a sealed envelope bearing the same motto outside and the author's name inside.

The Department of Scientific and Industrial Research has approved the formation of a Research Association for the Cast Iron and Allied Industries as complying with the conditions laid down in the Government scheme for the encouragement of industrial research. The secretary of the committee engaged in the establishment of this association is Mr. Thomas Vickers, 174 Corporation Street, Birmingham.

We learn from the *British Medical Journal* of February 12 that an institute of biology named after Ramon y Cajal has been established at Madrid. It consists of four sections, devoted to human and comparative histology, neurology, physiology, and experimental pathology respectively.

Our Astronomical Column.

Ionisation in the Sun.—Two papers by Dr. Megh Nad Saha have recently appeared in the *Phil. Mag.* (vol. xl., pp. 472, 809), in which the author suggests an explanation of the varying character of the spectra exhibited by different elements in the sun. It is well known that some elements are represented by both enhanced and arc lines. Others show enhanced lines only, while a few have not been found at all. Prof. Fowler has ascribed these variations very largely to the different atomic weights of the elements concerned, but Dr. Saha is of the opinion that atomic weight is only of minor importance, being largely balanced by selective radiation pressure, and regards the variations mentioned above as arising from the different responses of elements to the stimulus existing in the sun. The enhanced lines are assumed to be due to radiations from "ionised atoms" (*i.e.* atoms that have lost an electron) rather than to a mere increase in temperature, and the different ionisation potentials of the elements will thus cause their varying behaviour. Calculations are given of the percentage ionisation of various elements at different temperatures and pressures. The results certainly agree quite well with the observed differences of behaviour of the elements chosen, and also with their individual variations in different regions of the sun.

The First Voyage Round the World.—Prof. Pio Emanuelli, of the Vatican Observatory, contributes an article to the *Corriere d'Italia* of December 20 last on the voyage of Magellan four hundred years ago. Magellan sailed from Spain on September 20, 1519, with five ships. He stayed in Brazil for some months, during which, as his biographer Pigafetta tells us, the potato was tasted for the first time by Europeans.

On the resumption of the voyage to the south the Straits of Magellan were discovered and traversed, the ships reaching the Pacific on November 28, 1520. On April 27, 1521, Magellan and several of his companions were treacherously slain in the Island of Zebu, in the Philippines. Some of the ships were captured, while others had to be abandoned owing to insufficient crews. Only one ship, the *Victoria*, returned to Spain, arriving on September 6, 1522, with the 18 survivors of the expedition, which had originally numbered 237.

Prof. Emanuelli notes that the first clear and definite description of the Magellanic clouds dates from this expedition. Thus they deservedly perpetuate Magellan's name in the heavens. Attention is also directed to the fact that until this voyage the geography of the earth as a whole was less well known than that of the planet Mars at the present day.

Secular Change in the Period of δ Cephei.—Prof. Eddington, in studying the pulsation theory of the Cepheids, indicated that a fairly rapid secular change of period was to be expected, and referred to Hertzsprung's conclusion that the period of δ Cephei was diminishing by 0·079s. per annum. Mr. H. Ludendorff gives a further discussion of the early observations in *Ast. Nach.*, No. 5076. He has carefully re-reduced the original observations of Mr. F. M. Schwerd, made between 1823 and 1826, and finds that they accord closely with the change of period announced by Hertzsprung. The formula of the latter gives a shift of the time of maximum amounting to −0·0121 of a period in 1825, while Schwerd's observations give −0·0134±0·005. The following values of the shift as given from other early series of observations are deduced:—Goodricke, 1785: shift −0·036×period ±0·005; Pigott, 1785: shift −0·035×period ±0·011; Westphal, 1818: shift −0·010×period ±0·008. Mr. Ludendorff considers that the reality of the change is placed beyond doubt by this discussion.

University and Educational Intelligence.

CAMBRIDGE.—As was generally expected, Report B in favour of the foundation of a separate women's university at Cambridge was rejected last week. Three of the six signatories, who produced the scheme after six months' labour, had signed its death-warrant by issuing a fly-sheet against it. The new scheme—C it may well be called—is supported now by a group of fifty-two. It offers women students degrees, teaching by the University for a limited number, also certain undefined privileges, but no power and no votes in the Senate or any controlling body of the University. Even this scheme seems to open up too many and too serious risks to the more conservative members of the University, who are appealing for support for a fourth scheme D. While rigidly limiting the number of women students admitted to the University and ensuring that they shall pay proper fees for teaching and examinations, this scheme limits any advance from the present position to the granting by diploma of titular degrees. Already several defections have taken place from the moderate party to the extreme conservative wing.

What might have been an agreed solution in 1897 can scarcely be accepted in that light in 1921, and unless the moderates, having shed their right wing, are prepared to go further than their fly-sheet suggests, it seems probable that the intervention of some outside body—the Royal Commission at present sitting on the financial resources of the University—will be sought.

THE annual prize distribution at the Sir John Cass Technical Institute was held on Thursday, February 10, when the prizes were distributed by Sir Frederick Black, who afterwards delivered an address on "Liquid Fuel in Peace and War." A summary of the work of the institute during the past session shows that the total number of students was 1060—a higher figure than in any previous year, and an increase of more than 50 per cent. on the previous session. An important development contemplated was the initiation of courses of instruction on petroleum technology adapted to the needs of those already engaged in the industry. In the course of his address Sir Frederick Black said that whilst the United Kingdom had become an important consuming centre of petroleum products, it was at present only on a comparatively small scale that petroleum was produced in this country. So far as manufacture or refining was concerned, much more work of that nature was likely to be undertaken at home, for large British companies interested in oil had their headquarters and distributing agencies here. After briefly describing how the products of petroleum used for fuel were obtained, Sir Frederick gave a general description of their use in internal-combustion engines and for steam raising. The war has developed enormously their use and established their importance. The relative advantages of oil and coal for marine purposes were discussed, special reference being made to the progress in the building of motor-driven ships since 1912. Great attention was being given to such important matters as the elimination of waste on the oilfields and in the use of liquid fuels. Oils that admitted of complete refining into such products as motor spirit and lighting and lubricating oils should be so dealt with in preference to burning the more valuable fractions for steam raising, provided that a heavier oil not capable of such complete refining could be made available.

Calendar of Scientific Pioneers.

February 17, 1600. Giordano Bruno died.—An enthusiastic supporter of the views of Copernicus and of other new learning, Bruno, after several years spent in visiting France, England, and Germany, returned to his native country, was arrested, and, refusing to recant his philosophical and scientific heresies, was burnt at the stake in the Campo di Fiori, Rome.

February 17, 1867. Alexander Dallas Bache died.—One of the most influential of American men of science, Bache was director of the United States Coast Survey. He played a leading part in the founding of the National Academy of Sciences.

February 17, 1874. Lambert Adolphe Jacques Quetelet died.—The designer and first director of the Brussels Observatory, Quetelet was also a statistician and applied the theory of probabilities to the physical and intellectual qualities of man.

February 17, 1875. Friedrich Wilhelm August Argelander died.—Trained under Bessel, Argelander in 1837 became professor of astronomy at Bonn, where he compiled his great catalogue and atlas containing 324,000 stars visible in the northern hemisphere.

February 18, 1899. Marius Sophie Lie died.
February 19, 1897. Karl Theodor Wilhelm Weierstrass died.—Both Lie and Weierstrass were among the most prominent workers in pure mathematics of last century. The former, though a Norwegian, for some years held a chair of mathematics at Leipzig, while Weierstrass was long connected with Berlin University. Lie's chief work was on the theory of transformation groups; Weierstrass's on elliptic functions and the theory of functions.

February 20, 1762. Johann Tobias Mayer died.—Director of Göttingen Observatory, Mayer left behind him valuable lunar tables which greatly aided in solving the problem of finding the longitude at sea.

February 20, 1907. Henri Moissan died.—Moissan in 1886 was the first to isolate fluorine. He improved the electric furnace, and by suddenly cooling a solution of carbon in molten iron produced small artificial diamonds.

February 22, 1875. Sir Charles Lyell died.—Lyell was the greatest master of English geology, and the publication of his "Principles of Geology" marked an epoch in the history of that science. This work was "an attempt to explain the former changes of the earth's surface by reference to causes now in operation." Lyell is buried in Westminster Abbey.

February 22, 1901. George Francis FitzGerald died.—Erasmus Smith professor of natural philosophy at Trinity College, Dublin, FitzGerald is remembered for his knowledge and versatility, his brilliant conceptions, and his stimulating influence on his fellow-physicists.

February 23, 1812. Etienne Louis Malus died.—A French military engineer of distinction, Malus died at the age of thirty-six, having three years previously made his great discovery of the polarisation of light by reflection.

February 23, 1855. Karl Friedrich Gauss died.—Mathematics, astronomy, optics, and magnetism all engaged the attention of Gauss, who in 1807 became professor of mathematics and director of the observatory at Göttingen. His important investigation of terrestrial magnetism belongs to the latter part of his life. With Weber he invented new instruments, set up an electric telegraph, and built the first magnetic observatory. The Gauss Tower on the Hohenhagen, near Dransfeld, was erected to his memory in 1911.

E. C. S.

Societies and Academies.

PARIS.

Academy of Sciences, January 24.—M. Georges Lemoine in the chair.—The president announced the death of M. Georges Humbert, member of the Academy.—P. **Termier** and L. **Joleaud**: The age of the phenomena of transport in the mountains of Gigondas (Vaucluse).—G. **Gouy**: A theorem of geometrical optics and its application to systems of prisms.—M. Pierre Bazy was elected a member of the section of medicine and surgery in succession to M. Guyon.—J. **Andrade**: The transverse elastic displacements of the centre of gravity of a cylindrical spiral and its doublets.—C. **Féry**: A mechanical clock with free escapement.—A. **Liénard**: The electromagnetic energy and thermodynamic potential of a system of currents.—G. **Reboul**: A new property of bodies poor conductors of electricity. An attempt to discover the causes of phenomena described in an earlier communication.—M. **Collignon**: The propagation of the sound of guns to great distances. The annual periodicity. Confirmation of results given in a previous communication: the law of annual periodicity has been verified up to November 18, 1918.—L. **Forsén**: The systematic nomenclature and constitution of the derivatives of molybdic acid. Representing molybdic acid by the formula

$$H_6Mo_3O_{12}.(3H_2MoO_4),$$

the composition of the complex salts of molybdates can be satisfactorily represented.—E. **Rengade**: The isothermal concentration of a solution prepared starting with two salts with different ions. A study of the compositions of the solution and deposited salts produced by the isothermal evaporation at 25° C. of a solution of ammonium nitrate and sodium chloride.—Mlle. J. **Bonnefoy** and J. **Martinet**: 6-Methylisatin. Two new methods are given for the preparation of this compound, the first starting with metatoluidine and methyl mesoxalate, and the second with metatoluidine, carbon bisulphide, and hydrogen peroxide.—E. E. **Blaise**: Derivatives of 1:4-diketones and semicarbazide. The primary product of the reaction between the diketone and semicarbazide is a disemicarbazone; this is readily converted in formic acid solution into an *N*-ureo-pyrrol.—G. **Mignonac**: A new general method for the preparation of amines, starting with aldehydes or ketones. The aldehyde or ketone is dissolved in an alcoholic solution of ammonia, finely divided nickel added, and the mixture kept violently shaken, treated with hydrogen at atmospheric pressure. Examples of the application of the method are given.—P. **Glangeaud**: The mountains of Margeride: their porphyric eruptions, cycles of erosion, and glaciers.—J. **Savornin**: The distribution and direction of the phosphate basins in western Morocco. The deposits of Beni Meskine and Oulad Delim are rich, very extensive, and of great commercial importance. The other basins described are only of theoretical interest.—A. **Lumière**: The harmful action of dead leaves on germination. A study of the substances extracted from dead leaves by water showed the presence of reducing substances capable of preventing the germination of seeds. Numerous successive extractions were required before these substances were completely removed. From these observations it is supposed that after the fall of the leaves rain-water extracts these harmful substances during the winter, thus partially sterilising the soil and removing oxygen, and it is only after the lapse of a certain period of time that sufficient oxygen is present in the soil to permit the germination of seeds.—G. **Tanret**: The presence of quinic acid in the leaves of some conifers. The leaves of the cedar collected in July contain 5 gm. of quinic acid per kg. of dried leaves. Similar results were obtained with larch leaves, but the examination of other conifers gave no quinic acid.—A. **Magnan**: The action of the water on the body and head of diving birds.—C. **Dekhuyson**: The biological semi-permeability of the external walls of the Sipunculideæ. Experiments are described which show that the external walls of *Phascolosoma vulgare* and *Sipunculus nudus* are semi-permeable in so far as pure water, carbon dioxide, and oxygen pass through with much greater velocity than salts in solution.—P. **Goy**: The lower plants and the accessory factors of their growth. From studies of the growth under varying conditions of several species of yeasts, moulds, and bacilli, the conclusion is drawn that vitamines are not indispensable to the lower plants, but that their evolution is considerably influenced by the presence of an organic body which has been isolated in a pure crystallisable state from cultures of *Mucor mucedo*. This substance is not an amino-acid, and contains neither nitrogen nor phosphorus.—H. **Bierry** and F. **Rathery**: Diabetes and glycemia.

Diary of Societies.

THURSDAY, FEBRUARY 17.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. W. A. Herdman: Oceanography (The Sea-Fisheries).

ROYAL SOCIETY, at 4.30.—Dr. C. Chree: A Comparison of Magnetic Declination Changes at British Observatories.—Prof. H. M. Macdonald: The Transmission of Electric Waves Around the Earth's Surface.—Prof. T. H. Havelock: The Stability of Fluid Motion.—Prof. W. H. Young: The Transformation of Integrals.—J. L. Haughton and Kathleen E. Bingham: The Constitution of the Alloys of Aluminium, Copper, and Zinc containing High Percentages of Zinc.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. Martin Flack: Respiratory Efficiency in Relation to Health and Disease (Milroy Lecture).

LINNEAN SOCIETY, at 5.—Prof. G. B. De Toni: A Contribution to the Teratology of the Genus Datura.—Capt. J. Ramsbottom and A. J. Wilmott: A Plant Collection from Macedonia.—Dr. G. C. Druce: Shetland *Plantago* and Other Plants from the Northern Isles.

ROYAL SOCIETY OF MEDICINE (Dermatology Section), at 5.

ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts), at 5.30.—F. Handley Page: The Handley Page Wing.

INSTITUTION OF MINING AND METALLURGY (at Geological Society), at 5.30.—E. H. Clifford: A Scheme for Working the City Deep Mine at a Depth of 7000 ft.

INSTITUTION OF ELECTRICAL ENGINEERS (at Institution of Civil Engineers), at 6.—Prof. E. Wilson: Magnetic Susceptibility of Low Order: I. Instrumentation.

INSTITUTION OF AUTOMOBILE ENGINEERS (London Graduates' Meeting) (at 28 Victoria Street), at 7.30.—E. L. Bass: Engine Lubrication.

CHEMICAL SOCIETY, at 8.—L. J. Hudleston and H. Bassett: Equilibria of Hydrofluosilicic Acid. Part I. Mixtures of Hydrofluosilicic and Hydrofluoric Acids.—R. G. Fargher and H. King: Additive Compounds of Antipyrylaminodiacetic Acid and its Salts with Neutral Salts.—H. Bassett and T. A. Simmons: The System, Picric Acid—Phenyl Acridine.—F. S. Kipping: Organic Derivatives of Silicon. Part XXIV. *dl*-Derivatives of Silicoethane.—F. W. Atack: The Structural Isomerism of Oximes. Part I. Criticism of the Hantzsch-Werner Hypothesis of the Geometrical

Isomerism of Carbon-Nitrogen Compounds.—F. W. Atack: The Structural Isomerism of Oximes. Part II. Constitution of Oximes.—F. S. Kipping: Organic Derivatives of Silicon. Part XXV. Saturated and Unsaturated Silicohydrocarbons, Si_4Ph_8.

RÖNTGEN SOCIETY (at University College), at 8.15.—N. E. Luboshez: Intensifying Screens and Secondary Radiation.

FRIDAY, FEBRUARY 18.

ASSOCIATION OF ECONOMIC BIOLOGISTS, Annual General Meeting (in Botanical Lecture Theatre, Imperial College of Science), at 2.30.—Sir David Prain: Some Relationships of Economic Biology.

GEOLOGICAL SOCIETY OF LONDON, at 3.—Anniversary Meeting.

ROYAL SOCIETY OF ARTS (Indian Section), at 4.30.

ROYAL SOCIETY OF MEDICINE (Otology Section), at 5.—Dr. A. R. Friel: Zinc Ionisation and Electrolysis in the Treatment of Chronic Otorrhœa.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—J. F. Dobson: The Function of the Kidneys in Enlargement of the Prostate Gland (Arris and Gale Lecture).

INSTITUTION OF MECHANICAL ENGINEERS, at 6.—Annual General Meeting.—F. M. Farmer: The Desirability of Standardisation in the Testing of Welds.

INSTITUTION OF ELECTRICAL ENGINEERS (Students' Section) (at King's College, Strand), at 6.30.—L. B. Atkinson: Presidential Address.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at 11 Chandos Street, W.1), at 8.15.—Lt.-Col. J. G. Kennedy: Pathology of Relapsing Fever.—Dr. A. M. Cole: Five Cases of Sarciolopsia Infection.—Dr. A. Connall: Examination of Chrysops for Filaria in West Africa.

ROYAL SOCIETY OF MEDICINE (Electro-Therapeutics Section), at 8.30.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—S. J. Solomon: Strategic Camouflage.

SATURDAY, FEBRUARY 19.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. A. Fowler: Spectroscopy (Regularity in Spectra).

MONDAY, FEBRUARY 21.

VICTORIA INSTITUTE (at Central Hall, Westminster), at 4.30.—Lt.-Col. F. A. Molony: Prophecy.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—J. H. Evans: The Azygos System of Veins in their Association with Surgical Affections (Arris and Gale Lecture).

ARISTOTELIAN SOCIETY (at University of London Club, 21 Gower Street), at 8.—Miss H. D. Oakeley and Others: Space, Time, and Deity.

ROYAL SOCIETY OF ARTS, at 8.—Dr. E. K. Rideal: Applications of Catalysis to Industrial Chemistry: Processes of Oxidation (Cantor Lecture).

CHEMICAL INDUSTRY CLUB (at 2 Whitehall Court), at 8.—Lt.-Col. W. Cullen: South Africa.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—Dr. H. Rice: The Rio Negro Casiquiare Canal and Upper Orinoco.

MEDICAL SOCIETY OF LONDON (at 11 Chandos Street, W.1), at 9.—G. E. Gask: Surgery of the Lung and Pleura (Lettsomian Lecture).

TUESDAY, FEBRUARY 22.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. A. Keith: Darwin's Theory of Man's Origin, in the Light of Present Day Evidence.

ROYAL HORTICULTURAL SOCIETY, at 3.

ROYAL SOCIETY OF MEDICINE (Medicine Section) (at Guy's Hospital), at 4.—Dr. G. H. Hunt: An Experimental Oxygen Chamber.—Dr. G. Marshall: Apparatus for Induction of Artificial Pneumothorax.—Dr. G. H. Hunt and Dr. E. P. Poulton: Congenital Heart Disease with Analysis of the Arterial Blood.—Dr. C. P. Symonds: A Case of Charcot-Marie-Tooth Muscular Dystrophy with Pseudo-Hypertrophy.—Dr. G. H. Hunt: Cardiac Efficiency in Normal and Pathological Conditions.—J. M. H. Campbell: Factors in the Causation of Dyspnœa.—Dr. J. A. Ryle: The Diagnostic Value and the Limitations of the Fractional Test-meal.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. Martin Flack: Respiratory Efficiency in Relation to Health and Disease (Milroy Lecture).

ZOOLOGICAL SOCIETY OF LONDON, at 5.30.—Dr. P. Chalmers Mitchell: Report on the Additions to the Society's Menagerie during the Month of January, 1921.—Prof. Elliot Smith: Exhibition of Photographs of Live Examples of Tarsius.—A. Mallock: Colour-production in Relation to the Coloured Feathers of Birds.—E. Dukinfield Jones: Descriptions of New Moths from South-East Brazil.—Dr. J. Stephenson: Morphology, Classification, and Zoogeography of Indian Oligochæta.—Dr. N. S. Lucas: Report on Deaths in the Society's Gardens during the Year 1920.—Dr. R. Broom: The Structure of the Reptilian Tarsus.

INSTITUTION OF CIVIL ENGINEERS, at 5.30.—P. Allan: Port Improvements at Newcastle, N.S.W.

INSTITUTION OF PETROLEUM TECHNOLOGISTS (at Royal Society of Arts), at 5.30.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—D. Charles: Improvements in Flashlight.

ROYAL ANTHROPOLOGICAL INSTITUTE (at Royal Society), at 8.15.—Sir Alfred T. Davies: The Scheme of the Welsh Department of the Board of Education for the Collection of Rural Lore in Wales through the Schools. To be followed by a Discussion.

WEDNESDAY, FEBRUARY 23.

ROYAL SOCIETY OF ARTS, at 4.30.—Sir Daniel Hall: The Present Position of Research in Agriculture (Trueman Wood Lecture).

GEOLOGICAL SOCIETY OF LONDON, at 5.30.—Prof. W. J. Sollas: *Saccammina Carteri*, Brady, and the Minute Structure of the Foraminiferal Test.—Dr. T. S. Wilson: Notes on the Views of the Late Prof. C. Lapworth with Regard to Spiral Movements in Rocks during Elevation or Depression.

INSTITUTION OF CIVIL ENGINEERS (Students' Meeting), at 6.—J. H. Barker: Machinery Applied to Mass Production.

THURSDAY, FEBRUARY 24.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND (at 11 Chandos Street, W.1), at 2.45.—Sir Frederick Mott and Dr. Hayao: The Pathology of Dementia Præcox, especially in Relation to the Condition of the Ovaries.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—F. Balfour Browne: Mason Bees and Wasps.

ROYAL SOCIETY, at 4.30.—*Probable Papers.*—Sir Ray Lankester: A Remarkable Flint-implement from Selsey Bill.—Dr. E. J. Allen: Regeneration and Reproduction of the Syllid Procerastea.—E. C. Grey and E. G. Young: The Enzymes of *B. coli communis*. Part II. (*a*) Anaerobic Growth followed by Anaerobic and Aerobic Fermentation. (*b*) The Effects of Aeration during the Fermentation.—Dr. A. E. Everest and A. J. Hall: Anthocyanins and Anthocyanidins.

ROYAL SOCIETY OF MEDICINE (Tropical Medicine Section), at 5.—Sir Leonard Rogers: Presidential Address.—Dr. J. G. Thomson and Dr. A. Robertson: The Value of Laboratory Reports in the Diagnosis of Suspected Dysentery, and their Interpretation by the Clinician.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. Martin Flack: Respiratory Efficiency in Relation to Health and Disease (Milroy Lecture).

INSTITUTION OF ELECTRICAL ENGINEERS (at Institution of Civil Engineers), at 6.—Prof. E. Wilson: Magnetic Susceptibility of Low Order. II. Susceptibility Values.

ILLUMINATING ENGINEERING SOCIETY (at Royal Society of Arts), at 8.—Discussion: The Use of Light as an Aid to Publicity.

ROYAL SOCIETY OF MEDICINE (Urology Section), at 8.30.

FRIDAY, FEBRUARY 25.

ROYAL SOCIETY OF MEDICINE (Study of Disease in Children Section), at 4.30.—Sir Humphry Rolleston and Others: Discussion on The Diagnosis and Treatment of Congenital Syphilis and its Effects.

PHYSICAL SOCIETY OF LONDON (at Imperial College of Science), at 5.—R. H. Humphry: A Note on the Hot-Wire Inclinometer.—Profs. E. Wilson and Herroun: The Magnetic Susceptibility of Certain Natural and Artificial Oxides.—J. Guild: The Refractometry of Prisms.—T. Smith: Tracing Rays through an Optical System.

ROYAL SOCIETY OF MEDICINE (Epidemiology and State Medicine Section), at 8.30.—Dr. R. M. F. Picken: The Epidemiology of Measles in a Rural and Residential Area.

SATURDAY, FEBRUARY 26.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. A. Fowler: Spectroscopy (Celestial Spectroscopy).

National Aspects of the Fine Chemical Industry.

IN a speech rarely equalled for its quality and delicately woven argument, Lord Moulton recently put into clear perspective the case for fostering the fine chemical industry in this country. All who during the war-years shared with him the terror of what the chemical industry enabled our enemies to do will accept his view as to the imperative need of treating this as a key industry and stabilising it on a thoroughly satisfactory and efficient foundation. However vaguely we may visualise the boundaries of key industries in general, no one has any doubt as to whether the fine chemical industry comes within them.

One aspect of the importance of this industry may be compared with that of the shipping industry, for just as our maritime supremacy depends upon the strength of our Navy, and hence upon the ability to man it with a race of seafaring men directed by able officers, so also does our future position depend upon our chemical ability, and hence upon the employment of skilled workers directed by trained chemists engaged in a successful organic chemical industry. The necessary conditions for training our seamen are inherited as a birthright, while those for training our chemical workers have to be created. Such workers as those employed in the manufacture of organic chemicals and optical lenses must be trained from early life, and they become proficient only after many years.

It is reported from many quarters that German interests are making a determined effort to destroy those fine chemical manufactures already set up in this country by selling the particular commodities concerned at prices well below the cost of production here, whilst charging exorbitant prices for those chemicals of which they retain the monopoly. Such efforts should be resisted at all costs. The object is to relegate to the scrap-heap the costly plant set up in this country, and to terrorise those who might otherwise be willing to risk capital in developments of a like nature. As a nation we must in the long run pay more if we succumb to this attack and again allow the German monopoly to be established. Not only will a great loss of capital be incurred, but we shall also ultimately pay very dearly for the products now being sold at such low prices, because in a few years' time the far-reaching influence of the war debt will bring about a rise of production costs in Germany. It is also to be presumed that the exchange will become in a measure equalised.

Research workers in this country naturally feel concerned lest the machinery which the Government will make use of to effect the desired protection may adversely influence their work by limiting the supply, or increasing the cost, of research chemicals. It is to be hoped that the terms of the Bill will be such as can be interpreted to give satisfactory safeguards in both these respects. It cannot be supposed that British chemical manufacturers will welcome any measure which seriously hinders research, of which they have recently learned to appreciate the value so well. The patriotic manner in which the manufacturers of fine chemicals responded to the call made upon them at the outbreak of hostilities, and the unselfish service which many of them gave throughout the war, may be taken, we hope, as indicating their attitude in this matter. However, on account of the cost of labour, it is self-evident that the prices of chemicals made in this country must for a time be somewhat higher than those ruling in Germany. German workers to-day are paid the equivalent of 5*d.* an hour, while similar workers in England receive 2*s.* an hour. It is therefore clearly impossible immediately to equalise the prices of chemicals, even should we completely counteract the German effort to destroy the industry.

It is interesting to follow the course which the prices of many of these organic chemicals have taken since 1914. As soon as the supply of German products in the hands of dealers was insufficient to meet the demand, prices rose preposterously high; but as the manufactures became established here they were brought back to a level very near to, though a little higher than, the pre-war figure. This adjustment took place before the resumption of German competition. It may be assumed that the same factors will operate to reduce the cost of any new manufactures which are undertaken, if only we can patiently put up with the difficulties during the present years of transition.

Owing to the rate of exchange, it is possible for the moment to purchase research chemicals from Germany at very low prices. It is timely to remind those who have been ready at once to resume purchasing organic chemicals from Germany of the already successful efforts to supply research chemicals which have been made in this country at the instigation of the Association of British Chemical Manufacturers. Although it has been clearly impossible since the war to prepare a complete collection of the innumerable organic compounds required for research, like that previously held in Germany, a very considerable number of such compounds of British manufacture are now offered through trade channels.

British manufacturers should be encouraged to go on adding to their collection, temporarily supplementing it as may be necessary by purchasing abroad. Research chemicals being required in very small amounts, it cannot pay the manufacturers to continue their efforts unless they receive a large body of support.

The development of British chemistry is aided by any steps which result in giving employment and openings for more chemists. The extension of our chemical industries, especially in the domain of organic chemistry, helps not only by attracting to the profession men of ability who in the choice of a career must be guided by opportunities for useful service with good remuneration, but it helps also by supplying a good training ground for the graduated student who otherwise would not find the right opportunity for specialisation.

Chemists find employment in the organic chemical industry in great numbers because of the variety of ways in which they are needed. Complex reactions of the type involved must be controlled in every stage of manufacture by a chemist. Even old-established processes call for continued investigations both for the purpose of improving them and for grappling with new difficulties which are continually arising. There are also in every large works research, analytical, and process-control laboratories, in each of which young men are engaged under competent direction. These laboratories constitute a very valuable training ground for chemists, who in reality always acquire an important proportion of their chemical knowledge during the years following the completion of their university curricula. With the expansion of the fine chemical industry there would be fewer of those cases where young men of great talent have given up their career in chemistry because the opportunities were so few and the prospects so poor.

The general effect of expanding chemical industry will be to enhance the status of chemical science in this country. The academic life of a people is profoundly affected by the national industries, and any measures designed to foster and preserve those industries which call for the greatest exercise of scientific knowledge and skill are, therefore, closely concerned also with purely scientific studies. It is largely on this account that we give our support to action which will help to safeguard the fine chemical industry in this country.

A Physical Theory of the Universe.

Space, Time, and Gravitation: An Outline of the General Relativity Theory. By Prof. A. S. Eddington. Pp. vii+218. (Cambridge: At the University Press, 1920.) Price 15*s*. net.

"THE mind is not content to leave scientific truth in a dry husk of mathematical symbols, and demands that it shall be alloyed with familiar images. The mathematician, who handles x so lightly, may fairly be asked to state, not indeed the inscrutable meaning of x in Nature, but the meaning which x conveys to *him*."

This is a quotation from the preface to the work now before us, and it aptly summarises the author's task. It is a commonplace to say that no modern development of scientific thought has evoked such a widespread attempt on the part of the layman to understand its import. It would be equally true to say that no other development ever contained within itself such formidable barriers to comprehension. For the theory of relativity, in its general form, deals with conceptions which have had no place in the usual mode of thought, and a large part of our mental scaffolding must be pulled down before we are in a condition to attempt to form a picture of the external world which shall satisfy us as our older pictures have done. Other treatises on the subject now exist, but none which proposes, without the use of symbols beyond the simplest type and in small number, to tell us what x conveys to a relativist. This is the task of Prof. Eddington, who has already done more than any other authority in this country to clarify the whole subject, and to reduce it from a somewhat arid desert of mathematical symbolism, of a type unfamiliar even to most mathematicians, to something which can appeal to the mind of one used to the concepts of physics. This work is an attempt to make the appeal yet more general in its scope, and at the outset we should say that it is difficult to imagine a greater degree of success possible in regard to such a theory. As it leaves the pen of the author, this theory, while yet the same, is scarcely recognisable as the same, for in place of a scheme of pure mathematics we now have a fully developed physical theory of the universe expressed in physical terms.

The reader is first presented with a symposium —between an experimental physicist, a pure mathematician, and a relativist, who discuss the nature of space and of geometry—which brings out vividly the defects of our mental scaffolding in so far as it consists of ideas of space and time. He passes to the Michelson-Morley experiment and the FitzGerald contraction of matter in the direction of its motion. These are now almost matters of general knowledge. But there is a wealth of illustration from everyday events to give point to rather recondite or merely unusual ideas. The confusion of the aviator and his spectator, with their cigars, on pp. 24–25, cannot well fail to give to any reader, in a humorous way, an exact idea of a great part of the simpler restricted principle of relativity; and this type of illustration, which at once captures the mind, abounds throughout. It is made quite clear that in accepting this principle we are merely giving up some unproved and unprovable hypotheses which are an actual barrier to the comprehension of Nature.

The principle itself follows, with a survey of æthers of various historical types, and a general summary of the reasons which make the principle necessary. We do not, in this review, give any account of the theory itself. The world of four dimensions follows, and of this it is sufficient to say that it will probably focus the reader's interest more than anything else, and that it is by far the best realisation of the analysis into ordinary prose —if the author's vivid prose is ordinary—which we have seen or imagined. It is a relief to find that the author does not enter, or deem it useful to enter, into metaphysical speculations on the meaning of "imaginary time" as it appears in the Minkowskian world, but frankly descends to real time for his exposition.

After chapters on fields of force and types of space, we come to a comparison of the new and the old laws of gravitation. To a mathematician or physicist called upon by his lay friends to explain, several times in a week, just what awful fate has overtaken Euclid and Newton, this discussion seems completely indispensable, for the author has found words in which to express the matter to a lay friend, and such words have always failed the reviewer and probably many others. Included is a simple indication of the nature of the calculation—of deflection of light by the field of the sun—which observers, including Prof. Eddington, went far afield to test.

Much space could be occupied by a mere table of contents of this volume. Every aspect of the theory is touched upon, and all the alternative interpretations of the phenomena which have at various times been suggested receive due and fair consideration. We have a clear statement on all such points as "mass is a measure of energy," and so forth, which puzzle the uninitiated. The "weight of light" has a chapter to itself. The final chapter is of a highly metaphysical type, to follow on the conclusion of the theory. Apparently addressed to philosophers, we can see it raising many heated controversies. Perhaps we may, as we began with a quotation, also end with one—the penultimate paragraph of this chapter :—

"The theory of relativity has passed in review the whole subject-matter of physics. It has unified the great laws, which by the precision of their formulation and the exactness of their application have won the proud place in human knowledge which physical science holds to-day. And yet, in regard to the nature of things, this knowledge is only an empty shell—a form of symbols. It is knowledge of structural form, and not knowledge of content. All through the physical world runs that unknown content which must surely be the stuff of our consciousness. Here is a hint of aspects deep within the world of physics, and yet unattainable by the methods of physics. And, moreover, we have found that where science has progressed the farthest, the mind has but regained from Nature that which the mind has put into Nature."

A disappointing conclusion, perhaps, to many —but we congratulate the author on the way he has dealt with a task all the harder because the results read so easily and simply; we also congratulate the Cambridge University Press on the technical excellence of the volume, which is everything that we usually associate with the series to which this work belongs.

J. W. N.

The Methods of Cancer Research.

Some Conclusions on Cancer. By Dr. Charles Creighton. Pp. xiii + 365. (London: Williams and Norgate, 1920.) Price 42s. net.

"THERE is something common to all tumour-malignancies, which I take to be cells feeding on the substance of blood to their own aggrandisement, instead of metabolising it, storing it, or transmitting it to an ulterior end. But that risk arises in various ways. In all cases there must be an unfortunate occurrence of a number of factors, of which one may be prerogative in one case, another prerogative in another" (p. 83).

In these words Dr. Creighton summarises his conclusions on the nature and mode of origin of cancer. It is necessary to add that the cells involved are only rarely the cells of the specific parenchyma of the organ in which cancer arises. In most cases they are endothelial cells or plasma cells. The apparent reproduction of the structure of the specific parenchyma in the cells of the new growth is a mimicry, a pseudo-differentiation which it may at once be confessed has deceived three generations of pathologists. Metastases arise by a similar transformation of cells of distant organs, and not by embolism as currently believed. The similarity in structure to the primary growth which they present is mysterious —"mystical"—and no explanation is offered or suggested.

The credibility of a hypothesis is judged by the number of different observations which it harmonises: its utility by its power to suggest new methods and lines of work. In both directions Dr. Creighton's book is of little value. The author recognises that his views do not harmonise with the observations of others. He has a short way with them. The other observers are wrong. This is particularly well exemplified in his discussion of the histogenesis of carcinoma of stratified squamous epithelium. It is stated to arise from cells of a cambium layer lying between the basal layer of the stratum Malpighii and the corium in squamous cell carcinoma of the skin and tongue. In the œsophagus the same type of growth arises from capillary loops which penetrate the superjacent squamous epithelium. The evidence for these remarkable statements is based on rough semi-diagrammatic figures of large growths, several of which are ulcerated. A laborious summary is given of the earliest work on the subject by Thiersch and Waldeyer. The beautifully illustrated monographs of Ribbert and Borrmann on the same subject, in which new growths of microscopic size are analysed, almost cell by cell, are not mentioned. There is one short reference to the confirmatory work of Butlin in this country. The whole argumentation is irrelevant, and does not shake in the least the evidence that squamous cell carcinoma arises in minute circumscribed areas in stratified squamous epithelium. Once the primary transformation has been accomplished, no evidence can be found for increase in size by transformation of surrounding cells into cancer.

The origin of metastases is dealt with in the same way. Large nodules with vascular connections with the surrounding tissues are adduced in illustration of a transformation of the surrounding cells into new growth. The earliest stages in which cancer cells lie among unaltered blood corpuscles, such as are familiar to every working pathologist, are unknown to the author. The confirmatory evidence furnished by the experimental reproduction of blood-stream metastasis and by subcutaneous inoculation of cancer in laboratory animals is too damning to ignore, and a chapter and a half are devoted to the subject of "mouse-cancer." Here the author is completely out of his depth. Where the facts are too patent, they are passed over in silence or simply contradicted, as, for example, the absence of cancer in selected families inbred for generations, and the occurrence of cancer in female mice which have never borne young and in wild mice.

The origin of grafted tumours from introduced cells is denied, and the figures in which the continuity is traced day by day are described as showing an origin from nuclear débris lying in a formless mass of disorganised protoplasm. The adjacent intact cells in which mitosis proceeds are regarded as having nothing to do with the formation of the new tumour. The general confirmation in the rat, rabbit, guinea-pig, and dog of the observations on new growths of the mouse is not even mentioned.

It is unnecessary to review in detail the other chapters on chorion-epithelioma, glioma, cancer of the mamma, stomach, and rectum. It is only too evident that the author has approached the subject with vague preconceived ideas, any illustration of which can be made to function as rhetorical proof. As he naïvely remarks in the preface, "he can imagine nothing better for the future progress of these studies than that others, bringing their own prepossessions, should resort to the same cabinets [of slides in the pathological department of a great hospital] to find in the infinite variety of phenomena the proofs which they seek." As may easily be imagined, a work conscientiously written throughout in this spirit contains little that is suggestive for new investigations, whether histogenetic or experimental, and in this direction also the book fails of justification.

Cancer research, in addition to its occupation with the empirical treatment of the disease, is concerned with the answer to two questions. In what way do cancer cells differ from cells of the same kind which are not cancerous? What are the changes by which ordinary cells become cancerous? At present our knowledge only suffices to give the most general and superficial answer to the first question, and to the second no answer as yet can be given. In the unvarying parenchymata of transplantable tumours we possess an ideal material for investigating the first of these problems and for testing hypotheses framed to solve it. The advances which are even now being made in the experimental production of cancer are providing the means for a rational attack on the second. The time has come when speculation and hypothesis must take their proper place as servants in the investigation of cancer, not substitutes for observation, experiment, and proof.

J. A. MURRAY.

Virgil's Botany.

The Trees, Shrubs, and Plants of Virgil. By John Sargeaunt. Pp. vii+149. (Oxford: B. H. Blackwell, 1920.) Price 6*s.* net.

THERE are many lovers of Virgil who are neither scholars nor botanists, and their number seems to be increasing, just lovers of his poetry, who are content without any great knowledge of grammatical criticism—content with translating *quercus* and *robur* by the same word "oak," for whom *taeda, picea, pinus, abies* are equally "fir" or "pine," though they would, for the most part, hesitate to affirm on the authority of Gallus that "Violets are black and blaeberries (*vaccinia*) too." To all such the book now before us, written by a former master at Westminster, who grows Virgilian plants in his English garden, and has travelled in Italy, comes with the promise of help. We hope with its aid to attain to a better understanding and, therefore, to a truer appreciation of the poems, especially of the "Eclogues" and "Georgics," the country poems. And at first we are not disappointed.

It is true that we have to get over the initial difficulty of the title; for are not trees and shrubs plants too? Why not say "herbs"? It is as though we were to write of men and animals. Letting that pass, however, we find a very interesting introductory chapter, which deals with the geography and the distribution of plants in the valley of the Po two thousand years ago: what enormous changes, natural and artificial, have been wrought in the intervening years, turning Gallia Cisalpina of Virgil's day into Lombardy of our own!—the wolf no longer descends from the dense forests of the Apennines to ravage the flocks; the olive now flourishes on the shores of Benacus. Then we come to a very interesting discussion of the colours mentioned by Virgil—*purpureus* and *ferrugineus*, *niger* and *ater*, *candidus* and *albus*, *flavus*, *luteus* and *fulvus*; the particularly elusive *caeruleus* is, however, not mentioned, and it is a pity that when fields of ripe corn, yellow sands, auburn hair, gold are given as examples of objects to which the colour *flavus* is attributed, *flava oliva* is not given too. The subject of these colour names is a very obscure one. We know very little about it, and that "in some contexts white means little more than not black and black little more than not white" is wisely said. Might not the saying be further extended? Do not we, on the other hand, very often insist too minutely on the differentiation and discrimination of natural colours and of colour names? People have been known to fall out and almost to quarrel over the colour of autumn saffron, *Colchicum autumnale*: is it pink or is it mauve? What is mauve?

But when we pass from the introduction to the body of the book we are disappointed: it is full of solid and valuable information, but the many inaccuracies, some of which are so obvious that a very slightly informed reader can scarcely fail to detect them, rob it of a great part of its value and inspire a strong mistrust of even the better part.

P. 66. The true laurel is the bay (*Laurus nobilis*), from which we get camphor and cinnamon.

P. 97. The capsules [of *Papaver somniferum*] abound in opium or hashish.

Less obvious at a first reading are the wrong attribution of Acanthus to the Scrophularineæ (not Scrofularineæ); the statement (p. 37) that the purple crocuses of our gardens are *Crocus versicolor*, whereas they are *C. vernus*; and the confusion (p. 137) between Viscum, our mistletoe, and Loranthus, which, according to Arcangeli, grows on oaks and chestnuts.

What can be the meaning (p. 91) of: "The victors in the games are crowned with olive blossoms, which drop upon their yellow pollen" ("Æ." v. 309)? The line in the original is: . . . *flavaque caput nectentur oliva.* And why should the foliage of both the olive and the oleaster be called "heavy"? Is this a misprint for "hoary"?

Florentes ferulas et grandia lilia quassans: this is said of Silvanus and not of Pan—of Silvanus, *agresti capitis honore,* crowned with a wreath of oak leaves, and bearing in his hand, brandishing, *quassans,* flowering ferules and tall white lilies, leading in a train of weeping nymphs to Pan, over whose ruddled face the bloody juice of the dwarf elderberries trickles down. Cannot we see them all? *Panaque, Silvanumque senem, Nymphasque sorores.*

No. The book is not what we had hoped for, a safe guide, a trustworthy friend, a welcome companion, in the study or in the garden; it is disappointing. Such a book is needed—it has yet to be written. Why should not the author of this one write it? Here he has the first sketch of it, the half-carved block; the design is good, the material is good, they are worthy of further work. On his title-page he tells us that he was prompted by *tantus amor florum*; let him not omit to carry plenty of *suburra,* and he will be amply rewarded by the *generandi gloria mellis.*

William Sutherland: A Biography. By Prof. W. A. Osborne. Pp. 102. (Melbourne: Lothian Book Publishing Co. Pty., Ltd.; London: The *British Australasian,* 1920.) Price 7*s.* 6*d.*

THE friends of the late William Sutherland will welcome this little biography by Prof. Osborne. It is a faithful portrait of the man charmingly conveyed by a judicious selection of incidents from his life. William Sutherland's was a remarkable character, and he was an unexpected product of a new country, where a leisured class scarcely exists. This biographer has done justice to his extraordinary versatility and modesty. Many who valued his society on account of his knowledge and appreciation of literature, painting, and music will, no doubt, be surprised to learn from his biography that he possessed a world-wide reputation as an investigator in molecular physics, and was the author of upwards of fifty papers dealing with some of the fundamental properties of matter.

Sutherland had no private fortune, but, nevertheless, abstained from devoting more of his time to earning money than was necessary. Occasional work for the Press and infrequent examinerships produced sufficient income to supply his modest needs. This peculiarity kept him from accepting permanent academic posts. It is a matter for regret, however, that a small chair, which would have provided him with a laboratory, and brought him into contact with students, was not available for him. The value of the work he did with such devotion would have been enhanced thereby, and what a gain his inspiration would have been to any institution!

At the end of the volume Prof. Osborne has gracefully referred to Sutherland's saintliness. This is no exaggeration of his biographer. Although I loved him well and sought his society frequently, I was never quite comfortable in it because he was so singularly devoid of vices and so tolerant of other people's weaknesses. Notwithstanding his delightful sense of humour, it was scarcely more possible for us to attain complete harmony than for a drunkard to be quite at ease in the society of a teetotaler.

C. J. MARTIN.

Maryland Geological Survey: Cambrian and Ordovician. Pp. 424 + lviii plates. (Baltimore: The Johns Hopkins Press, 1919.)

THE Maryland Geological Survey has always been noted for the educational aspect of its publications, which are by no means a dry record of observations for the use of scientific specialists. They help the ordinary citizen to understand his State, and in so doing to appreciate the aims and methods of research. The results of much careful work in petrology and palæontology are brought together in the well-known green-covered volumes, so as to be accessible in private libraries and in schools. The present volume, by R. S. Bassler, covers a part of the Atlantic slope from the crest of the Alleghanies to the sea, thus including the three great belts of contrasted scenery that stretch from New England to Mississippi. The British controversy as to the nomenclature of the older Palæozoic systems is interestingly re-stated, and the author, on grounds of fairness to the original workers, would like to use Taconic and Cambrian for the systems now styled Cambrian and Ordovician respectively. He effects a proper compromise, however, and fairly discusses Ulrich's Ozarkian and Canadian systems.

There is certainly no "writing down" to a popular level in the stratigraphical and palæontological descriptions, though in one place, in a sketch of the life-processes of Cryptozoon, "lime" is accidentally used for "calcium carbonate." The results of investigations in other fields are brought together, and local fossils are illustrated by notable specimens, such as *Olenellus Thompsoni* from Vermont, which add interest to those already found in Maryland. Cryptozoon occurs in the Cambrian and Ordovician of Maryland, and its algal nature seems to be established, though the Cambrian fauna is generally poor. Does the author refer to this fact when he makes the general statement on p. 32 that the Pelecypoda appear for the first time in Ordovician strata?

The numerous photographs of wayside sections and rolling farmland country are a pleasing feature. Plate ii. shows, from the Virginian side, the fine gorge of the Potomac cut across the Cambrian sandstones at Harper's Ferry, a scene known alike to history, geography, and geology.

A Quantum Theory of Vision.

IN a paper appearing in the February issue of the *Philosophical Magazine* I have described a theory of vision which ascribes visual stimuli to the activity of light quanta in liberating electrons from the visual purple. Various phenomena associated with scotopic and photopic vision are considered. Those coming under the designation of simultaneous contrast did not appear to me, at the time of writing, referable to purely retinal actions. Since then it has occurred to me that simultaneous contrast effects find explanation in a very simple way on the same data as serve to explain successive contrast, *i.e.* in the external location of the sensitiser with reference to the cones and in the motion of these organs attending light stimulus.

Consider the case of a grey patch bordered by a black area. This disposition secures unused sensitiser around the retinal image of the central patch. When those cones which are covered by the image of this central patch retract, the unused sensitiser flows in around them. The conditions are, therefore, favourable to specially luminous sensation, and the grey patch looks bright. In the other case, when the grey patch is surrounded by a white area, the reverse conditions prevail. The retreat of the cones involves the inflow of used-up sensitiser around the cones covered by the central image. The conditions are favourable to lowered luminous sensation, and the grey area looks dark. When we substitute for the white border a coloured border, then the sensitiser invading the central area of the retinal image is "fatigued" for the particular tint of the border, and hence the central grey looks tinted with the complementary colour. The tissue-paper, which when laid over the patches accentuates these effects, acts probably in two ways. It renders good fixation impossible and, by the increased luminosity which it brings in, it causes the cone-movements to become more active.

In my paper I have invoked the "latent image" familiar to photographers. I think it explains more even than I claimed for it.

The latent image in the photographic plate may be ascribed to electrons which, having travelled a certain distance from their point of origin, become loosely attached to atoms. Afterwards they take part in the chemical effects attending development, or, if exposure is carried so far as to cause an accumulation of electrons to the point of instability under increasing electrostatic forces, the latent image runs down of itself. This is "solarisation" or "reversal." There may be a succession of such reversals under continued exposure.

It is quite to be expected that something of this sort will occur in the case of the cones, and possibly of the rods also. After-images find explanation in this way, and their theory becomes very complete when the motion of the cones under light stimulus is taken into account. As briefly referred to in my paper, the latent image serves also to explain the "dark" electrical response of the retina—a response which has the same sign as the "light" response. To understand this we have to consider that the latent image in the nerve-substance has less stability, very probably, than that which forms in the photographic plate, owing to the nature of the medium. It is probably kept in being by the continuous inflow of electrons from without the cone, and, normally, is also continually breaking down. When light is cut off, the whole accumulation runs down, attracted back to the positively charged ions developed around the cone. Hence there is a second stimulus, and it will, of course, be of the same sign as that attending the primary movement of the electrons. The final discharge of the latent image may be relatively slow, as the curves in some cases show. Looking at such a curve as that which Piper obtained for a pigeon's eye under brief periods of darkness alternating with light intervals, it needs little imagination to picture the happening of these events.

Fröhlich's results on the Cephalopod eye seem to involve the same effects. In this case the latent image builds up rapidly within the rods which are exposed directly to the light and as rapidly runs down, giving rise to rhythmic electrical responses from 20 to 100 per second. Just on account of this extreme instability of the latent image there is no definite dark response. In short, the dark response is a phenomenon connected entirely with the quasi-stability of the latent image, and is probably favoured by the location of the sensitiser external to the nerve.

From all this I think we must conclude that the stimulus is ascribable ultimately to the motion of the electron, its amount depending upon the kinetic energy, and this, in turn, upon the particular quantum which activates the electron. The return of the electron in some cases, under the electrostatic attraction at the point of origin, involves a fresh stimulus. This is a phenomenon similar to that which Lenard invokes in his explanation of phosphorescence.

On this view colour is appreciated in terms of the energy of the stimuli; brightness in terms of the concentration or density of the stimuli. Rhythmic succession of stimuli is not required, and does not exist. It will be understood that this theory does not involve views respecting the origin of the quantum. Thus, whether we believe that quanta originate at the source of light or come into existence upon its absorption—as Sir Oliver Lodge has suggested—the basis of the theory remains. The one thing essential is the relation between the energy of the photo-electron and the frequency of the light which gives rise to it.

I conclude with a question: Are there any good data available respecting the rate of motion of the cones under light stimulus? It is generally stated that it is slow even with strong lights (and faster for violet than for red). Definite information on this point seems worth seeking. For if the reaction towards the light were rapid, we could regard it as diminishing the effects of dispersion in the refractive system. It is probable (in harmony with the present theory) that the displacement would be greater for violet than for red rays. This would tend to bring cones illuminated by violet light nearer to the lens than cones illuminated by red light. There would be at least a partial correction for dispersion.

The Constitution of Lithium.

POSITIVE rays of the alkali metals were first obtained by Gehrcke and Reichenheim by using as anode a heated metal strip upon which a suitable salt was melted. Later they substituted for this a specially constructed composite anode which yielded the rays without the necessity of external heating.

Both these methods have been employed recently at the Cavendish Laboratory to investigate the constitution of lithium, the rays produced being analysed by Sir J. J. Thomson's "parabola" method which gives ample resolving power for this element.

By means of the composite anode (G. P. Thomson, Proc. Camb. Phil. Soc., vol. xx., p. 211, 1920) a number of plates were taken showing in several cases double parabolas corresponding to 6 and 7, but owing to the fact that spurious doubling had occasionally occurred, due to instrumental trouble, publication was withheld.

It has now been found possible to apply the externally heated anode, employed by Dempster in 1918 for potentials of about 1000 volts, to high potential rays. This arrangement is used at very low pressures, and under these conditions *metallic rays only* appear to be produced.

Exceedingly satisfactory parabolas corresponding to lithium have been obtained, a strong one at 7 and a faint companion at 6 (Na=23). The intensity of the latter appears to correspond well with the accepted atomic weight 6·94.

The foregoing results appear to leave no doubt that lithium is a complex element with isotopes of atomic weights 6 and 7. Of course, no accuracy can be claimed for these figures until higher resolution has been applied, but there seems no reason to doubt that they are very nearly whole numbers.

The Elementary Particle of Positive Electricity.

THE name "negative electron" was applied to the elementary particle of negative electricity after the experimental evidence for the variation of its mass with velocity had generally convinced physicists that its whole inertia was due to its electric charge. This meaning of the term "electron" was in accord with Dr. Johnstone Stoney's original use of the word to denote the elementary unit of electric charge. With the introduction of the principle of relativity it became clear that the variation of mass with velocity was no characteristic attribute of electrical inertia, and that therefore we have no proof that the negative electron's inertia is wholly electromagnetic in origin. In fact, the investigations of Abraham, Webster, and others have shown that there must be some mass present other than that due to the electron's electric field. If we abide by Dr. Stoney's original meaning of the word, it is therefore more than doubtful whether we are justified in calling this negatively electrified particle of matter an electron. Nevertheless, the term is now so well established in the literature that we use "electron" to denote this elementary particle regardless of our view concerning the origin of its mass.

The arguments for and against the electrical origin of the mass apply in exactly the same manner to the elementary particle of positive as to the corresponding particle of negative electricity. If the negative particle can legitimately be termed an "electron," it is thus equally legitimate to apply the term to the positive particle, since it likewise carries the fundamental unit of electric charge. Why not, therefore, denote both these elementary particles by the same generic term "electron," distinguishing the "positive" from the "negative" electrons when necessary, as several writers have long been accustomed to do?

It seems to me that the application of a distinctive name, such as "proton" or "hylon" or "hydrion," to the elementary particle of positive electricity can only suggest a distinction between the nature of the positive and negative electrons, which, so far as we are aware, does not exist. Thus, for example, when an atom of hydrogen is split into its two components the negative electron is just as really a hydrogen ion as is the positive electron. The fact that both components possess equally fundamental units of electric charge and are equally fundamental divisions of matter should suggest that the same generic name "electron" be applied to each.

The Peltier Effect and Low-Temperature Research.

I SHOULD like to inquire whether the Peltier effect has ever been considered as an aid to the production of very low temperatures. I understand that the lowest temperatures yet obtained are those produced by Dr. H. K. Onnes, of Leyden, who, by reducing the temperature of metals to that of liquid helium, has got down to within less than 4° of the absolute zero of temperature, or more than 450° below zero Fahrenheit. Onnes, moreover, found that at such a temperature pure metals lose practically all electrical resistance and become nearly perfect conductors.

The suggestion is to apply the Peltier effect, which consists in an observed diminution in temperature when an electric current is passed in a particular direction through a thermo-couple to obtain still lower temperatures.

At ordinary temperatures, when the metals composing the thermo-couple have appreciable resistance, the Peltier effect is largely masked by the C^2R heat produced in the metals by the passage of the current. At the temperatures attained by Onnes, when resistance practically vanishes, this condition should not obtain, with the result that the application of the Peltier effect would appear to give possibilities of obtaining materially lower temperatures than have yet been reached. Heredity and Biological Terms.

IT seems to me that the arguments of Sir Archdall Reid (NATURE, February 3, p. 726) and Sir Bryan Donkin (February 10, p. 758) leave the question of the meaning and use of the term "acquired characters" very much where it was before. Sir Bryan Donkin asks whether it may not be justly argued that if a child has a hand like its parent there is no change in "nature" or "nurture"; that if the child has a sixth digit which the parent had not there is a change in nature or heritage, but none in nurture; and that if the child has a scar there is no change in heritage, but only one in nurture. But I fail to perceive anything new in this or any difference from the usual conceptions which are general among biologists. It is a mere matter of terms and synonyms. The modern biologist would say that the normal hand was hereditary, or innate, or due to certain factors or genes in the chromosomes which usually are handed on unchanged "down the germ-tract"; that the sixth digit was a mutation, due to some change in the genes in the chromosomes, and therefore gametogenic; and that the scar was due to an injury which resulted in regenerative processes producing new tissue. Sir Bryan Donkin states that the scar is an "acquired difference," but in terms of the germ-plasm the hand and the scar indicate no change. What, then, is the objection to terming the scar an "acquired character"? Every biologist would agree that it does not indicate a change in the chromosomes. Its possible subsequent effect on heredity is expressly excluded from the discussion.

Yet Sir Bryan Donkin insists that the division of human characters into two groups, "innate" or "acquired," "constitutional" or "environmental," is a cause of much confusion—apparently because, as Sir Archdall Reid insists, "a vague terminology has caused neglect of the evolution of the power of developing in response to functional activity." But, so far as I know, that writer has produced no evidence of such an evolution, no evidence that functional activity has more effect in the higher animals than in the lower. It is difficult to think of cases of different functional activity among individuals in lower animals, but if we take conditions such as quantity and quality of food, we know that the difference between worker bees and queen bees is entirely due to this difference of "nurture"—in fact, is an "acquired character." Probably Sir Archdall Reid would consider insects as lower than man, though biologists would not admit that he was right. Sir Bryan Donkin writes that like exactly begets like when parent and child develop under like conditions; if we say, then, that the differences due to unlike conditions are acquired characters, what is the objection?

In my previous letter (January 13, p. 630) I criticised some of Sir Archdall Reid's statements by pointing out that they contradicted each other. In reply he referred to some supposed views as to what were acquired characters put forward in other publications of mine. But he is not entitled to do this. I made no offer to discuss my own views; I was merely criticising the arguments by which he attempted to show that all characters were "innate and acquired in exactly the same sense and degree." What I may have written elsewhere is not relevant to the present discussion. In the letter in the issue of NATURE for February 3, Sir Archdall Reid takes the case of a normal Englishman and a scarred negro as an example, and states that they differ in scars by acquirement, but that the scars are not acquired any more or less than the skin-colour. It follows, then, either that an acquirement is not acquired or that the skin-colour is also acquired in the same sense and degree as the scars. But the latter is not the case, for the different skin-colours will develop under the same conditions—that is, they do not correspond to different conditions, while the scars are related to a difference of conditions or stimuli, namely, injury in the one case which is absent in the other. If Sir Archdall Reid means that no character could be acquired unless the living substance of the organism had the potentiality of developing in a certain way under certain conditions or under a certain stimulus, that is, of course, a truism which does not require to be stated. But he has entirely failed to prove that all characters are innate and acquired, somatic and germinal, exactly in the same sense and degree. His own arguments and examples prove the contrary.

J. T. CUNNINGHAM.

Coloured Thinking.

IN view of Prof. Fraser Harris's letter in NATURE of February 3 and of his implied complaint that so little has been written on the phenomenon since Galton discovered it, possibly the record of some observations that I made upon my own son more than eleven years ago, when he was between seven and a half and eight years old, may be worth notice. I was in correspondence with Galton about the case shortly before his death; and, in fact, a letter to him, reporting the result of further inquiries suggested by him, was lying on my desk ready to be posted when I opened the daily paper and read the announcement of his death.

Having accidentally discovered that my son had coloured concepts, I noted down a series of these in the late autumn of 1909, taking great care to avoid any approach to leading questions or suggestions. Then, three months later, having meantime ignored the matter, I again tested him; and on this occasion, at Galton's suggestion, I carried the inquiry rather further. I will deal first with the numerals, since these afforded the most interesting results. Their colours were:

	In 1909	In 1910
1	Any sort of colour.	Black.
2	,, ,, ,, ,,	Brown.
3	(Not noted.)	White.
4	Blue.	Blue.
5	Yellowish.	Yellow.
6	White.	White.
7	Red.	Pink.
8	Rather dark red.	Red.
9	Greenish.	Green.
10	Black.	Not asked
11	Brown.	,, ,,
12	Blackish-grey.	,, ,,
35	Not asked.	White and yellow.
36	,, ,,	White and white.
55	,, ,,	Yellow and yellow.
80	,, ,,	Red.
800	,, ,,	Red.
100	,, ,,	Black.

On the second occasion I tested the obvious inference from his description of the colours of 35, 36, and 55, by asking him the colours of 49, 72, and 14; and my notes state that he made "ready replies."

49 was blue and green.
72 ,, pink and brown.
14 ,, black and blue.

I had already noted his statement that the colours of 35, 36, and 55, were "in their proper order."

Now obviously there is a marked difference between the colours of the numerals above 19—or possibly above 10—in this case and those seen by Miss A. M.; for she sees apparently all the twenties, thirties, forties, etc., in the colour of the first digit; whereas my son saw each digit in its own colour and unaffected by the combination with another. The deliberate tests with 49, 72, and 14, following his account of 35, 36, and 55, and the remark about the "proper order" of the colours, were conclusive on this point.

There is another matter of interest. Having told me the colour of 8 already, he was surprised at my asking the colours of 80 and 800, and replied that of course they were the same as 8. In other words, the zero was really zero to him, and therefore had no colour. Now in teaching him arithmetic during the preceding months I had endeavoured to make him realise that the value of a digit depended upon its position, and that the zero was simply a shorthand symbol for an empty place. His coloured thinking satisfied me that I had completely succeeded, and that the cipher 0 was really *nothing* to him.

I note that Miss A. M. sees 20, 30, 40, etc., coloured as 2, 3, 4, etc.; but since, apparently, 20–29 are coloured as 2, 30–39 as 3, and so on, there is no such inference possible in her case. It would, however, be of interest to learn whether she sees 0 coloured or not.

There was one exception to this nonentity of zeros in my son's mind; for he described 1000 as always yellow, adding that "it ought to be black really [*i.e.* the colour of 1], but it is not; that's the funny thing; it does not come in proper order." My interpretation was that a thousand seemed to him something so big and important that it stood by itself and rather out of relation to the lower numbers; and I suspect that, had he known it only as "ten hundred," it would have been duly black.

It will be observed that, although on the earlier occasion he gave no specific colours to 1 and 2, yet his colours for 10, 11, and 12 accorded pretty well with the colours assigned on the second occasion to 1 and 2. Otherwise there is no discrepancy between the two records.

I obtained from him also the colours of the points of the compass, of the names of various towns and countries, and of sundry other names; but too much space would be occupied by the account and discussion of these. He told me that "nearly everything I can think of is coloured."

My daughter similarly has coloured concepts; but she has also what I do not remember ever to have seen described in anyone else until I read Prof. Harris's letter, and that is *coloured tastes*. I think, too, that tastes are more strongly coloured for her than for Miss A. M. She has frequently, to our amusement, spoken of things having "a mauve taste"; and when we were discussing coloured thinking last vacation she remarked that "of course all tastes are coloured."

Prof. Harris emphasises the normally hereditary character of coloured thinking. A few words have always been coloured for me, and in a vague and misty way many probably are; but if I try to see (mentally) what precisely the colours are, I cannot succeed. It seems rather as though some words had polished or glittering surfaces, or a sheen, and reflected light, while others were sombre and light-absorbent. When I read Galton's book about thirty years ago I realised that I saw the numerals in a psychogram.

My wife, after declaring that coloured thinking was utterly unintelligible to her, mentioned that, of course, the vowels are coloured, and that she had supposed they were for everyone, but that the consonants are not. It appears, therefore, that my children started from a slight, but twofold, hereditary tendency to coloured thinking. FRANK H. PERRYCOSTE.

Polperro, Cornwall, February 12.

The Effects of Oil from Ships on Certain Sea-birds.

SIR ARTHUR E. SHIPLEY has recently directed attention to the probable effects upon our fisheries of the discharge of oil from ships into the sea. I should like to refer to another side of this matter, viz. the effects upon certain species of sea-birds.

For our present purpose we may divide sea-birds into three groups according to the number of eggs they hatch per season, and, further, in each group we may distinguish certain species as divers. All, I believe, are single-brooded.

In the first group we have those species which hatch a single egg each season, such as the petrels, fulmars, sherewaters, and the razorbill, kittiwake, guillemot, little auk, puffin, etc. In the second group are the terns and the great northern and black- and red-throated divers, usually hatching two eggs per season. With the exception of the cormorant and the shag, Group 3 consists of the more littoral species (chiefly Laridæ), which produce three or more eggs per season, and scarcely bear upon the present subject.

During the past five years large numbers of those species which dive beneath the surface of the water in order to obtain their food have been washed up on the Fife coast and elsewhere dead or in a dying condition and covered with a thick coating of oil. The actual total of dead birds must be enormous. In one day we counted more than 300 kittiwakes and almost the same number of razorbills and guillemots, and dozens of little auks and puffins, and this is of frequent occurrence. On the west sands at St. Andrews in October last dozens of dead gannets in a similar condition were washed ashore. Even admitting that these represent a concentration from a great sea area, the oft-repeated occurrence indicates a new factor of disturbance which is proving inimical to a large percentage of these birds. If this continues, or the disturbing factor grows more serious, the possibility of the extermination of such species seems not at all unlikely.

It is a generally accepted biological principle that the rate of reproduction of a species is a character very slow to change, and in the case of slow breeders, such as the species here referred to, any unusual factor leading to a higher rate of mortality can only lead to very serious consequences.

WALTER E. COLLINGE.

The University, St. Andrews.

The Annular Eclipse of the Sun on April 8.

As the annular eclipse of the sun on April 8 next may be of considerable interest to amateur observers, I am preparing a list of observations which may be made both within and without the region of annularity, and also full instructions for making the observations. Should any readers of NATURE care to suggest observations which might be made with small telescopes and the equipment generally possessed by an amateur, I should be very glad to receive their suggestions. May I also add that I am proposing to observe the eclipse from a point near the central line (probably Benbecula, in the Outer Hebrides), and if other amateurs would care to join me, would they please communicate with me with the view of forming a party? J. HARGREAVES.

The Priory, Royston, Herts, February 2.

A Rare Example of Melanism.

I WOULD like to record the occurrence of a rare case of melanism. Mr. Carl Carinus, in Rhodesia, sent me the complete skin and skeleton of an adult female oribi. It was entirely black, without any trace of white or red. The female was in the company of an adult male of normal colour.

F. W. FITZSIMONS.

Port Elizabeth Museum, Port Elizabeth,
January 27.

French Chemical Industry during the War.

IN the November–December issue of the *Bulletin de la Société d'Encouragement pour l'Industrie nationale* Prof. Haller gives a detailed and interesting account of the way in which the requirements of the fighting forces in munitions were met, and of the activities of French chemists in extending, improving, and creating processes for the manufacture of the necessary materials on the large scale.

The official policy before the war was to lay in stocks of explosives sufficient, in the judgment of the military authorities, to last out a "short, sharp war." The phenol required was obtained from Germany. In the middle of September, 1914, the use of explosives by the artillery was exceeding very considerably the amount estimated by the military authorities, and it was necessary to provide daily 40,000–50,000 75-mm. cartridges and to make schneiderite and ammonium perchlorate for trench mortars. The need for explosives continually increased, and it became evident that the character of the war was not at all like that for which the country had been prepared. A great national effort was required, and the part which the chemists of France played in this can be appreciated from the following table, giving the requirements of the Army in metric tons per day:

	Propellants	Nitrogenous explosives	Chlorate and perchlorate explosives
Mobilisation	24	0	0[1]
January 2, 1915	80	100	—
June 6, 1915	104–135	125–195	—
October 19, 1915	238–313	351–654	109–135
December 25, 1916	441–550	728–936	150–159
June 25, 1917	484–640	859–940	124–148
February 28, 1918	444	625	—

[1] Provided in stocks accumulated.

After April, 1918, the requisitions for explosives amounted to about 390 tons per day.

Sulphuric Acid.—Before the war there were 87 scattered works for the manufacture of sulphuric acid, producing 13,500,000 tons of 53° Bé. acid, of which 975,000 tons were used for the manufacture of superphosphates and the rest concentrated to 66° acid. This output was reduced by 15–20 per cent. by enemy occupation of territory. The production of explosives called for large quantities of concentrated acid, and steps were taken to force the production of the chambers from 5–6 kg. of acid per cu. m. to 7–8 kg., and to increase the Kessler and Gaillard concentrating plant in the ratio of 1 to 20. The use of acid was also restricted in industry, and nitre-cake began to be used in August, 1915. The Volvic lava of Puy-de-Dôme proved invaluable in the construction of concentrating apparatus. In addition, there were needed for the transport of acid 2000 20-ton tank wagons, 600 platforms for which were made in England and Spain.

Oleum containing 20 per cent. of sulphur trioxide was exclusively used, the consumption amounting to 1·5–1·9 tons per ton of nitrocellulose, and 2·2 tons per ton of trinitrotoluene. The oleum was, at the outbreak of war, made in a few works only, one of which, at Thann (Alsace), came under fire in 1914, and was transported by night to Saint Denis, where it was re-erected and came into operation in 1916. All the common processes (Tentelew, Grillo, and Mannheim included) were used, and a monthly output of 21,000–22,000 tons was secured. New works were put in hand, and in the meantime oleum was imported from America. The monthly consumption of sulphuric acid and oleum was as follows, in metric tons:—

	66° Bé. acid	20 per cent. oleum
February, 1915	6,000	1,000
January, 1916	42,000	5,000
January, 1917	80,000	20,000
January, 1918	60,000	19,000
June, 1918	40,000	18,000

Nitric acid was produced before the war almost exclusively from Chile nitre by the retort process, and during the war great extensions of these plants were made. The stock of nitre at the end of 1915 amounted to 90,000 tons; it increased during 1916, but from the beginning of 1917, when the submarine campaign was begun, the stocks of nitre diminished. In 1917 numerous ships laden with nitre were torpedoed. On account of the large amounts of raw material (coal, pyrites, and nitre) required in the manufacture of explosives, necessitating great shipping demands, it was decided in 1917 to ask the American Government to supply explosives ready-made. A programme was agreed upon, but the actual deliveries from America fell far short of the promises. Help was also given by Great Britain. The consumption of nitre and nitric acid (calculated as sodium nitrate) in metric tons per month was as follows:—

January, 1915,	3,600	March, 1916,	25,000
August, 1915,	9,600	July, 1917,	42,000

On account of the transport and storage difficulties it was decided to produce nitric acid by synthetic methods. These had an additional advantage, *i.e.* the economy in sulphuric acid which would otherwise be required in decomposing the nitre, which was even more important than the nitric acid. Before the war synthetic nitric acid was made by the Pauling arc process at La-Roche-de-Rame at the rate of 2 tons of 50 per cent. acid per day. This was continued, but a new factory on the Birkeland-Eyde principle was erected by the Société norvégienne de l'azote at Soulom, utilising 12,000 kw. from the hydro-electric installation in the Hautes Pyrénées of the Compagnie des chemins de fer du Midi. This works delivered 300 tons of nitric acid a month, partly as nitrates. The ammonia oxidation process was also largely used, the ammonia being derived from cyanamide. The first works was installed at the Poudrerie nationale d'Angoulême. Carbide was imported from Switzerland and converted into cyanamide by the Société des Produits azotes, nitrogen being obtained by the Claude process at Martigny, Notre-Dame de Briançon, and especially Bellegarde. From 2650 to 3500 tons of cyanamide per month were delivered at Angoulême. The first oxidation plants were operating in the autumn of 1916, and the whole were in operation in 1917. The programme was much enlarged in 1917 on account of the submarine warfare, and it was then decided to erect factories for making 500 tons of nitric acid and 150 tons of ammonium nitrate per day by the oxidation of ammonia. This programme required 800 tons of calcium carbide per day and 125,000 kw. Water-power from the Pyrenees, Central France, and the Alps, and even central steam-power plants at Nanterre and Carmaux, were brought into requisition. The most important works was at Lannemezan (50,000 kw.), and new oxidation works were installed at Toulouse, Bassens, Sorgues, and Saint Chamas. Toulouse and Bassens had begun to operate at the armistice, and the others were nearly finished. These works would have supplied all requirements in nitric acid and ammonium nitrate.

Alcohol was used, apart from minor requirements in the purification of trinitrotoluene and xylite, for the manufacture of ether for the gelatinisation of gun-cotton. Great economy was effected during the war in the latter process, the quantity of alcohol per ton of Poudre B being reduced, by solvent recovery, from 20 hl. to 8 hl. A sixty days' stock of alcohol had been accumulated and arrangements made with distillers for the regular supply of 550 hl. per day, sufficient for the estimated need of 24 tons of Poudre B. As the war proceeded, new supplies had to be obtained from the distillation of beets, molasses and cider, the saccharification of grain, horse-chestnuts and sawdust, and by recovery from stocks of confiscated absinthe and from liqueurs. Before the war the production of alcohol in France was 2,000,000 hl. per annum, with 6000 hl. of brandy per day, and was principally obtained from beets cultivated in the Départmente du Nord. The German occupation deprived the nation of this source, and there were labour difficulties. In August, 1915, the distilleries and stocks were requisitioned, and forced production was begun. From absinthe 40,000 hl. were obtained, 10,000 hl. from apples mixed with beets, and 500,000 hl. were imported from Canada and the United States. Experiments were made on synthetic alcohol from acetylene, with encouraging results. The total consumption of alcohol to (and including) 1918 was 4,713,607 hl.

Ether was made at the rate of 74 tons per day in 1915, 119 in 1916, and 166 in 1917, mostly in Government factories.

Aromatic hydrocarbons (benzene, toluene, and xylene) were used in large quantities, and their provision was one of the most difficult problems to be solved. The pre-war annual production of crude benzol from coking plants did not exceed 16,000–18,000 tons, the rest being imported from England and Germany. The yield from coking plants in occupied territory was a considerable loss during the war, and not more than 3–4 tons per day could be expected from the remaining plants, although 50 tons in 1915, and later as much as 250 tons, per day were required. Needs were supplied by the requisition of stocks, imports from England and (to a less extent) from America, the re-starting and erection of recovery ovens, extraction from town gas and from Borneo petroleum. The use in private factories was restricted, and every available means of rectification was brought into requisition. From one-third to one-fourth of the weight of crude benzol was recoverable as toluene, although the English supplies had been detoluated previous to export. Borneo petroleum was an important source (35–40 tons per day). Three fractions were obtained. The benzene fraction boiled at 80–81° C., the toluene fraction at 110–112°, and the xylene fraction at 130–132°. These fractions were nitrated and the unattacked hydrocarbons distilled off. The mononitrotoluene and mononitroxylene were converted into trinitrotoluene and xylite, the nitrobenzene being sent to the aniline factories for conversion into diphenylamine for use as a stabiliser. The production of trinitrotoluene rose from 10 tons per day in 1915 to 50 tons in 1916 and 60 tons in 1917.

Phenol and *metacresol* were used for nitro-explosives. Before the war all the phenol had been imported from Germany, and a large amount of work was necessary before the production from benzene (by fusion of sodium benzenesulphonate with caustic soda, and 2–3 tons per day from aniline by diazotisation) was in operation. The supplies of synthetic phenol (excluding relatively unimportant American imports) rose from 200 tons in 1914 to a maximum of 52,747 tons in 1917.

After the explosion in the *Liberté* in 1911, large quantities of gun-cotton were thrown into the sea outside Toulon. This was recovered in excellent condition and utilised. The two State factories of Angoulême and Moulin-Blanc were developed for the manufacture of propellants. New factories were later erected at d'Empalot (Toulouse) and Bergerac. The maximum productions of gun-cotton per day reached 120 tons at Angoulême, 38 tons at Moulin-Blanc, 140 tons at Toulouse, 100 tons at Bergerac, and 35 tons from private firms. Cotton cellulose was exclusively used. The preliminary washing and extraction of grease were carried out mainly at Angoulême, and to a less extent in paper- and dye-works. More than thirty works supplied 240 tons of cotton daily, sufficient for 360 tons of gun-cotton, which was brought up to 433 tons in 1916 by American importation. Nitration, with a mixture of nitric and sulphuric acids, was before the war carried out in pots. This method required much less apparatus than the new methods of Selwig and Thomson, which were introduced only when a crisis in the supply was feared. Pots were used at Toulouse, Angoulême, Bracqueville, and Bergerac. Angoulême later installed a Selwig plant for 60 tons, and replaced a pot installation by one using the Thomson process. The same change was effected at Bracqueville, and a Selwig plant was installed at Bergerac. The nitro-cotton, after washing, was stabilised by boiling with water, pulped, and dried to 30 per cent. moisture. Two varieties were made, CP_1 with 11 per cent. of nitrogen, soluble in a mixture of alcohol and ether, and CP_2 with 13 per cent. of nitrogen, insoluble in that mixture.

Poudre B was made by masticating the requisite proportions of these two varieties with a mixture of alcohol and ether, pressing into filaments, and drying. This was carried out at Le Bouchet, Pont-de-Buis, Ripault, Saint Médard, Sevran-Livry, Bergerac, and Toulouse. The maximum productions in tons per day from these works were 10, 48, 60, 140, 35, 60, and 130 respectively. Private industry furnished a maximum of 20 tons of ballistite (gelatinised nitro-cotton with nitroglycerin). The total production of Poudre B in France from 1914 to 1918 amounted to 306,693 tons, and 117,000 tons were during this period imported from America.

The manufacture of nitro-explosives was accompanied by strenuous endeavours to improve the methods of production and to replace these substances by others less difficult to produce. The 75-mm. shells, for example, were filled with ammonium nitrate and dinitronaphthalene; chlorates and perchlorates were introduced for filling hand grenades; and experiments were made with liquid air for charging aeroplane bombs.

The nitro-bodies picric acid and trinitrometacresol could be manufactured by known methods, but the production of trinitrotoluene, xylite, dinitrophenols, and mono- and di-nitronaphthalenes was introduced during the progress of the war. These explosives were used both alone and in the form of mixtures.

Three methods are available for the manufacture of picric acid (trinitrophenol): nitration of phenol in presence of sulphuric acid by nitric acid or sodium nitrate; chlorination of benzene, transformation of monochlorobenzene into dinitrochlorobenzene 1, 2, 4, saponification of this with formation of dinitrophenol, and trinitration of the latter; direct oxidation and nitration of benzene with nitric acid and mercury. The method of direct nitration alone was used. The second method was in use in Germany prior to the war, but as it required the use of pure chlorine it was not suited to French needs. Nevertheless, 1000 tons of chlorine were ordered from America in order to commence production in France. After the German gas attack of April 22, 1915, on the Belgian front, this chlorine was devoted to experiments on the new method of warfare. In the meantime the production of phenol had increased, and there was no longer any point in making use of the method of chlorination. The yield by the third method was poor (140 of picric acid per 100 of benzene, as compared with 190 with phenol), and the recovery of the mercury was difficult. The latter was important in view of the pressing need of mercury for the manufacture of fulminate. Picric acid so prepared may also contain small amounts of mercury picrate, which renders it very sensitive to shock.

There were three picric acid factories in operation before the war. Several chemical and dye factories in the Lyons district were requisitioned, including one of the Badische firm. State factories were also erected. Some of these factories were destroyed by explosions. The total productions of picric acid and trinitrotoluene, in tons per day, were as follows:—

Production of Trinitrotoluene in metric tons per day.

August, 1914, 0·31	January, 1917, 66·71 (maximum
August, 1915, 8·93	January, 1918, 24·02
August, 1916, 55·87	

Production of Picric Acid in metric tons per day.

August, 1915, 0·50	July, 1917, 166·1 (maximum)
January, 1916, 11·95	January, 1918, 58·86
January, 1917, 145·47	

Lack of cresol led to the use of dinitrophenol, made by nitrating phenolsulphonic acid. Picric acid was also formed, but as a mixture of the two substances was finally used, this was immaterial. The preparation by the nitration of chlorobenzene led to the installation of electrolytic chlorine apparatus producing 20 tons of chlorine per day.

The explosive *schneiderite* was used in large quantities, and was prepared by triturating in mills a dry mixture of 88 parts of ammonium nitrate and 12 parts of dinitronaphthalene. The ammonium nitrate was prepared to some extent by double decomposition of accumulated stocks of Norwegian calcium nitrate (for agricultural purposes) with ammonium sulphate, by neutralising nitric acid with ammonia solution, and by the interaction of ammonium sulphate and sodium nitrate according to a process worked out by M. Fosse, of Bordeaux, and by M. Danne, of Gif. Nearly all the ammonium nitrate, however, was imported from Norway at the rate of 200 tons per day.

Chlorate and perchlorate explosives were also manufactured. Paraffined ammonium perchlorate was tried for filling 75-mm. shells, but proved too sensitive to shock. It was, however, extensively used for trench-mortar bombs, hand grenades, and aeroplane bombs. Sodium chlorate and a mixture of 61·5 parts of ammonium perchlorate, 30 of sodium nitrate, and 8·5 of paraffin were used. The chlorates and perchlorates were made electrolytically at Cheddes, Vonges, Castres, and Grenoble, the production being 79 tons of ammonium perchlorate and 77 tons of sodium chlorate per day.

Many new products were made. Mustard gas, known as "yperite," was produced at the rate of 6 tons per day at the signing of the armistice, and plant for the manufacture of 12 tons per day was ready to be put into operation. A daily production of 24 tons was planned. Liquid nitrogen peroxide was produced at the rate of 70–80 tons per day at Angoulême, and of 25–30 tons at Bassens. It was used with a hydrocarbon in the manufacture of "anilithe" for aeroplane bombs.

Switzerland, Italy, and Spain delivered machinery and raw materials of various kinds; Chile furnished millions of tons of sodium nitrate; and Norway supplied more than 200,000 tons of ammonium nitrate. England supplied benzene, naphthalene, and coal, and America sent raw materials and finished explosives.

The tremendous strides made during the war may be appreciated from the following table, giving the productions in tons per day:—

	Before 1914	July, 1917
Poudres B	15	370
Nitro-explosives	6	700
Chlorate explosives	4	176

War-time Archæology.[1]

THE volume before us might truly be described as a "war number," for it represents not only the published work of the British School at Athens for the first regular session after the armistice, but also mainly the results of observations made while on duty by actual and former students. The seven students of the British School of Archæology who lost their lives during the war, and the school's distinguished and learned librarian, F. W. Hasluck, who died early in 1920 of a malady caused or aggravated by war service in Greece, are appropriately commemorated, and a brief summary shows the war work which fell to other students. It is a striking and varied record. If the school had done nothing beyond training for eventual public service in Greece and the Near East so large a body of men accustomed to observe accurately, handle native labourers tactfully and economically, and act with expert knowledge and executive efficiency, it would have earned many times over the miserable allowance which it receives annually from the Treasury. Special mention is made in the annual report and in a letter of thanks from the Secretary of State for Foreign Affairs of the services of the director, Mr. A. J. B. Wace, who was attached to the British Legation at Athens during the war while carrying on the school as a hostel for British officers in transit or on duty in Greece.

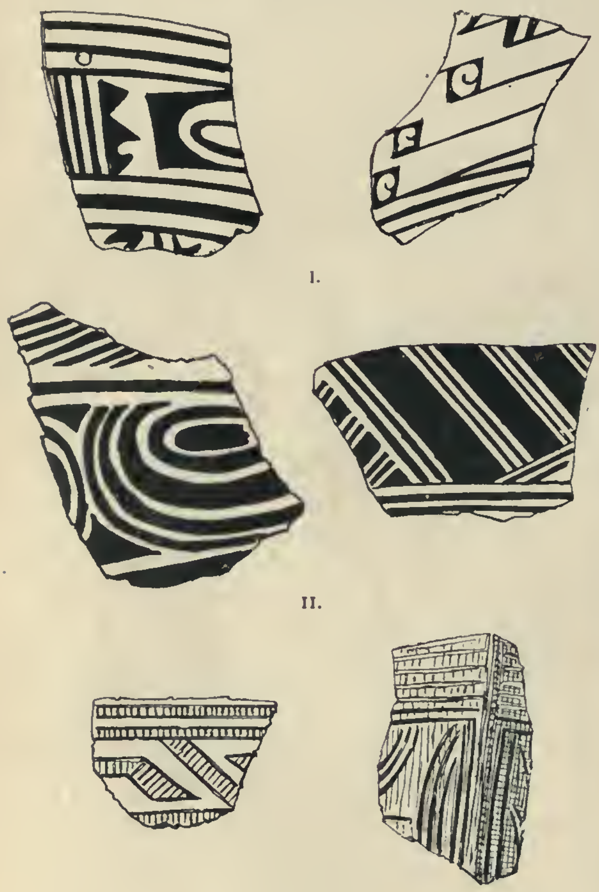

FIG. 1.—Specimens of prehistoric pottery from Dikilitash. I. Dimeni ware; fine reddish biscuit, surface usually bright chestnut; patterns, a mixture of geometrical and curvilinear figures in dull brown paint. II. Black or red biscuit; patterns, geometrical designs, parallel lines in sets of threes, and rows of concentric circles, in dull white paint. III. Coarse black or red biscuit; patterns, similar to those of I. and II. filled in with cross-hatching or painted; specimen on right is painted and incised. From "The Annual of the British School at Athens."

FIG. 2.—Wall of ruined fort near Kato Kastelli, in ancient Doris. From "The Annual of the British School at Athens."

The greater part of the volume is devoted to the publication, by Prof. E. A. Gardner, Messrs. Carson, Welch, Woodward, and others, of sites, inscriptions, and other antiquities discovered during the British occupation of Salonica. This district was previously very ill-explored, but numerous finds were made in trenching operations and military surveys. The contents of the museum formed at British G.H.Q. have now been presented by the Greek Government to the British

[1] "The Annual of the British School at Athens." No. xxiii. Session 1918–19. Pp. xvi+260+xvi pls. (London: Macmillan and Co., Ltd., n.d.) Price 30*s*. net.

nation, and are placed in the British Museum. The corresponding discoveries in the French zone of occupation, further west, are summarised by Capt. Ch. Picard, now director of the French Archæological School at Athens. The finds in both zones were of all periods. The most novel illustrate the earlier periods from the Neolithic to the early Iron age, revealing new distributions of pottery styles, and types of primitive figurines, and raising a number of questions which can only be solved by systematic excavation as soon as local conditions allow.

FIG. 3.—Ruins at Hagia Sophia in Lemnos. From "The Annual of the British School at Athens."

Mr. M. N. Tod publishes twenty-five Greek inscriptions from the same district, and Mr. A. M. Woodward adds a note on the Byzantine castle of Avret-Hissar (*Gynaikokastro*).

Other war surveys are published by Mr. F. W. G. Foat, who was in charge of "educational work on topography and archæology" at the Y.M.C.A. rest camps in ancient Doris, and on the island of Lemnos by Mr. F. L. W. Sealy, who appends also notes on birds and fishes observed there. Mention should also be made here of Mr. Hasluck's paper on "The Rise of Modern Smyrna."

Further afield, Mr. S. Casson, who was for a while in charge of the Salonica Museum, made good use of a flying visit to the Caucasus and Western Turkestan to describe an extensive series of prehistoric mounds, and to throw fresh light on Herodotus' account of the ancient routes eastward from Scythia.

Other papers, such as those on the fictitious legend of "Saint Gerasimos and the English Admiral" and on "The Folklore of a Turkish Labour Battalion," illustrate more special aspects of research under war conditions, and also the great variety of subjects which are studied by members of the British School at Athens.

The Annular Eclipse of April 8.

By DR. A. C. D. CROMMELIN.

THE occurrence of a central solar eclipse within the limits of the British Isles is a somewhat rare event. On the average, one total eclipse is visible here in seventy years, and one annular eclipse in about sixty years. It is, therefore, noteworthy that the decade now commencing supplies examples of both. There has been no British total solar eclipse since 1724, the interval being about three times the average; the last annular eclipse was in 1858. After the present decade there will be totalities in 1999 and 2090, and annularity in 2093.

The central line on April 8 passes across South Uist, just misses Cape Wrath, and then runs a few miles north-west of the Shetlands. The south limit of annularity enters Scotland near Ardnamurchan Point, and runs nearly parallel to the Caledonian Canal, emerging near Wick. Thus practically the whole of the counties of Ross and Cromarty, Sutherland and Caithness, and a corner of Inverness, together with the Outer Hebrides, Skye, and the Orkneys and Shetlands, will enjoy the annular phase.

The eclipse occurs about 9 a.m., the sun's altitude being about 23°; the duration of annularity is 111 sec., the width of the annulus of sunlight being 26″. This implies that 1/19 of the sun's disc will remain uncovered; in other words, the illumination will exceed normal sunshine on the planet Jupiter. Remembering what a resplendent object Jupiter appears in the night sky, it will be seen that there will be nothing approaching darkness. Venus will doubtless be readily visible, about 20° east of the sun; it will be a slender crescent, inferior conjunction occurring a fortnight later. The only other object that may possibly be visible is Vega, which will be high in the west, three hours past the meridian.

Dr. J. K. Fotheringham, who has made a special study of the records of ancient eclipses, intends to examine the question of its visibility, as it is important to know what degree of solar obscuration is implied by the frequently recurring phrase, "Stars were visible." It is used, for example, by Thucydides with reference to an eclipse which was not total anywhere.

As regards useful observations that may be made in the coming eclipse, the exact times of the beginning and end of annularity can be accurately noted, especially by the method of projection upon a white screen; they serve to correct the position of the moon; those who cannot determine absolute time can still do good work by timing the exact duration of annularity; this applies especially to observers fairly near the limit of annularity. Prof. Newcomb found numerous records of this kind, made in England during the total eclipse of 1715, which enabled him to correct Hansen's value of the centennial motion of the moon's node. Photographs taken about mid-eclipse, on as large a scale as possible, would be of value for determining the difference of the diameters and ellipticities of sun and moon.

Useful spectroscopic work can also be done, the diminution of sky-glare being of service in photographing the prominences or reversing layer. The British Astronomical Association, which has experience of a great number of eclipses, is prepared to organise work if a sufficient number of observers send in their names.

It is possible to reach observing stations by rail, either on the line to Wick and Thurso, or on that running westward from Dingwall to Loch Alsh (for Skye); the journey from London to the eclipse zone is in the neighbourhood of twenty-two hours, and the return fare (third class) in the neighbourhood of 8*l.* at present rates. The season is probably too early for the steamboat services, otherwise these would afford a ready means of reaching observing stations on the mainland or islands.

Besides astronomical work, the eclipse affords opportunities for at least three other studies: (1) Meteorological. The temperature is directly affected, and there are frequent indirect effects on barometer, wind, and cloud formation. (2) Magnetical. The work of the Carnegie Institution of Washington, under Prof. L. Bauer, has established a connection between eclipses and the elements of terrestrial magnetism. Such a connection is in no way surprising, for the diurnal variation in these elements has long been known, so it is to be expected that the interposition of the moon should act similarly to the interposition of the earth during the night hours. (3) Wireless telegraphy. A notable improvement in the clearness of signals has been observed during eclipses, which is again analogous to what happens during the hours of darkness. Advantage might be taken of this to make time comparisons for longitude about the time of greatest eclipse. The eclipse is large enough for this purpose throughout the British Isles. The magnitude at Edinburgh is 0·95; Dublin, 0·94; Oxford and Cambridge, 0·89; and Greenwich, 0·88.

FIG. 1.—Track of the annular eclipse of April 8, 1921.

There will be a total solar eclipse in England and Wales on June 29, 1927 (civil). The central line will run from near St. David's Head to near Whitby, where the sun will have risen about $1\frac{3}{4}$ hours, and totality will last 24 sec. At the total eclipse of January 24, 1925, the track of totality will graze the Western Hebrides, but with a very low sun. It will be necessary to go to the neighbourhood of New York for effective observations on that occasion.

Obituary.

PROF. EMILE BOURQUELOT.

BY the death of Emile Bourquelot, Professor of galenical pharmacy in the University of Paris, science has sustained an irreparable loss. Born in a small village in the Ardennes in 1852, Bourquelot was apprenticed in a pharmacy in Sedan while the town was still occupied by the Germans. He afterwards became chief pharmacist in the Hôpital Laeonec, and then successively assistant professor and professor of galenical pharmacy in the Ecole Supérieure de Pharmacie, now the faculty of pharmacy in the University of Paris. Bourquelot at once devoted himself to the investigation of various pharmaceutical problems, but gradually restricted himself almost entirely to the study of the enzymes occurring in drugs and various plants, their action and the changes brought about by them in the constituents of drugs and their galenical preparations. His researches in this direction, often in conjunction with M. Hérissey, M. Bridel, and other of his assistants and pupils, gained for him a world-wide reputation. His investigation of the constituents of gentian root and of the changes brought about by enzymes during the drying of the root and the making and keeping of preparations made from it may well serve as a model for future workers. The latter years of his life were mainly devoted to the study of the synthetical as well as the analytical action of enzymes, in which field remarkable results were obtained.

To his scientific attainments Bourquelot added a personal charm that fascinated everyone brought into contact with him. His unfailing courtesy and friendly disposition endeared him to all. He was one of the most eloquent of lecturers, and those who were fortunate enough to hear his lecture on "The Synthesis of Glucosides by Ferments" at the International Congress of Pharmacy at The Hague in 1913 will long remember his admirable lucidity, clear enunciation, and exquisite delivery.

Though Bourquelot had been in indifferent health for the last two or three years the end came with dramatic rapidity, and pharmacy was robbed of one of its most brilliant exponents.

COL. R. A. WAUHOPE.

COL. R. A. WAUHOPE, whose death is announced, was, perhaps, better known for the splendid quality of his practical work at map-making on the Indian frontier (and beyond it) than for researches into those branches of geodetic science which form the special objective of that section of the Indian Survey Department which is centred in Dehra Dun. He was one of the first and best of those surveyors who reformed the antiquated methods of geographical reconnaissance and proved that sound square mapping may be evolved on precisely the same principles of triangulation and topography in the field of an expedition or a campaign as govern the output of Ordnance mapping in the quiet fields of home survey.

Col. Wauhope's science consisted in the clever combination of exact methods, where they were possible, with the scientific adaptation of inexact methods (that is to say, methods not ordinarily recognised as permissible under normal conditions of map-making), and obtaining therefrom results which have proved to be satisfactory. The best instance of such adaptation was afforded when he fixed the initial point of the Russo-Afghan boundary at the head of Lake Victoria, in the Pamirs, by the method of instrumental resection from distant Himalayan peaks (the position of which had been determined by a regular geodetic series of the Indian triangulation) in circumstances where direct intersection from a regular series across the Himalayas was impossible. Such a direct series was eventually carried through with much difficulty and at great expense of money and time from India to the same point, when it was found in the first place that the result in absolute values of latitude and longitude was almost coincident with Wauhope's value, and, in the second, that it was doubtful whether the result of direct triangulation completed under abnormal conditions was the more trustworthy of the two. In this special case it must be remarked that few surveyors possess that physical capacity which enabled Col. Wauhope to attain the elevations necessary for observation.

T. H. H.

MR. GEORGE CLINCH, the librarian of the Society of Antiquaries, whose death, on February 2, we regret to record, joined the staff of the society in January, 1896, having previously been employed at the British Museum. In May, 1886, he exhibited to the society a collection of flint implements found by him during eight years in West Wickham, Kent. In December, 1888, Mr. Clinch reported to the society the results of excavations made by him during the ten previous years in the supposed pit-dwelling at Hayes Common, in the same county. Later, he published a volume entitled "Antiquarian Jottings," describing in a popular manner these and other researches in the same district. Mr. Clinch also wrote a number of the "Little Guides," and a work on old English churches. He prepared the annual Lists of Archæological Papers after they had been discontinued by Sir Laurence Gomme. As librarian he earned the esteem of the fellows and others using the library by his courtesy and readiness to assist. He was in his sixty-first year.

THE death is announced, in his sixty-sixth year, of DR. WILLIAM THOMPSON SEDGWICK, who had been connected with the Massachusetts Institute of Technology since 1883 as successively assistant professor, associate professor, and full professor of biology. He had also been, since 1897, curator of the Lowell Institute, Boston, and since 1902 a member of the advisory board of the hygienic laboratory of the U.S. Public Health Service. Prof. Sedgwick was author of "Principles of Sanitary Science and Public Health," and joint author of "General Biology," "The Human Mechanism," and "A Short History of Science."

WE much regret to announce the death, on February 17, at ninety-one years of age, of DR. W. ODLING, F.R.S., Waynflete professor of chemistry at the University of Oxford from 1872 to 1912; also on February 21, at seventy-eight years of age, of PROF. L. C. MIALL, F.R.S., Emeritus professor of biology at the University of Leeds; and on February 22, in his eighty-fifth year, of PROF. R. B. CLIFTON, F.R.S., lately professor of experimental philosophy in the University of Oxford.

THE death is announced, on February 16, in his seventy-ninth year, of MR. C. GROVER, for many years astronomical assistant at Sir C. E. Peek's observatory at Rousdon, Devon.

Notes.

LORD MOULTON has been elected an honorary member of the Institution of Civil Engineers.

AT the meeting of the Royal Society on May 12 a discussion on "The Quantum Theory of Line-Spectra" will be opened by Sir Ernest Rutherford, followed by Dr. N. Bohr.

THE thirtieth annual meeting of the Royal Society for the Protection of Birds will be held at the Middlesex Guildhall, Westminster, S.W., on Tuesday, March 8, at 3 p.m. The Right Hon. Field-Marshal Lord Methuen, vice-president of the society, will occupy the chair.

PROF. C. S. SHERRINGTON, president of the Royal Society, has been elected a member of the Athenæum under the provisions of the rule of the club which empowers the annual election by the committee of a certain number of persons "of distinguished eminence in science, literature, the arts, or for public service."

THE council of the Royal Statistical Society will in November next award the Frances Wood memorial prize, value 30*l*., for the best investigation of any problem dealing with the economic or social conditions of the wage-earning classes. Particulars may be obtained from the honorary secretaries of the Royal Statistical Society, 9 Adelphi Terrace, W.C.2.

THE twenty-fifth anniversary of the discovery of the "Zeeman effect" will take place on October 31 next. A committee has been formed by scientific men in Holland to mark the occasion by showing their appreciation of the importance of the discovery and of the distinguished services which Prof. Zeeman has rendered to science. It is intended to raise a fund to be placed at his disposal for researches to be conducted in the physical laboratory of the University of Amsterdam. Any contributions to this fund may be sent to Sir Arthur Schuster, Yeldall, Twyford, Berkshire, who will forward them to the Dutch committee.

THE annual general meeting of the Institute of Metals will be held in the room of the Institution of Mechanical Engineers on Wednesday and Thursday, March 9 and 10. A paper on the recrystallisation of aluminium sheet by Prof. H. C. H. Carpenter and Constance F. Elam, and another on calcium by Mr. P. H. Brace, will be presented at the morning session on March 9. The afternoon session of the same day and the morning session of March 10 will be devoted to four papers on copper and copper alloys by Prof. C. A. Edwards and Mr. A. M. Herbert, Mr. H. Moore and Mr. S. Beckinsale, Mr. H. Moore, Mr. S. Beckinsale and Mr C. E. Mallinson, and Dr. J. L. Haughton. The afternoon session of March 10 will take the form of a visit to the National Physics Laboratory. The annual dinner of the society will be held on the evening of March 9

SIR FRANCIS YOUNGHUSBAND, president of the Royal Geographical Society, announced to the society on Monday that since the previous meeting of the Mount Everest Committee further progress had been made with the organisation of the expedition. Subject to the approval of the Government of India, Major Morshead and Capt. Wheeler will accompany the expedition as survey officers. Dr. Kellas, who has for many years devoted himself to Himalayan exploration, has accepted an invitation to join the expedition, and also Mr. G. L. Mallory and Capt. George Finch. Sir Francis Younghusband added:—"Our party for the reconnaissance is thus complete, and we are now engaged in equipping it in the best possible manner for the important work it will have to do this summer in examining the mountain from every angle and testing the possible ways by which its summit may be reached."

AT the annual general meeting of the Association of Economic Biologists, held in the Imperial College of Science on Friday last, the following were elected officers and councillors for the year 1921:—*President:* Sir David Prain. *Hon. Treasurer:* Dr. A. D. Imms. *Hon. Secretary* (*Gen. and Bot.*) Wm. B. Brierley. *Hon. Secretary:* (*Zool.*): Dr. S. A. Neave. *Hon. Editor* (*Bot.*): Wm. B. Brierley. *Hon. Editor* (*Zool.*): D. Ward Cutler. *Council:* Dr. W. Lawrence Balls, Prof. V. H. Blackman, F. T. Brooks, A. B. Bruce, Dr. E. J. Butler, F. J. Chittenden, A. D. Cotton, J. C. F. Fryer, Prof. J. B. Farmer, E. E. Green, Dr. G. A. K. Marshall, and Dr. E. J. Russell. In view of the very great increase in the publishing costs of the *Annals of Applied Biology*, it was decided to establish a "Publication Fund," to which all interested in the progress of biology and in its application to the welfare of man are invited to subscribe. Sir David Prain then delivered his presidential address on "Some Relationships of Economic Biology."

AT the annual general meeting of the Physical Society held on February 11, the following officers were elected:—*President:* Sir W. H. Bragg. *Vice-Presidents who have filled the office of President:* Dr. C. Chree, Prof. H. L. Callendar, Prof. R. B. Clifton, Sir Richard Glazebrook, Sir Oliver J. Lodge, Prof. C. H. Lees, Prof. A. W. Reinold, Sir Arthur Schuster, Sir J. J. Thomson, and Prof. C. V. Boys. *Vice-Presidents:* Prof. W. Eccles, Prof. A. S. Eddington, the Right Hon. Lord Rayleigh, and Prof. Sir Ernest Rutherford. *Secretaries:* Mr. F. E. Smith, National Physical Laboratory, Teddington, and Dr. D. Owen, 62 Wellington Road, Bush Hill Park, N. *Foreign Secretary:* Sir Arthur Schuster. *Treasurer:* Mr. W. R. Cooper, 82 Victoria Street, S.W.1. *Librarian:* Prof. A. O. Rankine. *Other Members of Council:* Dr. G. B. Bryan, Mr. C. R. Darling, Prof. C. L. Fortescue, Dr. E. Griffiths, Dr. F. L. Hopwood, Dr. E. H. Rayner, Dr. A. Russell, Mr. T. Smith, Dr. J. H. Vincent, and Prof. W. B. Morton.

REPORTS have appeared in the daily Press respecting a serum treatment for tuberculosis introduced by M. Henri Spahlinger, of Geneva, shortly before the outbreak of war. Preliminary trials of the serum have been made upon a small number of selected cases by physicians in London and Paris, and it is stated that cases treated in 1913 are still alive and well. The nature and mode of preparation of the remedy do not appear to be disclosed, but according to a communication made by Prof. D'Arsonval to the Paris Academy of Sciences, M. Spahlinger divides tuberculosis cases into two classes for purposes of treatment, (1) acute cases treated by means of "complex antitoxic and bacteriolytic serums" and (2) chronic cases treated by "vaccination with a series of antigens and ferments," the former being derived from the bacillary substance of the tubercle bacillus. Patients are finally treated with a series of injections of the different antigens given separately. The preliminary trials have apparently been so successful that a tuberculosis specialist is being sent by the Ministry of Health to Geneva to investigate at first hand the Spahlinger cure.

CONSIDERABLE concern has been expressed at the announcement that the Treasury contemplates the withdrawal of grants hitherto given to the Industrial Fatigue Research Board, and at the recent conference on this subject at Olympia a resolution was carried urging the Government to revoke this decision. It appears that the withdrawal of the grant is regarded as a measure of economy, but anyone conversant with industrial matters is aware of the great waste occasioned by unnecessary fatigue, both in slowing down the speed of production and in leading to accidents and ill-health. Rightly regarded, therefore, researches having for their object the elimination of such fatigue are essentially "economical." The work of the Board has hitherto been conducted on a modest scale, and its expenditure has been small in comparison with the importance of its field of operations. Other countries, we believe, have followed our lead in instituting such inquiries, and their discontinuance would be most regrettable. It is also to be feared that the step proposed in regard to the Industrial Fatigue Research Board will constitute a regrettable precedent by discouraging investigators from taking up work of this nature, and that it may be followed by the restriction or withdrawal of facilities for research in other directions. We sincerely hope that the efforts being made to induce the Treasury to revoke the decision will be successful.

IN accordance with the provisions of the Dyestuffs (Import Regulation) Act, 1920, the President of the Board of Trade has appointed the following Committee to advise the Board of Trade with respect to the granting of licences under the Act:—Mr. V. Clay (joint managing director, Robert Clay, Ltd.), Mr. G. W. Currie, Mr. G. Douglas (managing director, Bradford Dyers' Association, Ltd.), Mr. E. V. Evans (treasurer of the Society of Chemical Industry), Dr. M. O. Forster (director of the Salter Institute of Industrial Chemistry), Mr. C. C. Railton (director, Calico Printers' Association, Ltd.), Mr. H. B. Shackleton (Messrs. Taylor, Shackleton and Co., Shipley), Mr. T. Taylor (Cornbrook Chemical Co., Stockport), Mr. S. A. H. Whetmore (British Dyestuffs Corporation, Ltd.), and Mr. W. J. U. Woolcock (general manager, Association of British Chemical Manufacturers). Pending the appointment of a permanent chairman, which it is hoped to make at an early date, Mr. Percy Ashley, assistant secretary, Industries and Manufactures Department, Board of Trade, will act as chairman of the Committee. The secretary to the Committee is Mr. W. Graham, and all applications for licences should be addressed to the Secretary, Dyestuffs Advisory Licensing Committee, Danlee Buildings, Spring Gardens, Manchester.

THE Lord President of the Council has established an Inter-Departmental Committee on Patents with the following terms of reference:—(1) To consider the methods of dealing with inventions made by workers aided or maintained from public funds, whether such workers be engaged (*a*) as research workers or (*b*) in some other technical capacity, so as to give a fair reward to the inventor and thus encourage further effort, to secure the utilisation in industry of suitable inventions, and to protect the national interest; and (2) to outline a course of procedure in respect of inventions arising out of State-aided or supported work which shall further these aims and be suitable for adoption by all Government Departments concerned. As at present constituted, the Committee consists of the following members:—Dr. Kenneth Lee (chairman), Mr. W. St. D. Jenkins, Mr. F. E. Smith, Sir E. L. Ellington, Mr. H. W. W. McAnally, Mr. P. W. L. Ashley, Col. W. H. D. Clark, Sir H. Frank Heath, Mr. A. J. Stubbs, Dr. H. H. Dale, Mr. W. J. Coombes, Lt.-Col. P. K. Lewes, Mr. P. Tindal Robertson, Sir Richard Gregory, Mr. D. M. Kerly, and Sir Charles A. Parsons. The secretary to the committee is Mr. A. Abbott, to whom all communications should be addressed at 16 and 18 Old Queen Street, Westminster, London, S.W.1.

MR. F. H. CARR, in a paper on the post-graduate training of chemical students for industry read at a meeting of the Old Students' Association of the Royal College of Science on February 8, outlined a scheme involving the establishment of a technological teaching laboratory which would, in practice, be a miniature manufacturing concern, attached to a college, providing the necessary lectures and class-room instruction. The plant would be available for technical-scale experiments interpreting the results of research work from research institutions or elsewhere. Further, it would be utilised for the manufacture of those fine chemicals that are not ordinarily obtainable in the chemical trade, and of which a restricted and irregular supply is required by colleges and research laboratories. This manufacturing laboratory would be conducted under conditions of strict and complete business organisation and discipline. A fundamental object of the instruction suggested would be the introduction of the cost factor in relation to power, heat, labour, material, and yield, whilst a spirit of reality would be maintained by disposing of the products so far as possible through existing trade channels. The nature of the work, as exemplified in the syllabus, would be general, and would not be identified with any particular branch of industry; it would keep in view the necessity for a training in the broad principles underlying chemical technology. If possible, arrangements would be made for the students to attend manufacturing works for courses of practical instruction, and special teaching would be provided by men actually engaged in the various specific chemical industries. An interesting feature of the discussion which followed Mr. Carr's paper was the united praise bestowed upon Prof. J. F. Thorpe's scheme—now approaching completion—of a technical-scale laboratory to be established as an adjunct to the Honours Organic Laboratory at South Kensington.

In the January issue of *Man* Mr. T. A. Joyce describes a carved wooden coffer from British Columbia which has been recently acquired by the British Museum. It is a fine specimen of native work, the central panel on one side representing a grizzly bear protecting its cub. The eyes, ears, nostrils, and fore-paws of the bear are inlaid with abalone (haliotis) shell, while the mouth of the larger figure is furnished with twelve graduated deer-teeth. Coffers of this kind were used by men of rank for storing valuable property, such as the hereditary insignia worn by individuals who had the right of impersonating certain legendary and supernatural beings at the winter ceremonials. The British Museum is indebted for the coffer to Mr. St. George Littledale, who obtained it and generously presented it to the nation.

Some time ago the Library Association instituted examinations in librarianship and granted certificates on the result. From the report of a discussion opened by Dr. W. E. Hoyle, and printed in the *Museums Journal* for February, it appears that the Museums Association contemplates similar action. Taking as a *sine qua non* a high standard of general education, the next essential is a good grounding in the particular branch of knowledge appropriate to the candidate's proposed work. Lastly follows a special training in museum administration and methods. Clearly it is in this last that the difficulty lies, both for training and for examining. Perhaps the most practical suggestion made in the discussion was that an apprenticeship should be served in the national museums. To some extent, by force of circumstances, that has been the case in the past, but it was not an accepted or organised method. Whether a man is to stay in the central museum or whether he is to take a post in the provinces, it is most desirable that he should pass through the mill and learn his business in the administrative and technical departments from the bottom upwards.

The first part of vol. lxv. of the *Quarterly Journal of Microscopical Science* marks a new era in the history of that well-known periodical. Prof. E. S. Goodrich has succeeded Sir Ray Lankester as editor-in-chief, and at the same time the publication has passed from the hands of Messrs. J. and A. Churchill into those of the Oxford University Press. Unfortunately, these changes are accompanied by a rise in price from 12*s*. 6*d*. to 1*l*. 1*s*. per number. We hope that this increase will not be counterbalanced by a corresponding decrease in the number of subscribers.

The current issue of the *Quarterly Journal of Microscopical Science* (vol. lxv., part 1) contains a rather startling paper by Mr. Arthur Bolles Lee on "The Structure of Certain Chromosomes and the Mechanism of their Division." After describing the animal chromosome as consisting normally of an axial core of basophilous chromatin twisted into a screw-like form with a spiral flange, and an investing sheath with acidophilous staining properties, he proceeds to deny that the longitudinal splitting of chromosomes which has formed the basis of so much theorising really takes place. According to Mr. Lee's view, the double character so suggestive of longitudinal splitting arises from the close approximation of the limbs of an originally **V**-shaped chromosome, and the division of the chromosome really takes place by rupture at the apex of the **V**. It will be interesting to see what other cytologists have to say about this iconoclastic statement.

We have received a copy of a special issue of *Die Naturwissenschaften* commemorating the twenty-fifth anniversary of the discovery of X-rays by Prof. Röntgen. A portrait of the discoverer forms the frontispiece, but is a rather disappointing reproduction. Original articles are the attraction, and are written by men well known in their respective spheres. Four out of the eight articles are devoted to the part which can be played by X-rays in the determination of atomic structure in crystals and other substances. The technical developments in the manufacture of X-ray tubes are described by Knipping in a brief article, the medical uses of X-rays being dealt with by Levy-Dorn. Radiographic reproductions receive scant justice, owing to the poor quality of the paper used. The issue concludes with a long article by Pfeiffer on the vital part which X-rays have played in many problems in chemistry.

In the November, 1920, issue of the *Journal de Physique et le Radium*, M. A. Dufour describes his cathodic oscillograph, which gives a photographic reproduction of any phenomenon which can be translated into a constant or variable magnetic or electric field so long as the frequency involved does not exceed 10^9 per second. The cathode rays utilised are produced at a plane cathode at the top of a vertical tube and are fired down through a pierced anode into a bell-shaped metal chamber, at the bottom of which a fluorescent screen or a cylindrical photographic film can be placed. The chamber can be exhausted, and provision is made for magnetic control from outside of the motor which rotates the cylinder. The electric or magnetic field is applied to the rays at the top of the bell chamber, and for low frequencies the cathode rays are moved parallel to the axis of the cylinder, which itself rotates at a uniform rate. For high frequencies the photographic film remains at rest while an auxiliary oscillation of low frequency but large amplitude at right angles to that to be studied is imparted to the rays. In order to prevent overlapping of the curves, a further slow motion of the ray parallel to the original motion is introduced by the slow change of a second auxiliary magnetic field.

WE learn from the *British Journal of Photography* for February 11 that at the meeting of the Royal Photographic Society held on February 9, Mr. Thorne Baker and Dr. L. A. Levy introduced "a new X-ray plate reducing exposure to one-twenty-fifth," and indicated its special application to radio-metallurgy. The plate is distinguished as the Imperial "Impex." Its extraordinary sensitiveness is obtained by incorporating the intensifying screen with the plate. The screen consists of a layer of calcium tungstate in soluble gelatine, and is coated on top of the emulsion which is hardened, so that after the exposure the screen can be dissolved off by water at 100° F. and development then carried out as usual. The screen being in optical contact with the emulsion, an "infinitely smaller" quantity of calcium tungstate is necessary to give the required intensification. The new plate takes a little longer to develop than usual (say 25 per cent.). The size of the particles of the calcium tungstate is some two or three times that of the particles of silver salt in the emulsion.

THE hope has often been expressed that means might be found for desensitising a photographic plate after its exposure, so that its development might be done without the extreme precautions that are necessary as to the light employed. This applies with the greatest force to highly sensitive panchromatic plates, which stand so very feeble a light that most persons prefer none at all, trusting to the time of treatment that is supposed to be suitable to the temperature of the developer. It has been found that certain substances possess the desired effect to a greater or less degree, but for one reason or another they have not proved acceptable. But "desensitol," which has just been put upon the market by Messrs. Ilford, Ltd., is simple to use and very effective. It is a solution of a red dye, and it is only necessary to dilute it with 50 parts of water and immerse the exposed plate in it, then after one minute the light may be increased to from 200 to 800 times the brightness that would previously have been safe, and the plate transferred to the developer and watched in comfort. From a scientific point of view there are many interesting points about such desensitising action, and we hope that we shall soon see the results of investigations into the changes, if any, produced by the desensitiser in the form of the characteristic curve and the proportional colour sensitiveness of plates of various kinds.

THERE can be very few officers who served in France who are not familiar with the co-ordinate reference card which was issued by the War Office to facilitate map descriptions and map measurements after the introduction of the application of a cartesian grid to all Service maps up to scales of 1 : 40,000. The same idea is embodied in the "Romer graph plotter" (A. G. Thornton, Ltd., Paragon Works, 49 King Street West, Manchester). A rectangular piece of cardboard (or celluloid), 8″×6″, is graduated along its edges with the zero graduations at the top right-hand and the bottom left-hand corners. By this means, given two rectangular axes, a point of given co-ordinates can be plotted and the co-ordinates of a given point read off without the use of squared paper and as accurately as would be possible if squared paper were employed. The advantages are obvious. Accurate graphs can be drawn in ordinary note-books or on ordinary paper; the attention of the student is concentrated on the graph rather than on the axes; and, more important still, the expense involved in the purchase of squared paper, by no means a small item, is avoided. Teachers of mathematics and science will probably not regret giving this instrument a trial.

A KINEMATOGRAPH projector of a new type was demonstrated by Mr. R. J. Trump at the Imperial College, South Kensington, on February 10. The invention of Mrs. Kingsley-Higginson, it employs, in place of the shutter and intermittent film-feeding gear of the ordinary machine, a continuously rotating ring of mirrors to stabilise the image and effect the change of picture while the film is run uniformly through the machine. The beam of light is thus always passing unobstructed to the screen, and the alternations of light and darkness produced by the shutter, which constitute the flicker of the ordinary projector, are avoided. The new apparatus can be run quite slowly if required, and in any case there is no necessity to speed it up in the way that is at present usual. The change of picture takes place zone by zone across the screen, which always shows a full image, derived from parts of two successive pictures on the film. The facets on the ring of mirrors are so arranged and set at such an angle that the two lights from the two partial film-pictures which are present at any instant in the gate are separated and transposed into their correct positions on the screen, and join up to form a complete image. There is no dark period and no overlapping or dissolving of the successive pictures into each other, as the first picture disappears at precisely the same rate that the second takes its place. A good and sharply defined image is obtained. The advantages of a uniform feed for the film are considerable, in that the wear and tear upon it are much reduced and the risk of breakage is negligible. The application of the same principles to kinemaphotography is under consideration, and there is every expectation that useful results will be obtained.

MESSRS. SOTHEBY, WILKINSON AND HODGE will sell by auction at their galleries at 34 and 35 New Bond Street, W.1, on Thursday and Friday, March 3 and 4, a large number (509 lots) of valuable works dealing with natural history and travel, the property of the late Dr. F. du Cane Godman. Many rare books are included, also several long runs of scientific journals and transactions of learned societies. The catalogue should be of great interest to many readers of NATURE.

SIR WILLIAM TILDEN has written for publication by Messrs. George Routledge and Sons, Ltd., a book on "Famous Chemists: The Men and their Work," in which the lives of twenty-one leading chemists, from Robert Boyle to Sir William Ramsay, will be dealt with in a non-technical manner. The sketches, while chiefly biographical in character, will give attention to the social and political conditions of the times in which the subjects dealt with lived, in order to show the relation of discovery in physical science to the progress of civilisation.

A SOMEWHAT novel way of keeping a book up to date, other than by issuing new editions, has been devised by the Cambridge University Press, which has projected a series of monographs intended to serve as supplements to Dr. Norman R. Campbell's "Modern Electrical Theory." The series will be edited by Dr. Campbell, who, however, will not write all the volumes. The first three monographs will deal with spectra, the quantum theory, and the constitution of atoms and molecules. It is proposed that the series shall correspond roughly with the chapters of the original book, and eventually supersede the latter.

ANNOUNCEMENT is made of the amalgamation of the firms of Messrs. John Wheldon and Co., of 38 Great Queen Street, Kingsway, W.C.2, and Messrs. William Wesley and Son, of 28 Essex Street, Strand, W.C.2. Both firms are well known in the world of science as booksellers and publishers of repute. The business of John Wheldon was established in 1844, and was concerned mainly with supplying collectors and institutions with scientific works; recently it has developed in the direction of economic and applied natural science. Of particular value to the new firm will be the collection of scientific journals held by John Wheldon and Co. The business of William Wesley and Son was established in 1855, and dealt similarly with books and journals of science. A valuable side of the firm's activities, which will be continued by the new company, is the numerous agencies which are held for the sale of publications of foreign and Colonial Governments and societies. The establishments will be carried on in future in the name of Messrs. Wheldon and Wesley, Ltd., under the guidance of Mr. H. K. Swann and Mr. E. F. Wesley, who have been managers and proprietors of their respective firms for a number of years.

Our Astronomical Column.

A STUDY OF THE STARS OF TYPE N.—The stars of type N (Secchi's fourth type) are of great interest; they were formerly supposed to be near the end of their career as suns. However, their concentration in the galaxy is a proof of great distance, and shows that they are in the giant stage. Lick Observatory Bulletin No. 329 contains a photographic study of the spectra of two bright stars of the class, 152 Schjellerup and 19 Piscium, by C. D. Shand. Lines in these spectra are very numerous, which increases the difficulty of identification. The presence of carbon, hydrogen, iron, titanium, vanadium, chromium, sodium, manganese, calcium, scandium, and yttrium is certain; four other elements are suspected. It is difficult to decide whether apparent bright lines are really emission lines or mere spaces between absorption lines; the author inclines to the former view.

The most striking feature of the spectra is the "Swan" carbon spectrum; the cyanogen bands are also prominent, and possibly carbon monoxide is indicated. The suggestion is made that the oxygen present may all combine with carbon, thus explaining the absence of titanium oxide, which is prominent in the M stars.

Many of the N stars are variable, resembling in this point the Md stars. It was formerly suggested that the variability of these faint red stars is due to incipient crust formation, which caused accumulation of heat within, leading after a time to the melting of the obstruction. However, the discovery that these stars belong to the giant class renders the crust theory unlikely. Dr. Merrill recently suggested an alternative; he postulates a veil of blue smoke above the photospheres of these stars, producing almost complete absorption of the shorter waves, and also to some extent obstructing the longer heat-rays. An accumulation of heat results which may suffice to vaporise the occulting clouds of carbon, so that a temporary increase of light occurs.

Spectral changes at various stages of the cycle are discussed. The bright hydrogen lines are most intense at maximum and practically absent at minimum, at which time the carbon absorption becomes stronger. These changes are closely analogous to those in the Md stars.

THE MADRID OBSERVATORY.—The Anuario of the Madrid Observatory, 1921, in addition to the usual tabular astronomical data, contains full details of sun-spots and prominences during 1919, with diagrams of remarkable prominences, including the great May one seen during the total eclipse. There is also an article on the spectrum of Nova Cygni 1920 by P. Carrasco. Spectra, photographed at Madrid on nineteen days between August 23 and September 29, are reproduced in a manner making it easy to trace the progressive changes. There is a full table of wave-lengths of lines, with probable origin, and comparison with the spectra of α Cygni and β Orionis. The earliest spectra (August 23–24) are almost purely absorption spectra. The bright bands are traceable on August 25 and conspicuous from August 27 onwards. The volume also contains the meteorological observations made at Madrid Observatory in 1919.

POPULAR ASTRONOMY IN SWEDEN.—*Populär Astronomisk Tidskrift* is an attractive and well-illustrated periodical the publication of which was commenced last year by the Swedish Astronomical Society under the editorship of S. Arrhenius, K. Bohlin, N. V. E. Nordenmark, and H. von Zeipel. The articles in Häfte 3–4 deal with Nova Aquilæ, the moving cluster of the Hyades (for which a parallax of 0·027″ is found), and Dr. Harlow Shapley's work on the globular clusters. Mr. Nils Tamm contributes an illustrated article on the Kvistaberg Observatory; the work during 1920 included studies of Mars, Jupiter, Saturn, nebular photography, and magnitude determinations of Nova Cygni. Mr. Gyllensköld reproduces several pictures of auroral streamers, including some interesting photographs obtained at Bossekop, Lapland, in 1910. Some artificial auroræ obtained by Birkeland by cathode rays are illustrated, and the forms deduced from his theory are discussed and shown to agree very closely with the streamers of the solar corona in the eclipse of 1901.

Scientific and Technical Workers in the United States Civil Service.

By MAJOR A. G. CHURCH.

THE work of our Civil Service National Council in producing a scheme for reconstruction dealing with the clerical and manipulative workers in British Government Departments has its counterpart in that of a Congressional Joint Commission appointed by the United States Senate to investigate the remuneration and conditions of employment and the need for reform in the Civil Service of the Republic. The Joint Commission commenced its inquiry in March, 1919, and completed its report on reclassification and readjustment of compensation in March last. The report has now been published, and provides an interesting and illuminating commentary on the conditions which prevailed in the American Service before the war, the bewildering and chaotic multiplication of class within class, the gross anomalies in salaries, the absence of any just and sane retirement scheme, and the accentuation of this unsatisfactory state of affairs by war conditions. In this respect Washington appears to have suffered far more than London by the introduction of the "business man" element into its administrative service.

The findings of the United States Commission are particularly interesting in those sections devoted to the scientific, technical, and professional classes—classes, incidentally, which are not yet being considered as a whole by our own National Council. While recognising that the Government Service possesses distinct advantages for these classes, it considers that the advantages are offset to some extent by certain personal restrictions generally unknown in the academic and business world. It finds that "there is serious discontent, accompanied by an excessive turnover and loss, among its best-trained and most efficient employees," and that "the National Service has become unattractive to a desirable type of technical employee." It emphasises the melancholy fact that the advance in the rate of turnover among the scientific technical employees has been three times as fast as the advance for clerical employees; for the former class the average advance in salary on leaving the Government Service was 53 per cent. The resignation curve at the Patent Office is still going up so rapidly that this Department has almost ceased functioning.

To remedy this alarming state of affairs the Commission urges that every effort should be made to stimulate initiative and originality on the part of scientific and other professional workers. "It is peculiarly appropriate that the Federal Government should take the lead in research work of all kinds, but it cannot do so unless it is able to attract and retain independent thinkers of the highest type. The reduction of red tape to a minimum, the encouragement of freedom of thought and action to a maximum, and the direction of research by thoroughly trained investigators would all assist to make this possible." This passage might with equal justice and appositeness have been written as a commentary on the position of scientific workers in our own Government Departments.

For scientific and technical staffs under the reclassification scheme the following titles of classes have been adopted:—Junior, Assistant, Associate, Full Rank (indicated by the absence of any adjective), and Senior. The following table gives the salaries recommended for the various grades in dollars and £ sterling (calculated on an exchange value of £1 = 3·5 dollars). The rates of pay for skilled mechanics and unskilled labourers in the service of the State are also given for purposes of comparison:

Scientific and Technical Workers.

	Minimum	Increment	Maximum
Junior	$1800 £515	$120 £34	$2160 £617
Assistant	$2400 £687	$120 £34	$3000 £857
Associate	$3240 £926	$120 £34	$3840 £1096
Full Rank (physicist, chemist, civil engineer, etc.) ...	$4140 £1185	$180 £52	$5040 £1445
Senior	No fixed scale		
Skilled mechanic ...			$2100 £600
Unskilled labourer ...			$1140 £326

In addition to the above, it is recommended that the cost-of-living factor should be taken into account in determining salary scales.

For the senior-class administrative, scientific, technical, and other professional workers no fixed scales of salary are recommended. It is considered that "the incumbents of these one man or woman positions are the real leaders of the Civil Service of the Republic," and rigid salary scales might prevent their entrance or retention in the Service. The scales quoted apply to all scientific and technical workers employed by the State except medical officers, whose initial salaries are lower and increments larger, but whose final salaries are also lower than those quoted above. The qualification for appointment as a junior scientific or technical worker is apparently the same as that laid down for similar appointments under the Government of this country.

It is laid down as a principle that there should be no discrimination on account of sex; men and women should receive equal pay for equal work, and the door of promotion should be opened impartially to members of both sexes.

Among other noteworthy recommendations by this Commission are the following:

(1) The appointment of an Advisory Council of twelve members to the Civil Service Commission: six to be nominated by the President of the United States and six to be elected by the employees.

(2) The adoption of an efficiency rating system to govern promotions, demotions, and increments.

(3) Interdepartmental promotions.

(4) Upon appointment to a position in a particular class an employee should be paid at the minimum rate prescribed for such class.

(5) Annual leave to be uniform throughout all classes of employees, viz. 2½ days per month.

(6) Investigation as to the possibility of the adaptation of psychological tests to the selection of candidates for the Civil Service.

It is improbable that the last two recommendations would be likely to find much favour in the eyes of the British authorities. As for an efficiency rating system, it is easy to predict the difficulty that will be experienced in adapting any such scheme to scientific workers; in its report the Joint Commission recognises this fact.

In a detailed criticism of the Reclassification Report

Dr. Edward B. Rosa, of the U.S. Bureau of Standards, lays stress on the departure from established custom which is entailed by the fourth recommendation. He considers that such a system will make the State Service the refuge of the mediocrity, since there is no incentive to the individual worker. He would wish to see initial salaries determined by the promise of the candidate for a class.

The most serious objection which can be raised to the report is the almost complete failure of the Joint Commission to suggest a remedy for a disease which is only too prevalent in the United States Service: the lack of co-ordination and co-operation in research. Before the war each Department was watertight, the idea being to prevent the overlapping of research—which many consider vital to its prosecution—and consequent waste. It is not clear that any particular attention has been paid to this aspect of departmental practice. Above all, it is not evident that the Commission has fully appreciated the possibilities of the co-ordination of research and other scientific Departments of the State.

Efficiency in Industry.

WE referred last week to the comprehensive exhibition at Olympia organised under the auspices of the *Daily Mail* with the object of encouraging modern methods of increasing efficiency by the application of scientific principles. The range covered is large, dealing as it does with education, commercial organisation, factory equipment, and general industrial matters, but the keynote of applying scientific rather than haphazard methods to obtain the improved results now so badly needed runs through it all.

Scientific education is represented on the stand of the University of London, where, among other things, is to be found an interesting display exemplifying the development of the thermionic valve, which is the basis of most modern wireless telegraph work. This goes back to lamps fitted with internal plates by Prof. J. A. Fleming in 1887–89 for the study of the unidirectional conductivity effect discovered by Edison in 1883. Some of the original oscillation valves made as a result of these researches in 1904, and practically used in wireless telegraphy, are also shown. The later developments of the three-electrode valve are exemplified by a large number of valves of different design, including the form to which de Forest gave the name of the "audion." A recent four-electrode valve of Prof. Fleming's own design is to be seen, and the very latest development in wireless telegraphy is exemplified by a large transmitting valve made by the Marconi-Osram Valve Co. Some historic apparatus used by Sir William Ramsay in his researches upon the rare gases is also shown, and a collection of historic electrical apparatus from the laboratories of King's College includes some used by Clerk Maxwell.

Sheffield University shows exhibits relating to the production of cupro-nickel and some special apparatus developed by the department of glass technology. Armstrong College, Newcastle, shows Dr. Bedson's apparatus for the investigation of coal-dust explosions and the inhibitory power of inert dusts. A small amount of the dust mixture to be tested is blown by a puff of air on to a heated platinum wire in a glass bulb, and the sudden rise of pressure due to the little explosion is noted. Another educational exhibit is that of Loughborough College, Leicestershire, which is largely devoted to the work of students of the college. The technical training of partly disabled men occupies a deservedly large section of the exhibition, where the men are seen working at their various trades. An interesting exhibit relating to industrial efficiency is that of Major F. B. Gilbreth, consisting of a working laboratory for the recording of the actual movements of operatives in performing any given operation with the view of determining the most economical and least fatiguing way in which it can be carried out.

Among exhibits in the general engineering section it is interesting to see the Constantinesco wave system of power transmission working rock drills and other appliances on the stand of Messrs. W. H. Dorman and Co., Ltd. Attention should also be directed to an instrument for the regulation of temperature shown by British Oil and Fuel Conservation, Ltd. This is known as the Freeman precision control, and depends on the change of volume of the air in a bulb placed within the furnace or other chamber being heated. The expansion and contraction of the air drive a little column of mercury up and down an inclined tube, causing it to open or close a contact which, by means of a relay arrangement, controls the valve or other device regulating the supply of the heating medium.

Various branches of electrical engineering are represented in the comprehensive exhibit of the British Thomson-Houston Co., Ltd., including an electric welding plant in operation. Particular attention may be directed to a portable Röntgen-ray outfit employing the Coolidge tube with heated cathode. This is arranged to make up into four easily carried packages, and can be erected at the bedside of a patient. It is worked by means of a small transformer, with or without a rotary converter, from any ordinary direct- or alternating-current supply circuit. The power required is about 600 watts. Another remarkable piece of portable apparatus is a wireless receiving set, weighing no more than 20 lb. and needing no external connections, which will pick up messages from the chief Continental stations. A rectifier for charging small batteries from alternating-current circuits, acting on the same principle as the thermionic valve, is also shown.

A representative display of wireless telegraph apparatus is made by the Marconi Wireless Telegraph Co. A complete 3-kw. valve transmitting station for land use is shown, as well as several smaller sizes of valve receiving and transmitting equipments down to a 20-watt portable apparatus, Demonstrations are given by means of the "radio-megaphone," which is a combination of a wireless telephone receiving apparatus and a Creed "stentorphone." This latter in its ordinary form is a loud-speaking gramophone in which the record actuates a valve controlling a flow of compressed air, and gives purer and more powerful sounds than the ordinary gramophone. A large example used in this way is placed in the gallery, where it discourses music, etc., which can be heard all over the building. In the "radio-megaphone," however, the gramophone needle is replaced by a piece of specially designed apparatus which enables the wireless telephone receiver to actuate the control valve. One of these combination instruments on the Marconi stand is used to make audible the time-signals received from the Eiffel Tower and from Nauen, and to reproduce music and speech from a small wireless station at Surbiton. These are picked up on an aerial just outside Olympia.

Messages are also sent periodically from Surbiton in the Morse code at a high speed and are printed in ordinary type automatically on the neighbouring stand of Messrs. Creed and Co., Ltd. The Creed type of printer was recently described in NATURE (December 9, 1920, p. 472). The apparatus here exhibited is of the improved form, in which the use of compressed air is entirely done away with and a revolving type-wheel takes the place of the lever typewriter mechanism of the older apparatus. The main principles of the selecting arrangement whereby the Morse message is translated into type are the same. The new instrument has a working speed of 175 words per minute.

The most complete line telegraph exhibit is that of the Eastern and Associated Telegraph Companies, which includes a complete set of apparatus as used on a long cable circuit. This works with a Creed printer of the older pattern used with the Muirhead type of receiving perforator. Among objects of historical interest is an example of the original form of the Kelvin siphon recorder. Attention may also be directed to examples of different forms of relays used in cable work and an example of an "electrolytic magnifier," which is somewhat similar to a relay except that instead of containing actual contacts that are opened and closed by the galvanometer portion of the apparatus, the moving pointer alters the relative position of wires dipping into an electrolyte, and makes an alteration of resistance which affects the balance of the duplex circuits and actuates the receiving apparatus accordingly.

Recent advances in optical science are exemplified by the exhibits of Messrs. Chance Brothers, Ltd. A special feature is the demonstration of the properties of "Crookes" glass for ophthalmic purposes, which relieves the eyes from strain by absorbing the ultra-violet rays while allowing the whole of the visible spectrum to pass. The company also exhibits for the first time a new "daylight" glass, by the aid of which colours may be matched by artificial light exactly as in daylight. This is a glass of a bluish tint which is accurately balanced in colour against the source of light to be used so as to absorb a selection of the rays and to allow a mixture to pass through which approximates very nearly to daylight. The problem is attacked in a different manner by the Sheringham Daylight, Ltd., who show specially constructed reflecting shades which achieve a similar result by reflection instead of by transmission. In both cases the source of light employed is the half-watt lamp. Another optical instrument which should not be missed is the Optophone, which enables the blind to read from ordinary type. This has already been fully described in NATURE (May 6, 1920, p. 295, and August 5, 1920, p. 722), and is exhibited by Messrs. Barr and Stroud, Ltd.

A very comprehensive example of the methods of modern medical research is presented by the display arranged by the Middlesex Hospital, which includes a large number of prepared sections relating to parasites and bacteria mounted in microscopes. Apparatus is also shown typifying the methods used both for routine and research in photomicrography, Röntgen-ray work, and various branches of biochemical and physiological investigation. St. Mary's Hospital Medical School has also an exhibit relating to the part played by medical research in the promotion of industrial efficiency. Among the subjects illustrated are breathing apparatus for diving, mining rescue work, and gas protection. Apparatus for the recording of muscular effort is also shown.

Human Tails.

AT a meeting of the Royal Anthropological Institute held on February 8, Dr. W. H. R. Rivers, president, in the chair, Prof. Arthur Keith, in making a report on a specimen of a human tail which had been bequeathed to the institute by the late Dr. J. C. McLachan, of Halifax, Yorks, took occasion to review the present state of our knowledge regarding the occurrence of true tails in human beings. The specimen submitted was a true human tail exactly similar to one very completely examined by Prof. Ross Harrison and described by him in the Johns Hopkins Hospital Bulletin of 1901. Prof. Harrison's specimen, which was removed from a boy aged six months, was 40 mm. long at birth, 70 mm. long when excised, contained striped muscle, and moved under various emotional states. Dr. McLachan's specimen was removed from a girl aged three months, measuring 105 mm. long in its preserved state, 11 mm. in diameter at the base, and tapering to a conical point. It also contained strands of striped muscle, and must have had the power of movement. As is the case in all such specimens, with three recorded exceptions, no vertebræ were present, nor could any segmental arrangement be observed in the central core. The skin covering the tail was studded with hair-roots and sebaceous and sweat glands.

Thanks to the labours of Keibel and Elze, and of Prof. Streeter, of the Carnegie Institution, and of his pupils, our knowledge of the development of a true tail in the human embryo may now be regarded as complete. At the end of the fifth week of development, when the human embryo is approaching 5 mm. in length, caudal (post-sacral) segments begin to be differentiated from the tail-bud represented by the growing tip of the tail. By the beginning of the seventh week, when the embryo is about 12 mm. long, the human tail reaches its maximum growth and differentiation, there being then eight to ten caudal segments within the projecting conical tail. In the seventh week retrogression of the terminal and free segments takes place, and towards the end of the eighth week, when the fœtus measures about 25 mm. (1 in.) in length, the surviving four or five basal or coccygeal segments become submerged, drawing with them the terminal atropic segments, the point of disappearance of the terminal atropic part being marked by a dimple. The caudal appendage which occasionally occurs in children represents a persistence of the terminal segmented part of the tail which normally atrophies by the end of the eighth week.

The disappearance of the tail from the body of man is not a human, but a pre-human problem. It is part and parcel of the wider problem of how and when the upright, or, as Prof. Keith would prefer to call it, the orthograde, posture was evolved. The orthograde group of Primates is represented to-day by the gibbon, orang, chimpanzee, gorilla, and man; in all of them the muscles of the spine, and of the thorax and abdomen, and all the spinal and other nerve reflexes which regulate the action of muscles, have been transformed to suit the orthograde posture; in all of them the external tail has disappeared and the basal or pelvic vertebræ of the tail have been reduced to a coccygeal form. The tail is more vestigial in the primitive small-brained gibbon than in man; it is the discovery of a pre-gibbon stock which should give us the history of the disappearance of the human tail, and from the scant data at present available we may infer that such a discovery is likely to be found in strata lying well towards the base of Tertiary deposits.

In pronograde apes, as in four-footed animals, the tail is made up of two parts which are structurally and functionally quite different. The free or terminal part is put to many uses; the pelvic or basal part is always associated with a visceral function. To it the rectum is always attached, and certain muscles which guard the pelvic outlet act upon the pelvic segments of the tail and use it as a perineal shutter. It is the external or post-pelvic segment of the tail which has disappeared from the body of man and the orthograde apes; the pelvic part has survived as the coccyx, and its visceral musculature as the levator ani muscle. With the evolution of the upright posture the pelvic muscles which act on the tail had to bear the steady burden of the abdominal viscera—had to be in action as long as the orthograde posture was maintained. They could not serve in the support of the viscera and the movements of the tail at the same time. Hence only the pelvic part of the tail was retained—the part on which the pelvic musculature acted. In pronograde apes the pelvic visceral musculature is attached to the peculiar chevron-like bones (hæmal arches) placed beneath the pelvic vertebræ of the tail; the reappearance of hæmal arches in the human embryo during the second and third months of development may be regarded as definite proof that man comes of a pronograde ancestry. Tarsius spectrum, for which Prof. Wood-Jones claims a special human relationship, is devoid of all features which mark the orthograde group of Primates; in its tail and tail musculature Tarsius is a pure pronograde Primate.

University and Educational Intelligence.

BIRMINGHAM.—The Doncaster Laboratory for Research in Mining is to be transferred to Birmingham University, under the directorship of Dr. J. S. Haldane, who has accepted the post of honorary professor.

CAMBRIDGE.—The council of St. John's College has appointed Dr. T. J. I'A. Bromwich to be prælector in mathematical science.

An interesting report issued by the Board of Research Studies shows that there are at present in residence seventy-two students admitted as candidates for the Ph.D. degree. The largest number working at any one subject is thirteen for physics. Botany and chemistry with eight each come next, followed by English and history with seven each. Graduates of British universities number thirty-three; sixteen come from Colonial universities, ten from India, and six from the United States.

An analysis of the voting last term on the admission of women as members of the University shows that there was a majority of 33 out of a poll of 405 among the resident teachers in the University in favour of their admission. The University professors also supported the proposal by 27 votes to 15.

Honorary degrees of LL.D. were awarded on Saturday to Sir Patrick Manson, G.C.M.G., and Dr. Albert Calmette, of the Pasteur Institute, Paris. Prof. J. Hjort, the oceanographer and marine biologist, was also given the honorary degree of Sc.D.

Mr. H. G. Carter has been appointed director of the Botanic Gardens.

LONDON.—The Prince of Wales has consented to attend the graduation dinner on the evening of May 5, on the afternoon of which day he will receive the honorary degrees of Master of Commerce and Doctor of Sciences, and will reply to the toast of "The New Graduates." The Guildhall has been kindly placed at the disposal of the University for this purpose by the Lord Mayor and Corporation, and the Lord Mayor has accepted an invitation to be present.

Dr. Anne Louise McIlroy has been appointed to the University chair of obstetrics and gynæcology tenable at the London School of Medicine for Women.

Prof. J. P. Hill has been appointed to the University chair of embryology tenable at University College.

The degree of D.Sc. in botany has been conferred on Miss K. M. Curtis, an internal student of the Imperial College (Royal College of Science), for a thesis entitled "The Life-history and Cytology of *Synchytrium endobioticum* (Schilb.), Perc., the Cause of Wart Disease in Potato."

The Graham Legacy Committee has appointed Mr. V. R. Khanolkar to the Graham scholarship in pathology for two years from April 1, 1921. The value of the scholarship is 400*l.* a year. Since October last Mr. Khanolkar has been assistant bacteriologist in University College Hospital.

IN response to the recent appeal of the University of Edinburgh for 500,000*l.*, the sum of 200,000*l.* has now been subscribed.

MR. W. D. EGGAR will deliver a course of four lectures on Greek mathematics at Gresham College, Basinghall Street, E.C., on Tuesday to Friday, March 1–4, at 6 p.m. Admission will be free.

PROF. E. W. SCRIPTURE, formerly of Yale University, has been appointed to the faculty of the University of Hamburg for the summer semester. He will lecture on English philology and experimental phonetics. Two articles by Prof. Scripture on the nature of vowel sounds appeared in NATURE for January 13 and 20.

AN election of Beit fellows for scientific research is to take place on or about July 15 next, and the latest date upon which applications can be received is April 19. Forms of application and information respecting the fellowships are obtainable by post from the Rector, Imperial College of Science and Technology, South Kensington, S.W.7.

IN connection with the 1920–40 Science Research Fund of Girton College, Cambridge, a fellowship of 300*l.* a year tenable for three years is being offered by the college for research in the mathematical, physical, and natural sciences. Particulars of the fellowship may be obtained from Miss Clover, Coleby, Grange Road, Cambridge, and applications for the fellowship will be received by her not later than March 31 next.

A COURSE of four public lectures on "The History of Plant Delineation" will be given in the lecture-room of the botany department of University College, London, on Wednesdays at 5 p.m., beginning on March 2. Dr. Charles Singer will deal with the art of the ancient empires and of the Dark and Middle Ages, and Dr. Agnes Arber with the period from the invention of printing to modern times. The lectures, which will be illustrated by lantern-slides, are open to the public without fee or ticket.

THE formal opening of l'Institut Français, Cromwell Gardens, S.W., will take place on Saturday, February 26, at 3 o'clock, under the presidency of his Excellency M. le Comte de Saint Aulaire, Ambassador of France. The Minister of Public Instruction, M. Léon Bérard, will represent the French Government. The English Board of Education and the

London County Council will be represented. The Paris Municipal Council and the University of Paris will each send three delegates. Among the latter will be M. Henri Bergson. The rector of the Institut's mother-University of Lille is also expected to be present.

PROF. LUIGI LUIGGI has accepted the invitation of the University of London to deliver a course of six lectures on "Recent Engineering Works in Italy" during his forthcoming visit to England. Dr. Luiggi is the professor of hydraulic engineering in the University of Rome, and also president of the Italian Society of Engineers. The lectures, which have been arranged to be given at the Institution of Civil Engineers at 5.30 p.m. on March 7, 9, 11, 15, 16, and 18, will be open to the public without fee or ticket. They will be illustrated with lantern-slides, which promise to be of particular interest. The chair at the first lecture will be taken by the Italian Ambassador.

THE Council, the Delegacy, and the Professorial Boards of King's College have resolved to found a memorial to the late Dr. R. M. Burrows, who guided the fortunes of the college with such brilliant success during his seven years' tenure of the office of Principal. The memorial will take the form of a tablet to be erected in the college chapel, together with a Ronald Burrows prize, exhibition, or scholarship to be awarded annually to a student of the college who has distinguished himself in the field of Greek studies. Prof. H. G. Atkins has consented to act as honorary treasurer of the memorial fund, and subscriptions may be sent to him at King's College, Strand, W.C.2.

THE annual general meeting of the Association of Technical Institutions will be held at the Grocers' Hall, Princes Street, London, E.C., on Friday and Saturday, March 4 and 5. The president-elect, the Right Hon. Viscount Burnham, will deliver his presidential address, and papers will be read by Principal C. T. Millis on "Junior Technical Schools: Their Status and Position," Dr. W. M. Varley on "The Report of the Departmental Committee on Scholarships and Free Places," Mr. H Stainsby on "Technical Instruction for the Blind," and Principal W. J. Chalk on "Technical Instruction in London of the Higher Branches of Commerce." Important resolutions dealing with the necessity for closer co-operation between the technical colleges and the universities will be submitted for consideration, together with other resolutions on educational matters.

THE annual dinner of the Finsbury Technical College Chemical Society was held on February 18. The president, Mr. A. J. Hale, who occupied the chair, expressed the hope that ultimately the function might develop into a reunion between the past and present chemical students of the college. Mr. J. H. Coste, in proposing the toast of the college, referred to the splendid work which has been done in the past and how every effort was being made by the Finsbury Technical College Defence Committee and by various institutes and societies to prevent the threatened closing of the college. Until the authorities definitely decided to keep the college open, Mr. Coste urged that no effort to gain that end should be relaxed by those interested. This view was warmly supported by Prof. G. T. Morgan. Attention was also directed to the plea for keeping open the college recently made in the columns of NATURE and supported by Sir Oliver Lodge (February 10, p. 757). Mr. C. R. Darling expressed a hope that in the event of the college remaining open its present curriculum would not be altered or its freedom interfered with in any way.

Calendar of Scientific Pioneers.

February 24, 1799. Georg Christoph Lichtenberg died.—The discoverer of the dust figures on electrified planes, Lichtenberg held the chair of physics at Göttingen, and in his day was well known in both Hanover and England.

February 25, 1723. Sir Christopher Wren died.—Before he became famous as an architect, Wren was known as a mathematician. He was one of the founders of the Royal Society, and for twelve years Savilian professor of astronomy at Oxford.

February 26, 1878. Angelo Secchi died.—The successor of the Jesuit father, de Vico, as director of the observatory at the Collegio Romano, Secchi was a pioneer worker in the field of stellar spectroscopy, and his grouping of stellar spectra into types represents one of the results of his extensive studies of this subject.

February 27, 1864. Edward Hitchcock died.—Schoolmaster, minister, and, lastly, professor of chemistry and natural history at Amherst College, Hitchcock suggested and carried out the geological survey of Massachusetts. He is recognised as one of the fathers of American geology.

February 27, 1906. Samuel Pierpoint Langley died.—The great pioneer of aviation, Langley was originally a civil engineer, but abandoned that profession for astronomy. For the study of the infra-red portion of the solar spectrum, in 1880 he devised the spectro-bolometer—an electrical resistance thermometer of extreme delicacy. In 1887 he became secretary to the Smithsonian Institution. Taking up the investigation of the resistance offered to planes moving through the air, he was led to the construction of the steam-driven model flying machine which in 1896 made successful flights of half a mile. Having thus demonstrated the practicability of mechanical flight, he left the commercial and practical development of the idea to others.

February 28, 1882. Thomas Romney Robinson died.—An Irish clergyman, Robinson for many years directed the Armagh Observatory. He was also a physicist, and in 1843 invented the well-known cup anemometer.

February 29, 1744. John Theophilus Desaguliers died.—Like Dollond, Demoivre, Demainbray, and others, Desaguliers was of Huguenot extraction. Educated at Oxford, for many years he lectured there and in London, and rendered notable services to science when some acquaintance with scientific principles was first considered fashionable. He was the second recipient of the Copley prize.

March 1, 1862. Peter Barlow died.—Professor of mathematics at Woolwich, Barlow was a pioneer in the study of the strength of materials, and did much important work in terrestrial magnetism.

March 2, 1840. Heinrich Wilhelm Mathias Olbers died.—A doctor at Bremen, Olbers, by limiting his sleep to four hours nightly, accomplished much astronomical work, and was the discoverer of the minor planets Pallas and Vesta.

March 2, 1911. Jacobus Henricus van't Hoff died.—A student under Kekulé and Wurtz, van't Hoff became a professor at Amsterdam, and in 1896 professor of chemistry to the Prussian Academy of Sciences. A great physical chemist, he developed the theory of solutions, and was one of the founders of stereochemistry. With Le Bel in 1893 he was awarded the Davy medal, and in 1901 he received the Nobel prize.

E. C. S.

Societies and Academies.

LONDON.

Royal Society, February 3.—Prof. C. S. Sherrington, president, in the chair.—Dr. G. B. **Jeffery**: The field of an electron on Einstein's theory of gravitation. Equations are obtained for the motion of a single electron about an atomic nucleus. If a ray of light passes through the field of the electron, provided that the distance of closest approach is not too small, the ray is deflected towards the electron. For closer approach the sense of the deflection is reversed until in the limit the ray is reflected back again along its original path. These results are used to ascertain whether any possible electric field of the sun would produce a measurable effect on the crucial phenomena of Einstein's theory. It is found that, while the sun's electric field would tend to diminish the displacement of the spectrum lines, the field required to produce compensation is of the order of 10^{13} volts per cm. at the sun's surface.—Dr. M. N. **Saha**: A physical theory of stellar spectra. Elsewhere a theory of thermal ionisation (and partly of thermal radiation) of gaseous elements has been developed and applied to the explanation of the ionisation observed in the solar chromosphere, and the absence of certain elements from the Fraunhofer spectrum. In the present paper the theory has been extended towards a physical explanation of the ordered gradation in the spectra of stars. The stellar data, particularly those accumulated by the Harvard College Observatory, are discussed from the point of view of the present theory, and it has been shown that the varying spectra of stars can be explained as functions of a single physical variable, viz. the temperature of the stellar atmosphere.—W. F. **Darke**, J. W. **McBain**, and C. S. **Salmon**: The ultra-microscopic structure of soaps. The ultra-microscopic observations of Zsigmondy and Bachmann on soap-curds have been confirmed, interpreted, and extended. The kinematograph has been employed as an aid in elucidating the formation and disappearance of the various structures observed. The curds of sodium, potassium, and hydrogen soaps are described and discussed.—Dr. J. **Mercer**: Linear transformations and functions of positive type. The paper contains developments of the theory of linear functional transformations as developed by F. Riesz in his paper "Untersuchungen über Systeme integrierbaur Funktionen" (*Math. Annalen*, vol. lxix., pp. 449–97).

Mineralogical Society, January 18.—Mr. A. Hutchinson, vice-president, in the chair.—A. F. **Hallimond**: The olivine group. Since the discussion of the densities by Thaddéef in 1896, and of the optical constants by Backlund in 1909, numerous additions have been made to the published data. These have been collected and the most probable values for the pure compounds obtained. The molecular volume of monticellite is slightly greater than the mean between forsterite and $\gamma-Ca_2SiO_4$. For the complex mixtures the density and mean refractive index yield additive relationships, but the birefringence and axial ratios follow no additive law. The conditions of plotting which must be observed if the variation of an additive property with composition is to be expressed by a straight line were briefly summarised.—W. A. **Richardson**: A method of rock-analysis diagrams based on statistics. Oxide variation diagrams, similar to those employed by Dr. Harker, can be used for expressing the chemical relations of rock groups and individuals. The diagrams obtained from plotting Iddings's selected analyses gave the maximum variation for all rocks.—L. J. **Spencer**: Identity of Trechmann's "β-tin" with stannous sulphide. A re-examination of the original material described by C. O. Trechmann in 1879 as an orthorhombic modification of tin proved that he made his crystallographic determinations on crystals of one kind (viz. stannous sulphide), whilst the chemical analysis was made on crystals of another kind (viz. metallic tin). Tin is, therefore, dimorphous and not trimorphous, "white tin" being tetragonal and "grey tin" cubic. Orthorhombic crystals of stannous sulphide (SnS) and tetragonal crystals of iron stannide ($FeSn_2$) from tin furnaces and rhombohedral crystals of tin arsenide (Sn_3As_2) isolated from a tin-arsenic alloy were described.

Linnean Society, January 20.—Dr. A. Smith Woodward, president, in the chair.—E. H. C. **Walsh**: Lhasa and Central Tibet. The lecturer gave first a brief description of the country, the people, the religion, and the government. The country extends 1600 miles in its greatest breadth, and 800 miles in its greatest width, from the Koko Nor to the southern bend of the Takiang or Blue River; the superficial area is more than a million square miles, comprises the highest portion of the earth's surface, and is bounded on its southern frontier by the Himalayas, the loftiest chain of mountains in the world. The Tibetans are a Turco-Mongolian race and speak a monosyllabic language; it is believed that they originally lived in China, but were driven out by conquering races. They are mentioned as early as 770 B.C., when they were at war with the Chinese. There are two acknowledged forms of religion, the Buddhist and the Bon, pronounced Pön; the latter has adopted some of the formulas of the former, but reversed them, as in the case of the "Swastika" or fyle-fot cross; also the Buddhist prayer-wheel, with its invocation "Om mani padme hum." The two sects lived peaceably side by side. The Dalai Lama, the Pope of the Lamaïst Church, is believed to be a continuous incarnation of previous Dalai Lamas, and of the Deity Avalokiteswara upon earth. When a Dalai Lama dies his reincarnation has to be looked for in some infant born shortly afterwards, and this is ascertained by the chief oracle indicating the part of the country and some clues, and the result of local inquiries is then reported to the leading Lamas, who decide by lot the actual child to be educated as the Dalai Lama.

Physical Society, January 28.—Sir W. H. Bragg, president, in the chair.—Prof. H. **Nagaoka**: The magnetic separation of neon lines and Runge's rule. The results of an investigation of the Zeeman effect for neon lines are given. The departures from Runge's rule—that the magnetic separation of the lines are aliquot parts of the separation of the normal triplet—are discussed. It is concluded that such discrepancies are due to variations of the ratio e/m.—E. V. **Appleton**: A method of demonstrating the retroactive property of a triode oscillator. The author, following Vallauri, gives an approximate treatment of the conditions which give rise to retro-action between the grid and anode circuits of a triode valve, and describes an arrangement of circuits whereby the property can easily be demonstrated to a large audience.—Dr. D. **Owen** and R. M. **Archer**: The quickness of response of current to voltage in a thermionic tube. Steady voltages were applied between the hot and cold electrodes of a thermionic tube for intervals of time varying from 0·00001 second to a minute or longer. The mean current during the interval was measured by the Wheatstone bridge, using a null ballistic method. Two types of thermionic tube were employed, one at a high gas pressure and the other at a higher degree of exhaustion. The initial rise of current to its maximum is followed by a fall, the rate of which diminishes with time. In the tube at the high gas pressure the final value of current may be less than half the initial value. In the case of the tubes at lower gas pressure the fall is less pronounced, say 3 or 4 per cent. This fall is not attributable merely to the high temperature of the filament, but is conditional on the thermionic current being permitted to flow.

Linnean Society, February 3.—Dr. A. Smith Woodward, president, in the chair.—M. **Christy**: Wistman's Wood. Wistman's Wood is a small grove of ancient, but exceedingly gnarled and diminutive, oak-trees (*Quercus pedunculata*) growing out of an extensive pile of huge angular blocks of granite (known as a "clatter") without a particle of visible soil. The wood is almost in the centre of Dartmoor at an elevation of about 1500 ft. It contains about 300 to 400 trees, which are overgrown by masses of moss and lichens. Particulars of the habit and age of the trees are given.—Dr. Agnes **Arber**: The leaf-tips of certain Monocotyledons. The leaves of Monocotyledons are studied from the point of view of the phyllode theory. In simple monocotyledonous foliage leaves terminating in a solid apex, and also in spathe leaves ending in a similar tip, the main part of the leaf is of leaf-sheath nature, while the apex represents a vestigial petiole. In complex monocotyledonous leaves which are differentiated into sheath, stalk, and "blade," certain cases are known in which the "blade" terminates in a solid apex. It is provisionally suggested that such apices represent the unexpanded tip of the petiole.—T. A. **Dymes**: Seeding and germination of *Ruscus aculeatus*, Linn., in the south-eastern quarter of England. The berries and seedlings perish by severe frost, although the adult is hardy. Many seeds fail to germinate because immature. Frost kills many seedlings during the first winter. Better results are obtained by sowing, as soon as the seeds are ripe, at a depth of 1 in. than at a greater depth or in the spring. Survivors in the second season produce an axis some 3 in. long, bearing about six phylloclades in the axils of scale-leaves. The radicle perishes and adventitious roots are produced. During the second winter the seedlings are unable to withstand severe frost. There is no recapitulation of the ancestry by the seedling.

Aristotelian Society, February 7.—Lord Haldane, vice-president, in the chair.—Prof. R. F. A. **Hoernle**: A plea for a phenomenology of meaning. The task of a phenomenology of meaning is to collect and examine all types of empirical situations in which signs function and meaning is present. This is the more necessary as all the higher activities and all control of social organisations depend on the use of signs. Yet current theories are fragmentary and one-sided. This is shown by an examination of the theories of F. C. S. Schiller, B. Russell, Lady Welby, C. S. Peirce, G. F. Stout, A. Meinong, and E. Husserl. A clue to a completer theory may perhaps be found in the distinction between the *indicative* and the *expressive* function of signs. We have the pure indicative function when the existence of A enables us to infer the existence (or non-existence) of B. We have the pure expressive function when an agent makes or utters signs. The two functions are curiously interlaced in intersubjective intercourse. The distinction, however, requires to be tested further by application to various kinds of non-verbal signs, to symbolic actions, and especially to the functions of sounds in music.

CAMBRIDGE.

Philosophical Society, January 24.—Prof. Seward, president, in the chair.—G. I. **Taylor**: (1) Experiments with rotating fluids. A summary of results on three subjects connected with the dynamics of rotating fluids was given without proof. The subjects treated were (*a*) difference between two- and three-dimensional motion, (*b*) stability of fluid contained between two cylinders, and (*c*) motion of a sphere in a rotating fluid. Experiments were described, and in the case of (*a*) and (*c*) some were shown at the meeting. (2) Tides in the Bristol Channel. It is shown that the Bristol Channel, which contains some of the largest tides in the world, can be represented with considerable accuracy by a channel the breadth and depth of which vary uniformly from the mouth to the head. Calculations of the effect of such a channel in increasing the tides are shown to agree well with the observed tides in the Bristol Channel. It appears, therefore, from the results obtained that the usual hydrodynamical theory of tides accounts quantitatively as well as qualitatively for the abnormally high tides which exist at the head of the Bristol Channel.—F. W. **Aston**: The deterioration of fabric under the action of light, and its physical explanation. The only serious factor in deterioration of unprotected aeroplane fabric, doped or undoped, when exposed to weather is found to be the action of sunlight. On investigation this action is shown to be relegated to the ultra-violet part of the spectrum. This deterioration appears to be due to the formation of ozone from the oxygen of the air which acts upon the fibres. This explanation is upheld by the fact that if the fabric is kept in a vacuum or in an atmosphere of hydrogen the effect is enormously reduced. Normally, ozone is formed in oxygen only by the action of light of wave-length too short to occur in sunlight at all, but this difficulty has been removed by Prof. Lindemann, who shows that the high refractive index of the fibres modifies the photo-electric action, increasing the maximum effective wave-length by a factor which brings the value up to that actually determined by experiment.—S. **Lees**: Note on constant-volume explosion experiments. An attempt is made to compute the order of the effect of temperature variations in an explosion vessel on the values of the total internal energy measured. The author gives reasons which indicate that the experimentally determined values of internal energy so obtained ought to be reduced slightly to get the corrected values for uniform temperatures. The correction is probably less than 1 per cent. for air at 1600° C. This correction is probably within the limits of experimental error at the present time.—V. **Brun**: The function $[x]$.

MANCHESTER.

Literary and Philosophical Society, November 30.—Sir Henry A. Miers, president, in the chair.—Prof. T. G. B. **Osborn**: Notes on stone implements from the Cooper's Creek District, South Australia. Most of the specimens were found in May last on old camping-grounds of the Deari tribe during a visit to Killalpannina, on the Barcoo (Cooper's Creek), in the Lake Eyre region. It seems probable that knives were manufactured in certain places and the finished articles carried away. A crude flake struck off at a single blow served as a temporary cutting instrument provided it had a sharp edge, and was then discarded. Scrapers, knives, flakes, hammer-stones, and stones for grinding and crushing food materials were found. The grinding stones were used for grinding small seeds of *Eucalyptus microtheca*, etc.; the crushing stones for breaking hard "beans" of "nardoo" (sporocarps of Marsilea sp.).—Prof. A. V. **Hill**: The purpose of physiology. As the handmaid of medicine, the task of physiology lies in the discovery and statement of the "normal" as distinguished from the "abnormal." As a pure science it is privileged to explore the mechanisms underlying the phenomena of life by any and every means provided by scientific progress. As an applied science, in co-operation with psychology, it deals with such questions as the conditions of maintenance of the "normal," the standards of fitness, mental, moral, and physical, and the biological factors in the economic or social system. Progress may be expected in the regions where physiology verges on the other, especially on the exact, sciences, while the stimulus to the applications of physiology appears on the borders of medicine, sport and physical training, industrial fatigue, sociology or economics.

December 9.—Mr. R. L. Taylor, vice-president, in the chair.—Prof. T. E. **Peet**: Ancient Egyptian mathematics. Known to us chiefly from the Rhind papyrus in the British Museum, Egyptian mathematics is not a speculative science, but one purely practical in scope. The author dealt with the cumbrous notation; the use only of fractions the numerator of which was unity (with the one exception of two-thirds); tables for multiplication by 2 only, and with division by 2 only, larger divisions being done by trial. Problems such as the division of food, the measurement of areas, the exchange of loaves of various sizes and of jugs of beer were easily accomplished. A parallelopiped was correctly cubed, the volume of a cylinder obtained, and the circle given as the square of eight-ninths of its diameter. The existence in Egypt of a standard of rings or *shatyw* of various metals was dealt with.

Dublin.

Royal Dublin Society, January 25.—Dr. F. E. Hackett in the chair.—J. J. **Dowling**: A direct-reading ultra-micrometer. The apparatus, which was exhibited in operation, depends on the variation of the plate current in an oscillating-valve circuit, which accompanies a variation in the capacity of the oscillating circuit. The sensitivity of the arrangement is very high, but even under unfavourable conditions it shows remarkable steadiness. Preliminary measurements show that a displacement of about 2×10^{-8} cm. is detectable under ordinary working conditions, and with suitable precautions very much greater sensitivity can be reached. Further work in connection with the apparatus is being carried out.—J. **Reilly** and W. J. **Hickinbottom**: The distillation constant of certain primary alcohols. The authors have applied their method of distillation in steam to methyl, ethyl, propyl, butyl, and *iso*amyl alcohols. Percentage of alcohol is estimated from density or by oxidation. Distillation constant varied with concentration.

Edinburgh.

Royal Society, January 10.—Prof. F. O. Bower, president, in the chair.—The late Dr. John **Aitken**: Thermometer screens. This paper was left in manuscript by Dr. Aitken, and was completed a few days before his death. It gives a new series of experiments summing up his results communicated from time to time during the last thirty years. The points emphasised were (1) the inadequacy of the Stevenson screen, which in sunny weather always makes the enclosed thermometers read too high; (2) the uncertainty of measuring the temperature of the air, which cannot be other than a time-average varying with the thermometer used; and (3) the description of a new simple form of screen which satisfies all practical needs.—Prof. W. **Peddie**: The avoidance of relativity which is not of Galileo-Newtonian type. It is the aim of natural philosophy to find more and more inclusive laws describing the course of inanimate Nature. Examples are the conservation of matter and energy, the law of least time, stationary action, varying action, and Einstein's recent development of relativity. Their chief value lies in the fact that they give results which are independent of the particular mechanism involved. All actions which seem to occur at a distance take place, according to Newton, through a medium or æther. It is sometimes asserted that in consequence of the results of the principle of relativity the æther is non-existent; but the natural philosopher is entitled to claim that any such deduction from a theory which obtains its results independently of the mechanism involved can have no validity. Within its range the principle is of great value and constitutes the greatest advance made in connection with general laws since the introduction of the principles of action. These general laws can only be judged by the coincidence of their conclusions with observation. In this respect Einstein's principle stood successfully the test of two facts of observation, one of which was a prediction. In connection with a third the result is doubtful. It is, therefore, desirable to consider possible modifications of the basis to which the principle is applied. The only one now possible seems to be that connected with the postulate that light is propagated through a uniform æther regarded as at rest in space. If light is propagated through æthereal strain-forms associated with the atoms and moving with them, the æther itself may be at rest, but this experimental foundation for the recent extensions of relativity would disappear. On the other hand, in this case a positive result should be given by the Michelson-Morley experiment if made with light from a star moving rapidly to or from the earth. The paper concluded with a discussion of the possibility of a mechanical foundation of this view in an extension of Osborne Reynolds's theory of a granular æther.—F. **Unwin**: The transverse galvanomagnetic and thermomagnetic effects in several metals. This investigation into these minute effects gave results which were compared with certain conclusions derived by Livens from the modern electron theory. The agreement was satisfactory as regards the ratios of the effects, but not as regards their magnitudes.—P. **Humbert**: The confluent hypergeometrical functions of two variables.

Paris.

Academy of Sciences, January 31.—M. Georges Lemoine in the chair.—The president announced the death of M. Emile Bourquelot, member of the section of chemistry.—L. **Favé**: Curves designed for the determination of orthodrome routes. On a sheet of transparent material curves are drawn representing, in Mercator's projection, a series of great circles cutting the equator at the extremities of a given diameter. A second family of curves of a different colour serve to measure the orthodrome distance.—A. P. **Dangeard**: Observations of an alga cultivated in the dark for eight years. *Scenedesmus acutus* has been cultivated in the absence of light since January, 1913, and is as green as specimens grown in the light in the ordinary way. The examination of the absorption spectrum of the chlorophyll shows no difference between the two series. A special culture medium is required, the composition of which is given.—E. **Mathias**, C. A. **Crommelin**, and H. K. **Onnes**: The rectilinear diameter of hydrogen. Supplementing earlier work, the densities of liquid hydrogen between $-239.91°$ C. and the boiling point, $-252.76°$ C., have been studied. The cryostat used consisted in a bath of superheated hydrogen vapour, obtained from the evaporation of the liquefied gas and heated by electrical means. The automatic current regulator employed permitted control of the temperature to within 0·01° C. for several hours. The experiments required the preparation of about 170 litres of liquid hydrogen and 400 litres of liquid air. The ordinate of the diameter was found to be $-0.06351-0.00039402\,\theta$. The critical density was 0·03 and the critical coefficient 3·276. Hydrogen obeys the law of the rectilinear diameter.—Auguste Béhal was elected a member of the section of chemistry in succession to the late Armand Gautier.—G. **Fubini**: Automorphic functions.—T. **Varopoulos**: A class of multiform functions.—A. **Véronnet**: The variation of a conical trajectory under the action of the resistance of a medium.—J. **Villey**: Experimental installations for aerodynamical researches. A discussion of the recent proposal by M. Margoulis, suggesting the use of carbon dioxide under high pressures and at low temperatures as the circulating gas in the testing of aeroplane models. Apart from certain difficulties of construction which would add to the cost of the apparatus, the author is of opinion that the use of carbon dioxide could only be complementary to the use of air, and could not safely be employed instead of the latter.—M. **Curie**: The action of red and infra-red rays on phosphorescent substances. An account of experiments in which zinc sulphide and other phosphorescent substances were submitted to the simultaneous action of ultra-violet rays (mercury lamp with nickel oxide glass filter) and infra-red rays (arc lamp with cuprous oxide glass filter). The sulphides examined behaved differently from fluorescent bodies such as uranium nitrate, barium platinocyanide, and fluorescein.—M. **de Broglie**: The corpuscular spectra of the elements.—A. **Léauté**: Complement to the theory of the induced reaction for saturated alternators.—H. **Colin** and Mlle. A. **Chaudun**: The application of the law of hydrolysis to the determination of molecular weights.—A. **Mailhe**: The catalytic preparation of secondary amines and an attempt to introduce the alkyl group into these bases. Schiff's bases, mixed with a small quantity of finely divided nickel and heated to 170° C., are reduced smoothly to secondary amines by hydrogen. An attempt to prepare tertiary amines by passing a mixture of the secondary amine and alcohol over alumina heated to 380°–400° C. was not successful, as the bases were split up in contact with the catalyst.—E. **Saillard**: The balance of chlorine during the manufacture of sugar and the proportion of chlorine in the beetroot.—L. **MacAuliffe** and A. **Marie**: The study and mensuration of 117 Belgians.—P. **Audigé**: The growth of fishes maintained in a medium at a constant temperature.—E. **Rabaud**: The paralysing instinct of the spiders.—R. **Bayeux**: Respiratory insufficiency at very high altitude and its correction by subcutaneous injections of oxygen.—A. **Lumière** and H. **Couturier**: The nature of the anaphylactic shock. Further experiments tending to show that the causes of the anaphylactic shock are the same as those of the anaphylactoid crises resulting from the sudden introduction of insoluble substances into the circulation.—Et. and Ed. **Sergent**: Attempts at vaccinating against paludism in birds due to *Plasmodium relictum*.—E. **Woolman**: The *rôle* of flies in the transport of pathogenic germs studied by the technique of aseptic cultivations. These experiments show that contaminated flies remain infected for some days only. Removed from the source of contamination, they free themselves very rapidly, probably mechanically, from the infecting germs.—MM. **Kohn-Abrest**, **Sicard**, and **Paraf**.

MELBOURNE.

Royal Society of Victoria, November.—Mr. F. Wisewould, vice-president, in the chair.—E. **Ashby**: A description of the Bracebridge Wilson collection of Victorian Chitons, with a description of a new species from New Zealand. This collection was made by the late Mr. J. Bracebridge Wilson, working in connection with the Port Phillip Exploration Committee of the Royal Society, and was dealt with by E. R. Sykes in the Proc. Malac. Soc. in 1896. In addition to the five species described by Sykes as new, the author notes four other species then undescribed, *Callochiton rufus*, Ashby, which has hitherto been known only by a single type-specimen dredged in South Australia, and a new species of Lepidopleurus from New Zealand.—Dr. J. M. **Baldwin**: Application of genetics to plant-breeding. The problems of genetics are those which grow out of a study of the resemblances and differences in individuals related by descent. There are four general lines of attacking the problems: (*a*) The method of observation used by Darwin in marshalling evidence in favour of the evolution theory; (*b*) biometrical methods employed with such success by Pearson; (*c*) cytological methods, which are primarily concerned with a study of cell-mechanism; and (*d*) experimental breeding, which involves the raising of pedigreed cultures of plants. From the last method have come many stimulating ideas of heredity and variation, including the Mendelian theory of heredity, the pure-line theory of Johannsen, and the mutation theory of De Vries.

Books Received.

Journal of the Royal Statistical Society. New Series. Vol. lxxxiv., part 1, January. Pp. x+165. (London.) 7*s*. 6*d*.

A New Bristol Flora: British Wild Flowers in their Natural Haunts. By A. R. Horwood. (In 6 vols.) Vol. i. Pp. ix+244. Vol. ii. Pp. xi+243+xvii plates. (London: Gresham Publishing Co.) 12*s*. 6*d*. net per vol.

Principles of Human Geography. By E. Huntington and S. W. Cushing. Pp. xiv+430. (New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd.) 21*s*. net.

Rapid Methods for the Chemical Analysis of Special Steels, Steel-making Alloys, their Ores and Graphites. By C. M. Johnson. Third edition, revised and enlarged. Pp. xi+552. (New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd.) 36*s*. net.

The Health of the Industrial Worker. By Prof. E. L. Collis and M. Greenwood. Pp. xix+450. (London: J. and A. Churchill.) 30*s*. net.

Poverty and its Vicious Circles. By Dr. J. B. Hurry. Second and enlarged edition. Pp. xvi+411. (London: J. and A. Churchill.) 15*s*. net.

The Mother and the Infant. By Edith V. Eckhard. (Social Service Library.) Pp. viii+256. (London: G. Bell and Sons, Ltd.) 6*s*. net.

The Microscope: Its Design, Construction, and Applications. Edited by F. S. Spiers. Pp. v+260+plates. (London: C. Griffin and Co., Ltd.) 21*s*. net.

Il Regime delle Acque nel Diritto Publico e Privato Italiano. By A. Vitale. Pp. x+480. (Milano: U. Hoepli.) 25 lire.

Diary of Societies.

THURSDAY, FEBRUARY 24.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND (at 11 Chandos Street, W.1), at 2.45.—Sir Frederick Mott and Dr. Hayne: The Pathology of Dementia Præcox, especially in Relation to the Condition of the Ovaries.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—F. Balfour Browne: Mason Bees and Wasps.

ROYAL SOCIETY, at 4.30.—Sir Ray Lankester: A Remarkable Flint-implement from Selsey Bill.—Dr. E. J. Allen: Regeneration and Reproduction of the Syllid Procerastea.—E. C. Grey and E. G. Young: The Enzymes of *B. coli communis*. Part II. (*a*) Anaerobic Growth followed by Anaerobic and Aerobic Fermentation. (*b*) The Effects of Aeration during the Fermentation.—Dr. A. E. Everest and A. J. Hall: Anthocyanins and Anthocyanidins.

ROYAL SOCIETY OF MEDICINE (Tropical Medicine Section), at 5.—Sir Leonard Rogers: Presidential Address.—Dr. J. G. Thomson and Dr. A. Robertson: The Value of Laboratory Reports in the Diagnosis of Suspected Dysentery, and their Interpretation by the Clinician.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. Martin Flack: Respiratory Efficiency in Relation to Health and Disease (Milroy Lecture).

INSTITUTION OF ELECTRICAL ENGINEERS (at Institution of Civil Engineers), at 6.—Prof. E. Wilson: Magnetic Susceptibility of Low Order. II. Susceptibility Values.

CONCRETE INSTITUTE, at 7.30.—E. S. Andrews: Methods of Securing Impermeability in Concrete.

ILLUMINATING ENGINEERING SOCIETY (at Royal Society of Arts), at 8.—Discussion: The Use of Light as an Aid to Publicity.

ROYAL SOCIETY OF MEDICINE (Urology Section), at 8.30.

FRIDAY, FEBRUARY 25.

ROYAL SOCIETY OF MEDICINE (Study of Disease in Children Section), at 4.30.—Sir Humphry Rolleston and Others: Discussion on The Diagnosis and Treatment of Congenital Syphilis and its Effects.

PHYSICAL SOCIETY OF LONDON (at Imperial College of Science), at 5.—T. Smith: Tracing Rays through an Optical System.—J. Guild: The Refractometry of Prisms.—R. H. Humphry: A Note on the Hot-Wire Inclinometer.—Profs. E. Wilson and E. F. Herroun: The Magnetic Susceptibility of Certain Natural and Artificial Oxides.

TECHNICAL INSPECTION ASSOCIATION (at Royal Society of Arts), at 7.30.

JUNIOR INSTITUTION OF ENGINEERS, at 8.—H. T. Davidge: Measurements of Precision in Engineering.

ROYAL SOCIETY OF MEDICINE (Epidemiology and State Medicine Section), at 8.30.—Dr. R. M. F. Picken: The Epidemiology of Measles in a Rural and Residential Area.

SATURDAY, FEBRUARY 26.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. A. Fowler: Spectroscopy (Celestial Spectroscopy).

MONDAY, FEBRUARY 28.

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.—Discussion of Professional Questions.

ROYAL SOCIETY OF ARTS, at 8.—Dr. E. K. Rideal: Applications of Catalysis to Industrial Chemistry: Hydrolytic Processes (Cantor Lecture).

ROYAL SOCIETY OF MEDICINE (Odontology Section), at 8.—W. W. James: Some Clinical Cases Associated with Dental Infection.—P. Cole: Condition of Two Pedicle Bone Grafts two years after Operation.

MEDICAL SOCIETY OF LONDON (at 11 Chandos Street, W.1), at 8.30.—Dr. J. H. Ryffel and Others: The Chemical Estimation of Gastric Function.

TUESDAY, MARCH 1.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. A. Keith: Darwin's Theory of Man's Origin in the Light of Present-Day Evidence.

INSTITUTE OF CHEMISTRY (Annual General Meeting), at 4.30.—Sir Herbert Jackson: Presidential Address.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. G. Graham: Glycæmia and Glycosuria (Goulstonian Lecture).

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—J. D. Johnston: A Plain Traveller's Tale, Rome to Naples.

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.—Jay Hambidge: Further Evidence for Dynamic Symmetry in Ancient Architecture.

WEDNESDAY, MARCH 2.

NEWCOMEN SOCIETY (at Marconi House), at 5.—L. St. L. Pendred: Trevithick's London Locomotive of 1808.

SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (at Chemical Society), at 8.—C. Ainsworth Mitchell: The Acidity of Ink and the Action of Bottle Glass on Ink.—G. Van B. Gilmour: The Detection of Adulteration in Butter by Means of the Melting-Point of the Insoluble Volatile Acids.—S. H. Blichfeldt and T. Thornley: Method and Apparatus for Routine Determination of Melting-Points of Fats and Fatty Acids.

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.—E. Warren: Architectural Impressions of a Recent Tour in Mesopotamia.

ROYAL SOCIETY OF ARTS, at 8.0.—Capt. J. M. Hollis: The Reeducation of the Disabled.

INSTITUTION OF AUTOMOBILE ENGINEERS (at Institution of Mechanical Engineers), at 8.—Dr. W. H. Hatfield: Automobile Steels.

THURSDAY, MARCH 3.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—F. Balfour Browne: Mason Wasps.

ROYAL SOCIETY, at 4.30.—Discussion on Isotopes to be opened by Sir J. J. Thomson, followed probably by F. W. Aston, Prof. F. Soddy, Prof. T. R. Merton, and Prof. F. A. Lindemann.

ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts), at 5.—J. W. W. Dyer: Airship Fabrics.—Major T. Orde Lees: Parachutes.

LINNEAN SOCIETY, at 5.—R. T. Günther: A Manuscript of Matthias de Lobel, from the Library of Magdalen College, Oxford.—Dr. B. Daydon Jackson: Naturalists and their Indebtedness to the National Trust.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. G. Graham: Glycæmia and Glycosuria (Goulstonian Lecture).

CHILD-STUDY SOCIETY (at Royal Sanitary Institute), at 6.—Miss M. C. Buysman: The Value of the Drama in the Training of the Child's Emotions.

CHEMICAL SOCIETY, at 8.

FRIDAY, MARCH 4.

ROYAL SOCIETY OF ARTS (Indian Section), at 4.30.

ROYAL ASTRONOMICAL SOCIETY (Geophysical Discussion), at 5.—Problems of Seismology: opened by Prof. H. Lamb, followed by Dr. G. W. Walker, R. D. Oldham, and J. J. Shaw. Chairman: Prof. H. H. Turner.

ROYAL ASTRONOMICAL SOCIETY (Geophysical Discussion), at 5.

INSTITUTION OF ELECTRICAL ENGINEERS (Students' Meeting) (at Faraday House), at 6.30.—A. Rosen: Telephonic Transmission through Submarine Cables.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—W. A. Tait: Severn Crossings and Tidal Power.

SATURDAY, MARCH 5.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir Ernest Rutherford: Electricity and Matter.
